[Invited] GREGORY MCKENNA (Presenter), HEEDONG YOON, Texas Tech University — A major challenge in glass physics is the determination of the temperature dependence of the relaxation times in the equilibrium state well below the laboratory glass temperature $T_g$. This is because the times required to achieve equilibrium in this regime become of geological/astronomical scale [1,2]. To finesse this problem, we are using materials with extremely low fictive temperature $T_f$ relative to $T_g$, hence unlocking an unexplored region of the glassy state to investigation. First, we measured the viscoelastic response of a 20 million year old amber with $T_f \sim 43.6$ K below $T_g$. The relaxation times deviated strongly from the expected VFT or WLF-behaviors turning towards an Arrhenius-response, albeit with a high activation energy. Though convincing as evidence that the dynamics of the glass do not diverge at a finite temperature, often linked to the Kauzmann [3] temperature $T_K$, the amber work is complicated because the natural origins of amber make reproducing the experiments difficult. We also built on the ultra-stable glasses exploited by Ediger and co-workers [4] and made an amorphous Teflon material with $T_f \sim 55$ K below $T_g$ and close to the putative $T_K$. Made only in microgram quantities, we needed the TTU bubble inflation [5] method to measure the creep response in the range between $T_f$ and $T_g$, expanding the amber work to $T_K$. The observed relaxation times deviate from the extrapolated WLF-line challenging the view that there is an "ideal" glass transition as posited by multiple theories and commonly considered an important aspect of glass-formation and glassy behavior.

9:12AM E51.00003: Edge fracture in polymeric fluids*
[Invited] SUZANNE FIELDING (Presenter), EWAN HEMINGWAY, Physics, Durham University — We study theoretically edge fracture in sheared polymeric fluids, using linear stability analysis and nonlinear simulations. We derive an exact analytical expression for the onset of edge fracture in terms of the shear-rate derivative of the second normal stress difference, the shear-rate derivative of the shear stress, the jump in shear stress across the interface between the fluid and the outside air, the surface tension of that interface, and the rheometer gap size. We provide a full mechanistic understanding of the edge fracture instability, and validate this against our simulations. These findings also suggest a possible route to mitigating edge fracture, potentially allowing experimentalists to achieve and accurately measure flows stronger than hitherto. We then consider the interaction of edge fracture with the fluid bulk. For fluids with a rather flat (but still monotonically increasing) bulk constitutive curve of shear stress as a function of shear rate, we show that edge fracture can cause a pronounced apparent shear banding that invades the fluid bulk to a distance of many gap widths in from the sample edge. To paraphrase this first scenario: "edge fracture causes (apparent) shear banding". For fluids that have a non-monotonic constitutive curve and therefore show bulk shear banding (even in the absence of any edge instabilities), we show that the jump in the second normal stress difference between the shear bands causes strong edge fracture at the fluid-air interface, consistent with the earlier intuition of Skorski and Olsmited. To paraphrase this second scenario: "shear banding causes edge fracture".

9:48AM E51.00004: Statistical Field Theory of Inhomogeneous Polarizable Soft Matter* (Invited) GLENN FREDRICKSON (Presenter), DOUGLAS GRZETIC, KRIS T DELANEY, JONATHAN MARTIN, University of California, Santa Barbara — Standard approaches to modeling the electrostatic properties of inhomogeneous soft matter systems involves either neglecting dielectric contrast entirely, or imposing an ad-hoc dielectric constitutive law that is not consistent with pairwise van der Waals (VDW) interactions included elsewhere in the model. We recently developed a framework for building statistical field theories from coarse-grained particle models where the force centers can optionally carry monopole charges, dipoles, and/or classical Drude oscillators that confer polarizability. The resulting polarizable field theories self-consistently embed dielectric constitutive laws, VDW interactions, and a rich variety of charge and structure correlation physics. This talk will report on recent analytical results from loop expansions and numerical results from complex Langevin simulations that address: 1) the VDW contribution to the Flory interaction parameter in polymer blends and block copolymers, 2) the dielectric decrement or increment on adding salt to a polar or polarizable solvent, and 3) the electric-field induced shift in the critical temperature of a binary dielectric fluid mixture.

10:24AM E51.00005: Fast but Inaccurate or Slow but Accurate: The Dilemma of Tubes and Slip Links* (Invited) SACHIN SHANBHAG (Presenter), Florida State University — The tube model for entangled polymers projects a complex multi-body problem of interacting chains onto a mean-field representation. This popular framework has been enormously successful at predicting the rheology of model (and even some industrial) polymers. However, its success cloaks several fundamental problems that become obvious when it is subjected to strong tests. One such example is binary blends with well-separated relaxation times. In such cases, slip link models which retain the multi-body character of the original problem offer a more accurate and robust alternative. However, slip link models are computationally demanding. Here, I resuscitate a super-fast slip link model that Ron Larson and I first introduced over 15 years ago. With a few small modifications, it predicts the linear rheology of binary blends with remarkable accuracy and speed.

Session E53 GSNP DCMP: Heineman and Oppenheim Award Session B6EC 253C - Greg Huber - Tag(s): Invited

8:00AM E53.00001: Dannie Heineman Prize for Mathematical Physics Talk: Solvable systems of nonlinear ODEs: old and new results (Invited) FRANCESCO CALOGERO (Presenter), Physics & Sezione di Roma 1, Universita' di Roma "La Sapienza" & Istituto Nazionale Fisica Nucleare — Some old and new "exactly solvable" dynamical systems will be tersely reviewed.

8:36AM E53.00002: Irwin Oppenheim Award Talk: The Thermodynamic Uncertainty Relation: Theoretical Introduction* [Invited] TODD GINGRICH (Presenter), Chemistry, Northwestern University, JORDAN HOROWITZ, Biophysics and Complex Systems, University of Michigan — In thermodynamic equilibrium, molecular motions cannot generate a non-vanishing average current—of particles, mass, charge, etc. This fact is elegantly seen as a consequence of the time-reversible nature of equilibrium dynamics, which obeys detailed balance. It is well known that detailed balance can be broken by external driving, either with a time-dependent protocol (as in flashing ratchets) or by coupling a system to multiple incommensurate reservoirs (say a high-chemical-potential bath on one side of a membrane and a low-chemical-potential bath on the other side). In this latter case, the system coupled to the baths experiences a time-independent thermodynamic driving force causing the system to relax into a nonequilibrium steady state (NESS) that generates current. Since the current is made up of individual transport events, it will fluctuate around the steady state value, and the scale of these fluctuations is constrained by the typical rate of dissipation into the reservoirs, a constraint which has been labeled a Thermodynamic Uncertainty Relation (TUR). In this talk I will outline this TUR and illustrate the large-deviation-theoretic arguments underlying its derivation.

*Gordon and Betty Moore Foundation

9:12AM E53.00003: Irwin Oppenheim Award Talk: The Thermodynamic Uncertainty Relation: Applications And Extensions* [Invited] JORDAN HOROWITZ (Presenter), Biophysics, University of Michigan, TODD GINGRICH, Chemistry, Northwestern — At the mesoscale, thermal noise is an unavoidable nuisance interfering with the function of molecular devices, from molecular motors to chemical clocks. For these devices to operate, they must constantly consume energy to suppress these fluctuations. Remarkably, the recently discovered thermodynamic uncertainty relation offers a universal bound on the energetic cost to attain precision in the face of such noise. In this talk, I will discuss examples drawn from the literature of how one can apply the thermodynamic uncertainty relation to gain insight into the design principles underpinning the function of such molecular-scale devices as stochastic heat engines, molecular motors, self assembly, chemical kinetics and nonlinear response. I will then turn to extensions and generalizations of the thermodynamic uncertainty relation to highlight new opportunities for applications and insight.

*This work was support by the Gordon and Betty Moore Foundation through Grant GBMF4513.

Session E54 DPOLY GSOFT: Dielectric Relaxation and Charge Transport of Soft Materials
BCEC 254A - Andreas Schoenhals - Tag(s): Focus

8:00AM E54.00001: E54 POLYMER PHYSICS PRIZE BREAK —

8:36AM E54.00002: Morphology and Conductivity in Sulfonated Polyphenylenes* AMALIE FRISCHKNECHT (Presenter), Center for Integrated Nanotechnologies, Sandia National Laboratories, ERIC SORTE, Dept of Organic Materials Science, Sandia National Laboratories, BENJAMIN PAREN, Dept of Materials Science and Engineering, University of Pennsylvania, CY FUJIMOTO, LAUREN J ABBOTT, NASA Ames Research Center, KAREN WINEY, Dept of Materials Science and Engineering, University of Pennsylvania, TODD ALAM, Dept of Organic Materials Science, Sandia National Laboratories — Proton conduction in hydrated, proton-conducting polymer membranes is highly affected by hydration level and membrane morphology. Here we examine morphology and dynamics in a promising proton-conducting polymer, a sulfonated Diels-Alder polyphenylene (SDAPP). We performed atomistic molecular dynamics (MD) simulations on a series of SDAPPs, systematically varying the degree of sulfonation and water content to determine their effect on the nanoscale structure, particularly for the hydrophilic domains formed by the ionic groups and water molecules. The static structure factors calculated from simulation are in good agreement with X-ray scattering data. NMR and impedance spectroscopy measurements show that the proton conduction mechanism evolves from being dominated by vehicular transport at low hydration and sulfonation levels to including a significant contribution from the Grötthuss mechanism at higher hydration and sulfonation levels.

8:48AM E54.00003: Phase Transition and Dynamics in Imidazolium-Based Ionic Liquid Crystals through a Metastable States*
KOJI FUKAO (Presenter), TOSHIHARU YAMANE, JUN YOSHIOKA, Department of Physics, Ritsumeikan University — The phase transition behavior and dynamics of ionic liquid crystals, 1-methyl-3-alkylimidazolium tetrafluoroborate with various alkyl chain lengths, were investigated by X-ray scattering, differential scanning calorimetry, optical microscopy, and dielectric relaxation spectroscopy to elucidate the mechanism of their structural and phase changes. A metastable phase was found to appear via a supercooled smectic phase on cooling. In the metastable phase, disorder in the smectic phase is partially frozen; thus, the phase has order higher than that of the smectic phase but lower than that of the crystalline phase. During the subsequent heating process, the frozen disorder activates, and a crystalline phase appears in the supercooled smectic phase before entering the smectic phase. The relationship between the phase behavior and the dynamics of charge carriers such as ions is also discussed.

9:00AM E54.00004: Revealing the fine features of charge transport mechanism in ionic glass-forming liquids by dielectric spectroscopy*
YANGYANG WANG (Presenter), Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — By examining the fine features of the dielectric spectra of a variety of ionic glass-forming materials, including ionic liquids and poly(ionic liquids), we show that the derivative of their real permittivity progressively broadens on the low-frequency side when the glass transition is approached from above. This phenomenon, ubiquitous and yet difficult to ascertain in the widely-used conductivity or modulus representation, is reminiscent of the spectrum broadening in supercooled dipolar liquids. Our finding provides direct evidence of heterogenous dynamics in ac conduction of ionic glasses and calls for a reconsideration of the classical models that predict a steep, Debye dispersion at low frequencies.

*This research was sponsored by the Laboratory Directed Research and Development Program of Oak Ridge National Laboratory, managed by UT Battelle, LLC, for the U.S. Department of Energy.

9:12AM E54.00005: Dielectric Relaxation and Conductivity in Polyelectrolyte Systems*
KHATCHER O. MARGOSSIAN (Presenter), MURUGAPPAN MUTHUKUMAR, Department of Polymer Science and Engineering, University of Massachusetts Amherst — Using Electrical Impedance Spectroscopy, we have monitored the dynamical relaxations of polyelectrolytes in concentrated solutions and in charged materials. Here, we explore the effects of chain length, ionic strength, cross-link density, and pH on the dynamics of charged macromolecular assemblies. We also report experimental results on the ionic conductivity of these systems. This research builds our understanding of the parameters necessary for tuning functional properties of polyelectrolyte-based systems, and motivates further work in logically designing electrically-responsive materials.

9:24AM E54.00006: Dielectric Spectroscopy on Choline Chloride based Deep Eutectic Solvents
DANIEL REUTER (Presenter), PETER LUNKENHEIMER, ALOIS LOIDL, Experimental Physics V, University of Augsburg — Deep eutectic solvents (DES) have caught the attention of the scientific community in recent years and are discussed as a promising new class of ionic liquid analogues [1]. Prominent examples are mixtures based on choline chloride (ChCl) with various hydrogen-bound donors like, e.g., glycerol [2]. Although dielectric spectroscopy is an ideal tool to investigate ionic-conductivity mechanisms, until now only a few DES were studied by this method. In this talk, we present dielectric spectroscopy data for three ChCl based DES, covering a broad frequency and temperature range. Our evaluation focuses on the often neglected molecular reorientational dynamics and its correlation with the ionic mobility, as also found in ionic liquids [3].

9:36AM E54.00007: Molecular Dynamics Simulations of Ion Transport in High Transference Number Polyelectrolytes for Li-ion Batteries  
KARA FONG (Presenter), Chemical and Biomolecular Engineering, University of California, Berkeley, JULIAN SELF, Materials Science and Engineering, University of California, Berkeley, KYLE DIEIDERICHSEN, Chemical and Biomolecular Engineering, University of California, Berkeley, KRISTIN PERSSON, Materials Science and Engineering, University of California, Berkeley, BRYAN MCCLOSKEY, Chemical and Biomolecular Engineering, University of California, Berkeley — Conventional liquid electrolytes for Li-ion batteries suffer from low Li\(^+\) transference numbers, which limit mass transport in porous electrodes and thus reduce the battery's energy density and rate capability. It has been proposed that replacing traditional Li-ion battery salts with lithium-neutralized polyanions dissolved in solution could be a means to increase the Li\(^+\) transference number while only modestly sacrificing ionic conductivity. While initial experimental studies have demonstrated the promise of this approach, rational design of optimal polyelectrolytes requires more fundamental, atomistic-level understanding of the ion transport mechanisms in these systems. To this end, we use classical molecular dynamics simulations to investigate the behavior of poly(allyl glycil ether-lithium sulfonate); this polyanion has been thoroughly characterized experimentally for this application, enabling validation of the computational model. By characterizing the Li\(^+\) diffusion mechanism as well as ion aggregation behavior in the system, we elucidate the atomistic phenomena that most strongly govern experimentally-measured conductivity and transference numbers.

9:48AM E54.00008: Temperature dependent vibrational modes of Ammonium Nitrate in terahertz regime*  
ABDUR RAHMAN (Presenter), Physics and Technology, Edinboro University, TOWFIQ AHMED, DAVID S. MOORE, ABUL K AZAD, Los Alamos National Laboratory — Ammonium Nitrate (AN), often used as an ingredient for making improvised explosives, does not show any spectral feature at room temperature. We employed terahertz time domain spectroscopy (THz-TDS), a non-invasive technique, in the range of 0.30 THz to 2.50 THz to measure the effective dielectric properties of AN embedded in a polytetrafluoroethylene (PTFE) binder in the temperature range 5K to 300K. We extracted the dielectric constants of AN using effective medium theories and fitted them using Lorentz dispersion model combined with Huang equation. We identified six low frequency vibrational modes of pure AN at low temperature (<240 K). These lattice vibrations in the low frequency range agree reasonably well against our first principles Density Functional Theory (DFT) simulation of molecular AN, that reveals four low frequency vibrational modes within 3THz.

*Los Alamos National Laboratory LDRD program.

10:00AM E54.00009: Low-frequency dielectric response of a periodic array of charged spheres in an electrolyte solution  
CHANG-YU HOU (Presenter), JIANG QIAN, DENISE FREED, Schlumberger-Doll Res Ctr — We study the low-frequency dielectric response of charged spheres arranged in a cubic lattice and immersed in an electrolyte solution. We focus on the influence of the out-of-phase current in the ionic charge neutral regime. In the thin double-layer limit, we use Fixman's boundary condition at the outer surface of the double layer to capture the direct interaction between the electric field and the flow of the ions. For periodic conditions, we combine the methods developed by Lord Rayleigh and by Korringa, Kohn and Rostoker. When the charged spheres occupy a very small volume fraction, smaller than one percent, our solution becomes consistent with the Maxwell Garnett mixing formula together with the single particle polarization response, as expected, because inter-particle interactions become less prominent in the dilute limit. By contrast, the inter-particle interaction, computable in the periodic geometry, greatly alters the dielectric response when charged spheres occupy even a slightly higher volume fraction, as low as two percent. Our results imply that the signature of the dielectric response of a system consisting of densely packed charged spheres immersed in the electrolyte can differ drastically from a dilute suspension.

10:12AM E54.00010: Low-frequency dielectric response of charged oblate spheroidal particles immersed in an electrolyte*  
CHANG-YU HOU, DENISE FREED (Presenter), PABITRA N SEN, Schlumberger-Doll Res Ctr — We studied the low-frequency polarization response of an oblate spheroidal particle with surface charge immersed in an electrolyte. Because the charged spheroid attracts counterions which form an electric double layer around the particle, the dielectric response involves an interplay between the motion of these counterions and the spheroidal shape of the particle. For two different counterion distributions in the thin electric double-layer limit, we obtained analytic expressions for the polarization coefficients to the first nontrivial order in frequency. We find that the polarization response normal to the symmetry axis depends on the total amount of charge carried by the oblate spheroid, while that parallel to the symmetry axis is suppressed when there is less charge on the edge of the spheroid. We then show that a dilute suspension of charged particles has an enhancement in the low-frequency dielectric response which is suppressed by high ion concentrations in the electrolyte. Both higher aspect ratios and smaller sizes of the spheroids lead to a stronger dielectric enhancement. The characteristic frequency associated with the dielectric enhancement scales inversely with the particle size, and it has a weak dependence on the shape of spheroid.

*Supported by Schlumberger.
Dielectric Study of Soft Materials at High Electric Fields [Invited]  RANKO RICHERT (Presenter), Arizona State University — The area of nonlinear dielectric effects began with Debye's work on saturation, its signature being a reduction of the dielectric constant, \( \varepsilon_s \), as the electric field is increased [1]. The work of Piekara [2] added the chemical effect, an increase in \( \varepsilon_s \) that originates from the equilibrium of two species with different dipole moments. Dielectric hole burning and similar techniques demonstrated that the energy absorbed from a field can accelerate dynamics, even when the temperature remains constant. Moreover, strong external fields can slow down the dynamics of polar liquids, a feature that may be associated with entropy reduction. The overall reversible field effects amount to amplitudes increasing and/or decreasing, and the loss spectrum being shifted to the left and/or right along the logarithmic frequency scale [3]. Additionally, crystallization outcomes can be modified by static fields of moderate amplitude [4]. The aim of this talk is to provide an outline of the various experimental approaches used with high fields and to present the different field protocols can be exploited to discriminate among the different sources of nonlinear polarization in soft materials. We will discuss the level of our understanding for each of the effects, and the progress of modeling the observed features. The results of time-resolved (with respect to the time at which the high field is applied) experiments will be connected to structural recovery and physical aging.

Tuesday, March 5, 2019 8:00 AM - 11:00 AM

Session E55 GSNP: Statistical Mechanics of Social Systems  BCEC 254B - Michel Pleimling, Virginia Tech

Statistical mechanics of Twitter*  GAVIN HALL (Presenter), Feinberg School of Medicine, Northwestern University, WILLIAM BIALEK, Physics, Princeton University and The CUNY Graduate Center — From fads to residential segregation, social processes depend on interactions among many individuals. Social phenomena are prototypically emergent, leading some to ask if we can build a statistical mechanics for these systems. We construct such models directly from data on individual participation in Twitter communities. We identify communities and topics of conversation within those communities, allowing the definition of binary (tweet/silent) variables for each individual during each conversation. We then build maximum entropy models that match the pairwise correlations among these variables, predicting the joint distribution of the binary variables across the entire community. These simple Ising-like models give an accurate quantitative description of many higher order features in the data, and lie near a critical surface in the space of possible models. Finally, we systematically coarse-grain the observed network states, finding hints that the macroscopic behavior is controlled by a non-trivial fixed point in the sense of the renormalization group.

*Supported in part by the NSF Center for the Physics of Biological Function (PHY-1734030), Center for the Science of Information (CCF-0939370), and grant PHY-1607612.
Empirical scaling and dynamical regimes for GDP: challenges and opportunities

HAROLD HASTINGS, TAI YOUNG-TAFT (Presenter), CHRIS COGGINS, THOMAS WANG, Bard College at Simon’s Rock — Analysis of GDP data and per capita GDP data from 1980 and 2016 finds three scaling regions. The GDP of the largest ~25 economies (nations, EU) follows a power law GDP ~ 1/rank; this is followed by a second scaling region in which GDP falls off exponentially with rank and finally a third scaling region in which the GDP falls off exponentially with the square of rank. The distribution of per capita GDP also displays these three scaling regions. Both patterns hold despite significant changes in technology, the size of the world economy, emergence of new economic powers such, and world trade (almost free communication, containerized shipping yielding sharp declines in shipping costs). Thus, empirically, these patterns may be universal [1-5]; in which case one of the targets for growth of those in the second and third scaling regions may be to identify and target causative differences between these economies and those in the first (power law) scaling region.

8:48AM E55.00005: Coarse-graining armed conflict*  EDWARD LEE (Presenter), Cornell University, BRYAN DANIELS, Arizona State University, VEIT ELSER, Cornell University, DAVID KRAKAUER, JESSICA FLACK, Santa Fe Institute — Large-scale armed conflict between groups is a defining phenomenon of modern human civilization, but the absence of a compelling model of conflict that agrees with the data means that prediction of conflict remains rudimentary. In a simple model, the spread of conflict might be described as a propagating avalanche or percolating component that extends across time and space and through a network of related actors. The presence of near power-law statistics in the sizes, durations, and actor network components of conflict suggests that such an abstracted model could provide both useful intuition and quantitative predictions about the structure of conflict on large scales. We explore this perspective in detail by performing a renormalization scheme on the surface of the Earth to generate statistics of conflict avalanches along coarse-grained spatiotemporal scales. We show that some kinds of armed conflict may obey scaling laws that could provide a basis for a predictive theory of conflict based on ideas from statistical physics.

9:00AM E55.00006: Impact Factors and the Central Limit Theorem: Why citation averages are scale dependent MANOLIS ANTONOYIANNAKIS (Presenter), Applied Physics and Applied Mathematics, Columbia University — We apply the Central Limit Theorem to study how citation averages, and Impact Factors (IFs) in particular, depend on scale. For a journal of \( n \) papers randomly selected from a population, we expect from the Theorem that its IF fluctuates around the population average \( \mu \), and spans a range of values proportional to \( \sigma / \sqrt{n} \), where \( \sigma^2 \) is the variance of the population's citation distribution. The \( 1/\sqrt{n} \) dependence has profound implications for IF rankings: The larger a journal, the narrower the range around \( \mu \) where its IF lies. IF rankings therefore allocate an unfair advantage to smaller journals in the high IF ranks, and to larger journals in the low IF ranks. This implies a scale-dependent stratification of journals in IF rankings, whereby small journals occupy all ranks, mid-sized journals occupy the middle ranks, and very large journals have IFs that asymptotically approach \( \mu \). We confirm these predictions by analyzing 20 years of Impact-Factor and journal-size data, and the citation distributions of 11,000 journals. We propose the \( \Phi \) index, a rescaled IF that accounts for size effects, and which can be readily generalized to account also for different citation practices across research fields [1].

9:12AM E55.00007: Higher-Order Correlations in Bursty Temporal Patterns  HANG-HYUN JO (Presenter), TAKAYUKI HIRAOKA, Asia Pacific Center for Theoretical Physics, MIKKO KIVELÄ, Aalto University — Temporal inhomogeneities in event sequences of natural and social phenomena have been characterized in terms of interevent times and correlations between interevent times. The inhomogeneities of interevent times have been extensively studied, while the correlations between interevent times, correlated bursts (CB), are far from being fully understood. Firstly, we numerically show that the strong CB, depicted by power-law burst size distributions, violates the well-established scaling relation between the power-law decaying autocorrelation function and the power-law interevent time distribution (PRE 2017). Next, for understanding empirical data sets for human activities showing power-law burst size distributions but negligible memory coefficient, we derive an analytic form of the memory coefficient between consecutive interevent times as a function of parameters describing interevent time and burst size statistics, to conclude that the memory coefficient might have some limits in quantifying CB (PRE 2018). Finally, in order to completely characterize the event sequence, we develop a detection method of the hierarchical burst structure by exactly mapping the event sequence onto a rooted tree, implying no loss of information on the original event sequence (in preparation).

9:24AM E55.00008: A Generalized Asset Exchange Model With Economic Growth and Wealth Distribution  HARVEY GOULD (Presenter), Physics, Clark University, KANG LIU, Physics, Boston University, NICHOLAS LUBBERS, Computer, Computational, and Statistical Sciences Division, Los Alamos National Laboratory, W. KLEIN, Physics, Boston University, JAN TOBOCHNIK, Physics, Kalamazoo College, BRUCE M BOGHOSSIAN, Mathematics, Tufts University — An agent-based yard-sale model of the economy is generalized to incorporate economic growth and its distribution to the agents according to their wealth as determined by a parameter \( \lambda \). In addition to providing insight into the relation between the nature of economic growth and wealth inequality, we find that the model has a phase transition at \( \lambda = 1 \) between a equilibrium phase with economic mobility and a non-stationary phase for which there is no mobility and wealth is concentrated among a few agents. We show that the critical exponents obtained for a fixed number of agents do not obey the usual scaling laws. However, the critical exponents are consistent with the scaling laws and mean-field theory if the Ginzburg parameter, which controls the accuracy of the mean-field approximation, is held fixed as the transition is approached and is much greater than one. The transition raises questions about whether the methods of equilibrium statistical mechanics can be applied to economic systems. We also discuss possible implications of our results for economic systems and for understanding critical point behavior in systems with long, but finite, range interactions such as metals, biological systems and polymers.
9:36AM E55.00009: Statistical Mechanics of Intractable Conflicts  MIRON KAUFMAN (Presenter), Cleveland State University, HUNG T. DIEP, University of Cergy-Pontoise, SANDA KAUFMAN, Cleveland State University — We extend a statistical physics model of two-group conflicts (H. T. Diep, et al Physica A 469, 183 (2017) to three conflicting groups. We apply mean field theory (for long range interactions) and Monte-Carlo simulations (for short range interactions) to study the time dependence of the mean attitudes in each group. Using the mean field approach, we observe that at some intermediate temperatures the means of group attitudes oscillate in time. Independent of initial conditions, attitude trajectories converge over time to an attractor in the three-dimensional space of group mean attitudes. In contrast, chaotic unpredictable time variation of attitudes is observed for short range interactions. This model with attractors and chaos is proposed as a tool for understanding intractable conflict dynamics. It can be used to generate scenarios of possible trajectories in time, which can be employed for managing intractable conflicts.

9:48AM E55.00010: Understanding the extreme Thouless effect in a simple, dynamic social network - the XIE model*  ROYCE ZIA (Presenter), Physics, Virginia Tech, WEIBIN ZHANG, MOHAMMADMEHDI EZZATABADIPOUR, KEVIN EBASSLER, Physics, University of Houston — A system undergoing a phase transition which exhibits the characteristics of both first and second order transitions is said to display the Thouless effect, e.g., the order parameter suffering a discontinuity and fluctuates through all values within the jump. In a simple model extreme introverts and extraverts, the former/latter cuts/adds a random link when chosen to act (the XIE model, EPL 100, 66007 and PRE91, 042102). The steady state consists of a networks of crosslinks between the i's and e's. The fraction of these, f, serves as an order parameter jumping from ~0 to ~1 as the ratio of i's to e's drops through unity. At unity, f wanders between "soft walls" at f0 and 1-f0. With f0 →0, the system is said to exhibit an "extreme Thouless effect." We present a novel approach based on a self-consistent mean field theory. The predictions agree spectacularly well with all simulation data. Further, we obtain the analytic form of the asymptotic behavior of f0 : It vanishes as [(lnL2/L)]1/2, where L is the size of each subgroup. Though this form sets in as late as L->2000, very good bounds (e.g., ~1%) for more accessible L's (e.g., 2000) can be found by solving a transcendental equation: x+lnx = ln(L^2/2π).

*This research is supported in part by NSF DMR-1507371.

10:00AM E55.00011: Price Measurement in Financial Markets and Quantum Coupled-Wave Model of Price Dynamics*  JACK SARKISSIAN (Presenter), Managing Director, Algostox Trading — We present a theory of bid and ask price dynamics in financial markets where the two prices form as a result of quantum-chaotic interaction between buy and sell orders. In this model the two prices are represented by eigenvalues of a 2x2 price operator corresponding to "bid" and "ask" eigenstates. We will present the trading process from physics point of view, discuss how each trade represents an elementary act of price measurement and demonstrate how the theory is built from this argument. We will show that the coupled-wave theory reflects important characteristics of bid and ask price dynamics and order density in the limit order book. Calibration examples will be provided for stocks at various time scales. This theory opens a new dimension in financial modeling providing a framework for liquidity pricing, illiquidity risk evaluation, position management, as well as brings up a discussion about the nature of processes in financial markets.

*The work was not funded by any external sources.

10:12AM E55.00012: Congested Equilibria in Large-Scale Traffic Networks: Existence, Stability and Robustness through Chemical Reaction Network Analogues  S SIVARANJANI (Presenter), VIJAY GUPTA, University of Notre Dame — Discrete fluid-like models such as the Cell Transmission Model (CTM) have proven successful in modeling traffic networks. In general, these models employ discontinuous dynamics or nonlinear terms to describe phenomena like shock waves and phantom jams. Given the complexity of the dynamics, it is not surprising that the stability properties of these models are not yet well characterized. Recent results prove the existence of a unique equilibrium in the free flow regime for certain classes of networks modeled by the CTM; however, these results restrict network demands and hold only for acyclic network topologies. Further, it is of interest to understand network behavior in congested regimes, since practical networks are often congested. We propose a new modeling paradigm for traffic networks, where an analogy between discrete fluid-like traffic models and a class of chemical reaction networks is constructed by suitable relaxations of key conservation laws in the CTM. Using this analogy, we provide structural conditions on the network graph topology for the existence of equilibria in congested regimes. Drawing upon entropy-like Lyapunov functions from chemical reaction network theory, we prove that the network admits multiple stable and robust congested equilibria.
Understanding the underlying mechanism of collaborative network formation is highly relying on the property of assortative/disassortative mixing patterns. Recent studies have shown that both of assortative and disassortative mixing patterns are widely existing in many social networks. However, it’s not always been well-confirmed that people tend to connect with someone who has similar or dissimilar individual traits. In this study, we build a scientific collaboration network by the common publishing relationship with the APS journal papers and measure the scholars’ degree assortativity and research interest assortativity. Our study has shown that the extent of assortative mixing behaviors of scholars may diversify from the different physics fields, or the social ties. In addition, the middle-level degree scholars play a vital role in bridging the collaborative communities and research fields, while this large group of members have not received adequate attention in the study of the science of science.

Most existing works modeling influence propagation assume that there is only one content spreading over networks. However, an influence propagation process could have multiple correlated contents spreading simultaneously and exhibiting positive (e.g., opinions on same-sex marriage and gun control) or negative (e.g., opinions on universal healthcare and tax-relief for the ‘rich’) correlation. In a nutshell, few researchers model an influence propagation with the simultaneous spread of multiple correlated contents. Thus, for this scenario, we first propose a new model, the vector threshold model. For this model, we analyze the expected size of global cascades and find the condition of the existence of global cascades. Then, we confirm the correctness of our analysis by numerical studies. Next, we discuss how the correlation among contents affects the expected size of global cascades. In particular, when the mean degree of nodes is at a low level, the competitive, independent, and cooperative relationships produce global cascades with similar size. Only when the mean degree is at a high level do we see significant differences between these relationships on the expected size of global cascades.

We present a stochastic microscopic model that exhibits the same properties as the Generalized Voter Model in its Langevin description. Building on a model introduced in 2011 by Blythe et al. for the investigation of ordering dynamics in the presence of symmetric absorbing states, we show that our model exhibits phase transitions belonging to three different universality classes: Voter, Ising, and Directed Percolation. These different universality classes are identified through a systematic investigation of various static and dynamic quantities. We also present some data on the aging processes taking place at Voter critical points and show that, depending on the values of some system parameters, properties of linear or non-linear voter models are recovered.

Emergence of a crystalline phase in sheared granular matter

HARRY SWINNEY (Presenter), CHARLES RADIN, University of Texas at Austin, FRANK RIETZ, MATTHIAS SCHROETER, Max-Planck-Institute for Dynamics and Self-Organization — One-half century ago a classic experiment by G.D. Scott (Nature 188, 908, 1960) showed that pouring steel balls into a rigid container filled the volume to an upper limit volume fraction of 0.64, which is well below the volume fraction 0.74 filled by spheres in a hexagonal close-packed (HCP) or face-centered cubic (FCC) lattice. Subsequent experiments confirmed a “random closed-packed” (RCP) volume fraction of about 0.64. However, the physics of the RCP limit has remained a mystery. We have conducted an experiment on a cubical box filled with 49400 precision glass spheres under weak shear imposed by a small slow angular oscillation of two opposite sidewalls. A phase transition occurred at a volume fraction of 0.645, from a disordered to an ordered state, consisting of crystallites of mixed FCC and HCP symmetry that coexist with the amorphous bulk. The transition is initiated by homogeneous nucleation. In the shearing process small crystallites with about ten or fewer spheres dissolve, while larger crystallites grow.

Jamming by shear in a dilating granular system

MEIMEI WANG (Presenter), Civil Engineering, University of Science and Technology Beijing, DONG WANG, JOSHUA SOCOLAR, HU ZHENG, ROBERT P BEHRINGER, Physics Department, Duke University — Jamming can occur in frictional granular materials undergoing shear at a fixed packing fraction, $\phi$, for $\phi$ within a range of packing fractions below the isotropic jamming point, and the amount of strain required to induce jamming, $\gamma$, increases with decreasing $\phi$. We are interested in how the shear jamming process is affected if the system is dilating as it is sheared. We conduct experiments to shear a 2D granular system while continuously increasing the system volume. Below a certain dilation rate, the system is still able to jam at packing fraction, $\phi_c$, smaller than the initial $\phi$. We measure $\gamma$ for different dilation rates and initial packing fractions by monitoring the coordination number of non-rattlers and the system pressure. We find that $\gamma$ is the same as the $\gamma$ required to jam a system with fixed packing fraction $\phi_c$ via pure shear.

System Size Dependence in Shear Jamming of 2D Frictional Grains

DONG WANG (Presenter), HU ZHENG, Duke University, JONATHAN BARES, CNRS, ROBERT P BEHRINGER, Duke University — Jamming jamming (SJ) occurs for frictional granular materials with packing fractions (\(\Phi\)) in a finite range below the isotropic jamming point, when the material is subject to a sufficiently large shear strain, $\gamma_{SJ}$, starting from a force-free state. Here we report experimental studies on the system size dependence for a quasi-2D frictional system composed of bidisperse photoelastic disks. The number of particles in the system ranges from 60 to 3000 by varying particle diameters while maintaining the number and size ratio between big and small disks the same. We observe that $\gamma_{SJ}$ increases with system size at the same $\Phi$ for systems with less than 1000 particles, reminiscent of a recent simulation work (Baity-Jesi et al., J. Stat. Phys. 167, 735 (2017)). However, such a dependence is much weaker comparing systems with 1000 and 3000 particles. Our results imply that SJ still exists in frictional granular materials in the thermodynamic limit.

Granular jamming transition: induced by shearing and compressing

HU ZHENG (Presenter), Duke University/Hohai University, DONG WANG, YIQIU ZHAO, ROBERT P BEHRINGER, Duke University — Jamming of a granular system can be achieved by either isotropically increasing the packing fraction (isotropic jamming) or applying pure shear over a range of packing fractions below the isotropic jamming point (shear jamming). We experimentally study jammed configurations obtained by isotropic biaxial compression or pure shear in a quasi-2D granular system composed of photoelastic disks. A density matching method is applied to avoid basal friction. The fabric anisotropy and stress anisotropy are clearly different in the two cases. However, studies of the scaling behavior near the jamming transition reveal that, as the transition is approached, the scaling exponent of the pressure is the same for the isotropic jamming and shear jamming cases.

8:48AM E56.00005: Experimental observation of shear jamming in 3D granular materials* DAVID Z CHEN (Presenter), RYAN KOZLOWSKI, ROBERT P BEHRINGER, Duke University — Frictional granular media can shear jam over a range of packing fractions below the isotropic jamming packing fraction. We experimentally study shear jamming in 3D by applying cyclic shear at fixed volume for a granular packing submerged in a density-matched solution; the effects of gravity are minimized in this environment, preventing compaction by grain weight. We observe signatures of shear jamming in the macroscopic pressure signal with a variety of packing fractions and shear amplitudes over many (on the order of 100) shear cycles. We report on analysis of particle positions (tracked via refractive index matched scanning [1]) from cycle to cycle that show correlations between microscopic rearrangements and changes in peak pressure across cycles.

*The following grants support this work: DARPA 4-34728, NSF-DMR1206351, NASA NNX15AD38G, Army Research Office Grant W911NF-18-1-0184.

9:00AM E56.00006: Nontrivial plasticity of a shear-jammed granular system* YIQIU ZHAO (Presenter), Duke University, JONATHAN BARES, Laboratoire de M‘(e)canique et G‘(e)nie Civil, Universit‘(e) de Montpellier, HU ZHENG, AGHIL ABED ZADEH, JOSHUA SOCOLAR, ROBERT P BEHRINGER, Duke University — We report shear experiments on a layer of photo-elastic disks in which shear is applied through basal friction with 21 independently controllable concentric rings below the granular layer in a Couette geometry. The rings rotate at different rates to make the local shear strain uniform inside the system. By applying this uniform shear in small steps, we create an ensemble of static shear jammed (SJ) configurations with different packing fractions (\(\phi\)) below the isotropic jamming packing fraction (\(\phi_J\)). We find that the average size and radial profile of plastic deformations between steps vary with packing fraction. A transition at \(\phi_c<\phi_J\) is observed. When \(\phi_c<\phi_c\), the plastic deformation is localized to a narrow shear band close to the inner boundary of the shear cell. When \(\phi_c>\phi_c\), the plastic deformation is spread through the entire system. We report power-law dependence of deformation amplitude on packing fraction close to \(\phi_c\). We also find similar behavior for non-uniform applied shears.

9:12AM E56.00007: Experiments on jamming with oil droplets instead of photoelastic disks* ERIC WEEKS (Presenter), YONGLUN JIANG, CARLOS S ORELLANA, XIA HONG, Emory University — We use quasi-two-dimensional emulsions as experimental models to study the flow of jammed materials. Our emulsions are oil droplets in water and are compressed between two parallel glass plates so that the droplets are deformed into pancake-like disks. We use microscopy to observe these droplets as they flow. From the deformed outlines of the droplets, we can measure all of the inter-droplet forces to within 10%. In this talk I’ll present some of the experiments we’ve done that were directly inspired by Behringer group experiments, and also briefly mention some recent results on flowing samples.

*Funded by NSF (earlier work by CBET-1336401, recent work by CBET-1804186)

9:24AM E56.00008: Dynamic Measurements of Normal and Tangential Coefficients of Restitution for an Inelastic Billiard JEFFREY OLAFSEN (Presenter), KAI YANG, Department of Physics, Baylor University — Driven granular media dissipate a large amount of energy in their particle-particle and particle-boundary interactions. As such, our understanding of the fundamental dynamics in these systems is complicated by the velocity-dependent nature of the coefficient of restitution. Even how a driven granular flow jams necessitates a better understanding of the details of this dissipative mechanism. Very sophisticated experiments have sought to better understand and characterize the velocity dependence of the coefficient of restitution by attempting to constrain and control aspects of the collisions. A careful and in-depth analysis for an inelastic billiard moving within a confining boundary allows the velocity-dependence to be measured as the dynamics freely evolve over multiple collisions in the driven system. The shape of the geometry can be varied to tease out details of the dynamics as well as the differences between the normal and tangential coefficients of restitution. The large amount of data generated in this experiment allows the contributions from both the normal and tangential velocity components in the particle-boundary interactions to be examined. Two derivative experiments, one for particle-boundary and the other for particle-particle collisions will also be discussed.
9:36AM E56.00009: Nontrivial power-law scaling of impact forces into granular materials  NASSER KRIZOU
(Presenter), ABE CLARK, Naval Postgraduate School — When an intruder strikes a granular material, the grains exert a force which decelerates and stops the intruder. Existing ballistic models can successfully describe much of the intruder-material interaction using a macroscopic force law, but these models often fail near the moment of impact. Here, we show results from experiments and numerical simulations, focusing on microscopic intruder-grain interactions during the early stages of impact. We record high-speed videos of intruders (of varying size and density) impacting assemblies of photoelastic disks, and we quantify both the intruder dynamics and the forces in the material. We show nontrivial power law scaling of peak forces during the initial transient phase of the impact into granular materials. Experiments and simulations indicate that this scaling is insensitive to many system details, such as friction, grain stiffness, and whether grain-grain interactions are linear (Hookean) or nonlinear (Hertzian). We also find important similarities to impact forces in dense suspensions, suggesting that our results may be generic for impacts into many kinds of soft, deformable materials.

9:48AM E56.00010: Experimental seismicity and avalanches in sheared granular media*  AGHIL ABED ZADEH
(Presenter), JONATHAN BARES, University of Montpellier, JOSHUA SOCOLAR, ROBERT P BEHRINGER, Duke University — We report on experiments investigating the dynamics of a 2D granular medium, consisting of a vertical layer of photo-elastic disks sheared by a slider that is pulled by a spring. The motion of the slider proceeds through a sequence of discrete events, analogues to seismic shocks, in which elastic energy stored in the spring is rapidly released. We measure the statistics of several properties of the individual events: the energy loss in the spring, the duration of the movement, and the temporal profile of the slider motion. We also study certain conditional probabilities and the statistics of mainshock-aftershock sequences. At low driving rates, we observe crackling with Omori-Utsu, Bath, and waiting time laws similar to those observed in seismic dynamics. At higher driving rates, where the sequence of events shows strong periodicity, we observe scaling laws and asymmetrical event shapes that are clearly distinguishable from those in the crackling regime.

10:00AM E56.00011: Dynamics of a grain-scale intruder in a granular system with and without basal friction*  RYAN KOZLOWSKI (Presenter), DAVID Z CHEN, HU ZHENG, JOSHUA SOCOLAR, Physics, Duke University, LOU KONDIC, Mathematical Sciences, New Jersey Institute of Technology, KAREN DANIELS, Physics, North Carolina State University, ROBERT P BEHRINGER, Physics, Duke University — When a granular medium is sheared by a spring-driven mechanism, the system can exhibit stick-slip dynamics: The grains form a rigid solid as the spring loads (stick event) which plastically deforms when the spring load exceeds the yield stress of the stable configuration (slip event). We experimentally investigate the dynamics of a single grain-scale intruder driven by a spring through a 2D annular bed of photoelastic disks. We vary the grain packing fraction, the interparticle friction, and the basal friction between grains and the table surface, and we measure the azimuthal force on the intruder. For grains resting on a dry surface, where basal friction is present, the system undergoes aperiodic stick-slip motion; when the grains are floating on a fluid and basal friction is negligible, the intruder flows unimpeded through the medium but occasionally clogs. These qualitative behaviors do not seem to depend on packing fraction and interparticle friction coefficient. We report on measurements of the intruder force and speed distributions as well as particle displacements.

10:12AM E56.00012: Tears of wine and shock dynamics*  YONATAN DUKLER, Mathematics, University of California, Los Angeles, ANDREA BERTOZZI (Presenter), Mathematics and Mechanical and Aerospace Engineering, University of California, Los Angeles, ANDREAS MUENCH, Mathematical Institute, Univ. of Oxford, HANGJIE JI, Mathematics, University of California, Los Angeles — We revisit the classical problem of “tears of wine” and discuss the role of the geometry of the wine glass in regards to the formation of tears. Transport of a thin liquid up the side of the glass is instigated by a Marangoni stress due to a combination of thermal gradient and surface tension gradient. This effect is balanced by both normal and tangential components of gravity. When gravity effects are non-negible the possibility of undercompressive shocks enters the picture. We discuss this implications of compressive versus undercompressive shocks for film morphologies and compare with prior experiments on the tears of wine problem and experiments on thermally driven films.

*This work is supported by Simons Math + X Investigator Award number 510776. YD is supported by an NSF graduate research fellowship.
10:24AM E56.00013: Vibration can enhance stick-slip behavior for granular friction* JACQUELINE KRIM (Presenter), Physics, North Carolina State University, ROBERT P BEHRINGER, Physics, Duke University, ABE CLARK, Physics, Naval Postgraduate School — We experimentally study the frictional behavior of a two-dimensional slider [1] pulled slowly over a granular substrate comprised of photoelastic disks while being vibrated at frequencies ranging from 0 to 30 Hz in a direction parallel to sliding. Measurements are performed at constant peak acceleration amplitude, which results in constant average friction levels, but varying frictional behaviors. Surprisingly, we find that stick-slip behavior, where stress slowly builds up and is released in intermittent slips, is enhanced as the frequency of vibration is increased. Our results suggest that increasing the frequency of vibration may help to combine many smaller rearrangements into fewer, but larger, avalanche-like slips. We also examine the manner in which the self-affine character of the force curves evolves with frequency, and find additional support for this interpretation.

10:36AM E56.00014: Nonlocal rheology of a dense granular flow in annular shear experiments KAREN DANIELS (Presenter), ZHU TANG, North Carolina State University, THEODORE ANTHONY BRZINSKI, Haverford College, MICHAEL SHEARER, North Carolina State University — The flow of dense granular materials at low inertial numbers cannot be fully characterized by local rheological models; several nonlocal rheologies have recently been developed to address these shortcomings. To test the efficacy of these models across different particle shapes, packing fractions and shear rates, we perform experiments in a quasi-2D annular shear cell using photoelastic particles. The apparatus is designed to measure both the stress ratio \( \mu \) and the inertial number through the use of a torque sensor, laser-cut leaf springs, and particle-tracking. We observe that across several different packing fractions and rotation rates, a single set of model parameters is able to capture the full range of data collected once we account for frictional drag with the bottom plate. While the model's local parameter is always approximately unity, the nonlocal parameter varies sensitively on both the particle shape and material. Our measurements confirm the prediction that there is a growing lengthscale at a finite value \( \mu_s \), associated with a frictional yield criterion. Finally, we newly identify the physical mechanism behind this transition at \( \mu_s \) by observing that it corresponds to a drop in the susceptibility to force chain fluctuations.

10:48AM E56.00015: Non-local effects in intermediate granular avalanching flows* NATHALIE VRIEND (Presenter), AMALIA L THOMAS, University of Cambridge, KAREN DANIELS, North Carolina State University — In this work we showed that photoelastic analysis allows the quantification of rheologies in an intermediate chute flow. We characterize stresses and velocities in a flow layer with regions below and above the yield ratio \( \mu_s \). We compare our experimental results with a nonlocal rheology. Preliminary results show that the timescale over which the force chains decorrelate is strongly associated with the inverse of the fluidity, a viscosity-like quantity. This provides a physical interpretation of its particle-scale origins.

Session E57 GSNP: Physics of Liquids III BCEC 256 - Yang Zhang, University of Illinois at Urbana-Champaign - Tag(s): Focus
8:00AM E57.00001: Can Statistical Physics Concepts Shed Some Light on the 73 Anomalies of Liquid Water?* [Invited]

H STANLEY (Presenter), Boston University — We focus on recent progress in understanding the 73 anomalies of water, by combining information provided by recent experiments and simulations on water in bulk, nanoconfined and biological environments designed to test the hypothesis that liquid water has behavior consistent with the novel phenomenon of “liquid polymorphism” in that low-temperature water can exist in two distinct phases [1,2]. We will utilize the properties of the Widom line—the locus of maximum correlation length—which can be measured experimentally at temperatures well above the critical temperature. Finally, we will discuss how the general concept of liquid polymorphism is proving useful in understanding anomalies in other liquids, such as silicon, silica, and carbon which have in common that they are characterized by two characteristic length scales in their interactions.

* This work has been supported by the NSF Chemistry Division grant CHE-1213217 and was performed in collaboration with, among others, C. A. Angell, S. V. Buldyrev, S.-H. Chen, D. Corradini, P. G. 8:36AM E57.00002: Liquid-Liquid Phase Transition in Metallic Alloy Melts Detected by Nuclear Magnetic Resonance*

EN-YI CHEN (Presenter), WEI-MING YANG, ALFRED KLEINHAMMES, YUE WU, Department of Physics and Astronomy, University of North Carolina at Chapel Hill — Liquid-liquid phase transition (LLPT) is thought to be exotic as it is not obvious what order parameters could be associated with qualitative changes in liquid structures. In some special cases where the valency of the element and bonding characters change substantially with pressure and temperature, such as the case of phosphorus and cerium, LLPT could take place accompanied by clear changes of the density. Here we show that non-density-driven LLPT can actually be common in metallic alloys, taking place above the liquidus temperature $T_{\text{liq}}$. High-temperature NMR is shown to be an effective tool for revealing such LLPT facilitated by its high sensitivity and high resolution. Subtle changes are detected that are difficult to detect by conventional thermodynamic measurement techniques. We will discuss the observation of LLPT in La-based alloys and Al-based alloys. We will show that the corresponding density change is exceedingly small. In addition, the kinetics of the transition process is also characterized systematically by NMR. This shows that the LLPT should have a profound influence on alloy solidifications.

8:48AM E57.00003: Liquid lipid phase separation on curved surfaces*

MELISSA RINALDIN (Presenter), PIERMARCO FONDA, LUCA GIOMI, DANIELA JUTTA KRAFT, Leiden University — By using colloid supported lipid bilayers of designed shape we proved how the interplay of the shape and the composition of a closed membrane determines the likelihood, the position and the composition of liquid domains [1]. Here, we show that if we open the membrane by connecting it to a reservoir of lipids, all these three properties are deeply affected. In particular, the pinning of the softer domains in high curvature regions is enhanced, leading to a consistent pattern on all colloids.

Genetic Competition in Weakly Compressible Turbulent Flows

ROBERTO BENZI, Tor Vergata University, GIORGIA GUCCIONE, Eindhoven University of Technology, ABIGAIL PLUMMER, DAVID ROBERT NELSON, Harvard University, FEDERICO TOSCHI (Presenter), Eindhoven University of Technology — The genetic competition for biological species living in marine environments can be severely influenced by fluid advection. Very often, in oceans and in lakes, cell generation times are precisely in the inertial range of eddy turnover times and therefore the influence of turbulence must be properly taken into account. We employ both an off-lattice agent-based simulation as well as an on-site density-based model to describe two competing populations in one and in two spatial dimensions under the influence of advecting (turbulent) velocity fields. The novel on-site density-based model allows us to accurately and efficiently describe the dynamics of the population and the genetics of a large number of individuals, making this the ideal tool to study populations in two dimensions. We find that the presence of compressible turbulent velocity fields can have a strong effect on genetic competitions. Even in regimes where the overall population structure is approximately unaltered, the flow can significantly diminish the effect of a selective advantage on fixation probabilities. We explain this effect in terms of the enhanced survival of organisms born at the sources in the flow and the influence of Fisher genetic waves.

Structure and Dynamics of Water Interacting with Hydrophilic, Nanostructured CuO Coatings

JAMES TORRES (Presenter), ZACHARY BUCK, HELMUT KAISER, XIAOQING HE, TOMMI WHITE, ROBERT WINHOLTZ, HASKELL TAUB, University of Missouri, MADHUSUDAN TYAGI, NIST Center for Neutron Research, KENNETH W HERWIG, EUGENE MAMONTOV, LUKE L DAEMEN, MICHELLE KIDDER, Oak Ridge National Laboratory, FLEMMING Y HANSEN, Technical University of Denmark — We have used neutron scattering and electron microscopy to investigate how the structure, dynamics, and phase transitions of water near a bare copper surface are affected by coating it with strongly hydrophilic CuO nanostructures. Our high-energy-resolution elastic neutron scattering measurements show the abrupt freezing transition of water near a bare Cu surface is spread into a continuous transition spanning a temperature range of ~80 K upon coating with the CuO nanostructures. From these elastic scans, we infer the presence of at least two distinct water populations, differing in their freezing behavior and their proximity to the nanostructures. Quasielastic neutron scattering measurements support this interpretation by providing evidence of three water components diffusing on different time scales. Our environmental-SEM images reveal micron-size water droplets wet to the nanostructures. In addition, neutron diffraction measurements indicate that the water closest to the CuO nanostructures freezes into an amorphous solid, while more distant water freezes into crystalline ice. The presence of the two forms of ice is consistent with vibrational spectra observed by inelastic neutron scattering.

The molecular description of amorphous ices and the mechanism governing their pressure induced interconversion

FAUSTO MARTELLI (Presenter), IBM Research, ROBERTO CAR, Princeton University, NICOLAS GIOVAMBATTISTA, Brooklyn College — We employ classical molecular dynamics simulations to investigate the molecular-level structure of water during the isothermal compression of hexagonal ice (Ih) and low-density amorphous (LDA) ice at low temperatures to high-density amorphous ice (HDA) [1], and the isothermal decompression of HDA by employing a sensitive local order metric [2]. Our results confirm that LDA and HDA are indeed amorphous, i.e., they lack of polydisperse ice domains. Interestingly, HDA contains a small number of domains that are reminiscent of the unit cell of ice IV, although the hydrogen-bond network (HBN) of these domains differ from the HBN of ice IV. Both nonequilibrium LDA-to-HDA and Ih-to-HDA transformations are two-steps processes where a small distortion of the HBN first occurs at low pressures and then, a sudden, extensive re-arrangement of hydrogen bonds at the corresponding transformation pressure follows.

9:36AM E57.00007: Multiple Protonic Kinetic Energy Band Models of Melted Ice Periodic Lattice for Pure Liquid Water  BIN JIE (Presenter), Physics Department, Xiamen University, TIANHUI JIE, Institution applied, CHIH-TANG SAH, Physics Department, Xiamen University — Existence of long-range order in fluid water under numerous daily conditions led us to extend the 1933 Bernal-Fowler Hexagonally Close Packed (HCP) crystalline ice lattice to model pure liquid water as Melted Ice. The 8 protons in the primitive unit cells (PUC) of the HCP lattice vibrate about their lattice positions, jump among the 16 possible proton sites, half empty and half occupied in the PUC and transport among the PUC’s. Propagating and localized proton vibrations are respectively the Protonic Fermions and Bosons, described by the Bloch and Wannier eigenfunctions, which are perturbed to form localized states (protonic traps) by rare random localizations. The eigenvalues of the frozen periodic lattice give the kinetic energy-band landscapes of the protonic Fermions and Bosons, while the long-range order in fluid water led us to model the proton transport by our 3-step (A, B, C) collision dynamics (DDGRT). The observed 3 thermal activation energies of pH and positive and negative ion electrical mobilities, are in excellent agreement with Slinky Toy Model of the proton vibration frequencies of dilute vapor water, providing the existence proof for this new two-phase approach to model liquid water, employing ice lattice and random distribution of water molecules in vapor.

Tuesday, March 5, 2019 8:00 AM - 11:00 AM

Session E58 GSOFT: Colloids I BCEC 257A - Vivek Sharma, University of Illinois at Chicago

8:00AM E58.00001: Impact of extreme softness on the crystallization of ultra-low crosslinked microgels in two and three dimensions*  STEFFEN BOCHENEK (Presenter), ANDREA SCOTTI, MONIA BRUGNONI, Institute of Physical Chemistry, RWTH Aachen University, LUCIO ISA, Department of Materials, ETH Zurich, WALTER RICHTERING, Institute of Physical Chemistry, RWTH Aachen University — Ultra-low crosslinked poly(N-isopropylacrylamide) microgels are used to elucidate the effect of softness on crystallization in two- and three-dimensions. 2D systems are produced by compressing and depositing microgels from oil-water interfaces. Ex-situ analysis by atomic force microscopy reveals that no crystals form upon compression, as opposed to the case of stiffer microgels. Once adsorbed at a fluid interface, microgels spread into disk-like objects whose size and stiffness are a strong function of polymer content and crosslinking. Consequently, interfacial confinement exacerbates size and mechanical polydispersity, effectively suppressing crystallization. In contrast, in 3D, the microgels crystallize at high concentrations, indicating that softness per se is not sufficient to suppress the liquid-solid phase transition, unless it is coupled to induced polydispersity. Furthermore, small-angle neutron scattering with contrast matching reveals that interpenetration is dominant over deswelling and deformation when these microgels are in 3D-overcrowded environments.

*The authors acknowledge the Deutsche Forschungsgemeinschaft within the SFB 985 “Functional Microgels and Microgel Systems” for financial support. A. S. thanks Alexander von Humboldt Foundation for financial support.

8:12AM E58.00002: Influence of Softness and Internal Architecture on Microgel Deswelling in Concentrated Suspensions*  ANDREA SCOTTI (Presenter), MONIA BRUGNONI, RWTH Aachen University, JUDITH HOUSTON, Forschungszentrum Juelich GmbH, FRIEDERIKE SCHULTE, STEFFEN BOCHENEK, WALTER RICHTERING, RWTH Aachen University — Microgels are soft polymeric networks swollen in a good solvent. They can be compressed, deformed or interpenetrated in concentrated suspensions. The prevalence of one of these mechanisms depends on both the softness and the architecture of the polymer network. By probing regular, ultra-low crosslinked, and hollow-poly(N-isopropylacrylamide) based microgels we show that for the same architecture, a decrease in the amount of crosslinker during the synthesis produces a more pronounced deswelling. Small-angle neutron scattering is used to directly access the form factors of the different microgels embedded within a matrix of regular crosslinked ones. This work clarifies that to obtain compressible microgels that adapt their size in concentrated suspensions, the presence of a cavity produces higher deswelling than decreasing the amount of crosslinker during the precipitation polymerization. The latter option leads to the opposite effect and interpenetration is dominant.

8:24AM E58.00003: Influence of Softness on the Stability of Binary Crystals  RONALD LACOUR (Presenter), CARL SIMON ADORF, SHARON GLOTZER, Chemical Engineering, University of Michigan — Binary systems of spherical colloids have shown the ability to self-assemble into many more superlattice structures than comparable monodisperse systems. Understanding the nature of the interparticle forces in such self-assembly is critical to target specific structures for self-assembly. Here we computationally investigate the influence of "softness", the steepness of the interaction potential, on the solid phase behavior of particles interacting with a purely repulsive, isotropic pair potential. We determine the ground state phase diagram for our model using a basin-hopping algorithm to optimize candidate structures for low enthalpy. The phase behavior of repulsive particles is often understood by looking at the packing fraction of different phases; however, we find that a very small amount of softness can change the stable ground state phase of a system away from the densest packing structure. We also find softness increases the stability of many experimentally observed structures. Our results provide further insight into why particular structures self-assemble and will be useful as a reference for experimentalists working with softly repulsive particles.

8:36AM E58.00004: Spontaneous deswelling of microgels controlled by counterion clouds  URS GASSER (Presenter), Paul Scherrer Institut, ANDREA SCOTTI, RWTH Aachen, Germany, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — Microgels based on poly(N-isopropylacrylamide) (pNIPAM) show a unique, spontaneous deswelling behavior at constant temperature below the deswelling transition of pNIPAM at 32C when brought above a critical concentration. We have shown that counterion clouds of pNIPAM microgels provide the mechanism for this spontaneous deswelling [A. Scotti et al., PNAS 113, 5576 (2016)]. Although pNIPAM is uncharged, charged groups are incorporated on the particle surface during synthesis. Counterions not bound by the surface charge set the osmotic pressure of the microgel suspension. At high concentration, the overlap of counterion clouds of neighboring particles causes an increase of the osmotic pressure in the space between the particles, while the pressure in the interior of the microgels does not increase. The resulting pressure difference deswells the microgels, if it exceeds their bulk modulus. Measurements of the microgel size at high concentrations using small-angle neutron scattering show that the volume fraction remains below random close packing up to effective volume fractions of about 1.0. We show that the essential aspects of the observed deswelling are captured with a Poisson-Boltzmann model of the microgels and without direct interaction of the microgels.

8:48AM E58.00005: Self-inflating Colloidal Microcapsules  ZHE XU (Presenter), STEFANO SACANNA, New York University — Hollow-structured particles have attracted great attention in both nanomaterials and colloidal science due to their high surface area and unique spatial confinement. Here I will present a self-inflation method to produce 3-(trimethoxysilyl)propyl methacrylate(TPM) based colloidal microcapsules with versatile design and tunability of structures. Detailed mechanistic study revealed the process is the result of a fine balance between surface tension and osmotic pressure from partial hydrolysis of TPM network. Microcapsule sizes can be accurately controlled by adjusting the osmotic pressure due to the semipermeable property of the membrane. We further demonstrate the feasibility of introducing an opening hole onto the capsules by hard-templating on a removable seed, and the whole network can be solidified to maintain stable and rigid morphology. Large-scale synthesis of monodisperse polymeric microcapsules with tunable and uniform hole can be easily obtained. As a result, these model particles laid solid foundation for studying fluid mechanics, self-assembly, packing and jamming in confinement, and showed great potential in dynamic transport, storage, separation and delivery of drugs or particles.

9:00AM E58.00006: Designing plasmonic-based colloidal pH microsensors*  REMI DREYFUS (Presenter), CNRS, CELINE BUREL, Solvay, BERTRAND DONNIO, CNRS — Many natural processes start with an alteration of their immediate environment at the microscopic level. Therefore there is a need to develop pH microsensors that can easily reveal local changes in pH in any heterogeneous system. In this presentation, we show that with a careful design of colloids made of closely packed gold nanoparticles embedded in a thin pH-responsive polymeric shells, we can synthesize sensors at the micron scales that can be dispersed into heterogeneous systems and from which we can read sensitive information on local pH. We found that at low pH, close-packed jammed gold nanoparticles experience strong coupling in their plasmonic resonance, changing the plasmonic resonance to the red part of the spectrum, and giving a strong blue color to the microparticles. As pH is increased, the polymeric crust of the particles gets charged and swells, increasing the distance between the nanoparticles, thus suppressing the plasmonic correlations and inducing a strong color change with an absorption in the blue part of the spectrum, changing the microcapsules into red. Our results demonstrate that these colloidal capsules provide us with an easy way to unambiguously detect local pH changes at the microscale level in heterogenous systems.

9:12AM E58.00007: Improved generative models for colloidal specimens in digital holographic microscopy*
RONALD ALEXANDER (Presenter), BRIAN LEAHY, VINOTHAN N MANOHARAN, Harvard University — Digital holographic microscopy (DHM) is an important tool for characterizing colloidal specimens. Traditionally, the inverse problem of determining the size, shape, orientation and composition of an object from a hologram obtained by DHM is approached by numerical reconstruction of the incident and scattered electromagnetic fields. Recently, we have made advances by comparing holograms to predictions of a forward model for hologram formation. For systems colloidal spheres and cylinders in which multiple scattering is negligible, the scattering problem is solvable analytically and/or numerically. These calculations provide the basis for a model of image formation in DHM. We present progress highlighting improvements to a generative model for DHM of systems of colloidal particles. In particular, we show that explicit modelling of the scattering and diffraction effects in a microscope's optical train increase the model's predictive power. We also investigate the challenges for extending our technique of characterization through fitting of a forward model to biological systems such as bacteria and and animal cells.

9:24AM E58.00008: A Quick Method to determine ensemble averaged Translational and Rotational Diffusion coefficients
NAMITA SHOKEEN (Presenter), ASHIS MUKHOPADHYAY, Wayne State University — The ensemble averaged translational diffusion of isotropic particles and coupled translational-rotational diffusion of anisotropic particles inside water and various polymer solutions were determined using dynamic differential microscopy (DDM). Initially, we applied this technique to characterize the dynamics of 25 nm radius particles within entangled high molecular weight, \( M_w = 600 \) kg/mol polyethylene oxide-water solutions, which extended the scope of DDM to study the dynamics and rheological properties of soft matter at nanoscale. We will demonstrate the application of this method to characterize the motion of colloidal ellipsoids of different aspect ratios.

9:36AM E58.00009: Dynamic properties of liquid states in systems with a short-range attraction and long-range repulsion*
PAUL D GODFRIN, Massachusetts Institute of Technology, PETER FALUS, LIONEL PORCAR, Institut Laue–Langevin, KUNLUN HONG, Oak Ridge National Laboratory, STEVEN HUDSON, National Institute of Standards and Technology, NORMAN J. WAGNER, University of Delaware, YUN LIU (Presenter), National Institute of Standards and Technology — Colloidal systems with a short-range attraction and long-range repulsion have been intensively studied in the past decade. A generalized phase diagram has been proposed with multiple liquid states. Using lysozyme as a model system, we have identified different liquid states of previous experimentally studied lysozyme samples within this generalized state diagram and explore the dynamic properties of each liquid state. Most lysozyme samples studied previously at low and intermediate concentrations are dispersed fluid states while a few high concentration samples are randomly percolated liquid states. In the dispersed fluid state, the short-time diffusion coefficient measured is found insensitive to the attraction strength, while it is very sensitive to the attraction strength in random percolated fluids. At high enough concentrations, the mean square displacement can be as slow as those of many glassy colloidal systems at time scales near the characteristic diffusion time even though these lysozyme samples remain in liquid states at the long-time limit. A localized glassy state is further identified by the mean square displacement.

9:48AM E58.00010: Hyperuniform defects in an isotropic liquid
RODRIGO GUERRA (Presenter), PAUL M CHAIKIN, New York University — The concentration and organization of topological lattice defects form the basis of our theoretical understanding of the two-step melting process of two-dimensional solids, as described by Kosterlitz, Thouless, Halperin, Nelson, and Young (KTHNY). In this description, particles surrounded by anything but six nearest neighbors act as topologically charged quasi-particles, called disclinations, that interact via Coulombic pair potentials when the material is in the liquid-crystalline hexatic phase. This description is presumed to break down in the fully-isotropic liquid phase, but we find that the spectrum of topological charge density fluctuations in the liquid obeys the same spatial and temperature scaling relationships, \( S(q \to 0) \sim k_B T q^2 \), expected for an idealized fluid of oppositely charged particles: except for temperatures much larger than the isotropic-hexatic transition temperature. This suggests that the quasi-particle description may provide valuable insights into the behavior of the fluid too, particularly to the coupling of Gaussian curvature and topological charge in the fluid.
10:00AM E58.00011: Colloidal gelation as a nonequilibrium continuous phase transition  JOEP ROUWHORST (Presenter), Institute of Physics, University of Amsterdam, CHRIS NESS, ALESSIO ZACCONE, Department of Chemical Engineering and Biotechnology, University of Cambridge, PETER SCHALL, Institute of Physics, University of Amsterdam — A new view on gelation as a second-order nonequilibrium phase transition is presented using combined experiments on critical Casimir colloidal suspensions, simulations, and analytic solutions to a simplified master kinetic equation. The critical Casimir forces provide effective, short-ranged colloidal interactions that can be tuned with temperature, allowing to study gelation over a range of moderate attractive strength (bond energy between 3 and 6kBT). The experiments and simulations show cluster sizes and correlation lengths diverging with exponents ~1.6 and 0.8, respectively, consistent with growth exponents in percolation theory. Cluster masses exhibit power-law distributions with exponents -3/2 and -5/2 before and after gelation, respectively, as predicted by a master kinetic equation with single-bonded particle detachment. As detailed balance is violated in this process, our results indicate that the observed gelation is a nonequilibrium continuous phase transition (nonequilibrium percolation). These results suggest that the observed gelation process, in which fluid particles aggregate and percolate into rigid structures, is an analogue, mirror-image process of yielding, where emerging fluid-like particles percolate within a rigid matrix.

10:12AM E58.00012: Evolution of a sedimenting colloidal sheet  RUO-YU DONG (Presenter), IBS Center for Soft and Living Matter, WEI WANG, Harbin Institute of Technology, SHANKAR GHOSH, Tata institute of fundamental research, STEVE GRANICK, IBS Center for Soft and Living Matter — A sedimenting 2D colloidal sheet shows curious stability and nonlinear behavior at small Re around 10^{-3}, which should be in the linear Stokes regime. Small-scale mechanical instabilities develop in the form of dynamic swirling of particles in transient clusters, which generate multiple critical points and highly entangled vortex lines. This nonlinearity results from the topological nature of the fluid flow. Spatial organization of swirling motions determines the overall shape. The observed phenomena may challenge our notion of a low Reynolds number hydrodynamic problem, and holds value for understanding other dissipative dynamical systems.

10:24AM E58.00013: Electrical resistance fluctuations as a probe to monitor colloidal flows*  CAGATAY KARAKAN (Presenter), KAMIL EKINCI, Mechanical Engineering, Boston University — Impedance measurements are widely used to detect particles or cells in a flow and to measure their various properties. The approach typically focuses on individual cell counting and sizing by passing the cells through artificial constrictions in which the channel diameter D is comparable to particle size d (D~d). Here, we explore the electrical impedance sensing technique to characterize colloidal flows in microchannels at different D/d limits. Our measurement is based on a standard four-wire probe of the mean electrical resistance R_m and its fluctuations ΔR(t) across the channel. We have applied this approach to measure flows with microbead and red blood cell suspensions in microchannels with different diameters. Flow properties such as flow rate, shear stress, concentration and composition are varied while monitoring the microchannel optically and electrically. Our results suggest that concentration can be inferred from R_m, while ΔR/R_m and its probability distribution contains information about other flow parameters, such as flow rate, particle composition and its properties. Based on our preliminary data, we will discuss how impedance sensing can be used to monitor flow parameters in vasculature networks.

10:36AM E58.00014: Solvent coarsening around laser-heated colloids and related effective forces  SUTAPA ROY (Presenter), Max-Planck Institute for Intelligent Systems, Heisenbergstr. 3, 70569 Stuttgart, Germany, and 2 IV. Institut für Theoretische Physik, Universität Stuttgart, Pfaffenwaldring 5, JUAN RUBEN GOMEZ-SOLANO, Universität Nacional Autonoma de Mexico, CHRIS NESS, ALESSIO ZACCONE, Department of Chemical Engineering and Biotechnology, University of Cambridge, PETER SCHALL, Institute of Physics, University of Amsterdam — Laser illuminating a Janus colloid which is suspended in a near-critical binary solvent leads to the formation of the concentration gradient and coarsening patterns around the colloid, which leads to its phoretic motion. Using analytical theory and numerical simulations, we investigate this non-equilibrium phenomenon under the influence of a time-dependent temperature gradient. Our predictions are also confirmed by experiments with Gold-capped Janus particles immersed in PnP-water binary liquid mixture. Time-dependent properties of the coarsening patterns for various surface adsorption properties of the Janus colloid are analyzed. We also present results for structure formation around colloidal particles kept confined in thin films with confining surfaces preferring one species of the binary liquid mixture over the other. Confinement leads to the formation of a bridge connecting the colloid and both the confining walls. It is observed that the particle starts to move much before the stationary state is achieved. Results will also be presented on the time-dependent effective interactions between two such heated colloidal particles.

Session E59 GSOFT: Rheology and Flow of Soft Matter II BCEC 257B - Scott Franklin, Rochester Institute of Technology

8:00AM E59.00001: Dynamical correlation lengths in shape-based models of confluent tissue DANIEL SUSSMAN (Presenter), Syracuse University, JOHN DEVANY, MARGARET GARDEL, University of Chicago, M. LISA MANNING, Syracuse University — It has become increasingly clear that the rheology of densely packed cells in confluent tissue helps control processes ranging from multicellular development to wound healing to cancer tumor development. However, the impact on tissue rheology of cell-autonomous active processes, such as active alignment of cell motility and cell proliferation, remains unclear. Moreover, our recent observations of cell monolayers that undergo extensive cell division indicate that
tissue rheology changes dramatically as cells proliferate, with interesting dynamical correlation length scales that depend on the mechanical environment. To understand these observations, we extend shape-based models of confluent tissues to include both cell alignment and proliferation. We find that shape-based models quite naturally generate the time-varying trends in cell density, cell shape, and cell motility observed in our monolayers, and that a coupling mechanism like cell-cell alignment is necessary to generate the observed correlation length scales. In this context, we additionally investigate the effects of using metric vs topological alignment rules in active matter systems where the interaction potential is itself explicitly topological.

8:12AM E59.00002: Perclosures induced by quasistatic shear in athermal systems with weak attraction* YUCHUAN WANG (Presenter), YOUJIN DENG, NING XIU, Department of Physics, University of Science and Technology of China — When quasistatically shearing athermal particulate systems with weak attraction, we observe both connectivity percolation and solidlike transitions over a wide range of packing fractions below the jamming transition point. It is already known that without shear connectivity percolation for the same system occur at specific packing fraction, \( \varphi_{cp} \). It is interesting that driven by shear the system undergoes percolation transition even far below \( \varphi_{cp} \). We find that \( \varphi_{cp} \) and another specific packing fraction approximately separate the whole packing fraction regimes into three parts, in which the connectivity percolation exhibits apparent differences. Combining the static structure factor, we come up with a novel phase diagram with percolation transitions, and regimes of phase separation, gelation, shear jamming, and jamming.

8:24AM E59.00003: Pressure Decay in 2D Molecular Dynamics Simulation with Varied Filter Pore Width and Fluid Impurity Diameter KEVIN VANSLYKE (Presenter), SURAJIT SEN, University at Buffalo, The State University of New York — Time dependent pressure in a 2D molecular dynamics model using Lennard-Jones Argon atoms is studied in a semi-periodic chamber containing a simple porous filter. In each case an initial velocity bias towards the filter leads to the buildup of pressure in a region adjacent to the filter. The pressure in this region is shown to exhibit damped oscillatory behavior as the pulse is reflected and travels across periodic boundary conditions. The effects of pore width and fluid impurity diameter on the exponential decay time constant are evaluated in detail. Our results demonstrate a negative linear relation between time constant and pore width for systems with a fixed impurity diameter, and a positive linear relation between time constant and impurity diameter in systems with a fixed pore width.
2d Shear of Granular Annular Sector Particles (ASPs)*

SCOTT FRANKLIN (Presenter), ELYSE ROOD, Rochester Institute of Technology, THEODORE ANTHONY BRZINSKI, SYKES CARGILE, Physics, Haverford College — We study the shear of granular annular sector particles (ASPs), open semi-circular rings that have previously been studied at colloidal scales. ASPs can be characterized by two dimensionless numbers: the subtended opening angle and the ratio of inner and outer radii. We place granular ASPs in an annular-planar Couette shear cell and visualize the entire 360° with six cameras. Particle tracking software identifies the position and orientation of each ASP and enables measurement of large-scale motion and particle-particle interactions. ASPs can entangle to form dimers, trimers and other structures and we measure the distribution, creation and annihilation of these structures. Dimers can be characterized by the dot product of constituent ASP orientations. I will describe our initial experiments and compare with collaborative experiments in avalanching geometries.

Effect of Acid Hydrolysis on the Rheology of Phytoglycogen Nanoparticles

HURMIZ SHAMANA (Presenter), MICHAEL GROSSUTTI, JOHN DUTCHER, University of Guelph — Phytoglycogen is a natural polysaccharide produced in the form of compact 35 nm diameter nanoparticles by some varieties of plants such as sweet corn. The highly-branched, dendrimeric structure of phytoglycogen leads to interesting and useful properties that make the particles ideal as unique additives in personal care, nutrition and biomedical formulations. One such property is the unusual polysaccharide rheology of aqueous dispersions of phytoglycogen nanoparticles [1]. When added to water, the zero-shear viscosity of the dispersions remains small up to large concentrations (~20% w/w). For higher concentrations, the zero-shear viscosity increases dramatically, reaching values that exceed that of water by more than a factor of $10^6$ at the highest concentrations of 30% w/w. We have used acid hydrolysis to partially digest the phytoglycogen nanoparticles, which not only reduces their diameter, but also removes the hairy chains on the outer surface of the particles thereby altering the interaction between particles. We compare the concentration dependence of the zero-shear viscosity of the smaller, acid hydrolyzed particles to that of the native particles. These results suggest new applications for the acid hydrolyzed particles.

Biased Brownian motion in a channel with symmetry and anisotropy*

KI WING TO (Presenter), Institute of Physics, Academia Sinica, WEI-HSUAN TSENG, National Taiwan Normal University, Department of Physics — We study biased Brownian motion of a bead in a quasi-two-dimensional horizontal channel consists of identical cells with asymmetric walls and anisotropic base connected in a circular loop. When the channel is shaken vertically, energy is injected to the bead by collisions with the base and converted to kinetic energy in the horizontal direction. Asymmetry and anisotropy of channel induce a driving force on the bead so that the bead performs biased Brownian motion along the channel axis with the drift velocity being proportional to the diffusivity. Furthermore, the distribution function of the escape time from a cell is found to be an exponentially decay function. These experimental results can be explained by the continuous time random walk theory (CTRW).

Tuning the Shear Thickening Response using Acoustic Perturbations*

PRATEEK SEHGAL (Presenter), Sibley School of Mechanical and Aerospace Engineering, Cornell University, MEERA RAMASWAMY, ITAI COHEN, Department of Physics, Cornell University, BRIAN J. KIRBY, Sibley School of Mechanical and Aerospace Engineering, Cornell University — Shear thickening behavior of dense particle suspensions is generally not considered an externally tunable response. In this work, we present a novel method to dynamically tune the rheological response of a non-Brownian shear thickening suspension using local acoustic perturbations. We apply resonant perturbations in two different directions orthogonal to the primary shear flow and show a tunable viscosity response of the suspension in the transitioning regime and the shear-thickened regime of the flow curve. We find that the acoustic perturbations increase the onset strain rate of shear thickening in addition to decreasing the viscosity (de-thickening) of the suspension. We attribute the mechanism of de-thickening to the breaking of shear-induced force chains and disruption of solid-solid frictional contact between the particles by local acoustic perturbations. With the temporal amplitude modulation of the perturbations, we further demonstrate a periodic thickening/de-thickening of the suspension and show that the response is dynamically tunable.

Geometric frustration induces the transition between rotation and counterrotation in swirled granular media

LISA LEE, Harvard University, JOHN PAUL RYAN, Department of Computer Science, Cornell University, MIRANDA HOLMES-CERFON, Courant Institute of Mathematical Sciences, New York University, SHMU EL RUBINSTEIN (Presenter), Harvard University — Marbles in a swirled teacup exhibit a curious dynamical transition: at small densities, the marbles circulate in the same direction as the container, but at larger densities, they transition to circulating in the opposite direction. This phenomenon occurs in a range of swirled and vibrated granular systems, from industrial vibration mills to baby rattles, each observation challenging our intuitive understanding of angular momentum conservation. Using an accelerating coordinate system, we use experiments and simulations to identify the cause for the transition to counterrotation. At low densities, the grains roll freely in the container, but as density increases, antiferromagnetic-like frictional interactions between beads lead to geometrical frustration, resolved only via global circulation. I will furthermore show that in the new frame of reference this system resembles a rotating drum.

Predicting and measuring shear rheology of soft interfaces

ADITYA RAGHUNANDAN (Presenter), NICHOLAS DEBONO, NICHOLAS PEARSON, PATRICK UNDERHILL, Rensselaer Polytechnic Institute, JUAN MANUEL LOPEZ, Arizona State University, A HIRSA, Rensselaer Polytechnic Institute — Measuring the non-Newtonian shear responses of monomolecular films or macromolecules like proteins at fluid-fluid interfaces has been limited by using linear (Newtonian) constitutive equations to determine rheological properties. Predicting this nonlinear behavior is integral to comprehending many biophysical processes such as breathing and in the pathology of diseases such as Alzheimer’s, which are marked by protein denaturation in vivo. We present a generalized 2-D constitutive equation for interfaces under steady shear with the interfacial shear viscosity generalized to be a function of the imposed shear-rate. We introduce non-Newtonian material properties that control nonlinear and linear shear responses of an interfacial system. Combining flow field predictions from the new equation and experiments in a knife-edge flow geometry, we demonstrate that monomolecular films of DPPC – the primary constituent of mammalian cell walls and pulmonary surfactant – are shear-thinning at near-physiological surface packing over six decades of shear-rate. Also, the role of interfacial rheology of an adsorbed protein film of insulin in the process of denaturation and subsequent amyloid fibril formation at the air/water interface is delineated.

Slip-link Simulations under Fast Flows: Effect of the Stretch/Orientation-Induced Reduction of Friction

TAKESHI SATO (Presenter), TAKASHI TANIGUCHI, Kyoto University — Macroscopic flows of entangled polymer melts are tightly connected with the microscopic polymer chain dynamics. One possible solution to this problem could be obtained with a multiscale simulation (MSS) approach, where a microscopic model is combined with a macroscopic model. To develop the MSS technique that can address polymer processing conditions, we need to develop a microscopic model that can correctly predict rheological behaviors under fast flows. However, the molecular mechanisms of entangled polymer chains under fast flows have not been fully understood. Yaoita et al. have introduced the concept of the stretch/orientation-induced reduction of molecular friction (SORF) to their slip-link (SL) model and found that SORF can improve the predictions of rheological behaviors under fast uniaxial elongational flows [Yaoita et al., 2012]. In this study, we have investigated the effect of SORF on the more coarse-grained SL model [Doi et al., 2003]. As a result, we have found that SORF can improve the rheological properties obtained from our SL model especially under uniaxial elongational flows. This result will help us to develop the MSS technique for fast entangled polymer melt flows.

Session E60 FOEP: Sharing Science: How to Communicate with the Public

Fermilab - Tag(s): Invited, Outreach, Undergraduate

Science Blogs and Talking Dogs: Reflections on 17 Years in Social Media [Invited] CHAD ORZEL (Presenter), Union College — In this talk I will discuss lessons learned about physics and science communication in the online world, drawing on my experiences since starting a weblog to discuss physics in 2002. This will include pros and cons of various media, including blogs, Twitter, and Facebook, and a discussion of the opportunities and risks these technologies offer for physicists interested in engaging with a broad public audience.
8:36AM E60.00002: Science News Online: Finding the Signal in the Noise [Invited]  ALLISON ECK (Presenter), NOVA —
You've been working in the lab for a long time, but you want to experiment with writing physics stories—or any kind of science story—for the public. So how do you do it? This session, led by Allison Eck, a digital editor for the award-winning PBS science documentary series NOVA, will introduce attendees to the vast and evolving landscape of digital science news. Attendees will also learn how to identify good science news stories, pitch them to editors, build a "beat," and more. Get ready to think like a reporter!

9:12AM E60.00003: Adventures in Podcasting [Invited]  SEAN CARROLL (Presenter), Caltech — Podcasts are a relatively new, but already popular and rapidly-growing, means of outreach and communication. They are essentially radio shows with episodes that are put on the internet rather than broadcast. I will describe my experiences as someone who listens to and appears on podcasts, as well as the creator and host of a new podcast, Mindscape.

9:48AM E60.00004: Science Festivals, Live Events, and the Importance of Face-to-Face Interaction* [Invited]  BEN WIEHE (Presenter), Science Festival Alliance, MIT Museum —
Since at least the dawn of agriculture, humans have gathered in the public square to celebrate what brings them together as a community. Even in our digital age, there is something special about festivals and live events. There is an immediacy to being there in-person: a unique don't-miss-out buzz and a compelling urgency. Events offer the chance to quickly develop real human relationships, and are rich with the potential for genuine dialogue and exchange. Events need not be tied to one location or venue, and can be quickly adapted to be meaningful and energizing for different audiences. Events can also work at any scale, budget, institutional backing, and level of professionalism, so anyone and any organization can get involved.

As they have for millennia, festivals and events still have the power to energize a community and then periodically reaffirm and renew that energy. What happens when that power is used in the name of science? Over the past two decades, there has been an explosion of experimentation with live public science events in the United States. From intimate discussions of science in a neighborhood pub, to science festival main events that draw tens of thousands in a single day, there is much to learn from these experiments.

Examples of past and ongoing events set the context for a presentation of notable evaluation and research findings related to science events, with a special emphasis on the direct participation of professional scientists. By situating these specific findings within the vast and multi-disciplinary literature dedicated to festival and event studies, a case is made for the importance of face-to-face interaction in every initiative seeking to share science with the public.

*The Science Festival Alliance is currently supported by funding from Science Sandbox (an initiative of the Simons Foundation), and the Alfred P. Sloan Foundation

10:24AM E60.00005: Tough crowd: Reaching beyond the usual science-interested audiences [Invited]  RAY JAYAWARDHANA (Presenter), Cornell University — For those involved in science communication and outreach, engaging with audiences who usually do not seek out science events/media/venues presents interesting challenges. I will reflect on those challenges, drawing upon a few attempts bring science content to unexpected places.

Tuesday, March 5, 2019 8:00 AM - 10:24 AM

Session E61 GSOFT DBIO GSNP: Active Matter II BCEC 258B - M Cristina Marchetti, University of California, Santa Barbara - Tag(s): Focus
8:00AM E61.00001: Defect loops in 3D active nematics [Invited] DANIEL BELLER (Presenter), Department of Physics, University of California, Merced, GUILLAUME DUCLOS, Martin A. Fisher School of Physics, Brandeis University, DEBARGHYA BANERJEE, Max Planck Institute for Dynamics and Self-Organization, Göttingen, MINU VARGHESE, MATTHEW PETERSON, ARVIND BASKARAN, APARNA BASKARAN, MICHAEL F HAGAN, Martin A. Fisher School of Physics, Brandeis University, FEDERICO TOSCHI, Department of Applied Physics, Eindhoven University of Technology, SEBASTIAN STREICHAN, Department of Physics, University of California, Santa Barbara, VINCENZO VITELLI, James Franck Institute and Department of Physics, University of Chicago, ZVONIMIR DOGIC, Department of Physics, University of California, Santa Barbara, ROBERT PELCOVITS, Department of Physics, Brown University, THOMAS POWERS, School of Engineering and Department of Physics, Brown University — In 2D active nematics, internally driven chaotic flows are characterized by the continual production, motion, and annihilation of point defect pairs. We investigate the behavior of active nematics in 3D, for which we have developed an experimental model system of microtubules and molecular motors, as well as numerical modeling approaches. The defects characterizing chaotic flow are here curvilinear rather than point-like. We present a theoretical model predicting a certain class of closed disclination loops to be the system's generic singularities. Through detailed analysis of experimental and numerically generated configurations, we show how our predictions of defect topology, geometry, and dynamics provide important insights into this highly complex 3D system.

8:36AM E61.00002: Synchronization and pattern formation in chiral active matter DEMIAN LEVIS (Presenter), Ecole Polytechnique Federale de Lausanne, BENNO LIEBCHEN, Heinrich-Heine-Universitat Dusseldorf, IGNACIO PAGONABARRAGA, Ecole Polytechnique Federale de Lausanne — The emergence of synchronized states in populations of mobile entities is widely observed in different contexts: from animal groups - like flocks of birds moving coherently or crowds of people walking cooperatively on the London's Millenium bridge - to synthetic colloidal systems. However, previous studies on synchronization have focused on, either immobile oscillators, or mobile oscillators which phase does not directly influence the way they move in space [1]. Here we focus on active oscillators - circle swimmers which rotate with an intrinsic frequency - and show that self-propulsion, induces a qualitatively new and generic synchronization scenario which generates two novel phases: (i) a phase where oscillators move collectively along a given direction; a phase showing long-range order in 2D (akin to the celebrated Toner-Tu flocking phase [2]). (ii) a second phase where particles of opposite chirality segregate into rotating clusters. Both phases feature activity-induced synchronization in 2D, which is not achievable for immobile oscillators in low dimensional systems [3].

8:48AM E61.00003: Active mixing, manifolds and barriers in imposed, laminar flows* CHRISTINA YU (Presenter), MICHAEL GERBER, BREE MCCULLOUGH, Dept. of Physics & Astronomy, Bucknell University, KEVIN MITCHELL, Dept. of Physics, UC-Merced, THOMAS SOLOMON, Dept. of Physics & Astronomy, Bucknell University — We present experiments and simulations on the motion of self-propelled tracers in imposed laminar fluid flows. The flows used are hyperbolic and vortex-dominated flows, generated in microfluidic (PDMS) cells and in laboratory-scale, magnetohydrodynamically-driven systems. The tracers are either brine shrimp (for large-scale flows) or bacillus subtilis (for microfluidic flows). Two types of bacillus subtilis are studied: a wild-type -- characterized by run-and-tumble trajectories in the absence of a flow -- and a mutated "smooth swimmer" strain in which the tumbling is suppressed. We analyze the results in conjunction with a theory that predicts the existence of "Swimming Invariant Manifolds" (SwIMs) that act as one-way barriers that impede the trajectories of self-propelled tracers. We explore how the shape and location of the SwIMs vary with the imposed flow, along with the different ways in which the swimming behavior of the organism affect these SwIMs.

*Supported by NSF Grants DMR-1361881, DMR-1806355 and DUE-1317446.
9:00AM E61.00004: Stability of interfaces in active fluids* WAN LUO (Presenter), HARSH SONI, ROBERT ALAN PELCOVITS, THOMAS POWERS, Brown University — We study the linear stability of an active nematic fluid at rest in its isotropic phase in the following geometries: (1) a membrane immersed in the fluid, (2) a fluid film of finite height, (3) a spherical droplet of fluid, and (4) a cylindrical thread of fluid. In all four cases, we observe two frequency modes due to the coupling between the dynamics of the interface of the fluid and the dynamics of the nematic molecules. Propagating waves are seen above a value of activity which is independent of surface tension and has the same value in all four cases. For the first three cases, the fluid becomes unstable as the activity is further increased. In cases (1) and (2) the critical activity for instability is the same as for an unconfined active fluid and independent of surface tension. For case (3), the critical activity is larger than that for an unconfined fluid, and increases with increasing surface tension. A cylindrical thread of radius $R$ is always unstable against harmonic perturbations of wavenumber $k$ if $kR<1$, but the growth rate can be controlled by varying the activity. Perturbations with $k>1/R$ become unstable above a critical activity which changes with $k$ and surface tension.

*National Science Foundation through Grants Nos. MRSEC-1420382 and CBET-1437195.

9:12AM E61.00005: 1D condensation and onset to collective motion of swimming droplets* PIERRE ILLIEN (Presenter), CHARLOTTE DE BLOIS, MARJOLEIN VAN DER LINDEN, OLIVIER DAUCHOT, Gulliver lab, ESPCI Paris, CNRS — We observe that swimming droplets confined in a 1D channel spontaneously develop clustering and collective motion. A careful examination of the individual and interaction dynamics suggest that it can be described by effective inelastic collisions followed by a relaxation to the nominal velocity prescribed by activity. Starting from these experimentally observed features, and inspired by paradigmatic lattice models of interacting particles, we develop a theoretical framework in which alignment rules emerge from the microscopic interactions between the particles. This model reveals a rich phase diagram, in which the onset to collective motion results from the competition between inelasticity and activity, and can be preceded by very long-lived but transient macroscopic clustered states. We provide quantitative arguments that account for the formation of clusters in the system, and for the emergence of collective motion.

Marie Curie Actions/PRESTIGE programme (PCOFUND-GA-2013-609102)

9:24AM E61.00006: Odd viscosity in a chiral active fluid* EPRAIM BILILIGN (Presenter), VISHAL H SONI, University of Chicago, SOFIA MAGKIRIADOU, École Polytechnique Fédérale de Lausanne (EPFL), STEFANO SACANNA, New York University, DENIS BARTOLO, ENS de Lyon, MICHAEL JOHN SHELLEY, New York University, WILLIAM T. M. IRVINE, University of Chicago — We spin a system of colloidal magnets in an external magnetic field, forming a cohesive material that behaves like a liquid. Along a boundary of the fluid, we observe lively dynamics, including unidirectional surface waves that propagate due to an interplay of viscous stresses and surface tension. Through broken time-reversal and parity symmetries, this system allows the emergence of an anomalous transport coefficient known as odd (or Hall) viscosity. Unlike ordinary viscosity, this coefficient is dissipationless and absent in simple fluids. By reducing substrate drag, we are able to experimentally observe odd viscosity through the decay of free surface waves.

9:36AM E61.00007: Universal scaling in defect-free active turbulence* RICARD ALERT (Presenter), Princeton University, JEAN-FRANCOIS JOANNY, ESPCI, JAUME CASADEMUNT, University of Barcelona — Active fluids exhibit turbulent flows at low Reynolds numbers. In active liquid crystals, these flows are strongly constrained by topological defects, whose density defines a characteristic length that prevents the scale invariance typical of turbulence. Here we show that, at zero Reynolds number, defect-free active nematics exhibit a new type of turbulence with a distinctive scaling regime at large length scales. The system self-organizes into a disordered spatiotemporal pattern of orientation domains with a characteristic wavelength selected by the nonlinear dynamics, at which the active energy injection is maximal. In contrast to inertial turbulence, the energy is entirely dissipated at the scale where it is injected, without energy transfer to other scales. Nevertheless, arbitrarily large flow vortices are generated by the instantaneous, long-range kernel of Stokes hydrodynamics. Hence, instead of the Kolmogorov $\sim q^{-5/3}$ scaling of inertial turbulence, the velocity power spectrum scales as $\sim q^{-1}$, with $q$ being the wave number. Thus, in the absence of the screening effects due to topological defects, active nematic fluids exhibit turbulence without energy cascades and with a new universal scaling.

9:48AM E61.00008: Polar active suspensions - stability, waves, turbulence  RAYAN CHATTERJEE (Presenter), Tata Institute of Fundamental Research Hyderabad, ADITI SIMHA, Madras, Indian Institute of Technology, SRIRAM RAMASWAMY, Department of Physics, Indian Institute of Science, PRASAD PERLEKAR, Tata Institute of Fundamental Research Hyderabad — We study the hydrodynamics of self-propelled fluids with polar orientational order, using linear stability analysis and direct numerical simulations. We show that inertia and system dimension lead to a threshold for the instability of such systems to spontaneous distortion, with a diffusive growth rate at small wavenumber, and we confirm numerically the prediction (Simha & Ramaswamy 2002) of long-wavelength propagating modes. We illustrate the varieties of disturbance growth and explore the effects of self-propulsion and fluid inertia on active turbulence.

10:00AM E61.00009: Shear-induced transitions in passive and active polar liquid crystals: A novel shear-elongation parameter*  TOMER MARKOVICH (Presenter), CTBP Bioscience Research Collaborative, MS 654, Rice University, 6500 Main S, Rice University, ELSN TJHUNG, MICHAEL E CATES, DAMTP, University of Cambridge — Polar order in molecular liquid crystals is relatively rare, hence, it was not thoroughly investigated as other liquid crystalline phases. Recently, it has been discovered that suspensions of magnetic platelets in nematic liquid crystals show polar order at room temperature. Furthermore, polar order is ubiquitous in biology. It is seen in cell migration, swimming bacteria, the cytoskeletal etc. The growing interest in active matter and these recent experimental advances call for further theoretical investigations of polar liquid crystals. In the presence of external shear, polar particles tend to align with the shear flow at the Leslie angle, much like nematics. However, unlike the nematic director, the polar order parameter is not of fixed size. In this talk I will introduce the shear elongation parameter. This often neglected parameter, give rise to new physics such as shear-induced first order transition and significantly changes the rheological properties of the fluid. Active fluids can further exhibit yield stress and negative apparent viscosity.

*Work funded in part by the ERC, EU’s Horizon 2020 Programme (Grant 760769). TM is funded by the Blavatnik fellowship and the NSF CTBP (Grant PHY-1427654). MEC is funded by the Royal Society.

10:12AM E61.00010: Active fluid of self-rotating particles*  CODY REEVES (Presenter), Applied Math, Northwestern, IGOR S ARONSON, Biomedical Engineering, Pennsylvania State University, PETIA M. VLAHOVSKA, Applied Math, Northwestern — Suspensions of self-propelled particles, such as bacteria, have received considerable attention. Recently there has been increased interest in suspensions of self-rotating particles, such as Quincke rotors in electric fields and ferromagnetic colloids in alternating magnetic fields. While the individual particles are governed by relatively simple dynamics, the interaction of the particles can result in incredibly complex and interesting phenomena. Experiments show phase separation, macroscopic directed motion, and structure formation (e.g. vortices and asters). Modeling these systems as discrete particles at the micro-scale is computational expensive and limits the study of the rotors collective dynamics. We develop a continuum model for such rotor systems based on derivation for dielectric fluids with internal rotation This model allows us to study properties of the fluid and the existence of active turbulence caused by the rotors. To study the effect of confinement, we include phase parameter to restrict the rotors inside a region with a defined diffuse interface. We then can study the interaction between the rotors and the interface for both a fixed and deformable interface.

Tuesday, March 5, 2019 8:00 AM - 11:00 AM

Session E62 DCOMP: Dealing With Spin-Orbit Coupling  BCEC 258C - David Vanderbilt, Rutgers Univ - Tag(s): Invited
Spin-orbit-proximitized ferromagnetic metals in spintronic phenomena: A first-principles Green's function approach

BRANISLAV NIKOLIC (Presenter), University of Delaware — The talk reviews first-principles Green's function methodology to obtain spectral function and spin texture at an arbitrary plane around interfaces within multilayers of different materials [1]. When applied to ultrathin ferromagnetic layer in contact with a material with strong spin-orbit coupling—such as topological insulators, heavy metals, monolayer transition metal dichalcogenides and Weyl semimetals (all of which have been utilized very recently to develop novel spintronic devices and they will be discussed in the talk)—this methodology reveals dramatic modification of ferromagnet electron and spin structures which acquire properties of the adjacent layer due to hybridization of their wave functions. In particular, such spin-orbit-proximitized ferromagnetic layer acquires spin textures that are noncollinear to its own magnetization. Passing unpolarized charge current parallel to the interface generates nonequilibrium spin density [2] in the presence of such textures, which becomes resource for spintronic devices operated by spin-orbit torques [3]. On the other hand, passing spin-polarized charge current or pure spin current perpendicular to the interface leads to spin memory loss due to the same spin textures [4] (even in the absence of disorder, intermixing and magnons at the interface) which adversely affects spintronic device operation. The talk will explain how to model spin-orbit torques and spin memory loss by employing first-principles Green's functions to construct relevant nonequilibrium density matrices [3,4].

Comprehensive modeling of band gaps and absorption spectra of complex semiconductors for solar applications

JULIA WIKTOR (Presenter), EPFL — The performance of photosorbing materials is closely related to their band gaps and absorption spectra. In the fields of solar cells and photocatalysis, search for novel materials is ongoing. To identify optimal compounds, a modelling approach yielding accurate predictions for their electronic and optical properties is highly desirable. We recently applied the quasiparticle self-consistent QSGW method, efficiently accounting for the vertex correction, to study the electronic structure of halide perovskites and complex oxides. In the calculations, we included effects such as spin-orbit coupling, electron-hole interaction, magnetic ordering, nuclear quantum motions, and thermal vibrations. I will show that when an accurate electronic structure method is applied, and the significant effects are correctly accounted for, the band gaps and absorption spectra of complex materials can be reliably determined.

Carrier recombination in materials with strong spin-orbit coupling

XIE ZHANG (Presenter), University of California, Santa Barbara — Materials that have large spin-orbit coupling and no inversion symmetry can display interesting spin texture. The hybrid perovskites, which are receiving a lot of attention for photovoltaic applications, are prominent examples in which the spin texture exhibits unexpected patterns. Based on model calculations, it has been suggested that due to mismatched spins the radiative recombination is severely suppressed. We have performed first-principles calculations to compute the spin texture in the prototypical hybrid perovskite, CH3NH3Pbl3. We find that the spin texture is dynamically evolving in various patterns with the rotation of the organic molecule [1]. However, the spin-orbit coupling always leads to spin-allowed optical transitions and the momentum splitting affects the radiative recombination coefficient by less than a factor of two [2]. The spin-orbit coupling does, however, significantly enhance the Auger coefficient due to a coincidental resonance between the band gap and interband transitions to spin-orbit-split conduction bands [3]. These insights demonstrate the importance of accurate treatment of spin-orbit coupling in describing materials properties, and also offer new computational approaches to quantitatively calculate the spin texture and its impact on carrier recombination.

9:48AM E62.00004: The role of temperature in spin-orbit materials† [Invited]  BARTOMEU MONSERRAT (Presenter), Physics, University of Cambridge — The spin-orbit interaction underlies multiple physical phenomena, including topological order and the spin splitting of bands in inversion asymmetric crystals, which could be harnessed in novel technologies including spintronics or quantum computers. However, for any practical device, the spin-orbit driven properties need to survive all the way to room temperature, and therefore understanding the role of electron-phonon coupling and thermal expansion in spin-orbit materials becomes central.

In this talk, I will describe our work exploring the role of temperature in spin-orbit materials. I will describe the temperature dependence of the bulk Rashba splitting in the bismuth tellurohalides [1], temperature induced topological transitions in the bismuth selenide family [2], and structural stabilization driven by spin-orbit coupling in superconducting InSbBi3.

10:24AM E62.00005: Impact of spin-orbit coupling on the magnetic phase diagram of the iron pnictides† [Invited]  MORTEN HOLM CHRISTENSEN (Presenter), University of Minnesota — Experimental research over the past few years has shown the presence of sizeable spin-orbit coupling (SOC) in the iron pnictides [1]. Here, we focus on the impact of SOC on the magnetic phase diagram of the iron pnictides and in particular the implications for competing magnetic states and quantum criticality. Magnetism in the pnictides occurs in three distinct types. The prevalent magnetic phase is the C2 symmetric stripe magnetism, with moments parallel to the ordering vector. Additionally, there are two tetragonal, or C4r, magnetic phases, one with out-of-plane moments observed close to optimal doping in several compounds [2], and another with in-plane moments forming a spin-vortex structure [3]. The intimate relation between the ordering vectors and the moment direction is a direct consequence of SOC. Interestingly, a proliferation of different magnetic phases in close proximity in the phase diagram is observed in different pnictide materials as the putative magnetic quantum critical point is approached, e.g. by changing doping or pressure. We demonstrate, using a renormalization group approach, that such a behavior is a natural consequence of the interplay between magnetic quantum fluctuations and SOC. Formally, this is due to the emergence of a Gaussian fixed point leading to an enhanced magnetic degeneracy. This leads to an increase in the phase space of fluctuations which can enhance the transition temperature of superconductivity. Furthermore, we show how a rich landscape of magnetic phases emerges as a result of frustration between spin-anisotropic and spin-isotropic interactions. These novel phases consist of admixtures of the known C2 and C4 orders, and provide possible candidates for experimental observations [4].

Dynamics of microbiota communities during physical perturbation.* [Invited] CAROLINA TROPINI (Presenter), School of Biomedical Engineering, Microbiology & Immunology, University of British Columbia, JUSTIN SONNENBURG, Stanford University — The consortium of microbes living in and on our bodies is intimately connected with human biology and deeply influenced by physical forces. Despite incredible gains in describing this community, and emerging knowledge of the mechanisms linking it to human health, understanding the basic physical properties and responses of this ecosystem has been comparatively neglected. Most diseases have significant physical effects on the gut; diarrhea alters osmolality, fever and cancer increase temperature, and bowel diseases affect pH. Furthermore, the gut itself is comprised of localized niches that differ significantly in their physical environment, and are inhabited by different commensal microbes. Understanding the impact of common physical factors is necessary for engineering robust microbiota members and communities; however, our knowledge of how they affect the gut ecosystem is poor.

As a model of a biophysical perturbation, we are investigating how changes in osmolality affect the host and the microbial community and lead to mechanical shifts in the cellular environment. Osmotic perturbation is extremely prevalent in humans, caused by the use of laxatives, lactose intolerance, or celiac disease. In our studies we monitored osmotic shock to the microbiota using a comprehensive and novel approach, which combined in vivo experiments to imaging, physical measurements, computational analysis and highly controlled microfluidic experiments. By bridging several disciplines, we developed a mechanistic understanding of the processes involved in osmotic diarrhea, linking single-cell biophysical changes to large-scale community dynamics. Our results indicate that physical perturbations can profoundly and permanently change the competitive and ecological landscape of the gut, and affect the cell wall of bacteria differentially, depending on their mechanical characteristics.

*This work was funded in part by a James S. McDonnell Postdoctoral Fellowship.

Evolution of Multicellular Specialization in Dynamic Fluids* GURDIP UPPAL (Presenter), DERVIS CAN VURAL, University of Notre Dame — Multicellularity and division of labor mark a major transition in the development of life. In this study, we determine the conditions for multicellular specialization to occur starting with a system of generalists that secrete two public goods. We look at two different fitness functions where either both public goods are necessary for any fitness gain or where either one is sufficient for a fitness gain. We denote these by AND and OR respectively, to resemble the logical AND and OR functions. Social structures arise naturally from our advection-diffusion-reaction model as self-replicating Turing patterns. We see that an AND structure is necessary for the specialists to stay together in the same social structure. Specialists in the OR case dissociate into separate groups of pure specialists. We look at the effects of varying the cost of cooperation and mutation rate on the emergence of specialization. When trade-off costs are small, we see that spatial structure can help facilitate the transition to specialization for either fitness function. At larger trade-offs in the AND case, we see that generalists are more stable.

Pinning and pulsed expansion in a spatially expanding bacterial mutualism AROLYN CONWILL (Presenter), JEFFREY GORE, Massachusetts Institute of Technology — Range expansions occur when a population expands in space due to dispersal and growth. These expansions can result from environmental change, introduction of invasive species, or evolutionary adaptation that enables a population to move into previously unoccupied territory. Theoretical work has shown that fragmented habitats and seasonal growth (discrete space and discrete time) can result in pinning and pulsed invasions in expanding populations with an Allee effect. However, it is not clear how underlying population dynamics such as limit cycle oscillations influence these phenomena. We probe this question in an experimental model system consisting of an oscillating bacterial mutualism inhabiting discrete population patches and subject to periodic growth cycles. For low nearest-neighbor migration rates, the mutualism cannot expand, and the population is pinned in place. For high nearest-neighbor migration rates, the mutualism expands at pulsed speeds. Furthermore, our experimental results are consistent with a mechanistic model prediction that the period of population oscillations locks into specific values during pulsed invasion, emphasizing the interplay between ecological interactions and spatial structure.
9:00AM E63.00004: Survival probabilities of mutants with antagonistic interactions  MAXIM O LAVRENTOVICH (Presenter), Physics and Astronomy, University of Tennessee, DAVID R NELSON, Department of Physics, Harvard University — Strains within a population interact not only via competition due to varying growth rates, but also via secretion of toxins, predation, parasitism, and other adaptations which result in frequency-dependent selection. These dynamics often play out in a spatial context, such as at the frontier of a growing spherical cell mass, or on the surface of a Petri dish. We study how a mutant, interacting antagonistically with a wild-type strain (i.e., the mutant grows more slowly in the presence of the wild-type), survives in two-dimensional populations with flat and curved geometries, representing, for example, the Petri dish surface and cell mass frontier, respectively. The antagonistic interactions significantly diminish the survival probability of the mutant even when, in isolation, the mutant grows much faster than the wild-type strain. We show that the survival probability can be thought of as a kind of “nucleation rate” of the mutant strain. The predictions of classical nucleation theory agree with our simulation results and provide an important modification, due to the antagonistic interactions, of the classic Kimura formula for the survival probability. We comment on both the effects of small-number fluctuations and the curved population geometry.

9:12AM E63.00005: Measuring cellular memory and heterogeneity at the single-cell level  TAMAS SZEKELY (Presenter), ZHIHAO CAI, MARTIN SAUZADE, ERIC BROUZES, GABOR BALAZSI, Stony Brook University — Microbial populations live in a wide range of ecological settings. In changing environments, survival is improved by heterogeneity. In contrast, in stable environments the population is best off when cells adopt the single optimal phenotype. In a clonal population, heterogeneity occurs at the phenotypic (protein) level; as cellular protein levels vary over time, phenotypes can change dynamically, with the timescale given by “cellular memory”. However, the population-level distribution of phenotypes remains stable, optimised by evolution to its ecological setting. An interesting situation occurs when a population moves from one setting to another. In this case, one can encounter a bimodal population in a constant environment for which it is not adapted. How does evolution shape this population? We examine this in yeast containing a synthetic gene circuit that gives a phenotypically bimodal population. We expose cells to a stable environment and observe changes in heterogeneity. Using a microfluidic platform, we measure the cellular memory of many single cells. Thus, we investigate the relationship between fitness, cellular memory and phenotype distribution during evolution in a constant environment.

9:24AM E63.00006: Bet-hedging strategies in expanding populations  PAULA VILLA MARTÍN, Okinawa Institute of Science and Technology, MIGUEL ANGEL MUÑOZ, Physics, University of Granada, SIMONE PIGOLOTTI (Presenter), Okinawa Institute of Science and Technology — Ecological species can spread their extinction risks in uncertain environments by adopting a bet hedging strategy, i.e. by diversifying individual phenotypes. We present a theory of bet-hedging for populations colonizing unknown environments that fluctuate either in space or time. We find that diversification is more favorable strategy in this scenario than for well-mixed populations, supporting the view that range expansions promote diversification. For slow rates of variation, spatial fluctuations open more opportunities for bet-hedging than temporal variations. Opportunities for bet-hedging reduce In the limit of frequent environmental variation, regardless of the nature of these fluctuations. These conclusions are robust against stochasticity induced by finite population sizes.

9:36AM E63.00007: Competition in dense bacterial biofilms through killing and replication  GABI STEINBACH (Presenter), MICHAEL SIULUNG, BRIAN K. HAMMER, PETER YUNKER, Georgia Institute of Technology — Typically, biofilms feature many different microbial species and strains. This diversity presents a challenge, as individuals must compete for resources and space. In response, microbial species have evolved antagonistic mechanisms such as the Type VI secretion system (T6SS). This is a contact-dependent toxin-delivery system that enables the injection of fatal toxins into other bacteria as well as eukaryotic cells. Previous studies have shown that such an antagonistic one-on-one interaction causes an initially well-mixed culture to phase separate, providing protection by number. We study biofilms consisting of V. cholerae, which express T6SS, as an experimentally controllable and practically relevant system of mutual killers. While we observe phase separation, the typical size of clonal patches stops changing much earlier than expected. In experimental and numerical studies of mutual killing strains of V. cholerae, we show that a protective layer of debris forms at the interface between patches, which slows down further killing. This poses major consequences for the role of antagonistic interactions and the survival dynamics in biofilms.

Phase Transition Behavior in Yeast Populations Under Stress*  
STEPHEN W. ORDWAY, Physics & Astronomy, University of Missouri -- St. Louis, DAWN M. KING, Slalom Consulting, DAVID FRIEND, Illinois Institute of Technology, CHRISTINE NOTO, Biology, Saint Louis University, SNOWLEE PHU, WENDY OLIVAS, Biology, University of Missouri -- St. Louis, SONYA BAHAR (Presenter), Physics & Astronomy, University of Missouri -- St. Louis — Nonequilibrium phase transition behavior has recently been observed in computational models of evolutionary dynamics (Scott et al., 2013; King et al. 2017). Dynamical signatures predictive of population collapse have been observed in yeast populations under stress (Dai et al., 2012). We experimentally investigate the population response of *Saccharomyces cerevisiae* to biological stressors (temperature and salt concentration) in order to investigate the dynamical behavior of the system in the vicinity of population collapse. While both conditions lead to population decline, the dynamical characteristics of the population response differ significantly depending on the stressor. Under temperature stress, the population undergoes a sharp change with significant fluctuations within a critical temperature range, indicative of a continuous absorbing phase transition. In the case of salt stress, the response is much more gradual.

A neural network model predicts the consequences of crosstalk in bacterial quorum sensing*  
JAMES BOEDICKER (Presenter), KALINGA PAVAN T SILVA, TAHRIR YUSUFALY, University of Southern California — Many bacteria use chemically similar molecules to communicate, resulting in crosstalk between bacterial signaling networks. Such crosstalk can have unexpected consequences for decision making in heterogeneous communities of cells. Here we examine crosstalk within a community composed of five strains of *Bacillus subtilis*, with each strain producing a variant of the quorum sensing peptide ComX. Co-cultures of these strains create in a mixture of ComX variants, resulting in variable levels of gene expression in each strain. To predict gene regulation in communities producing multiple signals, we implement a neural network model. Experimental quantification of crosstalk between pairs of strains parametrized the model, enabling the accurate prediction of activity within the full five-strain network. Interactions weights between the five signaling networks were both positive and negative, of variable magnitude, and asymmetric. Signal crosstalk within the five-strain community results in multiple community-level quorum sensing states, each with a unique combination of quorum sensing activation among the five strains. The community-level signaling state was influenced by the ratio of strains as well as dynamics of community composition.

Production of a biofilm polymer can benefit bacteria when grown in co-culture under low iron conditions*  
VERNITA GORDON (Presenter), JAIME B HUTCHISON, KARISHMA S KAUSHIK, CHRISTOPHER A RODESNEY, THOMAS LILIEHOLM, LAYLA BAKHTIARI, University of Texas at Austin — Biofilm formation is associated with resistance to antibiotics and the immune system. The opportunistic human pathogen *Pseudomonas aeruginosa* forms biofilm infections in lungs, wounds, and on medical devices. However, its ability to form biofilms originated in this bacterium's native environment, primarily plants and soil. Such environments are polymicrobial and resource-limited. The *P. aeruginosa* extracellular polysaccharide Psl can bind iron and, for the strain PAO1, is also the dominant "glue" holding together multicellular aggregates and biofilms. Here, we quantify early biofilm growth using time-lapse confocal microscopy. We find that aggregates of *P. aeruginosa* have a growth advantage over single cells of *P. aeruginosa* in the presence of *Staphylococcus aureus* in low-iron environments. This growth advantage is linked to aggregates' high Psl content and to the production of an active factor by *S. aureus*. We posit that this may have been linked to the evolutionary development of the strong biofilm-forming tendencies of *P. aeruginosa*.

10:24AM E63.00011: Oxygen dynamics in a two-dimensional microbial ecosystem* ALEXANDER PETROFF (Presenter), Clark University, FRANK TEJERA, ALBERT J LIBCHABER, Rockefeller University — Ecosystems persist over geological timescales by continuously cycling nutrients. However, we lack a quantitative model of how diverse organisms organize with respect to one another. We observe these dynamics in a quasi-two-dimensional microbial ecosystem, in which all microbes live within the penetration depths of oxygen and light. This community is composed of both photosynthetic bacteria, which produce sugars and oxygen, and aerobic bacteria, which consume oxygen and sugars. Shining a light on the community drives a nutrient cycle between these two groups of microbes. Illuminating a spot, we measure the resulting distribution of oxygen. Under normal conditions, diffusion alone stabilizes oxygen gradients. However, at freezing temperatures or low atmospheric oxygen concentration, the kinetics of microbial oxygen production and consumption dominate. Surprisingly, after three weeks, the initially uniform distribution of oxygen in the spot becomes an annulus. We present a robust method to invert the measured oxygen concentration for the distribution of oxygen sources and sinks.

10:36AM E63.00012: Thermodynamic constraints on cross-feeding in bacterial population TONG WANG (Presenter), University of Illinois at Urbana-Champaign, CHEN LIAO, Memorial Sloan Kettering Cancer Center, SERGEI MASLOV, University of Illinois at Urbana-Champaign — Overflow metabolism refers to the strategy of cells using fermentation instead of the more energetically-efficient respiration, even when the oxygen is available. Cross-feeding between two bacterial strains growing on a single primary carbon source can be established when one bacterial strain consumes overflow metabolites excreted by the other bacterial strain. Many overflow pathways are thermodynamically controlled and thermodynamic constraints on them are not included to consider the cross-feeding of overflow metabolites between two strains in the past. Motivated by experimental results of acetate cross-feeding polymorphism, in this paper, we developed a single cell growth model with coarse-grained metabolic pathways including proteome allocation and thermodynamic constraints on the overflow pathway. The model can accurately capture the flux of thermodynamically controlled overflow pathway and growth rate of cells under different growth conditions. Moreover, when it is applied to study the cross-feeding, the model can reveal the short-term dynamics and long-term dynamics of cross-feeding stable polymorphism seen in experiments.

10:48AM E63.00013: How can unsuccessful invaders drive long-term shifts in community state?* DANIEL R. AMOR (Presenter), CHRISTOPH RATZKE, JEFFREY GORE, Massachusetts Institute of Technology — The stability of virtually all microbial communities is frequently challenged by the arrival of new individuals that could potentially invade the system. This urges for a deeper understanding of how invasions can interfere the dynamics of microbial communities. I will present a bistable model system to study the dynamics between alternative stable states in microbial ecosystems. By introducing additional species into the system, we observed induced transitions between stable states. Interestingly, in many cases the invading species did not survive in the final community state, making these species what we call a “transient invader.” This suggests that short-term invasions (such as infections) could be a common mechanism driving transitions between stable states in microbial communities.

Session E64 DBIO GSNP: Physics of the Brain: Structure and Dynamics 8CEC 259B - Mukesh Dhamala, Georgia State University; Peter Robinson, University of Sydney - Tag(s): Focus

8:00AM E64.00001: Oscillation onset and wave propagation in neocortex* [Invited] TIMOTHÉE PROIX (Presenter), University of Geneva — In this talk, I will present recent findings on spatiotemporal patterns and wave propagation in neocortex based on intracortical microelectrode array recordings in primates during various states including optogenetic stimulation to probe neural dynamics, movement preparation and execution, and human epileptic seizures. I will follow with results based on neural-field models to account for the observed oscillation onset and wave propagation phenomena.

*This research was supported by the National Institute of Neurological Disorders and Stroke (NINDS), grant R01NS079533; the Department of Veterans Affairs, Merit Review Award I01RX000668; and the Pablo J. Salame ’88 Goldman Sachs endowed Assistant Professorship of Computational Neuroscience.
STEVEN J. SCHIFF (Presenter), Pennsylvania State University — There is a several decade history demonstrating that electrical polarization of neurons can modulate neuronal firing, and that such polarization can suppress (or excite) spiking activity and seizures. In recent years, we uncovered a unification in the computational biophysics of spikes, seizures, and spreading depression (Wei et al, Journal of Neuroscience 34:11733-11743, 2014). These findings demonstrated that the repertoire of the dynamics of the neuronal membrane encompasses a broad range of dynamics ranging from normal to pathological, and that seizures and spreading depression are manifestations of the inherent properties of those membranes. Most recently, we have demonstrated that neuronal polarization can suppress (or enhance), block, or prevent spreading depression (Whalen et al, Scientific Reports, 8:8769, 2018), the physiological underpinning of migraine auras. Remarkably, this suppression requires qualitatively different stimulation from that required to suppress spikes and seizures, and is fully consistent with the computational biophysical models of spreading depression. Further unexpected findings from these experiments were that suppression of spreading depression does not generate seizures, and vice versa, that when the brain is in seizure activity suppression does not generate spreading depression. The implications are that in controlling brain dynamics from different states of the brain, there can be state dependent control which is qualitatively very different from that required in other states.

SPASE PETKOSKI (Presenter), VIKTOR JIRSA, Aix-Marseille University — Neural network oscillations are a fundamental mechanism for cognition, perception and consciousness. Consequently, perturbations of network activity play an important role in brain disorders. Customization of healthcare with medical decisions tailored to the individual patient is a key aspect of personalized medicine.

When structural information from non-invasive brain imaging is merged with mathematical modelling, then generative brain network models constitute personalized in silico platforms for the exploration of causal mechanisms of brain function and clinical hypothesis testing. In partial epilepsy seizures originate in a local network, the so-called epileptogenic zone, before recruiting other brain regions. We build a Virtual Epileptic Patient (VEP) brain model that integrates patient-specific information, and we demonstrate that VEP derived from diffusion magnetic resonance imaging have sufficient predictive power to improve diagnosis and surgery outcome [1]. Individual brain models for 15 patients are validated against the presurgical electroencephalography data and the standard clinical evaluation, and are used to show that VEP brain models account for the patient seizure propagation patterns and explain the variability in postsurgical success [2]. Finally, we demonstrate how to develop novel personalized strategies towards therapy and intervention, by the example of applying linear stability analysis to the VEP in order to identify the minimal number of links that need to be removed for stopping the seizure propagation [3]. This suggests a less invasive paradigm of surgical interventions to treat and manage partial epilepsy.

9:48AM E64.00004: Influence of the Human Amyloidogenic precursor on Epithelial and Neuronal Cell Membrane*
IZABELA STROE (Presenter), BIBI NAJMA, Physics, Worcester Polytechnic Institute, AMITY MANNING, Biology & Biotechnology, Worcester Polytechnic Institute — The pathology of Alzheimer's disease (AD) is correlated with the amyloid fiber formation. The Aβ (1-42) amyloid fragment is the principal species associated with senile plaque. There is evidence that the Aβ (1-42) amyloid precursors, such as the monomers, dimers, oligomers, and the proto-fibrils are toxic to the neuronal cell. It is believed that the Aβ (1-42) amyloid precursors perturb the neuronal cell membrane integrity leading to its death; however, the molecular mechanism by which the neuronal cell death occurs is not yet understood. Dielectric relaxation spectroscopy was used to study the interaction of the oligomeric Aβ (1-42) with the cell membrane of epithelial and neuronal cells. We incubated both cell types with the Aβ (1-42) solution of monomers, oligomers, and fibrils. We measured the dielectric response of the incubated cells at different concentrations over a wide range of frequencies (from 10⁻² Hz to 10⁷ Hz). Two dispersion processes (α, β) can be observed for all concentrations of the cell suspensions. We observed changes in the conductivity and permittivity of the neuronal cells when incubated with Aβ (1-42), which suggests the toxicity of the precursors causing marked alterations in the electrical properties of the cell membrane.

10:00AM E64.00005: Impact of Damaged Neurons on Continuous Attractor Network Models of Grid Cells. YUDUO ZHI (Presenter), DANIEL COX, Department of Physics, University of California, Davis — Grid cells in the dorsolateral band of the medial entorhinal cortex(dMEX) display strikingly regular firing responses to animal’s position in 2-D space. This helps animals be able to encode relative spatial location without reference to external cues. Within a continuous attractor model of grid cell activity[1,2], we focus on the question of how two different kinds of damage to the dMEX that can arise from neurodegenerative diseases affect grid cell performance: I) randomly distributed discrete damage and II) diffusing damage that can arise from propagation of neurofibrillary tangles. Drawing on models from the existing literature, we employ 1- and 2-dimensional neural networks with background excitation sensitive to motion and a ring of inhibitory couplings modeled as a difference of Gaussians around each firing neuron. For sufficiently strong inhibition, the model always produces a stable 1-dimensional or 2-dimensional lattice. We will study the impact of the two damage types on the attractor model and contrast this with the impact of damage on an oscillatory grid cell model[3].

10:12AM E64.00006: Molecular Underpinnings of Postsynaptic Calmodulin-dependent Calcium Signaling*
MARGARET CHEUNG (Presenter), University of Houston — Calcium (Ca²⁺) signaling is a dynamic system where Ca²⁺ concentration fluctuates in range of 0.1-10μM with time. These short transient Ca²⁺ around the entry sites activate Ca²⁺-binding proteins such as calmodulin (CaM). The prototypical pathway describes CaM as encoding a Ca²⁺ signal by selectively activating downstream CaM-dependent proteins through molecular binding. However, CaM’s intrinsic Ca²⁺-binding properties alone appear insufficient to decode rapidly fluctuating Ca²⁺ signals. It has been proposed that the temporally varying mechanism for producing target selectivity requires CaM-target interactions that directly tune the Ca²⁺-binding properties of CaM through reciprocal interactions. I will focus on two unique and distinct CaM binding targets, neurogranin (Ng) and CaM-dependent kinase II (CaMKII), which are abundant in postsynaptic neuronal cells and are biochemically known to tune CaM’s affinity for Ca²⁺ in opposite directions. By employing an integrative approach of quantum mechanical calculations, all-atomistic molecular dynamics, and coarse-grained molecular simulations, we have revealed the molecular mechanisms of CaM’s reciprocal interaction between target binding and Ca²⁺binding.

10:24AM E64.00007: Dynamics of neuronal growth on surfaces with controlled geometries* ILYA YURCHENKO (Presenter), CRISTIAN STAII, Tufts University — Detailed knowledge of how the surface physical properties, such as mechanics, topography and texture influence neuronal growth and guidance is essential for understanding the processes that control neuron development, the formation of functional neuronal connections and nerve regeneration. I will present experimental results that demonstrate directional neuronal growth imparted by the surface geometry. We quantify axonal alignment and growth dynamics using a general stochastic model based on the Langevin equation. We relate the observed alignment in axonal growth to cellular contact guidance behavior, which results in an increase in the cell-substrate coupling on surfaces with micro-patterned structures. These results provide new insight into the role played by geometrical cues in neuronal growth and could lead to new methods for stimulating neuronal regeneration and the engineering of artificial neuronal tissue.

Non-parametric discovery of population dynamics from large-scale neural activity recordings*

MIKHAIL GENKIN (Presenter), TATIANA A. ENGEL, Neuroscience, Cold Spring Harbor Laboratory — Recent advances in neurotechnology enabled activity recordings from many neurons simultaneously, allowing us to study how neural populations are coordinated to drive behavior. Current population-analysis methods are based on fitting parametric models to data. However, these ad hoc models often distort dynamical features and result in ambiguous model comparisons. To overcome these limitations, we develop a non-parametric framework for discovering population dynamics directly from the data without a priori model assumptions. Our framework is based on latent Langevin dynamics, in which driving forces are directly optimized to effectively search the entire space of possible dynamics. The framework incorporates diverse, non-linear relationships between population-dynamics and firing-rates of single neurons. We derive a gradient descent algorithm for optimization over the space of continuous functions and use cross-validation and early stopping for regularization. Our framework accurately recovers qualitatively different population-dynamics simultaneously with diverse firing-rate profiles of single neurons.

Tracking multineuronal activity in unrestrained animals with a random access two photon microscopy*

AKIHIRO YAMAGUCHI (Presenter), DOYCHO P KARAGYOZOV, MIRNA MIHOVILOVIC SKANATA, RUI WU, MARC H GERSHOW, Department of Physics, New York University — Optical recordings of neuronal activity in freely behaving animals can reveal the correlation between the neural activity and behavioral outcome, such as decision making, learning, and multisensory integration. Such recordings require a microscopy that can overcome motion artifacts that accompany behavior. We recently developed a two-photon tracking microscope capable of recording activity from neurons in freely behaving larval fruit flies without motion artifacts[1]. However, due to the inertia of the scanning elements, the current technique is limited to recording only two neurons at a time. In order to study the correlation between neural activities and behavioral outcome across a range of neurons - sensory to motor neurons, it is essential to track multiple neurons at a time.

We extended the microscope using acousto-optic deflectors to relocate the laser beam in a constant time regardless of the distance between the two positions. Combined with improved feedback algorithms implemented in field-programmable gate arrays, this allows us to track and record the activities of many neurons at a high spatio-temporal resolution.

Session E65 DBIO DPOLY GSNP: Physics of Genome Organization I

8:00AM E65.00001: Complexity in transcription factor – DNA recognition [Invited] MARTHA BULYK (Presenter), Harvard Medical School — TBD
8:36AM E65.00002: Quantifying sequence readout by transcription factors through principled analysis of high-throughput SELEX data* [Invited] HANS RUBE (Presenter), CHAITANYA RASTOGI, JUDITH F KRIBELBAUER, XIAOTING LI, BACH-VIET DO, HARMEN J BUSSEMAKER, Columbia University — Transcription factors (TFs) control gene expression by binding to genomic DNA in a sequence-specific manner. In recent years, hundreds of TFs have been characterized using high-throughput in vitro DNA binding assays coupled with deep sequencing. Variations of these assays can characterize binding by TF complexes and by RNA-binding proteins, or binding to chemically modified DNA. However, no unified method for analyzing all these data yet exists. We recently developed an algorithm named No Read Left Behind or NRLB (Rastogi et al., PNAS, 2018), which infers biophysical binding specificity models across the full affinity range from single-round SELEX data. It predicts human MAX homodimer binding in near-perfect agreement with existing low-throughput measurements, captures the specificity of the full-length p53 tetramer, and distinguishes multiple binding modes within a single sample. In addition to the chemical identity of the DNA bases, TF binding affinity is sensitive to the local three-dimensional shape of the DNA double helix. We demonstrate that linear models based on mononucleotide features alone can account for 60–70% of the variance in the DNA shape parameters minor groove width, roll, helix twist, and propeller twist. We also show that NRLB binding models implicitly encode DNA shape readout. Building on these observations, we developed a post hoc analysis method that interprets NRLB models in terms of DNA shape readout (Rube et al., MSB, 2018). Finally, we will discuss our latest algorithm, ProBound, which, unlike NRLB, allows principled modeling of multiple SELEX rounds, chemically modified DNA, and complexes with variable spacing between the DNA binding domains. ProBound works on all currently available data and allows us to build a resource of DNA binding specificity models for hundreds of TFs.

9:12AM E65.00003: Heterodimer Transcription Factors as Novel Gene Regulators KYLE NAUGHTON (Presenter), JAMES BOEDICKER, University of Southern California — Synthetic bacterial communities often incorporate quorum sensing (QS) networks to enable cell-cell communication. An intrinsic component of most QS networks is dimerization of receptor proteins around QS signals. Dimers of receptors act as transcription factors, modulating gene expression in the presence of high signal concentration. For example, LuxR binds a signal, forms a homodimer, and activates an operon in a feed-forward manner that makes more signal, more receptors, and invokes bioluminescence in Vibrio fisheri. In cells with more than one type of receptor protein, homodimers and heterodimers may form. The role of heterodimers and the conditions for their formation, however, remains murky. Some authors suggest heterodimers mute genes by competitively binding QS signals or forming inactive dimers. It remains possible, however, that heterodimer formation occurs in a purposeful way. We explore the possibility that heterodimers directly regulate gene expression based on experiments with tethered dimers. From a theoretical perspective use simple thermodynamic models to examine under what conditions heterodimers might form. Using MCMC and QS receptor position weight matrices we suggest DNA binding sites may exist which favor the heterodimers over either homodimer.

9:24AM E65.00004: Gene clustering drives co-regulation of disparate biological pathways in eukaryotes RICHARD JOH (Presenter), MICHAEL LAWRENCE, MARTIN ARYEE, MO MOTAMEDI, Center for Cancer Research, Massachusetts General Hospital — The establishment of distinct transcriptional states in response to developmental or environmental cues is critical for survival. This involves the concordant or discordant transcriptional regulation of several distinct biological pathways, often involving thousands of genes. How these system-level changes to transcriptionomes are coordinated is an understudied problem in eukaryotic biology. Here, using computational and experimental approaches in eukaryotes ranging from yeast to human, we report that this coordination is in part achieved by the genic proximity of the regulatory nodes of disparate biological pathways whose co-regulation drives the transcriptional coherence of their respective pathways. Overall, our data identifies transcriptional co-regulation of hundreds of discreet biological pathways and suggest that genomic clustering of their transacting factors such as transcription factors create operon-like regulation in eukaryotes.

9:36AM E65.00005: Liquid-liquid phase separation driven organization of nuclear chromatin domains RABIA LAGHMACH (Presenter), DAVIT POTYOYAN, Chemistry department, Iowa State University — Chromatin of eukaryotic cells folds within few micrometers of nuclear space while still retaining dynamism and accessibility needed for function. Latest experiments have revealed a liquid like behavior of chromatin manifested in epigenetically mediated phase separation into micro-droplets with distinct transcriptional states. Motivated by these experiments we have devised a mesoscale liquid like model of nucleus (MELON) with chromatin states resolved as a viscoelastic fluid fields of type A and B corresponding to transcriptionally active and silent states. The model allows direct comparison with imaging experiments of different cell lines and during various stages in cell cycle. Using MELON framework, we investigate the roles of chromatin droplet diffusion, fluctuations and impact of phase separation kinetics on non-equilibrium processes of growth and inversion. We show that ideas based on classical theories of nucleation and phase separation can have a broad predictive power in capturing several salient features of intra-nuclear chromatin dynamics.
9:48AM E65.00006: Polymer Models of S. pombe Chromatin  PETER WILLIAMS (Presenter), Applied Physics, Yale University, SIMON G MOCHRIE, Physics and Applied Physics, Yale University, MEGAN KING, Cell Biology, Yale University, COREY SHANE O’HERN, Mechanical Engineering & Material Science, Physics, and Applied Physics, Yale University — Recent advances in Hi-C studies have laid the groundwork for understanding the organization of the genome at different points in the cell cycle. We present a coarse-grained polymer model with short-ranged attractions and volume exclusion that quantitatively recapitulates experimental Hi-C maps for the yeast strain, S. pombe. The polymer model gives rise to an ensemble of transient clusters corresponding to topologically associated domains. Insight on the dynamics of chromatin can be obtained from single particle tracking experiments on fluorescently tagged transgenic loci at strategic points in the genome. Transcription inhibitors have been shown to dramatically suppress the mean square displacements of the loci. These results imply that transcription is the source of activity within the nuclear envelope. We have also developed a coarse-grained model of polymerase translocating along a polymer. We model portions of the genome to identify the effect of activity on loci proximal and distal to regions of high gene expression.

10:00AM E65.00007: Bacterial chromosome organization: few special cross-links, cell confinement, and molecular crowders play the pivotal roles.*  TEJAL AGARWAL (Presenter), Department of Physics, Indian Institute of Science Education and Research, Pune, MANJUNATH G. P., Department of Biochemistry and Molecular Pharmacology, NYU Langone Medical Center, FARHAT HABIB, Inmobi, APRATIM CHATTERJI, Department of Physics, Indian Institute of Science Education and Research, Pune — Using a coarse-grained bead-spring model of bacterial chromosomes of C. crescentus and E. coli we show that just 33 and 38 effective cross-links in 4017 and 4642 monomer chain at special positions along the chain contour can lead to the large length-scale organization of the DNA polymer, where confinement effects of the cell walls play a crucial role in the organization. The positions of the 33/38 cross-links along the chain contour are chosen from the Hi-C contact map of bacteria C. crescentus and E. coli. We represent 1000 base pairs as a coarse-grained monomer in our bead-spring flexible ring polymer model of the DNA. Thus 4017/4642 beads on a flexible ring polymer represent the C. crescentus/ E. coli DNA polymer with ~4 million base pairs. Choosing suitable parameters from our preceding study, we also incorporate the role of molecular crowders and the ability of the chain to release topological constraints. We also validate our prediction of the organization of the bacterial chromosomes with available experimental data.

10:12AM E65.00008: Spatial proximity coordinates histone modification and expression of multiple genes*  JINGYU ZHANG, YAN ZHANG, IVET BAHAR, JIANHUA XING (Presenter), University of Pittsburgh — A cell type transition process requires temporally orchestrated global changes of gene expressions despite existence of large extrinsic and intrinsic stochasticity. One such major source of stochasticity is transcriptional bursting, where even under constant levels of trans-regulatory elements genes stochastically switch between a transcriptionally active and an inactive state. Such bursting dynamics may destroy temporal coordination of genes. We integrated datasets of gene expression, histone modification, and chromosome conformation for the mouse nervous system development and TGF-β treated MCF10A cells. We identified that genes having related functions and regulated by common TFs tend to cluster spatially and share similar histone modification patterns. Through a polymer-based model that describes cooperativity in histone modification dynamics, we predict that genes in proximity synchronize their transcriptions by synchronizing their stochastic switching between histone modification states with different transcriptional activities. This hypothesis is supported by analysis of allele-specific single cell RNAseq data, and we are further testing it with single cell FISH and superresolution imaging.

*This work is funded by NSF.
**10:24AM E65.00009: Interphase chromatin as a self-returning random walk: Can DNA fold into liquid trees?**

KAI HUANG (Presenter), VADIM BACKMAN, IGAL G SZLEIFER, Northwestern University — We introduce a self-returning random walk to describe the structure of interphase chromatin. Based on a simple folding algorithm, our de novo model unifies the high contact frequency discovered by genomic techniques, and the high structural heterogeneity revealed by imaging techniques, which two chromatin properties we theoretically prove to be irreconcilable within a fractal polymer framework. Our model provides a holistic view of chromatin folding, in which the topologically associated domains are liquid-tree-like structures, linked and isolated by stretched out, transcriptionally active DNA to form a secondary structure of chromatin that further folds into a "3D forest" under confinement. The model pivots an unprecedentedly wide array of experimental observations and suggests the existence of a universal chromatin folding principle. Based on a global folding parameter, the model reveals a unique structure-function relation of chromatin, which is abnormal from a polymer point of view but explains some experimental observations of how chromatin responses to stress.

**10:36AM E65.00010: Investigating dynamic chromatin states in a model cell organism**

MARY LOU BAILEY (Presenter), Applied Physics, Yale University, JESSICA F WILLIAMS, MEGAN KING, Cell Biology, Yale University, SIMON G MOCHRIE, Applied Physics, Yale University — Chromatin's biological functions are inextricably linked to its spatial organization and real-time dynamics. I will describe research aimed at gaining new insight into chromatin organization and dynamics, focused on the emerging model of Topologically-Associated Domains (TADs) – 50-100 kb-length regions of the genome that show unusually high contact probability. To date, approaches capable of linking the physical TAD structure to chromatin dynamics have been lacking. I will present a novel data acquisition and analysis pipeline and preliminary results: We label specific gene loci within a model cell organism, *S. pombe*, with lacO arrays bound by fluorescent LacI-GFP proteins. We then image cell populations over time on a widefield microscope. These movies are used to track the motions of loci for large populations of single cells. Next, we analyze the diffusive behavior of the chromatin loci by determining the mean-square displacement and velocity autocorrelation function. To further investigate the underlying biology that contributes to locus motion, we compare perturbations to a variety of biological inputs, including temperature, the cytoskeleton, and proteins that are hypothesized to have key roles in TAD formation.

**8:00AM E66.00001: Tissue fracture and healing dynamics govern extreme plastic shape changes in the *Trichoplax adhaerens*, a simple, early divergent animal**

VIVEK N. PRAKASH (Presenter), Department of Bioengineering, Stanford University, MATTHEW S BULL, Department of Applied Physics, Stanford University, MANU PRAKASH, Department of Bioengineering, Stanford University — While epithelial tissues provide robust mechanical support, they also exhibit local ‘flows’ during morphogenesis and development. In adults, epithelial tissues undergo repeated stretching (e.g. lungs), and an inability to withstand stretch can cause fractures leading to diseases. Tissue fractures so far have been associated with negative consequences, and we do not yet know if fractures can be beneficial. Here, we have discovered a novel fracture-based mechanism by which epithelial tissues can exhibit fast and extreme plastic shape changes in a simple, early divergent animal - the *Trichoplax adhaerens* (phylum Placozoa). Fracture dynamics play a critical role in the lifecycle of Placozoans by dictating asexual reproduction by binary fission. Using innovative experimental in-toto imaging and tagging techniques, we quantitatively demonstrate that innate mechanical forces (shear and tension) arising from organismoal motility govern tissue fracture dynamics. These physiological fractures can either enlarge or ‘heal’ rapidly – leading to dramatic tissue shape change. These tissues exemplify a novel paradigm in soft-active-living-matter since they ‘fluidize’ by creating transient, local, stochastic ‘soft zones’ that exhibit glassy dynamics and a yield stress behavior in living animals.
8:12AM E66.00002: Cell Shape Dependent Motility During the Establishment of Tissue Structure  JOHN DEVANY
(Presenter), Physics, The University of Chicago, DANIEL SUSSMAN, M. LISA MANNING, Physics, Syracuse University, MARGARET
GARDEL, Physics, The University of Chicago — Mature epithelial tissues have distinct cellular architecture, which is maintained
despite externally applied forces, wounding, and cell division or death. Here we investigate how a model tissue develops and
maintains cellular structure by quantifying single cell dynamics and cell shape in newly formed MDCK monolayers. Over time cells in
the monolayer become increasingly hexagonal and arrest at a final structure resembling a mature epithelium. Throughout this process we observe glassy dynamics controlled by cell shape, as predicted by vertex models. Varying substrate stiffness causes monolayers to form and evolve with different cell density, but a similar relationship between cell shape and dynamics. This suggests the changes in cell density often observed in tissue development may not directly impact cell motility. We find that inhibiting regulators of the actin cytoskeleton cause monolayers to arrest with elongated cell shapes. Interestingly, across a diverse set of conditions we find a relationship between the final cell shapes and velocity correlation length which we explore in vertex models by including cell alignment coupling. Our results demonstrate that multicellular coordination of motility affects the regulation of cell shape and determination of final tissue structure.

8:24AM E66.00003: Relationship between cell force, shape, and motion in collective cell migration  AASHRITH
SARASWATHIBHATLA (Presenter), JACOB NOTBOHM, University of Wisconsin - Madison — In biological tissues, collective cell
groups exhibit a transition from a solid-like state, wherein cell positions remain fixed, to a fluid-like state, wherein cells flow freely and rearrange their positions with their neighbors. Recent theoretical models and experiments have demonstrated that this transition can be predicted by average cell shape, with cells having more elongated shapes and greater perimeters more easily sliding past their neighbors. Cell perimeter is hypothesized to be controlled by the cell surface tension which is an interplay of the cell’s cortical actomyosin contractility and cell-cell adhesions. However, the hypothesis is still experimentally unexplored. Here, we investigate the factors affecting cell perimeter, and we quantify the corresponding effects on collective migration. For this, we perturb actin and myosin-II in epithelial (MDCK) cell monolayers and study the effects on force, shape, and motion. We employ traction force microscopy, fluorescent imaging, and quantitative image analysis to measure forces, cell perimeters, and migration respectively. By combining these experimental measurements, our study provides experimental testing of the theoretical models and establishes new principles relating cell force, shape, and motion.

8:36AM E66.00004: Embryonic Inversion in Volvox carteri: The Flipping and Peeling of Elastic Lips  PIERRE HAAS
(Presenter), RAYMOND E GOLDSTEIN, Department of Applied Mathematics and Theoretical Physics, University of Cambridge — The
embryos of the green alga Volvox are spherical sheets of cells that turn themselves inside out at the close of their
development through a program of cell shape changes. This process of inversion is a simple model for the mathematical
analysis of morphogenesis [1], yet shares many features with processes such as gastrulation in higher organisms. In Volvox
carteri, inversion starts with four lips opening up at the anterior pole of the cell sheet, flipping over and peeling back to
invert the embryo. Experimental studies have revealed that inversion in V. carteri is arrested if some cell shape changes
are inhibited, but the mechanical basis for these observations has remained unclear. We analyse the mechanics of this
inversion by deriving an averaged elastic theory for these lips and we interpret the experimental observations in terms of
the mechanics and evolution of inversion [2].

8:48AM E66.00003: Morphogenesis of termite mounds*  ALEXANDER HEYDE (Presenter), Harvard University, SAMUEL A
OCKO, Stanford University, L MAHADEVAN, Harvard University — Several species of termites across Africa, Asia, Australia, and
South America collectively construct meter-sized porous mound structures that regulate mound temperature, humidity,
and gas concentrations. These mounds display varied yet distinctive morphologies that range widely in size and shape. To
explain this morphological diversity, we introduce a mathematical model that couples environmental physics to insect
behavior: the advection and diffusion of heat and pheromones through a porous medium are modified by the mound
geometry and in turn modify that geometry through a minimal characterization of termite behavior. Our model captures
the range of naturally observed mound shapes in terms of a minimal parameter set and suggests several simple scaling
laws for mound morphology and construction time. An elaboration of our model that incorporates 3D internal nest
structure gives rise to regularly spaced floors and pillars, as well as the spontaneous generation of helical ramps, as have
been observed in scanned mounds across termite species. This framework makes testable hypotheses for the response of
mound morphology to external temperature oscillations and internal odors.

9:00AM E66.00006: Pattern Selection in Brine Shrimp Swarms  ANDREA WELSH (Presenter), FLAVIO FENTON, Georgia Institute of Technology — Swarming is a ubiquitous self-organization phenomenon which occurs in many biological systems such as flocks of bird and insect, schools of fish, and collections of bacteria. This sort of behavior emerges spontaneously, arising without any sort of centralized control or leadership. Many crustaceans such as brine shrimp produce swarms, in which individuals cluster together rather than spreading out uniformly in their environment. The size and distribution of these swarms are governed by local interactions between individuals. We will discuss the three-dimensional patterns that can be observed in brine shrimp swarms, specifically of the Great Salt Lake strain of Artemia franciscana, at high concentration. These patterns can be easily observed with simple tabletop experiments; however, the causes of these patterns are unknown. We experimentally test the effects of certain environmental conditions on the development of these swarms. We then develop a model an agent based model of shrimp which yields the same sort of spatial patterns as those that are observed. The model reproduces the basic length and times scales of the patterns, the type patterns selected, and the stability of those patterns.

9:12AM E66.00007: Social insect aggregations as inspiration for mesoscopic active matter*  SHANKAR LALITHA SRIDHAR (Presenter), TONG SHEN, KANGHYEON KOO, Mechanical Engineering, University of Colorado, Boulder, ROBERT JAMES WAGNER, Material Science and Engineering Program, University of Colorado Boulder, FRANCK J VERNEREY, Mechanical Engineering, University of Colorado, Boulder — Social insects such as ants and bees exhibit extraordinary co-operative behavior to form aggregations and are often called super-organisms due to their ability to achieve complex structures and functionalities. Individual interactions include attachment and detachment of legs, bodies and mandibles that result in active re-organization of the network that can drastically transform the aggregation from a solid-like to fluid-like material and vice-versa. As the interactions in these aggregations operate in the mesoscale, they are easily observable and are attractive candidates to emulate in synthetic systems. Drawing inspiration from insects, we have designed a synthetic mesoscopic aggregation in our lab made of particles resembling mini gears and interact through magnetic and shear forces to self-organize into a network. The aggregation is infused with leader particles containing battery powered motors that induce motion and activity in the entire network. The aggregation behavior can be tuned by varying the magnetic strength, motor activity of leaders and their positions and diversity in particle size. Using statistical mechanics, we show that the aggregation can be programmed to achieve specific shapes and even transport solid metal objects through them.

9:24AM E66.00008: Surface-mediated cell alignment using polymerized liquid crystal nanostructures*  GRETA BABAKHANOVA (Presenter), JESS KRIEGER, MIN-HO KIM, O D LAVRENTOVICH, Kent State University — The microenvironment of cells affects their morphology and alignment. The physical characteristics of a cell are of extreme importance as the function and viability of a cell is closely linked to its morphology. In this work, we demonstrate the control of the orientation of cultured human dermal fibroblasts (hDFs) using polymerized liquid crystal (LC) periodic nano- and microstructures. The desired pattern is created by controlling the boundary conditions of the LC molecules which exhibit a smectic-A phase. Doping the LC with a small amount of reactive monomers allowed us to fix the molecular orientation and preserve the nano- and microstructures after photopolymerization and subsequent washing. The plated hDFs respond to the polymerized LC topography by changing their shape and aligning their long axis parallel to the patterned grooves. Though fibronectin treatment promotes proliferation of the cells, when comparing the hDFs grown on fibronectin and fibronectin-free patterned surfaces, the cells on fibronectin-free surface show improved alignment and elongation. The demonstrated LC-based surfaces will potentially find practical applications to preprogram cells to form specific kinds of tissues.

9:36AM E66.00009: Fluid to solid transition in muscles*  KHOI NGUYEN (Presenter), NEELIMA SHARMA, MADHUSUDHAN VENKADESAN, Yale Univ — Roboticists have long sought to develop actuators that emulate the performance of muscle. These have mostly centered on the power and force capacity of muscle and more recently on muscle’s stiffness and damping characteristics. However, a critical aspect that remains missing in muscle-inspired actuators, and also poorly studied in muscle, is an activation-dependent fluid-to-solid transition in muscle’s mechanical response. For example, a highly activated muscle resembles a solid-like material that maintains posture and provides stiffness, whereas muscle under low activation yields like a fluid without much resistance against rapid motions. Understanding how this transition may arise in muscle could guide the development of new muscle-like actuators that use similar principles as muscle to achieve a fluid-to-solid transition. Current understanding of the sarcomere is based on mean-field models of Huxley-based crossbridge cycles. We find that models of varying complexity, from two- to five-state models of actomyosin, all fail to capture the fluid-to-solid transition. In analogy with jamming transitions in disordered solids, we postulate potential nonequilibrium dynamics that may underlie the fluid-to-solid transition in muscle.

9:48AM E66.00010: A web-based application of the Cellular Force-Inference Toolkit (CellFIT)*  XIAOJIA XU (Presenter), W. TYLER MCCLEERY, SHANE HUTSON, Physics and Astronomy, Vanderbilt University — Given an image of an epithelial cell sheet, CellFIT can infer cellular forces by segmenting the image into individual cells, constructing equilibrium equations for the points where cells meet at triple junctions, and finding a least-squares solution for the tensions at cell-cell interfaces. Similarly, cellular pressures can be estimated by constructing Laplace equations that relate the edge tensions, curvatures and cellular pressure differences. Despite these capabilities, the accessibility of CellFIT to scientists of all backgrounds is not yet optimized. We will present an updated web-based application of CellFIT that allows users to access the software from a browser. The updated version includes improved error handling and the implementation of additional functionality for reading and processing image stacks. Application of the web-based CellFIT to time-resolved image stacks of wound healing in Drosophila epithelia demonstrates spatial and temporal variations in cellular forces as the wounds close.

10:00AM E66.00011: Mechanical and Biochemical Simulations of Atherosclerosis*  NAVID MOHAMMAD MIRZAEI (Presenter), PAK-WING FOK, University of Delaware — Atherosclerosis is a disease considered to be one of the leading causes of death. Understanding the behavior and dynamics of the vessel wall before and after atherosclerosis has been a motivation for many studies. We investigate this phenomenon as a combination of mechanical deformation of the vessel wall along with the cell and chemical dynamics that happen inside of it. We consider the vessel wall as a growing hyperelastic material with three layers, each having a different set of mechanical properties. To describe tissue growth we use morphoelasticity as the mathematical framework. To include the stiffening effect of collagen fibers we employ a Holzapfel-Gasser-Ogden anisotropic strain energy function. In addition, we explore the distribution of oxidized lipids, macrophages, foam cells, oxygen and necrotic cells in the intima at each growth step via a system of PDEs. All numerical simulations are carried out via the finite element method on the FENICS framework. Altogether, this allows us to observe intimal thickening as a result of vessel growth along with histological changes within the wall such as the development of necrotic zones. Our simulations show results similar to the images acquired from ultrasounds scans.

10:12AM E66.00012: Pattern formation and ecological feedback in antigen-immunity co-evolution  HONGDA JIANG (Presenter), SHENSEN WANG, California State University, Los Angeles — Immune systems manifest self-tolerance and respond to foreign invaders. Despite our knowledge of the molecular mechanisms involved in immune response and tolerance, an intuitive understanding of the immune-antigen relationship that determines the overall efficacy of immune control is lacking. We suggest that both features of natural immunity can be described by immune-antigen co-evolution. Extending ecological insights, we consider predator-prey interactions between immune cells and foreign or self antigen that can reach a dynamic balance through mutual adaptation. We present a minimal model of the co-evolutionary dynamics as a pair of reaction-diffusion processes in a phenotypic shape space, coupled by reciprocal interactions with finite cross-reactivity. We find that asymmetry in cross-reactivity can lead to pattern formation, indicating the emergence of antigen niches. We show in a phase diagram the regimes of balance breaking caused by pattern-forming instability: antigen extinction occurs as a result of co-localized population densities, whereas antigen escape follows the formation of alternating patterns under immune homeostasis. Thus, it is important to consider the feedback between population dynamics and pattern formation in understanding immune function and abnormality.
8:00AM E67.00001: Complexity and Fly Swarms*  TROY TAYLOR (Presenter), JOELLE L MURRAY, Linfield College — A system is considered complex if it is composed of individual parts that abide by a set of simple rules while the system, as a whole, exhibits more elaborate, unexpected properties. The motivation for studying complexity stems from the fact that it is a feature of many different systems. We are particularly interested in fly swarms and the possible complex properties that swarms exhibit, arising from individual fly interactions. To better understand the nature of complexity exhibited by fly swarms, a simple stochastic fly swarm model was created to investigate the relationship between the average radius of the swarm and the number of individuals within it, as experimental data shows a power-law scaling of the number of flies to the average radius. In addition, the model will be used to explore the difference between swarming and non-swarming behavior.

*Linfield College Student-Faculty Collaborative Research Grant

8:12AM E67.00002: Quasiperiodic Earthquake Events in an Olami-Feder-Christensen Model  JACOB OWENS (Presenter), RACHELE DOMINGUEZ, Randolph - Macon College — We simulated an earthquake fault system using a variation of the OFC cellular automata model. The fault is represented by a 2D lattice structure wherein each site holds some amount of stress. Our model increases the stress on the system in a more realistic way and allows multiple sites to fail simultaneously. The model generates data that produces Gutenberg-Richter scaling, which is consistent with real earth data. Additionally, the model incorporates “asperity” sites into the lattice; these asperities have a much higher failure threshold relative to other sites in the lattice. The introduction of asperities to the system generates a characteristic period according to which we observe very large events. These main shocks are preceded by a gradually increasing number of large events (foreshocks) and followed by a gradually decreasing number of large events (aftershocks). By introducing multiple distinct failure thresholds for the asperity sites, we were able to identify characteristic periods related to the respective failure thresholds. In varying these parameters we can control the periodicity of large earthquake events. These results suggest that the spatio-temporal clustering observed in real seismic data is related to the physical structure of the fault system involved.

8:24AM E67.00003: Quantum Coherence Enhanced Phototherapy: A Step Towards Quantum Medicine  ZACHARY WITHERS (Presenter), DMITRI VORONINE, University of South Florida — Irradiation and phototherapy involves the application of electromagnetic radiation to infected or tumorous tissues. Historically, radiation dosage, energy, and specificity have been of significant research areas, but with the evolution of quantum optics, plasmonics, and nanotechnology new devices and enhancement schemes are being realized. We propose the use of aluminum SPASERs as an ultraviolet phototherapeutic treatment mechanism and discuss the role quantum coherence plays in treatment enhancement, efficiency, effectiveness, and specificity. We further discuss optimization of temporal nonlinear regimes and potential application of laser pulse shaping.

8:36AM E67.00004: Protein-Based Drug Delivery Nanoparticles*  TY NAQUIN (Presenter), Department of Physics and Chemistry, Department of Chemical and Biomedical Engineering, Troy University, Cleveland State University, KIRIL STRELETZKY, Department of Physics, Cleveland State University — Elastin-like polypeptides (ELPs) are a class of biopolymers that undergo a reversible phase transition occurring at a transition temperature. Recently, six-armed star polymers (G10 and G19) have been synthesized with arms composed of ELPs, namely repeats of the amino acid sequence GVGVP. Each arm of the G10 contains 10 repeats of this sequence, whereas the G19 contains 19 repeats. Above a certain temperature, these proteins aggregate due to the hydrophobic nature of ELP chains. They form specific aggregation structures, which may prove suitable for drug delivery applications. The proteins may collapse into individual molecules or assemble into nanoparticles that could be used to transport and protect slightly hydrophobic drug compounds. We have characterized the solution properties of G10 and G19. The transition temperatures of the proteins were measured using spectrophotometry for various protein concentrations, salt concentrations, and pH values. The samples were also investigated using light scattering. In particular, dynamic light scattering was used to probe the size of the aggregates above and below the transition temperature. Further measurements illustrate the effects of salt concentration and pH on particle dimensions.

Biocompatible Exchange-Coupled Magnetic Nanoparticles for Advanced Hyperthermia*

ELIZABETH FULLER (Presenter), Ohio State University, JOSHUA L ROBLES, MANH-HUONG PHAN, HARIHARAN SRIKANTH, Physics, University of South Florida — Exchange-coupled bimagnetic nanoparticles describe a potential for advanced hyperthermia treatment of cancer with an increased heating capability. The feasibility of magnetic hyperthermia in humans warrants magnetic nanoparticles (MNPs) with an Fe3O4 shell to meet biocompatibility standards. In our study, we compare the heating efficiency and magnetic properties of CoFe2O4@Fe3O4 MNPs with the inverse system, Fe3O4@CoFe2O4. We calculate the Specific Absorption Rate (SAR) values of both nanoparticle systems when dispersed in hexane, water, and agar in addition to proper morphological and magnetic characterization using TEM, XRD, and DC Magnetometry. At 80mT, we report SAR values of our CoFe2O4@Fe3O4 MNPs to be 62% greater in water and 2% greater in agar than the inverse MNPs. We observe a significant coercive field of the CoFe2O4@Fe3O4 MNPs when taking DC Magnetometry measurements at 10K, to which we attribute its superior heating power over the inverse system in media that limit Brownian movement. We anticipate an increase in saturation magnetization of the CoFe2O4@Fe3O4 system with negligible effect on coercive field with increased Fe3O4 shell thickness.

Computer simulation of a finite-time Carnot engine working under ecological conditions

DAVID A. ROJAS-GAMBOA (Presenter), JUAN I. RODRÍGUEZ, Escuela Superior de Física y Matemáticas, Instituto Politécnico Nacional, JULIAN GONZALEZ-AYALA, Departamento de Física Aplicada, Universidad de Salamanca, F. ANGULO-BROWN, Escuela Superior de Física y Matemáticas, Instituto Politécnico Nacional — In the context of finite-time thermodynamics some optimization criteria for heat engines have been proposed, such as the maximum power [1] or the ecological criterion [2], being the later the best compromise between high power output and low entropy production. In order to study these criteria, we present a molecular dynamics simulation of a hard-disk gas performing a finite-time cyclic process that is near to a Carnot one. While previous works analysed the maximum power regime [3], in the present work we discuss the ecological case. When the gas is in contact with a stochastic thermal wall (or heat reservoir), we show that the speeds distribution is well described by a Maxwell-Boltzmann function with an effective temperature that is lower/higher than the source/sink temperature (as in the endoreversible model). By obtaining the power output and total entropy production, the ecological efficiency of such an engine was computed via molecular simulations for the first time, showing good agreement with analytical approaches. Our results were reported in D. A. Rojas-Gamboa et al., Phys. Rev. E 98, 022130 (2018).

Higher-Order Numerical Solutions of the Quarter Car Suspension Model

ALBERT MATERDEY (Presenter), Roxbury Community College — Applying Newton’s second law to the sprung and un-sprung masses, the Quarter Car Suspension mathematical model was derived as a system of two coupled second-order differential equations. This system was rearranged into a system of four coupled first-order differential equations. Algorithms were derived to solve this system in the time domain using the Euler’s, second-order Runge-Kutta , and fourth-order Runge-Kutta methods. For larger values of the suspension and tire spring constants, for example in heavier vehicles with large tires such as utility, crane, and backhoe trucks, higher order algorithms are essential to describe the high-frequency oscillations of the vehicle suspension system.

Synchronization of Mid-Frequency Engines for Energy Harvesting.*

SEO YOUNG AHN (Presenter), University of Utah — Thermoacoustic engines convert heat to electricity by producing sound, which generates electricity by a piezo electric device. Multi-device arrays of such mid-frequency (2.5 kHz) thermoacoustic energy converters have been studied in order to raise the power output. Devices with 2 and 3 engines were investigated, eventually leading up to 6 engines. Being self-sustained oscillators with random phase, their synchronizations are crucial in attaining maximum power. Indeed, synchronization was observed; coupling between the engines is attributed to their radiation impedance and reflections from the acoustic cavity supporting them. The observed increased output levels substantiate synchronization through the absence of beats between engines, Fast Fourier Transforms, where a peak due to a common frequency is observed, and resultant common, lowered frequency. A benefit of the array is the reduction of onset temperature such as 50°C for 3 engines, and similarly onset times for oscillations.

Wearable textile-based energy harvester designed for human motion.*

REBECA GURROLA (Presenter), Physics and Mathematics, St. Mary's University, JANNA EAVES, CARY L PINT, Mechanical Engineering, Vanderbilt University — While there are many different methods of generating sustainable energy, small quantities of energy otherwise wasted in the pursuit of everyday activities are often overlooked. Recently, electrochemical energy harvesters joined the ranks of piezoelectric and triboelectric harvesters to convert mechanical energy into electrical energy. Here, we use materials with mechanochemical response to seamlessly integrate motion harvesting into textiles for wearable applications.

This study presents a novel class of safe and non-toxic “smart” energy harvesters which can be activated via sweat, simulated here by a solution of NaCl. The harvester comprised of a sodium tin alloy on copper fabric exploits ambient motion at frequencies of 0.1 Hz. In bend tests, the harvester generates a peak power of ~36.4 μW/cm² and energy of ~131.1μJ/cm² with each bend. Additionally, it is sensitive to changes in salt concentration, suggesting applications in hydration-monitoring. These results emphasize the exciting possibilities for a new class of wearable harvesters.

Increasing the Number of Sides of a Luminescent Solar Concentrator can Increase its Power Output*

BAILEY HOPKINS (Presenter), BRUCE PAUL WITTMERSHAUS, Penn State Erie — Luminescent Solar Concentrators (LSCs) are fluorescent sheets of glass or plastic that absorb sunlight and concentrate their fluorescence using total internal reflection onto a small area of photovoltaic solar cells for energy conversion. LSCs have the potential to generate electricity at a lower cost than standard solar panels. Current LSCs are designed as squares. This shape can cause non-uniform illumination along its edges leading to current mismatch in the solar cells resulting in loss of power output. We present results showing that changing the LSC’s shape closer to that of a circle decreases current mismatch by improving the uniformity of illumination.

Pretreatment of rice straw for enhancing fermentable sugar yield using a high-pressure reactor

PRATHAM GUPTA (Presenter), BAHIRU TSEGAYE, CHANDRAJIT BALOMAJUMDER, Chemical Engineering, Indian Institute of Technology Roorkee — Rice straw has proved to be a potential renewable energy source due to its high polysaccharide contents and abundance availability. Fermentable sugars are easily obtained on hydrolysing rice straw using different pretreatment techniques. In this study, organosolv was used to pretreat rice straw in high-pressure autoclave reactor, under different conditions, for the removal of lignin and release of trapped polysaccharides. The composition of rice straw was analyzed as per National Renewable Energy Laboratory (NREL) guidelines. The temperature was varied as 120, 140 and 160 degree Centigrade and the exposure time was varied as 15, 30 and 60 minutes. The amount of sugar and lignin were greatly affected by temperature and time. It was found that sugar yield was maximum at 140 degree Centigrade and 15 minutes. At this pretreatment condition, it was observed that almost all of the hemicellulose was solubilized and 73% and of lignin was removed and 82% cellulose was released from the biomass. The removal of the high amount of lignin facilitates the release of the cellulose from the biomass matrix. Overall, this study showed the possibility of a high-pressure reactor for effective removal of lignin, which enhances the yield of fermentable sugars.

Thermal Expansion in 3D Printing Materials for Interferometric Devices

THEODORE MORIN (Presenter), LUISA VELASCO, CATHERINE HAND, MICHAEL EWNETU, University of Dallas — 3D printed optomechanics offers a cheaper alternative to conventional machined parts with the potential for customization. Examples include the kinetic mounts, precise linear movement, and integrating sphere described by Salazar-Serrano et al (2017). When considering the use of 3D printed parts to make high precision interferometric instruments, thermal expansion becomes an important consideration. We present an inexpensive interferometric measurement of thermal expansion in 3D printed materials. Tests are performed with ABS and PLA plastics. We also explore variation with different colors of the plastics and different printing conditions. Finally, we present a design for a low-cost, 3D printed scanning Fabry-Perot interferometer with minimal thermal sensitivity and an anticipated finesse of about 50.
10:24AM E67.00013: Electrode Coatings for Neurostimulation and Cardiac Pacing Applications*  
SIERRA DUTKO (Presenter), ANTHONY VALENTI, NATALIE PAGE, ROBERT LOWE, RHANDY PALADINES, JEFFREY HETTINGER, Physics and Astronomy, Rowan University — Neurostimulation and cardiac pacing electrodes have many applications each requiring biocompatibility and the ability to exchange charge between the underlying metallic electrode and the ionic fluid surrounding it. The trend toward smaller electrodes as well as higher current applications has resulted in the need for improved charge transfer. With this goal, cubic nitride coatings with columnar microstructure have been added to the electrodes using reactive magnetron sputtering in a nitrogen rich atmosphere. These coatings which provide capacitive coupling between the electrode and the biological solutions increase the surface area improving the required charge transfer. Coating performance is measured electrochemically using cyclic voltammetry with the coated metal as the working electrode, a platinum coiled wire as the counter electrode, and phosphate buffered saline as the electrolyte. We report on the thickness dependence of the coating performance and delineate important parameters influencing this performance.

*This research has been funded in part by a grant from New Jersey Health Foundation.

10:36AM E67.00014: Hygroscopic Nature of Solution Processed Al2O3 Thin Film Dielectric and Impact on Electrical Characteristics*  
JAMES TRAN (Presenter), TREY B DAUNIS, JULIA WAN-PING HSU, University of Texas at Dallas — Metal oxides are a good candidate for gate dielectrics because of their high dielectric constant and low leakage current. Solution deposition is a favorable method for thin film fabrication due to its low cost and high throughput. Here, we compare the property and stability of solution-processed Al2O3 and ZrO2 films. Fourier transform infrared spectroscopy (FTIR) and electrical characterization reveal that Al2O3 absorbs moisture from air, while ZrO2 remains stable with no moisture gain. This conclusion is established by comparing Al2O3, ZrO2, and bilayers of Al2O3/ZrO2 and ZrO2/Al2O3. FTIR spectra show increased intensity in the water -OH region (3700-2500 cm⁻¹) when Al2O3 is exposed to air or purposely soaked in water. The change in surface contact potential indicates that the adsorbed water molecules’ dipoles point away from the surface. Effects of the moisture gain on electrical characteristics are studied with metal-insulator-metal capacitors and field effect transistors. Absorption of water in Al2O3 results in higher capacitance and dissipation at low frequencies and show a counter-clockwise hysteresis in transistor drain current vs. gate voltage curves.

8:00AM E68.00001: Golf ball simulation and aerodynamic characteristics*  
EDUARDO RIVERA (Presenter), MARCO FATUZZO, Xavier University — The flight trajectory of a golf ball depends upon the net effect of gravity, lift, and drag. The latter two forces result from the complex interaction between the ball surface and the air through which it moves, and are characterized in terms of drag and lift coefficients that depend upon the geometry, speed and spin rate of the ball as well as the density of the air. Our research focused on using both wind-tunnel results and ANSYS software analysis to obtain reliable lift and drag coefficients for different flight condition and ball dimple-pattern, and use the results to inform a robust flight simulation MATLAB program.

*John Hauck Foundation Summer Research Program
Waves crashing in the ocean generate large numbers of bubbles, which burst and can produce jets that break up into sea spray aerosol droplets. Wind can carry these aerosol drops into the atmosphere and seed cloud formation. Much of the research on bursting bubbles focuses on isolated bubbles; however, bubbles from breaking waves normally exist in close proximity to other bubbles. We therefore investigate how the presence of a neighboring bubble affects jet drop formation from a bursting bubble. Combining high-speed imaging experiments with numerical simulations, we show that a bubble bursting near another bubble ejects drops angled away from the neighbor bubble. We relate this ejection angle to the asymmetry in the collapsing bubble cavity and explore how bubble separation and bubble size affect the process. The observed effects could eventually help to improve aerosol production models and clarify the accuracy of previous assumptions.

*National Science Foundation Award #1351466

The printability regimes in inkjet bioprinting are the sets of printing conditions described using the , in which a stable . Previous experimental and simulation works of printability have mainly focused on millimeter-sized nozzles, while it is uncertain whether their conclusions can be applied to micrometer-sized nozzles. Because the capillary effect is significantly enhanced in the micrometer scale, the printability regimes in the micrometer scale are likely to differ greatly from that in the millimeter scale. In this study, the printability regimes in the micrometer scale are calibrated through three-dimensional computational fluid dynamics simulations. Our works are expected to be critically helpful in design of inkjet bioprinting with micrometer-sized nozzles.

Nanoparticles have been extremely useful in the treatment of diseases, such as cancer and bacterial infections, as well as for cleaning up pollutants like oil or minerals from water. Since it is hard to image any water-based solution in electron microscope, the behavior of charged nanoparticles in water is not well understood. This has been a barrier to the development of applications for nanoparticles.

The focus of the work presented here is to examine charge screening of positive and negatively charged gold nanoparticles (+/- AuNP) in water with different concentrations of salt. Aggregation and flocculation will be studied using a combination of transmission electron microscopy (TEM) and scanning transmission electron microscope (STEM), using liquid cells fabricated from nanoparticles in various solutions encapsulated by graphene. The degree of aggregation is determined by measuring the radial distribution function (RDF) of a field of particles in an image. RDF is directly related to the surface charges of nanoparticles. This information yields a much better understanding of the aggregation behavior of nanoparticles in water.

*Supported by the Chancellor's Undergraduate Research Award. This work made use of Electron Microscopy Services at Research Resources Center, UIC.

We seek to understand the dynamics of micro-swimmers by quantifying the stochastic forces generated by their motion. We are currently working with Chlamydomonas Reinhardtii—a green algae commonly used to study microscopic locomotion. Our approach is to use optical tweezers and a direct force calibration known as the photon momentum method (PMM) to measure micro-swimmer forces. The power spectral density (PSD) of the force dynamics is analyzed, providing information about the frequency content of the force signals. A simple stochastic model based on the generalized Langevin equation predicts the power spectral density to have a Lorentzian-type curvature. We compare our experimental data to the theoretical model to test if the model can predict our experimentally measured PSD. This approach allows the calculation of thermodynamic quantities such as work, power, efficiency, etc. to describe the microscopic motion. Our analysis seeks to apply concepts from stochastic thermodynamics to understand micro-swimmer dynamics.

9:00AM E68.00006: Pattern Formation in Driven Particulate Suspensions  WEI LU (Presenter), PRASHANT SHARMA, Suffolk University — Systems that are driven by energy from external sources are ubiquitous, and the rich phenomenology they display (e.g., ordered phases and pattern formation of bacteria, or nanoparticles in a fluid) is described by physical models that do not rely on conventional equilibrium physics. We study theoretically and computationally a class of such active-matter models with self-propelled motion and interactions and classify the resulting non-equilibrium ordered states using techniques from statistical physics.

9:12AM E68.00007: Density Driven Instability during Proppant Injection in a Hele-Shaw Cell*  RAM SUDHIR SHARMA (Presenter), RAUSAN JEWEL, ARSHAD KUDROLLI, Department of Physics, Clark University — We report an experimental investigation of granular matter suspended in a liquid injected between two parallel plates with a constant separation distance called a Hele-Shaw cell. These experiments are motivated by proppant injection in hydraulic fracturing of shale used to extract hydrocarbons. The cell is fully filled in with a similar ambient fluid to avoid capillary effects and pinning and dipinning dynamics of the front. We image the dynamics and deposition of the grains as they spread inside the cell as a function of injection rate and volume fraction of the grains. A finger-like instability is observed for sufficiently density difference between the particles and the ambient fluid. We will discuss the observed phase diagram as a function of the injection-rate of the fluid, its packing fraction and time. We demonstrate a correlation between the timescale for the sedimentation of the particles and for the onset of fingers as well as subsequent bifurcations. Corresponding length scales are studied as well, i.e. the finger lengths and widths as a function of the packing fraction of the injected fluid. Early analysis suggest that for a fixed packing fraction, regardless of the flow-rate, the sedimentation time determines the onset of the instability.

*Supported by DOE DE-SC0010274

9:24AM E68.00008: The Missing Model of the Liquid State, from Crystalline Solid State to Random Gas State  TIANHUI JIE (Presenter), Institution applied — Liquid state of materials has not had a successful physics-based model, for example, water, the most abundant and life-dependent, although the components of a successful model have been well-developed and successfully employed in applications, for examples, semiconductor physics-based solid-state electronics in communication (stereo, TV, PC, cell phone) and control (simple to complex robotics). The two missed culprits in physics are the long range order in the crystalline solid state which continues persistently into the higher kinetic energy fluidic liquid state, and also the dynamics of isolated molecules in a random ensemble of the gas phase at higher kinetic energies which continue persistently into the lower kinetic energy fluidic liquid state. The recent success of this new approach of combining the solid-state and gas-state to model the liquid state of pure water (such as the 80+ mega-ohm pure drinking water sold at the grocery stores for 75 cents) is described and extended to all the liquid states of materials in this presentation. [1] Binbin Jie, Tianhui Jie and Chihtang Sah, Studies of Water VI. Journal of Semiconductors, 2018, 39(11):111001. [2] Bin Jie, Tianhui Jie, Chih-Tang Sah, submitted to APS March Meeting 2019.

9:36AM E68.00009: Exploring self-organized criticality in driven cold gases  KAI KLOCKE (Presenter), GIL REFAEL, MICHAEL BUCHHOLD, Department of Physics and Institute for Quantum Information and Matter, California Institute of Technology — Recent experiments with strongly interacting, driven Rydberg ensembles have unambiguously demonstrated aspects of self-organized criticality (SOC) in the dynamics of the Rydberg pseudospins. Such experiments present a means for precise control of the microscopics from which SOC emerges and offer a new playground for the exploration of SOC with cold atoms. Here we simulate the dynamics of such Rydberg ensembles through numerical integration of the corresponding effective field theory. In particular, we discuss an experimentally feasible loading scheme by which the prototypical avalanche dynamics can be maintained and controlled. This gives access to three distinct dynamical regimes: i) a subcritical regime of periodically occurring avalanches, ii) an extended SOC regime featuring scale invariance and fractal real-space structures, and iii) a supercritical regime with constant avalanche activity. This relates Rydberg atom dynamics with SOC in neural networks, where similar scenarios have been observed. We sharpen this connection by analyzing the dependence of SOC on the size and dimensionality of the ensembles.

9:48AM E68.00010: Head-on Collisions of Vortex Rings with Solid Bodies*  MARY AGAJANIAN (Presenter), RYAN MCKEOWN, SHMUEL RUBINSTEIN, Harvard University — The head-on collision of vortex rings with slender wires creates complex vortex reconnection and breakdown behavior. Specifically, the interaction results in the rapid emergence of secondary vortical structures. These structures suggest that vortex lines are being created in the fluid; however, as, in the finite Reynolds number regime, vorticity must either close in on itself or begin or end on a boundary, the origin of the secondary structures is not well understood. We experimentally investigate the emergence and evolution of this behavior by varying the vortex ring dyeing technique, geometry of the wire, and Reynolds number. This allows us to characterize the interaction of the vortex core with the secondary vortical structures.

10:00AM E68.00011: Nonequilibrium power-law correlations in a system of tight-binding fermions with gapped spectrum  
JOSEPH GODOY (Presenter), JARRETT LANCASTER, High Point University — A quantum quench is explored in a system of tight-binding fermions in which a smooth, linearly-varying chemical potential is rapidly switched off at the same time a staggered chemical potential is turned on. The initial particle density profile is a “domain wall” shape and evolves unitarily under a Hamiltonian which possesses a gap in its spectrum. In the ground-state of the Hamiltonian generating time evolution, correlations decay exponentially with distance, while in this non-equilibrium setting, a steady state quickly forms within a central subsystem in which power-law correlations persist. The long-time average of the particle density, current and various correlation functions are shown to be obtainable from an effective momentum distribution which depends on the details of the Hamiltonian and the initial state. Intriguing similarities between the results in this model of free fermions and similar results obtained within interacting systems are discussed.

10:12AM E68.00012: Stochastic Simulations of Single-Cell Circadian Oscillations in Arabidopsis thaliana*  
YIAN XU (Presenter), ORRIN ABRAHAM BRUN SHINDELL, Trinity University — Chemical oscillations are a universal feature of living systems. In plants, for example, the daily periodicity of many functions is regulated by the oscillatory expression of circadian gene networks present in each cell. We analyze the chemically reacting system that controls the circadian rhythms in cells of the plant Arabidopsis thaliana by numerically solving a continuous kinetic model whose parameters were deduced from experimental data [1]. We find that the model exhibits slowly decaying oscillations and is situated near a Hopf bifurcation in parameter space. Then we implement Gillespie’s Stochastic Simulation Algorithm to simulate the system at the single-cell level and account for random fluctuations in particle numbers [2]. Finally, we comment on the relationship between the two approaches and on the possible biological significance of the model’s mathematical features.

*This work was supported by Murchison Fellowship from Trinity University.

10:24AM E68.00013: NSF IRES: Exploring the Effects of Single Point Mutations of Arabidopsis thaliana Cryptochrome 1 (AtCry1), a Plant Protein Involved in Blue Light Response*  
LILLIAN HAERR (Presenter), EMILY SHOCKLEY, JOHN STERNEN, JOHN KAVANAGH, JUSTIN J LINK, STEPHEN MILLS, DOROTHY ENGLE, Xavier University, MARGARET AHMAD, Sorbonne University — Cryptochromes are proteins that act as photoreceptors regulating development and the circadian clock in plants. It has been shown that mutations in cryptochromes, specifically AtCry1, alter the functionality of the proteins. These flavoprotein photoreceptors mediate growth, leaf expansion, and floral initiation. They act through blue-light dependent photoreduction of flavin adenine dinucleotide (FAD) via an electron transport chain. In the dark state, the flavin is oxidized and when stimulated with blue light, it is semi-reduced and in the active state which arguably causes protein conformational change and signal transduction. This photoreduction of FAD can be tracked using visible light absorption as the spectra of the oxidized and semi-reduced forms differ. Specifically, the oxidized FAD has an absorption at 450nm and once semi-reduced, the 450nm peak decreases and there is an increase in absorption at 550nm. Mutants studied show significant difference in appearance and plant growth in blue light when compared to native plants. Differences in absorption between mutant and native proteins were used to analyze potential differences in the photochemistry involved in plant growth.

10:36AM E68.00014: Membrane Simulations with Amyloid Beta*  
TYLER JENKINS (Presenter), GUOPING ZHANG, Indiana State University — Amyloid Beta is a misformed protein that is a key characteristic of Alzheimer’s disease. A plethora of research has been carried out to determine the structure of amyloid beta and mechanisms behind the plaque formation. We model 1-3 amyloid beta peptides in 3 different configurations inside a 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC) membrane in order to simulate a key step in the formation of amyloid plaques: the formation of pores in the cell wall of neurons due to amyloid beta. Our preliminary findings identify a configuration of amyloid beta in the membrane that appears to promote the formation of pores.

Focused Ultrasound as a Replacement for Endodontic Therapy

TALISI MEYER (Presenter), Chemistry and Physics, Simmons College, PHILLIP JASON WHITE, Radiology, Brigham and Women, MICHAEL JORDAN, Chemistry and Physics, Simmons College — Focused ultrasound has exhibited promising results as a therapeutic modality in its ability to minimize the invasiveness of a number of medical treatments that are physically and mentally traumatic to the patient. We propose the investigation of its use for non-invasive endodontic therapy (a.k.a. a “root canal”), with the ultimate goal of removing microbial infection from the root canal system of a contaminated tooth.

To avoid thermal damage to adjacent healthy tissues, we considered using the mechanical effects created by ultrasound, specifically that of cavitation. To generate proof-of-concept data, we designed, constructed, and tested a series of ultrasound transducers that delivered sufficiently low frequencies operating below 300 kHz and pressures below -30MPa to induce cavitation in degassed water with less than 3ppm. Our initial experiments have shown that sufficient ultrasound energy can be transmitted through intact ex vivo human teeth to elicit nonlinear streaming in the root canal of intact ex vivo human teeth. We have also demonstrated the use of equivalent parameters to kill bacteria. We will further determine and refine the optimal ultrasound parameters for eliciting bactericide in the intact tooth.

Session E69 FHP FIP: History of Contemporary Chinese Physics BCEC 052A - Yuanrong Lu, Peking University -

Creating A Center of Theoretical Physics at Christian Yenching University in Peking: British physicist William Band’s endeavor in the 1930s

DANIAN HU (Presenter), History, The City College of The City University of New York — William Band (1906-1993) was a practical physicist from Liverpool, who came to Yenching University in 1929. Having taught several years in Peking (Beijing) and worked mostly on experimental projects, Band had realized by the mid-1930s that “many Chinese students have a considerable natural aptitude for theoretical work,” and that there was no place in China where students could receive adequate training in theoretical physics. Thus he was determined to concentrate on theoretical study and aspired to build a center at Yenching to explore modern theoretical physics and its philosophical basis. For this purpose, he spent his sabbatical leave at Cambridge University, studying with Ralph Fowler, Arthur Eddington, Paul Dirac, and Rudolf Peierls. Based on extensive archival research, I examine in this paper Band’s endeavors in both China and England, demonstrating significant contributions of both Band and the American funded Yenching University to Chinese physics development and revealing a missed opportunity for Band to propose independently the effect of gravitational lensing.

Creating A Center of Theoretical Physics at Christian Yenching University in Peking: British physicist William Band’s endeavor in the 1930s

This project is in part supported by PSC-CUNY Research Awards and research grants from the Division of H & A at The City College of New York.

From Binoculars to Cinetheodolite: The Development of Applied Optics and the Optical Industry in China

LIE SUN (Presenter), Department of History of Science and Technology in Modern China, Institute for the History of Natural Sciences, Chinese Academy of Sciences — The emergence of the applied optics and the optical industry in China primarily started during the Second World War and the Cold War periods, while the applied optics and the optical industry in China mainly developed through three ways: setting up plants, sending students to study overseas, and engaging in mission-oriented disciplinary development. In the Anti-Japanese War (1937-1945), Gong Zutong and his colleagues, who had studied at the Technical University of Berlin, started to learn German optical technology. In 1939, the first batch of 6*30 Type Zhongzheng (Chiang Kai-shek) Binoculars were manufactured at the No. 22 Arsenal (Kunming) on a trial basis. The optical glass and accessories used by the binoculars were imported from Europe. From 1950s, industrial demand largely dominated the objectives and missions of China's sciences and industrial technologies. The mission-oriented disciplinary development model – the state's needs led the establishment and expansion of underlying disciplines – had direct impacts on the development of applied optics in China. Among others, an symbolic achievement was China's first large optical equipment developed by Wang Daheng and his colleagues in 1965 – a large cinetheodolite for observing satellite trajectories, fostering both a number of specialized research and development institutions on applied optics and the optics and instrument disciplines of some universities, and directly formulating one of the major features of the optics-related disciplines in China in the following decades, i.e., preferring development for practical purposes to fundamental researches.

This work is supported by the “Significant Breakthrough Project”of the Institute for the History of Natural Sciences (IHNS), Chinese Academy of Sciences (No. Y821101003).
9:12AM E69.00003: Entangled Worldlines: Four Physicists Whose Transnational Trajectories Reshaped Physics in China and the United States [invited] ZUOYUE WANG (Presenter), California State Polytechnic University — Chen Ning Yang and Tsung-Dao Lee are eminent Chinese American physicists who not only shared the 1957 Nobel prize in physics for their breakthrough on parity conservation, but also made other important discoveries as well as played active roles in promoting US-China scientific exchanges. Less well-known were Deng Jiaxian and Zhu Guangya, close friends to Yang and Lee respectively who also received their PhDs in physics in the US but who made the choice to return to China in 1950 and became prominent leaders in Chinese science and technology. This talk explores the entangled trajectories of these American-educated Chinese physicists in an attempt to present a nuanced picture of the transnational characters of both Chinese and American science.

9:48AM E69.00004: Chinese Physicists’ Construction of Straton (or Mao-particle) in the 1960s: the Chinese search for the structure of Hadrons under the guidance of Maoist philosophy* [invited] JINYAN LIU (Presenter), Chinese Academy of Sciences — Particle physics developed rapidly between the 1950s and the 1960s. The discovery of new particles at that time left particle physicists with an urgent need to make classification of them, to figure out their underlying relations and to put forward new conceptual and theoretical models. This brought about the proposition of the well-known Sakata model, Eight-fold way and quark model. What is rarely known is that Chinese particle physicists independently put forward a structure model of hadrons——straton model in 1966 inspired by Mao Zedong's philosophy. Mao Zedong explicitly supported Shoichi Sakata, a Japanese physicist, in applying materialistic dialectics to physics research, which influenced Chinese physicists in their study of particle physics. Starting in the early 1960s, Chinese particle physicists engaged in the theoretical research of elementary particles. From 1965 to 1966, they analyzed the experimental results and existing theories available to them, made a connection between their work and Mao Zedong's philosophy and proposed the straton model. In July 1966, the straton model was presented at the Summer Physics Colloquium of the Peking Symposium. Unfortunately, scientific research in China soon came to a halt due to the Cultural Revolution (1966–1976), the academic exchange between Chinese scientists and their foreign peers became even more difficult than before. The calculation results of the hadron model failed to be formally published in English as Chinese scientists had wanted. As a result, the straton model did not have the kind of influence upon the development of particle physics at the international level that these scientists had expected.

*Research and Teaching Project for youth of Chinese Academy of Sciences

10:24AM E69.00005: Physics and Politics Intertwined -- The manipulative moves in the 2016 supercollider controversy in China [invited] TIAN YU CAO (Presenter), Boston University — The controversy in 2016 over the worthiness of building an extremely expensive supercollider in China was both scientific and political. The intricacies of the asymmetrical manipulative moves on the science-politics interface by the pro-side and the con-side will be analyzed. The talk will end with some general remarks on the determinants in agenda-setting for fundamental researches in China, which will be compared with those in the US.

Tuesday, March 5, 2019 11:15 AM - 2:15 PM

Session F01 DCMP: Exotic Electronic States in Topological Systems BCEC 106 - Predrag Nikolic, George Mason University

11:15AM F01.00001: Exactly Solvable Majorana-Anderson Impurity Models SHANKAR GANESH (Presenter), JOSEPH MACIEJKO, University of Alberta — Majorana fermions emerge in topological superconductors as end zero modes in one dimension, and vortex-trapped zero modes or chiral edge modes in two dimensions. A question of much recent interest is the effect of electron-electron interactions on such Majorana fermions. We introduce exactly solvable Majorana-Anderson impurity models that describe an interacting Anderson impurity (i) immersed in tight-binding lattices of Majorana modes in one and two dimensions, (ii) coupled to the Majorana end mode of a Kitaev chain, and (iii) coupled to the edge mode of a chiral p-wave superconductor. The Ising slave-spin representation is used to map our interacting models to models of free auxiliary Majorana fermions. In each case, we calculate exact spectral functions for the impurity fermions and observe a nontrivial temperature dependence as a signature of interactions. Spectral functions for the host fermions are also calculated to study the feedback effect of the impurity on the superconducting host. We compare our exact results to those obtained from strong-coupling perturbation theory.
11:27AM F01.00002: Tuning Many-Body Interactions in a Thin Topological Insulator  NICHOLAS DALE (Presenter), ALEXANDER NGUYEN, DREW W LATZKE, University of California, Berkeley, NIKEH KOIRALA, Massachusetts Institute of Technology, PAVEL P SHIBAYEV, JISOO MOON, SEONGSHIK OH, Rutgers University, ALESSANDRA LANZARA, University of California, Berkeley — The conical dispersion of spinless Dirac fermion systems can become renormalized upon introduction to electron-electron interactions. It is an open question whether or not this behavior extends to the spin-momentum locked surface states of Topological Insulators. We investigate in Photoemission Spectroscopy the surface states of a thin Topological Insulator Bi2Se3 on SrTiO3 using temperature as a knob to tune electron-electron interactions.

11:39AM F01.00003: Surface band bending on cleaved strongly correlated topological insulators* CHRISTIAN MATT (Presenter), HARRIS PIRIE, Department of Physics, Harvard University, Cambridge, MA, United States, WENDEL S. PAZ, JUAN JOSE PALACIOS, Departamento de Fisica de la Materia Condensada, Universidad Autónoma de Madrid, DANIEL LARSON, MOHAMMAD H HAMIDIAN, JENNIFER HOFFMAN, Department of Physics, Harvard University, Cambridge, MA, United States — Strongly correlated topological surface states are promising platforms for next-generation quantum applications, but they remain elusive in real materials. Although angle-resolved photoemission (ARPES) experiments on the correlated insulator SmB6 appear to show spin-textured surface states, the Dirac point – the hallmark of any topological system – has not been resolved by ARPES. A key challenge is that SmB6 lacks a natural cleaving plane, thus limiting the ordered surface domains to tens of nanometers, with local energy band features shifted by tens of meV as observed by our scanning tunneling microscopy experiments. Here we simulate the full spectral function as an average over multiple domains with different surface potentials and band-bending. We thus explain the discrepancy between large-area measurements that average over multiple band-shifted domains and atomically-resolved measurements.

11:51AM F01.00004: Band topology in twisted bilayer graphene* HOI CHUN PO (Presenter), Physics, Massachusetts Institute of Technology, LIUJUN ZOU, Physics, Harvard University, SENTHIL TODADRI, Physics, Massachusetts Institute of Technology, ASHVIN VISHWANATH, Physics, Harvard University — Superconductivity and correlated insulators have been observed in "magic-angle" twisted bilayer graphene when the nearly flat bands close to charge neutrality are partially filled. The observed phenomenology resembles that of high-temperature superconductors like cuprates. Yet, the building blocks of the two systems are vastly different, since the states in TBG descend from graphene's Dirac dispersion. We argue that the Dirac character of the relevant states endows the nearly flat bands with a nontrivial band topology, which forbids any fully symmetric tight-binding description for the nearly flat bands alone. Extended models incorporating the higher energy bands, however, are possible. We constructing a family of such tight-binding models, and from them establish that the band topology is "fragile" in nature, in that it can be dissolved simply by adding additional atomic bands. Our models pave the way to developing a theoretical understanding of twisted bilayer graphene from a strong-coupling perspective.

12:03PM F01.00005: Magnetic structure of the antiferromagnetic Weyl semimetal candidates Mn3(Ge/Sn)* YOUZHE CHEN (Presenter), JONATHAN GAUDET, GUY G MARCUS, Johns Hopkins University, NAOKI KIYOHARA, AGUSTINUS A. NUGROHO, U Tokyo, ISSP, YANG ZHAO, NIST, SATORU NAKATSUJI, U Tokyo, ISSP, COLLIN BROHOLM, Johns Hopkins University — The recent discovery of Anomalous Hall Effect in Mn3X (X=Sn,Ge) suggests the existence of Weyl nodes in the electronic band structure of these non-colinear antiferromagnets. The magnetic structure of Mn3X is crucial to Weyl physics, but is still under debate due to the lack of experimental studies. To determine the structure, we report polarized neutron diffraction studies on Mn3X (X=Sn,Ge). In Mn3Ge, a k=0 antichiral structure was determined, which naturally explains the origin of a net in-plane magnetization along the [110] direction. In Mn3Sn, an additional incommensurate phase was discovered and further characterized with polarization analysis. The magnetic ground state selection of Mn3X (X=Sn,Ge) will be discussed in terms of exchange, Dzyaloshinskii-Moriya and crystal electric field interactions.

*This work is funded by DOE under DE-SC0019331.
12:15PM F01.00006: A topological classification of molecules and chemical reactions with and without interactions* LUKAS MUECHLER (Presenter), Center for Computational Quantum Physics, Flatiron Institute — In this talk, we propose a topological classification of molecules and their chemical reactions with and without many-body interactions. We consider 0-dimensional molecular Hamiltonians in a real-space tight-binding basis with time-reversal symmetry and an additional spatial reflection symmetry. On a single particle level, the reflection symmetry gives rise to a perplectic structure which can be probed by a Wilson loop after a flux-insertion. The classification in terms of Wilson loops remains stable in the presence of many-body interactions, which can be explained by the presence of zeros of the interacting single particle Green's function.

We argue that this topological classification has a universal contribution to the rate constants of chemical reactions and apply our model to a class of chemical reactions studied by Woodward and Hoffmann, where a reflection symmetry is preserved along a one-dimensional reaction path.

*The Flatiron Institute is a division of the Simons Foundation

12:27PM F01.00007: Spin-wave excitations in the antiferromagnetic Weyl semimetal candidates Mn3Ge and Mn3Sn* JONATHAN GAUDET (Presenter), YOUZHE CHEN, GUY G MARCUS, IQM, Johns Hopkins University, IKHLAS MUHAMMAD, NAOKI KIYOHARA, AGUSTINUS A. NUGROHO, SATORU NAKATSUJI, ISSP, U Tokyo, MATTHEW BRANDON STONE, Oak Ridge National Lab, MINORU SODA, TAKATSUGU MASUDA, ISSP, U Tokyo, COLLIN BROHOLM, IQM, Johns Hopkins University — Mn3X (with X = Ge or Sn) are semimetal antiferromagnets with large anomalous Hall and Nernst effects. These anomalous transport properties have been attributed to the presence of electronic Weyl nodes near the Fermi energy of these materials [1,2]. The magnetism of Mn3X remains relatively unexplored. For example, a detail knowledge of their magnetic excitations is still lacking. In this talk, we report the inelastic neutron scattering spectra of Mn3Ge and Mn3Sn. Our analysis reveals linear dispersive modes that are gapped by ~ 5 meV and have an energy bandwidth of ~ 80 meV. Spin Hamiltonians for both Mn3Sn and Mn3Ge have been derived and will be presented along with a detailed comparison between the two sister compounds. [1] S. Nakasutji et al., Nature 527, p.212–215 (2015) [2] M. Iklhas et al., Nature Physics 13, p. 1085–1090 (2017)

*Support from DOE EFRC (DE-SC0019331) and CMHC-NSERC Postdoctoral Fellowship.

12:39PM F01.00008: Field theory of incompressible topological quantum liquids in higher dimensions PREDRAG NIKOLIC (Presenter), George Mason University — I will discuss a derivation of field theories that describe quantum dynamics of topological defects in a broad range of topologically ordered phases. Beyond quantum Hall liquids in two dimensions, the obtained Lagrangians hint at the existence of stable topologically ordered states with fractional excitations in higher dimensions - involving defects such as monopoles and hedgehogs. I will outline some properties of these topological phases (e.g. fractionalized magnetoelectric effect), and touch upon the prospects for their observation in three-dimensional topological materials.

12:51PM F01.00009: Possible 3-dimensional Topological Excitonic Insulator in a Semimetal under Magnetic Field ZHIMING PAN (Presenter), RYUICHI SHINDOU, Peking University — Motivated by a recent graphite experiment under high magnetic field, we introduce an interacting electron model with a pair of electron pocket and hole pocket under magnetic field. We use a fermionic renormalization group (RG) method and study a parquet RG equation of the model for various types of effective electron-electron interactions. We found that, for a screened Coulomb interaction, the one-loop level RG equation exhibit an instability of the excitonic pairing, while, for a short-ranged repulsive interaction case, the excitonic instability and a charge-density wave instability appear simultaneously. We further argue that, depending on the sign of the interaction, the excitonic insulator phase can be either a symmetry-protected topological excitonic insulator or topologically trivial excitonic insulator. In the former case, an odd-parity excitonic pairing in the bulk reconstruct a chiral Fermi arc state of electron type and that of hole type into a helical surface state with gapless Dirac cone. The reconstructed surface state may provide a simple explanation for a mysterious in-plane transport behaviour observed in the graphite experiment under high magnetic field.

*The Flatiron Institute is a division of the Simons Foundation
Coexistence of metallic edge states and antiferromagnetic ordering in correlated topological insulators

GIORGIO SANGIOVANNI (Presenter), University of Wurzburg, ADRIANO AMARICCI, ANGELO VALLI, MASSIMO CAPONE, SISSA - Trieste, JAN CARL BUDICICH, TU Dresden, BJÖRN TRAUZETTEL, University of Wurzburg — We investigate the emergence of antiferromagnetic ordering and its effect on the helical edge states in a quantum spin Hall insulator, in the presence of strong Coulomb interaction [1-5]. Using dynamical mean-field theory, we show that the breakdown of lattice translational symmetry favors the formation of magnetic ordering with nontrivial spatial modulation. The onset of a nonuniform magnetization enables the coexistence of spin-ordered and topologically nontrivial states. An unambiguous signature of the persistence of the topological bulk property is the survival of bona fide edge states. We show that the penetration of the magnetic order is accompanied by the progressive reconstruction of gapless states in subperipheral layers, redefining the actual topological boundary within the system.

Kondo Hole Scattering in the Strongly Correlated Topological Insulator SmB6

HARRIS PIRIE (Presenter), YU LIU, Harvard University, SAGEN C COCKLIN, ERIC MASCOT, University of Illinois at Chicago, PENGCHENG CHEN, Harvard University, SHANTA SAHA, XIAOFENG WANG, JOHNPIERRE PAGLIONE, University of Maryland, MOHAMMAD H HAMIDIAN, Harvard University, DIRK MRR, University of Illinois at Chicago, JENNIFER HOFFMAN, Harvard University — Quantum materials combining strong correlations and spin-orbit coupling are predicted to generate multiple exotic ground states. For example, in topological Kondo insulators, interactions within a lattice of local moments open a hybridization gap in the conduction band, within which topologically protected heavy Dirac surface states emerge. When a lattice moment is removed, the resulting Kondo hole is predicted to create oscillations in the electron screening cloud, with accompanying magnetic fluctuations. Here we use scanning tunneling microscopy and spectroscopy to image the interaction between a Kondo hole and the topological surface state in SmB6. We show that Sm vacancies induce oscillations in the hybridization gap and electrochemical potential, matching predictions for Kondo holes [1], while B-site defects do not. Furthermore, we find that only Sm-site defects cause significant scattering of the topological surface state. Our results demonstrate how intrinsic, nominally nonmagnetic defects can generate magnetic fluctuations that provide a new mechanism for scattering topological surface states.

Pulsed field studies of Kondo insulator YbB12

ZIJI XIANG (Presenter), University of Michigan, YUICHI KASAHARA, Department of Physics, Kyoto University, TOMOYA ASABA, BENJAMIN LAWSON, COLIN TINSMAN, LU CHEN, University of Michigan, YUKI SATO, Department of Physics, Kyoto University, FUMITOSHI IGA, College of Science, Ibaraki University, JOHN SINGLETON, Los Alamos National Laboratory, YUJI MATSUDA, Department of Physics, Kyoto University, LU LI, University of Michigan — The Shubnikov-de Haas (SdH) effect, quantum oscillations in the electrical conductivity, have been detected in Kondo insulator YbB12 [1]. Such an observation suggests a highly exotic ground state in this material. Here we show the results of magnetoresistance and proximity detector oscillator (PDO) measurements in YbB12 in pulsed magnetic fields up to 65 T. SdH oscillations are observed both above and below the field-induced insulator-metal (I-M) transition. An abrupt increase in the oscillation frequency takes place at the transition. A unique angular dependence of the SdH frequencies is also revealed, which is related to the angle-dependent I-M transition field. The origin of the SdH effect in the insulating phase of YbB12 is discussed based on the pulsed field studies.

1:39PM F01.00013: Coupled-wire models of non-Abelian topological orders in 3D  
SYED RAZA (Presenter), JEFFREY C.Y. TEO, University of Virginia — Topological order corresponds to patterns of long-range entanglement in ground-states. The point-like and line-like excitations in 3D topologically ordered states can have fractional charge and spin degrees of freedom giving rise to fractional quantum statistics. In this work, we study 3D non-Abelian topological order via coupled-wire construction. By putting the wire configuration on a closed manifold, we study the properties of ground states and the Wilson algebra of various excitations. We study the topological order of previously proposed coupled-wire models of symmetry-preserving gapped Dirac (semi)metal and Dirac superconductor. We also study new non-Abelian topologically ordered states that inherit their topological properties from conformal field theories like SO(3)$_3$.

1:51PM F01.00014: Study of hysteretic magnetotransport of SmB$_6$ using local and non-local Corbino disk techniques.*  
YUN SUK EO (Presenter), TRISTIN E METZ, HYUNSOO KIM, Department of Physics, University of Maryland, College Park, WESLEY T. FUHRMAN, Schmidt Science Fellows, in partnership with the Rhodes Trust, SHANTA SAHA, Xiangfeng Wang, Department of Physics, University of Maryland, College Park, JUAN CHAMORRO, Department of Chemistry, Johns Hopkins University, SEYED KOOHPAEH, TYREL MCQUEEN, Henry A. Rowland Department of Physics and Astronomy, Johns Hopkins University, MICHAEL FUHRER, School of Physics & Astronomy, Monash University, JOHNPIERRE PAGLIONE, Department of Physics, University of Maryland, College Park — Recent experiments that have been reported during the past several years suggest that samarium hexaboride (SmB$_6$) is a true topological Kondo insulator (TKI). Particularly, the hysteretic magnetotransport at low temperatures is a remarkable feature that seems to be consistent with the TKI picture, but distinct from other topological insulators. Motivated by the growing interest in the role of disorder and impurities in bulk SmB$_6$, we revisit the surface transport, including the hysteresis features, using Corbino disk structures on flux- and floating zone-grown samples with small impurity concentrations (e.g., Gd, Ni, and Fe). Also, using bulk probing techniques such as non-local (inverted) Corbino transport and heat capacity, we investigate if the bulk channel has an influence on the hysteresis signals we observe in standard transport configurations.

*The work at IQM supported as part of the Institute for Quantum Matter, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0019331.

2:03PM F01.00015: Correlation Driven Topological Insulator to Weyl Semimetal Transition in Actinide System UNiSn  
VSEVOLOD IVANOV, SERGEY SAVRASOV (Presenter), Physics, UC Davis — We use a modern electronic structure method combining density functional theory of band electrons with dynamical self-energies of strongly correlated states to predict that two well known phases of actinide compound UNiSn, a paramagnetic semiconducting and antiferromagnetic metallic, correspond to Topological Insulator (TI) and Weyl semimetal (WSM) phases of topological quantum matter. Thus, the famous unconventional insulator-metal transition observed in UNiSn is also a TI to WSM transition. Driven by a strong hybridization between U f-electron multiplet transitions and band electrons, multiple energy gaps open up in the single-particle spectrum whose topological physics is revealed using the calculation of Z2 invariants in the strongly correlated regime. A simplified physical picture of these phenomena is provided based on a periodic Anderson model of strong correlations and multiple band inversions that occur in this fascinating compound. Studying the topology of interacting electrons reveals interesting opportunities for finding new exotic phase transitions in strongly correlated systems.

Tuesday, March 5, 2019 11:15 AM - 2:15 PM

Session F02 DMP DCOMP: Dielectric & Ferroic Oxides -- Structure, Phase Stability, and Competition I  
BCEC 107A - Jason Hoffman - Tag(s): Focus
11:15AM F02.00001: Diffuse scattering and the local structure of relaxors* [Invited] MATTHEW KROGSTAD, Argonne National Laboratory, PETER M GEHRING, National Institute of Standards and Technology, STEPHAN ROSENKRANZ, RAYMOND OSBORN, Argonne National Laboratory, FENG YE, YAOHUA LIU, Oak Ridge National Laboratory, JACOB RUFF, CHESS, Cornell University, WENZHI CHEN, Simon Fraser University, JUSTIN WOZNIAK, Argonne National Laboratory, YE ZUO-GUANG, Simon Fraser University, DANIEL PHELAN (Presenter), Argonne National Laboratory — Anomalous dielectric and electromechanical properties make relaxor ferroelectrics fundamentally and technologically appealing. We have used three dimensional diffuse scattering measurements (x-ray and neutron) to investigating several classes of relaxor ferroelectrics, including pseudo-cubic Pb-based perovskites and uniaxial tungsten bronze systems. We discuss the different components that are observed in these measurements and how they relate to the physics and material properties of these systems.

*Work at the Materials Science Division at Argonne National Laboratory was supported by the US Department of Energy, Office of Science, Materials Sciences and Engineering Division.

11:51AM F02.00002: Effects of Substrate Orientations on Phase Stability of Epitaxial HfO2 Thin Films* SHI LIU (Presenter), BRENDAN HANRAHAN, US Army Rsch Lab - Adelphi — The discovery of ferroelectricity in both pure and doped HfO2 thin films have revitalized the interest in using ferroelectrics for nanoscale device applications. Previous studies on epitaxial strain engineering of ferroelectricity have mostly focused on thin films grown on (001)-oriented substrates. There is increasing interest in applying biaxial strain along other crystallographic planes such as (101) and (111) by growing thin films on substrates of different cuts. In this work, we focus on the effects of film orientations on the phase stability of HfO2 thin films. We start by examining the ideal transition barriers between different phases of HfO2 with first-principles methods. We find that the three phases, P21/c, Pca21 , and Pbc are separated by relatively large barriers. We calculate the energetics of different polymorphs of hafnia with epitaxial constraints imposed on the {100}, {110}, and {111} planes. Our calculations suggest that the two orthorhombic phases can become the ground state in (111)-oriented thin films. This work suggests the possibility to better stabilize the ferroelectric phase in HfO2 thin films through substrate orientation engineering.

*Shi Liu is supported by SEDD Distinguished Postdoc Fellowship at US Army Research Laboratory

12:03PM F02.00003: Competing phases of HfO2 in applied electric field: A first principles insight* YUBO QI (Presenter), KARIN RABE, Rutgers University, New Brunswick — The recent discovery of ferroelectricity in doped HfO2 thin films has generated intense experimental and theoretical interest, with a particular focus on the precise nature of the HfO2 ferroelectric phase and the factors promoting the observation of ferroelectric switching. In this talk, I present first principles results and analysis to demonstrate how phases of HfO2 evolve under applied electric field as a function of field magnitude and direction. In particularly, the symmetry breaking of yttrium dopants is shown to open new reaction pathways for structural transformation, leading to an electric-field-driven transition from a metastable nonpolar tetragonal phase to the polar ferroelectric orthorhombic phase. The implications of the results for interpreting recent experimental observations will be discussed.

12:15PM F02.00004: Unconventional Stability of Subloop Behavior for Neuromorphic Computing in a Ferroelectric HfO2 KYOUNGJUN LEE (Presenter), SEUNG CHUL CHAE, Physics Education, Seoul National University — Recent discovery of ferroelectricity in HfO2 film has attracted not only as a conventional non-volatile memory application but as a neuromorphic analogue device. Multiple intermediate state in ferroelectric switching is one of good candidate for neuromorphic application. Though ferroelectric HfO2 have CMOS compatibility and ferroelectricity in thin film thickness, due to its large coercive field which can induce uncertainty in multi-level switching process, multilevel switching process research is needed. In this study, we present the stability of multi-level polarization states in terms of large activation energy and small critical domain volume. We measured switching dynamics and temperature dependence hysteresis of HfO2 thin films. The characteristic switching time and temperature dependence of hysteresis showed that ferroelectric HfO2 has large activation energy while the critical ferroelectric domain volume is small compared to the conventional perovskite materials. PFM results showed large domain wall activation energy due to stable small critical volume. Due to small critical size of ferroelectric domain in HfO2, the enhanced accuracy for the access of multiple states can be used for the analogue ferroelectric HfO2 memory for the neuromorphic memory application.
The need for efficient energy utilization is driving research into ways to harvest ubiquitous waste heat. Here, we explore pyroelectric energy conversion (PEC) from low-grade thermal sources that exploits strong field- and temperature-induced polarization susceptibilities in the relaxor ferroelectric 0.68Pb(Mg1/3Nb2/3)O3–0.32PbTiO3 (PMN-PT). Relaxors have attracted considerable attention due to their intriguing dielectric and piezoelectric properties including high reversible strains and high-temperature operation, but there has been only minimal study of their electrothermal effects. Here, we develop a comprehensive picture of the relationship between epitaxial strain, structure, properties, and local polar order in relaxor thin films. We will discuss how high-quality, coherently-strained films of PMN-PT provide new understanding of structure and properties which opens doors for new applications. In particular, we explore how the electric-field-driven enhancement of the pyroelectric response (−550 μC m−2 K−1) and suppression of the dielectric response (by 72%) yield substantial figures of merit for PEC. Field- and temperature-dependent pyroelectric measurements highlight the role of polarization rotation and field-induced polarization in mediating these effects. Solid-state, thin-film devices that convert low-grade heat into electrical energy are demonstrated using pyroelectric Ericsson cycles, and optimized to yield maximum energy density, power density, and efficiency of 1.06 J cm−3, 526 W cm−3 and 19% of Carnot, respectively; the highest values reported to date and equivalent to a thermoelectric with an effective ZT = 1.16 for a temperature change of 10 K. We will also explore the potential for electrocaloric effects and routes to enhance the energy conversion potential of materials.

Electrode material effect on the switching behavior of ferroelectric HfO2-based thin films

Application of HfO2-based films to ferroelectric memory and logic devices has generated considerable interest as they allow overcoming significant problems associated with poor compatibility of perovskite ferroelectrics with CMOS processing. However, detailed studies of such application-relevant properties as imprint and polarization switching dynamics with respect to the electrode material and processing condition are still sparse in literature. Here, we use a combination of Piezoresponse Force Microscopy (PFM) and pulse switching techniques to analyze the time- and field-dependent evolution of the domain structure in Hf0.5Zr0.5O2 thin film capacitors with oxygen rich/deficient electrodes. Switching spectroscopy-PFM (SS-PFM) maps revealed the electrode-dependent spatial variations in the local potential landscape, which strongly affect the domain switching kinetics. It is shown that stronger oxidation reduces the internal imprint bias while also leading to an increase in the remanent polarization.

Probing short-range polar order in PZN-xPT and PMN-xPT relaxor ferroelectrics with neutron scattering

We have performed neutron scattering measurements on single crystal PZN-xPT and PMN-xPT samples. One of the key issues in these materials is the role of polar nano-regions (PNR), how the short-range orders coexist with long-range polar order and influence the bulk property. With diffuse scattering measurements carried out under external field along different directions, we were able to monitor how the dominant part of the diffuse scattering of “butterfly diffuse” that extends along <110> directions change with field. We observe an anormal suppression of diffuse scattering in Tetragonal phase near 400K and recover in Rhombohedral phase. We also investigate acoustic phonon, which are also affected in the same narrow temperature range. Our results suggest that the polar nano-regions are robust local orders that are locked in within the surrounding polar environment below Tc, and also strongly interact with acoustic phonon modes that induces instability in these systems.
1:39PM F02.00009: New approaches to understanding the ferroic properties of perovskite oxide solid solutions*  
[invited]  ANDREW RAPPE (Presenter), University of Pennsylvania — The dielectric properties of ferroelectric materials are a key driver of smart materials applications. In this talk, two key aspects of anomalous dielectric enhancement will be analyzed: domain walls and relaxor ferroelectrics. A comprehensive theoretical viewpoint will be sketched that unifies these aspects, based on multi-scale materials modeling.

Incorporating quenched Coulombic disorder in ferroelectrics disrupts and changes the character of this transition; instead of a sharp transition in a small temperature range, these oxide alloys exhibit "relaxed" transitions over 100-200 K and are called "relaxor ferroelectrics." I will describe how a first-principles based multi-scale model can reveal the dynamic and statically correlated motions of ions that lead to relaxor behavior, and I will discuss their promise for next-generation piezoelectric and dielectric material systems, with emphasis on the emergent stabilization of a high density of low-angle domain walls.

I will also present molecular dynamics simulations of 90° domain walls (separating domains with orthogonal polarization directions) in the ferroelectric material PbTiO3 to provide microscopic insights that enable the construction of a simple, universal, nucleation-and-growth-based analytical model that quantifies the dynamics of many types of domain walls in various ferroelectrics. This new model illuminates domain wall influence on the dielectric responses of conventional and relaxor ferroelectrics.

Session F03 DCMP: Novel Transport Properties of Weyl and Dirac Semimetals BCEC 107B -
Dmytro Pesin, University of Virginia

11:15AM F03.00001: Fermi arc induced vortex structure in Weyl beam shifts  UDVAS CHATTOPADHYAY (Presenter), Nanyang Technological University, Singapore, LI-KUN SHI, Institute of High Performance Computing, A *STAR, Singapore, BAILE ZHANG, JUSTIN SONG, YIDONG CHONG, Nanyang Technological University, Singapore — In periodic media, despite the close relationship between geometrical effects in the bulk and topological surface states, the two are typically probed separately. We have recently found that when beams in a Weyl medium reflect off an interface with a gapped medium, the trajectory is influenced by both bulk geometrical effects and the presence of Fermi arc surface states. The reflected beam experiences a displacement, analogous to the Goos-Hänchen or Imbert-Fedorov shifts, that forms a half-vortex in the two-dimensional surface momentum space. The half-vortex structure is centered at the point where the Fermi arc of the reflecting surface touches the Weyl cone, and the magnitude of the shift scales as the inverse square root of distance from the touching-point. This striking feature provides a way to use bulk transport to probe the topological characteristics of a Weyl medium.

11:27AM F03.00002: Magnetotransport in Weyl nanowires*  VARDAN KALADZHYAN (Presenter), JENS BARDARSON, Department of Physics, KTH Royal Institute of Technology — We study longitudinal magnetotransport in Weyl semimetal nanowires. We show that depending on radii of nanowires and magnetic field amplitudes there exist two qualitatively and quantitatively different regimes of transport. It is demonstrated that in the strong magnetic field regime (magnetic length much smaller than the radius of the nanowire), Landau level spectrum contains the chiral 0-th Landau level, and thus the transport properties resemble that of a bulk Weyl semimetal. On the contrary, in the weak magnetic field regime (magnetic length much larger than the radius of the nanowire), the lowest-energy band is a Fermi arc surface-bulk state with a non-chiral dispersion, hence there appear transport features distinct from those attained at larger radii or larger magnetic fields. We argue that both regimes are relevant for the ongoing experiments. We also demonstrate that the contribution of Fermi arc surface states is salient and, therefore, crucial for understanding transport properties of finite-size Weyl semimetal systems.

*This work was funded by ERC Starting Grant No. 679722.
11:39AM F03.00003: Chirality in Weyl semimetals in strong circularly-polarized electric field FATEMEH NEMATOLLAHI (Presenter), VADYM APALKOV, JHIH-SHENG WU, MARK I STOCKMAN, Georgia State University — We theoretically study the interaction of three-dimensional topological Weyl semimetals with a single oscillation femtosecond long circularly-polarized pulse. The chiral pulse causes a finite electron population of the conduction band which is highly structured and is determined by the topological resonance. These textures can be probed by a linear pulse applied after the circularly-polarized pulse. The response of the system to the linear probe pulse is highly sensitive to the chirality of the circular pulse. Also, the pulse which consists of two oscillations of different chiralities causes conduction band population distribution in the reciprocal space which is highly chiral and is related to the intrinsic chirality of Weyl semimetals.

11:51AM F03.00004: Topological Nodal Lines from Crystalline Symmetry HEQUIU LI (Presenter), Physics, University of Michigan, CHEN FANG, Institute of Physics, Chinese Academy of Sciences, KAI SUN, Physics, University of Michigan — Topological nodal lines protected by the time-reversal symmetry and space-inversion symmetry $T$ and space-inversion symmetry $P$ can be classified into two categories, depending on the value of the $Z_2$ monopole topological index. Nodal lines with trivial (non-trivial) monopole charge can (cannot) be gapped out via shrinking the nodal line into a point. In this study, we show that for four-band models with $T^2=+1$, there are two special points in phase space where the system has a $Z_2$ symmetry, and any Hamiltonian can be adiabatically connected to one of these points. Utilizing this result, we provide a general principle for finding topological nodal lines with nontrivial monopole charge based on the interplay between lattice crystalline symmetries and the time-reversal symmetry. In addition, this study also reveals a new family of topological nodal lines, protected by the time-reversal symmetry and point group symmetries.

12:03PM F03.00005: Strong disorder in nodal semimetals: Schwinger-Dyson–Ward approach* BJOERN SBIERSKI (Presenter), FU Berlin — The self-consistent Born approximation quantitatively fails to capture disorder effects in semimetals. We present an alternative, simple-to-use non-perturbative approach to calculate the disorder induced self-energy. It requires a sufficient broadening of the quasiparticle pole and the solution of a differential equation on the imaginary frequency axis. We demonstrate the performance of our method for various paradigmatic semimetal Hamiltonians and compare our results to exact numerical reference data. For intermediate and strong disorder, our approach yields quantitatively correct momentum resolved results. It is thus complementary to existing RG treatments of weak disorder in semimetals.

12:15PM F03.00006: Parity anomaly in the nonlinear response of nodal-line semimetals* ALBERTO MARTIN-RUIZ, Centro de Ciencias de la Complejidad, Universidad Nacional Autonoma de Mexico, ALBERTO CORTIJO (Presenter), Theory and simulation department, Instituto de Ciencia de Materiales de Madrid — Nodal-line semimetals (NLSM) are topological semimetals where conduction and valence bands touch each other at one dimensional lines in the Brillouin zone. We will focus on the the PT-symmetric version of NLSM and see how adding and removing a PT symmetry-breaking parameter leaves scars in the electromagnetic response of these systems. Tilting breaks $P$ and $T$ but leaves their product invariant, not modifying the symmetry breaking procedure, but allows the parity anomaly to appear both in the linear and non-linear response. In the case of the linear response, we will show that the tilted NLSM display an axionic electromagnetic response, but with a different origin of the one appearing in Weyl semimetals.

*The authors acknowledge CONACyT postdoctoral Grant No. 234774, MINECO/AEI/FEDER, UE Grant No. FIS2015-73454-JIN, and Comunidad de Madrid MAD2D-CM Program (S2013/MIT-3007) for funding.

12:27PM F03.00007: Topological Amorphous Metals* YANBIN YANG (Presenter), TAO QIN, DONG-LING DENG, LUMING DUAN, YONG XU, Tsinghua University — A Weyl semimetal, a crystalline material with translational symmetry, possesses pairs of Weyl points in momentum space band structures and its topology is characterized by the first Chern number defined over a closed surface in momentum space. Here, we study amorphous systems with completely random sites and find that, through constructing and exploring a concrete model Hamiltonian, such a system can host an exotic phase of topological amorphous metal in three dimensions. In contrast to the traditional Weyl semimetals, topological amorphous metals break translational symmetry, and thus cannot be characterized by the first Chern number defined based on the momentum space band structures. Instead, their topological properties will manifest in the Bott index and the Hall conductivity as well as the surface states. Moreover, by studying the energy band and quantum transport properties, we find that topological amorphous metals exhibit a diffusive metal behavior. Our results open a door for exploring topological gapless phenomena in amorphous systems.

12:39PM F03.00008: Adiabatic dechiralisation and thermodynamics of Weyl semimetals  SERGEY SYZRANOV  
(Presenter), Physics Department, University of California, Santa Cruz, USA, YAROSLAV I RODIONOV, Institute for Theoretical and 
Applied Electrodynamics RAS and National Institute for Science and Technology MISIS, Moscow, Russia, BRIAN SKINNER, Department 
of Physics, Massachusetts Institute of Technology, Cambridge, USA — We study thermodynamic manifestations of the chiral 
anomaly in disordered Weyl semimetals. We focus, in particular, on the effect which we call "adiabatic dechiralisation", the 
phenomenon in which a change in temperature and/or an absorption or release of heat results from changing external 
electric and magnetic fields that change the imbalance of quasiparticles with different chiralities (at different Weyl nodes). 
This effect is similar to that of adiabatic demagnetisation, which is commonly used as a method of low-temperature 
refrigeration. We describe this phenomenon quantitatively and discuss experimental conditions favourable for its 
obervation. A related phenomenon, which we analyse and which is readily observable in experiment, is the dependency 
of the heat capacity of a Weyl semimetal on parallel electric and magnetic fields.

12:51PM F03.00009: Dynamical density response and optical conductivity in topological metals*  ANTON BURKOV  
(Presenter), University of Waterloo — Topological metals continue to attract attention as novel gapless states of matter. While 
there by now exists an exhaustive classification of possible topologically nontrivial metallic states, their observable 
properties, that follow from the electronic structure topology, are less well understood. Here we present a study of the 
electromagnetic response of three-dimensional topological metals with Weyl or Dirac nodes in the spectrum, which 
systematizes and extends earlier pioneering studies. In particular, we argue that a smoking-gun feature of the chiral 
anomaly in topological metals is the existence of propagating chiral density modes even in the regime of weak magnetic 
fields. We also demonstrate that the optical conductivity of such metals exhibits an extra peak, which exists on top of the 
standard metallic Drude peak. The spectral weight of this peak is transferred from high frequencies and its width is 
proportional to the chiral charge relaxation rate.

1:03PM F03.00010: Two-particle collisional coordinate shifts and hydrodynamic anomalous Hall effect in systems 
without Lorentz invariance*  DMYTRO PESIN (Presenter), University of Virginia — We show that electrons undergoing a 
two-particle collision in a crystal experience a coordinate shift that depends on their single-particle Bloch wave functions, 
and derive a gauge-invariant expression for such shift, valid for arbitrary band structures, and arbitrary two-particle 
interaction potentials. As an application of the theory, we consider two-particle coordinate shifts for Weyl fermions in 
space of three spatial dimensions. We also demonstrate that such shifts in general contribute to the anomalous Hall 
conductivity of a clean electron liquid.

*National Science Foundation Grant No. DMR-1738384.

1:15PM F03.00011: Optical responses of chiral multifold fermions*  MIGUEL ANGEL SANCHEZ-MARTINEZ, Neel Institute 
(CNRS), FERNANDO DE JUAN, DIPC, San Sebastian, ADOLFO GRUSHIN (Presenter), Neel Institute (CNRS) — Multifold fermions are 
generalizations of two-fold degenerate Weyl fermions with three-, four-, six- or eight-fold degeneracies protected by crystal 
symmetries, of which only the last type is necessarily non-chiral. Their low energy degrees of freedom can be described as 
higher spin generalizations of Weyl semimetals. In this talk I will discuss their linear and non linear optical responses 
including optical activity, linear optical conductivity and photogalvanic effects. These are typically enhanced compared to 
Weyl fermions of the same Fermi velocity and can be quantized in the case of the circular photogalvanic effect. We use 
these results to qualitatively predict optical responses in multifold materials such as RhSi or CoSi.

754303 (MASM).
1:27PM F03.00012: Intrinsic magnetoresistance in three-dimensional Dirac materials with low carrier density*
HUANWEN WANG (Presenter), BO FU, SHUNQING SHEN, The University of Hong Kong — Negative longitudinal and positive in-plane transverse magnetoresistance have been observed in most topological Dirac/Weyl semimetals and some other topological materials. Here we present a quantum theory of intrinsic magnetoresistance for three-dimensional Dirac fermions at a finite and uniform magnetic field B. In the semiclassical regime, it is shown that the longitudinal magnetoresistance is negative and quadratic of a weak field B while the in-plane transverse magnetoresistance is positive and quadratic of B. The relative magnetoresistance is inversely quartic of the Fermi wave vector and only determined by carrier density, irrelevant to the external scatterings in the weak scattering limit. This intrinsic anisotropic magnetoresistance is measurable in systems with low carrier density and high mobility. In the quantum oscillation regime, a formula for the phase shift in Shubnikov-de Haas oscillation is present as a function of the mobility and the magnetic field, which is helpful for experimental data analysis

1:39PM F03.00013: Novel Planar Hall Effect in Tilted Weyl Semimetals*
DA MA (Presenter), International Center for Quantum Materials, Peking University, HUA JIANG, School of Physical Science and Technology, Soochow University, HAIWEN LIU, Department of Physics, Beijing Normal University, XINCHENG XIE, International Center for Quantum Materials, Peking University — In addition to the chiral anomaly, the planar Hall effect has been proposed in the magnetotransport of the Weyl semimetals. We investigate the transport of the tilted Weyl semimetals semiclassically in an in-plane magnetic field. The results show that the longitudinal and the Hall conductivities in this system each has a linear term in magnetic field besides the quadratic terms and the angular dependence of them are different from the case without the tilt. The unusual magnetotransport is induced by the Berry curvature, either through the axial chemical potential or the anomalous velocity. The correction of the phase space volume factor is also presented, which has effects on both the angular and the magnetic field dependence of the conductivities.

*This work is financially supported by NBRPC and NSFC.

1:51PM F03.00014: WITHDRAWN ABSTRACT —

2:03PM F03.00015: Spin-to-charge conversion in magnetic Weyl semimetals.* SHULEI ZHANG (Presenter), Materials Science Division, Argonne National Laboratory, Lemont, Illinois, USA, ANTON BURKOV, Dept. of Physics and Astronomy, University of Waterloo, Waterloo, Ontario, Canada, IVAR MARTIN, OLLE HEINONEN, Materials Science Division, Argonne National Laboratory, Lemont, Illinois, USA — Weyl semimetals (WSM) are a newly discovered class of quantum materials which can host a number of exotic transport properties in bulk, such as the chiral magnetic effect, negative magnetoresistance, and the anomalous Hall effect. In this work, we investigate theoretically the inverse Edelstein effect (IEE) in a magnetic WSM, i.e., a charge current induced by spin accumulation at the interface between a magnetic WSM and a normal metal. Formally, the induced current is obtained by solving for the scattering wave functions and the nonequilibrium distribution functions in each layer. We find that both surface and bulk states contribute to the IEE, and that the induced current exhibits strong anisotropy: It vanishes along the direction parallel to the line connecting the two Weyl nodes, regardless of the direction of the injected spin. We also determined the dependence of the current on the position of the Fermi level as well as the separation between the two Weyl nodes, which provide extra knobs for controlling the spin-charge conversion in these topological materials.

11:15AM F04.00001: Shubnikov-de Haas oscillations of topological metal Pd$_3$Pb  
NIRMAL GHIMIRE (Presenter), Department of Physics and Astronomy, George Mason University, MOHAMMED ALAM KHAN, Argonne National Laboratory, ANITA S. BOTANA, Arizona State University, J. SAMUEL JIANG, JOHN MITCHELL, Argonne National Laboratory — The recent realization of topological electronic states such as Dirac and Weyl fermions in real materials and their potential for future energy and electronics applications has motivated interest in the study of new forms of topological behavior embodied through new materials. Pd$_3$Pb is one such candidate predicted recently to host unique topological features, including a dispersionless band near the Fermi level and triple nodal points hosting Dirac fermions and open Fermi arcs. Here, we report the crystal growth and electric transport properties of Pd$_3$Pb. Our low field magnetoresistance measurements indicate an anisotropic Fermi surface. We found that Pd$_3$Pb manifests a large transverse magnetoresistance, which reaches 650% at 1.8 K and 14 T, and pronounced Shubnikov-de Haas (SdH) oscillations. Preliminary analysis of the field dependence of the SdH oscillations points to the likelihood of nontrivial Berry phase in Pd$_3$Pb. Further studies in high field limit are desirable to extend the realization of the topological properties of the predicted novel fermions in this material.

11:27AM F04.00002: Quantum oscillations in topological semimetal candidate CaSn$_3$  
K A M HASAN SIDDIQUEE (Presenter), RIFFAT MUNIR, CHARUNI DISSANAYAKE, University of Central Florida, XINZHE HU, SWAPNIL YADAV, YASUMASA TAKANO, University of Florida, EUN SANG CHOI, Florida State University, YASUYUKI NAKAJIMA, University of Central Florida — Binary stannide CaSn$_3$ with a centrosymmetric cubic structure is theoretically predicted to be a topologically non-trivial semimetal, and undergoes superconductivity at $T_c \approx 4.2$K, providing an excellent platform for the understanding of interplay between topology and superconductivity. Here, we report a detailed study of de Haas–van Alphen (dHvA) quantum oscillations for CaSn$_3$ single crystals via torque magnetometry in high magnetic fields up to 35T. Analyzing the dependence of dHvA oscillation frequency and amplitude on temperatures and field angles, we will review the effective carrier masses and the normal state fermiology, and also discuss the non-trivial Berry phase in CaSn$_3$.

11:39AM F04.00003: Vector field STM study on transition metal based kagome magnet*  
JIAXIN YIN (Presenter), SONGTIAN SONIA ZHANG, GUOQING CHANG, ZURAB GUGUCHIA, Princeton University, SHUANG JIA, Peking University, HECHANG LEI, Renmin University of China, TITUS NEUPERT, University of Zurich, ZIQIANG WANG, Boston College, HSIN LIN, Academia Sinica, ZAHID HASAN, Princeton University — We recently found that the kagome magnet can have giant spin-orbit tunability (Nature 562, 91–95 (2018)). We use STM/S to elucidate the atomically resolved electronic states and their magnetic response in another transition metal based kagome magnet. We determine the chemical nature of the surface by atomic imaging of the native defects and surface step edges. On different surface terminations, we have observed different types of tunneling spectra, which corresponds well with our first principle calculation. Surprisingly, we find the tunneling signal has systematic magnetic field response, demonstrating an intriguing coupling of electronic structure and magnetism in a frustrated setting. We further discuss the connection of these results with the topological fermions and Berry phase theory.

*Work at Princeton was supported by the US DOE under Basic Energy Sciences programme (grant number DOE/BES DE-FG-02-05ER46200) and the Gordon and Betty Moore Foundation (GBMF4547/ Hasan)

11:51AM F04.00004: Evidence for edge states in trigonal layered PtBi$_2$  
XIAOANG NIE (Presenter), Shanghai Jiao Tong University, YOUGUO SHI, Institute of Physics, Chinese Academy of Sciences, HAO ZHENG, JINFENG JIA, Shanghai Jiao Tong University — PtBi$_2$ is predicted to be a 3D topological semimetal which possesses triply degenerate point close to Fermi level. Here, we observe that unpredicted edge states exist at the edge of PtBi$_2$ using scanning tunneling microscopy at 4.2K. More importantly, due to the inversion symmetry breaking, PtBi$_2$ features two inequivalent top and bottom surfaces. We detect the edge states at the step edges on both surfaces. Our experiment results, together with calculations, reveal the interesting physics of monolayer PtBi$_2$. 

954 of 3305
12:03PM F04.00005: Evidence of Charge density wave in Re doped MoTe\textsubscript{2}  SUMAN KAMBOJ (Presenter), ANSHU SIROHI, AASTHA VASDEV, Indian Institute of Science Education and Research, Mohali, MANASI MANDAL, SOURAV MARIK, RAVI PRAKASH SINGH, Department of Physical Sciences, Indian Institute of Science Education and Research Bhopal, Bhopal, 462066, India, GOUTAM SHEET, Indian Institute of Science Education and Research, Mohali — Transition metal dichalcogenides exhibit interesting structural and intercalation chemistry and consequent exotic physical properties. Superconductivity with a very low transition temperature of 0.1 K was earlier discovered in the orthorhombic MoTe\textsubscript{2}. MoTe\textsubscript{2} also shows a charge density wave (CDW) phase when grown in thin film form, but a CDW phase in bulk MoTe\textsubscript{2} has not been reported. It is also known that Re substitution for Mo sites leads to an increase in superconducting transition temperature. Mo\textsubscript{0.8}Re\textsubscript{0.2}Te\textsubscript{2} shows a high critical temperature $T_c$ of 3.8 K. Based on our transport and scanning tunneling microscopy experiments we will discuss that the compound Mo\textsubscript{0.8}Re\textsubscript{0.2}Te\textsubscript{2} also supports a CDW phase with an onset temperature of 150 K. Our results suggest that CDW and superconductivity may compete with each other in Re doped MoTe\textsubscript{2}.

12:15PM F04.00006: Topological Appearances between Two Type-II Weyl Semimetals  CHUNLIANG LIN (Presenter), National Chiao Tung University — Topology in abstract mathematics has revolutionized our conventional understanding of condensed matter physics, resulting in the emergence of exotic quantum phases such as topological insulators (TIs). Current realizations of the Weyl semimetals (WSMs) leads us to further study the topological phases of matter beyond TIs. WSMs have gathered great attentions because the quasiparticles in WSMs behave as Weyl fermions, massless chiral fermions. WSMs are classified into Type I and II, according to the topology of the Weyl point, where the electron and hole pockets touch each other. Quasiparticle interference (QPI) study with STM has shown the evidence that a T\textsubscript{d} phase Tungsten Ditelluride (WTe\textsubscript{2}) is type-II WSM\textsuperscript{1}, agreeing with the prior theoretical predictions. A similar measurement has also been performed to a T\textsubscript{d} phase Molybdenum Ditelluride (MoTe\textsubscript{2})\textsuperscript{2}. The difference in the topological appearance (i.e. the positions of the Weyl points and the Fermi arc surface states) of MoTe\textsubscript{2} from that of WTe\textsubscript{2} is clearly revealed.

12:27PM F04.00007: Andreev reflection and Josephson currents on the surface of line Weyl semimetals*  XIANG HU (Presenter), Physics, William and Mary, DMITRY PIKULIN, Microsoft Quantum, Microsoft Station Q, University of California, Santa Barbara, ENRICO ROSSI, Physics, William and Mary — We study the Andreev reflection of line Weyl semimetals' surfaces drumhead states. Drumhead states are expected to have a very large effective mass. We show that the measurement of the Andreev reflection can be a very effective way to detect such mass experimentally. We then investigate Josephson junctions in which the surface of a line Weyl semimetal is placed between two superconducting regions. Using a transfer matrix method we obtain the dependence of the Josephson current on the phase difference between the superconducting leads for long and short junctions. We then study how the interplay of drumhead and bulk states affects the Josephson current-phase relation.

**Observation of the nonlinear Hall effect in bilayer WTe$_2$**

SU Yang Xu (Presenter), Qiong Ma, Shen Huitao, David MacNeill, Valla Fatemi, Massachusetts Institute of Technology, Tay-Rong Chang, Physics, National Cheng Kung University, Andres M. Mier Valdivia, Sanfeng Wu, Massachusetts Institute of Technology, Zongzheng Du, Department of Physics, Southern University of Science and Technology, Chuang-Han Hsu, Department of Physics, National University of Singapore, Shiang Fang, Department of Physics, Harvard University, Quinn Gibson, Department of Chemistry, Princeton University, Kenji Watanabe, Takashi Taniguchi, National Institute for Materials Science, Robert Cava, Department of Chemistry, Princeton University, Efthimios Kaxiras, Department of Physics, Harvard University, Haizhou Lu, Department of Physics, Southern University of Science and Technology, Hsin Lin, Department of Physics, National University of Singapore, Liang Fu, NuH GediK, Pablo Jarillo-Herrero, Massachusetts Institute of Technology — The electrical Hall effect is the production of a transverse voltage under an out-of-plane magnetic field. In nonmagnetic materials without external magnetic fields, the electrical Hall effect is rarely explored because of the constraint by time-reversal symmetry. However, only the Hall effect in the linear response regime identically vanishes due to time-reversal symmetry. The Hall effect in the non-linear response regime, on the other hand, may not be subject to such symmetry constraints. Here, we report the observation of the nonlinear Hall effect (NLHE) in the electrical transport of the nonmagnetic 2D quantum material, bilayer WTe$_2$. The NLHE exhibits unusual properties sharply distinct from the AHE in metals: The NLHE shows a quadratic I-V characteristic; it strongly dominates the nonlinear longitudinal response, leading to a Hall angle of about 90 deg. We further show that the NLHE directly measures the “dipole moment” of the Berry curvature, which arises from layer-polarized Dirac fermions in bilayer WTe$_2$. Our results demonstrate a new Hall effect and provide a powerful methodology to detect Berry curvature in a wide range of nonmagnetic quantum materials in an energy-resolved way.

NG and SYX acknowledge support from DOE, BES DMSE (data taking and analysis), the Gordon and Betty Moore Foundations EPiQS Initiative through Grant GBMF4540 (manuscript writing) and National Science Foundation under Grant No. DMR-1809815 (modeling). Work in the PJH group was partly supported by the Center for Excitonics, an Energy Frontier Research Center funded by the US DOE, Office of Science, BES under Award Number DESC0001088 (fabrication and measurement) and partly through AFOSR grant FA9550-16-1-0382 (data analysis), as well as the Gordon and Betty Moore Foundation's EPiQS Initiative through Grant GBMF4541 to PJH. **Giant anomalous Hall and planar Hall effect in magnetic Weyl semimetal Co$_3$Sn$_2$S$_2$ nanoflakes**

Shuo-Ying Yang (Presenter), Max Planck Institute of Microstructure Physics, Enke Liu, Institute of Physics, Chinese Academy of Science, Claudia Felser, Max Planck Institute for Chemical Physics of Solids, Stuart S Parkin, Max Planck Institute of Microstructure Physics — Weyl fermions are chiral massless fermions manifested in crystalline solids by spin split conduction and valence bands crossing at discrete points. Magnetic Weyl semimetals with spontaneous time-reversal-symmetry-breaking are predicted to host large Berry curvature and resulting in a large intrinsic anomalous Hall effect (AHE). In this work, we perform detailed transport studies on the nanoflake devices of magnetic Weyl semimetal, Co$_3$Sn$_2$S$_2$. The two-dimensional nature of its Kagome-lattice allows Co$_3$Sn$_2$S$_2$ to be grown into nanoflakes as thin as 180 nm via the chemical vapor transport method. Through magneto-transport measurements, we observe a large intrinsic anomalous Hall conductivity (AHC) and anomalous Hall angle (AHA) generated by the Weyl-related Berry curvature that is robust against both temperature and charge conductivity. The AHC and AHA simultaneously reach 1422 S/cm and 23%, even higher than recent reports in single crystals [1]. Furthermore, we discuss the observation of the planar Hall effect (PHE) in Co$_3$Sn$_2$S$_2$ which can be caused by the chiral anomaly. Other possible origins of the PHE, including contributions from orbital magnetoresistance and interaction of the electrons with the magnetic order will also be discussed.

1:27PM F04.00010: Origin of the finite-temperature violation of the Wiedemann-Franz law in semi-metals*
ALEXANDRE JAOUÍ (Presenter), BENOIT FAUQUE, KAMRAN BEHNIA, ESPCI ParisTech — We present a study of the electrical and thermal conductivities of the semimetals WP₂, WTe₂ and Sb in the 2K-40K temperature range. At low temperature, the Wiedemann-Franz law holds (κ/T = L₀/ρ with κ the thermal conductivity, ρ the electrical resistivity and L₀ the Lorenz number). However, upon warming, a downward deviation from the Wiedemann-Franz law is observed. In the case of the Weyl semimetal WP₂ [1], the difference reaches an exceptionally large value compared to what we determined in WTe₂ and Sb and what was previously reported in other metals [2]. We identify electron-electron scattering as the origin of this departure [3]. We were further able to quantify the mismatch in the frequency of inter-electronic collisions which conserve momentum (i.e. electric current) but degrade energy (as in the case of normal-state liquid ³He). This sets a narrow temperature window between the ballistic and diffusive regimes where the hierarchy of scattering times corresponds to the hydrodynamic requirements for charge carriers [4].

1:39PM F04.00011: Low-dissipation edge currents without edge states*
GIOVANNI VIGNALE (Presenter), Department of Physics and Astronomy, University of Missouri, JUSTIN C. W. SONG, Division of Physics and Applied Physics, Nanyang Technological University — We show that bulk free carriers in topologically trivial multi-valley insulators with non-vanishing Berry curvature give rise to low-dissipation edge currents, which are squeezed within a distance of the order of the valley diffusion length from the edge. This happens even in the absence of edge states [topological (gapless) or otherwise], and when the bulk equilibrium carrier concentration is thermally activated across the gap. Physically, the squeezed edge current arises from the spatially inhomogeneous orbital magnetization that develops from valley-density accumulation near the edge. While this current possesses neither topology nor symmetry protection and, as a result, is not immune to dissipation, in clean enough devices it can mimic low-loss ballistic transport.

1:51PM F04.00012: Microwave electrodynamics of WP₂
JAMES DAY (Presenter), GRAHAM BAKER, Stewart Blusson Quantum Matter Institute, VICKY SÜSS, CHANDRA SHEKHAR, CLAUDIA FELSER, Max Planck Institute, DOUGLAS BONN, Stewart Blusson Quantum Matter Institute — We report on measurements of the microwave conductivity of WP₂ from 0.5 to 20 GHz and at low temperatures by way of bolometric broadband microwave spectroscopy. WP₂ is a recently discovered type-II Weyl semimetal that has been reported to host several anomalous transport properties, including a record-high residual resistivity ratio and magnetoresistance. Recent studies of the temperature-dependent electrical and thermal conductivities of WP₂ show that, at certain temperatures, electronic transport is in the hydrodynamic regime – in stark contrast to the diffusive transport found in most metals. Identification of the various scattering rates has thus far relied on measurement of DC quantities, whereas key signatures of charge dynamics are also manifested in the frequency dependence of these quantities. We will discuss our measurements of the microwave-frequency electrical conductivity in the context of hydrodynamic electronic transport in WP₂.
2:03PM F04.00013: NMR Investigation of the Weyl Semimetal TaAs* ARASH AKBARI-SHARBAF (Presenter), AIMÉ VERRIER, Department of Physics, Institut Quantique, Université de Sherbrooke, Sherbrooke, QC, NITAY NAIR, JAMES G. ANALYTIS, Department of Physics, University of California, Berkeley, California, JEFFREY QUILLIAM, Department of Physics, Institut Quantique, Université de Sherbrooke, Sherbrooke, QC — Weyl semimetals are expected to host topologically protected bulk states. Recently $^{181}$Ta nuclear quadrupolar resonance (NQR) was used as a bulk probe to investigate the band structure of the Weyl semimetal TaP near the Weyl nodes. [1] This is possible because nuclear spins couple to Weyl fermions via an anomalous hyperfine coupling influencing the temperature-dependent nuclear spin relaxation time $T_1$. [2] Depending on the position of the chemical potential with respect to the Weyl nodes, the temperature-dependent relaxation rate is expected to deviate from the Korringa relation, where $1/T_1 T = constant$. In this work we present $^{181}$Ta nuclear magnetic resonance (NMR) study of a single crystal TaAs Weyl semimetal, a material in which the chemical potential is typically closer to the Weyl nodes. The $1/T_1 T$ dependence of the $\pm 3/2 \leftrightarrow \pm 5/2$ transition is measured using progressive saturation, and results are compared to theoretical calculations [2] and results on TaP [1]. The $^{181}$Ta quadrupole parameters and Knight shift are also determined from the field and temperature dependence of the resonance frequency. [1] H. Yasuoka et al., Phys. Rev. Lett. 118, 236403 (2017). [2] Z. Okvátovity et al., Phys. Rev. B 94, 245141 (2016). *We acknowledge grants from the CFREF and FRQNT.

Session F05 DMP: Topological Superconductivity: 3D Materials 8CEC 108 - Tag(s): Focus

11:15AM F05.00001: Observation of Topological Surface State in High Temperature Superconductor MgB2* [Invited] XIAOQING ZHOU (Presenter), KYLE GORDON, University of Colorado, Boulder, KYUNG-HWAN JIN, Physics, University of Utah, HAOXIANG LI, DUSHYANT M NARAYAN, HENGDI ZHAO, HAO ZHENG, University of Colorado, Boulder, HUAQING HUANG, Physics, University of Utah, GANG CAO, University of Colorado, Boulder, NIKOLAI D ZHIGADLO, University of Bern, FENG LIU, Physics, University of Utah, DANIEL DESSAU, University of Colorado, Boulder — Most topological superconductors known-to-date suffer from low transition temperatures ($T_c$) and/or high fragility to disorder and dopant levels, which greatly hamper the progress in this promising field. In this work, we suggest BCS superconductor MgB2 as a superior candidate: not only is its superconducting $T_c=39K$ nearly triple the current record of all candidate topological superconductors, but it also has topological Dirac nodal line states which are highly tolerant against disorder and inadvertent doping variations. Our density functional theory (DFT) calculation and Angle-resolved Photoemission Spectroscopy (ARPES) measurements locate the topological Dirac Nodal Lines and their corresponding topological surface states on the [010] faces of MgB2, which could host topological superconductivity via the proximity effect to the bulk.

*This work was funded by DOE project DE-FG02-03ER46066 (Colorado) and by the DOE project DE-FG02-04ER46148 (Utah). Work in the Stanford Synchrotron Radiation Lightsource is supported by the Director, Office of Science, Office of Basic Energy Sciences, of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

11:51AM F05.00002: Termination-dependent Superconducting Topological Surface States in Non-centrosymmetric PbTaSe2 TIEN-MING CHUANG (Presenter), SYU-YOU GUAN, PENG-JEN CHEN, Institute of Physics, Academia Sinica, MING-WEN CHU, Center for Condensed Matter Sciences. National Taiwan University, RAMAN SANKAR, Institute of Physics, Academia Sinica, FANGCHENG CHOU, Center for Condensed Matter Sciences, National Taiwan University, HORNG-TAY JENG, Department of Physics, National Tsing Hua University, CHIA-SENG CHANG, Institute of Physics, Academia Sinica — TSCs are characterized by a full superconducting gap in the bulk and topologically protected gapless surface or edge states. Within each vortex core of TSCs, there exist the zero energy Majorana bound states, which are predicted to exhibit non-Abelian statistics and to form the basis of the fault-tolerant quantum computation. So far, PbTaSe2 is the only stoichiometric bulk material exhibits the required topological surface states at $E_F$ combined with fully gapped bulk superconductivity [1]. Interestingly, two distinct and stable cleaved surfaces have been identified to be Pb- and Se-termination by using spectroscopic imaging-scanning tunneling microscope. Two terminations exhibit striking difference in both atomic and electronic structures above $T_c$. In the superconducting state, both exhibit a full superconducting gap and zero energy bound state in the superconducting vortex cores. Our results show PbTaSe2 is a great platform for the study of 2D TSC.

12:03PM F05.00003: Topological superconductors in the Pb-Sn-In-Te system*  
GENDA GU (Presenter), RUIDAN ZHONG, JOHN A. SCHNEELOCH, YANGMU LI, QIANG LI, TONICA VALLA, JOHN TRANQUADA, Condensed Matter Physics & Materials Science, Brookhaven National Laboratory — The discovery of 3D topological insulator materials and topological superconductor open up a new research field in the condensed matter physics. In order to search for the new topological superconductor, we have grown a large number of the single crystals of Pb-system (Pb-Sn-In-Te) topological crystalline insulator and their topological superconductor. We have measured the physical properties on these single crystals by various techniques. We have studied the effect of crystal growth condition, impurity and composition on the bulk electrical conductivity of these single crystals. We try to find out which composition and crystal growth condition is the best for the best topological superconductor. We have got the bulk topological superconductor with Tc=4.8K.

*The work is supported by DOE.

12:15PM F05.00004: Approaching the type 2 Dirac point in Co-doped PdTe2*  
WENKAI ZHENG (Presenter), RICO SCHONEMANN, National High Magnetic Field Laboratory, GREGORY T. MCCANDLESS, Department of Chemistry and Biochemistry, The University of Texas at Dallas, GRETA CHAPPELL, SHIRIN MOZAFFARI, YU-CHE CHIU, National High Magnetic Field Laboratory, JULIA Y. CHAN, Department of Chemistry and Biochemistry, The University of Texas at Dallas, RYAN BAUMBACH, LUIS BALICAS, National High Magnetic Field Laboratory — Topological states of quantum matter have been investigated intensively in recent few years. A combination of superconductivity and topological order is considered to be a potential platform for realizing Majorana fermions. PdTe2 was classified as a type 2 Dirac semimetal where the Dirac points are located 0.5 eV below the Fermi level. Furthermore, PdTe2 is a superconductor with Tc below 2K. In order to preserve the Dirac points and lower the Fermi level we substituted up to 50% of Pd with Co. While the magnetoresistance is strongly reduced compared to the pure Pd compound, our Co doped samples still show superconductivity with a Tc of 0.22 K at a Co concentration of 50%. So far however, all evidences still point towards PdCoTe2 being a conventional superconductor.

*This work was supported by DOE-BES through Award No. DE-SC0002613. The National High Magnetic Field Laboratory is supported by the National Science Foundation through NSF/DMR-1644779 and the State of Florida.

12:27PM F05.00005: Effects of point-like disorder on electronic properties of PdTe2 superconductor*  
ERIK TIMMONS (Presenter), MAKARY TANATAR, KYUIL CHO, SERAFIM TEKNOWIJOYO, NA HYUN JO, SERGEY BUDKO, PAUL CANFIELD, RUSLAN PROZOROV, Ames Laboratory and Department of Physics & Astronomy, Iowa State University, Ames, IA 50010, USA, MARCIN KONCZYKOWSKI, Ecole Polytechnique, Palaiseau, France — Electric and thermal conductivities were measured before and after the introduction of a controlled point-like disorder in single crystals of PdTe2 by 2.5 MeV electron irradiation. Superconducting transition temperature is suppressed, but not strong enough that together with the exponential variation of the low-temperature London penetration depth indicates nodeless superconductivity. The normal state resistivity perfectly follows the Matthiessen’s rule as seen in a parallel upwards shift after irradiation. Its temperature variation can be fitted well by the Bloch-Grüneisen formula with Debye temperature determined from the specific heat. Thermal conductivity measurements show a good agreement with the Wiedemann-Franz law.

*This work was supported by the US DOE, Office of Science, BES Materials Science and Engineering Division under contract # DE-AC02-07CH11358. NHJ was funded by the Gordon and Betty Moore Foundation’s EPiQS Initiative through Grant GBMF4411.

12:39PM F05.00006: Enhanced Correlation Effects in Nodal-line Semimetal ZrSiSe  
YINMING SHAO (Presenter), Columbia University, ALEXANDER N. RUDENKO, Radboud University, JIN HU, University of Arkansas, YANGLIN ZHU, Tulane University, ALEXANDER I. LICHTENSTEIN, University of Hamburg, ZHIQIANG MAO, Pennsylvania State University, MIKHAIL KATSNELSON, Radboud University, DIMITRI BASOV, Columbia University — Three-dimensional (3D) Dirac fermions with highly-dispersive linear bands are usually considered weakly correlated, due to relatively large bandwidths (W) compared to Coulomb interactions (U). With the discovery of nodal-line semimetals, the Dirac dispersion has been extended to lines and loops, with reduced kinetic energy along the line [1]. However, experimental evidence for the predicted enhanced correlations in nodal-line semimetals has been rare. Here we show in ZrSiSe enhanced correlation effects through a combination of optical/magneto-optical spectroscopy and density-functional-theory (DFT) calculations. Near 40% kinetic energy reduction compared to DFT has been observed in ZrSiSe and the averaged Fermi velocity is also renormalized. ZrSiSe is therefore a novel candidate to study correlation-driven physics in Dirac systems as well as strong Berry curvature effects associated with spin-orbit-coupling.

12:51PM F05.00007: Possible valence skipping superconductivity in doped Dirac metal*  
TEPPEI UENO, Dept. of Physics, Okayama University, TAKANORI WAKITA, RII, Okayama University, TETSUYA FURUKAWA, TETSUAKI ITOU, Tokyo University of Science, TAKAYOSHI YOKOYA, JUN AKIMITSU, KAYA KOBAYASHI (Presenter), RII, Okayama University — We studied the superconductivity in NaCl-type structured AgSnSe2 (Tc~3-6 K). The material is perceived as Ag-doped to imaginary NaCl-type SnSe, a Dirac metal. By varying the ratio of Ag/Sn, i.e., changing the ratio of Sn valence states, 2+ and 4+, we found that the Sn 2+ state is crucial for the realization of superconductivity along with the lattice constant. This finding is supported by the XPS, showing the clear coexistence of Sn 2+ and Sn 4+ in the superconducting Ag-Sn-Se compounds, but not in non-superconducting Sn-Se. The NMR experiments on the same superconducting compounds, however, indicated the Sn state is almost 3+, as is expected from the neutrality. The disagreement on these experiments may come from the electronic states in the compound’s unique superconductivity.

*We thank MEXT Grand-in-Aid No. 18K03540 for support.

1:03PM F05.00008: Superconductivity and Nontrivial Band Topology in NbN Polytypes†  
KUNCHALA RAMESH BABU, GUANG-YU GUO (Presenter), National Taiwan University — Niobium nitride is a good superconductor in its cubic structure (d-NbN) with Tc = 17 K [1]. Recent experiments on hexagonal NbN (e-NbN) revealed the existence of superconductivity with a Tc of 12 K [2]. WC-type NbN possesses topological properties with three fold band crossings [3]. Here we study the electronic band structure and superconductivity in these NbN polytypes by performing density functional calculations. Interestingly, our results reveal that all three NbN polytypes are topological metals. Specifically, d-NbN and e-NbN are, respectively, type-II and type-I Dirac metals, while WC-NbN is a topological metal with triply degenerate nodes. Our results also show that the electron-phonon coupling in d-NbN is much stronger than in e-NbN and WC-NbN. This results in a much higher superconducting transition temperature (Tc = 18 K) than in e-NbN and WC-NbN. Our findings thus suggest that the NbN polytypes would provide valuable opportunities for studying exotic phenomena arising from the interplay between superconductivity and band topology.

†The authors acknowledge support from the MOST and NCTS of The R.O.C.

1:15PM F05.00009: Spontaneously polarized half-gapped superconductivity in UTe2*  
SHENG RAN (Presenter), University of Maryland, College Park & NIST, CHRIS ECKBERG, University of Maryland, College Park, QING-PING DING, YUJI FURUKAWA, Iowa State University & Ames Lab, TRISTIN E METZ, University of Maryland, College Park, SHANTA SAHA, I-LIN LIU, University of Maryland, College Park & NIST, MARK ZIC, University of Maryland, College Park, JOHNPIERRE PAGLIONE, NICHOLAS BUTCHE5, University of Maryland, College Park & NIST — We discovered novel nonunitary spin-triplet superconductivity in UTe2, with the highest Tc and Hc2 among all candidates. Superconducting state closely resembles that of ferromagnetic superconductors, but the normal state is paramagnetic and shows no indication of magnetic ordering. UTe2 exhibits an extremely large, anisotropic upper critical field Hc2, temperature independent NMR Knight shift in the superconducting state, and a large residual normal electronic density of states indicating that half of the electrons remain ungapped. All these results strongly indicate that the superconductivity in UTe2 is carried by nonunitary spin-triplet pairs. This discovery yields a new platform for encoding information using topological excitations and for manipulation of spin-polarized currents.

1:27PM F05.00010: Fermi-arc superconductivity in Dirac Semimetal $\text{Cd}_3\text{As}_2$  
CE HUANG (Presenter), Fudan University, TONG ZHOU, KAM TUEN LAW, The Hong Kong University of Science and Technology, FAXIAN XIU, Fudan University — $\text{Cd}_3\text{As}_2$ is a three-dimensional Dirac semimetal with separated Dirac points in momentum space which are connected by Fermi arcs. In spite of their extensive studies via transport and spectroscopic approaches, the coupling of Fermi-arc states to superconductivity remains elusive. Here, we report the observation of proximity-induced Fermi-arc superconductivity in SC/$\text{Cd}_3\text{As}_2$ hybrid structures. The proximity gap in Fermi arcs is comparable to the parent superconductor which exhibits a flat conductance plateau in differential conductance spectra. The proximity-induced pairing gap on bulk states, however, is small and manifests itself as a zero-bias broad peak (ZBBP). Corroborated with theory, we further unveil a systematic suppression of the ZBBP and an appearance of conductance plateau when the Fermi-arc states become gradually dominant.

1:39PM F05.00011: The spectral fingerprint of the enhanced surface superconducting gap in $\beta$–$\text{Bi}_2\text{Pd}$  
JIANYU GUAN (Presenter), LINGYUAN KONG, TIAN QIAN, YUJIE SUN, HONG DING, Chinese Academy of Sciences — Topological superconductors are attracting a majority of attentions and inspired community to investigate the candidate materials. The recent discovery of enhanced surface superconducting gap and zero bias conductance peak in $\beta$–$\text{Bi}_2\text{Pd}$ thin film by STM [1] provides a possibility to get higher $T_c$ topological superconductor. But the driving force behind the enhanced superconductivity is still under debate. We grown the $\beta$–$\text{Bi}_2\text{Pd}$ thin film by MBE system and detect using in-situ angle resolved photoemission spectroscopy. We observed quantum well bands due to the high quality of the grown thin film. More importantly, we clearly distinguished the bulk band and surface band in momentum space. In the surface band, we detected the spectral fingerprint of the enhance superconducting gap.

1:51PM F05.00012: Topologically nontrivial phases in superconducting transition metal carbides  
RICHARD ZHAN (Presenter), XUAN LUO, National Graphene Research and Development Center — Topological superconductors have shown great potential in the search for unique quasiparticles such as Majorana fermions. Combining nontrivial band topology and superconductivity can lead to topological superconductivity due to the proximity effect. In this work, we used first principle calculations to predict that rocksalt phases of VC and CrC are superconducting with topologically nontrivial states. The phonon dispersions of these transition metal carbides displayed no imaginary frequencies, which suggests dynamic stability. Therefore, these transition metal carbides are practical candidates for studying topological superconductors and their associated Majorana bound states.

2:03PM F05.00013: Topological character of A15 superconductors*  
MINSUNG KIM (Presenter), CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory — A15 superconductors are type-II $s$-wave BCS superconductors that have been known for decades. However, the topological aspects of their electronic structures remain unnoticed so far. In this study, we perform first-principles band structure calculations to show that the band topology of the A15 superconductors $\text{Ta}_3\text{Sb}$, $\text{Ta}_3\text{Sn}$, and $\text{Ta}_3\text{Pb}$ is nontrivial. We also find that there appear topological surface states in accordance with the bulk-boundary correspondence. Due to the bulk superconductivity and the proximity effect, topological superconductivity will be induced at the surface, which can host Majorana zero modes at vortices. Our results show that the A15 superconductors are promising candidate materials to realize the $p_x + i p_y$ type topological superconductivity and the Majorana mode.

*This work was supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division. The research was performed at Ames Laboratory, which is operated for the U.S. DOE by Iowa State University under Contract No. DE-AC02-07CH11358.

Session F06 DCMP: Exotic Transport Properties: Magnetoresistance, Quantum Hall, and Others  
BCEC 109A - Dmitrii Maslov, University of Florida
**11:15AM F06.00001: Giant magnetoresistance in BaMn$_2$Pn$_2$ (Pn = As, Sb, Bi)**

KHUONG HUYNH (Presenter), WPI-AIMR, Tohoku University, TAKUMA OGASAWARA, STEPHANE YU MATSUSHITA, Department of Physics, Graduate School of Science, Tohoku University, TAIMU TAHARA, TAKANORI KIDA, MASAYUKI HAGIWARA, Center for Advanced High Magnetic Field Science, Graduate School Science, Osaka University, DENIS ARCON, Jozef Stefan Institute, KATSUMI TANIGAKI, WPI-AIMR, Tohoku University — We report our discovery of a new kind of giant magnetoresistance (GMR) in the family of BaMn$_2$Pn$_2$ antiferromagnets, where Pn stands for As, Sb, and Bi [1, 2]. BaMn$_2$Pn$_2$'s are intriguing materials hosting a magnetic hexadecapole ordering that preserves the parity-time symmetry even though both time and space inversion are broken [3]. The hexadecapole ordering microscopically stems from symmetry-preserved spin-dependent d-p hybridization that governs the low energetic excitations and therefore promises exotic transport properties. Here we describe a new GMR in BaMn$_2$Pn$_2$'s with the following features [1,2]: (1) the magnitudes of the unique negative GMR are larger than 98 %, being comparable with those of other exotic GMR systems, (2) GMR exhibits a very unusual angular under the rotation of magnetic fields, (3) GMR is band selective in sign, showing negative and positive signs for hole- and electron-like carriers, respectively. These properties are incompatible to any known mechanism of magnetoresistance and call for new explanations.

*This work was supported by World Premier International Research Center Initiative (WPI), MEXT, Japan.

**11:27AM F06.00002: Hall effects in giant magnetoresistance system BaMn$_2$Bi$_2$**

TAKUMA OGASAWARA (Presenter), Department of Physics, Graduate School of Science, Tohoku University, KHUONG HUYNH, WPI-AIMR, Tohoku University, STEPHANE YU MATSUSHITA, Department of Physics, Graduate School of Science, Tohoku University, TAIMU TAHARA, TAKANORI KIDA, MASAYUKI HAGIWARA, Center for Advanced High Magnetic Field Science, Graduate School Science, Osaka University, DENIS ARCON, Jozef Stefan Institute, KATSUMI TANIGAKI, WPI-AIMR, Tohoku University — A new kind of giant magnetoresistance (GMR) is observed in the family of G-type antiferromagnets BaMn$_2$Pn$_2$ 's, where Pn denotes pnictide elements of As, Sb, and Bi. The -98% GMR appears intriguingly with an unique angular dependence under rotating magnetic fields [1, 2] on the background of a complex magnetic hexadecapole ordering that preserves the parity-time symmetry even though the parity and time reversal symmetries are broken respectively[3]. Among the BaMn$_2$Pn$_2$ 's , BaMn$_2$Bi$_2$ shows the largest MR in the smallest magnetic field range and therefore is the key material of the BaMn$_2$Pn$_2$ family [1] for further detailed studies. We have measured the angular dependence of magnetoresistance and Hall effect of BaMn$_2$Bi$_2$ to investigate the effect of magnetic field on the electrical conductivity. The results of our analyses suggest that the observed GMR stems from a large enhancement in the mobility of hole-like carriers induced by magnetic fields.

*This work was supported by World Premier International Research Center Initiative (WPI), MEXT, Japan.

**11:39AM F06.00003: Effect of Chemical Substitutions on the Extreme Magnetoresistance and Topological State of PtSn$_4$**

ALANNAH HALLAS (Presenter), CHIEN-LUNG HUANG, EMILIA MOROSAN, Rice University — It has recently been discovered that the extreme magnetoresistive material PtSn$_4$ [1] has a novel topological state, with the observation of Dirac node arcs in ARPES measurements [2]. This material has a quasi-two dimensional crystal structure composed of an edge-sharing network of PtSn$_4$-square antiprisms. We study the effect of chemical substitutions on the electronic properties of PtSn$_4$ via two pathways: (i) we consider the effect of replacing platinum by gold, giving AuSn$_4$ and (ii) we consider the effect of substituting tin with lead, giving PtPb$_4$. In the first substitution the crystallographic properties are left unaltered (ABAB stacking, orthorhombic) but in the second there is a minor structural modification (AAA stacking, tetragonal). Both materials superconduct at low temperatures with $T_c = 2.5$ K for AuSn$_4$ and $T_c = 2.8$ K for PtPb$_4$. In this talk, we will present our studies of the electronic and topological properties of these compounds and comment on their relationship to PtSn$_4$.

*Supported by the Gordon and Betty Moore Foundation’s EPiQS Initiative
11:51 AM F06.00004: Charge transport in doped SrTiO₃  
ABHISHEK KUMAR (Presenter), DMITRII MASLOV, University of Florida — Recent experiments identified an unusual T² dependence of the resistivity in doped strontium titanate (SrTiO₃). That this dependence is observed even at low doping, when umklapps are essentially impossible, and at temperatures far exceeding the Fermi energy eliminates electron-electron interaction as a possible source of the T² resistivity. The T² term may come from the interaction of electrons with two soft transverse optic (TO) phonons, characteristic for this material (the Epifanov-Levanyuk-Levanyuk mechanism). However, it is unclear within this model why the T² term would be observed at temperatures smaller than the TO phonon frequency. We show that this behavior can be understood within a model in which the TO frequency varies over the sample from a larger value, observed in neutron and Raman scattering experiments, to a smaller value. A microscopic justification of this model relies on the experimentally observed polar boundaries between antiphase domains. Within the same model, we showed that the next-order correction to T² term is T⁶ which is due to interaction of electrons with four TO phonons. Therefore, the TO phonon scattering is not able to explain the T³ behavior of the resistivity observed at higher temperatures.

12:03 PM F06.00005: Boundary layer theory for quantum Hall hydrodynamics  
SRIRAM GANESHAN (Presenter), Physics, City College of New York CUNY, ALEXANDER ABANOV, Stony Brook University, TANKUT CAN, ITS, CUNY Graduate Center, GUSTAVO M MONTEIRO, Physics, Universidade Estadual de Campinas-UNICAMP — In this talk, we consider non-dissipative two-dimensional broken parity fluids with odd viscosity and magnetic field with a free surface boundary condition. We show that for non-dissipative fluids, incompressibility must be violated at free surfaces to have a consistent hydrodynamic description of the dynamical boundary. Violation to incompressibility sources vorticity within the boundary layer which is an exclusive manifestation of odd viscosity. The thickness of the boundary layer is controlled by the velocity of sound. A non-dissipative boundary layer mechanism allows us to write the full variational principle for both bulk and boundary. In the limit of large sound velocity, we recover Quantum Hall like fluids where the bulk is incompressible but the thin boundary layer manifests compression modes. We discuss the applicability of our results to (fractional) quantum Hall fluids with a free surface.

12:15 PM F06.00006: Dynamics of the Phase Separated States in the Double Exchange Model  
JING LUO (Presenter), GIA-WEI CHERN, University of Virginia — We present large-scale simulations of spin dynamics in the phase-separated states of the one-orbital double-exchange model. These inhomogeneous electronic states consisting of ferromagnetic conducting clusters embedded in an antiferromagnetic insulating background play a crucial role in the colossal magnetoresistance phenomenon. We compute the dynamical structure factor of these nanoscale textures using an efficient real-space formulation of coupled spin and electron dynamics. Dynamical signatures of the various underlying magnetic correlations are identified. At small hole doping, the structure factor exhibits a dominating signal of magnons from the background Néel order and localized modes from small metallic clusters. A low-energy continuum due to large-size ferromagnetic clusters emerges at higher doping levels. Implications for experiments on magnetoresistive manganites are also discussed.

12:27 PM F06.00007: Detecting fractional Chern insulators through circular dichroism  
CECILE REPELLIN (Presenter), Massachusetts Institute of Technology, NATHAN GOLDMAN, Université Libre de Bruxelles — Great efforts are currently devoted to the engineering of topological Bloch bands in cold atomic gas. Recent achievements in this direction as well as the possibility of tuning inter-particle interactions suggests that strongly-correlated states reminiscent of fractional quantum Hall (FQH) liquids, could soon be generated in these atomic systems. In this context where transport measurements are limited, identifying unambiguous signatures of FQH-like states constitutes a challenge on its own. Here, we demonstrate that the fractional nature of the quantized Hall conductance, a fundamental characteristic of FQH states, could be finely detected in ultracold gases through a circular-dichroic measurement, namely by measuring the energy absorbed by the atomic cloud upon a circular drive. We discuss how such measurements, which were recently implemented in the integer-QH regime, could indeed be performed to distinguish FQH-type states from competing states (such as charge density waves). Our scheme offers a practical and powerful tool for the detection of topological order in quantum engineered systems.
12:39PM F06.00008: Bridging Hubbard Model Physics and Quantum Hall Physics in ABC Trilayer Graphene/h-BN moiré superlattice* YAHUI ZHANG (Presenter), SENTHIL TODADRI, Massachusetts Institute of Technology — Recently several phases resulting from electron correlations have been discovered in graphene moiré superlattice with narrow bands. In this talk I will focus on the moiré superlattice formed by ABC stacked trilayer graphene aligned with a hexagonal boron nitride substrate (TG/h-BN). Mott-like insulators in this system have already been observed experimentally by Feng Wang et.al. (Chen, Feng Wang et.al. arxiv: 1803.01985). Remarkably, in TG/h-BN, both the bandwidth and the topology can be tuned by an applied perpendicular electric field $D$. For $D<0$, the valence bands of the two valleys are trivial and the physics is governed by a spin-valley Hubbard model on triangular lattice. For $D>0$, the bands of the two valleys have non-zero Chern numbers $C=3,-3$. Therefore the TG/h-BN system can simulate both Hubbard model physics and nearly flat Chern band physics within one sample through a simple switch of the vertical displacement field. I am going to discuss several aspects of the resulting many body physics.

*The work was supported by NSF grant DMR-1608505, and partially by a Simons Investigator Award from the Simons Foundation to Senthil Todadri.

12:51PM F06.00009: Non-Abelian quasiholes in lattice Moore-Read states and parent Hamiltonians* JULIA WILDEBOER (Presenter), Department of Physics, Arizona State University, SOURAV MANNA, Max Planck Institute for the Physics of complex Systems, GERMAN SIERRA, Instituto de Fisica Teorica, UAM-CSIC, ANNE E. B. NIELSEN, Max Planck Institute for the Physics of complex Systems — A striking feature of fractional quantum Hall states is that they form an incompressible quantum state supporting emergent fractionally charged quasiparticle excitations with non trivial braiding properties. Excitations of non-Abelian nature command much attention from theorists and experimentalists due to their potential applications in quantum information especially topologically protected fault tolerant quantum computation. This talk will present Ising quasiholes in Moore-Read type lattice wave functions. We start by constructing Moore-Read type lattice states and then add quasiholes to them. By use of Metropolis Monte Carlo simulations, we analyze the features of the quasiholes, such as their size, shape, charge, and braiding properties. The braiding properties, which turn out to be the same as in the continuum Moore-Read state, demonstrate the topological attributes of the Moore-Read lattice states in a direct way. We also derive parent Hamiltonians for which the states with quasiholes included are ground states.

*JW thanks NSF DMR 1306897 and NSF DMR 1056536 for partial support.

1:03PM F06.00010: Theory of magnon transport in quantum Hall ferromagnet CHUNLI HUANG (Presenter), ALLAN MACDONALD, Physics, University of Texas at Austin — In two recent experiments, Stepanov et. al [Nat. Phys 14, 907–911 (2018)] and Wei. et al [Science 362, 6411, 229-233 (2018)] observed long distance, nonlocal magnon transport in quantum Hall magnetic states of graphene. In these experiments, bulk magnons are excited in close proximity to conducting spin polarized edge states that are under external voltage bias. While Stepanov et. al observed a nonlocal voltage linear in the bias voltage, Wei. et al observed a nonlocal voltage only when within a window of bias voltage that begins at Zeeman energy. Motivated by these observations, we present a simple theoretical model to study edge-current induced torque -- the coupled dynamics of itinerant spin-polarized edge states and insulating bulk magnons.

1:15PM F06.00011: Effective field theory of a vortex lattice in a bosonic superfluid* SERGEJ MOROZ (Presenter), Technical University of Munich, CARLOS HOYOS, Oviedo, CLAUDIO BENZONI, Technical University of Munich, DAM THANH SON, UChicago — Using boson-vortex duality, we formulate a low-energy effective theory of a two-dimensional vortex lattice in a bosonic Galilean-invariant compressible superfluid. The excitation spectrum contains a gapped Kohn mode and an elliptically polarized Tkachenko mode that has quadratic dispersion relation at low momenta. External rotation breaks parity and time-reversal symmetries and gives rise to Hall responses. We extract the particle number current and stress tensor linear responses and investigate the relations between them that follow from Galilean symmetry. We argue that elementary particles and vortices do not couple to the spin connection which suggests that the Hall viscosity at zero frequency and momentum vanishes in a vortex lattice.

1:27PM F06.00012: Electronic Spectral functions, $\rho(T)$ and Raman response in the 2-d $t$-$J$ model* PEIZHI MAI
(Presenter), Oak Ridge National Lab and University of California, Santa Cruz, B SHASTRY, University of California, Santa Cruz — We study the two-dimensional $t$-$J$ model with a second neighbor hopping parameter $t'$, in a broad range of doping $\delta$ using a closed set of equations from the Extremely Correlated Fermi Liquid (ECFL) theory. The electronic spectral function is found to yield asymmetric energy distribution curves and symmetric momentum distribution curves. These are broadly consistent with experimental data. Using our spectral functions, we calculate the resistivity, whose curvature changes with varying $\delta$ is presented, and connect this change to the intensity loss in Angle-Resolved Photoemission Spectroscopy (ARPES) experiments. We also present results for a set of closely related dynamical response functions: the non-resonant Raman susceptibility for three principal geometries germane to the square lattice, and the optical conductivity. Where available, these results are in close correspondence to available high-resolution experimental results. Our results provide a set of testable predictions for future experiments.

1:39PM F06.00013: Transport, multifractality and breakdown of single-parameter scaling in quasiperiodic systems. JAGANNATH SUTRADHAR (Presenter), SUBROTO MUKERJEE, RAHUL PANDIT, SUMILAN BANERJEE, Indian Institute of Science — We study the transport in 1d Aubry-Andre model, and its generalizations to 2d and 3d, which show significant deviations from single-parameter scaling theory providing a broad demarcation between QPS and RS. We study the conductance of open systems connected to leads as well as the Thouless conductance. Depending on dimension, the conductances show metal-insulator transition from localized to either ballistic, superdiffusive or diffusive transport typically through subdiffusive critical states. We show that, even though a beta function, $\beta(g) = d\ln(g)/d\ln(L)$, can be constructed separately for individual phases based on a overall length ($L$) dependence of typical dimensionless conductance $g$, in 1d and 2d, the single-parameter scaling is unable to describe the transition. Moreover, the conductances show strong non-monotonic variations (multifractal scaling in 1d) with system size and intricate resonant peak and subpeak structures of number theoretic origin, invalidating a strict definition of $\beta(g)$. We show that the non-monotonicity is very weak in 3d with a critical point having localization length exponent close to that of 3d Anderson transition and the single-parameter scaling is almost restored providing a good description of the metal-insulator transition.

1:51PM F06.00014: Pairing correlations in the incoherent phase of quantum Hall bilayers?* JAMES EISENSTEIN (Presenter), Physics, Caltech, LOREN PFEIFFER, KENNETH WEST, Electrical Engineering, Princeton — At sufficiently small layer separation, Coulomb interactions in bilayer 2D electron systems at high magnetic field can stabilize an excitonic phase in which electrons in one layer are bound to holes in the other. The excitonic phase is macroscopically phase coherent, exhibiting numerous remarkable transport properties analogous to those of superconductivity and superfluidity. While the excitonic phase is theoretically relatively well understood, the incoherent phase at layer separations slightly larger than the critical one is not. In this talk we will discuss recent transport and interlayer tunneling spectroscopy measurements which demonstrate the importance of interlayer Coulomb interactions in the incoherent phase. In addition to screening of the Coulombic repulsion between electrons in the same layer, our measurements suggest that interlayer electron-hole pairing correlations may persist into the incoherent phase at intermediate layer separations.

Session F07 DCMP: One and Two Dimensional Correlated Electron Systems BCEC 109B - Konstantin Matveev, Argonne National Laboratory
11:15 AM F07.00001: Sound modes in one-dimensional quantum liquids

KONSTANTIN MATVEEV (Presenter), Argonne National Laboratory, ANTON ANDREEV, University of Washington — We study sound in one-dimensional Galilean invariant quantum liquids. In contrast to classical fluids, instead of a single sound mode we find a broad range of frequencies in which the system supports two sound modes. The nature of these modes depends on the type of particles forming the quantum liquid. In systems of spin-1/2 fermions, we find the first and second sound modes propagating at two different speeds. Similarly to superfluid $^4$He, the first sound is a wave of density, whereas the second one is a wave of entropy. In spinless quantum liquids we find two hybrid sound modes, which are simultaneous oscillations of both density and entropy, with relative phase shifts 0 or π. Their speeds are nearly equal, with the difference scaling linearly with the temperature.

*Work at Argonne National Laboratory was supported by the U.S. Department of Energy, Office of Science, Materials Sciences and Engineering Division. Work at the University of Washington was supported by the U.S. Department of Energy Office of Science, Basic Energy Sciences under Award No. DE-FG02-07ER46452.

11:27 AM F07.00002: The fate of shock waves in quantum one-dimensional fluids at late times

THOMAS VENESS (Presenter), LEONID GLAZMAN, Yale Univ — Classical hydrodynamics generically leads to the formation of shock waves which, at the most basic level, correspond to nonanalyticities in the fluid density as a function of spatial coordinates. At this classical level, small and smooth perturbations inevitably lead to such shocks. It is known that in free fermionic systems such classical nonanalyticities are rounded off at the shock points due to semi-classical corrections. We investigate how shock formation eventually crosses over to the established framework of generalised hydrodynamics at late times, as well as consider the rôle of interactions in the one-dimensional shock problem.

11:39 AM F07.00003: Numerical evidence for continuous transition between Ising ferromagnet and valence bond solid in one dimension

BRENDEN ROBERTS (Presenter), SHENGHAN JIANG, OLEXEI MOTRUNICH, Caltech — We perform a numerical study of a spin-1/2 model with $\mathbb{Z}_2 \times \mathbb{Z}_2$ symmetry in one dimension which demonstrates an interesting similarity to the physics of two-dimensional deconfined quantum critical points (DQCP). Specifically, we investigate the quantum phase transition between Ising ferromagnetic and valence bond solid (VBS) symmetry-breaking phases. Working directly in the thermodynamic limit using uniform matrix product states, we find evidence for a direct continuous phase transition which lies outside of the Landau-Ginzburg paradigm. In our model, the continuous transition is found everywhere on the phase boundary. We find that the magnetic and VBS correlations show identical power law exponent, which is expected from the self-duality of the parton description of this DQCP. Critical exponents vary continuously along the phase boundary and are in agreement with predictions of the field theory for this transition. We also find a regime where the phase boundary splits with the appearance of an intermediate phase of coexisting ferromagnetic and VBS order parameters, as suggested by the theory.

11:51 AM F07.00004: Photoinduced enhancement of bond-order in the one-dimensional extended Hubbard model

CAN SHAO (Presenter), Beijing Computational Science Research Center, TAKAMI TOHYAMA, Tokyo Univ of Science, Katsushika, RUBEM MONDAINI, Beijing Computational Science Research Center, HONG-GANG LUO, HANTAO LU, Lanzhou University — Using the time-dependent Lanczos technique, we investigate the short-time evolution of the half-filled one-dimensional extended Hubbard model in the strong-coupling regime, when driven by a transient laser pulse. Starting from a phase displaying charge-density wave (CDW), a steady photoinduced in-gap state in the optical conductivity is found, depending on the parameters of the laser pulse. This potentially describes similar results of a recent experiment using organic salts [Nat. Phys. 7, 114 (2011)], also subjected to external drivings. On top of that, we parametrize the conditions of the pulse so as to maximize the overlap of the time-evolving wavefunction with excited states displaying the elusive bond-ordered wave of this model, with the focus on providing a protocol to experiments for its observation. Further, we try to make a connection between the emergence of this order and the formation of the aforementioned in-gap state, comparing with different types of excitations on the ground state.
12:03PM F07.00005: Competing orders in the one-dimensional Su-Schrieffer-Heeger model*  MANUEL WEBER
(Presenter), Department of Physics, Georgetown University, MARTIN HOHENADLER, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg — We study the phase diagram of the one-dimensional spinless Su-Schrieffer-Heeger (SSH) model at half filling as a function of phonon frequency and electron-phonon coupling. In the adiabatic limit of static phonons (vanishing phonon frequency), the ground state is well understood to be a bond-ordered Peierls state that supports topological excitations at domain walls. In the antiadiabatic limit (infinite phonon frequency), the model maps onto the t-V model with a Luttinger liquid phase below and charge-density-wave order above a critical coupling. Using a recently developed directed-loop quantum Monte Carlo method for retarded interactions [1], we study the competition between these orders at finite phonon frequencies.

*Manuel Weber is supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES) under Award DE-FG02-08ER46542.

12:15PM F07.00006: Critical Entanglement for the Half-Filled One-Dimensional Extended Hubbard Model*  JON SPALDING (Presenter), SHAN-WEN TSAI, University of California, Riverside, DAVID K CAMPBELL, Physics, Boston University — A fundamental problem in many-body physics is the characterization and classification of the ground states for materials involving strongly correlated electrons. For the Extended Hubbard Model at half-filling in one dimension, this has historically required challenging Quantum Monte Carlo or DMRG calculations for large system sizes in order to extract phase diagram information. Within the last two decades, advances in quantum information theory, and in particular, conformal field theory results for entanglement entropy scaling, have enabled unprecedented accuracy in computing critical properties of ground states. In this talk, we present new techniques based on conformal field theory that enable rapid, cheap extraction of critical points and critical exponents at both 2nd order and BKT transitions for open-boundary DMRG wave functions. The results of our study of the Extended Hubbard Model point to the broad applicability of the approach.

12:27PM F07.00007: Crossovers and critical scaling in the one-dimensional transverse-field Ising model*  JIANDA WU (Presenter), Tsung-Dao Lee Institute, LIJUN ZHU, University of California, Riverside, QIMIAO SI, Rice University — We consider the scaling behavior of thermodynamic quantities in the one-dimensional transverse field Ising model near its quantum critical point (QCP). We find that the crossovers obey a general scaling ansatz, and so does the critical scaling behavior of the specific heat and magnetic expansion coefficient. Furthermore, the Grüneisen ratio diverges in a power-law way when the QCP is accessed as a function of the transverse field at zero temperature. However, at the critical field, upon decreasing the temperature, the Grüneisen ratio approaches a constant instead of showing the expected divergence. This unusual result can be understood in terms of a peculiar form of the quantum critical scaling function for the free energy; the contribution to the Grüneisen ratio vanishes at the linear order in a suitable Taylor expansion of the scaling function. Our results establish the telltale thermodynamic signature of a transverse-field Ising chain, and will thus facilitate the experimental identification of this model quantum-critical system in real materials.

*This work was in part supported by the NSF Grant No.DMR-1611392 and the Robert A. Welch Foundation Grant No.C-1411. Q.S. acknowledges the hospitality of the Aspen Center for Physics (the NSF Grant No. PHY-1607611).
We describe the quantum phase transition in the N-state chiral clock model in spatial dimension $d=1$. With particular couplings, such a model is in the universality class of recent experimental studies of the ordering of pumped Rydberg states in a one-dimensional chain of trapped ultracold alkali atoms. For $N=3$, the model is expected to have a direct phase transition from a gapped phase with a broken global $Z_N$ symmetry, to a gapped phase with the $Z_N$ symmetry restored. The transition has dynamical critical exponent $z\neq1$, and so cannot be described by a relativistic quantum field theory. We map the transition onto that of a Bose gas in $d=1$, involving the onset of a single boson condensate in the background of a higher-dimensional N-boson condensate. We present a renormalization group analysis of the strongly coupled field theory for the Bose gas transition in an expansion in 2-d, with 4-N chosen to be of order 2-d. At two-loop order, we find a renormalization group fixed point which can describe a direct phase transition.

We show unambiguous evidence for thermal and non-thermal mechanisms behind the insulator-to-metal transition in current-driven Mott materials. Distinguishing between these two mechanisms has proven difficult due to inhomogeneity of the current distribution in the device. By reducing the dimensionality of the devices to a one dimensional nanowire, inhomogeneity is avoided, thus allowing the two different mechanisms to be identified. The differences between the switching mechanisms in two prototypical Mott materials, VO$_2$ and V$_2$O$_3$, are discussed. Our results have direct implications for applications in neuromorphic technologies.

*We acknowledge support from the Vannevar Bush Faculty Fellowship program sponsored by the Basic Research Office of the Assistant Secretary of Defense for Research and Engineering and funded by the Office of Naval Research through grant N00014-15-1-2848.

It is shown that Majorana edge modes appear in a strongly correlated phase of semiconducting nanowires with discrete rotational symmetry in the cross section. These modes exist in the absence of spin-orbit coupling, magnetic fields and superconductivity. They appear purely due to the combination of the three-dimensional Coulomb interaction and orbital physics, which generates a fermionic condensate exhibiting a topological ground state degeneracy in a sector of the spectrum which is gapped to continuum modes. The gap can be comparable in magnitude to the topological superconducting gap in other solid-state candidate systems for Majorana edge modes, and may similarly be probed via tunnel spectroscopy.

Danish National Research Foundation

A symmetry protected topological phase (SPT) is one which cannot be smoothly deformed into a trivial phase without breaking the symmetry. The symmetry which protects the phase acts “anomalously” on the edge of the SPT - for instance, in a non-onsite manner. Here, we examine the case when the anomaly is even more severe and the effective edge Hilbert space of the SPT does not admit a local tensor-product structure.

We begin with Fidkowski and Tarantino’s lattice model for the root SPT phase for the symmetry $G= Z_2 \times Z_2^f$ in 2d in the presence of an edge. Each site in the edge carries an Ising spin, and each domain wall hosts a Majorana fermion, so the size of the boundary Hilbert space does not scale simply with the number of sites. We introduce a description of this Hilbert space akin to the Jordan-Wigner bosonization of a fermion chain and find the action of the $Z_2$ symmetry on it. We construct a 3-site Hamiltonian which respects the $Z_2$ symmetry and find strong numerical evidence that it realizes an Ising CFT where the $Z_2$ symmetry acts as Kramers-Wannier duality.

1:39PM F07.00013: Non-Linear transport in low density 2D hole systems‡ DMITRII KRUGLOV (Presenter), ANDREI KOGAN, Physics, University of Cincinnati, CHIEH-WEN LIU, XUAN GAO, Physics, Case Western Reserve University, LOREN PFEIFFER, KENNETH WEST, Princeton University — We report measurements of non-linear magnetotransport in 10 nm wide p-doped GaAs/Al0.1Ga0.9As quantum wells with low hole density (n ~ 10¹⁰ cm⁻²) and high mobility (m ≈ 5 x 10⁵ cm²/Vs). The Quantum Hall plateau-to-plateau transitions exhibit a universal dependence on bias voltage. We compare the results to theoretical predictions by assuming that the narrowing of the plateaus is caused by the temperature rise in the sample caused by the Joule heating. We find a good qualitative agreement with the predictions, but, surprisingly, the data show a stronger dependence on bias in the zero-bias limit than the theory suggests. We also discuss the high-frequency rectification spectroscopy as an approach for exploring dynamic effects in low-density hole systems and, in particular, the physics of insulating phases in two-dimensional transport at low carrier densities.

2:03PM F07.00015: Phase diagrams of pi-flux quantum spin liquid in kagome lattice HYEOK-JUN YANG (Presenter), SUNGBIN LEE, Korea Adv Inst of Sci & Tech — We study possible phase transitions between spin liquids and magnetically ordered states of quantum spin ice in a pyrochlore lattice. Focusing on a Kagome layer in the presence of [111] magnetic field, the modified ice rule enables the effective action to be expressed in the language of compact U(1) gauge theory. While Ising interaction defines the ground-state manifold, the spin-flip term is mapped to hopping of gauge charge after perturbation. In particular, for frustrated J, the gauge charge experiences pi-flux around the hexagon built from the triangular plaquette. Analyzing the action, the phase diagram is developed which exhibits U(1) spin liquid and out of this phase. We will also compare our results with previous relevant experiments and quantum Monte-carlo simulations.

Session F08 DCMP: Superconductivity: Copper Oxide - Spectroscopy BCEC 150 - Ricardo Lobo, ESPCI ParisTech
11:15AM F08.00001: Terahertz spectroscopy of the cuprate superconductor La$_{2-x}$Sr$_x$CuO$_4$ in the photoexcited nonequilibrium state  
HIROAKI NIWA (Presenter), NAOTAKA YOSHIKAWA, Department of Physics, The University of Tokyo, 
DONGJOON SONG, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, 
RYO SHIMANO, Cryogenic Research Center and Department of Physics, The University of Tokyo — 

Ultrafast pump-probe spectroscopy has been a promising tool to study the interplay of complex orders and to reveal hidden states of condensed matter. In particular, the high-T$_c$ cuprate superconductors provide an interesting platform since they exhibit various electronic phases such as pseudogaps, charge/spin density-waves, stripe order, and superconductivity.

Here, we focused on an archetypal cuprate superconductor La$_{2-x}$Sr$_x$CuO$_4$ with the doping levels of $x = 0.125$ to $x = 0.15$, and investigated the dynamics after intense photoexcitation by utilizing near-infrared (800 nm) optical pump-terahertz probe spectroscopy. In the superconducting state, after photoexcitation we observed an emergence of a peak structure in the real-part conductivity accompanied by the destruction of the superconducting coherence indicated by the redshift of the Josephson plasma resonance. The peak structure sustains for several hundreds of picoseconds after the excitation and its height is strongly dependent on the excitation intensity. The doping dependence of the photoexcited state suggests the correlation between the peak structure and superconductivity.

11:27AM F08.00002: C-Axis Spectra of La$_{2-x}$Ba$_x$CuO$_4$ in the Normal and Superconducting State  
VLADIMIR MARTINEZ (Presenter), LUYI YAN, DAVID TANNER, Department of Physics, University of Florida, Gainesville, FL, USA, 32611, GENDA GU, Brookhaven National Labs, Long Island, NY, USA, 11973 — Reflectance spectra of superconducting La$_{2-x}$Ba$_x$CuO$_4$ have been studied for polarization parallel to the c-axis in a wide frequency range from 20-35,000 cm$^{-1}$, at doping from $0 \leq x \leq 0.155$ and temperatures above and below $T_c$. The samples are single crystals grown using the traveling solvent floating zone method. These samples were wet polished with alumina fine powder to make a good reflective surface. The c-axis spectra showed insulating behavior, with only lattice vibrations below the charge-transfer gap. We observed below $T_c$ no evidence for a Josephson plasma edge in the far infrared, despite seeing good superconducting behavior for the a-axis spectra. The results of annealing in an oxygen atmosphere will be discussed.

11:39AM F08.00003: Intrinsic electronic Raman spectrum and pairing symmetry in cuprate superconductors*  
HYUN-TAK KIM (Presenter), MIT & Quantum Lab., Electronics and Telecommunications Research Institute — Since the polarized electronic Raman scattering (ERS) measures the characteristics of the bulk rather than the surface, ERS data generate more accurate information. An ERS theory$^{1)$ is that, when $d_{x^2-y^2}$-wave symmetry is assumed, $I(\omega) \approx \omega$, linear behaviour in the $B_{2g}$ mode and $II(\omega) \approx \omega^3$ for the $B_{1g}$ mode were calculated below an energy gap. ERS experiments$^{1,2)$ showed the linear behaviour in the $B_{2g}$ mode of the node area below $T_c$ for underdoped cuprate crystals. This is evidence of $d$-wave symmetry. However, since the measured data in inhomogeneous crystals with at least two phases has an averaged effect of the two phases to the measurement region, the measured data should be decomposed to analyze the intrinsic property. The ERS data well decomposed in an electron-doped cuprate Pr$_{2-x}$Ce$_x$CuO$_{4+\delta}$ allow us to demonstrate the intrinsic effect. Here, we show the intrinsic nonlinear Raman spectrum obtained by subtracting the pseudogap characteristic of a nonlinear from the linear Raman spectrum measured in the $B_{2g}$ mode of the node area below $T_c$. The intrinsic nonlinear behaviour implies the existence of the nodal superconducting gap denying $d$-wave pairing symmetry. 1) PRL 72, 396 (1994). 2) PRB 72, 214510 (2005).

Photoinduced phase transitions in cuprate superconductors: ordering vs. doping effects
RALPH EL HAGE (Presenter), VICTOR ROUCO, ANKE SANDER, Unité Mixte de Physique, CNRS Thales, Université Paris-Sud, Université Paris Saclay, 91767 Palaiseau, France, FABIAN CUELLAR, DAVID SANCHEZ MANZANO, JACOBO SANTAMARIA, Grupo de Física de Materiales Complejos, Dpt. Física de Materiales, Universidad Complutense de Madrid, 28040 Madrid, Spain, JAVIER VILLEGAS, Unité Mixte de Physique, CNRS Thales, Université Paris-Sud, Université Paris Saclay, 91767 Palaiseau, France — Complex oxides possess an extremely rich phase diagram, in which the transitions between different ground states are triggered by small changes of the carrier density or by disorder. Interestingly, the interplay between these two mechanisms —and the resulting phase— can be externally manipulated by illumination. Despite the amount of work performed on cuprate superconductors, a clear picture of the mechanisms governing photo-induced effects has not emerged. In particular, whether doping or ordering effects are dominant has not been settled. Here we investigate that through light illumination effects in oxygen deficient YBa$_2$Cu$_3$O$_{7-x}$ thin films in which different degrees of disorder are induced through i) changes in the growth conditions (“quenching”) and ii) ion irradiation. Generally, light induces an increase in the superconducting critical temperature and in the carrier density coupled to a decrease in the normal state resistivity. However differences in the response of quenched and irradiated samples have been observed, which suggests that light-induced ordering may play an important role in the photoinduced effects.

Infrared linear dichroism resonance in over-, under-, and optimally-doped cuprate superconductors
JUNGRYEOL SEO (Presenter), ALOK MUKHERJEE, MUMTAZ MURAT ARIK, DEEPU GEORGE, ANDREA MARKELZ, JOHN CERNE, University at Buffalo, The State University of New York, CHAO ZHANG, HAO ZHANG, JOHN Y.T. WEI, Department of Physics, University of Toronto, PETER ARMITAGE, Department of Physics and Astronomy, Johns Hopkins University, GAD KOREN, TAL KIRZHNER, Physics department, Technion - Israel Institute of Technology — We report systematic measurements on epitaxial thin films of high-temperature cuprate superconductors using polarization sensitive measurements. We measure the complex Faraday angle at zero magnetic field as a function of temperature (10-300K), energy (3 to 2330 meV), and doping. We observe a Faraday rotation signal, which shows sample orientation dependence that can be best associated with linear dichroism (LD) [1]. The LD signal may be due to nematic charge ordering in the cuprates, as has been observed in dc Hall transport measurements [2]. The Faraday rotation signal, as large as 22 mrad near 400 meV, is strongest in under-doped films even at 300K and it shows strong frequency dependence as well as doping dependence, which provides important clues for resolving the microscopic mechanism responsible for the anisotropy.

High temperature RIXS study of charge transfer excitations in cuprates
BIQIONG YU (Presenter), School of Physics and Astronomy, University of Minnesota, KENJI ISHII, Synchrotron Radiation Research Center, National Institutes for Quantum, SHUN ASANO, MASAKI FUJITA, Department of Physics, Tohoku University, DIEGO M CASA, Argonne National Laboratory, GUICHUAN YU, MARTIN GREVEN, School of Physics and Astronomy, University of Minnesota — Resonant inelastic X-ray scattering (RIXS) is a promising technique to study momentum-resolved electronic excitations in strongly correlated materials. Here we present results of a recent Cu K-edge RIXS study on the archetypal hole-doped cuprate La$_{2-x}$Sr$_x$CuO$_4$ and electron-doped cuprate Nd$_{2-y}$Ce$_y$CuO$_4$. Our measurements, which range from low temperature (15 K) to very high temperature (1200 K), indicate distinct spectral weight changes of charge-transfer excitations below ~ 2 eV. We will make a detailed comparison of the temperature dependent charge-transfer excitations in electron- and hole- doped cuprates.

Work at the University of Minnesota funded by the Department of Energy through the University of Minnesota Center for Quantum Materials under DE-SC0016371.
12:27PM F08.00007: Doping Dependence of Charge Density Wave in Bi-2212 Cuprate Superconductors*  
HAIYU LU (Presenter), MATTHIAS HEPTING, MAKOTO HASHIMOTO, YU HE, SUDI CHEN, KEJUN XU, SLAC National Accelerator Laboratory, SHIGEYUKI ISHIDA, YOSHIYUKI YOSHIDA, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, RICCARDO ARPAIA, Chalmers University of Technology, GIACOMO GHIRINGHELLI, LUCIO BRAICOVICH, Politecnico di Milano, BRIAN MORITZ, EDWIN HUANG, SLAC National Accelerator Laboratory, KURT KUMMER, NICHOLAS B BROOKES, European Synchrotron Radiation Facility, ZHI-XUN SHEN, THOMAS DEVEREAUX, WEI-SHENG LEE, SLAC National Accelerator Laboratory — The origin of the charge density wave (CDW) in high-temperature superconductor, its interplay with superconductivity, and more importantly, to which extent it influences lattice and charge degrees of freedom remain an active area of research. To gain further insights into these questions, it is necessary to characterize its doping and temperature dependence. We performed high energy resolution momentum-resolved resonant inelastic soft x-ray scattering (RIXS) experiments at the Cu L3-edge on the high-temperature superconductor Bi2Sr2CaCu2O8+x with the doping level across the entire phase diagram (Antiferromagnetic, underdoped, optimally doped, and overdoped). Doping dependence of the CDW, the associated phonon softening, and excitations will be discussed.

12:39PM F08.00008: Anisotropically damped magnetic excitations in La2-xSrxCuO4*  
HANNAH ROBARTS (Presenter), STEPHEN HAYDEN, University of Bristol, KEJIN ZHOU, Diamond Light Source — The collective magnetic excitations in cuprate materials have been the subject of significant research to unravel their potential role in the superconducting pairing mechanism [1]. We have performed resonant inelastic x-ray scattering (RIXS) measurements on these excitations on the model cuprate superconductor La2-xSrxCuO4 with doping x=0, x=0.12 and x=0.16. We find that the line-shape of the excitations is fairly-well described by a damped harmonic oscillator response model [2]. The damping parameter is strongly q-dependent. We perform measurements along high symmetry directions and, for the doped compounds, extend beyond this to map a full portion of the Brillouin zone revealing the anisotropy of the damping of excitation. The results are compared with high-energy inelastic neutron scattering.

12:51PM F08.00009: Photo-enhanced metastable c-axis transport in stripe ordered cuprate La1.885Ba0.115CuO4*  
KEVIN CREMIN (Presenter), JINGDI ZHANG, University of California, San Diego, CHRISTOPHER HOMES, GENDA GU, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, ZHIYUAN SUN, Department of Physics, Columbia University, MICHAEL FOGLER, University of California, San Diego, ANDREW MILLIS, DIMITRI N BASOV, Department of Physics, Columbia University, RICHARD DOUGLAS AVERITT, University of California, San Diego — Numerous cuprate-based superconductors exhibit a complex interplay between spin order, charge order and superconductivity. Light-matter interaction can provide alternate pathways to initiate phase transitions via non-linear drive or by readjusting the energy landscape between competing order parameters. THz time domain spectroscopy is performed on stripe ordered La2-xBa_xCuO4 (x = 0.115) to monitor the c-axis Josephson Plasma Resonance (JPR), which acts a direct probe of the superconducting dynamics following near-infrared excitation. After photo-excitation of the superconducting state with 1.55 eV pulses, we observe the emergence of a new long lived metastable state which displays a blue shifted plasma edge. This new phase is suggestive of enhanced c-axis transport not observed in equilibrium and has implications for superconducting fluctuations appearing above Tc in the charge ordered state. We also investigate the mechanism for how the electronic transition at 1.55 eV couples to c-axis vibrational modes which may aid in the superconducting fluctuations above Tc.

consistent with the results at Cu

ALEXEI E KOSHELEV, ULRICH WELP, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory, KAZUO

implications for THz mesa source engineering.

We find that the optimal sidewall angle varies dramatically depending on the above parameters, and we discuss its sidewall angle as a function of device geometry, doping state, emission frequency, and intended operating temperature.

The drive voltage spread can be minimized by the correct choice of mesa sidewall angle. Here we calculate the optimal CO wave vector at O K-edge is consistent with the results at Cu L3-edge. Remarkably, the correlation length of CO at O K-edge is found to be longer than that from Cu L3-edge for all measured edges, indicating a stronger charge modulation associated with O sites than Cu sites. Different from one recent report on the existence of CO in heavily over-doped region, no CO is detected at both edges in slightly over-doped sample (p=0.18).

1:15PM F08.00011: Self-heating, phase coherence, and sidewall angle in stacked intrinsic Josephson junction Bi2Sr2CaCu2O8 terahertz sources

KAREN KIHSLSTROM (Presenter), TIMOTHY BENSEMAN, Physics, CUNY Queens College, ALEXEI E KOSHELEV, ULRICH WELP, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory, KAZUO KADOWAKI, Institute for Materials Science, University of Tsukuba — The extremely anisotropic high-temperature superconductor Bi2Sr2CaCu2O8 contains stacked ‘intrinsic’ Josephson junctions with a large superconducting gap energy. Mesa-shaped devices constructed from this material are therefore a promising source of coherent, continuous-wave radiation in the ‘terahertz gap’ range.

To optimize the THz emission power and linewidth performance of these devices, it is essential to create a phase-coherent state among the stacked IJJs. This in turn requires minimizing the spread in their drive voltages, which is far from trivial when the IJJs are current-biased and shunted in series. This is further complicated by self-heating in the mesa, due to the poor c-axis thermal conductivity of Bi2Sr2CaCu2O8.

The drive voltage spread can be minimized by the correct choice of mesa sidewall angle. Here we calculate the optimal sidewall angle as a function of device geometry, doping state, emission frequency, and intended operating temperature. We find that the optimal sidewall angle varies dramatically depending on the above parameters, and we discuss its implications for THz mesa source engineering.

1:27PM F08.00012: Evolution of charge order topology across a magnetic quantum phase transition in electron-doped cuprates

MIN GU KANG (Presenter), JONATHAN PELLICARI, Massachusetts Institute of Technology, ALEX FRANO, NICHOLAS BREZNAY, Physics, University of California, Berkeley, ENRICO SCHIERLE, EUGEN WESCHKE, BESSY, Helmholtz-Zentrum Berlin, RONNY SUTARTO, FEIZHOU HE, Canadian Light Source, PADRAIC SHAFER, ELKE ARENHOLZ, Advanced Light Source, MO CHEN, KETO ZHANG, ALEJANDRO RUIZ, ZEYU HAO, SYLVIA LEWIN, JAMES G. ANALYTIS, Physics, University of California, Berkeley, YOSHIIHARU KROCKENBERGER, HIDEKI YAMAMOTO, NTT Basic Research Laboratories, TANMOY DAS, Physics, Indian Institute of Science, RICCARDO COMIN, Massachusetts Institute of Technology — Charge order is now accepted as an integral constituent of the phase diagram of cuprate high-temperature superconductors. Unlike nesting-induced Peierls density waves, the charge correlations in the CuO2 planes have been predicted to display a rich momentum space topology depending on the detailed fermiology of the system. However, to date charge order has only been observed along the high-symmetry Cu-O bond directions. Here, using resonant soft X-ray scattering, we investigate the evolution of the full momentum space topology of charge correlations in 7T-Ln2CuO4 (Ln=Nd, Pr) as a function of intrinsic electron doping. We report that, upon electron doping the parent Mott insulator, charge correlations first emerge in a hitherto-unobserved form, with full (C4v) rotational symmetry in momentum-space. At higher doping levels, the orientation of charge correlations is sharply locked to the Cu-O bond high-symmetry directions, restoring a more conventional bidirectional charge order with enhanced correlation lengths. Our charge susceptibility calculations closely reproduce the drastic evolution in the topology of charge correlations across an antiferromagnetic quantum phase transition, highlighting the interplay between spin and charge degrees of freedom in electron-doped cuprates.
1:39PM F08.00013: Study of radiation spectrum of Bi$_2$Sr$_2$CaCu$_2$O$_{8+d}$ high-\(T_c\) superconducting terahertz emitters.  
TAKANARI KASHIWAGI (Presenter), GENKI KUWANO, TAKAYUKI IMAI, SHUNGO NAKAGAWA, YUUKI TANABE, RYUSEI OTA, KENTO NAKAMURA, YUKINO ONO, YOUTA KANEKO, SHINJI KUSUNOSE, MANABU TSUJIMOTO, University of Tsukuba, TAKASHI YAMAMOTO, QuTech Delft University of Technology, HIDETOSHI MINAMI, University of Tsukuba, RICHARD KLEMM, University of Central Florida, KAZUO KADOWAKI, University of Tsukuba — In order to understand the emission characteristics of Bi$_2$Sr$_2$CaCu$_2$O$_{8+d}$ (Bi2212) high-\(T_c\) superconducting THz emitters, it is very important to clarify the Joule heating characteristics of the devices. Recently, in order to reduce the self-heating from the Bi2212-THz emitters, we have proposed a stand-alone mesa structure of Bi2212 single crystals and its sandwich structures. The radiation characteristics obtained from these devices indicate clearly that the thermal management of the THz emitters is most important issue in order to obtain good radiation performance and reproducibility. 
In order to understand the details of the radiation characteristics of above thermal managed Bi2212-THz emitters, we have studied not only radiation frequency characteristics but also radiation linewidth characteristics. We measured the radiation spectrum ranging from 0.6 to 0.9 THz by using a sub-harmonic mixer. The observed radiation linewidths at low bias conditions seem to be broader than those at high bias conditions. The radiation spectrum at lower bias point have several peaks, however, the radiation spectrum at high bias condition seems to be single peak. The details of the these radiation characteristics will be discussed.

1:51PM F08.00014: Optical perturbation of the "hole-pockets" in the underdoped high \(T_c\) superconducting cuprates* 
SIMON FREUTEL, Fakultät für Physik, Universität Duisburg-Essen, Duisburg, Germany, JONATHON RAMEAU, Brookhaven National Laboratory, LAURENZ RETTIG, ISABELLA AVIGO, MANUEL LIGGES, Fakultät für Physik, Universität Duisburg-Essen, Duisburg, Germany, YOSHIYUKI YOSHIDA, HIROSHI EISAKI, National Inst. Adv. Industrial Science & Technology, Tsukuba, JOHN A. SCHNEELOCH, RUIDAN ZHONG, ZHIJUN XU, GENDA GU, Brookhaven National Laboratory, UWE BOVENSIEPEN, Fakultät für Physik, Universität Duisburg-Essen, Duisburg, Germany, PETER JOHNSON (Presenter), Brookhaven National Laboratory — The high \(T_c\) superconducting cuprates are considered doped Mott insulators. As a function of doping and temperature there is a crossover from this regime into a phase characterized a Marginal Fermi Liquid. Several calculations of the doped Mott insulating phase indicate that the Fermi surface defines small pockets which at higher doping levels switch to a full closed Fermi surface, characteristic of a more metallic system. Here we use femtosecond laser based pump-probe techniques to investigate the structure of the Fermi surface in underdoped Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ and compare it with that associated with the optimally doped material. We confirm the concept of a small pocket in the underdoped system consistent with theoretical predictions in this strongly correlated state.

2:03PM F08.00015: Pressure tuning of competing orders and superconductivity in Bi$_2$Sr$_{1.6}$La$_{0.4}$CuO$_6$  
JIWEI HU, JIE XIN, XIAO-JIA CHEN (Presenter), Center for High-Pressure Science & Technology Advanced Research, VIKTOR V. STRUZHKIN, ALEXANDER GONCHAROV, Geophysical Laboratory, Carnegie Institution of Washington, HAI-QING LIN, Beijing Computational Science Research Center, CHENG-TIAN LIN, Max-Planck-Institut für Festkörperforschung — Systematic measurements of Raman scattering and magnetic susceptibility are performed on an optimally doped Bi$_2$Sr$_{1.6}$La$_{0.4}$CuO$_6$ with well characterized change density wave and pesudogap. A pressure-temperature phase diagram is obtained for this superconductor. The superconducting transition temperature \(T_c\) is found to initially increase with increasing pressure and then decreases upon heavy compression after passing a maximum at a critical pressure of 15 GPa. Meanwhile, either the charge-density-wave or the pesudogap is suppressed by the applied pressure with the disappearance of their lock-in or opening temperature at the critical pressure. The significant \(T_c\) enhancement in the low-pressure region benefits from the suppression of the competing orders. The phonon frequency of the oxygen atoms in the charge reservoir is observed to be closely correlated to the evolution of \(T_c\) with pressure. Meanwhile, the emergence of the charge disorder and its growth with pressure are detected after the critical pressure, indicating its unfavorable role to superconductivity. A complete picture for superconductivity with the competing orders, reservoir layer, and charge disorder for a cuprate superconductor is thus established.

Session F09 DCMP: Superconductivity in Graphene etc.
11:15AM F09.00001: Nematic superconductivity stabilized by density wave fluctuations: Application to twisted bilayer graphene

VLADYSLAV KOZII (Presenter), HIROKI ISOBE, Massachusetts Institute of Technology, JORN VENDERBOS, Department of Physics and Astronomy, University of Pennsylvania, LIANG FU, Massachusetts Institute of Technology — Nematic superconductors possess unconventional superconducting order parameters that spontaneously break rotational symmetry of the underlying crystal. In this work we propose a mechanism for nematic superconductivity stabilized by strong density wave fluctuations in two dimensions. While the weak-coupling theory finds the fully gapped chiral state to be energetically stable, we show that strong density wave fluctuations result in an additional contribution to the free energy of a superconductor with multicomponent order parameters, which generally favors nematic superconductivity. Our theory shades light on the recent observation of rotational symmetry breaking in the superconducting state of twisted bilayer graphene.

11:27AM F09.00002: Antiferromagnetically ordered Mott insulator and d + id superconductivity in twisted bilayer graphene: A quantum Monte Carlo study

TONGYUN HUANG (Presenter), LUFENG ZHANG, TIANXING MA, Beijing Normal University — Using exact quantum Monte Carlo method, we examine the recent novel electronic states seen in magic-angle graphene superlattices. From the Hubbard model on a double-layer honeycomb lattice with a rotation angle \( \theta = 1.08^{\circ} \), we reveal that an antiferromagnetically ordered Mott insulator emerges beyond a critical \( U_c \) at half filling, and with a small doping, the pairing with \( d+id \) symmetry dominates over other pairings at low temperature. The effective \( d+id \) pairing interaction strongly increase as the on-site Coulomb interaction increases, indicating that the superconductivity is driven by electron electron correlation. Our non-biased numerical results demonstrate that the twisted bilayer graphene share the similar superconducting mechanism of high temperature superconductors, which is a new and ideal platform for further investigating the strongly correlated phenomena.

11:39AM F09.00003: Possible superconductivity through the magnetic exchange in transition-metal intercalated bilayer graphene

KEVIN LUCHT, Department of Physics, Florida State University, ADITI D MAHABIR (Presenter), ALEXANDRIA ALCANTARA, Department of Physics, University of North Florida, ALEXANDER BALATSKY, Los Alamos National Laboratory, Institute for Materials Science, JOSE L. MENDOZA-CORTES, Department of Physics, Florida State University, JASON HARALDSEN, Department of Physics, University of North Florida — This study examines the possibility of superconductivity in transition-metal intercalated bilayer graphene. Using density functional theory, we determine electronic and magnetic properties through the electronic structure and density of states for all ten 3d transition-metal elements in a honeycomb configuration between two layers of graphene. Through an analysis of the electron density, we assess the induction of the magnetic moment in each case, where we estimate the exchange coupling through a comparison of the ferromagnetic and antiferromagnetic configurations. Furthermore, we show that the electronic band structure of the transition-metal intercalated layers have similar characteristics to those graphene layers intercalated with alkali and alkaline-earth metals, where superconductivity has been observed. Using a similar analysis, we find that the carbon \( \pi \) bands are below the Fermi, which is a possible indicator of superconductivity. More interestingly, the \( \pi \) bands seem to be degenerate to the transition-metal \( d \) bands, which could indicate hybridization and may lead to unconventional superconductivity.

*Energy and Materials Initiative, High-Performance Computer cluster at Florida State University. Institute for Materials Science at Los Alamos National Laboratory
11:51AM F09.00004: Pairing symmetry and spontaneous vortex-antivortex lattice in superconducting twisted bilayer graphene: A Bogoliubov-de Gennes approach*  SHIZENG LIN (Presenter), YING SU, Los Alamos National Laboratory — We study the superconducting pairing symmetry in twisted bilayer graphene by solving the Bogoliubov-de Gennes equation for all electrons in Moiré supercells. With increasing the pairing potential, the system evolves from the mixed non-topological $d + id$ and $p + ip$ phase to the $s + p + d$ phase via the first order phase transition. In the time-reversal symmetry breaking $d + id$ and $p + ip$ phase, vortex and antivortex lattice accompanying spontaneous supercurrent are induced by the twist. The superconducting order parameter is nonuniform in the Moiré unit cell. Nevertheless, the superconducting gap in the local density of states is identical in the unit cell. The twist induced vortices and non-topological nature of the mixed $d + id$ and $p + ip$ phase are not captured by the existing effective models. Our results suggest the importance of long-range pairing interaction for effective models.

This work was carried out under the auspices of the U.S. DOE Award No. DE-AC52-06NA25396 through the LDRD program, and was supported by the Center for Nonlinear Studies at LANL and the U.S. DOE Office of Basic Energy Sciences Program E3B5 (S.-Z. L.).

12:03PM F09.00005: Quantum Monte Carlo Study of Metal-Insulator Transitions on the Honeycomb Lattice  JINGYAO WANG (Presenter), TIANXING MA, Beijing Normal University — We investigate the band insulator-metal-Mott insulator transitions in the ionic Hubbard model on the 12*12 honeycomb lattice at half filling using determinant quantum Monte Carlo method. The phase diagram as a function of interaction U and staggered potential Δ indicates that the metallic state develops only if the interaction value varies in a moderate range. The Mott insulator state is antiferromagnetic. The conductivity decreases as the lattice size increases in metallic phase. A qualitative contrast to results obtained using the dynamical mean field theory is made at the end.

12:15PM F09.00006: Carbon-nanotube based highly flexible superconducting wire*  JEONG-GYUN KIM (Presenter), Sungkyunkwan University, HAEYONG KANG, Pusan University, DONGSEOK SUH, Sungkyunkwan University — In this work, we explored the feasibility of new fabrication of superconducting wire by using carbon nanotube (CNT) based yarn combined with superconducting materials. CNT yarn has been extensively studied due to its various outstanding mechanical properties. And it also could show multifunctional characteristics by combining with various guest materials. Here, we used a sputter-deposition process for niobium nitride (NbN) to make superconducting yarn. It shows superconducting property that is not much different from NbN film. And also we showed the superior mechanical flexibility of the sample by performing as knot tying and bending. In addition, we tested to reduce the resistance in the normal state for the practical necessity such as superconducting cable application.

*Center for Integrated Nanostructure Physics (CINAP), Institute for Basic Science (IBS), Department of Energy Science, Sungkyunkwan University, Suwon 16419, Korea.

12:27PM F09.00007: Theory of insulating phase and superconductivity in twisted bilayer graphene*  XINGYU GU (Presenter), EVAN LAKSONO, CHUAN CHEN, JIA NING LEAW, NIMISHA RAGHUJUVANSHI, SHAFFIQUE ADAM, Department of Physics, National University of Singapore — A correlated insulating phase and superconductivity have been recently observed in twisted bilayer graphene (tBG). We study theoretically these two phases in both the weak and strong coupling limit. We study theoretically these two phases in both the weak and strong coupling limit. In the weak coupling limit, using the random phase approximation, we find various possible combinations of density wave phases and pairing symmetries [1]. In the strong coupling limit, the insulating phase is anti-ferromagnetically (AFM) ordered, like in monolayer graphene [2]. However, we find there is no local magnetic moment in this AFM phase due to the special form of Wannier functions. Using the spin-fermion model, we find attractive electron-electron interaction mediated by the critical AFM fluctuations. This attractive interaction leads to chiral $d + id$ superconductivity. Using a finite size tight-binding model, we show explicitly the existence of edge Majorana modes.

12:39PM F09.00008: Competing pairing propensities in twisted bilayer graphene

XIANXIN WU (Presenter), MARIO FINK, MICHAEL KLETT, Institut für Theoretische Physik und Astrophysik, Julius-Maximilians-Universität Würzburg, TIM WEHLING, Institute for Theoretical Physics, Bremen Center for Computational Material Science, University of Bremen, WERNER R HANKE, RONNY THOMALE, Institut für Theoretische Physik und Astrophysik, Julius-Maximilians-Universität Würzburg — We employ a synopsis of random phase approximation (RPA) and functional renormalization group (fRG) to investigate twisted bilayer graphene based on a two-orbital effective model on the honeycomb lattice. Exploiting the ability of N-patch fRG to resolve the harmonic composition of a given superconducting instability channel, we develop a detailed profile of electronically mediated unconventional superconducting instabilities in twisted bilayer graphene, and highlight experimental signatures to distinguish between the resulting possible scenarios.

12:51PM F09.00009: Magnetic and superconducting correlation in monolayer and twisted-bilayer graphene

TIANXING MA (Presenter), TONGYUN HUANG, LUFENG ZHANG, Beijing Normal University — Using exact quantum Monte Carlo method, we identify the phase diagram of the half filled, the lightly doped and heavily doped graphene, which shows a rather rich physical properties. At half filling, the system is driven to a Mott insulator with antiferromagnetic long range order by increasing interaction, and a transition from a d+id pairing to a p+ip pairing is revealed, depends on the next-nearest hoping and the electronic fillings. We also examine the recent novel electronic states seen in magic-angle graphene superlattices. From the Hubbard model on a double-layer honeycomb lattice with a rotation angle θ=1.08, we reveal that an antiferromagnetically ordered Mott insulator emerges beyond a critical U c at half filling, and with a small doping, the pairing with d+id symmetry dominates over other pairings at low temperature. The effective d+id pairing interaction strongly increase as the on-site Coulomb interaction increases, indicating that the superconductivity is driven by electron-electron correlation. Our non-biased numerical results demonstrate that the twisted bilayer graphene is a new and idea platform for further investigating the strongly correlated phenomena.

1:03PM F09.00010: Strain induced superconducting pair-density-wave states in graphene

CHUNG-YU MOU (Presenter), Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, FENG XU, School of Physics and Telecommunication Engineering, Shaanxi University of technology, Hanzhong, China, CHUNG-HOU CHUNG, Electrophysics Department, National Chiao-Tung University, Taiwan, TING-KUO LEE, Institute of Physics, Academia Sinica, Taiwan — Graphene is known to be non-superconducting. However, surprising superconductivity is recently discovered in a flat-band in a twisted bi-layer graphene. Here we show that superconductivity can be more easily realized in topological flat-bands induced by strain in graphene through periodic ripples. Specifically, it is shown that by including correlation effects, the chiral d-wave superconductivity can be stabilized under strain even for slightly doped graphene. The chiral d-wave superconductivity generally coexists with charge density waves (CDW) and pair density waves (PDW) of the same period. Remarkably, a pure PDW state with doubled period that coexists with the CDW state is found to emerge at a finite temperature region under reasonable strain strength. The emergent PDW state is shown to be superconducting with non-vanishing superfluid density, and it realizes the long searched superconducting states with non-vanishing center of mass momentum for Cooper pairs.

1:15PM F09.00011: Effective model for Majorana modes in graphene

ANTONIO MANESCO (Presenter), DURVAL RODRIGUES JUNIOR, GABRIEL WEBER, University of Sao Paulo — It was recently proposed that the interface between a graphene nanoribbon in the canted antiferromagnetic quantum Hall state and an s-wave superconductor may present topological superconductivity, resulting in the appearance of Majorana zero modes [1]. However, a description of the low-energy physics in terms of system parameters was still missing. Starting from a mean-field continuum model for graphene in proximity to a superconductor, we derive the low-energy effective Hamiltonian describing the interface of this heterojunction from first principles. A comparison between tight-binding simulations and analytical calculations with effective masses suggests that normal reflections at the interface must be considered in order to fully describe the low-energy physics.

*The work of ALRM was supported by FAPESP grant No. 2016/10167-8. DRJ is a CNPq researcher.
Bulk supercurrent at high magnetic field in Graphene Josephson junctions  
RUOYU CHEN (Presenter), YULU LIU, Ohio State University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, CHUN NING LAU, Ohio State University — Benefitted from its high mobility and gate-tunability, graphene could serve as an ideal platform hosting many innovative devices. Introducing superconductivity into graphene via proximity provides a path to complicated or large-scale graphene-based superconducting devices/circuits, and the combination of quantum Hall edge states and superconductivity may host Majorana Fermions which allows Fault-tolerant quantum computing. Here we report our efforts fabricating hBN-encapsulated graphene Josephson junctions in various geometries. While small supercurrent hosted by quantum Hall edge states has been reported in graphene before, we observed gate-tunable bulk supercurrent at moderate charge densities and magnetic fields up to 3 T. Latest data and comparison with theoretical models will be presented.

Andreev reflection in Graphene–superconductor junctions in the quantum Hall regime*  
JOSEPH CUOZZO (Presenter), STUART THOMAS, XIANG HU, ENRICO ROSSI, Physics, William & Mary — We investigate the Andreev reflection at an interface between a graphene layer in the quantum Hall regime and a superconductor. In graphene due to the spin and valley degrees of freedom there is an approximate SU(4) symmetry. The breaking of this symmetry due to interactions and the Zeeman effect leads to a splitting of the Landau levels. In this talk I will discuss the effect on the Andreev reflection of the breaking of the Landau levels' spin and valley degeneracy. I will then show results for the Andreev reflection amplitude, and the Andreev reflection contribution to the interface conductance, for various degrees of transparency of the interface.

SEBASTIAN BERGERET, Centro de Fisica de Materiales, CSIC-UPV/EHU, San Sebastian, Spain, JAVIER VILLEGAS (Presenter), Unite Mixte de Physique, CNRS, Thales, Univ. Paris-Sud, Université Paris Saclay, Palaiseau, France — Proximity-induced superconductivity is particularly interesting in graphene. Among other reasons, because that effect can be externally controlled by tuning the Fermi energy (and vector) via electrical gating. For example, using high-temperature superconducting YBa2Cu3O7/graphene planar junctions, we recently demonstrated [1] gate-controlled superconducting electron interferences that allow modulating the Andreev reflection at the superconductor/graphene interface via Klein tunneling of electron/hole pairs. Here we will discuss new experiments in the same type of junctions, in which a different type of interferences –this time controlled by the bias voltage– are observed which are due to geometrical resonances and coherent propagation of electron/hole pairs across a graphene channel. This is substantiated by the relationship of the oscillations period and the graphene channel length (up to hundreds on nm), as well as by numerical simulations of the device conductance -which reproduce both the observed resonances and the background conductance. Session F10 DMP GMAG: Fe-based Superconductors -- Magnetic properties  
BCEC 151B · Minjun Lee, Seoul National University
11:15AM F10.00001: Hedgehog spin-vortex crystal antiferromagnetic quantum criticality in \( \text{CaK(Fe}_{1-x}\text{Ni}_x\text{)}_4\text{As}_4 \) revealed by NMR

QING-PING DING (Presenter), WILLIAM MEIER, Ames Laboratory and Dept. of Phys. and Astro., Iowa State Univ., JINFANG CUI, Ames Laboratory and Dept. of Chem., Iowa State Univ., MINGYU XU, ANNA BOEHMER, SERGEY BUDKO, PAUL CANFIELD, YUJI FURUKAWA, Ames Laboratory and Dept. of Phys. and Astro., Iowa State Univ. — Two degrees of freedom, antiferromagnetism and nematicity, have been observed in most iron-based superconductors (SCs). In contrast to those compounds, the newly discovered SC \( \text{CaK(Fe}_{1-x}\text{Ni}_x\text{)}_4\text{As}_4 \) exhibits an antiferromagnetic (AFM) state, called hedgehog spin-vortex crystal (SVC) structure, without the orthorhombic distortion [1,2]. This system provides an opportunity to investigate the relationship between magnetic fluctuation and SC in a system that remains tetragonal. Here, we report an \(^{75}\text{As} \) nuclear magnetic resonance (NMR) study of \( \text{CaK(Fe}_{1-x}\text{Ni}_x\text{)}_4\text{As}_4 \) (0 \( \leq x \leq 0.049 \)). We will show the experimental evidence which suggests that, based on NMR data [3], a hedgehog SVC quantum-critical point (QCP) would exist around \( x = 0 \) in the normal state, but is avoided due to the onset of superconductivity. We will discuss the relationship of spin fluctuations and superconductivity in this system. Furthermore, the advantage of \( \text{CaKFe}_4\text{As}_4 \) over other iron-based SCs with QCP will also be discussed.

11:27AM F10.00002: Unusually stronger quantum fluctuation with larger spins: Novel phenomena revealed by emergent magnetism in pressurized high-temperature superconductor FeSe

WEI KU (Presenter), Tsung-Dao Lee Institute, YUTING TAN, School of Physics, Sun Yat-sen University, TIANYU ZHANG, School of Physics and Astronomy, Shanghai Jiao Tong University, TAO ZOU, Department of Physics and Astronomy, Michigan State University, ANTONIO M. DOS SANTOS, Quantum Condensed Matter Division, Oak Ridge National Laboratory, JIN HU, Department of Physics and Engineering Physics, Tulane University, DAO-XIN YAO, School of Physics, Sun Yat-sen University, ZHIQIANG MAO, Department of Physics and Engineering Physics, Tulane University, XIANGLIN KE, Department of Physics and Astronomy, Michigan State University — A counter-intuitive enhancement of quantum fluctuation with larger spins, together with a few novel physical phenomena, is discovered in studying the recently observed emergent magnetism in high-temperature superconductor FeSe under pressure. Starting with experimental crystalline structure from our high-pressure X-ray refinement, we analyze theoretically the stability of the magnetically ordered state with a realistic spin-fermion model. We find surprisingly that in comparison with the magnetically ordered Fe-pnictides, the larger spins in FeSe suffer even stronger long-range quantum fluctuation that diminishes their ordering at ambient pressure. This “fail-to-order” state then develops into an ordered state above 1GPa due to weakened fluctuation accompanying the reduction of anion height and carrier density. We further clarify the controversial nature of magnetism and its interplay with nematicity in FeSe in the same unified picture for all Fe-based superconductors. Our study establishes a generic exceptional paradigm of stronger quantum fluctuation with larger spins that complements the standard knowledge of insulating magnetism.

11:39AM F10.00003: Tuning the Magnetic and Superconducting Properties of Hole Doped BaFe\(_2\)As\(_2\): A Universal Scaled Phase Diagram

OMAR CHMAISSEM (Presenter), RYAN STADEL, Northern Illinois University, DANIEL BUGARIS, RAYMOND OSBORN, STEPHAN ROSENKRANZ, Argonne National Laboratory — Embarking on an extensive effort in which more than fifty hole-doped BaFe\(_2\)As\(_2\) samples have been produced and characterized by neutron diffraction allowed us to extract universal behaviors and properties of this rich system. All the measured magnetic and superconducting transitions values collapse into a single phase diagram. Strontium, calcium, and sodium substitutions at the barium site enabled the production of many samples in which both the re-entrant tetragonal double-Q magnetic C\(_4\) and the orthorhombic SDW magnetic C\(_2\) phases coexist and compete with superconductivity just before reaching the peak of the superconductivity-only region of the phase diagram. The evolution of \( T_N, T_c \) and the internal structural parameters are in agreement with recent theoretical models that correlate the stability of these observed phases with approaching a perfect tetrahedral FeAs\(_4\) angle and perfect Fermi surface nesting. Our results separate the individual roles played by either the As-Fe-As bond angles or the Fe-As bond lengths and demonstrate their combined effects in tuning the magnetic and superconducting properties.

11:51AM F10.00004: Possible multiple modes of neutron spin resonance in Ba$_{1-x}$K$_x$Fe$_2$As$_2$ and BaFe$_{2-x}$Ni$_x$As$_2^*$

HUIQIAN LUO, TAO XIE, SHILIANG LI, Institute of Physics, Chinese Academy of Sciences, UWE STUHR, TOM FENNELL, Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institute, SERGEY DANILKIN (Presenter), Australian Centre for Neutron Scattering, Australian Nuclear Science and Technology Organization — Motivated by the triple modes of neutron spin resonance with both odd and even L-symmetries in CaKFe$_4$As$_4$[1], we use inelastic neutron scattering to re-investigate the spin resonance in 122 system of iron-based superconductors. In the optimally hole doped Ba$_{1-x}$K$_x$Fe$_2$As$_2$, the spin resonance has very weak L-dependence both for intensity and center energy, while the H-dependence show a combination with an incommensurate mode at high energy and a commensurate mode at low energy. In the optimally electron doped BaFe$_{2-x}$Ni$_x$As$_2$, the spin resonance becomes L-dependent at low energy. A very weak even mode (L=2, 4, 6...) probably exist around 14 meV. Therefore, in contrast to the explanation based on weak L-dispersion on single spin resonance mode, we propose an alternative explanation based on the multiply Fermi surface nesting induced multi-modes with different symmetries, which give Q-dependent intensity either for out-of-plane or in-plane spin excitations.

12:03PM F10.00005: Multiple Distinct Magnetic and Superconducting Phases in LaFeAs$_{1-x}$P$_x$O 1111 Characterized Via X-ray and Neutron Diffraction*

RYAN STADEL (Presenter), Northern Illinois University, MATTHEW KROGSTAD, STEPHAN ROSENKRANZ, RAYMOND OSBORN, Materials Science Division, Argonne National Laboratory, KEITH TADDEI, HFIR, Oak Ridge National Laboratory, DMITRY KHALYAVIN, ISIS, Rutherford Appleton Laboratory, JINKE BAO, DUCK YOUNG CHUNG, Materials Science Division, Argonne National Laboratory, OMAR CHMAISSEM, Northern Illinois University — Following the discovery of the microscopic co-existence of antiferromagnetic spin density waves and superconductivity in Ba$_{1-x}$K$_x$Fe$_2$As$_2$ and the low temperature structural re-entrance to the novel magnetic C$_4$ tetragonal phase in Ba$_{1-x}$Na$_x$Fe$_2$As$_2$, an effort was made to seek similar phases in the related LaFeAs$_{1-x}$P$_x$O 1111 system. Previous work had reported two superconducting domes as well as two distinct magnetic regions. While the low doping magnetic phase had been well characterized by neutron diffraction, the higher doped magnetic region had been deduced from short range $^{31}$P-NMR measurements. We present a detailed characterization of the nuclear and magnetic structures based on high resolution and high intensity x-ray and neutron powder and single crystal diffraction. Our work demonstrates distinct magnetic symmetries for the two magnetic regions of the phase diagram.

*Work at the Materials Science Division at Argonne National Laboratory was supported by the US Department of Energy, Office of Science, Materials Sciences and Engineering Division.

12:15PM F10.00006: Anisotropic spin excitations in detwinned parent iron pnictides

QIMIAO SI (Presenter), Rice University, CHANGLE LIU, Fudan University, XINGYE LU, Beijing Normal University, PENGCHENG DAI, Rice University, RONG YU, Renmin University of China — Motivated by recent inelastic neutron scattering measurement on the fully detwinned BaFe$_2$As$_2$, we study the spin excitations of a local-moment model in the (π,0) collinear antiferromagnetically ordered phase. We show that the spin quadrupole modes can provide significant contributions to the spin excitation spectrum at high energies, and demonstrate this effect in an S=1 frustrated spin model with bilinear-biquadratic interactions using a flavor wave approach in an SU(3) representation. As a combined effect of the magnons and quadrupole modes, the spin excitation anisotropy drops with increasing energy. Our results are in good agreement with the salient features of the experimental observation.
12:27PM F10.00007: Breaking of four-fold rotational symmetry driven by stripe-type magnetism in semiconducting KFe$_{0.8}$Ag$_{1.2}$Te$_2$  
YU SONG (Presenter), University of California, Berkeley, HUIBO CAO, BRYAN C. CHAKOUMAKOS, Oak Ridge National Laboratory, YANG ZHAO, NIST Center for Neutron Research, National Institute of Standards and Technology, AIFENG WANG, HECHANG LEI, CEDOMIR PETROVIC, Brookhaven National Laboratory, ROBERT J BIRGENEAU, University of California, Berkeley — Superconductivity in the iron pnictides and chalcogenides emerges in the vicinity of an electronic nematic state, whose driving force remains controversial. We use X-ray and neutron scattering to study the semiconducting alkaline metal iron chalcogenide KFe$_{0.8}$Ag$_{1.2}$Te$_2$, that is structurally analogous to the prototypical iron pnictide BaFe$_2$As$_2$. We find that KFe$_{0.8}$Ag$_{1.2}$Te$_2$ realizes isolated 2x2 Fe blocks, separated by nonmagnetic Ag atoms. Long-range magnetic order sets in below $T_N = 35$ K, with magnetic moments within each Fe block ordering into a stripe-type configuration. A structural transition that breaks four-fold rotational symmetry of the lattice accompanies the magnetic transition, resulting in different lattice spacings along the two orthogonal Fe-Fe bond directions. This difference in lattice spacings is similar to that in BaFe$_2$As$_2$ in magnitude, and like BaFe$_2$As$_2$, the lattice spacing is longer along the antiferromagnetically aligned Fe-Fe direction. Since KFe$_{0.8}$Ag$_{1.2}$Te$_2$ is a semiconductor, local-moment magnetism is likely responsible for driving the breaking of four-fold rotational symmetry, and similar magnetic interactions may play an important role in the superconducting alkaline metal iron chalcogenides.

12:39PM F10.00008: Study of the pressure on magnetism in spin-ladder superconductor BaFe$_2$Se$_3$  
SHAN WU (Presenter), ROBERT J BIRGENEAU, University of California, Berkeley, JUNJIE YIN, MENG WANG, Sun Yat-Sen University, BENJAMIN FRANDSEN, Brigham Young University, TOM FORREST, Diamond light source, CRAIG L. BULL, NICK FUNNELL, ISIS Facility, Rutherford Appleton Laboratory, GEDIMINAS SIMUTIS, RUSTEM KHASANOV, Paul Scherrer Institute, THOMAS SMART, University of California, Berkeley, MARTIN KUNZ, ANDREW DORAN, Advanced Light Source, Lawrence Berkeley — Magnetic fluctuations were proposed as important for the pairing glue to the unconventional superconductivity (SC). The proximity of an antiferromagnetic (AFM) ordered has been found ubiquitously, with the majority of the iron-based superconductors exhibiting the same two-dimensional square lattice structural motif. Optimal SC typically appears when the magnetic order is suppressed by applying pressure or doping carriers. Pressure-induced SC in the BaFe$_2$X$_3$ (X=Se,S) introduces a quasi-one-dimensional prototype for the studies of the unconventional SC\cite{1,2}. BaFe$_2$Se$_3$ shows a block-type AFM transition below $T_N = 256$ K. By applying pressure, the Mott insulating state is gradually suppressed and displays a SC dome above 10 Gpa similar to the BaFe$_2$S$_3$. In this talk, I will present a systematic study of the magnetic and structural properties under hydrostatic pressure in BaFe$_2$Se$_3$ using neutron diffraction, x-ray diffraction and muon spin relaxation techniques. These provide the information on how the magnetic phase evolves approaching the SC and compares to the case of BaFe$_2$S$_3$. \cite{1}H. Takahashi,et al.,Nat. Mater.(2018).\cite{2}J. Ying,et al.,PRB (2017).

12:51PM F10.00009: Quantum critical point in Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ from London penetration depth measured by optical NV magnetometer  
KAMAL JOSHI (Presenter), NAUFER M NUSRAN, KYUIL CHO, MAKARIY TANATAR, SERGEY L. BUD'KO, PAUL CANFIELD, Ames Laboratory and Iowa State University, Ames, IA, USA, ALEX LEVCHENKO, University of Wisconsin, Madison, WI, USA, RUSLAN PROZOROV, Ames Laboratory and Iowa State University, Ames, IA, USA — Lower critical field, $H_{c1}$, allows direct access to London penetration depth, $\lambda$, which provides an insight into the normal-state electronic properties inside the dome of superconductivity in temperature-doping phase diagram. Using recently developed minimally invasive optical NV-centers magnetometry and the revised demagnetization corrections, $H_{c1}$ was measured in single crystals of electron-doped Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ for several $x$-values. The measurements reveal a sharp peak in $\lambda(x)$ near $x=0.057$, exactly the composition at which the long-range magnetic order becomes commensurate. Together with previous observation of quantum critical point (QCP) under the dome of superconductivity in isovalent AsP$_{122}$, our results provide strong evidence for a ubiquitous nature of QCP in iron pnictides at the disappearance of the long-range ordered magnetism at $T=0$.

*This work is funded by the U.S. DOE, Office of Basic Energy Sciences under Contract No. DE-AC02-05-CH11231

Effect of variable-energy electron irradiation on superconductivity in \(\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2\) crystals

KYUIL CHO (Presenter), MAKARIY A TANATAR, YONG LIU, THOMAS ANTONY LOGRASSO, RUSLAN PROZOROV, Ames Laboratory and Iowa state University, USA, MARCIN KONCZYKOWSKI, Ecole Polytechnique, Palaiseau, France — Point-like defects produced by MeV-range electron irradiation can be used as a phase-sensitive probe of the energy gap structure in superconductors. In complex compounds, the probability of knocking out an ion from a particular lattice site depends on the type of the ion and the incoming electron energy. Here we examine the effect of irradiation on superconducting \(T_c\) and electrical resistivity of in \(\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2\) single crystals using electrons of different energies, from 1.0 MeV to 2.5 MeV. From the resistivity measurements in-situ (during irradiation) and ex-situ (in a separate cryostat), the relation between the changes in \(T_c\) and residual resistivity as a function of electron energy was determined. The results will be discussed in a broader context of the connection between particular crystal structure and superconductivity.

*Work at the Ames Laboratory was supported by the Department of Energy- Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

Mapping the superfluid density in an Iron-based Superconductor

DOOHEE CHO (Presenter), KOEN BASTIAANS, DAMIANOS CHATZOPoulos, Leiden University, GENDA GU, Brookhaven National Laboratory, MILAN P ALLAN, Leiden University — Cooper pairs can tunnel through the vacuum barrier between two superconducting electrodes, known as a Josephson junction. Depending on the properties of the junction and the environment, one can extract the superconducting order parameter from the current-voltage spectra. Here, I will present the Josephson tunneling spectroscopic results of an unconventional Fe-based superconductor acquired with a superconducting STM tip. We demonstrate the Josephson tunneling induced characteristic current-voltage curves close to zero bias on a Pb(111) surface and a Fe-based superconductor. I will discuss the spatial variations of the superfluid density in this correlated superconductor and reveal their correlation with an inhomogeneous quasiparticle density of states.

Tuesday, March 5, 2019 11:15 AM - 2:15 PM

Session F11 DMP DCOMP FIAP: Defects in Semiconductors -- Quantum Defects

High frequency electrometry and imaging with defects in silicon carbide

GARY WOLFOWICZ (Presenter), University of Chicago — Optically active defects in wide bandgap host materials are promising sensors of local properties such as magnetic fields, electric fields, temperature and mechanical strain [1]. While magnetometry has received considerable interest owing to the spin properties of these defects, electrometry and strain sensing have been significantly more challenging due to the weak sensitivity of the ground spin state.

Here we demonstrate that the charge state of defects in silicon carbide (SiC), including divacancies and silicon vacancies, can be used to sense high frequency (MHz – GHz) electric fields and acoustics [2]. Optical excitation can convert the defect from a bright (photoluminescent) charge state to a dark charge state, and vice-versa [3]. This conversion rate depends directly on local high frequency electric fields and mechanical strains, resulting in direct modulation of the photoluminescence intensity and enabling sensing protocols. We further develop methods for spectroscopy (phase and frequency resolution) and vector measurements.

We explore electric field and strain sensing using both this novel charge technique and spin measurements in various electromechanical devices. We map the electric fields from lithographically patterned capacitors and observe mechanical modes in a surface acoustic wave resonator and in clamped membranes. We obtain 3D spatial and high frequency information typically challenging to achieve with other sensing techniques. This demonstrates the potential of optically active defects for in-situ electrical and micromechanical systems characterization in commercial materials such as SiC.

11:51AM F11.00002: Optimizing Spin Readout of the Nitrogen-Vacancy Center in Diamond with Spin-to-Charge Conversion* DAVID HOPPER (Presenter), Physics, University of Pennsylvania, JOSEPH LAUIGAN, SADHANA MARIKUNTE, LEE BASSETT, Electrical and Systems Engineering, University of Pennsylvania — The nitrogen-vacancy center in diamond is a mature platform for quantum technology, enabling sophisticated quantum information protocols as well as versatile quantum sensors operating in previously unreachable size and field regimes. The standard photoluminescence-based spin readout is fast (300 ns) but typical measurements yield only a few hundredths of a photon on average, necessitating tens of thousands of repeats to overcome shot noise in detecting the spin state. Spin-to-charge conversion (SCC) offers an alternative readout with significantly improved single-shot information. However, this benefit comes at the expense of orders of magnitude longer readout durations. Here, we present a framework for optimizing the SCC readout parameters that leads to dramatic reductions in overall measurement acquisition times [1]. The improvements arise from the combination of an analytical charge readout model with numerical optimization of the overhead durations. We discuss relevant applications such as T1 relaxometry and control of nuclear registers and outline how other spin readout methods can benefit from this framework.

*This work was supported by NSF CAREER award EECS-1553511.

12:03PM F11.00003: Coupled defect centers for diamond quantum nodes* MAARTEN DEGEN (Presenter), SUZANNE VAN DAM, JOE RANDALL, ALETTA MEINSMA, RONALD HANSON, TIM HUGO TAMINIAU, Delft University of Technology — Nitrogen-vacancy (NV) defect centers in diamond are well-suited to realize quantum networks owing to a coherent spin ground state, nuclear quantum memories and an optical transition for remote entanglement. State-of-the-art experiments with single NV centers used 13C atoms as quantum memories to perform entanglement distillation and quantum error correction [Kalb et. al., Science, 2017, Cramer et al., Nat. Commun., 2015]. Such experiments involve an intrinsic trade-off: reducing the coupling to the NV center improves 13C quantum memories, but reduces gate speeds.

In this work, we aim to extend the possibilities of quantum networks by creating systems of two or more coupled defects centers in diamond. Such coupled defects, hold the promise to combine fast gates with well-isolated quantum nuclear memories. I will present recent progress towards this goal.

First, we realized a long coherence time, exceeding two seconds, of the host nitrogen spin of a single NV center, demonstrating its potential as a quantum memory. Second, I will discuss our recent progress using ion implantation and other techniques to realize coupled defects.

*We thank the NanoFront joined program, the Kavli Institute of Nanoscience and NWO for their support.

12:15PM F11.00004: Linewidth of NV-detected Electron Spin Resonance* BENJAMIN FORTMAN (Presenter), SUSUMU TAKAHASHI, University of Southern California — A nitrogen-vacancy (NV) center in diamond possesses unique electronic, magnetic and quantum properties enabling magnetic field sensing through optically detected magnetic resonance (ODMR). Due to the extreme sensitivity of an NV center to magnetic fields, the NV is a promising candidate for applications of electron spin resonance (ESR) with single spin sensitivity. In addition to the sensitivity, ESR using a single NV has a significant advantage in spatial resolution of the detection volume over conventional ESR because of the nanometer sensing distance on single NV-detected ESR. In this presentation, we discuss the linewidth of NV-detected ESR. In the experiment, we study NV-detected ESR on substitutional nitrogen centers in diamond and identify components partially contributing to the linewidth. We also discuss differences of the ESR linewidth between conventional and NV-based detection.

12:27PM F11.00005: Ab-initio photoluminescence spectrum of NV⁻ centres by Time-Dependent Density Functional Theory  
AKIB KARIM (Presenter), Quantum Photonics Laboratory, RMIT University, IGOR LYSKOV, SALVY P. RUSSO, ARC Centre of Excellence in Exciton Science, RMIT University, ALBERTO PERUZZO, Quantum Photonics Laboratory, RMIT University — Quantum information and communication require single photons on demand, however current state of the art emitters are probabilistic. Defect centres in nanomaterials have shown promise as deterministic single photon sources. To investigate these materials, first principle models are required. Purely Density Functional Theory (DFT) models have met with much success, however, DFT is a ground state theory and excited states can only be calculated under strict assumptions. Here we demonstrate a method to calculate the ab-initio photoluminescence spectrum for NV⁻ centres using Time-Dependent Density Functional Theory (TD-DFT). Ground state properties are calculated using DFT. Excited state energies and transition dipole moments are calculated with Linear Response TD-DFT. Excited vibrational modes are given as normal modes the TD-DFT energy second derivatives. The emission rate is calculated from the transition dipole moment and Franck-Condon overlaps. Our technique can be extended to more general defects and is especially useful for edge effects like with small clusters or defects with Jahn-Teller distortions. The ability to recreate experimental photoluminescence spectra marks a step forward in understanding and controlling single photon emission for defect emitters.

12:39PM F11.00006: Simulation Driven Search for Promising Quantum Defects in Diamond  
ISAAC HARRIS (Presenter), EECS, MIT, CHRISTOPHER CICCARINO, BLAKE DUSCHATKO, SEAS, Harvard University, DIRK R. ENGLUND, EECS, MIT, PRINEHA NARANG, SEAS, Harvard University — Current research into quantum memories in diamond has mainly focused on the NV⁻ and SiV⁻ color centers, however both of these have clear limitations in spectral efficiency and spin coherence, respectively. More recent work has characterised the new group-IV centers GeV⁻, SnV⁻ and PbV⁻, as well as the neutral SiV, though other as yet unstudied defects in diamond are also possible. To efficiently screen these new defects, we use first-principles density-functional theory to predict important defect properties, including orbital structure, structural and charge stability, as well as vibrational effects on the emission profile. Promising defects are also investigated for possible Jahn-Teller distortions, and we discuss these implications. Overall, our results provide a roadmap toward the discovery of novel centers for quantum information.

12:51PM F11.00007: Optimizing the Production of Single Group IV Color Centers in Diamond*  
RODRICK KUATE DEFO (Presenter), EFTHIMIOS KAXIRAS, Harvard University, STEVEN L RICHARDSON, Howard University, Harvard University — The excitement of color centers, like the NV vacancy center in diamond, has been motivated by their use as single-photon emitters for applications in quantum information technology. Recent work has shown that a number of color centers in diamond using other Group IV elements (e.g. SiV, GeV, SnV and PbV)¹ may also be good candidates for quantum emitters. In this work we use density-functional theory (DFT) to study the thermodynamics and kinetics of these Group IV color centers in diamond. We find that for p-type diamond the production of isolated color centers will be enhanced. We further investigate the stability of complexes of these Group IV color centers in diamond with carbon vacancies which are present in diamond in abundance after implantation. We believe that this work may lead to optimal experimental conditions which lead to longer coherence times for color centers as previously discussed in the literature.²

*We are grateful for financial support from the NSF DMR-1231319, the Harvard Physics Graduate Prize Fellowship and the IACS Student Scholarship.
1:03PM F11.00008: Spin coherence properties of shallow donor-bound electrons in ZnO* [Invited]  KAI-MEI FU (Presenter), XIAYU LINPENG, MARIA L VIITANIEMI, University of Washington, ASWIN VISHNURADHAN, Applied Physics and QPEC, University of Tokyo, YUSUKE KOZUKA, National Institute for Materials Science, CAMERON W JOHNSON, University of Washington, MASASHI KAWASAKI, Applied Physics and QPEC, University of Tokyo — Defects in crystals are leading candidates for photon-based quantum technologies, but progress in developing practical devices critically depends on improving defect optical and spin properties. Motivated by this need, we study a new defect qubit candidate, the shallow donor in ZnO. We demonstrate all-optical control of the electron spin state of the donor qubits and measure the spin coherence properties. We find a longitudinal relaxation time $T_1$ exceeding 100 ms, an inhomogeneous dephasing time $T_2^*$ of 17 ns, and a Hahn spin-echo time $T_2$ of 50 us. The magnitude of $T_2^*$ is consistent with the inhomogeneity of the nuclear hyperfine field in natural ZnO. Possible mechanisms limiting $T_2$ include instantaneous diffusion and nuclear spin diffusion (spectral diffusion). These results are comparable to the phosphorous donor system in natural silicon, suggesting that with isotope and chemical purification long qubit coherence times can be obtained for donor spins in a direct band gap semiconductor.

*This material is based upon work supported by the National Science Foundation under Grant No. 1150647, 1820614.

1:39PM F11.00009: A first-principles study of the electronic structure of deterministically implanted donor arrays in silicon: multi-valley effects  WEI WU (Presenter), THORNTON GREENLAND, ANDREW JAMES FISHER, UCL Department of Physics and Astronomy and London Centre for Nanotechnology, University College London, WC1E 6BT, London, United Kingdom, H LE, STEVEN CHICK, BEN MURDIN, Advanced Technology Institute and Department of Physics, University of Surrey, Guildford, GU2 7XH, United Kingdom — Deterministically implanted donors in silicon provide an important route to develop quantum gates, analogue quantum simulators, and other atomic-scale devices [1]. We have computed the optical properties of a series of donor lines with up to 10 atoms in the spherical-band approximation (single isotropic valley) [2]. Our calculations show charge-transfer excitations play an important role, dominating the transition for separation $\sim$5nm and dropping down to 10 meV. We have also performed multi-valley calculations (with conduction-band anisotropy) for a donor pair and a three-donor linear cluster, which show distinct features in the excitation spectra arising from valley interaction. One consequence is to open up a gap between the ionic-state and the $1s\rightarrow2p$ intra-atom transition [3]. Single-valley calculations can be useful to understand the excited states of valley-polarized electrons [4]. Our calculations thus provide solid theoretical foundation to many promising applications for donor arrays, including valleytronics, quantum terahertz cascade laser devices, and quantum information technology.

1:51PM F11.00010: Creation and coherent control of Cr$^{4+}$ spin ensembles in commercial silicon carbide*  BERK DILER (Presenter), SAMUEL WHITELEY, CHRISTOPHER P ANDERSON, GARY WOLFOWICZ, University of Chicago, JOSEPH HEREMANS, Materials Science Division, Argonne National Laboratory, DAVID AWSCHALOM, University of Chicago — Optically active defect spins in solid-state materials, such as the nitrogen-vacancy center in diamond and vacancy complexes in silicon carbide (SiC), are an important resource for quantum technologies. Their electronic spins show promise as long-lived qubits with optical addressability. Recent work in 4H-SiC demonstrates the potential of transition metal defects [1]. In particular, Cr$^{4+}$ has a spin-1 electronic ground state with long $T_1$ times at cryogenic temperatures. High zero phonon line emission (73%), and narrow inhomogeneous optical ensemble linewidths (<7 GHz) of Cr$^{4+}$ enable optical spin initialization as well as readout using resonant near-infrared excitation. Here, we demonstrate that ion implantation followed by annealing at temperatures up to 1900 °C results in Cr$^{4+}$ ensembles with spectral-hole linewidths that are an order of magnitude narrower compared to as-grown samples. Improvements in material preparation and photon collection allow for coherent control and measurement of the spin properties of Cr$^{4+}$ defects, highlighting their potential for quantum information processing.

*ARO, AFOSR, NSF, UChicago MRSEC
Electric coupling and long dephasing times of single defect spins in commercial 4H-SiC

KEVIN MIAO (Presenter), ALEXANDRE BOURASSA, CHRISTOPHER P ANDERSON, SAMUEL WHITELEY, ALEXANDER CROOK, SAMUEL L BAYLISS, GARY WOLFOWICZ, University of Chicago, PETER UDVARHELYI, GERGO THIERING, VIKTOR IVADY, Hungarian Academy of Sciences, HIROSHI ABE, TAKESHI OHSHIMA, National Institutes for Quantum and Radiological Science and Technology, ADAM GALI, Hungarian Academy of Sciences, DAVID AWSCHALOM, University of Chicago — Divacancies (VV) in silicon carbide (SiC) are a promising platform for quantum communication owing to their long-lived spin coherence [1] and high-fidelity spin-to-photon interface [2] in a wafer-scale host material. Here, we investigate the properties of single basal $k\bar{h}$ VV in commercially available 4H-SiC. We report an electronic ground-state spin dephasing time ($T_2^*$) exceeding 60 µs for a single $k\bar{h}$ VV at 4 K, which is among the longest reported in a naturally abundant host. Furthermore, the $C_{1h}$ symmetry of $k\bar{h}$ VV quenches dynamic Jahn-Teller distortions, leading to long optical coherence and excited-state energy level coupling with ac electric fields. We observe optical Rabi oscillations with coherence times approaching the lifetime limit, permitting high-visibility quantum interference of emitted photons. We demonstrate coupling between excited-state energy levels and ac electric fields through the observation of a Floquet-dressed optical spectrum. These robust spin and optical properties make the $k\bar{h}$ VV a versatile candidate for quantum information processing and hybrid system applications.

Session F12 DMP: Devices from 2D Materials -- Transport BCEC 153A - Fengnian Xia, Yale Univ - Tag(s): Focus

11:15AM F12.00001: Electronic properties of correlated two-dimensional materials [Invited] YUANBO ZHANG (Presenter), Dept. of Physics, Fudan University — Two-dimensional (2D) atomic crystals, best exemplified by graphene, have emerged as a new class of material that may impact future science and technology. So far semiconducting 2D materials attracted most attention. Meanwhile, vast opportunities exists in correlated 2D materials: the reduced dimensionality may lead to novel properties that are vastly different from that in the bulk, and the exposed surface makes these materials highly tunable. In this talk I will discuss the emerging opportunities in correlated 2D materials. In particular, I will talk about two correlated 2D materials that we found particularly interesting – metallic 2D ferromagnet Fe$_3$GeTe$_2$ and monolayer Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$. We explore their electronic properties while the doping and dimensionality of the 2D systems are modulated.

11:51AM F12.00002: Studying Ambipolar Tellurene Field Effect Transistors using Microwave Near-Field Microscopy SAMUEL BERWEGER (Presenter), National Institute of Standards and Technology Boulder, GANG QIU, YIXIU WANG, Purdue University, BENJAMIN POLLARD, University of Colorado, KRISTEN L GENTER, ROBERT TYRELL-EAD, THOMAS M WALLIS, National Institute of Standards and Technology Boulder, WENZHUO WU, PEIDE (PETER) YE, Purdue University, PAVEL KABOS, National Institute of Standards and Technology Boulder — The successful development of nanoscale semiconducting devices requires precise control over adjoining regions of n- and p-type transport. Key challenges remain the development of new materials with bipolar transport as desired for homojunction devices as well as techniques capable of studying local variations in carrier type and associated conductivity with nanometer spatial resolution. Here we image local electronic variations in ambipolar field effect transistors made from 2D films (tellurene) of the 1D van der Waals material tellurium using near-field scanning microwave microscopy (SMM). We perform SMM imaging together with differential measurements to study spatial variations in both carrier type and the associated conductivity as a function of the applied global backgate voltage. We produce nanometer resolved maps of the local carrier equivalence backgate voltage and show that the apparent device conductivity minimum determined from transport measurements in fact arises from the local coexistence of p- and n-type regions.
12:03PM F12.00003: Effects of H$_2$ Interaction with MoS$_2$: Electronic Behavior and Sensing Applications* NATÁLIA REZENDE (Presenter), ALISSON RONIERI CADORE, ANDREJ DE CARVALHO GADELHA, CÍNTIA LIMA PEREIRA, VÍNICIUS ORNELAS DA SILVA, Departamento de Física, Universidade Federal de Minas Gerais, Belo Horizonte, 30123-970, Brasil, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Namiki, 305-0044, Japan, ANDRÉ SANTAROSA FERLAUTO, Centro de Engenharia, Modelagem e Ciências Sociais Aplicadas, Universidade Federal do ABC, 09210580, Brasil, ANGELO MALAQUIAS DE SOUZA, LEONARDO CRISTIANO CAMPOS, RODRIGO GRIBEL LACERDA, Departamento de Física, Universidade Federal de Minas Gerais, Belo Horizonte, 30123-970, Brasil — In this work, we probe the electronic properties of monolayer MoS$_2$ via interaction with H$_2$, aiming for sensing application. The MoS$_2$ FET exhibit a response to H$_2$ in a wide range of concentration (0.1-90 %) at relatively low temperatures (300-473 K). These H$_2$ sensor show desirable properties such absence of catalytic metal dopants (Pt or Pd) and full reversibility. Based in three experiments, we demonstrate that the conductivity of MoS$_2$ increases as a function of the H$_2$ concentration due to a reversible charge transferring process. Further, we propose that such process originates from the dissociative H$_2$ adsorption driven by interaction with sulfur vacancies in the MoS$_2$ surface ($V_S$). This proposal is in agreement with related DFT studies about H$_2$ adsorption on MoS$_2$. Finally, measurements on partially defect-passivated MoS$_2$ FETs using atomic layer deposited Al$_2$O$_3$ consisting of an experimental indication that the $V_S$ plays an important role in the H$_2$ interaction with the MoS$_2$. Our findings provide insights for futures applications in catalytic process between monolayer MoS$_2$ and H$_2$.

12:15PM F12.00004: Anisotropic electron transport behaviors in few-layer ReSe$_2$* WEN-BIN JIAN (Presenter), PANG-CHIA CHANG, CHUN-YANG HO, ZHENG-JI OU, National Chiao Tung University, CHING-HWA HO, National Taiwan University of Science and Technology, Graduate Institute of Applied Science and Technology — The transition metal dichalcogenide of ReSe$_2$ had drawn much attention for decades since it is a layered semiconductor with strong anisotropy on the basal plane. The Re atoms are arranged to form clusters with the clusters aligned in a specified ‘b’-axis. After the improvement of material science, the anisotropy on the basal plane can be studied on single layer ReSe$_2$. In this talk, we will discuss the electrical exploration of the anisotropy on the basal plane of ReSe$_2$. We applied the mechanical exfoliation to make few-layer ReSe$_2$ flakes and the standard electron-beam lithography to make circularly oriented probing electrodes on the basal plane. We checked that the contact resistance is very small as compared with the ReSe$_2$ channel resistance. Using the circularly arranged electrodes, we studied electron transport in the direction parallel to the b-axis and in the direction making an angle with the b-axis. We studied angle dependence of electron mobility, the disorder parameter T0 of the Mott’s variable range hopping model, the metal-insulator transition, and the thermoelectric power. We observe an enhanced conductivity in the b-axis on the basal plane of the ReSe$_2$.

12:27PM F12.00005: Low-Frequency Noise Spectroscopy of the Charge-Density-Wave Phase Transitions in Vertical Tantalum Disulfide Devices* RUBEN SALGADO (Presenter), Electrical and Computer Engineering, University of California, Riverside, MATTHEW BLOODGOOD, TINA T. SALGUERO, Chemistry, University of Georgia, ALEXANDER A. BALANDIN, Electrical and Computer Engineering, University of California, Riverside — Noise spectroscopy has proven itself as an effective tool for investigating the phase transitions in two-dimensional (2D) charge density wave (CDW) materials [1]. Almost all studies of CDW effects in 2D systems focused on transport along the atomic planes. Here we report results of investigation of CDW transitions in vertical 1T-TaS$_2$ devices. We observed two jumps in electrical resistivity – at the temperature range from 150 K to 180 K, and another at 80 K to 85 K. The low-frequency noise spectral density, revealed strong peaks at these transition points, sometimes changing by as much as three orders-of-magnitude. The higher temperature feature can be associated with the transition between the commensurate and nearly commensurate CDW states. The lower temperature transition can indicate the debated “hidden” CDW phase. The obtained results are important for the proposed applications of vertical van der Waals heterostructures in memory and logic gates.

Type Control of MoOx/MoS2 Heterostructure Transistors by Oxidation Treatments

Presenter: PANG-CHIA CHANG
Co-authors: JIAN-JHONG LAI, PO-SHENG WANG, BING-SHIUAN SHIE, WEN-BIN JIAN, National Chiao Tung University, YEN-FU LIN, National Chung Hsing University

Molybdenum disulfide (MoS2) has attracted much attention due to great potential applications as electronics devices. By mechanical exfoliation, few-layer MoS2 can be obtained and made into field-effect transistors (FETs). In particular, we demonstrated that heating device under ozone exposure for several hours can change the device behaviors from natively n-type to either ambipolar or p-type. The treatments resulted in oxidation of MoS2 surfaces to molybdenum oxide (MoOx). Due to exhibiting high work function, MoOx was used as an efficient hole contact. By adjusting the time and temperature of oxidation treatments, the formation of MoOx and the work function of contact electrodes can be modulated. The MoS2 FETs after weak and strong oxidation treatments presented ambipolar and p-type feature, respectively. In MoOx/MoS2 heterostructure, the devices showed the Schottky contact behaviors. The effective Schottky barrier depended on both the gate voltage and source-drain voltage. Additionally, the electrical transport and transfer characteristics of ambipolar and p-type FETs were separately explored. In this report, the oxidation treatments not only simplify the complex fabrication but also improve the diversity of applications for nanoelectronic devices.

Reduction of Current-Voltage Hysteresis in Graphene Field Effect Transistor Achieved with Dry Transfer Using Flexible Tape Supporter

Authors: SUNGCHUL JUNG, HOON HAHN YOON, Ulsan National Institute of Science and Technology, HANBYUL JIN, National Institute of Standards and Technology, KINUHYUNG MO, GAHYUN CHOI, JUNGHYUN LEE, HYESUNG PARK, KIBOG PARK

In the conventional wet transfer method of Chemical Vapor Deposition (CVD) graphene, it is inevitable to have water molecules trapped between graphene and substrate. The trapped water molecules can cause the hysteretic behavior in current-voltage curves of graphene field effect transistor (GFET). Here, a new dry transfer method adopting the Kapton tape as an additional flexible supporting layer is demonstrated. The N2 blowing and heating processes are added to vaporize the water molecules adsorbed on graphene layer right before the transfer step. By comparing the I-V characteristics of wet- and dry-transferred GFET, the field effect mobility is found to be larger for the dry-transfer GFET in comparison with the wet-transferred one, possibly due to the more uniform Coulomb potential landscape. Also, the hysteretic behavior is found to be reduced substantially in accordance with the decrease of trapped water molecules. The obtained electron field effect mobilities are ~1118 cm²/Vs and ~415 cm²/Vs for dry- and wet-transferred graphene, respectively. Our dry transfer method can provide a simple and reliable way to transfer the CVD graphene onto an arbitrary substrate with its as-grown electrical properties being preserved, regardless of the substrate size.

High-Efficiency Thermoelectric 2D Tellurium Devices with Accumulation-type Metal-to-Semiconductor Contacts

Presenter: GANG QIU
Authors: YIXIU WANG, WENZHUO WU, PEIDE (PETER) YE

The paradigm of a good thermal electrical material is usually a heavily doped narrow bandgap semiconductor with good electrical conductivity and low thermal conductivity. Bulk Te has been theoretically predicted and experimentally demonstrated to be an outstanding thermoelectric material. Recent achievements in growing high quality 2D Te films allow us to explore the thermoelectric performance of 2D Te. Using nano-fabricated heater and thermometer, we were able to measure the room temperature Seebeck coefficient and power factor of 0.41 mV/K and 31.7 μW/cm•K. Using the thermal conductivity of bulk Te, we can estimate the lower bound of ZT value to be ~0.32 at 300 K, whereas the true ZT value should be much higher considering the suppression of thermal conductivity in thin films. The details of film thickness dependence are on-going and will be reported. Thermoelectrical current mapping was performed with a laser heater, and we found high work function metals such as Palladium can form rare accumulation type metal-to-semiconductor contacts to Te, which allows thermoelectrically generated carriers to be collected more efficiently. High-performance thermoelectric Te devices will have broad applications for energy harvesting or as a Peltier cooler in microsystems.
crystals by direct evaporations of high and low work-function metals platinum and gadolinium. Since metal-induced improvement of overall device performance in MoS2 transistors as the Schottky barrier height is lowered from ~100 meV to ~40 meV by inserting a WSe2 interlayer between the MoS2 channel and the metal electrodes. A significant advantage of using 2D semiconductors as a contact interlayer as opposed to previously reported insulator interlayers is that 2D semiconductor interlayers with appropriate band alignments are able to effectively reduce the Schottky barrier height without introducing a substantial tunneling barrier at the contacts.

1:27PM F12.00010: Strong Spin-Orbit Interaction in ultra clean graphene/transition-metal dichalcogenide heterostructures DONGYING WANG (Presenter), SHI CHE, Department of Physics, The Ohio State University, RUI LYU, Department of Physics, University of California, Riverside, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Tsukuba, Japan, CHUN NING LAU, MARC BOCKRATH, Department of Physics, The Ohio State University — Van der Waals heterostructures based on stacking two dimensional materials gives rise to new possibilities for designing tunable electronic systems. While combining the merits of individual layers, heterostructures provide a platform for studying interfacial interactions [1]. Among the many phenomena achieved by this proximity effect, inducing spin-orbit coupling (SOC) in graphene has attracted much attention for potential applications in topological physics. We study the enhancement of SOC in graphene induced by transition-metal dichalcogenides (TMDs). High carrier mobility at low temperature suggests that our devices have high quality graphene and very clean graphene/TMD interfaces. We measure magnetoresistance in these devices, which is large and positive, indicating the presence of ultra-strong weak antilocalization (WAL), as a signature of SOC induced in graphene. In contrast to previous works [2-3], our WAL strength is much higher, and we have explored the variation with carrier density more systematically. The WAL feature gradually decreases with increasing temperature and becomes unobservable above 60K.

1:39PM F12.00011: Ultimate Limit in Size and Performance of WSe2 Vertical Diodes SUYONG JUNG (Presenter), GHAZANFAR NAZIR, HAKSEONG KIM, Korea Research Institute of Standards and Science, JONGHWA EOM, Physics, Sejong University — Precise doping-profile engineering in van der Waals (vdW) heterostructures is a key element to promote optimal device performance in various electrical and optical applications with two-dimensional vdW materials. Here, we report tungsten diselenide-(WSe2) based pure vertical diodes with atomically defined p-i-n heterojunctions characterized by a series of quantum tunneling events, namely direct tunneling, Fowler–Nordheim (FN), and Schottky emission (SE). With optimally selected WSe2 thickness, where FN and SE tunneling events prevail, our vertical heterojunctions show superb diode characteristics of an unprecedentedly high current density (∼2 × 10^5 A/cm²) and low turn-on voltages while maintaining good current rectification.

1:51PM F12.00012: Direct observation of ballistic transport in vertical direction of Black Phosphorus ANYUAN GAO (Presenter), FENG MIAO, YI SHI, XIAOMU WANG, School of Physics, National Laboratory of Solid State Microstructures — Ballistic transport is the transport of carriers without scattering. In this regime, carriers travel freely and coherently in semiconductors and therefore the ballistic transport is highly desirable for the development of low power, high speed logic and quantum circuits. Due to its puckered lattice structure, the out-of-plane mobility of BP is comparable to in-plane mobility. Here, we report the direct observation of ballistic transport of BP in out-of-plane direction. The ballistic transport observed in vertical direction of BP is within a 3D framework which is different from 1D ballistic transport. Our results shed light on the development of efficiently facilitating carriers on the nanoscale.
The realization of stable and reliable molecular junctions taking advantage of graphene electrodes faces several issues. Nanoscale gaps with graphene electrodes can indeed exhibit signatures mimicking those of molecules, with gate-dependent resonance features [1,2]. Substrate effects can also play a role: Silicon dioxide has for instance been reported to yield feature-rich charge-transport characteristics in nanoscale graphene gaps, primarily due to switching within the oxide [3].

We report here on the realization of mechanically and electronically robust graphene-based multi-molecule junctions [4]. The mechanical stability is achieved by anchoring molecules directly to the substrate using silanization, rather than to graphene electrodes. The electronic stability is due to a large overlap between the electronic π-systems of neighboring head groups. The nature of the stacking leads to junctions less sensitive to the electrode properties. The junctions are reproducible throughout several devices and operate up to room temperature.

**11:27AM F13.00002: Synthesis and characterization of large-area single-crystal sheets of borophene on Cu(111) surface**

 RONGTING WU (Presenter), Department of Applied Physics, Yale University, New Haven, CT 06520, USA, ILYA K. DROZDOV, Brookhaven National Laboratory, Upton, NY 11973, USA, STEPHEN ELTINGE, Department of Physics, Yale University, New Haven, CT 06520, USA, PERCY ZAHL, Brookhaven National Laboratory, Upton, NY 11973, USA, SOHRAB ISMAIL-BEIGI, Department of Applied Physics, Yale University, New Haven, CT 06520, USA, IVAN BOZOVIC, Brookhaven National Laboratory, Upton, NY 11973, USA, ADRIAN GOZAR, Department of Applied Physics, Yale University, New Haven, CT 06520, USA — Borophene, a theoretically proposed two-dimensional boron allotrope, has attracted attention as a candidate material platform for high-speed and flexible electronics. However, the single-crystal domains produced so far are too small for device fabrication. We report on synthesis of borophene on Cu(111) monitored in situ by low-energy electron microscopy (LEEM), diffraction and scanning tunneling microscopy, and ex-situ by X-ray photoelectron spectroscopy and atomic force microscopy. By growing borophene on Cu(111) surfaces, we obtain large single-crystal domains, up to 100 μm². We show that the crystal structure is a novel triangular network with h = 1/5 concentration of hexagonal vacancies. LEEM imaging capabilities provide detailed information about borophene growth, island faceting, evaporation and sub-surface dissolution. Data and calculations indicate charge-transfer coupling to substrate without significant covalent bonding. Our work sets the stage for fabricating borophene-based devices and substantiates the idea of borophene as a model for artificial 2D materials development.

**11:39AM F13.00003: Direct graphene growth on Anodic Aluminum Oxide (AAO) under different conditions using chemical vapor deposition**

 AAMNA ALSHEHHI (Presenter), IRFAN SAADAT, Electrical and Computer Engineering Department, Khalifa University Of Science and Technology, FAISAL ALMARZOQI, Chemical Engineering, Khalifa University Of Science and Technology, AMAL AL GHAFERI, Khalifa University of Science and Technology, KHADIJA AL DAGHAR, Abu Dhabi National Oil Company — Graphene is one of the promising 2D material due to their remarkable electrical, mechanical and chemical properties. In general growth conditions can be manipulated to synthesis graphene with different layer composition and properties. Direct synthesis of graphene is critical to establish new applications and come up with a manufacturing process for current applications. Recent studies started to focus on direct graphene growth on AAO and potential usage in new applications. The novelty of my study focusing on distinguishing between the quality of graphene growth with low pressure and ambient pressure. This paper will show the results of direct CVD graphene growth on AAO films with pore size ranging from 200 - 40(nm) under different conditions such as pressures (ambient & vacuum) and flow rates. (nm). These parameters play a critical role in the quality and various properties of graphene growth. The presence of graphene was confirmed via Raman spectroscopy with a laser wavelength of 532 nm. The D-mode, G-mode and 2-D mode appears at approximately 1348 cm⁻¹, 1616 cm⁻¹ and 2690 cm⁻¹ respectively. Additional characterization assessments such as SEM and AFM are ongoing and the results will be reported in the final paper.

---

**11:51AM F13.00004: Wafer-scale Growth and Assembly of 2D Semiconductors [Invited]**

 KIBUM KANG (Presenter), Dept. of Materials Science and Engineering, Korea Advanced Institute of Science and Technology (KAIST) — High-performance semiconducting films with precisely engineered thicknesses and compositions are essential for developing next generation electronic devices, which are becoming more integrated, complex, and multifunctional. My talk will introduce the novel processes that enable atomic-scale control of the thickness and spatial composition of semiconducting films on the wafer-scale. These processes include: (i) the wafer-scale generation of monolayer van der Waals semiconductors such as transition metal dichalcogenides (TMDCs) via metal-organic chemical vapor deposition (MOCVD), (ii) the atomic-level engineering of vertical thickness and composition through the layer-by-layer assembly of TMDC monolayers, and (iii) the transfer of atomically engineered films, using their van der Waals nature, onto arbitrary substrates. These capabilities provide a new material platform for both fundamental research and practical applications, including incorporation into existing integrated circuit technology to form hybrid materials (i.e. TMDC/CMOS) and boost electrical and optical functionality.
12:27PM F13.00005: Direct growth of mm-size twisted bilayer graphene (tBLG) by plasma enhanced chemical vapor deposition (PECVD)  
YEN-CHUN CHEN (Presenter), Physics, National Tsing-Hua University, Hsinchu, Taiwan, WEI-HSIANG LIN, Applied Physics, Caltech, Pasadena, CA 91125, USA, WEI-SHUAN TSENG, CHIEN-CHANG CHEN, Physics, Caltech, Pasadena, CA 91125, USA, GEORGE R ROSSMAN, Geological and Planetary Science, Caltech, Pasadena, CA 91125, USA, YU-SHU WU, Physics, National Tsing-Hua University, Hsinchu, Taiwan, CHIIDONG CHEN, Physics, Academia Sinica, Taiwan, NAI-CHANG YEH, Physics, Caltech, Pasadena, CA 91125, USA — PECVD techniques have been shown to be an efficient method to achieve single-step synthesis of high-quality monolayer graphene without the need of active heating. Here we report our progress in PECVD-growth of single-crystal hexagonal bilayer graphene (BLG) flakes and mm-size BLG films, both with the interlayer twisted angle controlled by the PECVD growth parameters. The twisted angle between stacked bilayer is determined by a combination of three experimental approaches, which include: 1) directly measuring the orientation of edges between two stacked layers by scanning electron microscopy, 2) evaluating the twisted angle-dependent Raman spectral characteristics of the G-, 2D- and R'-modes of graphene, and 3) analyzing the Moiré period captured by scanning tunneling microscopy. We find that the average twisted angle of BLG samples can be controlled from 0° (for perfect AB stacking) to ~ 20°, and the spread of twisted-angles for a given growth condition can be reduced to less than 7° over mm-size tBLG films. More comprehensive studies of various properties of PECVD grown-tBLG will be reported in this talk. 

The work at Caltech is supported by the National Science Foundation, and in Taiwan by the Ministry of Science and Technology.

12:39PM F13.00006: Synthesis of Artificial 2D Lattices of Monolayer Multi-junctions  
YI-CHENG CHIANG (Presenter), CHUN-AN CHEN, Materials Science and Engineering, National Tsing Hua University, KUAN-CHANG CHIU, Taiwan Semiconductor Manufacturing Company, Limited, KUAN-HUA HUANG, YING-YU LAI, XIN-QUAN ZHANG, ERH-CHEN LIN, MENG-HSI CHUANG, JENN-MING WU, YI-HSIEN LEE, Materials Science and Engineering, National Tsing Hua University — Recently, monolayers of transition metal dichalcogenides (TMDs) are ideal building blocks for constructing artificial 2D lattices. Heterostructures with multi-junctions of more than two monolayer TMDs are intriguing for exploring new physics. Here, the laterally stitched TMDs and the vertically stacked monolayers are constructed. A low growth temperature synthesis and a clean transfer method are developed for high quality hetero-interfaces. With optimized parameters, atomically sharp interfaces are successfully achieved in the synthesis of in-plane artificial lattices of the WS$_2$/WSe$_2$/MoS$_2$. Characterizations of the hetero-interfaces are presented.

12:51PM F13.00007: Boron and Nitrogen co-doping of Graphene by CVD  
TOMOTAROH GRANZIER-NAKAJIMA (Presenter), LAVISH PABBI, MAURICIO TERRONES, ERIC HUDSON, Pennsylvania State University — Substitutional doping of graphene offers a chance to modify its properties for various applications. Here using low pressure chemical vapor deposition we grow graphene doped simultaneously by both boron and nitrogen. Theoretical calculations have shown that in such systems boron and nitrogen dopants tend to segregate and form hexagonal boron-nitride like islands within the graphene sheet.\textsuperscript{1,2} Using STM we are able to observe these dopant structures with atomic resolution and show the results here.

1:03PM F13.00008: The Growth and Characterization of PECVD Silicene*  
BATTOGTOKH JUGDERSUREN (Presenter), KeyW Corporation, XIAO LIU, JAMES CLIFFORD CULBERTSON, NADEEM MAHADIK, US Naval Research Laboratory — Silicene, a two-dimensional nanoscale allotrope of silicon atoms with a buckled honeycomb structure, is predicted to have many interesting features. There is no evidence for the existence of natural silicene. Until recently, molecular-beam epitaxy (MBE) has been the only successful technique for silicene synthesis. Recently, we have found that plasma-enhanced chemical-vapor deposition (PECVD) has the potential to grow economically viable, large scale, high-quality mono- and multi-layer silicene comparable to that grown using MBE. In addition, we have shown that PECVD grown silicene is naturally hydrogenated and resistant to oxidation. In this work, we have grown PECVD silicene on polycrystalline and single crystalline silver thin films and characterized them using Raman spectroscopy, X-ray diffraction, and X-ray photoelectron spectroscopy. The results show that we can grow nearly defect-free silicene on single crystalline Ag(111) films. We will discuss crystalline structure, hydrogenation, and oxidation-resistance properties of the PECVD silicene.

*Work supported by the Office of Naval Research
1:15PM F13.00009: Growth Physics of MoS2 Layer on the MoS2 Surface: A Monte Carlo Approach  KAMALIKA GHATAK, DIBAKAR DATTA, JATIN KASHYAP (Presenter), Mechanical and Industrial Engineering, New Jersey Institute of Technology — Layered Transition Metal Dichalcogenides (TMDs) are getting attention due to their layer-dependent tunable optoelectronic and mechanical behavior and the control over the experimental growth technique is required to synthesize desired stacked products. Alongside, a probabilistic computational approach is necessary to gain deeper insight into the in-situ growth physics. We, therefore, performed Grand Canonical Monte Carlo (GCMC) simulation as implemented in LAMMPS package with ReaxFF potential, and developed our in-house Kinetic Monte Carlo (KMC) code to model the growth physics of MoS2 layer on the substrate. We considered various pristine and defective growth surface to track the movement of the individual Mo and S. Non-periodic surface with various edge termination (such as chalcogen and metal termination) was also explored. Our Monte Carlo study captures the formation of the MoS2 on the perfect MoS2 surface starting with the individual Mo and S flux. We find that the growth temperature plays a crucial role in governing growth mechanisms. Further investigation is on-going on the growth physics of MoS2 and other TMDs (e.g., WS2) on pristine and defective substrates. Our modeling approach provides guidelines for the experimentalists for the optimal design of TMD bilayer growth.

1:27PM F13.00010: Cooling-mediated One-step Synthesis of Monolayer WSe2/WSe2xTe2-2x Lateral Heterostructures for High-Performance Spectral Photodetectors*  SANGMIN KANG (Presenter), Department of Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, CHIA-HAO LEE, Department of Material Science and Engineering, University of Illinois at Urbana-Champaign, YIFEI LI, ZIJING ZHAO, KAI XIU, SHUSHAN XIA, HOJOON RYU, Department of Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, PINSHANE HUANG, WENJUAN ZHU, Department of Material Science and Engineering, University of Illinois at Urbana-Champaign — Tellurium (Te) based transition metal dichalcogenides (TMDCs), especially tungsten ditelluride (WTe2), have attracted intensively owing to their unique electrical and optical properties. However, the ternary alloy tungsten selenium telluride (WSe2xTe2-2x) and its lateral hetero-structure with other TMDCs remains largely unexplored due to the considerable challenge in synthesizing these materials, since WTe2 has very weak bonding and tends to decompose at high reaction temperature. Here, we demonstrate a successful one-step synthesis of monolayer WSe2/WSe2xTe2-2x lateral hetero-structures via cooling-mediated chemical vapor deposition. We find that the cooling rate and flow ratio between argon and hydrogen gas are crucial factors for the morphology. The Te incorporation in the alloy is studied by aberration-corrected scanning transmission electron microscopy. The correlation between Te composition and the bandgap of the alloy is simulated by density functional theory. Furthermore, through the study of the optical and electrical properties, we demonstrate the possibility of high-performance spectral photodetectors with spatially graded bandgap.

1:39PM F13.00011: Large homo pn junction using two type of atomic scale-thickness-MoS2  AHRUM SOHN (Presenter), JAEHWAN JUNG, SANG-WOO KIM, School of Advanced Materials Science & Engineering, Sungkyunkwan University — Molybdenum disulfide (MoS2) has attracted attention as a substitute material of Si for the next generation material due to its prominent physical properties. In order for MoS2 to replace Si, it must have not only such intrinsic properties but also be able to modulate the carrier type. Accordingly, several researchers have attempted to various doping methods for controlling the carrier type of MoS2, including coating physic or chemisorption of molecules, exposing plasma and substitutional doping process. In this study, we developed the layer-controllable and reproducible growth method of large scaled and Nb doped MoS2 films with reduction of growth time by 50 times as compared with previous method. To identify structural information of the films, atomic force microscopy (AFM), transmission electron microscopy (TEM), Raman spectroscopy, and X-ray spectroscopy (XPS) were conducted. p-type properties of Nb doped MoS2 was confirmed by STM and gate dependent transport measurement. Furthermore, we demonstrated ultra-thin homo p-n junction via vertical stacking and lateral stacking of n-type and p-type MoS2 grown by this method.
**1:51PM F13.00012: Synthesis of High Quality Monolayer Transition Metal Dichalcogenides using Direct Liquid Injection**

KATHLEEN MCCREARY (Presenter), ENRIQUE COBAS, AUBREY HANBICKI, BEREND JONKER, United States Naval Research Laboratory — In recent years, interest in monolayer transition metal dichalcogenides (TMDs) has rapidly increased, spurred by the possibility for integration into a variety of technologies such as photodetection, flexible electronics, and chemical sensing. While fundamental investigations can be performed on exfoliated flakes or chemical vapor deposition synthesized isolated islands, the limited size resulting from these techniques poses a significant barrier for implementation of TMDs in technological applications. To overcome these obstacles, new synthesis avenues should be explored. Here, we outline a novel technique that utilizes a commercially available Anneal Sys growth chamber equipped with direct liquid injection (DLI) heads for all precursors. The use of liquid, rather than solid precursors, provides fine control of both metal and chalcogen precursors leading to the synthesis of monolayer MoS$_2$ across cm$^2$ areas. Photoluminescence, Raman and XPS are used to evaluate DLI grown MoS$_2$, and indicate high quality material, with metrics comparable to or better than exfoliated and chemical vapor deposition grown MoS$_2$.

**2:03PM F13.00013: Controlled CVD growth of MoTe$_2$ and their use in near-infrared light detection**

ZHENG TANG LUO (Presenter), JIAWEN YOU, Department of Chemical and Biological Engineering, Hong Kong University of Science and Technology — Due to their low symmetry ultrathin structures and unconventional dielectric screening effects, 2D transition metal dichalcogenides (TMDs) have attracted significant research attention utilizing their tunable optical-electronic properties. We established general strategies for to synthesize high-quality graphene and TMDs layers with tailored properties using chemical vapor deposition (CVD). Here, we demonstrate a salt-induced CVD strategy to synthesize mono- and few-layer 1T’ and 2H phase MoTe$_2$, exploiting richer electronic properties of this materials derived from their tunable structures. The obtained materials has demonstrate exceptional performance when used for the near-infrared (NIR) light detection, arise from their reduced band gap of 2H phase MoTe$_2$. This study provides a new materials synthesis method aiming for the fabrication of for highly efficient, and broadband NIR photodetector.

**11:15AM F14.00001: Enhanced Raman scattering of graphene using double resonance in silicon photonic crystal nanocavities**

HIDENORI MACHIYA (Presenter), WIDIANTA GOMULYA, RIKEN, KOTARO KASHIWA, TAIKI INOUE, SHOHEI CHIAISHI, SHIGEO MARUYAMA, The University of Tokyo, YUICHIRO K. KATO, RIKEN — We demonstrate enhancements of Raman scattering from graphene on L3 photonic crystals using double resonances, which originate from simultaneous enhancements by a localized guided mode and a cavity mode [1]. By adjusting the photonic crystal cavity parameters, the double resonance [2] can be tuned to the G’ Raman scattering. Excitation wavelength dependence measurements show a large Raman peak enhancement when the excitation and emission wavelengths meet the double resonance condition. Furthermore, spatial imaging measurements are performed to confirm that the enhancement is localized at the cavity, and we find that the enhanced Raman intensity is 60 times larger compared to the on-substrate Raman signal. The observed cavity enhancement of Raman scattering opens up new possibilities for the development of graphene-based light sources for silicon photonics.

11:27AM F14.00002: Photonic Crystals for Nano-Light in Moiré Graphene Superlattices  SAI SUNKU (Presenter), GUANGXIN NI, Columbia University, BOR-YUAN JIANG, UC San Diego, HYOBIN YOO, Harvard University, AARON STERNBACH, MCLEOD SWINTON ALEXANDER, Columbia University, STAUBER TOBIAS, ICM, CSIC, Madrid, LIN XIONG, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, PHILIP KIM, Harvard University, MICHAEL FOGLER, UC San Diego, DIMITRI BASOV, Columbia University — Twisted bilayer graphene (TBG) consists of two layers of graphene rotated relative to each other. At very small twist angle, the atomic lattices relax and form a periodic array of Bernal-stacked domains separated by solitons. The solitons host topologically protected states and have previously been shown to efficiently scatter propagating surface plasmon polaritons (SPPs) [Jiang et al, Nano Lett, 17:7080 (2017)]. Therefore, an array of such solitons with a periodicity similar to the wavelength of SPPs should act as a photonic crystal for the SPPs. In this work, we use infrared nano-imaging to verify this proposition and demonstrate the interference of propagating SPPs in TBG. Furthermore, our calculations predict that a full plasmonic band gap is possible in this system.

11:39AM F14.00003: Fundamental Limits to graphene plasmonics  GUANGXIN NI (Presenter), MCLEOD SWINTON ALEXANDER, ZHIYUAN SUN, LEI WANG, LIN XIONG, Columbia University, KIRK W POST, University of California San Diego, SAI SUNKU, Columbia University, BOR-YUAN JIANG, University of California San Diego, JAMESHONE, CORY R DEAN, Columbia University, MICHAEL FOGLER, University of California San Diego, DIMITRI BASOV, Columbia University — Polaritons are hybrid excitations of light and matter that can confine the energy of long-wavelength radiation at the nano-scale. Plasmon polaritons may enable many enigmatic quantum effects including lasing, topological protection, and dipole-forbidden absorption. A necessary condition for realizing such phenomena is a long polariton lifetime, which is notoriously difficult to meet. Plasmon polaritons in graphene provide a platform for exploring light-matter interaction at the nano-scale. However, plasmonic dissipation in graphene has remained substantial and its fundamental limits remained undetermined. Here we use nanometre-scale infrared imaging to investigate propagating plasmon polaritons in high-mobility encapsulated graphene at cryogenic temperatures. In this regime, the propagation of plasmon polaritons is primarily restricted by the dielectric losses of the encapsulated layers, with a minor contribution from electron-phonon interactions. At liquid-nitrogen temperatures, the intrinsic plasmonic propagation length can exceed 50 plasmonic wavelengths, thus setting a record for highly confined and tunable polariton modes.

11:51AM F14.00004: Broadband mid-infrared graphene bolometer  SHAOFAN YUAN (Presenter), YALI QI, YAM INGO, YUAN RUIZ (Presenter), MARCIN MUCHA-KRUCZYNSKI, JOSHUA THOMPSON, Physics, University of Bath, VLADIMIR FALKO, National Graphene Institute — Using the continuum model, we study theoretically the purely electronic contributions to the Raman spectrum of twisted bilayer graphene (tBLG) for twist angles close to the magic angle [1]. We show that non-resonant excitations of electron-hole pairs between the first minibands above and below the neutrality point lead to a peak, the position of which is determined by the twist angle. We estimate the quantum efficiency of this Raman feature as $\sim 10^{-13}$, about two orders of magnitude less than the intensity of the G peak [2]. Because of its electronic origin, the new peak provides direct information about the flatness of the first minibands in tBLG.

12:15PM F14.00006: Photonic crystal for graphene plasmons LIN XIONG (Presenter), CARLOS FORSYTHE, ALEXANDER SWINTON MCLEOD, Columbia University, MINWOO JUNG, Cornell university, SAI SUNKU, GUANGXIN NI, Columbia University, SONG LIU, Kansas State University, MICHAEL FOGLER, University of California, San Diego, JAMES H. EDGAR, Kansas State University, GENNADY SHVETS, Cornell university, CORY DEAN, DIMITRI BASOV, Columbia University — Recent advancements in high-quality graphene devices enable long-lived surface plasmon polaritons which propagate over several microns. Various tunable parameters including gate voltage, twist angle, and superlattice potential enable efficient control of device functionalities. We used near-field nano-imaging techniques to study graphene plasmonic crystals at cryogenic temperatures. High-mobility graphene is transferred to a periodically patterned SiO2 substrate with Si back-gate. This heterostructure imprints the graphene with 80 nm-scale periodic variations in carrier density under application of a field effect, thus forming a gate-tunable photonic crystal for plasmons. We observed the formation of a selectively engineered full plasmonic bandgap where propagation of plasmons is strongly suppressed within the superlattice. Additionally, we implemented a designed domain wall within the superlattice which simultaneous supports strongly confined 1D plasmons within the plasmonic bandgap. These findings signify a new route towards designer-engineered band-structures to route and manipulate highly confined plasmons within high mobility graphene devices.

12:27PM F14.00007: Probing symmetry breaking in multilayer epitaxial graphene by circularly polarized magneto-infrared spectroscopy* YUXUAN JIANG (Presenter), ZHENGGUANG LU, National High Magnetic Field Laboratory, JAMES GIGLIOTTI, CLAIRE BERGER, WALTER DE HEER, Physics, Georgia Institute of Technology, DMITRY SMIRNOV, National High Magnetic Field Laboratory, ZHIGANG JIANG, Physics, Georgia Institute of Technology — Symmetry breaking in graphene in high magnetic fields has long been an intriguing problem. Here, we report a magneto-infrared transmission spectroscopy study of multilayer epitaxial graphene with circularly polarized light. A four-fold splitting of the zeroth Landau level is found in high magnetic fields and attributed to the lifting of the valley and spin degeneracies and the electron-hole asymmetry. We extract the magnetic field dependence of the splitting gaps and discuss their possible origins. We also observe a surprising electron-hole asymmetry reversal between the monolayer and bilayer graphene components of multilayer epitaxial graphene and propose a possible interpretation.

12:51PM F14.00009: Theory of entangled-plasmon-pair generation in graphene* ZHIYUAN SUN, DIMITRI BASOV, Department of Physics, Columbia University, MICHAEL FOGLER (Presenter), University of California, San Diego — We study spontaneous parametric down conversion of terahertz photons into entangled plasmon pairs in graphene. This process is permitted by both symmetry and kinematics in a ribbon with an electron density gradient. We show that the conversion rate is maximized in ribbons containing lateral p-n junctions. We discuss how the quantum entanglement of the generated pairs can be measured by near-field optics techniques. We specify requirements for achieving plasmonic two-mode squeezed states and plasmonic instabilities in the presence of losses. We also study nonlinear plasmonic effects in a large-area uniformly doped graphene sheets due to third-order optical response.

1:03PM F14.00010: Pseudo-Euler equations from nonlinear optics: plasmon-assisted photodetection beyond hydrodynamics  
ALESSANDRO PRINCIPI (Presenter), DENIS BANDURIN, School of Physics and Astronomy, University of Manchester, HABIB ROSTAMI, Nordita, KTH Royal Institute of Technology and Stockholm University, MARCO CORRADO POLINI, Graphene Labs, Istituto Italiano di Tecnologia — A great deal of theoretical and experimental efforts have been devoted in the last decades to the study of long-wavelength photodetection mechanisms in field-effect transistors hosting two-dimensional electron systems. A particularly interesting subclass of these mechanisms is intrinsic and based on the conversion of the incoming electromagnetic radiation into plasmons of a two-dimensional electron system, which resonantly enhance the photoresponse, and subsequent rectification via hydrodynamic nonlinearities. Here we show that such conversion and subsequent rectification occur well beyond the frequency regime in which hydrodynamic theory applies. We consider the nonlinear optical response of generic 2D electron systems and derive pseudo-Euler equations of motion for suitable collective variables. These are solved in one- and two-dimensional geometries for the case of graphene and the results are compared with those of hydrodynamic theory. Significant qualitative differences are found, which are amenable to experimental studies. Our theory expands the knowledge of the fundamental physics behind long-wavelength photodetection.

1:15PM F14.00011: Strong Dirac Photoconductance in Charge Neutral Graphene-Boron Nitride-Graphene Heterostructures  
TREVOR ARP (Presenter), JACKY WAN, NATHANIEL MONROE GABOR, University of California, Riverside — Photoexcited hot charge carriers may shed light on the intriguing dynamics of electrons and holes near charge neutrality in very clean graphene. When two graphene layers are separated by thin hexagonal boron nitride (hBN), interlayer photocurrent can occur due to the exponential tail of the hot carrier distribution extending into the valence band of the hBN.[1] Using an ultrafast pulsed laser we excite a graphene-boron nitride-graphene (G-BN-G) heterostructure with photon energy less than the gap of the hBN and observe strong and highly nonlinear interlayer photocurrent as a function of the interlayer voltage. In a fully encapsulated heterostructure (BN-G-BN-G-BN), we find that the differential photocurrent can occur due to the exponential tail of the hot carrier distribution extending into the valence band of the hBN.

VASILI PEREBEINOS (Presenter), EE department, University at Buffalo — While graphene absorbs only 2.3% in the mid infra red (IR) spectral region, graphene plasmons have much stronger absorption in the far IR. Plasmons tunability by the external electric fields and by the spatial confinement offer a promising platform for opto-electronic and sensor applications. In this work [1], we demonstrate both theoretically and experimentally that the plasmon–plasmon and plasmon–radiation interactions modify strongly the plasmon resonance energy, radiative damping, and oscillator strength in graphene nanoribbon arrays. Even for the moderate filling factors of about 50%, plasmon radiative lifetime reduces to a ps time scale from a convetional ns time scale in the isolated graphene nanoribbon. We find scaling of plasmons with respect to the graphene doping level and filling factor, which both modify the strength of the long-range Coulomb and plamson-radiative interactions. The surprisingly large plasmon energy shift and radiative damping significantly affect the graphene-based plasmonic device performance.

1:39PM F14.00013: Optical Properties of Graphene/Al Hetero-film*  
HAOZHE WANG (Presenter), Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, SIDAN FU, Thayer School of Engineering, Dartmouth College, WEI SUN LEONG, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, JIFENG LIU, Thayer School of Engineering, Dartmouth College, JING KONG, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology — When two metal films stack together forming “hetero-film”, it has been generally accepted that the effective transparency is lower than the respective metal film as a result of the absorption accumulation. Here, we report a counterintuitive phenomenon where transparency of a hetero-film is significantly higher compared to the original metal film. Specifically, we found that by layering one-atom-thick graphene on an aluminum (Al) film, the transparency of the Al film is dramatically increased from ~60% to 80% under 550 nm wavelength light. More surprisingly, similar transparency enhancement is captured when Al film was deposited on the graphene film. Systematic characterizations and numerical simulations were conducted to understand this unusual phenomenon observed in the graphene/Al hetero-film, including Raman, XPS, SEM, AFM analyses. Furthermore, Hall measurements revealed that our graphene/Al hetero-film holds great promise to be used as flexible transparent electrodes.

Resistively detected microwave absorption in highly twisted bilayer graphene

LIANGJI ZHANG (Presenter), JUSTIN LANE, Michigan State Univ, CHENYU ZHANG, J.I.A. LI, Brown University, CORY R DEAN, Columbia University, JOHANNES POLLANEN, Michigan State Univ — Resistively detected microwave absorption measurements of high-mobility two-dimensional (2D) electron systems are a powerful tool to explore the high-frequency spectroscopic and non-equilibrium response of correlated electron states in these systems. We have performed low-temperature magneto-transport experiments on a hexagonal boron nitride and dual graphite encapsulated twisted graphene bilayer while simultaneously irradiating the sample with microwave frequency photons. In this device the twist angle between the graphene flakes is relatively large, leading to a low-energy decoupling of the layers. Dual graphite gates allow us independent control of both the charge carrier density in the bilayer and a displacement electric field perpendicular to the 2D stack. We find that the differential magneto-conductance of the device, defined as the difference in conductance with and without microwave irradiation, shows well-defined oscillations in a large filling factor range down to the lowest Landau level. The dependence of these conductance oscillations on the magnetic field, displacement field, filling factor and microwave frequency will be discussed.

Resonant terahertz photoresponse and superlattice plasmons in graphene field-effect transistors

DENIS BANDURIN (Presenter), School of Physics, University of Manchester, Oxford Road, Manchester M13 9PL, United Kingdom, DMITRY SVINTSOV, Moscow Institute of Physics and Technology (State University), Dolgoprudny 141700, Russia, IGOR GAYDUCHEKNO, Physics Department, Moscow State University of Education (MSPU), Moscow, 119435, Russian Federation, SHUIGANG XU, ALESSANDRO PRINCIPI, School of Physics, University of Manchester, Oxford Road, Manchester M13 9PL, United Kingdom, MAKSIM MOSKOTIN, IVAN TRETYAKOV, Physics Department, Moscow State University of Education (MSPU), Moscow, 119435, Russian Federation, DENIS YAGODKIN, SERGEY ZHUKOV, Moscow Institute of Physics and Technology (State University), Dolgoprudny 141700, Russia, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, 1-1 Namiki, Tsukuba, 305-0044 Japan, IRINA GRIGORIEVA, School of Physics, University of Manchester, Oxford Road, Manchester M13 9PL, United Kingdom, MARCO POLINI, Istituto Italiano di Tecnologia, Graphene Labs, Via Morego 30, 16163 Genova, Italy, GREGORY GOLTSMAN, Physics Department, Moscow State University of Education (MSPU), Moscow, 119435, Russian Federation, ANDRE GEIM, School of Physics, University of Manchester, Oxford Road, Manchester M13 9PL, United Kingdom, GEORGY FEDOROV, Moscow Institute of Physics and Technology (State University), Dolgoprudny 141700, Russia — Plasmons, collective oscillations of electron systems, can couple light and electric current, and thus can be used to create compact photodetectors, radiation mixers, and spectrometers. Despite the effort, it has proven challenging to implement plasmonic devices operating at THz frequencies. The material capable to meet this challenge is graphene as it supports long-lived electrically-tunable plasmons. In this talk, we will demonstrate plasmon-assisted resonant detection of THz radiation by antenna-coupled graphene FETs that act as both rectifying elements and plasmonic Fabry-Perot cavities amplifying the photoresponse. We will show that by varying the plasmon velocity using gate voltage, our detectors can be tuned between multiple resonant modes, a functionality that we apply to measure plasmons' wavelength and lifetime in graphene as well as to probe collective modes in its moire minibands. Our approach offers a convenient tool for further plasmonic research that is often difficult under non-ambient conditions and promises a viable route for various THz applications.

**11:15AM F15.00001: Optical excitations of transition-metal dichalcogenides with charged adsorbates**

MARTIK AGHAJANIAN (Presenter), ARASH A MOSTOFI, JOHANNES LISCHNER, Imperial College London — Direct band-gap semiconducting monolayer transition-metal dichalcogenides (TMDs) have been previously shown to demonstrate enhanced light absorption, which has promising applications in photovoltaic devices. This work explores the effects of charged adsorbates in MoS$_2$, MoTe$_2$, WS$_2$ and WTe$_2$ on their optical properties. Charged impurities on TMDs can give rise to bound states that extend over tens of nanometers due to weak screening in two-dimensional materials, hence it becomes difficult to capture their effects with conventional electronic structure calculations based on density-functional theory. In our approach, we first determine the electronic structure using large-scale tight-binding calculations which include a screened defect potential obtained from first-principles random-phase approximation calculations. Next, the Bethe-Salpeter equation is solved to include excitonic effects and obtain the optical absorption spectrum to compare with photoluminescence experiments. We indicate how trigonal symmetry present at the valleys of the band extrema results in deviation from simple hydrogenic behaviour of the bound states, and show dependence of excitonic resonances on the defect charge.

*Funded by EPSRC through the Centre for Doctoral Training in Theory and Simulation of Materials.

**11:27AM F15.00002: Nearly 90% circularly polarized emission in monolayer heterogeneous WS$_2$ single crystals by chemical vapor deposition (CVD)**

WEI-HSIANG LIN (Presenter), Dept. of Applied Physics, Caltech, WEI-SHIUAN TSENG, CORA WENT, Dept. of Physics, Caltech, GEORGE R ROSSMAN, Division of Geological and Planetary Science, Caltech, HARRY ATWATER, Dept. of Applied Physics, Caltech, NAI-CHANG YEH, Dept. of Physics, Caltech — Monolayer transition metal dichalcogenides (TMDCs) are promising materials for valleytronic applications because the two inequivalent valleys in the Brillouin zone. We report here novel optoelectronic properties of heterogeneous domains in CVD-grown monolayer WS$_2$ single crystals. Spatially resolved PL, Raman, X-ray photoelectron spectroscopy and Kelvin probe force microscopy images revealed the formation of homojunctions in these single crystals, which implied a direct correlation between the chemical stoichiometry and the optoelectronic heterostructure. Conductive atomic force microscopy (AFM) measurements revealed nanoscale distributions of electronically active defects in the heterogeneous WS$_2$, and the local defect density was found to be inversely proportional to the local PL intensity. Additionally, by optically pumping WS$_2$ with CPL and measuring the resulting spatially resolved CP emission ($P_{\text{circ}}$) at room temperature (RT) and low temperature (80K), we found significant $P_{\text{circ}}$ intensities even at RT, and $P_{\text{circ}}$ was inversely correlated with the defect density. At 80K, the degree of circularly polarized emission in low-defect domains was found to approach ~ 90%, suggesting nearly perfect valley polarization.

*This work is supported by the ARO and NSF.

**11:39AM F15.00003: Exciton regulation of resonant Raman scattering in monolayer MoS$_2$**

YUANXI WANG (Presenter), Pennsylvania State University, BRUNO R. CARVALHO, Universidade Federal do Rio Grande do Norte, VINCENT HENRY CRESPI, Pennsylvania State University — Strong excitonic effects in 2D semiconductors such as monolayer MoS$_2$ not only downshift its excitation spectrum from a single-particle one, but also redistribute excitation levels and wavefunction characters that profoundly affect exciton-phonon scattering processes, leaving strong signatures in resonant Raman measurements. We present a first-principles GW-Bethe-Salpeter equation (GW-BSE) approach based on perturbation theory to calculate resonant Raman intensities beyond the Placzek approximation. We show how excitonic effects in MoS$_2$ strongly regulate Raman scattering amplitudes and explain two puzzling experimental observations: the near absence of Raman response at the A and B band-edge excitons and the pronounced strength of Raman response near the C exciton. This perturbative approach reduces the number of GW-BSE calculations from two per Raman mode in finite displacement methods to one for all modes and allows a natural extension to higher-order resonant Raman processes [Phys. Rev. B 98, 161405 (2018)].

11:51 AM F15.00004: Optical tuning of magnetism with valley polarized excitation  
XIAO-XIAO ZHANG (Presenter), LIZHONG LI, ZEFANG WANG, JIE SHAN, KIN FAI MAK, Cornell University — Magnetic 2D materials hold great promises to allow a more active control of magnetism. By interfacing other 2D monolayers with the atomically flat magnet, we can create new functional materials that combines different features and properties. In this talk, I would present my work on the heterostructure of ferromagnetic CrBr$_3$ and monolayer transition metal dichalcogenide (TMDC) of WSe$_2$. I would show how the optical excitation within the WSe$_2$ would also affect the magnetism in CrBr$_3$. By employing circularly polarized light, valley and spin polarized carriers are created within the TMDC as a result of the valley optical selection rule. Sequential modification in the magnetic response in CrBr$_3$ indicates that there exists efficient spin transfer from the excited TMDC into the interfaced magnet. Further characterizations including temperature dependence, excitation detuning etc. would also be discussed. The efficient optical tuning of magnetism opens up promising directions to manipulate magnetic domains in an all-optical method.

12:03 PM F15.00005: Measuring Valley Susceptibility of Transition Metal Dichalcogenides with Second-harmonic Spectroscopy*  
YI WEI HO (Presenter), NUS Graduate School for Integrative Sciences and Engineering, National University of Singapore, HENRIQUE GUIMARAES ROSA, IVAN VERZHBITSKIY, Centre for Advanced 2D Materials, National University of Singapore, MANUEL JOSE FERREIRA DE LIMA RODIGUES, Center of Physics and Department of Physics, Universidade do Minho, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, GOKI EDA, VITOR PEREIRA, JOSÉ CARLOS VIANA-GOMES, Centre for Advanced 2D Materials, National University of Singapore — Polarization-resolved (PR) photoluminescence (PL) [1] and Kerr rotation (KR) [2] are commonly used to probe the degree of valley polarization (VP) of transition metal dichalcogenides (TMDs). Recently, second-harmonic (SH) generation was proposed to also probe VP [3], with the advantage over PL and KR of not requiring the material to have a bandgap or strong spin-orbital coupling, and thus extending VP measurements to other materials such as graphene.

In this work, we have develop a technique that uses a single laser beam prepared in a polarization state that simultaneously creates VP and pumps the SH process. By increasing the ellipticity of this pump beam, which translates into a larger VP in the sample, we observed an additional SH signal due to the VP, in good agreement with our theoretical model. Based on a transient analysis within the duration of the laser pulse, our model confirms SH susceptibility induced by VP to be directly proportional to the degree of VP, with the effect an order of magnitude higher for a quasi-resonant VP pump when compared to the off-resonant case.

*I thank scholarship support from NGS.

12:15 PM F15.00006: Light based control of Exciton Polaritons in Van der Waals Semiconductors  
AARON STERNBACH (Presenter), Physics, Columbia University, SIMONE LATINI, HANNES HUEBENER, UMBERTO DE GIOVANNINI, Max Planck Institute for the Structure and Dynamics of Matter, SANGHOON CHAE, Mechanical Engineering, Columbia University, LIN XIONG, YINMING SHAO, Physics, Columbia University, NORMAN SHI, Columbia University, GUANGXIN NI, Physics, Columbia University, NANFANG YU, Columbia University, MICHAEL FOGLER, Physics, University of California, San Diego, JAMES HONE, Mechanical Engineering, Columbia University, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter, DIMITRI BASOV, Physics, Columbia University — In this work we focus on exciton polaritons in the Van der Waals (vdW) Semiconductor, WS$_2$, under intense femto-second (fs) photo-excitation. Photo-excitation initiates a blueshift of the exciton polariton. This corresponds to an extremely large photo-induced change of the dielectric function. Detailed investigation of the dispersion and the fluence dependence indicate the observed effect arises from light-based control of excitons. The change to the dielectric function evolves over two distinct timescales. On the femtosecond timescale a large coherent contribution is observed. On the picosecond (ps) timescale part of the effect is found to persist. The equilibrium state is fully recovered approximately one hundred ps after the photo-excitation event. The information-rich data-sets available from interrogating the exciton-polariton allow us to explore the pathways toward active control of excitons. Additionally, our experimental approach allows us to access key quantities, such as the group velocity and real-space confinement of the exciton polariton, in the non-equilibrium state. Finally, our findings indicate that strong-light matter interactions in vdW semiconductors may be used to achieve all-optical control of significant magnitude.
Spin-Valley dependent optical response at monolayer transition metal dichalcogenide/ferrimagnet interface  TAKATOSHI AKAMATSU (Presenter), TOSHIYA IDEUE, MASARU ONGA, YUKI ITAHASHI, YUJI NAKAGAWA, YOSHIHIRO IWASA, Department of applied physics, University of Tokyo — Monolayer transition metal dichalcogenides (TMDs) is one of the potential candidates for valley-based electronics, since valley degree of freedom in TMDs couples with orbital and spin degree of freedoms, so that it can be manipulated by optical or magnetic method. So far, valley-optical responses related with orbital degree of freedom have been elucidated in monolayer TMDs. Recently, TMDs/magnet interfaces are widely studied as an ideal platform for studying the spin-valley related phenomena[1][2].

Here I report the characteristic optical responses at new interface of TMDs and ferrimagnetic Fe₃O₄. Valley-Zeeman effect and the probable spin-valley relaxation, which has been reported in previous works of TMDs/ferromagnet interfaces, have been also observed at the new interface. In the presentation, I also discuss the microscopic origin of the observed spin-valley relaxation.

Ultrafast Dynamics of Excitonic Rydberg Series in Single Layer WSe₂  MEHMET B YILMAZ (Presenter), EMRE ERGECEN, Department of Physics, Massachusetts Institute of Technology, NATHAN P WILSON, Department of Physics, University of Washington, JOSEPH VARGHESE, STEVEN VITALE, MIT Lincoln Laboratory, XIAODONG XU, Department of Physics, University of Washington, NUH GEDIK, Department of Physics, Massachusetts Institute of Technology — Single layer transition metal dichalcogenides (TMD) such as MoS₂ and WSe₂ have been the subject of intense attention for their optically accessible valley polarization. In these materials, circularly polarized light can be used to break the time-reversal symmetry and lift the degeneracy of the K and K’ valleys. Such optical control is of great importance for possible valleytronic applications. In this work, we will present broadband transient reflection microscopy results obtained from hBN capped single layer WSe₂ flakes. In these high quality samples, it is possible to observe the excitonic Rydberg states in the reflectivity data. We have studied the dynamics of these states after photo-excitation via pump-probe spectroscopy. When the excitation light energy is tuned below the band gap, high quality of these samples enable observation of novel valley selective coherent response in addition to the previously observed optical Stark shift.

*We acknowledge support from the US Department of Energy, BES DMSE and from the Gordon and Betty Moore Foundation's EPiQS Initiative grant GBMF4540.

Suspended Excitons in 2D Materials  OZGUR BURAK ASLAN, YAN JOE LEE (Presenter), Stanford University, YIFEI YU, LINYOU CAO, North Carolina State University, MARK BRONGERSMA, Stanford University — Excitons in atomically thin transition metal dichalcogenides (TMDCs, 2D materials) are strongly influenced by their environment. To eliminate that influence, we prepare suspended monolayer (1L) WSe₂ samples, enabling suspended excitons. We perform reflectance measurements and calculate the excitonic binding energies from the experimental observables: the energy differences between the 1s, 2s, and 3s states. We employ the recently developed quantum electrostatic heterostructure model for the calculations. We see that the binding energy of the ground state A exciton increases from about 0.3 eV (on substrate) to above 0.4 eV (suspended). A more striking feature of the suspended excitons is the ability to tune them even further by applying mechanical strain. By applying air pressure, we obtain reversible 0.15 eV redshift in the exciton resonance of a suspended 1L sample on a circular hole of 8 μm diameter under a pressure of 40 psi. Interestingly, the linewidth of the A exciton decreases more than half from about 45-50 meV to 20 meV at room temperature, due to the suppression of the intervalley exciton-phonon scattering. Our results show that suspended 2D materials are novel systems for fundamental studies as well as strong and dynamic tuning of the excitons.
The discovery of graphene marked the start of research in 2D electronic materials which was expanded in new directions with MoS₂ and other layered semiconducting materials. They have a wide range of interesting fundamental properties and potential applications. New opportunities are enabled by the band structure of transition metal dichalcogenides (TMDCs) in which we could harness the valley degree of freedom for valleytronics and next-generation photonics. Long-lived interlayer excitons in van der Waals heterostructures based on TMDCs have recently emerged as a promising platform for this, allowing control over exciton diffusion length, energy and polarization. I will show here how by using MoS₂/WSe₂ van der Waals heterostructures, we can realize excitonic transistors with switching action, confinement and control over diffusion length at room temperature in a reconfigurable potential landscape. Heterostructures with a long-range moiré potential such as in MoSe₂/WSe₂, on the other hand, offer the way to control polarization, emission and wavelength emitted by different optically active regions in the moiré.

*We acknowledge support by the Swiss National Science Foundation (Grant 153298), H2020 European Research Council (ERC, Grant 682332), Marie Curie-Sklodowska-Curie Actions (COFUND grant 665667), European Union's Horizon H2020 Future and Emerging Technologies under grant agreements No 696656 and 785219 (Graphene Flagship).

**1:03PM F15.00010: Exciton Manipulation in 2D TMDC Heterostructures** [Invited] ANDRAS KIS (Presenter), EPFL, Lausanne, Switzerland — The discovery of graphene marked the start of research in 2D electronic materials which was expanded in new directions with MoS₂ and other layered semiconducting materials. They have a wide range of interesting fundamental properties and potential applications. New opportunities are enabled by the band structure of transition metal dichalcogenides (TMDCs) in which we could harness the valley degree of freedom for valleytronics and next-generation photonics. Long-lived interlayer excitons in van der Waals heterostructures based on TMDCs have recently emerged as a promising platform for this, allowing control over exciton diffusion length, energy and polarization. I will show here how by using MoS₂/WSe₂ van der Waals heterostructures, we can realize excitonic transistors with switching action, confinement and control over diffusion length at room temperature in a reconfigurable potential landscape. Heterostructures with a long-range moiré potential such as in MoSe₂/WSe₂, on the other hand, offer the way to control polarization, emission and wavelength emitted by different optically active regions in the moiré.

1:39PM F15.00011: Optical spectroscopy of excited Rydberg excitons to 65 tesla in monolayer semiconductors

ANDREAS STIER (Presenter), MATEUSZ GORYCA, JING LI, SCOTT CROOKER, Los Alamos National Laboratory, NATHAN P WILSON, XIAODONG XU, University of Washington, EMMANUEL COURTADE, CEDRIC ROBERT, XAVIER MARIE, BERNHARD URBASZEK, INSA Toulouse — Monolayer transition-metal dichalcogenide (TMD) semiconductors, such as MoS₂, host very tightly-bound excitons due to reduced dielectric screening and relatively heavy electron / hole masses. Advances in the encapsulation of monolayer TMDs in atomically-flat hexagonal boron nitride (hBN) result in narrow neutral exciton resonances, as well as spectral features associated with excited Rydberg states. Optical spectroscopy in high magnetic fields was recently demonstrated to be a powerful way to uniquely identify these states in WSe₂ and to determine fundamental properties such as the exciton size, mass and binding energy [1]. Here, we report 65 T magneto-absorption spectroscopy of excited Rydberg excitons in hBN-encapsulated WS₂, MoS₂ and MoSe₂ monolayers. The distinct diamagnetic shifts of these excited states (2s, 3s, ..., ns) permits their unambiguous identification, and provide a direct measure of the reduced exciton masses. We compare our experimental results with numerical simulations of the non-hydrogenic Rytova-Keldysh potential for strictly 2D semiconductors, and more general models describing Coulomb interactions in thin-film semiconductors. [1]Stier et al., PRL 120, 057405 (2018).

1:51PM F15.00012: Berry Curvature Induces Exciton Fine-structure and Valley-dependent Autler-Townes Doublet in Molybdenum Diselenide Monolayer

CHAW KEONG YONG (Presenter), IQBAL B UTAMA, FENG WANG, University of California, Berkeley — The geometry phase of Bloch states in the momentum space, characterized by the Berry curvature, can strongly modify the electron dynamics and lead to novel transport phenomena, such as the anomalous Hall effect. Recently it was predicted that the nontrivial Bloch band geometry can also modify the collective optical excitations in transition metal dichalcogenide monolayers, and lift the energy degeneracy of exciton states with opposite angular momentum through an effective valley-orbital effect. Here we report the first experimental observation of the Berry curvature signature in the exciton spectrum of MoSe₂ monolayer using novel techniques based on intraexciton optical Stark spectroscopy. We demonstrate the time-reversal-symmetric analog of the orbital Zeeman effect resulting from the valley-dependent Berry curvature, which leads to energy difference of +14 (-14) meV between the 2p+ and 2p- exciton fine-structure in the K (K') valley. The coherent light-matter coupling between intraexciton states are remarkably strong, leading to a prominent valley-dependent Autler-Townes doublet. Our study opens up new pathways to manipulate the quantum states with infrared radiation and suggests the possibility to control the light-matter interaction via topological quantum phase engineering.

2:03PM F15.00013: Understanding thickness-dependent electronic and optical transitions of Ruddlesden-Popper halide perovskites

YEONGSU CHO (Presenter), TIMOTHY BERKELBACH, University of Chicago — Ruddlesden-Popper halide perovskites are layered heterostructures that are promising candidates for effective optoelectronic devices due to their photoefficiency and stability. Despite their high tunability through substitution and stoichiometry, the physics that control the resulting electronic and optical properties are still not fully understood. We investigate the dependence of the band gap and exciton binding energy on the inorganic layer thickness through the tight binding approximation and nonlocal screened Coulomb potential, making use of material properties of three-dimensional perovskites. Our theory provides an analysis of the optical gap measured by absorption and photoluminescence.

11:15AM F16.00001: Machine learned defect level predictor for semiconductors

ARUN KUMAR MANNODI, Kanakkithodi (Presenter), Center for Nanoscale Materials, Argonne National Laboratory, DUYEN H CAO, NARI JEON, Materials Science Division, Argonne National Laboratory, JI-SANG PARK, Department of Materials, Imperial College London, MICHAEL J DAVIS, Chemical Science Division, Argonne National Laboratory, ALEX MARTINSON, Materials Science Division, Argonne National Laboratory, MARIA CHAN, Center for Nanoscale Materials, Argonne National Laboratory — Electronic levels introduced by impurities and defects in the band gap are critically important in semiconductors for optoelectronic and photovoltaic (PV) applications. The energetics and energy levels of point defects can be reliably predicted using density functional theory (DFT) computations. However, the requirement of large supercells and inclusion of charged states make these computations very expensive, and trends and knowledge from previous calculations are not exploited in subsequent ones. In this work, we develop machine learned defect level predictors based on substantial DFT data for two classes of semiconductors: halide perovskites (MAPbX₃, MA = methylammonium, X = Cl/Br/I), and Cd-based chalcogenides (CdX, X=Te/Se/S). DFT data was generated for formation energies and transition levels of hundreds of vacancy, interstitial and substitutional defects, following which correlation analysis and random forest regression were used to map the properties to a set of unique numerical descriptors, resulting in cheap, accurate, quantitative prediction models. Such models can lead to accelerated prediction of defect states and allow efficient materials design of defect-tolerant semiconductors as well as semiconductors with suitably placed defect levels.

11:27AM F16.00002: Ternary semiconductors with tunable band gaps from machine-learning and crystal structure prediction

MAXIMILIAN AMSLER, (Presenter), Cornell University, CHRISTOPHER WOLVERTON, LOGAN WARD, VINAY I HEGDE, Northwestern University — Computational tools are being employed at an increasing rate to discover and design novel materials with tailored properties to tackle global environmental challenges. Besides the two most common approaches based on high-throughput density functional theory (DFT) calculations and crystal structure prediction schemes, novel methods based on materials informatics and machine learning (ML) models have recently emerged to assist the search for materials with improved properties in industrially relevant applications.

Here, we present a computational investigation of a series of ternary X₄Y₂Z compounds with X={Mg, Ca, Sr, Ba}, Y={P, As, Sb, Bi}, and Z={S, Se, Te}, which we identify by a combined search using a machine learning model and the minima hopping crystal structure prediction method. According to our ab initio results, these compounds are thermodynamically stable and semiconducting with band gaps in the range of 0.3 to 1.8 eV, well suited for various energy applications. We show that several candidate compounds exhibit good photo absorption in the visible range, and excellent thermoelectric performance due to high power factors and extremely low lattice thermal conductivities.

11:39AM F16.00003: Polarization engineering with novel nitride heterostructures from first principles*

NICHOLAS ADAMSKI, (Presenter), DARSHANA WICKRAMARATNE, CHRIS VAN DE WALLE, University of California, Santa Barbara — Novel heterostructures based on II-IV-nitride semiconductors in combination with the widely used III-nitrides are being explored due to the ability to access a wide range of band offsets and polarization charges at the interface. The polarization charges arise from contributions due to spontaneous and piezoelectric polarization. Exploiting polarization requires a systematic methodology for evaluating the polarization properties and band alignments for a variety of materials and their heterostructures. We study the spontaneous and piezoelectric polarization of the II-IV-nitrides using density functional theory with a hybrid functional. To determine band offsets we use surface calculations as well as alignments based on the electronic level of interstitial hydrogen. We use our results to explore II-IV-nitride/III-nitride heterostructures that give rise to low polarization fields, which is favorable for light emitters.

*This work is supported by ARO.
Dielectric screening plays an important role in preventing carrier scattering and trapping by point defects for many electronic semiconductors. We performed a material search study using the dielectric properties as a screen to identify new electronic semiconductors such as the halide perovskite solar materials. However, it was rarely considered as a screen to find new materials for deep UV LED design. We show that boron incorporation into AlGaN allows for improved lattice matching to AlN with only a small effect on the band gap. The a lattice parameter is more sensitive to boron incorporation than the c lattice parameter. We predict similar boron incorporation limits (~15% boron) as in BAIN, but with easier incorporation of low boron content than in BAIN due to increased configurational entropy.

12:03PM F16.00005: First-principle study of phosphors for white-LED applications: Stokes shift, emission linewidth and thermal quenching. [Invited] XAVIER GONZE (Presenter), YONGCHAO JIA, ANNA MIGLIO, IMCN, Université catholique de Louvain, SAMUEL PONCÉ, Department of Materials, Oxford University, MASAYOSHI MIKAMI, Yokohama R&D Center, Mitsubishi Chemical Corporation — Despite current impact of white-LED technology, available blue-to-red phosphors exhibit a too wide emission linewidth or some other drawback, such as strong thermal quenching behavior. In view of large-scale high-throughput search for better phosphors, an accurate but fast computational methodology is needed, not restricted to the ground state (formation energy), but covering excitation and emission energies, Stokes shift, emission linewidth, and emission intensity reduction through thermal quenching. We will present results from a constrained density functional theory methodology for about 30 Ce- and Eu-doped materials [1,2] with 4f → 5d transitions. It matches experimental data within 0.3 eV for both absorption and emission energies (ranging between 2.0 eV and 5.0 eV) and provides Stokes shifts usually within 30%. By contrast, the largely used semi-empirical Dorenbos approach [3] does not perform as well, although it provides physical insights to explain trends among the materials, including the different Stokes shifts. This first-principles approach also delivers emission linewidth and assessment of mechanisms for thermal quenching, based on a simple 1-dimensional configuration coordinate approach. For our representative set of Eu-doped materials, we find that the 4f-5d crossover model cannot be the dominant thermal quenching mechanism: the predicted barrier at the 4f-5d crossing is always higher than 1.5 eV. Also, it will be shown how to waive the one-dimensional restriction in the search for the lowest 4f-5d crossing energy barrier. [1] Y. Jia, S. Poncé, A. Miglio, M. Mikami & X. Gonze, Adv. Opt. 12:39PM F16.00006: Dielectric Behavior as a Screen in Rational Searches for Overlooked Electronic Materials: Metal Pnictide Sulfosalts. XIN HE (Presenter), School of Materials Science and Engineering, Jilin University, DAVID JOSEPH SINGH, Department of Physics and Astronomy, University of Missouri, PATSORN BOON-ON, MING-WAY LEE, Institute of Nanoscience and Department of Physics, National Chung Hsing University, LIJUN ZHANG, School of Materials Science and Engineering, Jilin University — Dielectric screening plays an important role in preventing carrier scattering and trapping by point defects for many semiconductors such as the halide perovskite solar materials. However, it was rarely considered as a screen to find new electronic semiconductors. We performed a material search study using the dielectric properties as a screen to identify potential electronic materials in the class of metal-pnictide ternary sulfosalts, containing Bi or Sb. We find significant cross-gap hybridization between the Sₚ derived valence bands and pnictogen pderived conduction bands in many of the materials. This leads to enhanced Born effective charges, and highly enhanced dielectric constants. We find a chemical rule for high dielectric constant in terms of the connectivity of the structure. Through first principles screening, we find a series of compounds with low effective mass, high dielectric constant and other properties that suggest good performance as electronic materials, and also several potential thermoelectric compounds. The results illustrate the utility of dielectric properties as a screen for identifying complex semiconductors.

12:51 PM F16.00007: Sn(II)-containing phosphates as promising p-type optoelectronic semiconductors*  TIANSHU LI (Presenter), QIAOLING XU, Jilin University, HAOWEI PENG, Temple University, DAVID SINGH, University of Missouri-Columbia, LIJUN ZHANG, Jilin University — High-performance and stable p-type optoelectronic semiconductors, such as transparent conductors, have been searched for with decades of efforts. We herein proposed based on first-principles straightforward calculations and structure searches Sn(II)-containing phosphates Sn_nP_2O_{5+n} (n=2, 3, 4, 5, ...) as promising p-type semiconductors for optoelectronic applications. We found that these materials have large band gaps and can have moderate effective masses for both holes and electrons. Calculations of optical properties show that interband transitions in the visible are weak under hole doping. We also find an interesting inverse Burstein-Moss shift, which can be understood in terms of the Sn character of both the states at band edges. By investigating intrinsic defects properties, we identified dominant carrier traps and revealed ideal growth conditions for p-type Sn(II) phosphates. The results indicate that Sn_nP_2O_{5+n} with large n may be doped to p-type with promising attainable hole density. The unusual combinations of relatively high band gap, low carrier masses and high chemical stability suggest possible optoelectronic applications of Sn(II) phosphates.

*Work at Jilin University is supported by National Natural Science Foundation of China under Grant Nos. 61722403 and 11674121.

1:03 PM F16.00008: Computational design of new polymorphs of two-dimensional semiconductor InSe with enhanced interlayer interaction  YUANHUI SUN (Presenter), Jilin University, SONG-LIN LI, Nanjing University, KOUSHIK BISWAS, Arkansas State University, LIJUN ZHANG, Jilin University — Atomically thin, two-dimensional InSe has attracted considerable attention due to its widely tunable band gap and high electron mobility. The intriguingly high dependence of band gap on layer thickness remains poorly understood, and is generally attributed to quantum confinement effect. We demonstrated via systemic first-principles calculations in our previous work that strong interlayer coupling may be mainly responsible for this phenomenon, especially in the fewer-layer region. The interlayer coupling was also found to be an essential factor influencing other thickness-dependent material properties such as indirect-to-direct band gap transitions, fan-like phonon frequency diagrams, carrier mobilities, etc. In this work, by combining global structure search algorithm and first-principles calculations, we strikingly discovered two new polymorphs of InSe consisting of the monolayer in point group D_{3d}, distinct from the known one in point group D_{3h}. The new polymorphs show thermodynamic and lattice dynamical stability, and large transition barrier to the existing phases. One newly discovered polymorph exhibits the enhanced interlayer coupling, manifested by the most tunable band gap and the highest electron mobility among all the InSe phases.

1:15 PM F16.00009: A quantum-mechanical map for bonding and properties in materials*  JEAN-YVES RATY (Presenter), University of Liege, MATHIAS SCHUMACHER, RWTH Aachen, PAVLO GOLUB, National University of Singapore, VOLKER L DERINGER, University of Cambridge, CARLO GATTI, CNR-ISTM Università degli Studi di Milano, MATTHIAS WUTTIG, RWTH Aachen — Materials with rationally controlled properties play important parts in the development of new and advanced technologies. For instance, the properties of thermoelectric, phase-change, or topologically insulating materials can be traced back, to a significant extent, to the nature of bonding in materials. Here, we develop a two-dimensional map based on a quantum-topological description of electron sharing and electron transfer. This map intuitively identifies the fundamental nature of ionic, metallic, and covalent bonding in a range of elements and binary materials [1]. Furthermore, it highlights a distinct region for a mechanism recently termed “metavalent” bonding [2]. Extending this map into the third dimension by including physical properties of application interest, we show that bonding in metavalent compounds differs from the classical textbooks views of bonding. This map could be used to help designing new materials: by searching for desired properties in a 3D space and then mapping this back onto the 2D plane of bonding.

ABHIYAN PANDIT (Presenter), RAAD HALEOOT, BOTHINA HAMAD, University of Arkansas — Lead telluride (PbTe) and other lead-chalcogenides such as PbSe and PbS have been extensively investigated due to their potential applications in thermoelectric (TE) devices. Researchers previously reported good values of the figure-of-merit ($zT$) > 1.7 for PbTe – CdTe alloy at 775 K $^1$, and about 1.5 for doped PbTe with Thalium at 773 K $^2$. In addition, experiments showed that doping PbTe with Sn increases the figure of merit to 0.8 at 700 K $^3$. These promising experimental results were the motivation to carry out the electronic structure calculations of Pb$_{1-x}$Sn$_x$Te ($x = 0.25, 0.5, 0.75$) compounds using density functional theory $^4$ in this study. Based on the semi-classical Boltzmann theorem $^5$, the TE properties are computed and the results will be presented.

HUJUN GU (Presenter), Fudan University — The band offset between different semiconductors is an important physical quantity determining carrier transport properties near the interface in heterostructure devices. Computation of the natural band offset is a longstanding challenge. We propose an intermediate-phase method to predict the natural band offset between two structures with different symmetry, for which the superlattice model cannot be directly constructed. With this method and the intermediate phases obtained by our searching algorithm, we successfully calculate the natural band offsets for two representative systems, (i) zinc-blende CdTe and wurtzite CdS and (ii) diamond and graphite. The calculation shows that the VBM of zinc-blende CdTe lies 0.71 eV above that of wurtzite CdS, close to the result 0.76 eV obtained by the three-step method. For the natural band offset between diamond and graphite which could not be computed reliably with any superlattice methods, our calculation shows that the Fermi level of graphite lies 1.51 eV above the VBM of diamond. This method, under the assumption that the transitivity rule is valid, can be used to calculate the band offsets between any semiconductors with different symmetry on condition that the intermediate phase is reasonably designed.

Tuesday, March 5, 2019 11:15 AM - 2:03 PM

Session F17 DCOMP: Matter in Extreme Environments: Novel Materials BCEC 156A - Xiaolei Feng -

ANASTASIA NAUMOVA (Presenter), SERGEY LEPESHKIN, ARTEM OGANOV, Skolkovo Institute of Science and Technology — Understanding the high-pressure behavior of C-H system is of great importance due to its key role in organic, bio-, petroleum and planetary chemistry. We have performed a systematic investigation of the pressure-composition phase diagram of the C-H system at pressures up to 400 GPa using evolutionary structure prediction coupled with ab initio calculations and discovered that only saturated hydrocarbons are thermodynamically stable. Concluding our results, in C-H system only saturated hydrocarbons are thermodynamically stable. Several surprising stable methane-hydrogen co-crystals are predicted, some of them have potential energy storage purpose. We consider effects of temperature through the quasiharmonic approximation and report the pressure-temperature-composition phase diagram of the C-H system and pressure-temperature phase diagram of CH$_4$ (up to 2000 K).

We thank the Russian Science Foundation (grant 16-13-10459) for supporting this work. Calculations were performed on our Rurik supercomputer, the Arkuda supercomputer of Skolkovo Foundation, and at the supercomputer center of the University of Nizhny Novgorod.
**11:51AM F17.00002: Evolutionary prediction and experimental synthesis of SiOS at high pressure**

ONDREJ TÓTH, Department of Experimental Physics, Comenius University in Bratislava, Slovakia, MARIO SANTORO, FEDERICO GORELLI, GIANGAETANO PIETRAPERZIA, Istituto Nazionale di Ottica (CNR-INO) and European Laboratory for non Linear Spectroscopy (LENS), Sesto Fiorentino, Italy, MOHAMED MEZOUAR, GASTON GARBARINO, European Synchrotron Radiation Facility, Grenoble Cedex 9, France, ROMAN MARTONAK (Presenter), Department of Experimental Physics, Comenius University in Bratislava, Slovakia — SiOS represents a ternary generalization of the well-known and highly important family of binary AB2 compounds including CO2, SiO2, GeO2, CS2, SiS2, etc. The presence of two different bond lengths suggests that its crystal structures may be different from those found in SiO2 and SiS2. We applied evolutionary search based on DFT _ab initio_ calculations to determine crystal structures of SiOS for pressures up to 100 GPa. We predict the SiOS phase diagram at zero temperature and examined the structural, electronic and vibrational properties of the stable phases. At low pressure the stable phase is a tetrahedrally coordinated layered orthorhombic Cmc21 structure. This is predicted to transform at 14 GPa to an octahedrally coordinated layered monoclinic C2/m structure similar to the P-3m1 phase of SiS2. The system remains insulating up to 100 GPa with band gap above 1.8 eV. Following the theoretical prediction we synthesized SiOS by laser heating elemental Si, O and S in the diamond anvil cell at pressure of 8 GPa. The observed XRD pattern is in very good agreement with the theoretical prediction for the Cmc21 structure.

**12:03PM F17.00003: Structure identification at extreme conditions**

JENNIFER NIEDZIELA (Presenter), ANDREW MISKOWIEC, ASHLEY SHIELDS, BIANCA HABERL, Oak Ridge National Laboratory — We are investigating a series of low-crystallinity, amorphous uranium oxides relevant for long term storage of spent nuclear fuel. One compound has stoichiometry of ~UO3.5 (a-UO3), which appears to be x-ray amorphous. To understand the a-UO3 structure, we couple density functional theory with a genetic algorithm structure prediction mechanism to identify stable structures of non-stoichiometric uranium oxides. The lowest energy predicted structure with stoichiometry UO3.5 contains a peroxide bridge, compatible with a study of comparable material using neutron pair-distribution function techniques. We attempted to crystallize a-UO3 using a diamond anvil cell and Raman spectroscopy up to 25 GPa and observed highly anharmonic responses to pressure, but no long range order. Computational studies on the low-energy structure from the genetic algorithm show commensurate responses to the dynamical observations, along with anomalous changes in local bonding character, suggesting an indirect pathway for material identification.

**12:15PM F17.00004: Pressure-induced New Oxidation States for Gold Element**

JIANYAN LIN, SHOUTAO ZHANG, GUOCHUN YANG (Presenter), Department of Physics, Northeast Normal University, YANMING MA, State Key Lab of Superhard Materials, College of Physics, Jilin University — The formalism of the oxidation state of atoms in compounds is a key concept in chemistry. Finding novel compounds containing elements with unusually high oxidation states allows a deeper understanding of chemical behavior of elements. On the other hand, high oxidation state compounds usually bring new types of bonds with interesting physical and chemical properties. Thus, the preparation of compounds with unusual oxidation states becomes an attractive topic in chemistry and condensed-matter physics. Gold (Au) is a well-known fascinating element, but still hides interesting surprises to be discovered, especially for oxidation state. Here, we propose that high pressure becomes a controllable method for preparing high negative oxidation state of Au through its reaction with lithium. Au acts as a 6p-element in dense lithium aurides. Moreover, we identify two hitherto unknown stoichiometric compounds, AuF4 and AuF6, exhibiting typical molecular crystal character, in which Au demonstrates +4 and +6 oxidation states. Our work represents a significant step forward in a more complete understanding of the oxidation states of Au.
12:27PM F17.00005: Site-selective Mott insulator-metal transition in Fe$_2$O$_3$ under ultra-high pressures  
IGOR ABRIKOSOV (Presenter), Linköping University, Sweden and NUST "MISIS", Russia, IVAN LEONOV, Institute of Metal Physics, Yekaterinburg, Russia and NUST "MISIS", Russia, GREGORY KH. ROZENBERG, Tel Aviv University, Israel — The insulator-metal transition, induced by pressure, composition or by other means, represents perhaps the most profound transformation of the chemical bond in materials. Combining density functional plus dynamical mean-field theory (DFT+DMFT) calculations with experiment, we demonstrate that upon compression of Fe$_2$O$_3$ a novel type of Mott insulator-metal transition occurs, which is characterized by site-selective delocalization of the electrons [1]. Within the $P2_1/n$ crystal structure, which is stable in the pressure range 45-68 GPa, we observe equal abundances of ferric ions (Fe$^{3+}$) and ions having delocalized electrons (Fe$^M$). Thereby the transition is characterized by delocalization/metalization of the 3$d$ electrons on half the Fe sites, with a site-dependent collapse of local moments. Upon further compression above 75 GPa, we predict another phase transition, to a metal with a post-perovskite crystal structure and site-selective local moments [2]. Our results suggest that site-selective local moments in Fe$_2$O$_3$ persist up to ultra-high pressure of ~200-250 GPa, i.e. to pressure sufficiently above that at the core-mantle boundary.

12:39PM F17.00006: First-Principles Modeling and Evolutionary-Algorithm Prediction of Superhard B-C and B-N systems*  
WEI-CHIH CHEN (Presenter), CHENG-CHIEN CHEN, University of Alabama at Birmingham — Superhard materials with a Vickers hardness larger than ~40 GPa have a wide range of industrial applications such as cutting tools and protective coatings. Superhard boron-carbon (B-C) and boron-nitride (B-N) composites are especially important because of their superior high-temperature performance as compared to diamond and their low reactivity with ferrous metals. Here we employ evolutionary algorithm to predict the crystal structures of superhard B-C and B-N composites. We also apply density functional theory to study mechanical properties, electronic structures, phonon and Raman spectra of different B-C and B-N systems, including boron-doped cubic diamond and icosahedral boron subnitrides. Comparison of our calculations and recent experimental data will be discussed as well.

12:51PM F17.00007: A First-Principles Study of Two High-Pressure Modifications of Fe$_3$N*  
MARIBEL NÚÑEZ VALDEZ (Presenter), Goethe Universität Frankfurt am Main — Most of the iron nitride compounds of the type Fe$_x$N are unstable at ambient pressure and temperature. However, Fe-rich nitrides can be synthesized in a high pressure confined environment. Using a large volume press and X-ray diffraction in combination with scanning electron microscopy techniques, two new high pressure phases of Fe$_3$N were observed with symmetries $P6_322$ and $P312$ [1]. In this work, we perform a first-principles study based on density functional theory (DFT) within the general gradient approximation (GGA) and the local density approximation (LDA), and report on the structural, electronic, and phase stability properties as a function of pressure of these two iron nitride modifications. The exploration and understanding of high-energy density nitride materials is important as many of them exhibit remarkable technological applications due to their hardness, superconductivity or mechanical traits.

1:03PM F17.00008: Study of peptides under simultaneous application of high pressure and shear*  
Samantha Clarke (Presenter), Brad A Steele, Lawrence Livermore Natl Lab, Jasmine Hinton, Department of Physics, University of Nevada, Las Vegas, Matthew Kroonblawd, Joseph Michael Zaug, I-Feng W. Kuo, Nir Goldman, Lawrence Livermore Natl Lab, Vitali Prukapanka, Eran Greenberg, Advanced Photon Source, Argonne National Laboratory, Elissaios Stavrou, Lawrence Livermore Natl Lab — There is a renewed interest in the role of non-hydrostatic mechanical stress, or shear stress, as a driver for reactions. Combining high pressure with mechanical shearing can significantly alter reaction mechanisms and lead to a decrease in the onset pressure of structural transformations. Such conditions can be achieved with a rotational diamond anvil cell (RDAC). We will discuss the study of simple amino acids and peptides subjected to high-pressure, high-shear conditions using an RDAC. Amino acids have been studied extensively under static compression due to their significance in the fields of chemistry and biology. We compare amino acid behavior under high shear to that in a conventional DAC. μ-Raman spectroscopy and X-ray diffraction are used to probe the phase transitions and amino acid condensation. Theoretical calculations are also performed using USPEX, metadynamics, and quantum molecular dynamics to predict novel phases and reaction barriers under compressive shear.

1:15PM F17.00009: Effect of structure and composition on the electronic excitation-induced amorphization of La2Ti2-xZrxO7 ceramics  
Michel Sassi (Presenter), Tiffany Kaspar, Vaithiyalingam Shuttathanandan, Kevin Rossos, Steven Spurgeon, Pacific Northwest Natl Lab — An understanding of the response of ceramics (A2B2O7) operating in extreme environments is of interest for a broad range of applications, including potential nuclear wasteforms and in-core electronics. Here, ab initio molecular dynamic simulations have been used to investigate the effect of structure and B-site (=Ti, Zr) cation composition of lanthanum-based oxides on electronic-excitation-induced amorphization. We find that the amorphous transition in monoclinic layered perovskite La2Ti2O7 occurs for a lower degree of electronic excitation than for cubic pyrochlore La2Zr2O7. While in each case the formation of O2-like molecules drives the structure to an amorphous state, an analysis of the polyhedral connection network reveals that the rotation of TiO6 octahedra in the monoclinic perovskite phase facilitates the formation of O2-like molecules, while such octahedral rotation is not possible in the cubic pyrochlore phase. However, once the symmetry of the cubic structure is broken by substituting Ti for Zr, it becomes less resistant to amorphization. A compound made of 50% Ti and 50% Zr (La2TiZrO7) is found to be more resistant in the monoclinic perovskite than in the cubic pyrochlore phase, which may be related to the lower bandgap of the cubic phase.

1:27PM F17.00010: Structure and electrical properties of a single-crystal layered strontium manganese vanadate as a function of pressure*  
Victoria Soghomian (Presenter), Physics, Virginia Tech, Benjamin Medina, Mechanical Engineering, Virginia Tech, Qifan Yuan, Physics, Virginia Tech, Carla Slobodnick, Chemistry, Virginia Tech, Jing Zhao, Nancy Ross, Geosciences, Virginia Tech, C Stephen Hellberg, U.S. Naval Research Lab — We investigate the structural and electrical properties of a strontium manganese vanadate layered material, SrMn2(VO4)2(OH)(H2O), as a function of hydrostatic pressure. The material crystallizes in the space group C2/m. Variable temperature conductivity measurements, performed on single crystals, indicate semiconducting behavior, supported by DFT calculations. The manganese vanadate layers, consisting of chains of edge sharing MnO6 octahedra bridged by corner-sharing VO4 tetrahedra, are connected in the third dimension by octahedral Sr ions. Single-crystal x-ray diffraction under pressure up to 4 GPa indicates a reversible compression of the interlayer distance. The electrical conductivity of a single crystal as a function of pressure decreases at moderate pressures; beyond 0.4 GPa, the material is highly insulating. Interestingly, this change is not reversible. The same irreversible change in conductivity is also observed for the Ca and Ba analogs. Probing structural details at the lower pressure range by Raman spectroscopy, we observe a softening mode around 0.8 GPa related to the Mn octahedra.

Pressure-induced metallization and Superconductivity in PdSe₂

MOAZ ELGHAZALI (Presenter), PAVEL NAUMOV, HOSSEIN MIRHOSSEINI, VICKY SÜSS, Max Planck Institute for Chemical Physics of Solids, LUKAS MUECHLER, Princeton university, WALTER SCHNELLE, CLAUDIA FELSER, SERGEY MEDVEDEV, Max Planck Institute for Chemical Physics of Solids — Transition Metal Dichalcogenides (TMDs) continue to attract scientific interest due to their intriguing physical properties and potential technological applications. Here, we report the emergence of a pressure-induced dome-shaped superconductivity in PdSe₂ with a maximum critical temperature (T_c) of 13.1 K at 23 GPa, which is so far the highest T_c among TMDs family.

Lattice dynamics studies under pressure revealed a strong correlation between Se-Se dumbbells bonding and T_c. In addition, Ab initio calculations of the PdSe₂ electronic structure show the existence of topological non-trivial state with Dirac crossing and nodal lines in the vicinity of Fermi level. PdSe₂ provides therefore an exciting example to study the relationship between superconductivity and topologically non-trivial states, which can lead to discovery of novel superconducting states. We have revisited other TMD compounds to search for new superconductors. The related compounds NiSe₂ and PdS₂ have also been studied in comparison with PdSe₂. These compounds are not only interesting from the fundamental research perspective, but also for technological application as the electronically-driven insulator-metal transition at relatively low pressures could be promising in electronics applications such as memory devices.

High pressure synthesis of a new perovskite-type cuprate with doped Cu-O chains

MASAHARU ITO, HIDEFUMI TAKAHASHI, University of Tokyo, HIDEAKI SAKAI, Osaka University and JST-PRESTO, JUN FUJIOKA, University of Tokyo and JST-PRESTO, MASAYUKI OCHI, Osaka University, SHIRO SAKAI, RYOTARO ARITA, University of Tokyo and RIKEN CEMS, HAJIME SAGAYAMA, High Energy Accelerator Research Organization, YUICHI YAMASAKI, NIMS, YUICHI YOKOYAMA, HIROKI WADATI, University of Tokyo ISSP, YOSHIHIRO KUSANO, Okayama University of Science, YOSHINORI TOKURA, University of Tokyo and RIKEN CEMS, SHINTARO ISHIWATA (Presenter), University of Tokyo and JST-PRESTO — The discovery of high-temperature superconductivity in cuprates has spurred the search for novel low-dimensional cuprates such as spin-ladder compounds. On the other hand, less attention has been paid for the three-dimensional counterpart, the perovskite-type cuprates ACuO₃, presumably because of the difficulty in high-pressure synthesis. In this study, we have succeeded in the high-pressure synthesis of a novel GdFeO₃-type perovskite cuprate PrCuO₃ with quasi-one-dimensional Cu-O chains showing nearly metallic conductivity. Synchrotron x-ray diffraction and x-ray absorption spectroscopy reveal that the oxidation state can be described as Pr(4-δ)+Cu(2+δ)+O₃. The first principles calculations suggest that the formation of the Cu-O chain is caused by the A-B site charge transfer and the cooperative Jahn-Teller distortion of nearly divalent Cu ions. This system offers a unique opportunity to explore novel quantum phases of correlated electrons as the simplest one-dimensional counterpart of the high-temperature superconducting cuprates.

*This work is partly supported by Grant-in-Aid for Scientific Research, Japan Society for the Promotion of Science, Japan (Kakenhi No. 17H01195), JST PRESTO Hyper-nano-space design toward Innovative Functionality (Grant No. JPMJPR1412).
PETRU TIGHINEANU (Presenter), THOMAS FOESEL, Max Planck Institute for the Science of Light, TALITHA WEISS, Institute for Quantum Optics and Quantum Information, FLORIAN MARQUARDT, Max Planck Institute for the Science of Light — In our recent work [1] we showed how reinforcement learning with artificial neural networks (ANNs) can be a powerful tool to discover quantum-error-correction strategies fully adapted to the quantum hardware of a quantum memory. We employed a reinforcement-learning technique called natural policy gradient, in which the policy of the ANN is updated and improved according to the second-order gradient of the return (the cumulative sum of the reward) in the parameter space of the ANN.

The principal downsides of policy gradient are sample inefficiency and slow convergence, which can be critical in the case of a quantum system with an exponentially growing Hilbert space that is simulated classically. Here we conduct an in-depth study of the performance of more advanced reinforcement-learning techniques [2] applied to a noisy quantum memory. We find that the efficiency of training can be sped up by orders of magnitude via a careful choice of the technique and the corresponding hyperparameters, both of which are motivated by and related to the underlying physics.

VALENTIN STANEV (Presenter), JACK FLOWERS, ICHIRO TAKEUCHI, University of Maryland, College Park — Superconductivity in iron-based materials continues to be a focus of intense research effort a decade after its discovery. In particular, the interplay between structure and charge doping as drivers of superconductivity is still a matter of active debate. To address this question we use Machine Learning (ML) approach. Based on published data we created a database covering the available structural information of the 122 family of materials. Using the lattice parameters, pnictogen height and charge doping we trained several ML models designed to predict the critical temperature $T_c$ over the entire parameter space. The analysis of the models suggests that no single variable can fully explain and predict the evolution of $T_c$, and a combination of at least two parameters are needed. The ML predictions can be used to guide further exploration of the phase diagram of iron-based superconductors.

PAVAO SANTAK (Presenter), GARETH CONDUIT, University of Cambridge — The physical properties of many alkanes are unknown, which prevents engineers from optimally deploying them in base oil lubricants. In order to address this issue, we train neural networks that can work with fragmented data, enabling us to exploit the property-property correlations and increase the accuracy of our models. We encode molecular structure into five nonnegative integers, which enables us to exploit the structure-property correlations. We establish correlations between branching and the boiling point, heat capacity and vapor pressure as a function of temperature. Furthermore, we explore the connection between the symmetry and the melting point and identify erroneous data entries in the flash point of linear alkanes. Finally, we predict linear alkanes' kinematic viscosity by exploiting the temperature and pressure dependence of shear viscosity and density.

AYANA GHOSH (Presenter), SERGE M NAKHMANSON, Materials Science and Engineering, University of Connecticut, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory — Actinide- and lanthanide-based materials constitute an important playground for exploring exotic properties stemming from the presence of itinerant or localized $f$-electrons. For example, uranium-based compounds have exhibited emergent phenomena, including magnetism, unconventional superconductivity, hidden order, and heavy fermion behavior. Among them, the magnetic properties with varying ordered states and moment size are sensitively dependent on pressure, chemical doping and magnetic field due to the strong-correlation effects on $5f$-electrons. So far, there have even been no reports of systematic studies to map out connections between structures and properties of these compounds. In order to investigate such links and bridge between theoretical and experimental learnings, we have constructed two databases combining results of high-throughput DFT simulations and experimental measurements, respectively, for a family of uranium-based binary compounds. We then utilized different machine learning models to identify related accessible attributes (features) and predict magnetic moments and ordering in these compounds.

12:39PM F18.00006: Machine learning-assisted search for high performance plasmonic metals* ETHAN SHAPERA (Presenter), Department of Physics, University of Illinois at Urbana-Champaign, ANDRE SCHLEIFE, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign — Plasmonics aims to manipulate light through choice of materials and nanoscale structure. Finding materials which exhibit low-loss responses to applied optical fields while remaining feasible for widespread use is an outstanding challenge. Online databases compiled computational data for numerous properties of tens of thousands of materials. Due to the large number of materials and high computational cost, it is not viable to compute optical properties for all materials from first principles. Geometry-dependent plasmonic quality factors for a training set of ~1,000 materials are computed using density functional theory and the Drude model. We train then apply random-forest regressors to rapidly screen Materials Project to identify potential new plasmonic metals. Descriptors are limited to symmetry and quantities obtained using the chemical formula and the Mendeleev database. The machine learning models filter through 7,445 metals in Materials Project. We iteratively improve the model with active learning by adding DFT results for predicted high quality factor metals into the training set. From this we predict Cu₃Au, MgAg₃, and CaN₂ as candidates and verify their quality factors with DFT.

12:51PM F18.00007: Machine Learning and Crystal Structure Prediction of Molecular Crystals RUGGERO LOT, FRANCO PELLEGRINI, YUSUF SHAIDU, EMINE KUCUKBENLI (Presenter), International School for Advanced Studies — There is a natural synergy between data-hungry machine learning methods and crystal structure prediction of molecular crystals that requires a careful search in a vast potential energy landscape. In our previous study we demonstrated how taking advantage of machine learning methods can enable novel predictions even for well-studied molecular crystals [1]. In order to leverage this synergy further, we have been developing a deep neural network training tool, PANNA (Potentials from Artificial Neural Network Architectures), based on TensorFlow framework [2]. In creating transferable machine-learned potentials, the key step is the non-linear process of training the network model. We will demonstrate a variety of network training techniques that can be explored within PANNA, from ones that are commonly used in machine learning community to the ones that are specific to atomistic simulations. We will report the effect of data selection, input representation and training methods on the training dynamics and on the resulting potentials in the difficult case of molecular crystals.

1:03PM F18.00008: Fitting effective models using QMC parameter derivatives WILLIAM WHEELER (Presenter), SHIVESH PATHAK, LUCAS WAGNER, University of Illinois at Urbana-Champaign — Effective models are fundamental to our understanding of complex materials, but selecting the right model and parameters to accurately describe a particular material can be challenging. The recently developed density matrix downfolding method (DMD) [1] uses an ensemble of quantum Monte Carlo calculations to both select and fit parameters to effective models for materials. However, this method is computationally extremely demanding. In a similar spirit to force matching in classical model fitting [2], we improve the efficiency of DMD by computing derivatives of the energy and density matrix with respect to parameters of each trial wave function. We demonstrate the new technique by computing a band structure for silicon using first principles quantum Monte Carlo.

1:15PM F18.00009: Detection of Phase Transitions in Quantum Spin Chains via Unsupervised Machine Learning YUTAKA AKAGI (Presenter), NOBUYUKI YOSHIOKA, HOSHO KATSURA, Department of Physics, The University of Tokyo — In the field of machine learning, there has been an important breakthrough in recent years. What was at the center of it is the deep learning by artificial neural networks mimicking human brains. By deepening a process part which repeats extracting feature quantities through nonlinear transformations, so-called hidden layer, data/class separability and the discriminability have dramatically improved. Recently, the machine learning techniques have found a wide variety of applications in condensed matter and statistical physics. Examples include detection of phase transition and acceleration of Monte Carlo simulation. Meanwhile, most of these studies are based on supervised learning under well-known results, and there are only a few previous examples applying unsupervised learning. In this research, we investigate quantum phase transitions in various quantum spin chains by using an autoencoder which is one of unsupervised learning methods. In particular, we will show that the autoencoder whose input is only short-range correlators is capable of detecting even topological phase transition from the large-D phase to the Haldane phase without using either topological invariants or entanglement spectra.
1:27PM F18.00010: Supervised learning of phase transitions in classical and quantum systems* NICHOLAS WALKER (Presenter), KA-MING TAM, MARK JARRELL, Louisiana State University — Supervised machine learning methods are used to identify transitions in physical systems using the classical solid-liquid transition of a Lennard-Jones system as well as the strong coupling-local moment quantum transition in the soft-gap Anderson model as examples. Monte Carlo sampling was used to achieve a uniform sampling of configurational data across a large range of the relevant transition parameter for each system. Hyperbolic feature scaling is applied to the features followed by training a 1-dimensional convolutional neural network with the samples corresponding to the extreme parameters of each phase as training data. The rest of the configurational data is assigned phase classification probabilities by the neural network, allowing for the prediction of the transition point with respect to the chosen varied parameter. This is done by fitting the mean classification probabilities for each set of configurational data with respect to the varied parameter with a logistic function and taking the transition to be at the value of the parameter corresponding to the midpoint of the sigmoid. The results obtained are comparable to results using contemporary methods for each system.

Session F19 DCOMP DCMP: Precision Many Body Physics V BCEC 156C - Luca Fausto Tocchio - Tag(s): Focus

11:15AM F19.00001: High-precision data for the unitary Fermi gas from diagrammatic series with zero convergence radius [Invited] RICCARDO ROSSI, CCQ, Flatiron Institute, TAKAHIRO OHGOE, University of Tokyo, KRIS VAN HOUCKE (Presenter), FELIX WERNER, Ecole Normale Superieure — In this talk I will mainly focus on the unitary Fermi gas (spin 1/2 fermions with contact interactions in 3D, which describes cold atomic gases at a Feshbach resonance) in the normal phase. Thanks to a diagrammatic Monte Carlo algorithm, we accurately sample all skeleton diagrams (built on dressed single-particle and pair propagators) up to order nine [1]. The diagrammatic series is divergent and there is no small parameter so that a resummation method is needed. We compute the large-order asymptotics of the diagrammatic series, based on a functional integral representation of the skeleton series and the saddle-point method. We show that the radius of convergence is actually zero, but the series is still resummable, by a generalised conformal-Borel transformation that incorporates the large-order asymptotics [2]. This yields new high-precision data, not only for the equation of state, but also for Tan's contact coefficient and for the momentum distribution [3]. I will also highlight some recent developments in (determinant) diagrammatic Monte Carlo and present new high-precision data for the Fermi polaron, which is a single impurity atom immersed in a Fermi sea.

Understanding the metal-insulator transition in VO$_2$ from quantum Monte Carlo, DMFT, and experiment

JARON KROGEL (Presenter), ILKKA KYLANPAA, PANCHAPAKESAN GANESH, Oak Ridge National Laboratory, FRANK LECHERMANN, Universitat Hamburg, OLLE HEINONEN, Argonne National Laboratory, PAUL KENT, Oak Ridge National Laboratory — Vanadium dioxide displays the quintessential example of metal-insulator transition (MIT) physics in a strongly correlated material. Despite numerous studies, the nature of the MIT is still controversial and new perspectives are needed. Recent experiments view rutile VO$_2$ as an unconventional metal due to its anomalously low electronic thermal conductivity. Due to strong correlations in VO$_2$, beyond DFT approaches are required and here we study pristine and non-stoichiometric VO$_2$ with quantum Monte Carlo and DMFT. New perspective is provided by the momentum distribution, which contains no discontinuity in the metallic phase, indicating a non-Fermi liquid metal consistent with experimental findings. Quasi-1D back-scattering along the rutile c-axis is reminiscent of a Tomanaga-Luttinger liquid, where the scattering is induced by impurities. In non-stoichiometric VO$_2$ the calculated spectral function indicates a competition between $\alpha_{1g}$ and $\epsilon_{πg}$ orbitals which have a role in the formation of the insulating state. DMFT-VCA calculations show that the $\alpha_{1g}\epsilon_{πg}$ orbital dichroism falls below its pristine value at a doping concentration of $δ=0.07$, in near agreement with the experimentally determined critical doping threshold for the suppression of the insulating state.

Computable formulae for Hall and Nernst Coefficients of Strongly Correlated Metals

ASSA AUERBACH (Presenter), ILIA KHAIT, Technion - Israel Institute of Technology — Exact formulae for the temperature dependent Hall coefficient (published in Phys. Rev. Lett. 121, 066601 (2018)), and for a modified Nernst coefficient of metals are derived from the Kubo linear response functions. The formulae are valid for a large range of microscopic Hamiltonians of fermions and bosons, subject to arbitrary potentials and interactions. These DC transport coefficients (remarkably) depend solely on equilibrium susceptibilities, which are amenable to well controlled numerical algorithms - including Quantum Monte Carlo (in imaginary time), high temperature series expansions, and variational wavefunctions. Applications of these formulae are demonstrated for band electrons, the Bose Hubbard model, and for the t-J model.

This work is supported in part by the United States-Israel Binational Science Foundation, Grant No. 2016168, and the Israel Science Foundation, Grant No. 2022061.

Self Consistent Auxiliary Field Quantum Monte Carlo Method for Realistic Materials

SHIWEI ZHANG (Presenter), HAO SHI, Simons Foundation — The auxiliary field quantum Monte Carlo (QMC) calculations in interacting fermion systems require a constraint to control the sign and phase problem. The constraint involves an input trial wave function which restricts the random walks. We introduce a systematically improvable constraint for realistic materials. An independent-particle calculation is coupled to the phaseless auxiliary-field QMC calculation and the independent-particle solution is used as the constraint in QMC. The constraint is optimized by the self-consistency between the QMC and independent-particle calculations. We demonstrate this approach in transition metal oxides. Connection with other electronic structure methods will be discussed.

The Flatiron Institute is supported by the Simons Foundation.

Optimized multi-determinant trial wavefunctions for Constrained Path Monte Carlo

R. TORSTEN CLAY (Presenter), Mississippi State University — Two of the most successful types of methods for strongly-correlated models are quantum Monte Carlo and renormalization group methods. Both however suffer from limitations that make large calculations difficult except in special cases, for example one dimension (1D). The Density Matrix Renormalization Group method suffers from poor scaling beyond 1D. The Path Integral Renormalization Group (PIRG) method expands the wavefunction in Slater Determinants and is not limited by dimension, but by the strength of interactions. Quantum Monte Carlo calculations are severely limited by the Fermion sign problem. The Constrained Path Monte Carlo (CPMC) method prevents the exponential loss of precision from the sign problem through the use of a trial wavefunction. However, the trial wavefunction is an uncontrolled approximation with an unknown error. We demonstrate a way to combine the advantages of a renormalization method (PIRG) with those of a quantum Monte Carlo (CPMC), by using PIRG wavefunctions as CPMC trial wavefunctions. The advantage of PIRG wavefunctions as trial wavefunctions is that they can be systematically improved. We present results for PIRG-CPMC calculations on frustrated Hubbard models, comparing energies, spin correlations, and superconducting pair-pair correlations.
1:03PM F19.00006: Skeleton diagrammatic expansions with screened Hubbard interaction versus multivaluedness of the Luttinger-Ward functional  

AARAM JOO KIM (Presenter), EVGENY KOZIK, Department of Physics, King’s College London — We systematically study properties of high-order bold-diagrammatic expansions, which may converge to unphysical answers for the Hubbard interaction due to the multivaluedness of the Luttinger-Ward functional (LWF), by the prototypical example of the Hubbard atom. The diagrammatic Monte Carlo method with fully dressed propagator $G$ is adopted to generate the high-order series. By varying the level of screening in the interaction line; bare $U$, random-phase approximation $W_{rpa}$, and fully dressed $W_{exact}$, we present the convergence properties of the different bold series in connection with multiple branches of the LWF. In particular, we find that the bold-$GW_{exact}$ and bold-$GW_{rpa}$ series diverge well below the branching point of the LWF, but admit the analytic continuation beyond their convergence radius by standard techniques. We further explore the possibility of using the bold diagrammatic series in the strongly correlated regime to obtain precise results with controlled accuracy.

1:15PM F19.00007: Cluster Perturbation Theory Applied to Two-Particle Correlation Functions*  
PETER RAUM (Presenter), VITO SCAROLA, Virginia Tech, THOMAS MAIER, Oak Ridge National Lab — Developing techniques to solve Hubbard models is an active area of research due to their ability to capture the essential properties of many strongly correlated systems. Cluster Perturbation Theory (CPT) is an economic method to calculate the momentum and energy resolved single-particle Green's function that has been used extensively in direct comparisons with experiments. For example, the single-particle Green's Function can be observed with angle-resolved photoemission spectroscopy. However, many experimental observables are given by two-particle correlation functions. We extend CPT to compute these correlation functions and focus on a method to use CPT to calculate the transverse spin-susceptibility, measurable via inelastic neutron scattering on strongly correlated materials or with optical probes of atomic gases in optical lattices. We benchmark our method with the one-dimensional Fermi-Hubbard model at half-filling and compare with known results.

1:27PM F19.00008: Optimized higher-order Lie-Trotter-Suzuki decompositions for two and more terms  
YIKANG ZHANG (Presenter), THOMAS BARTHEL, Duke University — Lie-Trotter-Suzuki decompositions of operator exponentials have a lot of applications in physics. For example, they are employed to sample equilibrium states in quantum Monte Carlo and to simulate the dynamics of quantum systems on quantum computers or on classical computers using tensor network state techniques. They also provide symplectic integrators for classical physics. Good higher-order decompositions for exponentials of $n=2$ non-commuting operators are well-known. These cover one-dimensional quantum systems with nearest-neighbor interactions. We present some optimized decompositions for $n=2$ and new higher-order decompositions for $n=3,4$ which are needed for one-dimensional systems with longer-ranged interactions or quantum systems in higher dimensions. The ordering of operators in the decompositions turns out to have substantial influence on the attainable approximation order and magnitudes of the leading error terms.

1:39PM F19.00009: Diagrammatic Monte Carlo approach to angular momentum in quantum many-body systems*  
GIACOMO BIGHIN (Presenter), Institute of Science and Technology Austria, TIMUR V TSCHERBUL, Department of Physics, University of Nevada, Reno, MIKHAIL LEMESHKO, Institute of Science and Technology Austria — We introduce a Diagrammatic Monte Carlo (DiagMC) approach to molecular impurities, possessing rotational degrees of freedom [1]. The technique is based on a diagrammatic expansion [2] that merges the usual Feynman diagrams with the angular momentum diagrams known from atomic and nuclear structure theory, thereby incorporating the non-Abelian algebra inherent to quantum rotations. Due to the peculiar way in which angular momenta couple, the configuration space is larger with respect to most DiagMC applications, and a new class of updates is needed in order to span it completely.

We exemplify the technique by obtaining an all-coupling solution of the angulon model - essentially a molecular impurity in a quantum many-body environment - showing that our approach correctly recovers the strong-coupling limit. However, the technique is general and can be applied to a broad variety of systems possessing angular momentum degrees of freedom, thereby establishing a far-reaching connection between DiagMC techniques and molecular simulations.

1:51PM F19.00010: Electronic structure of semiconductor nanoparticles from stochastic evaluation of imaginary-time path integral: nonrelativistic U(1) lattice gauge theory in the Kohn-Sham basis  

ANDREI KRYJEVSKI (Presenter), North Dakota State University, THOMAS LUU, Institute for Advanced Simulation, Jülich Center for Hadron Physics, Forschungszentrum Jülich GmbH — In the Kohn-Sham orbital basis imaginary-time path integral for electrons in a semiconductor nanoparticle has a mild fermion sign problem and is, therefore, amenable to evaluation by the standard stochastic methods. Utilizing output from the density functional theory simulations we compute imaginary-time electron propagators in several silicon hydrogen-passivated nanocrystals, such as Si_{35}H_{36}, Si_{87}H_{76} and Si_{147}H_{100}, and extract energies of low-lying electron and hole levels. Our qasiparticle gap predictions are in very good agreement with the results of recent G0W0 calculations.

2:03PM F19.00011: Insulating states from increased kinetic energy: counterintuitive physics in the basic model of organic conductors and superconductors*  

ADRIAN KANTIAN (Presenter), Uppsala University, THIERRY GIAMARCHI, DQMP, University of Geneva — The U-V model at quarter filling is the canonical model of the organic Bechgaard and Fabre salts, the first materials to exhibit a superconducting phase based on repulsive electron interactions, which is accompanied by competing magnetic phases just as for the cuprates of high-Tc superconductivity. However, just as for the doped 2D Hubbard model, the U-V model can exhibit very rich and complicated physics, which are a challenge to treat reliably. In the presented work, we show that the U-V model can give rise to surprising physics in which an insulating state emerges from increased transverse kinetic energy, by combining large-scale DMRG results with analytic RG of bosonized models of the 2-leg U-V Hubbard ladder.

Session F20 DCOMP: First-principles Modeling of Excited-state Phenomena in Materials V: Time-dependent Density Functional Theory

[Invited]  

NATHALIE VAST (Presenter), OLEKSANDR MOTORNYI, Laboratoire des Solides Irradiés, CEA-DRF-IRAMIS, Ecole Polytechnique, CNRS UMR 7642, ANDREA DAL CORSO, SISSA — Over a decade ago, a new type of surface plasmons has been both predicted theoretically for surfaces that support Shockley electronic surface states [1], and experimentally reported [2]. The so-called acoustic surface plasmon (ASP) exhibits a dispersion different from the behaviour of conventional surface plasmons. ASPs in gold have a twofold advantage for plasmonics applications: due to the linear dispersion, a signal consisting of several ASP waves can propagate without distortion; and vicinal Au surfaces have a step-terrace structure that provides the intrinsic grating on the atomic level, allowing, potentially, to couple the ASP to light.

I will present a new algorithm based on the Lanczos recursion within TDDFPT [3] that allows for accurate and efficient computations of the electron-energy loss spectra for arbitrary values of the transferred momentum \( \mathbf{q} \). The vicinal Au (455) surface could be modelled with 5 nm of gold (253 atoms) separated by 5 nm of vacuum. The effect of spin-orbit coupling on the ASP dispersion, as well as the role of intra- and inter-band transitions, have been examined. I show that the computation of plasmons on the quantum level is within reach for systems of unprecedented size.

11:51AM F20.00002: Propagation of maximally localized Wannier functions in real-time TDDFT* DILLON C. YOST (Presenter), YI YAO, YOSUKE KANAI, Department of Chemistry, University of North Carolina at Chapel Hill — Real-time, time-dependent density functional theory (RT-TDDFT) has attracted much attention in recent years as an approach to study a variety of excited state phenomena ranging from optical excitations to electronic stopping. Many applications of RT-TDDFT involve the inclusion of a time-dependent applied electric field to perturb the system. In the length gauge representation, one can apply a scalar electric field to localized orbitals, such as maximally localized Wannier functions (MLWFs). We have implemented a method in the Q8@LL plane-wave pseudopotential RT-TDDFT code to transform the time-dependent Kohn-Sham (TDKS) states into MLWFs, allowing for simulations with time-dependent electric fields and for the calculation of absorption spectra and nonlinear optical responses for both isolated and periodic systems. The propagation of MLWFs in RT-TDDFT gives access to dynamic polarization and quantities such as the MLWF spread, allowing for detailed analysis of a wide range of excitation phenomena.

12:03PM F20.00003: Maxwell+TDDFT multiscale simulation for optical response of nanomaterials* MITSUHARU UEMOTO (Presenter), KAZUHIRO YABANA, University of Tsukuba — We have been developing a novel multiscale simulation method which combines the time-dependent density functional theory (TDDFT)-based first principles electron dynamics and finite-difference-time-domain (FDTD)-based electromagnetic calculations. We apply this method to light propagation / scattering problem by semiconducting silicon nanoparticles and nanodimer structures with the length scale at a few hundred nanometer, which are often used as building block of optical devices. Under an irradiation of an intense femtosecond laser pulse (I > 10^{10} W/cm^{2}), carrier excitations by multiphoton processes take place due to the enhanced light field at the focal spot / hotspot. Thus, this method offers a useful tool to analyze optical nonlinearity at nanostructures in the first principles level.

*This work was supported in part by MEXT as a social and scientific priority issue (Creation of new functional devices and high-performance materials to support next-generation industries; CDMSI) to be tackled by using post-K computer.

12:15PM F20.00004: Maxwell + First-Principles TDDFT-MD Multi-Scale Simulation and Application to Impulsive Stimulated Raman Scattering Spectroscopy ATSUSHI YAMADA (Presenter), KAZUHIRO YABANA, Center for Computational Sciences, University of Tsukuba — Nonlinear optics in solids includes complex physics arising from coupled nonlinear dynamics of light electromagnetic fields, electrons, and phonons. We have developed a novel multi-scale simulation method to track coupled dynamics of electromagnetic field inside the material in macroscopic scale and electrons and atoms in solid in microscopic scale, where the Maxwell equations are solved to describe propagation of the light while first-principles Ehrenfest molecular dynamics (MD) calculation is performed based on time-dependent density functional theory (TDDFT), extending our previously developed multi-scale method. We have applied the method to impulsive stimulated Raman scattering spectroscopy of diamond. Simulations of pump and probe pulse propagations mimicking the experimental measurement process are performed using our developed open source free software, SALMON. We show detailed dynamical processes of generation of coherent phonon and amplification of Raman scattered wave as well as measured transmission signals.

12:27PM F20.00005: Microscopic and macroscopic Maxwell-TDDFT descriptions for light-matter interaction in thin materials SHUNSUKE YAMADA (Presenter), MASASHI NODA, Center for computational sciences, University of Tsukuba, KATSUYUKI NOBUSADA, Institute for Molecular Science, KAZUHIRO YABANA, Center for computational sciences, University of Tsukuba — We present a comprehensive theoretical framework for interaction of an ultrashort light pulse with a thin material based on the time-dependent density functional theory (TDDFT). We introduce a microscopic description solving the Maxwell equations for the light electromagnetic fields and the time-dependent Kohn-Sham equation for the electron dynamics simultaneously in the time domain on a common real-space grid. This scheme can simulate the light-matter interaction in thin films irrespective of the film thickness and the light intensity. For two limiting cases of extremely thin and sufficiently thick films, we develop approximate schemes. For the former, a 2D macroscopic description is developed: 2D response functions are introduced for a weak field, while time evolution equation is derived for an intense field. For the latter, the 3D macroscopic description coincides with the ordinary electromagnetism with the 3D bulk response functions for a weak field, or the multiscale Maxwell-TDDFT scheme for a strong field, which our group developed previously. In this talk, we show results for Si thin films and discuss the applicability of the microscopic and macroscopic descriptions.
12:39PM F20.00006: Magnetic Excitations in TDDFT with GGA kernel  NISHA SINGH (Presenter), PETER ELLIOTT, Theory, Max-Planck Institute of Microstructure Physics, TASHI NAUTIYAL, Physics, Indian Institute of Technology Roorkee, J. KAY DEWHURST, Theory, Max-Planck Institute of Microstructure Physics, SANGEETA SHARMA, Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy — In ordered magnets of all forms (ferromagnets, antiferromagnets, ferrimagnets, etc.) we encounter wave like excitations that propagate through the lattice of ordered spins. Correctly predicting these collective excitation modes is essential for understanding the thermodynamic properties of such materials. Theoretically, TDDFT within the linear regime, can successfully capture these low energy spin waves. However, it requires an approximation to the exchange-correlation (XC) kernel, which encapsulates the electron-electron interactions of the many-body systems. Despite the plethora of approximations for the XC energy functional, only the ALDA kernel has been implemented and applied to study these magnetic excitations. In the work presented here we climb up the Jacob's ladder of functional and derive the XC kernel for GGA functionals. This is then tested by calculating the magnon spectra for simple ferromagnets and Heusler ferrimagnets using the PBE GGA functional.

12:51PM F20.00007: Orbital magneto-optical response of periodic insulators from first principles  DAVID STRUBBE (Presenter), Department of Physics, University of California, Merced, IRINA LEBEDEVA, Departamento de Física de Materiales, Universidad del País Vasco UPV/EHU, San Sebastián, ILYA V. TOKATLY, Universidad del País Vasco UPV/EHU, Donostia International Physics Center, and IKERBASQUE, ANGEL RUBIO, Universidad del País Vasco UPV/EHU and Max Planck Institute for the Structure and Dynamics of Matter — We present a reformulation of density matrix perturbation theory for time-dependent electromagnetic fields under periodic boundary conditions, which allows us to treat the orbital magneto-optical response of solids at the ab initio level. We use time-dependent density-functional theory (TDDFT) with the Sternheimer equation, implemented in the Octopus real-space code, to solve for the gauge-invariant part of the density matrix via the modern theory of polarization. Our computational scheme has an efficiency comparable to standard linear-response calculations of absorption spectra. Calculations of magnetic circular dichroism spectra for adenine, cyclopropane, and bulk silicon agree with the available experimental data. A clear signature of the valley Zeeman effect is revealed in the magneto-optical spectrum of a single layer of hexagonal boron nitride, with a g-factor similar to that observed in monolayer transition-metal dichalcogenides. The present formalism opens the path towards the study of magneto-optical effects in strongly driven low-dimensional systems.

1:03PM F20.00008: A General Model Order Reduction Scheme for the Evaluation of Spectroscopic Properties and Excited States  DAVID WILLIAMS-YOUNG (Presenter), ROEL VAN BEEUMEN, CHAO YANG, Computational Research Division, Lawrence Berkeley National Laboratory, XIAOSONG LI, Department of Chemistry, University of Washington — Due to the importance of spectroscopic methods in experimental physical chemistry, a primary directive in quantum chemistry is to be able to accurately and efficiently predict and interpret the response of molecular systems to external perturbations. Molecular response properties may be described in terms of propagators, such as the single particle Green's function and polarization propagator. Traditional methods to solve these problems, such as partial eigenvalue decompositions and direct linear system solves, become computationally intractable in cases where the spectral region of interest lies in the propagator's spectral interior. In this work is presented a novel model order reduction (MOR) technique for the rapid evaluation of molecular properties in arbitrary spectral regions. MOR accelerates the evaluation of these properties by constructing a rational Krylov subspace which spans the spectral region of interest. Numerical studies demonstrating the favorable computational cost and scaling of this method for linear response TDDFT are presented. Further, it will be demonstrated that bright eigenstates of the Hamiltonian may also be extracted from the same subspace. The proposed MOR algorithm will enable routine inquiry into previously intractable spectroscopic problems.

1:15PM F20.00009: Truncated methods applied to the direct calculation of exciton binding energies.  ARITZ LEONARDO (Presenter), University of the Basque Country, MIKEL ARRUBARRENA, centro de física de materiales (CFM), AI TOR BERGARA, University of the Basque Country, ANDRES AYUELA, centro de física de materiales (CFM) — Optical processes in insulators and semiconductors, including excitonic effects, can be described in principle exactly using time-dependent density-functional theory (TDDFT). Within this formalism, a family of exchange-correlation kernels known as long-range-corrected (LRC) kernels \((\text{fxc}=-\alpha/q^2)\) have shown to accurately reproduce optical spectra for several insulators and semiconductors. More recently, Ullrich and co-workers adapted the Casida equation formalism suitable for determining molecular excitations to periodic solids, this way the exciton binding energy may be calculated in a direct way without having to compute explicitly the response function. However, it appears that no LRC-type kernel is capable of simultaneously produce good optical spectra and quantitatively accurate exciton binding energies. In the present work we have adapted Casida's formalism following a different approach. The long range nature of the kernel, i.e. the \(q\to0\) singularity, is regularized employing a super-cell wigner-seitz truncation that clearly alters the previously calculated alpha values of the kernel. We will justify our calculation method and provide the alpha values for several insulating/semiconducting materials.
1:27PM F20.00010: Simulating valence and core excitons in solids within velocity-gauge real-time TDDFT.* SRI CHAITANYA DAS PEMMARAJU (Presenter), SLAC National Accelerator Laboratory — The application of real-time TDDFT (RT-TDDFT) to describe light-matter interactions in periodic solid-state systems has thus far been largely limited to situations where excitonic effects are not crucial primarily due to the inability of semi-local exchange-correlation (XC) functionals to describe exciton binding. In particular the simulation within TDDFT of accurate core-excitation spectra that are often strongly modulated by solid-state excitonic effects has been hindered. In this work, a recent atomic orbital basis implementation [1] of real-time TDDFT that exploits range-separated hybrid XC functionals within the generalized Kohn-Sham formulation [2] to simultaneously describe both valence and core excitonic effects in solids is presented. Optical properties and excitons in a number of representative solid-state systems are discussed from a time-domain perspective. Applications of the methodology to time-resolved core and valence spectroscopies are illustrated.

*This work was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, under Contract No. DE-AC02-76SF00515 through TIMES at SLAC.

1:39PM F20.00011: Relativistic real-time time-dependent density functional theory for molecular properties* LUKAS KONECNY (Presenter), MARIUS KADEK, KENNETH RUUD, MICHAL REPISKY, Hylleraas Centre for Quantum Molecular Sciences, University of Tromso — We present the development and applications of relativistic real-time time-dependent density functional theory. The method is based on the four-component Dirac–Coulomb Hamiltonian in the basis of restricted kinetically balanced Gaussian functions exploiting the noncollinear Kramers unrestricted formalism. A quasirelativistic two-component X2C Hamiltonian obtained from the original four-component Hamiltonian by an algebraic decoupling transformation is also considered. The equation of motion is formulated for the one-electron density matrix and solved in a series of discrete time steps utilizing the second order Magnus propagator corrected by a self-consistent extrapolation-interpolation procedure. Induced dipole moments recorded during simulations are transformed to the frequency domain to yield molecular spectra. Presented methodology includes scalar and spin-orbit relativistic effects variationally. It is demonstrated for valence and core electron molecular spectroscopies such as electron absorption and circular dichroism.

*Research Council of Norway Center of Excellence Grant No. 262695, Hylleraas Centre for Quantum Molecular Sciences Norwegian Supercomputer Program NOTUR Grant No. NN4654K

1:51PM F20.00012: Modes of Electron-Density Oscillation Corresponding to Absorption in Metal Clusters* RAJARSHI SINHA-ROY (Presenter), CINaM, Aix-Marseille University, CNRS, 13288 Marseille, France, PABLO GARcía-GONZÁLEz, Departamento de Física Teórica de la Materia Condensada and Condensed Matter Physics Center (IFIMAC), Universidade Autónoma de Madrid, E-28049 Madrid, Spain, XÓCHITL LÓPEZ-LOZANO, ROBERT L WHETTEN, Department of Physics & Astronomy, The University of Texas at San Antonio, One UTSA circle, 78249-0697 San Antonio, TX., USA, HANS-CHRISTIAN WEISSKER, CINaM, Aix-Marseille University, CNRS, 13288 Marseille, France — Time-Dependent Density-Functional Theory (TDDFT) is widely used for calculating electron excitations in clusters and large molecules. For optical excitations, TDDFT is customarily applied in two distinct approaches: transition-based linear-response TDDFT (LR-TDDFT), and the real-time formalism (RT-TDDFT). The latter does not require the calculation of empty electron orbitals, which is specially advantageous when dealing with large systems. However, RT-TDDFT does not provide direct information on the nature of the excitations, unlike LR-TDDFT where the transition densities and the decomposition of the actual excitations in terms of independent-particle Kohn-Sham transitions are naturally obtained. In the present work, we show that the transition densities of the optically allowed transitions can be efficiently extracted from a single δ-kick time-evolution calculation. We assess the results by comparison with the corresponding LR-TDDFT ones and also with the induced densities arising from RT-TDDFT simulations of the excitation process using a quasi-monochromatic laser.

Session F21 DCOMP DCMP GSNP: Advances in Computational Methods for Statistical Physics and Their Applications II BCEC 157B - Danny Perez, Los Alamos National Laboratory - Tag(s): Focus
11:15AM F21.00001: Sampling large deviations of mobility and its application to glassy dynamics [Invited]
FRANCESCO TURCI, PADDY ROYALL, University of Bristol, THOMAS SPECK (Presenter), Johannes Gutenberg University Mainz — A major challenge in the computational sciences is the accurate sampling of events that are rare and have a low probability. Consequently, a wealth of advanced numerical methods devoted to this purpose has been developed. I will review the use of transition path sampling techniques to sample fluctuations of the single particle mobility in trajectories of a model glass former. In the supercooled regime, the dynamics is characterized by correlations that are trivial in space but highly non-trivial in time. There is numerical evidence for a dynamic phase transition from liquid to a jammed glass, which can be probed through a structural order parameter. I will present numerical and experimental results on the coexistence of the normal supercooled liquid with a phase that is rich in locally favored structures and dynamically arrested. Most strikingly, the coexistence region narrows as temperature is decreased, with the possibility that coexistence terminates at a finite temperature in a lower critical point. I will briefly discuss consequences for our understanding of the glass transition.

MARTIN MAGILL (Presenter), ANDREW NAGEL, HENDRICK W DE HAAN, University of Ontario Institute of Technology — Partial differential equations (PDEs) in nanobiophysics (NBP) often arise in complicated geometries. Typically, such problems would be solved with mesh-based numerical solvers. However, the stochastic many-body systems common to NBP are described by high-dimensional PDEs. Mesh-based solvers fail for such problems, so instead these PDEs are solved indirectly using particle simulations. Still, these particles are often subject to force fields, which are themselves described by similar PDEs. Furthermore, to establish how observables, like molecular mobility, depend on problem parameters, like molecular size, simulations must be repeated many times.

A new method for solving PDEs is to approximate solutions with deep neural networks (DNNs). DNNs can even learn solutions directly from the PDE problem statement, without using any external data. In this talk, I will illustrate some benefits of this method for solving PDEs in NBP. DNNs are memory-efficient, enabling complicated electric fields to be used in GPU-accelerated particle simulations. Surprisingly, DNNs can actually solve high-dimensional PDEs directly, as an alternative to particle simulations. Finally, this method can naturally be extended to express target observables as differentiable functions of problem parameters.

12:03PM F21.00003: Machine Learning Surrogate Models to Accelerate Monte-Carlo Calculation*
MARKUS EISENBACH (Presenter), JIAXIN ZHANG, ZONGRUI PEI, MASSIMILIANO LUPO PASINI, YING WAI LI, JUNQI YIN, Oak Ridge National Laboratory — While modern Monte-Carlo algorithms are highly efficient for computational statistical mechanics in many systems, it is desirable for many materials simulations to utilize energies that are evaluated using density functional theory to capture the complex interactions in multicomponent systems. In the past we have performed calculations by combining our LSMS first principles code with Wang-Landau Monte-Carlo calculations. The number of Monte-Carlo steps limits the applicability of this method even on high-performance computer systems. Thus, we are integrating a machine learning derived surrogate model with Monte-Carlo calculations. Here we present our results of deriving surrogate models from total energy calculations that replicate the behavior of first principles calculations of alloy ordering transitions. In addition to evaluating the attainable speedup, we explore strategies for reducing the dimensionality of the surrogate model as well as the impact of the model on the accuracy of the Monte-Carlo results.

*This work is supported in part by the Office of Science of the Department of Energy and by the LDRD Program of Oak Ridge National Laboratory. It used resources of the Oak Ridge Leadership Computing Facility, supported by the Office of Science of the U.S. Department of Energy.

12:15PM F21.00004: Reinforcement Learning and the Scientific Method
RORY COLES, University of Ontario Institute of Technology, ISAAC TAMBLYN (Presenter), University of Ontario Institute of Technology, National Research Council of Canada — Model-based reinforcement learning allows an agent to learn how their environment behaves around them, allowing for an optimal solution to be planned preemptively. In past reports, model-based reinforcement learning has been found to sample an environment more efficiently than model-free reinforcement learning, in which the agent is learning the best action to take given any one state.

In this work, we present an alternative to model-based reinforcement learning in which exploring and updating the model are separate actions. As a result, the agent must act in an environment when there is uncertainty in the state and learn to take detailed observations accordingly to update the model. To achieve success, the agent needs to extrapolate from the known model, conduct a test in order to obtain new data, and then base future decisions on those results. This is a well-known process: the scientific method. We then show how our newly developed method can be used to learn the dynamics of physics-based models and exploit the knowledge gained to achieve a given objective with a measurable confidence.
ZHENG FANG (Presenter), HENRY D. I. ABARBANEL, Department of Physics, University of California, San Diego — We formulate an equivalence between deep learning and state/parameter estimation problems in nonlinear dynamical systems. We also propose a general method (named Precision Annealing) inspired by this equivalence to perform learning tasks without backpropagation. Using the language of statistical physics, we then explain the novel optimization routine of the PA method and compare it with optimizations in conventional deep learning. Furthermore, we show up-to-date results of the PA method in various settings including standard deep learning tasks.

**12:39PM F21.00006: Training Classifiers With a Multi-Grid DMRG Algorithm**  
JUSTIN REYES (Presenter), University of Central Florida, EDWIN M STOUDENMIRE, Physics, University of California- Irvine — We introduce a novel machine learning architecture for the classification of large vector data. The architecture mimics the MERA architecture, with each layer providing a new renormalization "scale" to perform a DMRG-like optimization for the training of the network. We observe a dependence of the accuracy and generalization on the number of layers within the architecture, testing on audio classification datasets. We also modify the algorithm for the prediction of future data points in a time-dependent data set, characterizing its performance by the average absolute error in its prediction.

*NSF Grant No. CCF-1525943

**12:51PM F21.00007: Expanded Wang-Landau simulations: Towards a partition function-based prediction of properties for single component systems, mixtures and adsorbed phases**  
CAROLINE DESGRANGES, JEROME DELHOMMELLE (Presenter), University of North Dakota — Conventional simulation methods are carried out for a given set of thermodynamic conditions and they generally provide access to a few thermodynamic properties. However, the development of recent and powerful sampling methods, like the Wang-Landau sampling, has allowed for the direct evaluation of the density of states of a system. In recent work, we proposed an approach, known as Expanded Wang-Landau simulations, that yields highly accurate estimates of the grand-canonical partition function for a wide range of applications, ranging from the bulk to fluids confined in nanoporous materials. This, in turn, yields all thermodynamic properties. In particular, we show how this approach gives access to properties that are notoriously difficult to compute, including free energy and entropy, thereby shedding light on e.g. adsorption or assembly processes.

**1:03PM F21.00008: Relaxation Augmented Free Energy Perturbation**  
YING-CHIH CHIANG (Presenter), CHRISTOPHER CAVE-AYLAND, MARLEY SAMWAYS, University of Southampton, FRANK OTTO, Department of Chemistry, University College London, JONATHAN ESSEX, University of Southampton — We re-examine the concept of free energy calculation via a single-step free energy perturbation (sFEP) method, which frequently fails to converge due to the problem of insufficient sampling. We find a close resemblance between the operation in sFEP and the vertical transition between two different electronic states in quantum mechanics. The insufficient sampling problem then has a vivid physical interpretation as lacking the relaxation process after perturbation. Upon augmenting the traditional sFEP with the relaxation process, the new method agrees well with the exact solution, shedding new light on the underlying physics in free energy calculations.

*YCC thanks the Royal Society for funding this research (Newton International Fellowship NF171278).

**1:15PM F21.00009: Directed random walks and global updates for improved convergence in multicanonical Monte Carlo algorithms**  
YING WAI LI (Presenter), National Center for Computational Sciences, Oak Ridge National Laboratory, ALFRED FARRIS, Center for Simulational Physics, University of Georgia, MARKUS EISENBACH, National Center for Computational Sciences, Oak Ridge National Laboratory — Modern Monte Carlo algorithms such as multicanonical sampling and Wang-Landau sampling are robust methods to obtain the density of states for physical systems. However, they require a long time to converge, making them computationally expensive. We propose a novel scheme to achieve faster convergence and improve the efficiency of these algorithms. By performing a global update of the sampling weights across the phase space, the algorithm achieves uniform sampling quickly. Combining this global update scheme with the recently proposed histogram-free multicanonical method [1,2], we have observed three orders of magnitude of speedup compared to existing flat-histogram methods on Heisenberg models and a homopolymer model.

*This work used resources of the Oak Ridge Leadership Computing Facility, which is supported by the Office of Science of the U.S. Department of Energy under Contract No. DE-AC05-00OR22725.
1:27PM F21.00010: Selecting initial distributions of states for efficient Monte Carlo sampling* THOMAS E BAKER (Presenter), Département de physique, Université de Sherbrooke, Institut quantique — A simple but massively parallel Monte Carlo method is demonstrated here [1]. Working with many different Monte Carlo samplers creates the opportunity to arrange the systems to partially cancel errors from insufficient relaxation. By averaging independent runs, auto-correlation is automatically canceled. This arrangement represents the idealized limit of parallel tempering. In order to determine an appropriate initial distribution, un-relaxed samples are randomly selected. Results from this method, called Genetic Tempering, for a variety of spin models are presented [2,3].

*This project was funded solely by Institut quantique. This research was undertaken thanks in part to funding from the Canada First Research Excellence Fund (CFREF).

1:39PM F21.00011: Development of effective stochastic potential method using random matrix theory for calculation of ensemble-averaged quantum mechanical properties at non-zero temperatures* JEREMY SCHER (Presenter), ARINDAM CHAKRABORTY, Syracuse University — An ensemble-averaged description of quantum mechanical properties is computationally prohibitive because it requires performing many electronic structure calculations. In this work, the effective stochastic potential (ESP) method is presented for performing large-scale calculations of ensemble-averaged quantum mechanical properties, and alleviates the computational cost associated with the conformational sampling required to obtain these properties. The ESP method represents the thermal fluctuations in a chemical system as an effective stochastic potential, derived using random-matrix theory. We introduce the concept of a deformation potential and demonstrate its existence by the proof-by-construction approach. A statistical description of the deformation potential arising from non-zero temperature was obtained using an infinite-order central moment expansion of the distribution. The formal definition of the ESP was derived using a functional minimization approach to match the infinite-order expansion for the deformation potential. The ESP method was implemented using both HF and KS-DFT formalism, and ensemble-averaged ground and excited state energies will be presented.

*This material is based upon work supported by the National Science Foundation under Grant No. CHE-1349892.

1:51PM F21.00012: Constructing Generative Models via the Functional Renormalization Group NAHOM YIRGA (Presenter), DAVID K CAMPBELL, Boston University — Inference problems invert the traditional flow of statistical physics requiring the construction of a probability distribution given a limited set of observations. The fundamental challenge of inverse problems is separating the true couplings between variables from correlations that measure interactions between variables mediated by the entire system. We consider, for cases were additional measurements are possible, the functional renormalization group (fRG) as a tool for such a separation. Standard fRG flows start with a model Hamiltonian modified with a regulator that suppresses all interactions below a certain scale. As the flow proceeds the regulator slowly moves down through all scales until we converge to the fully interacting system. We invert this program and systematically freeze and remove long range correlations from a fully interacting system. We apply this inverted fRG scheme to the Ising and XY models. Finally, we address the required set of observables to make an fRG reconstruction a viable scheme.

Tuesday, March 5, 2019 11:15 AM - 2:15 PM

Session F22 DCOMP: Education and Modern Computation BCEC 157C - Rubin Landau, Oregon State University - Tag(s): Invited
11:15 AM F22.00001: The Practical and Theoretical Future of Computation in Physics [Invited] STEPHEN WOLFRAM (Presenter), Wolfram Research — I started using computers for physics around 1972, and for the past 30+ years I've been building things like Mathematica and Wolfram|Alpha that have been used to do a lot of physics. Around 1980 realized that computation can be used not only for the practical doing of physics, but also as a framework for thinking about physics. Among other things that led to my book A New Kind of Science, and by now many new models in many fields (including physics) are getting made in terms of programs rather than traditional mathematical constructs.

In this talk, I'll discuss the framework I've been building for doing physics by computer, and its future implications—both in terms of theoretical modeling, data analysis and machine learning, as well as connections to the knowledgebase we've accumulated, and to real-time data taking. I'll also discuss what it means to think about the foundations of physics in computational terms—the implications of phenomena like undecidability and computational irreducibility, and what one can anticipate about the theoretical structure of physics in the future.

11:51 AM F22.00002: Computational Problems for Physics Courses Throughout the Curriculum* [Invited] RUBIN LANDAU (Presenter), Oregon State University — Physics courses too often include computation to illustrate physics, with little discussion of the underlying applied math and its commensurate level of precision and reliability. The authors have spent over two decades thinking up computational problems and demonstrations for their Computational Physics texts and for conference tutorials and institutional talks. A new book Computational Problems for Physics with Guided Solutions Using Python extends those problems and demos with the aim of having computation supplement a variety of existing courses. The text includes a large number of worked problems with fully guided solutions in Python, with other languages (Java, C, Fortran, Maple, and Mathematica) available on the Web.

*Funding over the last two decades has come from the National Science Foundation.

12:27 PM F22.00003: Hitting the ground running: Computational physics education that prepares students for research [Invited] AMY GRAVES (Presenter), ADAM D LIGHT, Swarthmore College — Integrating computation into the standard physics curriculum is becoming increasingly common for reasons of enhancing physics education. This begs the question of which elements of this type of teaching also feed into creating students ready to enter a computational physics research group, and come up to speed as contributing members. In this talk, we will review strategies currently being employed to train undergraduates to this task. We suggest that there is a need for the computational physics research community to collect and rank priorities for student skills. The issue of which computational tools and skills are needed (There are many!) will be rephrased as a question of which tools our incoming research students should (i) already know (ii) know exist in principle (iii) not know, but would be taught in the research lab setting. In other words: which skills and ideas are both natural and feasible to include in the classroom environment, and which are more suited to on-the-job training? We suggest resources within the domain of computational physics as well as in computer science, software engineering, and data science, for optimizing students' preparedness and productivity.
1:03PM F22.00004: Probing quantum mechanical energy on a local scale [invited] NITHAYA CHETTY (Presenter), Department of Physics, University of Pretoria — We explore the usefulness of using quantum mechanical energy densities, and investigate the computation of physically meaningful results despite the non-uniqueness of these quantities. In the case of the kinetic energy density, we define two different forms, the one form involving the \(-\hbar^2/2m \phi(x) \nabla^2 \phi(x)\), and the other involving \(+\hbar^2/2m |\phi(x)|^2\). Since the difference of these two approaches includes a boundary term, we specifically explore the kinetic energy current densities at the boundaries and demonstrate why the first form gives physically more meaningful results than the second form.

We carry these notions over to many electron systems, within the framework of density functional theory, where we consider the Coulomb energy. Once again, we note the non-uniqueness in defining the Coulomb energy density, the one form involving the square of the electric field vector, and the other involving the product of the Coulomb potential with the density. We demonstrate why the first form gives physically more meaningful results than the second form.

This sets the stage for extracting even more useful information from the computational studies of real material systems using standard methods.

1:39PM F22.00005: Developing the educational value of visualizations in physics [invited] JOAN ADLER (Presenter), Technion - Israel Institute of Technology — Many interesting physical phenomena occur at length scales that cannot be accessed with the naked eye. Some, especially those related to atoms and molecules, are too small. Astrophysical scales can be too large. Modern computations leading to computer visualizations enable access across all length scales. These types of calculations require a large amount of computer resources to carry out the basic computations with sufficient detail and elapsed time. One must think how to maximise the learning experience while minimising the student's technical effort. (Not to speak of minimizing the teachers' preparation effort so they can concentrate on pedagogy rather than developing theirs and their students' computer techniques.) If 3D material is simply presented as flat images its impact is curtailed. Thus interactivity, three dimensional images (stereo where possible) and some carefully curated student activity are needed. I will describe material prepared at the Technion that aids comprehension for not-too-great student effort, but at the same time allows for some ``hands-on'' interaction. Two approaches we use are: smoke visualization for electronic density of wavefunctions and fluid flow (3D, stereo) and WebGL for rotatable, zoomable images of lattices and molecules. The former require substantial running time and RAM memory to provide the raw data. All of the final visualizations are website based and accessible also on cellphones. The former have an analglyphic stereo option, the latter can be used with Oculus viewers.

Session F23 DLS: Laser Science BCEC 158 - Richard Averitt, Univ of California - San Diego

11:15AM F23.00001: High-resolution spectroscopy of whispering gallery mode optical microcavities in the evanescent field of tapered optical fibers.* NATHAN JORDAN (Presenter), ALEX KING, Physics, Gordon College, ADDISON OGOVOSKI, PRANAY SULTANIA, MARSHALL MA, Mechanical Engineering, Boston University, MUCHENG LI, YUNDONG REN, YUXIANG LIU, Mechanical Engineering, Worcester Polytechnic Institute, KAMIL EKINCI, SEAN ANDERSSON, Mechanical Engineering, Boston University, OLEKSIY SVITELSKI, Physics, Gordon College — Optical cavities with whispering gallery mode (WGM) resonances are interesting as building blocks for photonic devices, including fiber-integrated couplers and spectrometers, photonic crystals, and lasers. The high Q factors (10^3-10^5) along with their sensitivity to the surrounding environmental conditions allow the use of optical cavities as sensors of various physical quantities. We present results on polarized optical spectroscopy of spherical WGM resonant microcavities (D~5-50 micron) made of plastic, and silica and barium titanate glass, performed in air and water. The resonances were excited by evanescent light from optical fibers tapered either by chemical etching or by thermal pulling. The results of our experiments are consistent with theoretical predictions. We will discuss how to use these WGM resonances in order to apply forces to microparticles for microfluidic and biomedical applications.

*This work was partially supported by NSF CMMI awards # 1661700 and 1661586.
11:27AM F23.00002: Home-made Spectrometer to Study Whispering Gallery Mode Resonators* MARSHALL SHENDU MA (Presenter), ADDISON OGONOSKI, PRANAV SULTANIA, KAMIL EKINCI, SEAN ANDERSSON, Mechanical Engineering, Boston University, OLEKSIY SVITELSKYI, Department of Physics, Gordon College — Whispering gallery mode (WGM) resonances are promising phenomena for fiber-based photonic applications such as directional couplers, spectrometers, and light generators. These resonances can also be useful for applying forces to dielectric microbeads and sorting them. We designed and built a simple system to excite and detect the WGM resonances of microbeads in atmosphere and in a liquid environment. The system consists of a tunable laser, an optical fiber with a tapered region where the WGM resonators are placed, and a photo detector to monitor the power transmitted through the fiber. The tunable laser has a wavelength range of approximately 1500-1600 nm and a peak output power of 1.5 mW. The tapered region is produced by chemical etching with hydrofluoric acid of a standard SMF-28 optical fiber. The WGM resonances are excited in plastic or glass microbeads with diameters in the 10 to 45 micron range. The preliminary results were obtained at steps of 1 and 0.1 nm/s in a wavelength sweeping mode. The power transmission was more than 40% which is sufficient to overcome the substantial power loss occurred in a liquid environment.

*This work was partially supported by NSF CMMI awards 1661700 and 1661586.

11:39AM F23.00003: Efficient, phase-resolved polarization-dependent two-dimensional coherent spectroscopy JARED WAHLSTRAND (Presenter), GALAHAD WERNSING, LEON LU, Physical Measurement Laboratory, National Institute of Standards and Technology, ALAN D BRISTOW, Department of Physics and Astronomy, West Virginia University — Capturing spectra for multiple polarization configurations in two-dimensional coherent spectroscopy allows access to different quantum pathways in the light-matter interactions probed by the technique. This is typically done by manually rotating waveplates. We demonstrate a liquid crystal variable retarder-based control scheme to efficiently capture common polarization configurations of the rephasing four-wave mixing of a semiconductor microcavity, showing that the presence of biexcitons alters the nonlinear response of the exciton polaritons. We find the proper phase of the complex 2D spectrum for the collinear polarization configuration in the usual way, by comparing the four-wave mixing emission to the spectrally-resolved transient absorption. Importantly, because the phase shift induced by the variable retarders is known, spectra for all other polarization configurations can be correctly phased.

11:51AM F23.00004: Coupling length phase matching scenarios in dual-core silica fibers JING SU (Presenter), IVAN BIAGGIO, Lehigh University — We analyze optical dual core silica fiber configurations that can be achieved to obtain phase matched third-order nonlinear optical frequency conversion to obtain farther infrared laser sources from near-infrared lasers. The phase matching principle is based on the coupling length phase matching (CLPM) principle, which allows to tune the phase matching condition by tuning the distance between the two cores in the fiber. We describe the corresponding phase matching tuning curves for different choices of pump lasers and discuss the advantages and limitations of the technique.

12:03PM F23.00005: Floquet optical ring resonators* KATHLEEN MCGARVEY-LECHABLE (Presenter), PABLO BIANUCCI, Concordia University — This work discusses Floquet optical ring resonators (FORRs) on the silicon nitride photonics platform. A FORR builds upon the principles of a standard ring resonator with the addition of a small, periodic perturbation to the ring's dielectric material. Similar to a standard photonic crystal, this perturbation results in the formation of multiple photonic band gaps (PBGs) in the ring's optical spectrum. The size of the PBGs can be related to the degree of coupling between degenerate propagating and counter-propagating resonances of the ring. Through application of Bloch-Floquet theory, it is seen that the degree of spectral splitting between two degenerate modes can be precisely controlled by varying the strength of the l-th order Fourier coefficient of the ring's dielectric profile. Additionally, multiple Fourier coefficients may be added to the unperturbed ring's dielectric profile to split resonances across a broad spectrum of the ring. As a result, FORRs provide a new degree of freedom in manipulating the dispersion relation of a ring resonator, providing control over the spectral frequency and group velocity dispersion of a resonance. Potential applications of FORRs include dispersion engineering of optical frequency combs and integrated single photon sources.

12:15PM F23.00006: Exceptional points in microresonator Brillouin laser systems* YUKUN LU (Presenter), YU-HUNG LAI, MYOUR-GYUN SUH, KERRY VAHALA, Applied Physics, Caltech — We theoretically proposed and experimentally demonstrated the existence of exceptional points (EPs) in an on-chip microresonator Brillouin laser system. The coalescence of the eigenfrequencies as well as the eigenmodes is presented. When the laser system is operating near the EP, the boosted rotational sensitivity is confirmed, which enables on-chip optical gyroscopes with unprecedented sensitivity. Moreover, EPs also emerge below the lasing threshold, and the coherent perfect absorption (CPA) can be realized by tuning the pump power. EPs in on-chip microresonator Brillouin systems have applications in precise sensing and optical information manipulating.

12:27PM F23.00007: Spontaneous symmetry breaking in an optical microcavity QI-TAO CAO (Presenter), YUN-FENG XIAO, School of Physics, Peking University, China — Spontaneous symmetry breaking is a ubiquitous property in diverse fields of modern physics, which is, however, elusive in optical domain. As a prominent photonic platform, the ultrahigh-Q whispering-gallery (WG) microcavity supports clockwise (CW) and counterclockwise (CCW) propagating waves with balanced amplitudes. Such chiral symmetry in a WG microcavity can be explicitly broken by removing the parity or time-reversal symmetry in previous works [1,2]. In this work, we report the experimental demonstration of the spontaneous chiral symmetry breaking in a single WG microcavity. The Kerr nonlinearity gives rise to an intensity-dependent CW-CCW coupling that becomes zero beyond a threshold, causing the original standing-wave mode to be unstable and spontaneously evolve into two chiral states with the unbalanced CW and CCW components [3,4]. Furthermore, we extended such the spontaneous symmetry breaking to the active regime and realized a unidirectional microlaser with the controllable chirality.

12:39PM F23.00008: Spatiotemporal Mode-Locking is Generalized Mode-Locking* LOGAN WRIGHT (Presenter), PAVEL SIDORENKO, ZACHARY M ZIEGLER, ANDREI ISICHENKO, Cornell University, BORS MALOMED, Department of Physical Electronics, School of Electrical Engineering, Faculty of Engineering, and the Center for Light-Matter Interaction, Tel Aviv University, CURTIS ROBERT MENYUK, Department of Computer Science and Electrical Engineering, University of Maryland Baltimore County, DEMETRIOS CHRISTODOULIDES, CREOL/College of Optics and Photonics, University of Central Florida, FRANK W WISE, Cornell University — In mode-locking, light in a resonator self-organizes into a nonlinear attractor, the dissipative soliton, often with rich dynamics. Mode-locking has enabled a myriad of applications through ultrashort duration pulses, high peak intensity, and broad frequency comb spectra. Virtually all work on the topic has considered light propagating on only one dimension, as in single-mode fiber. We recently demonstrated spatiotemporal mode-locking [1], the self-organized locking of many spatial and longitudinal modes into coherent pulses, i.e., three-dimensional mode-locking. Adding new dimensions to light's self-organization gives rise to new ways to control the light field. Here, we outline a general theory of spatiotemporal mode-locking, showing it to be a generalization of mode-locking, and present new experimental measurements of qualitatively new mode-locked states, comprising nearly 30 million locked modes. Additionally, we predict numerous other novel forms of mode-locking, and phenomena, such as spatiotemporal dissipative soliton competition. 1. L.G. Wright, D.N. Christodoulides, & F.W. Wise (2017). Spatiotemporal mode-locking in multimode fiber lasers. Science, 358(6359), 94-97.

12:51PM F23.00009: Optically pumped lasing from Er-doped GaN epilayers in the infrared region YIZHOU WANG, HO VINH, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech, HONGXING JIANG (Presenter), JINGYU LIN, Department of Electrical and Computer Engineering, Texas Tech University, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — We report the realization of room-temperature, stimulated-emission in Er-doped GaN epilayers prepared by metal-organic chemical vapor deposition in the infrared region at room temperature. The lasing action of the Er doped GaN epilayers under optically pumped using an UV laser for the above bandgap excitation has been characterized. The observation of the amplified spontaneous emission has been presented through characteristic features of threshold behavior of emission intensity as functions of pump intensity, excitation length, and spectral linewidth narrowing by the variable stripe technique. Varying excitation length of the variable stripe setup, we have observed the optical gain of the GaN:Er epilayers is up to 75 cm-1. The generation of coherent radiation at 1.54 μm at room temperature paves the way for extended functionalities and integration capabilities for optoelectronic devices.
1:03PM F23.00010: A new high-efficiency regime for gas-phase terahertz lasers: Experiment and ab-initio theory*

FAN WANG (Presenter), Massachusetts Institute of Technology, PAUL CHEVALIER, ARMAN AMIRZHAN, MARCO PICCARDO, FEDERICO CAPASSO, Harvard University, STEVEN G JOHNSON, Massachusetts Institute of Technology, HENRY O EVERITT, Duke University — In this work, we present both a new theoretical description and experimental validations of molecular gas optically pumped far infrared (OPFIR) lasers that have much higher efficiency than traditional OPFIR lasers with much more compact volumes. First, we demonstrate a $^{13}$CH$_3$F OPFIR laser that achieves 10× greater efficiency and 1000× smaller volume than comparable commercial lasers. To fully understand this, we developed a new ab-initio theory that matches experiments quantitatively, within experimental uncertainties with no free parameters, by accurately capturing the interplay of millions of degrees of freedom in the laser—unlike previous OPFIR-laser models involving only a few energy levels that failed to even qualitatively match experiments at high pressures. Our model is general enough to capture the lasing behaviors of many other gases. By optically pumping N$_2$O with a QCL instead of a CO$_2$ laser, we predict a new regime of broad frequency-tunability for this traditionally narrow-band THz source. These results offer the possibility of a new generation of compact, frequency-tunable THz sources.

1:15PM F23.00011: A White Random Laser*

YUN-TZU HSU (Presenter), SHU-WEI CHANG, WEI-CHENG LIAO, YU-MING LIAO, CHENG-FU HOU, YING-HUAN CHEN, CHIA-TSE TAI, CHEN-YOU SU, Physics, National Taiwan University, TAI-YUAN LIN, Physics, National Taiwan Ocean University, YANG-FANG CHEN, Physics, National Taiwan University — Random laser with intrinsically uncomplicated fabrication processes, high spectral radiance, angle-free emission, and conformal onto freeform surfaces is in principle ideal for a variety of applications, ranging from lighting to identification systems. In this work, a white random laser (White-RL) with high-purity and high-stability is designed, fabricated, and demonstrated via the cost-effective materials (e.g., organic laser dyes) and simple methods (e.g., all-solution process and self-assembled structures). Notably, the wavelength, linewidth, and intensity of White-RL are nearly isotropic, nevertheless hard to be achieved in any conventional laser systems. Dynamically fine-tuning colour over a broad visible range is also feasible by on-chip integration of three free-standing monochromatic laser films with selective pumping scheme and appropriate colour balance. With these schematics, White-RL shows great potential and high application values in high-brightness illumination, full-field imaging, full-colour displays, visible-colour communications, and medical biosensing.

1:27PM F23.00012: High-order harmonic generation from hybrid lead halide perovskites*

HIDEKI HIRORI (Presenter), Kyoto Univ - Uji Campus, PEIYU XIA, Institute for Solid State Physics, University of Tokyo, YASUSHI SHINOHARA, Graduate School of Engineering, University of Tokyo, TOMOHITO OTOBE, Kansai Photon Science Institute, National Institutes for Quantum and Radiological Science and Technology, YASUYUKI SANARI, HIROKAZU TAHARA, Kyoto Univ - Uji Campus, NOBUHISA ISHI, JIRO ITATANI, Institute for Solid State Physics, University of Tokyo, KENICHI ISHIKAWA, Graduate School of Engineering, University of Tokyo, TOMOKO AHAREN, MASASHI OZAKI, ATSUSHI WAKAMIYA, YOSHIHIKO KANEMITSU, Kyoto Univ - Uji Campus — Nonlinear optical current induced by strong laser fields produces coherent radiation in spectral ranges inaccessible by lasers. Such high-harmonic generation (HHG) in solids is different from that in atomic gases; it has been shown that the intraband current caused by ultrafast acceleration of electron wave packets constitutes the nonlinear current [1,2]. However, how the concurrent field-driven population change in valence band contributes the nonlinear current remains unclear. Here, we studied the crystal orientation dependence of HHG intensity for hybrid organic-inorganic halide perovskites, which is well reproduced by the calculations based on an ab-initio approach. Our picture indicates that the virtual population change in the valence band is responsible for the HHG, which is of vital importance for achieving high generation efficiency and taking a full of information on bandstructure.

*This study was supported by CREST (No. JPMJCR16N3 and No. JPMJCR15N1), PRESTO (No. JPMJPR1427) grants, and the Center of Innovation Program from JST and KAKENHI (Nos. 18H03682, 18K14145, 17K05089, 18K13481, and No. 16H03881) grants from JSPS.
1:39PM F23.00013: Time- and angle-resolved photoemission spectroscopy using ultrafast XUV source at around 20 eV*  
YANGYANG LIU (Presenter), JOHN BEETAR, MD MOFAZZEL HOSEN, GYANENDRA DHAKAL, CHRISTOPHER SIMS, FIROZA KABIR, KLAUSS DIMITRI, SABIN REGMI, MICHAEL CHINI, MADHAB NEUPANE, Physics, University of Central Florida — Time- and angle-resolved photoemission spectroscopy (trARPES) has several advantages over conventional static ARPES measurements. Using trARPES, one can measure electronic states above the Fermi level, track femtosecond or picosecond dynamics in materials, and study transient laser-dressed band structures. We have developed a trARPES setup using high-order harmonic probe pulses produced using a commercial turn-key Yb:KGW laser. The laser, which emits 1030 nm, 290 fs laser pulses with average power of 20 W and tunable repetition rate between 50-200 kHz, is frequency-doubled using a BBO crystal, and focused into a krypton-filled gas cell to generate high-order harmonics. We eliminate low-order harmonic using an aluminum foil filter and optimize the harmonic cutoff using the laser intensity, thereby isolating the 9th harmonic at 21.7 eV. The 9th harmonic probe will be combined with a portion of the 1030 nm laser with a variable time delay for pump-probe experiments. Here, we will present the full characterization of the harmonic light source, as well as first time-resolved measurements in topological materials.

1:51PM F23.00014: Ultrafast relaxation of laser-excited flat nanoislands and nanoparticles investigated by ultrafast electron diffraction*  
AHMED ESMAIL, HUI XIONG, HANI ELSAYED-ALI (Presenter), Old Dominion Univ — Ultrafast electron diffraction is used to probe the electron-phonon energy relaxation and phonon dynamics in Bi flat nanoislands and nanoparticles. The sample was excited with 110-fs laser pulses. By controlling the temperature and laser fluence during the annealing of thin Bi films, we prepare polycrystalline flat nanoislands and nanoparticles and investigate their relaxation dynamics. The temporal development of the various relaxation pathways is probed with a temporal resolution up to ~1.5 ps. The results show dependence on direction and varies between the nanoislands and nanoparticles. The response of the (110) diffraction peak for the 5-nm thick flat nanoislands is found to be faster than ~16 nm diameter nanoparticles. The response of diffraction for both particle shapes is found to be anisotropic. We also investigate the superheating of flat nanomaterials and nanoparticles by monitoring the long-range order with excitation at various levels.

*This material is based upon work supported by the National Science Foundation under Grant No. DMR-000304287.

2:03PM F23.00015: Ultra-high speed laser-surgery with ultrafast bursts of pulses  
FATIH ILDAY (Presenter), Bilkent University — Ultrafast lasers allow thermal damage-free ablation irrespective of the material type. However, this process is slow and inefficient, with ablation volume having the remarkably poor logarithmic dependence on incident pulse energy. We recently demonstrated (Ilday et al., Nature 2016) ablation-cooled laser-material, whereby ultrafast pulses are sent in bursts, each containing hundreds of pulses separated by merely 100s of picoseconds, such that there is no time for heat to diffuse away from the processing region. The ablation rate increases by orders of magnitude and ablation becomes the dominant heat removal mechanism. Thus, the rest of the target material remains cool and without damage. We also reduced the required laser pulse energies by 1000 times and achieved record speeds in cutting biological tissue, metals and semiconductors (reaching 1 mm³/s). This new regime, where the ablation volume scales linearly with burst energy, has received much industrial interest, but there is also remarkable potential for extremely high-efficient and fast laser surgery. Is it possible to reach 1 mm³/s with biological tissue without thermal damage? As a more basic question, what the limitations to further decreasing the pulse separation time to less than the time it takes for ablation to occur.

Microscopic studies of doped cold-atom Fermi-Hubbard antiferromagnets

CHRISTIE S CHIU (Presenter), GEOFFREY JI, Harvard University, ANNABELLE BOHRDT, Harvard University and Technical University of Munich, MUQING XU, Harvard University, JUSTUS BRÜGGENJÜRGEN, Harvard University and University of Hamburg, MICHAEL KNAP, Technical University of Munich, EUGENE DEMLER, FABIAN GRUSDT, MARKUS GREINER, DANIEL GREIF, Harvard University — The experimental platform of ultracold fermionic atoms in optical lattices offers new perspectives for studying the physics of strongly correlated materials. We use this platform to implement the Fermi-Hubbard model, a paradigmatic model thought to capture the physics of high-temperature superconductivity, the pseudogap, and other phenomena containing longstanding open questions. The additional tool of quantum gas microscopy enables site-resolved readout and access to projections of the many-body wavefunction in the Fock basis. I will report on our most recent studies of doped antiferromagnets, where there is no universally agreed-upon mechanism for the interplay between hole motion and antiferromagnetic order.

Toward low-entropy states in the Fermi-Hubbard model with quantum gas microscopy

MUQING XU (Presenter), CHRISTIE S CHIU, GEOFFREY JI, Harvard University, JUSTUS BRÜGGENJÜRGEN, University of Hamburg and Harvard University, ANTON MAZURENKO, MAXWELL F PARSONS, MARTON KANASZ-NAGY, RICHARD SCHMIDT, FABIAN GRUSDT, EUGENE DEMLER, DANIEL GREIF, MARKUS GREINER, Harvard University — Ultracold atoms in optical lattices are a powerful platform for studying strongly correlated quantum systems. We study the repulsive Fermi-Hubbard model through quantum gas microscopy with fermionic Lithium-6 atoms in a square lattice. This technique allows for single-site resolved readout and manipulation, and has enabled us to achieve long-range antiferromagnetic order across our entire sample by performing entropy redistribution. Accessing intriguing phases in the Fermi-Hubbard model, requires development of new techniques for low-entropy quantum state preparation. Here we report on our low-noise interfering optical lattice, which offers dynamically tunable lattice geometry and allows for studies of the Fermi-Hubbard model in dimerized, honeycomb, and triangular lattices. This tunability can alternatively facilitate an adiabatic ramp from an ultralow-entropy initial state, prepared through entropy redistribution, toward strongly-correlated quantum phases. Another possible application of this interfering lattice is to provide simultaneous readout of both spin species.

Photoemission spectroscopy of a Fermi-Hubbard system with a quantum gas microscope

PETER T. BROWN (Presenter), ELMER GUARDADO-SANCHEZ, WASEEM S BAKR, Princeton University — Strongly correlated systems with superconducting ground states, including the high-temperature superconducting cuprates and the unitary fermi gas, exhibit normal state precursors to the superconducting gap in their single-particle excitations. A quantitative understanding of these so called pseudogap regimes may elucidate details of the ground states, but developing this is difficult in real materials because the parameters of the microscopic Hamiltonian are not known. In cold atom experiments the development of fermionic quantum gas microscopes has enabled high-precision studies of fermions in optical lattices. The Hamiltonian parameters of these systems can be calculated from first principles, and good agreement between theory and experiment has been reported in recent studies of equal-time spin and density correlations. In this talk I will report on the development of angle-resolved photoemission spectroscopy (ARPES) compatible with quantum gas microscopy and its application to studying pseudogap physics in an attractive Fermi-Hubbard system across the BEC-BCS crossover, setting the stage for future studies of the pseudogap regime in repulsive Hubbard systems.

Progress toward a dipolar quantum gas microscope with an expandable lattice

ANNE HEBERT (Presenter), GREGORY PHELPS, AARON KRAHN, FURKAN OZTURK, MARKUS GREINER, Harvard University — Highly dipolar atoms present an exciting opportunity to extend previous experiments to more complex systems influenced by long range, anisotropic interactions. Erbium, with its large dipole moment, numerous isotopes, and rich Feshbach spectrum, is an excellent element for such research. We present on current progress toward the construction of a novel optical lattice expandable in all three dimensions. This expandable lattice gives us tunability of the lattice spacing by a factor of 20. This allows for short spacing lattice that maximizes the strength of the dipole-dipole interaction, and then allows for in situ imaging in a larger spacing lattice with higher fidelity.
12:03PM F24.00005: Progress toward an Erbium Dipolar Quantum Gas Microscope* GREGORY PHELPS (Presenter), ANNE HEBERT, AARON KRAHN, S. FURKAN OZTURK, MARKUS GREINER, Harvard University — Quantum gas microscopy provides an exciting platform for the study of in situ atom-atom interactions. Recent advances in quantum gas microscopy have allowed probing of the Bose-Hubbard and Fermi-Hubbard Hamiltonian. We are currently extending these platforms with the introduction of an Erbium Dipolar Quantum Gas Microscope allowing us to study dipole-dipole interactions in a lattice. Erbium has several exciting properties, which increase the control and flexibility of these systems. These include stable bosonic and fermionic isotopes, a large magnetic dipole moment (7μB), a large spin value (J=6 and F=19/2 for bosonic and fermionic isotopes), a rich Feshbach spectrum, and several broad and narrow atomic transitions. Here we are presenting our recent progress toward an Erbium Quantum Gas Microscope. This features the integration of several unique systems, such as a high-resolution reflective objective, an accordion lattice for imaging, and a low disorder optical lattice. These developments will allow us to benefit from the long-range interaction of Erbium and probe the Extended Bose-Hubbard and Extended Fermi-Hubbard Hamiltonian to an unprecedented degree.

*This work is supported by the ARO DURIP grant, MIT-Harvard CUA, and MIT MURI grant.

12:15PM F24.00006: Antiferromagnetic Order and Non-Equilibrium Distributions in the Floquet-Engineered Hubbard Model* NICKLAS WALLDORF, Department of Micro- and Nanotechnology, Technical University of Denmark, DANTE KENNES, Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, JENS PAASKE (Presenter), Niels Bohr Institute, University of Copenhagen, ANDREW MILLIS, Department of Physics, Columbia University — The periodically driven half-filled two-dimensional Hubbard model is studied via a saddle point plus fluctuations analysis of the Keldysh action. The drive is implemented as an alternating electric field, and the system is coupled to a metallic substrate in thermal equilibrium to allow for a non-equilibrium steady state synchronized to the drive. For drive frequencies below the equilibrium gap, and strong enough drive amplitudes, the mean-field equation has multiple solutions with a substantial time-dependent component. Even for "Magnus" drive frequencies much larger than the equilibrium gap, a one-loop analysis around the mean-field solution shows that even if no real electron-hole pairs are excited, the ac drive produces a highly excited, generically non-thermal distribution of fluctuations, which can affect the physics significantly, for example destroying zero-temperature long-ranged antiferromagnetic order for large enough drive amplitudes.

*This research was funded by the Danish National Research Foundation (CNG and QDev), the Basic Energy Sciences Division of the U.S. Department of Energy (DE-SC0018218) and the Deutsche Forschungsgemeinschaft through the Emmy Noether program (KA 3360/2-1).

12:27PM F24.00007: Strong correlations in magic-angle semimetals JUSTIN WILSON (Presenter), YIXING FU, ELIO KOENIG, Department of Physics, Rutgers University, YANG-ZHI CHOU, Department of Physics, University of Colorado, Boulder, JED PIXLEY, Department of Physics, Rutgers University — In magic-angle graphene, Moiré patterns lead to an enlarged unit cell, mini-Brillouin zone, and strongly correlated phases (as shown experimentally). We generalize this behavior to a whole class of semimetallic models from one- to three-dimensions, and we show that the key ingredients are (1) an "untwisted" semimetallic band structure and (2) a spatially quasiperiodic structure (e.g., a "twist") [1]. As the quasiperiodic structure is enhanced, the velocity of the effective low-energy semimetal decreases until it vanishes at a quantum phase transition. The magic-angle phenomena are associated with this eigenstate phase transition which is a unique type of “Anderson delocalization” transition in momentum space. Further, it is accompanied with flat-bands and behaves universally across models. Lastly, we build effective Hubbard models on the new bands by computing Wannier states. The interactions in these Hubbard models are strongly enhanced at this transition, indicating the existence of strongly correlated phases. All ingredients to realize our proposal are available in present-day cold-atomic laboratories for which the magic-angle effect can be exploited to induce strong correlations in quantum degenerate gases.

**12:39PM F24.00008: Enhancement and destruction of superfluidity: Unusual effects of population imbalance of atomic Fermi gases on a 1D optical lattice**

QIJIN CHEN (Presenter), Department of Physics, Zhejiang University, JIBIAO WANG, School of Physics and Astronomy, Sun Yat-Sen University (Zhuhai Campus), China — We study the superfluid behavior of population imbalanced ultracold atomic Fermi gases with a short range attractive interaction on a 1D optical lattice, using a pairing fluctuation theory. Due to the lattice-continuum mixing in a 1D optical lattice, population imbalance now has highly unusual effects. While the transition $T_c$ in the balanced case decreases and scales as $k_F a$ in the BEC regime, it approaches a constant BEC asymptote in imbalanced case. Therefore, population imbalance may strongly enhance the superfluidity by raising $T_c$ to the constant BEC asymptote. In addition to the destruction of superfluidity in some range of intermediate pairing strengths, the BEC regime may also become inaccessible when the lattice spacing $d$ and the population imbalance $p$ become large, and/or the lattice hopping integral $t$ becomes small, in contrast to the 3D continuum or dilute 3D lattice case, for which the BEC regime is always accessible. Furthermore, even when the BEC regime is accessible, not all minority atoms are paired up in the BEC limit. Upon destruction of the superfluidity due to increasing $(d,p)$ or decreasing $t$, only 50% of the minority atoms form pairs.

**12:51PM F24.00009: Harmonic potential effect on the ground state of the “g-e” model**

JERESON SILVA VALENCIA (Presenter), RODRIGO CASTELLANOS CARO, ROBERTO FRANCO, National University of Colombia — Alkaline-earth fermionic atoms confined in one-dimensional optical lattices can be described by the so-called "g-e" model [Nat. Phys. 6, 289 (10)], which at half filling shows four interesting insulating phases (CDW, Orbital density wave (ODW), Spin Haldane (SH) and Spin-Peierls) [PRB 91, 075121(15)]. However, the confining potential has not been considered so far, for this reason we explore an extended "g-e" model where a harmonic potential for both $^1S_{0}$ (g) and $^3P_{0}$ (e) atoms was considered. Using the density-matrix renormalization group method, we found that diverse insulating phase coexist in the ground state and that the spin Haldane and the spin Peierls phases disappear with the confining potential, meaning that these phases will not be observed in the experiments. The evolution of the CDW and the ODW phases around the middle of the trap was studied for different parameters. This work is motivated by recent experimental results about $^{171}$Yb atoms confined in optical lattices [Arxiv:1810.00536v1].

*The authors are thankful for the support of DIEB-Universidad Nacional de Colombia.

**1:03PM F24.00010: Light-cone like spreading of correlations in the Bose Hubbard model at strong coupling**

MALCOLM KENNETT (Presenter), MATTHEW R FITZPATRICK, Simon Fraser University — We study the spreading of correlations in space and time after a quantum quench in the Bose Hubbard model. We derive equations of motion for the single-particle Green's function within the contour-time formalism, allowing us to study dynamics in the strong coupling regime. We discuss the numerical solutions of these equations and calculate the single-particle density matrix for quenches in the Mott phase. We demonstrate light-cone like spreading of correlations in the Mott phase in one, two, and three dimensions and calculate propagation velocities in each dimension. Our results show excellent agreement with existing results in one dimension and demonstrate the anisotropic spreading of correlations in higher dimensions.

Rigorous Results for the Ground States of the Spin-2 Bose-Hubbard Model

HONG YANG (Presenter), HOSHO KATSURA, Department of Physics, The University of Tokyo — In this work, we prove rigorous theorems for the ground states of the spin-2 Bose-Hubbard model, concerning the magnetic properties, degeneracies and forms of the wave functions. The theorems are highly universal in the sense that they do not depend on the lattice structure (including spatial dimension), particle number and spin-independent interaction.

The spin-2 Bose-Hubbard model is a model for ultracold \( f = 2 \) spinor bosonic atoms in optical lattices. We prove that, with \( c_1 \) and \( c_2 \) being the coefficients of the two spin-dependent interaction terms of the Hamiltonian, the ground state has a maximum total spin when \( c_1 < 0 \) and \( c_2 \geq 5c_1 \), while tends to be a singlet if \( c_1 = 0 \) and \( c_2 < 0 \). When \( c_1 = c_2 = 0 \), the model has SU(5) symmetry. Furthermore, the ground-state degeneracies and the forms of wave function are also exactly determined in each coefficient region. Our approach takes the advantage of the symmetry of the Hamiltonian and employs sophisticated mathematical tools including the Perron-Frobenius theorem and the min-max theorem, as well as the representation theory of so(5) Lie algebra.

Metal-Insulator-Superconductor Transition in Two-Channel Interacting Many-Body Systems*

THEJA DE SILVA (Presenter), Physics, Augusta University — Using a slave-rotor approach within a mean-field theory, we study two-channel interacting systems to investigate the competition of metallic, Mott-insulating, and superconducting phases. Considering spin-3/2 cold atoms on optical lattices as a model system and treating a spin-3/2 atom as a bound state of a charge and a spin, we uncover a novel form of matter due to the competition between metal and superconducting phase. This novel unconventional phase emerges as a result of the global U(1) broken symmetries with respect to both roton and spinon fields. Further, we argue that the emergence of this unconventional phase is a generic phenomenon associates with many body systems where there are competing interactions. As such, we show that this unconventional phase can exist in rubidium doped fullerides under pressure.

Quantum Joule expansions in one-dimensional lattices*

SHAN-WEN TSAI (Presenter), JIN ZHANG, University of California, Riverside, YANNICK MEURICE, University of Iowa — We discuss the expansion dynamics of nonintegrable systems that contain bosons or fermions in one-dimensional lattices. The particles are initially confined in half of the system with a thermal state described by the canonical ensemble. At short times after we remove the barrier before the front hits the other boundary of the lattice, the radial velocity of the expansion is a constant. The center of mass is accelerated with a constant acceleration. At long times, local observables can be approximated by a thermal expectation of another canonical ensemble with an effective temperature. The weights for the diagonal ensemble and the canonical ensemble match well for high initial temperatures that correspond to negative effective final temperature after the expansion. The negative effective temperature for finite systems goes to positive inverse temperatures in the thermodynamic limit for bosons but is a true thermodynamic effect for fermions. We also compare the thermal entanglement entropy and density distribution in momentum space for the canonical ensemble, diagonal ensemble and instantaneous long-time states calculated by exact diagonalization.

11:15 AM F25.00001: NV-Diamond Magnetometry in the NV-NV Interaction Limit

CONNOR HART (Presenter), ERIK BAUCH, Harvard University, JENNIFER SCHLOSS, MIT, RAISA TRUBKO, MATTHEW J TURNER, DIANA PRADO LOPES AUDE CRAIK, Harvard University, RONALD L WALSWORTH, Harvard-Smithsonian CfA — In nitrogen-vacancy (NV) ensembles in diamond, the magnetic sensitivity is commonly limited by a bath of other impurity spins, which decoheres the NV sensor spins. We demonstrate mitigation of NV-bath interactions by RF control of the spin bath or dynamical decoupling of the NV centers. In this regime, mutual NV-NV dipolar interactions dominate the ensemble spin properties ($T_2, T_2^*$). These techniques may yield improved DC and AC magnetic sensitivity up to a limit set by NV-NV dipolar interactions. For example, we show NV ensemble coherence times under XY8-n dynamical decoupling protocols limited by instantaneous diffusion. We present progress toward mitigating NV-NV interactions while preserving magnetic sensitivity, and conversely we outline ideas to leverage strong NV-NV interactions to further improve magnetic sensitivity.

11:27 AM F25.00002: A high-speed, strain-free NV-diamond magnetic imager for neuroscience

JENNIFER SCHLOSS (Presenter), Physics, Massachusetts Institute of Technology, CONNOR HART, MATTHEW J TURNER, Physics, Harvard University, PATRICK JAN SCHEIDEGGER, ETH Zurich, ERIK BAUCH, Physics, Harvard University, RONALD L WALSWORTH, Harvard-Smithsonian CfA — Real-time wide-field imaging of dynamic magnetic fields finds broad applications from condensed matter physics to neuroscience. We present a broadband, high-sensitivity magnetic imaging system designed to map magnetic fields from arrays of firing neurons. The imager employs pulsed Ramsey protocols on an ensemble of nitrogen-vacancy (NV) centers in diamond, and it achieves enhanced sensitivity, bandwidth, and uniformity compared to conventional continuous-wave optically detected magnetic resonance (CW-ODMR) imaging. We show further improvements through implementing double-quantum coherence imaging, which mitigates inhomogeneous crystal-lattice strain and microwave gradients over the field-of-view, and we demonstrate novel noise cancellation protocols. We present first images of nontrivial dynamic magnetic fields and steps toward real-time imaging of bio-magnetic fields from live, firing neurons.

11:39 AM F25.00003: Large-Scale Uniform Optical Focus Array Generation with a Phase Spatial Light Modulator

DONGGYU KIM (Presenter), Mechanical Engineering, MIT, ALEXANDER KEESLING, AHMED OMRAN, HARRY LEVINE, HANNES BERNIEN, MIKHAIL LUKIN, Physics, Harvard University, DIRK R. ENGLUND, Electrical Engineering and Computer Science, MIT — Uniform optical focus arrays are needed in a range of applications including multifocus multiphoton microscopy and multi-beam laser machining. Recently, such focus arrays were also developed as an essential tool for controlling ultra-cold atoms for quantum information processing. A challenge in these applications is to efficiently produce uniform large-scale optical focus arrays (LOFAs). Here, we present a new method for generating uniform LOFAs using a phase spatial light modulator. By identifying and removing undesired phase rotation in the iterative Fourier-transform algorithm, we demonstrate rapid and reliable generation of LOFAs containing O(10^3) optical foci with > 98% intensity uniformity.

11:51 AM F25.00004: Continuous frequency-domain multiplexing of heralded single-photon sources

THOMAS PARKER (Presenter), Physics, Imperial College London, THOMAS HIEMSTRA, PETER HUMPHREYS, ANDREAS ECKSTEIN, Physics, University of Oxford, BRIAN SMITH, University of Oregon, STEVE KOLTHAMMER, Physics, Imperial College London, IAN WALMSLEY, Physics, University of Oxford, MICHAL KARPINSKI, University of Warsaw, MARK BECK, Reed College, JOHANNES TIEDAU, Paderborn — Single-photon sources are an important tool for experiments in quantum optics and quantum information [1]. Heralded single-photon sources based on non-linear processes such as parametric down-conversion are ubiquitous. However, significant limitations arise due to the probabilistic nature of photon pair emission, as well as the possibility of generating more than one photon per pump pulse. In a technique known as multiplexing [2-3], the probability of generating a single photon can be increased by switching the output from multiple sources into a single channel.

We present a frequency-multiplexed single-photon source which increases the single-photon delivery probability without increasing multi-photon noise. This is accomplished by spectral detection and controlled frequency translation that both have a resolution greater than the single-photon bandwidth. In addition, we have measured the purity of the heralded photon by Hong-Ou-Mandel (HOM) interference showing a non-classical visibility of ~64%.

*EPSRC
Cooperative ultrastrong atom-light coupling from an effective mapping picture of single-photon superradiance. YAO ZHOU (Presenter), ZIHAO CHEN, JUNG-TSUNG SHEN, Electrical and System Engineering, Washington University in St Louis — As a manifestation of cooperative atom-light interaction from a cluster of atoms, single-photon superradiance has attracted considerable attention for its salient feature of a fast collective spontaneous emission rate and an enhanced coupling strength. It is found that when a cluster of atoms in a dense atom cloud or spatially distributed QED system obtains a largest collective spontaneous emission rate, which is the superadiant emission rate, their optical response is always indistinguishable with a single effective atom. From such effective mapping picture, one can obtain the superradiance conditions for a QED system. Specifically, we have analytically calculated the superradiance conditions for atoms trapped along a waveguide and for atoms coupled to whispering gallery mode resonators and computationally validated them. Based on strong coupling regime, an ultrastrong coupling strength proportional to atom number is accessible by exploiting the superradiance condition, and meanwhile the coherence between atoms remains without distorting the profile of optical response from a single atom. The ultrastrong coupling strength would benefit in the design of ultrafast optical devices, atomic mirror, and controllable optic add/drop filter.

X² Optical Frequency Comb by Cavity Phase Matching* NI XIN, ZHENDA XIE (Presenter), National Laboratory of Solid State Microstructures, School of Electronic Science and Engineering, School of Physics, and College of Engineering and Applied Sciences, Nanjing, SHUWEI HUANG, Department of Electrical, Computer, and Energy Engineering, University of Colorado Boulder, BAICHENG YAO, Key Laboratory of Optical Fiber Sensing and Communications (Education Ministry of China), University of Electronic Science and Technology of China, HUAYING LIU, NICOLÒ SERNICOLA, XINJIE LV, GANG ZHAO, ZHENLIN WANG, SHINING ZHU, National Laboratory of Solid State Microstructures, School of Electronic Science and Engineering, School of Physics, and College of Engineering and Applied Sciences, Nanjing — Micro-resonator-based optical frequency combs (OFC) are portable frequency standards with high beat note frequencies, which can be used for high precision spectroscopy, navigation, telecommunication and astronomy. Compared to the conventional micro-ring resonators, the resonators can benefit from much stronger nonlinearity for the comb generation from optical parametric down conversion processes, with new physics in these platforms. Here we report the optical frequency comb generation by cavity phase matching, where the large phase matching bandwidth enables broad comb span over 80 nm. The sheet cavity design allows high slope efficiency and peak output power, which exceed 22.6 % and 14.9 kW. Comb lines are measured to be equidistant within the instrument-limited accuracy. Therefore, we show that the sheet parametric oscillator is a promising candidate for portable integrated optical frequency comb generation.

Terahertz-optical intensity grating for creating high-charge, attosecond electron bunches JEREMY LIM (Presenter), Science and Maths cluster, Singapore University of Technology and Design, YIDONG CHONG, Nanyang Technological University, LIANG JIE WONG, Singapore Institute of Manufacturing Technology — Ultrashort electron bunches are useful for applications like ultrafast imaging, coherent radiation production, and compact sources of accelerated electrons. Currently, however, the shortest achievable bunches, at attosecond time scales, have only been realized in the single or very few electron regime, limited by Coulomb repulsion and electron energy spread. We will present ab initio simulation results and theoretical analysis which show that highly-charged bunches are achievable by subjecting moderately-relativistic (few MeV-scale) electrons to a superposition of terahertz and optical pulses. Using realistic electron bunches and laser pulse parameters which are within the reach of current compact setups, we provide two detailed examples: one with final bunches of ~1 fC contained within sub-400 as durations and 8 micron radii, and one with bunches of > 25 electrons contained within 20 as durations and 15 micron radii. Our results reveal a route to achieve such extreme combinations of high charge and attosecond pulse durations with existing technology.
12:39PM F25.00008: Investigating the nonlinear refraction index of Rb vapor by scanning the laser frequency through the atomic resonances.*
CLAUDIA PATRICIA MEJIA VILLAGRÁN (Presenter), Universidad Nacional de Colombia, ALEXANDRE ANDRADE CAVALCANTI DE ALMEIDA, SANDRA SAMPAIO VIANNA, Universidade Federal de Pernambuco (UFPE) —
We have observed self-focusing and defocusing in rubidium vapor by scanning the laser frequency through atomic resonances. These phenomena originate from the third order electric susceptibility, and have been used to measure the nonlinear refractive index of materials with the well-known technique Z-scan. However, few experimental measurements have been carried out near the resonances of atomic systems. In our experiment we scan the frequency of a diode laser through the resonances of rubidium vapor, contained in a fixed cell. The transmittance of the beam as a function of frequency detuning is detected after a small aperture, for different laser intensities and aperture radius. The theoretical model is a two-level system considering velocity distribution. A reasonably good fit of the experimental data is obtained, indicating that it is possible to measure the intensity-dependent term of the refractive index with this technique.
*Work supported by CNPq, FACEPE and CAPES (Brazilian Agencies).

12:51PM F25.00009: Revisiting the Photon-Drag Effect in Gold Films
JARED H STRAIT (Presenter), GLENN HOLLAND, WENQI ZHU, CHENG ZHANG, AMIT AGRAWAL, Physical Measurement Laboratory, National Institute of Standards and Technology, DOMENICO PACIFICI, School of Engineering and Department of Physics, Brown University, HENRI J LEZEC, Physical Measurement Laboratory, National Institute of Standards and Technology —
The photon-drag effect, the rectified current in a medium induced by conservation of momentum of absorbed or redirected light, is a unique probe of the detailed mechanisms underlying radiation pressure. We revisit this effect in gold, a canonical Drude metal for infrared frequencies. We discover that the signal for p-polarized illumination in ambient air is affected in both sign and magnitude by adsorbed molecules, opening previous measurements for reinterpretation. Further, we show that the intrinsic sign of the photon-drag effect is contrary to the prevailing intuitive model of direct momentum transfer to free electrons.

1:03PM F25.00010: Optical Forces between Coupled PT-symmetric Waveguides
MOHAMMAD-ALI MIRI (Presenter), Queens College, MICHELE COTRUFO, ANDREA ALU, Advanced Science Research Center, CUNY —
Evanescent wave coupling between two dielectric waveguides results in an optical force between the waveguides. This force is attractive (repulsive) when the coupled waveguide system is excited with the symmetric (anti-symmetric) mode and is transverse to the axis of wave propagation. Through energy conservation considerations, it is shown that the optical bonding force is proportional to the gradient of the propagation index of the symmetric and anti-symmetric supermodes with respect to the distance between the two guides. However, when gain or loss is involved in the waveguides, this derivative becomes undefined at an exceptional point singularity. In order to investigate forces at the exceptional point singularities, here we consider a PT-symmetric model of two coupled waveguides and calculate the force through Maxwell's stress tensor. Our results show that the optical bonding force is finite at the exceptional point. In addition, we find an extra force component which is directed along the axis of propagation.

1:15PM F25.00011: Floquet dynamics of classical and quantum cavity fields*
IVAR MARTIN (Presenter), Argonne National Laboratory —
We show that the time-dependence of electromagnetic field in a parametrically modulated cavity can be effectively analyzed using a Floquet map. The map relates the field states separated by one period of the drive; iterative application of the map allows to determine field configuration after arbitrary number of drive periods. For resonant and near-resonant drives, the map has stable and unstable fixed points, which are the loci of infinite energy concentration in the long time limit. The Floquet map method can be applied both to classical and quantum massless field problems, including the dynamical Casimir effect. The stroboscopic time evolution implemented by the map can be interpreted in terms of the wave propagation in a curved space, with the fixed points of the map corresponding to the black hole and white hole horizons. More practically, the map can be used to design protocols for signal compression/decompression, cavity cooling, and photon sensing.

1:27PM F25.00012: Reducing detrimental electrostatic effects in precision Casimir force measurements using argon ion bombardment and UV light  MINGYUE LIU (Presenter), JUN XU, ROBERT SCHAFTER, Department of Physics and Astronomy, University of California, Riverside, VLADIMIR MIKHAILOVICH MOSTEPANENKO, GALINA LEONIDOVNA KLIMCHITSKAYA, Institute of Physics, Nanotechnology and Telecommunications, Peter the Great Saint Petersburg Polytechnic University, UMAR MOHIDEEN, Department of Physics and Astronomy, University of California, Riverside — In precision Casimir force measurements between two neutral and grounded surfaces, the role and effect of electrostatic forces have to be fully understood in vacuum. The two Au coated surfaces can be contaminated with adsorbates leading to potential electrostatic patches. We have used 500 eV Ar ion bombardment of the surfaces and UV cleaning to remove the adsorbates prior to Casimir force measurements. The measurements were performed by means of dynamic atomic force microscopy operated in frequency shift mode. The force was measured between an Au coated hollow glass sphere attached to a Si cantilever and an Au coated silicon plate. To improve the sensitivity of the cantilever by reducing its spring constant, it was etched using concentrated KOH solution prior to attachment of the sphere. The residual potential difference between the Au sphere and the plate was reduced using Ar ion bombardment and UV light and checked to be independent of the sphere-plate separation. The measured Casimir force has been compared to theoretical prediction of the Lifshitz theory. For the distance ranges measured the experimental data are consistent with the electric permittivity of Au using the lossless plasma model behavior at zero frequency and tabulated optical data at all other frequencies.

1:39PM F25.00013: Casimir Force Measurement in the Cylinder-Plate Geometry  ROBERT SCHAFTER (Presenter), MINGYUE LIU, JUN XU, ROYA ZANDI, UMAR MOHIDEEN, University of California, Riverside — The Casimir effect has broad implications for the creation and operation of MEMS devices operating in the submicron regime. Experimental studies of the Casimir effect with smooth boundaries have primarily involved simple geometries such as the sphere-plate configuration. As Casimir forces are strongly dependent on the boundary shape, more complicated geometries will introduce modifications in the collective charge fluctuation anisotropy induced by the scattering of the zero point photons. In this work, we examine the Casimir forces between a cylinder and a sphere in a UHV environment, particularly examining the boundary effects of the 1-D role of the cylinders. To reduce the ellipticity of the cylinders involved, we have used an etched glass optical fiber, coated with Au to provide a conductive surface. Co-location of the sphere and cylinder was achieved using a piezoelectric stage with a capacitive sensor controlled PID loop. To eliminate residual electrostatic effects from surface adsorbates and resulting patches, we utilize in situ Ar ion bombardment and UV cleaning in the high vacuum environment prior to the measurement of the Casimir force. We compare the experimental results to theories using both the Proximity Force Approximation and the multiple scattering approach.

1:51PM F25.00014: Quantum sensing of large nuclear-spin clusters in diamond with atomic-scale resolution  MOHAMED ABOBEIH (Presenter), JOE RANDALL, CONOR BRADLEY, HANS BARTLING, MICHEL BAKKER, MAARTEN DEGEN, VIATCHESLAV DOBROVITSKI, TIM HUGO TAMINIAU, QuTech and Kavli Institute of Nanoscience Delft — The ability to resolve the 3D structure of large clusters of nuclear spins has the potential to be a revolutionary tool for NMR imaging of single molecules and solids. The nitrogen-vacancy (NV) center in diamond is a promising platform to achieve this goal. At the same time, its local nuclear spin environment already provides a model system to study, develop and test such new methods. Here we report on quantum sensing and atomic structure analysis of a 10+ nuclear-spin cluster in diamond with atomic-scale resolution. We develop pulse sequences to coherently control the nuclear spins forming the cluster, and directly measure the pairwise dipolar couplings between the nuclear spins with high precision. We then utilize the measured nuclear-nuclear couplings between the spins to determine their 3D structure with atomic-scale resolution. The methods developed in this work can be extended to samples outside the diamond, and mark an important step towards the ultimate goal of structural imaging of single molecules and proteins.

Session F27 DQI: Programming and Compilation -- the Quantum Computing Stack BCEC 160C

- Peter Groszkowski, University of Chicago - Tag(s): Focus

11:15AM F27.00001: The quantum computing stack: From quantum algorithms to optimized resource estimates  [Invited] THOMAS HAENER (Presenter), DAMIAN STEIGER, MATTHIAS TROYER, ETH Zurich — It is known that quantum computers offer up to exponential speedups over their classical counterparts for solving certain computational tasks. However, concrete comparisons of resource requirements for specific problem instances are still scarce. In this talk, I will discuss how software for quantum computing can support researchers in carrying out such analyses. Specifically, I will focus on automatic compiler optimizations and how these may offer great benefits even in the presence of hand-optimized libraries.
11:51AM F27.00002: Automatic Compilation for Portable and Scalable Quantum Software  ROBERT S SMITH (Presenter), ERIC C PETERSON, Rigetti Computing — Noisy intermediate-scale quantum (NISQ) processors are becoming larger (20–150 qubits) and more expressive (e.g., supporting a plurality of two-qubit interactions). However, since NISQ processors are error-prone, there is a great disparity between those programs which are desirable to write and those which execute reliably. Together, these aspects make it difficult to write quantum programs which are both portable (i.e., readily executable on different devices) and efficient (i.e., produce more accurate results using fewer resources). We discuss how automatic compilation helps achieve these simultaneous goals more consistently, and compare results of an open-source, extensible automatic compiler quilc to semi-manual counterparts.

12:03PM F27.00003: Compiler tools for hybrid quantum-classical algorithms  NIKOLAS TEZAK (Presenter), LAUREN CAPELLUTO, PETER KARALEKAS, ERIC C PETERSON, ROBERT S SMITH, MARK SUSKA, ADAM MOCARSKI, STEPHAN BROWN, CELENA TANGUY, RODNEY SINCLAIR, NIMA TAIE-NOBARIE, CHLOE SONG, STEFAN TURKOWSKI, MICHAEL RUST, GLENN JONES, SCHUYLER FRIED, DIEGO SCARABELLI, DEANNA ABRAMS, SHANE CALDWELL, COLM RYAN, PRASAHNT SIVARAJAH, WILLIAM J ZENG, BLAKE JOHNSON, CHAD RIGETTI, Rigetti Computing — We describe the Rigetti compilation toolchain and in particular how it supports optimized implementations of certain hybrid quantum-classical algorithms. Programs written in Quil are transpiled into a restricted subset of Quil instructions that are realizable on the available control hardware and target chip topology. These transpiled programs are further compiled into binary executables for custom FPGA pulse sequencers. The toolchain provides two key features that enable high performance hybrid computing: (1) gate parameters from the original input Quil program are translated to sequencer instructions that load from classical memory shared between the sequencer and classical host computer; (2) compiled programs can contain arbitrary control flow that branches off of single-qubit measurement results. The first feature enables the compilation of Quil into binaries that can be updated at run-time and the second, enables active reset of qubit states. Together these allow for rapid iteration in applications such as the optimization of a variational quantum algorithm, because these binaries can be re-executed many times for different input parameters without need for re-compiling or waiting for qubits to relax. We provide quantitative benchmarks of the improved wall-clock performance.

12:15PM F27.00004: Quantum Circuit Compilation to NISQ processors*  ELEANOR RIEFFEL (Presenter), DAVIDE VENTURELLI, NASA Ames Research Center — We describe automated reasoning approaches for QCC-NISQ, quantum circuit compilation to NISQ (noisy intermediate-scale quantum) processor architectures. We tested the approaches for different NISQ processor architectures and QAOA (quantum alternating operator ansatz) circuits. This approach is integrated into our software suite for automated, architecture aware, compilation for emerging gate-model quantum computers. We give an overview of the key components of this suite: a circuit synthesizer, a QCC-NISQ solver, and a visualizer.

*The authors would like to acknowledge support from the NASA Advanced Exploration Systems program, NASA Academic Mission Services (NNA16BD14C) and the NASA Ames Research Center.

12:27PM F27.00005: Less than a million CNOTs should be enough to solve a classically intractable instance of a scientific problem with a quantum circuit* [Invited]  DMITRI MASLOV (Presenter), IBM — The question I will try to answer in this talk is the following: what is the size of the smallest quantum computation capable of solving an instance of a scientifically interesting problem that is intractable for a classical computer? The problem I consider is Hamiltonian dynamics simulation, in the sense of the ability to sample probability distribution given by a state evolved under the target Hamiltonian for a specified time t and accurate to within a specified error epsilon. The core of the talk concerns the development and application of a range of algorithm design, circuit optimization, and hardware/software co-design techniques, the combination of which leads to the reduction in the quantum resource counts provided by pure algorithmic formulations by several orders of magnitude. Specifically, the best physical-level quantum circuit features under 650,000 CNOT gates, and the best fault-tolerant circuit features under 6.8x10^6 T gates. This illustrates that algorithmic and software-level optimizations will be indispensable for practical quantum computing.

Overview and Comparison of Gate Level Quantum Software Platforms

RYAN LAROSE (Presenter), Michigan State University — Quantum computers are available to use over the cloud, but the recent explosion of quantum software platforms can be overwhelming for those deciding on which to use. In this paper, we provide a current picture of the rapidly evolving quantum computing landscape by comparing four software platforms—Forest (pyQuil), QISKit, ProjectQ, and the Quantum Developer Kit—that enable researchers to use real and simulated quantum devices. Our analysis covers requirements and installation, language syntax through example programs, library support, and quantum simulator capabilities for each platform. For platforms that have quantum computer support, we compare hardware, quantum assembly languages, and quantum compilers. We conclude by covering features of each and briefly mentioning other quantum computing software packages.

*Ryan LaRose acknowledges support from an Engineering Distinguished Fellowship through Michigan State University.

A case study for quantum software development: Linear systems solver

JAN GUKELBERGER (Presenter), MARTIN ROETTELER, MATTHIAS TROYER, Microsoft — As the power of quantum computing hardware is growing, software implementations and tools for accurate resource estimation that goes beyond simple asymptotic scaling become crucial for judging the feasibility of an application. Solving linear systems of equations is one of the prime applications for which quantum algorithms with an exponential advantage over the best known classical algorithms have been developed. In this talk, we report on the implementation of state-of-the-art quantum algorithms solving partial differential equations within the Microsoft Quantum Development Kit, which provides robust simulation, debugging, and resource estimation facilities. A key point in this work has been the handling of arithmetic functions: Gate synthesis facilitates accurate resource counts and is a requisite for deployment to quantum hardware, whereas emulation by the classical simulator allows for software testing on larger systems. To this end, we have equipped the Microsoft Quantum Development Kit with a generic and efficient emulation capability for quantum oracles defined by classical functions.

Two-step approach to scheduling quantum circuits

GIAN GIACOMO GUERRESCHI (Presenter), JONGSOO PARK, Intel Labs — As the effort to scale up existing quantum hardware proceeds, it becomes necessary to schedule quantum gates in a way that minimizes the number of operations. There are three constraints that have to be satisfied: the logical dependency of the quantum gates in the algorithm, the fact that any qubit may be involved in at most one gate at a time, and the restriction that two-qubit gates are implementable only between connected qubits. The last aspect implies that the compilation depends not only on the algorithm, but also on hardware properties like connectivity. Here we present a two-step approach in which logical gates are initially scheduled neglecting connectivity considerations and routing operations are added at a later step in ways that minimize their overhead. We rephrase the subtasks of gate scheduling in terms of graph problems like edge-coloring and maximum subgraph isomorphism. While this approach is general, we specialize to a one-dimensional array of qubits to propose a routing scheme that is minimal in the number of exchange operations. As a practical application, we schedule the quantum approximate optimization algorithm in a linear geometry and quantify the reduction in the number of gates and circuit depth that results from different scheduling strategies.

Real-time randomized compilation of quantum algorithms

GUILHEM RIBEILL (Presenter), MATTHEW WARE, BRIAN DONOVAN, LUKE GOVIA, BBN Technologies — Recent experiments have indicated the effectiveness of Pauli Frame Randomization (PFR) as a noise shaping technique. Not only does PFR tailor general noise into Pauli-stochastic noise, it also decouples qubits from their noise environment increasing system Markovianity. Presently, the randomization process requires extensive pre-compilation of pulse sequences. Here, we demonstrate an in hardware implementation of PFR on the BBN Arbitrary Pulse Sequencer II that generates randomized sequences in real-time. We first implement randomized benchmarking without pre-computing pulse sequences before using this capability to randomize a Gate Set Tomography experiment on a superconducting quantum processor.

*This material is based upon work supported by the U.S. Army Research Office under Contract No: W911NF-14-C-0048. 1:51PM F27.00010: SKQuant-Opt: Optimizers for Noisy Intermediate-Scale Quantum Devices*  WIM LAVRIJSEN (Presenter), Computational Research Division, Lawrence Berkeley National Laboratory, ANA TUDOR, Department of Electrical Engineering and Computer Sciences, University of California, Berkeley, JEFFREY LARSON, Mathematics and Computer Science Division, Argonne National Laboratory, KEVIN J. SUNG, Google Inc., LUCY LINDER, Institute of Complex Systems, Haute Ecole de Fribourg, JULIANE MUELLER, Computational Research Division, Lawrence Berkeley National Laboratory, JARROD R. MCCLEAN, RYAN BABBUSH, Google Inc., MIROSLAV URBANEK, COSTIN IANCU, WIBE A DE JONG, Computational Research Division, Lawrence Berkeley National Laboratory — Classical optimizers play an important role in quantum computing, e.g., in the hybrid Variational Quantum Eigensolver (VQE) and Quantum Approximate Optimization algorithms. They are used in hyperparameter tuning, calibration, machine learning, etc. Unfortunately, most of the easily accessible optimizers do not handle noise well, leaving them below threshold for use with Noisy Intermediate-Scale Quantum (NISQ) devices. We present skquant-opt, part of scikit-quant.org, a set of optimizers tuned for the needs of NISQ. We have taken the state-of-the-art optimizers and tested them on a range of VQE applications and on hyperparameter tuning for optimization on D-Wave. Mesh methods, including hybrids that add local models, yield the best results. We present these results as well as guidance on use. Collected in skquant-opt, we provide the best optimizers in Python, the most used language in quantum computing, through the standard channels. The interfaces are made consistent with default parameters attuned to quantum computing problems, allowing for easy application and fast evaluation.

Tuesday, March 5, 2019 11:15 AM - 2:03 PM

Session F28 DQI: Quantum Computing with Open Quantum Systems BCEC 161 - Camille Lombard Latune, University of KwaZulu-Natal

11:15AM F28.00001: Dynamics of Quantum Photocells Driven by Periodic or Stochastic Photon Pulses  SANGCHUL OH (Presenter), Qatar Environment and Energy Research Institute, Hamad Bin Khalifa University — We investigate the dynamics of a quantum photocell as a quantum heat engine, driven by external photon pulses. The photocell is assumed to be only in thermal contact with a cold reservoir, and the stream of work sources from a work or hot reservoir is represented by repeated photon pulses. The interaction between photon pulses and the photocell is described by the pumping term in a Lindblad master equation. By solving the Lindblad master equation, we study numerically the dynamics of a photocell driven by periodic, random, and Poisson photon pulses. We find that the fluctuations in power output of the photocell change dramatically, depending on the statistics of photon pulses and the parameters of the photocell. At low power output, the level occupation probabilities change somewhat smoothly over a long-period of time, even if the photocell is driven by random photon pulses. We analyze how the fluctuation in photon pulses affects the fluctuation in power output for various photon pulses and the parameters of the photocell.

11:27AM F28.00002: Coherent fluctuation relations: from the abstract to the concrete*  ZOE HOLMES (Presenter), Imperial College London, SEBASTIAN WEIDT, University of Sussex, DAVID JENNINGS, University of Leeds, JANET ANDERS, University of Exeter, FLORIAN MINTERT, Imperial College London — Recent studies using the quantum information theoretic approach to thermodynamics show that the presence of coherence in quantum systems generates corrections to classical fluctuation theorems. To explicate the physical origins and implications of such corrections, we here convert an abstract framework of an autonomous quantum Crooks relation into quantum Crooks equalities for well-known coherent, squeezed and cat states. We further provide a proposal for a concrete experimental scenario to test these equalities. Our scheme consists of the autonomous evolution of a trapped ion and uses a position dependent AC Stark shift.

*We acknowledge support from the Engineering and Physical Sciences Research Council, the U.K. Quantum Technology hub for Networked Quantum Information Technologies and the Royal Society.
KUN ZHANG (Presenter), JIN WANG, Stony Brook University — We study the macroscopic realism through Leggett-Garg inequality (LGI) for a two-qubit quantum system coupled with two environments characterized by either the bosonic (thermal and photonic) baths or fermionic (electronic) baths with different temperatures or chemical potentials respectively. Analytical form of LGI and the maximal values of LGI based on the quantum master equation beyond secular approximation are derived. We found that the nonequilibriumness quantified by the temperature difference or chemical potential difference can lead to the LGI violation or the increase of the maximal value of LGI, restoring the quantum nature from certain equilibrium cases where LGI is preserved giving classical realism. Our results shed light on the nature of the macroscopic realism and the relationship between the nonequilibriumness and quantum temporal correlation. Our finding of nonequilibrium promoted LGI violation suggests a new strategy for the design of quantum information processing and quantum computational devices to maintain the quantum nature and quantum correlations for long.

11:51AM F28.00004: Discord vs Distortion: Classical vs Quantum*  BARRY C SANDERS (Presenter), National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, WEI-WEI ZHANG, Physics, University of Sydney, YUVAL R SANDERS, Physics and Astronomy, Macquarie University, NIGUM ARSHED, National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China — Quantum discord is a popular quantum-resource measure but a nonzero value does not necessarily imply quantumness; nonzero classical discord arises if local measurements disturb the stochastic information state [V. Gheorghiu, M. C. de Oliveira and B. C. Sanders, Phys. Rev. Lett. 115, 030403 (2015)]. The classical interpretation of discord breaks down if and only if entanglement of formation for the informational state is nonzero, thereby creating a tight link between entanglement and genuine quantum discord. Here we present mathematical relations, and specifically monotonicity between discord and channel-distortion measures such as mean-squared distortion and Kullback-Leibler divergence. Whereas the previous result showed discord can be nonzero for stochastic information, our new results demonstrate a tight link between classical discord and other information-theoretic measures of noisy channels.

12:03PM F28.00005: Information-theoretic aspects of the generalized amplitude damping channel  SUMEET KHATRI (Presenter), KUNAL SHARMA, MARK M WILDE, Louisiana State University — In this work, we provide an information-theoretic characterization and analysis of the generalized amplitude damping channel (GADC), which is the qubit analogue of the bosonic thermal loss channel. This channel can be used to model the dissipation in a qubit system in the presence of an environment at a finite temperature, and it arises in the study of spin chains. The purpose of our work is to provide bounds on the fundamental limits of the GADC for communicating classical, quantum, and private information. Using the notion of approximate degradability, we provide upper bounds on the quantum and private capacities of this channel. We also provide upper bounds based on data processing inequalities by exploiting the mathematical decomposition of the GADC into channels for which the quantum capacity is known exactly. Using a similar decomposition technique, we are able to provide upper and lower bounds on the classical capacity of the GADC.

12:15PM F28.00006: Superadditivity and boosting coherent information using useless channels  VIKESH SIDDHU (Presenter), Carnegie Mellon University — Superadditivity of the coherent information makes it hard to understand and compute the quantum capacity of a quantum channel, a central quantity in quantum information.

Recently, by using a qubit channel in parallel with itself, Leditzky, Leung and Smith [Phys. Rev. Lett. 121, 160501 (2018)] produced simple examples of superadditivity. We extend their results to a larger class of channels with qubit inputs and some channels with qutrit inputs. Some of these exhibit superadditivity in the sense that the coherent information of a channel is boosted when placed in parallel with a zero capacity channel, in particular a symmetric amplitude damping channel. Our superadditivity examples include limits of simple pcubed qubit and qutrit channels [Phys. Rev. A 94, 052331 (2016)].
Consequences of measurement back-action from quantum monitoring: non-standard speed limits and spontaneous symmetry breaking

LUIS PEDRO GARCIA-PINTOS (Presenter), university of massachusetts boston, DIEGO TIELAS, Universidad de la Plata, ADOLFO DEL CAMPO, university of massachusetts boston — The information acquired during the monitoring of a quantum system provides a state description that can differ greatly from the description given by agents ignorant of the outcomes. While the lack of information in the later results in a mixed density matrix following open system dynamics, the measurement back-action in the former case provides a more accurate description. We present consequences of such measurement back-action to two problems in quantum theory: the limits to the speed of evolution, and the process of spontaneous symmetry breaking.

For the problem of the speed of evolution, we show that there are trajectories for which standard quantum speed limits are violated, and determine the dispersion of the speed of evolution in an ensemble of realizations of continuous measurement records. Regarding the problem of spontaneous symmetry breaking, which is typically understood as a consequence of random fluctuations either in the Hamiltonian governing the evolution or in the state of the system, we present a novel alternative mechanism, induced by the measurement back-action. We show that, depending on the nature of the quantum monitoring, an observer can alter the topology and the pattern of symmetry breaking.

Characterizing Initial Correlations via Spectroscopy

PARTH JATAKIA (Presenter), SAI VINJANAMPATHY, KASTURI SAHA, Physics, Indian Institute of Technology Bombay — In the presence of initial correlations, quantum evolution cannot be described in terms of completely positive trace preserving maps. Such initial correlations can arise due to strong coupling between the system and environment and inform the applicability of important results in physics, such as the quantum regression formula. Therefore it is vital to characterize these correlations for a better understanding of the system and proper quantum control.

Taking inspiration from correlated spectroscopy, we demonstrate a method to determine the correlation between the system and the environment. Our spectroscopic method extracts information about the initial correlations from the system by benefiting from the system - environment interactions. We apply this formalism to Nitrogen-Vacancy centers in diamonds interacting with photonic modes of a cavity.

Quantum Forking for Open Quantum Systems Simulation

JUNE-KOO(KEVIN) RHEE (Presenter), KAIST, ILYA SINAYSKIY, University of KwaZulu-Natal, DANIEL KYUNGDEOCK PARK, KAIST, FRANCESCO PETRUCCIONE, University of KwaZulu-Natal — Many quantum information processing tasks spend non-negligible computational costs for preparing an input quantum state. However, a quantum input state prepared for a specific algorithm cannot be reused for another task once measured by the postulate of the quantum measurement. Moreover, the quantum state cannot be cloned. Hence, in general, one is forced to repeat the state preparation routine per algorithm, even when individual algorithms receive the same input. Meanwhile, many quantum algorithms demand repetitions for sampling the answer. Thus while information processing tasks have the potential to benefit from laws of quantum mechanics, they also impose unavoidable redundancy. Here we introduce quantum information forking that allows an array of qubits to undergo independent processes in superposition to reduce the number of the state initialization procedure. As an example, we demonstrate the application of quantum forking to quantum Monte-Carlo sampling. In this case, quantum forking allows for the implementation of the independent propagation of the quantum trajectories, while maintaining the constant cost of initial state preparation.

1:03PM F28.00010: Experimental Test of Decoherence Theory using Electron Matter Waves*  
PETER BEIERLE (Presenter), Physics, University of Cincinnati, LIYUN ZHANG, Physics, Xian Jiantong University, ZILIN CHEN, Physics, University Of Nebraska-Lincoln, HANS PETER WAGNER, Physics, University of Cincinnati, HERMAN BATELAAN, Physics, University Of Nebraska-Lincoln — A controlled decoherence environment is studied experimentally by free electron interaction as it travels over a [semi]conducting plates. The results are compared with physical models based on decoherence theory to investigate the quantum-classical transition. This first of its kind integrated approach may both further solidify previous claims that such matter-wave experiments are measuring the quantum-classical transition. 

Here we present these findings and progress towards monitoring the environment using space-time resolved optical methods [2], with the aim to study if we can also measure the loss of coherence of the environment induced by the free electron. This first of its kind integrated approach may both further solidify previous claims that such matter-wave experiments are measuring the quantum-classical transition. 

*We gratefully acknowledge support by the U.S. National Science Foundation under Grant No. 1602755.

1:15PM F28.00011: Using a Shot Noise Junction to Characterize a Josephson Travelling Wave Parametric Amplifier*  
JACOB EPSTEIN (Presenter), KYLE MCELROY, Johns Hopkins University Applied Physics Laboratory, LAFE SPIETZ, Spietz Applied Sciences, LLC, TIMOTHY M SWEENEY, Johns Hopkins University Applied Physics Laboratory, JOSE AUMENTADO, NIST Boulder, JOAN A HOFFMANN, Johns Hopkins University Applied Physics Laboratory — The Josephson Travelling Wave Parametric Amplifier (JTWPA) is a solution for a broad band amplifier with near quantum limited noise characteristics. Reported techniques using AC Stark shifts to characterize the noise of a JTWPA show excellent noise characteristics but are inherently narrow band. Using a shot noise tunnel junction (SNTJ) allows for broadband characterization of the noise temperature of the JTWPA. Techniques for optimizing the JTWPA for different measurement uses will also be discussed.

*The authors would like to acknowledge MIT Lincoln Laboratory for providing the JTWPA for this work.

1:27PM F28.00012: Stabilization of cavity Hilbert subspaces in cavity quantum electrodynamics by measurement-based quantum feedback*  
YVES BERUBE-LAUZIERE (Presenter), RÉMI AZOUIT, Electrical and Computer Engineering, Université de Sherbrooke — Measurement-based quantum feedback (MBQFB) for actively preparing and stabilizing Fock number states in a cavity quantum electrodynamics (CQED) set-up has been achieved by Haroche et al. The approach relies on injecting, after each weak dispersive measurement of the cavity state using Rydberg atoms flying through the cavity as sensors, a low average photon number classical coherent field to steer the cavity towards the targeted number state. Preparing and stabilizing a superposition of Fock states using MBQFB is more challenging since the superposition must be an eigenstate of the quantum measurement operators. This condition requires that each Fock state composing the superposition be an eigenstate with the same eigenvalue for each measurement operator. Owing to the special form of the measurement operators in the dispersive regime, this constrains the phase shift per photon to specific values and leads to the stabilization of subspaces. Results from realistic simulations taking into account decoherence and imperfections in a CQED set-up will be presented. These support the validity of the underlying theory that generalizes the previous theory for preparing Fock number states.

*Rémi Azouit acknowledges a Prized Postdoctoral Fellowship from Institut Quantique.

1:39PM F28.00013: Ground state cooling in the strong-coupling regime  
CHUNG KOW (Presenter), Physics and Applied Physics, University of Massachusetts Lowell, HAKAN TURECI, Electrical Engineering, Princeton University, ANJA METELMANN, Physics, Free University Berlin, ARCHANA KAMAL, Physics and Applied Physics, University of Massachusetts Lowell — Strong coupling between quantum systems, whereby the coupling strength greatly exceeds the decay rates, is a mainstay in quantum information platforms. Notably, this regime is explored in hybrid quantum systems involving entanglement between a microscopic and a macroscopic degree of freedom. Nonetheless, in certain instances it can be a liability; for instance, active cooling of a system to its ground state in the strong coupling regime leads to hybridization of the system and the bath modes. Here we present a novel approach using dissipation engineering that mitigates normal-mode splitting between the system and the bath, while preserving strong coupling between the two. Specifically, we employ an optomechanical setup where the mechanical mode is cooled without hybridizing with the optical bath. The connection of such dissipation-engineered cooling with the physics of exceptional points will also be discussed.
Engineered Dissipation as Your Side-kick: A Hybrid Scheme for Quantum Error Correction.

LASSE BJØRN KRISTENSEN (Presenter), Department of Physics and Astronomy, Aarhus University, MORTEN KJÆRGAARD, Research Laboratory of Electronics, Massachusetts Institute of Technology, CHRISTIAN KRAGLUND ANDERSEN, Department of Physics, ETH Zurich, NIKOLAJ T ZINNER, Department of Physics and Astronomy, Aarhus University — The main adversary when trying to harness the power of quantum computation is the ever-present occurrence of errors and decoherence. These effects constantly conspire to alter the state of the quantum bits of your quantum computer, thereby slowly corrupting the stored information and messing up the output of your beautiful quantum algorithms. Luckily, a plethora of quantum error correcting codes have been invented to help mitigate this problem. One interesting branch of this field is the study of autonomous error correction codes that attempt to fight fire with fire by engineering dynamics and dissipation of systems so that they become able to detect and correct errors on their own, without relying on an external experimenter doing costly measurement- and correction-steps. In this talk, we present a scheme that combine these ideas with traditional measurement-based error correction into a 6-qubit hybrid scheme capable of protecting qubits from photon-loss and dephasing errors, achieving 10-fold improvements in dephasing times and 5-fold improvements to relaxation times for realistic superconducting-qubit parameters and noise while employing only relatively simple local 2-qubit interactions.

Session F29 DFD GSOFT GSNP: Flow of Complex Fluids, Polymers, and Particles BCEC 162A -
Marco G. Mazza, Max Planck Institute for Dynamics and Self-Organization

11:15AM F29.00001: Probing multiphase flows with x-ray near-field speckles*
JIN WANG (Presenter), QING ZHANG, YANG, QINGTENG ZHANG, MIAOQI CHU, Argonne National Laboratory — Multiphase flows of simple and complex fluids are of great fundamental and practical interests due to their multitude of applications. However, multiphase flows are also often difficult to study optically because of intense multiple light scattering from the phase boundaries in the flow, such as liquid/gas interfaces. X-rays are highly penetrable in a multiphase flow because of the weak interaction between x-rays and materials. X-ray near-field speckles can be generated readily when x-rays pass through the flow. The x-rays do not need to be completely coherent. A partial or local coherence is sufficient to produce significant intensity fluctuation in the transmitted beam that can used to probe both morphology and dynamics. Combined with ultrafast imaging, x-ray near-field speckles and their spatiotemporal correlations have been proven powerful to interrogate multiphase flows highly transient and far from equilibrium.

11:27AM F29.00002: Effects of passive hydrodynamics force on harmonic and chaotic oscillations in nonlinear chemical dynamics
JEAN BIO CHABI OROU (Presenter), Université d'Abomey-Calavi — This work studies the nonlinear dynamics and passive control of chemical oscillations governed by a forced modified Van der Pol–Duffing oscillator. We considered the dynamics of nonlinear chemical systems subjected to fluctuating hydrodynamic drag forces. The computation of fixed points of the nonlinear chemical system is made in detail by utilizing Cardan's method. The harmonic balance method is used to find the amplitudes of the oscillatory states. The Floquet theory and the Whittaker method are utilized to analyze and analytically determine the stability boundaries of oscillations. The influences of system parameters in general and in particular the effect of the parameter K and the constraint parameter ß which shows the difference between a nonlinear chemical dynamics order two differential equation and ordinary Van der Pol–Duffing equation are observed on the state of the second stability criterion. The effects of the control process on chaotic dynamics states are investigated through bifurcation structures, Lyapunov exponent, phase portraits and Poincaré section. The results obtained by the analytical methods are validated and complemented by the results of numerical simulations.
11:39AM F29.00003: HYDRODYNAMIC RESISTANCE DUE TO POLYMER-INDUCED ELASTIC TURBULENCE IN MICROFLUIDIC SERPENTINE FLOWS  SIDDHARTHA GUPTA (Presenter), RAJU NEELAMEGAM, SIVA A VANAPALLI, chemical engineering, texas tech university — It has been shown that viscoelastic curvilinear flows transition to turbulence in the limit of diminishing Reynolds numbers (Re → 0) with the onset determined by a critical Weissenberg number (Wic). Serpentine microfluidic geometries have been used to characterize such flows, however, the pressure drop-flow rate dynamics during elastic turbulence is still unexplored. To quantify the hydrodynamic resistance due to elastic turbulence, we map the pressure drop versus flow rate relationship due to elastic turbulence using the iCapillary technique. The instability was investigated for high molecular weight poly ethylene oxide in aqueous-glycerol solvents and a scaling relationship with a saturation plateau was observed for different solvent viscosities based on normalized solution driving pressure with respect to the solvent (ΔP/ΔP_{sol}) and plotting against the Weissenberg number. Additionally, Lagrangian representation of the flow was done with digital holography microscopy and CFD simulations were used to analyze deviations from simple shear thinning flows. Thus, we report the first known characterization of flow resistance due to elastic turbulence. The flow resistance relations may provide new insights for structural characterization of polymeric and biofluids.

11:51AM F29.00004: Heat Transfer Enhancement in Helically Micro-Coiled Tubes Using Nanoparticle-Viscoelastic Fluids by Elastic Turbulence  HAIE YANG (Presenter), Beihang University, GUICE YAO, Leeds University, HAICHUAN JIN, DONGSHENG WEN, Beihang University — In recent years, the application of micro-systems has received more and more attention. However, the microsystem scale is small, which greatly limits the flow Reynolds number. It’s difficult for the flow of Newtonian fluid to be turbulent flow at low Reynolds number, limiting the mixing and heat transfer in micro-systems. Nanoparticle-viscoelastic fluids (henceforth referred to as NPVE fluid) were utilized as the experimental group and water as the comparison group. Heat transfer performance of these two groups of fluids under different Reynolds numbers was tested, respectively. Heat transfer efficiency is approximately 35% stronger than water under the same conditions after using a viscoelastic suspension of nanoparticles.

12:03PM F29.00005: Turbulent Submerged Jets of Dilute Polymer Solutions  SAMI YAMANIDOUZISORKHABI (Presenter), GARETH MCKINLEY, IRMGARD BISCHOFBERGER, Massachusetts Institute of Technology — Dilute synthetic polymer solutions have been shown to reduce turbulent drag in pipelines and around marine vehicles. Water-soluble biopolymers such as flax seed mucilage extracts have the potential to serve as cheap and environmentally friendly alternatives to synthetic polymers. In this work, we employ Schlieren imaging to unveil the mixing dynamics and recirculating regions that develop in turbulent jets of dilute aqueous polymer solutions submerged in quiescent water. At the interface of the viscoelastic jet and water, a free shear boundary layer develops leading to momentum transfer between the two fluids. We demonstrate the impact of viscoelasticity on this momentum transfer and evaluate the performance of both synthetic polymers and biopolymers in damping turbulent vortical structures.

12:15PM F29.00006: Hydrodynamics around aggregating charged grains*  CHAMKOR SINGH (Presenter), MARCO G. MAZZA, Max Planck Institute for Dynamics and Self-Organization — The growth of protoplanetary dust from sub-millimeter sized particles to much larger scales is not well understood. There is considerable debate about the role of electrostatic charging of grains in the aggregation process. Additional complexity arises due to the presence of complex hydrodynamic flow that couples to the aggregating grains. We study this growth process using massively parallel molecular dynamics simulations for the granular particles in combination with the smoothed-particle hydrodynamics for the interstitial flow. The results from a detailed cluster analysis are presented. Finally we propose an effective kinetic model for the charged grain aggregation inside interstitial flow.

*Max-Planck Society

12:27PM F29.00007: Gravity-Driven Flow and Clogging in the Presence of an Obstacle*  ANNA BELLE HARADA (Presenter), KERSTIN NORDSTROM, Mount Holyoke College — We present experimental results of 2D gravity-driven flows of >10,000 monodisperse hard spheres (diameter = D) through an aperture (width = W). We introduce into the system a fixed obstacle of varying size (diameter = D_0) and distance above the aperture (L). We use a force sensor to measure the bulk flow rate, and high-speed, high-resolution video to track individual grains. We observe that obstacles tend to decrease the flow rate, but also decrease the clogging probability, and specifically measure the flow rate and clogging probability as a function of D_0 and L for different aperture widths. As our packing is crystalline, we can correlate these features with structural measurements in the material such as dislocations and the bond order parameter. We also present dynamical measurements such as nonaffine rearrangements and cooperative motion.

12:39PM F29.00008: Large-scale flow out of spatiotemporal chaos in electroconvection of cholesteric liquid crystal*
YOHSUKE FUKAI (Presenter), MASAKI SANO, Department of Physics, the University of Tokyo — Convection in a thin layer of liquid crystal driven by an electric field has long been studied as a model system to investigate pattern formation in out-of-equilibrium systems. In particular, it has been known that the flow typically shows spatiotemporal chaotic patterns called dynamic scattering mode with high voltage. In this presentation, we report our observation that this chaotic pattern organizes itself into a large-scale flow perpendicular to the electric field in the case where cholesteric liquid crystal with the negative dielectric constant difference is used. The typical scale of this flow pattern is more than 100 times larger than the distance between the electrodes, the characteristic length scale of the convection. We will discuss the effect of the anchoring and boundary conditions, and possible interpretation toward understanding the mechanism.

*This work is supported by Grant-in-Aid “KAKENHI” for JSPS Fellows (Grant No. 17J05559)

12:51PM F29.00009: Chemical and hydrodynamic instabilities produced by enzymatic surface reactions OLEG SHKLYAEV (Presenter), VICTOR V YASHIN, ANNA CHRISTINA BALAZS, Univ of Pittsburgh — Chemical oscillations are ubiquitous in nature and have a variety of promising applications. Here, we examine a linear stability of a multicomponent reactive fluid that contains two species, X and Y, which undergo transformations catalyzed by enzymes immobilized at two infinite horizontal plates confining the fluid. The surface reactions with the enzymes provide a negative feedback in the system. The first enzyme, localized on the first plate, promotes production of chemical X, while the second enzyme, immobilized on the second plate, promotes production of chemical Y, which inhibits the production of chemical X. Depending on the reaction rates and densities of the reactants, the monotonic and oscillatory instabilities could occur in the system. The first instability (similar to Rayleigh-Benard case) leads to roll-like convective structures that are periodically distributed along the layer. The second instability produces horizontally uniform temporal oscillations of concentrations of the chemicals X and Y. The findings provide guidance for designing micro-scale chemical reactors with improved functionalities.

1:03PM F29.00010: RMD2Kin: an automated, self-consistent, first-principles based approach to extract kinetic data from reactive molecular dynamics simulations* DANIIL ILYIN (Presenter), WILLIAM GODDARD, JULIUS OPPENHEIM, TAO CHENG, SERGEY ZYBIN, ROBERT NIENLEN, California Institute of Technology — Capturing intricate details of the chemistry of important technological processes such as combustion and chemical vapor deposition is a challenge in large-scale simulations. Conventionally, necessary kinetic data are obtained either empirically or from experiments in dilute conditions, and these data may not fully describe interactions that occur in realistic systems. We present here an automated, self-consistent, first-principles based approach to extract kinetic data and reaction mechanisms from reactive molecular dynamics simulations. This approach provides a detailed analytic description of the evolution of a complex chemical system from reactants through various intermediates to products, which can then be used to incorporate the correct reaction chemistry into computational fluid dynamics and/or continuum chemical dynamics simulations. This approach is self-consistent and does not require previous knowledge of the specific chemistry of the system. We refer to this approach as RMD2Kin.

1:15PM F29.00011: Distribution of tracer particles around a catalytic Janus particle WILLIAM USPAL (Presenter), Department of Mechanical Engineering, University of Hawai'i at Manoa, JAIDEEP KATURI, Institute for Bioengineering of Catalonia (IBEC), The Barcelona Institute of Science and Technology (BIST), MIHAIL N. POPESCU, Theory of Inhomogeneous Condensed Matter, Max Planck Institute for Intelligent Systems, Stuttgart, SAMUEL SANCHEZ, Institute for Bioengineering of Catalonia (IBEC), The Barcelona Institute of Science and Technology (BIST) — Active Janus particles self-propel by catalyzing the decomposition of molecular “fuel” available in the surrounding solution. The resulting self-generated chemical gradients drive phoretic flow in an interfacial layer surrounding the particle, as well as chemi-osmotic interfacial flows along nearby container walls. Through experiments and theory, we consider the distribution of small tracer particles around a Janus particle in the vicinity of a planar wall. The Janus particle is either free to move or stuck to the wall, and its axis of symmetry is oriented in the plane of the wall. Experimentally, we observe that, under certain conditions, the catalytic cap of a particle is surrounded by a tracer-free exclusion zone. To understand this finding, we model the motion of tracer particles. In our model, the tracers are advected by fluid flows driven in the bulk solution by phoretic and/or chemi-osmotic interfacial flows. Additionally, the tracers can respond to chemical gradients through phoresis, providing a third contribution to tracer velocity. We find that these three ingredients can combine to create an exclusion zone. In particular, we highlight the essential role of chemi-osmotic flow, which is often neglected in modeling and interpretation of experiments.
Reducing Blood Viscosity and Suppressing Turbulence with Magnetic Field to Prevent Heart Attack and Stroke*

RONGJIA TAO (Presenter), Temple University — Heart attacks and strokes are the leading causes of death. High blood viscosity and turbulence in blood circulation are the keys to trigger these diseases, as they place much heavier workload on the heart, develop atherosclerotic plaque and may rapture blood vessels. Reducing blood viscosity and suppressing turbulence is thus the key to prevent cardiovascular diseases. Unfortunately, these two tasks conflict each other. Presently, the only method to reduce blood viscosity is to take medicine, but this method makes the turbulence worse because the Reynolds number goes up with viscosity reduction. Here we report our discovery with magnetorheology (MR): applying a strong magnetic field to blood along its flow direction, red blood cells are polarized and aggregated into short chains. The blood viscosity becomes anisotropic: it is significantly reduced along the flow direction, but is considerably increased in the directions perpendicular to the flow. The blood flow thus becomes laminar and turbulence is suppressed. Our lab and animal tests show that this technology can successfully prevent plaque development. The clinical trials further confirm that this MR technology can effectively cure hypertension and help people to prevent heart attack and stroke.

Exploiting magnetocapillary interactions for swimming along liquid interfaces

NICOLAS VANDEWALLE (Presenter), GALIEN GROSJEAN, GRASP, Physics Dept, University of Liege, Belgium — When soft ferromagnetic particles are suspended at air-water interfaces in the presence of a vertical magnetic field, dipole-dipole repulsion competes with capillary attraction such that 2d structures self-assemble. The complex arrangements of such floating bodies are emphasized. The equilibrium distance between particles exhibits hysteresis when the applied magnetic field is modified. Irreversible processes are evidenced. By adding a horizontal and oscillating magnetic field, periodic deformations of the assembly are induced. We show herein that collective particle motions induce locomotion at low Reynolds number. The physical mechanisms and geometrical ingredients behind this cooperative locomotion are identified. These physical mechanisms can be exploited to much smaller scales, offering the possibility to create artificial and versatile microscopic swimmers. Moreover, we show that it is possible to generate complex structures that are able to capture particles, perform cargo transport, fluid mixing, etc...

Session F30 DPOLY GSOFT DFD DBIO: Extreme Deformation II: Rate and Size Effects in Glasses, Networks, and Fibers

Deformation of Matrix-Free, Glassy Single Component Polymer NanoComposite at Extreme High Strain Rates

JINHO HYON (Presenter), EDWIN THOMAS, Rice University, JASON STREIT, RICHARD VAIA, Air Force Research Laboratory — Very thin, freestanding glassy polystyrene (PS) films show unexpectedly large energy absorption under rapid axisymmetric tensile loading at ballistic strain rates (~ 10^7/s). For supersonic microprojectile (3.7 μm diameter) impact (350~800 m/s), the more mobile and less entangled near-surface regions of the PS facilitate crazing and dramatically increase craze multiplication and subsequent growth with accompanying large adiabatic temperature rise of the highly deforming film. Here, we investigate the influence on the high rate deformation of grafting of the PS chains to nanoparticle (NP) surfaces. The covalent anchoring of several hundred polymer chains to individual silica NPs and the well-entangled coronal regions between NPs improve the stress transfer through the composite, yielding polymer nanocomposites with excellent energy absorption. The single component nanocomposite PS grafted nanoparticle (PSgNP) films (~ 1% v/v, 16nm diameter SiO2 NPs) show 25% enhanced high kinetic energy absorption per unit mass of the target film over the previous record specific energy absorption of the thin, freestanding homopolymer PS films.
EDWIN CHAN (Presenter), Materials Science and Engineering Division, National Institute of Standards and Technology, WANTING XIE, Department of Mechanical and Industrial Engineering, University of Massachusetts, CHRISTOPHER SOLES, Materials Science and Engineering Division, National Institute of Standards and Technology, JAE-HWANG LEE, Department of Mechanical and Industrial Engineering, University of Massachusetts — The fracture behavior of amorphous polymer glasses is strongly linked to the entanglement density. Traditionally, it is established that polymers exhibiting strain hardening, such as polycarbonate, tend to undergo ductile fracture rather than brittle fracture due to its high entanglement density. In this work, we use Laser-induced Projectile Impact Testing (LIPIT) to study the supersonic fracture behavior of polycarbonate films as a function of entanglement density. We show that the kinetic energy for microparticle penetration through the polymer film is affected by the molecular mass of the polymer or the plasticizer content. We show that this variation in the penetration energy to a change in the mechanism of fracture. Specifically, the fracture mechanism transitions from crazing to shear yielding due to changes in the entanglement density of polycarbonate film.

11:39AM F30.00003: Strain Rate Effects During Ultra-High Strain Rate Penetration of Polymeric Materials  
M. HUNTER BOWERING, Dave C Swalm School of Chemical Engineering, Mississippi State University, W. F. HEARD, U. S. Army ERDC, THOMAS E. LACY, JR, Department of Mechanical Engineering, Teaxs A&M University, CHARLES U. PITTMAN, JR., Department of Chemistry, Mississippi State University, SANTANU KUNDU (Presenter), Dave C Swalm School of Chemical Engineering, Mississippi State University — Energy dissipation during penetration of a material is an important consideration in designing lightweight armor to protect structures, equipment, and personnel from impact damage. A series of impact tests, with projectile velocities in the range 2-7 km/s, was performed on monolithic plates of ultra-high molecular weight polyethylene (UHMWPE), high density polyethylene (HDPE), and poly(methyl methacrylate) (PMMA). A relationship between back face debris cloud (BFDC) velocity and impact velocity was developed for each material. Damage zone sizes were compared, offering insights into the effects of molecular architecture on stress delocalization and energy dissipation during perforation. Monolithic plate thicknesses were varied in the UHMWPE and HDPE target populations to assess thickness effects on damage zone size and BFDC. Comparison of the apparent failure mechanisms and damage metrics, in conjunction with thermal analysis, were used to explain the relative performance of each material. PMMA demonstrated glass-like failure with finely particulated BFDCs, while perforation of HDPE resulted in fluid-like BFDCs. UHMWPE damage morphology possessed qualities of both PMMA and HDPE.

Permission to publish was granted by Director, Geotechnical & Structures Laboratory

11:51AM F30.00004: The Role of Fast Polymer Dynamics on the Mechanical Toughness of Polymeric Materials  
CHRISTOPHER SOLES (Presenter), KANAE ITO, ADAM B BURNS, Materials Science & Engineering Division, NIST, KEVIN A. MASSER, JOSEPH L. LENHART, Weapons and Materials Research Directorate, US Army Research Laboratory, MADHU SUDAN TYAGI, Center for Neutron Research, NIST — It is understood that there is a link between molecular relaxations in glassy polymers and mechanical toughness. The notion is that these relaxations dissipate the energy of impact and thereby enhance toughness. Decades of research have focused on correlating the mechanical toughness of a polymer with the relaxation processes quantified by relatively slow characterization techniques such as dynamic mechanical analysis, dielectric spectroscopy, or solid-state nuclear magnetic resonance. However, there is a disconnect because the time and length scale of the molecular mechanisms are typically several orders of magnitude faster and more localized than the experimental techniques used to characterize them. We revisit this by using quasielastic neutron scattering (QENS) to quantify both the collective excitation and molecular relaxations that occur on the time scale of ps to ns, and see how these motions correlate with mechanical toughness. We demonstrate a strong correlation between these fast polymer relaxations and toughness. We show that these fast polymer relaxations play a critical role in predicting the ability of a material mitigate impact under ballistic conditions where the strain rates can approach an inverse microsecond.
12:03PM F30.00005: A Quasi-mimetics Approach for Uncovering Starch-based Hybrid Materials* YIN FANG (Presenter), YUANWEN JIANG, ENDAO HAN, YILIANG LIN, James Franck Institute, University of Chicago, XIANGHUI XIAO, JIN WANG, Argonne National Laboratory, HEINRICH M JAEGGER, BOZHI TIAN, James Franck Institute, University of Chicago — Materials design through biomimetics aims to achieve functions similar to those found in nature. However, this requires a thorough understanding of the system used for mimicking (SuM), which would become a challenge when SuM is complex. Here, we propose a quasi-mimetics approach, which focuses on partial components in the SuM. Different from biomimetics, quasi-mimetics aims to probe the elusive behaviors in the complex SuM, as well as to uncover new functions not found in SuM. We illustrate this approach with a starch particle-embedded hydrogel composite where noodle dough serves as a SuM. The starch hybrid composite displays unprecedentedly high stretchability both in air and water, self-healing behavior, and strain-dependent mechanical training effect. Our mechanistic study showed that the unique mechanical features of the starch hybrid gel are related to the formation of covalent bonds between the interface of the starch particles and polymer network, as well as the dynamic hydrogen bonds in the hydrogel matrix. The new quasi-mimetics approach can be broadly applied to other material exploration and device applications.

12:15PM F30.00006: Starch embedded hydrogels: Linking macroscopic mechanical properties with microscopic particle configurations* ENDAO HAN (Presenter), YIN FANG, James Franck Institute, University of Chicago, XIANGHUI XIAO, JIN WANG, Argonne National Laboratory, BOZHI TIAN, HEINRICH M JAEGGER, James Franck Institute, University of Chicago — When noodles are made, a flour dough can be stretched to an extremely long length without breaking. What can we learn from it in order to synthesize innovative hydrogels? Mimicking the microstructure of flour dough, we synthesized a hybrid hydrogel by embedding wheat starch granules in an alginate-PAA gel network. This hybrid hydrogel shows many amazing mechanical properties, such as substantially improved stiffness and toughness, extremely high stretchability (up to 8000% strain), and persistent memory that is rewritable with training. With the help of x-ray microtomography, we found direct links between the macroscopic stress-strain curves and the microscopic particle structures when such hybrid hydrogels are deformed under uniaxial extension. This quasi-mimetic process allows us to not only produce materials with novel properties, but also explore new physics with simple, highly controlled systems.

12:27PM F30.00007: The Thermoviscoelastic Behavior of a Main-Chain Liquid Crystal Elastomer* THAO NGUYEN (Presenter), Johns Hopkins University — Liquid crystal elastomers (LCEs) combine the anisotropic ordering of liquid crystals and viscoelastic behavior of an elastomeric network. This leads to remarkable mechanical properties, including reversible shape change in response to temperature or light, deformation induced soft elasticity and anisotropy, and extreme dissipation behavior. In this presentation, I will describe our efforts to characterize the rate-dependent and temperature-dependent large deformation behavior of an acrylate main-chain LCE networks to investigate the effects of mesogen order and chain alignment on the stress-strain response, soft elasticity behavior, and hysteresis. The experimental results showed that time-temperature superposition can be applied to the stress response of the LCEs in the nematic state throughout the soft elasticity plateau. All LCE networks, polydomains and monodomains stretched parallel and perpendicular to the director, exhibited the same rate-dependence for the modulus and hysteresis. However, the onset strain and duration of the soft elasticity plateau were relatively insensitive to the strain rate. These findings suggest that the rate-dependent stress response of the acrylate LCEs in the nematic state is insensitive to mesogen reorientation.

Understanding failure processes of polymer gels is critical for numerous applications, ranging from adhesives to protective materials. We discuss the failure processes associated with the deep indentation and puncture of soft gels with an axisymmetric probe. We commonly observe that the first critical transition, associated with puncture, occurs at nominal stresses that can be as much as 100 to 1000 times the elastic modulus. To understand how soft gels can sustain such stress levels prior to initial failure, we have studied puncture as a function of size scale, velocity, and material network structure. Spherically-tipped indenters of radii, R=0.4-66 um were used to characterize puncture at length scales well above the network mesh size (nm), on the same order of magnitude as the elasto-capillary length (um), and significantly below the elasto-fracture length (mm). Critical energy release rate was found to be in agreement with the predicted scaling from the classical Lake-Thomas model modified for gel fracture via the failure mechanism of chain pull-out and plastic yielding of micelles. These experiments and proposed relationships provide new insight into how gels fail and how design paradigms may be shifted to more effectively engineer with soft gels.

Electrospun polymer nanofibers have garnered significant interest due to their strong size-dependent material properties, such as tensile moduli, strength, toughness, and glass transition temperatures. These properties are closely correlated with polymer chain dynamics. In most applications, polymers usually exhibit viscoelastic behaviors such as stress relaxation and creep, which are also determined by the motion of polymer chains. However, the size-dependent viscoelasticity has not been studied previously in polymer nanofibers. Here, we report the first experimental evidence of significant size-dependent stress relaxation in electrospun Nylon-11 nanofibers as well as size-dependent viscosity of the confined amorphous regions. In conjunction with the dramatically increasing stiffness of nano-scaled fibers, this strong relaxation enables size-tunable properties which break the traditional damping-stiffness tradeoff, qualifying electrospun nanofibers as a promising set of size-tunable materials with an unusual and highly desirable combination of simultaneously high stiffness and large mechanical energy dissipation.

*National Science Foundation, CMMI-1762560

The mechanical properties of semi-crystalline polymeric materials are largely determined by the architecture and amount of the crystalline domains. It is known for UHMWPE fibers that the toughest and stiffest fibers exhibit a structure consisting of extended chain crystals and lamella. This structure is produced via a post-drawing process where the fiber is deformed causing the re-organization of the polymer chains. There is a lack of understanding regarding how the crystalline structure develops during drawing and what role the various structural aspects play in the mechanical properties. We show, using SAXS/WAXS, that various crystalline structures can be produced during the manufacturing of PE fibers and that these architectures develop along unique pathways when drawn. Using a VADER1000 to perform post-drawing and tensile testing, understanding of the fibers mechanical response is found. We show that unique structures exhibit distinct relaxations and a critical stress at failure of PE fibers. This study provides a much deeper understanding of crystalline behavior in extension and allows for improved design of the post-drawing process.

The buckling and twisting of slender, elastic fibers is a deep and well-studied field. Recently, there has been great interest in applying this knowledge to the development of miniature linear actuators (artificial muscle), but also to investigate linkages with the formation of helices in nature (e.g. tendrils) as well as DNA supercoiling. A slender rod that is twisted with respect to a fixed end will spontaneously form a hockle, or loop, to relieve the torsional stress that builds. Further twisting results in the formation of plectonemes — a helical excursion in the fiber that extends with additional twisting. Here we investigate the energy stored and subsequently released by hockles and plectonemes as they are pulled apart, in analogy with force spectroscopy studies of DNA and protein folding. Hysteresis loops in the snapping and unsnapping inform the stored energy in the twisted fiber structures.

Fiber networks with inter-fiber adhesion: role of adhesion in extreme network mechanics*

VINEET NEGI, AHMED SENGAB, CATALIN PICU (Presenter), Rensselaer Polytechnic Institute — Many soft materials of biological and industrial interest are composed from nanofibers. In such cases, inter-fiber adhesion may produce fiber bundling and organization on scales larger than that of individual components. We study both non-cross-linked [1] and cross-linked [2] networks with adhesive interactions between filaments. We determine the parametric range in which adhesion reorganizes the network and study the mechanical behavior of the resulting structures. We observe a broad range of tunable properties, including softening in tension, large strain range in which the structure responds linearly to applied strains, and adhesion-dependent elastic moduli. The results provide guidelines for material design and demonstrate that controlling inter-fiber adhesion may lead to fibrous materials with exceptional properties and behavior.

Intrinsic Chiroptical Response: Can We Predict the Right Answer for the Right Reasons?*

PAUL M. LEMLER, CLAYTON L. CRAFT, PATRICK H. VACCARO (Presenter), Department of Chemistry, Yale University — The "intrinsic handedness" that distinguishes the mirror-image forms (enantiomers) of a chiral molecule gives rise to a variety of intriguing phenomena, perhaps none of which has had as profound and sustained an impact on the physical sciences as the characteristic interactions that take place with polarized light. Although the signatures of this optical activity have been recognized for over two centuries, their fruitful application for the determination of absolute stereochemical configuration has been revolutionized by the advent of computational paradigms capable of predicting such properties from first principles. Efforts to probe the dispersive circular birefringence (CB) of isolated chiral molecules at nonresonant wavelengths will be presented, with emphasis directed towards the marked influence that intramolecular dynamics and intermolecular forces can exert on intrinsic electronic response. Requisite isolated-molecule measurements have been made possible by ongoing development of cavity ring-down polarimetry (CRDP), an ultrasensitive chiroptical probe that has permitted the first quantitative studies of optical rotatory dispersion (ORD or wavelength-resolved CB) to be conducted in rarefied gaseous media. Quantum-chemical analyses have been enlisted to unravel the provenance of experimental findings and to elucidate the synergism among electronic and nuclear degrees of freedom that ultimately governs observed behavior. By alleviating the pronounced effects incurred from environmental perturbations (e.g., solvation), vapor-phase ORD benchmarks will be shown to afford a critical assessment of burgeoning optical-activity calculations, as well as an incisive means to expose the strengths and shortcomings inherent to various computational protocols.

Probing electronic processes in large molecules

FRANCESCA CALLEGARI (Presenter), DESY — Attosecond science is nowadays a well-established research field, which offers formidable tools for the investigation and control of electronic processes [1,2]. The possibility to study molecules of increasing complexity with attosecond time resolution paves the way to disclosing the role of the electron dynamics in the photo-chemistry and photo-biology of complex systems. In this context, we have recently demonstrated that attosecond pulses can initiate charge migration between different functional groups of aromatic amino-acids [3]. In this talk I will first present a time-resolved study of photo-fragmentation of the nucleobase adenine, one of the key building blocks of DNA. Our most intriguing observation is that a stable dication of the parent molecule can be produced if (and only if) the probing NIR pulse is very briefly delayed from the XUV pulse. Our experimental and theoretical findings indicate that this short delay corresponds to the lifetime of the inner valence hole. The process also evidences the presence of a laser-assisted stabilization of the nucleobase.

In the second part of the talk I will show the results we have recently obtained for a very large polyatomic molecule, namely the C60 molecule. Here we have investigated delays in photoemission after exciting the Giant surface Plasmonic Resonance (GPR) around 20 eV. Clear signatures of the collective electron dynamics initiated by the XUV pulse can be extracted from the experimental data.

Designing Ligands to Control Molecular Nanomagnets: Strategies for 3d vs 4f

ANNIE POWELL (Presenter), Karlsruhe Institute of Technology — NA

Luminescence Measurements of the Hyperthermal Reactions of N⁺/N + NH₃

MICHAEL HAUSE (Presenter), Boston College Institute of Scientific Research, BENJAMIN PRINCE, RAYMOND BEMISH, Air Force Research Laboratory — Chemi-luminescence emitted in the ultraviolet, visible and near infrared from the collision of N⁺ or N with NH₃ at collision energies between 20-300 eV (center of mass) was measured and the energy dependence of the respective emissions quantified in the emission excitation cross sections. For both primary collision species, the strongest features are assigned to emissions from NH (A-X) and the hydrogen Balmer series. Additional features originating from N I and NH (c-a) emissions were also observed. Most of the transitions are consistent with short-range interactions resulting in collision induced dissociation of the NH₃ molecule. It has been found previously that the NH (A-X) cross sections are independent of collision partner in studies with Ar⁺, Kr⁺ and Xe⁺ with NH₃. Reaction with N⁺ largely agrees with these findings, but the cross sections from collisions with neutral N is much reduced.

Laser-Ionization of Energetic Compounds: Differences and Similarities between Structures and Energetics of Gaseous Monomers and Solid State

FATMA AKIN (Presenter), Bogazici University — As one of the processes following pulsed nanosecond or ultrafast laser ablation of solids, ionization is expected to direct molecular dissociation events. Ionization-induced effects on the RDX(s) and RDX (g) are computationally investigated using DFT methods and normal mode displacement calculations incorporating the Duschinsky effect. Structures, dissociation enthalpy and free energies of the resulting [(RDX)₂⁺] clusters show that ionization caused 75% of the conformers to be unstable in their neutral isomeric composition and orientation. Ionization causes charge-polarization, hydrogen-transfer, N-N dissociation and assisted HONO formation in solid RDX. The assisted HONO formation occurs via and suggests hydrogen mobility within the charged moieties, causing the greatest stabilization. The energy costs of ion-neutral dissociation are comparable to the hydrogen-transfer and NO₂ loss processes. The RDX conformational identity is a determining factor in the emerging dissociation pathways in both dimeric and monomeric forms. Ionization of the RDX surface is proposed as another source of NO₂ and HONO precursors of the NO⁺ ion observed previously.

Neural network - assisted analysis of X-ray spectra of bimetallic nanoparticles

NICHOLAS MARCELLA (Presenter), ANATOLY I FRENKEL, Stony Brook University — In X-ray absorption spectroscopy, it is problematic to analyze and interpret polyatomic systems consisting of elements that are neighbors in Periodic Table due to the overlapping edge regions and similar photoelectron scattering properties. This limits our ability to solve the local structure of interesting bimetallic nanocatalysts such as PtAu PdAg, IrPt, and RhAu. We have shown, recently, that X-ray absorption near edge structure (XANES) can be inverted to provide structural properties due the region's sensitivity to photoelectron scattering. Now, we take advantage of XANES sensitivity to electronic structure, specifically charge transfer. In this work, we demonstrate how our new Neural Network XANES (NN-XANES) method can be used to solve the structure of these difficult systems with better accuracy than existing methods. Our work suggests that NNs can yield distinct partial Pt-Au and Pt-Pt coordination numbers from Pt L3-edge XANES in PtAu, a feat impossible with EXAFS and other Z-contrast-limited techniques.

Raman enhancement effect using 2D materials as substrates: mechanism and application

HIKARI KITADAI, Department of Chemistry, Boston University, NANNAN MAO, Massachusetts Institute of Technology, SHENGXI HUANG, School of Electrical Engineering and Computer Science, Pennsylvania State University, XI LING (Presenter), Department of Chemistry, Boston University — Graphene enhanced Raman scattering (GERS) was first reported in our previous work in 2010, which opened the door of using 2D materials as substrates for Raman enhancement. Here, we will present a systematic study on the Raman enhancement effect on a variety of 2D materials. Raman enhancement effect at different levels is observed on different 2D materials, which is attributed to the chemical enhancement. The degree of charge transfer between molecule and 2D materials is obtained based on the selection rule of the enhancement to vibrational modes with distinct symmetries. A strong correlation is found between the Raman enhancement effect and the degree of charge transfer. Moreover, advantages of the Raman enhancement on 2D materials for practical applications will be discussed.

Probing the dynamics of small anions in optical cavities

ANDREA GRAFTON (Presenter), ADAM DUNKELBERGER, KENAN FEARS, RODERICK B. DAVIDSON, BLAKE SIMPKINS, JEFFREY OWRUTSKY, United States Naval Research Laboratory — Coupling vibrational modes to optical cavities offers a method to systematically and predictably modify the vibrational energy landscape of a molecule. A confined optical mode can couple to a resonant material transition and lead to enhanced absorption/emission rates, excited state population control, and the formation of new hybrid states. There is a rich history of coupling to electronic transitions, including quantum wells and J-aggregates, coupling to vibrational transitions has only been explored recently. We reported time resolved IR studies on strongly coupled vibration-cavity polaritons for W(CO)$_6$ in hexane. The result demonstrated that much of the response is due to uncoupled reservoir excited state absorption and there is evidence for an angle-tuning dependent decay time for the upper polariton (UP) to $\nu = 2$ transition. We have explored other solutes with shorter dephasing times vibration-cavity systems. Dicyanamide and thiocyanate have strong mid-IR absorptions and are capable of strong coupling to optical fields. However, in both anions, we do not observe the UP to $\nu = 2$ transition that was observed in the W(CO)$_6$ cavity. The results are discussed in terms of how they impact the prospects for observing polariton relaxation effects in vibration-cavity systems.

Session F33 FIAP: Energy Conversion and Storage Materials

11:15AM F33.00001: Shift current bulk photovoltaic effect influenced by quasiparticle and exciton* RUIXIANG FEI (Presenter), University of Pennsylvania, LIANG TAN, Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, ANDREW RAPPE, University of Pennsylvania — We compute the shift current bulk photovoltaic effect (BPVE) in bulk BaTiO$_3$ and two dimensional monochalcogenide SnSe considering quasi-particle corrections and exciton effects. We explore changes in shift current peak position and magnitude reduction due to band renormalization. For BaTiO$_3$, we demonstrate that shift current is dramatically reduced near the band edge but enhanced at high energies due to exciton effect. Additionally, we reveal that the shift current is reduced in two dimensional monochalcogenide SnSe due to the enhancement of optical reflectivity from many-body corrections. Comparison of these results with experiments on BaTiO$_3$ indicate that mechanisms other than shift current may be contributing to BPVE. These results suggest that many-body corrections are important for accurate assessments of bulk photovoltaic materials and to understand the mechanisms behind the BPVE.

11:27AM F33.00002: Bulk photovoltaic effects in the presence of a static electric field* BENJAMIN M. FREGOSO (Presenter), Physics, Kent State University — Irradiated crystalline insulators in the presence of a static electric field exhibit three new types of nonlinear photocurrents. They represent physical singularities of the third order free electron polarization susceptibility and hence generalize the standard second order bulk photovoltaic effects. In the absence of momentum relaxation and saturation effects they grow as $t^n$ ($n=2,1,0$) with illumination time and are dubbed jerk, modified injection, and modified shift current, respectively. The presence of a static electric field gives rise to new processes which are described in detail. Experimental signatures and extensions to higher order susceptibilities are also discussed.

11:39AM F33.00003: Core-shell colloidal quantum dots for photovoltaics with improved open circuit voltage* YIJIN GUO (Presenter), SUE SHI, GILLIAN HAGEN, BENJAMIN A ZANK, ALEXI C ARANGO, Physics, Mount Holyoke College — High carrier recombination rates in lead sulfide (PbS) colloidal quantum dot (CQD) photovoltaics (PV) can result in a reduction in open circuit voltage (Voc). Surface states and sub-gap states are thought to increase recombination which leads to Voc loss. Here we present a method of forming an oxide shell on the CQD surface capped with native oleic acid ligands prior to the deposition of the CQD film and ligand swap. The core-shell QDs exhibit a narrowing in size distribution and the resulting devices yield improved Voc. In addition, films of core-shell QDs are more resilient to damage incurred during sputter deposition of overlying films. Because the thickness and uniformity of the oxide shell can be precisely controlled, a natural balance between trap passivation and charge transport can be achieved.

Tuesday, March 5, 2019 11:15 AM - 2:03 PM
11:51AM F33.00004: Si24: a next-generation semiconductor with growing promise for future solar energy* MICHAEL GUERETTE (Presenter), Geophysical Laboratory, Carnegie Institution for Science — The recently discovered allotrope of silicon, Si24, is an exciting material for the future of solar energy due to a quasi-direct bandgap near 1.3 eV [1]. Synthesized via precursor Na4Si24 at high temperature and pressure (~850 °C, 9 GPa), free standing single crystals of on the 1 mm scale are now achievable [2]. An epitaxial relationship between Na4Si24 and diamond cubic silicon (DC-Si), observed through high-resolution transmission electron microscopy (HRTEM), is proposed to facilitate the growth of these high-quality Na4Si24 crystals from DC-Si wafers mixed with metallic Na. These observations illuminate a path toward scaling of Na4Si24 and Si24. Removal of Na from Na4Si24 on this length scale is shown to be effective, revealing intrinsic optical and electronic properties of Si24. Our results encourage the pursuit of Si24 for future solar energy conversion and efficient optoelectronics.

12:03PM F33.00005: Tailoring the structure and defects of non-toxic nanocrystalline Bi2S3 solar cells MARYAM MASROOR SHALMANI (Presenter), PRATAP RAO, Worcester Polytechnic Institute — Solar cells can satisfy the increasing demand for energy worldwide, but the toxicity of semiconductors used in solar cells can overshadow their utility as a renewable source of energy. Bi2S3, with a desirable band gap of 1.3eV, and as a non-toxic n-type semiconductor can be a favorable replacement for toxic semiconductors containing Pb, Cd or Te. However, nanocrystalline Bi2S3 films synthesized by various techniques such as successive ionic layer adsorption and reaction (SILAR) have not reached high solar energy conversion efficiencies hitherto, and have primarily been studied as sensitizers for photoelectrochemical applications. Here, we report the synthesis and characterization of non-toxic all-inorganic solid-state Bi2S3 photovoltaic solar cells. We enhanced the solar energy conversion efficiency of the nanocrystalline Bi2S3 solar cells by optimizing the structure of the electron and hole transport layers, and by tailored annealing treatments that modify the size of the Bi2S3 nanocrystals and decrease their defect concentrations.

12:15PM F33.00006: The fluid-like nature of solid cubic halide perovskites* XINGANG ZHAO (Presenter), GUSTAVO DALPIAN, ALEX ZUNGER, University of Colorado, Boulder — X-ray diffraction ‘see’ in the high temperature phase of ABX3 halide perovskites a macroscopically averaged cubic structure with a single formula unit (FU) per cell. Yet DFT calculations on this structure reveal a number of anomalies: i) It has dynamically unstable phonons, ii) its band gap is lower than both experiment and molecular dynamics (MD) predictions, iii) the trends with A cation show inconsistency with experiment e.g., cubic FASnI3 has larger gap than the orthorhombic CsSnI3, and iv) it has higher total energy than the relaxed supercell with many repeated FUs. We find via DFT that the real microscopic structure of cubic halide perovskites is polymorphous, i.e., it contains a dynamic fluid-like distribution of different local motifs, each having differently tilted/rotated/B-atom displaced BX6 octahedra and differently oriented A molecules, the average of which is the fictitious monomorphous cubic structure. The polymorphous configurations have stable phonons and much larger band gaps, forming the correct description of trends in gaps and structures in the ABX3 group of materials. We will present the main effects that govern band gaps in perovskites, via carefully constructed static supercell approximants to the dynamic MD structure.

*Supported by DOE/EERE DE-EE-0008153
Due to the unique optical properties and high quantum efficiency, the lead halide perovskites have obtained great attentions in the recent years. Currently, the research focuses not only on their potential applications in solar cell, LED, and laser, but also on several unsolved fundamental issues, such as the origin of the luminescence of Cs$_4$PbBr$_6$. The mechanism of the luminescent Cs$_4$PbBr$_6$ perovskite is still under debate. Some people think that the pure Cs$_4$PbBr$_6$ crystals are non-emissive while the strong green PL (Photoluminescence) originates from the CsPbBr$_3$ nanocrystals encapsulated in the Cs$_4$PbBr$_6$ bulk crystals. The others claim that the strong emissive comes from the structural defects of the Cs$_4$PbBr$_6$ crystals. Despite the various reports to support each opinion, no final conclusion has been made up to now. In this work, we plan to controllably synthesize emissive and non-emissive Cs$_4$PbBr$_6$ crystals as well as CsPbBr$_3$ nanocrystals with a strong photoluminescence. By combining various techniques, such as Raman, XRD, (HR)TEM, PL, etc., we attempt to confirm the contribution of CsPbBr$_3$ dopants to the photoluminescence of Cs$_4$PbBr$_6$ crystals.
1:15PM F33.00011: Use of LIBS Technology for CO2 Leak Detection in Carbon Sequestration* CHET BHATT (Presenter), JINESH JAIN, DANIEL HARTZLER, AECOM, National Energy Technology Laboratory, DUSTIN MCINTYRE, National Energy Technology Laboratory — In this study, the in-situ measurement capability of Laser-Induced Breakdown Spectroscopy (LIBS) to detect CO2 leakage in geological carbon storage (GCS) was evaluated. As LIBS is an optics-based (contains no electronics) spectroscopic technique, it can perform contamination-free analysis in extreme conditions of underground environment. During the leakage, the interaction of CO2 with carbonate rocks at elevated pressures can release various metals which can potentially contaminate the drinking water sources above storage sites. Therefore, we evaluated the underwater LIBS technique for studying the carbonate dissolution with increased CO2 pressure. Dissolution experiments using four carbonates (CaCO3, SrCO3, MnCO3, and MgCO3) at the elevated CO2 pressure (ranging from ambient to 250 bars) were carried out by analyzing LIBS spectra obtained from aqueous solutions containing these carbonates. The results indicated the dissolution of all carbonates. However, the rate of dissolution varied from carbonate to carbonate. This study shows that in-situ monitoring of carbonate dissolution by underwater LIBS can be used for CO2 leak detection in GCS.

*National Energy Technology Laboratory

1:27PM F33.00012: Energy-Saving Meta-Glasses with Embedded Plasmonic Nanoparticles LUCAS VAZQUEZ BESTEIRO (Presenter), Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, XIANG-TIAN KONG, Department of Chemistry, University of Washington, ZHIMING M WANG, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, FEDERICO ROSEI, Énergie, Matériaux et Télécommunications, Institut National de la Recherche Scientifique, ALEXANDRE GOVOROV, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China — Plasmons are collective charge carrier excitations. Using different plasmonic materials to fabricate nanocrystals and controlling their size and geometry allows us to obtain sharp resonances from UV to near IR. By embedding ensembles of nanocrystals in dielectric materials, we can design metamaterials with specific transmission profiles that filter out a broad spectrum while remaining transparent to selected frequency bands.1 We discuss this idea in the specific context of its application in energy-saving windows.2 By blocking UV and IR radiation from the solar spectrum they reduce the energy expenditure of active cooling systems in warm climates, but they retain the desirable property of being transparent to visible light. In this talk we will present theoretical results for plasmonic glasses created with different nanoparticle geometries3 and materials, offering alternatives to current industrial fabrication standards, with comparable efficiencies and potentially lower costs.

1:39PM F33.00013: Unsteady State of a Solid State Device: Characteristic Cooling Length* PABLO EDUARDO RUIZ-ORTEGA (Presenter), MIGUEL OLIVARES ROBLES, SEPI ESIME Culhuacan, Instituto Politecnico Nacional — Thermoelectric modules (TEM) are solid state devices that can work as a Thermoelectric cooler (TEC). TECs can reach temperatures below that obtained with a steady-state current by applying an electrical current pulse which enables a transitory state in a Peltier couple. This phenomenon is known as supercooling. The objective of this work is to analyze characteristics parameters such as minimum cooling temperature, COP and temperature spatial profile in a TEC operated under current pulses and cooling load (Qc) pulses. We study a numerical model of a one-dimensional thermoelectric cooling system in the unsteady state. In this work, we propose a new parameter called characteristic cooling length to describe the distance in which occurs minimum cooling temperature in the elements of a TEM. Our results show the transient temperature spatial profile along the thermoelements of the TEM and the characteristic cooling length for different materials. We propose a general principle to make a judgment how the temperature profile will occur along the elements due to material properties under current pulse operation.

1:51PM F33.00014: Highly-Miscible and Bandgap-Tunable (Li\(_x\)Cu\(_{1-x}\))\(_2\)ZnSnS\(_4\) Alloys  HE LI (Presenter), XIAN ZHANG, TAO ZHANG, MENG LIN HUANG, SHIYOU CHEN, East China Normal University — Doping or alloying lithium into Cu\(_2\)ZnSnS\(_4\) (CZTS) has drawn extensive attention recently because it is crucial for fabricating high-performance Cu\(_2\)ZnSnS\(_4\) thin film solar cells. Experiments showed that lithium can be alloyed into CZTS with a high content and even completely substitute copper to form a new compound Li\(_2\)ZnSnS\(_4\) (LZTS). Using the first-principles calculations, we found that Li\(_2\)ZnSnS\(_4\) adopts wurtzite-kesterite as ground state structure with a band gap around 3.29 eV. The valence band offset between Li\(_2\)ZnSnS\(_4\) and Cu\(_2\)ZnSnS\(_4\) is 2.20 eV. As the Li content increases, the band gap of (Li\(_x\)Cu\(_{1-x}\))\(_2\)ZnSnS\(_4\) alloy increases rapidly with a big band gap bowing. The mixing enthalpies of (Li\(_x\)Cu\(_{1-x}\))\(_2\)ZnSnS\(_4\) alloys in the kersterite and wurtzite-kesterite structures are both small, suggesting that the (Li\(_x\)Cu\(_{1-x}\))\(_2\)ZnSnS\(_4\) alloys can easily form at a low growth temperature. These results demonstrate that the lithium alloying may be an effective way for adjusting the band structure and the optoelectronic properties of CZTS.

Session F34 DPOLY FIAP: Polymer Physics to Address the Dual Energy Challenge at Global Industrial Scale

11:15AM F34.00001: A New Carbon Ontology: Hydrocarbons as Benign Material Resource for Civilizational-Scale Building  MARK GOULTHORPE (Presenter), Massachusetts Institute of Technology — The talk will frame the macro scale of building and infrastructure development forecast for coming decades, especially in regions of population and economic growth, and highlight the startling environmental impact implicit in current building materials and methods as well as the in-use energy and maintenance footprints. Alternative materials that mitigate such impacts will be considered, such as mass timber, but the prime focus will be on emerging polymeric composite material-processing that has proved so successful in many other manufacturing sectors, especially in their remarkable structural capacity. A case will be made that adoption of polymeric composites offers potential for radical revision of building methods, with potential for civilizational-scale adoption in short timelines; and it will map out the environmental benefits that this might offer in both embodied and in-use impact. The challenges and impediments to broad uptake of hydrocarbon-derived buildings will be considered, and thoughts offered as to how these might be addressed effectively, with particular focus on fire retardancy and the economics of production. Emerging gas-deposition of carbon nanotube and graphene materials will be probed, which offer remarkable potential for poly-functional carbon dwellings that are suggestive of an elegant new carbon ontology: a carbon shroud for a carbon organism!

The talk will serve as a call for collaboration between upstream and downstream actors as vital to breaking into a highly entrenched and deeply conservative building “industry”. The need for radical new building technologies merits a purposeful mobilization (political, technical, logistical) that aims at nothing less than a massive re-orientation of hydrocarbon assets from prime use as fuel to prime use as building materials at a period of unprecedented urban development and against the backdrop of a mounting environmental crisis.
**11:51AM F34.00002: Tools for polymer design: predicting rheology from molecular weight distribution and branching topology** [Invited] DANIEL READ (Presenter), CHINMAY DAS, VICTOR BOUDARA, University of Leeds — Polymers make wonderful, useful materials! Yet, their success and ubiquity has itself caused problems, provoking examination of their sustainability and recyclability, and of the energy efficiency of their processing. In this context, the design and optimisation of new materials and processes requires tools with the ability to predict material properties and behaviour on the basis of their molecular structure. This talk will present our efforts to address the challenge of predicting the flow properties (rheology) of polymeric liquids, and discuss the physics underpinning the software we have developed. The potential design space is vast: practical polymers are polydisperse (broad and variable molecular weight distribution) and may contain branches (with potential to control the statistics of branch placement). These molecular variables affect the response of the polymers to flow: whether the strands align, or stretch, and by how much, in a given flow field. These dynamics in turn gives rise to relevant processing phenomena such as extension hardening, or shear thinning. We will focus on polydisperse linear polymers, for which we have developed a constitutive model ("Rolie-Double-Poly") embedded in software (https://reptate.readthedocs.io/) that quantitatively predicts non-linear rheology from molecular weight distribution. We will also discuss how chain branching affects the physics, as encoded within our "BoB" software (https://sourceforge.net/projects/bob-rheology/).

*EPSRC grant number EP/P005403/1

**12:27PM F34.00003: Micromechanics of oriented semi-crystalline polymers: from structure to properties** [Invited] HANS VAN DOMMELEN (Presenter), MOHSEN MIRKHALAF, Eindhoven University of Technology, JEVAN FURMANSKI, ExxonMobil Research and Engineering Company, LEON GOVAERT, Eindhoven University of Technology — The microstructure of semi-crystalline polymers, in terms of for example the degree of crystallinity, crystal type, size and orientation, may vary drastically depending on subtle details of the manner in which the polymer is shaped into the final product. For this material, often an oriented microstructure is formed, leading to anisotropic yield and failure kinetics.

To obtain a fundamental and quantitative understanding of how these anisotropic properties depend on the structure, a multiscale micromechanical model is developed. The modelling approach is based on a mean field framework, accounting for the crystalline phases, which are modelled by crystal plasticity and amorphous domains. The anisotropy of these amorphous regions is incorporated in the micromechanical model in the form of a pre-stretch of the amorphous network and anisotropic visco-plastic flow. Both aspects are found to be crucial for predicting the experimentally observed orientation dependence of the yield kinetics. With this combined experimental-modelling approach, new insight in the physical processes that govern the mechanics of semi-crystalline polymers are obtained.

*The authors gratefully acknowledge ExxonMobil corporation for financial support of this study.

**1:03PM F34.00004: A better future for fossil hydrocarbons and carbon nanomaterials** [Invited] MATTEO PASQUALI (Presenter), Rice University — Every year we extract over 4.2 GT of oil, 2.5 GT of natural gas, and 3.4 GT of coal to sustain our economy. That’s equivalent to 8.7 GT of carbon and 1.3 GT of Hydrogen. Almost all of these resources are burned to generate energy, causing over 30 GT of CO2 to enter the atmosphere which is unsustainable in view of climate change—the only significant exception is polymers, which fix 0.35 GT/yr of hydrocarbon resources (~3% of the total production) into valuable solid materials. At the same time, every year we use over 12% of the world energy production (over 60 EJ) towards primary metals; most of this energy goes into mining, refining, and processing ~3 GT/yr of metal ores into usable metals, chiefly 1.6 GT/yr of steel, 50 MT/yr of Aluminum, and 20 MT/yr of Copper; it is accompanied by the generation of 3.7 GT of CO2 emissions, equivalent to ~20% of the emissions caused by burning oil and gas. This is the extent of our “materials-energy nexus”.

Can we break this inefficient cycle and replace metals with materials made directly from hydrocarbons? Carbon Nanomaterials—primarily CNTs and graphene—offer an opportunity. They can be made via pyrolysis of methane and other hydrocarbons, with concurrent production of hydrogen. In the past decade, methods have been developed to convert CNTs and graphene into macroscopic materials (fibers, sheets, 3D structures) that could displace metals based on their properties—strength, electrical and thermal conductivity. In this talk, I will discuss why carbon nanomaterials could be great candidates to utilize natural gas on a very large scale (GT/yr) to make materials with zero CO2 footprint and positive hydrogen production. I will outline the scientific problems that need to be solved to realize highly-efficient synthesis and conversion of these materials and will present an estimate of the potential benefits of such a transition in our use of fossil hydrocarbons.

1:39PM F34.00005: Quantifying tie-chain fraction and its impact on charge transport in model conjugated polymers

[Invited] LYNN LOO (Presenter), Princeton University — The presence of tie chains that connect between crystallites can critically impact the electrical properties of conjugated polymers. Yet, the community has not yet been able to directly visualize them, let alone quantify their content in conjugated polymers. We applied the Huang-Brown model, a framework commonly used to elucidate the structural origins of mechanical properties in polyolefins, to quantify the tie-chain contribution to charge transport in a series of model poly(3-hexylthiophene), P3HT, and its blends. Plotting field-effect mobility as a function of tie-chain fraction, as extracted from the Huang-Brown model, collapses the data on a single curve not previously seen when the charge transport property is plotted against molar mass. We find a threshold tie-chain fraction of 10⁻³, below which intercrystallite connectivity limits macroscopic charge transport. Structural characterization via x-ray paracrystallinity analysis of these P3HT films suggests intracrystallite disorder to be the bottleneck that limits charge transport when crystallites are connected. Our study affirms the importance of connectivity between crystalline domains, with the Huang-Brown model implicating long polymer chains with rigid backbone to facilitate macroscopic charge transport.

Tuesday, March 5, 2019 11:15 AM - 2:15 PM

Session F35 APS: Apker, Greene, Metropolis Award Session

BCEC 205B - Renata Wentzcovitch, Columbia

11:15AM F35.00001: LeRoy Apker Award Talk: Anyons in a Dynamical Toric Code Model* [Invited] NICHOLAS SHERMAN (Presenter), Physics, University of California, Berkeley, BRUNO NACHTERGALE, University of California, Davis — In 3+1 dimensions, all particles are classified as either bosons or fermions. However the story is different in 2+1 dimensions, where a new type of particle exists: anyons. Beyond the fundamental interest of anyons, they also harness the ability to implement fault-tolerant universal quantum computation. The use of anyons for the purposes of quantum computation was first proposed by Kitaev with the development of the toric code model. However, the anyons in this model are stationary states, and the dynamics of anyons are an essential ingredient in quantum computation. In this work, we introduce a dynamical toric code model by perturbing the toric code Hamiltonian. Anyons in this model have non-trivial dynamics while the anyon numbers are conserved. In this talk I will discuss the model, the dispersion relation of the low energy excitations, and the role symmetry plays in the features of the spectrum.

11:51AM F35.00002: Nicholas Metropolis Award for Outstanding Doctoral Thesis Work in Computational Physics

Talk: Astrophysical Simulations in the Era of Massively-Parallel Computation [Invited] EVAN E. SCHNEIDER (Presenter), Astrophysical Sciences, Princeton University — In this talk, I will describe my thesis work developing Cholla, a new hydrodynamics code for astrophysics that was designed to run natively on the graphics processing units (GPUs) that power the world’s fastest supercomputers. By harnessing the power of this new technology, Cholla is allowing us to run astrophysics simulations with unprecedented numerical resolution, leading to new insights regarding the physical structure of gas in galaxies. In addition to describing the design of the Cholla code (including details of both physical and numerical algorithms), I will also discuss the results of a recent project using Cholla to explore an interesting problem in galaxy evolution - the physics of galactic winds. Star-forming galaxies are commonly observed to be driving gas out at a variety of densities, temperatures, and velocities. These outflows are invoked to explain the discrepancy between the dark matter halo mass function and the stellar mass function of low-mass galaxies. Using petascale simulations run with Cholla on the Titan supercomputer, we can better resolve the hydrodynamic interactions between phases in these outflows, allowing us to constrain their origin and evolution. This combination of new software with new computer architectures has ushered in a new era of massively-parallel astrophysics simulations.
12:27PM F35.00003: LeRoy Apker Award Talk: The Aerodynamics of Ballistic Seed Dispersal in the Plant Family Acanthaceae* [Invited] ERIC COOPER (Presenter), Pomona College/ Stanford University — Plants in the Acanthaceae family ballistically launch seeds that rotate at up to 1660 Hz – one of the fastest rotation rates in the natural world. In numerous species, this high rate of backspin stabilizes seeds in a streamlined orientation, which we have analytically determined is a property of all ballistic spinning discs. Using high-speed video, we quantify the effect that this stability has on aerodynamic drag and dispersal range. Study of several species within the Ruellia genus shows plants reach the largest seed dispersal ranges (up to 10 m) when utilizing the aerodynamic benefits of stable backspin. This research opens the door to further comparative study across the 4000+ species of the Acanthaceae family. Combining systematic measurements of seed dispersal aerodynamics with existing phylogenetic data promises to shed light on open biological questions about the adaptive significance of seed dispersal.

* This work was done in collaboration with Molly Mosher, Carolyn Cross, Cole Becker and Professor Dwight Whitaker at Pomona College. We acknowledge the support of NSF MRI award 0722532, Pomona College, and the Pomona College SURP program.

1:03PM F35.00004: Richard L. Greene Dissertation Award Talk: Coherent Light-Matter Interactions in 2D Materials [Invited] EDBERT JARVIS SIE (Presenter), Stanford University — Monolayer transition-metal dichalcogenides are prime examples of 2D semiconductors that exhibit remarkable electronic properties. They have a pair of electronic valleys that can serve as a new degree of freedom to carry information. However, these valleys are normally locked in the same energy level, which limits their potential use for applications. Here, we discuss a direct optical method to tune the exciton energy levels of monolayer W52 in a valley-selective manner through the optical Stark effect [1] and the Bloch-Siegert shift [2], performed at MIT. The two effects are found to obey opposite selection rules, which enables us to separate the two effects at two different valleys. Finally, I will briefly discuss our recent experiments where the topological phases of semimetal WTe2 can be manipulated using light-induced atomic-scale lattice distortions [3], performed at SLAC/Stanford University.

1:39PM F35.00005: Richard L. Greene Dissertation Award in Experimental Condensed Matter or Materials Physics: Engineering Synthetic Quantum Operations [Invited] URI VOOL (Presenter), Harvard University — Coherent quantum effects are the hallmark of atomic systems. The field of circuit quantum electrodynamics also allows for the control of coherent quantum systems. However, these quantum states do not correspond to atomic degrees of freedom, but to the quantized behavior of the electromagnetic field in a macroscopic superconducting circuit. These “artificial atoms” simulate many of the effects in atomic systems, with the added benefits of tunability and fast control and measurement. In this talk we present the basic quantum objects accessible using superconducting circuits, and techniques we can use to create a richer variety of artificial atoms and quantum operations. One experiment focuses on selection rules in superconducting circuits. Using non-linear coupling, we are able to break the selection rules of a fluxonium artificial atom and drive forbidden transitions. We use this technique to construct a Λ system from the fluxonium coupled to a resonator at the fluxonium sweet spot. Another experiment focuses on the new artificial atoms and operations accessible by adding continuous external drives to the circuit. By taking the Jaynes-Cummings (JC) Hamiltonian of a qubit coupled to a cavity and adding two continuous tones, we are able to simulate an effective JC Hamiltonian in the transverse basis. The energies and interaction terms are completely governed by the drives, and the system can be tuned to any interaction regime in situ. This scheme also allows us to cool the qubit to the eigenstates of the transverse basis, and perform a continuous quantum non-demolition measurement of the transverse component of a qubit.

This talk presents work done during my Ph.D. in Michel Devoret's lab at Yale University.

**Tuesday, March 5, 2019 11:15 AM - 2:15 PM**

**Session F36 GMAG GMED: In-vivo Magnetic Measurements for Medical Diagnosis, Therapy and Discovery** BCEC 205C - Stephen Russek, National Institute of Standards and Technology Boulder - Tag(s): Invited
11:15AM F36.00001: Magnetic functional neuroimaging and transcranial magnetic stimulation [invited] AAPO NUMMENMAA (Presenter), Harvard Medical School — TBD

11:51AM F36.00002: MRI Magnetic Susceptibility Mapping In Vivo* [invited] KARIN SHMUELI (Presenter), Medical Physics & Biomedical Engineering, University College London — The magnetic susceptibility of living tissues depends on their composition and microstructure. Therefore, the emerging, non-invasive, magnetic resonance imaging (MRI) technique of quantitative susceptibility mapping (QSM) is beginning to yield clinically useful information on pathophysiology-related changes in tissue composition and microstructure. I will outline the physical principles underpinning QSM and describe QSM applications we have developed in sickle cell anaemia, healthy brain ageing and head-and-neck cancer.

Weak tissue susceptibilities (Schenck, Med Phys 1996) cause small magnetic field perturbations seen in phase of the complex MRI signal. In QSM we calculate susceptibility maps from MRI phase images. MRI phase is a 0 to 2π angle in the complex plane and must be unwrapped. The unwrapped images are dominated by large-scale background phase variations caused by the relatively large air-tissue susceptibility difference. Once the background field variations are removed the result is the input for susceptibility calculation. This is an ill-posed inverse problem for which many regularisation methods have been proposed. There is a plethora of algorithms available for each stage in the QSM pipeline and the MRI QSM community is working to achieve consensus on the best methods.

QSM has important advantages over phase images and a widespread precursor known as susceptibility weighted imaging (SWI): it overcomes the non-local and orientation-dependent phase contrast (Shmueli, MRM 2009) to improve visualisation of tissue structure and composition.

Clinical applications are emerging based on QSM's sensitivity to tissue calcifications, iron, myelin and deoxyhaemoglobin content. QSM highlights iron-rich brain structures in Parkinson's disease, microbleeds and haemorrhages and distinguishes these from calcifications. QSM allows quantification of venous oxygenation with functional QSM now able to detect brain activity.

*European Research Council Consolidator Grant

12:27PM F36.00003: Magnetoencephalography using optically-pumped magnetometers* [invited] SVENJA KNAPPE (Presenter), SEAN KRZYZEWSKI, NICHOLAS NARDELLI, BRANISLAV KORENKO, GLEB ROMANOV, ORANG ALEM, JERAMY HUGHES, Mechanical Engineering, University of Colorado — Current magnetoencephalography (MEG) uses a helmet-shaped array of low-temperature superconducting quantum interference devices (SQUIDs) to image the magnetic field produced by the neural currents inside the head with millisecond temporal resolution. Moving the sensors closer to the scalp holds the promise of simultaneously increasing the spatial resolution of MEG. Our optically-pumped magnetometers (OPMs) are room-temperature sensors that work on the principle of laser spectroscopy of alkali atoms in a vapor cell. They can be microfabricated and placed in close proximity to the scalp for MEG. The MEG test system we present consists of 48 microfabricated OPMs, that are integrated into pairs on small flying lead sensor heads, such that they form 24 first-order gradiometers with a baseline of 2 cm. The gradiometer and magnetometer data are read out simultaneously. The sensors are assembled on a conformal 3D printed helmet with spokes that can be adjusted in the radial direction through a ratchet system. The magnetic field in the radial direction to the head is recorded with the magnetometers and radial gradiometers. We present first standard MEG recordings of resting-state measurements and evoked responses.

NIH: R01 NS094604
NIH: R44 NS090894
1:03PM F36.00004: Smart magnetic probes for in-vivo metrology [Invited] GARY ZABOW (Presenter), Applied Physics, National Institute of Standards and Technology (NIST), STEPHEN DODD, ALAN KORETSKY, NINDS, National Institutes of Health (NIH) — Magnetic resonance imaging (MRI) represents one of the most outstanding examples of the successful application of something that began as fundamental physics research. Together with related NMR technologies, it now impacts many fields including food, pharmaceutical, chemical, energy, and of course medical industries, where it has rapidly become one of the most widely used medical imaging and diagnostic tools. Not requiring ionizing radiation, it can benignly probe deep within the body, offering excellent soft tissue contrast and, compared with other radiological methods, high resolution imaging.

But there remains much room to further develop the technologies. Specifically, this talk will discuss several recent examples [1,2] of how work in physics and engineering is enhancing the functionality of MRI through (i) new contrast agents 10-100x more powerful than existing alternatives that enable in vivo tracking of cells down to the single cell level, (ii) new micromagnetic structures that add "color" or multiplexing capabilities to traditionally black-and-white MRI, and (iii) smart polymer – magnetic composites that enable new radio-frequency (RF) addressable microsensors, or smart probes, for quantitative sensing. The talk will focus on the basic physics and engineering behind these imaging and sensing agents, including how they are made and some example first applications. Presentation will be at a general, introductory level; no prior knowledge of NMR/MRI required.

1:39PM F36.00005: Ultra-low field and nonconventional MRI* [Invited] MATTHEW ROSEN (Presenter), Radiology, A.A. Martinos Center for Biomedical Imaging — A promising approach to portable MRI is operation at ultra-low magnetic field where cost-effective electromagnets become practical. MRI in the ultra-low field (ULF) regime — when the magnetic field used for signal detection is below 10 mT—is inherently challenging mainly due to intrinsically low Boltzmann polarization. We will discuss hardware methods to improve attainable SNR in the Johnston-noise-dominated regime of ULF using improved coils such as quadrature volume coils at 276 kHz (6.5 mT). We will also discuss our work to reduce noise and increase attainable information per unit time using compute-based approaches that leverage low-cost GPU. These include magnetic resonance fingerprinting (MRF) to enable multiple quantitative contrasts at ULF, and the use of our neural network deep learning approach, AUTOMAP (AUtomated TransfOrm by Manifold APproximation), to reconstruct highly-undersampled low SNR imaging data..

Tuesday, March 5, 2019 11:15 AM - 2:15 PM

Session F37 GMAG DMP: Pyrochlores I: Moment Fragmentation, Quantum Spin Liquids, and Beyond BCEC 206A - Bella Lake, Helmholtz-Zentrum Berlin - Tag(s): Focus

11:15AM F37.00001: Search for quantum phases in the rare earth zirconate and hafnate pyrochlore frustrated magnets [invited] MONICA CIOMAGA HATNEAN (Presenter), Department of Physics, The University of Warwick — Pyrochlores are interesting due to their versatile structure, frustrated magnetic lattice and their wide variety of exotic magnetic ground states (spin ices, spin frozen states, or long-range ordered states). The most studied pyrochlore oxides are the classical spin ices Dy2Ti2O7 and Ho2Ti2O7. One of the most interesting avenues of current research is into systems which exhibit novel magnetic ground states, such as quantum spin liquid (QSL) and quantum spin ice (QSI). Pr, Tb or Yb pyrochlores are good candidates for the realisation of quantum states. We have studied the zirconate and hafnate \(R_2M_2O_7\) (\(R=\) Rare Earth, \(M=\) Zr, Hf) oxides. Recent results show that they exhibit a variety of exciting magnetic behaviours and emergent properties, ranging from a disordered state with quadrupolar correlations and spin-ice-like excitations in \(Pr_2Zr_2O_7\), the fragmentation of magnetic moments into an ordered phase and a fluctuating state in \(Nd_2Zr_2O_7\), a disorder-induced QSL state in \(Tb_2Hf_2O_7\), to a potential QSI ground state with fractionalized excitations in \(Pr_2Hf_2O_7\). These investigations have been motivated by the availability of large high-quality single crystals of these materials. I will discuss the structural and magnetic characteristics of some of the zirconate and hafnate pyrochlores.
Antiferromagnet Ce₂Zr₂O₇

The pyrochlore antiferromagnet Ce₂Zr₂O₇ is sensitive to an instability of the Ce³⁺ oxidation state, whereby the 4f¹ electronic configuration of Ce³⁺ can be diluted via sample oxidation and the concomitant introduction of Ce⁴⁺ to the lattice.¹ For that reason, reduction of Ce₂Zr₂O₇ samples is required to enable a neutron scattering study of this material, the subject of this presentation. The spins in Ce₂Zr₂O₇ possess a local Ising anisotropy and interact via an antiferromagnetic coupling, which typically results in all-in all-out antiferromagnetic order. However the crystal electric field (CEF) wavefunctions of the Ce³⁺ ground state can have a dipole-octupole nature which is an ingredient for moment fragmentation and can allow for a disordered U(1) quantum spin liquid ground state.² High energy neutron spectroscopy confirms the dipole-octupole CEF ground state, and higher energy resolution inelastic neutron scattering shows a disordered ground state for Ce₂Zr₂O₇.

Neutron scattering study of breathing pyrochlore lattice material LiGaCr₄S₈

LiGaCr₄S₈ is a breathing pyrochlore lattice where the ordering of the Li⁺ and Ga³⁺ cations on the A-site of the spinel structure leads to the periodic expansion and contraction of Cr⁴⁺ tetrahedra. Strong magneto-elastic coupling drives negative thermal expansion in the temperature range 12-110 K. Neutron diffraction and inelastic neutron scattering experiments were carried out on polycrystalline samples of LiGaCr₄S₈ to investigate the spin configuration and spin-spin interactions. No long-range magnetic order is observed above 1.5 K. However, neutron diffraction shows the gradual appearance of a magnetic signal centered at |Q|~0.51 Å⁻¹ on cooling below ~100 K and a second contribution at |Q|~0.64 Å⁻¹ appears below 15 K. The inelastic neutron scattering data shows spin excitations with a zone boundary energy 12.6 meV at 4 K. The intensity of the inelastic signal weakens above 10 K though persists to nearly 100 K. At low energies the dynamic susceptibility can be described with a single temperature dependent relaxation.

1. Gordon and Betty Moore Foundation's EPIQS Initiative through Grant GBMF4416.
Non-spin-ice quantum spin liquid (QSL) with Ce-based dipole-octupole doublets Ce₂Zr₂O₇

Ce₂Zr₂O₇ is a high-quality single crystal grown by a floating zone method. We confirmed the Kramer doublet ground state in Ce³⁺ ions from crystal electric field measurements. We revealed that the quasi-elastic structure factor and Pauling entropy is totally suppressed in this system by carrying out diffuse neutron scattering and heat capacity measurements. Our AC magnetic susceptibility and muon-spin relaxation measurements suggest no spin freezing down to 0.02 K. Inelastic neutron scattering experiments display broad excitation continua along Brillouin zone boundaries, indicating fractional spin excitations, which is the key feature of QSL. This, together with the absence of features of spin ice and spin glass, suggest the system is a non-spin-ice QSL state at low temperature, where spins are highly correlated but fluctuate strongly.

Pyrochlore antiferromagnet CdYb₂Se₄ studied by neutron scattering

CdYb₂Se₄ is a geometrically frustrated pyrochlore lattice with exotic magnetic behavior. Our results give deeper insight into the CEF scheme and k=0 magnetic ground state. Additionally, we observed low energy spin excitations evolving with temperature and magnetic field. This grants a possibility to identify the exchange Hamiltonian of this frustrated antiferromagnet with strong quantum character.

Pyrochlore antiferromagnet CdYb₂Se₄

The pyrochlore lattice is well-established in titanates R₂Ti₂O₇ (R=rare earth) [1]. Spinel compounds AR₂X₄ with R-ions also residing on the pyrochlore lattice similarly exhibit unconventional magnetism [2, 3]. The basic distinction between the two families is the local environment of the rare earth ions [4, 5]. Here, we present a neutron scattering study of the crystal electric field (CEF), magnetic ground state, and spin dynamics of CdYb₂Se₄. Extending recent studies on CdYb₂Se₄ [2, 4], our results give deeper insight into the CEF scheme and k=0 magnetic ground state. Additionally, we observed low energy spin excitations evolving with temperature and magnetic field. This grants a possibility to identify the exchange Hamiltonian of this frustrated antiferromagnet with strong quantum character.

*SNF grant 200020_162626
12:39PM F37.00006: Ultrasound investigation of Ce$_2$Zr$_2$O$_7$ at low temperatures and in high magnetic fields.
ANDREA BIANCHI (Presenter), JÉRÉMIE DUDEMAIN, Université de Montréal, JONATHAN GAUDET, EVAN SMITH, BRUCE GAULIN, Department of Physics and Astronomy, McMaster University, YULIA GRITSENKO, SERGEI ZHERLITSYN, JOACHIM WOSNITZA, Hochfeld-Magnetlabor Dresden, Helmholtz-Zentrum Dresden-Rossendorf — Through careful controlling the atmosphere during the growth of Ce$_2$Zr$_2$O$_7$ we have been able to stabilize Ce$^{3+}$ and prevent the formation of non-magnetic Ce$^{4+}$. This allows us to study the interesting case of doublet-octupole moment on a pyrochlore lattice. In the pyrochlore structure the Ce$^{3+}$ J = 5/2 multiplet is split by crystal field interactions resulting in wave functions for the ground state Kramers doublet which correspond to a linear combination of m$_J$ = ±3/2 states. A generic model for these unusual doublets supports two distinct symmetry enriched U(1) QSL ground states in the corresponding quantum spin ice regimes. We measured ultrasound down to 20 mK and in magnetic fields of up to 10 T with the field applied along the [111] direction for transversal and longitudinal modes. In zero field we observe a softening of the modes for temperatures below 0.8 K, which is an indication for quantum fluctuations. At 20 mK, an increase of the magnetic field leads to decrease of the sound velocity and the curves show hysteresis which is reminiscent of the behaviour observed in Dy$_2$Ti$_2$O$_7$ and Ho$_2$Ti$_2$O$_7$.

12:51PM F37.00007: Extended Coulomb Liquid of Paired Hardcore Boson Model on a Pyrochlore Lattice
CHUN-JIONG HUANG (Presenter), University of Science and Technology of China, CHANGLE LIU, Fudan University, ZI YANG MENG, Institute of Physics, CAS, YUE YU, Fudan University, YOUJIN DENG, University of Science and Technology of China, GANG CHEN, Fudan University — There is a growing interest in the U(1) Coulomb liquid in both quantum materials in pyrochlore ice and cluster Mott insulators and cold atom systems. We explore a paired hardcore boson model on a pyrochlore lattice. This model is equivalent to the XYZ spin model that was proposed for rare-earth pyrochlores with "dipole-octupole" doublets. Since this model has no sign problem for quantum Monte Carlo(QMC) simulations in a large parameter regime, we carry out both analytical and QMC calculations. We find that the U(1) Coulomb liquid is quite stable and spans a rather large portion of the phase diagram with boson pairing. Moreover, we numerically find thermodynamic evidence that the boson pairing could induce a possible Z$_2$ liquid in the vicinity of the phase boundary between Coulomb liquid and Z$_2$ symmetry-broken phase. Besides the materials' relevance with quantum spin ice, we point to quantum simulation with cold atoms on optical lattices.

1:03PM F37.00008: Magnetic phase diagram of dipolar-octupolar pyrochlores
OWEN BENTON (Presenter), RIKEN — Recent experiments have revealed intriguing magnetic properties in a variety of rare-earth pyrochlores R$_2$M$_2$O$_7$ with magnetic ions R=Nd, Sm, Ce. Common to these systems is a low energy crystal field doublet with so-called "dipolar-octupolar" character. This is associated with several interesting phenomena including magnetic moment fragmentation and possible quantum spin liquid ground states. Additionally, the application of a magnetic field in the (1,1,1) or (1,1,0) directions allows tuning from a fully 3-dimensional state in zero field to 2-dimensional or 1-dimensional states in high field. This rich set of phenomena calls for a unified description with which we can quantitatively understand and predict the properties of dipolar-octupolar pyrochlores. In this talk, we will explore the magnetic phase diagram of these materials in applied magnetic fields using a combination of analytical and numerical methods. Particular attention will be paid to the emergent low dimensional states induced by external fields along the (1,1,1) and (1,1,0) directions. This work will enable us to explain the behaviour of diverse dipolar-octupolar pyrochlores and the emergence of new quantum states in these systems.
1:15PM F37.00009: Dynamical structure factor of the three-dimensional quantum spin liquid candidate NaCaNi$_2$F$_7^*$

HITESH CHANGLANI (Presenter), Florida State University, SHU ZHANG, Johns Hopkins University, KEMP PLUMB, Brown University, OLEG TCHERNYSHYOV, Johns Hopkins University, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems — We study the spin-1 pyrochlore material NaCaNi$_2$F$_7$ [1] with a combination of molecular dynamics simulations, stochastic dynamical theory and linear spin wave theory. The dynamical structure factor from inelastic neutron scattering is well described by a near-ideal Heisenberg Hamiltonian incorporating small anisotropic terms and weak second-neighbor interactions [2]. We find that all three approaches reproduce remarkably well the momentum dependence of the scattering intensity and its energy dependence with the exception of the lowest energies. We find (i) a complete lack of sharp quasiparticle excitations in momentum space over much, if not all, of the energy range; (ii) linear spin-wave theory appears to apply in a regime where it would be expected to fail for a number of reasons. We elucidate what underpins these surprises, and note that basic questions about the nature of quantum spin liquidity in such systems pose themselves as a result [3].

1:27PM F37.00010: Intermultiplet transitions and long-range order in Sm-based pyrochlores

VIVIANE PECANHA-ANTONIO (Presenter), ERXI FENG, Jülich Centre for Neutron Science at MLZ, Forschungszentrum Jülich GmbH, D. T. ADROJA, FABIO ORLANDI, Rutherford Appleton Laboratory, ISIS Facility, THOMAS BRÜCKEL, Jülich Centre for Neutron Science and Peter Grünberg Institut, Forschungszentrum Jülich GmbH, YIXI SU, Jülich Centre for Neutron Science at MLZ, Forschungszentrum Jülich GmbH — We present bulk and neutron scattering measurements performed on the isotopically enriched $^{154}$Sm$_2$Ti$_2$O$_7$ (titanate) and $^{154}$Sm$_2$Sn$_2$O$_7$ (stannate) samples. Both compounds display sharp heat capacity anomalies, at 350 mK and 440 mK, respectively. Inelastic neutron scattering measurements are employed to solve the crystalline electric field (CEF) excitations scheme, which includes transitions between the ground and first excited $J$ multiplets of the Sm$^{3+}$ ion. In order to further validate those results, the single-ion magnetic susceptibility of the compounds is calculated and compared with the experimental static susceptibility measured in low applied magnetic fields. We show that the inclusion of intermultiplet transitions in the crystal field analysis is fundamental to the understanding of the intermediate and, more importantly, low temperature magnetic behaviour of the Sm-based pyrochlores. Finally, the heat capacity anomaly is shown to correspond to the onset of an all-in-all-out long-range order in the stannate sample, while in the titanate a dipolar long-range order can be only indirectly inferred.

1:39PM F37.00011: The magnetic structure of the antiferromagnetic pyrochlore Gd$_2$Ti$_2$O$_7$

JOSEPH PADDISON, University of Cambridge, GEORG EHLERS, SNS, Oak Ridge National Lab, JASON GARDNER, NSRRC Taiwan, ROSS STEWART (Presenter), ISIS neutron and muon source, STFC — Canonical examples of highly frustrated antiferromagnets are the gadolinium pyrochlores Gd$_2$Ti$_2$O$_7$ (GTO) and Gd$_2$Sn$_2$O$_7$ (GSO) both of which order at ~1 K with different structures. GSO forms the Palmer-Chalker structure with a $k = 0$ propagation vector while GTO is reported to form a more complicated - and still controversial - partially ordered state with a propagation vector of $k=(1/2, 1/2, 1/2)$, splitting the crystallographically equivalent Gd sites into non-equivalent magnetic sites [1]. Standard neutron diffraction techniques don't allow unambiguous determination of the k-state, (i.e. 1 or a combination of the 4 possible propagation vectors). However, using a combination of single crystal diffraction, diffuse and inelastic neutron scattering on both powder and single crystal samples of GTO, we have determined that the partially ordered magnetic structure is double-k with orthorhombic space group symmetry. This is in agreement with recent theoretical predictions of a double-k structure based on mean-field-theory with thermal fluctuations [2]

1:51PM F37.00012: Tuning Epitaxial Strain in XY Pyrochlore Er₂Ti₂O₇  CONNOR BUHARIWALLA (Presenter), EVAN SMITH, McMaster University, JONATHAN GAUDET, Johns Hopkins University, ADAM ACZEL, Oak Ridge National Laboratory, PATRICK FOURNIER, Université de Sherbrooke, BRUCE GAULIN, McMaster University — Tuning parameters in frustrated magnetism allow us to explore the complex landscape of magnetically fragile ground states. In epitaxial thin film samples, we can study the statespace of epitaxial strain (caused by the lattice mismatch between substrate and film) and the reduced dimensionality inherent to a thin film. Thin film works on frustrated titanate pyrochlores have focused on spin ice compounds (Ho₂Ti₂O₇ and Dy₂Ti₂O₇)[1-3] and the unconventional magnetic ground state of Tb₂Ti₂O₇[4]. This study examines the ordered magnetic ground state of Er₂Ti₂O₇. The ground state selection between the Ψ₂ and Ψ₃ basis states of the Γ₅ manifold and the relative stability of Γ₅ to Palmer-chalker configurations have been shown to be sensitive to a number of tuning parameters such as magnetic dilution and isovalent non-magnetic substitution. By fabricating films of different thicknesses using pulsed-laser deposition, we tune the epitaxial strain on the magnetic lattice, and examine the subsequent magnetic groundstate through bulk characterization and neutron scattering.

2:03PM F37.00013: Pyrochlore titanates RETi₂O₇ (RE = Ho & Er): Stoichiometry and Crystal Growth*  ALIREZA GHASEMI (Presenter), SEYED KOOPPAYEH, Johns Hopkins University — The pyrochlore cubic structure, with a corner sharing tetrahedra network, is the host for candidates of frustrated magnetic materials such as spin ices, spin liquids, and compounds with non-collinear XY orders [1–3]. Pyrochlore titanates, as a subgroup of the pyrochlore family, have been extensively studied; however, the reported physical properties have been shown to significantly vary from one sample to another. Here, we report a systematic study of synthesis and crystal growth by the float-zoning techniques. Structural quality, lattice parameters, stuffing defects and oxygen vacancies were found to depend on synthesis and growth conditions. A method to grow stoichiometric and high-quality single crystals of titanates is also reported [4].

Session F38 GMAG DMP: Molecular Nanomagnets  BCEC 206B - Stephen Hill, Florida State University - Tag(s): Focus

11:15AM F38.00001: Experimental Evidence for Non-Collinear Antiferro-toroidic Ground State in a Dy₉ Molecule*  QING ZHANG (Presenter), SHIQI LI, MYRIAM SARACHIK, City College of New York of CUNY, MICHAEL L BAKER, The University of Manchester, THEOCHARIS STAMATATOS, Brock University — The single molecular toroics are a class of coordination complexes that exhibit spin vortex chiral ground states due to non-collinear arrangements of local magnetic moments. While ab initio methods can predict local magnetic moments, unequivocal experimental determination has proven more challenging. Typically, angular dependent single crystal magnetization would be a good method to obtain anisotropy information. However, periodicity resultant from the cluster symmetry has hindered the use of this method for the study of many complexes including Dy₃ [1]. In this work, we consider a snub square molecule, Dy₈ [2]. Multiple orientation single crystal magnetization, measured at 0.3 K, reveal the orientation of moments. These measurements, with a simple Ising model, are used to identify a zero toroidal ground state in Dy₈, highlighting the robustness of vortex chirality within larger Dy based molecular lattices.

*Supported by ARO W911NF-13-1-1025 (CCNY); the synthesis of the Dy₈ cluster was supported by NSERC (Discovery grant to Th.C.S.).
11:27AM F38.00002: Calculation of Exchange Coupling Constants in Mn-Ce Molecular Magnets

DIANTENG CHEN
(Presenter), XIANGGUO LI, YUN-PENG WANG, Department of Physics and Quantum Theory Project, University of Florida, SAYAK DAS GUPTA, Department of Chemistry, University of Florida, XIAOGUANG ZHANG, Department of Physics and Quantum Theory Project, University of Florida, GEORGE CHRISTOU, Department of Chemistry, University of Florida, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida — Recently several Mn-Ce molecular magnets have been synthesized, including Mn$_3$Ce$_2$ and Mn$_5$Ce$_3$ with three different ligands, but their magnetic properties are yet to be detailed. We calculate the energies of all the spin configurations of each of these molecules by density functional theory. From the calculations of each molecule, we determine a Heisenberg Hamiltonian with antiferromagnetic or ferromagnetic exchange coupling constants using both spin-projected and non-spin-projected energies of the broken symmetry solutions and compare the results to the coupling constants fitted from experimental susceptibility data.

*This work was supported by the US National Science Foundation DMREF program under Grant No. CHE-1534401.

11:39AM F38.00003: Spin Echo Measurements with a Customized Electron Spin Resonance Spectrometer of an Atomic-clock Transition in the Molecular Nanomagnet Cr$_7$Mn

KAI-ISAAK ELLERS (Presenter), GAJADHAR JOSHI, CHARLES COLLETT, JONATHAN FRIEDMAN, Physics and Astronomy, Amherst College, DANIEL SAVA, GRIGORE TIMCO, RICHARD WINPENNY, Chemistry, University of Manchester — Molecular nanomagnets are promising systems for quantum computation but such applications require sufficiently long coherence times ($T_2$) to permit quantum logic operations. We report on the development of low-cost, customized instrumentation for measuring $T_2$ in such molecules, as well as promising results from the spin-1 molecular nanomagnet Cr$_7$Mn. We dilute Cr$_7$Mn samples in toluene at concentrations between 0.00001% and 10% and perform spin echo measurements using our home-made electron-spin resonance spectrometer. This is achieved by coupling our samples to a loop-gap resonator with adjustable resonant frequency and irradiating with short (~100 ns) electromagnetic microwave pulses controlled by an FPGA. We observe spin echo and Rabi nutation from our sample and measure both $T_2$ and $T_1$, the spin-lattice relaxation time. Further, we find an enhancement of $T_2$ by a factor of three at the avoided level crossing that occurs at zero field, evidence of an atomic-clock transition, where the dependence of the transition frequency on magnetic field vanishes to first order.

*Work supported by U. S. National Science Foundation under Grant Nos. DMR-1310135 and DMR-1708692.

11:51AM F38.00004: Enhancing spin-spin coherence times in a Cr$_7$Mn molecular nanomagnet at a clock transition

GAJADHAR JOSHI (Presenter), KAI-ISAAK ELLERS, CHARLES COLLETT, Physics and Astronomy, Amherst College, DANIEL SAVA, RICHARD WINPENNY, GRIGORE TIMCO, Department of Chemistry, The University of Manchester, JONATHAN FRIEDMAN, Physics and Astronomy, Amherst College — The development of quantum computing based on the spin qubits is contingent on the synthesis of spin qubits with long spin coherence time. Molecular nanomagnets (MNMs) are unique systems that allow chemical engineering of physical parameters in order to enhance their spin relaxation times. Atomic-clock transitions afford a method to significantly increase the spin-spin relaxation times ($T_2$) for MNMs [1]. In dilute samples of Cr$_7$Mn MNM with effective spin $S=1$, we have measured $T_2$ values as high as 3 µs near a clock transition. We find that the effects of the clock transition are more pronounced with increased dilution and reduced temperature. We present the results of detailed studies of these effects and suggest ways to increase the coherence times further.

Forming a Two-Qubit System from Dimers of Molecular Nanomagnets*

CHARLES COLLETT (Presenter), Department of Physics and Astronomy, Amherst College, Amherst, MA 01002, USA, PAOLO SANTINI, STEFANO CARRETTA, Dipartimento di Fisica e Scienze della Terra, Universita di Parma, Parma 43123, Italy, JONATHAN FRIEDMAN, Department of Physics and Astronomy, Amherst College, Amherst, MA 01002, USA — Molecular nanomagnets (MNMs) are a class of materials that can make good spin qubit candidates due to their chemical engineerability. We present a method for constructing two-qubit gates using dimers of Cr7Mn, a spin S=1 MNM that features a zero-field clock transition. Operating at this transition increases T2, allowing for more gates during the lifetime of the quantum state. We show that such a dimer system can be used to behave as a two-qubit system in which all of the transitions between states are clock transitions. One-qubit gates can be achieved using pulsed electron-spin resonance, and two-qubit gates can be implemented using an always-on exchange interaction between the molecules of the dimer. After truncating the Hamiltonian to its four lowest-energy states and transforming into the interaction picture, we simulated both a one-qubit gate as well as a CNOT gate sequence that has a duration of 85 ns, finding average fidelities of 99.5% for both gates. We will briefly discuss ongoing work to experimentally implement these protocols.

*Work supported by U. S. National Science Foundation under Grant Nos. DMR-1310135 and DMR-1708692.

Pulsed Electron-Spin Resonance Studies of Atomic Clock Transitions in a Dimer of the Molecular Nanomagnet Cr7Mn*

MICHAEL CHA (Presenter), JONATHAN FRIEDMAN, Department of Physics and Astronomy, Amherst College, Amherst, MA, USA, DANIEL SAVA, GRIGORE TIMCO, RICHARD WINPENNY, School of Chemistry, The University of Manchester, Manchester UK, CHARLES COLLETT, Department of Physics and Astronomy, Amherst College, Amherst, MA, USA — Qubits, or quantum bits, rely on a quantum system that can hold any superposition of two states as opposed to just 0 or 1 as with a classical bit. Various systems have been explored as qubit candidates, including photons, trapped atoms, and both nuclear and electron spins. Our research focuses on constructing two-qubit systems using dimers of molecular nanomagnets (MNMs), a class of magnetic material that can be chemically engineered to achieve various desired attributes. The focus of our current work, dimers of the MNM Cr7Mn, features such an attribute: clock transitions between multiple spin states that increase the lifetime of the quantum state. We present pulsed electron-spin resonance (ESR) studies of dilute Cr7Mn dimers in loop-gap resonators, including spectroscopic exploration of two clock transitions in the dimer as well as progress on implementing two-tone ESR for two-qubit gates.

*Work supported by U. S. National Science Foundation under Grant Nos. DMR-1310135 and DMR-1708692.

Entanglement in a molecular magnet dimer*

[Invited] TATIANA GUIDI (Presenter), ISIS, STFC, ISIS facility, Rutherford Appleton Laboratory, ELENA GARLATTI, STEFANO CARRETTA, PAOLO SANTINI, GIUSEPPE AMORETTI, Dipartimento di Science Matematiche, Fisiche e Informatiche, Universita’ di Parma, JACQUES OLLIVIER, HANNU MUTHA, Institut Laue-Langevin, GRIGORE TIMCO, RICHARD WINPENNY, School of Chemistry, The University of Manchester — Entanglement is a crucial resource for quantum information processing and its detection and quantification is of paramount importance in many areas of current research. Weakly coupled molecular nanomagnets provide an ideal test bed for investigating entanglement between complex spin systems. However, entanglement in these systems has only been experimentally demonstrated rather indirectly by macroscopic techniques or by fitting trial model Hamiltonians to experimental data. We have exploited the capabilities of four-dimensional inelastic neutron scattering (INS) to portray entanglement in weakly coupled molecular qubits and to quantify it [1]. The INS measurements on the prototype (Cr7Ni)2 supramolecular dimer has allowed us to demonstrate the potential of this approach, which allows one to extract the concurrence in eigenstates of a dimer of molecular qubits.

1:03PM F38.00008: Observation of Anisotropy-driven Quantum Dynamics of Single-Molecule Magnet Spins at 100mK* REBECCA CEBULKA (Presenter), ENRIQUE DEL BARCO, University of Central Florida — We will present the continuing results of the implementation of our novel experimental technique to allow pulse EPR studies (spin echo) of condensed samples of single-molecule magnets and single-atom magnets (non-diluted crystals) at temperatures at or below 100mK. The aim is to eliminate dephasing due to dipolar fluctuations by freezing the spin state of all molecules in the crystal in the ground state without the need of applying strong magnetic fields. We expect that these conditions would allow us to study the quantum dynamics of the spins as governed by the intrinsic molecular magnetic anisotropy, which should give rise to non-well defined Rabi oscillations of the spin state, including metastable precessional spin states.

1:15PM F38.00009: Combined THz and Pulsed EPR studies on a Yb(III) Single Ion Magnet JONATHAN MARBEY (Presenter), Florida State University, STERGIOS PILIGIKOS, Chemistry, University of Copenhagen, JOSCHA NEHRKORN, MYKHAYLO OZEROV, National High Magnetic Field Lab, STEPHEN HILL, Florida State University — Recently, the development of single molecule magnets has shifted rapidly away from the use of transition metals in favor of lanthanides due to their large single ion anisotropy. This is a direct consequence of the relatively strong spin-orbit coupling inherent to lanthanides, which, in the presence of the appropriate crystal field, gives rise to well separated spin-orbit projected states that can permit slow relaxation of the magnetization. The motivation for studying such systems presumes that the so-called Orbach process provides the primary pathway through which the magnetization relaxes. However, previous studies on Yb(trensal) (1) have shown that simply having a large zero field energy barrier is not a sufficient criterion to achieve a high blocking temperature. In doing so, it was demonstrated that 1 also has the additional potential for use as a molecular spin qubit. To further investigate these properties in 1, we employ both Fourier Transform Far Infrared spectroscopy and pulsed EPR measurements to: i) characterize the zero field splitting associated with the crystal field and ii) probe the interactions that limit both spin-lattice and spin-spin relaxation by measuring the dependence on temperature and magnetic field.

1:27PM F38.00010: Zero field stability of holmium single atom magnets* PATRICK FORRESTER (Presenter), FRANÇOIS PATTHEY, EDGAR FERNANDES, HARALD BRUNE, FABIAN NATTERER, Ecole polytechnique federale de Lausanne — Since their magnetic remanence was first measured in 2016, holmium single atom magnets on MgO/Ag(100) have garnered significant attention due to their hour long spin lifetimes, read and write-ability with spin-polarized scanning tunneling microscopy (SP-STM), and high coercive magnetic field [1-3]. Despite having been characterized with X-Ray absorption, STM, and electron spin-resonance STM, the system has not been measured at zero field. This has led to ambiguities concerning the electronic ground state of Ho/MgO and the stability of the system at zero field [3]. Here we present SP-STM measurements demonstrating the zero-field stability of Ho single atom magnets. Using antiferromagnetic Mn$_{88}$Ni$_{12}$ tips, we read the atom's magnetic state, allow it to evolve under zero field conditions, and read it again. We discuss how these measurements can be used to determine the electronic ground state of the system.

In photo-excited Rb_xCo[Fe(CN)_y]_z@K_nNi[Cr(CN)_b]_d core@shell spin-transition nanoparticles, the rate of the relaxation in the core is accelerated by more than an order of magnitude due to the presence of the shell [1]. In addition, the relaxation rate continues accelerating with increasing shell thickness, which an electro-elastic model explains as a change in the mechanical properties of the core due to its interface with an increasingly rigid shell [1,2]. Here, nuclear inelastic scattering (NIS) was used to study a series of heterostructures with different shells and selectively determine the stiffness of the core, using the low-energy phonon modes and the partial phonon density of states. The results show a significant softening of the low-temperature state in the core with increasing shell thickness, providing a possible explanation for the observed relaxation rate increase. The bulk modulus for each sample was determined using PXRD, and interestingly, shells of different compositions appear to have dissimilar effects on the stiffness of the low-spin state of the core, expected to predominate at low temperatures.

Supported by NSF DMR-1708410 (MWM).

Detection of emergent magnetic states at molecular interfaces by LE-μSR

MATTHEW ROGERS (Presenter), University of Leeds, RHEA STEWART, STEPHEN LEE, University of St. Andrews, THOMAS PROKSCHA, Paul Scherrer Institute, OSCAR CESPEDES, University of Leeds — The interfacial states that form due to orbital hybridisation and charge transfer at molecular interfaces can lead to fascinating magnetic properties. Several approaches to the characterisation of these surface states have been taken in the recent past such as SQUID magnetometry and XMCD. However, the resolution of these methods is often tested due to the confinement of these effects to interfaces. In this study, we use low energy muon spin rotation (LE-μSR) to probe such phenomena. Probing the transition oscillations between hyperfine energy levels of C_60 that has been interfaced with non-magnetic copper layers. We observe an increase in the transition frequency due to Zeeman splitting of the hyperfine tensor. We may eliminate this state through demagnetisation of the interface allowing us to attribute this observation to the emergent magnetic states at the CuC_60 interface. In a second system comprised of a metal oxide-C_60 interface. We have shown that optical gating of this photovoltaic device leads to increases in local fields at the interface due to a spin-dependent trapping of charge, thereby acting as a ‘spin capacitor’. These measurements demonstrate the capability of the μSR technique for the characterisation of novel thin film molecular structures and devices.

Session F39 GMAG DMP: Magnetic Coupling and Exchange Bias

BCEC 207 - Nathan Satchell, Michigan State University - Tag(s): Focus
Although ferromagnetism (FM) is in general a long-range collective phenomenon, it is possible to induce local spatial variations of magnetic properties in FM materials. For example, systematic variation of the exchange coupling strength can be used to create systems that behave as if they are composed of virtually independent segments that exhibit "local" Curie temperatures (Tc). While it is obvious that such localization should be possible across some lengthscale, the magnitude of that lengthscale is not so intuitive, nor is the expected behavior of a material exhibiting a nearly continuous variation in exchange strength. We have explored these questions in real materials by using neutron scattering and mean-field simulations to study novel compositionally graded transition metal multilayer films as model systems [1-3].

Remarkably, we have found that non-local magnetic effects are significant only over distances less than 3 nm (possibly much less). Beyond that the structures behave as a continuum of decoupled layers with distinct Tc. This leads to fascinating functionality, including FM phase boundaries that can be reversibly moved up and down the thickness of a film with temperature, and modified with an applied magnetic field. Since we have demonstrated this for an itinerant metal, we assert that for virtually any modulated magnetic material system, collective effects should be suppressed to down to nanometer length scales, so that magnetic behavior overall can be well described in terms of local material properties.

11:51AM F39.00002: Magnetization Depth Profile in a Magnetic Insulating Film Under a Thermal Gradient*
TIMOTHY CHARLTON (Presenter), ERJIA GUO, ANDREAS HERKLOTZ, MICHAEL R. FITZSIMMONS, HO NYUNG LEE, Oak Ridge National Laboratory — By eliminating mobile electrons, insulator spintronics offer opportunities to reduce power loss and signal decay of metallic interconnects in complicated integrated circuits. As a consequence, there are no energy losses due to the heating by the conducting electrons or eddy currents. This strategy requires methods to generate, transport, and detect the spin and transfer them into a charge-based signal for further processing. A temperature gradient has been shown to generate a pure spin current inside a magnetic insulator that could be detected in an adjacent metallic film with a high spin-orbital angle (spin Seebeck effect, SSE). Little experimental evidence is known about the depth dependence of spin structure. Using a similar sample design, we have measured the polarized neutron reflectivity (PNR) from a YIG film with and without a temperature gradient. We will present the magnetization as a function of depth in the magnetic insulator extracted from the PNR along with structural, magnetic, and electric transport characterization. We have observed a larger than expected magnetization in the GGG substrate which may contribute to the size of the SSE in similar samples.

12:03PM F39.00003: Quantum Magnon Casimir effect  
RAN CHENG (Presenter), Electrical and Computer Engineering, University of California, Riverside — Magnons are the quanta of spin-wave excitations in magnetically ordered media. Spin-up and spin-down magnons coexist in antiferromagnets (AFs) where they act similarly as photons in many different phenomena. We find that the zero-point quantum fluctuation of magnons in AFs can play a significant role in determining the properties of magnetic thin films. When two ferromagnets are separated by an insulating AF, they can couple and exert spin torques on each other even at absolute zero temperature, thanks to the zero-point quantum fluctuation of magnons confined in the AF. This is in perfect analogy to the Casimir effect of photons confined between two plates. Moreover, we find that in a ferromagnet/AF bilayer, the magnonic Casimir effect leads to a counterintuitive temperature dependence of the overall magnetization.
We present results on an exchange biased spin valve whose interlayer undergoes a magnetic phase transition. The structure consisted of 3 variations of Py_xCu_{1-x}: Py_0.8Cu_0.2/Py_0.4Cu_0.6/Py_1.0Cu/IrMn. The IrMn serves to exchange bias the Py layer; the degree to which the rest of the sample exhibits exchange bias depends on ferromagnetic coupling between the Py_xCu_{1-x} layers. Magnetization and angle with respect to temperature (M v. T and $\phi_M$ v. T, respectively) measurements from polarized neutron reflectometry (PNR) indicate a sharp transition temperature at T = 160 K, which is the Curie temperature (TC) of the spacer layer. Below this, both the Py_0.8Cu_0.2 and Py layers exhibit exchange bias. As the temperature increases and the system approaches 160 K, the portion of the loop corresponding to the bottom free layer (Py_0.8Cu_0.2) shifts closer to zero, showing a Néel-like transition. When T > 160 K, the coupling between the top and bottom layers is broken, and EB is only observed for the Py layer in direct contact with IrMn. Additional measurements studying the dependence on layer thickness will be reported.

*This work is supported by NSF Grant #1609066.

We report on high stability and enhanced exchange bias (EB) of ultra-dense (Tb/inch^2) arrays of sub-100 nm Co/CoO nanodisks. Exchange-biased nanodisks are grown by electron beam deposition of Co (15nm) using nanoporous anodic aluminum oxide (AAO) templates as a mask [1]. The thickness of the CoO layer, and therefore the EB of the nanodisks, can be tuned by the oxidation time of the disks. We have found that an annealing time of 10 minutes at 250°C in air produces the maximum EB (800 Oe) at 50K. A comparative study with a reference Co thin film is presented, showing that the nanodisks develop larger EB and higher blocking temperatures at each oxidation time. Although magnetic dots suffer lateral oxidation, which is not possible in the film, a simple model that takes into account this effect demonstrates that the exchange energy density in dots must be higher than that in the Co/CoO film. This is an exciting example of how nanopatterning can improve the physical properties of thin film systems.

Effects of field annealing on MnN/CoFeB exchange bias systems

PATRICK QUARTERMAN (Presenter), National Institute of Standards and Technology, INGRID HALLSTEINSEN, Lawrence Berkeley National Laboratory, MAREIKE DUNZ, Center for Spinelectronic Materials and Devices, Faculty of Physics, Bielefeld University, D-33615 Bielefeld, Germany, ALEXANDER GRUTTER, National Institute of Standards and Technology, MARKUS MEINERT, Center for Spinelectronic Materials and Devices, Faculty of Physics, Bielefeld University, D-33615 Bielefeld, Germany, ELKE ARENHOLZ, Lawrence Berkeley National Laboratory, JULIE BORCHERS, National Institute of Standards and Technology — Antiferromagnets are commonly used in magnetic tunnel junction based spintronics to fix the ferromagnetic reference layer using the exchange bias effect. The antiferromagnetic MnN Θ-phase exhibits large exchange bias fields on CoFe films on order of 1800 Oe which can be enhanced with increased annealing temperature [1,2]. The exchange bias field in MnN/CoFeB systems is observed to be dependent on annealing temperature and MnN thickness. The effect of annealing temperature (as-deposited, 325 and 525 C) and MnN thickness (30 and 48 nm) on the magnetic and structural properties of MnN/CoFeB samples have been examined with polarized neutron reflectivity (PNR), x-ray absorption spectroscopy (XAS) and x-ray magnetic circular dichroism (XMCD). PNR fits show that nitrogen increasingly diffuses from MnN to the underlying seed layer as the annealing temperature increases, which leads to a disappearance of the exchange bias effect when the MnN thickness is not sufficient. Intermixing of Mn, Fe, and Co at the MnN/CoFeB interface is also observed in PNR, XAS and XMCD measurements and is correlated to observed changes in magnetization.

EXCHANGE BIAS IN IrMn3/Py BILAYERS

JOSE HOLANDA DA SILVA JUNIOR (Presenter), JOHN E. PEARSON, MICHAEL VOGEL, AXEL F HOFFMANN, Materials Science Division, ARGANNE NATIONAL LABORATORY — Recently antiferromagnets have gained increased interest as active components for spintronics due to their intrinsic high frequency dynamics and resulting zero net magnetic moment. One such material is IrMn3 with the magnetic moments forming a triangular structure in the (111) planes and a giant magnetocrystalline anisotropy energy of 10 meV per formula unit. We prepared films of IrMn3 on different substrates ([001]MgO, [0001]Al2O3 and Si). Since spin-orbit torques are most pronounced for [100] oriented IrMn3 we investigated the temperature and cooling field dependence of exchange bias. X-ray diffraction shows predominantly [100] crystallographic orientations, with also a small contribution due to [111] oriented grains. Magnetometry measurements using a quantum design superconducting quantum interference device (SQUID) show that the exchange bias decreases with increasing temperature and an anisotropy of the coercivity with in-plane field direction.

*This work was supported by the U.S. Department of Energy, Office of Science, Materials Science and Engineering Division and CNPq, Conselho Nacional de Desenvolvimento Científico e Tecnológico - Brasil (Scholarship).

Exchange bias induced by molecular spinterface

JUNHYEON JO (Presenter), Ulsan National Institute of Science and Technology, JINHO BYUN, Pusan National University, INSEON OH, JUNGMIN PARK, MI-JIN JIN, Ulsan National Institute of Science and Technology, BYOUNG-CHUL MIN, Korea Institute of Science and Technology, JAEEKWANG LEE, Pusan National University, JUNG-WOO YOO, Ulsan National Institute of Science and Technology — Molecular spins as individual are promising quantum states for coming computation technology. The “on surface” configuration of molecules in proximity to a magnetic film allows control over the orientations of molecular spins and interfacial coupling between them. The stacking of planar molecular spins could favor antiferromagnetic interlayer coupling and lead to pinning of the magnetic underlayer via exchange bias, extensively utilized in magnetic devices. Here, we show tunable molecular exchange bias and its asymmetrical magnetotransport features by varying composition of metalloporphyrin/ferromagnet bilayers. The systems exhibit a wide range of interfacial coupling (ferromagnetic or antiferromagnetic) and exchange bias. Transport measurements of the bilayers reveal the molecular exchange bias effect on a fabricated device, representing asymmetric behaviors on anisotropic and angle-dependent magnetoresistance. Theoretical calculations demonstrate the orientation of spins and interfacial magnetic coupling, and further understanding to exchange bias. A study of interfacial coupling in molecule/ferromagnet systems and its impact on magnetic and magnetotransport behaviors will extend functionalities of molecular spinterface for emerging information technology.
1:27PM F39.00010: Effect of CoFe Dusting Layer and Annealing on the Magnetic Properties of Sputtered Ta/W/CoFeB/CoFe/MgO Layer Structures*  JUSTINE DROBITCH (Presenter), Electrical and Computer Engineering, Virginia Commonwealth University, YU-CHING HSIAO, HAO WU, KANG WANG, Electrical and Computer Engineering, University of California, Los Angeles, CHRISTOPHER S LYNCH, College of Engineering, University of California at Riverside, SUPRIYO BANDYOPADHYAY, Electrical and Computer Engineering, Virginia Commonwealth University, DANIEL B GOPMAN, Materials Science and Engineering Division, National Institute of Standards and Technology — Ultrathin CoFeB films are an essential building block of most emerging spintronic applications due to the tunable perpendicular magnetic anisotropy (PMA) energy, low Gilbert damping and high annealing stability. Improvements in these magnetic properties are being explored through interface engineering. We explored the effect of a CoFe wedge inserted as a dusting layer (0.1 nm – 0.3 nm thick) at the CoFeB/MgO interface of a sputtered Ta(2 nm)/W(3 nm)/CoFeB(0.9 nm)/MgO(3 nm) film – a typical structure for spin-orbit torque devices. Films were annealed in a Rapid Thermal Annealer (RTA) at temperatures varying between 300 °C and 400 °C in an Ar environment. Ferromagnetic resonance studies were carried out to estimate the effective PMA field and the Gilbert damping as a function of the CoFe thickness and across several annealing temperatures. While as-deposited films present only easy-plane anisotropy, a transition along the wedge from easy-plane to out-of-plane was observed across several annealing temperatures. Interlaying a CoFe dusting film between CoFeB and MgO provides an alternative approach for PMA in ultrathin films.

1:39PM F39.00011: Hydrogen-driven switching of the magnetic surface anisotropy at the Co/Pd interface* GRACE CAUSER (Presenter), ANSTO, MIKHAIL KOSTYLEV, University of Western Australia, DAVID CORTIE, XIAOLIN WANG, University of Wollongong, FRANK KLOSE, Guangdong Technion-Israel Institute of Technology — Heterostructures exhibiting perpendicular magnetic anisotropy (PMA) have proven to be indispensable within the magnetic recording industry. By exploiting the hydrogen-induced modifications to PMA which occur exclusively at the ferromagnetic/Pd interface, an opportunity exists to expand the potential applications of PMA-based heterostructures into the realm of hydrogen sensing using ferromagnetic resonance (FMR) - an electron-spin based technology. Here, we present an interface-resolved in-operando study of a Co/Pd film which features tailorable PMA in the presence of hydrogen gas. We combine polarized neutron reflectometry with in-situ FMR to explore the nanoscopic interactions of hydrogen at the Co/Pd interface which affects the spin-resonance condition during hydrogen cycling. Key experimental data and theoretical modelling reveal that the interfacial PMA of the Co/Pd film suppresses non-reversibly upon primary exposure to hydrogen gas – highlighting a potential avenue for spintronics-based hydrogen sensing.

*The Australian Government Research Training Program Award and the Australian Institute of Nuclear Science and Engineering Postgraduate Research Award.

1:51PM F39.00012: Perpendicular Magnetocrystalline Anisotropy on 3d Transition-Metals Multilayers – A First-principles Study  THI PHUONG THAO NGUYEN (Presenter), Institute of Scientific and Industrial Research, KOHJI NAKAMURA, Department of Physics Engineering, Mie University, TAMIO OGUCHI, Institute of Scientific and Industrial Research — Magnetic tunnel junctions (MTJ) with perpendicular magnetocrystalline anisotropy (MCA) have much attention for applications to high-density, high-thermal stability, nonvolatile memories. Strong perpendicular MCA appears in transition-metal films such as Co/Pt, Co/Pd and CoFeB/Pd due to the strong hybridization between the 3d and 5d orbitals at the interfaces. The remaining challenge in these systems is to understand the role of the hcp-fcc phase transition that occurs in cobalt, which leads to the change of the easy magnetization direction. To address this challenge, the mechanisms of MCA in hcp-like and fcc-like stacking of Co-based 3d transition-metal multilayers are systematically investigated by using full-potential linearized augmented plane wave calculations. The MCA energy of possible atomic-layer alignments of Co-based films including Mn, Fe, and Ni layers is presented. The results predict that large perpendicular MCA can be achieved in Co/Ni multilayers for both hcp-like and fcc-like stackings. The large perpendicular MCA arises from a second-order effect of spin-orbit coupling between occupied and unoccupied Ni $d_{yz,xz}$ states near the Fermi level. A promising transition-metal film for MTJ with giant perpendicular MCA and the preferred stacking stability is demonstrated.
Ab initio calculations of structural, optical and magnetic properties of ordered MxPt1-x, (M= Co, Ni, Fe and Mn) binary alloys — Ab initio calculations of the structural, optical and magnetic properties of ordered M x Pt 1-x, (M= Co, Ni, Fe and Mn) binary alloys have been performed. The optimized parameters of L10 CoPt, FePt and MnPt systems have been calculated and found to be (a o = 3.805, c o = 3.707 )Å, (a o = 3.88 , c o = 3.73 )Å and (a o = 4.03 , c o = 3.69 )Å, respectively. In addition, we found that L12 Ni 3 Pt exhibits a o = 3.64 Å. Our calculations of electronic band structure, density of states (DOS) and partial density of states of M x Pt 1-x binary alloys indicate that the contributions to total DOS of M x Pt 1-x come mainly from M-3d and Pt-5d electronic states, in CoPt, Ni 3 Pt, FePt and MnPt. Furthermore, magneto-crystalline Anisotropy Energy (MAE) of CoPt, FePt and MnPt systems have been calculated using The Force theorem and the slap approach and found to be (5 × 10 7 erg/cm 3 ), (6.5× 10 7 erg/cm 3 ) and (1.2 × 10 7 erg/cm 3 ) respectively. Our results reveal that ordered M x Pt 1-x exhibit attractive optical and magnetic properties that make them potential candidates for optical-electronic and magneto-optical devices.

Session F40 GMAG DMP: Transport in Magnetic Materials — Qiming Shao, University of California, Los Angeles — Tag(s): Focus

Current polarity-dependent manipulation of antiferromagnetic domains (Invited) — PETER WADLEY (Presenter), SONKA REIMERS, STUART POOLE, OLIVER AMIN, MU WANG, School of Physics and Astronomy, University of Nottingham, JOAO GODINHO, Department of Spintronics and Nanoelectronics, Institute of Physic, ASCR, Prague, KEVIN EDMONDS, RICHARD CHAMPION, School of Physics and Astronomy, University of Nottingham, VÍT NOVÁK, JOERG WUNDERLICH, TOMAS JUNGWIRTH, Department of Spintronics and Nanoelectronics, Institute of Physic, ASCR, Prague, BRYAN GALLAGHER, School of Physics and Astronomy, University of Nottingham — Antiferromagnetic spintronics offers the potential for ultrahigh speed dynamics, stability against strong magnetic field perturbations, higher component packing density owing to the lack of stray fringing fields, as well as a wider material base and qualitatively new physical phenomena. Tetragonal CuMnAs is a testbed system in which the antiferromagnetic order parameter can be switched reversibly using electrical currents (1). Previously, orthogonal in-plane current pulses were used to induce 90 degree rotations of antiferromagnetic domains in a multi-terminal geometry(2). This type of switching has now also been demonstrated in another antiferromagnet system with similar symmetry properties (4,5).
Here, we demonstrate a new mechanism by which antiferromagnetic domain walls in CuMnAs can be manipulated to realize stable and reproducible domain changes using only two electrical contacts. In this geometry, current polarity is reversed changing the sign of the current-induced fields. The resulting Néel spin orbit torque acts primarily on the domain wall. The reconfigurations are imaged using x-ray magnetic linear dichroism microscopy, and detected electrically. The switching by domain wall motion can occur at much lower current densities than coherent domain switching.

**11:51AM F40.00002: Dynamic Spin Transport in Antiferromagnetic Insulators: Non-sinusoidal Angular Dependent Spin Pumping in Y\textsubscript{3}Fe\textsubscript{5}O\textsubscript{12}(YIG)/NiO/Pt Trilayers**  
YANG CHENG (Presenter), Ohio State University, RICARDO ZARZUELA, Physics, University of California, Los Angeles, JACK T BRANGHAM, AIDAN J LEE, SHANE WHITE, P CHRIS HAMMEL, Ohio State University, YAROSLAV TSERKOVNYAK, Physics, University of California, Los Angeles, FENGYUAN YANG, Ohio State University — Antiferromagnets (AF), which usually serve as the passive layer in spintronics research, have recently been found as effective spin transport media in the FMR driven spin pumping measurement. For example, a YIG/Pt bilayer shows that with the insertion of a 1 nm NiO interlayer could enhance the inverse spin Hall voltage ($V_{\text{ISHE}}$), which scratches the surface of the promising antiferromagnetic spintronics. Recently, we studied the out-of-plane angular dependence of $V_{\text{ISHE}}$ in YIG/NiO/Pt heterostructures with different thicknesses of NiO under a large range of temperatures. The appearance of plateaux for $V_{\text{ISHE}}$ over the out-of-plane field angle is very different from the YIG/Pt bilayer, which should have a sinusoidal dependence. A maximum is even found at around 30° from the surface normal for specific values of NiO thickness and temperature. By modeling the spin structure of NiO under an out-of-plane magnetic field after considering the interplay among the interfacial exchange coupling, the AF easy-plane anisotropy, and the field-induced hard-axis anisotropy in NiO, the main features of the experimental data in the nontrivial angular dependence of the spin pumping in YIG/NiO/Pt trilayers have been reproduced.

**12:03PM F40.00003: Spin-Orbit Torque Switching in a Nearly Compensated Heusler Ferrimagnet**  
JOSEPH FINLEY (Presenter), Massachusetts Institute of Technology, CHIA-HAO LEE, PINSHANE HUANG, Materials Science and Engineering, University of Illinois Urbana-Champaign, LUQIAO LIU, Massachusetts Institute of Technology — Ferrimagnetic materials combine the advantages of the low magnetic moment of an antiferromagnet and the easiness of realizing magnetic reading of a ferromagnet. Recently, it was demonstrated that compensated ferrimagnetic half metals can be realized in Heusler alloys, where high spin polarization, zero magnetic moment, and low magnetic damping can be achieved at the same time. In this work, by studying the spin-orbit torque induced switching in the Heusler alloy Mn$_2$Ru$_{1-x}$Ga, we found that efficient current-induced magnetic switching can be achieved in a nearly compensated sample with strong perpendicular anisotropy and large film thickness. Our work demonstrates the possibility of employing compensated Heusler alloys for fast, energy-efficient spintronic devices.

**12:15PM F40.00004: Magnetism and Magneto-Electric Transport in Amorphous Cobalt- and Iron-Germanium Thin Films**  
DINAH SIMONE BOUMA (Presenter), Department of Physics, University of California, Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory, FRANK BRUNI, Department of Physics, University of California, Berkeley, ROBERT STREUBEL, Materials Sciences Division, Lawrence Berkeley National Laboratory, XIAOQIAN M CHEN, Materials Sciences Division, Lawrence Berkeley National Laboratory, and University of Kentucky, SUJOY ROY, Advanced Light Source, Lawrence Berkeley National Laboratory, NOAH KENT, Materials Sciences Division, Lawrence Berkeley National Laboratory, and Department of Physics, University of California, Santa Cruz, ZHANGHUI CHEN, LIN-WANG WANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, PETER FISCHER, Materials Sciences Division, Lawrence Berkeley National Laboratory, and Department of Physics, University of California, Santa Cruz, STEPHEN DOUGLAS KEVAN, Advanced Light Source, Lawrence Berkeley National Laboratory, FRANCES HELLMAN, Department of Physics, University of California, Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory — Thin films (65 < t < 100nm) of amorphous cobalt- and iron-germanium (a-Co$_x$Ge$_{1-x}$ and a-Fe$_x$Ge$_{1-x}$) with 0.40 < x < 0.61 exhibit similar electrical resistivity but remarkably different magnetization for a fixed transition metal concentration x. For all compositions investigated, the resistivity depends weakly on temperature but strongly on x, with only slight differentiation between the Fe and Co transition metal species. However, a low-temperature upturn in resistivity associated with resonant impurity scattering is observed in a-Fe$_x$Ge$_{1-x}$ but absent in a-Co$_x$Ge$_{1-x}$ due to their different magnetic properties: where all measured compositions of a-Fe$_x$Ge$_{1-x}$ are itinerant ferromagnets with a Curie temperature that increases with x, a-Co$_x$Ge$_{1-x}$ is paramagnetic down to $T = 2$ K in the same composition range. This behavior parallels these materials' crystalline cousins: B20 FeGe hosts a rich magnetic phase diagram, while B20 CoGe is paramagnetic thanks to a pseudogap just above the Fermi level in its density of states. The long-range order that enables this explanation in those materials is absent in our amorphous films, leading us to ascribe the magnetic behavior of these alloys to more localized, short-range physics.

Parametric resonance is a versatile tool for excitation of spin waves in nano-magnonic devices. Here we present a joint theoretical and experimental study of parametric resonance of magnetization in nanowires made from bilayers of Pt and Permalloy (Py). In this system, damping of spin waves in Py can be tuned via antidamping spin Hall torque arising from electric current in the Pt layer. We report parametric excitation of spin waves driven by microwave current applied to the nanowire, and tuning of the resonance properties by direct current. Under magnetic field applied perpendicular to the wire axis, we observe parameter excitation of two types of spin wave eigenmodes: bulk and edge modes. Comparison of our theoretical description of parametric resonance of these modes to the experimental data reveals important role played by the Oersted field produced by ac and dc currents for the excitation process. Theoretical analysis of the data allows us to extract information on the spin Hall efficiency in the Pt/Py device as well as on damping parameters of the excited spin wave modes.

Reciprocity relations between the entries of the conductance matrix of a multi-terminal linear device, comprising normal metallic and strong ferromagnetic elements with spin-inactive interfaces between them. In particular, reciprocity equates the spin transmissions through a two-terminal element in the opposite directions. When applied to “geometric spin ratchets”, reciprocity shows that certain effects, announced for such devices, are, in fact, impossible. Finally, we discuss the relation between our work and the spintronic circuit theory formalism.

Ya. B. is grateful to CNRS for financial support of the visits to the Laboratoire de Physique Theorique, Toulouse.

Spin current-driven transitions of magnetic domain patterns in a prototypical multilayer stack of Ta/CoFeB/MgO. The transition processes are demonstrated to be greatly related to responses of topological defects to the spin orbit torque. A moderate perpendicular magnetic field favors stripe domains in the ferromagnetic layer; however, the stripes are cut into dense skyrmions with applying current pulses, where half-skyrmions at the ends of stripes have been proposed to be important. More types of topological excitations are observed in labyrinthine domain patterns at a zero magnetic field. The topological defects can be deleted/generated by spin current with lower/higher current densities. The current-induced deletion/generation of topological defects leads labyrinthine domains to transform into phases with a strong/weak orientational order. We conclude from a derived Thiele equation and micromagnetic simulations that both the current-driven motion of topological defects and magnetization manipulations at domain walls are of significance in current-induced transitions.

1:03PM F40.00008: Activation barriers for creation and annihilation of magnetic droplet solitons  GABRIEL CHAVES-O’FLYNN (Presenter), Department of Thin Films, Institute of Molecular Physics Polish Academy of Sciences, DANIEL L STEIN, ANDREW D KENT, Department of Physics, New York University — Droplet solitons are magnetization fluctuations that preserve their shape as they precess with uniform frequency $\omega=0$. They satisfy a delicate balance between anisotropy and exchange interactions, and decay in the presence of dissipation. To prevent this, a spin polarized current $\sigma$ can be applied via a nanocontact of radius $\rho^*$. The magnitude of the current can be increased to induce switching between uniform precession at the ferromagnetic resonance frequency ($\omega=1$), and a stable precession at a frequency larger than the Zeeman frequency ($\omega=0$, in zero applied field).

In the absence of dissipation, conservative solitons of frequency $\omega_0$ are described by a function $\Theta(\rho;\omega_0)$ where $\Theta$ is the angle of the magnetization with the easy axis ($z$) and $\rho$ is the distance to the center of the nano contact [1].

We introduce an effective energy $\xi$ that quantifies the work done (against damping and spin torque) to create a fluctuation of arbitrary shape $\Theta(\rho)$. We show that, for specific values of $\sigma$, some conservative soliton solutions are saddles of $\xi$. This allows us to calculate activation barriers $\Delta\xi$ between uniform precession at the ferromagnetic resonance and stable solitons. We present results of $\Delta\xi$ as a function of $\sigma$ for a variety of nanocontact radii $\rho^*$ and spin-torque anisotropy parameters $\nu$.

1:15PM F40.00009: Effect of magnetic tunneling layer in van der Waals Josephson Junction  HIROSHI IDZUCHI (Presenter), Tohoku University(IMRAM) and RIKEN(CEMS), KEN HARADA, CEMS, RIKEN, KO-FAN HUANG, Physics department, Harvard University, NA HYUN JO, Iowa State University and Ames Laboratory, DAISUKE SHINDO, Tohoku University(IMRAM) and RIKEN(CEMS), PAUL CANFIELD, Iowa State University and Ames Laboratory, PHILIP KIM, Physics department, Harvard University — Van der Waals (vdW) material has been attracted much attention recently because of their unique features including the accessibility to atomically thin and flat single-crystalline heterostructure. The two-dimensional (2D) nature of these heterointerfaces often enhances the quantum effect. Here, we report vdW ferromagnet can provide a unique opportunity to study the interplay of superconductivity and magnetism. We fabricated a ferromagnetic tunneling device consisting of vdW ferromagnet and superconductor. We observed that the devices exhibit Josephson coupling through magnetic tunneling across 1-6 atomic unit cell thick ferromagnetic insulating layers. Our observation is in contrast with the lack of Josephson coupling reported across traditional ferromagnetic insulating materials such as EuS. We also observed that our superconductor/ferromagnet hybrid devices show the hysteretic critical current against magnetic field sweep. The observed hysteresis differs from the one expected from the coercive field of the ferromagnet. Further study on magnetic structure and switching current distribution indicates the observed phenomena arisen from the interplay between magnetic domain and superconducting vortex structures.

1:27PM F40.00010: Noncollinear Spin Torque Effect in Magnetic Heterojunctions: Combined First-Principles Calculation and TB-NEGF Method*  BAO-HUEI HUANG (Presenter), CHIA-CHIA CHAO, YU-HUI TANG, Department of Physics, National Central University, CHAO-CHENG KAUN, Academia Sinica, Research Center for Applied Sciences — In this study, our newly developed “JunPy” [1] package has successfully combined the self-consistent Hamiltonian by using the first-principles calculation [2], including multi-band dispersion relation and complicated interfacial coupling, with the TB model and the non-equilibrium Green's function (NEGF) method to investigate the noncollinear magnetotransport properties in nm-scale magnetic heterojunctions. This program is first testified by the spin-polarized currents and the noncollinear spin torque effect in conventional Fe/MgO/Fe MTJ. We further employed it to predict the giant field-like spin torque (FLST) effect in the amine-ended single-molecule magnetic junction [3], which may open a new avenue for multifunctional manipulation in next-generation organic FLST-MRAMs with lower power consumption.

*This work is supported by the Ministry of Science and Technology (MOST 106-2112-M-008-011- and 106-2633-M-008-002-) and the National Center for Theoretical Sciences, Republic of China.
1:39PM F40.00011: Double Tunnel Junction Experiments With Asymmetric Barriers* LEONARDO RIÓS E (Presenter), EDGAR PATINO, University of the Andes, DENIS CHEVALLIER, University of Basel — Magnetic tunnel junctions constitute a research area of great promise due to its potential application in faster and non-volatile memories. Current studies on Magnetic Tunnel Junctions (MTJ) are abundant for different magnetic and insulator materials. Nevertheless, available references for Double Magnetic Tunnel Junctions (DMTJ) are scarce. Previous studies on Tunneling Magnetoresistance (TMR) Oscillations in DMTJ indicate that asymmetry in the potential barriers is a significant aspect for controlling the TMR. In the present work we show the fabrication of Al/Al₂O₃/Al/Al₂O₃/Al double tunnel junctions with asymmetric barriers by e-beam evaporation and oxygen plasma processes in UHV chamber. The experimental process allows us to characterize each of the junctions separately. This way the parameters, width and thickness, were easily extracted for each of the junctions, prior to be used in a model for double tunnel junctions.

1:51PM F40.00012: Low frequency noise in MgO magnetic tunnel junctions with magnetic flux concentrator* YIOU ZHANG (Presenter), GUANYANG HE, GANG XIAO, Brown University — Magnetic tunnel junctions (MTJ) have been widely studied as ultra-sensitive magnetic sensors, due to their high sensitivity, low power consumption, and small size. Field detectability of MTJ sensor, particularly at low frequency, is primarily limited by its intrinsic 1/f noise. Hence understanding in the noise performance of MTJ sensor is important for its application. Also, magnetic flux concentrator can enhance signal level of MTJ sensor, yet its role in the noise performance of the sensor system is not fully investigated. In this work, we have measured sensitivity and low-frequency noise spectrum (1 Hz – 10 kHz) of MgO-based MTJ sensor incorporated with an on-chip magnetic flux concentrator. We have found that 1/f noise strongly depends on the bias magnetic field, and a linear relationship between 1/f noise and sensitivity is observed. This result indicates that 1/f noise in highly-sensitive MTJ sensor is dominated by magnetic noise, originated from thermal magnetic fluctuations. Role of magnetic flux concentrator in noise performance will also be discussed.

*The work was supported by National Science Foundation through Grants No. DMR-1307056, and by King Abdullah University of Science and Technology (KAUST).

2:03PM F40.00013: All-electrical control of spin transport in a three-terminal yttrium iron garnet/platinum nanostructure* MATTHIAS ALTHAMMER (Presenter), TOBIAS WIMMER, STEPHAN GEPRÄGS, MATHIAS WEILER, RUDOLF GROSS, HANS HUEBL, Walther-Meißner-Institut, Bavarian Academy of Sciences and Humanities — Pure spin currents, i.e. the flow of angular momentum without an accompanying charge current represents a new paradigm in the field of spintronics. Most importantly, pure spin currents can be transported by fermions, i.e. by electrons, in electrical conductors as well as by bosons, i.e. by quantized magnetic excitations, in magnetically ordered insulators. Interestingly, heterostructures consisting of spin-orbit coupled metals with magnetically ordered insulators allow to investigate pure spin current transport in both regimes and their interconversion at the interface [1]. We here report on the control of magnon spin currents via a DC charge current injected pure spin current. To this end, we utilize three electrically isolated platinum (Pt) electrodes deposited on an ultrathin yttrium iron garnet (YIG) film. Employing all-electrical injection and detection mechanisms, we provide evidence for efficient spin transport manipulation by a DC charge current in these devices. Moreover, we discuss the physical origin of non-linear effects in such structures.

Observation of magnetic vortex pairs at room temperature in a planar α-Fe₂O₃/Co heterostructure

PAOLO G. RADAELLI (Presenter), FRANCIS CHMIEL, NOAH WATERFIELD PRICE, ROGER JOHNSON, Clarendon Laboratory, University of Oxford, ANNE D LAMIRAND, Diamond Light Source, Didcot, UK, JONATHON L SCHAD, Department of Materials Science and Engineering, University of Wisconsin-Madison, GERRIT VAN DER LAAN, Diamond Light Source, Didcot, UK, DAVID T HARRIS, Department of Materials Science and Engineering, University of Wisconsin-Madison, JULIAN J IRWIN, MARK S RZCHOWSKI, Department of Physics, University of Wisconsin-Madison, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison — Vortices, occurring whenever a flow field 'whirls' around a one-dimensional core, are among the simplest topological structures, ubiquitous to many branches of physics. In the crystalline state, vortex formation is rare, since it is generally hampered by long-range interactions: in ferroic materials (ferromagnetic and ferroelectric), vortices are observed only when the effects of the dipole–dipole interaction are modified by confinement at the nanoscale, or when the parameter associated with the vorticity does not couple directly with strain. We observed an unprecedented form of vortices in antiferromagnetic haematite (α-Fe₂O₃) epitaxial films, in which the primary whirling parameter is the staggered magnetization [1]. Remarkably, ferromagnetic topological objects with the same vorticity and winding number as the α-Fe₂O₃ vortices are imprinted onto an ultra-thin Co ferromagnetic over-layer by interfacial exchange. Our data, supported by micro-magnetic modelling, suggest that the ferromagnetic vortices may be merons (half-skyrmions, carrying an out-of-plane core magnetization), and indicate that the vortex/meron pairs can be manipulated by the application of an in-plane magnetic field, giving rise to large-scale vortex–antivortex annihilation.

Collinear Anomalous Hall Antiferromagnets

HUA CHEN (Presenter), Colorado State University, ALLAN MACDONALD, The University of Texas at Austin — It is now well established both theoretically and experimentally that the anomalous Hall effect (AHE) can exist in certain noncollinear antiferromagnets with vanishing total magnetization. Using similar symmetry arguments we propose that the AHE and the related properties such as magneto-optical Kerr effect, anomalous Nernst effect, orbital magnetization, etc., can also exist in many collinear antiferromagnets with symmetry-allowed spin canting. Similar to the noncollinear case, these AHE-related effects will still be finite when the net spin magnetization vanishes. We give two classic examples, NiF₂ and α-Fe₂O₃, corresponding to different mechanisms for spin canting, i.e. single-ion anisotropy and Dzyaloshinskii-Moriya interaction. Although these two materials are good insulators and may not be easily doped in order to measure the AHE, the discussion is general and can be applied to many other canted antiferromagnets. We construct minimal models with spin-orbit coupling terms compatible with these canting mechanisms, and discuss the similarities and differences between the collinear and the noncollinear cases.

Nonlocal Spin Transport Mediated by a Vortex Liquid in Superconductors

SE KWON KIM (Presenter), Department of Physics and Astronomy, University of Missouri - Columbia, ROBERTO MYERS, Department of Materials Science and Engineering, The Ohio State University, YAROSLAV TSERKOVNYAK, Department of Physics and Astronomy, University of California, Los Angeles — Departing from the conventional view on superconducting vortices as a parasitic source of dissipation for charge transport, we propose to use mobile vortices as topologically-stable information carriers [1]. To this end, we start by constructing a phenomenological theory for the interconversion between spin and vorticity, a topological charge carried by vortices, at the interface between a magnetic insulator and a superconductor, by invoking the interfacial spin Hall effect therein. We then show that a vortex liquid in superconductors can serve as a spin-transport channel between two magnetic insulators by encoding spin information in the vorticity. The vortex-mediated nonlocal signal between the two magnetic insulators is shown to decay algebraically as a function of their separation, contrasting with the exponential decay of the quasiparticle-mediated spin transport.

This work was supported by the Army Research Office under Contract No. W911NF-14-1-0016 and the NSF-funded MRSEC under Grant No. DMR-1420451.
12:15PM F41.00004: Detecting spin current fluctuations in quantum magnets via microwave resonators

JOSHUA AFTERGOOD (Presenter), SO TAKEI, Physics, Queens College — We theoretically examine spin transport across coupled quantum spin chains that are further coupled to a microwave cavity in series with a transmission line. Spins in the quantum magnet couple inductively to the microwave field and imprint spin transport signatures into the output photon field detected on the transmission line. We first show that in the non-invasive coupling limit the total output photon power is directly proportional to spin current noise at the cavity resonance frequency, and thus that spin current noise is detectable without recourse to destructive techniques. We also discuss the possibility of photon feedback effects on the spin conductivity and noise for the invasive coupling limit.

12:27PM F41.00005: Development of a System for Low Temperature Optical Measurement of Three-Dimensional Magnon, Plasmon and Spin Torque Transfer Dynamics

YU-SHENG OU (Presenter), XINRAN ZHOU, HARSHA KANNAN, HANG CHEN, RASOUL BARRI, STEPHANIE ANN LAW, JOHN Q XIAO, MATTHEW F DOTY, University of Delaware — Spin-dependent phenomena in magnetic heterostructures and topological insulators (TIs) have attracted lots of attention from the perspective of both fundamental science and device development. For example, the spin orbital interaction in ferromagnet (FM)/heavy metal (HM) bilayers allows for all-electrical manipulation of magnetization. Moreover, the protected and linear-dispersed surface states of TIs leads to the unique spin-momentum locking. Despite extensive studies of these novel phenomena, there remain important questions about their underlying mechanisms. For example, the dynamics of these phenomena, which are critical for device applications, remain poorly understood. To address these important questions in the field, we have developed an experimental apparatus allowing ultrafast and quasi-DC optical study of magnon, plasmon, and spin orbit torque (SOT) in a wide variety of magnetic systems at low temperature and in the presence of a two-dimensional magnetic field. To benchmark the capability of this instrument, we present data demonstrating time-resolved Magneto-Optical Kerr Effect (TRMOKE) study of the SOT-driven magnetization dynamics in both Py/Pt and CoFeB/Ta bilayers.

*NSF (DMR-1624976)

12:39PM F41.00006: Time-resolved Magneto-optical Kerr Effect Studies on Permalloy/Ru/Permendur Trilayers

HENGZHOU LIU (Presenter), CHRISTOPHER E STEVENS, Department of Physics, University of South Florida, MOJTABA RANJBAR, Department of Physics and Astronomy, Uppsala University, JOHAN AKERMAN, Department of Physics, University of Gothenburg, YEVDGEN POGORYELOV, OLOF KARIS, Department of Physics and Astronomy, Uppsala University, DARIO A ARENA, DENIS KARAISKAJ, Department of Physics, University of South Florida — We investigate a series of magnetic trilayer samples consisting of Ni_{20}Fe_{80}(Py)/Ru [x]/Fe_{49}Co_{49}V_{2}(Pmd), where the Ru spacer thickness [x] is varied from 0.7 nm to 17 nm to change the indirect exchange coupling (IEC) between the two magnetic layers. We study the dynamics of these structures by using time-resolved magneto-optical Kerr effect (TR-MOKE) to observe the initial demagnetization and subsequent precession of the magnetic moments as the system returns to equilibrium. Even though the TR-MOKE signal is generated primarily from the top Pmd layer, we observe an unusual beating pattern in the TR-MOKE signal indicative of two coupled oscillators with different precession frequencies. The coupling between the two oscillators depends on the thickness of the Ru spacer layer and hence the strength of the IEC. The results point to the usefulness of TR-MOKE in investigating dynamic coupling effects, including spin pumping, in layered magnetic films.

12:51PM F41.00007: Structural, Magnetic, and Transport Properties of Fe(1-x)Rh(x)/MgO(001) Films Grown by Molecular-Beam Epitaxy

ANTONIO MEI (Presenter), DARRELL G. SCHLOM, Materials Science & Engineering, Cornell University — Fe(1-x)Rh(x) layers are grown with varying rhodium fraction x on (001)-oriented MgO substrates by molecular-beam epitaxy. Film structural, morphological, magnetic, and transport properties are investigated. At room temperature, layers are ferromagnetic (FM) for x ≤ 0.48 and antiferromagnetic (AF) for x > 0.48. Separating the two magnetically ordered phases at x = 0.48 is an abrupt change in the Fe(1-x)Rh(x) lattice parameter of Δa = 0.0028 nm (Δa/a = −0.9%). For AF layers, the FM state is recovered by heating across a first-order phase transition. The transition leads to a large resistivity modulation, Δρ/ρ = 80%, over a narrow temperature range, ΔT = 3 K, in stoichiometric Fe(0.50)Rh(0.50)/MgO(001). The resistivity change is explained using a model based on independent spin conduction channels. For samples with compositions deviating from x = 0.50, fluctuations broaden ΔT and defect scattering reduces Δρ/ρ.
Recent discoveries in antiferromagnets (AFs) such as spin-orbit torques, spin Seebeck effects and inverse spin Hall effects have opened up new possibilities for spintronics devices.[1] Of particular interest is the equiatomic FeRh, which undergoes a temperature driven antiferromagnet-to-ferromagnet magnetic phase transition. This metallic AF is also promising for spintronics applications due to its relatively large spin-orbit coupling arising from Rh. We have grown epitaxial FeRh films on MgO (100) and patterned them into measurement devices using photolithography and ion milling. We performed anomalous Hall effect (AHE) and anomalous Nernst effect (ANE) measurements on 20-nm-thick FeRh films at various temperatures. Our findings show a drastic suppression of both AHE and ANE signals in the AF phase. Interestingly, these non-vanishing signals are opposite in sign compared to their ferromagnetic counterparts, which may suggest changes of inherent symmetries in the electronic structure of FeRh across its magnetic phase transition.

The spin-reorientation transition occurring in perpendicularly-magnetized films as a function of film thickness is well known. Long-range dipole interactions act to form antiparallel domains in the perpendicular phase that precedes the reorientation to in-plane magnetization via a canted phase. In equilibrium, the domains walls move freely to minimize the global energy and form a uniform striped pattern. This spatial averaging causes the reorientation to occur at a non-integer number of monolayers (ML). When the domain walls are pinned in thinner films, the system minimizes energy locally, and a metastable reorientation transition occurs on isolated islands that are 1 ML thicker than the surrounding film. These two versions of the same transition produce two separate peaks in the susceptibility $\chi_\perp$ (in a perpendicular field), if it is measured as the film is grown. We report here observation of a dynamical version of the reorientation transition as the domain walls depin and the system moves from locally to globally determined energetics. The measured susceptibility $\chi_{001}$ (in an in-plane field) exhibits a divergence. These observations provide insight to the role of dipole interactions in the transitions from the perpendicular phase to the paramagnetic and canted phases.

Relaxation effects are of primary importance in the description of magnetic excitations, leading to a myriad of methods addressing the phenomenological damping parameter. In this work [1], we compare several well-established forms of calculating the intrinsic Gilbert damping within a unified theoretical framework, mapping out their connections and approximations required to derive each formula. Most methods lead to similar results for the bulk ferromagnets Fe, Co and Ni, due to the low spin-orbit interaction strength and the absence of the spin pumping mechanism. Starting from simulated ferromagnetic resonance spectra based on the underlying electronic structure, we unambiguously demonstrate that the damping parameter obtained within the constant broadening approximation diverges for three-dimensional bulk magnets in the clean limit, while it remains finite for monolayers. Our work puts into perspective the several methods to compute the Gilbert damping, building a solid foundation for future investigations of magnetic relaxation effects in any kind of material.

1:39PM F41.00011: Quantum spin-transfer torque induced nonclassical magnetization dynamics and electron-magnetization entanglement  PRIYANKA MONDAL (Presenter), Dept. of Physics & Astronomy, University Of Delaware, MARKO PETROVIĆ, PETR PETR PLECHAC, Department of Mathematical Sciences, University Of Delaware, BRANISLAV NIKOLIC, Dept. of Physics & Astronomy, University Of Delaware — Spin transfer torque (STT) is usually known to appear from non-collinearity of two spins but recent experiments [A. Zholud et al., Phys. Rev. Lett. 119, 257201 (2017)] have shown change in magnetization in spin valves at cryogenic temperature even when electron spin is collinear to magnetization, pointing at overlooked quantum effects in STT (which can lead to highly nonclassical magnetization states). Using fully quantum many-body treatment, we showed that change in magnetization below cryogenic temperature come from entanglement between injected electron subsystem and anisotropic quantum Heisenberg ferromagnetic chain, caused by STT coming from non-collinearity of the two subsystems (which explains the experiment). Furthermore, the same processes—entanglement and thereby induced decoherence—are present also in standard noncollinear geometry, together with the usual magnetization rotation. This is because STT in quantum many-body picture is caused only by electron spin-down factor state, and the only difference between collinear and noncollinear geometries is in relative size of the contribution of the initial separable state containing such factor state to superpositions of separable many-body quantum states generated during time evolution.

1:51PM F41.00012: Time-retarded damping and magnetic inertia in the Landau-Lifshitz-Gilbert equation self-consistently coupled to electronic time-dependent nonequilibrium Green functions*  UTKARSH BAJPAI (Presenter), BRANISLAV NIKOLIC, University of Delaware — The conventional LLG equation is a widely used tool to describe dynamics of local magnetic moments, viewed as classical vectors. Here we demonstrate that recently developed [M. D. Petrovic et al., arXiv:1802.05682] self-consistent coupling of the LLG equation to time-dependent quantum electrons using time-dependent nonequilibrium Green function (TDNEGF) microscopically generates time-retarded damping in the LLG equation described by a memory kernel. For sufficiently slow dynamics, the memory kernel can be expanded to extract a time dependent Gilbert damping and magnetic inertia terms. Using examples of precessing single or multiple magnetic moments, as well as field-driven motion of a magnetic domain wall, we quantify the difference in their time evolution computed from conventional LLG equation vs. our TDNEGF+LLG approach. The faster DW motion predicted by TDNEGF+LLG approach reveals that important quantum effects are missing from conventional classical micromagnetics simulations. We also demonstrate large discrepancy between TDNEGF+LLG-computed nonperturbative result for charge current pumped by a moving DW and the same quantity computed by perturbative spin motive force formula combined with the conventional LLG equation.

Session F42 DQI: Applications of Noisy Intermediate Scale Quantum Computers III  BCEC

210A - Kristan Temme - Tag(s): Focus

11:15AM F42.00001: Gate-efficient simulation of molecular eigenstates on a superconducting qubit quantum computer  MARC GANZHORN, DANIEL EGGER, PAULINE OLLITRAULT, PANAGIOTIS BARKOUTSOS, GIAN SALIS, NIKOLAJ MOLL, ANDREAS FUHRER, PETER MUELLER, IBM Research - Zurich, MARCO ROTH, Forschungszentrum Juelich, STEFAN WOERNER, IVANO TAVERNELLI, STEFAN FILIPP (Presenter), IBM Research - Zurich — A key requirement to perform simulations of large quantum systems on current quantum processors is the design of quantum algorithms with short circuit depth. To achieve this, it is essential to realize a gate set that is tailored to the problem at hand and which can be directly implemented in hardware [P. Barkoutsos et al., Phys. Rev. A 98, 022322 (2018)]. Here, we experimentally demonstrate that exchange-type gates are ideally suited for calculations in quantum chemistry [M. Ganzhorn et al., arXiv:1809.05057]. We determine the energy spectrum of molecular hydrogen using a variational quantum eigensolver algorithm based on exchange-type gates in combination with a method from computational chemistry to compute the excited states. We utilize a parametrically driven tunable coupler to realize exchange-type gates that are configurable in amplitude and phase on two fixed-frequency superconducting qubits. With gate fidelities around 95% we are able to compute the eigenstates within an accuracy of 50 mHartree on average, a limit set by the coherence time of the tunable coupler.
11:27AM F42.00002: Improved variational algorithms for optimization problems in a quantum computer

PANAGIOTIS BARKOUTSOS (Presenter), ANTON ROBERT, IBM Research - Zurich Research Laboratory, GIACOMO NANNICINI, IBM Research - Thomas J. Watson Research Center, IVANO TAVERNELLI, STEFAN WOERNER, IBM Research - Zurich Research Laboratory

— Recent advances in Noisy Intermediate-Scale Quantum (NISQ) computers allow us to solve combinatorial optimization problems encoded in Hamiltonians via hybrid quantum/classical variational algorithms. Current approaches minimize the expectation of the problem Hamiltonian for a parameterized trial state generated in the quantum circuit. The expectation is obtained by sampling the full outcome of an ensemble of measurements of the corresponding matrix element, while the trial wavefunction parameters are optimized classically. This procedure is fully justified for quantum mechanical observables (i.e. molecular energy). However, in the case of the simulation of classical optimization problems, which yield diagonal Hamiltonians, we argue that it is more natural to aggregate the samples using a different aggregation function than the expected value. In this talk, we present results of the aforementioned scheme for a plethora of interesting optimization problems where we demonstrate faster convergence towards more accurate solutions.

11:39AM F42.00003: Variational Approaches for Quantum Simulation

TIMOTHY HSIEH (Presenter), Perimeter Institute for Theoretical Physics, WEN WEI HO, Harvard, CHERYNE JONAY, Perimeter Institute for Theoretical Physics

— Many non-trivial quantum states, such as quantum critical points or topological phases, can potentially be realized in synthetic quantum systems, such as trapped ions or superconducting circuits. However, finding efficient and realizable approaches for such state preparation is challenging. I will show how a variant of the Quantum Approximate Optimization Algorithm (QAOA), originally introduced as a variational approach for solving classical optimization problems, serves as an efficient and general approach for realizing non-trivial quantum states. I will then show how long-range interactions, for example those in trapped ions systems, can further facilitate quantum state preparation.

11:51AM F42.00004: Quantum gate-model approaches to exact and approximate optimization [Invited]

STUART HADFIELD (Presenter), USRA / NASA Quantum Artificial Intelligence Laboratory

— Many of the most challenging computational problems arising in practical applications are tackled by heuristic algorithms which have not been rigorously proven to outperform other approaches but rather have been empirically demonstrated to be effective. While quantum heuristics have been proposed since the early days of quantum computing, true empirical evaluation of the real-world performance of these algorithms is only becoming possible now as increasingly powerful quantum gate-model devices continue to come online.

In this talk, I will give an overview of the NASA QuAIL team's ongoing investigation into quantum gate-model heuristic algorithms for exact and approximate optimization. In particular, we consider the performance of the Quantum Approximate Optimization Algorithm on NP-hard optimization problems, and describe algorithm parameter setting strategies for real-world quantum hardware. We then show a generalization of QAOA circuits, the Quantum Alternating Operator Ansatz, especially suitable for low-resource implementations of QAOA for problems with hard (feasibility) constraints. The talk will conclude with a discussion of research challenges, particularly for optimization and sampling applications of QAOA, and the potential of more general quantum heuristics to give advantages over classical computers.

12:27PM F42.00005: Simulating Transmon Lattices for Analysing System Constraints in the Noisy Intermediate Quantum Scale

JONATHON MILLER (Presenter), University of Houston, Clear Lake

— Thermal noise from electrical circuit components and noise due to fluctuations in energy levels of Transmon circuits have the cumulative effect of decreasing the coherence time of these systems. As coupled Transmon systems scale to the noisy intermediate quantum scale, accurate characterization of noise accumulation and its effects on coherence time and quantum logic gate fidelity is vital. The answer this work aims to provide is the limitations on the coherence time imposed by the noise as the system scales from a few to many (50-100) qubits. The noise analysis is being carried out by a computational simulation of a linear Transmon chain forced into a confinement and surrounded by a bath of thermal photons characteristic of the circuit component radiation. A Generative Artificial Intelligence is used to explore the space of superconducting circuits to develop an understanding of the thermal constraints of a Noisy Intermediate Scale Quantum Computer.
12:39PM F42.00006: Characterizing quantum circuits by short-cutting quantum errors and a unitary-dissipative "polar" decomposition for quantum channels*  ARNAUD CARIGNAN-DUGAS (Presenter), Applied Mathematics, University of Waterloo, MATTHEW ALEXANDER, JOSEPH EMERSON, University of Waterloo — The richness of quantum dynamics allows for a plethora of noise models which, given only a partial knowledge of a device's components can result in widely different conclusions regarding the quality of larger circuits. In fact, the sole formulation of an assessment regarding the overall operational performance is demanding in that it typically requires invoking a broad range of quantum dynamical scenarios. In this work, we pave the way between partially characterized elementary operations and circuits thereof. Our paving stone consists of a simplified picture of quantum processes that we refer to as the leading Kraus (LK) approximation. This incomplete dynamical representation closely prescribes the evolution of celebrated characterization figures of merit, namely the average gate fidelity, which captures the overlap between an implemented operations and their targets, and the unitarity, which captures the level of coherence in the noise. Moreover, the transparency in the LK parametrization allows the derivation of a quantum unitary-dissipative (polar) factorization for quantum channels.

12:51PM F42.00007: Quantum Feedback Protocol for Approximating Single-Body Green's Functions at Finite Temperature*  JEFFREY COHN (Presenter), KHADIJEH NAJAFI, JAMES FREERICKS, BARBARA JONES, Georgetown University — We present a quantum feedback algorithm that aims to approximate single-body Green's functions at finite temperature. Extracting a single particle Green's function from a quantum computer is a well known process, but if one is interested in thermal properties the challenges and resources necessary for full Gibbs state preparation are generally too expensive for these machines in the near future. Here, we examine how sampling from more easily preparable states can yield precise approximations to single-particle Green's functions at finite temperature. We also show, through a feedback mechanism, that one can test for convergence and extract the effective temperature of the system being simulated. Further, we compare the trade-offs of different approaches to make these techniques applicable on near term devices. We draw on the ideas of the Eigenstate Thermalization Hypothesis as well as specific properties of Green's functions and use a family of 1-D Fermi-Hubbard models as our test case.

1:03PM F42.00008: Quantum simulation and Time-Dependent Density Functional Theory*  JAMES WHITFIELD (Presenter), JAMES BROWN, JUN YANG, Dartmouth College — Time evolution of quantum systems is of interest in physics, in chemistry, and, more recently, in computer science. One route to numerically propagating quantum systems is time dependent density functional theory. The application of TDDFT to a particular system's time evolution is predicated on V-representability which we've analyzed in previous work. Here we consider the application of quantum simulation to the problem of characterizing time-dependent Kohn-Sham potentials. We consider both the V-representability of some simple 1D examples numerically and their implementation using quantum computation. The measurement of the one-body electronic probability density on quantum hardware given various qubit encodings is also discussed.

1:15PM F42.00009: Digital quantum simulation of a two-dimensional electron gas pierced by a strong magnetic field  MICHAEL KAICHER (Presenter), SIMON BALTHASAR JÄGER, FRANK K WILHELM, Univ des Saarlandes, RYAN BABBUISH, Google Inc., PIERRE-LUC DALLAIRE-DEMERS, Xanadu — A two dimensional electron gas, confined to a finite disk geometry and pierced by a strong transversal magnetic field at zero temperature describes the physical setting of the fractional quantum Hall effect. We give an ab-initio roadmap on how this system may be simulated on a quantum processor. We show how the approximate ground state could be extracted through a hybrid quantum-classical variational algorithm and how to extract ground state properties. This heuristic method can be extended to incorporate more physical effects, such as impurity models, to ultimately test theoretical models against experimental data beyond the limits of classical computational power.
1:27PM F42.00010: Linear Depth Circuit Unitary Coupled Cluster Wavefunctions for Quantum Computation*
WILLIAM HUGGINS (Presenter), JOONHO LEE, MARTIN HEAD-GORDON, BIRGITTA K WHALEY, University of California, Berkeley
— Motivated by the rapid development of quantum computing hardware we introduce a new unitary coupled cluster wavefunction ansatz for quantum chemistry which we call k-UpCCGSD. k-UpCCGSD employs k products of the exponential of a sparse generalized doubles excitation operator, together with generalized single excitation operators, resulting in a wavefunction which can be approximated by a linear-depth circuit. We compare its performance with that of the generalized unitary coupled cluster ansatz employing the full generalized singles and doubles excitation operators (UCCGSD), as well as with the standard ansatz containing only excitations between occupied and virtual orbitals (UCCSD). We find that k-UpCCGSD offers an appealing tradeoff between accuracy and cost, and dramatically outperforms the standard UCCSD, particularly for the calculation of low-lying excited states.

1:39PM F42.00011: Quantum digital simulation of three toy models using IBM quantum hardware.*  PEDRO CRUZ, Departamento de Fisica, Universidade de Porto, RONAN GAUTIER, CentraleSupélec, GONÇALO CATARINA, JOAQUIN FERNANDEZ-ROSSIER (Presenter), QuantaLab & Quantum Materials and Energy, International Iberian Nanotechnology Laboratory — Using the phase estimation algorithm it is possible, in principle, to obtain the eigenstates of a large family of many-body Hamiltonians. In this talk we will present the results of our attempts to implement phase estimation algorithms to obtain the eigenvalues of 3 simple model Hamiltonians, using IBM quantum hardware. For that matter, we have considered a two level system, a two site Ising model with longitudinal magnetic field, and a two site Hubbard model at half filling. We have made use of both the phase estimation and iterative phase estimation algorithms. We have explored to which point the unwanted hardware noise compromises the accuracy of the algorithm. In the case of the Hubbard model, for which a Trotterization procedure is required, we study the optimal number of Trotter steps. Our results illustrate the limits of the phase estimation approach for quantum digital simulation in state of the art hardware.

1:51PM F42.00012: Implementing the Variational Quantum Eigensolver with native 2-qubit interaction and error mitigation*  TAKAHIRO TSUNODA (Presenter), ANDREW D PATTERSON, Condensed Matter Physics, University of Oxford, XIAO YUAN, SUGURU ENDO, Materials, University of Oxford, JOSEPH RAHAMIM, PETER A SPRING, MARTINA ESPOSITO, SALHA JEBARI, KITTI RATTER, SOPHIA SOSNINA, GIOVANNA TANCREDI, BRIAN VLASTAKIS, Condensed Matter Physics, University of Oxford, SIMON BENJAMIN, Materials, University of Oxford, PETER LEEK, Condensed Matter Physics, University of Oxford — The variational quantum eigensolver (VQE) is an algorithm that may provide near-term applications of small-scale quantum computers, in quantum chemistry and optimisation problems. In order for the VQE to provide accurate solutions to problems on real devices, methods have been proposed recently to mitigate the errors caused by imperfect gates. In this presentation, we report a quantum chemistry simulation using the VQE on a 2-qubit superconducting device in which we use fixed frequency qubits and build the algorithm using the native 2-qubit interaction resulting from a static capacitive coupling. The hardware ansatz of the VQE is constructed by varying the timings of echo pulses to manipulate the native ZZ coupling. This method allows us to implement a VQE algorithm without needing repeated 2-qubit-gate tune-up, and enables simple and understandable implementation of error mitigation.

Session F43 DCMP GMAG: Topological Spintronics  BCEC 210B - Nitin Samarth, Pennsylvania State University - Tag(s): Invited
11:15AM F43.00001: Topological Insulator Surface States for Spintronics* [Invited] ALLAN MACDONALD (Presenter), University of Texas at Austin — Spintronics is the study of the mutual influence between charge transport in conductors and charge neutral spin degrees of freedom, especially the collective spin degrees of freedom of magnetically ordered systems. The effects of spintronics all require coupling between spin and orbital degrees of freedom. Systems containing thin-films of three dimensional topological insulators (TIs) are in many cases ideal hosts for spintronics studies because of the strong spin-orbit coupling present in the protected TI surface states, which can also serve as an isolated two-dimensional charge transport channel. I will discuss theories of the closely related anomalous Hall, spin Hall, spin-orbit torque, magneto-resistance, and spin-pumping effects in isolated TI thin films, and in TI thin films proximity coupled to conducting and insulating ferromagnets and antiferromagnets. My talk will focus on discussing possible applications of topological insulators in thin-film devices for electrically controlled magnetism, and emphasize the separate roles played by top and bottom TI surfaces.

*This work is supported by the DOE office of Basic Energy Sciences under grant DE-FG02-02ER45958 and by the Army Research Office MURI program under Grant Number W911NF-16-1-0472.

11:51AM F43.00002: Magnetic Topological Insulator Heterostructures: From Axion Physics to the Topological Hall Effect* [Invited] CUI-ZU CHANG (Presenter), Pennsylvania State University — Topological insulator is a material in which the interior is insulating but wherein the electrons travel without resistance along surface/edge conducting channels. The nontrivial Dirac surface/edge states of a TI are induced by intrinsic strong spin-orbit coupling and protected by time-reversal symmetry (TRS). Breaking the TRS of a TI with magnetic doping can lead to many exotic topological quantum phenomena such as the quantum anomalous Hall (QAH) effect [1]. The QAH effect has been experimentally demonstrated in magnetic TI thin films, specifically Cr- and/or V- doped (Bi,Sb)Te [2]. Recently, we fabricated magnetic TI based sandwich heterostructures wherein two TI films doped with the same or different magnetic ions are sandwiched by an undoped TI layer. The undoped TI layer serves as a spacer to decouple the exchange interaction between the two magnetic TI layers, thus the magnetization in each magnetic TI layer can be treated independently. In heterostructures with different magnetic TI layers, we realized a zero Hall conductance plateau in the antiparallel magnetization alignment region, which is a realization of the axion insulator state. This observation provides a promising platform for the exploration of axion electrodynamic physics [3]. In heterostructures with the same magnetic doping, we observed a crossover from the QAH to topological Hall (TH) effects. The combination of QAH and TH effects in a single sample facilitates the study of the interplay of momentum-space and real-space Berry curvatures in magneto-transport phenomena [4].

*This work is supported by the ARO Young Investigator Program Award (W911NF1810198), the U.S. DOE Award # DE-SC0019064 and the Alfred P. Sloan Research Fellowship.

12:27PM F43.00003: Dirac-Surface-State Modulated Spin Dynamics in a Ferrimagnetic Insulator at Room Temperature* [Invited] JING SHI (Presenter), University of California, Riverside — In heterostructures of magnetic insulator/topological insulator or MI/TI, a large enhanced spin Seebeck effect was attributed to the spin-momentum locking of the TI surface. In this work, we demonstrate dramatically modified spin dynamics of MI by the spin-momentum locked Dirac surface states of the adjacent TI. As the Bi-concentration $x$ is systematically tuned in 5 nm thick (Bi$_x$Sb$_{1-x}$)$_2$Te$_3$ TI film, the weight of the surface relative to bulk states peaks at $x = 0.32$ when the chemical potential approaches the Dirac point. At this concentration, the Gilbert damping constant of the precessing magnetization in 10 nm thick Y$_2$Fe$_5$O$_{12}$ MI film in the MI/TI heterostructures is enhanced by an order of magnitude, the largest among all concentrations. In addition, the MI acquires additional strong magnetic anisotropy that favors the in-plane orientation with similar Bi-concentration dependence. These extraordinary effects of the Dirac surface states along with the enhanced spin Seebeck effect distinguish TI from other materials such as heavy metals in modulating spin dynamics of the neighboring magnetic layer, which can be harnessed for spintronic applications.

*This work was supported as part of the SHINES, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award No. SCO012670, NSF Grants No. DMR-1207469, ONR Grant No. N00014-16-1-2657, and the STC Center for Integrated Quantum Materials under NSF Grant No. DMR-1231319.
1:03PM F43.00004: Discovery of quantum confinement effect in sputtered topological insulator films and observation of room-temperature high spin–orbit torque* [Invited] MAHENDRA DC, ROBERTO GRASS, JUNYANG CHEN, MAHDI JAMALI, DANIELLE HICKEY, DELIN ZHANG, ZHENGYANG ZHAO, HONGSHI LI, PATRICK QUARTERMAN, YANG LV, MO LI, University of Minnesota, AURELIEN MANCHON, King Abdullah University of Science and Technology, K. ANDRE MKHOYAN, TONY LOW, JIANPING WANG (Presenter), University of Minnesota — In this talk, we will report and discuss the experimental demonstration and first-principles calculation of quantum confinement in topological insulator. First, we report Bi$_{x}$Se$_{(1-x)}$ films with high SOT at RT grown onto thermally oxidized silicon substrates by magnetron sputtering, which is a semiconductor industry compatible process. The dc planar Hall and ST-FMR methods were used for the characterization of SOT in Bi$_{x}$Se$_{(1-x)}$/CoFeB heterostructures with in-plane CoFeB. At RT, the of the sputtered Bi$_{x}$Se$_{(1-x)}$ film is up to two orders of magnitude larger than that of HMs. Notably, we developed perpendicular CoFeB multilayers on Bi$_{x}$Se$_{(1-x)}$ films, and we demonstrated switching of the magnetization using SOT arising from the Bi$_{x}$Se$_{(1-x)}$ with very low switching current density in bilayers at RT. Second, we will report our discovery of the quantum confinement effect in topological insulators. The sputter deposited Bi$_{x}$Se$_{(1-x)}$ has granular structure with grain size as small as approximately 6 nm. Electronic band-structure analysis indicates that the reduced dimensionality and quantum confinement strongly influences the spintronic properties of the TI. Our theory identifies the presence of lowly dispersive surface bands with large charge-to-spin conversion efficiency in nanoscale grains, which might explain the experimentally observed enhancement in the figure-of-merit. The demonstrated ease of growth of the films on a silicon substrate, and successful growth and switching of perpendicular CoFeB multilayers on Bi$_{x}$Se$_{(1-x)}$ film provide an avenue for the use of Bi$_{x}$Se$_{(1-x)}$ as a spin-density generator in SOT-based memory and logic devices.

Mahendra DC, et al, “Room-temperature high spin–orbit torque due to quantum confinement in sputtered Bi$_{x}$Se$_{(1-x)}$ films” Nature Materials. 17, 800-807 (2018); DOI: 10.1038/s41563-018-0136-z

1:39PM F43.00005: Exploring Non-Trivial Nature of Topological Surface States in SmB6 [Invited] MINGZHONG WU (Presenter), TAO LIU, Colorado State Univ, YUFAN LI, Johns Hopkins University, LEI GU, University of California, Irvine, JUNJIA DING, Argonne National Laboratory, HOUCHEN CHANG, PRAVEEN JANANTHA, Colorado State Univ, BORIS KALINIKOS, St. Petersburg Electrotechnical University, VALENTYN NOVOSAD, AXEL F HOFFMANN, Argonne National Laboratory, RUQIAN WU, University of California, Irvine, CHIA-LING CHIEN, Johns Hopkins University — Being the first rare earth mixed valence system and the first Kondo insulator, SmB6 may very likely be the first topological Kondo insulator too. Recent studies have confirmed the existence of topological surface states (TSS) and surface chiral spin textures in single-crystal SmB6 bulk materials, but the non-trivial nature and depth scale of the TSS remain unresolved. In this talk I will report our recent work on the use of spin pumping to study the non-trivial feature of the TSS in SmB6 [1]. Our experiments used SmB6 thin films grown on magnetic insulator Y$_3$Fe$_5$O$_{12}$ (YIG) bulk materials. Upon the excitation of magnetization precession in the YIG, a pure spin current is generated that flows from the YIG into the SmB6 film and produces, via spin-orbit coupling, a lateral electrical voltage in the SmB6 film. The spin-pumping voltage signal becomes considerably stronger as the temperature decreases from 150 K to 10 K. Such an enhancement most likely originates from the spin-momentum locking feature of the TSS of the SmB6 film and may thereby serve as a strong evidence for the nontrivial nature of the TSS. The voltage data also show a unique film thickness dependence that suggests a TSS depth of about 32 nm for the TSS. The data also indicate a spin diffusion length of about 39 nm in the SmB6 film. The spin-pumping results are supported by temperature-dependent transport measurements and theoretical analyses using a tight binding model.

Session F44 DCMP: Manifestations of Phonon Hydrodynamics in Thermal Transport BCEC

21OC - Andrea Cepellotti, University of California, Berkeley - Tag(s): Invited
11:15AM F44.00001: Novel Vistas in Thermal Transport: Relaxons, Frictions, Viscosities, and Coherences* [Invited]  
NICOLA MARZARI (Presenter), Ecole polytechnique federale de Lausanne — We examine the emergence of correlated transport phenomena in systems described by the linearized Boltzmann transport equation (LBTE), with examples then centered around heat transport. First, we show how phonons, traditionally considered the carriers of heat, are only a high-temperature approximation to the exact carriers, that we term relaxons, showing how thermal conductivity can be mapped exactly into a kinetic theory of the relaxon gas, and where the effect of boundaries can be understood in terms of frictions. Second, we show how the LBTE admits coherent propagating solutions with well defined wavevectors and lifetimes, of which second sound is a special case. Last, we discuss generalizations towards the Navier-Stokes continuum, and towards disordered materials. Work performed in collaboration with Andrea Cepellotti (UC Berkeley), Michele Simoncelli (EPFL), and Francesco Mauri (Sapienza U. of Rome).

*This research was supported by the Swiss National Science Foundation through Project ID 200021_143636 and the National Centre of Competence in Research MARVEL.

11:51AM F44.00002: Observation of the Poiseuille flow of phonons in black phosphorus [Invited]  
YO MACHIDA (Presenter), Department of Physics, Gakushuin University — The travel of heat in an insulating solid is commonly pictured as a flow of phonon quasi-particles. In such a picture, phonons are decelerated by scattering with each other. However, in rare circumstances, momentum-conserving scattering between phonons dominate, and phonons can enter a hydrodynamic regime, where they flow like fluids inside a crystalline lattice and retard only by hitting the sample boundaries. This phenomenon dubbed “phonon Poiseuille flow”, which is a phononic counterpart of the Poiseuille flow in classical hydrodynamics, was thought to occur only in ultrapure solids.

In the presentation, we report on a study of heat flow in bulk black phosphorus, a material attracting renewed attention for a variety of fundamental and technological reasons. We show that the thermal conductivity of this material exhibits a faster than cubic temperature dependence just below the peak temperature of thermal conductivity. Consequently, the effective phonon mean free path shows a nonmonotonic temperature dependence at the onset of the ballistic regime, with a size-dependent Knudsen minimum. These are hallmarks of Poiseuille flow previously observed in a handful of solids. Comparing the phonon dispersion in black phosphorus and silicon, the low-energy phonon density of states in black phosphorus is found to be much larger, favoring normal momentum-conserving scattering events. Contrary to the previous belief, our results imply that the most important requirement for the emergence of Poiseuille flow is the facility of momentum exchange between acoustic phonon branches [1].

12:27PM F44.00003: Phonon Hydrodynamics in Graphene and Graphite [Invited]  
GANG CHEN (Presenter), ZHIWEI DING, SAMUEL HUBERMAN, RYAN DUNCAN, VAZRIK CHILOYAN, KEITH ADAM NELSON, ALEXEI MAZNEV, Massachusetts Institute of Technology — In the hydrodynamic regime, phonons drift with a nonzero collective velocity under a temperature gradient, reminiscent of viscous gas and fluid flow. The study of hydrodynamic phonon transport has spanned over half a century but has been mostly limited to cryogenic temperatures (<20 K). Recently, we predict based on first principles calculations that hydrodynamic phonon transport can occur in suspended graphene at significantly higher temperatures and wider temperature ranges compared to bulk materials. Furthermore, we identified graphite as a three-dimensional material that supports phonon hydrodynamics at significantly higher temperatures (~100 K). The significant hydrodynamic nature of phonon transport in graphite is attributed to its strong intralayer sp² hybrid bonding and weak van der Waals interlayer interactions. The hydrodynamic transport is manifested through drift motion of phonons, phonon Poiseuille flow, and second sound. Recent experiments demonstrating second sound up to 100K will be discussed.

1:03PM F44.00004: Thermal conductivity of strontium titanate: signatures of phonon hydrodynamics* [Invited]  
KAMRAN BEHNIA (Presenter), ESPCI ParisTech — Temperature dependence of thermal conductivity in strontium titanate reveals four different regimes of heat flow between 2K and 400 K. At high temperature, in the kinetic regime, phonons are scattered off each other by Umklapp processes and thermal conductivity is inversely proportional to temperature. At low temperature, their mean-free-path is set by domain boundaries. This is the ballistic regime. Between these two limits, one can detect the Ziman regime where Umklapp events are rare. The hybridization of soft optical phonon with acoustic phonons enhance Normal (momentum-conserving) collisions and leads to a faster-than cubic temperature dependence of thermal conductivity in a narrow tempearture window. This is a hallmark of Poiseuille flow of phonons previously observed in a handful of solids.

Hydrodynamic heat transport in semiconductors at the nanoscale* [Invited] XAVIER ALVAREZ (Presenter), JAVIER BAFALUY, JUAN CAMACHO, Physics Department, Universitat Autònoma de Barcelona, XAVIER CARTOIXA, Electrical Engineering Department, Universitat Autònoma de Barcelona, POL TORRES, ALBERT BEARDO, LLUC SENDRA, Physics Department, Universitat Autònoma de Barcelona — Recent experiments in heat transport on silicon using ultrafast laser heating techniques have shown significant discrepancies with Fourier like behaviour[1-3]. The interpretations of these results using only a ballistic to diffusive transition of the carriers have shown to be unfruitful. The consequence is that heat transport at the nanoscale is still an incompletely described topic.

Phonon hydrodynamics has emerged in the last years as a candidate to cover this gap. The appearance of this regime has been associated to the dominance of normal collisions. Its presence has been proven in 2D materials or at low temperatures[4-5], when N-collisions are dominant and in consequence collective effects can be observed easily. But recent works have shown that hydrodynamic effects can still have an important impact when resistive collisions are dominant[6-7]. In this case its presence has to be noticed through indirect evidences. Hydrodynamics has been used to understand the lack of validity of the Mathiessen rule in silicon or the dependence of the Thermal Boundary Resistance on the size of the contact.

Kinetic Collective Model (KCM) has been developed to describe heat transport using two key concepts. On one side, the splitting in collective regime (when normal scattering is dominant) and kinetic regime (when it is not important). On the other side, the inclusion of nonlocal and memory effects that introduce hydrodynamic behavior in the description. From the combination of both concepts it can be shown that hydrodynamic phenomena can emerge in both, collective and kinetic regimes, with different particularities in each case.

Tuesday, March 5, 2019 11:15 AM - 2:15 PM

Session F45 DCMP: Surface Physics BCEC 211 - Steven Erwin, United States Naval Research Laboratory

11:15AM F45.00001: Atomic and Electronic Structures in Intermetallic CaBi₂ Thin Films YANFENG LYU (Presenter), HANMINING YUAN, SAMIRA DANESHMANDI, SHUYUAN HUYAN, PAUL C. W. CHU, Texas Center for Superconductivity, University of Houston — Bismuth-based alloys and compounds are promising candidates for novel topological nontrivial materials due to the strong spin-orbit coupling effect in the heavy bismuth element. The search for topological superconductivity and Majorana fermions in these materials have attracted significant interest. Recently, intermetallic CaBi₂ single crystal was reported to be superconducting, while the atomic, electronic, and topological properties have never been investigated. Using molecular beam epitaxy, we have successfully grown CaBi₂ thin film on TiO₂-terminated SrTiO₃(100) substrate. The lattice and electronic structures were probed by using in-situ reflection high-energy electron diffraction, scanning tunneling microscopy and ex-situ X-ray diffraction. We found the epitaxial CaBi₂ thin film has a Volmer-Weber growth mode and the surface has four totally different terminations: two are non-reconstructed, and the others are reconstructed to 1×2 and c(5×5), respectively. The different electronic density of states and physical properties relevant to these different surface terminations were also investigated.
Tellurium has a curious crystal structure where one dimensional covalently bound chains are held together by van der Waals interactions in a hexagonal pattern. Additionally, theory predicts that the (0001) surface (perpendicular to the chains) of tellurium is a candidate to host a zero-energy bound state. Since evaporated thin films tend to grow in the (1000) direction, we use a Te single crystal to examine the (0001) surface by low temperature scanning tunneling microscopy/spectroscopy. The samples were cut from a larger single crystal and chemo-mechanically polished. After introduction into the ultra-high vacuum system the samples were carefully cleaned by Ar ion sputtering and annealing cycles. We found two surface structures as candidates for the native (0001) surface. The first is a row structure with a period of twice the lattice constant hinting at dimerization of the dangling bonds. The second is more complicated with rows separated by terraces of variable width. This might be a higher-index surface or induced by residual contamination. Initial spectroscopy measurements will also be discussed.

**Quantum saturation of capacitance in metals**

There are two contributions to the electronic capacitance in between two electrodes. First, there is the classical capacitive effect as an electric field is being developed in between these. Another contribution, which has often been neglected for metals, is related to the Pauli exclusion principle for the difficulty to accumulate charges on the electrode surface, the so-called quantum capacitance [T. Christen and M. Büttiker. Phys. Rev. Letters 77 (1996), 1]. Here we report the use of a Scanning Tunneling Microscope at low temperatures to study the variations of the capacitance as we approach two metallic electrodes made of Pt or Au. Three regimes are clearly visible in this process: A classical increase of capacitance which at short distances turn to saturation to the quantum capacitance limit, and finally, a leak of capacitance due to quantum tunneling.

**Comparison of Features for Au and Ir Adsorbed on the Ge (110) Surface**

The surface is modeled by a slab consisting of 108 Ge atoms with a 10 Å vacuum region. Hydrogen atoms are used to saturate the dangling orbitals at the other side of the vacuum region. The relaxed surface with the Au or Ir adatom shows the following distinct features: (1) Au is located at the top of the surface while Ir is located below the top layer of the Ge atoms, as a result of the smaller 1.423Å atomic radius of Ir vs. 1.503Å for Au. (2) No bond formation occurs between the metallic adatoms and the Ge atoms because the more tightly bound nature of the d-states in the metal elements do not allow hybridization to form sp³-type directional orbitals, as seen in charge density plots. (3) The Ir charge density is more deformed than Au, because the partially filled d-shell in Ir can be more easily polarized than the completely filled d-states of Au. Comparisons will be made to Ir/Ge(111) and Au/Ge(110) data measured by STM and LEEM.

12:03PM F45.00005: Step-Spacing Distributions Revisited: Curved Crystals Bring Many Opportunities and Challenges to Analysis* THEODORE L. EINSTEIN (Presenter), University of Maryland, College Park, J. ENRIQUE ORTEGA, FREDERIK SCHILLER, MARTINA CORSO, IGNACIO PIQUERO-ZULAICA, CSIC and U. Basque Country, San Sebastian (Spain), JORGE LOBO-CHECA, CSIC and U. Zaragoza (Spain), AITOR MUGARZA, ICN2 Barcelona (Spain) — While the properties of vicinal surfaces with close-packed steps are long well understood, recent experiments using curved crystals invite examination of many orientations under the same temperature and other conditions [1]. In addition to having simultaneously a range of geometries, each of which may be preferred for specific epitaxial growth and chemical reactions, one can now test scaling theories of terrace-width distributions (TWDs) based on fundamental theories and the existence of a single characteristic length, the mean terrace width. For close-packed steps, TWDs are well described by a single-parameter Wigner distribution. For fully-kinked steps, the stiffness tends to vanish, and some of the underlying assumptions of that analysis fail [2]. Hence, TWDs typically do not scale. Furthermore, surface states introduce a new length, λF, which can confound the scaling analysis. For large terrace widths, a description in terms of quantum well states offers a novel accounting of the TWD. Other subtleties and open questions are discussed.

12:15PM F45.00006: Tunneling Spectroscopy of the excitonic insulator phase in Ta₂NiSe₅* JINWON LEE (Presenter), Department of Physics, Pohang University of Science and Technology (POSTECH), CHANG-JONG KANG, Department of Physics and Astronomy, Rutgers University, MANJIN EOM, Department of Physics, Pohang University of Science and Technology (POSTECH), JUN SUNG KIM, Center for Artificial Low Dimensional Electronic Systems, Institute for Basic Science (IBS), BYUNG IL MIN, Department of Physics, Pohang University of Science and Technology (POSTECH), HAN WOONG YEOM, Center for Artificial Low Dimensional Electronic Systems, Institute for Basic Science (IBS) — The excitonic insulator phase is one of the novel electronic ground states driven by many-body interactions. Despite its theoretical proposal about 60 years ago, its material realization is still unclear. Ta₂NiSe₅ is a strong candidate, exhibiting a temperature-driven phase transition without any other competing phase such as the charge-density-wave. Experimental evidence so far includes an anomalous increase of the electric resistivity, the flat valence band maximum, and optical gap measurements. We provide further evidence of the excitonic insulator phase in Ta₂NiSe₅ using scanning tunneling microscopy/spectroscopy. At 78 K, the single-particle gap is measured as 300 meV and the orbital characters at the valence band maximum (-175 meV) are inverted from the high-temperature phase. These results indicate the strong interband (or electron-hole band) interaction in the gap opening, which is in a good agreement with the excitonic scenario. Moreover, our model calculation reveals that the non-interacting phase in Ta₂NiSe₅ has a semimetallic band structure, implying the excitonic condensation in Ta₂NiSe₅ is close to the Bardeen-Cooper-Schrieffer (BCS) regime.

12:27PM F45.00007: STM investigation of oxygen dissociation on Ag/Cu(111) near surface alloy* LAURA CRAMER (Presenter), CHARLIE EMILE SYKES, Tufts University — Both experiment and theory have demonstrated the ability of near surface alloys (NSAs) to desirably tune catalyst properties. These alloys consist of a solute metal confined to the first few atomic layers and present in lower concentrations than the host metal. This alters the electronic and thus catalytic properties of the alloy. Deposition of Ag on Cu(111) leads to a well-characterized NSA with Ag confined to the uppermost layer. The presence of Ag in the topmost layer forms a dislocation loop in the underlying Cu(111) due to strain from lattice mismatch. Ag-based catalysts are the current industrial standard for many partial oxidation reactions, guiding our interest in oxidation dissociation on Ag/Cu(111). Herein, we report on the observation of oxygen dissociation on extended Ag ensembles on Cu(111) via room-temperature scanning tunneling microscopy (STM). Atomic oxygen coverage was observed to scale with increasing oxygen exposure. Through time-lapse STM images, we observed localized diffusion of oxygen on Ag ensembles. These results hint at the potential for this surface to perform partial oxidation reactions with enhanced selectivity and activity.

Phase Transitions of Condensates Investigated in an Atom by Atom Way

AISHA AHSAN
(Presenter), S. FATEMEH MOUSAVI, THOMAS NIJS, SYLVIA NOWAKOWSKA, OLHA POPOVA, ANELIIA WÄCKERLIN, Department of Physics, University of Basel, JONAS BJORK, Department of Physics, Chemistry and Biology, IFM, Linköping University, LUTZ H GADE, Anorganisch-Chemisches Institut, Universität Heidelberg, THOMAS JUNG, Paul Scherrer Institute — Condensation processes and phase transitions are investigated in an atom-by-atom way in on-surface nanosized confinements. Structural transformations are induced thermally and by local probe excitation. The pores of a metal-organic network occupied with 1 up to 9 Xe atoms have been investigated in their propensity to undergo ‘condensed solid’ to ‘confined fluid’ transitions. Different transition temperatures are identified, which depend on the number of Xe atoms in the condensate and relate to the stability of the Xe clustering in the condensed ‘phase’. This work is of fundamental interest and reveals the feature-rich behaviour of transitions of confined planar condensates which provide a showcase towards future ‘phase-transition’ storage media patterned by self-assembly.

Macroscopic Transport Signatures of Alkali Metal Surface Doping in Quantum Materials

CHRISTOPHER PARZYCK (Presenter), BRENDAN FAETH, KYLE M SHEN, Cornell University — Carrier injection by surface deposition of alkali metals has become a staple technique in the investigation of doping effects in many materials. Owing to their extremely low ionization potentials, alkali metals act readily as electron donors and since the resulting free carriers are localized to the material surface this technique has traditionally been used in conjunction with surface sensitive probes of the electronic structure, namely ARPES and STM. Here we present the use of macroscopic electrical transport measurements, in conjunction with potassium surface dosing, to examine doping effects in bulk single crystals of Ba(Fe1-xCox)2As2 and MoS2 as well as thin film FeSe. This technique allows measurement of the effects of doping on macroscopic electrical properties while maintaining a high level of crystalline order in the doped structure. Additionally, it provides a promising route to studying the evolution of electronic properties with carrier concentration in materials less amenable to electrostatic gating techniques, namely superconductors with a metallic parent state.

A Comprehensive Computational Study of Adatom Diffusion on the Aluminum (1 0 0) Surface

JAMES CHAPMAN (Presenter), Materials Science and Engineering, Georgia Institute of Technology, ROHIT BATRA, Materials Science and Engineering, University of Connecticut, BLAS PEDRO UBERUAGA, GHANSHYAM PILANIA, Materials Science and Technology Division, Los Alamos National Lab, RAMAMURTHY RAMPRASAD, Materials Science and Engineering, Georgia Institute of Technology — The complexity of adatom diffusion on the Al (100) surface is reflected by the existence of several low-energy non-trivial atomic exchange or vacancy formation mechanisms. Interestingly, these mechanisms have energy barriers lower than or comparable to that of the simple (and intuitive) hopping mechanism. While prior studies mainly used classical potentials to understand diffusion processes active on Al (100) surface, here we use accurate (and expensive) density functional theory (DFT) computations to estimate barriers associated with nine low-energy adatom diffusion mechanisms. We find that there exist several exchange mechanisms with energy barriers less than or equal to that of the trivial hop mechanism, thereby highlighting mechanisms that can be relevant during surface/crystal growth. Our results paint a highly complex picture of the diffusion landscape on Al (100) and provide insights into how such mechanisms may contribute toward large length- and time-scale surface phenomena. Further, we show that some of the commonly used interatomic potentials fail to accurately capture the details of adatom diffusion on Al (100).

which are relatively inert on their own. Density-functional-theory calculations demonstrate that, when a H₂ molecule enters the channel between the jaws, it splits into two H atoms by quantum interactions and a gentle mechanical squeeze.

Indirect experimental evidence is consistent with the present predictions. Au-based nutcrackers are predicted to operate at room-temperature, while less-expensive Cu-based ones are predicted to be active at a slightly elevated temperature. Indirect experimental evidence is consistent with the present predictions. Such in silico design holds promise for inexpensive, high-performance heterogeneous catalysts for H₂ dissociation and may inspire new approaches to other complex reactions.
2:03PM F45.00015: Structural stability and electronic properties of the chiral topological superconductor Pb$_3$Bi/Ge(111): A first-principles study

LEIQIANG LI (Presenter), WEI QIN, SHANG REN, PING CUI, ZHENYU ZHANG, University of Science and Technology of China — In a separate study, we have shown that a hole-doped Pb$_3$Bi monolayer can serve as a highly appealing new platform for realizing two-dimensional (2D) intrinsic chiral topological superconductivity. Using first-principles calculations, here we systematically investigate the structural stability of Pb$_3$Bi grown on Ge(111) substrate, and find two nearly degenerate lattice configurations labeled as T$_1$ and H$_3$. For the T$_1$ structure, the appearance of type-II van Hove singularity in the density of states arises from the Bi doping, where the $p$ orbit of Bi hybridizes with that of Pb, leading to the emergence of saddle-like band structures. Moreover, for both the T$_1$ and H$_3$ structures, Bi doping gives rise to larger Rashba-type splittings of the energy bands. We also find a sizable energy barrier of $\sim$0.30 eV per formula unit from the T$_1$ to H$_3$ structure. These findings are expected to stimulate new research activities in searching for 2D intrinsic topological superconductors.

Session F46 DMP GMAG: 4d/5d Transition Metal Systems -- Perovskite Iridates

BCEC 212 - Gang Cao, University of Colorado, Boulder - Tag(s): Focus

11:15AM F46.00001: “Molecules” in solids against magnetism in 4d and 5d compounds

[Invited] DANIEL KHOMSKII (Presenter), University of Cologne — Close to Mott transition several novel states can appear [1]. In particular, “molecular clusters” can be formed in the solid, such as dimers, trimers, etc. [2]. Especially important for these phenomena is the role of different d-orbitals, which leads to different orbital-selective effects. In my talk I will formulate the main ideas and will illustrate such phenomena, especially dimer formation, on many examples, especially for systems with 4d and 5d electrons. The concept of orbital-selective Peierls transitions will be proposed and justified [3, 4]. In systems containing structural metal dimers there may exist in the presence of different orbitals a special state with partial formation of singlets by electrons on one orbital, while others are effectively decoupled and may give e.g. long-range magnetic order or stay paramagnetic. Similar situation can be realized in dimers spontaneously formed at structural phase transitions, which can be called orbital-selective Peierls transition [5]. Yet another consequence of this picture is that for odd number of electrons per dimer there exist competition between double exchange mechanism of ferromagnetism and the formation of singlet dimer by electron on one orbital. Such molecular states can strongly reduce and effectively suppress double exchange ferromagnetism [6]. I will discuss some implications of these phenomena, and consider examples of real systems, in which orbital-selective phase are realized.

11:51AM F46.00002: Mott transition and collective charge pinning in electron doped Sr$_2$IrO$_4^*$  KAI WANG, NIMROD BACHAR (Presenter), JEREMIE TEYSSIER, WEIWEI LUO, WILLEM RISCHAU, GERNOT SCHEERER, ALBERTO DE LA TORRE, Department of Quantum Matter Physics, University of Geneva, ROBIN S. PERRY, London Centre for Nanotechnology and UCL Centre for Materials Discovery, University College London, FELIX BAUMBERGER, DIRK VAN DER MAREL, Department of Quantum Matter Physics, University of Geneva — We studied the in-plane dynamic and static charge conductivity of electron doped Sr$_2$IrO$_4$ using optical spectroscopy and DC transport measurements. The optical conductivity indicates that the pristine material is an indirect semiconductor with a direct Mott gap of 0.55 eV. Upon substitution of 2% La per formula unit the Mott gap is suppressed except in a small fraction of the material (15%) where the gap survives, and overall the material remains insulating. Instead of a zero energy mode (or Drude peak) we observe a soft collective mode (SCM) with a broad maximum at 40 meV. Doping to 10% increases the strength of the SCM, and a zero-energy mode occurs together with metallic DC conductivity. Further increase of the La substitution doesn’t change the spectral weight integral up to 3 eV. It does however result in a transfer of the SCM spectral weight to the zero-energy mode, with a corresponding reduction of the DC resistivity for all temperatures from 4 to 300 K. The presence of a zero-energy mode signals that at least part of the Fermi surface remains ungapped at low temperatures, whereas the SCM appears to be caused by pinning a collective frozen state involving part of the doped electrons.

12:03PM F46.00003: electric control of the structural properties of spin-orbit coupled 5$d$ iridate Sr$_2$IrO$_4^*$  FENG YE (Presenter), CHRISTINA HOFFMANN, WEI TIAN, Oak Ridge National Laboratory, JIEMING SHENG, Physics Department, Renmin University of China, HENGDI ZHAO, HAO ZHENG, GANG CAO, Department of Physics, University of Colorado at Boulder — The unique competition between spin-orbit interactions (SOI) and Coulomb correlation in 5$d$ elements compounds drives unusual physical behaviors. Due to the entanglement of spin and orbital degrees of freedom, the form of magnetic interactions depends on the underlying lattice geometry. In the case square-lattice Sr$_2$IrO$_4$, the Hamiltonian is governed by an isotropic Heisenberg plus a dipolar-like anisotropy term and leads to a weak canted antiferromagnetic order. Recent bulk measurement identified a novel coupling between the applied electric current and the canted IrO$_6$ octahedra. This drives a large nonlinear structural response closely tracking the magnetization. Neutron diffraction study on the structural evolution reveals an anomalous response of local IrO$_6$ distortion with respect to the applied electric current in the basal plane. Our results indicate the combination of SOI and the canted antiferromagnetic order provides a new paradigm for simultaneous electric control of the physics properties.

12:15PM F46.00004: Fracturing the inter-plane magnetic correlation in Sr$_2$IrO$_4$ with single laser pulse*  RUITANG WANG (Presenter), JIAQI LIN, Institute of Physics, Chinese Academy of Sciences, HAIDAN WEN, Argonne National Laboratory, DEREK MEYERS, Brookhaven National Laboratory, JIAN LIU, University of Tennesse, XUERONG LIU, ShanghaiTech University — Pump and probe type experiments have been generally performed to study the non-equilibrium dynamics of the charge, spin and lattice. Besides the generally expected full recovery to the ground states after long enough time, meta-stable states, which are not available from thermal equilibrium evolution, can emerge. We show that, upon single laser pulse pumping, the 3D AFM ordering in Sr$_2$IrO$_4$ is fractured into lower dimension and the system enters a meta-stable state. Such effect was studied as function of laser fluence. Our results show that the in-plane spin ordering correlation length is macroscopic (micron size), and the same before and after the pumping. While the out-of-plane correlation in the meta-stable state is quickly suppressed with the increasing of laser fluence, and saturates to be about ~1 unit cell without further reduction.

*Work at ShanghaiTech U. was partially supported by MOST of China under the grand No. 2016YFA0401000. R. 12:27PM F46.00005: Relativistic Quasi-particle Nature Emerging in semi-metallic Sr$_2$IrO$_4$. JEONG WOO HAN (Presenter), Physics and photon science, GIST, SUN WOO KIM, Physics, Hanyang University, WONSHIK KYUNG, Lawrence Berkeley National Laboratory, CHANGYOUNG KIM, Physics and astronomy, Seoul National University, GANG CAO, Physics and Astronomy, University of Kentucky, JINCHEN WANG, Physics, Renmin University of China, SANGMO CHEON, Physics, Hanyang University, JONGSEOK LEE, Physics and photon science, GIST — Whereas Dirac carrier responses have been extensively investigated in weakly-correlated-systems, it is rare to observe the Dirac physics in strongly-correlated-materials. Here, we provide experimental and theoretical evidences of an emergence of a Dirac dispersion in Tb-doped Sr$_2$IrO$_4$ which exhibits a semi-metallic and paramagnetic ground state. From the symmetry analyses, we find that the multiple crystal symmetries including nonsymmorphic symmetry play a pivotal role in the development of the Dirac dispersion, and furthermore, an intrinsic d-wave gap order collapse the line-nodal Dirac dispersion into the point-nodal dispersion. Linear dispersion of the energy band near the Fermi level is confirmed by angle-resolved photoemission spectroscopy, and the Dirac carrier responses are further manifested by an extremely low-scattering rate (~6 cm$^{-1}$) of free carriers.

12:39PM F46.00006: Evidence of resistive switching into a dynamical state in antiferromagnetic iridates* MORGAN WILLIAMSON (Presenter), SHIDA SHEN, Physics Department and Texas Materials Institute, University of Texas at Austin, GANG CAO, Department of Physics, University of Colorado-Boulder, JIANSHE ZHOU, Texas Materials Institute, University of Texas at Austin, MAXIM TSOI, Physics Department and Texas Materials Institute, University of Texas at Austin — Resistive switching, which is targeted for antiferromagnetic (AFM) memory applications [1], has recently been observed in the AFM iridates Sr$_2$IrO$_4$ [2] and Sr$_3$Ir$_2$O$_7$ [3, 4]. Here we demonstrate that the switching state at high electrical biases displays an increased noise pattern, which is indicative of a dynamical state at high biases. We employ a spectrum analyzer to characterize the noise pattern associated with the high-bias switching state and investigate the dependence of the noise spectrum on the magnitude of applied bias and magnetic field. The emergence of the noise was found to be strongly correlated with the onset of resistive switching. The noise power density displayed a 1/f$^2$ frequency dependence with an amplitude mimicking the hysteretic behavior of the resistance switching. We argue that the observed noise spectrum could be associated with a random switching between different states and discuss various interpretations of its origin.

*This work was supported in part by NSF grants DMR-1712101 and DMR-1122603, and by KAUST Award No. OSR-2015-CRG4-2626.

12:51PM F46.00007: Magnetic frustration revealed by the two-magnon Raman scattering in Sr$_2$IrO$_4$ and Sr$_3$Ir$_2$O$_7$ EKATERINA PÄRSCHKE (Presenter), Department of Physics, University of Alabama at Birmingham, YAO WANG, Department of Physics, Harvard University, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory and Stanford University, Stanford Institute for Materials and Energy Sciences, CHENG-CHIEN CHEN, Department of Physics, University of Alabama at Birmingham — Exploring the physics of spin-orbit Mott insulators such as iridates is expected to shed light onto high-temperature superconductivity as well as provide valuable insights into the interplay of spin-orbit coupling, Hund’s and Coulomb interactions. Of particular interest are low-energy magnetic excitations in one- and two-layer perovskites Sr$_2$IrO$_4$ and Sr$_3$Ir$_2$O$_7$. While one-magnon excitations in these materials are fairly well understood, their two-magnon Raman energies have been reported to vary greatly and lack simple correlation with single-magnon bandwidth. Here, we employ exact diagonalization to compute the Raman response of both systems and show that magnetic frustration and finite spin gap are responsible for the unexpectedly low two-magnon peak in Sr$_3$Ir$_2$O$_7$. We also present a modified spin wave approach for an intuitive explanation of the numeric results. Our analysis highlights magnetic frustration as one of the important differences between single- and double-layer perovskites iridates and emphasizes its impact on the two-magnon Raman response in general.

1:03PM F46.00008: Angle-resolved photoemission spectroscopy studies on Rh-doped Sr2IrO4 JIMIN KIM (Presenter), CALDES, Institute for Basic Science, SUNWOOK PARK, Department of Physics, POSTECH, JONATHAN DENLINGER, Lawrence Berkeley Natl Lab, BUMJOON KIM, Department of Physics, POSTECH — Doped Mott insulator feature a plethora of rich physics, most of which remain unclear, owing to strong correlation between electrons therein. Sr$_2$IrO$_4$, a spin-orbit coupled Mott insulator, is a prominent candidate to host such emergent phenomena, especially, similar to those in cuprate high-temperature superconductors. Therefore, it is worthwhile to study a phase diagram of Sr$_2$IrO$_4$ as a function of dopant density to unveil possible instabilities or exotic phases. To this end, we performed angle-resolved photoemission spectroscopy (ARPES) studies on hole-doped Sr$_2$IrO$_4$, achieved by ionic substitution of Rh for Ir, due to the relatively weak spin-orbit coupling of Rh. Obtained ARPES spectra and related phenomena will be discussed in terms of the phase diagram.
Correlation Effects and Hidden Spin-Orbit Entangled Electronic Order in Parent and Electron-Doped Iridates Sr$_2$IrO$_4$*  

SEN ZHOU (Presenter), Institute of Theoretical Physics, Chinese Academy of Sciences, KUN JIANG, Physics, Boston College, HUA CHEN, Physics, Zhejiang Normal University, ZIQIANG WANG, Physics, Boston College — Recent experiments discovered hidden order in the parent and electron-doped iridates Sr$_2$IrO$_4$, some with striking analogies to the cuprates, including Fermi surface pockets, Fermi arcs, and pseudogap. Here, we study the correlation and disorder effects in a five-orbital model derived from the band theory. We find that the experimental observations are consistent with a d-wave spin-orbit density wave order that breaks the symmetry of a joint twofold spin-orbital rotation followed by a lattice translation. The associated staggered circulating Jeff = 1/2 spin current can be probed by advanced techniques of spin-current detection in spintronics. This electronic order can emerge spontaneously from the intersite Coulomb interactions between the spatially extended iridium 5d orbitals, turning the metallic state into an electron-doped quasi-2D Dirac semimetal with important implications on the possible superconducting state suggested by recent experiments.

Pseudogap and electronic structure of electron-doped Sr$_2$IrO$_4$*  

ALICE MOUTENET (Presenter), CPhT, Ecole Polytechnique, ANTOINE GEORGES, Collège de France, MICHEL FERRERO, CPhT, Ecole Polytechnique — We present a theoretical investigation of the effects of correlations on the electronic structure of the Mott insulator Sr$_2$IrO$_4$ upon electron doping. A rapid collapse of the Mott gap upon doping is found, and the electronic structure displays a strong momentum-space differentiation at low doping level: The Fermi surface consists of pockets centered around (π/2,π/2), while a pseudogap opens near (π,0). Its physical origin is shown to be related to short-range spin correlations. The pseudogap closes upon increasing doping, but a differentiated regime characterized by a modulation of the spectral intensity along the Fermi surface persists to higher doping levels. These results, obtained within the cellular dynamical mean-field-theory framework, are discussed in comparison to recent photoemission experiments and an overall good agreement is found.

Magnetic excitations in Sr$_2$IrO$_4$ measured with inelastic neutron scattering  

STUART CALDER (Presenter), DANIEL PAJEROWSKI, MATTHEW BRANDON STONE, ANDREW MAY, Oak Ridge National Laboratory — The widespread current interest in 5d materials stemmed from the observation that relativistic spin-orbit coupling drives a Mott-like insulating ground state with pseudospin $J_{\text{eff}}=1/2$ magnetic moments in the iridate compound Sr$_2$IrO$_4$. One surprising and enduring aspect of the physics of Sr$_2$IrO$_4$ is the observation of similarities to the parent unconventional cuprate La$_2$CuO$_4$. The degree to which this analogy holds, and if this suggests a proximate unconventional superconducting regime in Sr$_2$IrO$_4$, stands as an important outstanding question. In particular, a central issue in Sr$_2$IrO$_4$ is to understand how the strong spin-orbit coupling affects the magnetic excitations. Inelastic neutron scattering (INS) allows direct access to the magnetic excitations, but measurements have so far been lacking due to several hurdles posed by iridates. Utilizing time-of-flight INS with a gram sized single crystal array we successfully overcame these challenges. The results reveal direct evidence for two-dimensional in-plane magnetic interactions in Sr$_2$IrO$_4$ and allows a definition of the spin-gap. Modelling of the INS results with an isotropic 2D Hamiltonian supports a robust analogy with the physics of unconventional cuprates.
1:51PM F46.00012: Ferroelectric field and magnetic field effect on the spin-orbit coupled Mott insulator Sr$_2$IrO$_4$

ARNOUD EVERHARDT (Presenter), Materials Sciences Division, Lawrence Berkeley National Laboratory, YUN-LONG TANG, XIAOXI HUANG, Department of Materials Science and Engineering, University of California, Berkeley, JAY LEFEBVRE, SHANE CYBART, University of California, Riverside, R RAMESH, Department of Materials Science and Engineering, University of California, Berkeley — The 4d and 5d transition metals are commonly characterized by a decreased Hubbard repulsion $U$ which diminishes correlation effects, but simultaneously by an increased spin orbit coupling to create a new type of correlation effects which have been leading to such as spin-orbit coupled Mott insulators, Weyl semimetals, axion insulators and spin liquids. This rich physics allows small perturbations to create large effects in these strongly correlated materials. The Ruddlesden-Popper series of Sr$_{x+1}$Ir$_x$O$_{3x+1}$ shows large differences in conductive behavior, where the $n=\infty$ perovskite SrIrO$_3$ is metallic while the $n=1$ Sr$_2$IrO$_4$ is an insulator due to a spin-orbit coupling band splitting to a $J_{\text{eff}}=1/2$ state. This state has many similarities to the high $T_C$ cuprate superconductors which show an $S=1/2$ state, which loses its antiferromagnetism and becomes superconducting upon hole doping. Likewise, theoretically it is argued that under electron doping it is possible to drive Sr$_2$IrO$_4$ superconducting. Here a ferroelectric field effect is used on ultrathin Sr$_2$IrO$_4$ films to drive it to a more metallic state, by playing on the competition between electron doping and the canted antiferromagnetic transition at $\sim$200K.

2:03PM F46.00013: Effects of spin-orbit coupling on the metal-insulator transition in Sr$_2$Ir(1-x)T(x)O$_4$ (T = Rh,Ru)

BEREND ZWARTSENBERG (Presenter), RYAN P DAY, ELIA RAZZOLI, MATTEO MICHARDI, Quantum Matter Institute, University of British Columbia, NAN XU, MING SHI, Swiss Light Source, Paul Scherrer Institute, JONATHAN DENLINGER, Advanced Light Source, Lawrence Berkeley National Laboratory, STUART CALDER, Oak Ridge National Laboratory, BUMJOON KIM, Physics, Pohang University of Science and Technology, HIDENORI TAKAGI, Max Planck Institute for Solid State Research, ILYA ELFIMOV, ANDREA DAMASCELLI, Quantum Matter Institute, University of British Columbia — We study the role of spin-orbit coupling (SOC) in the metal-insulator transition of Rh- and Ru-substituted Sr$_2$IrO$_4$. Although similar, Rh and Ru have significantly different effects in driving the insulator to metal transition. Whereas Rh substitution realizes a Fermi surface at concentrations of 0.16 and higher, Ru substituted samples are insulating for similar values. We study the progression of effective SOC in the Rh substituted samples through a method based on photoemission matrix elements. We find that Rh reduces the effective SOC. This interpretation is substantiated by cluster models which show that SOC mixes into an average of the two subspecies. This mixing however, is strongly dependent on orbitals having similar energies. We argue that this quantitatively explains the difference between Ru and Rh substitution: since Ru has one less electron, the orbital energies are different from Ir, hence SOC mixing is ineffective. The model thus does not only explain the observed reduction of SOC in the Rh doped samples, it also shows why this reduction does not occur in Ru doped samples, thereby demonstrating that SOC is a key parameter in describing the MIT in Rh substituted Sr$_2$IrO$_4$.

Session F47 GERA: Energy Storage: Li Ion Batteries BCEC 213 - Sarbajit Banerjee, Texas A&M Univ

11:15AM F47.00001: The Hierarchical Structure of Nanoporous Carbon Electrode Materials Elucidated by Water Sorption: a Comparison of Multiple Structural Models

JOSE ESPITIA (Presenter), JOSE L BANUELOS, University of Texas, El Paso — The total amount of energy that an electrical double layer capacitor (EDLC) can store depends on the voltage and the accessible surface area for ion electrosorption. Nanoporous carbon materials with a high specific surface area, such as carbide derived carbon (CDC), make ideal electrodes for EDLC devices. Recent reports of water’s diffusional dynamics dependence on CDC pore size indicate confinement effects similar to that observed in pores of 16 Å. Small-angle neutron scattering (SANS) was used to find to what degree pores are filled with water (D2O) at intermediate stages of loading for four TiC-CDC powders, each with different pore size distributions. We present models to reproduce the SANS data, consisting of subnanometer pores as well as mesopores. In addition, the structure of the room temperature ionic liquid (RTIL) [C4mim]+[Tf2N]- and water confined inside the micropores (< 2 nm) of carbide derived carbon (CDC) were investigated using small angle x-ray scattering (SAXS). This study provides information on the length scales of the CDC porosity, the extent to which RTIL enters micropores, and how confinement affects the charge-ordered structure of the RTIL.
11:27 AM F47.00002: Achieving Fast kinetics and enhanced Li storage capacity for Ti$_3$C$_2$O$_2$ by intercalation of quinone molecules.

EDIRISURIYA SIRIWARDANE (Presenter), Department of Physics and Astrophysics, University of North Dakota, ILKER DEMIROGLU, CEM SEVIK, Department of Mechanical Engineering, Anadolu University, DENIZ ÇAKIR, Department of Physics and Astrophysics, University of North Dakota — In this work, we demonstrated that high Li storage capacity and fast kinetics are achieved for Ti$_3$C$_2$O$_2$ by preintercalating organic molecules C$_6$H$_4$O$_2$ and C$_6$F$_4$O$_2$. As compared to Ti$_3$C$_2$O$_2$ bilayer without linkers, considered pillared structures facilitate a much faster transport and higher charge/discharge rate for Li. For example, while the diffusion barrier of a Li ion within pristine Ti$_3$C$_2$O$_2$ bilayer is around 1.0 eV, it becomes 0.3 eV in pillared structures. Although we can only intercalate one monolayer of Li within pristine Ti$_3$C$_2$O$_2$ bilayer, our calculations showed that at least two layers of Li can be stored between Ti$_3$C$_2$O$_2$ layers of pillared structures, without forming bulk Li and losing the pillared structure upon Li loading/unloading. A small change in the in-plane lattice parameters (<1%) and interatomic bond lengths, and ab-initio molecular dynamics simulations prove the stability of the pillared structures against Li intercalation and thermal effects.

11:39 AM F47.00003: Direct-write Lithiation of Silicon Using a Focused Ion Beam of Li.

WILLIAM MCGEHEE (Presenter), EVGHENI STRELCOV, VLADIMIR OLESHKO, CHRISTOPHER SOLES, NIKOLAI BORISOVICH ZHITENEV, JABEZ J MCCLELLAND, National Institute of Standards and Technology — We report progress in developing Li$^+$ focused ion beams (FIB) as a novel probe for exploring nanoscale electrochemistry in battery-relevant materials. Electrochemical processes involve numerous parallel reactions that complicate our microscopic understanding of these systems, and new tools are needed to probe ionic transport at the level of grain boundaries, interfaces, and single defects. Here, we demonstrate the use of Li$^+$ FIB to direct-write controlled quantities of Li into 35 nm thick crystalline silicon membranes in vacuo at doses from $10^{15}$ cm$^{-2}$ to $10^{18}$ cm$^{-2}$. The concomitant morphological, structural, and functional changes in the implanted silicon are characterized using a combination of electron and scanning probe microscopy. We observe saturation of interstitial lithium in μm-scale implanted regions as well as spill-over of excess lithium on the membrane's surface. Prospects for future work exploring transport across grain boundaries and implantation at higher resolution are discussed.

RAJENDRA JOSHI (Presenter), VERONICA BARONE, Department of Physics and Science of Advanced Materials, Central Michigan University, Mt. Pleasant, MI, 48858, JESSE EICKHOLT, Department of Computer Science, Central Michigan University, Mt. Pleasant, MI, 48858, JUAN ERNESTO PERALTA, Department of Physics and Science of Advanced Materials, Central Michigan University, Mt. Pleasant, MI, 48858 — Data driven machine learning approaches have been increasingly adopted in the materials science community as an efficient alternative to density functional theory calculations to predict the properties of materials. In this work, we show how machine learning can be applied to energy storage materials. In addition, we compare the performance of different machine learning approaches for predicting the future energy storage materials.

12:03 PM F47.00005: Structure-Property of Li-S Nanoparticles via Molecular Dynamics Simulation.

KAH CHUN LAU (Presenter), Physics and Astronomy, California State University, Northridge, CA 91330, USA., YING LI, NICHOLS ANTHONY ROMERO, Computational Science Division and Leadership Computing Facility, Argonne National Laboratory, Lemont, IL 60439, USA. — Lithium-sulfur (Li-S) batteries offer higher energy densities than most reported lithium-ion batteries. However, our understanding of Li-S battery is still largely unknown at the level of the nanoscale. The structural properties of Li-S materials were investigated via molecular dynamics (MD) simulations using the ReaxFF force field. Several Li-S nanoparticles with different Li:S composition ratios and various structures are studied. Our MD simulations show that, among the four structures we constructed for Li$_2$S$_8$ nanoparticles, the core-shell structure is the most thermodynamically stable one during the charging (delithiation) process. In contrast to bulk crystal Li$_2$S, we find the presence of mixed lithium sulfide and polysulfide species are common features for these Li-S nanoparticles. The complex distribution of these sulfide and polysulfide speciation are dictated by both stoichiometry and local atomic structures in the nanoparticle. These findings will provide insight into further development of functionalized lithium-sulfur cathodes.

12:15PM F47.00006: Chemo-mechanical modeling of defective graphene for energy storage in Lithium-Ion Battery
VIDUSHI SHARMA (Presenter), DIBAKAR DATTA, Department of Mechanical and Industrial Engineering, New Jersey Institute of Technology — The process of Li insertion and extraction imparts repeated mechanical loading and unloading of anode materials which ultimately leads to mechanical degradation and battery failure. With the persistent need to model efficient anode materials that can withstand repeated mechanical loading, we have looked into the potential of defective graphene(DG) based 2D materials which have enhanced Li adsorption and good mechanical strength to undergo several cycles of charge-discharge. In this work, we have primarily used grand canonical Monte Carlo and molecular dynamics (GCMC-MD hybrid) to model complete charge and discharge profiles of DG varying from single layer to multilayered systems. Stress distribution upon charge and discharging have been analyzed to predict crack nucleation and propagation. Density Functional Theory (DFT) was used to benchmark our GCMC-MD results. Enhanced adsorption of Li resulted in incomplete desorption during discharging which resulted in decreased over-all charge-discharge cycle stability of the system. Further, inherently having low shear strength, it was determined that the presence of Li atoms significantly affects the overall slippage of one DG over another along with their load-bearing capacity.

12:27PM F47.00007: First-Principles Study of Lithiation of Type I Ba-Doped Silicon and Germanium Clathrates
XIHONG PENG (Presenter), ANDREW DOPILKA, QUN WEI, CANDACE K CHAN, Arizona State University — Si and Ge clathrate materials have recently been investigated for their electrochemical properties as anodes for Li-ion batteries due to their unique cage structures and ability to incorporate extrinsic guest atoms. First-principles calculations were used to investigate the type I clathrate compounds Si_{46}, Li_{x}Ba_{x}Si_{46}, Li_{x}Ba_{x}Al_{6}Si_{40} and Li_{x}Ba_{x}Ge_{43}, for understanding the preferred structures of small degrees of lithiation and Li diffusion paths. The results showed that Li insertion into framework or Ba vacancies could stabilize the clathrate structure. Si substitution by Al lowered the formation energies of the lithiated compounds. For Ba-doped Ge clathrates, it was found that Li insertion into the three framework vacancies in Ba_{9}Ge_{43} is energetically favorable. However, the high energy barrier (1.6 eV) for Li diffusion between vacancies and around Ba guest atoms suggests that framework vacancies are unlikely to significantly contribute to lithiation processes unless the Ba guest atoms are absent. The study elucidated the preferred structural configurations for Li in type I, Ba-doped Si/Ge clathrates and also be informative for efforts related to understanding the structures obtained after electrochemical insertion of lithium into the clathrates.

*NSF DMR-1710017

12:39PM F47.00008: Linear stability analysis of time-dependent electrodeposition in charged porous media
EDWIN KHOO (Presenter), HONGBO ZHAO, MARTIN BAZANT, Massachusetts Institute of Technology — We study the linear stability analysis of time-dependent electrodeposition in a charged porous medium flanked by a pair of planar metal electrodes. Discretization of the linear stability problem results in a generalized eigenvalue problem that is solved numerically. Analytical approximations obtained from a boundary layer analysis valid at high wavenumbers agree well with the full numerical solutions. Under galvanostatic conditions, in the classical case of zero pore surface charges, the voltage and electric field at the cathode diverge when the cation concentration there vanishes at Sand's time. The same phenomenon happens for positive surface charges but at a time earlier than Sand's time. In contrast, negative surface charges allow the electrochemical system to sustain an overlimiting current via surface conduction past Sand's time, keeping the voltage and electric field bounded. Therefore, at Sand's time, negative surface charges greatly reduce the electrode surface instabilities while zero and positive surface charges magnify them. We also use the stability analysis to analyze how using a pulse current in electroplating and metal battery charging reduces diffusion limitations and electrode surface instabilities at high currents in the presence of negative surface charges.

12:51PM F47.00009: Developments in X-ray full-field nano-tomography at the Advanced Photon Source for in situ characterization of battery and fuel cells
VINCENT DE ANDRADE (Presenter), SUNIL BEAN, MICHAEL WOJCIC, FRANCESCO DE CARLO, ALEX DERIY, Advanced Photon Source, Argonne National Laboratory — The Transmission X-ray Microscope (TXM) at beamline 32-ID of the Advanced Photon Source beamline at Argonne National Laboratory has been tailored for high throughput and high spatial resolution in operando nano-tomography experiments. Over the first 5 years of operations, it imposed as a very productive instrument, particularly in the domain of battery research. It benefits from the in-house development of cutting-edge X-ray optics, complex opto-mechanical components and a suite of software including Tomopy and other based on machine learning to push the limit of 3D nano-imaging while reducing total X-ray dose. It operates either with a moderate spatial resolution (40-50 nm) and large field of view (~50 µm) or at very high spatial resolution (16 nm) at a smaller field of view (~10 µm). This presentation will give an overview of in situ experiments on batteries with different kind of cells, as well as our efforts for characterizing low-Z material like Li oxide, black carbon or polymers.
1:03PM F47.00010: Tailoring storage capacity and ion kinetics in Ti2CO2/graphene heterostructures by functionalization of graphene  
DENIZ CAKIR (Presenter), University of North Dakota, CEM SEVIK, Eskisehir Technical University  
— Using first-principles calculations, we evaluated the electrochemical performance of heterostructures made of Ti2CO2 and chemically modified graphene for Li batteries. We found that heteroatom doping and molecule intercalation have a large impact on storage capacity and Li migration barrier energies. While N and S doping do not improve the storage capacity, B doping together with molecule interaction make it possible to intercalate two layers of Li which stick separately to the surface of Ti2CO2 and B-doped graphene. The calculated diffusion barrier energies (E_diff), which are between 0.3 and 0.4 eV depending on Li concentration, are quite promising for fast charge/discharge rates. In addition, the predicted E_diff as much as 2 eV for the diffusion of Li from Ti2CO2 surface to B-doped graphene surface significantly suppress the interlayer Li migration, which diminishes the charge/discharge rates. The calculated volume and lattice parameter changes indicate that Ti2CO2/graphene hybrid structures exhibit cyclic stability against Li loading/unloading. Consequently, the performed first-principles calculations evidently highlight the favorable effect of molecular intercalation on the capacity improvement of ion batteries.

1:15PM F47.00011: Lithium Interaction with Graphene Materials at Finite Temperature  
YUSUF SHAIDU (Presenter), EMINE KUCUKBENLI, STEFANO DE GIRONCOLI, Condensed Matter Physics, International School for Advanced Studies  
— The increasing demand for high energy density lithium ion batteries motivates a search for alternative electrode materials. Experimentally obtained graphene based structures have been suggested to replace the state-of-the-art graphitic anode [1]. We characterized the Li adsorption on graphene both at zero and finite temperatures. The zero temperature study was carried out by means of density functional theory (DFT) accounting for van der Waals interactions while the finite temperature behavior was studied by Monte Carlo techniques with DFT-derived Li-graphene interaction potential constructed via cluster expansion method. At zero temperature, the dispersed Li configurations are unstable with respect to metallic Li. At higher temperatures, entropic effects stabilize lower concentrations with respect to bulk Li while below 400\,K, the formation of 2D Li-clusters is stable over a random distribution of Li. In order to understand the nature of Li interactions with all carbon materials rather than single layer graphene, we are developing an artificial-neural-network based lithium-carbon interaction potential employing Behler and Parrinello symmetry functions[2] as structural descriptors. This will allow a detailed investigation and characterization of Li interaction with these materials.

1:27PM F47.00012: Simulated studies of Li-Mn-O heterostructured nanoparticles on lithiation*  
PHUTI NGOEPE (Presenter), DONALD HLUNGWANI, RAESIBE LEDWABA, Materials Modelling Centre, University of Limpopo, Sovenga, 0727, South Africa  
— Simulated amorphisation and recrystallization (A+R) technique is employed to synthesise Li-Mn-O nanoparticles, particularly those in the range of 3000 atoms, which are amenable to linear scaling DFT methods. The A+R method has been previously successfully used to study nanostructures of MnO2 [1], with composite structures. The discharge cycling process of the nanoparticle was simulated by lithiating the Li-Mn-O composite nanoparticle at different lithium concentrations. Each nanoparticle was characterized by interrogating their radial distribution functions (RDFs) and simulated X-ray diffraction patterns (XRDs). Furthermore, the structural changes with lithiation were visualised and details of various defects, including grain boundaries could be observed from microstructures. The presence of layered and spinel components were also noted and validated by XRDs. In the future, the simulated structures will be used to voltage profiles using linear scaling DFT methods.

*We acknowledge support of the SARCHI of the National Research Foundation, Department of Science and Technology in Pretorua and the Centre for High Performance Computing in Cape Town.
1:39PM F47.00013: Probing Electrical Degradation of Lithium Ion Battery Electrodes with Nanoscale Resolution
SEONG HEON KIM (Presenter), SEONG YOUNG PARK, HEECHUL JUNG, Samsung Advanced Institute of Technology —
The investigation of the electrical conductivity evolution during cycling can lead to a better understanding of the
degradation in electrode materials for Li-ion batteries (LIBs). In this study, we probed the electrical degradation of LIB
electrodes with nanoscale resolution via quantitative and comparative scanning spreading resistance microscopy (SSRM).
First, the electrical degradation of cathode materials, LiNi_{0.8}Co_{0.15}Al_{0.05}O_2 (NCA), was studied [1]. After 300
charge/discharge cycles, stepwise-increasing resistance distributions toward the centers of the secondary particles were
observed. Second, the electrical degradation of LIB anodes, the blended Si-C composites with graphite (Gr) particles, was
investigated using SSRM [2]. From the SSRM measurements, it was obviously demonstrated that the electrical conductivity
of the Si-C composite particles is considerably degraded by 300 cycles of charging and discharging, although the Gr
particles maintain their conductivity. Our approach using SSRM technique can be an effective method to study the
nanoscale electrical properties of various LIB electrode materials.

1:51PM F47.00014: TiSe2 as a Cathode for Multivalent Ion Batteries*
MANUEL SMEU, TAYLOR JURAN (Presenter), Binghamton University — To drive large scale energy storage, it is imperative to investigate the properties of multivalent ion batteries (MVIBs). TiSe_2 cathodes experience electron delocalization in metal-ligand units, a trait shown to improve battery performance. Both TiSe_2 and the Chevrel phase (CP) experience d-p orbital hybridization, suggesting TiSe_2 may demonstrate similar MVIB performance to the CP, an established MVIB cathode. TiSe_2 has been previously studied with a Mg anode, though it was not studied with other multivalent metals, in particular Ca, which has demonstrated superior performance to Mg in some respects. In this computational study, we investigate the intercalation of TiSe_2 with several mono/multivalent ions from the following metal anodes: Li, Na, Mg, Ca, Zn, and Al (with a particular focus on Ca-ion). We used density functional theory methods, including the SCAN functional, to calculate the average voltages for the aforementioned metals paired with TiSe_2. We consider other crucial battery properties, including volume change, diffusion kinetics, material characterization, and stability.

*Supported as part of the Multidisciplinary GAANN fellowship in Smart Energy Materials, a Graduate Areas of National Need, funded by the U.S. Department of Education, Award P200A150135.

2:03PM F47.00015: Infrared Imaging of Batteries During Charging by Magnetic Augmented Rotational System (MARS)
LAILA ALQARNI, VISHWAS DANTHI SHIVARAM, NAVJOT S PANCHHI, SHUANG DUE, New Jersey Institute of Technology, TIEN SEE CHOW, ETD Inc., RAVINDRA NUGGEHALLI M (Presenter), New Jersey Institute of Technology —
Modern-day rechargeable batteries such as lithium-ion based batteries exhibit major benefits over previous iterations. Their longer-useful & higher-cycle life without significant loss of capacity makes them suitable for the current market. Downside, Li-ion batteries require sophisticated voltage management systems to prolong their life and stop thermal runaway. Safety is a major concern for large-scale Li-ion batteries.

In our study, we use Infrared Thermography (IT) to monitor, map and interpret the thermal behavior of batteries during charging/discharging with the electromagnetic contactless gear system that charges the batteries (Magnetic Augmented Rotation System-MARS). Data relating to heat generation and the internal and external heat transfer obtained from IT will be utilized for a detailed analysis of the heat distribution in the system, as well as to identify and locate areas of excess heat.

As increased heating is a signal of non-uniform distribution of charge/failure, infrared is the best diagnostic tool to identify these hot spots in the early stages of degeneration. Experimental and analytical techniques will be used to construct a model for charge transfer and the associated thermal map.
Tuesday, March 5, 2019 11:15 AM - 1:27 PM

Session F48 DFD GSNP: Fluid Mechanics -- General BCEC 251 - Michael Allshouse, Northeastern University

11:15AM F48.00001: Strain rate effects on front propagation in advection reaction diffusion systems*  THOMAS NEVINS (Presenter), DOUGLAS H KELLEY, University of Rochester — The growth of a reactive scalar in a flowing fluid is known as an advection-reaction-diffusion (ARD) system. In this talk I will focus on effects of flow strain rate (deformation) within ARD systems - specifically chemical systems - through experiments measuring front propagation. Fronts in this context are the borders of reacted regions. Fronts are often modelled as moving with velocity equal to the sum of flow and chemical front speed in stagnant fluid. We find strain rate to have profound effects in multiple contexts. For example, I will present how reactive mixing in a two-dimensional (2D) experimental flow does not behave like a 2D ARD system due to strain rate. We also perform experiments on reactions in the presence of straining flows to demonstrate how chemical front speed is altered, how bulk reaction is changed in turn, and how in special situations stirring can actually inhibit reaction. We identify various processes by which shear strain changes front speed, and make predictions about the size of these changes. These results may explain part of why mixing changes reactions and how flow sometimes creates reaction barriers.

*Funded through the Department of Defense National Defense Science and Engineering Graduate Fellowship (NDSEG).

11:27AM F48.00002: Front induced feedback in convective flowfields*  SAIKAT MUKHERJEE (Presenter), Biomedical Engineering and Mechanics, Virginia Tech, MARK RICHARD PAUL, Mechanical Engineering, Virginia Tech — We numerically study the feedback between a propagating front and the underlying flowfield for a range of different parameters. The flowfields are generated by a modified form of the Boussinesq equation, which generates counter rotating convection rolls in a long shallow layer of fluid. The strength of the convection rolls is quantified by the Rayleigh number. In many reaction-advection-diffusion systems, a difference in buoyancy between the products and the reactants creates secondary fluid rolls which interact with the existing convection rolls and affect the velocity and geometry of the propagating front and the underlying flowfield. This roll formed due to the backaction of the front on the flowfield also affects the geometry of the front interface, noticeably making it more tilted and stretched. We quantify the strength of this backaction roll by a quantity called the solutal Rayleigh number, which is related to the ratio of the buoyancy difference between the products and the reactants to the diffusion coefficient of the products. We investigate the interaction of this front induced backaction roll and the convection rolls in two dimensional cellular flow and for three dimensional spatiotemporally chaotic flow.

*Partial support by DARPA Grant No. HR0011-16-2-0033.

11:39AM F48.00003: Coherent Structure Detection using Topological Tools and a Graph Theoretic Approach  CALEDONIA WILSON (Presenter), SPENCER SMITH, Mount Holyoke College — For general aperiodic fluid flows, coherent structures help organize the dynamics, much as invariant manifolds and periodic orbits do for autonomous or periodic systems. The prevalence of such flows in nature and industry has motivated many successful techniques for defining and detecting coherent structures. However, these approaches often require very fine trajectory data to reconstruct velocity fields. Instead, we use topological techniques to help detect coherent trajectory sets in relatively sparse 2D fluid advection problems. More specifically, we use a homotopy-based algorithm, the ensemble-based topological entropy calculation (ETEC), which evolves fluid material curves forward in time as minimal length bands stretched about the moving data points. These bands are represented as the weighted edges of a triangulation, which allows us to analyze flows using graph theoretic tools. In this way, highly connected components of appropriately constructed graphs can be used to partition the fluid particles into coherent trajectory sets.

11:51AM F48.00004: The Phase Diagram of Leaking Flows  HEATHER KURTZ (Presenter), CAROLINE TALLY, KATHARINE JENSEN, Williams College — When a pipe springs a leak, the exiting fluid can either jet away cleanly, dribble down along the surface, or not flow out at all. Past investigations of this “teapot effect” have focused on jetting and dribbling liquid flows separately as functions of initial flow velocity, wetting, and viscosity, but there has been little focus on the transition between flow regimes. In this work, we characterize a liquid leaking from a small hole as the flow transitions from jetting to dribbling, and dribbling to no flow. We map the phase diagram of these leaking flow transitions as a function of hydrostatic pressure and pipe tipping angle, and investigate the contributions of fluid viscosity, hole size, and surface wetting to the boundaries on this phase diagram.
12:03PM F48.00005: Ensemble-based Topological Entropy Calculation in Three Dimensions  ERIC ROBERTS (Presenter), SUZANNE SINDI, University of California, Merced, SPENCER SMITH, Mount Holyoke, KEVIN MITCHELL, University of California, Merced — Topological entropy measures the number of distinguishable orbits in a dynamical system, thereby quantifying the complexity of chaotic dynamics. Such knowledge aids greatly in a wide variety of natural and industrial fluid systems, including the rapidly developing field of microfluidics and the large-scale dispersion of pollutants in the Earth's atmosphere and oceans. We introduce a computational geometry framework for estimating a three dimensional flow's topological entropy from the collective motion of an ensemble of system trajectories. This work is analogous to the entropy calculation extracted from the "braiding" of system trajectories in two dimensions and is a first step towards building a triangulation-based method for computing topological entropy from an ensemble of trajectory data in three dimensions and higher. In it, we consider a two-dimensional rubber sheet stretched around a collection of points in a three-dimensional flow. A 3D triangulation may be used to track point-face or edge-edge collisions and the rubber sheet may be chosen as one of the faces in the initial triangulation. As the points evolve in time, they carry the sheet along with them, stretching and folding it so that its growth reflects the flow complexity.

12:15PM F48.00006: Uncertainty quantification in Lagrangian clustering analysis  GUILHERME SALVADOR VIEIRA (Presenter), MICHAEL ALLSHOUSE, Mechanical Engineering, Northeastern University — Partitioning ocean flows into regions that minimally mix with their surroundings can identify materially coherent vortices and assist in search and rescue planning by reducing the search domain. One method for such partitioning is the Lagrangian clustering analysis, which identifies sets of trajectories that move as a compact set. This method has been applied to deterministic, chaotic systems, revealing underlying transport barriers. For ocean models, however, in addition to the complex dynamics, there are several sources of uncertainty, such as model initialization and parameters, limited knowledge of oceanographic processes, and ocean boundary conditions and forcing. Therefore, the Lagrangian clustering analysis, when applied to ocean forecasts, should incorporate uncertain parameters and the resulting coherent structures should be robust to model uncertainty. Through application to a geostrophic flow, we present an investigation of the sensitivity of the spectral clustering method to uncertain parameters and an approach for applying this method to an ensemble of simulations.

12:27PM F48.00007: Lubricated motion in an elastic tube*  MARIE TANI, Tokyo Metropolitan University, THOMAS CAMBAU, JOSE BICO, ESPCI, PMMH, ETIENNE REYSSAT (Presenter), CNRS-ESPCI, PMMH — The motion of objects through elastic constrictions is relevant to various problems in physiology and biology. We describe a model experiment where a rigid sphere is displaced through a narrower elastic tube. Lubricating the contact with a fluid significantly reduces friction on the wall of the tube. The friction force increases as the sliding velocity to the power 1/3 and depends on the fluid viscosity, mechanical properties of the tube and geometric mismatch. We derive a scaling law and a minimal numerical model to account for our experimental data.

*We thank JSPS for funding Marie Tani.

12:39PM F48.00008: A Random Choice SPH Scheme with Adaptive Viscosity*  ZHIXUAN CAO (Presenter), FBU (Fluids Business Unit), ANSYS Inc., ABANI K PATRA, Department of Mechanical and Aerospace Engineering, State University of New York at Buffalo, E. BRUCE PITMAN, Department of Materials Design and Innovation, The State University of New York at Buffalo — Classical smoothed particle hydrodynamics (SPH) method employs explicit artificial viscosity, which typically produce more dissipation than need, incorrectly smears contact discontinuities and overwhelms fluid turbulence. Several studies have proposed highly tuned versions of artificial viscosity, turning on and off near shocks or other troublesome wave features. A different scheme adapts Godunov's idea of solving local Riemann problems as building blocks for SPH solver. However, these methods still introduce an effective numerical diffusion that can infect the entire numerical solution. We propose a new SPH scheme that combines an approximate version of Glimm's Random Choice method (RCM) with SPH. Our version approximately resolves hydrodynamic waves, and samples the approximate solution without explicit artificial viscosity. Several attractive features of this method is demonstrated by 1D shock tube tests. First, this method introduces adaptive artificial viscosity, assigning larger dissipation near discontinuities and smaller elsewhere. Secondly, it is less dissipative than classical SPH and GSPH resulting in less smearing of shock. Thirdly, this method also ameliorates pressure ``wiggle" around contact discontinuity.

12:51PM F48.00009: Dimensionality reduction of convection-dominated flows on an optimally morphing grid
RAMBOD MOJGANI (Presenter), MACIEJ BALAJEWICZ, University of Illinois at Urbana-Champaign — Foundations and preliminary results of a new projection-based model order reduction approach are summarized. The method is specifically designed for convection dominated nonlinear fluid flows. In this method, the evolution of the flow is approximated on an optimally morphing grid. The low-rank grid deformation, a solution of an optimization problem, is generated in such a way that the low-dimensional representation of the states on this morphing grid has lower error when compared to traditional POD on an Eulerian grid. Global basis functions are used to approximate the state variables on the low-rank grid. It is demonstrated that in this framework, certain wave-like solutions exhibit low-rank structure and thus, can be efficiently compressed using relatively few global bases. The proposed approach is successfully demonstrated for the reduction of several representative 1D and 2D problems, featuring nonlinearities, and bi-directional waves with different boundary conditions and is compared with the traditional method on the Eulerian grid.

1:03PM F48.00010: An Exact Simple Solution of the Compressible Navier-Stokes Equation*
AMADOR MURIEL (Presenter), Natural Science Research Institute —
We display a simple exact solution of the compressible Navier-Stokes equation without an external field. The field velocities and density are:

\[ v_x = n_0 v_{x_0} \exp[-a((x-v_{x_0} t)^2+(y-v_{y_0} t)^2+(z-v_{z_0} t)^2)] \]
\[ v_y = n_0 v_{y_0} \exp[-a((x-v_{x_0} t)^2+(y-v_{y_0} t)^2+(z-v_{z_0} t)^2)] \]
\[ v_z = n_0 v_{z_0} \exp[-a((x-v_{x_0} t)^2+(y-v_{y_0} t)^2+(z-v_{z_0} t)^2)] \]
\[ n = n_0 \exp[-a((x-v_{x_0} t)^2+(y-v_{y_0} t)^2+(z-v_{z_0} t)^2)] \]

where all variables are defined and explained in A. Muriel, Results in Physics 6, 461 (2016) or ResearchGate, amadormuriel@gmail.com. The pressure tensors are calculable from the above field velocities using the Navier-Stokes equation itself. The density, the field velocities and the derivable pressure tensors constitute the simplest exact solution to date of the Navier-Stokes equation. We invite readers to check the self-consistency of the solution. The origin of this solution, as well as others, will be explained and illustrated. Surprisingly, this simple solution meets all stipulations of the problem definition by the Clay Institute of Mathematics. This solution is valid for a compressible fluid instead of an incompressible fluid required by the Institute.

*We acknowledge the Balik Scientist Program of DOST, Philippines for its support.

1:15PM F48.00011: Bottom up lattice Boltzmann: the path from Molecular Dynamics to lattice Boltzmann methods
ALEXANDER WAGNER (Presenter), M. REZA PARSA, North Dakota State University, ALEKSANDRA PACHALIEVA, Mechanical Engineering, TU Munich — We show how lattice Boltzmann simulations can be understood as a coarsegraining and averaging of Molecular Dynamics simulations. Typically lattice Boltzmann methods are verified by analyzing the hydrodynamic limit of the method. It is known that this approach is not sufficient for several kinds of application. In contrast, our approach allows to bottom up derivation of lattice Boltzmann methods, and gives guidance for the design of lattice Boltzmann (or lattice gas) methods for fluctuating and/or non-ideal systems and gives an alternative path to compare competing collision operators and equilibrium distributions as well as forcing terms currently used and gives a fundamental test of what the correct form of these terms is.

Session F49 DPOLY: Advanced Morphological Characterization of Polymer III: Anomalous Soft X-ray Scattering BCEC 252A - Cheng Wang, Lawrence Berkeley Natl Lab - Tag(s): Focus
11:15AM F49.00001: Critical-Dimension Grazing-Incidence Small Angle X-Ray Scattering: Applications using Soft, Tender and Hard X-Rays*  GUILLAUME FREYCHET (Presenter), DINESH KUMAR, ISVAR CORDOVA, RONALD J PANDOLFI, PATRICK NAULLEAU, CHENG WANG, ALEXANDER HEXEMER, Advanced Light Source, Lawrence Berkeley National Laboratory — As the lithographically manufactured nanostructures are shrinking in size, conventional techniques, such as microscopies (SEM, AFM) reach their resolution limits. We have developed a high performance Grazing Incidence SAXS simulation tool to reconstruct the in-depth profile highly ordered material such as line gratings [1]. Here, we will present the latest development and applications of the technique using hard x-rays on line gratings and contact holes. Moreover, the CD-GISAXS approach was extended to study line edge roughness, latent images [2] and lamellae structure of diblock copolymers, taking advantage of the full energy range provided at the advanced light source and more specifically of the chemical sensitivity provided by soft and tender x-rays scattering.

11:27AM F49.00002: Label-free measurement of core-shell Pluronic F127 Micelle nanostructure determined using in-situ Resonant Soft x-ray Scattering*  TERRY MCAFEE (Presenter), ISVAR CORDOVA, Advanced Light Source, Lawrence Berkeley National Laboratory, THOMAS FERRON, Physics & Astronomy, Washington State University, CHENG WANG, Advanced Light Source, Lawrence Berkeley National Laboratory, BRIAN COLLINS, Physics & Astronomy, Washington State University — Micelles are key to many applications such as drug delivery, and their size, shape and internal molecular conformation are of critical importance to their performance. By having both hydrophobic and hydrophilic monomer groups, polymers like Pluronic F127 self-assemble into spherical core-shell structures called Micelles. However, confirming the structural parameters, in particular conformation, is difficult if not impossible to date. Here we demonstrate a novel technique capable of such measurements based on Resonant Soft X-ray Scattering (RSoXS), which is uniquely sensitive to bond orientation and capable of probing organic materials using their intrinsic chemical structure for contrast manipulation rather than laborious and potentially disruptive isotopic labeling that is required in techniques such as neutron scattering. Like electron microscopy, RSoXS requires a high vacuum environment. By adapting a Poseidon Protochips TEM holder for use at BL11.0.1.2 of the Advance Light Source, we show that RSoXS can now be performed in in-situ/operando environments, allowing sample structure and interactions to be measured in the same conditions/environment as the intended application.

11:39AM F49.00003: Correlating anisotropy in polarized resonant soft X-ray scattering of block copolymer active layers with organic photovoltaic device performance  JOSHUA LITOFSKY (Presenter), ENRIQUE D GOMEZ, Pennsylvania State University — The use of Resonant Soft X-ray Scattering (RSoXS) allows the study of domain spacing and molecular orientation of conjugated polymers in the active layer of organic photovoltaics through tuning of the X-ray energy and polarization. Using the conjugated block copolymer system of poly(3-hexylthiophene) with acceptor blocks poly(fluorene-alt-dithienylbenzothiadiazole), (PFTBT), poly(carbazole-alt-dithienylbenzothiadiazole) (PCDTBT), and poly(phenylene-alt-dithienylbenzothiadiazole) (PPDTBT), along with alkyl side chain-added analogs PFT6BT, PCT6BT, and PPT6BT, we can examine the effects that morphological changes have on electronic device performance. The addition of hexyl side chains to the acceptor blocks decrease the degree of molecular order, as measured by the scattering anisotropy from RSoXS. This anisotropy has been shown to define the strength of alignment of chains with respect to the block copolymer interface within nematic domains, and can be used to directly compare long-range order between polymers. Based on our early findings, we believe that suppression of the long-range order is directly related to lower fill factors and lower device efficiencies. Studies into the charge carrier mobilities and crystallinity support these findings across the polymer systems.
11:51AM F49.00004: Advanced characterization of molecular nanostructures and interfaces with resonant X-ray scattering* [invited] BRIAN COLLINS (Presenter), Washington State University — Emergent properties within molecular materials are determined by their nanoscale ordering, in particular at interfaces. This has revealed a potential for their use in drug delivery, printable electronics, and bottom-up nano-assembly if their ordering can be controlled. A major roadblock is the lack of nanoprobes that can precisely characterize ordering within these delicate materials that contain light elements, 3D structures, and low crystallinity. I will discuss recent progress in developing a new class of measurements based on X-rays resonant with molecular transitions to enable quantitative characterization of molecular order. Resonant soft X-ray scattering (RSoXS) combines polarized spectroscopy with scattering, enabling sensitivity to bond type and orientation — similar to ellipsometry and Raman spectroscopy but with higher spatial resolution. Contrast variation can be achieved by tuning the photon energy — similar to deuteration in neutron scattering but without the need of laborious and disruptive chemical labelling. I will highlight our recent progress in developing quantitative RSoXS analyses for characterizing molecular interfaces as well as ordering within and between nanostructures. In particular, the ability of polarized RSoXS to measure local molecular orientation even in polydisperse 3D matrices is not possible with any other technique. I will also touch on our work in developing a new instrument to measure structural evolution of solvated nanoparticles and operando electrochemical processes. As RSoXS continues to mature, it will enable increased understanding and control of molecular and hybrid nanostructures resulting in revolutionary new technologies based on these novel materials.

*DOE Early Career Award, NSF Major Research Instrumentation

12:27PM F49.00005: Probing Molecular Orientation using Polarized Resonant Soft X-ray Reflectivity* JACOB THELEN (Presenter), National Institute of Standards and Technology, CAMILLE BISHOP, University of Wisconsin - Madison, DANIEL SUNDAY, ELIOT H GANN, National Institute of Standards and Technology, MARK EDIGER, University of Wisconsin - Madison, DEAN DELONGCHAMP, National Institute of Standards and Technology — Charge transport in organic semiconducting films is inherently anisotropic: it depends on the orientation and packing of the molecules, which in turn are influenced by molecular structure and film processing conditions. A technique capable of non-destructively depth-profiling molecular orientation with (sub)nanometer-level depth resolution would enable a significant improvement in the understanding of structure-property-processing relationships in organic semiconductor devices. We explore the feasibility of using polarized resonant soft X-ray reflectivity (p-RSoXR) as a tool to profile molecular orientation by studying a model set of glassy small molecule (posaconazole) films with different net orientations. By comparison with variable angle spectroscopic ellipsometry (VASE) and near edge X-ray absorption fine structure (NEXAFS) data, we show that p-RSoXR is sensitive to both surface and bulk molecular orientation in the films. We conclude by demonstrating our approach to extracting orientation profiles from p-RSoXR data, as well as discussing the current strengths and limitations of the technique.

*J.L.T. was supported by a National Research Council (NRC) postdoctoral fellowship at the National Institute of Standards and Technology (NIST).

12:39PM F49.00006: Effects of Confinement on the Structure of Bottlebrush Polymers in Thin Films DANIEL SUNDAY (Presenter), National Institute of Standards and Technology, ALICE CHANG, Chemistry and Chemical Engineering, California Institute of Technology, MOSHE DOLEJSI, PAUL F NEALEY, Institute for Molecular Engineering, University of Chicago, ROBERT H GRUBBS, Chemistry and Chemical Engineering, California Institute of Technology, R. JOSEPH KLINE, National Institute of Standards and Technology — Bottlebrush block copolymers (BCPs) have intriguing potential in nanopatterning and photonics applications as they lack entanglements and can rapidly assemble. As a result, bottlebrush BCPs can self-assemble with periodicities over 100 nm, a length scale which is challenging to achieve with linear BCPs. Nanopatterning applications will require confinement of bottlebrush BCPs in thin films, where their behavior is still poorly understood. The assembly of bottlebrush BCPs of polystyrene-b-poly(lactic acid) (PS-b-PLA) in thin films was studied using a combination of techniques. Blade coating was used to produce a controlled thickness gradient so that the impact of the thickness/periodicity ratio can be studied. The resulting structures were evaluated using a combination of atomic force microscopy (AFM), grazing incidence X-ray scattering (GISAXS) and resonant soft X-ray scattering (RSoXS). The effects of solvent and annealing conditions on the resulting morphologies was also explored.
Improving Optical Models of Polarized R-SoXS for Quantitative Measurement of Molecular Orientation within Polymer Nanostructures

VICTOR MURCIA (Presenter), Materials Science and Engineering, Washington State University, BRIAN COLLINS, Physics and Astronomy, Washington State University — Resonant soft X-ray scattering (RSoXS) with polarized X-rays is sensitive to local molecular orientation within nanostructures but it is difficult to interpret the scattering patterns due to a lack of appropriate optical models. Uniaxial optical tensors have been used successfully to measure average global molecular orientation in X-ray absorption spectroscopy (XAS) and ellipsometry. The model reduces into diagonal tensors whose elements correspond to parallel and perpendicular alignments of the incident electric field with respect to the transition dipole moment. It is uncertain, however, if such a model will work in polarized RSoXS as it assesses differences in local ordering. We show how to create such a model using XAS measurements and test it against polarized RSoXS measurements on pure films of a semicrystalline conjugated polymer. We show the model works for the pi* resonances but breaks down in regions that include other transitions. DFT calculations demonstrate how not all transitions follow uniaxial symmetry and require a lower symmetry model to reproduce measurements. Combining XAS and DFT into such a new model may enable further details of local molecular orientation to be extracted by pol-RSoXS that remove current limitations of XAS.

*DOE Career Award DE-SC0017923

Characterization of ion distribution around the surface of micelles under high salt conditions using small angle neutron scattering and resonant soft x-ray scattering

HANQIU JIANG (Presenter), GREG BEAUCAGE, KARSTEN VOGTT, University of Cincinnati — Surfactants can self-assemble into micelles once reaching critical micellar concentration. Industrially, high concentration of inorganic salts are frequently employed as additives for surfactant systems to depress the CMC of the system, enhance further growth of micelle and eventually alter the rheological behavior of targeted systems. Although frequently employed in commercial surfactant products and in biological systems, little was known about how ions behave around these aggregates under high salt condition. An ion cloud model was recently developed based on the screening effect observed in small angle neutron scattering for the high salt condition. To verify this model, resonant soft x-ray scattering was performed by setting the energy of the incident x-ray close to the absorption edge of Cl atom, which allows the manipulation of the scattering length density. The scattering contribution of the ion cloud layer can thus be obtained through the subtraction of scattering curves measured at different energies. This also allows verification of the forcefield and other protocols applied in micelle simulations and enhance the predictability of micelle behavior.

Elucidating microphase separation in perfluoropolyether triblock copolymers using scattering techniques

DEEP SHAH (Presenter), University of California, Berkeley, KEVIN OLSON, University of North Carolina, Chapel Hill, XIUHONG LI, BRUCE ALLEN GARETZ, New York University, SUE MECHAM, JOSEPH M. DESIMONE, University of North Carolina, Chapel Hill, NITASH BALSARA, University of California, Berkeley — Short chain perfluoropolyether (PFPE) polymers have recently been shown to conduct and solvate lithium salts, and thus can be used as homopolymer electrolytes for battery applications. In an attempt to improve the transport characteristics, poly(ethylene oxide) (PEO) has been covalently bonded to the ends of PFPEs to form triblock copolymers of type A-B-A. By increasing the lengths of the PEO segments, the segregation strength of the copolymers increases; at the highest PEO molecular weight, the copolymers microphase separate. While phase separation was not immediately apparent using small angle X-ray scattering (SAXS), measuring birefringence with depolarized light scattering (DPLS) allows for the conclusion of phase separation. The Flory-Huggins interaction parameter between PEO and PFPE was calculated to determine the segregation strength as a function of salt concentration. This work provides thermodynamic data on the interactions between non-fluorinated end-groups and fluorinated backbones.
1:27PM F49.00010: Stability of Complex Spherical Packing Phases in Low-Molecular-Weight Diblock Copolymers
JIAYU XIE (Presenter), CHI TO LAI, ANCHANG SHI, McMaster University — Block copolymers are known for their ability to self-assemble into an array of ordered structures. Of special interest are the spherical packing phases due to their similarity to the atomic crystals. Until the past decade, the packing arrangement was believed to be primarily body-centered cubic for diblock copolymers. However, recent experimental and theoretical studies have revealed the emergence of various complex spherical phases including the Frank-Kasper phases. Qualitatively, the agreement between experimental and theoretical phase behaviour of diblocks is remarkable. On the other hand, quantitative differences still exist. These discrepancies could be due to numerous factors, such as polydispersity and the non-Gaussian nature of low-molecular-weight polymers used in experiments. In this work, we examine the formation of complex spherical phases for low-molecular-weight polymers with conformational asymmetry. Using the self-consistent field theory applied to freely-joint polymer chains, we model the conformational asymmetry by a difference in the bond lengths of the A and B blocks. Our results indicate that, consistent with the experiments, the inclusion of polydispersity and short-chain statistics leads to a shift of the phase boundaries between different ordered phases.

1:39PM F49.00011: Effect of Free-Volume Holes on Dynamic Mechanical Properties of Epoxy Resins for Carbon-Fiber-Reinforced Polymers Studied by Positron Annihilation* HONGJUN ZHANG (Presenter), SELVAKUMA SELLAIYAN, T. KAKIZAKI, AKIRA UEDONO, Division of Applied Physics, Faculty of Pure and Applied Science, University of Tsukuba, Y. TANIGUCHI, K. HAYASHI, Epoxy Resin Materials Center, Nippon Steel & Sumikin Chemical Co. Ltd. — We studied the effect of free-volume holes on dynamic mechanical properties (storage modulus $E'$, loss modulus $E''$, damping factor $\tan \delta$, and complex viscosity $|\eta^*(T)|$) for six types of amine-cured epoxy resins with different chemical structures. Positron annihilation lifetime (PAL) experiments were applied to determine the free-volume hole properties of each sample. The correlations between hole fraction and dynamic mechanical parameters were studied by Williams-Landel-Ferry equation. In the temperature range of $T_g(PAL) < T < T_g(PAL)+100$ °C ($T_g$ given by PAL experiments), regular variations of dynamic mechanical parameters with increasing relative hole fraction $(1-h_{PAL}@T)/h_{PAL}$, where $h_{PAL}$ is the hole fraction from PAL experiments, and $h_{PAL}@T_{ref}$ is the $h_{PAL}$ at reference temperature $T_r$ are revealed: (1) $\log[E'(T)]$ and $\log[|\eta^*(T)|]$ initially decrease linearly and then remain nearly unchanged; (2) $\log[E''(T)]$ and $\log[\tan \delta(T)]$ initially increases linearly and then decreases linearly. In this work, PAL spectroscopy provided precious quantitative information of free-volume holes in polymers [1].

1:51PM F49.00012: Effect of temperature on thermal conductivity of aligned amorphous polyethylene - Molecular Dynamics study RAJMOHAN MUTHAIAH (Presenter), JIVTESH GARG, University of Oklahoma — The effects of temperature dependence of the thermal conductivity ($k$) of chain-oriented amorphous polyethylene (PE) using Molecular Dynamics Simulation. We found that the temperature corresponding to a peak $k$ progressively decreases by increasing the levels of orientation. Un-oriented PE exhibits the peak $k$ at 350K, while aligned PE under an applied strain of 400% shows a maximum at 100K. This transition of peak $k$ to lower temperatures with increasing alignment is explained in terms of a crossover from disorder to anharmonicity dominated phonon transport in aligned polymers. The disorder in the polymer chain is manipulated to support this crossover corresponding to peak $k$. Disorder is controlled through a change in the dihedral parameters of the potential function, allowing a change in the relative fraction of trans and gauche transformations. The results shed light on the underlying thermal transport processes in aligned polymers and hold importance for low temperature applications of polymer materials in thermal management technologies.
**11:15AM F50.00001: Emergence of large-scale chirality in photonic crystals in insects and butterflies** [Invited] GERD SCHROEDER-TURK (Presenter), School of Engineering and IT, Murdoch University — The biological world is filled with chiral structures, formed from a soup of building blocks that usually include both achiral and chiral molecules. In this talk, I will focus on chiral structures that emerge at the scale of hundreds of nanometers in solid insect nanostructures, and that then act as biophotonic crystals. Of particular interest in this context are the Gyroid nanosolids that form in several butterflies, as highly ordered 3D network-like porous materials, and which then contribute in particular to green coloration. I will review in particular what we understand (and not understand) about the formation of these structures; in this context, the fortuitous discovery of a butterfly nanostructure in Thecla Opisena is noteworthy. It appears to show a time-frozen snapshot of various stages of the formation which allows us to infer properties of the formation from high-resolution electron and X-ray tomography images.

**11:51AM F50.00002: Chiral Gyroidal Thin Films from Block Copolymer Self-Assembly as Structural Directing Templates for Fabrication of Mesostructured Crystalline Inorganic Materials** QI ZHANG, FEI YU (Presenter), ULRICH WIESNER, Cornell University — It has always been a challenge to fabricate crystalline materials with well-defined mesopores, which could find applications in microelectronics and catalysis. Block copolymer self-assembly offers a scalable, facile pathway to intricate mesostructures. We present on the use of amphiphilic triblock terpolymer co-assembly with additives to prepare high-temperature stable, mesoporous thin-film templates with chiral alternating gyroid structures (G^A). This mesoscale chirality emerges from the calcination and preservation of only one of the interpenetrating G^A domains and is inaccessible via conventional top-down approach. The resulting mesoporous molds can be backfilled with a wide range of inorganic materials to direct their mesostructures. Upon melting via transient laser heating on the nanosecond time scale, crystallized materials conformally fill the 3D continuous mesopores and inherit the chirality, without destroying the underlying template. Template removal yields mesoporous, crystalline inorganic materials, with optional epitaxy on the substrate.

*We thank the National Science Foundation (DMR-1707836) for funding support. This work made use of the Cornell Center for Materials Research Shared Facilities, Cornell NanoScale Facility, and the Cornell High Energy Synchrotron Source.

**12:03PM F50.00003: New Spontaneously Chiral 3D Network Structures in Thermotropic Liquid Crystals** GORAN UNGAR (Presenter), Xian Jiaotong University, HUANJUN LU, YAXIN LI, XIANG-BING ZENG, Materials Science and Engineering, University of Sheffield — Spontaneous mirror symmetry breaking has been discovered recently in bicontinuous cubic phases [1], as well as in a special isotropic melt phase [2] of achiral rod-like mesogens. While the double gyroid Ia-3d phase is always achiral, the triple network cubic, previously given the Im-3m spacegroup, is always chiral. More recently in such compounds another chiral phase was found [3], turning out to be the so-called “SmQ”. This phase has previously been found only in enantiopure chiral compounds, and its structure was unclear. Now we find that it is also bicontinuous, with two isochiral networks of orthogonal twisted columns [3]. We have also re-examined the triple-network phase; due to its now recognised chirality, a new lower-symmetry spacegroup is assigned, resulting in a new structural model, still a triple network. It thus turns out that all known bicontinuous phases formed by transverse-lying rods in networks segments feature induced chirality, which is cancelled only in the racemic double gyroid.

*Financial support from EPSRC (EP-P002250) is acknowledged.

**12:15PM F50.00004: Self-assembly of chiral networks in achiral block copolymer systems using coarse-grained simulations** POORNIMA PADMANABHAN (Presenter), NATALIE BUCHANAN, KRYSSIA BROWKA, Rochester Institute of Technology — Ordered network materials, such as the double gyroid, are comprised of two interwoven networks embedded in a matrix and can be formed via the self-assembly of block copolymers. Using a triblock copolymer, one can form an alternating gyroid thereby breaking network symmetry and resulting in a structurally chiral morphology. In this talk, we investigate the self-assembly of model achiral block copolymers into gyroid morphologies using coarse-grained molecular simulation. By co-assembling with a selective homopolymer, the thermodynamic stability of the morphology is further improved. The geometric topology is quantified, and the effect of varying volume fraction on net chirality is explored.

*Kate Gleason College Fund
**12:27PM F50.00005: Chirality from segments to domain shapes in ordered block copolymer networks**  
ABHIRAM REDDY (Presenter), ISHAN PRASAD, GREGORY GRASON, University of Massachusetts Amherst — Multi-continuous structures offer an attractive route to devise functional materials where three dimensional microphase geometry can influence transport, mechanical, and optical properties. BCPs, assemble into a variety of such network phases, provide the ability to tune the properties of the network structures. Recently, it has been shown that underlying the inhomogeneous spatial density profiles of BCP domains, are intra-domain segment orientation textures that couple to the domain geometry. Here, we will quantify chirality at different length scales in these self-assembled systems and ask specifically what is the coupling of domain geometry on local segment twist. To this effect, we define two measures of chirality at global (inter-node dihedral rotation at the network scale) and local (cholesteric ordering at segment scale) and study their correlation in network morphologies self-assembled from ABC terpolymers. We use SCFT to show how these chiral order parameters change upon varying volume fraction, interblock repulsion and network symmetry. This study forms the basis to understand the thermodynamics of chirality transfer from chiral interactions at the segment scale to controllable chiral network symmetries at the mesodomain scale.

*Work supported by the Brandeis NSF MRSEC

**12:39PM F50.00006: Lyotropic Liquid Crystals: The Emergence of Chiral Structures**  
MOHAN SRINIVASARAO (Presenter), School of Materials Science and Engineering, and School of Chemistry and Biochemistry, Georgia Institute of Technology, KATHIK NAYANI, JUNG OK PARK, JINXIN FU, RUI CHANG, School of Materials Science and Engineering, Georgia Institute of Technology — Crystallization of tartrates by Pasteur provided the first glimpse of spontaneous mirror-symmetry breaking, and that led to the foundation of stereochemistry as a discipline. A consequence of mirror-symmetry breaking is optical activity, and since the time of its discovery by Biot in the early 1800s, has fascinated scientist. Since those early studies, the appearance of macroscopic chirality from both chiral and achiral molecules has been of interest. In this talk, we discuss the appearance of macroscopic chiral structures from a class of liquid crystals, referred to as lyotropic liquid crystals under various conditions.

**12:51PM F50.00007: A different kind of Lyotropic Liquid Crystalline Phase: The case of Orange-II and gamma-Cyclodextrin**  
GERMANO IANNACCHIONE (Presenter), Physics, Worcester Polytechnic Institute, JUNG OK PARK, MOHAN SRINIVASARAO, School of Materials Science and Engineering, Georgia Institute of Technology — Liquid crystallinity, either thermotropic or lyotropic, arises from species which are either rod or disk shaped. Lyotropic systems occur when an asymmetrically shaped species is dissolved in a solvent at a concentration high enough to force the formation of an anisotropic phase. For either case, the asymmetrically shaped species can be built solely from covalent bonds, where no additional assembling process is required for the species to have an appropriate aspect ratio. Here, we report on the formation of a different kind of lyotropic liquid crystal formed by the non-covalent association of two species, g-cyclodextrin and a dye molecule, Orange II, in water as the solvent. This system is different in that it requires two different compounds that self-assemble to build a larger species with geometrical asymmetry. In an effort to understand the complexation and the formation of the liquid crystalline phase, we present data on UV-Visible spectra, conductometric titrations, fluorescence spectroscopy as well as heat capacity measurements on the formation of the anisotropic structure in water solutions. The studies point to a stoichiometry of 2 dye molecules per g-cyclodextrin, that eventually form a rodlike entity, giving rise to the formation of a liquid crystalline phase.

**1:03PM F50.00008: Microdomain morphology, curvature and twist in colloidal membranes of bidisperse rod mixtures**  
DOUGLAS HALL (Presenter), University of Massachusetts Amherst, JOIA MILLER, Brandeis University, JOANNA ROBASZEWSKI, University of California, Santa Barbara, MICHAEL F HAGAN, Brandeis University, ZVONIMIR DOGIC, University of California, Santa Barbara, GREGORY GRASON, University of Massachusetts Amherst — Long and short rod-like viral particles condense into a single-layer membrane driven by a dextran depletant. The organization of the micron-sized rods is more easily probed experimentally than nanometer scale structures in phospholipid membranes, yet both systems are described by liquid crystalline models. In the colloidal membrane system, rods microphase separate and form circular raft domains with self-limiting domain size in equilibrium, much larger than the range of rod-rod interactions. Recent experimental evidence shows that the intra-membrane domain boundaries discriminate between long-rod and short-rod sides, so that short-rod rafts twist significantly more than long-rod rafts. Also, long-rod rafts are unstable to asymmetric and concave morphologies. We develop a model to describe the microstructure and thermodynamic effects of the intra-rod domain edge, and we predict a thermodynamic coupling between domain edge curvature and rod-tilt. This coupling is achiral and distinct from the aspects of raft formation previously captured by a chirality driven model. We argue that this curvature/tilt coupling should exist in any model of phase-separating membranes as a coupling between in-plane tilt and second-derivatives of composition.

*Work supported by the Brandeis NSF MRSEC
**1:15PM F50.00009: Microphase Separation and Stability of Chiral Rafts in Colloidal Membranes**
CHAITANYA JOSHI (Presenter), JOIA MILLER, ARVIND BASKARAN, Physics, Brandeis University, GREGORY GRASON, Polymer Science and Engineering, University of Massachusetts Amherst, ZVONIMIR DOGIC, Physics, University of California, Santa Barbara, MICHAEL F HAGAN, APARNA BASKARAN, Physics, Brandeis University — Colloidal membranes are an experimental system composed of rod-like chiral particles that are driven by depletion interactions to self-assemble into one-rod-length thick monolayers. Their large size enables the study of behaviors that cannot be visualized in lipid bilayers, as they are described by the same continuum theory. Membranes formed from a mixture of short right-handed rods and long left-handed rods exhibit microphase separation, wherein one rod species forms finite-sized rafts floating in a background membrane of the other rod species. This system exhibits complex membrane-mediated interactions between rafts, which depend on the depletant concentration and the chirality of the rods. In this talk I will present a Ginzburg-Landau theory that explains the existence and interactions of rafts. Consistent with recent experiments, we find that decreasing the background chirality allows rafts to form with either right-handed (in the direction preferred by chirality) or left-handed (counter to the preferred direction) twist. Further, pairs of like-twisted rafts have repulsive interactions, while pairs of oppositely-twisted rafts have attractive interactions. The theory allows for a mechanistic understanding of these behaviors.

**1:27PM F50.00010: Light-Matter Interactions of Chiral Inorganic Nanomaterials**
NICHOLAS KOTOV (Presenter), University of Michigan — The studies of photonics phenomena in chiral inorganic nanoparticles (NPs) encompass sophisticated nanoscale constructs from metals, semiconductors, ceramics, and nanocarbons with multiple chiral geometries with characteristic scales from Ångströms to microns. What drives the rapid development of this field are the uniquely high values of optical anisotropy are attributed to resonances of incident electromagnetic radiation with plasmonic and excitonic states typical for metals and semiconductors as well as resonant states. Distinct similarities between the geometries and light-matter interactions involving chiral supramolecular and biological systems can also be traced. The analysis of these similarities with known biological, supramolecular, and liquid crystalline materials help us understand in greater depth the role of chiral asymmetry in Nature and accelerate the development of technologies based on chiroplasmonic, chiroexcitonic, and chirmagnetic effects. Technological prospects of chiral inorganic materials with current front-runners being biosensing, chiral catalysis, polarization optics and chiral photonics will be discussed in this talk.

**1:39PM F50.00011: Exploiting shape to control percolation of grain boundaries in packings of ellipsoids on curved surfaces**
ZHAOYU XIE (Presenter), TIM ATHERTON, Tufts University — Packings of hard objects provide insights into the properties of crystals, glasses and granular media. When the packing occurs on a curved surface, it requires defects to accommodate the curvature. For identical spheres packed on a spherical surface, the packings are largely crystalline with grain boundaries or “scars”, while for sufficiently polydisperse spheres the packings typically form an amorphous state. We recently showed that these regimes can be connected by a percolation transition on the neighbor graph, whereby the scars grow as a function of particle size anisotropy. Here we show that manipulating particle shape can cause a similar transition. Ellipsoids of varying aspect ratio are packed on a spherical surface with scars at low aspect ratio; these scars elongate and disconnect the crystalline regions with increasing aspect ratio. The cluster growth and scaling are shown to agree with percolation theory. The influence on the cluster growth of interactions between the particle shape and the surface on which they are packed will also be presented, as well as prospects for the exploitation of other particle shapes, such as chiral particles, to control the transition.

**1:51PM F50.00012: Formation of Twisted Bundles from Small Regular Arrays of Polymer Nanopillars**
CHENG ZENG (Presenter), ISAAC BRUSS, MOHAMMAD SHAHJAMALI, EDVIN MEMET, VINOTHAN N MANOHARAN, Harvard University — Elastocapillary assembly has been used to form twisted bundles in large arrays of nanopillars, often placed in square lattices. We study how the emergence of twisting can be controlled by both the dimensions of individual pillars and the local bundle geometry. Using direct laser writing, we fabricate nanopillars with high spatial resolution in arbitrary lattices. The bundles are composed of a central pillar surrounded by 4 to 7 outer pillars that are evenly spaced from one another. Although no chirality is programmed into the design, we find that twisted bundles form under certain combinations of pillar spacing (D) and pillar height (H). Interestingly, we find that achiral bundles always form when D/H is small, even with long and flexible pillars. We find a transition from achiral to chiral bundles when D/H is 0.2 to 0.3. To understand this transition, we use a scaling model and numerical simulations.

*This work was supported by DARPA under grant no. FA8650-15-C-7543.*
MOHAMMAD SHAHJAMALI (Presenter), School of Engineering and Applied Sciences, Harvard University — We present experimental self-assembly of high aspect ratio nanopillars into chiral clusters in response to capillary force. We take advantage of pillars with an aspect ratio of up to 500 with adjustable dimension, shape, porosity and two-dimensional arrangement fabricated by two-photon lithography and oxygen plasma etching. Using such freedom of design in combination with the kinetically controlled evaporation of a liquid, we devise systems where we can externally introduce five-fold disclination defects on the surface of clustered pillars due to geometrical frustration. In addition, we can kinetically control the number of assembled clusters per array and adjust the handedness of the twists in asymmetrical arrays of nanopillars.

Session F52 DPOLY: Padden Award Symposium BCEC 253B - Amalie Frischknecht, Sandia National Laboratories - Tag(s): Focus

11:15AM F52.00001: 24 MINUTE DELAYED START TIME —

11:39AM F52.00002: Dynamic Heterogeneity in Entangled Linear and Ring Polymers: Single Molecule Studies Reveal Surprises due to Molecular Architecture YUECHENG ZHOU (Presenter), Materials Science and Engineering, University of Illinois at Urbana-Champaign, CHARLES SCHROEDER, Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign — We directly observe the non-equilibrium dynamics of single ring polymers suspended in semi-dilute solutions of linear chains. Our results show that ring polymers fluctuate drastically in chain extension even at steady-state, yet ring polymers exhibit markedly less molecular individualism during transient stretching compared to linear chains. We hypothesize that ring polymer extension fluctuations arise due to threading of linear polymers through open ring polymer chains in flow. The fluctuation frequency as a function of strain rate and concentration is quantified, and trends are consistent with increasing concentration. We further study the relaxation of linear polymers in entangled solutions of purely linear chains. Our results show dynamic heterogeneity in relaxation such that single polymer relaxation trajectories exhibit either a single-mode or double-mode exponential decay, which starkly contrasts relaxation behaviors from dilute and semi-dilute unentangled solutions. We interpret the power law scalings of these relaxation times as a function of concentration, and our single molecule results are discussed in the context of the classic tube model and reptation theory. Our results show that molecular behavior is markedly heterogeneous in non-dilute polymer solutions.

11:51AM F52.00003: Leveraging conductivity-enhancing pathways in homopolymer-blended block polymer electrolytes MELODY MORRIS (Presenter), Department of Chemical and Biomolecular Engineering, University of Delaware, RYAN NIEUWENDAAL, Materials Science and Engineering Division, National Institute of Standards and Technology, JOSEPH DURA, Center for Neutron Science, National Institute of Standards and Technology, THOMAS H EPPS, Department of Chemical and Biomolecular Engineering, Department of Materials Science and Engineering, University of Delaware — Block polymer (BP) electrolytes are appealing alternatives to liquid, gel, or homopolymer systems because the mechanical, thermal, and conductive properties are decoupled such that enhanced stability and performance are achievable. As a method to increase conductivity, polystyrene-b-poly(oligo-oxyethylene methacrylate) [PS-b-POEM] BPs were blended with a more mobile, ion-conducting POEM homopolymer; the blends then were doped with lithium salts. By adding homopolymers of different molecular weights, wet brush or dry brush regimes were achieved, as confirmed via neutron reflectometry. The wet brush polymer blends increased the mobility of both the polymer and lithium as suggested by the reduction of T_g,POEM and via line narrowing in variable temperature Li-7 solid-state nuclear magnetic resonance measurements, respectively. However, the dry brush blend demonstrated an overall higher ionic conductivity, likely due to the presence of homopolymer-rich ion channels. The results of this study provide key design parameters to promote enhanced conductivity via homopolymer-rich pathways in BP-based electrolytes.

12:03PM F52.00004: Designing Coacervate-forming Systems Using Charge Sequence    TYLER LYTLE (Presenter), CHARLES SING, University of Illinois at Urbana-Champaign — Oppositely-charged polyelectrolytes can associatively phase separate in a salt solution via a process known as ‘complex coacervation’. Coacervation is driven in part by a large entropic gain due to counterion condensation and release. This drives coacervation by replacing condensed counterions with the oppositely-charged polyelectrolyte, leading to a significant increase in the counterion translational entropy. The magnitude of this entropy change can be tuned by altering the sequence of charged and neutral monomers, which leads to significant changes in phase behavior. We have developed a theoretical model to understand this connection between sequence and phase behavior by mapping the coacervate molecular structure to a 1D adsorption model that can be evaluated using the transfer matrix method. This transfer matrix theory uses inputs from Monte Carlo simulations to determine the phase separation and is able to determine the phase separation of sequence-defined polyelectrolytes. Theoretical results exhibit qualitative agreement with experimental and simulation results. These sequenced systems provide insights into the phase separation of intrinsically-disordered proteins and a method to use sequence specificity to tune the phase behavior of coacervate-based materials.

12:15PM F52.00005: Interaction parameters governing self-assembly of ion-containing block copolymers    WHITNEY LOO (Presenter), NITASH BALSARA, University of California, Berkeley — Block copolymers have been studied for use in lithium metal solid-state batteries due to their ability to decouple ion transport and mechanical properties. It is not surprising that several theoretical models have been developed to describe the effect of salt on self-assembly including the counter-ion entropy model of Rabin, the Born solvation approach of Wang, the ionic self-consistent field theory (SCFT) of Sing and de la Cruz, the polarizable field theory of Fredrickson, and the free ion SCFT of Qin. In order to discriminate between theories, we have determined the morphology of a series of block copolymer/salt mixtures as a function of composition, chain length, salt concentration and temperature. The effect of salt on chain dimensions is determined independently from neutron scattering experiments on homopolymer/salt mixtures. The effective interactions between the blocks are determined by two methods: from characterization of disordered concentration fluctuations and from the locations of phase boundaries. Comparisons between experiment and theory will be presented. The experiments show the presence of coexisting phases at some phase boundaries (e.g. two BCC phases with different lattice constants) that have not been seen in salt-free systems nor captured by any theory.

12:27PM F52.00006: Spontaneous degrafting of polyelectrolyte brushes from solid substrates    YEONGUN KO (Presenter), JAN GENZER, North Carolina State University — Polymer brushes grafted covalently to solid substrates may degraft in some instances. We study the stability of strongly and weakly charged polymeric grafts derived from poly(2-dimethylaminoethyl methacrylate) (PDMAEMA). We employ surface-initiated atom transfer radical polymerization to prepare polymer assemblies featuring gradients of grafting density and molecular weight. The degree of permanent charge in strong electrolytes is adjusted by reacting PDMAEMA with methyl iodide to a given extent. We interrogate the stability of those surface-grafted polymers under various pH at ionic strength values in solution. Swelling of the brush due to electrostatic charging in aqueous media (adjusted by varying pH and degree of quaternization) generates tension along the grafted macromolecular backbone. Such tension focuses at the bottom-most section of the polymer brush close to the substrate. This lowers the activation energy for breaking labile chemical bonds either in the initiator itself or the head-group chemistry of the initiator that links the initiator to the underlying substrate. Weak polyelectrolyte brushes are more stable than strong polyelectrolyte grafts. The stability of brushes decreases with increasing pH and decreasing ionic strength of surrounding solution.

12:39PM F52.00007: Crystallization Modes of Poly(3-dodecylthiophene)-based Block Copolymers Depend on Regioregularity    JIN-SEONG KIM (Presenter), KAIST, JONATHAN P COOTE, Chemical and Biomolecular Engineering, University of Tennessee, Knoxville, JUNGHUN HAN, KAIST, GILA E STEIN, Chemical and Biomolecular Engineering, University of Tennessee, Knoxville, BUMJOON KIM, KAIST — Conjugated block copolymers (BCPs) can self-assemble into highly ordered nanostructures in a melt state. However, when cooled below the melting temperature, crystal growth can disrupt the self-assembled structure and produce a poorly-ordered fibrillar texture. Here, we demonstrate that crystallization modes of poly(3-dodecylthiophene) (P3DDT)-based BCPs can be tuned through regioregularity (RR) and morphology. When cylindrical BCP structure is formed, crystal growth tends to break through the morphology even with low RR, showing both “break-out” and “template” crystallization modes. In contrast, when lamellar structure is formed, crystal growth remains confined by the second block domain with high RR. This morphology-dependent behavior is attributed to geometric compatibility of P3DDT crystal growth and the self-assembled symmetry: in a lamellar phase, the P3DDT chain orientations at the block interface are compatible with crystal growth, and both the alkyl-stacking and π-π growth directions are unrestricted within a lamellar sheet. In a cylindrical phase, the radial orientation of P3DDT chains at the block interface is not compatible with crystal growth, and the hexagonal close-packed symmetry only allows for one direction of unrestricted crystal growth.
Manipulating chain architecture has long been explored as a strategy to tailor the properties of polymer melts and solutions; as such, there is a rich body of literature probing the physics of nonlinear polymer architectures. Herein, we examine the chain scaling exponent ($\nu$) and effective polymer-solvent and polymer-polymer interactions as a function of architecture, solvent quality, and polymer concentration. We find striking quantitative agreement between our coarse grained (CG) molecular dynamics (MD) simulations, Polymer Reference Interaction Site Model (PRISM) theory, and small-angle neutron scattering (SANS) experiments to study linear and cyclic polymer solutions. Specifically, we examine the chain scaling exponent ($\nu$) and effective polymer-solvent and polymer-polymer interactions as a function of architecture, solvent quality, and polymer concentration. We find striking quantitative agreement between our computational and experimental results, and we show that the linear and cyclic $\nu$ and effective interactions are similar in good solvents but significantly depart from one another as solvent quality decreases. These surprising trends are most pronounced at low polymer concentrations due to the balance between available intra- vs. inter-chain contacts in the linear and cyclic architectures. We also discuss the benefits and drawbacks of varying CG model resolution, providing guidance for others to make the correct choice of model when studying the polymer physics of similar systems.

Self-consistent field theory (SCFT) provides impressive predictive capabilities for the equilibrium phases of a variety of block copolymer systems. When solved to high accuracy, qualitative as well as quantitative results can be compared to experiments. In this work, we exploit neural networks (NN) unique capability as a universal function approximator to evolve the fields in SCFT for several iterations during free energy minimization. To fully evolve the system, we use a hybrid algorithm mixing a proper PDE solver with the trained NN. The hybrid approach is verified on a diblock copolymer system. Convergence is achieved in all cases, independent of computational cell size, and molecular characteristics (volume fraction, and degree of block incompatibility). The lessons drawn from the NN-SCFT implementation can be extended to other energy minimization problems such as density functional theory (DFT).

Assembly of soft matter into three-dimensional structures at the nanoscale holds promise in fields including microfluidics and photonics, and transfer molding offers a low-cost, large-area approach to patterning such structures. In transfer molding, an ink is coated into a nano-patterned stamp, cured, and transferred to a substrate in a layer-by-layer fashion. We studied wetting, surface treatment, and adhesion in the context of continuous processing techniques with a focus on selective filling of stamps, a size scale dependence on adhesion following plasma exposure, and comparison of batch and continuous surface treatments. Residual-layer-free transfer molding was achieved through identification of wetting regimes related to the coating process combined with plasma doses orders of magnitude lower than the optimal dose suggested in prior literature on plasma bonding. Comparison of plasma treatment and corona discharge treatment for multi-layer adhesion further underscored the importance of brief surface treatments for both process throughput and stamp lifetime. This work brings transfer molding to new size scales, opening new opportunities for research in low-cost, multi-layer nano-patterning.
LIWEN CHEN (Presenter), SANGWOO LEE, Rensselaer Polytechnic Institute, HAN SEUNG LEE, Characterization Facility, University of Minnesota — Block copolymer micelles are versatile model spherical particles in the investigation of self-assembling structures of spherical particles and associated phase transformation phenomena. We investigated the close-packed structures of spherical poly(butadiene-b-ethylene oxide) (PB-PEO) diblock copolymer micelles dispersed in water using synchrotron X-ray scattering measurements. Remarkably, rapid thermal quenching of disordered PB-PEO micelle solutions to different temperatures induced three representative close-packed structures: face-centered cubic (fcc), random stacking of 2-dimensional hexagonal close-packing (rhcp), and hexagonal close-packing (hcp). Careful examination of the 2-dimensional scattering patterns revealed that the clear correlation between the type of close-packed structures and the size of crystallites controlled by the depth of thermal quenching: the smallest crystallites stabilize hcp, and as the size of crystallites increases, the hcp transforms to rhcp and eventually settled to fcc. This observation shows the interfacial tension effect is crucial for the selection of the metastable crystal structures confined in small crystallites.

Session F53 GSNP: Marginal Stability in Amorphous Materials and Beyond BCEC 253C - Patrick Charbonneau, Duke University - Tag(s): Invited

11:15AM F53.00001: Aging, Jamming and the Mechanisms of Marginal Stability in Amorphous Solids [Invited] PETER WOLYNES (Presenter), Rice University — The random first order transition theory of glasses provides a route to understanding not only the dynamics of the supercooled liquid state, but also the history dependent properties of nonequilibrium amorphous states, i.e., glasses. I will review its implications for preparing marginally stable amorphous packings as well as the dynamic implications of the competing existence of thermodynamically stable periodic crystals for obtaining such amorphous assemblies.

11:51AM F53.00002: Jamming of particles and machine learning models* [Invited] PIERFRANCESCO URBANI (Presenter), Institut de physique théorique, Université Paris Saclay, CNRS, CEA, F-91191 Gif-sur-Yvette — In this talk I will describe the analogy between hard spheres in high dimension and some machine learning problems focusing on the properties of their landscape and their jamming transition. I will highlight how marginal stability emerges in both cases and what are its consequences.

*This work is supported by “Investissements d’Avenir” LabEx PALM (ANR-10-LABX-0039-PALM).

12:27PM F53.00003: Marginally stable phases in structural glasses* [Invited] CAMILLE SCALLIET (Presenter), LUDOVIC BERTHIER, Laboratoire Charles Coulomb, Universite de Montpellier, FRANCESCO ZAMPONI, Laboratoire de Physique Theorique, ENS — A novel form of amorphous matter characterized by marginal stability was recently discovered in the mean-field theory of structural glasses. In the marginally stable phase, structural glasses inherit the richness of spin-glass physics characterized by ergodicity breaking transitions, complex free energy landscapes, rejuvenation and memory effects. We study analytically and numerically Weeks-Chandler-Andersen glasses. By changing external parameters, we continuously explore physical regimes relevant to granular matter, foams, emulsions, hard and soft colloids, and molecular glasses. Our results suggest that marginal phases should be observable for colloidal and non-Brownian particles near jamming. In this regime, we numerically observe rejuvenation and memory effects. By contrast, we find that molecular glasses do not present marginally stable phases, but our study reveals instead the presence of localised excitations presumably relevant for mechanical and vibrational properties of structural glasses.

1:03PM F53.00004: A jamming transition controls the landscape in deep learning* [Invited] MATHIEU WYART
(Presenter), Physics, EPFL — Deep learning has been immensely successful at a variety of tasks, ranging from classification to
AI. Learning corresponds to fitting training data, which is implemented by descending a very high-dimensional loss
function. Understanding under which conditions neural networks do not get stuck in poor minima of the loss, and how the
landscape of that loss evolves as depth is increased remains a challenge. Here we predict, and test empirically, an analogy
between this landscape and the energy landscape of repulsive ellipses. We argue that fully-connected networks a phase
transition delimits the over- and under-parametrized regimes where fitting can or cannot be achieved. In the vicinity of this
transition, properties of the curvature of the minima of the loss are critical. This transition shares direct similarities with
the jamming transition by which particles form a disordered solid as the density is increased, which also occurs in certain
classes of computational optimization and learning problems such as the perceptron. Our analysis gives a simple
explanation as to why poor minima of the loss cannot be encountered in the overparametrized regime, and puts forward
the surprising result that the ability of fully connected networks to fit random data is independent of their depth. Our
observations suggests that this independence also holds for real data. We also study a quantity Δ which characterizes how
well (Δ<0) or badly (Δ>0) a datum is learned. At the critical point it appears to be power-law distributed, suggesting that
near the transition the loss landscape has a hierarchical structure and that the learning dynamics is prone to avalanche-
like dynamics, with abrupt changes in the set of patterns that are learned.

Wyart). M.W. thanks the Swiss National Science Foundation for support under Grant No. 200021-165509.

1:39PM F53.00005: Marginal stability in finite dimensions [Invited] SHO YAIDA (Presenter), Facebook AI Research, Facebook
Inc. — Glassy materials are omnipresent in everyday life from windows to plastics to piles of sand. Yet our understanding
of both their (equilibrium) liquid and (out-of-equilibrium) solid phases lags far behind that of crystalline counterparts.
Recent advances are rapidly changing the ways in which we understand these common-yet-physically-enigmatic materials.
This talk overviews one such advance -- the discovery of the Gardner phase transition from normal to marginally-stable
glasses. Our work in particular indicates that such a transition, first found in abstract infinite-dimensional models, can
survive down to the three-dimensional world. This transition reinforces the overriding role of rugged free-energy
landscapes that dictate physics of glassy systems, with tangible consequences on jamming, yielding, and beyond.

Tuesday, March 5, 2019 11:15 AM - 2:15 PM

Session F54 DPOLY GSOFT GSNP: Confined Polymer Glasses I: Modeling, Aging, and Local
Connectivity BCEC 254A - Reika Katsumata, University of Massachusetts, Amherst - Tag(s): Focus

11:15AM F54.00001: Relaxation-Function-Dependent Two-Barrier Model for Nanoconfinement Effects on the Glass
Transition* DAVID SIMMONS (Presenter), DANIEL MAURICIO DIAZ VELA, Chemical and Biomedical Engineering, University of
South Florida — One of the central challenges in the study of nanoconfined systems has been the fact that distinct
measures of these systems can report quantitative and qualitative differences in perturbations from bulk. This scenario
has been further complicated by the recent observation in experiment of an apparent onset condition of
nanoconfinement effects at temperatures only modestly above Tg. This observation has raised additional questions
regarding the interpretation of large observed nanoconfinement effects in simulated systems at temperatures relatively
much further above Tg. Here, using simulations and scaling theory, we show that this rich phenomenology can be unified
via the combination of a two-barrier model of the glass transition with a barrier-truncation scenario for nanoconfinement
effects. We discuss strong implications of these results for the viability of existing theories of the glass transition.

authors acknowledge the W. M. Keck Foundation for generous support enabling development of simulation
methodologies employed in this work.
11:27AM F54.00002: Modeling the Depth-dependent Dynamics of Confined Systems*  JANE E LIPSON (Presenter), RONALD WHITE, Dartmouth College — This talk will focus on our recent results modeling dynamics and glassiness in confined systems. One technique is the Limited Mobility model (LM), a coarse-grained kinetic simulation approach where mobility at a site depends on facilitation through mobility at nearby sites. LM results include mobile layer depths in freestanding films, as well as the effect of nanoparticles on the surrounding matrix. Our Cooperative Free Volume model (CFV) is a different approach. This is a rate model in which the system’s free volume ($V_{\text{free}}$), predicted through our Locally Correlated Lattice (LCL) equation of state analysis of bulk thermodynamic data, plays the key role in determining the local molecular cooperativity. The CFV model describes independent $T$- and $V_{\text{free}}$-contributions to the pressure-dependent segmental relaxation times, $\tau(T,V)$. This talk will focus on our ability to describe the dynamics of confined systems, where the local density (and thus the $V_{\text{free}}$-contribution) is altered by the presence of an interface. For example, our recent CFV work reveals the point at which film samples lose the contribution from regions of bulk-like dynamics, which will lead to insight on the position-dependent mobility across an interfacial region.

11:39AM F54.00003: The Important Roles of Topological Constraints on Interfacial Effects of Nanoconfined Polymers*  BIAO ZUO (Presenter), Department of Chemistry, Zhejiang Sci-Tech University, Princeton University, RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University, XINPING WANG, Department of Chemistry, Zhejiang Sci-Tech University — Interfaces play a significant role in determining the dynamics of nanoconfined polymers. Recent experiments and simulations have revealed the long-range nature over which interfacial effects originating at the polymer-substrate interface can propagate within a thin film. Here, we show that topological constraints, that is, the interpenetration and entanglement between chains directly adsorbed to the substrate and neighboring non-adsorbed chains, play a major role in the suppression of thin film dynamics. This is because such constraints increase motional coupling of free and adsorbed chains, thus giving rise to a mechanism for the propagation of substrate effects. In addition, we demonstrate that the propagation of the suppressed interfacial dynamics can be tuned by controlling the local conformation of chains adsorbed to the substrate surface.

11:51AM F54.00004: Surprising Impact of Chain Connectivity in Altering Local Glass Transition Temperature Near Interfaces [invited]  CONNIE ROTH (Presenter), XINRU HUANG, ROMAN R BAGLAY, MICHAEL THEES, YANNIC GAGNON, JENNIFER A MCGUIRE, Physics Dept, Emory University, Atlanta, Georgia USA — Our group has recently investigated how the local glass transition temperature $T_g(z)$ changes across interfaces between two polymers with widely different bulk glass transition temperatures $T_{gbulk}$. Starting with a single interface between two semi-infinite domains ($\Delta T_{gbulk} \approx 80$ K), we used a localized fluorescence method to demonstrate broad profiles in $T_g(z)$ across dissimilar polymer-polymer interfaces spanning hundreds of nanometers and observed to be asymmetric relative to the composition profile. A key finding of these results is the observation that the broad coupling of dynamics across the dissimilar polymer-polymer interface only occurs if this interface is annealed to equilibrium. Efforts to understand what factors during polymer interface formation cause these broad profiles in $T_g(z)$ find that chain connectivity appears to be surprisingly important. This is confirmed by measurements near silica substrates with tethered chains where low grafting densities (~10 vol% tethered chains) are observed to cause large +50 K increases in local $T_g$. We now explore what property changes take place in multilayer systems during interface annealing using different experimental techniques with the goal of understanding how interfaces mediate dynamical coupling across dissimilar polymer domains. Advanced materials design is headed towards increasing amounts of interfaces with progressively smaller domain sizes where the geometrical arrangement of these interfaces can be utilized to alter local material properties for desired applications.
12:27PM F54.00005: Comparison of Physical Aging and Local Glass Transition in Glassy-Rubbery Bilayer Films

JENNIFER A MCGUIRE (Presenter), MICHAEL THEES, CONNIE ROTH, Physics Dept, Emory University — Block copolymers consisting of glassy and rubbery polymers in direct contact with each other are common in many industrial applications, with the stability of the glassy domains critical to the material’s function. Recent fluorescence measurements by our group have shown large changes in local glass transition temperature $T_g(z)$ across glassy-rubbery polystyrene (PS) / poly(n-butyl methacrylate) (PnBMA) multilayer films. Previously we have demonstrated a correlation between reduced physical aging rates in thin single layer PS films with local $T_g$ reductions near the free surface. Here we explore if a similar correlation between physical aging and local $T_g$ exists near glassy-rubbery polymer interfaces. Physical aging of PS films capped with rubbery PnBMA layers are measured using ellipsometry, avoiding the competing effects of the free surface and allowing us to isolate the impact of a single glassy-rubbery interface. Reductions in physical aging rate with decreasing PS layer thickness are observed, but the reduced layer thicknesses needed to make the ellipsometry measurements viable induce finite size effects altering the local $T_g(z)$ profile relative to previous profiles on semi-infinite bilayers, necessitating direct comparisons on equivalent systems with both techniques.

12:39PM F54.00006: Role of hydrophilic support on the physical aging and stress development in thin polynorbornene films

ELIZABETH LEWIS (Presenter), Polymer Engineering, The University of Akron, CHRISTOPHER M STAFFORD, NIST - Natl Inst of Stds & Tech, BRYAN VOGT, Polymer Engineering, The University of Akron — Thin film properties can be impacted by their local environment, especially when in contact with other polymers. Here physical aging of poly(butylnorbornene-ran-hydroxyhexafluoroisopropyl norbornene), BuNB-r-HFANB, thin films coated on ultra-thin (2nm) layers of poly(acrylic acid), PAA, or poly(styrene sulfonate), PSS, is examined along with residual stress evolution in BuNB-r-HFANB during aging. Decreasing BuNB-r-HFANB film thickness tends to decrease the physical aging rate ($\beta$), but this quantitatively is altered by PSS or PAA. Even for thick films (>500nm), aging rate at 100°C is accelerated on PAA compared to silicon, while thickness dependence of BuNB-r-HFANB aging is enhanced (compared to silicon) when in contact with PSS with apparent aging rate decreasing by a factor of 2 as film thickness decreases from 1000 nm to 250 nm. Removal of BuNB-r-HFANB from substrate enables mechanical properties (elastic modulus and residual stress, $\sigma_R$) to be resolved via wrinkling. Elastic modulus is effectively invariant of substrate (polymer layer), while there is a small effect of physical aging on the modulus. The stress in the films is compressive and evolves non-monotonically during aging. $\beta$ can be mostly collapsed when scaled as $h\sigma_R^{-1/3}$.

12:51PM F54.00007: Effect of Substrate on the Stability of Ultra-thin Vapor Deposited Molecular Glasses

YI JIN (Presenter), YUE ZHANG, CONNOR WOODS, ZAHRA FAKHRAAI, University of Pennsylvania — We have recently demonstrated the existence of long-range correlation between the free surface and substrate dynamics in ultrathin supported molecular glass films such that when the substrate interactions are changed from weakly interacting to neutral, the extent of $T_g$ reduction and enhanced film dynamics is reduced and the stability against dewetting is increased for films as thick as 30 nm. The stability of vapor-deposited glasses is strongly influenced by the surface mobility and its gradients. Since the surface dynamics are affected by the substrate for ultra-thin films one would expect the stability to follow. Here, we show that ultra-thin films of TPD ($N,N'$-diphenyl-$N,N'$-bis(3-methylphenyl)-1,1' -biphenyl-4,4'-diamine) vapor-deposited on a neutral substrate have higher stability (higher density change and lower fictive temperatures) compared to those deposited on a weakly-interacting substrate. The density change is also found to be higher in ultrathin films (<50 nm) compared to the bulk films (>200 nm, steady state condition). These results suggest a possibility that film/substrate interactions could speed up effective aging rates, or deter dewetting during deposition, giving rise to more efficient amorphous packings.

Role of Solvent Washing Conditions on the Creation of Adsorbed Layers from Melt Films

MICHAEL THEES (Presenter), JENNIFER A MCGUIRE, XINRU HUANG, CONNIE ROTH, Physics Dept, Emory University — Recent reports have proposed the presence of adsorbed layers may strongly affect dynamics in thin supported films. Often assumptions are made about the presence of adsorbed layers within melt films based on annealing time and temperature, where subsequent washing of films with solvent is interpreted as “revealing” the structure of the adsorbed layer within the melt (so-called Guiselin experiment). However, this interpretation is contrary to extensive literature studies from the 1980-90s on displacement experiments of adsorbed chains in solution measuring exchange kinetics with a third component called the “displacer”, either another polymer or second solvent, that displaces the initially adsorbed polymer due to its preference for the substrate interface. These studies, along with direct surface diffusion measurements by Granick’s group in the regime of strong adsorption, suggest adsorbed polymer chains are extremely mobile during solvent washing. We test this interpretation by demonstrating the measured residual adsorbed layer strongly depends on solvent washing conditions. Consistent with work by Cohen Stuart’s group, we show acetone as a displacer removes nearly all of the initially adsorbed chains, even after melt films were extensively annealed at elevated temperatures.

Substrate Effect on $T_g$ of Random Copolymers of 4-tert-butylstyrene and 4-acetoxy styrene

TONG WANG (Presenter), JINSONG YAN, HAILIN YUAN, Department of Physics, Hong Kong University of Science and Technology, HO YI LAM, Department of Chemical and Biological Engineering, Hong Kong University of Science and Technology, CHAO LV, BINYANG DU, Department of Polymer Science and Engineering, Zhejiang University, OPHELIA TSUI, Department of Physics, Hong Kong University of Science and Technology — Confinement effect on the dynamics of polymers in nanoscale films is known to cause variations in the glass transition temperature, $T_g$, of the films with film thickness. We studied the $T_g$ of random copolymers of 4-tert-butylstyrene (4TBS) and 4-acetoxy styrene (4AS). Our result indicates that the component with a stronger substrate confinement effect dominates the $T_g$ of the copolymer films. We have also explored the influence of pre-annealing time on the $T_g$'s. According to a previous study, by shortening the pre-annealing time, the $T_g$ reductions of thin 4TBS films were enhanced. In our copolymer films, we found that that adjusting the pre-annealing time only affected the $T_g$ of the copolymer films in which 4TBS is the majority component.

Theory of interface-nucleated changes of dynamical constraints and their spatial transfer in glass-forming films

KENNETH SCHWEIZER (Presenter), ANH D. PHAN, University of Illinois at Urbana-Champaign — We formulate a new force-based microscopic theory for how dynamic caging constraints in glass-forming liquids at an interface are modified and spatially transferred into the film interior in the context of the dynamic free energy concept of the Nonlinear Langevin Equation (NLE) approach. The caging constraints vary exponentially with distance from the interface with a correlation length of modest size and weak sensitivity to thermodynamic state. This imparts a roughly exponential spatial variation of all key features of the dynamic free energy, and a double exponential form for the alpha time gradient. Results have been obtained for vapor, rough pinned particle solid, vibrating (softened) particle solid, and smooth hard wall interfaces, with the crucial dynamical differences arising from the first layer where caging constraints can be weaken, softened or hardly changed. Comparison of the predictions for the dynamic localization length and glassy modulus with simulations and experiments for vapor interface films reveals good agreement. Using the new ideas in Elastically Collective NLE theory yields quantitative results for the relaxation time gradient, decoupling phenomena, $T_g$ gradient and other properties of colloidal, molecular and polymeric films.
1:39PM F54.00011: Heterogenous dynamics, connectivity and domain formation in polymer glasses: a fractal dimension analysis approach* ANNA LAPPALA (Presenter), Los Alamos National Laboratory, DOMINIC PHILLIPS, Physics, University of Cambridge, JAKOB JAZBEC, Department of Applied Mathematics and Theoretical Physics, University of Cambridge, TURAB LOOKMAN, KARISSA SANBONMATSU, Los Alamos National Laboratory — Dynamical heterogeneity in glassy systems was first proposed in order to explain non-exponential relaxation patterns in single-component glassy systems, with different relaxation times contributing to produce the observed relaxation. It has been suggested that due to the influence of intramolecular interactions and chain connectivity, there is a fundamental difference between the nature of the glass transition in polymers and in standard glass-formers. Here, we study polymer collapse using fractal dimension (Df) analysis, demonstrating that dynamical arrest upon glass transition affects the evolution of Df in a non-trivial manner. We identify heterogenous dynamics both in bulk and near the free surface, showing characteristic domain patterns in local displacement and connectivity. We demonstrate that although covalent bonding promotes glass formation and caged dynamics, bonding sequentiality that defines a polymer chain is not critical in bulk: glassy dynamics is purely a result of the number of connections per particle, independently of how these connections are formed. However, bonding sequentiality does play an important role in the surface effects of the glass, highlighting a major difference between polymeric and colloidal glasses.

1:51PM F54.00012: Novel calculation method for the work of adhesion of polymer-grafted surface MASAYUKI URANAGASE (Presenter), SHUJI OGATA, Nagoya Institute of Technology — Molecular simulations are often used to elucidate solid-liquid interfacial properties. In the problem of adhesion, several methods to calculate the work of adhesion, which enables quantitative evaluation of the strength of the adhesion between two materials, have already been proposed. However, application of these methods is restricted to the flat solid surface. It is necessary to improve existing methods for efficient calculation of the work of adhesion for the complex solid surfaces such as polymer-grafted surfaces. We developed the novel method to calculate the work of adhesion using molecular simulation. In this method, we introduced two techniques to perform efficient calculation for complex solid surfaces. First, liquid molecules contacted with the solid surface are separated from it using spherical potentials around atoms grafted to the surface. This enables separation of liquid molecules according to the surface structure. Second, appropriate update scheme of parameters contained in the potential is found to suppress the variation in the free energy gradient, which reduces the error of numerical integration. Using this method, we studied the dependence of hydrophilicity of the gold surface modified by poly(ethylene oxide) on the ratio of poly(ethylene oxide).

2:03PM F54.00013: Slip Length in Deeply Supercooled Molecular Glass Formers* CONNOR WOODS (Presenter), GUI GAO, PATRICK J WALSH, Chemistry, University of Pennsylvania, ROBERT RIGGLEMAN, Chemical and Biological Engineering, University of Pennsylvania, ZAHRA FAKHRAAI, Chemistry, University of Pennsylvania — In polymer melts, the hydrodynamic boundary condition at the substrate interface can deviate from the normally assumed no-slip boundary condition such that fluid velocity at the substrate is non-zero in supported high-molecular weight polymer thin films. Depending on the substrate/polymer interactions, the measured slip lengths can be on the order of the film thickness or larger, greatly influencing film dynamics during dewetting. De Gennes’ original theory for slip in polymers predicts that the slip length should approach the monomer size in molecular liquids. We show that for deeply supercooled molecular glass formers near their Tg, in which chain dynamics cannot play a role in slip, the slip lengths can be surprisingly large and still on the order of the film thickness on a weakly interacting substrate. To better understand the origin of slip in these systems, we investigate the role of molecular shape and orientation near the substrate using a series of molecules that range from rod-like to nearly spherical. We also employ coarse-grained molecular dynamics simulations to gain insight into the origins of the observed slip.

Session F55 DPOLY DCOMP DBIO GSNP: Advancing Polymer and Biopolymer Physics though Simulation and Theory II: Functional Polymers and Gels BCEC 254B - Yaroslava Yingling, North Carolina State University - Tag(s): Focus
11:15AM F55.00001: Effects of Ion Group Distribution on the Structure and Dynamics of Amorphous Ionomers^*  
GARY GREST (Presenter), Sandia National Laboratories, DIPAK ARYAL, University of Texas, Austin, DVORA PERAHIA, Clemson University — Ionic clusters control the structure, dynamics, and transport in ionic polymers. These ionic groups associate into random clusters in melts, where the distribution and morphology of the clusters impact the transport in these materials. Using fully atomistic molecular dynamics simulations we study melts of polystyrene sulfonate with 10% sulfonation with random, precise and blocky distributions of of the SiO₃⁻ sulfonate groups along the backbone. We find that for random distribution, the clusters in average are elongated, whereas the clusters are more globular when the sulfonate groups are equally spaced along the backbone. Elongated and globular coexists for blocks of sulfonate groups. The average ionic cluster size is comparable for the random and precise distributions and larger for the blocky distribution. We show that the low wavevector peak in the structure factor S(q) is much more well-defined for the precise and block cases compared to the random one. Interestingly, over the time scales of 1000 ns studied, the mobility of the block chains is higher than the random and precise, even though the ionic clusters are larger. The Na⁺ counterions are condensed and move at the same rate as the sulfonate groups.

11:27AM F55.00002: Modeling Explicit-Ion Effects in Weak Polyelectrolyte Complexes  
VIKRAMJIT RATHEE (Presenter), HYTEM SIDKY, BEN J SIKORA, JONATHAN WHITMER, University of Notre Dame — Polyelectrolytes may be classified into two primary categories (strong and weak) depending on how their charge state responds to the local environment. Both of these find use in many applications, including drug delivery, gene therapy, layer-by-layer films, and fabrication of ion filtration membranes. The mechanism of polyelectrolyte complexation is, however, still not completely understood. Here we detail computer simulations aimed at providing a comprehensive picture of the titration and complexation behaviour of these weak polyelectrolytes and perform thermodynamic investigation through coarse-grained molecular simulations permitting us to calculate the free energy of complex formation and its dissection into energetic and entropic contributions. Our investigations indicate that entropic contributions indeed dominate the free energy of complex formation for strong polyelectrolytes, which is in agreement with experiments, but are less important than energetic contributions when weak electrostatic coupling or weak polyelectrolytes are present.

11:39AM F55.00003: Polyelectrolytes under spatial and dielectric confinement  
TRUNG NGUYEN (Presenter), Chemical and Biological Engineering, Northwestern University, MONICA OLVERA DE LA CRUZ, Materials Science and Engineering, Northwestern University — Understanding the conformational behavior of polyelectrolytes inside viral capsids and lipid vesicles is crucial for gene delivery and drug loading applications. In this talk, we focus on the collective effects of dielectric mismatch and spatial confinement on the conformational behavior of a model polyelectrolyte chain and counterions confined in a spherical cavity. We show that surface polarization due to dielectric mismatch between the media inside and outside the cavity influences the chain conformational behavior. Specifically, it is found that surface polarization increases the work required to change the equilibrium (unconfined) chain conformation and favors the collapsed conformations with smaller size. The roles of surface charge density, electrostatic strength between the monomers and counterions and multivalent counterions are also discussed. The findings therein offer insights into the effects of dielectric mismatch, which were often overlooked in previous studies on confined polyelectrolytes.

11:51AM F55.00004: Electronic Structure of Polymer Dielectrics: The Role of Chemical and Morphological Complexity  
LIHUH CHEN (Presenter), ROHIT BATRA, School of Materials Science and Engineering, Georgia Institute of Technology, RAGHAVAN RANGANATHAN, School of Materials Science and Engineering, Georgia Institute of Technology, GREGORY SOTZING, YANG CAO, University of Connecticut, RAMAMURTHY RAMPRASAD, School of Materials Science and Engineering, Georgia Institute of Technology — The electronic structure of polymers contains signatures that correlate with their short-term and long-term integrity when subjected to large electric stresses. A detailed picture of the electronic structure of realistic models of polymers has been difficult to obtain, mainly due to the chemical and morphological complexity encountered in polymers. In this work, we have undertaken a comprehensive analysis of the electronic structure of six model polymers displaying chemical and morphological diversity, namely, polyethylene (PE), polypropylene (PP), polystyrene (PS), poly(methyl methacrylate) (PMMA), polyethylene terephthalate (PET) and polybutylene terephthalate (PBT), using first-principles density functional theory computations and classical molecular dynamics simulations. In particular, we have studied the role of monomer chemistry, tacticity and large-scale morphological disorders in shaping the electronic structure of these polymers. Appropriate connections and comparisons between the computed results and the available experimental data have also been provided. Critical insights on physico-chemical and electronic structures relationships are revealed, providing a pathway for understanding the factors that control electrical conduction and degradation of polymers.
12:03PM F55.00005: Microscopic origin of the morphotropic-like phase boundary in P(VDF-TrFE)  BING ZHANG (Presenter), WENCHANG LU, Department of Physics, North Carolina State University, YANG LIU, HAIBIBU AZIGULI, WENHAN XU, QING WANG, Department of Materials Science and Engineering, The Pennsylvania State University, JERRY BERNHOLC, Department of Physics, North Carolina State University — Ferroelectric materials with compositions near a morphotropic phase boundary (MPB) exhibit dramatically enhanced electromechanical properties, which could be utilized in advanced actuators, transducers, sensors and energy-harvesting applications. We have recently observed [1] a morphotropic-like phase boundary for the first time in an organic material, poly(vinylidenefluoride-co-trifluoroethylene) [P(VDF-TrFE)], which makes it possible to develop high-performance electroactive polymers. This talk describes the results of our extensive first-principles calculations for this class of polymers. We find that chirality introduced by the TrFE monomers plays the central part in the structural competition that leads to a phase boundary between the trans-planar and the 3/1-helical chain conformations, explaining and supporting the experimental results.

12:15PM F55.00006: Molecular Modeling of Polyetherimides* CHENGYUAN WEN (Presenter), SHENGFENG CHENG, Virginia Tech — Molecular modeling plays an increasingly important role in quantifying properties of polymeric materials and clarifying molecular mechanisms underlying material behavior. We use both atomistic and coarse-grained molecular dynamics (MD) and Monte Carlo (MC) simulations to investigate polyetherimides (PEIs), which are widely used for automotive industry, aircrafts, medical instruments, and chemical devices. We have developed a transferrable coarse-grained MD model of PEIs that is able to capture their thermal expansion properties and mechanical moduli, and demonstrated the importance of including entropic correction terms in the calculation of potentials of mean force when the coarse-grained force field is trained with atomistic MD simulations. To understand the dispersity of branched PEIs, we have developed a MC simulation tool based on the Gillespie algorithm for their polymerization reaction including branching. The comparison between MC simulations, the Stockmayer theory, and experiments on the molecular weight distributions of branched PEIs will be discussed. We use simulations to clarify the application range of the Stockmayer theory and to investigate the branching behavior of PEIs when the theory is not applicable.

12:27PM F55.00007: A unifying perspective on rigidity in under-constrained materials* MATTHIAS MERKEL (Presenter), Syracuse University & Université Aix-Marseille, KARSTEN BAUMGARTEN, BRIAN P TIGHE, Delft Univ of Tech, M. LISA MANNING, Department of Physics, Syracuse University — We present a novel approach to understand rigidity in under-constrained materials, including sub-isostatic spring networks as well as 2D and 3D vertex models for dense biological tissues. We show that the onset of rigidity is determined by a purely geometric criterion. This allows us to analytically predict the elastic material properties close to the transition, which depend only on few geometric coefficients. We obtain exact expressions for the magnitudes of bulk modulus and shear modulus discontinuities at the rigidity transition, several scaling relations of the shear modulus, and the magnitude of the anomalous Poynting effect. Moreover, we show that the ratio of the excess shear modulus to the shear stress is inversely proportional to the critical shear strain with a prefactor of three, which we expect to be a general hallmark of rigidity in under-constrained materials induced by geometric incompatibility.

Quantum Chemistry Simulations for Dynamic Network Polymers*  
MICHAEL BUCHE (Presenter), Theoretical and Applied Mechanics, Cornell University, ZACHARY SPARROW, Chemistry and Chemical Biology, Cornell University, YUVAL VIDAVSKY, Mechanical and Aerospace Engineering, Cornell University, ROBERT DISTASIO, Chemistry and Chemical Biology, Cornell University, MEREDITH SILBERSTEIN, Mechanical and Aerospace Engineering, Cornell University — Conventional elastomers are crosslinked by covalent bonds. These covalent crosslinks create a permanent network, substantially increasing stiffness but decreasing stretchability. Alternatively, if polymers can be made with crosslinks that are strong, but able to break and reform, they will have similar stiffness benefits as the covalently crosslinked material without sacrificing stretchability, resulting in a high toughness material. Additionally, properties such as self-healing and solid-liquid transitions are also possible through this mechanism. In this talk, I will discuss a dynamic network polymer synthesized using organometallic coordination compounds as crosslinks, focusing on the behavior of the crosslinks as investigated using density functional theory. The potential energy surface of these crosslinking structures is reshaped as force is applied. The reaction paths of the structures are discovered using the growing string method, and are studied under increasing force. These studies yield force-dependent kinetics information that can be used to create a physics-based constitutive model of the material to compare with experimental mechanical tests.

Molecular Simulation Study of Orientational Dynamics in a Cross-linked Epoxy Network*  
KETAN S KHARE, FREDERICK PHELAN JR. (Presenter), National Institute of Standards and Technology — Subtle changes in the chemistry of cross-linked epoxy networks have a drastic impact on the thermomechanical properties of cross-linked epoxy, which indicates the strong connection between chemical topology and polymer physics in these materials. Here, we study the orientational dynamics of cross-linked epoxy using atomistic molecular dynamics simulations. Specifically, we characterize the reorientation of vectors defined at atomic and molecular length-scales using first and second order Legendre polynomials (C1 and C2, respectively) at temperatures across the glass transition. For atomic length scales, we use the bond vectors of selected groups of atoms. For molecular length scales, we use end-to-end vectors of the epoxy monomer and the cross-linker that comprise the network. We then use the time—temperature superposition (TTS) principle to create master curves of C1 and C2. We find that while TTS can be successfully applied at molecular length scales, the topological location of the atoms can cause a distinct signature in the orientational dynamics of the bond vectors, which can be teased out using TTS. We are interested in using atomistic simulations to connect molecular insight with macroscopic properties.

Soft Nanoparticles as Adhesives for Gel-like Materials*  
RYAN SAYKO (Presenter), ZHEN CAO, HEYI LIANG, ANDREY DOBRYNIN, The University of Akron — It is known that nanoparticles can act as effective adhesives for soft polymeric materials. Using a combination of molecular dynamics simulations and theoretical calculations, we study the ability of soft nanoparticles to glue together gel-like surfaces. In particular, we have shown that at the interface between two gel-like surfaces nanoparticles can be in a bridging state, Pickering state, or engulfed state. The depth of indentations produced by nanoparticles into soft substrates is controlled by nanoparticle size, nanoparticle and substrate Young's modulus, and their surface properties. Using molecular dynamics simulations, we have elucidated relationships between deformations of the nanoparticles and substrates and their elastic and surface properties. By varying moduli of nanoparticles and gel-like substrates, we find that it is possible to observe a coexistence of both bridging state and Pickering state. Furthermore, we use the Weighted Histogram Analysis Method to calculate the work required for separation of two gels which interface is reinforced by nanoparticles. To explain our simulation results, we have developed a model relating the work of substrate separation with the physical parameters describing contact phenomena in nanoparticle/substrate systems.

*NSF DMR-1624569
1:15PM F55.00011: Modeling mechanics of large colloidal microgel suspensions*  
SVETOSLAV V NIKOLOV (Presenter), Mechanical Engineering, Georgia Institute of Technology, ALBERTO FERNANDEZ-NIEVES, School of Physics, Georgia Institute of Technology, ALEXANDER ALEXEEV, Mechanical Engineering, Georgia Institute of Technology — Large colloidal suspensions, comprised of soft and deformable microgel particles, exhibit a rich mechanical and phase behavior. As the particle density increases above close packing, individual particles start to deform and interpenetrate. Experimentally, these systems exhibit a high energy storage capacity and fast response times which makes them particularly attractive as self-healing and reconfigurable materials. The soft nature of the particles and their responsiveness to stimuli, such as temperature and pH, allows for external control of the emergence of liquid, liquid-crystal, and glassy phases. In our work, we utilize dissipative particle dynamics to construct large colloidal suspensions and study how the mechanical behavior of these suspensions changes with packing fraction and solvency. The colloidal suspensions are represented by an array of soft and deformable polymeric gels which are comprised of interconnected of polymer chains. We seek to determine how the behavior of individual chain parameters affects the underlying mechanical behavior of the suspensions in this multiscale system.

1:27PM F55.00012: Tuning microscopic interactions in dry (co-)polymer systems for improved thermal conductivity  
DEBASHISH MUKHERJI (Presenter), Stewart Blusson Quantum Matter Institute, University of British Columbia, JOERG ROTTLER, Department of Physics and Astronomy, University of British Columbia — Polymers are an important class of soft matter whose properties are dictated by large fluctuations. Because of this reason commodity polymers are perfect candidates for the fully flexible design of advanced functional materials. However, while polymers are highly useful in a wide range of everyday materials, one of the greatest drawbacks of polymeric materials is their poor thermal conductivity in an amorphous state (i.e., between 0.1 - 0.5 W/m/K). Using molecular dynamics simulations of an all atom model, we propose new (co-)polymer systems in their dry state that are otherwise water soluble in dilute solutions and thus dictated by strong hydrogen bonding. These results may serve as a design principle for the dry polymer systems with improved thermal properties.

1:39PM F55.00013: Advancing Polymer and Biopolymer Physics through Simulations and Theory: a few examples  
[Invited]  ALEXANDER GROSBERG (Presenter), New York University — In the talk, a few examples of successfull theoretical developments in biopolymer physics will be given.

Tuesday, March 5, 2019 11:15 AM - 2:15 PM

Session F56 GSNP: Granular Materials and Flows  
BCEC 255 - Mark Shattuck, City College of New York

11:15AM F56.00001: The influence of pressure on segregation and diffusion in a shear flow*  
PAUL UMBANHOWAR (Presenter), ALEXANDER M FRY, JULIO MARIO OTTINO, RICHARD LUEPTOW, Northwestern University — The effect of confining pressure on segregation and diffusion of granular material is studied in Discrete Element Method (DEM) simulations of horizontal planar shear flow, where a feedback scheme maintains a constant shear rate for varying pressure. Both the segregation rate and the ultimate degree of segregation in initially mixed size-bidisperse and density-bidisperse beds decrease with increasing pressure. In contrast, the collisional diffusion is pressure independent. Consequently, segregation is reduced relative to diffusive mixing with increasing pressure. To test these findings, we compare DEM results to predictions of a continuum model that includes a pressure dependent segregation velocity and a pressure independent diffusion term. The model accurately predicts the steady-state segregation for both size and density bidisperse mixtures over a wide range of flow conditions. Additional simulations with segregated initial conditions demonstrate that a high enough overburden pressure reduces segregation sufficiently that significant mixing occurs, implying that manipulation of the shear-pressure state in granular flows could be used to drive particle mixtures to either mixed or segregated states as desired.

*Funded by the Procter & Gamble Company and NSF Grant No. CBET-1511450.
11:27AM F56.00002: Kinetic Theory Approach for Modeling Granular Segregation  RICHARD LUEPTOW (Presenter), YIFEI DUAN, PAUL B UMBANHOWAR, Northwestern University — Momentum conservation equations for individual constituents have been used to derive expressions for the percolation velocities of bidisperse segregating species in a granular flow. Many gravity-driven segregation models assume that the inter-species drag takes the form of Darcy's law, which gives a linear relation between the drag forces and the percolation velocities. However, a simple linear drag law is not sufficient to describe the segregation behavior. To address this, we propose a relation based on the kinetic theory of granular flow that includes terms to account for the effects of the particle surface friction, the coefficient of restitution, and the local inertial number. The percolation velocity derived from the momentum balance equation with this drag model agrees well with DEM simulations of uniform shear flows of density bidisperse particles, accurately predicting the difference between upward species velocity and downward species velocity through the depth of the flowing layer for different density ratios and relative constituent concentrations.

11:39AM F56.00003: Size segregation in driven granular media*  PHILIP WANG (Presenter), Mechanical Engineering and Materials Science, Yale University, ABE CLARK, Physics, Naval Postgraduate School, NICHOLAS OUELLETTE, Civil and Environmental Engineering, Stanford University, MARK SHATTUCK, Physics, The City College of the City University of New York, COREY SHANE O’HERN, Mechanical Engineering and Materials Science, Yale University — Granular flows involve grains of different sizes and mass densities, which either remain well-mixed or segregate. We perform discrete element simulations of model granular systems composed of frictionless, bidisperse disks (with diameter $D_l$ and $D_s$, mass density $\rho_l$ and $\rho_s$, for large and small disks) under gravity and driven by either simple shear or vibration to understand parameters that control mixing and segregation. We have shown that sheared granular system possess 1) a geometrically-segregated regime, where the system becomes increasingly segregated with decreasing $D_s/D_l$, 2) a weight-segregated regime, where the system becomes less segregated as $D_s/D_l$ decreases further, and 3) well-mixed states. We identified the boundaries between these three regimes as a function of $D_s/D_l$ and $\rho_s/\rho_l$. We performed similar studies of vibrated systems to determine if the boundaries between mixed and segregated states depend on the driving method. We show that the large particles rise to the top only if $\rho_l<\rho_s$, i.e. we only find weight-segregation in vibrated systems. We also show that by driving only large particles in vibrated systems, large particles will rise for intermediate packing fractions (0.7>$\phi$>0.5).

*P.W. and C.S.O. acknowledge support from ARO Grant No. W911NF-17-0164.

11:51AM F56.00004: Lift force in size and density segregation  LU JING (Presenter), ADITHYA SHANKAR, PAUL UMBANHOWAR, RICHARD LUEPTOW, Northwestern University — We computationally study the forces experienced by a large intruder in a sheared particle bed. The intruder is attached to a virtual spring, which allows measurement of segregation forces when the intruder reaches an equilibrium position. By subtracting a buoyancy-like contribution from the overall segregation force, the lift force on the intruder is measured for a variety of size and density ratios, and local shear rates. We find that lift force depends only on size ratio and shear rate, but not on density ratio. At a given shear rate, the lift force scales with the square of the size ratio. We propose a lift force model that successfully predicts the combination of size and density ratios at which the intruder rises or sinks. In the future, the lift force model will be used to predict segregation velocity in size and density disperse mixtures.

12:03PM F56.00005: Mesoscopic features of a granular dynamics under cyclic compression*  ZACKERY BENSON (Presenter), ANTON PESHKOV, MICHELLE GIRVAN, IREAP, IPST, University of Maryland, College Park, DEREK C. RICHARDSON, Department of Astronomy, University of Maryland, College Park, WOLFGANG LOSERT, IREAP, IPST, University of Maryland, College Park — We study the reversibility of rotational motion of spherical grains via molecular dynamics simulations. From the simulations, we are able to capture the motion, position, and force distribution of grains during cyclical compression and dilation and find excellent agreement with our experimental data. Additionally, we analyze the network structure formed from the contact forces between individual grains and show how the network dynamics are affected by compression amplitude as well as the evolution of the network from a transient to a steady state. Further, we use a simple machine learning approach combined with experimental data to characterize different states of our granular system.

*This work was supported by National Science Foundation grant #5244620 as well as the National Science Foundation Graduate Research Fellowship Program.
12:15PM F56.00006: Avalanche precursors in a frictional model  

AXELLE AMON (Presenter), IPR, University of Rennes, 
BAPTISTE BLANC, JEAN-CHRISTOPHE GEMINARD, Physics Department, ENS Lyon — An experimental approach to study precursors to avalanches is to progressively tilt a box filled with sand and to monitor the events that take place below the avalanche angle. Such experiments have shown the existence of two types of events: localized rearrangements implying only a few grains and large coherent events implying an increasing part of the sample. Those micro-ruptures occur with an angular periodicity, starting from about half of the avalanche angle until the avalanche takes place.

We will present a numerical and theoretical study of a simple one-dimensional model which captures most of those experimental features. The model consists in elastically coupled sliders on a frictional incline of variable tilt. This simplified model allows a statistical approach leading to master equations describing the state of the system as a function of the angle of inclination. Our central results are the possibility of incomplete stick-slip events under the threshold and the existence of an internal threshold for the outbreak of rearrangements well below the avalanche.

12:27PM F56.00007: Modeling avalanches in granular matter  

PIERRE SOULARD (Presenter), ESPCI ParisTech, DENIS DUMONT, PAUL RAMBACH, Université Mons, THOMAS SALEZ, LOMA, University of Bordeaux, ELIE RAPHAEL, ESPCI ParisTech, PASCAL DAMMAN, Université Mons — Sand is a complex material. At rest, a sand pile is a solid. But as soon as the external stress exceeds a certain threshold, it starts flowing like a liquid. During an avalanche, the two states coexist: a liquid phase rolls on the top of a solid phase, the latter is the result of the sedimentation of the liquid phase. The global description of the rheology of the granular material is still an open question and an active field of research.

In 1994, Bouchaud et al. developed a phenomenological description of the complex interactions between the two phases for starting avalanches. Inspired by this approach, we build a new description of the physics of an avalanche, and applied it to the collapse of a granular column. We compare our theoretical predictions to 3D DEM numerical simulations and experiments for various granular materials.

12:39PM F56.00008: Collapse of Granular Column: an Adequate Tool to Characterize Granular Matter  

DENIS DUMONT (Presenter), University of Mons, PIERRE SOULARD, ESPCI, PAUL RAMBACH, University of Mons, THOMAS SALEZ, University of Bordeaux, ELIE RAPHAEL, ESPCI, PASCAL DAMMAN, University of Mons — In spite of a large effort of the scientific community, a global description of the rheology of granular assembly remains largely elusive. To gain a better insight into the mechanical behavior of granular matter, we focus on a canonical set-up: the collapse of columns under gravity. We carried on 3D DEM numerical simulations and experiments for various granular columns on a frictional plane.

Interestingly, this flow configuration is dictated by only two parameters: the aspect ratio of the initial column, a, and the friction. The dynamics and final shape of the pile can be rationalized through a modified BCRE scheme. The model only includes two parameters, the aspect ratio of the initial column and the dynamic or neutral angle. Interestingly, all the friction coefficients, grain-grain and grain-wall, are encoded in this single value.

12:51PM F56.00009: Inertial Phenomena and Resistive Force Theory in Wheeled Locomotion on Dry Granular Media*  

ANDRAS KARSAI (Presenter), Physics, Georgia Institute of Technology, SHASHANK AGARWAL, KEN KAMRIN, Mechanical Engineering, Massachusetts Institute of Technology, DANIEL GOLDMAN, Physics, Georgia Institute of Technology — We use an automated testbed to systematically conduct single-wheel (20 cm diam.) locomotion experiments in dry granular media (~1 mm poppy seeds) at angular velocities \( \omega \) (0.7-6.4 rad/s) where substrate-based inertial effects emerge. In contrast to Resistive Force Theory based predictions for which translation speed is proportional to angular velocity, as \( \omega \) increases, the translation speed plateaus to a speed dependent on wheel geometry and the system's force distributions. A frictional plasticity model shows similar phenomena despite lacking a rate-dependent constitutive model. This effect can be explained through a force-momentum balance which accounts for the inertial effects caused by changes in substrate inflow/outflow in the system's local volume. This force balance creates a net force loss that increases with translational velocity, creating a material-enforced speed limit for wheeled locomotion. Current RFT models describe quasistatic kinematic bodies, but an inertial correction to the RFT forces shows promise in extending RFT into capturing speed-dependent scenarios as well.

*This work was funded by the Army Research Office, Triangle Park.
1:03PM F56.00010: Understanding slipping of wheels in granular media locomotion

SHASHANK AGARWAL (Presenter), Massachusetts Institute of Technology, ANDRAS KARSAI, DANIEL GOLDMAN, Georgia Institute of Technology, Atlanta, KEN KAMRIN, Massachusetts Institute of Technology

Slipping of circular wheels at high rotation rates on granular media like sand is a commonly experienced phenomenon. At the same time, granular materials themselves are known to be rate-insensitive for a fairly large range of strain rates. In order to identify the fundamental phenomena responsible for the sudden increase in the slipping of wheels above a certain rotational velocity, a plasticity-based continuum modelling study is performed. Lugged wheel locomotion simulations, validated against experimental findings, are performed for a wide range of rotation rates. A momentum conservation-based argument is proposed to explain and predict the onset of increased slipping. An empirical form of optimal rotation rates for wheel locomotion in terms of various associated system parameters is also suggested.

1:15PM F56.00011: Clogging of soft particles in vibrating 2D hoppers

MIA MORRELL (Presenter), ERIC WEEKS, Emory University

We study the outflow of soft, low-friction hydrogel beads from a quasi-2D hopper, examining the probability of clog formation as a function of hopper exit width. By tilting the hopper chamber, we vary the force of gravity driving the flowing bead system. We find that clogging of soft beads requires the hopper aperture to be only slightly larger than the bead diameter, and increasing the force driving the beads towards the exit results in a decreased probability of clogging, holding exit width constant. We then investigate the effects of vibration of the entire hopper system, working in a high frequency limit. Vertical vibrations decrease the clogging probability, due to a disruption of clogging arches. Horizontal vibrations increase the clogging probability, due to an effectively smaller slit size.

1:27PM F56.00012: Measuring the yield stress of charged granular media: how a net charge leads to cohesive powders

C. MARK LEWIS, JEREMY M. LAPRADE, BRANDON M. HOOVER, ABDOUN R. AYOUBA, FREEMAN S. DONG, OSCAR S. HERNANDEZ-DAGUER, ANTHONY DINSMORE (Presenter), University of Massachusetts Amherst

Charged powders are common in nature and industry yet still exhibit many surprising behaviors that are poorly understood. Here we report that piles of grains that all carry the same sign of net charge can, surprisingly, behave like a brittle, cohesive solid. Our experiments probe slab-shaped piles placed on an insulating substrate atop a grounded plate. Sample were irradiated with ions from a corona discharge device and the final surface voltage, $V_S$, was measured. For ordinary sand, removing the pile from the ground plate caused the charged grains to fly off. By contrast, sand grains with hydrophobic coating formed piles that were stable, cohesive and rigid. We measured the rigidity of these piles in two ways: the minimum tilt angle $\theta$ that led to failure, and the yield shear stress, $\sigma_Y$. We found that both quantities increased as $V_S^2$. $\theta$ can exceed 90° and $\sigma_Y$ can reach three times its zero-charge value. We also measured the decay of $V_S$ over time and found that a stretched exponential function fit the data over timescales of many days. These results may lead to new ways to manipulate charged granular materials and provide new insights into the properties of lunar or Martian soils.

1:39PM F56.00013: Jamming and Tiling in Aggregation of Rectangles

ELI BEN-NAIM (Presenter), Theoretical Division, Los Alamos National Laboratory, DANIEL BEN-NAIM, Department of Computer Science, University of California, Santa Barbara, PAUL KRAPIVSKY, Department of Physics, Boston University

We study a random aggregation process involving rectangular clusters. In each aggregation event, two rectangles are chosen at random and if they have a compatible side, either vertical or horizontal, they merge along that side to form a larger rectangle. Starting with $N$ identical squares, this elementary event is repeated until the system reaches a jammed state where each rectangle has two unique sides. The average number of frozen rectangles scales as $N^2$ in the large-$N$ limit. The growth exponent $\alpha=0.229\pm0.002$ characterizes statistical properties of the jammed state and the time-dependent evolution. We also study an aggregation process where rectangles are embedded in a plane and interact only with nearest neighbors. In the jammed state, neighboring rectangles are incompatible, and these frozen rectangles form a tiling of the two-dimensional domain. In this case, the final number of rectangles scales linearly with system size.
1:51PM F56.00014: Analyzing The Flow of a System of Spheres Using Shape-Anisotropic Particles  JUSTIN ROBERTS (Presenter), SHUBHA TEWAR, University of Massachusetts Amherst — We report here on a simulation conducted using LAMMPS [https://lammps.sandia.gov] of a small concentration of dimers in a gravity-driven flow of spheres. The simulation box is a quasi-2D vertical hopper with a rectangular outlet containing a 1% concentration of dimers in an equal mixture of frictional spheres of diameter ratio 1.2. Each dimer consists of two contacting spheres glued together, and all spheres undergo the same Hertzian contact interactions. We track the positions, velocities and orientations of the dimers relative to the flowing spheres and find that while the flow is collisional, the dimers do not reorient significantly except near the walls and near the outlet, where the fluctuations in the sphere velocities are higher. However, as outlet size changes, the region with the largest reorientation per dimer moves from near the edges for large openings, to near the center for small openings, thus appearing to track where velocity fluctuations are large.

2:03PM F56.00015: Confined Packing of Granular Rods* JULIAN FREEMAN (Presenter), CONG CAO, Emory University, SEAN F PETERSON, School of Physics & Astronomy, Rochester Institute of Technology, YUJIE WANG, Department of Physics, Shanghai Jiao Tong University, SCOTT FRANKLIN, School of Physics & Astronomy, Rochester Institute of Technology, ERIC WEEKS, Emory University — We conduct a series of experiments and simulations to observe the effects surfaces have on the packing structure of randomly packed rods. Our experiments use cylindrical containers of different diameters, and rods of aspect ratios ranging from 4 to 32. We find that the rods packed into smaller cylindrical containers yielded lower volume fractions than in larger containers. Our results are extrapolated to an infinite container size, and the subsequent volume fraction decreases with increasing aspect ratios, in agreement with previous simulations. We also do x-ray tomography experiments and study simulated rod packings, which reveal boundary layers where the packing differs from the bulk. At the bottom, rods form layers, although their average volume fraction is similar to that of the bulk. The sides and top layers are both packed with lower volume fractions than the bulk. In particular, the top boundary layer has the strongest perturbation to the overall volume fraction.

Session F57 GSNP: Systems Far from Equilibrium, including Fluctuation Theorems and Fluctuation-Dissipation Relations BSEC 256 - Martin Bazant, Massachusetts Inst of Tech-MIT

11:15AM F57.00001: Numerical Measurement of the Anomalous Dimension in a Two-Species Reaction-Diffusion Model  BENJAMIN VOLLAMAYR-LEE (Presenter), JOSHUA D. HELLERICK, Bucknell University, ROBERT C. RHOADES, Center for Communications Research, Princeton, NJ — We consider a two-species reaction-diffusion model that consists of the trapping reaction $A + B \rightarrow A$ with traps that either annihilate $A + A \rightarrow \emptyset$ or coalesce $A + A \rightarrow A$. Both species undergo diffusion with distinct diffusion constants $D_A$ and $D_B$. We introduce a simulation technique that provides the full probability distribution of $B$ particles for a given realization of the trap dynamics, greatly improving statistical accuracy. We measure in one dimension the $\beta$ particle density decay exponent and the recently predicted anomalous dimension $\varphi$ that appears in the asymptotic $B$ particle correlation function $C_B(r, t) \sim r^\varphi f(r/t^{1/2})$. These exponents are predicted via renormalization group calculations to be universal for dimensions $d \leq 2$, depending only on the diffusion constant ratio and the trap reaction type. We compare our measured values to the renormalization group predictions, and to various exact solutions based on 3-walker and 4-walker problems.

11:27AM F57.00002: Towards a bolometric measurement of the heat of erasure in superconducting logic* OLLI SAIRA (Presenter), MATTHEW MATHENY, RAJ KATTI, Caltech, GREGORY WIMSATT, UC Davis, SIYUAN HAN, U Kansas, JAMES CRUTCHFIELD, UC Davis, MICHAEL ROUKES, Caltech — In his seminal 1961 paper, Landauer derived a lower bound on the heat dissipation by any computing device per irreversible logical operation, such as erasing (resetting) a bit. I will outline a new approach for an unencumbered measurement of the heat of bit erasure using a superconducting flux qubit and an ultrasensitive bolometer. First, using a gradiometric flux qubit as the physical bit subsytem, I will revisit a classical trajectory-tracking demonstration of efficient bit erasure. Owing to the high intrinsic speed of superconducting flux logic, we are able to extract a high-resolution histogram of the work exerted on the system during an erasure cycle. The experimental work histogram display universal features expected for a generic efficient implementation of bit erasure. In addition, the experimental work distributions enable us to test recently-discovered Fractional Fluctuation Theorems, generalizing Landauer’s erasure bound. Second, I will argue that a combination of superconducting logic cell and a bolometer is an ideal way to measure the heat of erasure through its effect on the dissipative environment.

11:39AM F57.00003: Collective Power: Minimal Model for Thermodynamics of Nonequilibrium Phase Transitions
TIM HERPICH, JUZAR THINGNA, MASSIMILIANO ESPOSITO (Presenter), University of Luxembourg — We propose a thermodynamically consistent minimal model to study synchronization which is made of driven and globally interacting three-state units. This system exhibits at the mean-field level two bifurcations separating three dynamical phases: a single stable fixed point, a stable limit cycle indicative of synchronization, and multiple stable fixed points. These complex emergent dynamical behaviors are understood at the level of the underlying linear Markovian dynamics in terms of metastability. Stochastic thermodynamics is used to study the dissipated work across dynamical phases as well as across scales. This dissipated work is found to be reduced by the attractive interactions between the units and to nontrivially depend on the system size.

11:51AM F57.00004: Number of hidden states needed to physically implement a given conditional distribution
JEREMY OWEN (Presenter), Physics, Massachusetts Institute of Technology, ARTEMY KOLCHINSKY, DAVID WOLPERT, Santa Fe Institute — We consider the problem of constructing a physical process over a state space X that applies some desired conditional distribution P to initial states to produce final states. This problem arises in various scenarios in the thermodynamics of computation and nonequilibrium statistical physics (e.g., when designing processes to implement some desired computation, feedback-control protocol, etc.). It is known that there are conditional distributions that cannot be implemented using any master equation involving just the states in X. Here we show that any conditional distribution P can be implemented if additional “hidden” states are available, and provide an upper bound on how many such states are required to implement any P in a thermodynamically reversible manner. Our results imply that for certain P that can be implemented without hidden states, having additional states available permits an implementation that generates less heat. These results can be seen as uncovering a novel type of cost of the physical resources needed to perform information processing—the size of a system’s hidden state space.

12:03PM F57.00005: The thermodynamics of computing with circuits
DAVID WOLPERT (Presenter), ARTEMY KOLCHINSKY, Santa Fe Institute — As Landauer showed, any physical process that implements a given computation must generate a minimal amount of heat. Common engineered systems implement computations using circuits, as do many biological systems (e.g., gene regulatory networks). The topology of such circuits introduces additional constraints on the physical system implementing the computation. One might expect that this increases the minimal amount of heat needed to implement that computation, beyond the minimal amount needed if there are no constraints on how the computation can be implemented. We derive exact equations for the minimal amount of heat that is generated by any physical process that implements a given computation using a specified circuit. We also quantify how that minimal amount of heat compares to the minimal amount when the constraint of implementing the computation with the specified circuit is removed. These results provide a rich, new set of optimization problems that must be addressed by any designer of a circuit, if they wish to minimize thermodynamic costs.

*We would like to acknowledge the Santa Fe institute, and Grant No. CHE-1648973 from the U.S. National Science Foundation.
12:15PM F57.00006: Population dynamics of driven autocatalytic reactive mixture* HONGBO ZHAO (Presenter), MARTIN BAZANT, Massachusetts Institute of Technology — A reactive mixture undergoes thermal fluctuation and reacts with the reservoir when chemically driven. We apply the Fokker-Planck equation consistent with statistical physics to describe the ensemble dynamics. We illustrate the effect of autocatalysis on the ensemble dynamics by comparing systems with identical thermodynamics yet different reaction kinetics. Fictitious phase separation may occur in autocatalytic systems. Reversely, autoinhibition may suppress phase separation, leading to dynamic phase behavior entirely different from thermodynamic equilibrium.

We also present examples found in electrochemical systems such as lithium iron phosphate and LiNi1/3Mn1/3Co1/3O2 (NMC). XRD, STXM and other analytical techniques have revealed intriguing asymmetric autocatalytic or autoinhibitory reaction kinetics and the corresponding phase transition behavior during charge and discharge. As an application, we obtain the inherent reaction kinetics from XRD and electrochemical experiments performed on NMC and demonstrate the agreement between experiments and simulation.

*This work is supported by Toyota Research Institute.

12:27PM F57.00007: Information Thermodynamics of Turing Patterns GIANMARIA FALASCO (Presenter), RICCARDO RAO, MASSIMILIANO ESPOSITO, University of Luxembourg — We set up a rigorous thermodynamic description of reaction-diffusion systems driven out of equilibrium by time-dependent space-distributed chemostats. Building on the assumption of local equilibrium, nonequilibrium thermodynamic potentials are constructed exploiting the symmetries of the chemical network topology. It is shown that the canonical (resp. semigrand canonical) nonequilibrium free energy works as a Lyapunov function in the relaxation to equilibrium of a closed (resp. open) system and its variation provides the minimum amount of work needed to manipulate the species concentrations. The theory is used to study analytically the Turing pattern formation in a prototypical reaction-diffusion system, the one-dimensional Brusselator model, and to classify it as a genuine thermodynamic nonequilibrium phase transition. The framework paves the way to study the energy cost of pattern manipulation and information transmission in complex biochemical systems.

12:39PM F57.00008: Thermolubricity and the Jarzynski equality* ERIOS TOSATTI (Presenter), SISSA and ICTP, Trieste, Italy, FRANCO PELLEGRINI, EMANUELE PANIZON, SISSA, Trieste, Italy, GIUSEPPE SANTORO, SISSA and ICTP, Trieste, Italy — Two different pieces of physics in nanoscale sliding friction are thermolubricity and the Jarzynski identity. The first: a dry slider can at high temperature and low velocity exhibit thermolubric friction \( f \propto v \) replacing ordinary stick-slip friction \( f \propto \log v \) in opposite conditions. The second: satisfaction (violation) of Jarzynski's identity is tied to the abundance (scarcity) of negative work events ("free lunches"). Thermolubricity and Jarzynski are general in nature and separately met in experiments including sliding emulations in optical lattices, and protein force spectroscopy. We prove analytically and demonstrate numerically in the classical Prandtl-Tomlinson point slider model that the presence or absence of thermolubricity is exactly equivalent to satisfaction or violation of the Jarzynski equality. The divide between the two regimes simply coincides with the total frictional work per cycle falling below or above \( kT \) respectively. This concept can, with due caution, be extended to more complex sliders, and invites crosscheck experiments, such as searching for free lunches in cold ion sliding as well as in forced protein unwinding, and alternatively checking for a thermolubric regime in dragged colloid monolayers.

12:51PM F57.00009: Dynamic critical properties of non-equilibrium Potts models with absorbing states* JAMES STIDHAM (Presenter), AHMADREZA AZIZI, MICHEL PLEIMLING, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — We present the results of numerical simulations of non-equilibrium Potts models with absorbing states that allow for different scenarios, depending on the range of the spin-spin interactions [1]. These scenarios encompass a voter critical point, as well as the presence of both a symmetry-breaking phase transition, and an absorbing phase transition. We investigate time-dependent quantities that provide insights into the transient properties of the models.

*Research was sponsored by the US Army Research Office and was accomplished under Grant Number W911NF-17-1-0156.
1:03PM F57.00010: Stability of dynamical quantum phase transitions in disordered systems  
CHRISTIAN MENDL (Presenter), JAN CARL BUDICH, TU Dresden — Dynamical quantum phase transitions (DQPTs) appear at critical times (so-called Fisher zeros) of the Loschmidt amplitude \( G(t) = \langle \psi | e^{-iHt} | \psi \rangle \), where \( | \psi \rangle \) denotes the initial quantum state and \( H \) the Hamiltonian governing the nonequilibrium time evolution. So far DQPTs have mostly been investigated for systems with momentum conservation, but the fate of DQPTs in the presence of spatially uncorrelated disorder remains a largely open question. In this work we address this question by resorting to a supercell representation, which allows us to maintain a generalized version of the momentum space framework. Specifically, Fisher zeros appear as vortices of the complex phase of \( G(t) \) in the momentum-time plane; these vortices can only continuously change with the onset of disorder. Thus we hope to shed light on the dynamical behavior of disordered systems out of equilibrium.

1:15PM F57.00011: Femtosecond imaging of nonequilibrium phase transitions: Symmetry breaking and prethermalization in interacting CDW systems*  
JOSEPH WILLIAMS (Presenter), FARAN ZHOU, TIANYIN SUN, Michigan State Univ, MERCOURI KANATZIDIS, CHRISTOS MALLIAKAS, Northwestern University, CHONG-YU RUAN, Michigan State Univ — In correlated many-body systems, the fundamental processes of spontaneous symmetry breaking (SSB) to form long-range order may be intercepted by competing interactions between particles. In such cases, the transition becomes sharp over the control parameters, and surprising synchronicity develops to manifest macroscopic switching between two stable long-range orders. This departure from SSB behavior has been the hallmark of macroscopic switching of quantum materials, but never before have the microscopic processes been captured with atomic detail. Here we demonstrate a surprising post-laser-quench self-organization of an interacting CDW system exhibiting critical slowdown near thermal and interaction driven critical points. Unlike in SSB system, such photoinduced criticalities primarily emerged in the time domain and manifested in the prethermalization and dynamical phase transition. Using femtosecond (fs) imaging, we capture these highly tunable, nonequilibrium processes and the emerging unconventional symmetry-broken intermediate state, opening up an entirely new dimension in studying and controlling phase transitions far from equilibrium.

1:27PM F57.00012: Nanoscale virtual potentials using optical tweezers*  
JOHN BECHHOEFER (Presenter), AVINASH KUMAR, Simon Fraser University — We combine optical tweezers with feedback to impose arbitrary time-dependent potentials on a colloidal particle. The feedback trap detects a particle’s position, calculates a force based on an imposed “virtual potential,” and shifts the trap center to generate the desired force. This kind of feedback trap can both extend the capabilities of optical tweezers and test fundamental ideas in stochastic thermodynamics. For the former, we have controlled trap stiffness to make tweezer response truly isotropic in three dimensions, allowing unbiased measurement of dynamics. For the latter, we have created virtual double-well potentials with well separations of 11 nm and dwell times of a few ms, scales that approach those of protein-folding dynamics. Such a speed-up of dynamics will allow measurement of stochastic trajectory-based quantities for systems far from equilibrium.

*Work funded by NSERC (Canada).

1:39PM F57.00013: Disordered Kitaev chain with long-range pairing: Loschmidt echo revivals and dynamical quantum phase transitions  
UTKARSH MISHRA (Presenter), Asia Pacific Center for Theoretical Physics (APCTP), Pohang, Gyeongbuk, 790-784, Korea, ROUHOLLAH JAFARI, Department of Physics, Institute for Advanced Studies in Basic Sciences (IASBS), Zanjan 45137-66731, Iran, ALIREZA AKBARI, Asia Pacific Center for Theoretical Physics (APCTP), Pohang, Gyeongbuk, 790-784, Korea — We explore the dynamics of long-range Kitaev chain by varying pairing interaction exponent, \( \alpha \). In a finite size system, it is known that Loschmidt echo has periodic revivals for quenching to the critical point. We find that the revivals in the Loschmidt echo are connected to the energy gap at finite size system, regardless of the initial state. Moreover, and contrary to expectations, for the long-range pairing case, \( \alpha < 1 \), the first revival time (periodicity) scales inversely with the group velocity at the gap closing point, instead of the maximum group velocity. Analyzing the effect of quenched averaging disorder shows the robustness of the first revival time against disorder. For the dynamical phase transition, the presence of disorder washes out the non-analyticities in the rate function of return probability.
The Boltzmann distribution predicts the collective behavior of systems at thermodynamic equilibrium as a function of their constituent parts. Yet most systems in nature—especially living systems—are not at equilibrium, and a unified theory of their behavior does not currently exist. I will show that the Boltzmann distribution is a special case of a general probability flow equation (PFE) that governs stochastic systems, even if far from equilibrium. The PFE is an analog of the voltage equation governing electronic circuits, where resistors, batteries, node voltages, and path currents correspond to equilibrium rate constants, driven rate constants, probabilities, and probability flows, respectively. I will discuss how this new approach can be used to recapitulate known properties of weakly driven systems as well as derive new relations applicable to strongly-driven systems. These relations include general limits on performance and efficiency which are independent of system details; experimental data are used to show that living systems often operate at those limits.

Session F58 GSOFT: Colloids II BCEC 257A - Urs Gasser, Paul Scherrer Institute

11:15AM F58.00001: Synthesis and Assembly of Janus Particles  MENEKA BANIK (Presenter), RABIBRATA MUKHERJEE, Indian Institute of Technology Kharagpur — Over the years, a wide variety of Janus particles with anisotropy in terms of size, shape and chemical functionality have been explored. Synthesis and self-assembly of such particles has been an area of active research. Owing to their anisotropic nature Janus particles experience highly directional interaction. However, assembly of Janus particles on a surface driven by attractive interaction is an area not yet properly explored. One of the probable reasons for this is that most of the synthesized Janus particles are surface immobilized and suffer from significant damage during dislodgement. Also, the anisotropic particles synthesized by chemical route lack uniformity and monodispersity.

Here we have developed a technique for dislodging surface bound Gold-PS Janus particles by UV induced degradation of a PMMA layer. By this method of dislodging Janus particles no damage to the particles occur. Also, an adhesion promoting layer is not required and PS particles with very thin gold coating (~5 nm) can be dislodged. We have also studied the assembly of the dislodged Janus particles on different surfaces and observed that on such surfaces the particles orient in a preferred fashion depending on the particle-substrate interaction.

11:27AM F58.00002: Adsorption and denaturation of structured polymeric nanoparticles at an interface  JIE FENG (Presenter), Mechanical Science and Engineering, University of Illinois at Urbana-Champaign, CHANG TIAN, H. JEREMY CHO, SUJIT DATTA, ROBERT K PRUD'HOMME, Chemical and Biological Engineering, Princeton University — Nanoparticles (NPs) have been widely applied in fields as diverse as energy, environment, and human health. However, the adsorption and trapping of NPs at interfaces is still poorly understood. In many applications, such as drug delivery, understanding NP interactions at an interface is essential to determine and control adsorption onto targeted areas. Therapeutic NPs are especially interesting because their structures involve somewhat hydrophilic surface coronas, to prevent protein adsorption, and much more hydrophobic core phases. Here, we investigate the evolution of NP attachment and structural evolution at the air–liquid interface over time scales from 100 ms to 10s of seconds. We document three distinct stages in NP adsorption. In addition to an early stage of free diffusion and a later one with steric adsorption barriers, we find a hitherto unrealized region where the interfacial energy changes due to surface "denaturation" or restructuring of the NPs at the interface. We adopt a quantitative model to calculate the diffusion coefficient, adsorption rate and barrier, and extent of NP hydrophobic core exposure at different stages. Our results deepen the fundamental understanding of adsorption of structured NPs at an interface.
Phase Separation of Ferromagnetic Nematic and Isotropic Colloidal Suspensions*

MIN SHUAI (Presenter), XI CHEN, CHEOL SOO PARK, JOSEPH E MACLENNAN, MATT GLASER, NOEL ANTHONY CLARK, Department of Physics, University of Colorado Boulder — Suspensions of disk-shaped ferromagnetic barium hexaferrite nanoplates in isotropic solvent spontaneously form a ferromagnetic nematic phase for nanoplate concentrations higher than the Onsager isotropic–nematic phase transition point for hard disks [Nat Comm, 7: 10394, 2016]. At an overall concentration below this value and within the coexistence region, such suspensions phase separate into ferromagnetic nematic and isotropic domains. Under these conditions, the suspension can be driven into a uniform state by mechanical or magnetic stirring, and undergoes a dynamic process of phase separation immediately after the removal of stirring forces, which we have investigated by polarized optical microscopy. Starting from a diffuse, birefringent mesh, nematic regions rapidly coalesce into a three-dimensional network of fine, short, straight filaments. If left undisturbed, these filaments coarsen, combining with each other until the isotropic phase between them is eliminated. In the presence of a weak external magnetic field, filaments along the field direction tend to grow most quickly. We also observe ferromagnetic nematic domains with exotic topological structures, particularly under sudden changes in external field.

Topological Protection in Densely Packed Anisotropic Colloids*

WILLIAM ZYGMUNT (Presenter), Chemical Engineering, University of Michigan, ERIN TEICH, Applied Physics, University of Michigan, GREG VAN ANDERS, Physics, Engineering Physics & Astronomy, Queen's University, SHARON GLOTZER, Chemical Engineering, University of Michigan — It has been long known that there exist topologically protected phases in strongly coupled systems dominated by quantum effects. Recently, analogous phases have been discovered in classical systems of mechanical metamaterials. Here, we demonstrate the existence of topologically protected phases in systems of densely-packed, hard, anisotropic colloids. Previously reported transitions in dense packings as a function of the constituent particle shape lead to the existence of topologically protected thermodynamic phases in such systems, which are shown to be stable away from the limit of densest packing, down to packing fractions of about 75%. Our discovery expands the library of topological phases, and realizing these phases in experiment could provide a new means of producing complex soft materials that are resistant to thermal fluctuations, with applications in robust information storage and processing, and plasmonic materials.

Pitch-dependent behavior of colloids in confined cholesteric liquid crystals*

GIUSEPPE BONIELLO (Presenter), Chemical and Biomolecular Engineering, University of Pennsylvania, FRANCESCA SERRA, Physics and Astronomy, Johns Hopkins University, KATHLEEN STEBE, Chemical and Biomolecular Engineering, University of Pennsylvania — Confined soft matter provides unique opportunities to impose energy landscapes to address and control colloid dynamics. In this context, the geometry of bounding surfaces can be employed to mold an energy landscape. Within this landscape, colloids assemble into reconfigurable, hierarchically organized structures, a leading challenge in material science. Example soft matter systems include liquid crystals. For instance, when nematic liquid crystals (NLCs) are confined in a vessel, bend and splay distortions can be used to position particles. Here we study cholesteric liquid crystals (ChLCs) in a vessel with undulated boundaries. ChLCs have an “intrinsic” twist distortion which adds to the ones imposed by the solid boundaries. The cholesteric pitch competes with the other length scales in the system (colloid radius, vessel thickness, wavelength of boundaries undulations), enriching the possible configurations. Depending on the pitch-to-radius and pitch-to-thickness ratios the interaction can be attractive or repulsive, alternatively. By tuning the pitch (i.e. changing the concentration of the chiral dopant), it is possible to selectively promote or inhibit particle trapping at the docking sites.

12:15PM F58.00006: Microstructure and stress propagation in the nematic glass phase of colloidal cellulose nanocrystals  MATTHEW SARTUCCI (Presenter), Georgetown University, BHARATH NATARAJAN, JEFFREY GILMAN, NIST, JEFFREY S URBACH, Georgetown University — Suspensions of cellulose nanocrystals (CNC's) in low ionic strength aqueous solutions can undergo an isotropic-nematic phase transition due to the anisotropic nature of CNC's. At concentrations above a certain threshold, when the system is well into the nematic regime but far below the maximum stable concentration, these suspensions can form a soft solid with a modulus of approximately 500 Pa. The nematic phase is not homogeneous throughout this system but instead forms many domains, each consisting of collectively aligned CNC's with an average orientation that differs from neighboring domains. This work seeks to understand the mechanical contribution of the domain structure, as observed through cross polarization and boundary stress microscopy, to the macroscopic properties measured through bulk rheology.

12:27PM F58.00007: Modulated colloidal deposition and accumulation in model porous media  GAETAN GERBER (Presenter), IFSTTAR / SEAS, Université Paris-Est / Harvard University, PHILIPPE COUSSOT, Université Paris-Est — Suspended colloids flowing through porous structures are subject to various events, including size-exclusion clogging [1], surface adsorption, or interactions with previously attached bodies. Current models [2,3] qualitatively describe those local mechanisms, while observations are mostly limited to break-through analysis and 2D geometries.

Here, we observe and quantify the local adsorption mechanisms on the internal surface of a 3D porous structure. We consider the accumulation of charged colloids (1µm) in model packs of silica grains and vary the intercolloidal interactions to modulate colloidal aggregation. Deposition is followed by confocal microscopy to identify the precise deposition mechanisms (grain scale) and estimate the spatiotemporal distributions of deposited particles (cm scale). We observe and model two main regimes: (i) deposition of a Langmuirian single-layer of particles due to repulsive intercolloidal interactions, and (ii) multi-layer deposits reaching a critical size (cohesion to drag equilibrium; including potential clogging), when screening those interactions. This provides new tools to predict the transport of suspensions, e.g. for soils remediation or filtration processes.

[1] Gerber, PRL 2018

12:39PM F58.00008: Size Control and Monodispersity of Silica Nanospheres and Applications in Nanofiltration*  RYAN VINCENT (Presenter), SEAN MCBRIDE, Physics, Marshall University — Due to their low reactivity and high thermostability, amorphous silicon dioxide nanoparticles have drawn much attention in the field of nanotechnology. This work reports on the synthesis methods and reaction parameters used to produce monodispersed silica nanospheres of systematically varied sizes using modified Stöber methods. Employing W/O microemulsion systems assisted by amino acid monomers and more traditional Stöber systems, nanosphere diameters were well controlled from single-digit nanometers to several micrometers. Effects of chemical compositions and other reaction parameters effecting TEOS hydrolysis were optimized for each Stöber system. Additionally, the monodispersed spheres were assembled into close-packed systems where the porosity and volumetric flowrates were controlled by the nanoparticle radii. Detailed characterization of the particles and arrays was performed using atomic force microscopy and scanning electron microscopy. Developing a porous system with a tunable effective pore size is a fundamental interest in the field of filtration.

12:51PM F58.00009: Non-Stokes drag of electrophoresis: a new insight into an old problem  MAIJIA LIAO (Presenter), Yale University, MING-TZO WEI, Chemical and Bio-molecular engineering, Princeton University, H DANIEL OU-YANG, Physics Department, Lehigh University, PING SHENG, Physics Department, Hong Kong University of Science and Technology — Mobility, the ratio of a charged-particle drift speed in a DC electric field to the magnitude of the field is typically used to quantify electrophoresis. Drag coefficient cannot be measured in a DC field because application of an external force to measure force alters the flow pattern, yielding an apparent drag force that is Stokes-like. The intrinsic electrophoretic drag can be determined, however, by optically trapping a charged particle and placing it in a low-frequency AC field. Using the frequency-dependent phase shift of the particle motion relative to that of the AC field and the magnitude of the particle displacement, this approach yields drag coefficient, effective charge and also a mobility that is the same as that measured using a DC field. The drag coefficient is markedly different from that of the Stokes. Using the drag coefficient and the mobility as input for numerical calculations based on the Planck-Nernst-Poisson equation and the Stokes equation reveals a well-defined transition between an inner and outer flow in the vicinity of the particle. This study provides a new insight into an old problem by providing experimentally measurable quantities, i.e., effective charge, electric force and drag coefficient a microscopic definition.
1:03PM F58.00010: Gradient expansions to capture the nonlocal physics of the electrical double layer* PEDRO DE SOUZA (Presenter), MARTIN BAZANT, Chemical engineering, MIT — A hallmark of highly charged surfaces or concentrated electrolytes is strong, nonlocal electrostatic and density correlations. In these regimes, the classical Poisson-Boltzmann (PB) mean-field theory for dilute electrolytes breaks down, and the predictions using PB can be qualitatively and quantitatively incorrect. For example, the influence of nonlocal electrostatic correlations lead to charge reversal and like-charge attraction, even though PB theory predicts an exclusively repulsive interaction between like-charged surfaces. Size correlations can lead to oscillatory density profiles that are not captured by PB theory. Here, we explore using a nonlocal Landau-Ginzburg-like free energy functional to describe the structure of an electrical double layer at a charged surface, as well as overlapping electrical double layers, at high charge density and concentration. We show that the correct boundary conditions of such a nonlocal model are given by a force balance at the interface, where the nonlocal effects must vanish. We apply the model to calculate surface forces, interactions between biological molecules, and electrokinetic flows.

1:15PM F58.00011: Computer Simulations of Packed Soft Colloids* TOM RIDLEY, DANIEL READ (Presenter), OLIVER G HARLEN, JOHAN MATTSSON, University of Leeds — Soft colloids are micron-scale structured objects such as polymer microgels, that are compressible and deformable. Even at high packing ratios, a soft colloid may still be able to undergo cage-breaking due to particle deformation. The link between the detailed elastic properties of soft colloids and the resulting dynamics are presently not well understood. Soft colloids show rich rheological behaviour we wish to understand the links between the single particle elastic properties and the resulting rheology. We use a recently developed algorithm, Fluctuating Finite Element Analysis, for simulating viscoelastic objects undergoing thermal excitation. While symmetric soft particle potentials have been much studied, our approach captures the detailed shape deformations of the colloidal particles so that the structure and anisotropic deformation of the particles are taken into account. We investigate varying effective volume fraction and find evidence of cage-breaking events even where the effective volume fraction exceeds the close packed limit. Additionally, we present results of varying modulus and steady shear rates for a constant effective volume fraction.

1:27PM F58.00012: Diffusion of DNA-coated colloids on DNA coated surface JEANA(AOJIE) ZHENG (Presenter), DAVID J PINE, New York University — In order for DNA-coated colloids to anneal and form crystals, they must roll and diffuse while attached to each other. Here we report on the diffusion of DNA-coated colloidal spheres on a flat DNA-coated substrate. Near the DNA-melting temperature, the mean square displacement is linear in time as expected for normal diffusion, but the diffusion coefficient is much smaller than for free diffusion. As the temperature is lowered, the motion becomes subdiffusive, which suggests the presence of random free energy barriers in the DNA-mediated interactions.

1:39PM F58.00013: Microscopic dynamics of stress relaxation in a nanocolloidal soft glass YIHAO CHEN (Presenter), Johns Hopkins University, SIMON ROGERS, UIUC, SURESH NARAYANAN, Argonne, JAMES HARDEN, U. Ottawa, ROBERT LEHENY, Johns Hopkins University — Following the cessation of flow-inducing shear, soft disordered solids often display a protracted recovery during which the stress slowly decreases to a finite value known as the residual stress. While numerous rheology studies have characterized the macroscopic nature of this stress relaxation, little is known about the underlying microscopic structural dynamics. We report x-ray photon correlation spectroscopy (XPCS) experiments with in situ rheometry performed on a soft glass composed of a dense suspension of charged silica nanoparticles subject to step strains that induce yielding. The XPCS measurements characterize the particle-scale and mesoscale motions within the glass that underlie the subsequent slow decay of the stress. The XPCS correlation functions indicate these dynamics are anisotropic, with slow, convective-like particle motion along the direction of the preceding shear that persists for surprisingly large times after flow cessation and that is accompanied by highly intermittent motion in the perpendicular (vorticity) direction. The close correspondence between these dynamics and the stress relaxation is demonstrated by power-law scaling between the characteristic velocity of the convective motion and the rate of stress decay.
1:51PM F58.00014: Particle anisotropy tunes emergent behavior in active colloidal systems  
SHANNON MORAN (Presenter), University of Michigan, ISAAC BRUSS, Harvard University, SHARON GLOTZER, University of Michigan — Since early studies of active systems, investigators have sought to understand the role of particle interactions on a system's emergent collective behavior. Particle anisotropy has been shown to impact the collective behavior of active systems, but studies to date have been qualified demonstrations of concept rather than systematic treatments. In this computational work, we investigate the role of particle anisotropy in shape and driving force director on the phase behavior of an active colloidal system. We find that these anisotropic interactions can combine to enable critical densities lower than those found in systems of isotropic particles, while in some cases actually elevating the critical density. Specifically, we find that tailoring particle anisotropy can enable more "effective" inter-particle collisions to tune the critical system density for phase separation. Additionally, we observe nucleation of multiple clusters in the phase separation regime, similar to those observed in biological systems. In designing programmable active colloidal systems, steric interactions such as those described here may offer a simple route for tailoring emergent behaviors in active materials.

2:03PM F58.00015: Reversible cluster formation and dynamical arrest in colloidal dispersions  
RAMON CASTANEDA PRIEGO (Presenter), Physical Engineering, University of Guanajuato — Combining molecular simulations, experimental characterizations and theoretical calculations: 1) we conclusively demonstrate that the cluster morphology in short-ranged attractive colloidal systems (SRACS) at equilibrium conditions can be uniquely determined by the reduced second virial coefficient; our findings link the reversible colloidal aggregation with the extended law of corresponding states, 2) we show that gelation in adhesive hard-sphere dispersions is the result of the rigidity percolation with coordination number equal to 2.4; these results connect the concept of critical gel formation in SRACS to the universal concept of the rigidity percolation and, finally, 3) we provide a unified description and a general overview of the different aspects of the glass transition in largely asymmetric binary mixtures of hard-spheres; we highlight the fundamental relevance in considering explicitly the dynamics of both large and small particles to properly account for the glassy scenario.

Session F59 GSOFT DPOLY DBIO: Rheology of Gels I
BCEC 257B - Jacinta Conrad, University of Houston - Tag(s): Focus

11:15AM F59.00001: Failure precursors in colloidal and biopolymer gels  
[Invited] LAURENCE RAMOS (Presenter), STEFANO AIME, ANGELO POMMELLA, LUCA CIPELLETTI, CNRS/University Montpellier, Laboratoire Charles Coulomb — Material failure is widespread and occurs on vastly different lengthscales, from earthquakes to the atomic level. It often involves sudden and unpredictable events, with little or no macroscopically detectable precursors. A better understanding of the mechanisms leading to failure is however highly desirable and would have deep implications, possibly paving the way to predicting failure.
We will present experiments probing failure precursors in two types of gel: colloidal and biopolymer gels. Colloidal gels can be regarded as model network forming materials, are brittle and exhibit a power law linear viscoelasticity, whereas biopolymer gels are more complex, show strain-hardening and develop negative normal stresses under shear. We use original set-ups that simultaneously probe the macroscopic rheological response and the microscopic structure and dynamics of a gel submitted to a constant shear stress. We show that the failure is systematically preceded by qualitative and quantitative change of the dynamics, from reversible particle displacement to a burst of irreversible plastic rearrangements with a complex spatial evolution in the sample. Those plastic events are failure precursors of the materials and may be regarded as a novel tool to understand the sudden failure of solids.

**12:27PM F59.00005: Tunable viscoelasticity of binary colloidal gels** JAE HYUNG CHO (Presenter), IRMGARD BISCHOFFBERGER, Mechanical Engineering, Massachusetts Institute of Technology — The mechanical properties of colloidal gels depend strongly on the inter-particle interactions. We investigate the potential to engineer the linear viscoelastic properties of colloidal gels at low volume fractions by mixing two types of home-made polystyrene-poly(N-isopropylacrylamide) core-shell particles of largely different attraction strengths, 5kT and 30kT. We show that we can systematically tune the viscoelastic moduli of the binary mixtures by two orders of magnitude, and the spectra of the relaxation time by seven orders of magnitude, simply by altering their mixing proportions. Using confocal fluorescence microscopy and differential dynamic microscopy, we link these changes in the mechanical properties to the microscopic characteristics of the structure and dynamics of the gel networks.
12:39PM F59.00006: Enhanced gelation in binary mixtures of nanoparticles with tunable short-range attraction
JAMES HARDEN (Presenter), University of Ottawa, HONGYU GUO, NIST, MARTINE BERTRAND, University of Ottawa, TYLER SHENDRUK, Loughborough University, SUBRAMANIAN RAMAKRISHNAN, Florida State University, ROBERT LEHENY, Johns Hopkins University — We report a combined experimental, theoretical, and simulation study of the phase behavior and microstructural dynamics of concentrated binary mixtures of spherical nanoparticles with a size ratio near two and with a tunable, intrinsic short-range attraction [1]. In the absence of the attraction, the suspensions behave as well mixed, hard-sphere liquids. For sufficiently strong attraction, the suspensions undergo a gel transition. Rheometry measurements show that the fluid-gel boundary of the mixtures does not follow an ideal mixing law, but rather the gel state is stable at weaker interparticle attraction in the mixtures than in the corresponding monodisperse suspensions. X-ray photon correlation spectroscopy measurements reveal that, in contrast with depletion-driven gelation at larger size ratio, gel formation in the mixtures coincides with dynamic arrest of the smaller nanoparticles while the larger nanoparticles remain mobile. Molecular dynamics simulations indicate the arrest results from microphase separation that is caused by a subtle interplay of entropic and enthalpic effects and that drives the smaller particles to form dense regions.

12:51PM F59.00007: Rheology of Colloid Gels with Depletion and Bridging Attractions*
NA PARK (Presenter), JACINTA CONRAD, Chemical and Biomolecular Engineering, University of Houston — Polymers are often added to suspensions as viscosity modifiers or stabilizers, but they can induce attractive interactions between particles that alter the suspension phase behavior and, in turn, the rheology. These attractions may be depletion attractions or bridging attractions, depending on whether the polymers adsorb on the surface of the particles. Here, we developed a model attractive colloidal suspension with depletion and bridging attractions. Co-polymer particles of 2,2,2-trifluoroethyl methacrylate and tert-butyl methacrylate were suspended in a refractive index- and density-matched mixture of glycerol and water. To these suspensions, we added poly(acrylamide) or poly(acrylic acid) to induce depletion or bridging attractions, respectively. The rheology was measured and analyzed for each set of samples with increasing concentration of polymer, corresponding to stronger attraction strengths. Significantly different rheology resulted by simply changing the polymer additive in these suspensions, suggesting that processability of suspensions may be tuned by changing the type and interactions of polymer additives in formulations.

1:03PM F59.00008: Analyzing Onset of Non-Linearity of a Fractal Colloidal Gel in the Neighborhood of Critical Point
KHUSHBOO SUMAN (Presenter), YOGESH M JOSHI, Department of Chemical Engineering, Indian Institute of Technology Kanpur India — A colloidal dispersion of Laponite exhibits all the rheological features of a sol-gel transition. While undergoing gelation, Laponite dispersion passes through the critical state stress characterized by a percolated space-spanning fractal network for which the relaxation modulus shows a time dependent power law decay in the linear regime. When subjected to step strain in the non-linear regime, relaxation modulus shifts vertically to the lower values such that the deviation from linearity can be accommodated by use of a strain dependent damping function. We also perform creep-recovery, startup shear and large amplitude oscillatory shear (LAOS) experiments on the Laponite dispersion at the critical gel state and record deviation in the response as flow becomes nonlinear. We also develop a quasi-linear integral model with relaxation modulus weighted by damping function to account for the effect of non-linear strain. Remarkably the proposed quasi-linear integral model predicts the deviation from linearity in the creep-recovery, startup shear and LAOS very well, leading to a simple formulation to analyze the nonlinear rheological behavior of fractal gels.

1:15PM F59.00009: Singular dynamics in the failure of soft adhesive contacts
JUSTIN BERMAN (Presenter), KATHARINE JENSEN, Williams College — We use optical microscopy and high-speed imaging to characterize the rapid recoil of soft, silicone gels after an extreme deformation and release from a point contact during the failure of a soft adhesive contact. The gel immediately recoils away from the final contact point with a self-similar surface profile that evolves as a power law in time, suggesting that adhesive detachment is a space-time singularity. The singular dynamics we observe are consistent with a relaxation process driven by surface stress and hindered by viscous flow of the gel's free fluid phase through its porous, elastic network. Our results emphasize the importance of accounting for both the liquid and solid phases of gels in understanding their mechanics, especially in extreme deformation.
**States of self stress in disordered solids: memory, heterogeneity, and yielding**

SHANG ZHANG (Presenter), University of Michigan, Ann Arbor; VISHWAS VASISHT, University of Grenobles Alpes (France); LEYOU ZHANG, University of Michigan, Ann Arbor; EMANUELA DEL GADO, Georgetown University; XIAOMING MAO, University of Michigan, Ann Arbor —

States of self stress (SSSs), equilibrium stress distributions in a mechanical network with zero net force on any component, govern load-bearing abilities of this network. SSSs are determined by the geometry of the network (because they span the null space of the network's equilibrium matrix), and thus encode the memory of how the mechanical network is prepared. We present our results on SSSs in disordered solids generated by molecular dynamics simulations, and discuss how SSSs are affected by the preparation history of these solids (e.g., cooling rate, compression, shear), and explore the relation between SSSs in a disordered solid and its yielding under stress.

**Scaling theory for mechanical critical behavior in fiber networks**

JORDAN SHIVERS (Presenter), SADJAD ARZASH, Department of Chemical and Biomolecular Engineering, Rice University; ABHINAV SHARMA, Leibniz Institute for Polymer Research; FRED C. MACKINTOSH, Department of Chemical and Biomolecular Engineering, Rice University —

As a function of connectivity, spring networks exhibit a critical transition between floppy and rigid phases at an isostatic threshold. For connectivity below this threshold, fiber networks were recently shown theoretically to exhibit a rigidity transition with corresponding critical signatures as a function of strain. Experimental collagen networks were also shown to be consistent with these predictions. We develop a scaling theory for this strain-controlled transition. Using a real-space renormalization approach, we determine relations between the critical exponents governing the transition, which we verify for the strain-controlled transition using numerical simulations of both triangular lattice based and packing-derived fiber networks.

**Structure and Dynamics of Hydrogen Bonds in the Deep Eutectic Solvent Choline Chloride/Urea: from Molecular Dynamics Simulation with Ab-Initio Polarizable Force Field**

KYEONG-JUN JEONG (Presenter), HYUNTAE JUNG, Department of Chemistry and Theoretical Chemistry Institute, University of Wisconsin - Madison; JESSE MCDANIEL, School of Chemistry and Biochemistry, Georgia Institute of Technology; ARUN YETHIRAJ, Department of Chemistry and Theoretical Chemistry Institute, University of Wisconsin - Madison; CHANG YUN SON, Division of Chemistry and Chemical Engineering, California Institute of Technology; —

Deep Eutectic Solvents (DESs) are a novel class of chemical solvents with beneficial properties. DESs consist of an ionic compound and a neutral hydrogen bond donor (HBD) species, where intermediate compositions of these result in large melting point depression. Although the hydrogen bond of HBD with anions is now known as a key factor in this eutectic phase behavior, the relation between microscopic details and bulk properties is not fully understood. In this study, we develop and import a first-principle-based polarizable force field for choline chloride/urea DES in molecular dynamics simulation. The bulk liquid properties are reproduced without applying charge scaling on the ions. The pair correlation and lifetime of hydrogen bond between HBD and ions exhibit strong character only when the model is polarizable, while its non-polarizable counterpart loses such specificity. Our study implies that the essential rebalancing of molecular interactions in DESs is contingent on polarizability of the model.

11:15AM F60.00001: Herbert P. Broida Prize Talk: Spectroscopic and dynamical probes of atmospheric reaction pathways* [Invited] MARSHA LESTER (Presenter), University of Pennsylvania — Alkene ozonolysis is a primary oxidation pathway for alkenes, the most abundant organic compounds in the Earth's troposphere after methane, and also an important source of atmospheric hydroxyl radicals (OH). Alkene ozonolysis takes place through a complicated reaction pathway with multiple intermediates and barriers on the way to OH products. A carbonyl oxide species, known as the Criegee intermediate (RR’COO), represents a critical branching point on the pathway that controls the products formed in this important class of reactions. In this laboratory, the simplest Criegee intermediate CH2OO and methyl-, dimethyl-, ethyl-, and vinyl-substituted Criegee intermediates are generated by alternative synthetic schemes. Recent studies have focused on characterizing the Criegee intermediates utilizing infrared and ultraviolet spectroscopic methods, and examining their unimolecular and bimolecular reactions under laboratory and atmospheric conditions. Infrared 'fingerprint' and electronic spectra reflecting π-conjugation of the Criegee intermediates are obtained, along with time-resolved studies of their unimolecular decay to OH radical products. Remarkably, the conformation and nature of the substituents (R, R’) of the Criegee intermediates are found to have a profound effect on their reaction dynamics and subsequent chemistry in the atmosphere.

11:51AM F60.00002: Irving Langmuir Prize in Chemical Physics Talk: Interphase Human Chromosome Exhibits Glassy Dynamics [Invited] DAVE THIRUMALAI (Presenter), University of Texas at Austin — The structural organization of the condensed chromosomes is being revealed using chromosome conformation capture experiments and super-resolution imaging techniques. Fingerprints of their three-dimensional organization on length scale from about hundred kilo base pairs to millions of base pairs have emerged using advances in Hi-C and super-resolution microscopy. I will describe using a minimal Chromosome Copolymer Model (CCM) with two loci types corresponding to euchromatin and heterochromatin that the dynamics is similar to that observed in glasses. Chromosome organization is hierarchical involving the formation of chromosome droplets (CDs) on short genomic scale followed by coalescence of the CDs, reminiscent of Ostwald ripening. Glassy landscapes for the condensed active chromosomes might provide a balance between genomic conformational stability and biological functions.

12:27PM F60.00003: Earle K. Plyler Prize for Molecular Spectroscopy & Dynamics Talk: Energy transfer and conversion in molecular junctions* [Invited] ABRAHAM NITZAN (Presenter), University of Pennsylvania and Tel Aviv University — In molecular conductance spectroscopy, the current through a molecule (or molecules) connecting two metal or semiconductors electrodes is measured as a function of the applied voltage. With eye on potential applications, the main issues facing researchers are fabrication, characterization, stability, functionality and control. These considerations bring into focus the need to study systems comprising molecules and metal nanostructures not only for their electrical transport properties but also for their optical, thermal and mechanical response and for their function as energy conversion devices. This talk will review our work on these subjects, and present recent results on current induced light emission, photovoltaic response and electron transfer induced heat conduction in such systems.

*This research has been supported by the NSF (Grant No. CHE1665291) and by the US-Israel Binational Science Foundation.

1:03PM F60.00004: Nonadiabatic dynamics at metal surfaces: Surface hopping and electronic friction WENJIE DOU (Presenter), University of California, Berkeley, JOSEPH E SUBOTNIK, University of Pennsylvania — The coupled electron-nuclear dynamics at molecule-metal interfaces that involve electrons transfer as well as nuclear motions are intrinsically nonadiabatic and difficult to model. Here we present two approaches to treat such nonadiabatic dynamics. In the weak molecule-metal interaction regime, we propose a surface-hopping scheme, where nuclei evolve on diabatic potential energy surfaces with stochastic hopping between them. We demonstrate that such a surface-hopping scheme gives correct detailed balance and recovers Marcus electron transfer rate at molecule-metal interfaces. In the strong molecule-metal interaction regime, we derive a Langevin equation, where classical nuclear degrees of freedom evolve on an adiabatic potential energy surface, while experiencing electronic friction and random force from electronic response. Our form of electronic friction is completely general, but does reduce to previously published expressions without electron-electron interaction. When electron-electron correlations are included, we show electronic friction exhibits Kondo resonance, whereas a mean-field treatment is completely inadequate.
**1:27PM F60.00005: A molecular perspective on the structure and thermodynamics of ice interfaces in atmospherically relevant systems**  
ARPA HUDAIT (Presenter), University of Utah — The processes at the surface of ice modulate crystal growth, adsorption of solutes and atmospherically relevant chemical reactions. These processes are not well characterized, in part, due to lack of spatial and temporal resolution of the existing experimental techniques. Despite decades of investigation, how ice interface modulate the structure of ice grown in atmospheric conditions is yet to be elucidated. In this presentation I will discuss my work using molecular simulations and theory to elucidate the role of thermodynamics of ice interfaces in modulating the structure of atmospheric ices, and the behavior of solutes at the ice interface.

**1:51PM F60.00006: Cavity-Enhanced Ultrafast Spectroscopy**  
[Invited] YUNING CHEN (Presenter), Chemistry, Stony Brook University, MYLES C SILFIES, THOMAS ALLISON, Physics, Stony Brook University — Using the general pump-probe concept, there are various spectroscopy techniques, such as transient absorption spectroscopy and 2D spectroscopy, for studying ultrafast dynamics. These methods are typically restricted to optically thick samples, such as solids and liquid solutions. In these systems, the dynamics often have broad spectral features due to the collisions between the sample molecules and the solvent molecules.

In a molecular beam, the molecules are cold and isolated from the disturbance of solvent molecules. Measurements taken in these gas-phase molecules can be more directly compared to theoretical predictions. Using frequency comb lasers and optical cavities, we have developed an all-optical technique, Cavity-Enhanced Ultrafast Spectroscopy, to study dynamics in molecular beams with femtosecond temporal resolution. The narrow-linewidth frequency comb laser is coupled into two optical cavities that overlap at the focus. The sample molecules under study are introduced to the overlap by a molecular beam with a noble gas carrier. We have carried out a series of transient absorption measurements in I₂ and I₂-Ar clusters in a molecular beam and have demonstrated ultrafast transient absorption measurements with a detection limit of ΔOD = 2×10⁻¹⁰(1×10⁻⁹/√Hz). Such a high sensitivity enables one to take all-optical ultrafast spectroscopy measurements in samples with column densities less than 10¹⁰ molecules/cm² and overall, this represents a nearly 4 orders of magnitude improvement over the previous state of the art. In this talk, I will discuss the technical details of this spectrometer and the experiment in I₂. I will also present a widely tunable version of this spectrometer operating at probe wavelengths between 450 and 700 nm using only one set of dispersion-managed cavity mirrors.

Alignment and controlled formation of topological defects in living fibroblast cells by liquid crystals

TARAS TURIV (Presenter), Advanced Materials and Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, JESS KRIEGER, School of Biomedical Sciences, Kent State University, HAO YU, Advanced Materials and Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, IRAKLI CHAGANAVA, Institute of Cybernetics, Georgian Technical University, 0186 Tbilisi, Georgia, QI-HUO WEI, Advanced Materials and Liquid Crystal Institute and Chemical Physics Interdisciplinary Program and Physics Department, Kent State University, MIN-HO KIM, School of Biomedical Sciences, Kent State University, O D LAVRENTOVICH, Advanced Materials and Liquid Crystal Institute and Chemical Physics Interdisciplinary Program and Physics Department, Kent State University — Arrays of living tissue-forming cells behave as orientationally ordered active nematics and create topological defects of strength +1/2 and -1/2. These defects play an important role in compressive-dilative stresses in tissues and facilitate effects such as apoptosis and cell migration. The challenge is to design orientational patterns of cells with predetermined spatial locations of topological defects in them. We propose an approach to control the alignment of human dermal fibroblast (HDF) cells by substrates with photoaligned liquid crystal polymers (LCPs). With a plasmonic metamask alignment method, we patterned the director orientation of the LCPs with topological defects of integer (+1, -1) and semi-integer (+1/2, -1/2) strength. Combination of polarized, phase contrast and fluorescent microscopies proves that the HDF cells align along the patterned director of the LCP substrate. The patterns cause a modulation of cell density, as the cells accumulate near the cores of the defects with positive topological charge. The approach could be used to control the locations of defect formation in tissues of living cells and potentially control the extrusion of undesirable cells.

The work is supported by NSF DMREF grant DMS-1729509 and by Office of Sciences, DOE, grant DE-SC0019105.

Bioenergetics of cell jamming

STEPHEN J DECAMP (Presenter), NICOLAS CHIU OGASSAVARA, JENNIFER MITCHEL, JEFFREY FREDBERG, Harvard University — Cellular jamming is a ubiquitous phenomenon in epithelial biology that has been shown to govern processes ranging from development in the drosophila gastrulation and zebrafish embryo vertebrate axis elongation, to disease pathophysiology including carcinoma metastasis and asthmatic airway remodeling. A jammed epithelial monolayer remains quiescent and solid-like, whereas unjamming of the monolayer leads to a solid-to-fluid transition in which the cellular collective gains a migratory phenotype, elongated cell shapes, and accompanying mechanical softening. Although jamming has been demonstrated to play a fundamental role in the dynamics of confluent epithelial tissues, the metabolic requirements that fuel the jamming transition and its associated far-from-equilibrium cellular mechanics remain unexplored. Here we measure the metabolic state of individual cells within a confluent monolayer using the cytosolic redox ratio (NAD+/NADH), a reporter of overall cellular bioenergetic potential. Surprisingly, we find that jammed cells near a PDMS barrier have a significantly increased metabolic demand. After barrier removal, and subsequent unjamming, the redox potential of cells near the leading edge of an advancing monolayer decreases to a baseline value consistent with the jammed bulk.

Spatial heterogeneity of cilia contributes to directed flow generation

GUILLERMINA RAMIREZ-SAN JUAN (Presenter), Bioengineering, Stanford University, MU HE, Physiology, University of California San Francisco, ARNOLD MATHIJSSEN, Bioengineering, Stanford University, LILY JAN, Physiology, University of California San Francisco, WALLACE MARSHALL, Biophysics and Biochemistry, University of California San Francisco, MANU PRAKASH, Bioengineering, Stanford University — In living organisms arrays of thousands of micrometer-scale motile cilia coordinate over centimeters to transport fluid. Tissues need to accommodate a variety of specialized cell types, thus cilia do not cover surfaces uniformly. However, how the density and localization of cilia impact flow generation is unknown. Here we combine measurements of cilia organization in the mouse airway with a reduced order hydrodynamic model, to study how spatial organization of cilia integrates across scales to produce long-range flows. Our measurements show that ciliated cells are uniformly distributed but occupy only a fraction of the total surface of the tissue. Furthermore, we measure basal body alignment and tissue-scale cilia orientation (from nm to cm) and find large variations in the local and global orientation of cilia. Despite this spatial heterogeneity, flow measurements show that ciliated cells produce large-scale directed steady flows. Using our model we explore the robustness of the flow to changes in density and orientation of cilia. We find that a fractional coverage of the area by ciliated cells allows the flow to be robust to changes in cilia orientation. Altogether our results highlight the importance of collective cilia properties for flow generation by cilia arrays.
12:27PM F61.00005: Cellular herding: learning from swarming dynamics to experimentally control collective cell migration  DANIEL COHEN (Presenter), Princeton University — Multicellular life is driven by collective cell migration spanning morphogenesis, growth, wound healing, and even cancer invasion. Our lab works to interactively manipulate collective cell migration in living tissues, akin to how a shepherd herds sheep. Our first approach relies on ‘Outside-In’ perturbations to direct epithelial collective migration in real-time by exposing cells to programmable electric fields (electrotaxis). Crucially, we have shown that collective migration patterns within a tissue will track even complex 2D field commands (e.g. diverging fields)—a fact that we are exploiting to interactively ‘sculpt’ living tissues via collective migration control. In parallel, we have developed an ‘Inside-Out’ swarm control approach based on introducing ‘cellular mimics’—3D microstructures mimicking the geometry and cadherin presentation of native cell-cell junctions—to tissues in order to recapitulate cell-cell recognition and adhesion between a living tissue and a cellular mimic. By linking into the endogenous coupling network (cell-cell adhesion), these cellular mimics are allowing us to manipulate and program collective cell migration from within a tissue. Together, our swarm control approaches offer new tools to interactively control the behavior of living tissues.

12:39PM F61.00006: Collective mechanical properties of insect swarms† KASPER VAN DER VAART (Presenter), MICHAEL SINHUBER, NICHOLAS QUELETTE, Stanford University — Social animals routinely form groups, which are thought to display emergent, collective behavior. This suggests that animal groups should have properties at the group scale that are not directly linked to the individuals, much as bulk materials have properties distinct from those of their constituent atoms. We show that laboratory insect swarms possess emergent mechanical properties, displaying a collective viscoelastic response to applied oscillatory visual stimuli. We find that the swarms strongly damp perturbations. Thus, unlike bird flocks, which appear to use collective behavior to promote lossless information flow through the group, our results suggest that insect swarms use it to stabilize themselves against environmental perturbations.

†This research was jointly funded by the Federal Ministry of Education and Research of Germany and the Max Planck Society.

12:51PM F61.00007: Adhesion Strategies of Chlamydomonas in Heterogeneous Habitats  CHRISTIAN TITUS KREIS, ALEXANDROS FRAGKOPOULOS, MARINE LE BLAY, CHRISTINE LINNE, ALICE GRANGIER, MARCIN M MAKOWSKI, OLIVER BAEUMCHEN (Presenter), Max Planck Institute for Dynamics and Self-organization (MPIDS), Göttingen, Germany — In contrast to marine phytoplankton, many photoactive microbes live in complex environments, such as liquid-infused soil and moist rocks, where they encounter and colonize a plethora of surfaces. We discovered that the adhesion of Chlamydomonas to surfaces can be reversibly switched on and off by light [1]. Our in vivo single-cell micropipette force spectroscopy experiments suggest that light-switchable adhesiveness is a natural functionality to actively regulate the transition between freely-swimming (planktonic) and surface-associated state, which yields an adhesive adaptation to optimize the photosynthetic efficiency of the cells in variable and inhomogeneous light conditions. Probing the adhesion forces on model substrates with tailored properties and dissecting the contributions from different intermolecular interactions reveal a universal protein-mediated adhesion mechanism that allows the cells to effectively colonize any type of abiotic surface in their heterogeneous natural habitats. Complementary to our single-cell force measurements, we characterize the surface colonization by cell adsorption assays from which we extract population level morphological and dynamical characteristics.

1:03PM F61.00008: Out-of-plane beating components of active axonemes isolated from Chlamydomonas reinhardtii‡ AZAM GHOLAMI (Presenter), Max-Planck Institute for Dynamics and Self-organization, Göttingen, Germany, SOHEIL MOJIRI, Göttingen University, ALBERT JOHANN BAE, Department of Biomedical Engineering, University of Rochester, JÖRG ENDERLEIN, Göttingen University, EBERHARD BODENSCHATZ, Max-Planck Institute for Dynamics and Self-organization, Göttingen, Germany — Cilia and flagella are ubiquitous in the living world. They are essential for micro-scale driven transport of fluids or cells by cilia/flagellar beating. Their slender bodies are composed of a microtubule/molecular motor structure that when taken independently are called an axoneme. Axonemes move by bending waves that emerge from the interplay between internal stresses generated by dynein motor proteins. Here we use the novel multi-plane phase contrast imaging technique to record the three dimensional beating pattern of isolated axonemes from Chlamydomonas reinhardtii that beat in the vicinity of a substrate. We measure the torsion of the axoneme along the contour length with high spatiotemporal resolution. High precision information on out-of-plane beating component of axonemes allows us to check the validity of the resistive-force theory.

OLGA SHISHKOV (Presenter), MICHAEL MACALINO, DAVID L HU, Georgia Institute of Technology — Black soldier fly larvae are a non-pest insect under consideration as a method of recycling food waste to sustainable protein. These larvae live in large groups in rotting food waste, where they experience hydrostatic forces from the dirt they are in and active forces from their bodies colliding. We investigate how larvae react to these forces by compressing larva aggregations and measuring their response. Larvae align in a container as they follow their instinct to dig downwards, and thus increase their packing fraction and elastic modulus. This study will benefit how larvae are raised in industry by ensuring that larvae are comfortable with their environment and level of substrate, do not expend energy on hiding, and eat and grow quickly.

MICHAEL SINHUBER (Presenter), KASPER VAN DER VAART, NICHOLAS OUELLETTE, Stanford University — In the wild, many animal species form aggregations that behave collectively. Unavoidably, these systems are subject to ubiquitous environmental perturbations such as wind, acoustic and visual stimuli. The way these environmental perturbations influence the animals’ collective behavior, however, is poorly understood, in part because conducting controlled quantitative perturbation experiments in the wild is challenging. To circumvent the need for controlling environmental conditions in the field, we study collective swarms of the midge *Chironomus riparius* in a laboratory experiment where we have control over external perturbations. In this talk, we consider the effect of laboratory-generated perturbations like air flow or variable light exposure on the swarming behavior.

We find that not only do individuals in the swarm respond to these perturbations by changing their kinematics, but also the swarm as a whole can respond by changing its global properties such as its volume, attraction of individual midges to its center or its pressure, indicative of a collective reaction.

HANGJIAN LING (Presenter), Civil and Environmental Engineering, Stanford University, GUILLAM E MCIVOR, Center for Ecology and Conservation, University of Exeter, KASPER VAN DER VAART, Civil and Environmental Engineering, Stanford University, RICHARD T VAUGHAN, School of Computing Science, Simon Fraser University, ALEX THORNTON, Center for Ecology and Conservation, University of Exeter, NICHOLAS OUELLETTE, Civil and Environmental Engineering, Stanford University — Collective animal motion has long been modeled using self-propelled particles that are assumed to be identical and to follow same interaction rules. In nature, however, group members can be quite different, and such differences may shape the group behavior. Here, we study how social relationships in bird flocks affect the local interactions and group dynamics. We used 3D optical tracking to study flocks of jackdaws (*Corvus monedula*), a highly social corvid species that forms lifelong, monogamous pair bonds. We show that jackdaw flocks contain discrete pairs that are likely to reflect the pair bonds. We find that paired birds interact with fewer neighbors than unpaired birds and use less energy when flying. Pairing thus appears to grant energetic benefits. However, we also find that flocks with more pairs have shorter velocity correlation lengths, in agreement with a generic self-propelled particle model, indicating that social relationships may inhibit efficient information transfer through the group. Our results reveal a critical tension between individual- and group-level benefits during collective behavior in species with differentiated social relationships, and have many evolutionary and cognitive implications.

Active flow of low density pedestrian crowds

ALESSANDRO CORBETTA (Presenter), Eindhoven University of Technology, CHUNG-MIN LEE, California State University Long Beach, JORIS WILLEMS, Eindhoven University of Technology, ROBERTO BENZI, University of Rome Tor Vergata, FEDERICO TOSCHI, Eindhoven University of Technology — The dynamics of pedestrian crowds share deep connections with the statistical physics of active matter. Pedestrians move following own will and objectives: this amounts in huge variability in the motion, observable even in diluted conditions. Despite such individual unpredictability, ensemble-level universal physical features emerge and encompass common and rare fluctuations of both the solo and the interacting dynamics. Reaching a quantitative understanding of these features is a major scientific challenge with deep societal impact, e.g. in the design of civil infrastructures or of crowd management measures.

We investigate from observational experiments held in real-life settings (stations, festivals, museums) and in diluted conditions statistical features of pedestrian motion. We leverage on datasets including millions of trajectories acquired with and without external influencing stimuli (i.e., crowd control measures, like signage or visual cues), via home-made high-fidelity tracking systems. On this basis, we quantify the PDFs of individual velocity, position, body rotation and mutual-contact-avoidance "social" forces - possibly in dependence on stimuli. We propose an active-Brownian particle model of the dynamics based on Langevin-like equations statistically quantitative.

Session F62 DQI: New Avenues for Quantum Error Correction

Fault-tolerant quantum computation with few qubits [Invited] BEN REICHARDT (Presenter), University of Southern California — Reliable qubits are difficult to engineer, but standard fault-tolerance schemes use seven or more physical qubits to encode each logical qubit, with still more qubits required for error correction. We give space-efficient methods for fault-tolerant error correction and computation.

For example, with the Steane seven-qubit code, we give a scheme that uses three extra qubits, arranged in two dimensions, to fault-tolerantly extract three syndromes in parallel. With a 19-qubit system, we show that one can protect and compute fault tolerantly on seven encoded qubits. The procedures could enable testing more sophisticated protected circuits in small-scale quantum devices.

New prospects for fault-tolerant quantum error correction with biased-noise cat-qubits [Invited] SHRUTI PURI (Presenter), Yale Univ — Exploiting the structure of noise or "noise-bias" in physical qubits could improve the threshold and overhead requirements for fault-tolerant quantum error correction. The challenge however is to be able to maintain the noise bias while performing elementary operations such as a CNOT gate. I will show how this challenge can be overcome by using the so called stabilized cat-qubits in a parametrically driven non-linear oscillators. In such a qubit, the bit-flip errors increase linearly with the size of the cat, while phase-flips are exponentially suppressed with the cat-size. The stabilized cat-qubit, therefore, exhibits a strongly biased-noise channel. In fact, the phase of the drive determines a continuous family of biased noise cat-states. I will discuss how a bias-preserving CNOT gate can be implemented with these cat-qubits by rotating them through the continuous family of the cat-states in the phase space. I will also present a set of other bias-preserving operations that can be performed with the stabilized cat-qubit. These results provide a new direction for designing error correction codes with high thresholds and reduced overheads.
Experimental quantum error correction with binomial bosonic codes

Scalable quantum error correction with the bosonic GKP code

We review the bosonic GKP (Gottesman-Kitaev-Preskill) code which encodes a qubit into an oscillator and its possible implementation in a microwave mode in circuit-QED hardware. We discuss how GKP code states can be created from Schroedinger cat states or from a dispersive interaction with a qubit. We propose a scalable architecture which uses a surface code on top of the GKP qubits. For a noise model of Gaussian stochastic displacement errors, we discuss how to decode such toric-GKP code and give estimates for the threshold standard deviation, corresponding to a low (4 or more) number of average photons in the GKP code states.

Encoding and controlling a GKP logical qubit in a trapped-ion oscillator

We describe trapped-ion experiments in which we encode a logical qubit using the motion of a single trapped ion. One powerful code of this type is constructed from a set of logical and error-check operators which are displacements in the oscillator phase space [1,2]. We create, measure and manipulate logical information stored in such a code, including teleportation of non-Clifford rotations onto the code space [3]. Alongside the direct focus on quantum computation, the techniques developed for this work also provide new perspectives for quantum control and measurement.

11:15AM F63.00001: Observing the interplay between bacterial behaviors and the physical landscape inside the zebrafish gut* [Invited] RAGHUVEER PARTHASARATHY (Presenter), University of Oregon — In any ecosystem, the structure of the landscape and the activities of its organisms influence one another. This is true in the vertebrate gut as well, where vast numbers of microbes cooperate, compete, and influence both normal and disease-related functions of their hosts. In gut ecosystems, however, we know little about spatial structure, bacterial behaviors, and physical forces. Most of our knowledge comes from sequencing-based studies lacking spatial or temporal information, severely limiting our ability to understand, let alone manipulate, the gut microbiome. To address this, my lab applies light sheet fluorescence microscopy to a model system that combines an in vivo environment with a high degree of experimental control: larval zebrafish with defined sets of bacterial species. I will describe this approach and experiments that have revealed how a species can manipulate intestinal mechanics to facilitate invasion; how differences in bacterial behaviors across species correlate with differences in spatial distributions; and how genetic switches and antibiotics can reveal the roles of individual behaviors such as motility in governing community outcomes. In all of these cases, the physical structure of the microbiome emerges as a major determinant of its population dynamics.

11:51AM F63.00002: Growth strategy of microbes on mixed carbon sources XIN WANG (Presenter), Harvard Medical School, KANG XIA, XIAQJING YANG, CHAO TANG, Center for Quantitative Biology, School of Physics and Peking-Tsinghua Center for Life Sciences, Peking University — A classic problem in microbiology is that bacteria display two types of growth behavior when cultured on a mixture of two carbon sources: in certain mixtures the bacteria consume the two carbon sources sequentially (diauxie) and in other mixtures the bacteria consume both sources simultaneously (co-utilization). The search for the molecular mechanism of diauxie led to the discovery of the lac operon and gene regulation in general. However, questions remain as why microbes would bother to have different strategies of taking up nutrients and in the case of co-utilization what determines the partition and distribution of carbon sources in the cell. Here we show that diauxie versus co-utilization can be understood from the topological features of the metabolic network. A model of optimal allocation of protein resources quantitatively explains why and how the cell makes the choice when facing multiple carbon sources. When two carbon sources are being co-utilized, the model predicts the percentage of each carbon source in supplying the synthesis of every type of amino acid, which is quantitatively verified by experiments. Our work solves a long-standing puzzle and provides a quantitative framework for the carbon source utilization of microbes.

12:03PM F63.00003: A quorum sensing-controlled program of aggregation in V. cholerae* MATTHEW JEMIELITA (Presenter), NED WINGREEN, BONNIE BASSLER, Princeton University — Bacteria communicate and collectively regulate gene expression using the process called quorum sensing (QS). QS relies on population-wide responses to extracellular signal molecules called autoinducers. We demonstrate that, in Vibrio cholerae, QS activates a novel program of multicellularity, which we call aggregation. Aggregation is distinct from the canonical surface-biofilm formation program, which QS represses. Specifically, aggregation is induced by autoinducers, rapidly occurs in cell suspensions, and does not require cell-division, features distinct from those characteristic of V. cholerae biofilm formation. A genetic screen identifies components required for aggregation, revealing proteins involved in V. cholerae intestinal colonization, stress response, as well as a protein that distinguishes the current V. cholerae pandemic strain from earlier pandemic strains. We propose that aggregate formation is important for V. cholerae to transit between the marine niche and the human host. Further exploration of the aggregation process may yield insight into principles that allow bacteria to rapidly build multicellular communities and collectively defend against environmental insults or withstand starvation.

12:15PM F63.00004: Verticalization of bacterial biofilms* FARZAN BEROZ (Presenter), Physics, University of Michigan, Ann Arbor, JING YAN, BENEDIKT SABASS, Princeton University, YIGAL MEIR, Ben-Gurion University of the Negev, HOWARD A STONE, BONNIE BASSSLER, NED WINGREEN, Princeton University — Biofilms are communities of bacteria adhered to surfaces. Recently, biofilms of rod-shaped bacteria were observed at single-cell resolution and shown to develop from a disordered, two-dimensional layer of founder cells into a three-dimensional structure with a vertically-aligned core. In this talk, I will discuss how verticalization is driven by a series of localized mechanical instabilities on the cellular scale. For short cells, these instabilities are primarily triggered by cell division, whereas long cells are more likely to be peeled off the surface by nearby vertical cells, creating an "inverse domino effect". The interplay between cell growth and cell verticalization gives rise to an exotic mechanical state in which the effective surface pressure becomes constant throughout the growing core of the biofilm surface layer. This dynamical isobaricity determines the expansion speed of a biofilm cluster and thereby governs how cells access the third dimension. In particular, theory predicts that a longer average cell length yields more rapidly expanding, flatter biofilms. We experimentally show that such changes in biofilm development occur by exploiting chemicals that modulate cell length.

12:27PM F63.00005: Light dependent motility of microalgae induces pattern formation in confinement ALEXANDROS FRAGKOPOULOS (Presenter), JOHANNES FREY, FLORA-MAUD LE MENN, JEREMY VACHIER, Dynamics of Complex Fluids, Max Planck Institute for Dynamics and Self-Organization, MARCO G. MAZZA, Department of Mathematical Science, Loughborough University, OLIVER BAEUMCHEN, Dynamics of Complex Fluids, Max Planck Institute for Dynamics and Self-Organization — A collection of self-propelled particles can undergo complex dynamics due to hydrodynamic and steric interactions. In highly concentrated suspensions, it is possible for such particles to form large-scale concentration patterns, where the active suspension separates into regions of high and low particle concentrations. Here we present that suspensions of Chlamydomonas reinhardtii cells, a unicellular soil-dwelling microalgae and a model organism of puller-type microswimmers, may form patterns of high and low cell density regions in confinement under specific light conditions. We find that there are significant deviations in the motility of the cells under different light intensities and cell densities, which regulate patron formation in such active suspensions. Finally, by performing active Brownian simulations of such active particles with the observed motility characteristics, we show that we can re-create the pattern observed in our experiments.

12:39PM F63.00006: The universal dynamics of the human microbiome AMIR BASHAN (Presenter), Bar-Ilan University, TRAVIS GIBSON, HMS, JONATHAN FRIEDMAN, Hebrew University, VINCENT CAREY, SCOTT WEISS, HMS, ELIZABETH HOHMANN, MGH, YANG-YU LIU, HMS — In this talk I will address a simple but fundamental question: are the microbial ecosystems in different people governed by the same host-independent (i.e. "universal") ecological dynamics? Answering this question determines the feasibility of general therapies and control strategies for the human microbiome. I will introduce our novel methodology that distinguishes between two scenarios: host-independent and host-specific underlying dynamics. This methodology has been applied to study different body sites across healthy subjects. We also analyzed the gut microbial dynamics of subjects with recurrent Clostridium difficile infection and the same set of subjects after fecal microbiota transplantation. The results can fundamentally improve our understanding of forces and processes shaping human microbial ecosystems, paving the way to design general microbiome-based therapies.

12:51PM F63.00007: Deciphering Functional Redundancy in the Human Microbiome LIANG TIAN (Presenter), Department of Physics, Hong Kong Baptist University, XUWEN WANG, ANGKUN WU, YUHANG FAN, Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, JONATHAN FRIEDMAN, Department of Plant Pathology and Microbiology, Faculty of Agriculture, Food and Environment, The Hebrew University of Jerusalem, AMBER DAHLIN, Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, MATTHEW WALDOR, Division of Infectious Diseases, Brigham and Women's Hospital and Harvard Medical School, GEORGE WEINSTOCK, The Jackson Laboratory for Genomic Medicine, SCOTT WEISS, YANG-YU LIU, Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School — Although the taxonomic composition of the human microbiome varies tremendously across individuals, its gene composition or functional capacity is highly conserved. The striking conservation of functional capacity implies an ecological property known as functional redundancy. Although this redundancy is thought to underlie the stability and resilience of the human microbiome, its origin is elusive. Here, we decipher the basis for functional redundancy in the human microbiome by analyzing its genomic content network --- a bipartite graph that links microbes to the genes in their genomes. We show that this network exhibits special topological features that favor high functional redundancy. Moreover, we find that the assemblage of microbes plays a more important role than their abundances in determining the high functional redundancy of the human microbiome. We propose a simple genome evolution model to explain the key topological features observed in the real genomic content network. These observations deepen our understanding of species-function relationships, a critical step for developing function-based diagnostics and therapeutics.
1:03PM F63.00008: A numerical model of Vibrio fischeri growth and intraspecific competition* YUEXIA LIN (Presenter), Paulson School of Engineering and Applied Sciences, Harvard University, STEPHANIE NICOLE SMITH, ALECIA SEPTER, Marine Sciences, The University of North Carolina at Chapel Hill, CHRISTOPHER RYCROFT, Paulson School of Engineering and Applied Sciences, Harvard University, EVA KANSO, Aerospace and Mechanical Engineering, University of Southern California — E. scolopes squid are colonized with V. fischeri bacteria, and this symbiosis serves as a model system for studying host-microbe interactions. Wild-caught adult squids harbor multiple strains of V. fischeri that engage in intraspecific competition during initial host colonization. However, little is known about how competing strains interact at the single-cell level to influence their spatial structure as they coexist. When grown on agar surfaces, two competing strains form segregated spatial patterns that is dependent on their ability to kill one another. We developed an experimentally informed, multi-agent numerical model of cell growth, division, and death in 2D that can simulate intercellular interactions and environmental factors. In particular, the model accounts for intraspecific competition via mutual killing and differences in growth. This computational model is used to explore conditions that allow a diversity of strains to coexist, as well as investigate the spatiotemporal properties of this coexistence. We present results that demonstrate the method's ability to capture the segregated patterns and their length scales, and explore parameter space that is hard to access in experiments.

1:15PM F63.00009: Machine learning the space-time phase diagram of bacterial swarm expansion* HANNAH JECKEL (Presenter), ERIC JELLI, RAIMO HARTMANN, PRAVEEN SINGH, Max Planck Institute for Terrestrial Microbiology, RACHEL MOK, Department of Applied Mathematics, Massachusetts Institute of Technology, JAN FREDERIK TOTZ, Department of Theoretical Physics, Technische Universität Berlin, LUCIA VIDAKOVIC, Max Planck Institute for Terrestrial Microbiology, BRUNO ECKHARDT, Department of Physics, Philips-University Marburg, JORN DUNKEL, Department of Applied Mathematics, Massachusetts Institute of Technology, KNUT DRESCHER, Max Planck Institute for Terrestrial Microbiology — Coordinated dynamics of individual components in active matter are an essential aspect of life. Establishing a comprehensive, causal connection between intercellular and macroscopic behaviors has remained a major challenge due to limitations in data acquisition and analysis techniques suitable for multi-scale dynamics. Here, we combine a high-throughput adaptive microscopy approach with machine learning, to identify key biological and physical mechanisms that determine distinct microscopic and macroscopic collective behavior phases which develop as Bacillus subtilis swarms expand over five orders of magnitude in space. Our experiments and particle-based simulations reveal that the microscopic swarming motility phases are dominated by physical cell-cell interactions. These results provide a unified understanding of bacterial multi-scale behavioral complexity in swarms.

1:27PM F63.00010: Switching and Torque Generation in Swarming Bacteria* KATIE FORD, JYOT ANTANI (Presenter), ARAVINDH NAGARAJAN, Texas A&M University, MADELINE JOHNSON, Chemical and Biomolecular Engineering, Vanderbilt University, PUSHKAR LELE, Texas A&M University — Escherichia coli swarm on semi-solid surfaces with the aid of flagella. It has been hypothesized that swarmer cells overcome the increased viscous drag near surfaces by developing higher flagellar thrust and by promoting surface wetness with the aid of a flagellar switch. The switch enables reversals between clockwise (CW) and counterclockwise (CCW) directions of rotation of the flagellar motor. Here, we measured the behavior of flagellar motors in swarmer cells. Results indicated that although the torque was similar to that in planktonic cells, the tendency to rotate CCW was higher in swarmer cells, surprisingly. Consistent with earlier reports, moisture added to the swarm surface restored swimming in a CCW-only mutant, but not in a FliG mutant that rotated motors CW-only (FliGCW). Fluorescence assays revealed that FliG<sub>CW</sub> cells grown on agar surfaces carried fewer flagella than planktonic FliG<sub>CW</sub> cells. The surface-dependent reduction in flagella correlated with a reduction in the number of putative flagellar preassemblies. These results suggest that the conformational dynamics of switch proteins play a role in the proper assembly of flagellar complexes and flagellar export, thereby aiding bacterial swimming.

1:39PM F63.00011: Geometric control of bacterial surface accumulation\*  RACHEL MOK (Presenter), JORN DUNKEL, Massachusetts Institute of Technology, VASILY KANTSLER, University of Warwick — Controlling and suppressing bacterial accumulation at solid surfaces is essential for preventing biofilm formation and biofouling. Whereas various chemical surface treatments are known to reduce cell accumulation and attachment, the role of complex surface geometries remains less well understood. Here, we report experiments and simulations that explore the effects of locally varying boundary curvature on the scattering and accumulation dynamics of swimming Escherichia coli bacteria in quasi-two-dimensional microfluidic channels. Our experimental and numerical results show that a non-convex periodic boundary geometry can decrease the average cell concentration at the boundary by more than 50% relative to a flat surface.

1:51PM F63.00012: Atomistic modeling of molecule-lipid interactions to understand small-molecule induced outer membrane vesicle biogenesis in Gram-negative bacteria  AO LI (Presenter), JEFFREY W SCHERTZER, XIN YONG, Binghamton University — With the role of packing biochemical cargos, outer membrane vesicles (OMVs) of Gram-negative bacteria have great importance in many disease-related processes. Recent studies have shown a strong link between a self-produced small molecule, Pseudomonas Quinolone Signal (PQS), and OMV biogenesis in Pseudomonas aeruginosa. We conducted all-atom molecular dynamics simulations to elucidate the interactions between PQS and a model outer membrane. We discovered two characteristic states of PQS, namely attachment on the membrane surface and insertion into the Lipid A leaflet. The time-resolved position of PQS and the angle between its heterocyclic ring and alkyl side chain reveal a four-staged dynamical process: flotation, attachment, folding, and insertion. Remarkably, PQS bends its hydrophobic chain into a closed conformation to lower the energy barrier for penetration through the hydrophilic Lipid A head-group zone, which was confirmed by the potential of mean force (PMF) measurements. Simulation with multiple PQS exhibit significant aggregation of these amphiphilic molecules in the surrounding aqueous phase. Yet, both attached and inserted states were simultaneously observed even in the presence of PQS aggregation. These findings provide critical insight into OMV biogenesis.

Session F64 DBIO GSOFT: Physics of the Cytoskeleton Across Scales II  BCEC 259B - Loren Hough -

11:15AM F64.00001: Physical Guidance of Cytoskeletal Dynamics* [Invited]  WOLFGANG LOSERT (Presenter), University of Maryland, College Park — The guided migration of cells is a complex dynamical process involving carefully regulated polymerization and depolymerization of the elements of the cellular scaffolding, in particular actin. Recent work has shown that polymerizing and depolymerizing actin can be described as an excitable system which exhibits natural waves or oscillations on scales of hundreds of nm, and that wave-like dynamics can be seen in a wide range of natural contexts. I will show that surface nanotopography on scales observed in vivo nucleates and guides the wave-like dynamics of actin polymerization, and that such guided actin waves control cell migration for a broad range of cell types. Furthermore controlled actin waves provide a simple framework to understand seemingly complex aspects of cell migration including the response to chemical and electrical guidance cues, and the ability of cells to follow each other precisely in streams. Thus the excitable systems character of the cellular scaffolding provides a simple, universal framework for analyzing guided migration in living systems.

11:51AM F64.00002: Fluctuation-driven contractility without motors*  SIHAN CHEN (Presenter), TOMER MARKOVICH, FREDERICK MACKINTOSH, Rice University — Contractility in cells is usually due to molecular motor activity, such as in the case of the contractile ring, in which actin and myosin generate during cytokinesis. Recent experiments, however, have suggested non-motor-based contraction in some cells. Here, we present a model for contraction based on stochastic binding of actin filaments that are known to have an asymmetric force response. This leads to continuous net contraction via a Brownian ratchet-like mechanism, provided that the crosslinking is active and violates detailed balance. Using this model, we calculate the force-velocity relation and find a stall force for the system, which could be used to test this model.

*This work was supported in part by the National Science Foundation (Grants DMR-1826623 and PHY-1427654).
12:03PM F64.00003: Regulation of Pulsed Contraction of Actomyosin Networks  JING LI (Presenter), QILIN YU, Purdue University, MICHAEL MURRELL, Yale University, TAEOYON KIM, Purdue University — Actomyosin contractility regulates various biological processes including cell migration and cytokinesis. Cell cortex underlying a membrane, which is a representative actomyosin network in eukaryote cells, exhibits dynamic contractile behaviors. Interestingly, the cell cortex shows reversible aggregation of actin and myosin called pulsed contraction in diverse cellular phenomena. While contractile behaviors of actomyosin machinery have been studied extensively in several in vitro and computational studies, none of them successfully reproduced pulsed contraction observed in vivo. In this study, we first reproduced the pulsed contraction only with the mechanical and dynamic behaviors of cytoskeletal components. We found that clusters with physiologically relevant size and duration can appear in the presence of both F-actin turnover and angle-dependent F-actin severing resulting from buckling induced by motor activities. In addition, we showed that RhoA signaling regulating the dynamics of F-actin and myosin can enhance the stability and durability of pulsed clusters. Our study sheds light on the underestimated significance of F-actin dynamics for the pulsed contraction and on the cooperative mechanism between mechanical and biochemical factors.

12:15PM F64.00004: Regulation of Motions of Myosin Motors in the Actin Cortex  WONYEONG JUNG (Presenter), Purdue University, ALI TABEI, University of Northern Iowa, TAEOYON KIM, Purdue University — Active transport driven by molecular motors in the cytoskeleton plays an important role in various cellular processes. It has been hypothesized that motions of myosin motors in the cortex are determined by the architecture of the cortex. However, the effects of dynamic, force-dependent behaviors of cytoskeletal components on myosin motors remain elusive despite their potential importance. In this study, we employed an agent-based computational model to study motions of myosin in the cell cortex. The model accounts for possible governing factors, including force-dependent walking of motors and the turnover of cross-linkers and F-actin. We found that motions of motors can be suppressed due to three reasons. Motors can slow down significantly either by local force generation or global force transmission between motors. It is also possible F-actin aggregation prevents motors from consistently walking. However, F-actin turnover can recover motor motility in all three cases by inducing force relaxation on motors and cross-linkers. Our results shed light on how myosin motions are regulated by many factors in vivo.

12:27PM F64.00005: Dynamics of focal adhesion orientation in response to time varying stretch  RUMI DE (Presenter), Department of Physical Sciences, Indian Institute of Science Education and Research Kolkata, Mohanpur 741246, India — Mechanical forces play a central role in determining cell function and fate. The effect of time varying stretch is particularly striking which affects many cellular processes such as adhesion, orientation, migration, wound healing to name a few. Focal adhesions act as mechanosensors and in turn regulate the response of cells in tissues. It is not yet well understood how the stretch induces cytoskeletal organization, or how it affects the assembly of focal adhesions. We present a simple theoretical model based on a novel approach in the understanding of stretch sensitive bond association and dissociation processes together with the elasticity of the cell-substrate system to predict the growth, stability and the orientation of focal adhesions in the presence of static as well as cyclic stretches. Our model agrees well with several experimental observations; most importantly, it explains the puzzling observations of parallel orientation of focal adhesions under static stretch and nearly perpendicular orientation in response to fast varying cyclic stretch. Moreover, it also elucidates the existence of threshold frequency and stretch magnitude for orientational response that have been found to vary across cell types.

12:39PM F64.00006: Mechanism of Generating Pulling Force via Actin Polymerization*  FOWAD MOTAHARI (Presenter), ANDERS CARLSSON, Department of Physics and Center for Engineering Mechanobiology, Washington University in St. Louis — Actin polymerization is the primary mechanism for overcoming the large turgor pressure that opposes endocytosis in yeast. Actin-based pulling forces are less well understood than pushing forces. We stochastically simulate a system of 144 semiflexible actin filaments in a square network, treating all subunits explicitly. Each filament interacts with the membrane via a potential having both attractive and repulsive components. The protein Sla2, which binds actin filaments to the membrane, is assumed to slow the growth of the filaments near the array center by having a strongly attractive potential. The (de)polymerization rates depend on the filament-membrane gap. We include both actin network elasticity and filament-tip bending. We find that the outer filaments push on the membrane, while the inner filaments pull on it. We calculate the force distribution for various model parameters, including the potential depths, the free filament on- and off-rates, the numbers of fast- and slow-growing filaments, and the network rigidity. Under the most favorable conditions, the total pulling force is the sum of the stall forces of all the pushing filaments.

The role of the actin filament brancher Arp2/3 in the dynamics and structures of actomyosin networks

JAMES LIMAN (Presenter), Bioengineering, Rice University, CARLOS A. BUENO, Systems, Synthetic, and Physical Biology, Rice University, YOSSI ELIAZ, Department of Physics, University of Houston, PETER WOLYNES, HERBERT LEVINE, MARGARET CHEUNG, Center for Theoretical Biological Physics, Rice University — Actomyosin network contractility underlies the motility and division of a cell, involving contraction and expansion that are driven by active protein motors and actin treadmilling. In this work, we present novel computational and theoretical approaches to model contractility and growth in actomyosin networks and evaluate the spatiotemporal patterns of actin reorganization. We consider two different actomyosin network morphologies, unbranched and branched. For the unbranched case, the system includes motor proteins (non-muscle myosin IIA (NMIIA)) and cross-linker proteins (α-actinin). For the branched case, the system includes a third component—Arp2/3 complexes—that allows us to investigate the role of branching in actomyosin contractility. We observe that linkers modulate contraction in the unbranched and the branched actomyosin networks. The branched actomyosin networks relax more slowly than their unbranched counterparts. However, the branched networks show pronounced convulsive contractions. We expect our results to give an insight into the importance of the branched morphological formation in enhancing contractility of the actomyosin networks.

Actin Dynamics Measured and Characterized by Optical Flow

LEONARD CAMPANELLO (Presenter), RACHEL LEE, MATT J. HOURWITZ, JOHN T FOURKAS, WOLFGANG LOSERT, University of Maryland, College Park — Actin dynamics are an important component of critical functions such as cell migration and immune response. Specifically, waves of actin are present in a wide range of conditions such as cell-cell adhesion formation and immune cell activation. We utilize periodic surface topographies comparable in size to in vivo collagen fiber networks to generate actin dynamics consistent with what would be observed in real cell microenvironments. We show that, when in contact with such textured surfaces, many cell types exhibit esotaxis — guidance of the actin waves by the surface texture. The one-dimensional waves of actin are very reproducible, which allows us to quantify these actin dynamics in cell types with dissimilar migratory modes and physiological purposes — slowly migrating epithelial MCF10A cells and fast migrating neutrophil-like HL60 cells. Using a computer vision algorithm called Optical Flow, we designed and employed an automated analysis program to characterize the pixel scale guidance of actin waves, as well as their mesoscale characteristics.

Epithelial Wound Healing Coordinates Distinct Actin Network Architectures to Conserve Mechanical Work and Balance Power

ALAN TABATABAI, VISAR AJETI, ANDREW FLESZAR, Yale Univ, MICHAEL F STADDON, Physics, University College London, DANIEL S. SEARA, Yale Univ, CHRISTIAN SUAREZ, Molecular Genetics and Cell Biology, University of Chicago, MUHAMMAD YOUSAFZAI, Yale Univ, DAPENG BI, Physics, Northeastern University, DAVE KOVAR, Molecular Genetics and Cell Biology, University of Chicago, SHILADITYA BANERJEE, Physics, University College London, MICHAEL MURRELL (Presenter), Yale Univ — How cells with diverse morphologies and cytoskeletal architectures modulate their mechanical behaviors to drive robust collective motion within tissues is poorly understood. During wound repair within epithelial monolayers in vitro, cells coordinate the assembly of branched and bundled actin networks to regulate the total mechanical work produced by collective cell motion. Using traction force microscopy, we show that the balance of actin network architectures optimizes the wound closure rate and the magnitude of the mechanical work. These values are constrained by the effective power exerted by the monolayer, which is conserved and independent of actin architectures. Using a cell-based physical model, we show that the rate at which mechanical work is done by the monolayer is limited by the transformation between actin network architectures and differential regulation of cell-substrate friction. These results and our proposed mechanisms provide a robust quantitative model for how cells collectively coordinate their non-equilibrium behaviors to dynamically regulate tissue-scale mechanical output.

We acknowledge funding ARO MURI W911NF-14-1-0403, NSF CMMI-1525316, NIH RO1 GM126256 and NIH U54 CA209992.
Molecular crowding modulates actin filament mechanics and structure* NICHOLAS CASTANEDA, MYEONGSANG LEE, HECTOR RIVERA-JACQUEZ, RYAN MARRACINO, THERESA MERLINO, Nanoscience Technology Center, University of Central Florida, HYERAN KANG (Presenter), Department of Physics, Nanoscience Technology Center, University of Central Florida — The cellular environment is crowded with macromolecules that reduce accessible volume for biomolecule interactions and protein assembly. Actin filament assembly and mechanics play critical roles in many cellular functions including structural support, cell movement, and force generation. Although the effects of molecular crowding on actin assembly have been shown, how crowded environments affect filament conformations and mechanical properties remain unclear. Here, we investigate the effects of molecular crowding on actin filament mechanics and structure both in vitro and in silico. Direct visualization of filaments in the presence of crowders allows for the quantification of filament thermal bending dynamics and mechanics. Biophysical analysis show that molecular crowding enhances filament’s effective bending stiffness and reduces average filament lengths. Utilizing molecular dynamics simulations, we demonstrate that molecular crowding leads to changes in filament conformations and inter-subunit contacts affecting filament mechanics. This work suggests that the interplay between excluded volume effects and non-specific interactions induced by molecular crowding may modulate actin filament mechanics and structure.

*We thank NSF for support of this work through REU site EEC 1560007.

How multivalent crosslinker proteins affect the self-assembly of actomyosin networks* YOSSI ELIAZ (Presenter), MARGARET CHEUNG, University of Houston; Center for Theoretical Biological Physics (Rice University) — Actomyosin networks are nonequilibrium active matter systems with millions of nanometer-scale proteins that self-assemble to form complex biomechanical structures 10,000 times larger than its constituent proteins. These networks play a key role in the morphology of neuronal dendritic spines whose plasticity regulates long-term memory formation and retention. We use a coarse-grained model to simulate actomyosin networks with both active and passive multivalent crosslinker proteins. Passive crosslinkers bind filaments statically while active crosslinkers (motor proteins) exert force and walk along the polarized filaments. So far, only systems with divalent crosslinkers have been simulated in large scales. Our computational simulations allow us to understand how and when active and passive multivalent crosslinkers promote bundled, scaffolded, isotropic, or clustered phases of the networks. More specifically, our model reveals the dependencies between the network structure and the multivalent crosslinker’s type, concentration, and properties.

Tug-of-war by active gel shapes positioning symmetry in cell-sized compartment RYOTA SAKAMOTO (Presenter), Department of Physics, Kyushu University, MASATOSHI TANABE, Department of Physics, Waseda University, TETSUYA HIRAIWA, Department of Physics, The University of Tokyo, KAZUYA SUZUKI, SHIN’ICHI ISHIWATA, Department of Physics, Waseda University, YUSUKE T. MAEDA, Department of Physics, Kyushu University, MAKITO MIYAZAKI, Department of Physics & The Hakubi Center for Advanced Research, Kyoto University — Force generation powered by actin cytoskeleton is underlying a wide range of phenomena from heart beating to cell migration [1]. To understand the underlying physical principles, in vitro reconstruction of actin cytoskeleton in water-in-oil droplet has been developed as a cell model, in which spontaneous F-actin flow and actomyosin clusters were self-organized [2]. However, it remains unclear how the spatial positioning of these structure is determined. To understand actomyosin-mediated geometric positioning, we confined actomyosin droplets in quasi two-dimensional chamber. We find that periodic actomyosin waves move the cluster to center, while the cluster is towed to edge by percolation of radial actomyosin network. By considering time-lag between maturation of actomyosin cortex and that of percolated network, active gel model recovers size-dependent two-state cluster positioning, which will give insights into the nucleus and spindle positioning in vivo [3]. We revealed active role of physical confinement to control intracellular positioning through actin cytoskeleton.

Dynamic stiffening and softening of a system of colloids cross-linked via polymers

ELISABETH RENNERT (Presenter), Rochester Institute of Technology, GASTON MOORHEAD, University of San Diego, JENNIFER ROSS, University of Massachusetts, Amherst, MICHAEL RUST, University of Chicago, RAE ROBERTSON-ANDERSON, University of San Diego, MOUMITA DAS, Rochester Institute of Technology — With the goal of deciphering the design principles for biomimetic materials that can autonomously stiffen and soften, we investigate colloids as a model system that can dynamically transition between fluid-like and gel-like states when crosslinked with polymers. The model is first developed with a system of colloids interacting via Lennard Jones potential, a fraction of which are further connected via passive crosslinkers. We study this system using Brownian Dynamics simulations and obtain collective properties, such as the time needed to form system spanning networks and elastic moduli, for various colloid volume fractions, interaction strengths, and cross-linker concentrations. Using experimental parameters for polystyrene spheres and Bovine Serum Albumin (BSA) crosslinkers, we predict the behavior of real systems. Next, we replace the passive, one-shot crosslinkers in our model by active cross-linkers that can dynamically attach and detach, and characterize the degree of order and the mechanical response of the system as a function of time. Our results provide insights into the design of self-sustaining soft materials that can dynamically stiffen and soften, and how the properties of such materials can be tuned.

Molecular Mechanics of Mussel Inspired Copolymers and Coatings [Invited] PEYMAN DELPARASTAN, KATERINA MALOLLARI, University of California, Berkeley, HAESHIN LEE, KAIST, PHILLIP MESSERSMITH (Presenter), University of California, Berkeley — A number of marine organisms rely on adhesive secretions for attachment to substrates in wet, turbulent environments. In the case of mussels, adhesion is mediated by the byssus- a remarkably strong and tough tissue comprised of collagenous protein threads terminally anchored by an adhesive pad. Byssal proteins have very specialized amino acid compositions, likely related to the specific challenges of achieving adhesion in the wet marine environment. Several byssal proteins contain high levels of 3,4-dihydroxy-L-alanine (DOPA), and there is a growing interest in developing mussel-inspired materials that contain catechols and other functional groups such as primary amine. Mussel inspired coatings derived from the spontaneous polymerization of dopamine, so-called ‘polydopamine’ coatings, have been widely reported in the literature for their ability to be deposited on a variety of substrates. However, the composition of polydopamine remains unknown. In this talk, we will describe our recent results on the molecular mechanics of polydopamine and related coatings using single molecule force spectroscopy. The results favor a ‘polymer’ model of polydopamine structure, casting doubt on models suggesting polydopamine is a supramolecular aggregate of small molecules and oligomers.
Adhesion Strategies of Dictyostelium discoideum - a Force Spectroscopy Study

MARCO TARANTOLA (Presenter), NADINE KAMPRAD, Max Planck Institute for Dynamics and Self-Organization, HANNES WITT, Physical Chemistry, University of Goettingen, MARCEL SCHROEDER, CHRISTIAN TITUS KREIS, OLIVER BAEUMCHEN, Max Planck Institute for Dynamics and Self-Organization, ANDREAS JANSCHOFF, Physical Chemistry, University of Goettingen — Biological adhesion is essential for all motile cells and limits locomotion to substrates displaying a compatible surface chemistry. However, organisms that face vastly varying environmental challenges require a different strategy. Dictyostelium discoideum (D.d.), a soil-living slime mould, faces the challenge of overcoming variable chemistry by employing fundamental forces of colloid science. To understand the origin of D.d. adhesion, we realized and modified a variety of conditions comprising specific adhesion proteins, glycolytic degradation, ionic strength, surface hydrophobicity and van der Waals interactions by generating tailored model substrates. Employing AFM-based single cell force spectroscopy we show that experimental force curves upon retraction exhibit two regimes. The first part up to the critical adhesion force can be described in terms of a continuum model, while a second regime of the curve beyond the critical adhesion force is governed by stochastic unbinding of individual binding partners and bond clusters. This versatile mechanism allows D.d. to adhere to a large variety of natural surfaces.

In-vivo study of Yielding and Post-yielding behavior of Cytoplasm and its linkage with the cytoskeleton

SIJIE SUN (Presenter), JING XIA, DAVID A WEITZ, Harvard University — We study the yielding and post yielding behavior of cytoplasm in vivo. Cytoplasm, as an omnipresent component of the cells, is known to have finite Young's modulus and resists deformation, while intracellular cargo transports as fast as micron per second is observed in cytoplasm. In this study, the 3T3 cell line is adapted as a template to investigate the yielding and post yielding behavior of the cytoplasm. We find that cytoplasm yields at $10^2$ Pascal scale. The post yielding behavior may be modelled as Bingham fluid. Further control experiment illustrates that both heterogeneity and microtubules significantly contribute to the yielding behavior: The resistance of cytoplasm has multiple resources, and the dynamic assembling and dissembling of the microtubules are essential for yielding. Also, the cytoplasm close to microtubule-organizing centre (MTOC) has higher resistance towards yielding. Our experiment demonstrates the solid to fluid transform of cytoplasm under finite force.

Load-dependent bond kinetics have varied effects on the dynamics and mechanics of actomyosin contractility

PASHA TABATABAI (Presenter), DANIEL S. SEARA, IAN LINSMEIER, MICHAEL MURRELL, Yale Univ — Within the cytoskeleton, myosin motor proteins consume chemical energy and generate mechanical work within the filamentous actin network essential for diverse cell functions like migration, division, and shape change. Myosin unbinding kinetics are force dependent- exhibiting "catch-bond" behavior which decreases the probability of unbinding under load. Altering the binding kinetics of proteins is prohibitively difficult, thus the impact of load dependent binding kinetics on the dynamics and mechanics of actomyosin contractility are unclear. To this end, we use coarse grained molecular dynamics simulations to explore the effect of catch bonds on the accumulation and dissipation of mechanical energy in the actomyosin cytoskeleton. We find that motor binding that increases under load sensitizes the network to myosin motor concentration, increasing the rate of contractility while simultaneously increasing network toughness, or the storage of mechanical energy.

12:27PM F65.00005: High stretchability, strength and toughness of living cells enabled by hyperelastic vimentin network*  JILIANG HU (Presenter), YIWEI LI, MING GUO, Department of Mechanical Engineering, Massachusetts Institute of Technology — In many normal and abnormal physiological processes, including cellular migration during normal development and invasion in cancer metastasis, cells are required to withstand severe deformations. The structural integrity of eukaryotic cells under small deformations has been known to depend on the cytoskeleton including actin filaments (F-actin), microtubules and intermediate filaments (IFs). However, it remains unclear how cells resist severe deformations since both F-actin and microtubules fluidize or disassemble under moderate strains. Here, we demonstrate that vimentin intermediate filaments (VIFs), a marker of mesenchymal cells, dominate cytoplasmic mechanics at large deformations. Our results show that cytoskeletal VIFs form a stretchable, hyperelastic network. This network works synergistically with other dissipative cytoplasmic components, substantially enhancing the strength, stretchability, resilience and toughness of the living cytoplasm.

12:39PM F65.00006: Fibril formation kinetics of insulin solutions in an interfacial shearing flow  NICHOLAS DEBONO (Presenter), ADITYA RAGHUNANDAN, HANNAH R. MIDDLESTEAD, A HIRSA, Rensselaer Polytechnic Institute — The formation of amyloid fibril plaques and the accumulation of such structures in vivo is the hallmark of disorders such as Alzheimer's and type-II diabetes. Fibril formation can be accelerated by several factors including changes to pH and temperature conditions. However, the role of the dominant and most varying in vivo factors of fluid flow and shear at hydrophobic interfaces in protein aggregation pathways remain poorly understood. Proteins adsorbed at the air/fluid interface are also subjected to significant hydrodynamic stresses during bioprocessing and drug handling, which leads to unwarranted denaturation/aggregation and subsequent loss in drug efficacy. Here, we study the kinetics of fibril formation for human recombinant insulin solutions in an interfacial shearing flow using fixed time-point ThT fluorescence and native-protein absorbance assays across a wide range of rotation rates. We identify differences in the morphology of the fibril structures formed at the air/fluid interface and in bulk solution at different stages of fibril seeding and growth. This is key to elucidating the aggregation pathway and toxicity of shear-induced denaturation and protein fibril formation.

12:51PM F65.00007: MULTI-SCALE MICRORHEOLOGY USING FLUCTUATING SEMIFLEXIBLE FILAMENTS AS STEALTH PROBES  KENGO NISHI (Presenter), University of Gottingen, CHRISTOPH F. SCHMIDT, Duke University, FREDERICK MACKINTOSH, Rice University — Microrheology is commonly performed using micron-sized beads embedded in the (soft) medium to be studied. Inserting beads can be problematic in confined or hard to access places and can cause artifacts. Here, we introduce the use of single-walled carbon nanotubes (SWNTs), which are model semi-flexible polymers with non-photobleaching fluorescence, as “stealth probes”. We embedded SWNTs in viscoelastic media and analyzed thermally driven shape fluctuations. We show that the bending dynamics of SWNTs embedded in soft media can be used to probe the viscoelastic properties of such media at multiple scales, corresponding to the wavelengths of the modes analyzed. We found that the viscoelastic moduli of polymer solutions measured by SWNTs are in excellent agreement with those by measured by conventional micro/macrorheology, which validates the method.

1:03PM F65.00008: In situ imaging of strained collagen fibrils*  CHRIS PEACOCK (Presenter), LAURENT KREPLAK, Department of Physics and Atmospheric Science, Dalhousie University — Damage to collagenous tissues remain difficult to treat due to uncertainty of how their constituents operate under tension. The smallest of these constituents is the collagen fibril, a rope-like aggregate of collagen molecules with a structure comparable to man-made fibres. While the force-elongation curve of collagen fibrils is fairly well characterized, structural changes due to elongation remain poorly understood. In this talk I will present an in situ atomic force microscopy approach to probe the morphology and cohesiveness of strained fibrils.

*C.P. and L.K. acknowledge funding from the Natural Sciences and Engineering Research Council of Canada (NSERC) and the Canada Foundation for Innovation (CFI)
1:15PM F65.00009: Collagen-inspired self-assembly of twisted filaments  MARTIN FALK (Presenter), Massachusetts Institute of Technology, LUCY COLWELL, University of Cambridge, AMY DUWEL, Draper Labs, MICHAEL PHILLIP BRENNER, Harvard University — There have been dramatic developments in our ability to functionalize submicron scale objects with molecules enabling specific interactions between building blocks, opening up an enormous design space for solutions of particular engineering problems. Here, we explore the physics of collagen self-assembly in order to deduce design rules for the self-assembly of twisted filaments. Despite the well-known structure of collagen, identifying which aspects of its design are required for reproducing collagen-like features in synthetic analogues is unknown. Using computer simulations, we propose a scheme mediated by specific interactions to self-assemble collagen-like triple helices. The assembly nucleates chiral defects, in which two of the filaments switch orientations. Such defects can be eliminated with a modest energetic bias, or nucleated by introducing mechanical weak spots. By inducing spatial variation of the enthalpy of helix formation, we can localize another type of defect where the helix becomes locally unbound. Local unbinding slows assembly, evoking kinetic pathologies previously ascribed to mutations in the primary collagen amino acid sequence. In analogy to collagen, controlled formation of defects could enable hierarchical self-assembly of bundles of twisted filaments.

1:27PM F65.00010: Mechanism of metal-like conductivity in bacterial protein nanowires*  SOPHIA YI, YANGQI GU, JENS NEU, J. PATRICK O’BRIEN, SIBEL EBRU YALCIN, DENNIS VU, WINSTON HUYNH, VICTOR BATISTA, CHARLES A SCHMUTTENMAER, NIKHIL MALVANKAR (Presenter), Yale Univ — Proteins are considered electronically insulators. However, nanofilaments produced by Geobacter sulfurreducens exhibit metal-like conductivity. To elucidate the mechanism of electron transport, we measured the electrical and optical conductivity of filaments from multiple mutant strains as a function of molecular length, temperature, frequency, pH and π-stacking. We demonstrate that intrinsic conductivity of individual filaments can be described by theoretical model for quasi-one-dimensional materials. To determine the molecular architecture responsible for conductivity, we are using a suite of complementary experimental and computational methods. Our studies show that filaments show π-stacking, that can cause intermolecular electron delocalization, conferring metallic conductivity to filaments. Furthermore, increasing π-stacking improves their crystallinity, yielding a longer mean free path for electrons, and stronger electronic coupling which yields 1000 times lower electron attenuation than other proteins. These studies will help development of genetically programmable biomolecular materials with tunable functionality through precise control of their electronic and protein structure.

1:39PM F65.00011: Cancer, p53, and non-classical self-assembly of amyloids and their first order phase transitions*  [Invited]  MOHAMMAD SAFARI, Biochemistry, Princeton University, ANATOLY BORIS KOLOMEISKY, Chemistry, Rice University, JACINTA CONRAD, PETER VEKILOV (Presenter), University of Houston — About half of human cancers are associated with mutations of the tumor suppressor p53. Gained oncogenic functions of the mutants have been related to aggregation behaviors of wild-type and mutant p53. The thermodynamic and kinetic mechanisms of p53 aggregation are poorly understood. Here we find that wild-type p53 forms an anomalous liquid phase. The liquid condensates exhibit several behaviors beyond the scope of classical phase transition theories: their size, ca. 100 nm, is independent of the p53 concentration and decoupled from the protein mass held in the liquid phase. Thermodynamic analyses elucidate another unusual property of this liquid phase: lack of constant solubility. The nucleation of p53 fibrils deviates from the accepted mechanism of sequential association of single solute molecules. We find the liquid condensates serve as pre-assembled precursors of high p53 concentration that facilitate fibril assembly. Fibril nucleation hosted by precursors represents a novel biological pathway, which opens avenues to suppress protein fibrillation in aggregation diseases.

11:15AM F66.00001: Bounding Information flow in E. Coli chemotaxis

HENRY H MATTINGLY, Dept. of Molecular Cellular and Developmental Biology, Yale University, THIERRY EMONET, Dept. of Physics and Dept. of Molecular Cellular and Developmental Biology, Yale University, BENJAMIN MACHTA (Presenter), Dept. of Physics and Systems Biology Institute, Yale University —

The bacteria *Escherichia coli* climbs shallow gradients by tumbling - randomly reorienting their directed runs - when they sense they are moving away from chemical attractants. In the absence of any information from their receptors *E. coli* would be unable to move in a directed fashion, moving stochastically by runs and tumbles with an effective long-scale diffusion constant D. Here we show that to climb a gradient with average speed V requires a transfer entropy rate, I, from direction of motion, through receptor activity, and ultimately to tumbling behavior of at least I = V^2/2D. This provides a lower bound on the requirements of the signaling cascade that can be inferred from single bacteria trajectories. We discuss how this bound constrains the design of the receptor and signaling system.

11:51AM F66.00002: Towards a New Theory of Biological Information

DANIEL INAFUKU (Presenter), Physics, University of Illinois at Urbana-Champaign, KAY KIRKPATRICK, Mathematics, University of Illinois at Urbana-Champaign — Many attempts have been made to understand biomolecular machines, such as the ribosome, from a computational and information-theoretic perspective. However, it is well-understood that current information theory is limited to symbolic (i.e., syntactic) manipulations only and is not equipped to deal with objects that possess functions beyond such manipulations. In this study, we present a quantitative analysis of the information-processing abilities of several classes of biomolecular machines that demonstrates their capacities for biological information. Furthermore, we argue that such machines possess functions that lie beyond the scope of traditional Shannon information theory and require a new description to completely characterize them. Finally, we propose new ways to extend current models by rigorously abstracting the structure and dynamics of these machines.

12:03PM F66.00003: Information transmission and evolution of crosstalk in noisy signal transduction networks

AMMAR TAREEN, Cold Spring Harbor Laboratory, NED WINGREEN, Department of Molecular Biology, Princeton University, RANJAN MUKHOPADHYAY (Presenter), Clark University — Reliable transmission of information about the environment along cellular signaling pathways is crucial for accurate regulation of cellular function. However, signaling pathways are often highly interconnected, creating signal transduction networks consisting of multiple pathways. How did such complex, interconnected networks evolve and what constraints did the dynamics of evolution place on their architecture? Does crosstalk between pathways necessarily lead to reduction in the amount of information that can be reliably transmitted? In this talk, we will study information transmission and the evolution of cross-talk between noisy signaling pathways with the aim of addressing these and related questions. For this purpose, we develop a sequence-based evolutionary algorithm and evolve networks consisting of more than one pathway based on physically motivated fitness functions. We show how two fitness functions, both related to measures of information transmission, lead to very different evolutionary outcomes, one with a high degree of crosstalk and the other without. We relate the evolutionary outcomes to the fitness landscapes, and discuss the biological implications of our results.

12:15PM F66.00004: Information loss under coarse graining: A geometric approach

ARCHISHMAN RAJU (Presenter), Centre for Studies in Physics and Biology, Rockefeller University, JAMES PATARASP SETHNA, Cornell University, BENJAMIN MACHTA, Yale University — We use information geometry, in which the local distance between models measures their distinguishability from data, to quantify the flow of information under the renormalization group. We show that information about relevant parameters is preserved, with distances along relevant directions maintained under flow. By contrast, irrelevant parameters become less distinguishable under the flow, with distances along irrelevant directions contracting according to renormalization group exponents. We develop a covariant formalism to understand the contraction of the model manifold. We then apply our tools to understand the emergence of the diffusion equation and more general statistical systems described by a free energy. Our results give an information-theoretic justification of universality in terms of the flow of the model manifold under coarse-graining.

12:27PM F66.00005: The strength of protein-protein interactions controls the information capacity and dynamical response of signaling networks*  CHING-HAO WANG (Presenter), Physics, Boston University, CALEB BASHOR, Bioengineering, Rice University, PANKAJ MEHTA, Physics, Boston University — Eukaryotic cells transmit information by signaling through complex networks of interacting proteins. Here we develop a theoretical and computational framework that relates the biophysics of protein-protein interactions (PPIs) within a signaling network to its information processing properties. We formulate a statistical physics-inspired model and combine it with information-theoretic methods to find that PPIs are a key determinant of information transmission within a signaling network, with weak interactions giving rise to “noise” that diminishes information transmission. While noise can be mitigated by increasing interaction strength, the accompanying increase in transmission comes at the expense of a slower dynamical response. This suggests that the biophysics of signaling protein interactions give rise to a fundamental “speed-information” trade-off. We further use this framework to interrogate the relationship between pathway cross-talks and information capacity, as well as its implications in synthetic biology.

12:39PM F66.00006: Random input expansion improves classifier accuracy  JULIA STEINBERG (Presenter), MADHU ADVANI, HAIM SOMPOLINSKY, Harvard University — We have discovered a surprising phenomena in the problem of inference with noisy high dimensional data: that adding random input dimensions (completely uncorrelated to the data) can lead to lower generalization error when training max-margin classifiers. When applied appropriately, we prove that this expansion of the network can yield equivalent solutions to the addition of slack variables in support vector machine learning. We also consider two layer networks and demonstrate that this phenomenon can allow wide random neural networks with sparse activity to handle output noise more effectively than networks exactly matched to the structure of the teacher network. This finding has implications for the design of neural networks and in understanding the role of neurogenesis and short-lived synapses in biological neural network structures.

12:51PM F66.00007: The renormalization group and information bottleneck: a unified framework  ANDREW TAN (Presenter), University of Toronto, LEENOY MESHULAM, Massachusetts Institute of Technology, WILLIAM BIALEK, Princeton University, DAVID SCHWAB, City University of New York — Achieving useful simplified descriptions of high-dimensional systems is a fundamental problem in statistical physics. A central issue is formalizing which details should be retained and which discarded, such that we are left with only “relevant” information. In statistical physics, the outcome of the renormalization group is a reduced description where we are left with an accurate description of the macroscopic behavior of the system. In information theory, we use the information bottleneck to determine the optimal balance between features we accurately convey and those that are irrelevant complexity. Here we present an approach that unifies the concepts of the renormalization group and the information bottleneck. We achieve a coarse-graining procedure where we can control what “relevant” information we choose to keep, e.g. retaining information about long-distance features while removing local information. Studying the method in the information plane allows us to automatically select the best representation at each size. Variational approaches allow us to scale up our implementation, so that this approach can be successfully applied to large systems. We test our method on a variety of datasets from both physics and machine learning.

1:03PM F66.00008: Optimal visual motion estimation in a natural environment*  WILLIAM BIALEK (Presenter), Physics, Princeton University and The CUNY Graduate Center, SHIVA SINHA, ROBERT DERUYTER VAN STEVENINCK, Physics, Indiana University — Many organisms, from flies to humans, use visual signals to estimate their motion through the world. In flies we know that the precision of motion estimation is close to the limits set by photon shot noise and diffraction blur, yet the actual estimates suffer from systematic errors, some of which are shared by human perception. To explore the structure of the motion estimation problem, we have constructed a camera/gyroscope system that allows us to sample, at high temporal resolution, the joint distribution of input images and rotational motions during a long walk in the woods. From these data we construct the optimal estimator of velocity based on spatial and temporal derivatives of image intensity in small patches of the visual world. Over the bulk of the naturally occurring dynamic range, the optimal estimator exhibits the same systematic errors seen in neural and behavioral responses, including the confounding of velocity and contrast. These results suggest that apparent errors of sensory processing may reflect an optimal response to the physical signals in the environment.

1:15PM F66.00009: The Stochastic Complexity of Spin Models: Are Pairwise Models Really Simple?  ALBERTO BERETTA, Quantitative Life Sciences, The Abdus Salam International Centre for Theoretical Physics (ICTP), Strada Costiera 11, I-34014 Trieste, Italy, CLAUDIA BATTISTIN, Kavli Institute for Systems Neuroscience and Centre for Neural Computation, Norges Tekniske-Naturvitenskapelige Universitet (NTNU), Olav Kyrres Gate 9, 7030 Trondheim, Norway, CLÉLIA DE MULATIER (Presenter), Department of Physics and Astronomy, University of Pennsylvania, 209 South 33rd Street, Philadelphia, PA 19104-6396, USA, IACOPO MASTROMATTEO MASTROMATTEO, Capital Fund Management, 23 rue de l'Université, 75007 Paris, France, MATTEO MARCELLI, Quantitative Life Sciences, The Abdus Salam International Centre for Theoretical Physics (ICTP), Strada Costiera 11, I-34014 Trieste, Italy — Models can be simple for different reasons: because they yield a simple and computationally efficient interpretation of a dataset (e.g. in terms of pairwise dependencies)--as in statistical learning--or because they capture the laws of a specific phenomenon--as in physics--leading to non-trivial falsifiable predictions. In information theory, the simplicity of a model is quantified by the stochastic complexity, which measures the number of bits needed to encode its parameters. In order to understand how simple models look like, we study the stochastic complexity of spin models with interactions of arbitrary order. We show that bijections within the space of possible interactions preserve the stochastic complexity, which allows to partition the space of all models into equivalence classes. We thus found that the simplicity of a model is not determined by the order of the interactions, but rather by their mutual arrangements. Models where statistical dependencies are localized on non-overlapping groups of few variables are simple, affording predictions on independencies that are easy to falsify. On the contrary, fully connected pairwise models, often used in statistical learning, appear to be highly complex, because of their extended set of interactions, and are hard to falsify.

1:27PM F66.00010: Who is your neighbor? Inferring locality from pairwise correlations  MAHAJABIN RAHMAN (Presenter), ILYA NEMENMAN, Emory University — Modeling multivariate biological systems, such as multielectrode neural recordings, genetic sequences, or gene expression patterns, requires identification of combinatorial interaction coefficients coupling the measured variables. This is impossible to do from data sets of realistic sizes. One could hope to regularize the inference by imposing the constraint that interactions must be local. However, whether two variables are neighbors and thus can interact is unknown for many biological data sets. Here we explore the possibility that neighborhood relations can be inferred from the pairwise correlation matrix, even in the undersampled data limit. Our toy model consists of a set of images whose pixels are shuffled randomly, but in the same way for all images, such that spatial information is lost, but pixel-to-pixel correlations are preserved. We use t-SNE, a dimensionality reduction and visualization technique, to embed the shuffled pixels in space, such that strongly correlated pixels end up next to each other. We observe that embedding the data in 2D space produces images nearly identical to the originals, save for global transformations. This shows that analysis of the covariance matrix correctly identifies local neighborhoods, as well as the global dimensionality of the data.

1:39PM F66.00011: Mean Field Analysis of Batch Normalization  MINGWEI WEI (Presenter), Department of Physics and Astronomy, Northwestern University, JAMES STOKES, Tunnel Technologies, DAVID SCHWAB, The Graduate Center, City University of New York — Batch Normalization (BatchNorm) is an extremely useful component of modern neural network architectures, enabling optimization using higher learning rates and achieving faster convergence. In this paper, we use mean-field theory to analytically quantify the impact of BatchNorm on the geometry of the loss landscape for multi-layer networks consisting of fully-connected and convolutional layers. We show that it has a flattening effect on the loss landscape, as quantified by the maximum eigenvalue of the Fisher Information Matrix. These findings are then used to justify the use of larger learning rates for networks that use BatchNorm, and we provide quantitative characterization of the maximal allowable learning rate to ensure convergence. Experiments support our theoretically predicted maximum learning rate, and furthermore suggest that networks with smaller values of the BatchNorm parameter achieve lower loss after the same number of epochs of training.

1:51PM F66.00012: Nonequilibrium cooperative sensing  VUDTIWAT NGAMPRUETIKORN (Presenter), Northwestern University, DAVID J. SCHWAB, The Graduate Center, CUNY, GREG STEPHENS, Vrije Universiteit (Amsterdam) & OIST Graduate University (Okinawa) — While cellular sensing relies on both cooperation between receptors and energy consumption to suppress noise, their combined effect is not well understood. Here we introduce a minimal model of interacting sensors which allows for the detailed exploration of signal statistics and cooperation strategies in the context of optimal sensing. For two sensors we show that the sensing strategy which maximizes the mutual information between the signal and the sensors depends both on the noise level and the statistics of the signals. For signals on a single sensor, nonequilibrium, asymmetric couplings result in maximum information gain in the noise-dominated limit while for joint, correlated signals, the improvement is greatest in the low-noise limit. In particular we show that optimal sensing does not always require energy consumption. We detail the difference in mechanism behind nonequilibrium improvement for univariate and correlated signals and our results provide insight into the principles of optimal sensor design.
A Novel Algorithm for Unsupervised Behavioral Classification

ADAM FINE (Presenter), NIRAG KADAKIA, THIERRY EMONET, Yale Univ — I present a novel software package used for extraction of behavioral patterns from a data matrix with no a priori assumptions about the form of the data. The underlying algorithm transforms a data matrix into the time-frequency domain using a wavelet transform, which is analogous to taking a Fourier transform at each time step. This equalizes the power between frequency components, to ensure repeated high frequency motions do not dominate. The transformed matrix is then decomposed into behavioral patterns and their relative activity over time using an algorithm called seqNMF [1]. Though the algorithm was originally developed for positional data from an assay of Drosophila, it has been used to extract behavioral patterns from other organisms (e.g. E. coli) as well. The algorithm is robust with respect to both the number of underlying patterns in the data as well as the length of the patterns. In addition, the lack of any input other than the data itself makes the software package a powerful unsupervised classification tool with broad potential applications.

Tuesday, March 5, 2019 11:15 AM - 1:27 PM

Session F67 APS/SPS: Undergraduate Research VI

11:15AM F67.00001: Fabrication of Sensitive MEMS-based Magnetometer for Biomagnetic Applications* ZAINAB BATOOL (Presenter), RALITSA MIHAYLOVA, ANDY CLARK, Department of Physics, Bryn Mawr College, JOSH JAVOR, Department of Mechanical Engineering, Boston University, XUEMEI CHENG, Department of Physics, Bryn Mawr College, DAVID JOHN BISHOP, Department of Mechanical Engineering, Boston University — The electrocardiogram (ECG) is the standard method of heart disease detection but is inconveniently sized and susceptible to conductive tissue noise and signal attenuation by filtering. Additionally, the superconducting quantum interference device (SQUID) systems operate in vacuum, are expensive and large, and are rivaled by atomic magnetometers (AMs), which are compact and sensitive but limited by spin relaxation. Here we report the development and fabrication of a MEMS-based, 100pT/cm sensitive, inexpensive magnetometer device, which may overcome the mentioned limitations. The device measures gradient fields by detecting magnetic force exerted on a commercial MEMS capacitive accelerometer through the coupled micro-sized, permanent magnet. Present limitations of this device are fabrication throughput and magnet characterization. Here we discuss characterization by a vibrating sample magnetometer (VSM) and obstacles in a custom micro-gluing technique.

*This work was jointly supported by CELL-MET, an NSF Engineering Research Center, under award number 1647837 and by the Center for Engineering Mechanobiology (CEMB), an NSF Science and Technology Center, under grant agreement CMMI: 15-48571

11:27AM F67.00002: Low-Frequency Vibration Isolation for Atom Interferometry* NINA INMAN (Presenter), Physics, Bryn Mawr College, FONG EN OON, RAINER DUMKE, Physics and Applied Physics, Nanyang Technological University, MICHAEL LIM, Rowan University — The isolation of low-frequency vibrational noise must be applied in most gravimeters to allow for accurate measurement of Earth's local gravitational acceleration. Optimal performance of a gravimeter can be achieved by mitigating the effects of vibration on inertial acceleration measurement. A seismometer is used to detect vibrational noise and produce a voltage signal from which the magnitude and frequency of vibrations can be calculated. A system was constructed to record vibrational noise and compute its Fourier Transform. The output is low-pass filtered and can be fed back to a voice coil to correct residual noise detected on a vibration isolation platform. The next steps include determining the appropriate cut-off frequency range and benchmarking the performance in various environments.

*The authors acknowledge support from NSF-IRES 1559410.

11:39AM F67.00003: Quantization of the Vibrations of a Thin Elastic Plate ELIOT HEINRICH (Presenter), DENNIS CLOUGHERTY, University of Vermont — Suspended thin films have been successfully used as high-Q mechanical oscillators in hybrid optomechanical systems to study fundamental quantum mechanical effects. Motivated by these experiments, we consider a Hamiltonian description of the vibrations of a clamped, elastic circular plate. The Hamiltonian of this system features a potential energy with two distinct contributions: one that depends on the local mean curvature of the plate, and a second one that depends on its Gaussian curvature. We quantize this model using a complete, orthonormal set of eigenfunctions for the clamped, vibrating plate. The resulting quanta are the flexural phonons of the thin circular plate. As an application, we use this quantized description to calculate the rms displacement of the plate's center for arbitrary temperature.
**11:51AM F67.00004: Measuring Viscosity with A Damped Harmonic Oscillator**

DONAVAN EBERSOLE (Presenter), TY NAQUIN, JAMES SANDERS, Physics and Chemistry Department, Troy University — The damped harmonic oscillator is a staple of undergraduate physics education, and the Stokes' Law drag is often used as an example of such damping. This force has the required form of $F = -bv$; however, the coefficient $b$ is dependent on the fluid viscosity, which is itself a function of the fluid's temperature. We attached a spherical mass to the end of spring that was suspended in the liquid; the other end of the spring was attached to a force sensor. After slightly displacing the mass, we used Pasco software to record the Hooke's Law force during the motion. A graph of force versus time yields the damping coefficient, from which we could measure the fluid's viscosity. By comparing the viscosity to a table of known values, we could then determine the fluid's temperature.

*This work was funded by an NSF grant through a program called Louis Stokes Alliances for Minority Participation (LSAMP).*

**12:03PM F67.00005: Nonlinear resonance for a generalized parametric oscillator**

YAO LUO (Presenter), Nanjing University — Multiple discrete stationary solutions, namely "amplitude quantization", found in kick-excited pendulums have not been well understood over decades. We show that these discrete solutions are subharmonic resonance originated from the nonlinear periodic driving force. From theoretical analysis, we reveal the relationship between subharmonic resonance frequency and symmetry of the driving force: odd subharmonic resonance occurs under even symmetric driving force and vice versa. We also show that multiple periodic solutions coexist near subharmonic resonance frequencies, in particular dual solutions are discovered. While the usual parametric oscillator has periodic driving force proportional to displacement and experience subharmonic resonance at even multiples of the pendulum's frequency, our mathematical model can be viewed as generalized parametric resonance which has nonlinear periodic driving force and experience subharmonic resonance at integral multiples of the pendulum's frequency. In order to investigate the stability conditions and evolution of the solutions, we calculate the frequency response curves, bifurcation diagram, phase diagrams, Poincare maps and the stability diagrams.

**12:15PM F67.00006: Exploring Resonance Effects on Ferromagnetic Microwire Solenoid Sensitivity for Motion Tracking Applications**

JAKE POLER (Presenter), VALERY J ORTIZ, TATIANA M EGGERS, MANH-HUONG PHAN, University of South Florida — The high frequency GMI effect is a sensitive phenomenon found in amorphous, soft ferromagnetic materials. The GMI effect has potential to introduce a new class of long range, contact-free small field magnetic sensing[1]. GMI sensors allow for low-cost, robust systems capable of a wide range of motion tracking applications. A challenge these sensors present to applications comes from the quick decay of magnetic field lines, restricting their sensing distance. In an attempt to achieve better sensitivity and longer ranges, Cobalt-based microwires have been wound into solenoids around Plexiglas molds with various lengths of wire. Further, the number of turns used, affects the magnitude and frequency of transmission line resonance. GMI responses were measured around resonance to determine the optimal operating frequency for each sensor and to observe the relation to the circuit's current nodes. Of the solenoids constructed, the 12 turn, 203 mm solenoid had the highest sensitivity. The optimal operating frequency was 32.4 MHz, which allowed for a range of 250 mm. For comparison, GMR sensors have a detection range of 190 mm[2].

*NSF REU #1560090*

**12:27PM F67.00007: Building time-dependent temperature field in a multi-field coupling system**

JIAHAO DONG (Presenter), Nanjing University — Solving time-dependent field remains challenging in most situations due to convergence difficulty. In this paper, we systematically research the solving method of the time-dependent temperature field in case of a multi-field coupling system, including mesh partition methods, decoupling strategies, iterative algorithms, etc. We apply our method to an apparatus called “Curie Point Engine”. In the example, a nickel disc located in an inhomogeneous magnetic field is heated asymmetrically, and then is driven to rotate around the axle by the asymmetrical magnetic force. In this case, the temperature field, magnetic field and the motion of the disc are all time-dependent and coupled. We apply the dynamic mesh method due to the motion of the disk. The validity of our method is confirmed by comparing the simulation results to our experimental images of a Curie Point Engine recorded by a thermal imager.
12:39PM F67.00008: A statistical comparison of OAR doses between Helical Tomotherapy and VMAT plans*  
Micheal Taylor (Presenter), Physics, University of South Florida, Dawn Gintz, Jimmy Caudell, Vladimir Feygelman, Kujtim Latifi, Eduardo Moros, Radiation Oncology, Moffitt Cancer Center — Head & neck cancer patients have a high risk of nutritional problems caused by their cancer and the toxic side effects of radiotherapy. The feasibility dose-volume histogram (fDVH) algorithm available in the PlanIQ software (Sun Nuclear Corporation, Melbourne, FL) has been validated to optimally aid in the sparing of certain organs-at-risk (OAR's) in head & neck volumetric modulated arc therapy (VMAT) plans. This study evaluates the met or missed opportunities for limiting dose to OAR's by applying the fDVH tool to head & neck Helical Tomotherapy plans and compare them to VMAT plans of similar dose and staging. Head & neck cancer patients treated in 2014 were selected. All patients had the following OAR's reviewed in an imaging handling software (Mirada Medical, Oxford, UK): larynx, inferior pharyngeal constrictor, submandibular glands, and parotids. Any missing or inadequate contours were edited. Only patients treated with a 70 Gray Simultaneous Integrated Boost Tomotherapy/VMAT plan with a bilateral elective neck were analyzed. Patients with the same or a similar cancer stage as defined by the American Joint Committee on Cancer were grouped, and the differences in areas under the fDVH's and actual DVH's were statistically compared.

*Funded by NSF REU grant #1560090

12:51PM F67.00009: Symmetry Breaking and Iterated-Map Networks  
Houssemeddine Mhiri (Presenter), Moyi Tian, Lars Q English, Dickinson College — The logistic map is a simple mathematical model commonly used to explore discrete-time systems. L’Her, et al. [1] implemented an electronic circuit that mimics the behavior of coupled logistic maps to great precision. While L’Her’s circuit provides the basis for our experimental exploration of logistic map networks, it lacks practical control of initial conditions. We reproduced L’Her’s circuit and introduced automated manipulation of the initial conditions and of the coupling voltage through an Arduino Uno Microcontroller. This additional control allows for a close exploration of symmetric states and symmetry-broken states that the coupled logistic maps exhibit under specific conditions. Indeed, for fixed values of the growth rate, the manipulation of initial conditions produces an array of symmetric and symmetry-broken states. We will use this data to generate basins of attraction for the corresponding growth parameters. Conversely, if we fix the growth rate and iteratively increment the coupling strength, we experimentally observe interesting bifurcation behavior involving the symmetric, symmetry-broken, as well as phase-shifted solutions.

1:03PM F67.00010: Comparing Classical And Quantum Finite Automata*  
Kaitlin Gili (Presenter), Department of Physics and Engineering Physics, Stevens Institute of Technology, Rudy Raymond, Rodney Van Meter, IBM Q Hub, Keio University, Kohei M Itoh, Department of Applied Physics and Physico-Informatics, Keio University — Quantum computers offer advantages that motivate the exploration of quantum algorithms and models with the expectation that they can solve many more complex problems than classical computers. Here, we are exploring one of the simplest models of computation by comparing Deterministic Finite Automata and Quantum Finite Automata (Ambainis and Freivalds, 1998). This research focuses on applying quantum principles to the following problem: Consider a string $a^i$ with $i$ letters. We want to determine whether the string is in the language $L$ where $L = \{a^i \mid i \text{ divides } p\}$ and $p$ is a given prime number. If $i$ divides $p$, we accept the string into the language with a 0 qubit state, and if not, we reject it with a qubit state of 1. Classically, using the highest known prime integer, this algorithm requires a minimum of 77,232,917 bits, whereas the quantum finite automata only requires 27 qubits. Using Python's Quantum Information Software Kit (Qiskit), I have implemented a program [1] that can determine if the length of a string is divisible by a large prime number with exponentially fewer qubits.

*This work was supported by the Nakatani Foundation and Keio University.
A code was generated in MATLAB to model the temperature of plant (Arabidopsis) leaves ($T$) during 25 s periods of hypo- ($\mu g$) and hyper- ($2g$) gravity ($g$) produced by parabolic flights. Temporal data $T(t)$ vary inversely with $g(t)$ and are reproduced by a model that accounts for heat transfer across the boundary layer (BL) between the leaf and air [1,2], conduction through the stem into the growth media, and heat from the plant metabolism. While the BL and stem conduction terms are analytically known, the metabolic power is approximated as a function of $T$ to simulate the $T(t)$ data. Extending the metabolic power term to include time dependent dose-response mechanisms requires comparison of model predictions to $T(t)$ data from longer periods of low-$g$. Thus, analysis of $T(t)$ data from parabolic flights simulating lunar gravity over longer times will check the fully adaptive $T(t)$ at low-$g$. Sub-orbital flights with 5 min periods of $\mu g$ will test further extensions of the model.

*Supported by UF CCMS Undergraduate Fellowship (JJK-P), NSF DMR-1708410 (MWM) and DMR-1156737 (UF REU), and NASA NNX15AB12G (RJF and ALP).
11:39AM F68.00003: Tailoring machine learning for tackling the Large Hadron Collider problems  ANTONY HALIM (Presenter), Minerva University — Machine learning has proven its vitality in devising complex systems. The wide range of tasking techniques allowed machine learning to be a qualified tool for analyzing the vast amount of data obtained from the Large Hadron Collider. These tasks can range from tracking pattern recognition, particle identification, to search for rare decays. As a new tool starts to spread, the need for modifying increases to adapt to the new users' tasks. One approach is the design of packages. Here I present a machine learning package in R, designed for analyzing the Large Hadron Collider data, focusing mainly on particle identification through the measured particle parameters and the detector system, and also spotting rare decays using the supervised learning based classification techniques of machine learning. Machine learning does not only focus on easing the data analysis process that is already taking place, but it offers an opportunity for implementing new search strategies for rare phenomena through novel techniques. This step aims to assist physicists and researchers, and it also takes a further step ahead of enabling users to personalize more the tool through having an open source of the package accessible to users.

11:51AM F68.00004: Heavy Graviton Search at the Large Hadron Collider*  YUHAN GUO (Presenter), ALFREDO GURROLA, SAVANNA R STARKO, PAUL DOUGLAS SHELDON, WILL JOHNS, OISHIK RAY, Vanderbilt University, ANDRES FLOREZ, Universidad de los Andes — The Standard Model (SM) of particle physics, aimed to relate particles and forces, fails to build such relation for gravitation. Certain theories predicting “Graviton,” mediator for gravitation, to be a massive (hence potentially detectable) spin-2 particle have raised high experimental interest. Yet so far no search has discovered such particle at the Large Hadron Collider (LHC). This research develops a search methodology for a massive spin-2 particle using Vector Boson Fusion (VBF) processes at the LHC. We consider potential reasons the current searches, mainly relying on Drell-Yan (DY) production mechanisms, have observed no graviton, including potentially low coupling strength between the graviton, quarks, and gluons. The VBF topology, with no reliance upon the QCD coupling strength, offers an alternative and complementary search strategy. We further combine the VBF topology with the diphoton decay channel, a novel search for the LHC. We show that the requirement of a high mass diphoton pair combined with two high pT forward jets with large dijet mass and with large separation in pseudorapidity can significantly reduce the SM backgrounds. We expect discovery potential for TeV scale graviton masses.

*This work is supported by NSF Award PHY-1506406.

12:03PM F68.00005: Survey of Tensor Networks*  SAMUEL DESROSIERS (Presenter), GLEN EVENBLY, THOMAS E BAKER, Département de physique & Institut quantique, Université de Sherbrooke — Tensor networks have become a robust method over the past few decades to represent quantum systems and solve them efficiently. These numerical methods can optimize a system by keeping the most important degrees of freedom, allowing us to solve large systems more efficiently. We review the fundamentals of this field, including a deep connection with entanglement. Basic aspects of tensor networks and common algorithms are presented. Specifically, algorithms for classical spin systems are compared to study their effectiveness.

*S.D. graciously thanks the 2018 Institut Transdisciplinaire d'Information Quantique (INTRIQ) undergraduate internship project scholarship. T.E.B. thanks Institut quantique for funding through the postdoctoral fellowship program. G.E. thanks Institut quantique and the Département de physique. This research was undertaken thanks in part to funding from the Canada First Research Excellence Fund (CFREF).

12:15PM F68.00006: Clifford Algebraic Representations of SU(n)  DAVID KELLEY (Presenter), Rochester Institute of Technology — The SU(n) groups are Lie groups defined as the set of all unitary n-by-n matrices with determinant 1, whose operation is multiplication. Although defined in terms of matrices, these groups are abstract mathematical structures, and are thus independent of their representation. One representation of SU(n), often used in the standard model of particle theory, constructs the elements using Clifford Algebra. This representation has been shown to be valid for SU(3), but higher dimensions remain unexplored. We investigate such representations of the SU(n) groups.
Enhanced Global Symmetry of N = 4 Gauge Theories in 3d

ZHAOZHEN TONG (Presenter), Department of Physics, Imperial College London — Moduli spaces of some 3d N = 4 quiver gauge theories are studied by computing the Hilbert series of their Coulomb branch. Although this had been recognized as the traditionally difficult branch to study due to quantum correction, development of monopole formula has provided a simple approach to solving the problem. Our work focuses on obtaining the global symmetry of a quiver gauge theory from its Hilbert series. Many of the quivers being studied are A, D, B Dynkin diagrams with a minimally unbalanced gauge node and the results show that their global symmetries have been enhanced to symplectic groups, corresponding to freely generated Coulomb branches. We have made an argument that simplifies the process of identifying symplectic global symmetries. A potential class of quivers is also proposed as a generalisation of some obtained results, and the quiver is compared with some previous work that takes different approaches to the problem, such as brane construction etc. B type quivers are not included in the proposed generalisation, and its symplectic global symmetry may indicate an extension of previous work to non-simply laced quivers.

This work was supported by Department of Physics, Imperial College for undergraduate student research.

Numerical analysis of nonlinear localized modes in vibrational and magnetic lattices

HIEU LE (Presenter), LARS Q ENGLISH, Dickinson College — We numerically investigate the existence of nonlinear, spatially localized modes for various lattice Hamiltonians using Newton-Raphson method to obtain numerically exact solutions. We start by examining the well-known one-dimensional Fermi-Pasta-Ulam lattice with quadratic and quartic potentials and obtain solution branches in both frequency and nonlinear coefficient via continuation. We continue by propagating the solution in time with Runge-Kutta degree 4 (RK4) method. We then turn to two-dimensional ferromagnetic and antiferromagnetic lattices: here intrinsic localized modes were demonstrated in previous research, and more recently the topological magnetic skyrmions has stimulated intense interest. We again apply the Newton-Raphson method to obtain nontrivial solutions for certain spin-lattice Hamiltonians, and then propagate the solution in time with RK4method.

Cosmic Ray Detector Array Project

ANDREW REYES (Presenter), CHRISTIAN HERNANDEZ, ARAM NINO CANIZAL, Hartnell College — Supernovae across the universe eject cosmic rays that impact atomic nuclei in Earth's atmosphere to create secondary particles like muons. In order to measure the cosmic rays and the secondary radiation, we used light sensitive Photomultiplier detectors connected to scintillator sheets by optical fibers enclosed in a light tight box. We assembled multiple detector boxes to measure the high speed muon particles and using 3 different detector boxes we formed an array. The properties of the cosmic ray muons were studied by using a four fold coincidence experimental setup. The detector signals were converted using the DRS4 digitizer and analyzed using CERN PAW package. In this conference, our results of the cosmic ray array would be presented. In addition, we would discuss how the pressure and temperature of the Earth's atmosphere may cause variations in the collected counts of cosmic rays.

Using Eclipses to Probe Physical Conditions Along the Jet in the X-Ray Binary SS433

XINYI LIU (Presenter), Wheaton College, HERMAN MARSHALL, MIT Kavli Institute, DIPANKAR MAITRA, Wheaton College, MICHAEL NOWAK, NOBERT SCHULZ, MIT Kavli Institute, DIEGO ALTAMIRANO, University of Southampton, JACK STEINER, MIT Kavli Institute, THE Galactic X-ray binary SS 433 is the only known astrophysical object to exhibit strong, relativistically red- and blue-shifted emission lines from elements such as S, Si, Fe, Ni. The X-ray emission lines originate in a jet outflow that is launched somewhere very close to the compact accretor (a black hole or a neutron star). Between 2018 August 10-14, SS 433 was observed using the High Energy Transmission Grating Spectrometer system on the Chandra X-ray Observatory, and also using the Neutron star Interior Composition Explorer (NICER) mission aboard the International Space Station. The observations were designed to take advantage of the eclipse and carry out time-resolved spectroscopy and timing studies to infer spatial variation of physical properties such as composition, temperature, and density at different distances along the jet. Preliminary analysis of the Chandra data reveals a plethora of emission lines due to various ionization states of different elements such as Fe XXV, Si XIV, and others. In addition to phenomenological fits to determine properties of the observed emission lines, we will present results from fitting collisionally ionized plasma models, and timing results from NICER.

*We gratefully acknowledge funding from the Chandra Guest Observers Program.

12:30PM G71.00001: Students Lunch with the Experts — Students may sign up to enjoy a complimentary box lunch while participating in an informal and stimulating discussion with an expert on a topic of interest to them.

Tuesday, March 5, 2019 2:00 PM - 2:00 PM

Session G70: Poster Session I (2:00pm-5:00pm) BCEC Exhibit Hall - Tag(s): Poster, Undergraduate

G70.00001: UNDERGRADUATE RESEARCH —

G70.00002: Machine Learning Applied to Mult-Electron Events in Scintillator* HARRISON LABOLLITA (Presenter), Mathematics and Physics, Piedmont College, MORTEN HJORTH-JENSEN, SEAN LIDDICK, National Superconducting Cyclotron Laboratory — Conversion electron spectroscopy is a viable tool when studying the nuclear phenomenon, shape coexistence. When a neutron-rich nucleus beta decays, a neutron transforms into a proton and emits an electron. Due to electromagnetic interactions, this can result in the ejection of an electron from the atom, a process called internal conversion. Because this process is essentially simultaneous in time, it is pivotal to differentiate between the electron emitted from the nucleus and the internal conversion electron emitted from the atom. Here we apply supervised machine learning algorithms to distinguish between one and two electron events, as well as determine the origin of the electron. With simulated data, we were able to successfully train a convolutional neural network (CNN) to distinguish between a one and two electron event with 96.79% accuracy. Furthermore, we successfully trained a CNN to predict the origin of the electron for one electron events. Our results show promise that our models’ performance will generalize to experimental data. Once our models are complete, machine learning will be an important data analysis tool for conversion electron spectroscopy.

*Funded by the NSF through Research Experience for Undergraduates at Michigan State University.

G70.00003: Radio Emission of Supernova Remnants in the Large Magellanic Cloud* KAUALANI MANEAFAGE (Presenter), California Lutheran University, JOHN R. DICKEL, Physics & Astronomy, University of New Mexico — A supernova remnant (SNR) is an expanding shell of gas that results from the explosive death of a star. When observing a SNR at radio wavelengths, the object appears fainter in the higher frequencies and brighter in the lower frequencies due to synchrotron radiation. There has not been a complete catalog of SNRs in the Large Magellanic Cloud (LMC), shown in Figure 1. As a result, in May 2017, Luke M. Bozzetto and Miroslav D. Filipović et. al published an article with a catalog of 59 SNRs, using their own measurements and references of other data. Their paper also proposed 15 SNR candidates, all located in the LMC. Their measurements focused on the radio properties of these objects. One of these properties is the spectral index, which is the brightness as a function of frequency, and is shown in Figures 4 and 5. However, some of the objects cataloged and proposed have missing radio data. Using the Astronomical Image Processing System (AIPS) and data previously collected by John R. Dickel, we analyzed the missing radio data for these objects cataloged in the 3-, 6-, and 20-cm radio wavelength bands.

*I would like to thank the National Science Foundation (NSF) for funding the internship and University of New Mexico for allowing me the opportunity to participate in the research.
**G70.00004: Mössbauer Investigation of Hafnium Oxide-Hematite Nanoparticles**

MONICA SORESCU, ABIGAIL FERRIS (Presenter), Duquesne University — Hafnium-oxide-doped hematite, $x\text{HfO}_2(1-x)\alpha\text{-Fe}_2\text{O}_3$, with molar concentrations $x=0.1, 0.3, 0.5,$ and $0.7$ was prepared by high-energy ball milling at sample times of BMT=$0, 2, 4, 8$ and $12$ hours. The Mössbauer spectra of the nanoparticle systems were parameterized using NORMOS-90. It can be said that concentrations of $x=0.1, 0.3$ and $0.5$ show general trends, but once concentration rose to $x=0.7$ the sample had more subspectra, allowing new phases to be identified. Each concentration at BMT=$0$ had one sextet, pertaining to hematite. As the BMT and the concentration of the sample increased, the splitting increased, denoting a greater substitution of the hafnium ions into the hematite lattice. Concentration $x=0.1$ did not show additional splitting until reaching BMT=$4$ hours, where the data split from one sextet to two sextets then split further by BMT=$12$ hours resulting in four sextets and a doublet. Concentration $x=0.3$ was similar, with BMT=$0$ displaying only one sextet but BMT=$12$ hours resulted in five sextets and a doublet necessary for an accurate fit. Concentrations higher than $x = 0.3$ at BMT=$0$ required one sextet and one doublet, but no other time had such a pattern aligned with it.

**G70.00005: Experimental Multi-Photon Quantum Walk on a Directed Graph**

TONG WU, School of Physics, Nanjing University, JOSH IZAAC, School of Physics, The University of Western Australia, ZIXI LI (Presenter), KAI WANG, ZHAOZHONG CHEN, SHINING ZHU, School of Physics, Nanjing University, JINGBO WANG, School of Physics, The University of Western Australia, XIAOSONG MA, School of Physics, Nanjing University — Quantum walks are of crucial importance in the development of quantum information processing algorithms. Recently, another potential application has been proposed, where one could efficiently perform network analysis with quantum walks, especially on vertex centrality ranking. However, it is challenging to rank the centrality of a directed network via quantum walks, since it corresponds to a non-Hermitian Hamiltonian, which leads to non-unitary dynamics and thus cannot be simulated by conventional quantum walks. In this presentation, we solve the non-unitary challenge by introducing pseudo-Hermitian evolutions. We report the first experimental realization of centrality ranking of a directed graph on a photonic platform with multi-photon parity-time-symmetric quantum walks. The experimental results agree well with theoretical predictions.

**G70.00006: Making a Video to Teach a General Audience about Memristors**

EMMA RHODENIZER (Presenter), NADINE GERGEL-HACKETT, Mary Baldwin University — Memristors are a novel nanotechnology with the potential to enable faster and smarter computing. Because of the impact that these nanoelectronic devices could have on our everyday technology, it is important to educate the general public about memristor physics, including their applications and advantages. My research involved learning about the memristor-related work performed by previous Mary Baldwin University undergraduate physics students and then creating a video describing this work to a general audience. The video was made using a combination of Blender animation software and VideoPro video production software, along with still images and audio. My final product is a YouTube video that explains the Mary Baldwin University memristor research and highlights potential future applications of that research.

**G70.00007: Mössbauer Investigation of Molybdenum Trioxide-Hematite Nanoparticles**

MATTHEW KNAUSS (Presenter), MONICA SORESCU, Physics, Duquesne — Molybdenum trioxide-doped hematite, $x\text{MoO}_3(1-x)\alpha\text{-Fe}_2\text{O}_3$ with molar concentrations $x=0.1, 0.3, 0.5,$ and $0.7$ was prepared using high-energy ball milling, taking samples at $0, 2, 4, 8,$ and $12$ hours. The resulting Mössbauer spectra of nanoparticle systems were parametrized using NORMOS-90. At ball milling time (BMT) $0$ hours, each concentration produced a spectrum consisting of $1$ sextet since no lattice substitutions occurred. For all concentrations, a doublet subspectrum emerges from the initial sextet as the BMT increases. For each sample, this appears around BMT $= 4$ hours and is more intense as the BMT increases, indicating the substitution of Fe$^{3+}$ into the MoO$_3$ lattice. Most fits only had $1$ sextet except for concentration $x = 0.1$, BMT 4, 8, and 12 hours, and concentration $x=0.3$, BMT 12 hours. This additional sextet indicates Mo was substituted into the Fe$_2$O$_3$ lattice. The absence of this Mo substitution is due to the difference in ionic radii of Mo$^{6+}$ to Fe$^{3+}$ since the ionic radius of Mo$^{6+}$ is over twice the ionic radius of Fe$^{3+}$. Since the substitution of Fe$^{3+}$ into the MoO$_3$ was more present than the substitution of Mo$^{6+}$ into Fe$_2$O$_3$, the solid solution has a limited mutual solubility.

*This work was supported by the National Science Foundation under grants DMR-0854794 and DMR-1002627.

**G70.00008: ABSTRACT WITHDRAWN**
G70.00009: Investigation of correlation of chemical structure and electronic band structure of Fe-Ga system*  
JEAN ALVAREZ (Presenter), Bergen Community College, KALANI HETTIARACHCHILAGE, The Collage of New Jersey, NEEL HALDOLAAARACHCHIGE, Bergen Community College — Fe-Ga phase diagram is studied in detail to investigate the correlation of chemical structure and electronic band structure. There were 6 different phases reported on this system only one of them studied in detail experimentally and theoretically. We investigated chemical structure and electronic band structure of all other phases. Electronic band structure revealed an interesting detail of Ga rich non-magnetic semiconducting phase transforms into a series of magnetic phases towards the Fe rich side. It also revealed that the physical properties of the materials are very sensitive to the stoichiometry and structural deviations of the phases. This study will provide the groundwork to further studies of this materials and also provide an interesting avenue to investigate verity of new materials with potentially interesting physical properties.

*Department of Education, STEMatics grant, Bergen Comunity College.

G70.00010: Detection and Classification of High Energy Beta Radiation induced Damage of Raspberry Pi Zero intended for OPAL CubeSat*  
JONH MOJICA DECENA (Presenter), JOHN R DENNISON, BRIAN D WOOD, Physics, Utah State University, RYAN MARTINEAU, Space Dynamics Laboratory, MICHAEL J TAYLOR, Physics, Utah State University — Radiation survivability of a Raspberry Pi Zero was studied with extended exposures from 0.2 to 2.5 MeV beta radiation of >200krad of total ionizing dose (TID) while undergoing continuous diagnostic cycles. Determining the threshold for radiation damage of inexpensive commercial-off-the-shelf (COTS) components is critical as a cost-saving method in the construction of spacecraft. Characterizing radiation induced damage of COTS with TID allows for proper precautionary measures to maintain spacecraft functionality over the duration of their mission. The specific point and type of failure due to TID is determined to mitigate deleterious effects through enhanced shielding and software or hardware redundancy. TID in the memory and processor units before system failure was measured, along with type, frequency of error, and possibility of system recovery. Careful determination of heat conduction in vacuo of IC’s was conducted to avoid overheating due to delivered battery power and radiation energy deposition. The results will facilitate construction and design of the USU-led OPAL CubeSat, to determine if this COTS can survive >200krad TID received during its 1-2yr mission in LEO orbit.

*Supported through partial funding from a USU Office of Research and Graduate Studies URCO grant.

G70.00011: Reconstruction of HIPPO Supersonic Gas Jet Target*  
XIANFENG WANG (Presenter), Xi'an Jiaotong University, SHANE MOYLAN, CHRISTOPHER J SEYMOUR, LUIS A MORALES, GWENAELLE GILARDY, DANIEL J ROBERTSON, EDWARD STECH, MANOEL COUDER, Univ of Notre Dame — HIPPO, a supersonic windowless helium gas jet target, is designed and reconstructed as the target for the beam from the 5 MeV 5U electrostatic accelerator located at the Nuclear Science Laboratory (NSL) of the University of Notre Dame. Connected to the target area, St. George recoil separator has been developed to perform, in inverse kinematic, radiative capture experiments of interest to nucleosynthesis. Inverse kinematics, here, means that a heavy ion beam is bombarding a lighter nuclear target. The nozzle-catcher system and chamber have been designed and prepared. A differential pumping system is set up to lower the pressure in the target chamber down to $10^{-7}$ torr in the beamline. The advantages of the windowless design and advantages that gas target compared with the solid target will be discussed. An Arduino based system is set up and now we are able to control the pumps with the touch screen. We have performed the pressure measurement and got the thickness data. Initial experiments are discussed along with plans for future use at the NSL.

*This work is supported by the National Science Foundation and the University of Notre Dame.
G70.00012: Training Neural Networks for Object Recognition Using Blurred Images* AZHAR HUSSEIN (Presenter), Department of Chemical and Physical Sciences, University of the Virgin Islands, XAVIER BOIX, TOMASO POGGIO, Department of Brain and Cognitive Sciences, Massachusetts Institute of Technology — A shortcoming of deep neural networks is that they require a vast amount of data to train. An example of this is object recognition, a computer vision technique for identifying objects in images or videos. We hypothesized that, when training with few data examples, blurring the input images would cause the neural network to perform better compared to non-blurred images, because of the removal of unnecessary details. In this study, we trained a convolutional neural network on the blurred images, varying the amounts of blur in order to determine how the validation accuracy changes. Our preliminary results suggest that blurring the images does not help when learning from few examples; however, we cannot fully disprove the hypothesis because it requires further experimentation with other data sets and convolutional neural network models. In the future, we can use image blurring to study eccentricity dependence, a property of the human visual system that standard convolutional neural networks do not currently replicate. This research will ultimately bring us closer to understanding and replicating how the human brain processes vision.

*This material is based upon work supported by the Center for Brains, Minds and Machines (CBMM), funded by NSF STC award CCF-1231216.

G70.00013: Response of Photoreceptors, Dynamic Modeling of Adaptation and Saturation ANNA SMITH (Presenter), KENNEDI L TURNER, TIRTHABIR BISWAS, Loyola University New Orleans — Photoreceptors have the ability to generate biological responses as a result of stimulation via light. The purpose of this research project is to mathematically model the photoreceptor responses such that we are able to quantitatively capture its key aspects, like the observed adaptation over time and saturation under extreme stimulus. Past photoreceptor models were examined and modified to yield a new dynamic model that was able to provide excellent fits to response of the retinal cells under a variety of stimulus conditions, such as bright and “dark” flashes of light on top of some given initial “background” lighting. Our analysis strongly suggests that just a direct coupling of membrane potential to light is not sufficient to capture the behavior of photoreceptors. Nonlinear coupling between the membrane potential and some “internal” variable that controls adaptation in the cell is necessary to accurately predict the photoreceptor response. On one hand our research may provide insight into the microphysical processes inside the cell, and on the other, help improve exploring the complexities of neural networks.

G70.00014: Electrospun PEDOT:PSS nanoribbon field effect transistor with a ferroelectric polymer gate insulator* ALONDRA ROSARIO (Presenter), NICHOLAS PINTO, University of Puerto Rico at Humacao — Poly(3,4-ethylenedioxythiophene) doped with poly(styrene sulfonic acid) – PEDOT:PSS was electro-spun to produce high aspect ratio nanoribbons. The ribbons of varying thicknesses were electrically characterized in a field effect transistor (FET) configuration with ferroelectric (FE) poly(vinylidene fluoride-trifluoroethylene)-PVDF-TrFE as the top gate insulator. The devices exhibited p-type behavior consistent with hole charge transport in PEDOT-PSS and a memory window characteristic of a FE-FET. Such a ferroelectric (FE) poly(vinylidene fluoride-trifluoroethylene)-PVDF-TrFE as the top gate insulator. The devices exhibited p-type behavior consistent with hole charge transport in PEDOT-PSS and a memory window characteristic of a FE-FET. Such a ferroelectric (FE) poly(vinylidene fluoride-trifluoroethylene)-PVDF-TrFE as the top gate insulator. The devices exhibited p-type behavior consistent with hole charge transport in PEDOT-PSS and a memory window characteristic of a FE-FET. Such a ferroelectric (FE) poly(vinylidene fluoride-trifluoroethylene)-PVDF-TrFE as the top gate insulator. The devices exhibited p-type behavior consistent with hole charge transport in PEDOT-PSS and a memory window characteristic of a FE-FET. Such a ferroelectric (FE) poly(vinylidene fluoride-trifluoroethylene)-PVDF-TrFE as the top gate insulator. The devices exhibited p-type behavior consistent with hole charge transport in PEDOT-PSS and a memory window characteristic of a FE-FET. Such a ferroelectric (FE) poly(vinylidene fluoride-trifluoroethylene)-PVDF-TrFE as the top gate insulator. G70.00015: A Schottky diode fabricated by crossing MoS2 with an electro-spun PEDOT-PSS nano-ribbon* KELOTCHI FIGUEROA (Presenter), JOSÉ PEREZ, AHMAD MATAR ABED, IDALIA RAMOS, NICHOLAS PINTO, Physics and Electronics, University of Puerto Rico at Humacao, MENGQIANG ZHAO, ALAN T JOHNSON, Physics and Astronomy, Univ. of Pennsylvania — Monolayer MoS2 was grown via chemical vapor deposition while PEDOT-PSS nanoribbons were fabricated via electrospinning. Each of these materials was electrically characterized separately in a field effect transistor configuration using SiO2 as the gate dielectric. MoS2 exhibited n-type behavior while PEDOT-PSS showed an Ohmic response. By crossing MoS2 with a PEDOT-PSS nanoribbon, the current-voltage curve across the junction was non-linear and similar to that of a diode. When a positive (negative) voltage was applied to PEDOT-PSS (MoS2), the device turned on in the first quadrant of the I-V curve. Reversing the external connections resulted in the diode turning on in the third quadrant. The rectification ratio was 625 and the turn-on voltage was 0.1V. The device output data was analyzed using the standard thermionic emission model of a Schottky junction yielding an ideality parameter of 1.9 and a barrier height of 0.18eV. A low turn voltage from our diode makes it better for small signal detection and has the advantages of having a higher ac rectification efficiency and a lower power loss compared to standard Si or Ge p-n diodes.

G70.00016: Investigation into the Interface Between Salt Solutions and Hydrophobic Surfaces  
ANTHONY FLORIMBIO (Presenter), CAYTON HORNBERGER, ZACHARY ZOLL, ADELE POYNOR, Allegheny College — When water is forced into contact with a hydrophobic surface a depletion layer, a region of low density water, is formed at the interface. In nature surfaces do not deal with pure water, rather instead they interact with various aqueous salt solutions. We study octadecanethiol, a hydrophobic self-assembled monolayer, and mercaptoundecanoic, a hydrophilic self-assembled monolayer, in various aqueous salt solutions. We use contact angle measurements, scanning electron microscopy, and surface plasmon resonance to study the interfacial properties of these surfaces.

G70.00017: Exploring how protamine folds DNA in sperm*  
YUXING MA (Presenter), ADAM D. D. SMITH, ASHLEY CARTER, Amherst College — DNA compaction is crucial for the transmission of genetic information. In sperm, the protein protamine binds to the major groove of DNA and compacts the DNA more tightly than histones. The more highly folded the DNA, the more hydrodynamic the sperm and the more likely it will reach the oocyte without UV damage. To understand the mechanism by which protamine packs DNA, we used an in vitro tethered particle motion assay and video microscopy to visualize the folding of 25 nm DNA. Because this length is shorter than the diameter of a DNA-protamine loop, we did not expect the DNA to fold. However, when we graphed the standard deviation of beads’ motion over time, we found that the standard deviation decreases as protamine concentration increases. Our results suggest that protamine can fold short-length DNA molecules. Understanding the process by which this interaction occurs has applications in male infertility, epigenetics, and nanoengineering.

*Dean of the Faculty Funding from Amherst College, the Cottrell Science Award from the Research Corporation (ARC, Award #23239) and the CAREER award from the National Science Foundation (ARC, Project #1653501).

G70.00018: AFM analysis of protamine-induced compaction in short-length DNA fragments*  
RYAN MCMILLAN (Presenter), LUKA DEVENICA, ASHLEY CARTER, Amherst College — During spermatogenesis, small, positively charged protamine proteins dramatically condense the DNA in the nucleus. This tight compaction both minimizes hydrodynamic drag on the sperm and protects the DNA from ultraviolet radiation. Protamine also is an excellent candidate for use in nanoengineering as a way to self-assemble DNA nanostructures. Here our goal is elucidate the physical mechanism for how protamine causes DNA to fold into a ring of ~50 nm in diameter. To study this question, we used an atomic force microscope (AFM) to image protamine-DNA complexes. By varying the concentration of protamine in the assay, we are able to image the intermediate steps in the folding pathway. We find that short-length (50 nm or less) DNA fragments form half loops that become increasingly more folded as the protamine concentration is increased. Future work will investigate whether this looping is induced by enthalpic or entropic forces.

*This research was supported through the Amherst College SURF Program, the Amherst College Dean of the Faculty, and NSF CAREER Award #1653501.

G70.00019: Simulation of long range ordering in an ionic liquid using molecular dynamics*  
ALEXIS PUYLEART (Presenter), St. Norbert College, EMILY DALBEY, RALPH WHEELER, Northern Illinois University — In the last few years, a startling amount of electronic devices have been recalled due to issues regarding the safety of the battery. This is because the current electrolytes in batteries are volatile and flammable. Ionic liquids are currently being explored as possible alternatives to current electrolytes in lithium ion batteries. As a result, it is important to understand the structure of ionic liquids when lithium is added. Experimental structure factors of N-alkyl-N-methylpyrrolidinium and bis(trifluoromethylsulfonyl)imide (TFSI) from x-ray diffraction data show three peaks at low wavenumber values: a prepeak, a second peak due to charge alternation, and a third peak due to charge adjacency. Molecular dynamics computer simulations were used to calculate structure factors and investigate why the charge alternation peak disappears after adding LiTFSI.

*National Science Foundation REU Grant CHE -1659548
**G70.00020: Electronic Band Structure Studies of Binary Iridates in Ir-Ga Phase Diagram**

DAVID GORDON (Presenter), Bergen Community College, KALANI HETTIARACHCHILE, The Collage of New Jersey, NEEL HALDOLAARACHCHIGE, Bergen Community College — Binary iridates in Ir-Ga system is studied in detail by using the computational method. Correlation of chemical structure and electronic band structure of Ir-Ga are investigated in detail. There were several different phases reported on this systems but none of them were studied in detail experimentally or computationally. Electronic band structure studies revealed an interesting detail of the phases of Ir-Ga systems. This study also suggested that the physical properties of these materials can be tuned by using the stoichiometry and structural deviations of the phases. We also propose that some of the phases could be interesting to search for novel physical properties. This result will generate the enthusiasm of experimentalist to further studies these iridate materials and also open a new avenue to broaden the search for new materials with potentially important novel physical properties.

*Department of Education, STEMatics grant, Bergen Community College.

**G70.00021: Computational Modelling of the Photo-Field Effect**

WILLIAM SCHENKEN (Presenter), REUBEN T COLLINS, IDEMUDIA AIRUOYO, Colorado Sch of Mines — The photoresponse of a thin film transistor depends on the mode of operation the transistor is in, in an effect known as the photo-field effect. The extent of this effect then depends on the properties of material composing the transistor. This intensity and state dependent photosresponse is explored in amorphous silicon (a-Si) thin film transistors (TFTs) with computational modelling. Results of the numerical simulation agree with observed experimental results. Possible sources of the effect are analyzed and related to parameters in the model. The results from a-Si TFTs are then related to experimental results of TFTs consisting of a-Si embedded with nanocrystalline silicon (nc-Si) quantum dots (the composite material denoted as a/nc-Si), and future work involving a more explicit relationship between the parameters in the model and the properties of a/nc-Si is discussed.

*This research was supported in part by the NSF through award number DMR-1810463.

---

**G70.00022: Optimization of Serpentine Micromixers with Non-Rectangular Cross-Sections**

JOSHUA CLARK (Presenter), PETRU STEFAN FODOR, CHANDRASEKHAR KOTHAPALLI, Cleveland State University — Serpentine or spiral-shaped microchannels have been popular choices for microfluidic mixers due to their relatively easy fabrication and possibility for re-use. The technique used in these types of microchannels aims to utilize the cross-sectional transversal (Dean) flows experienced by the fluids as they round a curved channel. Because of the reliance on centrifugal forces the mixing quality is strongly Reynolds number-dependent, with quality mixing occurring only at Re>100. It has been shown that the use of channels with non-rectangular cross-sections can be used as an effective strategy in this type of design to induce mixing at much lower flow rates. In this work, we seek to optimize the geometrical parameters of these channels to maximize their overall mixing performance. The results of the optimization process were obtained numerically through computational solutions of the flow fields and fluid concentration. Experimental results are also included showcasing the increase in mixing quality. We found that our optimized designs substantially outperformed standard serpentine geometries with rapid mixing being achievable down to Re~20.

---

**G70.00023: Measurement of Adhesion between Nanoparticles and Model Calcite Interfaces**

TAYLOR TROTTIER (Presenter), NANCY BURNHAM, Worcester Polytechnic Institute — The extractive efficiency of primary and secondary oil extraction techniques is generally limited to ~30% of total volume. The most popular and cost-effective secondary recovery techniques are based on the premise of waterflooding, which uses water injection wells to increase subsurface pressure and improve oil yield. Some of the water utilized in these methods is seawater adulterated with surfactants and nanoparticles.[1] In order to accurately predict diffusion of this solution underground it is necessary to understand how modifying seawater chemistries affect the nanoparticles used to tag injection wells. Previous research has shown an inverse correlation between calcium concentration and adhesive forces measured by an Atomic Force Microscope.[2] Adhesion rates between various nanoparticles and a calcite interface were determined using Total Internal Reflection Fluorescence microscopy and single particle tracking techniques.

**G70.00024: Evidence of Particles During Electrochemical Pd-D Co-deposition**

MICAH KARAHADIAN (Presenter), HEIDE M DOSS, Point Loma Nazarene University — Palladium deuterium co-deposition is used to explore condensed matter reactions. CR-39, a thermoset resin is a well characterized integrative detector that, when etched, shows tracks created by energetic charged particles produced in nuclear reactions. Analysis of tracks provides particle minimum energy and insights into identification (e.g. alpha versus proton). Certain tracks infer neutrons interacting with carbon atoms within the detector, resulting primarily in three alphas (e.g. triple tracks). We report our findings of Pd/D co-deposition on Au wire in an electrolytic cell, and our controls. Our findings imply the presence of nuclear reactions.

**G70.00025: Probing a Mixed Dark Matter Scenario with the CLASS Code**

ADDY EVANS (Presenter), Physics, Oklahoma State University-Stillwater, ROUZBEH ALLAHVERDI, Physics, University of New Mexico — The purpose of our research is to further understand the physical properties of dark matter. We present the physical constraints of a mixed dark matter scenario in which there is a mixture of both warm and cold dark matter. The warm dark matter in our model arises from a non-thermal decay of a heavy particle that occurs when the Universe is \( \sim 0.1-1 \) second old. By using the CLASS code, we have plotted the linear matter power spectrum of these scenarios and compared them to the observed matter power spectrum of Lyman-alpha forests. We find that warm dark matter with a mass of 50 GeV to 450 GeV can exist in fractional amounts, while warm dark matter with a mass of 460 GeV to 1 TeV can potentially comprise the entire dark matter population.

*This work was supported by the National Science Foundation, award number 1659618.

**G70.00026: Room Temperature Field Effect Investigation in SrIrO3/SrTiO3 Thin Films**

ALEJANDRO ZAFRA (Presenter), Department of Physics, California State University, San Marcos, JIAN LIU, Department of Physics, University of Tennessee, Knoxville, STEPHEN A TSUI, Department of Physics, California State University, San Marcos, LIN HAO, Department of Physics, University of Tennessee, Knoxville — Insulating thin films of layered SrIrO3/SrTiO3 (SISTO) have been chosen as a candidate system in which to explore field effect resistance switching, where the application of an electric field induces a reversible change in the electrical resistance. This allows for the possibility of creating a new field effect transistor (FET). The SISTO films were synthesized via pulsed laser deposition. The resistance was measured at room temperature using the 4-wire method. The field effect gate was created by placing an ion gel droplet on the film covered by a sheet of Pt foil. Preliminary data demonstrates the change of electrical resistance of the film upon application of voltage across the ion gel. Future work will include improving the experimental setup to reduce the likely temperature-dependent drift in the resistance measurements and investigating the effects of altering the voltage.

**G70.00027: Temperature Dependent Self-Assembly of 9,10-dibromo-anthracene on Ag(111)**

CORY F. ASHWORTH (Presenter), TRISTAN D. BLACKWELL, Physics, Radford University, TIMOTHY J. FUHRER, Chemistry, Radford University, THOMAS P PEARL, Physics, North Carolina State University, SHAWN HUSTON, Physics, Radford University — Thin film growth of 9,10-dibromo-anthracene (DBA) on Ag(111) up to a full monolayer has been studied via UHV scanning tunneling microscopy (STM). Prior studies of thin film growth for deposition of this molecule on the same substrate while at room temperature has demonstrated debromination of the molecule followed by self-assembly of a chain-like structure mediated by Ag adatoms [1]. However, our results show no debromination and instead a honeycomb network is formed. The reason for this discrepancy is still under investigation, with present studies focused on accurately cataloguing substrate temperature during film growth. We note that other STM studies of brominated organic molecules grown at reduced substrate temperatures have shown debromination of those molecules only upon subsequent annealing of the film [2]. A molecular model of our film growth will be presented, with the organization of the film most likely driven by weak bromine-bromine bonding between adjacent molecules.

G70.00028: Systems-level Transcriptomic Analyses for Comprehensive Characterization of the IgG3 B Cell Subclass
ANUSH DEVADHASAN (Presenter), Ragon Institute of MGH, MIT and Harvard — Prior studies have suggested that HIV antiviral control may be achieved via the induction of highly polyfunctional IgG3 antibodies (Abs). Here we employ a systems approach to characterize the IgG3 transcriptional profile by identifying intrinsic differences between IgG3 B cells vs IgG1 and IgM B cells that might suggest mechanisms by which B cell molecular circuitry can be programmed to induce and preserve IgG3 Abs. Strikingly, differentially expressed genes between isotype pairs reveal IgG3 is substantially different from other subclasses independent of patent phenotype and time point and subsequently observe clustering by subclass, as opposed to phenotype/time point. Significantly enriched KEGG and Hallmark pathways and GSEA immunological signatures in differentially expressed genes indicate increased activation of basic cellular processes and restriction of transient signaling in IgG3. Therefore this study 1) demonstrates transcriptomic analyses are an effective strategy for characterization of highly homogenous cell subpopulations and 2) offers critical insight into systems level transcriptional signatures of the IgG3 subclass, paving the path for future downstream experiments.

G70.00029: Robust laser frequency drift tracking and data sharing platform to perform qubit calibration for an ion trap quantum computer
SHUQI XU (Presenter), ELI MEGIDISH, WEI-TING CHEN, JOSEPH BROZ, CLEMENS MATTHIESEN, HARTMUT HAEFFNER, Physics, Univ of California - Berkeley — One of the fundamental requirements for using optical transitions as qubits is an accurate control of the phase of the electric field of the laser field driving the qubit transition. For this it is necessary to calibrate the laser frequency accurately. The calibration can be achieved by simple spectroscopy scan of the optical transition. Alternatively, one can use Ramsey spectroscopy achieving a higher signal-to-noise ratio in a given time. However, if the laser frequency jumps significantly with respect to the atomic transition, one may switch by one Ramsey fringe. Here we implement a laser frequency drift tracker for the Ca⁺ quadrupole transition at 729 nm based on the Ramsey method. An algorithm adjusts automatically the Ramsey wait time to stay in tracking range while maintaining the accuracy. In addition, we develop a platform such that different ion trap experiments can share and use tracking results from other ion trap experiments.

G70.00030: Measurements with Position-Momentum Entangled Photons*
ZEENAT BAIG (Presenter), ZOYA SHAFIQUE, SEAN JAMES BENTLEY, Adelphi University — We constructed a system to generate position-momentum entangled photons. These particles interact non locally therefore anything done to one photon affects the other. We produce 405 nm photons that become two entangled 810 nm photons through the process of spontaneous parametric down conversion. We are able to extract data about the position and momentum properties such as joint uncertainties of these photons. The spatial uncertainty was found through near-field detection, a process where we imaged our crystal onto a single slit. Through far-field detection, we were able to get the momentum uncertainty. This involved focusing the beam onto slits which resulted in a fourier transform. Once optimized, we used our system as the basis for a high-sensitivity magnetic field sensor.

*We would like to thank Adelphi University

G70.00031: The Dynamics of Polymeric Microgels with Varying Crosslinker Concentration*
SAMANTHA TIETJEN (Presenter), JACOB ADAMCZYK, KIRIL STRELETZKY, Cleveland State University — Polymeric microgels synthesized by crosslinking amphiphilic polymer chains exhibit a reversible volume phase transition under the effect of environmental conditions such as temperature of a solution. The common behavior of these microgels is to deswell from a large to small size with an increase in temperature above the transition. Microgels in this study were synthesized by crosslinking a polysaccharide in a surfactant solution. When varying the amount of crosslinker by a factor of a hundred, three apparent behavioral regimes emerged from light scattering measurements: at low crosslinker concentrations, microgels deswelled and became more diffusive with temperature increase, at mid-range crosslinker concentrations they didn’t significantly change their size with temperature, and, at high concentrations, microgels showed a reversed behavior, where they grew and became less diffusive with increase in temperature. These apparent regimes are possibly due to nonuniform crosslinker distribution in the polymer microgel, which becomes more prevalent at large concentrations of the crosslinker.

G70.00032: Models for diffusion and Island growth of hydrogen on graphene  SKY SEMONE (Presenter), University of Pittsburgh, MAJID KARIMI, CARL LEBLOND, Indiana University of Pennsylvania, GIAN FRANCO VIDALI, Syracuse University — A Hydrogen atom can either physisorb or chemisorb on a graphene surface. A model for the diffusion of a hydrogen atom, between nearest neighbor chemisorption sites on graphene surface, is presented. The parameters of the model are optimized against a full set of barriers obtained from the first principles. The energy barrier of the hopping hydrogen is related to the local environment of the hopping hydrogen. In model I, the local environment of the migrating hydrogen include four sites (or 24 configurations). Depending on whether these sites are occupied or empty a total of sixteen configurations (barriers) are required to be calculated. Due to symmetry, only 10 of these configurations are independent. In model II, the local environment of the migrating hydrogen include eight sites (28 configurations). Out of these 256 configurations, a little more than half of them are independent. Models I and II have three and four parameters, respectively. The parameters of the two models are obtained by fitting the barriers to the corresponding ones from the Quantum Espresso code. The comparisons between the models and the first principles would serve as a gauge as to whether extension to a larger local environment is warranted.

G70.00033: Modeling Superconducting Resonators for Astronomical Photon Detection*  DANIEL MORALES (Presenter), Physics, Texas Lutheran University, KARWAN ROSTEM, EDWARD J WOLLACK, NASA GSFC — The current generation of Cosmic Microwave Background (CMB) polarization experiments demand high-performance background-limited sensor arrays to achieve the desired levels of instrument sensitivity. One particularly promising approach, known as MKIDs (Microwave Kinetic Inductance Detector), is based on monitoring the response of a resonator in the presence of radiation with sufficient energy to influence the device's superconducting properties. This sensor architecture is amendable to realizing high focal plane density while maintaining readout with low parasitic thermal loads in a sub –kelvin cryogenic environment. We explore the use of a finite element analysis method solver to carry out electromagnetic simulations of representative sensor geometries.

*Society of Physics Students 2018 Internship Program

G70.00034: Investigation of Nanoparticles Using QCM  CELESTE CISNEROS (Presenter), CARLY NICOLE CUEVAS, Hartnell College — The essential purpose of this research project was to construct and develop a method to quantify nanoparticle concentration using a very sensitive apparatus known as the Quartz Crystal Microbalance (QCM). An airtight glove box was constructed to facilitate sensitive measurements with the QCM. A temperature probe and a inspection camera were added to monitor the environment and the evaporation process of the nanoparticle droplets. The QCM works by a shift in its resonance frequency when small mass of nanoparticles are introduced to it. When the solvent liquid evaporates, the QCM measures the nanoparticle concentration by evaluating the remaining solute residue that is left on the quartz surface. We did extensive measurements using typical alcohol such as methanol and ethanol to determine the sensitivity of the QCM. In this conference we would like to present the data using the QCM with different concentrations of nanoparticles, specifically we would like to present results of titanium dioxide suspensions.

G70.00035: Fabrication and characterization of multicoil neural probes  AMELIA CULP (Presenter), LUKE D'IMPERIO, MICHAEL J NAUGHTON, ANDREW MCCROSSAN, Boston College — There is virtue in long-term neural stimulation for the treatment of symptoms associated with neurological disorders. To date, implanted electrical probes have had great success in mitigating seizures and symptoms of e.g. Parkinson's disease and other pathologies. However, chronic stimulation has proven challenging as electrode performance degrades over time. Alternatively, new technologies are exploring electrical stimulation via changing magnetic fields, harnessing the physical properties set out by Maxwell's equations. Most magnetic neural probes use a single coil design on silicon substrates; multiple coils using substrate materials with increased pliability may improve these technologies. Here, we discuss the modeling, making, and measuring of multicoil magnetic probes microfabricated on flexible polymer substrates for potential long-term neural stimulation. This novel device design is characterized toward the goal of recording of device-driven action potentials in spatially removed neurons.

G70.00036: Phase Transitions in Polymeric Gels Induced by Crosslinking Entropy  JACOB ADAMCZYK (Presenter), MIRON KAUFMAN, KIRIL STRELETZKY, Physics, Cleveland State University — Microgels are polymer-based particles which can change size and shape during volume phase transitions in response to external stimuli. We have specifically investigated microgels which respond to changes in temperature. Hydrodynamic radii were obtained from light scattering data on Hydroxypropylcellulose (HPC) microgels and then modelled with the standard Flory-Huggins theory. We present a numerical study of a thermodynamic theory (M. Kaufman, Entropy, 20(7), 501, 2018) which includes the entropy associated with crosslinking between polyfunctionals and monomers at the ends of linear polymers. This theory predicts a strong first-order transition due to the saturation of possible crosslinks when the number of polyfunctionals is of the same order of magnitude as the number of polymers. We will present numerical results based on this thermodynamic model.

G70.00037: Modeling transport in paper microfluidics  RAYLEIGH PARKER (Presenter), TIM ATHERTON, CHARLES MACE, Tufts University — Paper based microfluidic devices are extremely promising as an inexpensive and highly customizable platform for assays. Flow and particle transport in these highly porous and disordered materials are not well characterized, however, presenting a challenge for the construction of reliable devices that may require well-timed transport of cells and media such as blood. In this work, we identify design and material parameters crucial to transport, and experimentally characterize their influence through a sequence of test devices, where the fluid flow is tracked using our new open-source software package developed for this purpose. Measurements are compared with theoretical modeling to identify the physical processes and relevant timescales involved. Prospects for control and design of future devices will also be discussed.

G70.00038: Development of Cosmic Ray Shower Array and Measurement of the Speed of the Muon  ARAM NINO CANIZAL (Presenter), CHRISTIAN HERNANDEZ, ANDREW REYES, Hartnell College — Supernovae across the universe eject cosmic rays that impact atomic nuclei in Earth's atmosphere to create secondary particles like muons. The muon is an unstable particle that decays quickly and it can penetrate deep into matter. To measure the cosmic rays, we used light sensitive Photomultiplier detectors connected to scintillator sheets by optical fibers enclosed in a light tight box. We assembled multiple detector boxes to measure the high speed muon particles and using 3 different detector boxes we formed an array. In addition, we collected data with a water Cherenkov detector to determine the speed of the muon by varying the distance of separate detectors. By running a program in the Linux OS the speed of the muon was determined and analyzed. In this conference, we present data from our detector array together with our result of the speed of the muon determined to be 99% of the speed of light using the Cherenkov detector.

G70.00039: The Yarkovsky Effect on Near-Earth Asteroid (101955) Bennu, Target of the OSIRIS-Rex Mission: A review of the literature, by Robert Melikyan  ROBERT MELIKYAN (Presenter), Ithaca College — The Yarkovsky effect is a nongravitational phenomenon resulting from anisotropic thermal emissions of rotating asteroids. It took more than 100 years between theory and detection (first seen in asteroid 2489 Golevka in 2003). Now, the near-earth asteroid 101955 Bennu has shown a mean semi-major axis drift da/dt = 284 ± 1.5 m/year due to the Yarkovsky effect. Non-gravitational drift can greatly affect the probability of asteroid impact with earth making accurate modeling of the Yarkovsky effect a high priority for NASA. The OSIRIS-REx mission is currently delivering a satellite into orbit around Bennu. Amongst the mission objectives is the measurement of the asteroid's thermophysical properties that contribute to the Yarkovsky effect, such as the thermal conductivity of the surface. This is important because the observations necessary to measure thermophysical properties from Earth are much more difficult than from a spacecraft platform. Another difficulty is that the highly elliptical orbits of most near-earth asteroids can greatly increase error. Bennu, with the “eyes” of the OSIRIS-REx mission, acts as the perfect aid for observing and understanding the characteristics of this important nongravitational effect that makes asteroid orbits so hard to predict into the future.

G70.00040: Optical Properties of MBE-grown (Bi 1-x Sb x ) 2 Te 3 Thin Films*  PHOEBE KILLEA (Presenter), FRANK C PEIRIS, Kenyon College, ANTHONY R. RICHARDELLA, TIMOTHY PILLSBURY, NITIN SAMARTH, Materials Research Institute, Pennsylvania State University — Spectroscopic ellipsometry was used to determine the dielectric functions of a series of (Bi1-xSbx)2Te3 thin films. The films were grown using molecular beam epitaxy and were deposited on InP substrates. X-ray diffraction, XPS and AFM experiments indicated that the films were of high-quality. Ellipsometry measurements were obtained in the spectral range between 0.05 eV and 6 eV. A standard inversion technique was used to model the ellipsometry spectra, which produced the dielectric functions of each of (Bi1-xSbx)2Te3 thin films. By representing the dielectric function with Kramers-Kronig-consistent oscillators, the fundamental band gap and the higher order transitions of these films were obtained. A Drude oscillator, which represents the absorption of free carriers, was needed to model some films.

* The work at Kenyon is funded by DMR-1609245 and the work at Penn State is funded by DMR-1539916
G70.00041: Developing an Interactive Demonstration for the Science of Smell  
CARISSA GIULIANO, MATTHEW WRIGHT (Presenter), Adelphi University — We present our work towards developing an interactive demonstration for middle school and high school students on the science behind how we smell. We will discuss the results of our literature search which shows there are three models for how we smell: the Lock and Key model, the Vibration Theory model, and the most widely accepted model that combines the two. We will discuss how we plan to demonstrate these three concepts to young science students and how we plan to use it as a tool to generate interest in science.

G70.00042: Progress toward Coherent Control of Ultracold Collisions with Frequency-Chirped Laser Light*  
OLIVIA CHIERCHIO, ZAFIR MOMIN, MICHAEL ROBBINS, AREEBA KHALID, MATTHEW WRIGHT (Presenter), Adelphi University — Frequency-chirped laser light as recently been shown to coherently control collisions and photoassociation. We are planning to use short (~ 3 ns), intense (> 100 mW/cm²), frequency-chirped (~1 GHz in 6ns) laser light to control excited-state collisions between Rb atoms in a MOT. We will discuss our progress towards this aim, including stabilization of our MOT and our computer control system.

*National Science Foundation Award Number: 1803837

G70.00043: ABSTRACT WITHDRAWN

G70.00044: The Effects of Ionized Impurities on the Nanoscale Spatial Distribution of the Schottky Barrier  
STEVEN GASSNER (Presenter), JACK ROGERS, HYEONSEON CHOI, WESTLY NOLTING, VINCENT LABELLA, Colleges of Nanoscale Science and Engineering, SUNY Polytechnic Institute, Albany, NY — The influence of ionized impurities in the semiconductor upon the local Schottky barrier height of a metal-semiconductor interface is important for contacts in nanoscale devices. A computational model simulates spatially-resolved measurements of the electrostatic potential of various metal-semiconductor interfaces acquired using ballistic electron emission microscopy (BEEM), an STM-based technique. The model assumes a uniform charge density with a set of point charges close to the interface, and generates simulated datasets in the form of Schottky barrier height maps and histograms. The introduction of localized charges causes skewing of the distributions, which are compared to BEEM measurements of Au/Si and Cu/Si Schottky barrier height maps.

G70.00045: A High Power Set-up to Test Optical Coatings  
ANDREW POVERMAN, BRUNO BECHER (Presenter), LOGAN KAEUBLING, ISOBEL CURTIN, RITI BAHL, ANTONIOS KONTOS, Bard College — To detect gravitational waves, the LIGO detectors need to limit the noise from multiple sources. Noise related to the quality and characteristics of the coating that is used on the test masses is one of the most important and most difficult to mitigate. Significant effort is invested in finding new types of coatings that satisfy the many stringent requirements of LIGO, which include low thermal noise, low scattering and low absorption. In addition, these coatings need to withstand high CW power without exhibiting any significant deterioration. It is therefore crucial to develop optical set-ups that will measure all the relevant coating properties, and under conditions similar to LIGO. Here we describe one such set-up at Bard College. The main characteristics of our set-up include a high finesse cavity inside an ultra-high vacuum chamber, in which mirror samples will be tested for scattering and aging over long periods of time.

G70.00046: Directed Self-Assembly of Nanoparticles under Electric Fields  
MATTHEW WITHERS (Presenter), MITCHELL ROBERTS, DAN MAZILU, IRINA MAZILU, Department of Physics and Engineering, Washington and Lee University — We develop an experimental and theoretical approach to study the effect of electric bias on particle-coverage densities produced during nanoparticle self-assembly. Experimentally, we utilize a parallel plate capacitor to allow for the application of a uniform external electric field during the self-assembly of SiO₂ nanoparticles on glass slides. We refer to this procedure as directed self-assembly of monolayers (DSAM). To determine particle-coverage densities, we use scanning electron microscopy. In our theoretical analysis, we modify existing cooperative sequential adsorption models to account for diffusion under an applied electric field. We then apply the mean field approximation to these modified models to obtain master equations, which we solve for particle-coverage densities. To ascertain the validity of these models, we compare computer simulations produced using our theoretical approach to our experimental data.
G70.00047: Modeling Senate Voting Behavior using Mathematical Modeling.  
ANTHONY LORSON (Presenter), SHO GIBBS, JUSTIN PUSZTAY, Washington and Lee University, WILL HANSTEDT, Rockbridge County High School, IRINA MAZILU, Washington and Lee University — Using purely quantitative methods to analyze and explain Congress’ actions is rare, yet has the potential to be extremely valuable. We aim to model the voting patterns of the Senate by adapting the Ising model and incorporating economic game theory, with each individual senator being a node with a voting-state and a partisanship value. Our assumptions include symmetry between voting yes and no before the introduction of partisanship and a lack of an external field. The coupling constants of the Ising model reflect the nature of the issue at hand and are individualized for each senator, reflecting their own partisanship as well as the positions of senators who interact with them. The stochastic model was run using Monte Carlo simulations in Python, with several different graph types allowing for multiple ways for senators to be connected to one another. By looking at the properties of the graph such as magnetization and correlations between nodes, we hope to gain insight into how the Senate operates.

G70.00048: Using an Arduino in a Coupled Logistic Map Circuit to Explore Basins of Attraction for Symmetry-broken States  
MOYI TIAN (Presenter), HOUSSEMEDDINE MHIRI, LARS Q ENGLISH, Dickinson College — L’Her et al. [1] recently constructed a circuit designed to implement the logistic map electronically, and thus generated bifurcation diagrams in growth rate, \( r \), as well as in coupling parameter, \( \varepsilon \), for two coupled maps. We show that in the coupled logistic-map system, the dynamics is not only determined by \( r \) and \( \varepsilon \), but also by the initial conditions, due to the multi-stability of different solutions. By experimentally adding control over initial conditions and incorporating an Arduino Uno Microcontroller, we explore basins of attraction associated with symmetric states, symmetry-broken states and phase-shifted states.

G70.00049: Implementation of a Causal Spectral Decomposition Representation for the Neutron Star Equation of State for Gravitational Wave Parameter Estimation*  
DEVON NOTHARD (Presenter), LESLIE WADE, Kenyon College — On August 17, 2017 LIGO observed a binary neutron star merger 130 million lightyears away by detecting ripples in the fabric of spacetime called gravitational waves. Information about the neutron star equation of state (EOS), an equation relating the state variables of a system, is encoded in these waves. Currently the neutron star EOS is highly unconstrained. However, constraining this equation through gravitational wave measurements may provide us unprecedented knowledge about a naturally occurring source of nuclear matter at densities unachievable in a laboratory. Theoretical physicists use knowledge of microscopic and thermodynamic properties of nuclear matter in order to invent potential candidate EOSs that are consistent with current neutron star observations. Prior to LIGO’s monumental discovery, NS observations and EOS constraints came exclusively via optical telescopes. However, we can extract NS EOS information from gravitational waves as well. In this project, I incorporated an EOS model with physical conditions such as causality and thermodynamic stability built in. I have developed software that will be incorporated into LIGO’s parameter estimation algorithms to measure the neutron star EOS from future gravitational wave observations using this model.

G70.00050: 3-Color Two-Beam Broadband Nonlinear Frequency Mixing: From Physics to Applications for Spectroscopy*  
BENNY SCHUNDELMIER (Presenter), LASZLO JANOS UJJ, University of West Florida — We report the theoretical summary of 3-color two-beam broadband nonlinear frequency mixing by using the double-sided Feynman diagrams and the phenomenological picture of the light matter interactions. We measured the intensity dependence of the signal beam via excitation beams and recorded the scattering spectra that originated from molecular solutions and crystals. Pure vibrational spectra were extracted from the measured spectra with model independent phase retrieval methods. We have used our spectroscopy system published recently [1] to characterize the method. We showed that the method is extremely useful to measure molecular vibrational and vibronic spectra in the low frequency, terahertz range.

*The authors acknowledge the financial support from the Department of Physics and the UWF Office of Undergraduate Research.
G70.00051: HIV-1 Gag Protein Nanoparticle Systems: Assembly and Viral Inhibition Strategies*  JAIME GARCIA (Presenter), Physics, St. Mary's University, Texas, DANITZA VASQUEZ, DELVIN CARABALLO, Chemistry, University of Puerto Rico- Rio Pierdas, DELANEY ALEJANDRO, Esc Brígida Alvarez High School, DANIEL RAMOS-PEREZ, MARVIN BAYRO, Chemistry, University of Puerto Rico- Rio Pierdas — Current drug therapies available to individuals infected with the HIV-1 virus work to target reverse transcriptase and the viral protease via a drug cocktail. However, during the process of maturation in HIV-1, viral protease cleaves Gag and initiates conformational changes in CA proteins which foster its assembly into the capsid, a fullerene shaped shell composed of ~1500 copies of CA. This capsid houses the viral genetic information and poses as a viable target for treatment to combat the virus. Current knowledge of the mechanisms and processes of this conformational shift is very limited. To enhance our understanding of the process of maturation we studied the effects of protein crowding by constructing Gag virus-like particles (VLPs) alone (control), in the presence of C-terminal capsid, cytochrome-c, lipids, and ribonucleic acid so we can study the effects the presence may have on Gag's ability to self-assemble. Our results indicate that Gag retains its ability to self-assemble into VLPs despite protein crowding effects and competitive inhibition of its dimerization interface.

*Supported by the NSF Grant 1757365 to University of Puerto Rico- Rio Pierdas.

G70.00052: Molecular Dynamics Simulations of Patterned Complex Coacervates  NATALIA MARKIEWICZ (Presenter), Chemical Engineering, University of Illinois at Urbana-Champaign, TYLER LYTLE, Chemistry, University of Illinois at Urbana-Champaign, CHARLES E. SING, Chemical Engineering, University of Illinois at Urbana-Champaign — Complex coacervation is the liquid-liquid phase separation of polyelectrolytes in aqueous salt solution into a polymer-dense phase (coacervate), and a polymer-dilute phase (supernatant). These materials are simplified analogues of membraneless compartments in cells, where the sequence of charge has been altered to alter resistance to the presence of salt. Previous work using Monte Carlo simulations demonstrated that changing the sequence of charged and neutral monomers while keeping the charge fraction constant alters the phase separation. We have run molecular dynamics simulations to elucidate the interplay between charge fraction and charge sequence, showing comparisons to existing Monte Carlo simulations and experimental data demonstrating that charge blockiness enhances phase separation. This model is then used to demonstrate the structural effects of varying the charge fraction, in particular showing the emergence of microphase separation at low salt concentrations for blocky polyelectrolytes.

G70.00053: Analysis and Comparison of Light Intensity Spectra Using Wavelet and Fourier Analysis.  BRIENA FELTNER (Presenter), JOSEPH TROUT, Richard Stockton College of New Jersey — This is a continuation of research on the analysis of light intensity spectra of stars that began in the Fall 2017. Using Fourier Analysis and Wavelet analysis, both are typically used for analyzing stellar light curves, a comparison of the recorded light spectra can be made between a space telescope and a ground telescope. Long term, continuous time series of light intensities are needed for the analysis of astronomical phenomena such as the orbit of previously unseen planets. Since the space telescope time series records are sometimes missing data, it has been suggested that land based telescopes can be used to fill in the missing data. This poster presents the comparison of data collected and analyzed with Fourier Analysis and Wavelet analysis.

G70.00054: Morlet wavelet analysis of planetary atmospheres.  VATSALA ADILE (Presenter), ESPEN FREDRICK, DARSA DONELAN, Gustavus Adolphus College — This study investigated the use of Morlet wavelet analysis in the detection of gravity wave structure in the atmosphere of terrestrial bodies, primarily Mars, Venus, and Titan. Atmospheric profiles from data collected by planetary probes and satellites were processed to generate 2D images of wave structure in each analyzed atmosphere. The analysis shows a correlation between vertical wave structure at altitudes and wavelengths to those previously found using other methods such as comparing temperature gradient profiles to the dry adiabatic lapse rate. This suggests the use of Morlet wavelet analysis as a viable alternative to previously used methods for detection of small-scale variability.

G70.00055: The Coefficient of restitution by Microcontrollers*  THY DOAN MAI LE (Presenter), DAN A. BRIOTTA, Physics & Astronomy, Ithaca College — The project began with the traditional setup for a coefficiency of restitution experiment that is failing and has been abandoned by students of Advanced Lab, which was a call for a major upgrade. After the project is complete, the experimental set-up now has a completely new circuitry with calibrated frequency responses, the ability to handle a wider range of inputs, a digitizer circuit, an Arduino and an accompanying program for data acquisition and a Python GUI that takes in data via serial connection from the Arduino, plots the live data and analyzes it to find the coefficient of restitution. The goal of the project was to reignite students' interest in the classical experiment, expose students to microcontrollers and give students an opportunity to learn how to program parts of a system to work together, all at a very small cost compared to previous setups using NI devices and Matlab interfaces.

*This project was supported by Ithaca College's Department of Physics & Astronomy, the School of Humanities & Sciences' Summer Scholars Program and the Dana Internship program of Ithaca College.
G70.00056: Effects of structural order on magnetic properties of $S = 1\ \left[\text{Ni(HF}_2\text{)(pyz)}_2\right]\text{PF}_6\ (\text{pyz = pyrazine})^*$

ASHLEY GLOVER (Presenter), JAMIE MANSON, Chemistry, Eastern Washington University, SAM CURLEY, ROBERT WILLIAMS, PAUL GODDARD, Physics, University of Warwick, JOHN SINGLETON, NHMFL, Los Alamos National Laboratory, SAUL H. LAPI DUS, Advanced Photon Source, Argonne National Laboratory, ROGER JOHN SON, PASCAL MANUEL, ISIS Pulsed Neutron Source, Rutherford Appleton Laboratory, WEI ZHOU, National Institute of Standards and Technology, NIST Center for Neutron Research, JESPER BENDIX, University of Copenhagen, Chemistry — We have discovered a third polymorph in the $\left[\text{Ni(HF}_2\text{)(pyz)}_2\right]\text{PF}_6$ family of coordination polymers. As compared to the previously published structures that possess structurally ordered frameworks $^1$, a new example features a disordered, monoclinic unit cell. This new variant allows us to examine the effects of structural order and disorder on superexchange pathways, specifically along the Ni-FHF-Ni and Ni-pyz-Ni directions. We consider the local distortions to the Ni(II) coordination sphere and the geometries afforded by the ligands. This presentation will address the possible discrepancies in magnetic properties for these polymorphs as gleaned by examination of their structures.

*NSF DMR-1703003 (EWU), DMR-1157490 (MagLab), DoE, FL, ERC, EPSRC

G70.00057: Applying Machine Learning to Ultrasound Computational Simulations to Determine Scattering Location

NAOMI BRANDT (Presenter), NGUYEN NGUYEN, MARIA TERESA HERD, Mount Holyoke College — In the field of ultrasound imaging, it has been theorized that imaging noise, known as speckle, may be the product of unresolvable scatterers. This would result in certain speckling patterns revealing themselves over large datasets, which could be utilized to predict the early formation of tumors. Such a dataset would be difficult to analyze by hand, but machine learning algorithms can be used to recognize these patterns in an effective manner. As of now, few attempts have been made apply machine learning to predict scatterer placement from ultrasound scans.

We have constructed a computational simulation which consistently and accurately reproduces experimental data, and can be used to train a machine learning algorithm. Using Field II, a Matlab-based program for ultrasound modelling, simulations were created to replicate data produced from experimental phantoms composed of glass beads and agarose gel. Simulations were designed to account for bead placement and size, as well as experimental conditions. Comparisons between simulated and experimental data using statistical analysis show that computational methods can accurately predict ultrasound images. This verification allows us to begin training a machine learning algorithm using both simulated and experimental data.

G70.00058: Field Electron Emission of Hafnium Carbide*$^*$

MORGAN CHAMBERLAIN (Presenter), Linfield College, WILLIAM MACKIE, JOSH LOVELL, Applied Physics Technologies — Hafnium carbide, or HfC, is a robust material whose high melting point makes it an advantageous electron source for a variety of uses, including imaging. This research focused on the effects of an applied field at high temperature on HfC crystals, which induces a faceting effect over time. The cause of this faceting was studied to determine whether it could be correlated to evaporation or self-diffusion during use. The method for electrochemically etching hafnium carbide cathodes was also optimized, and the crystallographic geometry of the tip surfaces was studied using field emission microscopy.

Applied Physics Technologies

G70.00059: Comparison of Capacitance-Voltage, Current-Voltage, and BEEM Measurements of Metal-Graphene-Semiconductor Schottky Barrier Heights

HYEONSEON CHOI (Presenter), JACK ROGERS, STEVEN GASSNER, WESTLY NOLTING, Colleges of Nanoscale Science and Engineering, SUNY Polytechnic Institute, VINCENT LABELLA, Nanoscience, Colleges of Nanoscale Science and Engineering, SUNY Polytechnic Institute — Capacitance-voltage, current-voltage, and ballistic electron emission microscopy (BEEM) measurements were performed to determine the Schottky Barrier Heights of Au/Si and Au/graphene/Si samples. In addition, measurements were performed on a commercial diode for reference. Data were acquired as a function of temperature, which indicate that the graphene had little effect upon the barrier heights that were measured.
G70.00060: Self-Assembly of Spheres on a Cone Surface  
TALHA REHMAN (Presenter), Berea College, NABILA TANJEEM, VINOTHAN N MANOHARAN, Harvard University — Self-assembly in confined space can lead to formation of unique 3-D structures. We study self-assembly of submicron-sized colloidal spheres on the surface of a micron-sized cone. Fabrication of micron-sized cones is challenging using conventional photolithography. We explored alternative techniques for fabrication of cones. By using a 3-D laser lithography tool called Nanoscribe, we successfully manufactured cones of various cone angles and diameters. By using a micropipette puller, we pulled glass capillary tubes into cones with very smooth surfaces. We performed experiments to self-assemble colloidal spheres on both types of conical surfaces. To assemble spheres, we use depletion interaction. It results in a short-ranged attraction between the spheres, and between the spheres and the conical surface. We observed crystal growth on the cones that were fabricated from glass capillary tubes. This result suggests that a smoother cone surface is preferred to study self-assembly on a cone using depletion interaction.

G70.00061: Measurement of the Tissue Properties of Three Cell Lines using Quantitative Ultrasound*  
PENELOPE TAYLOR (Presenter), AMY LONGSTRETH, MARIA TERESA HERD, Mount Holyoke College — We are measuring the ultrasonic characteristics of cells to find the fundamental differences between cancerous and non-cancerous cells by calculating and comparing the attenuation and speed of sound. We are comparing both the attenuation and the speed of sound because these properties are dependent on the medium being used, and thus should have differences in their ultrasonic characteristics. In this experiment, the three cell lines being used are prostate cells, cancerous colon cells, and cancerous prostate cells. To test for these differences, we are using unfocused transducers of 5, 10, and 15 MHz to find the data for the cumulative range of 2 to 18 MHz. These transducers are placed in water and aligned for optimal wave amplitude travelling between them. The results of the comparisons of cell lines shows a noticeable difference between colon cancer and the other two cell lines, prostate and prostate cancer. The difference between prostate cells and prostate cancer cells is much less significant. This research may lead to the ability to better detect whether lesions are cancerous or non-cancerous using the non-invasive method of quantitative ultrasound.

*Mount Holyoke Lynk UAF

G70.00062: Systematic Removal of Self Assembled Monolayers from Au(111) surfaces, investigated via Atomic Force Microscopy and Contact Angle Measurements*  
INDRAJITH SENEVIRATHNE (Presenter), KELLY M GERRITY, Lock Haven University of Pennsylvania — Self-Assembled Monolayers (SAMs) of thiols on Au(111) surface on mica substrates are used in many instances to study various proof of concept devices such as Nanosensors and Nanoelectronics. However, once used, the Au on mica substrate, upon which the SAM layer sits on, is discarded as surface integrity could deteriorate in the cleaning steps. We have used combinations of organic solvents to critically clean and gently remove the SAM surfaces from the Au(111) substrates. Subsequent surfaces were investigated using Atomic Force Microscopy (AFM) and the Contact Angle measurements. Results were compared with Au(111) surface before SAM deposition and after SAM removal. We have used 1-Dodecanethiol as our SAMs on Au(111) surface. AFM was used in intermittent contact mode to image the investigated surfaces. Discussion of the results obtained compared with the existing literature will follow.

*Lock Haven University Nanotechnology Program and Lock Haven University Nano Club.

G70.00063: Optical Tweezer Measurements in Chlamydomonas*  
MAURICIO GOMEZ (Presenter), CORBYN JONES, WYLIE AHMED, California State University, Fullerton — Optical tweezers have been used to study force fluctuations in microscopic systems and to determine the physical properties of complex materials. We implement two calibration methods, the photon-momentum method and the active-passive method, to measure displacements and forces at the nanometer and piconewton scales. Here, we study the force fluctuations of chlamydomonas microswimmers by applying the photon-momentum method. We calculated the stochastic force spectrum (P_{total}) by estimating the power spectral density of the fluctuating force signal. We apply a theoretical framework to extract the non-equilibrium microswimmer forces from the total force spectrum. We then apply a spectrogram analysis to understand the frequency-time dynamics of the chlamydomonas microswimmer. We hope to extract the force kinetics of the agella and molecular motors.

*CSUF Dan Black Family Fellowship
G70.00064: Conductivity vs. Temperature Measurement for PEDOT:PSS
JOSE PERALTA (Presenter), MADISON GUERRERO, PATRICK MILAN, LAYLA LOGLETREE, PROF WEINING WANG, Seton Hall University — Conducting polymers can be applied to a broad range of specialties, such as solar cells, light-diodes, sensors and other optoelectronics. In particular, poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS), a conducting polymer, is the most popular due to its high conductivity and stability. It has been used widely as contact material in solar cells, which may operate at different temperatures other than room temperature. Because of this, it is important to examine how the polymer, and its characteristics, are affected at different temperatures, which ultimately affect the performance of the polymer and its application in solar cells.

In this study, we show the temperature dependence of conductivity measurement of the PEDOT:PSS. The PEDOT:PSS samples with different conductivities were studied under different temperatures, using a temperature-varying device. It was found that the PEDOT:PSS samples exhibit an Arrhenius behavior as a function of temperature ($\sigma = \sigma_0 \exp(-E_a/kT)$).

From the results that we collected we were able to obtain the activation energy of the samples.

* Cottrell College Science Award

G70.00065: Development of Apparatus for Simultaneous Measurement of Photocurrent and SHG
AUSTIN KACZMAREK (Presenter), LIUYAN ZHAO, University of Michigan — Many studies have been done investigating the second order nonlinear response of noncentrosymmetric materials to gain insight to the electronic structures of these materials. Photocurrent and optical second harmonic generation (SHG) are two second order nonlinear phenomena that share the same form of the second order nonlinear susceptibility tensor but are sensitive to distinct energy regimes of the electronic structure of the material under investigation. We present the development of an experimental apparatus for the simultaneous measurement of these two nonlinear phenomena using an ultrafast laser-based scanning approach. We show that the laser scanning provides a spatial resolution of these two nonlinear responses down to the optical diffraction limit, and the confocal imaging scheme adopted in our design assures a constant incident electric field over a wide scanning area. We also discuss our effort in enhancing these nonlinear responses, by compressing the laser pulse to its transform limit. Finally, we will discuss future opportunities brought by this apparatus, such as developing time resolved scanning nonlinear optical techniques.

G70.00066: Looking for Variability in Cygnus X1
BAILEY CONRAD (Presenter), ALEX STORRS, Towson University — We present observations of HDE 226868, the companion to Cygnus X-1. Low resolution (R=4.3 Å per pixel) spectra of the visible region, 6500 Å to 3000 Å, made with Maryland Space Grant Consortium’s 0.5-meter telescope at John Hopkins University over the summer. This region includes emissions from hydrogen and helium which are shown to be time variable by Gies et al. (2003). We examined these spectra for variability.

G70.00067: Understanding the determination factors of the formation of large flocks of swimming sperm in viscoelastic fluid
JELANI LYLES (Presenter), North Carolina Agricultural and Technical State University, DANIEL SUSSMAN, Syracuse University, SOON HON CHEONG, SUSAN S SUAREZ, Cornell University, M. LISA MANNING, Syracuse University, CHIH-KUAN TUNG, North Carolina Agricultural and Technical State University —

When bovine sperm swim in viscoelastic fluid, they form dynamic clusters that coexist with individually swimming sperm in a steady state. By tuning the viscoelasticity of the fluid, we are able to generate clusters in the size of ~20 cells. By using a pulse of flow to align them upstream momentarily, we were able to generate large flocks, from a range of 60-200 cells. This large flock formation is also known as mass motility in a clinical setting, which is used for semen motility evaluation from bulls and other ruminants in the field for veterinarians, where environmental control is not available, and sperm die quickly on an optical system. We employ a numerical self-propelled particle (SPP) model to identify the factors that lead to bigger flock formation, or better mass motility. Our model includes nearby sperm orientation alignment and attraction, volume exclusion, and heterogeneity among cells. We will compare the data from the numerical model with the experiments.

*NSF-HRD-1665004, APS Bridge Program MSI Travel Award.
G70.00068: Synthesis and Characterization of Cobalt Ferrite (CoFe$_2$O$_4$) Magnetic Nanoparticles by Ball-Milling and Sol-Gel Techniques

THOMAS LONGO (Presenter), Physics Department, Villanova University, BRYAN EIGENBRODT, Chemistry Department, Villanova University, JEREMY CARLO, ARTHUR VIECAS, GEORGIA C PAPAEFTHYMIOU, Physics Department, Villanova University — Magnetic nanostructures play an important role in nanotechnology allowing for technological advances in electronic devices, photocatalysis, sustainable energy, biotechnology and medicine. In particular, cobalt ferrite (CoFe$_2$O$_4$) magnetic nanoparticles (MNP) have strong uniaxial magnetic moments, which allow for applications in hyperthermia and targeted drug delivery. Therefore, these particles were synthesized using two different techniques: mechanochemical ball-milling and sol-gel. Using Mössbauer Spectroscopy, X-Ray diffraction, Transmission Electron Microscopy, SQUID magnetometry, and Specific Absorption Rate (SAR) measurements, their magnetic, structural, and thermal transfer characteristics were analyzed and compared to maghemite (gamma-Fe$_2$O$_3$) and magnetite (Fe$_3$O$_4$) MNPs. In addition, for cobalt ferrite nanoparticles to be used within the body they must be rendered bio-compatible through surface ligand exchange processes in order to avoid being targeted by the body's auto-defense system. Therefore, different ligands were experimented with to determine an optimal coating for usage in the body.

G70.00069: Establishing Monomer vs. Aggregate Composition of Squaraine-Based Organic Photovoltaics Using Atomic Force Microscopy

ADRIANA CRUZ (Presenter), CATHERINE RYCZEK, Physics, Hamilton College, ZHILA HOOSHANGI, SOUMYA GUPTA, CHRISTOPHER COLLISON, Chemistry, Rochester Institute of Technology, KRISTEN BURSON, Physics, Hamilton College — Organic photovoltaics (OPV) offer exciting possibilities for energy production and in optimizing OPV devices, a greater understanding of the organic solar cells' morphology is needed. Structural order is thought to improve charge mobility and energy transfer. Here we present a method for determining the monomer vs. aggregate composition for squaraine-based thin films using measurements of each film's absorptivity, thickness, and area. Population can be measured through absorption measurement, provided that the extinction coefficient of the species in question (aggregate or monomer) and the path length for the light through the sample are known. Therefore the ability to measure populations depends on an accurate values for the film thickness, typically 50-150 nm. We employ atomic force microscopy (AFM) to measure film thickness and assess two techniques for removing thin-film material to establish accurate heights. Both techniques yield consistent height data and we discuss their merits. AFM measurements yield average thickness measurements for each type of film with an uncertainty under 17% and area measurements with an uncertainty under 3%. These low uncertainties are crucial as they allow for the monomer to aggregate population to be measured with a high level of precision.

G70.00070: Development and Characterization of a Prototype Cosmic Microwave Background Calibration Target

DAVID STILWELL (Presenter), DAVID B GREENE, DAVID CHUSS, MARTIN DEGEORGE, Villanova University, KARWAN ROSTEM, EDWARD J WOLLACK, NASA Goddard Space Flight Center — The capability to construct devices that have low reflectance (and high absorptivity) of electromagnetic radiation at long wavelengths has many potential applications ranging from radar evasion to EMI control to calibration of sensitive detectors for cosmology. In cosmology, characterization of the spectrum and polarization of the cosmic microwave background, the afterglow of the Big Bang, requires measurements that are accurate to one part in 10$^7$. We describe the fabrication of a prototype cosmic microwave background calibration target that consists of an array of 169 cones, each constructed of loaded epoxy that is molded around an aluminum core for mechanical attachment and thermal stability. By testing the target over a range of frequencies, we achieved a reflectance of -50 dB. These processes were developed as a key technology to support a future NASA space mission to measure the spectrum and polarization of the cosmic microwave background to probe the physics of the early universe.

G70.00071: Schottky diode based on large area CVD-grown WSe$_2$

AHMAD MATAR ABED (Presenter), ANAMARIS MELENDEZ, NICHOLAS PINTO, IDALIA RAMOS, Physics and Electronics, University of Puerto Rico at Humacao — Two-dimensional transition metal dichalcogenides have attracted great attention due to their unique optoelectronic applications. Of these, tungsten diselenide (WSe$_2$) is a semiconductor with a trigonal structure, and a small bandgap ~1.6eV. Here we report electronic transport measurements of CVD-grown WSe$_2$ configured as a Schottky diode. To prepare the device, the WSe$_2$ film was transferred onto an n-doped Si/SiO$_2$ wafer with pre-patterned gold electrodes over the oxide surface. The diode parameters were analyzed using the standard thermionic emission model of a Schottky junction. Results obtained at room temperature include a forward turn-on voltage of ~0.46 V, ON to OFF current ratio at ± 1 V of ~1100, barrier height of 0.41 eV and an ideality parameter of n~1.3. The device was tested as a half-wave rectifier showing a rectification ratio of 1150 with an output/input voltage ratio of 46.3%. Efforts to investigate the temperature-dependent transport mechanisms of the device will also be presented.

*The WSe$_2$ films were provided by the PSU 2DCC-MIP, which is supported by NSF cooperative agreement DMR-1539916. Research at UPRH was supported by NSF under grant NSF-DMR-1523463 (PENN-UPRH Partnership for Research and Education in Materials).
G70.00072: In-vitro effects of low intensity ultrasound exposure on prostate cancer cells* BARBARA MARQUEZ (Presenter), MARIA TERESA HERD, Mount Holyoke College — Ultrasound has been utilized in diagnostic and treatment of cancerous lesions. Most research focuses on high intensity focused ultrasound (HIFU) as a viable treatment option; however, there have been studies showing cell apoptosis due to low intensity ultrasound exposure. We have thus studied the effect of low energy ultrasound on cancerous prostate cells compared to healthy prostate cells in vitro. We report on the intensity of ultrasound reaching the cells and attenuation through cell culture flasks. Our study compares cell counts before and after ultrasound exposure with accurate energy measurements as a function of frequency.

*Mount Holyoke College

G70.00073: A Novel Application of Focused Ultrasound for the Treatment of Port Wine Stain Birthmarks KRISTEN DOUCETTE (Presenter), Department of Chemistry and Physics, Simmons University, JOHN O’MALLEY, Department of Dermatology, Brigham & Women’s Hospital, PHILLIP JASON WHITE, Department of Radiology, Brigham & Women’s Hospital — Annually, 0.3-0.5 % of the population is born with a Port Wine Stain (PWS) birthmark. A PWS is a capillary malformation that results in a visible, localized vascular lesion. This lesion is characterized by an increased number of dilated capillaries that give the PWS its red discoloration. The gold standard of PWS treatment is photothermolysis with Pulsed Dye Laser (PDL) emitting at a wavelength of 595 nm. The PDL selectively damages the PWS by using the wavelength at which hemoglobin absorbs light to thermally destroy capillaries. Due to limitations of PDL penetration depth, the deepest capillaries are often left untreated. This can form seed locations where new capillaries can develop, causing the PWS to darken in color over time.

Focused ultrasound therapies are non-invasive alternatives to treating tissue at depth. We investigated a novel application of therapeutic ultrasound to treat PWS. We used a transducer operating at 1.47 and 4.42 MHz and FDA-approved microbubbles to induce cavitation as a non-thermal mechanism of damage to the PWS. An ultrasound phantom was created to mimic the vasculature of the PWS for determining the functional ultrasound parameters. We report on the ability of these parameters to selectively damage vasculature in phantoms and ex vivo animal tissues.

G70.00074: Optimization of nanopillar dimensions for maximum light absorption EVANGELINE BEECHING (Presenter), Slippery Rock University of Pennsylvania — Conductive organic polymers such as Poly(3-hexylthiophene-2,5-diy) P3HT, and Poly(2,2′-[(2,5-bis(2-hexyldecyl)-3,6-dioxo-2,3,5,6- tetrahydropyrrolo[3,4-c]pyrrole-1,4-diy]dithiophene)- 5,5′-diyl-alt-thiophen-2,5-diy) PDPP3T are being studied for use in solar cells due to their flexibility, cost effectiveness, and low environmental impact when compared to traditional inorganic thin films. However, these organic polymers do not yet have the same efficiency as their inorganic counterparts and are not being largely produced. It is established that replacing thin films with nanopillars enhances the light absorption when the diameter of the nanopillar is less than that of the wavelength of light. We fabricate P3HT nanopillars with approximate diameters of 76 nm using a porous alumina template. We will be optimizing the dimensions (diameter, height and interval) of the nanopillars for maximum light absorption of wavelengths between 400-700 nm. The dimensions of the pores can be controlled by varying the timing of the pore widening process which in turn changes the dimensions of the nanopillars. We aim to fabricate nanopillars of various polymers and compare the intensity of absorption of their thin films with the nanopillars using UV-Vis spectroscopy.

G70.00075: Exploring two-dimensional devices† WILLIAM SHANNON (Presenter), BYRON GREENLEE, JOEL TOLEDOUNERA, JOSEPH MURPHY, JENNIFER T. HEATH, Linfield College — Two-dimensional materials and devices are opening up a wide range of possibilities for both fundamental and applied research, yet are accessible to the undergraduate lab. We have built a system to layer two-dimensional exfoliated materials into stacks, opening up the possibility of creating a wide range of device structures. This system has been tested by creating twisted bilayer graphene structures, which are known to exhibit Moiré patterns and have electrical properties that vary with twist angle. These bilayers and other simple field effect devices are being studied further with Atomic Force Microscopy, Kelvin Probe Force Microscopy, and bulk electrical measurements to understand electric field screening and potential barriers. Two-dimensional devices have big potential for the future of electronics, and understanding their behavior is an important first step.

†Work funded by the M. J. Murdock Charitable Trust
G70.00076: Treatment of Pancreatic Cancer Cells with SWCNT-Polymer Nanocomplexes as Drug Carriers

CRISTINA ROSAS (Presenter), JUAN MONTEMAYOR, PAUL A WITHEY, University of Houston, Clear Lake — Recent studies show an alternative treatment for cancer that uses single-walled carbon nanotubes (SWCNTs) as drug delivery agents because of their ability to cross cell membranes easily. SWCNTs were dispersed with polyvinyl alcohol (PVA) and Pluronic biocompatible polymers before introducing anti-cancer drugs in the CNTs. Camptothecin (CPT) and Doxorubicin, the anti-cancer drugs used, formed non-covalent CNT-polymer-drug conjugates in aqueous solution when attached to CNTs with a biocompatible polymer. Near-infrared (NIR) fluorescence emission peaks of (7,5) and (7,6) CNTs verified the polymeric dispersion of SWCNTs by both polymers. Pancreatic cancer cells that came from PaCa-2, a pancreatic cell line, were exposed to various concentrations of PVA and CPT with varying SWCNTs to examine the effectiveness of these complexes. The number of viable cells were observed to also determine how effective the treatment was. Preliminary results demonstrate SWCNTs serve as good drug delivery agents and can help increase the effectiveness of anti-cancer drug on the cancer cells.

G70.00077: Modeling Ultracold Atomic Clouds Confined by Atom-chip Magnetic Traps*

XIAOLE JIANG (Presenter), NATHAN LUNDBLAD, Physics and Astronomy, Bates College — NASA’s Cold Atom Laboratory (CAL) conducts experiments on ultracold atoms in orbital microgravity using microfabricated electromagnets (atom chips). We report on the creation of a generalized model, applicable to CAL experiments, for calculating the properties of magnetic traps associated with Bose-Einstein condensates (BECs). While atom-chip BEC machines offer relative simplicity and compactness, such modeling tools are necessary to elucidate certain features (such as the aspect ratio of the trapped ultracold cloud) which might not be intuitive to typical users of the CAL facility. The model (written in Mathematica) is designed such that its interface and setting is generalized, so that users with different priorities or experimental goals, or who are unfamiliar with the code, could use it. We plan to use this model to inform the creation of radiofrequency-dressed magnetic traps and bubble-geometry BECs aboard CAL.

*NASA Fundamental Physics / JPL RSA No. 1597429

G70.00078: Barrier Height Measurement of Cadmium Telluride (CdTe) Solar Cells*

PATRICK MILAN (Presenter), JOSE PERALTA, MADISON GUERRERO, PROF WEINING WANG, Physics, Seton Hall University — Among the thin film generation, the Cadmium Telluride (CdTe) solar cell is favored for research because it has a low cost and a relatively high efficiency (22.1% in 2016). However, its efficiency is still lower than the theoretical limit. One major problem is at the back-contact junction. Since CdTe solar cells have a high electron affinity (about 4.5 eV), typical back contacts such as metals fail to create good ohmic contacts and as a result a Schottky barrier is formed at the back-contact junction. The Schottky barrier affects charge carrier collections and lowers the efficiency of the cell.

In this work, we show our studies on the effect of the barrier height on the performance of CdTe solar cells. We tested CdTe cells with different back contacts and found they had different characteristics and efficiencies. Using the turning point technique, we were able to obtain the barrier heights at the back-contact junction using the current-voltage characteristics of the solar cells at various temperatures. Our results showed that there is a correlation between the barrier height and cell performance: the lower the barrier height, the better the cell performed. These results yielded parameters that will aid us in choosing a superior back contact material for CdTe solar cells.

G70.00079: The Effect of Contact Material on Perovskite Solar Cell Efficiency*

MADISON GUERRERO (Presenter), PATRICK MILAN, JOSE PERALTA, Physics Department, Seton Hall University, HONGKUN CAI, Department of Electrical Science and Engineering, Nankai University, Tianjin, China, WEINING WANG, Physics Department, Seton Hall University — Perovskite solar cells have made tremendous improvements since it was first reported on 2009. Its efficiency has increased from 3% to an outstanding 22.1% in less than eight years. Due to its rapid increase in efficiencies and low cost fabrication process, the perovskite solar cell technology was named as one of the biggest scientific breakthroughs in the year of 2013 by Science. In the Perovskite solar cell structure, poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) is usually used on top of ITO as the conducting electrode.

In this work, we show our study on how the efficiency of the Perovskite solar cells depend on the conductivity and work function of PEDOT:PSS. A series of PEDOT:PSS solutions with different conductivity and work function were used to make the Perovskite solar cells. The Kelvin Probe technique was used to measure the work function of the polymer film and the Keithley sourcemeter was used to measure current-voltage characteristics of the solar cells were. Our results help us gain a better understanding of Perovskite solar cells and give us insight on how to improve the efficiency of those solar cells.

*Clare Booth Luce Program
G70.00080: Image analysis of microgravity Bose-Einstein condensation

MAXWELL GOLD (Presenter), NATHAN LUNDBLAD, Physics and Astronomy, Bates College — With the recent production of Bose-Einstein condensates aboard the International Space Station using NASA's Cold Atom Laboratory (CAL), research is underway focusing on new condensate geometries made available by a microgravity environment. We report fitting analysis and trap frequency characterization of imaging data from condensates in both conventional and rf-dressed magnetic potentials. This information will be used for calibration and design of future experiments with CAL examining ellipsoidal shell condensate geometries.

*We would like to thank NASA Fundamental Physics / JPL RSA Grant No. 1597429.

G70.00081: Modular Smart Home: A proof of concept, by Wyatt Vigilante

WYATT VIGILANTE (Presenter), Ithaca College — Current smart home systems can cost upwards of 15,000. This project seeks to create a similar system for 500 or less. A modular smart home contains a network of smart devices that work together to perform homely functions such as turning on lights or adjusting temperature in a room if movement is detected. To bring costs down an Arduino Mega 2560 microcontroller will be connected to the sensors and output the incoming data to the Raspberry PI which will act as an interface for the user. This system also avoids the use of an internet connection to make it more difficult for potential hacking of the system. To validate the effectiveness of the modular smart home system, devices such as RFID card access, light switches, temperature sensors, fans, sonar sensors, RGB lighting, and motion sensors will be implemented into a 1/32 scale model of a 2-bedroom house. Once the system has been implemented into the scale house, estimates of cost efficiency in the modular smart home will be taken to compare against the $15,000 standard smart home to prove the effectiveness of the system.

G70.00082: Exploring the Structural Transformation of Zirconia Films

MARK LEWIS (Presenter), FRANK C PEIRIS, Physics, Kenyon College, SANTOSH SHAW, LUDOVICO CADEMARTIRI, Materials Science and Engineering, Iowa State — Using a combination of experimental techniques, including Raman spectroscopy, Fourier Transform IR spectroscopy (FTIR), X-ray diffraction, atomic force microscopy (AFM) and ellipsometry, the structural transformation of a series of zirconia films were investigated. The zirconia nanoparticles (diameter of around ~4 nm) were first treated with ligands (either oleic acid or trioctylphosphine oxide), and then were spin-coated onto Si substrates. The as-grown samples were then exposed to an oxygen-plasma, and were subsequently calcined at various temperatures (300° C - 900° C). Raman, FTIR and X-ray diffraction show that the zirconia films transform from amorphous to tetragonal and monoclinic phases as a function of the calcined temperature. Using an effective medium approximation to model the ellipsometry spectra, the porosities of the zirconia films were recovered. While the porosity values decrease for both types of samples, the porosity seems to decrease faster for the samples that were capped with oleic acid. The RMS values determined from AFM measurements optimized the ellipsometry models, which included a surface-roughness layer to fit the experimental spectra.

*The work at Kenyon was supported through funding from American Chemical Society (Petroleum Research Fund Grant).

G70.00083: Single Photons for a Modular Ion Trap Quantum Network

SOPHIA SCARANO (Presenter), MARTIN LICHTMAN, CLAYTON CROCKER, KSENIA SOSNOVA, ALLISON CARTER, CHRISTOPHER ROY MONROE, Physics, Joint Quantum Institute at the University of Maryland — Trapped atomic ions of different species are an ideal candidate for a modular quantum computing network partially due to low crosstalk between memory and communication qubits. A dual species Yb+/Ba+ ion trap is used to create entanglement between memory spin qubits and photonic qubits. The flying qubits are emitted via the 6S_{1/2} ↔ 6P_{1/2} transition in 138Ba+. It is advantageous to excite the atom on the 5D_{3/2} ↔ 6P_{1/2} transition at 650 nm, while still collecting 493 nm photons. This removes the excitation light as a source of noise and reduces double excitation errors. Most significantly, the D ↔ P transition allows us to use a slower excitation, such that instead of requiring a picosecond pulsed laser, we can gate a CW laser using AO modulators. We demonstrate a single photon source for quantum networking based on a trapped barium ion subject to pulsed excitation with a second-order coherence of g^{(2)}(0) ≈ (8.1 ± 2.3) × 10^{-5} without background subtraction, a state-of-the-art result for replicable single photon sources.

*This work is supported by the ARO with funding from the IARPA LogiQ program, the AFOSR, the ARO MURI on Modular Quantum Circuits, the AFOSR MURI on Quantum Transduction, and the ARL Center for Distributed Quantum Information.
G70.00084: Modeling of Cytoskeletal Filaments in C17.2 Cells using ImageJ  JULIA HUTSKO (Presenter), JAY MAGERS, Physics, Susquehanna University, SABRINA JEDLICKA, SWETHA CHANDRASEKAR, Material Science, Lehigh University, SLAVA V. ROTKIN, Material Research Institute, Penn State, LISA SCHNEIDER, Math and Computer Science, Salisbury University, MASSOOMA PIRBHAI, Physics, Susquehanna University — Cytoskeletal filaments, such as actin, and nestin assist in sustaining many cellular function, including: differentiation, motility, cell shape, force generation, etc. Studies on how actin reorganizes can give us insights into how external stimuli affect cellular processes. The external stimuli chosen for this research was carbon nanotubes, which are single atom carbon sheets rolled into cylinders. For this study, neural stem cells, specifically C17.2 cells, were the focus. The goal is to observe how the distribution of actin is altered in the presence of carbon nanotubes. Over the last semester, I collected a catalog of data on the volume of actin in both treated and untreated C17.2 cells. Images of actin were captured using confocal microscopy. ImageJ then characterized the volume of the filaments at each level in the neural stem cells and quantified the actin distribution using thresholding techniques. The results, I obtained from comparing my data, showed how carbon nanotubes impact the distribution of actin throughout the cell.

G70.00085: Application of a Retired Burst Gravitational Wave Data Analysis Method to Investigate the Origin of the Blip Glitch  SARAH CHOATE (Presenter), AMBER L STUVER, Villanova University — The Laser Interferometer Gravitational-Wave Observatory (LIGO) is a collaboration with the goal to observe and study events that create gravitational waves detectable on Earth. During the process of data acquisition, glitches in the data can occur as a result of the observation of transient noise. One class of these glitches that occurs in burst data analysis is the blip glitch, which results in an almost identical signal to that of a gravitational wave detection and has an unknown origin. SLOPE is a data analysis method originally used for gravitational wave detection. This research has redeveloped SLOPE for the purpose of investigating glitches and has readied the algorithm to be applied to auxiliary channels to search for glitches. Results presented includes operating parameters for which SLOPE can be effectively run.

G70.00086: Properties of PVDF Films Blended with Zwitterionic Copolymers*  MIRIAM SALCEDO (Presenter), NELAKA DILSHAN GOVINNA, Physics and Astronomy, Tufts University, SAMUEL LOUNDER, AYSE ASATEKIN, Chemical and Biological Eng., Tufts University, PEGGY CEBE, Physics and Astronomy, Tufts University — Poly(vinylidene fluoride), PVDF, is a semicrystalline polymer used as a membrane for filtration and separation applications. Its properties can be enhanced by blending together with zwitterionic co-polymers which alter the hydrophobicity. In this work, we study the structure and electrical properties of PVDF blended with the random copolymer poly(methylmethacrylate-r-sulfobetaine-2-vinylpyridine). Solutions in dimethylacetamide/ acetone are prepared by varying the concentration of the blend components. Doctor-blading is used to make films of uniform thickness for further investigation by wide angle X-ray scattering, calorimetry, scanning electron microscopy, and dielectric relaxation spectroscopy. The crystalline and glassy structure of these films is determined by the manner in which the solvent is removed from the film, either by slow and continuous evaporation of the solvent, or rapid solvent removal by water immersion. These casting methods create different pore size and distribution which affect the structure and dielectric properties of the films.
*NSF-DMR 1608125; Universidad Autónoma de Madrid; Tufts-Skidmore Spain Program

G70.00087: Microtubule Patterns Through Growth and Crosslinking  AUSTIN MORRISSEY (Presenter), Biochemistry and Molecular Biology, UMass Amherst, LENITA HERBST, Microbiology, UMass Amherst, BIANCA EDOZIE, Biochemistry and Molecular Biology, UMass Amherst, JENNIFER ROSS, Physics, UMass Amherst — Life is never static, and its propagation is possible due to the dynamic dance of continuous cellular motion. Microtubules are a fundamental and dynamic cellular component of eukaryotes. These microfilaments make up essential structures, such as the neuronal axon, and the mitotic spindle. In this study, we explore the self-organized polymerization patterns of microtubules using both macromolecular crowding agents and crosslinking microtubule-associated proteins. Previously, we have found that the phases and patterns depend very sensitively on the filament length and the percentage of MAP65 crosslinkers present. Specifically, there is a range of concentrations that result in spindle-like “tactoids” which could act as model mitotic spindles. Here, we investigate whether similar microtubule organizations are observed when changing the identity of and respective concentration of crowding agents used alongside MAP65. This work will allow further elucidation on self-organization of the mitotic spindle, using a systematically controlled in vitro reconstitution system.
G70.00088: Super-Resolution Patterns in Quantum Dots* HAMID JALILI (Presenter), THOMAS DANZA, RICHARD MOURADIAN, SEAN JAMES BENTLEY, Adelphi University — In this research, quantum dots and other materials were measured for their ability to absorb nonlinearly. Using the second harmonic of a nanosecond Nd: YAG laser an interference pattern was etched onto a quantum nanoparticle thin-film sample and a reference sample which were then compared against linear and nonlinear absorption. After one pattern was formed, a second pattern was interlaced with the first by introducing a phase shift into one arm of the interferometer. Due to the nonlinear nature of the absorption, this allows the formation of a pattern with twice the resolution possible with linear techniques. While the visibility of the combined pattern is reduced as compared to simple interference, it is still sufficiently high for many applications.

*We would also like to thank Adelphi University and the Horace McDonell Summer Fellowship for funding.

G70.00089: Observations of Dislocation Etch Pits in SmB6 SHRIYA SINHA (Presenter), ALEXA RAKOSKI, CAGLIYAN KURDAK, University of Michigan, PRISCILA ROSA, Los Alamos National Laboratory, MONICA CIOMAGA HATNEAN, GEETHA BALAKRISHNAN, University of Warwick, BOYOU N KANG, MYUNG-SUK SONG, BEONGKI CHO, Gwangju Institute of Science and Technology — Samarium hexaboride (SmB6) is a strongly correlated topological insulator, showing insulating behavior from 4-40 K and a conduction plateau below 4 K due to the topological state. Recent transport results on the bulk have demonstrated that SmB6 is not sensitive to point defects but extended defects such as one-dimensional dislocations may still be present. Such dislocations may provide an additional current path beside the topologically protected surface state. The one-dimensional dislocations must terminate on the surface and can be identified by the use of proper chemical etching. In order to characterize the bulk defects in SmB6, we developed an etching technique using equal parts sulfuric acid and nitric acid. Using this etchant we found etch pits in the shape of inverted pyramids aligned with the crystalline axis, which are expected to indicate dislocations. In aluminum flux grown samples, dislocation etch pit densities range from 2x10⁶ to 9x10⁶ cm⁻². A comparison of flux grown samples and floating zone grown samples will be presented.

G70.00090: A demonstration of quantum key distribution with single photons for the undergraduate laboratory* BAIBHAV SHARMA (Presenter), ENRIQUE JOSE GALVEZ, AAYAM BISTA, Physics and Astronomy, Colgate University — The goal of this work was to create a laboratory experiment feasible in an undergraduate setting that demonstrates quantum key distribution and security attacks on quantum key distribution using single photons. The basic principle behind this experiment is that when a measurement is made on a quantum state, it modifies the information it conveys. This principle has been extended to quantum secure communications and is a teaching moment for physicists, computer scientists and engineers alike. We mimicked Eve or the eavesdropper by using an intercept and resend method, which include using an interferometer and a quartz plate. We used polarization entangled photons produced by parametric down-conversion.

*This work was funded by NSF grant PHY-1506321.

G70.00091: ABSTRACT WITHDRAWN —

G70.00092: Lithography-Free Confinement of 2-D Materials Using Precision Laser Ablation* ETHAN RICHMAN, YANPEI DENG, CAMERON MILLER, ZACH WIENER, LI-HENG CHANG, VISHRUT TIWARI, CHRISTOPHER LAFRATTA, PAUL CADDEN-ZIMANSKY (Presenter), Bard College — The ever-expanding array of two-dimensional materials and heterostructures susceptible to alteration in oxygen environments motivates the search for lateral confinement techniques outside conventional lithographic and etching methods. Laser ablation of such materials using a femtosecond pulsed Ti:Sapphire laser and programmable x-y stage is a single-step process that can in principle be used as a flexible tool for device processing. However, scanning probe analysis of sub-micron graphene ribbons fabricated with this technique reveals considerable defect accumulation under ambient condition. We show that such defects are largely alleviated by the simple change in the ablation environment from air to water.

*We thank the Sherman Fairchild foundation and Bard Summer Research Institute for support of this research.
G70.00093: Scanning Electron Microscopy – New Approaches in Imaging Biological Specimens*  INDRAJITH SENEVIRATHNE (Presenter), SYLVIANA HANNA, Lock Haven University of Pennsylvania — Scanning Electron Microscopy (SEM) of biological systems has a long and illustrious history. However due to the inherent complexities of biological hard and soft matter interaction with electrons and with the imaging system, one must overcome certain hurdles. We have attempted to optimize typical biological SEM sample preparation such as critical point drying, fixing of microbes via Osmium Tetroxide and other techniques in this investigation. In the study, we have also focused on the effect of the conductive coating (magnetron sputter deposited) on the specimen. The study concluded with stereoscopic 3D imaging of the specimen acquired by the SEM Secondary Electron and Backscattered Electron Detectors. We will discuss the results and compare them with the current literature.

*Lock Haven University Nanotechnology Program and the Nano Club.

G70.00094: Modulating the Magnetism of LaCoO₃ Thin Films Via Strain Engineering*  RONALDO RODRIGUEZ (Presenter), TOYANATH JOSHI, DAVID LEDERMAN, University of California, Santa Cruz — LaCoO₃ thin films grown on SrTiO₃ (100) single crystals exhibit an anomalous ferromagnetic transition at T_c= 87 K. This material is normally not ferromagnetic and the mechanism of the transition is not well understood, although the O-Co-O bond angle is believed to play a crucial role. It is shown that the compound is not ferromagnetic when grown on LaAlO₃. Further strain, which presumably alters the bonding angle, can be achieved by growing LaCoO₃ on large angle miscut SrTiO₃ substrates in a layer-by-layer growth mode with the angle of miscut being α ~10°. Films are grown using pulsed laser deposition employing a a 248nm KrF excimer laser to ablate a stoichiometric LaCoO₃ target. The growth is studied via in-situ reflection high energy electron diffraction (RHEED), which can detect layer-by-layer growth when the RHEED intensity oscillates as a function of growth time. Crystallinity and topography are measured using X-ray diffraction and atomic force microscopy, respectively, and magnetometry as a function of temperature and magnetic field is measured using a superconducting quantum interference device (SQUID) magnetometer.

*This work was partially funded by the National Science Foundation REU program, grant #1659744.

G70.00095: PHYSICS EDUCATION —

G70.00096: An advanced laboratory course based on the construction and modeling of a magneto-optic atom trap  LEE E HARRELL (Presenter), MARY CLARE CASSIDY, KIRK A INGOLD, DAVID O KASHINSKI, COREY S GERVING, United States Military Academy — Undergraduate physics labs often entail the collection of data using an apparatus that is set up and sometimes even fully adjusted before the students arrive. Various physical phenomena and data analysis techniques can be explored with this approach; however, students are unlikely to develop the experimental design and construction skills that are necessary for conducting original research. We present a magneto-optical atom trap designed and constructed for use in an undergraduate lab class that is organized to address the shortcomings of the more traditional approach. While the basic design and necessary equipment are made available, the students are required to build a working atom trap starting from an empty optics table. Additionally, students must model and simulate the operation of the trap to determine the necessary operating parameters and their tolerances. The results of these simulations provide a basis for interpretation of data collected from the operating trap.
The employment of a glowing LED to determine Planck's constant accurately.  

CHETAN KOTABAGE (Presenter), Department of Physics, KLS Gogte Institute of Technology — Planck’s constant is a fundamental constant in Physical sciences and Millikan was awarded Noble prize for its experimental determination. With the advent of solid state electronic devices, experiments were designed to determine the Planck’s constant utilizing LED [1], [2]. Herrmann, Schätzle [3] and Morehouse [4] have discussed the validity of this experiment. In this article, the validity of this experiment is re-examined. The measurements of the longest wavelength light emitted by LED and precise determination of band gap energy of LED are essential for accurate determination of Planck's constant by utilizing LED [5].

[5] Can a glowing LED light a road to accurate determination of Plank's constant?, Chetan Kotabage, Accepted for Resonance - Journal of Science Education

Physics Education Research on Inexpensive Active-Learning Lab Modules  

ZOE MUTTON, CORINNE RYWALT (Presenter), Physics, Worcester Polytechnic Institute, MEGAN VARNEY, Mathematical Sciences, Worcester Polytechnic Institute, NANCY BURNHAM, Physics, Worcester Polytechnic Institute — Active learning strategies, including hands on activities and lab work, have proved to be beneficial to student comprehension and success in physics classrooms. Despite this, many high school physics classrooms lack lab equipment necessary to supplement learning, mostly due to budget limitations and the high cost of traditional mechanics lab equipment. This project aims to design three modular, inexpensive, and demonstrative labs to enhance student knowledge in friction, conservation of energy, and torque. These labs, including a worksheet for students to complete, are designed to be easily implementable, take 20-30 minutes to complete, and be cost effective. These labs were tested with high school teachers and students to show that they are easy for teachers to implement in their classrooms and that they are easy to understand and effectively demonstrate their respective learning objectives to students. The implementation of these modular labs in high school classrooms will aid learning by kinesthetically illustrating the topics taught in lectures, leading to better student comprehension and higher success rates in introductory mechanics. Furthermore, high schools that cannot afford traditional lab equipment now have the opportunity to provide mechanics lab work to students.

Engaging and Sustainable High School Physics Lab Curriculum Using Smartphones*  

SAVANNAH GRUNHARD, ZAINIL CHARANIA (Presenter), SHENG-CHIANG LEE, Mercer University — The purpose of our research was to develop an engaging and low-cost, hence sustainable physics lab curriculum for implementation in Bibb County, GA, public high schools. Each public high school in Bibb County receives $1000 per year for the whole science curriculum. This is barely enough to restock consumable items in chemistry and biology and leaves nothing for physics. The lack of sufficient funding for proper lab equipment and qualified teachers disadvantages students. We believe that this contributes to the low rate of Bibb County high school students taking at least one physics course before graduating (only half of the national average).

The curriculum is developed to make adoption easy for teachers. It includes student activities (with instructor manuals) and instructions for both class demonstrations and construction of DIY apparatuses. The pedagogical approach of our curriculum is student-centered and inquiry-based. These activities utilize smartphone sensors in place of typical laboratory sensors. The use of existing smartphones in an educational setting serves to engage students and encourages them to explore physics in their everyday lives without adding any financial burden to school budget.

*This work is funded by the Mercer University Research That Reaches Out Office.
Children's interest in science. The results of the surveys show some promising data for this first attempt.

The objective of each survey is to see if the children would retain scientific information after the summer camp, particularly, their science vocabulary, and to see if they can recognize science phenomenon in their everyday lives. This poster will discuss the findings and lessons learned for this past summer camp in an attempt to help us improve the children's interest in science. The results of the surveys show some promising data for this first attempt.

*St. Mary's University

G70.00101: Designing Introductory Physics Experiments for the Visually Impaired  
MORGANNE KENDYLL BENNETT (Presenter), PAUL QUINN, Kutztown University of Pennsylvania — "The only thing worse than being blind is having sight but no vision," is a famous quote from Helen Keller. Teachers of students with visual impairments, must constantly look at the world from a different perspective, one without sight. For these educators, it becomes necessary to adapt the learning environment, making it more accessible to visually impaired students. This becomes more difficult in the STEM fields, particularly physics. This project redevelops some common introductory physics labs in a more tactile fashion, so that the same conclusions can be drawn without visual tools. This involved the design of various pieces of equipment such as a tactile graph board, making it possible for visually impaired students to experience the relationship between variables in the physical world. In this project, we were able to take topics, such as current and resistance, and make them more accessible to the visually impaired population. We discuss the various techniques and pieces of equipment designed to accomplish this goal. Also, the results of these experiments are discussed, after using the more tactile process in collecting and analyzing the physical data.

G70.00102: Learning physics by experiment: IV. Kinematics  
SAAMI SHAIBANI (Presenter), Instruction Methods, Academics & Advanced Scholarship — The trajectory of a ball in sports settings provides extensive opportunities for students to see how principles from physics can be applied to a familiar activity. Advanced equations[1] in mechanics are employed in this research to design an investigation of the relationship between launch speed and launch angle under a variety of circumstances, such as launch height and distance from target. Students are not given access to these theoretical results because they are unduly cumbersome; instead, students identify launch outcomes solely on an empirical basis. Data from such laboratory experiments are high in quality even in the absence of any numerical context, and students report that they are not concerned about the latter because they enjoy the freedom of exploring without constraint. Other educational benefits include a relaxed learning environment and enthusiastic communication between students. Such advantages are further validation of the pedagogy that has been applied to multiple topics[2-7] with considerable success.

G70.00103: Learning physics by experiment: V. Ambulation  
SAAMI SHAIBANI (Presenter), Instruction Methods, Academics & Advanced Scholarship — A multitude of devices associated with developing and maintaining fitness have been introduced in the past decade or so; examples include activity trackers and other wearable instruments, which have the capability of wireless communication for sharing data that they capture. Although the use of such equipment is becoming more widespread, favorable health outcomes (such as weight loss and improved cardiovascular function) have either been too low to be noticeable or have only a small impact[1,2]. The purpose of this study is to compare these devices with those based on much simpler technology (that typically costs an order of magnitude less) to determine to what extent, if any, the considerably greater expense of the former provides commensurately greater benefits than the latter. Experimental procedure is limited to be appropriate for students at the introductory level. Parameters of interest include design, temporal, geometrical, physiological, environmental and human factors. The research conducted here not only expands the number of projects having a similar educational value[3], but also extends the variety.

SAAMI SHAIBANI (Presenter), Instruction Methods, Academics & Advanced Scholarship — A critical piece of medical equipment for use in trauma environments has an inherent, and yet necessary, mechanical instability in its design. This instability can pose danger to operators of the equipment if certain safety measures are not observed; however, it is not always possible to implement every precaution in the high-risk settings usually associated with life-threatening emergencies. The author has direct experience of how the subject equipment is employed during pre-hospital care by first responders, including being present when the equipment caused injury even before it was needed. Application of fundamental principles in this research enables the dynamic properties of the equipment to be calculated with basic calculus and algebra, with the latter being particularly extensive. The behavior of the equipment under recommended procedures is then analyzed to produce a baseline performance, against which the response of the equipment in adverse circumstances is compared. As with other studies conducted throughout this innovative series[1], powerful techniques for superior student understanding are developed from the real world in a manner that transcends the most creative examples in standard textbooks.

JOSEPH TROUT (Presenter), Physics, Stockton University — At Stockton University an interdisciplinary course was developed by a physicist, chemist, and food scientist, which studies the science of ice cream. Ice Cream can be an excellent vehicle for teaching concepts in physics and chemistry. For example the process of the phase change from a liquid to a solid of water in the ice cream mix is an interesting comparison to the process which occurs in pure water. The course is composed of a lecture portion and a lab portion. Topics covered include Newtonian dynamics, fluid mechanics, and thermodynamics. This presentation briefly describes the course and provides a preliminary assessment of the course.

DIEGO VALENTE (Presenter), NIRAJ GHIMIRE, JASON HANCOCK, University of Connecticut — The University of Connecticut is currently in the initial stages of an extensive reform to several of its introductory physics courses seeking to shift away from the traditional framework of isolated lectures and laboratory sessions in favor of a studio-based instructional model blending lectures, problem-solving tutorial sessions and hands-on experimental activities. When completed, we expect this large-scale pedagogical reform spanning a total of 3 introductory sequences and 6 courses to impact approximately 2,000 students each year. In this work we discuss details of our current pilot program preparing us to make the transition to studio-based instruction in our larger introductory courses, as well as some of the challenges we face. We also present preliminary data on student learning comparing normalized gains on concept inventory assessments administered in our pilot courses to similar data collected in previous implementations of these courses taught in a traditional format.

BRIANNA BILLINGSLEY (Presenter), CORY CHRISTENSON, Washington & Jefferson College — If you look through any physics textbook you will encounter canonical names such as Newton and Galileo. While their contributions are indeed significant, presenting the history of physics solely in terms of these western scholars hides a much deeper and complex history that is not often taught. Here we will discuss how to incorporate contributions from Chinese and Arab civilizations. These concepts can be introduced to students through labs, homeworks, and discussion questions. A broader and more culturally diverse scientific history can engage student interest, teach them about how science actually happens, help them to appreciate the value of diversity.

The authors acknowledge the support the Washington & Jefferson College Ken Mason Faculty Development grant.

MATT PREZIOSO (Presenter), CORY CHRISTENSON, Washington & Jefferson College — This poster will explain how computer operated robotic cars can be implemented in college physics lab classes to introduce students to programming while also teaching them about kinematics. Arduino-based toy cars were built that can respond to light and distance stimuli, simulating the effect of traffic lights. The students are provided a basic code and asked to modify it to control the car's motion, and compare the observed motion to the theoretical kinematics equations. This combines the core physics concepts with real-world examples and useful programming skills. These cars can also be used to study traffic flow and energy use in transportation grids.

The authors acknowledge the support of the Washington & Jefferson College Center for Energy Policy and Management (CEPM).
**G70.00109: A Short-Term Physics Study Abroad Experience for General Education Student**  
DAVON W FERRARA  
(Presenter), Chemistry and Physics, Belmont University — Students looking for general education science courses often try to avoid those in physics. However, there are many concepts in physics that students ultimately enjoy learning about once in the course. One way to motivate students to take a conceptual physics course is to teach it while traveling through Italy on a short-term study abroad program. The conceptual laboratory science course described here has been taught four times since 2014 during “Maymester”, a three-week term between spring and summer semesters. The course uses the Galilean scientific revolutions during the Italian Renaissance as a starting point to understanding some of the major developments from classical mechanics to modern physics and the interactions between science and culture, including with respect to religion. Although this short-term study abroad course is in continual development, with changes to the itinerary and pedagogy each year, this presentation will give an overview of the trip, examples of laboratory experiments done while abroad, and a discussion of ways to keep non-science majors engaged in learning physics throughout the trip.

**G70.00110: Common Student Misconceptions in Physics Classes: Mechanics**  
KYLE BAUTISTA (Presenter), CAROLINA C. ILIE, SUNY Oswego — Physics is an important and amazing field of study. However, Physics can be a complicated subject for some students. There are several different topics and areas of physics where students seem to develop or have previously acquired misconceptions. It is possible for these common misconceptions to be found by taking a closer look at what a students’ rational is when they are answering a question. To do this, a Physics survey was created based on several topics in the introductory mechanics unit covered in a college-level physics course. Participants were asked to answer ten questions covering a range of topics including graphs of motion, force, and mechanical energy. Answers to the survey were multiple choice along with a brief explanation with each answer to better identify the cognitive process of participants and diminish guessing. The surveys were collected and all responses were analyzed for any common errors. Using the data collected, we identified the physics misconceptions. We created and implemented new pedagogical strategies aimed to clarify the physics concepts. Some say Physics can be a challenging subject to learn, but with the appropriate student-centered classroom techniques, it is possible for anyone to not only succeed, but find a greater passion for the field.

**G70.00111: A Useful End-of-Semester Physics Course Assessment Survey**  
NORMA CHASE (Presenter), School of Arts and Sciences, MCPHS University - Boston — This scantron-based survey examines the teacher-learner collaboration. It includes questions which probe student preparedness, behaviors, attitudes, and expectations – as well as questions addressing key measures of excellence in teaching and course structure. We find that the most valuable information is revealed when survey responses are displayed at the level of individual students - for it is there that we find data which we can use to improve our guidance of student learning and cognitive development. Bar graphs are used to look for any interdependence between responses to pairs of survey questions. By thus examining the data in its entirety, we obtain insights which might inform future students, as well as faculty and administrators.

**G70.00112: A training course design for developing a student into an academic researcher**  
BING SHEN (Presenter), School of Physics, Sun Yat-Sen University, China — For the undergraduate student who want to enter the academic in the future, the basic scientific training is important and necessary. However, this kind of training is not like the regular course which need design in a different way. In this talk, we study the students from the condensed matter physics. By interviewing the students, teachers and researchers, we found the experiment technique and strategy changing are important to the developing a student into an academic researcher.

**G70.00113: Characterizing Hand-Made Planar Inductor Components in the Series RLC Circuit**  
DANIEL CANSECO-CHAVEZ (Presenter), STEPHEN A TSUI, Physics, California State University San Marcos — In the introductory physics curriculum, students are taught induction and inductance by examining the behavior of the current-carrying coil. As electronic devices approach the nanoscale, one might ask a student how would it be possible to fit an inductor onto an electronic chip. A commercial microelectronics solution is the planar spiral inductor, which are conductive thin film patterns deposited on substrates especially used for high frequency applications. Although synthesizing a thin film is beyond the reach of most classrooms, the principles and advantages of a thin film inductor can be taught using very affordable copper tape. An instructional laboratory activity based on this design introduces students to inductors using a geometry not covered in the introductory text and also offers them insight into the solutions necessary to build devices at the micro- and nanoscale, which would especially be useful to careers in engineering and applied physics. In this work, we demonstrate the construction of macroscale planar spiral inductors using commercially available copper tape and compare their behavior to an off-the-shelf inductor.

*Support provided by the TRIO McNair Scholars Program at California State University San Marcos.

**G70.00114: PHYSICS OUTREACH AND ENGAGING THE PUBLIC** —
G70.00115: Paper-based controllable illumination for multi-mode microscopy  SIMREN KAUR (Presenter), RYAN J. MCGORTY, University of San Diego — A paper-based microscope makes for a rugged and versatile solution to bringing science and science education to a variety of settings including those that are resource-scarce. This has been well demonstrated by the Foldscope project. Here, we describe an extension to that idea. We designed a paper-based method to control the sample illumination in a portable microscope. Controlling the illumination of the sample allows us to employ a variety of microscope imaging modalities including bright-field, dark-field and phase contrast. With this instrument, students can explore those different techniques. Additionally, it can be used to perform advanced imaging, including quantitative phase imaging, in the field, away from advanced and costly instrumentation.

G70.00116: AI framework to solve sustainability issue based on social and political dynamics  DEEDER AURONGZEB (Presenter), University of Maryland, College Park — Sustainable product development requires long term model building that may require social dynamics input. Scaling up temporal causality analysis to very large scale state spaces and extending the framework to handle large relational data is a critical undertaking to create a large scale dynamic model. We extend cross-sectpral model by C Granger, J. of Econometric Soc, V37,N3,424, in light of modern casual models and provide a AI framework on how AI can provide sustainability models in various aspect of social and political conditions using temporal logic.

G70.00117: HISTORY OF PHYSICS  —

G70.00118: Bibliographic Visualizations of Early Work in Neutron Diffraction  MATTHEW MARSTELLER (Presenter), Carnegie Mellon University — The literature of neutron diffraction was explored using Web of Science data and VOSviewer for data visualization. The timespan covered was from the advent of the topic through 1955 when Clifford Shull left Oak Ridge. The search query in Web of Science allowed for either "neutron diffraction" or "neutron scattering" to appear in the resulting records. Visualizations will include networks of co-authors with numbers of documents produced. Co-author groups readily appear in the visualization and allow for identification of important research teams. Shull and Ernest Wollan appear in one cluster. George Bacon of AERE, D.G Hurst and D.G Henshaw of Chalk River are easily visible as well. Other visualizations include citation networks of documents, authors or sources.

G70.00119: EARLY CAREER SCIENTISTS  —

G70.00120: Density Functional Theory Calculations of Stability and Absorption Spectra of Au8- Conjugated Complexes with Met and Trp Amino Acids and Trp-Met Dipeptide  MARWA ABDALMONEAM (Presenter), Physics, Michigan Technological University — Interactions of Au8 (D4h) gold cluster with the functional groups of the amino acids; L-Methionine (Met) and L-Tryptophan (Trp), and the dipeptide L-Tryptophyl-L-Methionine (Trp-Met), in their zwitterionic forms and in presence of solvent have been investigated using the density functional theory (DFT). Specifically, the binding energies and Ultraviolet-Visible (UV-Vis) absorption spectra of the bioconjugated complexes of Au8-Met, Au8- Trp, and Au8- Trp-Met have been analyzed. Our calculations show that; the pristine Au8 (D4h) cluster has strong absorption spectrum in the near-ultraviolet range, in agreement with the literature. The optical activity of the pristine cluster is the major influencing factor on the absorption spectra of the studied bioconjugated complexes, but the spectra of the complexes carry sufficient remarks that allow them to be distinguished from that of the pristine cluster. The interactions of Au8 with each specific functional group (either indole or thiol ether) led to very similar absorption spectra whether this group existed in a mono or in a dipeptide amino acid.

G70.00121: PUBLIC POLICY  —

G70.00122: Research Integrity, the Responsible Conduct of Research, and Plagiarism Analysis  AARON MANKA (Presenter), National Science Foundation — Among its duties, the National Science Foundation (NSF) Office of Inspector General (OIG) is responsible for helping ensure the integrity of research programs at NSF. We investigate allegations of research misconduct (plagiarism, falsification, and fabrication) in NSF proposals and awards. We also handle allegations of conflict of interests and violations of the confidentiality of NSF’s merit review to ensure the integrity of that process. We completed a review of how grantees implemented NSF’s requirement to provide responsible conduct of research training to undergraduate students, graduate students, and postdoctoral researchers. We are currently reviewing our plagiarism cases of the past decade to accumulate data and potentially identify institutional and NSF strategies for preventing and reducing plagiarism. I will briefly discuss these topics and present our results.
Determining the Asymptotic Expansion of Prolate Spin-Weighted Spheroidal Eigenvalues

DANIEL VICKERS (Presenter), GREGORY B COOK, Physics, Wake Forest University — Spin-Weighted Spheroidal Harmonics (SWSHs) are a complete orthonormal basis of tensors on the surface of spheroids. While SWSHs are used in many fields of physics for modeling, this research is focused on their application to describing the normal modes of transmission on the surface of black holes in the Kerr Geometry. Much is known for the oblate case of SWSHs; however, the asymptotic behavior of the prolate case has yet to be well described. In this work, the prolate SWSHs problem was numerically solved, which was used to create a power series approximation for their eigenvalues.

WITHDRAWN ABSTRACT

GRADUATE STUDENT AFFAIRS

Deific Naturalism: A Paradigm Shift from Matter to Consciousness as the Basis of Reality Consistent with all the Scientific Evidence

AMY LANG (Presenter), University of Alabama — “Science has to have a metaphysical framework to operate with confidence.”(Beyond Matter, Trigg) The prevailing scientific philosophy of naturalism assumes only physical causes, excluding any spiritual cause (God) to explain the inherent order of the universe evidenced by the laws of physics. This philosophy conflicts with surveys that show 51% of scientists believe in God or a higher power, with younger scientists at 66%. A paradigm shift to a metaphysical basis would explain this order. Physicists such as Planck have argued that quantum physics infers an observer-dependent reality based in consciousness, not matter. Deific naturalism, as defined by Mary Baker Eddy with her discovery of Christian Science in 1866, defines God as the universal Principle of good which orders the material universe and to which all consciousness, since matter is a mental construct, is steadily yielding. Deific naturalism is also consistent with the growing body of documented evidence anomalous to naturalism and is verified by over 83,000 archived Christian Science healings (many medically documented) where the metaphysical method of prayer applies a spiritual cause to universally and repeatedly restore health and order, and explains Biblical miracles as divinely natural scientific demonstrations.

Selective-Jet Electrochemical Processing for Low-Cost Additive Manufacturing of Metallic Components at Room-Temperature.

WAEL OTHMAN (Presenter), OMAR ALMELHI, LÜTFİYE Y. OZER, Materials Science and Engineering, Khalifa University, MARCO STEFANCICH, Dubai Electricity and Water Authority (DEWA), MATTEO CHIESA, Materials Science and Engineering, Khalifa University — Selective-Jet Electrochemical (SJE) processing has emerged as a novel approach for manufacturing metallic components with a lower cost in comparison with other conventional techniques. In addition, this technique allows metal processing at room temperature, which is considered a benefit as it reduces the need for expensive vacuums and temperature-regulating setups. Basically, SJE performs reduction of metal ions from one electrode and gives it back at the other electrode which is oppositely charged. One of the key characteristics is the capability of adding or subtracting material simply by reversing the polarity applied during the process, which helps in optimizing the AM process. One of the remaining drawbacks of this technique is the slow deposition rate that needs to be enhanced to achieve fully the promises of SJE. In this work, both deposition and etching of copper were monitored by using various polymer-printed nozzles diameters, along with varying current densities and process time. More specifically, relations of the dimensions, density and electrical conductivity of the deposited/etched materials to the mentioned parameters are reported that provide the critical parameter space to be optimized in order to achieve a speedy deposition and obtain the desired density.

Characterizing Uncertainty in Carbon Sources/Sinks using Top-Down Modeling

SIONA PRASAD (Presenter), Thomas Jefferson High School — Carbon dioxide (CO2) emissions, especially from large cities have resulted in the build-up of greenhouse gas concentrations responsible for climate change. Existing sensor technology is too expensive for large-scale use in urban areas, and cannot distinguish between anthropogenic and biogenic emissions. In this paper, we develop a low-cost in-situ sensor for direct CO2 measurements and a spectral imaging system to remotely monitor vegetation phenology. The sensor and camera were installed on a low-powered drone to serve as a mobile platform for accurate measurements and Bayesian models used this data to estimate emission inventories and model uncertainty. The predicted CO2 emission inventory for Washington DC showed a large contribution from the transportation sector. In summary, we demonstrate a methodology to measure and monitor city-wide CO2 emissions by combining low-cost in-situ measurements, multispectral imaging, small drone technology and puff modeling, and taking the first step to targeting specific greenhouse gas sources and reducing overall emissions.

MAGNETISM
G70.00131: FeCo-based Ferrofluid for ELF Transmitter Applications
BRYAN AUGSTEIN (Presenter), WILLIAM ZIMMERMAN, NAVEEN REDDY KADASALA, STEPHEN BLAMA, MARY SAJINI DEVADAS, VERA SMOLYANINOVA, Towson University — Developing compact and efficient extremely low frequency (ELF) transmitter antennas remains a challenge. A rotating magnetic dipole can be used for this application. In our approach we employ magnetic fluid, where suspended single domain nanoparticles act as rotating magnetic moments. The role of particle size and composition needed for optimal performance will be discussed. The FeCo nanoparticles were fabricated by wet chemical synthesis. Static magnetization and AC performance were measured. The role of nanoparticle concentration, type of superparamagnetic behavior, and AC permeability of FeCo magnetic fluid will be discussed.

*This work is supported by DARPA MTO AMEBA grant.

G70.00132: A preliminary investigation of large shift in transition temperature (Tc) in Gd5Si3 nanoparticles
SHIVAKUMAR HUNAGUND (Presenter), SHANE M HARSTAD, Virginia Commonwealth University, SHALABH GUPTA, Ames Laboratory, US Dept. of Energy, Iowa State University, Ames, IA 50011, VITALIJ K PECHE Hur, Dept. of Material Science and Engineering, Ames Laboratory, Iowa State University, Ames, IA 50011, MAGUNDAPPA HADIMANI, Virginia Commonwealth University — Magnetic ordering temperatures in nanostructures depend on size. Curie temperature (Tc) of a bulk material where exchange interactions are comparable to thermal fluctuations tends to decrease in particles. The decrease of ordering temperature with size is described by the scaling theory of Fisher & Barber. However, a large increase in Tc in Gd5Si3 NPs have been observed in the ball-milled gadolinium silicide. SEM images shows particle sizes ranging from 50 nm to >2 μm. XRD analysis on pre-separated sample show that ferromagnetic Gd5Si4 is the major phase while paramagnetic Gd5Si3 is the minor phase. Magnetic properties measured in VSM reveal that the Tc decreases for Gd5Si4 phase from 332K for bulk to 315K for ball-milled sample. Another Tc observed at 80K is attributed to Gd5Si3 phase undergoes large shift in its transition temperature at 110K and remains constant irrespective of particle sizes. Plausible reasons for the increase in Tc for Gd5Si3 NPs could be due to the effect of high energy mechanical ball-milling process that could induce structural changes, lattice strains, exchange interaction between phases in a particle, or formation of new phase.

*Work at the Ames Lab was supported by DOE (contract No. DE-AC02-07CH11358). Work at VCU was funded by NSF, Award No.: 1610967.

G70.00133: Ferrimagnetism of Ti-Adsorbed Graphene
ZHENZHEN QIN (Presenter), Zhengzhou University, MIN FENG, XU ZUO, Nankai University — Using the first-principles calculations, we investigate the magnetism of isolated Ti-adsorbed graphene and the magnetic ground state of Ti adatoms at various concentrations. For isolated Ti adatom on graphene, we analyze the localization of magnetic impurity states and moment formation that can be understood in terms of hybridization between C-pz and Ti 4s-3d orbitals. To examine the magnetic ground state of Ti adatoms, we construct graphene cells with Ti adatom at various concentrations and set up the magnetic configurations for a triangle lattice. It is found that a ferrimagnetic (FI) phase is the most stable in a wide range of Ti concentration by comparing the total energies of different magnetic states. In addition, the exchange integrals between the nearest neighbor and next-nearest-neighbor Ti adatoms are calculated by applying a classical Heisenberg model. The prediction of a graphene-based FI metal monolayer will open the door to applications of spintronics, given that Ti obeys a 2-D growth mechanism on graphene.

G70.00134: Perpendicular magnetic anisotropy in one-dimensional Rashba system under external electric fields: First-principles study
ZHENZHEN QIN (Presenter), Zhengzhou University, GUANGZHAO QIN, University of South Carolina, BIN SHAO, Massachusetts Institute of Technology, XU ZUO, Nankai University — External electric field (EEF) control of magnetization attracts much attention for potential applications in spintronics and is also a key challenge for designing quantum magnetic properties. Noticed, the role of EEF on magnetic properties of one-dimensional (1D) Rashba system has not been explored, even lacking in theoretical. In this work, we comprehensively studied the effect of EEF (parallel or vertical) on the magnetic properties of our previous predicted 1D Rashba system—Gd adsorbed zigzag graphene nanoribbons (Gd-ZGNRs) from first-principles study. Our calculations show that a moderate negative (positive) electric field stabilizes out-of-plane magnetization, where Gd-ZGNR performs perpendicular magnetic anisotropy (PMA) whether the direction of the electric field is vertical or parallel, and intrinsic Rashba effect always exist. It is confirmed that the Rashba spin splitting and PMA are interrelated in 1D Gd-ZGNR, in consistent with previous theoretical models. Furthermore, the (non)-perturbed band structures under EEFs are analyzed to explore the underlying physics of MAE based on our proposed methods combined with traditional second-order theory. Our results would provide a new insight into the mechanism of the magnetoelectric coupling at low-dimensional Rashba system.
STENNING (Presenter), ALEXANDER VANSTONE, JACK C GARTSIDE, LESLEY COHEN, WILL BRANFORD, Physics, Imperial College London reveals that the large spin-orbit coupling of Bi (from non-magnetic elements is an interesting issue recently. Using first-principles calculations based on DFT, we study of $M_z/M_{x,y} \approx 3)$. Our studies provide a potential candidate system for achieving an intrinsic quantum anomalous Hall effect where the in-plane ferromagnetism, giving rise to an exceptionally large magnetic anisotropy energy up to 6.5 meV (with significant ferromagnetic phase transition. Moreover, the relatively large and anisotropic Rashba splitting at the interface shifts towards the higher temperature region and the hysteresis width becomes wider. These size dependencies reproduce that reported experimentally.

**G70.00136: Ice Sculpting: Neuromorphic Training of Geometrically-Frustrated Magnetic Metamaterials**

KILIAN D STENNING (Presenter), ALEXANDER VANSTONE, JACK C GARTSIDE, LESLEY COHEN, WILL BRANFORD, Physics, Imperial College London — Artificial spin ice (ASI) consists of ferromagnetic arrays populated by Ising-like nanopatterned macrospins. The array 'microstate' describes the magnetic orientations of all macrospins, with the ASI microstate manifold notable for its vast range of energetically-degenerate states arising from geometric frustration. ASI has displayed capacity to 'memorise' specific microstates, returning to them with perfect fidelity even under strong magnetic perturbations. This property, termed return point memory (RPM), is a signature of systems which may be trained to act as artificial neural networks.

Today's software-based neural networks are powerful but crucially limited by their non-neuromorphic host hardware. Designing novel computational hardware which is fundamentally neuromorphic in design and operation may greatly enhance the scope and utility of artificial neural networks.

Combining recent development of a nanomagnetic writing technique allowing for access to the entire ASI microstate space and computer-vision microstate recognition with the inherent RPM properties of ASI, we explore the viability of ASI as a hardware platform for directly implementing neural net functionality with no software layer.

*The work was funded by the Leverhulme Trust RPG-2017-257 and an EPSRC DTP award to KS.*

**G70.00137: Magnetic anisotropy driven by enhanced spin-orbital coupling of sp metal Bi on Au /Si(111) root3 surface**

CHONG LI (Presenter), School of physics and engineering, Zhengzhou University, HAN WANG, Renssela Polytechnic Institute, CHUNYAO NIU, FEI WANG, YU JIA, School of physics and engineering, Zhengzhou University, ZHENYU ZHANG, University of Science and Technology of China, SHENGBAI ZHANG, Renssela Polytechnic Institute — Realization of magnetic properties from non-magnetic elements is an interesting issue recently. Using first-principles calculations based on DFT, we study of 1/3 monolayer Bi-covered Au/Si(111) surface and find that such system can be magnetic remarkably. Our further analysis reveals that the large spin-orbit coupling of Bi ($p_x, p_y$) multi-orbitals at the Fermi level leads to an occupancy disparity between spin channels. And this occupancy disparity will break Kramers degeneracy, resulting in a non-magnetic to significant ferromagnetic phase transition. Moreover, the relatively large and anisotropic Rashba splitting at the interface damps the in-plane ferromagnetism, giving rise to an exceptionally large magnetic anisotropy energy up to 6.5 meV (with $M_z/M_{x,y} \approx 3$). Our studies provide a potential candidate system for achieving an intrinsic quantum anomalous Hall effect with temperature up to 70 K.

**G70.00138: Electronic properties of chemically functionalized armchair GaN nanoribbons: A computational study**

NARESH ALAAL (Presenter), IMAN ROQAN, Physical Science and Engineering Division, King Abdullah University of Science and Technology — Graphene synthesis has spurred immense progress in the study of low-dimensional materials, as they offer distinct properties when compared with their three-dimensional bulk counterparts. Nanoribbons (NRs) are quasi-one-dimensional materials that exhibit interesting electronic properties based on their width and edge configurations. Edge functionalization is one of the techniques by which the electronic structure of NRs can be tuned. In this work, we employ first-principles spin-polarized calculations to study electronic and magnetic properties of oxygen- and sulfur-passivated armchair GaN nanoribbons (AGaNNRs). Unlike bare AGaNNR, which is a nonmagnetic semiconductor, oxygen-passivated AGaNNR (O-AGaNNR) displays magnetic behavior with a magnetic moment of 1 $\mu$B, as its band structure splits into spin-up and spin-down channels. Such behavior is caused by additional states that arise from the non-bonding electrons of the edge oxygen atoms. On the other hand, the sulfur-passivated AGaNNR (S-AGaNNR) exhibits semiconducting properties and has a reduced band gap relative to its bare counterpart. Thus, we will discuss the physical mechanism that leads O- and S-AGaNNRs to be good candidates for optoelectronic and spintronic device applications.
**G70.00139: Longitudinal Resonance for Thin Film Ferromagnets with Random Anisotropy**

WAYNE M SASLOW (Presenter), Department of Physics, Texas A&M University, CHEN SUN, Department of Physics, Brown University — At the microscopic level, individual spins in ferromagnets with random anisotropy tip transversely with distinct local angles relative to the magnetization M. When driven by an rf field along the equilibrium M₀, which changes dM = M₀ · dM, the transverse tipplings rotate about M₀, corresponding to a new macroscopic collective angle Ø about M₀. The coupling of dM and Ø leads to a new longitudinal mode, which in bulk has a frequency that is largely independent of field H. A longitudinal mode has been observed in thin films of ferromagnets with random anisotropy, but its frequency is H-dependent; for H at angle θ to the film normal and fixed resonator frequency f₀, H cos θ was constant to angles of 80°, with H saturating for larger angles. When the demagnetization field is included the theory yields such as H vs θ for θ <80°, thus providing evidence for the predicted angle θ. However, lower frequency resonators are needed to manifest the predicted macroscopic anisotropy energy.

**G70.00140: Spin reorientation, magnetocaloric effect and metamagnetic transitions in 50% Mn substituted RFeO₃ (R = Eu, Ho and Er)**

KARTHIKA CHANDRAN (Presenter), SANTHOSH P N, Physics, Indian Institute of Technology Madras — The magnetic and magnetocaloric properties of rare earth orthoferrites are studied with 50% Mn substitution in the Fe site. Polycrystalline samples of RFe₀.₅Mn₀.₅O₃(R=Eu, Ho, Er) were synthesized and the crystal structure was resolved by Rietveld refinement of X-ray diffraction patterns. All samples exhibit a PM to AFM transition near room temperature as follows: Tₙ₁(EuFe₀.₅Mn₀.₅O₃)~280K, Tₙ₁(HoFe₀.₅Mn₀.₅O₃)~290K, Tₙ₁(ErFe₀.₅Mn₀.₅O₃)~245K. As temperature decreases, all samples except HoFe₀.₅Mn₀.₅O₃ show a sudden drop in the magnetization which is similar to the spin reorientation (SR) observed in RFeO₃. As temperature further reduces below SR, ErFe₀.₅Mn₀.₅O₃ shows magnetization reversal for FCW curves taken in fields less than 50 Oe. Both Er and Ho based samples show high isothermal magnetic entropy change values of ∆Sₘₗ= 13.4 J/Kg.K (ErFe₀.₅Mn₀.₅O₃, at ~9.5 K, ΔH = 7 T) and ∆Sₘₗ=11.9 J/Kg.K (HoFe₀.₅Mn₀.₅O₃, at ~9.5 K, ΔH = 7 T). EuFe₀.₅Mn₀.₅O₃ shows a metamagnetic transition at low temperatures. Our studies confirm that, by substituting 50% Mn in Fe site, Tₙ reduces and Tₛᵣ increases. High isothermal magnetic entropy change, room temperature Tₙ and Tₛᵣ make these interesting multifunctional materials.

**G70.00141: Phase Diagram of Magnetic System Ca₃Co₂-xMnxO₆**

BENJAMIN WHITE (Presenter), JAN JESENOVEC, ALEX MANTILLA, Central Washington University — The crystal structure of Ca₃Co₂O₆ is constructed from relatively isolated chains of Co ions oriented along the c direction. Strong intrachain magnetic exchange interactions and weak interchain coupling lead to a quasi-one-dimensional ferromagnetic ground state. Chemical substitution studies show that Co and Mn ions alternate along the chains in the system Ca₃Co₂-xMnxO₆ and that the magnetic structure is tuned from ferromagnetic to antiferromagnetic. Symmetry breaking through exchange striction also leads to multiferroic states in the vicinity of x = 1. Such a highly complex environment is expected to produce a rich temperature vs. manganese concentration phase diagram. In this study, polycrystalline samples in the system Ca₃Co₂-xMnxO₆ were synthesized via a solid state reaction in the range 0 ≤ x ≤ 1; these samples were studied with measurements of magnetic susceptibility and heat capacity. Using these results, we constructed a temperature-Mn concentration phase diagram.

*Research was supported by the Central Washington University (CWU) Science Phase II Project and CWU Office of Undergraduate Research. Travel support was from CWU COTS and Provost Faculty Development Funds, and a CWU Graduate Studies Faculty Travel Award.

**G70.00142: Room-temperature ferromagnetism induced by boundary defects in graphene oxide nanoplatelets**

JOHN PRIAS (Presenter), HERNANDO ARIZA, Universidad del Quindío, KATHERINE GROSS, PEDRO PRIETO, Universidad del Valle — Graphene oxide nanoplatelets from bamboo pyroligneous acid (GO-BPA) show room-temperature ferromagnetism, by using the double thermal decomposition (DTD) method at different carbonization temperatures from 673 to 973 K. The GO-BPA samples were characterized by using Raman, FTIR, XRD, XPS, HR-TEM, I-V curves, MFM and VSM techniques. Magnetic measurenets suggest that increased carbonization temperature increases graphite conversion, boundary defects, desorption of some organic compounds, phonon response and magnetization saturation, respectively. Room-temperature ferromagnetic behavior was correlated with the variation of the boundary defect density.

*We would like to thank the Interdisciplinary Institute of Sciences and EITP, Universidad del Quindío and the Center of Excellence for Novel Materials at Universidad del Valle, Cali for the financial support.
G70.00143: Many electron, spin-orbit and resonant polaron effects in the THz cyclotron resonance of modulation-doped CdMnTe/CdMgTe Quantum Wells. IMTIAZ TANVEER (Presenter), BRUCE MCCOMBE, University at Buffalo, The State University of New York, ADAMUS ZBYSZEK, MACIEJ WIATER, GRZEGORZ KARCZEWSKI, TOMASZ WOJTOWICZ, Institute of Physics, Polish Academy of Sciences, Warsaw, Poland, XIAOGUANG WU, Chinese Academy of Science, Beijing, China, FRANCOIS M PEETERS, Department of Physics, University of Antwerp, Antwerp, Belgium — We present low temperature THz cyclotron resonance studies of modulation-doped CdMnTe/CdMgTe quantum wells with Mn compositions $x = 1$-3.6% in magnetic fields up to 17T. Electron densities $n_e$ are $(1 - 4) \times 10^{11}$ cm$^{-2}$. We focus on B-regions where the giant Zeeman splitting of Landau levels (LLs) leads to the 1$\parallel$ level crossing 0$\perp$ at a field $B_C$. LLs are resonantly coupled and split by the spin-orbit interaction, and a gap due to many-electron exchange can also occur (Quantum Hall Ferromagnetism) when $B_C$ is close to the field for filling-factor (FF) 2 at low enough temperatures. For $x=2.85\%$ $B_C$ lies at 8.65T, and CR is below our Ge:Ga detector onset. With exchange corrected LLs $B_C$ should occur at ~10T, but no splitting is observed. Between 9 and 15T, FF<1.67 so only spin-orbit coupling is important. Two samples do show a clear splitting of CR into two lines near 15T; strong TO phonon absorption blocks CR transmission at higher B. The origin of this splitting is not understood. For low $x$ samples $B_C$ lies between 3 and 4.5 T, depending upon temperature and sp-d exchange. No LL splittings are observed at 4.2 K, but at 1.5K there is a small splitting near 4.5T. A strong resonant magnetopolaron effect is also observed in all high B in all samples. Effect of e-e exchange will be presented.

G70.00144: The H field dependence of magnon diffusion length basing on Boltzmann transport methods* WEI WANG (Presenter), TAO LIU, YUHENG LI, JIANWEI ZHANG, School of Physics, Tongji University — The urgent demand for high-capacity and high-speed logical storage device gives rise to the further study on spin and magnon. In this abstract, we construct a new magnon Boltzmann equation from full quantum magnon Hamiltonian in magnetic insulator system, which contains the factors related to boundary injection, temperature gradient and magnetic field gradient. In our methods, we first calculate the change of magnon accumulation and magnon current with thickness of magnetic oxide film, under interaction of interface with spin-magnon, which implies that there are two parts in the process of magnon transport: magnon diffusion and magnon relaxation. Second, we calculate the change of magnon current with distance, which explains the dependence of magnon diffusion length on magnetic field theoretically. We find that the magnon diffusion length is inversely proportional to H field which was first observed by experiment [1]. Last but not least, we predict the rate of change of magnon current corresponding to the anisotropy energy change in magnetic insulator with strong anisotropic exchange energy and anisotropy energy.

G70.00145: Interplay between oxygen vacancies, strain, and magnetism in SrMnO$_3$: a self-consistent site-dependent DFT+U study CHIARA RICCA (Presenter), University of Bern, IURII TIMROV, NICOLA MARZARI, Ecole polytechnique federale de Lausanne, ULRICH ASCHAUER, University of Bern, MATTEO COCOCCIONI, Ecole polytechnique federale de Lausanne — Motivated by indications that strain and defects can stabilize a ferromagnetic ground state in normally antiferromagnetic SrMnO$_3$ thin films, we use self-consistent site-dependent (SCSD) DFT+U calculations to investigate the interplay between oxygen vacancies, strain, and magnetism in this material. Already for the stoichiometric material, using a self-consistent U increases the accuracy of lattice parameter predictions, which is crucial to study strain-induced changes in properties and results in critical strain values for the magnetic phase transition in better agreement with experiment compared to previous theoretical studies. Defect formation leads to changes in geometry and occupation on transition metal sites surrounding the defect. We find that taking into account the site-dependence of U around a defect has a strong impact on the computed formation energies and consequently on all related properties. As such $U_{\text{SCSD}}$ prevents overestimating the stability of the ferromagnetic order thanks to a proper description of excess charge localization upon defect formation and helps in rationalizing different ordering of oxygen vacancies depending on the magnetic order in the epitaxial thin film.
G70.00146: Perpendicular magnetic anisotropy and spin mixing conductance in polycrystalline europium iron garnet thin films

JACKSON BAUER (Presenter), ETHAN RAPHAEL ROSENBERG, CAROLINE ANNE ROSS, Materials Science and Engineering, Massachusetts Institute of Technology — Rare earth iron garnets (REIG) are a diverse class of magnetic insulators in which properties such as the anisotropy and magnetostriction can be tuned by choice of rare earth ion. Garnet films with perpendicular magnetic anisotropy (PMA) are attractive for studies of spin orbit torque and chiral spin textures. PMA has been achieved in epitaxial REIG on garnet substrates due to magnetoelastic anisotropy from epitaxial lattice mismatch strain, but for making devices on non-garnet substrates, PMA without epitaxy is essential. Here we report the growth and properties of polycrystalline europium iron garnet (EuIG) with PMA. Films were grown by pulsed laser deposition followed by a rapid thermal anneal. Films on quartz (0001) substrates demonstrated PMA attributed to the in-plane compressive thermal mismatch strain, whereas films on (11-20) quartz, Si, and fused SiO2 exhibited an in-plane easy axis due to tensile strain, consistent with the positive magnetostriction of EuIG. Spin transport measurements on Pt/EuIG/quartz heterostructures gave an anomalous Hall effect-like spin Hall magnetoresistance and spin mixing conductance similar to single crystal epitaxial EuIG. These results show that polycrystalline garnet can be grown with PMA, making it useful for applications in spintronics.

G70.00147: The structural and magnetic properties of the SrTiO3/SrRuO3/SrTiO3(100) Heterostructure

UDDIPTA KAR (Presenter), AKHILESH SINGH, TSUNG-CHI WU, BIPUL DAS, MING-CHIN CHEN, WEI-LI LEE, Institute of Physics, Academia Sinica, Nankang, Taipei 11529, Taiwan — The itinerant ferromagnetism in the ultrathin SrRuO3 films, grown by pulsed laser deposition, above a critical thickness of 3-4 unit cell (uc) has been reported previously by few groups[1-3]. On the other hand, in SrTiO3/SrRuO3/SrTiO3(100) heterostructure and (SrRuO3)1–(SrTiO3)5 superlattices grown by oxide molecular beam epitaxy (MBE) technique, the ferromagnetism was found to persist even with a 1-uc of SrRuO3[4]. It was suggested that the RuO6 octahedral tilting angle may be affected by the SrTiO3 capping layer, which in turn influences the ferromagnetism of the underlying SrRuO3[4]. Detailed investigations on the SrTiO3 capped and uncapped SrRuO3 films are required to fully understand the intrinsic mechanism involved for the magnetic properties of ultra-thin SrRuO3 films. In this work, Systematic studies of the structural and magnetic properties of the SrTiO3(x-uc)/SrRuO3(y-uc)/SrTiO3(100) heterostructure with various thicknesses of x-uc and y-uc will be presented and discussed[3, 5].

G70.00148: Current-induced spin polarization and anomalous Hall and Nernst effects in heterostructures with k-cubed Rashba spin-orbit coupling

ANNA DYRDAL (Presenter), Institut fur Physik, Martin-Luther Universitat Halle-Wittenberg, D-06099 Halle, Germany, ANNA KRZYZEWSKA, Faculty of Physics, Adam Mickiewicz University in Poznan, ul. Umultowska 85, 61-614 Poznan, Poland, LUKASZ KARWACKI, Institute of Molecular Physics, Polish Academy of Sciences, ul. M. Smoluchowskiego 17, 60-179 Poznan, Poland, JAMAL BERAKDAR, Institut fur Physik, Martin-Luther Universitat Halle-Wittenberg, D-06099 Halle, Germany, JOZEF BARNAS, Faculty of Physics, Adam Mickiewicz University in Poznan, ul. Umultowska 85, 61-614 Poznan, Poland — We will discuss our recent results on current induced nonequilibrium spin polarization and the anomalous Hall and Nernst effects within the effective models describing 2DEG in semiconductor heterostructures and perovskite oxide interfaces [L. Karwacki et al., Phys. Rev. B 97, 235302 (2018), A. Krzyzewska et al., pss RRL (2018), doi:10.1002/pssr.201800232]. We will focus on the role of k-cubic Rashba spin-orbit interaction which seems to play an important role in these materials. We will present the temperature dependence of the nonequilibrium spin polarization in nonmagnetic and magnetic cases, and indicate the role of the Berry phase on this effect when the system is magnetic. Moreover, we will show that there is a substantial intrinsic contribution to both anomalous Hall and Nernst effects, that are robust against impurity scattering processes. Additionally, the sign of the anomalous Nernst conductivity can be changed by tuning the temperature. This sign change appears below the critical temperature of the magnetic phase transition.

*A. Dyrdal and J. Berakdar acknowledge the support of German Research Foundation (DFG) through SFB 726 and SFB TRR 227.
G70.00149: Effects of second order surface anisotropy in YIG sputtered onto GGG (100) oriented substrate

ROBERTO RODRIGUEZ (Presenter), Physics, Pontificia Universidad Catolica de Chile/Physics, ALEXANDRE OLIVEIRA, CARLOS CHERMAN, RICARDO BORGES DA COSTA, U. C SILVA, NEYMAR DA COSTA, Fisica, Universidade Federal do Rio Grande do Norte, B.G SILVA, R. L SOMMER, Fisica, Centro Brasileiro de Pesquisas, FELIPE BOHN, MARCIO CORREA, Fisica, Universidade Federal do Rio Grande do Norte — In this work, we produced Y$_3$Fe$_5$O$_{12}$ textured films, with thicknesses between 50 nm and 500 nm, onto (100) GdGaO$_3$ by magnetron sputtering and post annealing, and investigated the first and second order surface and cubic anisotropy constants using the ferromagnetic resonance technique. The surface anisotropy constants exhibited different behaviors with film thickness, with the first order presenting the usual inverse of ferromagnetic layer thickness. Besides this inverse of thickness behavior, the second order also came up with a constant value. In the frame of spin reorientation transition phenomenon, we evaluated volume and surface contribution to the surface anisotropy. Although the second order cubic anisotropy constant is one order of magnitude stronger than the first order, they did not show any explicit thickness dependence. As an important finding of this work, in order to correctly characterize the magnetic properties of the YIG films, it is essential to measure both, the out-of-plane and in-plane angular dependence of the FMR resonance field.

*This research is supported by the Brazilian agencies CNPq, CAPES, FAPERJ, FAPERJ, and in Chile by Fondo Nacional de Desarrollo Científico y Tecnológico (No. 1170723).

G70.00150: Effect of electron transport on demagnetization on the shortest time scale

GUOPING ZHANG (Presenter), YIHUA BAI, TYLER JENKINS, Indiana State University, THOMAS F GEORGE, University of Missouri-St. Louis — It is generally believed that there are at least two ways to use an ultrafast laser pulse to demagnetize a magnetic sample [1]. One is to directly photo-demagnetize the system through spin-orbit coupling (SOC), and the other is to utilize ultrafast hot electron transport without SOC. The challenge is that these two processes are entangled on the same time scale. However, we do not even know how fast electrons move under laser excitation, nor far they move [2]. Here we carry out a first-principles time-dependent calculation to investigate how fast electrons actually move under laser excitation, and how large the electron transport affects demagnetization on the shortest time scale. To take into account the transport effect, we implement the intraband transition in our theory. For bulk fcc Ni, we find the effect of spin transport on demagnetization to be extremely small, no more than 1% [3].

*Supported by the U.S. Department of Energy under Contract No. DE-FG02-06ER46304.

G70.00151: The magnetic order of antiferromagnetic Mn3NiN thin films under biaxial strain

DAVID BOLDRIN, FREYA JOHNSON (Presenter), Blackett Laboratory, Imperial College London, ANDREI MIHAI, BIN JOU, Department of Materials, Imperial College London, JAN ZEMEN, Faculty of Electrical Engineering, Czech Technical University in Prague, WILL BRANFORD, Blackett Laboratory, Imperial College London, JOERG WUNDERLICH, Hitachi Laboratory, University of Cambridge, LESLEY COHEN, Blackett Laboratory, Imperial College London — We explore the magnetic phase diagram of piezomagnetic antiperovskite Mn$_3$NiN thin films grown on different substrates as a function of the induced biaxial strain using magnetotransport and neutron scattering. We find that the anomalous Hall effect is an effective probe of the out-of-plane magnetisation in our films. Under compressive in-plane biaxial strain, the films support a canted antiferromagnetic (AFM) state with large coercivity at low temperature that transformed at a well-defined Neel transition temperature into a soft ferrimagnetic-like (FIM) state at high temperatures. In stark contrast, under tensile strain the magnetisation value decreases rapidly above the Neel transition. The resulting magnetic phase diagram shares many characteristics with that predicted for thin films of the closely related antiperovskite Mn$_3$GaN.

*UK EPSRC
Long-range, dynamic noncollinear textures \cite{1} can be sustained in ferromagnetic nanowires by the non-local compensation of damping \cite{2}. In contrast to current-driven magnons, noncollinear textures exhibit (1) frequencies under ferromagnetic resonance that are inversely proportional to damping; (2) an excitation threshold that is proportional to the in-plane anisotropy; and (3) coherence over the length of the nanowire. We analytically demonstrate that nonlinearities are fundamental to describe these characteristics. Two generic solutions when the nanowire is subject to spin injection at one edge are found, exhibiting opposite frequency tunabilities. This is in stark contrast to the linear frequency tunability predicted for spin superfluids. By micromagnetic simulations, we show that these predictions hold in the presence of in-plane anisotropy and non-local dipole fields.

——

Spin Hall effect is a phenomenon of spin current generation from an applied charge current, arising from the two distinct regimes: intrinsic and extrinsic mechanism. The intrinsic contribution derives from the Berry curvature associated with band structure of the material while extrinsic one originates from spin dependent scattering on structural defects or impurities. In previous reports, SHE has been tuned by alloying, changing the combination of the host and impurity metals or changing the concentration of the impurities in many alloy systems. Nevertheless, the mechanism of SHE is governed by either effect, the crossover between extrinsic and intrinsic regime induced by alloying has remain elusive.

In this study, we focus on AuCu as a material for observation of extrinsic-intrinsic crossover of the SHE. We demonstrate spin Hall angle (SHA) of Au$_{100-x}$Cu$_x$ alloys by changing Cu concentration $x$. The SHA changes the sign only in a limited range of the Cu concentration due to the extrinsic skew scattering, while the intrinsic contribution becomes dominant with increasing the Cu concentration. These results provide an evidence of crossover from extrinsic regime to intrinsic regime in the metallic alloy system.

Electronic vs magnonic contributions to unidirectional magnetoresistance

The effect of spin current on magnetoresistance is of central importance to modern spintronics. We have investigated unidirectional magnetoresistance (UMR) in Permalloy (Py)/Pt bilayers, a magnetoelectronic effect whose origin is currently debated. Two different mechanisms are believed to contribute to UMR. The first mechanism is due to magnon generation/suppression in Py by pure spin current produced by the spin Hall effect in Pt. The second one is due to spin dependent electronic scattering near the Py/Pt interface, where spin accumulation is modulated due to the spin current generated in Pt. By engineering the geometric and material properties of our samples, we enhanced magnon relaxation, thus suppressing the spin current-induced changes of magnon population. We observed a significantly reduced UMR, suggesting that this effect in the studied structures is dominated by the magnon contribution. We also discuss how the dependence of UMR on field temperature provides information about the spectral characteristics of the generated magnons, and their generation mechanisms. Our results suggest the UMR can be utilized as an efficient technique for the characterization of spin current-driven dynamical magnetization states.

Observation of the evolution of magnetic domain structures related to magnetic polaron cluster formation in a single crystal of EuB$_6$

DIBYA SIVANANDA (Presenter), ANKIT KUMAR, ARIF ALI, Indian Institute of Technology Kanpur, PINTU DAS, Physics, Indian Institute of Technology Delhi, JENS MULLER, Physics, Goethe University, SATYAJIT BANERJEE, Indian Institute of Technology Kanpur — EuB$_6$ is a ferromagnetic semi-metal which shows colossal magnetoresistance at a temperature of $T_c1\approx15.5K$ and also exhibits nanoscale phase separation between conducting ferromagnetic and insulating paramagnetic domains. Here, we have performed high sensitivity magneto-optical imaging of EuB$_6$ which images the local magnetic field distribution on the surface of a sample. From our measurements, we identify three characteristic boundaries, $T^*(H)$, $T_{c1}(H)$ and $T_{c2}(H)$, in a field - temperature magnetic phase diagram and identify their behavior with field. Using scaling and modified Arrott's plot analysis of isothermal bulk magnetization data, we identify critical transition into a ferromagnetic state below $T_{c2} = 12 \pm 0.2K$. High-resolution imaging of magnetic domains reveals large magnetized domains below $T_{c2}$. With increasing $T$ ($>T_{c2}$) the magnetic domains disintegrate into finger-like patterns before fragmenting into disjoint magnetized puddles at $T_{c1}$ and ultimately disappearing at $T^*$. At $T^*_{c1}$ we observe a significant increase in the spatial inhomogeneity of the local magnetic field distribution associated with the magnetic domains disintegrating into smaller magnetized structures. We explain our results via the formation and the subsequent coalescing of magnetic polaronic clusters.

Towards sub-wavelength spin and charge control of nitrogen vacancy centers using super-resolution microscopy

HARISHANKAR JAYAKUMAR (Presenter), SIDDHARTH DHOMKAR, JACOB HENSHAW, CARLOS MERILES, City College of New York — Super resolution microscopy has enabled addressing single nitrogen vacancy centers with a spatial resolution that is an order of magnitude higher than the diffraction limit. Here, we present the latest experimental results towards the utilization of stimulated emission depletion based super resolution techniques to manipulate the charge and spin degrees of freedom of a diamond nitrogen vacancy (NV) center. This technique is applicable to various NV center sensing modalities and data storage applications that demand high spatial resolution with minimal perturbation of the NV environment.

Thermally induced spin polarization in 2D systems with Rashba spin-orbit interaction

ANNA DYRDAL (Presenter), Institut für Physik, Martin-Luther Universität Halle-Wittenberg, D-06099 Halle, Germany, Jozef Barnas, Faculty of Physics, Adam Mickiewicz University in Poznan, ul. Umultowska 85, 61-614 Poznan, Poland, Vitalii Dugaev, Department of Physics and Medical Engineering, Rzeszow University of Technology, Al. Powstancow Warszawy 6, 35-959 Rzeszow, Poland, Jamal Berakdar, Institut für Physik, Martin-Luther Universität Halle-Wittenberg, D-06099 Halle, Germany. — We present the theory of spin polarization induced by a temperature gradient (heat current) in a magnetized two-dimensional electron gas (2DEG) with a Rashba spin-orbit interaction. Within the Matsubara Green's function formalism, we calculated the temperature dependence of the spin polarization not only in non-magnetic case but also in the presence of a nonzero exchange field oriented arbitrarily in the space. For the magnetic system, among others, we identified a term in the spin polarization that stems from the Berry curvature of the corresponding electronic bands. Moreover, we show that the electrically induced and the thermally induced spin polarizations obey the Mott relation in a nonmagnetic 2DEG as well as in the magnetic system but in the latter case only for the spin polarization normal to the electric field and to the thermal gradient. The components along the driving forces in a magnetic system do not obey this relation. This is mainly due to the fact that these components are determined by the Berry curvature of the electronic bands in the presence of both spin-orbit and exchange interactions.

G70.00158: Frustrated bilayer spin one XY model on the honeycomb lattice*  ANTONIO PIRES (Presenter), Universidade Federal de Minas Gerais — The study of quantum magnetism on geometrically frustrated lattices has been an active field of interest due to the possibility of finding new states of matter such as spin liquids and nematic phases. In this context, honeycomb lattices have attracted a lot of attention due to their interesting and poorly understood magnetic properties. The honeycomb lattice has the lowest value $z = 3$ of the coordination number, leading to a strong effect of quantum fluctuations. In contrast to the spin 1/2 model, not so much theoretical attention has been dedicated to the $S = 1$ model in spite of its relevance to several materials with spin one. Here I study the spin one bilayer XY antiferromagnet on the honeycomb lattice at zero temperature, with nearest-neighbor $J_1$ and next-nearest neighbor $J_2$ exchange interactions and single-ion easy plane anisotropy, using the SU(3) Schwinger boson formalism. The ratio between the interlayer to the intralayer nearest neighbor exchange interactions exhibits a quantum phase transition at a critical ratio 13.8 that separates the Neel phase from a quantum disordered paramagnetic phase. The effect of next nearest neighbor interactions is discussed and the phase diagram is presented.

G70.00159: Cooperative Two-Sublattice Model for Frustrated Pyrochlore Gd$_2$FeSbO$_7$  SAIKAT NANDI (Presenter), Department of Physics, University of Kalyani — DC and AC magnetization and heat capacity data of frustrated pyrochlore Gd$_2$FeSbO$_7$ are studied within the framework of cooperative two-sublattice model [1] in presence of easy-plane single-ion anisotropy at Gd-site. There are three types of interactions: intra-sublattice Gd-Gd antiferromagnetic interaction, intra-sublattice Fe-Fe ferromagnetic interaction, and inter-sublattice Gd-Fe antiferromagnetic interaction. The interaction between Fe$^{3+}$ $3d$ moments, which is stronger than 4f$^7$ interaction, generates a molecular field at Gd-site through a weaker cooperative Gd-Fe ramification. Fe$^{3+}$ sublattice orders at $T_C \sim 5$ K possibly in ‘two-in, two-out’ spin-configuration due to FM exchange interaction. Gd moments are fixed perpendicular to local <111> axes of tetrahedron due to crystal-field anisotropy and antiferromagnetic Gd-Gd exchange interactions. Such magnetic structure for Gd tetrahedra may resemble the Palmer-Chalker ground state, which is subdued due to stronger B-site Fe-Fe interactions. Saturation magnetization of 13.04μB is expressed as the vector coupling of directional magnetic moments of Gd and Fe. Finally magnetocaloric properties of Gd$_2$FeSbO$_7$ are estimated from magnetization and heat capacity results.

G70.00160: Density functional study of the electronic structure of the non-collinear helical magnet Ba$_3$NbFe$_5$Si$_2$O$_{14}$ (Langasite): Magnetic exchange and Dzyaloshinskii-Moriya interactions*  CHURNA BHANDARI (Presenter), SASHI SEKHAR SATPATHY, University of Missouri — Ba$_3$NbFe$_5$Si$_2$O$_{14}$ is an iron based compound, which consists of a Fe trimer in the ab-plane with a large spin moment $\approx 5$ μB/Fe. The spins of Fe trimer form a 120° non-collinear antiferromagnetic structure in the ab-plane followed by a helical structure with a propagation vector $q = (0,0,1/7)$. We study the electronic band structure using density functional theory (DFT), which shows an insulating gap due to the exchange splitting of the 3d bands. The features of the computed optical spectra are discussed in terms of the band structure. In addition, we study the magnetic exchange parameters by mapping the density functional total energy to exchange models. The absence of inversion symmetry in conjunction with the spin-orbit interaction leads to the Dzyaloshinskii-Moriya interaction (DMI) of the type $D S_1 \times S_2$, which is necessary to explain the observed spin-wave energies. We study the DMI from a model extracted from the DFT in order to gain insight into the magnetic interactions in the system.

**G70.00161: 'Local-Ising' type magnetism and metamagnetism in the rare-earth pyrogermanates**  KEITH TADDEI (Presenter), LIURUKARA SANJEEWA, Oak Ridge National Laboratory, JOSEPH KOLIS, Chemistry, Clemson University, ATHENA S. SEFAT, CLARINA DELA CRUZ, DANIEL PAJEROWSKI, Oak Ridge National Laboratory — The rare-earth pyrochlores have long been the system of choice for the study of frustrated magnetism due to the inherent geometric frustration of the rare-earth sublattice which can beget 'local-Ising' behavior. The combination of a large local-anisotropy and geometric frustration lead to the famous 'spin-ice' rules and consequently to exotic physics such as magnetic monopoles. The rare-earth pyrogermanate family of materials has seen significantly less study yet has similar potential due to a spiraling triangular rare-earth sublattice. We report the results of neutron scattering experiments on rare-earth pyrogermanate Er$_2$Ge$_2$O$_7$ which reveal a 3D spiral magnetic structure below 1.2 K. Under applied field we find a metamagnetic transition of spin-flip type indicating a large local anisotropy of the rare-earth site. This transition selectively inverts magnetic moments anti-parallel to the applied field yet leaves to moments along their locally determined easy-axis. This describes a local-Ising type behavior as seen in the spin-ice pyrochlores and encourages further study of these materials.

**G70.00162: Observation of magnetoelastic effects in a quasi-one-dimensional spiral magnet**  CHONG WANG, DAIWEI YU, XIAOQIANG LIU (Presenter), RONGYAN CHEN, XINYU DU, BIAOYAN HU, LICHEN WANG, International Center for Quantum Materials, Peking University, KAZUKI IIDA, KAZUYA KAMAZAWA, Neutron Science and Technology Center, Comprehensive Research Organization for Science and Society, SHUICHI WAKIMOTO, Materials Sciences Research Center, Japan Atomic Energy Agency, JI FENG, NAN LIN WANG, YUAN LI, International Center for Quantum Materials, Peking University — We present a systematic study of spin and lattice dynamics in the quasi-one-dimensional spiral magnet CuBr$_2$, using Raman scattering in conjunction with infrared and neutron spectroscopy. Along with the development of spin correlations upon cooling, we observe a rich set of broad Raman bands at energies that correspond to phonon-dispersion energies near the one-dimensional magnetic wave vector. The low-energy bands further exhibit a distinct intensity maximum at the spiral magnetic ordering temperature. We attribute these unusual observations to two possible underlying mechanisms: (1) formation of hybrid spin-lattice excitations and/or (2) "quadrumerization" of the lattice caused by spin-singlet entanglement in competition with the spiral magnetism.

*Work at Peking University is supported by NSFC (Grants No. 11374024, No. 11522429, and No. 11174009) and MOST (Grants No. 2013CB921901, No. 2013CB921903, No. 2015CB921302, and No. 2016YFA0301004). The neutron experiment using 4SEASONS at the MLF, J-PARC was performed under a user program (Proposal No. 2014B0032).

**G70.00163: Effects of boundary on a kagome Ising model with magnetic-charge interaction**  TOMONARI MIZOGUCHI (Presenter), YASUHIRO HATSUGAI, Department of Physics, University of Tsukuba — In frustrated Ising models on kagome and pyrochlore lattices, the system is described by conserved charge degrees of freedom [1]. Conserved charges serve as a "fractionalized" elementary excitation, which characterizes the topological nature of spin liquid state. The conserved charge description is useful to seek novel states induced by perturbations against the conventional nearest-neighbor model. For instance, it has been found that father-neighbor exchange interactions induce an interaction between the charges, which becomes a source of novel spin liquid state [2].

In this presentation, we elucidate the effect of boundary on this novel spin liquid state. The conserved nature of the charges naturally connects the bulk and boundary quantities through "Gauss' law", thus the interplay between interactions of charges and boundary effects is expected to induce a novel physics. By using Monte Carlo simulations, we demonstrate that the spin state at the edges induce a finite bulk charge, which can be regarded as "bulk-boundary correspondence" in an Ising spin system [3].

Spin-flip and magnetoelectric coupling in acentric and non-polar Pb$_2$MnO$_4$*  

HUNG-DUEN YANG  

(Presenter), Physics, National Sun Yat-Sen University, Taiwan, D CHANDRASEKHAR KAKARLA, Center of Crystal Research, National Sun Yat-sen University, Kaohsiung, 804 Taiwan, HUNG-CHENG WU, Texas Center for Superconductivity, University of Houston, Texas 77204, USA, DONG-JIE HSIEH, PO-JUNG SUN, Physics, National Sun Yat-Sen University, Taiwan, JIUNN-YUAN LIN, Institute of Physics, National Chiao Tung University, JIMLONG HER, Division of Natural Science, Chang Gung University, Tao-Yuan 333, Taiwan, YASUHIRO H. MATSUDA, Institute for Solid State Physics, University of Tokyo, 5-1-5 Kashiwanoha, Kashiwa, Chiba 277-8581, Japan, LIANGZI DENG, GOOCH MELISSA, PAUL C. W. CHU, Texas Center for Superconductivity, University of Houston, Texas 77204, USA — Acentric and non-polar Pb$_2$MnO$_4$ was predicted to exhibit unique multipiezo induced magnetoelectric (ME) phenomena [1]. Here, we present the results of measurements from magnetization as well as the dielectric, as a function of temperature (T), magnetic field (H), pressure (P), and electric field (E) primarily to address the ME coupling and identify the underlying mechanism behind this phenomenon. Magnetization measurements reveal the antiferromagnetic (AFM) ordering of Mn$_4^+$ spins at $T_N = 17$ K. For $T_N = 17$ K, a robustly multiple partial spin-flip transitions were also observed. The existence of ME coupling is supported by the observed dielectric anomaly near $T_N$. The lattice dielectric response is strongly influenced by spin-flip transitions that trigger the pronounced ME coupling below the $T_N$. The magnetic-field-induced ME phenomenon in Pb$_2$MnO$_4$ has been ascribed to the strong coupling of lattice polarization with the magnetic interactions and thereby offers a route to attain novel ME materials.

G70.00165: Probing variable range hopping lengths by magneto conductance in carbonized polymer nanofibers*  

YUNG PARK (Presenter), Physics and Astronomy, Seoul National University & University of Pennsylvania, KYUNG HO KIM, SAMUEL LARA-AVILA, HANS HE, Microtechnology and Nanoscience, Chalmers University of Technology, HOJIN KANG, Physics and Astronomy, Seoul National University, SERGEY KUBATKIN, Microtechnology and Nanoscience, Chalmers University of Technology — Using magneto transport, we report hopping length scales in the variable range hopping conduction of carbonized polyacetylene and polyaniline nanoribers. In contrast to pristine polyacetylene nanofibers that show zero magneto conductance at large electric fields (it clarifies the charge and spin states of 1-D topological insulator, namely the solitons in polyacetylene nanofibers.), carbonized polymer nanofibers display a negative magneto conductance that decreases in magnitude but remains finite with respect to the electric field. We show that this behavior of magneto conductance is an indicator of the electric field and temperature dependence of hopping length in the gradual transition from the thermally activated to the activation-less electric field driven variable range hopping transport. This reveals magneto transport as a useful tool to probe hopping lengths in the non-linear hopping regime.

G70.00166: Single Crystal Synthesis of Frustrated Magnet Y$_{0.5}$Ca$_{0.5}$BaCo$_4$O$_7$  

YUKI TATSUMI (Presenter), LINDA YE, TAKEHITO SUZUKI, JOSEPH CHECKELSKY, Massachusetts Institute of Technology — Neutron scattering experiments on Y$_{0.5}$Ca$_{0.5}$BaCo$_4$O$_7$ powders have reported suppression of magnetic order and flat magnonic bands down to low temperatures [1]. In order to study the physical properties of these materials in greater detail, we have synthesized bulk single crystals of this compound by the optical floating zone method. We present the details of the material preparation and characterization, including the dependence of magnetic properties on the growth conditions as well as plans for probing the unique magnetic dispersion of this system.

Role of anti-site disordering in magnetic properties of Sm2NiMnO6 double perovskite

SUPRIYO MAJUMDER (Presenter), MALVIKA TRIPATHI, R.J. CHOUDHARY, D. M. PHASE, Thin film magnetism group, UGC-DAE Consortium for Scientific Research — We have investigated the structural, magnetic and electronic properties of B-site disordered Sm2NiMnO6 DP oxide. XPS measurements indicate mixed valency of both Ni2+/3+ and Mn4+/3+ species. RE2NiMnO6 ordered DP is commonly believed to show two magnetic phase transitions viz, PM-FM transition at TC due to Ni2+/3+-O-Mn4+/3+ super exchange interaction and at Tf due to coupling of RE spins with Ni-Mn network [1, 2]. In our present study, we have observe that the presence of intrinsic B-site disorder results in an additional AFM coupling [3], mediated by Ni2+/3+-O-Ni2+/3+ and Mn4+/3+-O-Mn4+/3+ pairs. In M(T) measurements we have observed an inverted cusp like trend and thermal irreversibility in FCC and FCW cycles in Tf<T<TC both of which vanishes on application of higher magnetic fields. The observed thermal hysteresis indicates towards the possibility of either coexisting FM-AFM phases or magnetic frustration originating from different exchange interaction paths between mixed valence ions. MH isotherms in Tf<T<TC exhibit two step reversibility loop behavior, which further confirms the presence of competing FM-AFM phases.

Specific heat measurements of Ce2Zr2O7 in magnetic field

ROMAN MOVSHOVICH (Presenter), Los Alamos National Laboratory, ANDREA BIANCHI, JÉRÉMIE DUDEMAIN, Département de physique, Université de Montréal, Montréal, QC, H3T 3J7, Canada, MICHAEL NICKLAS, Max Planck Institute for Chemical Physics of Solids, Nöthnitzer Str. 40 D-01187 Dresden, Germany, EVAN SMITH, BRUCE GAULIN, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, Canada L8S 4M1, JONATHAN GAUDET, Johns Hopkins University, Baltimore, MD 21218, Institute for Quantum Matter and Department of Physics and Astronomy — We measured specific heat of the pyrochlore Ce2Zr2O7 in magnetic field up to 14 T and temperatures down to 60 mK. In zero field we observe a monotonic rise of the specific heat, with the values of C/T reaching 30 J/mol-K at 100 mK, and without saturation, at least in some compounds. The field was applied in either [100] or [110] directions. Even small magnetic field on the order of a kilogauss pushes the entropy up in temperature, developing a broad maximum in C(T), which moves up in temperature with increasing magnetic field. The calculated entropy is consistent with a doublet ground state. Extreme sensitivity to small magnetic field is consistent with a disordered zero-field ground state, with entropy piling up towards T=0, indicating a possible spin-liquid.

*We acknowledge the support of the Natural Sciences and Engineering Research Council of Canada (NSERC). Measurements at LANL were supported by the US DOE, Division of Materials Sciences and Engineering.

Monte Carlo Simulations of Classical Spin Liquids

HANNAH PRICE (Presenter), XIAOJIAN BAI, MARTIN MOURIGAL, Georgia Institute of Technology — Using Monte Carlo, we simulate the ground state spin configurations of spin liquids at low temperatures. The program requires only basic unit cell and coupling energy information to be run. Thus, most materials can be easily simulated. We have modeled the frustrated diamond lattice for a range of J2/J1 energies. As well as the frustrated pyrochlore lattice. In particular, we compare the modeled critical temperature and structure factor, with that from previous models and experiments.

Impact of interlayer coupling on magnetic skyrmion size

CANER DEGER (Presenter), ILHAN YAVUZ, Physics Department, Marmara University, FIKRET YILDIZ, Physics Department, Gebze Technical University — We study the magnetic skyrmion formation in thin-film stacks, consist of two magnetic layers separated by a non-magnetic spacer. The Landau-Lifshitz-Gilbert equation, comprising the spin precession term and the damping term with all relevant contributions, is numerically solved within the micromagnetic framework. Through extensive systematic calculations, we find that skyrmion size can be controlled by the interlayer exchange coupling, as well as the external magnetic field. z-component of the magnetization of the layers, which can be tailored by the coupling, strongly affects the skyrmion diameter. The skyrmion phase coexists with the helical phase for both types of coupling, being antiferromagnetic or ferromagnetic, in the absence of the magnetic field. The size of the skyrmions at zero field can also be controlled by the interaction. We anticipate that our predictions not only expand our fundamental understanding of the physical mechanisms responsible for skyrmion formation but also provide rational basis for the next-generation logic/memory device applications.

G70.00171: Current-driven coherent magnetic skyrmion generation* CANER DEGER (Presenter), ILHAN YAVUZ, Physics Department, Marmara University, FIKRET YILDIZ, Physics Department, Gebze Technical University — The next-generation logic and memory devices which use magnetic skyrmions as the information carrier are frequently studied due to its remarkable magnetic stability, extremely compact size and very-low-cost driving force within the nanostructure. To realize skyrmion-based spintronic devices, it is essential to understand the dynamics of skyrmion generation. In this study, we have carried out a systematic theoretical study on coherent magnetic skyrmion generation by an anti-notch in a channel of finite width. We found that, the coherent skyrmion generation is crucially effected by both damping ($\alpha$) and nonadiabaticity ($\beta$) parameters, as well as the geometry of the anti-notch. The periodicity of the generation is also investigated for certain current densities and $\alpha/\beta$ ratios. We anticipate that our predictions provide rational basis for skyrmion-based devices in which skyrmions are used as information carriers.

G70.00172: Topological Hall effect in diffusive ferromagnetic thin films with spin-flip scattering* SHULEI ZHANG (Presenter), OLLE HEINONEN, Materials Science Division, Argonne National Laboratory, Lemont, Illinois, USA — So far, most electrical measurements of magnetic skyrmions have been based on the interpretation that the topological Hall (TH) resistivity is proportional to the number of skyrmions multiplied by the magnetic flux quantum, which only applies to bulk systems in the strong exchange-coupling and nondiffusive regimes. In this work, we theoretically studied the TH effect in diffusive ferromagnetic metal thin films by solving a Boltzmann transport equation in the presence of spin-flip scattering. We found that, even in the strong exchange limit, the TH effect itself is not topologically protected in the presence of spin diffusion, owing to the spin accumulation built up in the vicinity of the skyrmions. A more general formula for the TH resistivity was derived, which establishes the relation between the TH resistivity and the ratio of the spin diffusion length to the skyrmion radius and would be increasingly important for extracting information about skyrmion density from experimental data when the size of room temperature skyrmions is further reduced to tens of nanometers, close to the spin diffusion lengths of most transition metal ferromagnetic thin films.

G70.00173: Robust Hund rule without Coulomb repulsion and exclusion principle in quantum antiferromagnetic chains of composite half spins* SOLOMON DUKI (Presenter), YIKUO YU, National Institutes of Health — Quantum spin chains with composite spins have been used to approximate conventional chains with higher spins. For instance, a spin 1 (or 3/2) chain was sometimes approximated by a chain with two (or three) spin 1/2’s per site. However, little examination has been given as to whether this approximation, effectively assuming the first Hund rule per site, is valid and why. In this work, the validity of this approximation is investigated numerically. We diagonalize the Hamiltonians of spin chains with a spin 1 and 3/2 per site and with two and three spin 1/2’s per site. The low energy excitation spectrum for the composite chain is found to coincide with that of the conventional chain. We find that as the system size increases, an increasingly larger block of consecutive lowest energy states with maximal spin per site is observed, robustly supporting the first Hund rule even though the exclusion principle does not apply and the Coulomb repulsion is absent. We show that this effective Hund rule emerges as a plausible consequence of the Lieb–Mattis theorem, which is originally for the ground state of ferrimagnetic and antiferromagnetic spin systems.

*This research was supported by the Intramural Research Program of the National Institutes of Health, National Library of Medicine.

G70.00174: Quantum phase interference in nanomagnetic particles coupled to the Josephson $\phi_0$ junction GWANG-HEE KIM (Presenter), Department of Physics and Astronomy, Sejong University, Seoul 05006, Republic of Korea, HAN-YONG CHOI, Department of Physics and Institute for Basic Science Research, Sungkyunkwan University, Suwon 16419, Korea/ Asia Pacific Center for Theoretical Physics, Pohang 37673, Korea — We study suppression of magnetization tunneling in nanomagnetic systems coupled to the Josephson $\phi_0$ junction. Employing spin coherent state path integral method, we find that the tunnel splitting is topologically quenched by the bias current applied to the junction as well as an external magnetic field along the hard axis. Considering tunnel splitting as a function of the current, we show that the quenching period is controlled by the external magnetic field and the number of frozen points decreases with increasing the magnetic field. The condition for switching from oscillations to the monotonic growth of the tunnel splitting is presented.
G70.00175: Giant superconducting proximity effect on spintronic anisotropy* KRZYSZTOF WOJCIK, Institute of Molecular Physics Polish Academy of Sciences, Poznan, Poland, MACIEJ MISIORYN, Chalmers University of Technology, Goteborg, Sweden, IRENEUSZ WEYMANN (Presenter), Adam Mickiewicz University, Umultowska 85, 61-614 Poznan, Poland — We investigate theoretically the interplay of proximity effects due to the presence of a superconductor and normal ferromagnetic leads on the formation of the spintronic quadrupolar exchange field in a large-spin magnetic molecule. We show that the spintronic anisotropy can be enhanced by a few orders of magnitude, and tuned by changing the strength of coupling to the superconductor. Especially large anisotropy is generated in the vicinity of the charge parity changing transition of the molecule. We also provide predictions of measurable spectral properties being the hallmarks of these phenomena. The calculations are performed with the aid of the numerical renormalization group method.

G70.00176: Phase transitions in the one-dimensional transverse Ising model in a longitudinal magnetic field OSIEL BONFIM (Presenter), Physics, University of Portland, B. BOECHAR, J. FLORENCIO, Physics, Universidade Federal Fluminense — The phase transitions in the one-dimensional transverse Ising model in the presence of a longitudinal magnetic field were studied by the quantum fidelity method. We used exact diagonalization to obtain the ground-state energies and corresponding eigenvectors for lattice sizes up to 24 spins. The maximum of the fidelity susceptibility is used to locate the various phase boundaries present in the system. The type of dominant spin ordering for each phase was identified by examining the corresponding ground-state eigenvector. For a given antiferromagnetic nearest-neighbor interaction ($J_z$), we calculated the fidelity susceptibility as a function of the transverse field ($B_x$) and the strength of the longitudinal field ($B_z$). The phase diagram in the ($B_x$, $B_z$)-plane shows three phases. These findings are in contrast with the published literature that claims the system has only two phases. For $B_z < 1$, we observed an antiferromagnetic phase for small values of $B_x$ and a paramagnetic phase for large values of $B_z$. For $B_x > 1$ and low $B_z$, we found a disordered phase that undergoes a phase transition to a paramagnetic phase for large values of $B_z$.

G70.00177: Spin wave excitation and propagation in ultra-thin nm-thick yttrium iron garnet films* HANCHEN WANG (Presenter), Fert Beijing Institute, BDBC, School of Electronic and Information Engineering, Beihang University, Xueyuan Road 37, Beijing 100191, China, TAO LIU, Department of Physics, Colorado State University, Fort Collins, Colorado 80523, USA, CHUANPU LIU, JILEI CHEN, YOUGUANG ZHANG, WEISHENG ZHAO, Fert Beijing Institute, BDBC, School of Electronic and Information Engineering, Beihang University, Xueyuan Road 37, Beijing 100191, China, MINGZHONG WU, Department of Physics, Colorado State University, Fort Collins, Colorado 80523, USA, HAIMING YU, Fert Beijing Institute, BDBC, School of Electronic and Information Engineering, Beihang University, Xueyuan Road 37, Beijing 100191, China — Magnonics has received increasing attention over the past decades, and it is widely considered to open up new opportunities to transport information by using spin waves (SWs) without charge currents. In our paper, we investigate experimentally the excitation and propagation of SW in 7-nm thick yttrium iron garnet (YIG) thin films with an ultra-low damping constant. On the top of YIG, conventional coplanar waveguides are integrated to excite a large series of short-wavelength spin waves (SWs). The scattering parameters are measured by using a vector network analyzer, which give access to observe the transmission of SW in the films. Consequently, by utilizing the experimental results, we calculate and extract the group velocity as well as the dispersion relation of SWs. Our work may be useful for providing the basis for SW logic devices at GHz rates with low power consumption.

G70.00178: Local short-scale correlations and the origin of negative magnetization*  
MALVIKA TRIPATHI (Presenter), Thin film magnetization, UGC DAE Consortium for Scientific research, T. CHATTERJI, Institut Laue-Langevin, S. MAJUMDER, R. M. CHAUDHARY, D. M. PHASE, Thin film magnetization, UGC DAE Consortium for Scientific research — Negative Magnetization (NM) defined as the opposite alignment of net magnetization with respect to applied magnetic field in magnetically ordered systems has been associated with a number of unsettled debates regarding the origin and reliability of this phenomena. The presence of two highly neutron absorbing isotopes of natural Gd has prevented to understand the microscopic magnetic structure and consequently the microscopic outlook of NM in GdCrO₃ so far. We have utilized λ = 0.499Å hot neutrons, a value much higher than the resonance energy, to record the thermal evolution of neutron diffraction patterns. Using magnetic pair distribution function analysis, significant local short range Gd³⁺ correlations in disordered state are observed ranging up to ~9 Å. Calculations suggest the frustrated S= 3 ground state of locally ordered Gd ions with competing FM- AFM exchange interactions and states corresponding to NM are comparatively more stabilized. The externally small excitation gap between energy levels is argued to be responsible for the different spin state populations characterized by distinct kinetic rates corresponding to cooling and warming cycles, which explains the observed path dependency of NM in GCO.

*Funding will be received by Department of Science and Technology, India.

G70.00179: Anomalous Nernst effect in a microfabricated Weyl magnet Mn₃Sn  
HIDEKI NARITA (Presenter), TOMOYA HIGO, IKHLAS MUHAMMAD, SATORU NAKATSUJI, YOSHICHIKA OTANI, University of Tokyo — Weyl magnets have attracted much attention in condensed matter physics due to both the fundamental interest and the potential application of a new thermoelectric power generation and heat current sensor. An anomalous Nernst effect is a thermoelectric phenomenon typically observed in ferromagnets under the application of a temperature gradient. The anomalous Nernst effect provides a simple and powerful tool to track the position and motion of a domain wall propagating. Recent theoretical and experimental studies have shown that magnetic domains exist in noncollinear antiferromagnetic Weyl magnets. In this study, we have investigated the anomalous Nernst effect in a microfabricated antiferromagnetic Weyl magnet Mn₃Sn to detect magnetic domains and observed step structures in hysteresis of the anomalous Nernst effect. We discuss the origin of the step structures in the hysteresis and compare the anomalous Nernst effect in the device to that in a bulk single crystal.

G70.00180: Domain wall motion influenced by a standing spin wave in antiferromagnetic systems  
INHYEOK CHOI (Presenter), HYOSEOK KIM, JONGSEOK LEE, Gwangju Institute of Science and Technology — In antiferromagnetic systems, spin dynamics are described by coupled Landau-Lifshitz-Gilbert equation for two order parameters of staggered and magnetic moments. It is also known that the time-varying magnetic field drives a collective motion of domain wall (DW). By using a micromagnetic simulation, we investigate a coupling effect between the spin wave and the DW motion which can be simultaneously driven by the oscillating magnetic field. In an antiferromagnetic nano-rod, a standing spin wave can be formed when its length is multiples of the wavelength of the excited spin wave. Depending on a phase relationship between the DW position oscillation and the standing spin wave, we find that the DW position oscillation is significantly influenced; its oscillation amplitude becomes negligible in the out-of-phase condition, and is enhanced by about twice in the in-phase condition.

G70.00181: Structure and Magnetic Properties of Gd₂₋ₓSrₓNiO₄, a Ruddlesden-Popper type solid solution*  
RENATA MIRANDA (Presenter), RAUL ZÜÑIGA MEDINA, Facultad de Química, Universidad Nacional Autonoma de Mexico, PABLO DE LA MORA, Facultad de Ciencias, National Autonomous University of Mexico, JORGE BARRETO, Instituto de Física, Universidad National Autonoma de Mexico, GUSTAVO TAVIZÓN, Facultad de Química, Universidad Nacional Autonoma de Mexico — Gd₂₋ₓSrₓNiO₄ complex oxide of the Ruddlesden-Popper series, was first prepared by James, M. et al.[1] Several compositions of the Gd₂₋ₓSrₓNiO₄ system were prepared by the complex polymeric route (Pechini). In this work we report the Sr composition stability range for this solid solution. Crystal structure of samples in the 0.75≤x≤1.25 range, were studied by Rietveld structure refinements. Magnetic measurements of samples (2-300 K) show a Curie-Weiss paramagnetic behavior for all x compositions, with a weak antiferromagnetic coupling. Electrical properties were measured in the 20-300 K range and we found that this system displays a metal-insulator transition for x≥1.0. Spectroscopic data (UV-Vis-NIR) at room temperature and magnetic moment measurements of this system reveal the nature of Ni oxidation states of this system.

[1] M. James, J.P. Attfield, Synthesis, crystal structure and magnetic properties of Ln₂₋ₓSrₓNiO₄±δ solid solutions (Ln = La, Nd, Sm and Gd; 1.0≤x≤1.67), J. Mater. Chem. 6 (1996) 57-62.

*Authors of this work acknowledge support from PAPIIT-IN115618 (UNAM).
G70.00182: Structure, Electrical and Magnetic properties of Sm$_{1-x}$Ca$_x$CrO$_3$, orthochromites*  
ALEJANDRO DURAN HERNANDEZ (Presenter), Centro de Nanociencias y Nanotecnología, Universidad Nacional Autonoma de Mexico, JORGE BARRETO, JESÚS ÁNGEL ARENAS, Instituto de Física, Universidad Nacional Autonoma de Mexico, PABLO DE LA MORA, Facultad de Ciencias, National Autonomous University of Mexico, GUSTAVO TAVIZÓN, Facultad de Química, Universidad Nacional Autonoma de Mexico — We have synthesized Sm$_{1-x}$Ca$_x$CrO$_3$ chromite and investigated the influence of calcium (Ca) doping at Sm-sites on the crystal structure, magnetic and electrical properties in a series of compounds in the 0≤x≤2.0 range. No structural transition was observed in this composition range and the doped compound crystallized into distorted orthorhombic structure with Pnma space group, which was confirmed by Rietveld refinement using Mo-Kα X-ray radiation. Samples of the Sm$_{1-x}$Ca$_x$CrO$_3$ series (x=0.0, 0.02, 0.04, 0.10 and 0.20) were prepared by Pechini polymeric precursor method and the polycrystalline samples were characterized by X-ray photoelectron spectroscopy (XPS), Magnetization vs. Temperature measurements, UV-Vis spectroscopy and electrical measurements (10-300 K). The effect of Sm substitution by Ca has important effect on the cell volume; the antiferromagnetic transition decreases from TN= 193K (x=0) to 150K (x=0.20) and the magnetization reversal also decreases from 35K (x=0) to 9K (x=0.20). These changes in magnetic behavior of Sm$_{1-x}$Ca$_x$CrO$_3$ can be associated with the Cr(VI) content in samples.

*Authors of this work acknowledge support from PAPIIT-IN115618 (UNAM)

G70.00183: A possible Hund's metal and unusual second-order metal insulator transition in perovskite La$_{1-x}$Pr$_x$RuO$_3$*  
ZONGYAO LI (Presenter), University of Texas at Austin, JOSÉ ANTONIO ALONSO, Instituto de Ciencia de Materiales de Madrid, JIANSHI ZHOU, University of Texas at Austin — 4d perovskite LaRuO$_3$ is a paramagnetic metal whereas PrRuO$_3$ is a paramagnetic insulator. Although Ru$^{4+}$ ruthenates have shown very rich physics due to the subtle interplay of Coulomb repulsive potential $U$, Hund's rule coupling $J$, the crystal-field splitting $\Delta$, and the spin-orbit coupling (SOC), limited information of Ru$^{3+}$ perovskite RRuO$_3$ (R=rare earth metals) family has been obtained since these perovskites have to be synthesized under high pressure. We report a successful synthesis of perovskite La$_{1-x}$Pr$_x$RuO$_3$ compounds by spark plasma sintering. A thorough characterization on La$_{1-x}$Pr$_x$RuO$_3$ system has been made by measurements of magnetic and transport properties and specific heat. The samples La$_{1-x}$Pr$_x$RuO$_3$ (0.2 < x < 0.8) exhibit a second-order metal-insulator transition as temperature decreases without any sign of magnetic order in the insulator phase. Due to the reduction of Ru-O-Ru bond angle, substituting La$^{3+}$ ions with smaller Pr$^{3+}$ ions reduces the bandwidth so as to lead to an insulator phase at low temperatures. The strong SOC and Hund's coupling on low spin 4$d^5$ Ru$^{3+}$ are responsible for the anomalous metallic phase found in LaRuO$_3$ and the absence of magnetic ordering in the insulator phase in La$_{1-x}$Pr$_x$RuO$_3$.

G70.00184: Evidence of Martensitic Phase Transitions in Boron Substituted Ni-Mn-In Thin Films*  
SUDIP PANDEY (Presenter), Department of Physics, Southern Illinois University Carbondale, IL 62901 USA, ALPHA N’DIAYE, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 USA, IGOR DUBENKO, ANIL ARYAL, DIPANJAN MAZUMDAR, Department of Physics, Southern Illinois University Carbondale, IL 62901 USA, SUJOY ROY, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 USA, SHANE STADLER, Department of Physics & Astronomy, Louisiana State University, LA 70803 USA, NAUSHAD ALI, Department of Physics, Southern Illinois University Carbondale, IL 62901 USA — Ni-Mn-In-B thin films were synthesized on Si substrates using ultra-high vacuum magnetron sputtering. Metamagnetic transitions with thermal hysteresis have been observed on 30 nm thin films using the magnetization measurements. The temperature dependences of the magnetization curves were found to be similar to those of the bulk counterpart. Electronic and magnetic properties of Ni-Mn-In-B thin films were studied using X-ray absorption spectroscopy (XAS) and X-ray magnetic circular dichroism (XMCD). From the XAS and XMCD spectra, we have observed that Ni plays a dominant role in the overall magnetism. Element-specific XMCD hysteresis loops of Ni in the NiMnInB films were measured as a function of temperature and observed minimum magnetic hysteresis at martensitic transformation. Possible mechanisms responsible for the changes in electronic and magnetic properties of thin films through the effect of redistribution of d electrons are discussed.

*This work was supported by the Office of Basic Energy Sciences, Material Science Division of the U.S. Department of Energy, DOE Grant No. DE-FG02-06ER46291 (SIU) and DE-FG02-13ER46946 (LSU).
**G70.00185: Beyond spin wave theory on a 5d transition-metal oxide**

JINKWANG KIM (Presenter), Pohang University of Science and Technology, JUNGHO KIM, Advanced Photon Source, Argonne National Laboratory, BUMJOON KIM, Pohang University of Science and Technology — 5d transition metal oxides (TMOs) offer a new playground for quantum magnetism with some unique features. For instance, a Heisenberg antiferromagnet in square lattice iridate Sr2IrO4 reveals similar low-energy effective physics with high-Tc superconductor parent antiferromagnet, La2CuO4, with its spin-orbit coupling driven isospins. However, there are some different features in detailed physics between them, one of which is small deviation of low-energy magnetic dispersion from what spin wave theory gives. In this regard, we used resonant inelastic x-ray scattering to show that the spin wave theory cannot perfectly explain the low-energy magnetic behavior of a 5d transition-metal oxide, Sr2IrO4. The high momentum-resolution low-energy dispersion and its temperature dependent behaviors cannot be fully understood only by spin wave theory, but higher-order exchange order terms should be included to describe these behaviors.

**G70.00186: Flux-driven and geometry-controlled spin filtering for arbitrary spins in aperiodic quantum networks**

AMRITA MUKHERJEE (Presenter), ARUNAVA CHAKRABARTI, DEPARTMENT OF PHYSICS, UNIVERSITY OF KALYANI, KALYANI, WEST BENGAL-741235, INDIA, RUDOLF ROEMER, DEPARTMENT OF PHYSICS AND CENTRE FOR SCIENTIFIC COMPUTING, UNIVERSITY OF WARWICK, COVENTRY CV4 7AL, U.K. — We demonstrate that an aperiodic array of certain quantum networks comprising magnetic and nonmagnetic atoms can act as perfect spin filters for particles with arbitrary spin state. This can be achieved by introducing minimal quasi-one dimensionality in the basic structural units building up the array, along with an appropriate tuning of the potential of the non-magnetic atoms; the tunnel hopping integral between the non-magnetic atoms and the backbone, and, in some cases, by tuning an external magnetic field. The proposed networks have close resemblance with a family of recently developed photonic lattices, and the scheme for spin filtering can thus be linked, in principle, to a possibility of suppressing any one of the two states of polarization of a single photon, almost at will. We use transfer matrices and a real space renormalization group scheme to unravel the conditions under which any aperiodic arrangement of such topologically different structures will filter out any given spin projection following an energy-independent commutation of the transfer matrices. Our results are analytically exact, and corroborated by extensive numerical calculations of the spin polarized transmission and the density of states of such systems.

**G70.00187: Spin Hall Torque Mediated by Metallic Antiferromagnet**

YAN WEN (Presenter), FENGJUN ZHUO, AURELIEN MANCHON, XIXIANG ZHANG, King Abdullah University of Science and Technology — We report an enhancement of spin current in //Ta/IrMn/Cu/NiFe multilayer heterostructure. A thin metallic IrMn can enhance the spin current from Ta to NiFe. The spin current enhancement with a pronounced maximum value around the Neel temperature of the thin antiferromagnetic (AFM) layer was found. Through varying the measurement temperature and the thickness of the AFM layer, both electronic and magnonic spin current was observed. At low temperatures, where the convertance is weak, a comparable small spin conductivity is observed. The spin conductivity increases when the temperature rises until Neel temperature due to a more convertance process from electronic spin current to magnonic spin current. The spin conductivity decreases when further rising temperature, in which the AFM order is well-established and magnonic spin current starts to vanish.

*The work reported was funded by King Abdullah University of Science and Technology (KAUST).

**G70.00188: Spin-orbit torque generated by Pd oxides**

SATOSHI HAKU (Presenter), HONGYU AN, AKIRA MUSHA, KAZUYA ANDO, Keio University — Current-induced spin-orbit torques enable the manipulation of magnetization in ultrathin ferromagnetic metals. Recent studies have revealed that the spin-orbit torques can be generated by spin-orbit coupling at ferromagnetic-metal/heavy-metal-oxide interfaces. Here, we report the generation of spin-orbit torques using Pd oxides, PdOx. Pd is known as a heavy metal with high conversion efficiency between charge and spin currents because of the strong spin-orbit coupling. In this work, we quantified the spin-orbit torques generated by PdOx using spin-torque ferromagnetic resonance for NiFe/PdOx bilayers with various oxidation levels. The oxidation level of the PdOx layer was manipulated by varying the oxygen gas flow during the reactive sputtering. By increasing the oxidation level of the PdOx layer, we found that the damping-like torque efficiency is significantly suppressed, showing vanishingly small interface spin-orbit torques in the NiFe/PdOx bilayers. This is in stark contrast to the spin-torque generation in NiFe/PtOx bilayers, where the damping-like torque efficiency is not sensitive to the oxidation level of PtOx. Our results therefore will be essential for fundamental understanding of the spin-orbit torques generated by metal oxides.
First-principles study of the carrier doping effect on all-Heusler GMR junctions

FUMIAKI KURODA
(Presenter), MaDis-CMI2, National Institute for Materials Research, Japan, TETSUYA FUKUSHIMA, Institute of Scientific and Industrial Research, Osaka University, Japan, TAMIO OGUCHI, MaDis-CMI2, National Institute for Materials Research, Japan — In this work, we investigate interfacial magnetic couplings and spin-dependent transport property in all-Heusler based CPP-GMR junctions with a semimetallic \( \text{Fe}_2\text{VAl} \) spacer on the basis of first-principles calculations. A half-metallic ferrimagnet \( \text{Mn}_2\text{VAl} \) is used to investigate interfacial magnetic couplings and spin-dependent transport property in all-Heusler based CPP-GMR junctions. When carriers are introduced in the spacer by a gate voltage, magnetoresistance might be changed significantly. Moreover, from comparison with a spin injector with another half-metallic Heusler alloy \( \text{Co}_2\text{MnSi} \), the chemical trend in this type of CPP-GMR junctions is discussed.

Investigation of h-BN/Graphene Spin Valve

TINGYU QU (Presenter), JUNYE HUANG, DEYI FU, JIAWEI LIU, BARBAROS OZYILMAZ, Center for Advanced 2D Materials, National University of Singapore — Spintronics via two-dimensional materials offer promising applications in spin communications. Due to the extraordinary mobility and long diffusion length, graphene is still the subject of intense interest in spin transport. This study focuses on the investigation of the spin lifetime and diffusion length in graphene spin valve, including the extrapolation of the exponential decay of the spin signal with channel length and Hanle precession model. The graphene spin valve exhibits large non-local spin signal up to 40 Ω, with small switching field less than 200 Gauss. The extracted spin lifetime was between 100 and 200 ps, and the diffusion length was more than 4 μm. The spin-injection efficiency in graphene spin valve is further improved by controlling direct current as an injection source and using h-BN as a tunneling barrier.

*Competitive Research Programme (CRP Award No. NRF-CRP9-2011-3)

Spin transport properties in ultra-thin black phosphorus

JIAWEI LIU (Presenter), Department of Physics, National University of Singapore, DEYI FU, BARBAROS OZYILMAZ, Centre for Advanced 2D Materials, National University of Singapore — The discovery of graphene and two-dimensional materials provided new platforms to study electronic spin transport and to be used for novel spintronics applications. Graphene has been shown to exhibit desirable spin transport properties such as long spin life time\(^1\), long spin relaxation length\(^2\) and up to 100% spin injection efficiency\(^3\), even at room temperature. Beyond graphene, in our previous work, we demonstrated all electric spin injection, transport and detection in ultra-thin black phosphorus. In the non-local spin valve geometry, the measured spin relaxation time is as high as 4ns with spin relaxation lengths exceeding 6 μm\(^4\). In this work, we measured the spin signal and lifetime at different doping level in the black phosphorus. We also studied the relation between the spin and momentum relaxation time as a function of temperature.

The role of the spin-orbit coupling in the Transition metal dichalcogenides vertical spin valves

XINHE WANG (Presenter), XIAOYANG LIN, YUAN CAO, WEISHENG ZHAO, Beihang University — As a family of two-dimensional (2D) layered materials, Transition metal dichalcogenides (TMDCs) MX\(_2\) (M=Mo,W; X=S,Se) have been demonstrated to have potential for applications in the field of spintronics because of their strong spin-orbit coupling, spin-splitting with broken inversion symmetry and spin-valley degrees of freedom. In our work, the 2D MX\(_2\) were grown using chemical vapor deposition, and vertical spin valves with cross-strip geometry were constructed. The spin valve effects are measured, with layer and stacking variations. Which show the signature of the spin-valley coupling and spin-orbit torques. they pave the way for magnetic and electric control of spin and valley-polarized transport in magnetic tunneling junctions. Then, metallic behavior of the junction barrier is discussed; the temperature (50K-300K) dependence of the magnetoresistance ratio is reported; the role of the anisotropic magnetoresistance in the typical cross-strip geometry and the annealing effect on the device is discussed. Finally, the feature of the vertical spin valves based on the different TMDCs are listed and compared.
G70.00193: Edge magnetic properties and transport of spin current in an SU(2)-symmetric Kitaev spin liquid

VANUILDO DE CARVALHO (Presenter), School of Physics and Astronomy, University of Minnesota, HERMANN FREIRE, Institute of Physics, Federal University of Goias, EDUARDO MIRANDA, IFGW, University of Campinas, RODRIGO G PEREIRA, International Institute of Physics, Federal University of Rio Grande do Norte — We investigate the edge magnetism and the spin transport properties of an SU(2)-symmetric Kitaev spin liquid (KSL) model put forward by Yao and Lee [Phys. Rev. Lett. 107, 087205 (2011)] on the honeycomb lattice. In this model, the spin degrees of freedom fractionalize into a $\mathbb{Z}_2$ static gauge field and three species of either gapless (Dirac) or gapped (chiral) Majorana fermionic excitations. We find that, when a magnetic field is applied to a zigzag edge, the Dirac KSL exhibits a nonlocal magnetization associated with the existence of zero-energy edge modes. The application of a spin bias $V = \mu^+ - \mu^-$ at the interface of the spin system with a normal metal produces a spin current into the KSL, which depends, in the zero-temperature limit, as a power-law on $V$ for both Dirac and chiral KSLs, but with different exponents. Lastly, we study the longitudinal spin Seebeck effect, in which a spin current is driven by the combined action of a magnetic field perpendicular to the plane of the honeycomb lattice and a thermal gradient at the interface of the KSL with a metal. Our results suggest that edge magnetization and spin transport can be used to probe the existence of charge-neutral edge states in quantum spin liquids.

G70.00194: Magnetic impurity bands in Ga$_{x-1}$Mn$_x$S: Towards understanding the anomalous spin-glass transition

THOMAS PEKAREK (Presenter), M.C. MASSEY, I. MANUEL, PAUL S. EDWARDS, D. PARKER, JASON HARALDSEN, University of North Florida — We report on magnetic and electronic properties of a quasi-2D single-crystalline Ga$_{0.91}$Mn$_{0.09}$S diluted magnetic semiconductor (DMS) that shows an anomalously high spin-glass $T_c$ at 11.2 K. Using density functional theory (DFT), we characterize the properties contributing to the spin-glass transition through an examination of electronic and magnetic properties for Ga$_{1-x}$Mn$_x$S ($0 < x < 0.18$). The Mn produces impurity bands in the electronic structure, where an analysis of the density of states shows an increase in magnetic impurity bands at the Fermi level that lowers the semiconducting gap consistent with DMS. This is similar to other DMS, where the primary mechanism is likely through magnetic exchange. The increased electron density with Mn doping could explain the anomalously higher $T_c$ in Ga$_{0.91}$Mn$_{0.09}$S. In comparison with the substantially lower transition temperatures in related II-VI based systems (e.g., Zn$_{1-x}$Mn$_x$Te), the high $T_c$ is associated with more metallic spin-glass systems that interact through RKKY exchange, which leads to the conclusion that there may be a combination of interactions occurring in these systems.

G70.00195: Spin pumping driven by magnon-phonon coupled mode

HIROKI HAYASHI (Presenter), KAZUYA ANDO, Applied Physics and Physico-Informatics, Keio University — The properties of magnons and phonons, quasiparticles of spin waves and acoustic waves, have been investigated independently for more than half a century. However, the interaction between magnons and phonons can arise from spin-orbit, dipole-dipole, and exchange interactions in magnetic crystals. The coupling strength is most enhanced in the proximity of the intersection of the uncoupled magnon and phonon dispersions. In the coupling region, the quasiparticle with admixtures of both magnetic and elastic properties, magnon-polarons, is formed.

We report the observation of a resonant enhancement of spin pumping induced by the magnon-phonon coupled mode at room temperature. In this experiment, we measured the spin pumping and inverse spin Hall effect in a Pt/Y$_3$Fe$_5$O$_{12}$ (YIG) bilayer under microwave parametric pumping. We found that spin currents pumped from the YIG layer show an anomaly when the microwave excites dipole-exchange magnons in the proximity of the intersection of the uncoupled magnon and phonon dispersions. Our result shows that the spin pumping driven by the magnon-phonon coupled mode is enhanced compared with the purely magnonic value, consistent with previous works on the spin Seebeck effect.

G70.00196: Computing dynamic spin structure factor using matrix product state method and the time dependent variational principle

LING WANG (Presenter), Beijing Computational Science Research Center — We demonstrate that matrix product state combined with the time dependent variational principle can accurately reproduce a real time evolution of a disturbed ground state. From real time correlation of spin operators respect to the ground state, we compute the dynamic spin structure factor. We will show benchmark results for 1d Heisenberg chain, as well as extensive calculations on 2d square lattice Heisenberg model.

*L.W. is supported by National Natural Science Fundation of China (Grant No. NSFC-11874080).
Critical behavior of the layered ferromagnet $\text{Fe}_{1/4}\text{TaS}_2$*  

CHENHUI ZHANG (Presenter), YE YUAN, YAN WEN, XIXIANG ZHANG, King Abdullah University of Science and Technology — The critical behavior of single-crystalline layered ferromagnet $\text{Fe}_{1/4}\text{TaS}_2$ were studied by bulk dc magnetization around the paramagnetic to ferromagnetic phase transition. Critical exponents $\beta = 0.459(6)$ and $\gamma = 1.205(11)$ are extracted from the Kouvel-Fisher plot, whereas $\delta = 3.69(1)$ is obtained by the critical isotherm analysis at $T_c = 100.7$ K. These critical exponents obey the Widom scaling relation $\delta = 1 + \gamma / \beta$. Moreover, the self-consistency and reliability of the results are further verified by scaling equations. The determined exponents match well with those calculated from the results of renormalization group approach, and our analysis suggests that $\text{Fe}_{1/4}\text{TaS}_2$ possesses three-dimensional long-range magnetic interactions with the exchange distance decaying as $J(r) \approx r^{-4.8}$.

*This research was supported by King Abdullah University of Science and Technology (KAUST)

All-optical Control of the Magnetization in EuS, a Versatile Magnetic Insulator*  

ANDRE HENRIQUES, XAVIER GRATENS, PAVEL USACHEV (Presenter), VALMIR CHITTA, Departamento de Física dos Materiais, Universidade de São Paulo, YUNBO OU, Plasma Science and Fusion Center and Francis Bitter Magnet Laboratory, Massachusetts Institute of Technology, JAGADEESH MOODERA, Department of Physics, Massachusetts Institute of Technology — Finding new mechanisms of all-optical control of the magnetic state of matter is highly sought for the development of new devices and for optoelectronic quantum computing. Recently we demonstrated that a single incident photon can generate several thousand spin coherent electrons in antiferromagnetic EuSe, by forming a supergiant spin polaron [1]. Because of the gigantic magnetic moment of the spin polaron, a tiny magnetic field can induce coherence in the spin polaron ensemble. We extend this mechanism of magnetization control with few photons into other materials. Experimentally we show that in the Heisenberg ferromagnetic semiconductor EuS, near the Curie temperature, light induces spin polarons that are even larger than those observed in EuSe. Our Monte Carlo simulation offer a description of the magnetization process. The characteristic times of the spin polaron formation and extinction were measured using time-resolved pump-probe Faraday rotation. We shall present and discuss these results.

Hybrid quantum-classical method for simulating spin-spin relaxation in solid-state NMR.*  

GRIGORY STARKOV, BORIS FINE (Presenter), Skolkovo Institute of Science and Technology — We propose a new hybrid quantum-classical method for first-principles calculations of NMR free induction decay (FID) in solids where spin-1/2 nuclei form periodic lattices. The method is based on the simulations of a finite cluster of spins 1/2 coupled to an environment of interacting classical spins via a correlation-preserving scheme. Such simulations are shown to lead to accurate FID predictions for one-, two- and three-dimensional lattices with a broad variety of interactions. The accuracy of these predictions can be efficiently estimated by varying the size of quantum clusters used in the simulations.

**G70.00200: Prediction of intrinsic properties of Fe-doped CeCo$_5$**

DURGA PAUDYAL (Presenter), RENU CHAUDHARY, Ames Laboratory — Due to high uniaxial anisotropy and abundant nature of Ce, CeCo$_5$ has become a subject of intense research for getting an excellent permanent magnet with low cost. CeCo$_5$ comes under the materials having a crystal structure of CaCu$_5$-type with space group P6/mmm. The changes in the valence state of the Ce atom from +4 to +3 due to the presence of Cu in CeCo$_5$ can enhance the coercivity of CeCo$_{5-x}$Cu$_x$. The replacement of Co-atom by another transition metal can manipulate the magnetization. The first principles calculations were performed to study the effect of Fe-doping on the magnetic properties of CeCo$_{4.5-x}$Fe$_x$Cu$_{0.5}$ to increase the magnetic moment with sufficient anisotropy. Fe doping increases the total moment. The anisotropy is highly dependent on the sites occupied by Fe and Cu. 20% Fe gives high uniaxial anisotropy in CeCo$_{4.5-x}$Fe$_x$Cu$_{0.5}$ for Cu at the 3g site, whereas 10% Fe in CeCo$_{4.5-x}$Fe$_x$Cu$_{0.5}$ gives high uniaxial anisotropy for Cu at the 2c site. Site preference of Fe is also checked for the compounds separately with Cu at 2c and 3g sites. Depending upon the concentration, Fe prefers both 3g and 2c sites in a CeCo$_{4.5-x}$Fe$_x$Cu$_{0.5}$ indicating the importance of the structural geometry.

*This research is supported by the CMI, an Energy Innovation Hub funded by the USDOE, Office of EERE, AMO.

**G70.00201: New roots for synthesis of Cobalt carbide nanoparticles for rare earth free permanent magnets**

EDUARDO MARTÍNEZ-TERÁN (Presenter), AHMED EL-GENDY, University of Texas, El Paso — Magnets have made a great impact in our daily lives, since they are present in all kind of modern devices. However, one of the problems we may encounter in near future is that the supply of materials from which the magnets are made, rare earths, may not be able to supply their demand. In addition, the usual production of magnets involves many steps in between, the melting of raw materials, mold casting, cooling, crushing and then pressing them into the desired shape. For those reasons, we propose the creation of permanent magnets from abundant materials, Cobalt and Carbon. Therefore, we propose synthesis of Co$_x$C nanoparticles using super critical conditions (pressure and temperature). The materials precursors are mixed with solvent and heated up to its supercritical conditions where it decomposes to nanoscaled particles in powder shape, ready for being pressed. The morphology and phase structure were characterized using SEM and XRD to reveal cylindrical like shape and Co$_x$C orthorhombic phase structure respectively. The magnetic properties have been measured to yeild coercivity (Hc) of 760 Oe with saturation magnetization (Ms) of 37.41 emu/g, with an energy product of 2.84 MGOe. This method is still under optimization to reach the single phase of Co3C with higher Hc and Ms.

**G70.00202: Enhanced magnetic anisotropy in Sm–Co magnets due to tensile strain**

SO-YOUNG JEKAL, JÖRG F. LÖFFLER, Department of Materials, ETH Zurich, MICHALIS CHARILAOU (Presenter), Department of Physics, University of Louisiana at Lafayette — The SmCo$_5$ system exhibits one of the strongest magnetocrystalline anisotropy energies (MAE) among the rare-earth based magnets, essentially setting the limit of anisotropy strength in such materials. Based on Density-Functional-Theory calculations, we propose that tensile strain in this compound can in fact increase the MAE [1]. We have found that a tensile strain of 1% is enough to enhance the magnetocrystalline anisotropy by as much as 30%, whereas 5% tensile strain results in a 80% increase of MAE. Further, we predict that such a strain in the structure can be introduced by partial substitution. Specifically, we found that 25% substitution of Sm by Ce, a much lighter element that induces local tensile strain, enhances the magnetocrystalline anisotropy energy by 28%. Preliminary experiments with melt-spun ribbons confirm these predictions and Monte Carlo simulations predict a strong high-temperature performance of magnets based on this material. These findings suggest that it is possible to develop magnets that are substantially more anisotropic by fine-tuning the local atomic arrangements.

corresponding first principles techniques, but with very similar accuracy. The agreement between them is excellent. Thus this realistic tight-binding method provides an effective approach to describe MAE into intra-sublattice and inter-sublattice contributions using both perturbation and scaling procedures, and as FePt and FeNi. This method can accurately calculate the MAE over the whole band filling range. The smaller basis set allows us to efficiently resolve MAE with a very high resolution in reciprocal space. The $k$-resolved MAE using the force theorem and perturbation theory agree well with each other, both reflecting the aspects of the Fermi surface. We resolve MAE into intra-sublattice and inter-sublattice contributions using both perturbation and scaling procedures, and agreement between them is excellent. Thus this realistic tight-binding method provides an effective approach to describe and analyze MAE. Once the real-space Hamiltonian is constructed, this approach is orders of magnitude faster than the corresponding first principles techniques, but with very similar accuracy.

In conventional spin crossover systems, the vibrational degrees of freedom enhances the entropic effect in excited high-spin terms resulting from the softening of vibrations [1]. Here, we show an opposite effect of vibration on the spin-crossover taking $C_60^{3-}$ as an example [2]. $C_60^{3-}$ anion takes either high ($S = 1/2$) or low ($S = 1/2$) spin state, and in the latter the dynamical Jahn-Teller effect arises. It is found that the large dynamical Jahn-Teller stabilization energy lowers the low-spin levels, resulting in the violation of Hund’s rule. The Jahn-Teller dynamics influences the thermodynamic properties via strong variation of the density of vibronic states with energy. Thus, the vibronic entropy in the low-spin states enhances the effective spin gap of $C_60^{3-}$ quenching the spin crossover. This finding is used for the rationalization of the experimental data on the spin gaps in various fullerenes. The vibronic mechanism is not limited to fullerene: It can play a crucial role when Hund and Jahn-Teller couplings are comparable to each other.

Perpendicular MAE and unconventional MAE contributions in $k$-space are found in the self-assembled Gd-ZGNR system, which presents a remarkable Rashba effect (the estimated strength is 1.89 eV Å) due to the strong SOC and the asymmetric adsorption sites at the nanoribbon edge. Moreover, first-order MAE is connected to the intrinsic Rashba effect beyond the traditional second-order MAE. The dependence on the ribbon width of the first-order MAE and the Rashba effect are also examined. This work not only opens a new gate for designing the 1D Rashba system but also provides insight into the unconventional MAE due to the intrinsic Rashba effect.
In this work, we chemically deintercalated layered ionic compound to an air-stable van-der-Waals material which can be mechanically exfoliated down to thin layers while preserving its magnetic properties. In addition, unlike the materials mentioned above, the material reported here exhibits signs of frustrated magnetism.

**G70.00210:** Structural and magnetic properties of Co$_{2-x}$Ti$_x$FeGe ($0 \leq x \leq 1$) alloy series with plausible half-metallic behavior

SHAMBUH KC (Presenter), Physics and Astronomy, The University of Alabama — We report the synthesis and characterization of a Co$_{2-x}$Ti$_x$FeGe ($0 \leq x \leq 1$) alloy series by substituting Co with Ti atoms in a stoichiometric Co$_2$FeGe alloy. Based on prior microscopic and structural characterization, Co$_2$FeGe is reported not to be phase pure$^1$. By Ti substitution, however, we investigated and found single-phase behavior for $0.375 \leq x \leq 0.875$, while the other composition studied showed multi-phase behavior, supporting previous work. XRD analysis reveals cubic crystal structure for all single-phase samples with the lattice parameter increasing almost linearly with increasing Ti substitution. The extracted magnetic moments at 5 K show strong agreement with the Slater-Pauling moments. Further, the spin-resolved DOS calculated predicts a gap in the minority channel. Moreover, with the addition of Ti, it is seen that the Fermi level shifts from the right edge of the band gap to the left and it falls exactly in the gap for $x = 0.5$. Our experimental and theoretical studies of different single-phase sample compositions suggest that Co$_{1.5}$Ti$_{0.5}$FeGe is a plausible half metal.

**G70.00211:** Low-damping magnetic materials in FM-NM-FM structures on flexible substrates for RF/microwave applications

XINJUN WANG (Presenter), IVAN LISENKO, NIAN-XIANG SUN, Northeastern University, KATIE HAUCK, KEVIN WALKER, NAVAIR — New magnetic materials can open a way for energy-efficient and flexible antenna and RF microwave devices. Low damping magnetic materials have been attributed to single-crystal magnetic insulators. High-quality with low damping magnetic materials, are deposited on flexible substrates, are needed to enhance the performance of flexible devices. Here, we demonstrated low magnetic damping in a ferromagnetic (FM)/non-magnetic(NM)/ferromagnetic(FM) structure fabricated on a flexible Mica substrate, which comparable with the one found in solid structures. With different Ru thickness, the two FM layers shows parallel(P) and antiparallel(AP) interaction, which is called the Ruderman–Kittel–Kasuya–Yosida (RKKY) interaction. For an AP coupling, the linewidth demonstrates a different behavior. For low external fields (and low frequencies in the range 4GHz – 6GHz) the linewidth is practically independent with the frequency, which shows great potential applications for RF/microwave devices and antenna.

**G70.00212:** Tuning structural and magnetic properties by vanadium substitution in Fe$_3$Ge

RABIN MAHAT (Presenter), University of Alabama — The structural and magnetic properties of Fe$_{3-x}$V$_x$Ge intermetallic alloy series (0<x≤1) have been investigated. The samples were prepared by arc-melting under argon atmosphere. After annealing, alloys with 0.375≤x≤0.625 are found to crystallize in the cubic Heusler structure, while alloys with 0<x≤0.25 crystallize in the hexagonal DO$_{19}$, which is the high temperature phase of parent Fe$_3$Ge. Optical microscopy, EDX, and XRD reveal uniform granular microstructures for x≤0.75. The calculated lattice parameter increases linearly with increasing x, while the magnetic moment at 5K decreases linearly for cubic alloys, deviating only about 7% from the Slater-Pauling values, which indicates possible half-metallic behavior. The hexagonal samples have markedly higher moments. The saturation magnetizing field is found to decrease with the increase of x making the system softer at higher V concentrations. The martensitic phase transformation in all stable cubic phases is confirmed by DSC which is being reported for the first time for this system. Vanadium is found to play a crucial role in stabilizing the cubic structure and shifting the martensitic transformation temperature to higher values from that of parent Fe$_3$Ge.

**G70.00213:** The SSRL BL13 Scanning Transmission X-ray Microscopy for the Study of Magnetic Materials

HENDRIK OHLDAEG (Presenter), Lawrence Berkeley National Laboratory — Today's magnetic device technology is based on complex magnetic alloys or multilayers that are patterned at the nanoscale and operate at gigahertz frequencies. To better understand the behavior of such devices one needs an experimental approach that is capable of detecting magnetization with nanometer and picosecond sensitivity. In addition, since devices contain different magnetic elements, a technique is needed that provides element-specific information about not only ferromagnetic but antiferromagnetic materials as well. Synchrotron based X-ray microscopy provides exactly these capabilities because a synchrotron produces tunable and fully polarized X-rays. In this contribution we will present the capabilities of synchrotron based X-ray microscopy, which is becoming a tool available at every synchrotron. The particular capabilities of the instrument discussed here is the ability to detect very small changes in the magnetization induced by external stimuli like currents or fields. It also allows to follow magnetization dynamics with a time resolution of the order of 10 ps. We will show results that demonstrate the ability to image spin waves, electric field induced changes in antiferromagnets as well as spin accumulation in non-magnets.
G70.00214: Magneto-Raman Spectroscopy on Vanadium-derived Lacunar Spinel GaV$_4$S$_8^*$

CALVERT BARCLAY (Presenter), D. OLOGUNAGUBA, Physics, Florida A&M University, ZHENGUANG LU, Condensed Matter Science, National High Magnetic Field Laboratory, GANESH POKHAREL, HASITHA SURIYA ARACHCHIGE, Materials Science and Engineering, University of Tennessee, ANDREW D CHRISTIANSON, Neutron Scattering Division, Oak Ridge National Laboratory, DAVID MANDRUS, Materials Science and Engineering, University of Tennessee, DMITRY SMIRNOV, Condensed Matter Science, National High Magnetic Field Laboratory, KOMALAVALLI THIRUNAVUKKARASU, Physics, Florida A&M University — Chalcogenides with the GaM$_4$S$_8$ structure are hetero- cubane like [M$_4$X$_4$]$^{n^+}$ cubes (M = Mo, Re,V, Nb, Ta; X = S, Se, Te) and [AX$_4$]$^{n^-}$ tetrahedra (A= Ga, Ge), these adopt the NaCl structure [1,2]. GaV$_4$S$_8$ is a known Mott insulator because of the long inter-cluster distances approximately 4 Å apart [1]. GaV$_4$S$_8$ (GaVS) is a magnetic semiconductor with a Neel-type skyrmion phase displaying multiferroic properties [3]. Magnetic susceptibility measurements showed structural transition at T$_{JT}$ of 42 K followed by a ferromagnetic order at 12 K [4] and 12.7 K [5]. Temperature-dependent infrared and Raman measurements identified phonon modes and Jahn-Teller distortions [6]. For detailed information on the various exchange interactions in GaV$_4$S$_8$, we performed magneto-Raman measurements at magnetic fields up to 20 T and temperatures down to 5 K.

G70.00215: Characterization of microstructure and residual stresses using Barkhausen noise measurements

NEELAM PRABHU GAUNKAR, Iowa State University, GAJANANA PRABHU GAUNKAR, Mechanical Sciences, Indian Institute of Technology, Goa, DAVID C JILES (Presenter), Iowa State University — Micromagnetic measurement methods based on Barkhausen Noise (BN) measurements are increasingly being used as a versatile and cost effective tool for in-situ examination and evaluation of microstructural changes. They are also used for measurement of surface residual stresses. Interpretation of the observations and measurements, however, require validation with the help of appropriate calibration procedures.

In the present paper, we examine the characterization of a broad spectrum of microstructures such as produced in steels and also lattice strains which sometimes accompany the microstructural changes. Such changes also affect the BN response. Characteristic residual lattice strains or residual stress patterns also get generated around stress raisers including flaws such as surface cracks which need to be detected and evaluated for their consequences during continued service exposure of the material. We will present observations of the mapping of surface residual stress pattern in the vicinity of a part through surface crack produced by controlled fatigue loading of a 15 mm thick martensitic stainless steel plate showing residual stress variations around a dormant crack.

G70.00216: ATOMIC, MOLECULAR, AND OPTICAL (AMO) PHYSICS —

G70.00217: Dynamics of a 2D disordered dipolar interacting spin ensemble on the surface of diamond

KRISTINE REZAI (Presenter), Harvard University, PHILLIP E WEINBERG, Physics, Boston University, SOONWON CHOI, Physics, University of California, Berkeley, MIKHAIL LUKIN, Harvard University, ALEXANDER SUSHKOV, Physics, Boston University — Statistical mechanics has long been the framework which connects the microscopic world to macroscopic observables. However, its fundamental assumption has been shown to break down in a class of strongly disordered systems, resulting in a slowdown or absence of thermalization. In this work, we use a shallow nitrogen-vacancy center to probe the dynamics of disordered dipolar interacting electronic spin-1/2 defects on the diamond surface. Using magnetic resonance techniques, we characterize and control the strength of disorder and dipolar interactions among the electronic spins. We measure the autocorrelation of individual spin projection, which exhibits a decay on a time scale much slower than the inverse interaction strength, indicating a substantial slowdown of thermalization.
Exploring quantum correlations in a many-body localized system

Julian Leonard (Presenter), Matthew Rispoli, Alexander Lukin, Robert Schittko, Sooshin Kim, Joyce Kwan, Markus Greiner, Harvard University — An interacting quantum system that is subject to disorder may cease to thermalize due to localization of its constituents, thereby marking the breakdown of thermodynamics. We realize such a many-body-localized system in a disordered Bose-Hubbard chain and characterize its entanglement properties through particle fluctuations and correlations.

We observe that the particles become localized, suppressing transport and preventing the thermalization of subsystems. Notably, we measure the development of non-local correlations, whose evolution is consistent with a logarithmic growth of entanglement entropy - the hallmark of many-body localization. These results experimentally establish many-body localization as a qualitatively distinct phenomenon from localization in non-interacting, disordered systems.

Furthermore, we study the critical properties of the many-body localization transition. We identify a spatially separated, sparse-resonant structure of the system, which emerges at intermediate disorder strength and drives sub-diffusive particle motion. This structure persists into non-factorizable higher-order correlation functions. Our work identifies the many-body nature of the critical regime and lays a foundation for characterizing dynamic phases via high-order correlation.

Optical black-hole analog in inhomogeneous photonic lattice

Meng Kang (Presenter), Wuhan University, Huaqing Huang, University of Utah, Hongxing Xu, Wuhan University, Feng Liu, University of Utah — Hawking radiation, a key to quantum gravity, has stimulated extensive theoretical and experimental studies of various black-hole analogs. Here we theoretically develop a new laboratory analog of black hole in an inhomogeneous two-dimensional graphyne-like topological photonic lattice. A predesigned lattice transition from type-II to type-I Dirac cone creates an analogous curved space time crossing the event horizon (type-III Dirac cone). Photons tunneling through the horizon emit a spectrum of Hawking radiation with a Hawking temperature of 14 μK. Our approach provides a universal design for the optical black-hole analogs in topological photonic crystals and metamaterials.

Coherent coupling of fluctuations in mesoscopic systems in optomechanics

Devender Garg, Asoka Biswas (Presenter), Indian Institute of Technology Ropar — Interaction between a quantum and a mesoscopic system has always been intriguing in understanding the quantum-classical interface. In this context, we show how the energy fluctuations can be adiabatically exchanged, by using laser pulses, between two mirrors or between the motional degree of freedom of an ion trapped inside the cavity and that of one of the cavity mirrors. In the former case, two membranes are suspended inside a cavity. The zero-eigenvalue eigenstate of the matrix governing their fluctuation dynamics indicates that a suitable sequence of pulses to drive the cavity modes can lead to a deterministic adiabatic transfer of energy fluctuations from one membrane to the other, in a way akin to stimulated Raman adiabatic passage. Similar results can also be obtained in the later setup, in which a single ion is trapped inside an optical cavity, with one of the mirrors oscillating. Our results show that it is possible to coherently couple the fluctuations of two mesoscopic systems. Interestingly, this also indicates that the motion of a trapped ion (a quantum system) can lead to motional fluctuation in a mesoscopic mirror. This opens up possibilities for an ion-controlled long-distance transfer of fluctuations among mirrors, using more cavities.

Emergent Floquet prethermalization signatures in out-of-time ordered correlations

Pai Peng (Presenter), Department of Electrical Engineering and Computer Science, MIT, Xuan Wei, Oles Shtanko, Department of Physics, MIT, Iman Marvian, Departments of Physics & Electrical and Computer Engineering, Duke University, Chandrasekhar Ramanathan, Department of Physics and Astronomy, Dartmouth College, Seth Lloyd, Department of Mechanical Engineering, MIT, Paola Capellaro, Department of Nuclear Science and Engineering, MIT — How a many-body quantum system thermalizes -- or fails to do so -- under its own interaction is a fundamental yet elusive concept. Here we demonstrate nuclear magnetic resonance observation of the emergence of prethermalization by measuring out-of-time ordered correlations. We exploit Hamiltonian engineering techniques to tune the strength of spin-spin interactions and of a transverse magnetic field in a spin chain system, as well as to invert the Hamiltonian sign to reveal out-of-time ordered correlations. At large fields, we observe an emergent conserved quantity due to prethermalization, which can be revealed by an early saturation of correlations. Our experiment not only demonstrates a new protocol to measure out-of-time ordered correlations, but also provides new insights in the study of quantum thermal dynamics.
G70.00224: Rebuilding of destroyed spin squeezing in noisy environments
PENG XU (Presenter), Wuhan University — We investigate the process of spin squeezing in a ferromagnetic dipolar spin-1 Bose-Einstein condensate under the driven one-axis twisting scheme, with emphasis on the detrimental effect of noisy environments (stray magnetic fields) which completely destroy the spin squeezing. By applying concatenated dynamical decoupling pulse sequences with a moderate bias magnetic field to suppress the effect of the noisy environments, we faithfully reconstruct the spin squeezing process under realistic experimental conditions. Our noise-resistant method is ready to be employed to generate the spin squeezed state in a dipolar spin-1 Bose-Einstein condensate and paves a feasible way to the Heisenberg-limit quantum metrology.

G70.00225: On Local Simulations of Local Fluxes in Molecular Junctions*
GABRIEL CABRA (Presenter), University of California, San Diego, ANDERS WESTERGAARD JENSEN, University of Copenhagen, MICHAEL GALPERIN, MASSIMILIANO DI VENTRA, University of California, San Diego — We present a pedagogical review of the current density simulation in molecular junction models indicating its advantages and deficiencies in the analysis of local junction transport characteristics. In particular, we argue that current density is a universal tool which provides more information than traditionally simulated bond currents, especially when discussing inelastic processes. On the other hand, current density simulations are sensitive to the basis set and the electronic structure method utilized. We note that while discussing the local current conservation in junctions, one has to account for the source term caused by the open character of the system and intra-molecular interactions. Our considerations are illustrated with numerical simulations of a benzenedithiol molecular junction.

G70.00226: Solution of the independent boson model with quadratic coupling
AURELIA CHENU (Presenter), Los Alamos National Laboratory, SHIU-E-YUAN SHIAU, Academia Sinica, MONIQUE COMBESCOT, Sorbonne Universite — We revisit the model of a two-level system coupled to phonons, and provide analytical solutions including a quadratic coupling, which was until now unsolved. Indeed, current techniques to analytically solve this important problem, like the polaron transformation which eliminates what is commonly called system-phonon couplings, hide the fundamental physics. These couplings can be eliminated using a diagonal basis, in which phonons depend on the electronic level. Doing so, we obtain analytical results through a simple algebra, by switching back and forth from ground-phonons to excited-phonons. We easily recover standard results for linear coupling, like state dynamics and correlation functions for absorption/emission lineshapes, in a way far simpler than previous procedures. More importantly, we find solution for the Hamiltonian including quadratic coupling, for which no analytical results have been reported yet. This approach opens a conceptually new route to more complicated matter-boson systems.

G70.00227: A Quantum Mechanical Study of Francium and Radium Clusters*
DAVID NUNN (Presenter), AJIT HIRA, JOSE PACHECO, JARETH BACA, Math and Physics, Northern New Mexico College — This report presents our research on the small atomic clusters of francium (Fr\textsubscript{n}), and radium Ra\textsubscript{n} (n = 1-9), and their hybrids Fr\textsubscript{n}Ra\textsubscript{n} clusters. Francium is a heavy, unstable, radioactive metal with a maximum half-life of only 22 minutes. Radium is the heaviest and most reactive element of the alkaline earth metals family. Hybrid ab initio methods of quantum chemistry (particularly the DFT-B3LYP model) were used to derive optimal geometries for the clusters of interest. We compare calculated binding energies, bond-lengths, ionization potentials, electron affinities and HOMO-LUMO gaps for these clusters. The theoretical study of Fr\textsubscript{n} clusters, such as ours, is particularly important because very little experimental data is available on its physical properties. It is interesting to check the stability of francium in cluster form. The interactions of Fr\textsubscript{n} clusters with O atoms, O\textsubscript{2} molecules, H\textsubscript{2}O molecules, and with some C\textsubscript{n} clusters will be compared to similar interactions for Ra\textsubscript{n} clusters. The possible implications of our computational results for the roles of Radium and Francium as cancer-causing materials will be examined.

*Financial support from the New Mexico Alliance for Minority Participation (NM-AMP) program of the National Science Foundation (NSF).
Developments in quantum dynamics of full-dimensional diatom-diatom collisions at pre-exascale*
BENHUI YANG (Presenter), YIER WAN, PHILLIP STANCIL, University of Georgia, BALAKRISHNAN NADUVALATH, University of Nevada Las Vegas, ROBERT C FORREY, Penn State Berks Campus — Accurate rate coefficients for molecular rovibrational transitions due to collisions with H$_2$ are critical for interpreting IR astronomical observations. Theoretical results are the primary source of such rate coefficients. The most accurate theoretical approach is the quantum close-coupling method. Recently we extended full-dimensional quantum dynamics calculations of rovibrationally inelastic scattering large systems including CO-H$_2$, CN-H$_2$, SiO-H$_2$, and CS-H$_2$. The rovibrational cross sections have been computed using various implementations of the TwoBC code based on 6D potential energy surfaces. To date, full-D scattering calculations are mainly focused on the target molecule in its ground and first excited vibrational states with H$_2$ treated as a rigid rotor. To perform scattering computations with larger vibrational excitation of both diatoms further increases the computational demands. This relies on the availability of leadership-class computational resources. We present preliminary results for rovibrational scattering computations on Titan, SummitDev, and Summit with a progression of optimization efforts with MPI, OpenMP, OpenACC, and Magma.

Multidimensional Bin-Width Optimization for Histogram and Its Application to Four-Dimensional Neutron Inelastic Scattering Data
KENSUKE MUTO (Presenter), HIROTAKA SAKAMOTO, KEISUKE MATSUURA, TAKA-HISA ARIMA, MASATO OKADA, Graduate School of Frontier Sciences, The University of Tokyo — We propose a method for optimizing bin widths for multidimensional histograms. In recent years, a large amount of four-dimensional event data has been obtainable in neutron inelastic scattering experiments conducted by chopper spectrometers[1]. As preprocessing, researchers make histograms from obtained event data. At present, the researchers only empirically select bin widths and slice conditions to get a two-dimensional histogram, while checking the histogram in a visual approach[2]. We propose a method which can automatically make a multi-dimensional histogram from event data. Our method was derived from the one-dimensional bin width optimization method[3]. In this paper, we use artificial data to investigate the behavior of our method. We applied the proposed method to both sliced two-dimensional event data and the whole four-dimensional event data. Comparing their results, we have found that the optimized bin-width strongly depends on the dimensionality of the data. Moreover, the optimum bin widths are affected by the number of events and the magnitude of the white background noise.

Diffusion of carbon adatoms on gold ion trap electrode surfaces
HOSSEIN JOOYA (Presenter), ITAMP, Harvard-Smithsonian Center for Astrophysics, KYLE S. MCKAY, NIST, Boulder, Colorado, EUNJA KIM, Department of Physics and Astronomy, University of Nevada, Las Vegas, PHIL WECK, Sandia National Laboratories, DAVID PAPPAS, DUSTIN A HITE, NIST, Boulder, Colorado, HOSSEIN SADEGHPOUR, ITAMP, Harvard-Smithsonian Center for Astrophysics — In ion traps, the electric field noise emanating from the trap electrodes remains as a major obstacle to the realization of ion-trap based scalable quantum computing architectures. The source of this anomalous noise has been identified as the fluctuating surface adatom dipoles (mostly carbon-bearing). The original microscopic theory of fluctuating surface dipoles is static. In order to provide a more realistic picture of the surface dynamics, the mobility of these dipoles whose magnitude change with motion on the electrode surface should also be considered. One of the unknown parameters in the electric field noise spectral power is the diffusion constant of such adsorbates. In this study, classical molecular dynamics (MD) simulations are used to calculate long-time diffusion constant and transition rates of carbon adatoms on various gold surface orientations. The resultant fluctuation in the induced dipole moment is then obtained by computing the work function of the surface, using the density-functional theory method. Such time domain calculations also provide us with a clear picture of carbon structure and cluster formation on various gold surfaces.
According to the mean-field theory, an atomic Bose-Einstein condensate (BEC) will collapse when the interaction between atoms is attractive. However, the mixture of two miscible or phase separated condensates, collapsing, and the droplet of the double BEC of Rb and Na atoms. With the help of an interspecies Feshbach resonance, we have created format of self-bound quantum droplets. In this talk, I will present our progress in studying the heteronuclear quantum BECs with attractive interspecies interaction can be stabilized by the beyond mean-field Lee-Huang-Yang correction in the Einstein condensate (BEC) will collapse when the interaction between atoms is attractive. However, the mixture of two BECs with attractive interspecies interaction can be stabilized by the mean-field Lee-Huang-Yang correction in the format of self-bound quantum droplets. In this talk, I will present our progress in studying the heteronuclear quantum droplet with the double BEC of Rb and Na atoms. With the help of an interspecies Feshbach resonance, we have created double BECs with nearly arbitrary interaction strengths and signs. This should allow us to cover the full phase diagram from two miscible or phase separated condensates, collapsing, and the droplet.

*Wataru Kohno is a JSPS Research Fellow, and this work was supported in part by JSPS KAKENHI Grant Number 18J13241.

Recently, one of the authors has been constructed a variational wave function, which describes weakly interacting Bose–Einstein condensates (BECs) with dynamical 3/2-body correlations, where one of the two colliding non-condensates drops into the condensate and vice versa. In this presentation, we apply the variational method to (1) M-component BEC and (2) BEC trapped by a general trap to investigate the properties of 3/2-body correlations in BECs more qualitatively. From our numerical results in both cases, the 3/2-body correlations lower the ground-state energy in an amount comparable to the mean-field contribution.

G70.00234: Ground State Properties for a Bose Gas Within a Periodic, Multi-Rods Structure* OMAR ABEL RODRÍGUEZ-LÓPEZ (Presenter), MIGUEL SOLIS, Theoretical Physics, Institute of Physics, Universidad Nacional Autónoma de México — We calculate the ground state (gs) energy and the static structure factor at zero temperature of an interacting Bose gas confined by a one-dimensional, periodic, multi-rod structure created by an external Kronig-Penney potential. We employ the Diffusion Monte Carlo (DMC) method to solve the Schrödinger equation exactly up to a statistical error. The gs energy is compared with the results previously obtained using the Variational Monte Carlo method (VMC), as well with the results obtained using the Mean-Field theory approximation by solving analytically the Gross-Pitaevskii equation. In the limit of zero external potential, we recover the results for the well-known Lieb-Liniger model [1]. For nonzero external potential, we find a phase transition from the superfluid state to a Mott insulator state as the lattice height increases. [1] E. H. Lieb and W. Liniger, Phys. Rev. 130, 1605 (1963).

*We thank the partial support from grants CONACyT 221030, PAPIIT IN107616 and PAPIIT 110319.
G70.00236: Magnetic model for supersolidity* JOSÉ MARTÍNEZ-HERRERA (Presenter), MIGUEL SOLIS, Sociedad Mexicana de Fisica — The well known correspondence between the lattice liquid (or solid) model and a magnetic model like the Ising model, is used to obtain the thermodynamic properties of an one-dimensional quantum crystal whose lattice is divided in two different interpenetrating sublattices α and β. Among others, we introduce a Bose-Einstein condensation and an order-disorder parameters to solve the equilibrium state. Then, we calculate the Helmholtz free energy in a mean field theory approximation and, applying the standard minimization method respect to the condensate and order-disorder parameters, we find a critical temperature different from zero at which the system presents a phase transition like the Bose-Einstein condensation which we connect with the possibility of a supersolid transition.

*We acknowledge partial support from grants PAPIIT IN107616, IN110319 and CONACyT 221030.

G70.00237: Chiral Majorana edge states in the vortex core of a $p + ip$ Fermi superfluid* JING BO WANG (Presenter), University of Science and Technology of China — We study Majorana modes in the vortex core of a two-dimensional $p + ip$ Fermi superfluid interacting with a Bose-Einstein condensate. Under a repulsive $s$-wave contact interaction between fermions and bosons, fermions are depleted from the vortex core when the bosonic density becomes sufficiently large. This gives rise to a dynamically-driven local interface emerges between fermions and bosons, along which chiral Majorana edge states should appear. We examine in detail the variation of vortex-core structures as well as the formation of chiral Majorana edge states with increasing bosonic density, where the circulation of the vortex plays an important role. Whereas both the Majorana modes and vortex-core structures can be controlled and manipulated by tuning the bosonic density and the Bose-Fermi interaction strength, our study presents an illuminating example on how topological defects can be dynamically controlled in the context of cold atomic gases.

*This work has been supported by the Natural Science Foundation of China (11522545) and the National Key R&D Program (Grant Nos. 2016YFA0301700,2017YFA0304100). J.-S. P. acknowledges support from National Postdoctoral Program for Innovative Talents of China under Grant No. BX201700156.

G70.00238: Ultra-cold dysprosium for quantum simulation PIERRE BARRAL (Presenter), MICHAEL A CANTARA, LI DU, WILLIAN LUNDEN, ALAN JAMISON, WOLFGANG KETTERLE, MIT — Dysprosium is in many respects an atom of interest for quantum simulation. Its large angular momentum (J=8) in the ground state gives rise to one of the highest magnetic moments (10 Bohr magneton) in the periodic table, and one can therefore simulate an extended version of the Hubbard model with dipole-dipole interactions. This large angular momentum combined with narrow transitions also allows one to implement strong atom-light coupling with reduced heating. It opens the way to create gauge fields, e.g., spin-orbit coupling. We will report the most recent progress in our dysprosium apparatus.

G70.00239: One-dimensional Bose polarons beyond the Fröhlich paradigm: localized impurities HONG LING (Presenter), Department of Physics and Astronomy, Rowan University, Glassboro, New Jersey 08028, BEN KAIN, Department of Physics, College of the Holy Cross, Worcester, Massachusetts 01610 — Grusdt et al. [New J. Phys. 19, 103035 (2017)] recently made a renormalization group study of a one-dimensional (1D) Bose polaron in cold atoms that goes beyond the usual Fröhlich description. We study the same model in the localized impurity limit where the ground state is described by a multimode squeezed state instead of the multimode coherent state in the static Fröhlich model. We solve the system exactly by applying the generalized Bogoliubov transformation, an approach that can be straightforwardly adapted to higher dimensions. Using our exact solution, we obtain a polaron energy free of infrared divergences and construct analytically the polaron phase diagram. We find the repulsive polaron is stable on the positive side of the impurity-boson interaction but is always thermodynamically unstable on the negative side of the impurity-boson interaction, featuring a bound state, whose binding energy we obtain analytically. We find the attractive polaron is always dynamically unstable, featuring a pair of imaginary energies which we obtain analytically.

G70.00240: ABSTRACT WITHDRAWN —

G70.00241: Quantum Simulation of the Fermi-Hubbard Model GEOFFREY JI (Presenter), CHRISTIE S CHIU, Harvard University, ANNABELLE BOHRDT, Harvard University and Technical University of Munich, MIUQING XU, Harvard University, JUSTUS BRÜGGENJÜRGEN, Harvard University and University of Hamburg, MICHAEL KNAP, Technical University of Munich, EUGENE DEMLER, FABIAN GRUSDT, MARKUS GREINER, DANIEL GREIF, Harvard University — Developments in quantum gas microscopy have enabled detailed studies of the repulsive Fermi-Hubbard model. Using fermionic Lithium-6 in a square lattice, we observe the transition into an antiferromagnet at temperatures below the superexchange energy. We use a novel pattern-finding algorithm to characterize the system’s behavior upon hole-doping. This new observable provides evidence that holes may be hiding the antiferromagnetic order rather than destroying it. We then investigate the deterministic injection of a single mobile dopant into an antiferromagnet and observe how it propagates. Finally, we discuss our progress towards an optical lattice with dynamically tunable interference contrast, which enables several low-entropy state preparation schemes and spin-resolved readout.
**G70.00242: $^6$Li in optical ring lattices**  DANIEL ALLMAN, YANPING CAI (Presenter), KEVIN WRIGHT, PARTH SABHARWAL, Dartmouth College — Optical ring lattices provide a convenient setting for studying, i.e., many-body correlations and emergent topological phenomena in low-entropy, low-temperature Fermi ensembles. Due in part to technical challenges involved in creating and maintaining stable optical ring lattices, there has been no detailed experimental study of the behavior of fermions in periodic lattice geometries. We report on progress toward loading and trapping $^6$Li atoms in optical ring lattices of $\leq 100$ sites. By preparing low-entropy quantum states within the lattice, along with the ability to tune interactions with $^6$Li’s broad Feshbach resonance, we hope to observe a fermionic metal-to-Mott insulating transition in a strictly periodic geometry. We will also have the ability to investigate more exotic lattice structures, potential arenas for realizing several paradigmatic topological lattice models, such as the Su-Schrieffer-Heeger model.

**G70.00243: Boosting the BEC critical temperature of an ideal Bose gas within a crystal with vacancies**  JUAN GARCIA (Presenter), MIGUEL SOLIS, JOSÉ MARTÍNEZ-HERRERA, National Autonomous University of Mexico — We show that an ideal Bose gas in one or two-dimensional imperfect crystal presents Bose-Einstein condensation at a finite critical temperature, which does not happen when the crystal is perfect. For the three-dimensional imperfect crystal case, the BEC critical temperature is higher than that of the gas in the perfect crystal. We have obtained the energy spectrum of the particles using the transfer and dispersion matrix methods as well as the use of the Green function, transfer matrix and dispersion, which we use to calculate, in addition to the critical temperature, the specific heat for the Bose gas within imperfect two-dimensional structures such as multilines or grids, and for three-dimensional cases such as multiplanes, multitubes and multicubes.

*We thank the partial support from grants CONACyT 221030 y DGAPA-PAPIIT IN107616.

**G70.00244: Ultracold YbF molecules for measuring the electron’s electric dipole moment**  MICHAEL TRIGATZIS (Presenter), Centre for Cold Matter, Blackett Laboratory, Imperial College London — Theories that extend the Standard Model (SM) generally contain additional sources of CP-violation and predict the electron to have an electric dipole moment (eEDM) large enough to be measured by today's experiments. The eEDM may be measured by observing spin precession in YbF molecules in an electric field [1]. Recent results [1-4] already strongly constrain beyond-SM theories.

Laser cooling of molecules was first demonstrated in 2010 [5]. An ultracold beam of YbF could increase the eEDM measurement sensitivity by two orders of magnitude [6]. We have demonstrated 1D sub-Doppler transverse cooling of our YbF beam to below 100 $\mu$K [6] and recently extended the technique to 2D.

*Work supported by STFC Grant No. ST/N000242/1, EPSRC Grants No. EP/M027716/1 and EP/P01058X/1, the Centre for Doctoral Training Controlled Quantum Dynamics EP/L016524/1, and the European Research Council under the European Union’s Seventh Framework Programme (FP7/2007–2013)/ERC Grant Agreement No. 320789.

**G70.00245: Progress towards quantifying the impacts of state mixing on the Rydberg excitation blockade**  ANDREW LESAK (Presenter), AARON WHTYE REINHARD, Kenyon College — Rydberg atoms are ideal for studying quantum phenomenon due to their exaggerated properties relative to ground-state atoms. During excitation, the highly polarizable atoms interact and the resonant frequencies of the atoms are shifted, leading to a suppression of excitation known as the “Rydberg excitation blockade.” In an ideal blockade, many atoms share one excitation and a more complete blockade is achieved when neighboring atoms interact more strongly. However, near a Forster resonance, stronger interactions can lead to the excitation of unwanted states, breaking the blockade. In order to implement scalable quantum computers, the Rydberg excitation blockade must be used in large samples and therefore state-mixing properties must be rigorously studied in order to minimize their negative impacts. We laser cool rubidium atoms to microkelvin temperatures and use state-selective field ionization spectroscopy to determine the distribution of atoms in each Rydberg state. We present preliminary results in which we seek to quantify exactly how much state-mixing reduces blockade efficiency and to determine the number of interacting bodies that lead to large amounts of state-mixing.

*This work was supported by NSF Grant No. PHY-1553179.
G70.00246: Two-dimensional Condensation of Polar Molecules with Field-induced Dipoles  I-KANG LIU, Department of Physics, National Changhua University of Education, Changhua, Taiwan, DAW-WEI WANG, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, SHIH-CHUAN GOU (Presenter), Department of Physics, National Changhua University of Education, Changhua, Taiwan — We theoretically investigate the ground-state structures of a two-dimensional condensation composed of ultracold polar molecules, in which the condensed particles are subjected to an effective vector potential induced by the Raman coupling between two rotational levels of the molecule. With all dipoles aligned by a DC field in the axial direction and the two counter-propagating Raman beams in the radial direction, the effective dipole moment induced by the light-matter coupling, which is much larger than the intrinsic dipole moment of the molecule, predominates the interaction between molecules. Based on the previous studies, the effective interaction features not only the standard long-range dipolar form but also a spatial dependence on the relative phase between two coupled rotational states. In the mean-field approximation, the ground state is found to possess four phases: plane-wave phase, zero-momentum phase and two of Stoner-type phase. The first two phases appear when the system is in the coupling-dominant regime, while the last two are in the interaction-dominant regime. Numerical results obtained by solving the Gross-Pitaevskii equation agree with the variational analysis. Dynamical stability of the Stoner-type phases is examined via calculating the Bogoliubov spectrum.

G70.00247: Conclusive Precision Bounds for SU(1,1) Interferometers*  CHENGLONG YOU (Presenter), SUSHOVIT ADHIKARI, Louisiana State University, XIAOPING MA, Department of Physics, Ocean University of China, MASAHIDE SASAKI, MASAHIRO TAKEOKA, National Institute of Information and Communications Technology, JONATHAN P DOWLING, Louisiana State University — We revisit the quantum Fisher information (QFI) calculation in SU(1,1) interferometer considering different phase configurations. Firstly, when one of the input modes is a vacuum state, we show by using phase averaging, different phase configurations give same QFI. In this case, the QFI is linearly proportional to the average photon number of the second input state, and quadratically proportional to the average photon number generated by the OPA. This suggests that when fixing the squeezing strength of the OPA, to achieve higher sensitivity, one simply needs to inject a state with higher average photon number. Secondly, we compared the results of the phase-averaging method and the quantum Fisher information matrix method, and then we argued that for a SU(1,1) interferometer, phase averaging or quantum Fisher information matrix method is generally required, and they are essentially equivalent. Finally, we used the quantum Fisher information matrix method to calculate the precision limit for other common input states, such as two coherent state inputs or coherent state with squeezed vacuum inputs.

*CY, SA and JPD would like to acknowledge support from Army Research Office and National Science Foundation.

G70.00248: Phase estimation in an SU(1,1) interferometer with displaced squeezed states*  SUSOHOVIT ADHIKARI (Presenter), NARAYAN BHUSAL, CHENGLONG YOU, HWANG LEE, JONATHAN P DOWLING, Louisiana State University — We study the phase sensitivity of an SU(1,1) interferometer with coherent and displaced-squeezed-vacuum (DSV) states as inputs, and parity and on-off as detection strategies. Our scheme with parity is sub-shotnoise limited and approaches the Heisenberg limit with increasing squeezing strength of the optical parametric amplifier (OPA). Also, for the on-off detection scheme, we show that sub-shotnoise sensitivity is possible by increasing the squeezing strength of the OPA.

*Air Force Office of Scientific Research, Army Research Office

G70.00249: Three-photon molecule generation through coherent scattering process off single dipole emitter in quantum nanophotonics  ZIHAO CHEN (Presenter), YAO ZHOU, JUNG-TSUNG SHEN, Electrical and System Engineering, Washington University in St. Louis — Bound state refers to the quantum state wherein wave function of constituent particles is localized, which typically require interactions between individual particles, e.g., two hydrogen atoms form bound state of a hydrogen molecule due to Coulomb interactions. Thus, photons do not form bound states (also called photonic molecules) easily due to its electric neutrality. Recently, it has been reported that, when three photons interact with a single emitter, photon-photon entanglement mediated by the emitter may induce the formation of 3-photon molecules. However, the underlying generation mechanism is not yet clear.

Here we present a computational study to confirm that, through coherent scattering process for three uncorrelated photons off a single dipole emitter, 3-photon molecule is generated. In particular, three prominent signatures: (1) exponentially decaying wave function as photon distance increases; (2) anti-correlation signature; and (3) pi-phase shift, are unveiled by examining correlation functions and wave functions of scattered photons. Moreover, we show that our results account for recent experiment in ultra-cold atomic gas well. Such a 3-photon molecule has potential applications in designing photonic quantum logic gate and three-photon fluorescence microscopy.
Towards Using Trapped Ions as Memory Nodes in a Photon-mediated Quantum Network

JAMESON O’REILLY (Presenter), Northeastern University, Boston, MA 02115, USA, JACKSON BELL, DANIELA BOGORIN, Air Force Research Laboratory, Rome, NY 13441, USA, BENJAMIN BONENFANT, Northeastern University, Boston, MA 02115, USA, PAUL COOK, Air Force Research Laboratory, Rome, NY 13441, USA, SAVANNAH DECKER, Boston University, Boston, MA 02215, USA, LESTER DISNEY, TYLER DOLEZAL, Air Force Research Laboratory, Rome, NY 13441, USA, BENJAMIN DRIESEN, Northeastern University, Boston, MA 02115, USA, PAIGE HAAS, Air Force Research Laboratory, Rome, NY 13441, USA, NICHOLAS HOUGLAND, Carnegie Mellon University, Pittsburgh, PA 15213, USA, DAVID HUCUL, Air Force Research Laboratory, Rome, NY 13441, USA, BRAD LIU, SPAWAR, San Diego, CA 92110, USA, SAMUEL MARTHAGE, Syracuse University, Syracuse, NY 13244, USA, BRENNAL NELSON, JUSTIN PHILLIPS, Northeastern University, Boston, MA 02115, USA, KAITLIN POOLE, Air Force Research Laboratory, Rome, NY 13441, USA, BRANDON ROBINSON, Northeastern University, Boston, MA 02115, USA, HARRIS RUTBECK-GOLDMAN, LAURA WESSING, KATHY-ANNE SODERBERG, Air Force Research Laboratory, Rome, NY 13441, USA — Quantum networking exploits features of quantum mechanics to provide ultrasecure networks that are both tamper-proof and tamper-evident. Such networks can be implemented as distant memory nodes connected via photon-based interfaces. Trapped ions are nearly ideal quantum network nodes due to the precise control possible over both their internal and external degrees of freedom as well as for their superior performance as long-term quantum memories. Photon-based qubits are the natural choice to transfer information within the network due to their ability to transmit quantum information over long distances and the capability to process information "on-the-fly" between the memory nodes. We present the quantum research being done at the Air Force Research Laboratory (AFRL) with a focus on trapped ion qubits, the short- and long-term goals of the lab, and some of the unique resources we have access to at AFRL. Approved for Public Release [Case # 88ABW-2018-2102] Distribution Unlimited.

Contractor acknowledges Government's support in the publication of this paper. This material is based upon work funded by AFRL under AFRL Contract No. FA8750-17-3-6005.

G70.00251: MEST-Spacetime Center, Gluon, and New String Theory

DAYONG CAO (Presenter), Avoid Earth Extinction Association — MEST is a balance systemic model of mass, energy, space, and time.

There is a balance MEST system between gluons and quarks. The gluon is “spacetime”.

According to Einstein field equation and negative Einstein equation, there are massenergy center with massenergy structure and spacetime center with spacetime structure which has gravity of the spacetime (as negative gravity).

The spacetime center structure can explain of dark matter and dark energy.

A balance structure between massenergy and spacetime can explain of the homogeneous, isotropic, and flat structure of the universe. It can suppose a balance system between the sun and a dark sun (as a spacetime center of Oort cloud).

And the quantum spacetime of the wave, new atomic model, and dark atomic model of the dark matter-dark energy had brought forward.

A advanced string theory can explain of the gravitons of the spacetime center, a gravity of the spacetime of the glunos (as one kind of strong force), the gluon field between a quark and an anti-quark, and Regge Trajectories. It also can study the spacetime structure (wave structure) of the quark-gluon plasma.

That can help us to look for big bang of the spacetime and big bang of the massenergy.

http://meetings.aps.org/Meeting/APR16/Session/M13.8
DAYONG CAO (Presenter), AEEA — The thought waves remotely (wireless) simultaneously radiate to increase background photo-voltages of the four solar cells at the same changed rates by cold photoelectric effect.

Because the luminous sensitivities of the solar cells are different and the photo-voltages are nonlinear functions, there are different “changed rates” in general experiments by light.

Brain is made up of balance between stellar matter and dark matter which has spacetime center structure, such as a balance between gluons (spacetime structure) and quarks (massenergy structure), a balance between nucleus structure and electron cloud, and a balance between the basis (massenergy structure of the crystal) and the crystal lattice (spacetime structure of the crystal), and has cold dark radiations.

The cold photoelectric effect of cold dark radiations of brain wave is a probability effect of the spacetime structure (of Confined Structural non-Newtonian Fluids) between brain wave and a balance structure between Electron Clouds and electron holes of P-N Junction.

The relationship between brain wave and consciousness effect will be considered.

As the decade of the brain research and the “BRAIN” Initiative, a “decade of the consciousness research” need be taken.

http://meetings.aps.org/Meeting/APR16/Session/M13.8

WONWOOK LEE (Presenter), SUNGYONG SHIM, CHA-HWAN OH, Physics, Hanyang University — Stark broadening is widely used to determine the electron density of the astrophysical plasmas and the atmospheric pressure plasmas. In low temperature plasmas Doppler broadening is larger than Stark broadening and the Stark broadening can be measured after removing Doppler broadening. In this research, the model for Stark broadening to determine the electron density was discussed in low temperature plasmas when Doppler broadening of plasma radiation was removed. The spectral line broadenings of van der Waals broadening, resonance broadening, natural broadening, and Stark broadening were calculated and compared with each other in low temperature He plasmas. As well the helicon plasma source of which electron density was higher than \(10^{11}\) cm\(^{-3}\) was constructed to investigate the helium Stark broadening. Stark broadening for \(2^1S-4^1P\) was measured using the saturation absorption spectroscopy and the electron density could be determined by analyzing the Stark broadening.

*This research was supported by National R&D Program of “Basic nuclear fusion research” through the National Research Foundation of Korea(NRF) funded by the Ministry of Science and ICT (NRF-2017M1A7A1A02016145).

YONGQIANG LI (Presenter), JIAYU DAI, XIAOWEI WANG, ZENGGXIU ZHAO, JIANMIN YUAN, Department of Physics, National University of Defense Technology — Both coherent pumping and energy relaxation play important roles in understanding physical processes of ultra-intense coherent light-matter interactions. Here, using a large-scale quantum master equation approach [1], we describe dynamical processes of practical open quantum systems driven by both coherent and stochastic interactions. As examples, we investigate coherent dynamics of inner-shell electrons of a neon gas irradiated by a high intensity X-ray laser along with vast number of decaying channels. In these single-photon dominated processes, we find that, due to coherence-induced Rabi oscillations and power broadening effects, the photon absorptions of a neon gas can be suppressed resulting in differences in ionization processes and final ion-stage distributions. Second, we demonstrate a new scheme for the investigation of hole dynamics of complex atoms based on two-color ultrashort X-ray pulses.

KUAN-HSUN CHIANG (Presenter), National Central University, IO-CHUN HOI, National Tsing Hua University, YUNG-FU CHEN, National Central University — We study the level structure of a tunable coupling qubit (TCQ) [Ref. 1, 2] by microwave spectroscopy in superconducting circuit architecture. Based on the two independently tunable SQUID loops, the multi-level structure of a TCQ can be tuned in-situ. We demonstrated that a TCQ is a charge qubit while providing tunable selection rule. Accompanied with the mode-tunability in coplanar waveguide design, V-type, lambda-type and many other structures can be achieved in a TCQ-based architecture. TCQs have potential for the application of microwave quantum optics.

CHONG YE (Presenter), QUANSHENG ZHANG, YONG LI, Beijing Computational Science Research Center — In the mean-field theory, the stabilization of chiral molecules is understood as a quantum phase transition where the mean-field ground state of molecules changes from the achiral eigenstate of the molecular Hamiltonian to one of the degenerated chiral states due to the increase of the intermolecular interaction. However, the existing mean-field models are either unavailable to chiral molecules whose electric dipoles do not change in sign for |L⟩ and |R⟩ or with free parameters. In this work, starting from the Many-body Hamiltonian with electric dipole-dipole interaction, we give the static Gross-Pitaevskii equations in the vibrational dimension. Our model can be applied to all chiral molecules and has no free parameters.

SUNGYONG SHIM (Presenter), WONWOOK LEE, CHA-HWAN OH, Department of physics, Hanyang university — Helium 23S metastable atoms play key roles in discharge plasmas because of the long lifetime and large excitation energy. In this research, 23S state helium density in an inductively coupled plasma (ICP) was measured by laser absorption spectroscopy. He plasma was operated at the He pressure of 20~50 mTorr and by a RF power supply with the maximum power of 1.5 kW. Electron temperature and electron density of plasma were 2~3 eV and ~1012 cm⁻³, respectively. Absorption spectra for the 23S₁->23Pᵢ (ᵢ=0, 1, 2) transitions were measured by an external cavity laser diode (ECLD) at 1083 nm. The 23S state helium density was analysed and discussed with the RF power and the radial position in the plasma chamber.

JAMES BOYLE (Presenter), Boyle, PLLC — The bispinor solution to the Dirac equation is used to construct a conserved current. The possibility that the conserved current can take on marginal negative values is addressed as a condition that can be set and altered with constraints. Specifically, a Dirac bispinor solution is constructed and subject to constraints such that the marginal negative probability value in the corresponding conserved current is cancelled completely. Unexpectedly, and for a superposition of positive- and negative-energy states using these bispinor solutions, the conserved current derived here is shown to be completely absent of all Zitterbewegung terms. Various uses of the conserved current and the bispinor solutions derived here are also illustrated in conventional contexts, such as in computing scattering amplitudes across barrier potentials.
We report progress on an ongoing experiment to measure the electron EDM using YbF molecules [1].

We have increased the initial population of YbF molecules in the ground state by a factor of six through a combination of repump lasers, microwaves and rf fields. We have also improved our detection efficiency by a factor of 40. This is due to better collection optics, and a better detection scheme which can scatter many more photons per molecule. The new detection scheme also allows us to measure both quadratures of the interferometer.

Spurious magnetic fields are a major source of random and systematic error in our experiment, and therefore we have improved our control and measurement of magnetic fields. This was done by re-designing the electric field plates for lower magnetic Johnson noise, and by installing several low-noise magnetometers inside the machine.

Together, we will be able to measure the electron EDM at the $10^{-29}$ e cm level, which is competitive with the current limit of $1.1 \times 10^{-29}$ e cm set by the ACME collaboration [2].

*I acknowledge funding from the Controlled Quantum Dynamics Centre for Doctoral Training at Imperial College London.

A broad range of chemical reactions are triggered by the absorption of light. Examples include photosynthesis and charge transfer in semiconductors and molecules. Electronic dynamics which evolve on the few femtosecond to attosecond timescale are expected to play an important role in these processes. We aim to investigate these dynamics with transient X-ray absorption near edge structure (XANES) spectroscopy. XANES spectroscopy uses resonant excitation of particular atoms in a molecule to provide a highly localised probe of electronic structure. By employing attosecond soft x-ray pulses generated via high harmonic generation for XANES spectroscopy this atomic scale spatial resolution can in principle be combined with the attosecond temporal resolution required for tracking electronic dynamics. I shall present development of a beamline for transient XANES spectroscopy and progress towards visible pump, soft x-ray probe experiments in the organic polymer poly(hexylthiophene).

*This research is supported by the EPSRC grants EP/N018680/1 and EP/1032517/1 and the Controlled Quantum Dynamics Centre for Doctoral Training

Electron spin resonance (ESR) lock-in sensing protocols with nitrogen vacancy (NV) centers in diamond allow for wide-field, real time imaging of magnetic fields for biological applications ranging from bio-current imaging to wide-field tracking of magnetic nano-particles. ESR lock-in NV measurements have previously been utilized for the optical detection of firing action potentials in giant axons [1]. By modulating the applied microwave driving field and imaging the NV fluorescence with a specialized lock-in camera, we are able to create real time videos of local magnetic fields with high spatial (~1 μm) and temporal (~1 ms) resolution over a large field of view (~1 mm). Here we show demonstrate a volume-normalized sensitivity of ~100 nT*μm^3/2*Hz^-1/2 and compatibility with living biological systems. This work paves the way for the development of broadband quantum diamond microscopes for imaging bio-magnetic fields from neuronal activity.

WALSWORTH, Harvard-Smithsonian CFA — Magnetic field sensors and imagers employing nitrogen vacancy (NV) centers in
diamond require strong, uniform microwave (MW) fields near 3 GHz. We present a new design for a planar waveguide
structure fabricated on silicon carbide (SiC), which combines homogeneous microwave delivery with the heat-spreading
benefits of SiC. We perform finite element simulations in COMSOL, we fabricate and test MW structures, and we compare
experimental performance with simulation results. We demonstrate optimized MW power delivery and improved MW field
uniformity. We implement these MW delivery structures in quantum diamond microscopes (QDMs) to improve magnetic
imaging performance in fields ranging from Earth and planetary sciences to biology.

KAI SHINBROUGH, BIN FANG, Physics, University of Illinois at Urbana-Champaign, YANTING TENG (Presenter), Physics, Harvard University, YUJIE ZHANG, OFFIR COHEN, VIRGINIA O LORENZ, Physics, University of Illinois at Urbana-Champaign — Deterministic production of high purity photon states is essential for robust quantum communication and information applications. One way to implement the deterministic single photon production is the Duan-Lukin-Cirac-Zoller (DLCZ) protocol via phonon-mediated Raman processes. Although Raman processes have been well demonstrated, the purity of photons has remained largely unexplored. We investigate the effects experimental parameters have on the purity of single photons by using a phenomenological hamiltonian. We show how single photon purity depends on the length of the crystal and the bandwidth of the pump used to generate the photons. We compare our numerical simulations against experimental data showing qualitative agreement.

LIN XIN (Presenter), MICHAEL S CHAPMAN, Georgia Institute of Technology — Squeezing, which redistributes the quantum fluctuations between two noncommuting observables while preserving the minimum uncertainty product, has been extensively studied in boson systems. In addition, research in squeezed spin states (SSSs) is a topical area due to its significant applications in high-precision measurement and in quantum information science. The building block of spin squeezing is One-axis twisting (OAT). A two-axis counter-twisting mechanisms (TAT) is introduced as a natural extension of OAT and is shown to further reduce the quantum noise. So far, there are plenty of experiments that realized OAT while TAT haven't been achieved due to the experimental complexity. In this talk, I will present a way to produce TAT in spin-nematic squeezed system by Floquet driving. Periodically microwave and radio frequency pulse sequence can adjust the direction of spin squeezing and thus generates an effective TAT Hamiltonian. By adapting this method, there is no need to change the setup of the apparatus, but instead, changes only the time sequence, improving the current experimental limit of spin squeezing.

YOUSEF SALAMIN (Presenter), Physics Department, American University of Sharjah — Bessel beams carry orbital angular momentum (OAM). Opening up of the Hilbert space of OAM to information coding makes Bessel beams potential candidates for utility in data transfer and optical communications. The ultra-short and tightly-focused analogue of a non-diffracting and non-dispersing laser Bessel beam is often referred to as a laser bullet. Electromagnetic fields of a laser Bessel-Bessel bullet are presented, following from solution to the wave equations of the scalar and vector potentials in the presence of an under-dense plasma. Intensity distributions based on the derived fields are shown to propagate over many centimeters, without significant diffraction or distortion. The reported fields are derived, to lowest order, from a vector potential containing an ordinary Bessel function of arbitrary order and a zero-order spherical Bessel function, hence the designation Bessel-Bessel bullet.
G70.00268: Supercontinuum generation with octave-spanning bandwidth in the high order mode based Ta2O5 waveguide*  
FU-YAN YAN (Presenter), CHUNG-LUN WU, RARAN FAN, PIN-SHUO HWANG, CHAO-WEI LIU, CHIN-YU LIU,  
Department of Photonics, National Sun Yat-sen University, Taiwan, MIN-HSIUNG SHIH, Research Center for Applied Sciences, Academia Sinica, Taiwan, YI-JEN CHIU, ANN-KUO CHU, CHAO-KUEI LEE, Department of Photonics, National Sun Yat-sen University, Taiwan — Super-continuum generation (SCG) has been attracting plenty of attention due to its wide application, such as OCT and communication. In this work, anomalous dispersion Ta2O5 based waveguide was designed and fabricated for the super-continuum generation (SCG) due to its nature of two-photon absorption free and high optical nonlinearity. The 5mm length air cladding Ta2O5 waveguide with a dimension of 800nm x 700nm was designed and fabricated for fulfilling anomalous dispersion requirement which is crucial for SCG. For excitation laser wavelength of 1056nm, with excitation peak power of around 400W, the 1.5 octave-spanning was demonstrated. Compared to a SiN-based nonlinear waveguide, the resulting exhibit Ta2O5 based waveguide a promising material for SCG.

G70.00269: GENERAL THEORY AND COMPUTATIONAL PHYSICS  —

G70.00270: Theoretical Prediction of Sulfides Under Pressure  
NISHA GENG (Presenter), Chemistry, SUNY at Buffalo — Inspired by the discovery of high temperature superconductivity in the hydrogen/sulfur system, the XtalOpt evolutionary algorithm has been used to predict the structures of binary and ternary sulfides under pressure. A number of stable and metastable phases with novel stoichiometries are found at pressures attainable in diamond anvil cells. The electronic structure and superconducting properties of these phases are analyzed.

G70.00271: First-principles calculation of third-order elastic constants via numerical differentiation of the second Piola-Kirchhoff stress tensor  
DAVID CUFFARI (Presenter), ANGELO BONGIORNO, College of Staten Island — Third-order elastic constants (TOECs) of materials are difficult to measure experimentally and produce large errors. Computational methods are needed for overcoming these difficulties. Previous methods to calculate TOECs are based on fitting energy-strain and/or stress-strain curves calculated from density functional theory (DFT). These methods rely on symmetry relationships, and for this reason, so far they have been applied mainly to cubic and hexagonal crystals. In this paper, we present a novel method to calculate TOECs that is applicable to any system, regardless of its symmetry and dimensionality. This method relies on second-order numerical differentiation of the second Piola-Kirchhoff stress tensor. In this work, we combine this method to a plane-wave DFT approach to calculate the TOECs of aluminum, diamond, silicon, magnesium, graphene, and graphane. A comparison to experimental results shows that our new method is valid and accurate.

G70.00272: Development of Multiphase EOS Table for Gallium*  
CARRIE PRISBREY (Presenter), CHRISTINE J WU, Lawrence Livermore Natl Lab — We present a multiphase equation of state (EOS) table created at Lawrence Livermore National Laboratory for Gallium (Ga). Gallium is an interesting material as it has a low melting temperature of only a few degrees above room temperature, and the Ga-I solid, found at room temperature and pressure, exhibits the properties of both covalent and metallic bonding. Gallium is unusual in that its liquid phase is more dense than the Ga-I solid, leading to a melt line of negative slope. Our EOS captures the anomalous behavior of the liquid phase as well as the three commonly known solid phases, Ga-I, Ga-II, and Ga-III. The table is constrained by published experimental data such as DAC, isobars, and Hugoniot measurements. In addition, we plan to test our EOS against the newest dynamic measurements taken at the Z facility at Sandia National Laboratory.

*This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344
**Mechanisms of optically initiated decomposition of MgO-PETN and MgO-TNT composites**

ROMAN TSYSHESVSKIY (Presenter), University of Maryland College Park, ANTON S. ZVEREV, ANATOLY Y. MITROFANOV, Kemerovo State University, MAIJA M KUKLA, University of Maryland College Park — Optical initiation to detonation of energetic materials (EMs) opens up new ways for safe handling, storage, and use of high explosives. EM-oxide interfaces have distinct optical and electronic properties because of the alignment of the filled and vacant electronic states of oxides and EMs. These changes are key factor for achieving tunable sensitivity through controllable initiation of decomposition reactions. We report here results of experimental and theoretical study on photoinitiation of PETN-MgO and TNT-MgO composites. We discuss electronic and optical properties of these materials and reveal mechanisms of photoinitiation reactions involving charge transfer from metal oxide to explosive compound. We also show how chemical stability of ionized explosive compounds can be critical for design composite materials with controllable optical sensitivity.

**Orientation dependence of plasticity and transformation kinetics in Zirconium at higher shock pressure**

HONGXIANG ZONG, University of Edinburgh, TURAB LOOKMAN, Los Alamos National Laboratory, ANDREAS HERMANN (Presenter), GRAEME ACKLAND, University of Edinburgh — We simulated the high pressure phase transformation in zirconium using molecular dynamics with a new EAM potential fitted using force matching. Under quasistatic ("Hugoniostat") conditions the transformation from α-ω follows the phase diagram, as expected. However under directly simulated shock conditions the structure transforms from α-β (hcp-bcc) rather than the expected ω phase. Assuming sudden, isotropic pressurization we trace this to a different phase transformation mechanism (so-called TAO1) in which bcc appears as an intermediate state, and under pressure the barrier hcp-bcc is lower than bcc-ω. The assumption of isotropic loading requires significant plasticity, which we also simulated and found to be of marginal validity. Plasticity depends on the crystal orientation and in the absence of ideal plasticity, so does the transformation path and, indeed, the observed high pressure phase. We have determined the orientational dependence of the transformation kinetics between hcp-ω-bcc and hcp-bcc at higher shock pressure.

*Research funding through the ERC grant HECATE is gratefully acknowledged.

**Electron-Phonon Coupling in Ag-Au Alloys**

SURENDER SINGH (Presenter), DASARI PRASAD, Department of Chemistry, Indian Institute of Technology Kanpur — Superconductivity at ambient temperature and pressure has been recently inferred from the data of electrical resistance and magnetic susceptibility measurements on Ag-Au alloy nanostructures [1]. In view of this, electron-phonon interactions have been calculated by means of density functional perturbation theory to search for the signatures of superconductivity in stable and metastable Ag-Au bulk and nanostructured alloys within the BCS-like pairing mechanism. The electronic structure and phonons of the alloys are found to be similar to that of the constituent elements in their ground states. And, therefore, the estimated superconducting transition temperatures resulted in less than a mK. Our computational results corroborate with the findings of absence of superconductivity in Ag/Au modulated nanostructures grown by pulsed laser deposition [2]. The results will be discussed in detail in two parts: alloy structure solutions and electron-phonon – superconductivity.

*We acknowledge the CC, RNJJ & CHM HPC facilities at IIT Kanpur. S.S. thanks the CSIR-India for a SRF fellowship. D.L.V.K.P. acknowledges Initiation-Grant:IITK/CHM/20130116.
G70.00276: Thermal transport theory of organic semiconductors
NIANDUAN LU, JIAWEI WANG (Presenter), LING LI, MING LIU, institute of microelectronics, chinese academy of sciences — Organic semiconductors (OCSs) have very recently received much attentions as potential thermoelectric materials, originating from the fact that they are both semiconducting and that they exhibit relatively low thermal conductivity than that of inorganic materials. The low thermal conductivity of OCSs can remarkably increase the energy conversion efficiency. Generally, thermal transport in OCSs fundamentally differs from that in inorganic materials and is determined by the charge carriers and phonons in localized states. Understanding thermal transport performance of OCSs is important for a fundamental description of energy flow and then a better design of organic thermoelectric devices. We present a unified theoretical model to describe the thermal transport performance of the OCSs based on hopping transport theory. The proposed model predicts that the contribution from phonon to the thermal conductivity is larger than that from charge carrier in the OCSs. Moreover, the proposed model can well interpret the thermal transport feature of the OCSs by combining the disorder, temperature, and carrier concentration. Simulation results imply that thermal conductivity in the OCSs could be strongly affected under large electric field, high carrier and dopant concentration.

G70.00277: Dimensionality-induced phonon softening: effect on electron-phonon coupling and transport
SUSHANT KUMAR (Presenter), RAVISHANKAR SUNDARARAMAN, Rensselaer Polytechnic Institute — Classical elasticity theory predicts that finite-thickness unstrained materials should exhibit a quadratic flexural phonon mode. However, state-of-the-art computational methods have been largely inconsistent in yielding such a behavior for the phonon dispersion curves of two-dimensional (2D) materials and their heterostructures. Given the enormous attention 2D materials have received in recent decades, it is imperative to understand the impact of this phonon softening on \textit{ab initio} predicted electron-phonon coupling strength and resultant transport properties. Recently, a new formulation of phonon calculations based on internal rather than Cartesian coordinates has observed that capturing rotational invariance in addition to translation invariance captures the quadratic mode correctly. Here, we investigate the role of rotational invariance on predicted phonon dispersion curves rigorously, and systematically quantify its impact on electron-phonon scattering rates. We show that the cross-over from a linear to quadratic dispersion of the transverse acoustic branch strongly affects transport properties such as electrical and thermal conductivity when we move from bulk to few- and single-layer materials.

G70.00278: Laplace transform approach for the dynamics of \( N \) qubits coupled to a resonator
MIRKO AMICO (Presenter), OLEG BERMAN, ROMAN KEZERASHVILI, CUNY Graduate Center — An approach to use the method of Laplace transform for the perturbative solution of the Schrodinger equation at any order of the perturbation for a system of \( N \) qubits coupled to a cavity with \( n \) photons is suggested. We investigate the dynamics of a system of \( N \) superconducting qubits coupled to a common resonator with time-dependent coupling. To account for the contribution of the dynamical Lamb effect to the probability of excitation of the qubit, we consider counter-rotating terms in the qubit-photon interaction Hamiltonian. As an example, we illustrate the method for the case of two qubits coupled to a common cavity. The perturbative solutions for the probability of excitation of the qubit show excellent agreement with the numerical calculations.

G70.00279: Size-Controlled Carrier Multiplication in Graphene Nanoribbons*
JUNHYEOK BANG (Presenter), Korea Basic Science Institute — Carrier multiplication (CM) is a fundamental dynamic process of an excited carrier generating multi-electron-hole pairs from single-photon absorption. As such, CM can improve the efficiency of optoelectronic devices. However, CM is rarely witnessed in conventional semiconductors, calling for the need to discover unconventional materials. Here, using real-time time-dependent density functional theory, we show that CM occurs in armchair graphene nanoribbons (AGNRs). The subband structure of AGNRs plays a key role, as it releases the constraints of energy and momentum conservation in the CM process. The subband structure varies depending on nanoribbon width, and thus it provides the way to control the carrier dynamics and carrier multiplication in AGNRs.

*This work was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) (NRF- 2018R1D1A1B07044564) and KBSI grant D38614.
However, the adsorption of O2 molecule on monolayer Ti-doped MoS2 shows relatively higher affinity. The results showed perturbative regime.

Ground and excited state energies, our results will give accurate descriptions of light-emission phenomena in the non-perturbative regime.

Beyond accurate calculation of emitter levels and many photon modes that go beyond solvable model systems in quantum optics. One important result is that we arrive at the first theory of Lamb shifts and Casimir-Polder forces in the ultrastrong coupling regime, which reveals new saturation effects that strongly suppress energy shifts as light-matter coupling grows. Beyond accurate calculation of ground and excited state energies, our results will give accurate descriptions of light-emission phenomena in the non-perturbative regime.

*Work funded by the German Research Foundation within the CRC 951

G70.00281: First-principles ultrafast charge carrier dynamics at the hybrid F4TCNQ:H-Si(111) interface

To do so, we adopt the formalism of real-time time-dependent density-functional theory as implemented in the octopus code [2]. Our results offer insights into the earliest-stage formation of the optical excitations in hybrid interfaces.

G70.00280: First-principles photoelectron spectroscopy in molecular solids from multiscale GW-BSE/MM embedding

Here, we present a multiscale study of the photoemission spectra of MADN thin films using a first principle scheme consisting of Metropolis Monte Carlo-based simulated annealing, Many Body Green's Function Theory within the GW approximation, a QM/MM embedding procedure, and explicit treatment of electron-vibrational coupling. We discuss effects of disorder, quasiparticle corrections, and electrostatic embedding on spatially resolved HOMO levels. Predicted UPS signals are in excellent agreement with experiment.

[1] GIANLUCA TIRIMBO (Presenter), XANDER DE VRIES, PETER BOBBERT, REINDER COEHOORN, BJÖRN BAUMEIER, Humboldt Universität zu Berlin — Hybrid inorganic-organic materials are typically characterized by charge-transfer excitations across their interface that make them appealing candidates for opto-electronic applications [1]. However, the fundamental processes leading to the formation and the evolution of these states are still under debate. To address this question, we investigate from first principles the hybrid interface formed by the strong acceptor F4TCNQ adsorbed on the Si(111) surface, which is p-doped in the ground state. Its linear-absorption spectrum exhibits two maxima in the visible region corresponding to transitions between the electronic states across the inorganic and components. We investigate the dynamics of these excitations triggered by resonant ultrafast laser pulses, following the evolution of the charge-carrier population. To do so, we adopt the formalism of real-time time-dependent density-functional theory as implemented in the octopus code [2]. Our results offer insights into the earliest-stage formation of the optical excitations in hybrid interfaces.

G70.00282: Adsorption of molecular oxygen on Ti-doped monolayer MoS2 and effect of applied electric field: A DFT study

XIANGXUAN DENG (Presenter), Department of materials science and engineering, City University of Hong Kong — It is proposed that by tuning the O2 adsorption on Ti-doped MoS2, the resulting materials system can be used as nanocatalyst. To this end, density functional theory calculations was first performed to study the adsorption of molecular oxygen on pristine MoS2 and Ti-doped MoS2. It was found that O2 molecule adsorption energy on pristine MoS2 was very weak. However, the adsorption of O2 molecule on monolayer Ti-doped MoS2 shows relatively higher affinity. The results showed that the Ti-bridge-O2 configuration is most stable. The analysis of molecular projected density of state and charge transfer indicates that the interaction between the O2 molecule and the Ti dopant is chemisorption via two Ti-O bonds, which affects the magnetic, electronic, and atomic properties of Ti-doped MoS2. Furthermore, the adsorption energy and O-O distance of Ti-doped MoS2 under electric field have been studied. It is hoped that together with electric field, the tuned O2 adsorption on Ti-doped MoS2 could become a nanocatalyst.

G70.00283: First principles theory of ground and excited states of correlated light-matter systems in the non-perturbative regime

NICHOLAS RIVERA (Presenter), JOHANNES FLICK, PRINEHA NARANG, Applied Physics, Harvard University — Ultra-strong coupling between light and matter promises to bring about new means to control material properties, concepts for manipulating light at the atomic scale, and insights into quantum electrodynamics (QED). Thus, there is need to develop quantitative theories of QED phenomena in complex electronic and photonic systems. Here, we develop a new variational paradigm to analyze ultra-strongly coupled light-matter systems which gives ground and excited state information as well as real-space information about electromagnetic fields as they are modified by strong light-matter coupling. Our method gives highly accurate energies for both ground and excited states for systems with many emitter levels and many photon modes that go beyond solvable model systems in quantum optics. One important result is that we arrive at the first theory of Lamb shifts and Casimir-Polder forces in the ultrastrong coupling regime, which reveals new saturation effects that strongly suppress energy shifts as light-matter coupling grows. Beyond accurate calculation of ground and excited state energies, our results will give accurate descriptions of light-emission phenomena in the non-perturbative regime.

systems. This study, in future, can be applied in the development of the efficient photovoltaic cell. The calculation indicates that there is a linear correlation between electrostatic polarization energy and dipole moments of Sc3NC80 and Sc3NC80_ZnPc with the dielectric permittivity of the solvents. However, the trend for Sc3NC80_Pc is deviated slightly, which is scrutinized in DFT level by considering cationic and anionic clusters to study solvent effect. A comparison of results is made with earlier studies of Sc3NC80 systems using DFT in a gas phase, which established small charge transfer from the external complex to the fullerene, takes place even more rigorously in solvent perturbed Sc3NC80 systems. This study, in future, can be applied in the development of the efficient photovoltaic cell.

**G70.00285: Exciton Characteristics in Carbon Nitride and Graphene Quantum Dots**  
NAEEM ULLAH, SHUNWEI CHEN, RUIQIN ZHANG (Presenter), City University of Hong Kong — Graphene quantum dots (GQDs) and Carbon nitride quantum dots (CNQDs), the latest addition to the carbon material family, promise numerous novel applications in optical sensing, photocatalysis, bio-sensing, and photovoltaics. However, understanding the photocatalytic capability of CNQDs compared to the graphene quantum dots (GQDs) have not been investigated thoroughly. Time-dependent density functional tight binding (TD-DFTB) calculations in this work revealed that CNQDs have superior carrier charge separation, sensitive to the size of the QD. Strong localization of the frontier molecular orbitals (FMOs and excited state charge separation was observed in the first excited state due to the relaxation of the structure. The exciton structure reveals spatial confinement to the stretched C-N bonds independent of the size of the QDs while there is no such exciton structure found for GQDs. The optical absorption and emission of CNQDs is sensitive to size, with no dependence on the shape of the QD.

**G70.00286: Electrical Contacts in Monolayer Blue Phosphorene Devices**  
JINGZHEN LI (Presenter), School of Engineering, Applied Science, Harvard University — Semiconducting monolayer (ML) blue phosphorene (BlueP) shares similar stability with ML black phosphorene (BP) and has recently been grown on the Au surface. Potential ML BlueP devices often need a direct contact with metal to inject carrier. Using *ab initio* electronic structure calculations and quantum transport simulations, we perform a systematic study of the interfacial properties of ML BlueP in contact with metals spanning a wide work function range in a field effect transistor (FET) configuration for the first time. There is a strong Fermi level pinning (FLP) in the ML BlueP FETs due to the metal induced gap states (MIGS). The MIGS are eliminated by inserting graphene between ML BlueP and the metal electrode accompanied by a transition from a strong FLP to a weak FLP. Our study not only provides an insight into the ML BlueP-metal interfaces but also helps to design the ML BlueP device.

**G70.00287: Deep Bandgap and Band Structure Engineering by Machine Learning**  
ZHE SHI (Presenter), Materials Science and Engineering, Massachusetts Institute of Technology, EVGENII TSYMBALOV, Skolkovo Institute of Science and Technology, MING DAO, Materials Science and Engineering, Massachusetts Institute of Technology, SUBRA SURESH, Nanyang Technological University, ALEXANDER SHAPEEV, Skolkovo Institute of Science and Technology, Ju LI, Materials Science and Engineering, Massachusetts Institute of Technology — The ability to deform and keep silicon at large strains harbingers a new age of deep elastic strain engineering (ESE) of electronic materials. Current strained-Si technology thus represents only "tip of the iceberg" of what silicon can do as the most versatile and processable electronic material. Deep ESE explores the full six-dimensional space of admissible elastic strain and its effect on physical properties, beyond linear elasticity and perturbation theory. Here we present a general method that combines machine learning and *ab initio* calculations to guide rational ESE whereby unprecedented material properties and performance could be designed. This method invokes recent advances in artificial intelligence by utilizing a limited amount of *ab initio* data for the training of a surrogate model. In particular, an artificial neural network predicts the electronic bandstructure within the accuracy of 19 meV. Our model is utilized to discover the indirect-to-direct bandgap transition and semiconductor-to-metal transition in the entire strain space. By finding out the most energy efficient deformation manner to achieve a desirable bandgap, we demonstrate for the first time how to identify novel pathways to tailor any material figure of merit, which is of central importance for ESE.
Machine learning predictions of nuclear stability*  ROBERTO PÉREZ (Presenter), ALEXANDER BALATSKY, Nordic Institute for Theoretical Physics — Machine learning (ML) methods have become a useful tool in many areas of physics, including Nuclear Physics. ML methods’ ability to take in aggregate information about the behaviour of the system and predict trends is able to make relevant and verifiable predictions. The existence of super heavy stable nuclei in currently experimentally inaccessible regions has been predicted by the nuclear shell effect, however, its location and extension are still in dispute by different models (e.g. Z=120 N=172 from relativistic models) [1]. We aim to apply ML tools to develop accurate statistical models to predict isotopic lifetimes in regions of heavy nuclei, such as the fabled stability island. We explore various ML methods, and study the predictive power of different nuclear representations. We use ML models both with and without theoretical bias from nuclear models, such as isotopic magic numbers, over different radioactive decay channels to possibly offer a glimpse of the next stability region.

Low-energy physics of the bilinear-biquadratic spin-1 chain  MORITZ BINDER (Presenter), THOMAS BARTHEL, Duke University — The bilinear-biquadratic spin-1 chain features various interesting quantum phases, including the Haldane phase, a dimerized phase, and an extended critical phase. Here, we apply an efficient density matrix renormalization group (DMRG) algorithm utilizing infinite boundary conditions to compute precise dynamic spin structure factors for a comprehensive set of points in the phase diagram. Analyzing both dynamic spin and quadrupolar correlations, we gain detailed insights into the nature of low-lying excitations of the model. We compare our results to Bethe ansatz solutions at the SU(3)-symmetric ULS point and the TB point as well as at the pure biquadratic point, which can be mapped to an anisotropic spin-1/2 XXZ chain in the gapped Néel phase. In the Haldane phase, we relate our results to the approximate description in terms of the non-linear sigma model.

Spin-charge co-operation in even-parity three dimensional nodal superconductivity in strained Sr₂RuO₄*  SWAGATA ACHARYA, CEDRIC WEBER, MARK SCHILFGAARDE (Presenter), King’s College London — We develop a three-tier \textit{ab initio} technique to study the origin and nature of the pairing in Sr₂RuO₄. The technique starts with the quasi-particle self consistent GW (QSGW) approximation to build a reference hamiltonian, augment it with dynamical mean field theory (DMFT) to add spin fluctuations left out of QSGW, and also generate the vertices entering into spin, charge, and pairing susceptibilities. Finally we solve multi-orbital Bethe-Salpeter equations to calculate these properties in both strained and unstrained single crystals. We identify what leads to the recently observed dependence of Tc on strain and also gain insights into what limits it. We find a one-to-one correspondence between Tc and the coherence and intensity of the spin susceptibility under application of strain. Finally, we establish connections between spin fluctuations and superconducting pairing symmetries in Sr₂RuO₄, and dimensionality of the fluctuations associated with these degrees of freedom.

Optimized higher-order Lie-Trotter-Suzuki decompositions for two and more terms  YIKANG ZHANG (Presenter), THOMAS BARTHEL, Duke University — Lie-Trotter-Suzuki decompositions of operator exponentials have a lot of applications in physics. For example, they are employed to sample equilibrium states in quantum Monte Carlo and to simulate the dynamics of quantum systems on quantum computers or on classical computers using tensor network state techniques. They also provide symplectic integrators for classical physics. Good higher-order decompositions for exponentials of n=2 non-commuting operators are well-known. These cover one-dimensional quantum systems with nearest-neighbor interactions. We present some optimized decompositions for n=2 and new higher-order decompositions for n=3,4 which are needed for one-dimensional systems with longer-ranged interactions or quantum systems in higher dimensions. The ordering of operators in the decompositions turns out to have substantial influence on the attainable approximation order and magnitudes of the leading error terms.
ParaMonte: A user-friendly parallel Monte Carlo optimization, sampling, and integration library for scientific inference

AMIR SHAHMORADI (Presenter), University of Texas at Arlington — At the foundation of predictive science lies the scientific methodology, which involves multiple steps of observational data collection, developing testable hypotheses, and making predictions. Once a scientific theory is developed, it can be cast into a mathematical model whose parameters have to be fit via observational data. This leads to the formulation of a mathematical objective function for the problem at hand, which has to be then optimized to find the best-fit parameters of the model, or sampled to quantify the uncertainties associated with the parameters, or integrated to assess the performance of the model. Toward this goal, a highly customizable, user-friendly high-performance parallel Monte Carlo optimizer, sampler, and integrator library is presented here, which can be used on a variety of platforms with single to many-core processors, with interfaces to popular programming languages including Python, R, MATLAB, Fortran, C/C++. The algorithms implemented in the library include variants of Markov Chain Monte Carlo that utilize Machine Learning techniques to improve the algorithm's performance, as well as Parallel Tempering, and Nested Sampling.

G70.00293: Numeric Analytic Continuation via Rational Function Regression (Padé Regression)

JIAN WANG (Presenter), SUDIP CHAKRAVARTY, physics and astronomy, UCLA — We have developed a simple and natural method to perform numeric analytic continuation of quantum Monte Carlo data. It is based on the Padé approximation, and uses linear regression and bootstrapping statistics to get rid of extreme unstable results, and estimate the error. Unlike maximum entropy method, no prior information is needed here. Test cases have shown that various spectrum is recovered for relative error as large as 0.1%. Physical reasonings are also explained for its success.

Beam Size Prediction and Control using Neural Network

SHUAI LIU (Presenter), University of California, Berkeley, CHARLES MELTON, HIROSHI NISHIMURA, ALEXANDER HEXEMER, SIMON C LEEMANN, Lawrence Berkeley National Lab — Experimental results from beam lines are sensitive to the size of the beam itself. However, predicting and controlling the beam size still prove to be a challenge. Even with the feed-forward strategy using recorded control data (aka look-up tables), the beam size variance on vertical direction is still ~2 μm. Herein, we provide a machine learning based approach to predict the beam size using neural network. We perform a systematic study to optimize the prediction result using different neural network architectures and regularizers. Based on the model, we propose a neural network based beam size stabilization strategy by tuning a certain experimental parameter (dispersion wave parameter). The variance of beam size on vertical direction is reduced to ~0.3 μm in the online test.

Conservation law presumption from the manifold structure captured by Deep Neural Networks

YOHICHI MOTOTAKE (Presenter), fronteer science, The university of Tokyo — It is suggested that Deep Neural Networks (DNN), which continues to develop in recent years, has a function to extract information of data sets necessary to achieve a given task by modeling the distribution as a manifold. In addition to confirming the usefulness of DNN technology, numerous researchers and engineers are developing various DNN algorithms and tuning parameters. This situation means that enormous knowledge on the manifold structure for various data sets is being accumulated. The purpose of this research is to propose a method to extract manifold structure with complex shape extracted in an interpretable form. Specifically, we propose a method to extract the symmetry of manifold for coordinate transformation. Applying the proposed method to the time series data of the moving object according to the central force potential, it was confirmed that symmetry according to the conservation law of angular momentum could be extracted.
G70.00296: Effect of Different Types of Sulfur Precursors on Chemical Vapor Deposition Synthesis of MoS2 layers: A Reactive Molecular Dynamics Study*  
SUNGWOOK HONG (Presenter), RURU MA, KEN-ICHI NOMURA, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, University of Southern California — Layered transition metal dichalcogenides (TMDCs) like MoS2 layers are promising materials for next-generation electronic applications. Large-area monolayer MoS2 samples for these applications are typically synthesized by chemical vapor deposition (CVD) using MoO3 reactants and sulfur precursors. Recent experimental and computational studies have greatly improved our understanding of reaction pathways in CVD synthesis. However, effect of different types of sulfur precursor on CVD synthesis of MoS2 layer has yet to be fully investigated. In this work, we present quantum-mechanically informed and validated reactive molecular dynamics (RMD) simulations to investigate CVD synthesis of MoS2 layer using S2 and H2S molecules. Our goal is to clarify the different sulfidation and reduction rates of MoO3 surface by S2 and H2S precursors. Our RMD results provide an atomic scale understanding of the CVD reactions for higher-quality MoS2 and other TMDCs.

G70.00297: Fracture in α-Quartz under weak shock condition  
SUBODH TIWARI (Presenter), University of Southern California, MASAAKI MISAWA, KYUSHU SANGYO UNIVERSITY, TOMOKO SATO, Hiroshima University, FUYUKI SHIMOJO, Kumamoto University, AIICHIRO NAKANO, University of Southern California, TOSHIMORI SEKINE, Osaka University, PAULO S BRANICIO, PRIYA VASHISHTA, University of Southern California — Shock response of α-Quartz has been extensively studied using both experiment and theory. Here we present a large scale molecular dynamics simulations to study the atomistic mechanism underlying the weak shock response of α-Quartz. First, classical potential (BKS) employed is verified against Density functional theory (DFT). We computed the shock hugoniot curve using BKS potential which show a quantitatively agreement with DFT. Further, we perform non adiabatic molecular dynamics for plane shock loading in [210] direction. Shock simulation reveals the formation of 5 coordinated Si atom in the banded region. 5 coordinated Si relax to form an banded amorphous region in the system. System between these banded amorphous region shows an elastic compression. Further, The generation of shock-induced plastic deformation is characterized using machine learning methods.

G70.00298: Multi-objective forcefield parameterization for thermal transport in 2D materials*  
NICHOLAS GRABAR (Presenter), ANKIT MISHRA, ARAVIND KRISHNAMOORTHY, AIICHIRO NAKANO, RAJIV KALIA, PRIYA VASHISHTA, University of Southern California — Forcefields for the calculation of thermal properties of nanomaterials must be parameterized to match empirical material properties. Here, the third generation of the Non-Dominated Sorting Genetic Algorithm (NSGA-III) is used to construct forcefields to model 2D semiconducting materials by optimizing structure parameters (lattice constants), mechanical properties (elastic modulus) and vibrational behavior (phonon dispersion curve) from ab initio simulations. The algorithm is a parallelized, cross-platform workflow, written in C, that uses GULP as the engine for validating constructed forcefields. NSGA-III is a reference-point-based many-objective algorithm emphasizing population members that are non-dominated, yet close to a set of supplied reference points. It can handle up to fifteen variables and reference point tuning allows for user tuned diversity in the end product. This will allow for future expansion into forcefields finely-tuned over additional variables.

*This work was supported as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award Number DE-SC0014607. The simulations were performed at the Center for High Performance Computing of the University of Southern California.
G70.00299: Learning Structure-Thermal Property Relationships in 2D Materials* NITISH BARADWAJ (Presenter), ARAVIND KRISHNAMOORTHY, AIICHIRO NAKANO, RAJIV KALIA, PRIYA VASHISHTA, University of Southern California — Two dimensional monolayer semiconductors, alloys and patterned lateral heterostructures are extremely promising candidates for the next generation of nanoelectronic devices. Quantification of thermal transport of such two dimensional materials and heterostructures is necessary for the design of such nanoelectronic and thermoelectric devices. However, direct experimental measurements of intrinsic thermal conductivity is challenging at these length scales and, therefore, the role of material stoichiometry and phase distribution on thermal transport properties of these materials remains unknown.

Here, we use fully atomistic non-equilibrium molecular dynamics simulations to compare the calculated intrinsic thermal conductivity of a Mo$_{1-x}$W$_x$Se$_2$ monolayer alloy with that of a self-similar fractal MoSe$_2$/WSe$_2$ heterostructure. Machine learning applied to the compositional phase space of these materials is used to predict heterostructures with desired thermal transport properties.

*This work was supported as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award Number DE-SC00014607

G70.00300: Global warming impact on low frequency acoustic propagation in Pacific Ocean equatorial surface ducts: a potential paradox. DAVID BROWNING (Presenter), Browning Biotech — A typical Pacific Ocean pH profile has a value of 8.1 at the surface decreasing to 7.7 at the axis of the SOFAR channel (400m). Absorption in seawater of low frequency sound is pH dependent, so that the low frequencies that are contained in a surface duct will be absorbed at twice the rate of those in the SOFAR channel. Global warming is producing ocean acidification which is reducing the pH, hence the low frequency sound absorption, and this will first impact the surface duct. But global warming is also predicted to increase the rainfall and as these equatorial surface ducts are produced from monsoon conditions, the surface duct would be deepened and thus expand the low frequencies contained in it, which would now be absorbed at a higher rate than in the SOFAR channel. This is just a first look into one aspect of what may prove to be a multifaceted and complex interaction of global warming on acoustic propagation conditions in the ocean.

G70.00301: Aimsbg: An algorithm and open-source python library to generate periodic grain boundary structures* KESONG YANG (Presenter), JIANLI CHENG, University of California, San Diego — An algorithm implemented in an open-source python library was developed for building periodic grain boundary models in a universal fashion. The software framework, aimsbg, aims to generate tilt and twist grain boundaries from an input cubic or non-cubic crystal structure for ab-initio and classical atomistic simulation. It can output a coincidence site lattice (CSL) grain boundary for a cubic input structure and a non-CSL grain boundary for a non-cubic input structure. This framework has two useful features: (i) it can calculate all the CSL matrices for generating CSL from a given Sigma (Σ) value and rotation axis, allowing the users to build the specific CSL and grain boundary models; (ii) it provides a convenient command line tool to enable high-throughput generation of tilt and twist grain boundaries by assigning an input crystal structure, Σ value, rotation axis, and grain boundary plane. The developed algorithm in the open-source python library is expected to facilitate studies of grain boundary in materials science. The software framework is available on the website: aimsbg.org.

*The author acknowledges support by National Science Foundation under award number ACI-1550404.

G70.00302: Electrochemical Stability Window of Polymeric Electrolytes LIHUA CHEN (Presenter), SHRUTI VENKATRAM, CHIHO KIM, ANAND CHANDRASEKARAN, RAMAMURTHY RAMPRAKASH, Georgia Institute of Technology — The electrochemical stability window (ESW) is a fundamental consideration while choosing polymers for electrolytes in lithium-ion batteries. In this work, we propose two computational procedures, viz. first-principles density functional theory (DFT) computations coupled with classical molecular dynamics (MD) simulations and machine learning (ML) methods to efficiently and accurately estimate ESW of polymers electrolytes. Six model polymers were investigated, namely, polyethylene (PE), polyethylene oxide (PEO), polyvinyl alcohol (PVA), poly(methyl methacrylate) (PMMA), polycaprolactone (PCL) and polyvinyl chloride (PVC). The role of polymer chemistry and the morphological complexity in determining ESW of these polymers have been elucidated. Comparison with established experimental values revealed that the ESW can be accurately predicted using DFT calculations coupled with MD simulations. However, this method is still time-consuming and the relevant force fields are limited, therefore ML methods are proposed to predict the ESW of single chain models with a first-order accuracy instantaneously. Overall, these two computational procedures proposed in this work can assist the rational design of novel solid polymer electrolytes with desired ESW values.
Co-evolutionary search for Cu-Pd-Ag nanoparticle ground states accelerated with neural network potentials

AIDEN CULLO (Presenter), SAMAD HAJINAZAR, ERNESTO D. SANDOVAL, ALEKSEY KOLMOGOROV, Physics, Applied Physics and Astronomy, Binghamton University — Unconstrained optimization of nanoparticles requires advanced search methods capable of locating global minima in large configuration spaces. In this study, we demonstrate that algorithm efficiency can be improved substantially if ground state searches are performed across a range of nanoparticle sizes simultaneously. In this symbiotic co-evolutionary approach implemented in our MAISE package [1], stable motifs are periodically exchanged among tribes with neighboring nanoparticle sizes. The algorithm was extensively tested on elemental Cu, Pd, and Ag nanoparticles up to 80 atoms using both traditional classical potentials and our neural network models. Examination of the lowest-energy configurations revealed that the neural network set was consistently more stable at the density functional theory level. Lastly, we used our Cu-Pd-Ag neural network model to identify stability regions in binary and ternary systems.

Are Small Polarons Always Detrimental to Transparent Conducting Oxides?

GUILLAUME BRUNIN (Presenter), GIAN-MARCO RIGNANESE, GEOFFROY HAUTIER, Universite catholique de Louvain — Transparent conducting oxides (TCOs) are critical components in many devices like solar cells or touchscreens. The search and development of new TCOs combining high conductivity and transparency is a major endeavor of modern Materials Science. Novel p-type TCOs are especially greatly sought for as they lie much behind their n-type counterpart and the discovery of a high performance p-type TCO would enable important technological breakthroughs. There are two types of carrier transport mechanism in materials: band transport involves delocalized carriers while small-polaron transport involves carriers trapped in the crystalline lattice. Materials exhibiting transport through small polarons have been traditionally disregarded for TCO applications as they offer small mobilities. In this work, we use well-established physical models to compare the performances of TCOs based on band- and small-polaron transports. Surprisingly, we demonstrate that small-polaron TCOs can outperform band TCOs in terms of transparency and conductivity, especially p-type. Using our analysis, we outline the materials properties necessary for high performance small-polaron TCOs, leading to a series of design principles for the search of new efficient small-polaron p-type TCOs.

Point charged defects in 2D and 3D h-BN: A density functional theory study

PRADIP NIRAULA (Presenter), ANGELO BONGIORNO, College of Staten Island — In this work, we first calibrated a density functional theory (DFT) approach, and then I carried out DFT calculations to study the properties of charged point defects in monolayer, bilayer, and bulk h-BN. In particular, we considered a DFT approach using a semiempirical scheme to account for Van der Waals forces, and we optimized the dispersive coefficient of B to obtain a description of the structural and mechanical properties of bulk h-BN in agreement with the experiments. The resulting optimized DFT scheme was used to calculate formation energies and electronic properties of neutral and charged B and N vacancies, as well as C substitutional defects for both N and B sites. To correct the formation energies of charged defects, we used a novel polarizable force field. Our calculations show that, due to electrostatic polarization, the formation energy of charged defects in bilayer h-BN is about 0.5 eV lower than in monolayer h-BN. Furthermore, we found that assuming that the aforementioned four types of point defects are present with a finite concentration in mono- and bi-layer h-BN, there is always a class of defects that is likely to be charged, regardless of the position of the Fermi level.

Is Defect Segregation Facile in the Grain Boundary of Methylammonium Lead Iodide?

XIN HE (Presenter), Jilin University, WISSAM SAIDI, University of Pittsburgh, LJUN ZHANG, Jilin University — Methylammonium Lead Iodide (MAPbI3) is emerging as one of the most promising materials for solar cells. Grain boundaries (GBs) and native point defects are ubiquitous in MAPbI3 given that solution-based methods generate polycrystalline materials. Our previous study has shown that there is a strong thermodynamic preference of iodine point defects to exist in the GB region rather than in the interior of the MAPbI3 grain [Shan and Saidi, J. phys. Chem Lett. 8, 5935 (2017)]. This would generate defect segregation to the GB, provided that defect diffusion is not hindered at room temperature. In this talk, we examine the energy barriers and possible kinetic limitations of the diffusion of iodine interstitials and vacancies in Σ5 (210) MAPbI3 GB, and contrast the results with their diffusion in crystalline system.

*Work at Jilin University is supported by National Natural Science Foundation of China under Grant Nos. 61722403 and 11674121.
G70.00307: Lone-pair electrons induced anomalous enhancement of thermal transport in strained planar two-dimensional materials GUANGZHAO QIN (Presenter), MING HU, University of South Carolina — Manipulating heat conduction is an appealing thermophysical problem with enormous practical implications, which requires insight into the lattice dynamics. Strain engineering is one of the most promising and effective routes towards continuously tuning the thermal transport properties due to the flexibility and robustness. However, previous studies mainly focused on quantifying how the thermal conductivity is affected by strain, while the fundamental understanding on the electronic origin has yet to be explored. In this talk, I would like to show that the thermal conductivity (κ) of planar monolayer group III-nitrides is unexpectedly enlarged by one order of magnitude with bilateral tensile strain applied, which is in sharp contrast to the strain induced κ reduction in graphene despite their similar planar honeycomb structure. The anomalous positive response of κ to tensile strain is attributed to the attenuated interaction between the lone-pair s electrons around N atoms and the bonding electrons of neighboring (B/Al/Ga) atoms, which reduces phonon anharmonicity. The microscopic picture for the lone-pair electrons driving phonon anharmonicity would have great impact on future research in materials design with targeted thermal transport properties.

G70.00308: Surface plasmon polariton excitation in exfoliated MoS2 flakes on Au nanogratings SOYEONG KWON (Presenter), MIN HEE KWON, JUNG EUN SONG, BO RA KIM, EUNAHAH KIM, SANG WOOK LEE, DONG WOOK KIM, Physics, Ewha Womans University — We prepared MoS2 flakes on Au nanogratings to investigate how the surface plasmon polariton (SPP) excitation can affect physical properties of MoS2. SPP – the propagating electromagnetic and charge wave at metal/dielectric interface – can be excited using grating structures by overcoming the momentum mismatch between the impinging photons and the SPPs. The MoS2 flakes were exfoliated from its bulk and transferred on the Au nanogratings (period: 500 nm) fabricated by electron beam lithography. The number of MoS2 layers was identified using micro-Raman and atomic force microscopy measurements. Finite-difference time-domain simulations showed clear signature of the SPP excitation in the electric field intensity distributions and optical reflection spectra of the Au nanogratings. The work function of the MoS2 flakes was measured using Kelvin probe force microscopy, and its variation in dark and light was studied to understand the interaction between the SPPs at the MoS2/Au interface and charge carriers in the MoS2 flakes. This study can help us to develop new kinds of 2D transition metal dichalcogenide semiconductor-based plasmonic devices.

G70.00309: Giant effect of spin-lattice coupling on the thermal transport in two-dimensional ferromagnetic CrI3 GUANGZHAO QIN, MING HU (Presenter), Department of Mechanical Engineering, University of South Carolina — Recently, two-dimensional monolayer chromium triiodide (CrI3) with intrinsic magnetism was experimentally discovered, which shows promising applications in many technologies ranging from sensing to data storage where thermal transport plays a critical role. However, so far, the effect of spin-lattice coupling on the thermal transport properties has not been explored yet. In this talk, I will present the giant effect of spin-lattice coupling on the lattice thermal conductivity (κL) of monolayer CrI3. The lattice thermal conductivity is more than two orders of magnitude enhanced by considering the spin-lattice coupling. The effect is found to be especially stronger for the acoustic phonon modes, which dominates thermal transport with spin-lattice coupling. The mechanism lies in the weakened phonon anharmonicity by spin-lattice coupling. The bond angle and atomic position are changed due to the spin-lattice coupling, making the structure much stiffer and more symmetric, which lead to the weaker phonon anharmonicity, and thus the enhanced thermal conductivity. This study uncovers the effect of spin-lattice coupling on the thermal transport, which would deepen our understanding on thermal transport and shed light on future research of thermal transport in magnetic materials.

G70.00310: Size and Substrate effect on excitation dynamics of 2D materials* SUBODH TIWARI (Presenter), University of Southern California, HIROYUKI KUMAZOE, SHOGO FUKUSHIMA, Kumamoto University, ARAVIND KRISHNAMOORTHY, University of Southern California, FUUYUKI SHIMOJO, Kumamoto University, RAJIV KALIA, AILICHIRO NAKANO, PRIYA VASHISHTA, University of Southern California — Excitation dynamics of 2D materials has been extensively studied by different theoretical and experimental methods. However, effect of substrate and size effect on the excitation dynamics of 2D materials has not been well delineated due to large number of atoms. We perform quantum molecular dynamics simulations at high electron temperatures within the density functional theory framework to understand the effect of substrate and size. We computed the intralayer mean square displacement and Debye-waller factor of top and bottom layer of WSe2. The simulation results show that interaction between substrate and transition metal dichalcogenide layers create distinct anisotropy in electronic excitation-induced lattice dynamics that may be experimentally observable.

*This work was supported as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, and Basic Energy Sciences, under Award Number DE-SC0014607. The simulations were performed at the Argonne Leadership Computing Facility under the DOE INCITE program and at the Center for High Performance Computing of the University of Southern California.
G70.00311: Ab-initio Study of Electronic Properties of Ti-doped VO₂ Nanowire* PRABAL BHUYAN (Presenter), Department of Physics, Gujarat University, Ahmedabad, India, SANJEEV K. GUPTA, Department of Physics, St Xavier’s College, Ahmedabad, India, YOGESH SONVANE, Department of Applied Physics, SV National Institute of Technology, Surat, India, P. N. GAJJAR, Department of Physics, Gujarat University, Ahmedabad, India — Vanadium oxide (VO₂) nanowire undergoes a phase transition at 341K and shows metal-insulator transition (MIT). We have considered high-temperature VO₂-NW structure, which is stable in rutile form. The state of art density functional calculation has shown metallic in VO₂ (R) rutile structure nature. Further, we have investigated the doping effect of Ti substitution for V in VO₂-NW. A transition of metallic to semiconducting behaviour is observed by the presence of Ti-3d orbital and it is also confirmed by the partial density of states (PDOS) that contribution of Ti-3d orbital near the Fermi level at conduction band. We have observed band gap of 1.83eV, however band gap decreases with the increase in Ti concentration. Furthermore, Ti-doped VO₂-NW shows adsorption energy at visible region, which attributes to its potential application in nano-optoelectronic devices.

*Prabal Dev Bhuyan would like to thank Science and Engineering Research Board (SERB), India for financial support (Grant no.: YSS/2015/001269).

G70.00312: Lithium adsorption and diffusion on Janus Mo/WXY (X,Y = S, Se, Te) GRACIE CHANEY (Presenter), FATIH ERSAN, CAN ATACA, University of Maryland, Baltimore County — One of the most important factors in improving the efficiency of anode materials for Li-ion batteries is the mobility of Lithium atoms in these materials. On the basis of first-principles plane-wave calculations, we examined the adsorption and diffusion of lithium atoms on the hexagonal Janus Mo/WXY (X,Y=S, Se and Te) monolayers. We found the lowest energy adsorption positions of the Li adatom to be on the top site of the transition metal atom, on both sides of all considered Janus monolayers. Due to electronegativity differences of the chalcogenides in the Janus structures and induced dipole moment, both the Li adatom adsorption and the diffusion barrier energies on the surfaces of Janus structures differ from the bare Mo/WX₂ monolayers. For instance, Li diffusion barrier energy for the Tellurium sides of the Mo-Janus structures are about 0.09-0.12 eV lower than that of MoTe₂ monolayers which is 0.23 eV. Also, Li diffusion barrier energy on the Sulfur sides of the Mo-Janus monolayer is about 0.04-0.08 eV larger than its MoS₂ energy value. All considered structures turn to metal after Li atom absorption. Our electronic transport calculations concluded inn an increase in conductivity. This makes them superb candidate materials for the electrodes of Li-ion batteries.

G70.00313: WITHDRAWN ABSTRACT —

G70.00314: Electronic structure and optoelectronic properties of 4',5'-dibromo-2',7'-dinitro-3-oxo-3H-spiro[2-benzofuran-1,9'-xanthene]-3',6'-dialate JEAN BAPTISTE FANKAM FANKAM (Presenter), Physics, University of Yaounde I — The molecular structure, electric parameters and optoelectronic properties of 4',5'-dibromo-2',7'-dinitro-3-oxo-3H-spiro[2-benzofuran-1,9'-xanthene]-3',6'-dialate have been theoretically studied. We used the RHF and DFT (PBE1PBE, MPW1PW91, B3PW91 and B3LYP) approach to calculate the optimized parameters, molecular structure, electric parameters and optoelectronic properties of the tilted compound with cc-pVDZ basis set. The larger the HOMO-LUMO energy gap, the harder and more stable (less reactive) the compounds. The lowest value (3.78eV) is shown in B3LYP is most stable and the highest value (8.81eV) in RHF is least stable. The effect of correlation decreased the value of HOMO-LUMO energy. Our results suggest that this molecule have potential applications as linear and nonlinear optical materials. Due to the large hyperpolarizability of this molecule, we think that these molecules have potential applications in thoptoelectronic and can be a promising material for optical limiting applications.
G70.00315: High-accuracy large-scale DFT calculations using localized orbitals in complex electronic systems: The case of graphene-metal interfaces*  CARLOS ROMERO-MUÑIZ (Presenter), Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, AYAKO NAKATA, National Institute for Material Science (NIMS), PABLO POU, Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, DAVID R BOWLER, Physics & Astronomy, University College London, TSUYOSHI MIYAZAKI, National Institute for Material Science (NIMS), RUBEN PEREZ, Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid — Over many years, computational simulations based on Density Functional Theory (DFT) have been used extensively to study many different materials at the atomic scale. However, its application is restricted by system size, leaving a number of interesting systems without a high-accuracy quantum description. In this work, we calculate the electronic and structural properties of a graphene-metal system significantly larger than in previous plane-wave calculations with the same accuracy. For this task we use a localized basis set with the Conquest code, both in their primitive, pseudo-atomic orbital form, and using a recent multi-site approach [1]. This multi-site scheme allows us to maintain accuracy while saving computational time and memory requirements, even in our exemplar complex system of graphene grown on Rh(111) with and without intercalated atomic oxygen. This system offers a rich scenario that will serve as a benchmark, demonstrating that highly accurate simulations in cells with over 3000 atoms are feasible with modest computational resources.

G70.00316: GTPack: A Mathematica group theory package for application in solid-state physics and photonics*  RICHARD GEILHUFE, Nordic Institute for Theoretical Physics, KTH Royal Institute of Technology, Stockholm University, WOLFRAM HERGERT (Presenter), Martin-Luther University Halle-Wittenberg — We present the Mathematica group theory package GTPack providing about 200 additional modules to the standard Mathematica language. The content ranges from basic group theory and representation theory to more applied methods like crystal field theory, tight-binding and plane-wave approaches capable for symmetry based studies in the fields of solid-state physics and photonics. GTPack is freely available via http://gtpack.org. The package is designed to be easily accessible by providing a complete Mathematica-style documentation, an optional input validation and an error strategy. We illustrate the basic framework of the package and show basic examples to present the functionality.

G70.00317: Band structure theory of twisted bilayer graphene  XING-JU ZHAO (Presenter), DONG-BO ZHANG, Simulation of Physical Systems Division, Beijing Computational Science Research Center — Twisted bilayer graphene show various interlayer interaction under different rotation angles, which make the system presents nontrivial physical properties, such as unconventional quantum hall effect and berry's phase, correlated insulator behaviour and unconventional superconductivity in magic angle graphene superlattice, et al. However, when the rotation angle is small, the electronic structure, such as band, can’t be simulated by the first-principles method. In this project, combine tight-binding method and first-principles simulation, we construct interlayer Hamiltonian matrix element and improve the effective continuum model in band structure theory. Based on this, we construct the wavefunction of each layer in superlattice and then build the Hamiltonian matrix, which further simplify the band structure theory model. Finally, we extend this model to other 2D bilayer systems. The success implementation of this project will construct a simple, cheap and general method for band structure simulation of twisted bilayer graphene, and provide a useful tool for the relative physical effects study of 2D bilayer materials.
G70.00318: Is self-interaction corrected density functional theory straying from the path toward the exact functional? SEBASTIAN SCHWALBE, TORSTEN HAHN, JENS KORTUS, Theoretical Physics, TU Bergakademie Freiberg, KAI TREPTÉ (Presenter), KOBLAR ALAN JACKSON, Physics, Central Michigan University — As recently pointed out [1] higher rung functionals (e.g. MGGA or hybrids) may deliver a better description of the total energy but not necessarily a better description of the density for the calculated systems. We present an additional perspective to this discussion and present the performance of self-interaction corrected densities for LDA, GGA and MGGA rungs of density functionals for an extended benchmark set considering atoms, molecules and stretched bond situations.

G70.00319: Strong correlation effect on the Seebeck coefficient from Density Functional Theory* ROBERTO D’AGOSTA (Presenter), University of the Basque Country, KAIKE YANG, Chinese Academy of Science, ENRICO PERFETTO, GIANLUCA STEFANUCCI, University of Rome “Tor Vergata”, STEFAN KURTH, University of the Basque Country — Density Functional Theory (DFT) has become the standard for transport calculations due to its simplicity and widespread implementations. It has been shown that the theory fails, especially when dealing with strongly correlated systems. The standard approximations associated with the theory are the culprit for most of these failures, but we should also realize that static DFT should not deal with transport problems. In this talk, we will discuss how to build a DFT theory that is able to describe strongly correlated effects [1]. In particular, we will discuss the correction for the Seebeck coefficient in the Coulomb blockade regime in a quantum dot in linear response [2]. We will show how the theory can compare with experiments and outline future research lines to extend the methods beyond linear response.

G70.00320: ABSTRACT WITHDRAWN —

G70.00321: Self-Interaction Error Free Magnetic Exchange Couplings: LSDA vs PBE vs SCAN.* RAJENDRA JOSHI (Presenter), KOBLAR ALAN JACKSON, JUAN ERNESTO PERALTA, Department of Physics and Science of Advanced Materials, Central Michigan University, Mt. Pleasant, MI, 48858 — We analyze the effect of self-interaction error removal from density functional theory on magnetic exchange couplings using Fermi-Lowdin orbital self-interaction correction (FLOSIC) methodology. We compare self-interaction corrected LSDA, PBE, and SCAN exchange couplings to the respective uncorrected ones and to more accurate quantum chemistry calculations and experiments. In addition, we discuss the effect of spin projection on magnetic exchange couplings.

*We acknowledge the financial support from U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under award #DE-SC0001330.

G70.00322: Crossover Behavior of Entanglement Entropy for Energy Eigenstates of 1d and 2d Fermionic Systems QIANG MIAO (Presenter), THOMAS BARTHEL, Department of Physics, Duke University — The entanglement entropy in ground states of typical condensed matter systems obeys the area law or a log-area law for critical systems. Subsystem entropies in random and thermal states obey a volume law. Here, we discuss the distribution of entanglement entropy in energy eigenstates of quasi-free fermionic systems as a function of energy and subsystem size. Numerical results are obtained with a Monte Carlo approach. We characterize the crossover behavior from the area or log-area law in the vicinity of the ground state and for small subsystem size to the volume law at higher energy and larger subsystem size. The coefficients of the volume law scaling can be matched to entropy densities in equilibrium thermal ensembles. For critical 1d systems at low energies, the universal crossover function matches the prediction from 1+1d conformal field theory for systems at nonzero temperatures. For 2d systems, we find a similar crossover behavior.
**G70.00323: Large N Tensor and SYK Models**  
JAEWON KIM (Presenter), University of California, Berkeley, IGOR R KLEBANOV, Physics, Princeton University — The SYK model consists of Majorana fermions that interact randomly four at a time. A holographic dual may exist for this model, which makes it interesting in the study of quantum gravity. It has been found that the SYK model is similar to large N tensor models: in both models, only the melonic diagrams survive in the large N limit. In this paper, we explore the large N tensor model with O(N)^3 symmetry containing two flavours of Majorana fermions in the fundamental representation, the quartic Hamiltonian of which depends on a real parameter. We derive the kernels of the four point functions. With these, we calculate the scaling dimensions of several types of conformal primaries. We also find a duality relation between two Hamiltonians of different real parameters. This is not a perfect duality, because the normalization of energy scales with the transformation. Nevertheless, the ratios of the energies are the same, and the operator dimensions are preserved. Last, for real parameters > 1 or < 0 the scaling dimensions of one of the conformal primaries become complex, rendering the model unstable.

**G70.00324: Molecular dynamics simulation for collective phenomena in collisionless plasmas**  
RYUSUKE NUMATA (Presenter), YUTARO IKEHATA, University of Hyogo — Plasmas are constituted of many charged particles interacting via the long range Coulomb force, and exhibit various collective phenomena. To describe plasma dynamics, we usually utilize some theoretical models, such as fluid models, or kinetic models, depending on the scale we are focusing on. Those theories are developed by employing some coarse-graining assumptions. However, essentially, plasma dynamics can be understood by individual particle dynamics. Particle based simulations for macroscopic plasma dynamics are still computationally demanding, yet they become feasible (eg. [1]) thanks to the rapid growth of computation technology and simulation techniques.

In this work, we develop a molecular dynamics simulation code for collisionless plasmas using FDPS [2] (a framework for developing parralel particle simulation codes). The aim of this study is to demonstrate collective phenomena in plasmas, such as Debye shielding, waves, and Landau damping, from the first principle. This code will provide a useful tool to study multiscale nature of plasmas.

**G70.00325: The von Neumann and Double Slit Paradoxes Lead to a New Schrödinger Wave Mathematics**  
JEFFREY BOYD (Presenter), Retired — John von Neumann states a paradox. Why does measuring something disrupt the smooth Schrödinger wave, causing it to collapse for no mathematical reason? This paradox is embedded in the double slit experiment. When a dot appears on the target screen, how does that cause the Schrödinger wave to collapse everywhere else, faster than the speed of light? Von Neumann didn't follow his mathematics to its logical conclusion. If wave function collapse irreversibly changes reality, then the math is telling us that the timing and location of that event cannot be at the target screen. An event fitting that description happens only once: at the gun. A gunshot CAN change history. We propose a new mathematics of Schrödinger waves. Zero energy waves from the target screen pass backwards through the double slits and impinge on the gun prior to the gun firing. A particle randomly chooses one to follow backwards. The particle's choice of wave is proportional to the amplitude squared of that wave at the gun, determined by the superposition of the two waves moving backwards through the two slits. Why follow a wave of zero energy? Because Schrödinger waves convey amplitudes determining the probability density of that path.

**G70.00326: Effect of Electron-electron Scattering on Linear Conductivity for Graphene-like Band Structure**  
FERESHTEH MEMARIAN (Presenter), University of California, Merced, BEN YU-KUANG HU, Physics, University of Akron — We study theoretically the effect of electron-electron scattering on the electrical conductivity of two-dimensional materials with linear bands such as graphene, both with and without a perpendicular magnetic field. The Boltzmann transport equation was utilized, where phonon and impurity scattering are modeled using the relaxation-time approximation. In graphene-like materials with linear bands, for a constant relaxation time, the conductivity decreases as the temperature increases from absolute zero. Furthermore, in linear band materials, the electron-electron scattering also decreases the conductivity. This is in contrast to parabolic band materials, where the conductivity for a constant relaxation time does not depend on temperature or the electron-electron scattering rate. We also investigate the magneto-conductance for linear band materials in the absence and presence of electron-electron scattering.
G70.00327: Efficient Calculation of Lattice Thermal Conductivity by Molecular Dynamics Simulation: Role of Isobaric-Isothermal Relaxation and Potential Cutoff Distance

SANGWOO KWON (Presenter), WON BO LEE, Seoul National University — This work studied the Green-Kubo approach of calculating thermal conductivity with molecular dynamics (MD) simulation. In MD lattice thermal conductivity calculation, zero-pressure volume relaxation in the isobaric-isothermal (NPT) ensemble which determines lattice parameters, is often not included in standard procedure. Several MD simulations of fcc-based structures with different lattice parameters were performed to calculate lattice thermal conductivity and phonon density of states. The results were compared to experimental references and ab initio datas to suggest that NPT relaxation is crucial for accurate thermal conductivity calculation. Moreover, dependency between potential cutoff and lattice thermal conductivity in MD simulation was also studied. The results suggested that lattice thermal conductivity is not strictly dependent on potential cutoff distance, but exactly function of lattice parameters given by NPT relaxation. We concluded that properly reducing the cutoff distance can greatly improve computation cost of thermal conductivity calculation without sacrificing the accuracy.

G70.00328: Electronic Band Structure of ZnO, CdO, MgO and related alloys

NICK BOECKER (Presenter), MACK ADRIAN DELA CRUZ, GARY PENNINGTON, Physics, Towson University — The electronic band structure of rocksalt CdO, ZnO, MgO and their ternary alloys are investigated using the empirical pseudopotential method and the virtual crystal approximation. This method is computationally efficient and highly advantageous when the band structure is needed on a very fine k-space mesh. A nonlocal pseudopotential correction with l = 2 symmetry is included for CdO and ZnO to account for the interaction between d and p electrons known in these materials. Additionally, an alloy compositional disorder potential term is included. Results are shown to agree well with known experimental band gap and band spacing energies. The cross over between direct and indirect minimum band gaps along with the conduction and valence band effective masses is studied for CdO, ZnO, MgO and their ternary alloys. Results have potential applications in optoelectronic devices.

*We acknowledge support from NSF grant DMR 1709781 and the Fisher General Endowment grant from the Jess and Mildred Fisher College of Science and Mathematics at Towson University.

G70.00329: Nonequilibrium Electric Current-induced Phonon Distribution in Microscale Metallic Structures

GUANXIONG CHEN (Presenter), SERGEI URAZHDIN, Emory University — The downscaling of modern electronic circuits places an increasing demand on the efficiency of heat dissipation. Electric current-induced heating is generally described in terms of Joule heating – an increase of phonon temperature due to the scattering of electrons on impurities and phonons. We experimentally demonstrate that this interpretation is not universally applicable to microscopic metallic structures. We study the current-dependent resistance R(I) in Pt nanowires. For a 7 μm-long nanowire, we observe a parabolic dependence R(I) at all temperatures T=5 K – 295 K, consistent with the Joule heating. A 1 μm-long nanowire exhibits a similar dependence at T=295 K. In contrast, we observe a singular piecewise-linear dependence at 5 K. As consequence, current-induced resistance increase is much larger than expected from Joule heating at small I, but smaller at large I. The linear dependence persists at modestly increased temperatures, but the singularity becomes broadened, reminiscent of common spectroscopic effects. Our observations are consistent with the non-thermal phonon distribution produced by electron scattering on impurities. The demonstrated effects provide an approach to characterizing and controlling thermal energy dissipation mechanisms.

*DOE grant DE-SC2218976
G70.00330: Ionization energies and excited state lifetime of charged defects in Two-dimensional Materials*  
YUAN PING (Presenter), TYLER SMART, Department of Chemistry and Biochemistry, University of California Santa Cruz, MARCO GOVONI, Institute for Molecular Engineering and Materials Science Division, Argonne National Laboratory, FENG WU, Department of Chemistry and Biochemistry, University of California Santa Cruz — Defects in 2D materials such as ultrathin h-BN have been found to be promising candidates for single-photon emitters and quantum bits. However, first-principles prediction of accurate defect properties in 2D materials remains challenging, mainly because of the highly anisotropic dielectric screening and strong many body interactions in 2D materials. In our previous work[1], we solved the numerical convergence issues for defect charge transition levels in 2D materials at both DFT and many body perturbation theory (MBPT) levels; in this talk we will compare different levels of theory and propose the fundamental principles to obtain reliable ionization energies of charged defects in 2D materials. Next, we will show preliminary results of radiative exciton recombination lifetime based on MBPT and phonon-assisted non-radiative recombination lifetime of defects in 2D materials. We compared different recombination processes between defect-defect and defect-band edge states for complex defects in monolayer BN. With our methods, we will design promising quantum defects that have deep defect levels, weak electron-phonon coupling and long excited state lifetime. [1] F. Wu et al, Phys. Rev. Mater. 1, 071001(R), (2017)

G70.00333: Ab-initio study of new, correlated color pigments*  
ANNA GALLER (Presenter), SILKE BIERMANN, Centre de Physique Théorique, Ecole Polytechnique — Conventional color pigments used in plastics, ceramics, paint or coatings often contain toxic heavy metals. Recently, the search for non-toxic and environmentally-benign alternatives has led to the experimental discovery of several new pigments, among them blue Y11-xMnxO3 and several rare-earth fluorosulfides. Here, we present first results of a theoretical study of these compounds by means of combined density functional and dynamical mean-field theory.

*FWF - Fonds zur Förderung der wissenschaftlichen Forschung (Austria)
G70.00334: Structural, vibrational, electrical and optical properties on Cr-doped LaAlO$_3$* ROMUALDO SANTOS SILVA JUNIOR, RAFAEL SILVA GONÇALVES, PETRUCIO BARROZO DA SILVA (Presenter), Physics Department, Federal University of Sergipe — The oxides with perovskite-type structure have been largely studied in last decades. This classes of materials show a large variety of properties such as ferroelectricity, superconductor, multiferroic, transparent conductor oxides among other properties. The perovskite compound LaAlO$_3$ has been used as a substrate in many applications. The high dielectric constant observed in this compound is ideal to reduce the loss of energy in devices working at high frequency. In this work, we will report the structural, vibrational, electric and optical of Cr-doped LaAlO$_3$ ceramics produced by combustion method. We observe a structural phase transition from rhombohedral to an orthorhombic structure with the increase of the Cr amount. It was possible to observe a reduction of the optical bandgap as well as a reduction of the resistivity of the compound. The Raman spectrum as a function of temperature reveals the nature of the structural transition in this compound. The change of the Cr amount can be used to produce new color pigments range from orange/yellow to green/blue.

*Thanks to Brazilian fund agencies CNPq and CAPES

G70.00335: Molecular influence on dynamic stiffening of synthetic polyurethanes through laser-induced supersonic microscale impact tests* YUCHEN SUN (Presenter), Chemistry, MIT, DAVID VEYSSET, Institute for Soldier Nanotechnologies, MIT, YOU-CHI MASON WU, Chemistry, MIT, ALEX J HSIEH, US Army Research Laboratory, RDRL-WMM-G, STEVEN E KOOI, Institute for Soldier Nanotechnologies, MIT, A A MAZNEV, Chemistry, MIT, JAN W ANDZELM, US Army Research Laboratory, RDRL-WMM-G, TIMOTHY M SWAGER, KEITH ADAM NELSON, Chemistry, MIT — High-strain-rate response is an important characteristic of protective elastomers. To discern the molecular influences on dynamic stiffening in polyurethane (PU), we synthesized two-component PUs from poly(tetramethylene oxide) (PTMO) and either hexamethylenediisocyanate (HDI) or 4,4'-methylenediphenyldiisocyanate (MDI). From dynamic mechanical analysis, HDI-PU displays semicrystallinity while MDI-PU appears amorphous. We also synthesized three-component PUs with the chain extender butanediol (BD) to introduce segmented hard domains. We performed supersonic microscale impacts with a laser-induced particle impact test in which a silica microsphere is accelerated up to ~1000 m/s. The impact is recorded with micron spatial resolution and nanosecond temporal resolution on an ultra-high-speed camera. In a velocity range of 50 to 1000 m/s, we show that MDI-PU exhibits greater dynamic stiffening than HDI-PU. We hypothesize that greater intermolecular hydrogen bonding in MDI-PU plays an important role. Finally, we discuss the role of segmented hard domains in dynamic stiffening of polyurethanes.

*This material is based upon work supported in part by the U. S. Army Research Office through the Institute for Soldier Nanotechnologies, under Cooperative Agreement Number W911NF-18-2-0048.

G70.00336: Anomal behavior of tellurium under pressure JAIME OLIVEIRA, Centro Brasileiro de Pesquisa Física, Rio de Janeiro, Brasil, MARCUS MOUTINHO, CARSTEN ENDERLEIN, Campus de Duque de Caxias, UFRJ, Rio de Janeiro, Brasil, ELISA BAGGIO-SAITOVOITCH (Presenter), Centro Brasileiro de Pesquisa Física, Rio de Janeiro, Brasil — Elemental tellurium is a small bad-gap semiconductor with a unique chiral crystal structure and a spin texture of the valence bands, which allows in-parallel current-induced magnetization of p-doped samples. Under pressure the band gap narrows and the structure of the valence band changes from a narrow camel-back close to the H-point to a single maximum with radial spin texture. Here, we present a theoretical and experimental study of the low-temperature behavior of the chemically extremely pure, but doped by vacancies, tellurium under pressure. We identify an anomaly at low temperatures, which is related to the orbital structure of the vacancy states and the respective spin texture. The pressure induced change of the valence band leads to the emergence of a change of the orbital structure of the vacancies, effectively leading to an exotic quantum critical point. At one side of the transition strong weak antilocalization is observed, which is consistent with our DFT-calculations, which show a change in spin texture.
G70.00337: Structural and dynamic properties of Fe\((1-x)S_x\) melts at core conditions* ALDEMAR DE MOYA CAMACHO (Presenter), Ciencias Naturales y Exactas, Universidad de la Costa, GUILLAUME MORARD, Institut de Minérologie, de physique de Matériaux, et de Cosmochimie, Sorbonne Université, CARLOS PINILLA, Universidad del Norte, Colombia — Earth’s core is subjected to conditions of 320-350 GPa and 5000-6500 K. The core is lighter than the density of pure iron by around 5% to 10%. In addition, the density jump between inner and outer core is 4.5%, being too large to be explained by simple solid-liquid phase transitions. Because of this, it has been suggested that the outer and inner core contain a percentage of light elements (5-10wt% and 2-3wt% respectively). These light elements affect processes from core’s dynamics to recrystallization of the inner core. One of the candidates to be part of the core is Sulphur. In this work, we used \(ab-initio\) Molecular Dynamic methods to study structural and dynamical properties of liquid Fe\((1-x)S_x\) alloys with S concentrations from 5.8 to 16wt%. We looked at the behavior of structural properties as a function of \(x\), \(P\) and \(T\) as well as to provide information on diffusion and viscosity coefficients. A P-V-T equation of state for melts whose S concentration falls within 5-10wt% is reported. We find density values in agreement with other theoretical and experimental results and show that concentrations between 10-12wt% of S agree with the densities expected for the outer core.

*COLCIENCIAS through grant No. 121571051568 contract 023-2016

G70.00338: Anisotropy in shock compression of different polymorphs of SiC* NILANJAN MITRA (Presenter), DIPAK PRASAD, Indian Institute of Technology Kharagpur — High hardness and melting point makes SiC an important ceramic material having wide application in defense industry. Typically, SiC utilized for armor and or other applications in defense is a polycrystal having different polymorphs and with numerous defects and thereby the properties of these materials have significant scatter. It can be quite anticipated that the response of the polymorphs of SiC exhibit significant differences in response. In this study anisotropy in shock Hugoniot response of SiC is shown not only amongst the different polymorphs but also between different orientations of the same polymorph. It is expected that this molecular dynamic study will lay the fundamental grounds explaining the scatter is experimental observations of SiC under different loading conditions. However, it should be noted that the study is only limited to considering pristine single crystal materials with no defects.

*None

G70.00339: Kinetic Monte Carlo Simulation of Oxygen Diffusion in Yttrium Monosilicate BRIAN GOOD (Presenter), NASA Glenn Research Center — Ceramic Matrix Composite (CMC) materials are of interest for use in next-generation turbine engines, offering a number of significant advantages, including reduced weight and high operating temperatures. However, in the hot environment in which such components operate, the presence of water vapor can lead to corrosion and recession, limiting the useful life of the components. Such degradation can be reduced through the use of Environmental Barrier Coatings (EBCs) that limit the amount of oxygen and water vapor reaching the component. Candidate EBC materials include Y and Yb mono- and disilicates. In order to better understand the diffusion of oxygen in such coatings, kinetic Monte Carlo computer simulations are performed for vacancy mechanism oxygen diffusion in Y monosilicate. Oxygen vacancy formation energies and migration barrier energies are computed using density functional theory, showing that all reasonably short migration paths involve relatively large barrier energies. In addition, the vacancy formation energies are relatively large as well, indicating that intrinsic vacancy concentrations will be small, leading to the conclusion that oxygen permeation associated with vacancy-mechanism oxygen diffusion will be small in this material.

G70.00340: An Atomistic Study of the Incorporation and Diffusion of Noble Gases in Silicate Minerals* CARLOS PINILLA (Presenter), ALFREDO LORA, Physics and Geosciences, Universidad del Norte, NEIL ALLAN, Chemistry Department, University of Bristol — Trace elements are widely used to unravel magmatic processes and constrain the chemical differentiation of the Earth. Central to this enterprise is understanding the controls on trace element fractionation between solid and liquid phases and thus the energetics of incorporating trace elements into crystals. In this contribution we focus on the incorporation of noble gases into crystals. We use \(ab-initio\) simulations to study the uptake of noble gases (He, Ne, Ar) into solid silicates. We calculate defect energies of incorporation both at vacancies and at interstitial positions in the solid and use these energies to estimate the total uptake of the noble gases into the crystal as a function of temperature. Such concentrations are found to be very low \((10^{-3} \text{ and } 10^{-10} \ \text{ppm})\) for He up to Ar respectively with the noble gases incorporated predicted to be more favorable at intrinsic vacancies or interstitials sites. We also look at the diffusion of these elements within the lattice and estimate activation energies for such processes. Our results support the hypothesis that noble gases have very low solubilities in bulk solid minerals.

Complicated diffusions of dense hydrogen in accurately predicted liquid-liquid phase transition

JIAYU DAI (Presenter), ZENGXIU ZHAO, National University of Defense Technology, Department of Physics — We present results of extensive calculations of the liquid-liquid phase transition (LLPT) in dense liquid hydrogen by path-integral molecular dynamics simulations. The satisfactory nonlocal density functional rVV10 and the hybrid functional PBE0 are used to improve the description of electronic structure of hydrogen. Within density functional theory calculations, we report the best consistent results to the quantum Monte Carlo and coupled electron-ion Monte Carlo results so far of the LLPT in dense liquid hydrogen. The critical point at temperature between 1500 K and 2000 K is estimated according to the equation of state. Interestingly, we find that the self-diffusion coefficients of dense liquid hydrogen exhibit complicated behaviors in the vicinity of the transition point, which can be used as a criterion to diagnose the phase transition, and the first-order LLPT and metallization of dense hydrogen do not occur simultaneously.

WITHDRAWN ABSTRACT

A Stochastic approach to thermal DFT

YAEL CYTTER (Presenter), Chemistry, Fritz Haber Center for Molecular Dynamics, Hebrew University of Jerusalem, Israel, DANIEL NEUHAUSER, Department of Chemistry and Biochemistry, University of California Los Angeles, USA, ERAN RABANI, Chemistry, University of California and Lawrence Berkeley National Laboratory, USA, ROI BAER, Chemistry, Fritz Haber Center for Molecular Dynamics, Hebrew University of Jerusalem, Israel — Despite progress in observational astronomy, some elements such as the internal composition of planets are still not well-understood. A root cause is our limited understanding of matter under extreme conditions (MEC) - pressures in the GPa-TPa range and temperatures (T) up to $10^5$ K. Due to the difficulty in preparing MECs, the experimental input is limited, and ab initio calculations are sometimes the only source of information. The Kohn-Sham density functional theory (KS-DFT) seems as a reliable and useful tool for obtaining information on MEC. Calculations in finite temperatures, however, are expensive due to the large number of fractionally occupied KS orbitals involved. A stochastic method developed recently\cite{1},\cite{2}, appears to be a fitting approach to this problem. By performing a stochastic trace, the KS Hamiltonian is directly obtained from the density, resulting in a scaling of $T^{-1}$.

I will introduce the convergence and errors involved in calculations of the canonical free energy. In addition, a stochastic approach to calculate the Kubo-Greenwood conductivity will be presented.

External Electric Field Driving the Ultra-low Thermal Conductivity of Silicene

GUANGZHAO QIN (Presenter), MING HU, University of South Carolina — Manipulation of thermal transport (pursuing ultra-high or ultra-low thermal conductivity) is on emerging demands, since heat transfer plays a critical role in enormous practical implications, such as efficient heat dissipation in nano-electronics and heat conduction hindering in solid-state thermoelectrics. It is well established that the thermal transport in semiconductors and insulators (phonons) can be effectively modulated by structure engineering or materials processing. However, almost all the existing approaches involve altering the original atomic structure, which would be frustrated due to either irreversible structure change or limited tunability of thermal conductivity. Motivated by the inherent relationship between phonon behavior and interatomic electrostatic interaction, we comprehensively investigate the effect of external electric field, a widely used gating technique in modern electronics, on the lattice thermal conductivity ($k$). Taking two-dimensional silicon (silicene) as a model system, we demonstrate that, by applying electric field ($E_z = 0.5 \, \text{V/Å}$) the thermal conductivity of silicene can be reduced to a record low value of $\sim 0.091$ W/mK. Our study paves the way for robustly tuning phonon transport in materials without altering the atomic structure.

QUANTUM INFORMATION, CONCEPTS, AND COMPUTATION
**G70.00346: Yield Analysis of Superconducting Qubit Fabrication in KRISS**

GWANYEOL PARK (Presenter), Korea University Sejong Campus & KRISS, JIMAN CHOI, University of Science and Technology (UST) & KRISS, GAHYUN CHOI, Ulsan National Institute of Science and Technology (UNIST), SOON-GUL LEE, Korea University Sejong Campus, KIBOG PARK, Ulsan National Institute of Science and Technology (UNIST), WOON SONG, Korea Research Institute of Standards and Science (KRISS), YONUK CHONG, Korea Research Institute of Standards and Science (KRISS) & UST — In order to achieve scalable quantum circuits, large-scale qubit fabrication capability is essential. We have been working on superconducting transmon qubits, and in this study we will present our process' yield analysis on our wafer-scale qubit fabrication. Our qubit fabrication uses 3 inch wafers, either sapphire or silicon, and tunnel junctions are made by two-angle evaporation using the Dolan bridge. We checked the tunnel resistances on the wafer at room temperature and we typically get 5 to 6% standard deviation across the wafer. For targeting, we usually get resistance within 10% of the target value. We also have a couple of outliers on the wafer, typically less than 5 out of ~100 junctions, in which we need improvements. There are many control parameters to improve the yield and spread, so in the end we will discuss the substrate cleaning, e-beam patterning, deposition and oxidation conditions, which are to be controlled tightly in order to get a robust large scale fabrication process of the Josephson junctions.

*This research was supported by the R&D convergence Program of NST (National Research Council of Science and Technology) of Republic of Korea (Grant No. CAP-15-08-KRISS).

**G70.00347: Superconducting qubit-qutrit circuit: A toolbox for efficient quantum gates**

THOMAS BÆKKEGAARD (Presenter), LASSE BJØRN KRISTENSEN, NIELS JAKOB LOFT, Department of Physics and Astronomy, Aarhus University, CHRISTIAN KRAGLUND ANDERSEN, Department of Physics, ETH Zurich, DAVID PETROSYAN, Institute of Electronic Structure and Laser, FORTH, NIKOLAJ T ZINNER, Department of Physics and Astronomy, Aarhus University — We propose a superconducting circuit which implements an effective tunable spin chain consisting of a qutrit (three-level system) coupled to two qubits (spin-1/2). In our paper [1] we show the derivation leading to an effective spin-model system which has highly tunable qutrit energy levels and Heisenberg XXZ-like interactions between the three effective degrees of freedom.

Our system can very efficiently accomplish various quantum information tasks, including entanglement of the two qubits and conditional three-qubit quantum gates such as the Toffoli and Fredkin gates. Furthermore, our system realizes a double-conditional non-adiabatic holonomic quantum gate.

The efficiency, robustness, and universality of our circuit makes it a promising candidate to serve as a building block for larger spin networks capable of performing involved quantum computational tasks.

We are currently working on a system implementing two qutrits, realizing an effective AKLT spin model.

*Supported by the Carlsberg Foundation and the Danish Council for Independent Research under the DFF Sapere Aude program.

**G70.00348: Enhancement in the cross-resonant gate performance**

XUEXIN XU (Presenter), MOHAMMAD H. ANSARI, Peter Grünberg Institute, Forschungszentrum Julich — In this poster we describe how the performance of two qubit gates in a superconducting circuits made of capacitive shunted flux qubits and transmons sharing interaction with a bus resonator, can get boosted up as the direct result of capacitive direct coupling between the qubits. For this aim we consider circuit parameters that allow small capacitive coupling between qubits and after quantizing the circuit Hamiltonian within the dispersive regime we make comparison the gate performance with a typical all transmon circuit.
G70.00349: Hole spins in Ge/Si nanowires  FLORIAN NM FRONING, MIRKO REHMANN, Physics, University of Basel, J RIDDERBOS, Physics, University of Twente, MATTHIAS BRAUNS, Physics, Institute of Science and Technology, FLORIS ZWANENBURG, Physics, University of Twente, ANG LI, Physics, Beijing University of Technology, ERIK P. A. M. BAKKERS, Physics, TU Eindhoven, DOMINIK ZUMBUHL, FLORIS BRAAKMAN (Presenter), Physics, University of Basel — Single hole spins confined in quantum dots (QDs) in Ge/Si core/shell nanowires (NWs) combine several properties which make them potentially very unique qubits. The natural abundance of non-zero nuclear spins in both Si and Ge is small and can be further reduced to a negligible amount by isotopic purification. Furthermore, hole spins have no contact hyperfine interaction due to their p-type wavefunction. These properties make hole spin qubits in Si and Ge resilient against dephasing via interaction with nuclear spins.

A particularly promising feature of hole spins in Ge/Si core/shell NWs is the nature of spin-orbit interaction (SOI) in this system. Confinement to one dimension gives rise to an SOI in the valence band, which is predicted to be both strong and electrically tunable. This promises electrical gating of the SOI, allowing to switch to a large SOI for high interaction strengths and fast quantum operations, or to turn off SOI for increased qubit coherence.

We demonstrate and characterize single, double and triple QD arrays in Ge/Si NWs, all with low hole occupation numbers. In the double QD configuration, we observe Pauli spin blockade and see indications of a sizeable SOI causing spin flips. Finally, we report progress towards electrically tuning the SOI.

G70.00350: Emission of entangled photons via the biexciton formation and decay in core/shell nanoplatelets  MATTHEW OTTEN, XUEDAN MA, CNM, Argonne National Lab, PATRICK SERAFIN, GERMAN KOLMAKOV (Presenter), Physics, New York City College of Technology, STEPHEN K GRAY, CNM, Argonne National Lab — Quasi-two-dimensional nanoplatelets (NPLs) possess fundamentally different excitonic properties from zero-dimensional quantum dots including exceptionally narrow spectral features and large lateral carrier mobility. We numerically study carrier dynamics of individual CdSe/CdS NPLs in an optical microcavity and find the emitted photon statistics using the density matrix formalism. We find that, due to formation of biexcitons in an NPL and their subsequent decay, the emitted pairs of cavity photons are entangled at temperatures below 20 K. Under favorable conditions the photon pair can be nearly maximally entangled with the relative photon pair population ~0.5. We also show that second-order photon correlation (g(2)) can be used as a measure of the photon pair entanglement. At temperatures higher than 20 K, the photon entanglement is suppressed due to dephasing caused by thermal fluctuations. Finally, we discuss possible experiments, in which the NPL generated photon pair entanglement can be observed, as well as potential applications in integrated quantum photonics.

G70.00351: State Recognition of qubits in Two-Dimensional Quantum Dots Arrays with Machine learning  ALI RAD (Presenter), Physics, University of Maryland, College Park — Application of quantum dot is not limited to a one-dimensional array. For the purpose of quantum computation, we need to deal with a two-dimensional array of quantum dots. The technical difficulty of large-scale and higher dimensional arrays of quantum dots lies a the grow of parameter space substantially with the number of qubits. fortunately, we are able to use machine learning techniques to recognize the pattern of dots and find the tune parameters more efficiently.

G70.00352: Measurement and advances in hybrid quantum system with P1 centers and superconducting qubits  ZHILING WANG (Presenter), TIANQI CAI, XIYUE HAN, IIS, Tsinghua University, MAODONG GAO, Department of Physics, Tsinghua University, HONGYI ZHANG, YIPU SONG, LUMING DUAN, IIS, Tsinghua University — A hybrid quantum system which contains spin ensembles, superconducting resonators and superconducting qubits, has been proposed as a way to realize quantum computer. In the first part of this poster, we coupled substitutional nitrogen centers (P1 centers) in diamond to a superconducting resonator with Zeeman effect. We observed a fast relaxation of spin population on the millisecond scale, which is much faster than the intrinsic spin longitudinal relaxation of P1 centers. By pump-probe experiments we attributed this process to a cross relaxation among different hyperfine splitted spin subensembles. In the second part, we demonstrate iSWAP gate and CR gate by using a 5-qubit quantum processor. The qubit anharmonicity is enhanced by using a parallel capacitor, meanwhile the qubit is still operated in transmon regime. Furthermore, we have proposed a new architecture of scalable superconducting qubits based on ring network structures. This design can efficiently avoid breakpoints of superconducting patterns and significantly improve the robustness of intra-connections of qubits. We will demonstrate a quantum processor based on this architecture, to implement a fault-tolerant operating scheme with fourteen transmon qubits, which support reliable logical qubits and universal gates.
G70.00353: Heralded Bell State of Dissipative Qubits Using Classical Light  XIN ZHANG (Presenter), HAROLD U BARANGER, Duke University — Maximally entangled two-qubit states (Bell states) are one of the most exotic states in the quantum world and have important applications from testing quantum foundations to quantum information processing. Here we show that a Bell state can be generated using classical light by coupling two qubits to a one-dimensional (1d) waveguide. Even though the steady state of the qubits is a trivial product state with no coherence or entanglement, continuous monitoring unravels the steady state nontrivially such that a Bell state is generated in its trajectories and heralded by a reflected photon. This provides a particularly sharp illustration that information gained by measuring an open quantum system can affect its physical state and lead to surprising and useful results. Further, the specific role of information in our system is explored by including imperfect photon detection as a source of information loss.

G70.00354: Floquet-engineered quantum state preparation in a noisy qubit  ERIC BOYERS (Presenter), MOHIT PANDEY, DAVID K CAMPBELL, ANATOLI S POLKOVNIKOV, Department of Physics, Boston University, DRIES SELS, Department of Physics, Harvard University, ALEXANDER SUSHKOV, Department of Physics, Boston University — The ability to manipulate quantum states is important to many areas of quantum science including quantum simulation and computation. Adiabatic evolution is a common strategy for preparing quantum states, but it is slow and susceptible to decoherence. Existing methods for speeding up adiabatic evolution require complex multi-qubit gates or are difficult to construct for many-qubit systems. Our approach for constructing approximate fast-forward (FF) protocols uses the tools of Floquet engineering utilizing only the interactions in the original Hamiltonian. We apply this approach to a two level system and demonstrate it experimentally using the electronic spin of a Nitrogen-vacancy center in diamond. We show that our Floquet-engineered FF protocol performs comparably to the conventional FF protocol, achieving target state preparation with an upper bound on infidelity (1-F) of 0.01 at the 1σ level. We study the performance of our protocol when external noise acts on the qubit and find that it is significantly more robust than the conventional FF protocol.

G70.00355: Quantum interpolation for digital quantum simulation  JORDAN HINES (Presenter), Physics, Massachusetts Institute of Technology, YI-XIANG LIU, Nuclear Science and Engineering, Massachusetts Institute of Technology, ASHOK AJOY, University of California Berkeley, PAOLA CAPPELLARO, Nuclear Science and Engineering, Massachusetts Institute of Technology — Quantum simulation enables understanding complex dynamics with experimentally implementable dynamics. Digital quantum simulation enabled by Trotter expansion finds many applications due to its flexibility and universality. However, Trotter expansion higher than second order requires complicated coefficients that are hard to implement in experiment. Here we present Quantum Interpolation, a new exponential product second order approximation of exponential operators, motivated by realistic experimental limitations. We show that Quantum Interpolation has higher fidelity than the most commonly used second order Trotter expansion without any complicated coefficients. We also present the application of Quantum Interpolation in nano nuclear magnetic resonance imaging.

G70.00356: Spooky Action at a Distance is Not Spooky—It Is Knowledge: Combining Entanglement And Negative Observation To Show How The Einstein-Podolsky-Rosen Experiment Works, Not Just How It Doesn't Work  DOUGLAS SNYDER (Presenter), independent research — EPR considered positive measurement (where there is a physical interaction between the measuring device and the particle measured). EPR did not consider that knowledge is responsible for the effect of one of the entangled particles on the other entangled particle. If they had considered negative measurement (where there is no physical interaction between a measuring device and the particle measured), they would have deduced that knowledge is responsible for the effect of a negative measurement on one particle on the other particle. They would have seen that knowledge is also responsible in the case of positive measurements, that the essence of a positive measurement is that it supplies information just as negative measurements do. A sample experiment has been presented to show how the above points work in practice. Implications for the relationship between knowledge and reality are presented. The term “reality” is substituted for “physical reality” since physical reality is not independent of knowledge.
G70.00357: Does Unitarity Necessitate That an Entanglement Cannot be Destroyed Until a Measurement of 1 of the Entangled Particles is Made? The Answer Is No.  DOUGLAS SNYDER (Presenter), none, independent — The generally held view is that an entanglement of two particles cannot be broken until a measurement is made on one of the entangled particles. One reason given for the above thesis is unitarity. Great empirical evidence does indicate the importance of unitarity in the evolution of the wave function itself and also for the mathematical processes for making a measurement prediction. Both unitarity in wave function evolution before measurement and also the mathematical processes for making measurement predictions are supported by great empirical evidence. The view of entanglement that it cannot be broken until a measurement is made on one of the entangled particles is an extension of the view that a wave function is not destroyed until a measurement associated with the wave function is made. It is proposed that one lose or destroy an entangled particle and any which-way information the particle holds (and that the particle supplies to the other entangled particle before any measurements are made) through the use of a large system interacting with the particle to be destroyed. Whether or not the entangled particles is destroyed in the manner noted is correlated to different distributions of the other entangled particle.

G70.00358: A single-world consistent interpretation of quantum mechanics from fundamental time and length uncertainties  LUIS PEDRO GARCIA-PINTOS (Presenter), University of Massachusetts Boston, RODOLFO GAMBINI, Instituto de Fisica, Universidad de la Republica, JORGE PULLIN, Louisiana State University - Baton Rouge — Within unitary quantum mechanics there exist global protocols that allow to verify that no definite event ---an outcome to which a probability can be associated--- occurs. Instead, states that start in a coherent superposition over possible outcomes always remain as a superposition. We show that, when taking into account fundamental errors in measuring length and time intervals, that have been put forward as a consequence of a conjunction of quantum mechanical and general relativity arguments, there are instances in which such global protocols no longer allow to distinguish whether the state is in a superposition or not. All predictions become identical as if one of the outcomes occurs, with probability determined by the state. We use this as a criteria to define events, as put forward in the Montevideo Interpretation of Quantum Mechanics, analizing in detail the occurrence of events in the case of a particle in a superposition of two different locations. We argue that our approach provides a consistent (C) single-world (S) picture of the universe, thus allowing an economical way out of the limitations imposed by a recent theorem by Frauchiger and Renner showing that having a self-consistent single-world description of the universe is incompatible with quantum theory.

G70.00359: Review Article on Quantum Entanglement & Growing Quantum Information  ADITYA CHINCHOLE (Presenter), ELECTRONICS AND TELECOMMUNICATION, YESHWANTRAO CHAVAN COLLEGE OF ENGINEERING,NAGPUR,INDIA, SHUBHAM REDDY, Computer Science and Engineering, Ramdeobaba College of Engineering & Management, Nagpur, India — This paper presents the study on quantum entanglement till date, its applications and the research going on in the quantum communication field. It highlights the work on quantum Satellite "Micius" and the future scope of quantum communication. Quantum Information science is also discussed broadly. EPR paradox and Bell inequalities, quantum measurement theory and conceptual work in quantum interpretations mainly many worlds interpretation and Niels Bohr’s copenhagen interpretation are also covered. Future applications of the quantum entanglement including the quantum computers is displayed in this paper.

G70.00360: Universe’s Order Based on the Quantum Disorder  HASSAN GHOLIBEIGIAN (Presenter), AmirKabir University of Technology — One of the central challenge in physics is to understand how the ordered systems in macro scales in the universe can arise and how these systems can be characterized from disordered quantum systems in depth of the matter. In other words, how the quantum confuse systems are transformed to the macro scale ordered systems which we see in our daily life in the universe.

If the universe is a symphony of fundamental particles (vibrating strings), how is led this symphony orchestra?

On the other hand, the life need to the ordered systems for its evolution. In this way, it seems that, transformation of disordered quantum systems to the large scale ordered systems should be led by communication of information process. Because, fundamental particles need to know their next quantum states. In this process, fundamental particles get packages of information by sub-particles (quantum soft particles) from dimension of information for analysis and drawing the road map of the quarks.

It seems these are four sub-particles of mater, plant, animal and human in substructure of each quark as the origins of the life and cause of differences between spins of those elementary particles.[Gholibeigian, 2015 APS. APR. L1027G].

G70.00361: Counterfactual Assessment of The Quantum Zeno Effect  ONOFRIO RUSSO (Presenter), OKTAY H GOKCE, New Jersey Institute of Technology — We consider counterfactual measurements of the decay process for an unstable quantum mechanical system. In particular, there is a region during the decay process for which frequent observations or measurements of the initial decay states result in a delay in the decay time. The phenomenon is referred to as the quantum Zeno effect. We contend that this can be achieved counterfactually.
Subsequently, we use a generalized Wilson-loop order-parameter, namely, the equal-time Fredenhagen-Marcu order parameter, to distinguish between the different phases. Furthermore, we calculate perturbatively the energy gap of the toric code in the presence of Cooper-pair tunneling. Our results are relevant for the current efforts to experimentally realize the Majorana toric code.

* A.R. acknowledges the support of the Alexander von Humboldt foundation.

In this mapping, a successful decoding of the error syndrome of the TQC corresponds to a certain phase of the corresponding SPM. The error-correction performance of several TQC-s have been analyzed using Monte Carlo (MC) simulations.

We, on the other hand, use high-temperature series expansion to analyze the decoding performance of the toric code. In contrast to zero temperature simulations, which estimate the threshold of the minimum-weight perfect-matching decoder, our method naturally provides an estimate of that of the maximum-likelihood decoder. First, we analyze the phase diagram of the 2D random-bond Ising model to a higher order than previously performed. Our results provide an estimate of the decoding threshold of the toric code in absence of measurement imperfections. We compare our result to those obtained by MC simulations and network model analysis. Then, we perform the analysis of the free-energy and the Wilson loop order parameter in the 3D Ising gauge theory in the presence of quenched disorder. The latter model describes the decoding of the toric code subject to measurement errors.

*AR is funded by the Huboldt Foundation. NPB is a UCLQ Fellow at UCL.

We developed the mathematical framework for extending Harlow’s results to the more physical case where a Von Neumann algebra on the bulk, but assumes a simple tensor product structure on the boundary Hilbert space. In this work, we developed the mathematical framework for extending Harlow’s results to the more physical case where a Von Neumann algebra is also given on the boundary CFT. We showed that the resulting code more accurately captures the properties of AdS/CFT.

G70.00365: Quantum machine learning for electronic structure calculations* RONGXIN XIA (Presenter), Department of Physics and Astronomy, Purdue University, SABRE KAIS, Department of Chemistry, Department of Physics and Astronomy and Birck Nanotechnology Center, Purdue University — Considering recent advancements and successes in the development of efficient quantum algorithms for electronic structure calculations—alongside impressive results using machine learning techniques for computation—hybridizing quantum computing with machine learning for the intent of performing electronic structure calculations is a natural progression. Here we report a hybrid quantum algorithm employing a restricted Boltzmann machine to obtain accurate molecular potential energy surfaces. By exploiting a quantum algorithm to help optimize the underlying objective function, we obtained an efficient procedure for the calculation of the electronic ground state energy for a small molecule system. Our approach achieves high accuracy for the ground state energy for H2, LiH, H2O at a specific location on its potential energy surface with a finite basis set. With the future availability of larger-scale quantum computers, quantum machine learning techniques are set to become powerful tools to obtain accurate values for electronic structures.

*Sabre Kais and Rongxin Xia are grateful for the support from Integrated Data Science Initiative Grants, Purdue University.
G70.00366: Quantum Linear Regression With Regularization  XIAOKAI HOU (Presenter), XI HE, CHUFAN LV, DINGDING WEN, XIAOTING WANG, University of Electronic Science and Technology of China — The problem we are trying to solve in this article is how to execute linear regression algorithm with regularization based on quantum mechanics system. In the field of machine learning, linear regression is a powerful tool modeling input and output variables using the least squares function of linear equations. And regularization is a technical method to solve the overfitting phenomenon which can be caused when the training data is lack or not universal. The approach we mainly adopt to transform classical linear regression to quantum version is to construct Hamiltonian containing the training data information. And via HHL algorithm and swap test, we can accomplish the training process and also make a prediction with input variable state. Compared with classical analogue, the quantum linear regression algorithm demonstrates quadratic speed up.

G70.00367: Decomposable Coherence and Quantum Fluctuation Theorems*  ERICK HINDS MINGO (Presenter), Imperial College London, DAVID JENNINGS, Physics, University of Leeds — How can one define work on a quantum system without requiring the existence of a classical agent manipulating macroscopic equipment? To answer this question, we formulate the problem as can be done in Newtonian mechanics - by introducing a `weight system' with strict global energy conservation. By allowing a system in an arbitrary pure quantum state to interact with a weight system prepared in a well defined state, we are able to study the structure of `coherent energy transfers'. We then define a coherent work process and show that this is related to the notion of decomposability of a classical random variable. Maintaining the nomenclature, we introduce the notion of decomposable coherence. Furthermore, we show that coherent work processes can only map coherent states to coherent states, and they become classical work processes in a conservative potential as h goes to 0.

We then relate this framework to recent work in the study of quantum fluctuation theorems [1,2]. We find an induced definition of coherent work consistent with the previous framework. Furthermore, we show that entanglement generation is exponentially more probable than de-correlating dynamics.

*EPSRC - Centre for doctoral training.

G70.00368: An iterative variational algorithm for optimization on near-term quantum devices  OMID KHOSRAVANI (Presenter), Georgia Institute of Technology — Hybrid quantum-classical optimization algorithms have recently attracted interest for applications in the noisy intermediate-scale quantum devices (NISQ) era of quantum computing. However, as it has been recently shown by Jarrod McClean et. al. (arXiv:1803.11173v1), many such algorithms could suffer from the issue of Barren Plateaus even at shallow depth circuits, which corresponds to the phenomenon of vanishing of gradients in training classical deep neural networks. Here we introduce a variational method which restricts the entropy of the batch Hamiltonian per circuit complexity and propose an algorithm that attempts to avoid this issue by iteratively recombining the solutions while approaching an optimal solution. Finally we compare the performance of our algorithm with existing variational and quantum approximate optimization algorithms.

G70.00369: Separating Quantum and Classical Entropies: A unified treatment of quantum and classical information  AMRO DODIN (Presenter), ADAM P. WILLARD, Massachusetts Institute of Technology — Information in open quantum systems can be influenced by the presence of classical and quantum sources of uncertainty, complicating the quantification of the information encoded in such systems. By considering classical distributions on quantum state space, quantum and classical uncertainty can be separated, allowing for the simultaneous treatment of quantum (von Neumann) and classical (Shannon) entropies. In this presentation, a method for simultaneously quantifying quantum and classical entropies of quantum ensembles will be presented and the manner in which quantum operations (e.g. measurements and dynamical channels) transform one form of entropy into another will be discussed.
Superadiabatic quantum friction suppression in finite-time thermodynamics

SHUJIN DENG, East China Normal University, AURELIA CHENU, Los Alamos National Laboratory, PENG PENG DIAO, FANG LI, SHI YU, East China Normal University, IVAN COULAMY, Universidade Federal Fluminense, ADOLFO DEL CAMPO (Presenter), University of Massachusetts Boston, HAIBIN WU, East China Normal University — Optimal performance of thermal machines is reached by suppressing friction. Friction in quantum thermodynamics results from fast driving schemes that generate nonadiabatic excitations. The far-from-equilibrium dynamics of quantum devices can be tailored by shortcuts to adiabaticity to suppress quantum friction. We experimentally demonstrate friction-free superadiabatic strokes with a trapped unitary Fermi gas as a working substance and establish the equivalence between the superadiabatic mean work and its adiabatic value.

Optimal Quantum Approximate Optimization Algorithm: Success Probability and Runtime Dependence on Circuit Depth

MURPHY YUEZHEN NIU (Presenter), Physics, Massachusetts Institute of Technology, SIRUI LU, Physics, Tsinghua University, ISAAC CHUANG, Physics, Massachusetts Institute of Technology — Due to its simplicity, universality and optimality, quantum approximate optimization algorithm (QAOA) has been considered a useful near-term algorithm for conducting classical optimization and quantum simulation. We answer an open question of how the success probability and runtime of QAOA depend on the quantum circuit depth by focusing on a specific problem: state transfer in one-dimensional spin chain. We provide an analytic proof on the success probability scaling by leveraging the spectral property of the XY Hamiltonian. We show both analytically and numerically a Grover like quadratic dependence on the circuit depth in the short circuit depth limit and an exponential scaling in the large circuit depth limit. We prove the perfect state transfer needs $O(N)$ time using Lieb-Robinson bound for a spin chain of length $N$ and confirm this numerically.

Locally accurate matrix product state approximations with constant bond dimension for ground states of gapped 1D models

ALEXANDER DALZELL (Presenter), FERNANDO BRANDAO, Caltech — The numerical success of the DMRG method has been explained by the observation that it can be recast as a variational algorithm over the set of matrix product states (MPSs) with a specified bond dimension. The bond dimension need only increase like a polynomial in the number of sites on the 1D chain to guarantee that some element of the MPS manifold represents a good approximation to the ground state of a given gapped local Hamiltonian. But DMRG is often successful even for very small values of the bond dimension. We provide a partial justification for this success by showing that the MPS bond dimension may be kept constant as the number of sites increases if one desires an approximation that is good only in a local sense, that is, the reduced density matrix of the true ground state is close to that of the approximating MPS when all but a constant segment of the chain is traced out. While a similar result was known for matrix product operator (MPO) approximations, MPSs are superior to MPOs as an ansatz for variational algorithms since verifying that a certain MPO is positive (and thus represents a valid quantum state) is difficult, whereas MPSs do not have this issue.

G70.00373: Quantum enhanced metrology with noise assistance and error correction  
YU CHEN (Presenter), HAI-DONG YUAN, Mechanical and Automation Engineering, The Chinese University of Hong Kong — Quantum metrology has seen various important applications in science and engineering, ranging from atomic frequency estimation to gravitational wave detection. It has been shown that quantum resources can outperform their classical counterparts as regard to improving the precision of parameter estimation. However, there is inevitable difficulty in manipulating a quantum system because the system keeps leaking out information to the environment that it is coupled to, making superiority brought by the "quantumness" disappear beyond decoherence time. Therefore, it is critical to protect the system from noise, which can be achieved by means of adding control signals.

Most of the previous work has a focus on time-invariant parameter-independent Hamiltonian and noise. By contrast, in this paper we provide a sufficient and necessary condition under which one can employ control to recover the Heisenberg precision limit for systems with time-invariant parameter-dependent Hamiltonian and noise. We further consider the case where both Hamiltonian and noise are time-varying and parameter-dependent. We show a detailed technique via quantum error correction to harvest, or even beat the optimal quantum Fisher information in the noiseless case.

G70.00374: Dark matter search with the Cosmic Axion Spin Precession Experiment (CASPeR)  
DENIZ AYBAS (Presenter), Department of Physics, Boston University — The nature of dark matter is an open question in fundamental physics. The Cosmic Axion Spin Precession Experiment (CASPeR) is a laboratory scale search for the axion as a dark matter candidate [D. Budker, et al., Phys. Rev. X 4, 021030]. The range of axion-like dark matter masses to which CASPeR is sensitive extends from feV to μeV with sensitivity beyond current astrophysical limits. CASPeR uses Nuclear Magnetic Resonance (NMR) techniques and precision magnetic sensors, such as Superconducting Quantum Interference Devices (SQUIDs). The current status and preliminary results of CASPeR will be presented.

G70.00375: Josephson Metamaterial with a Tunable Kerr Constant*  
MATTHEW BELL (Presenter), WEN TING HSIEH, University of Massachusetts Boston — Superconducting circuits rely heavily on the non-linearity inherent in Josephson Junctions. The magnitude of this nonlinearity can be set either at fabrication or tuned with a superconducting quantum interference device (SQUID). Generally, the sign of the Kerr coefficient in the cosine energy phase relation for Josephson junctions cannot be tuned. Here we will present a unit cell design of a metamaterial which allows the Kerr coefficient to be tuned over a wide range in magnitude and can even change sign from positive to negative. Experimental results will be presented showing agreement with theory for the Josephson chain. We will also demonstrate how this metamaterial can be applied to recent efforts in realizing large superinductors and efficient traveling-wave parametric amplifiers (TWPA), two applications which have heavily relied on series arrays of Josephson junctions.

*NSF DMR-1838979, NSF ECCS-1608448, and NSF DUE-1608448

G70.00376: Practical algorithm for determining Hamiltonian identifiability*  
XIAOYANG HUANG (Presenter), Physics, Massachusetts Institute of Technology, ROBERTO GAUNA, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, AKIRA SONE, PAOLA CAPPELLARO, Nuclear Science and Engineering, Massachusetts Institute of Technology — We demonstrate a practical algorithm for determining the identifiability of Hamiltonian parameters with local accessibility. We consider the problem of estimating the parameters of the Hamiltonian of one-dimensional spin chain systems with nearest-neighbor interaction and assume that we only have access to a single quantum probe coupled to the target system. We demonstrate a practical implementation of Hamiltonian identifiability by the eigensystem realization algorithm and Gröbner basis. Furthermore, we also provide a practical code to estimate the Hamiltonian parameters from the experimental results. XH and RG equally contributed to this work.

G70.00377: Room-Temperature Quantum Non-Demolition Measurement Enhanced by Machine Learning  
MO CHEN (Presenter), YI-XIANG LIU, PAOLA CAPPELLARO, Massachusetts Institute of Technology — Projective measurements of qubits are a key resource for quantum computation. For qubits based on Nitrogen-Vacancy centers in diamond at room-temperature, projective measurement has been achieved using quantum non-demolition measurement schemes enabled by an ancillary qubit. In this scheme, the nuclear spin (qubit) state is repetitively read out by a mapping to the NV electronic spin (ancillae) until the photon number distribution from one qubit state is distinguishable from the other in a single shot. High readout fidelity requires a few to tens of thousands of repetitive readouts. This, unfortunately, imposes a heavy time overhead to any quantum algorithms. The readout time is on the same order of the decoherence time of the best physical qubit in the system, preventing feed forward protocols. In this work, we describe a method to improve the single shot readout fidelity using machine learning with information already recorded, but traditionally discarded in the experiment. Hence, our method does not impose an additional experimental time penalty. Combined with photonic structures that enhance photon collection efficiency, we expect this technique will enable room-temperature feed forward quantum information processing.

G70.00378: Integrated Fibre Detection Architectures for Distributed Quantum Magnetometry*  
CHRISTOPHER FOY (Presenter), SHAI MAAYANI, DIRK R. ENGLUND, YOEL FINK, Massachusetts Institute of Technology — Distributed magnetic sensing over large distances is of interest for a diverse range of applications including remote detection of ferrous metals, geophysics, and biosensing. Unfortunately, the capability to measure magnetic fields over large distance is unrealized. Here, we address this problem by introducing a diamond spin magnetometer directly embedded into an optical fibre alongside high-performance optoelectronic devices. Our magnetometer relies on the translation of an ensemble of nitrogen vacancy (NV) centers in micro-diamonds within a microfluidic channel. The NV's spin-dependent fluorescence is detected by embedded Si photodiodes. This device allows for distributed magnetic field measurements along a 300 meter-long fibre with a DC sensitivity of 81 nT Hz-1/2. We will discuss next steps and the deployment of this technology.

G70.00379: Single-photon switching inside a polarizatcavityion-selective*  
JEREMY FLANNERY (Presenter), MICHAL BAJCSY, University of Waterloo — We propose a scheme for single-photon switching that employs the phenomenon of vacuum induced transparency (VIT) and an ensemble of a three-level atoms in a polarization-selective cavity. In this system, light of one polarization (H) couples to one of the atomic transitions with high single-atom cooperativity, while the orthogonal polarization (V) couples to the other atomic transition. When both a weak probe and the cavity mode are resonant with their respective transitions, the otherwise opaque system becomes transparent to the probe through VIT. By setting the cavity mode and probe field far detuned, the regime of a Raman two-photon absorption (TPA) is reached, however because we use a vacuum cavity mode, this may be referred to as a vacuum induced Raman absorption (VIRA). The benefit of this regime is that the resonance condition for the VIT, allowing for full transmission, and the VIRA, resulting in a large absorption, can be very close in frequency. We exploit this by setting the probe photon on the VIRA resonance. The optical switch can then be opened by injecting a single photon into the cavity mode, shifting the VIRA resonance such that the probe field is instead at the VIT resonance, allowing for large transmission.

G70.00380: Time-resolved probing of many-body states in circuit-QED systems  
KIRILL SHULGA (Presenter), RIKEN Center for Emergent Matter Science, IHOR VAKULCHYK, MIKHAIL FISTUL, Center for Theoretical Physics of Complex Systems, Institute for Basic Science (IBS), YASUNOBU NAKAMURA, RIKEN Center for Emergent Matter Science — Circuit-QED quantum simulators based on superconducting circuits provide a tool to study many-body phenomena in strongly interacting qubit systems. In this work, we perform experimental studies of time-resolved dynamics of superconducting qubit arrays embedded in a superconducting resonator. We demonstrate an occurrence of many-body Rabi oscillations and complex dynamics in the dispersive and the resonant regimes. At variance with single qubit Rabi oscillations, the many-body Rabi oscillations emerge as the amplitude of applied microwave pulse exceeds the critical value. The magnetic field tunable crossover between many-body and single particle Rabi oscillations is obtained. We also experimentally explore a possibility to realize a time crystalline order in an array of superconducting qubits by applying periodic sequence of pulses with excitation of nonequilibrium states in the system.
G70.00381: Fast dispersive, Purcell-filtered measurement and reset using smooth and simple analytic pulse shapes
LUKAS F BUCHMANN, FELIX MOTZOI (Presenter), Aarhus University, CHRISTIAN DICKEL, TU Delft — We present a dispersive, measurement pulse shaping technique that allows for arbitrarily fast quantum non-demolition, single-quadrature measurements of non-linear systems and unconditionally leaves the measurement resonator empty. Leftover cavity population from short measurements with square or composite digital pulses can be suppressed using instead simple smooth pulse shapes from an analogous family of DRAG shapes; here, it can be derived exactly for arbitrarily many measured modes. The results are easily generalizable, including single-shot, single-quadrature, measurements of multi-qubit and multi-state (leakage) systems. One can also straightforwardly incorporate Purcell filter cavities, which can be depopulated simultaneously via the same technique. Finally, we show how to apply the technique to cascaded cavity networks, e.g. for fast remote entanglement generation, or in non-dispersive single-photon networks, and discuss applicability to single flux quantum (SFQ) readout.

G70.00382: Deep Learning-Based Prediction and Optimal Sequential Measurement of a Quantum Dot*
DOMINIC LENNON (Presenter), HYUNGIL MOON, Materials, University of Oxford, MICHAEL OSBORNE, Department of Engineering, University of Oxford, LEON CAMENZIND, LIUQI YU, DOMINIK ZUMBUHL, Department of Physics, University of Basel, GEORGE ANDREW DAVIDSON BRIGGS, Materials, University of Oxford, EDWARD LAIRD, Department of Physics, Lancaster University — Spin qubits defined in quantum dots are promising for creating a scalable quantum computer. However, they are time-consuming to characterise, and as the size of these systems increases, this task will become intractable without the aid of automation. We present a machine learning algorithm that decides where to measure next and demonstrate it operating on a real quantum dot device in real-time. The algorithm utilises a probabilistic deep-generative model to make reconstructions of a full current map given partial measurement and information theory to select the most informative measurements to perform next. We demonstrate, for two different measurement configurations, that the algorithm outperforms standard grid scan techniques, reducing the number of measurements required by up to 4 times and the measurement time by 3.7 times.

*We acknowledge J. Zimmerman and A. C. Gossard for the growth of the AlGaAs/GaAs heterostructure.

G70.00383: Tunneling-noise-induced spin dephasing of two electrons in an arbitrarily detuned double quantum dot
PEIHAO HUANG (Presenter), Shenzhen Institute for Quantum Science and Engineering, and Department of Physics, Southern University of Science and Technology — Recent progress enables operations of a two-qubit gate for two electron spin qubits in a double quantum dot (DQD), which is an important step towards scalable semiconducting quantum computing. In an asymmetric DQD, it has been shown that 1/f charge-noise-induced tunneling noise can dominate spin decoherence under condition relevant in a two-qubit experiment. Here, we study spin decoherence due to 1/f charge noise for two electrons in a DQD with arbitrary detuning. We show that, in a symmetric DQD, charge-noise-induced tunneling noise can have a profound contribution compared to detuning noise, where the contribution of detuning noise is vanished due to the destructive interference while the contribution of tunneling noise remains finite. We study the spin decoherence for various detuning and tunneling and discuss its consequence on the figure of merit of a two-qubit gate.

G70.00384: 12-photon entanglement and scalable scattershot boson sampling with optimal entangled photon pairs from parametric down-conversion
HAN-SEN ZHONG (Presenter), YUAN LI, WEI LI, LI-CHAO PENG, ZU-EN SU, YI HU, YU-MING HE, XING DING, Hefei National Laboratory for Physical Sciences at Microscale and Department of Modern Physics, University of Science and Technology of China, WEIJUN ZHANG, HAO LI, LU ZHANG, ZHEN WANG, LIXING YOU, State Key Laboratory of Functional Materials for Informatics, Shanghai Institute of Micro system and Information Technology (SIMIT), Chinese Academy of Sciences, JUN ZHANG, XI-LIN WANG, LI LI, YU-AO CHEN, NAI-LE LIU, CHAO-YANG LU, JIAN-WEI PAN, Hefei National Laboratory for Physical Sciences at Microscale and Department of Modern Physics, University of Science and Technology of China — Spontaneous parametric down-conversion (SPDC), one of the most popular entanglement source, enable thousands of quantum optics experiment during the past few decades. We have been devoted on optimizing the property of SPDC. One of the major task is to design a near perfect SPDC entanglement source with high indistinguishability and high efficiency simultaneously. Recently, an SPDC entangled photon pair source of which the heralding efficiency is 97% and the indistinguishability is 96% has been developed.

To prove the powerful of this SPDC source, we produced the first 12-photon entangled GHZ state and implement 3-, 4-, and 5-photon scattershot boson sampling experiment. In 12-photon entanglement experiment, we extend the previous scheme directly. We measured the population and coherence of the GHZ state, and then calculated the fidelity of 0.576(24), which exceed the threshold 0.5 more than 3 times of standard deviation. In scattershot boson sampling experiment, 12 SPDC photon pair sources are employed. The count rate of 3-, 4-, and 5-photon coincidence is 3.9 kHz, 44 Hz and 0.3 Hz, respectively. We validate the sampling result with a modified likelihood ratio test. All of them show a continual deviation from distinguishable particle.
G70.00385: Investigating the Effectiveness of Measurement-Device-Independent Quantum Key Distribution with Weak Coherent Pulses

ANNIKA DUGAD (Presenter), JOSEPH CHAPMAN, ANDREW CONRAD, PAUL G KWIAT, University of Illinois at Urbana-Champaign, DANIEL J GAUTHIER, Dept. of Physics, OSU — Quantum key distribution (QKD) is a quantum cryptographic task that allows a random secret key to be generated and communicated between two parties in the presence of an eavesdropper. Although QKD systems are theoretically foolproof and completely secure according to the laws of quantum mechanics, many security loopholes have been found in practice. Measurement-device-independent quantum key distribution (MDI-QKD) improves upon previous QKD systems by removing all detector side-channels, therefore rendering many of the loopholes obsolete. However, in order to successfully implement MDI-QKD, the sources (representing the two communicating parties) must be indistinguishable. We will be implementing MDI-QKD with two independent sources of light coming from attenuated laser pulses, or resonant cavity LEDs; as a result, the sources will be rigorously tested and characterized to determine how indistinguishable they truly are.

G70.00386: Why We Should Be Skeptical of Quantum Computing

ALAN M. KADIN (Presenter), Consultant, Princeton Junction, NJ 08550 — It is widely believed that quantum computing is on the threshold of practicality, with performance that will soon surpass that of classical computing. On the contrary, it is argued that both the present and the future of quantum computing may be highly uncertain, for the following reasons:

1) The promised performance depends on entanglement-based scaling to massive parallelism, which has not been verified, and may be tested [1].
2) Even if the theory were correct, exponential sensitivity to noise for highly entangled states could make the technology impractical [2].
3) Evidence for entanglement in superconducting qubits can be explained using the nonlinear properties of classical Josephson junctions [3].
4) Evidence for entanglement in arrays of coupled qubits can be explained using conventional energy-band theory with delocalized states.

G70.00387: Single-channel Hadamard gate through single-photon Raman Scattering in Chiral Quantum Nanophotonics

ZHIAO CHEN (Presenter), YAO ZOU, JUNG-TSUNG SHEN, Washington University in St. Louis — Hadamard gate (H-gate) is indispensable to constitute complete sets of logic gates for universal quantum computing. Practical implementations can be classified into atom- and photon-based. While atom-based techniques are rather mature by employing consecutive electromagnetic pulses to drive qubit rotations on Bloch sphere, it is of limited coherent time, and may not be compatible with photon-based quantum communication protocol in scalable quantum internet blueprint. Henceforth, photon-based implementations may play significant roles, which are typically realized by using linear optical elements. However, such schemes require different photonic channels to accommodate binary qubits, thus resulting in limited spatial utility.

To enhance spatial utility, we propose a novel single-channel H-gate scheme by chirally coupling Lambda-type atoms to 1D waveguide, and exploiting photon frequency degree of freedom as qubit. The underlying physics of gate operations here, is frequency conversion through single-photon Raman scattering. The single-channel feature enhances the spatial utility to be highly scalable. Such a scheme is readily feasible due to the advent of chiral coupling technique using photon spin-momentum locking and polarized dipole moment in quantum nanophotonics.
G70.00388: Quantum computing methods for electronic states of the water molecule*  TENG BIAN (Presenter), Physics, Purdue University, DANIEL MURPHY, Physics, Georgia Institute of Technology, RONGXIN XIA, Physics, Purdue University, AMMAR DASKIN, Computer Engineering, Istanbul Medeniyet University, SABRE KAIS, Chemistry, Purdue University — We compare recently proposed methods to compute the electronic state energies of the water molecule on a quantum computer. The methods include the phase estimation algorithm based on Trotter decomposition, the phase estimation algorithm based on the direct implementation of the Hamiltonian, direct measurement based on the implementation of the Hamiltonian and a specific variational quantum eigensolver, Pairwise VQE. We explain how each method works and compare the simulation results in terms of gate complexity and the number of measurements. In conclusion, among methods based on the phase estimation algorithm, the second order direct method provides the most efficient circuit implementations in terms of the gate complexity. With large scale quantum computation, the second order direct method seems to be better for large molecule systems. Moreover, Pairwise VQE serves the most practical method for near-term applications on the current available quantum computers. Finally, the possibility of extending the calculation to excited states and resonances is discussed. This work is posted on arXiv: Quantum computing methods for electronic states of the water molecule.

*Sabre Kais and Teng Bian are grateful for the support from Integrated Data Science Initiative Grants, Purdue University.

G70.00389: Quantum Bernoulli Factories in a Classical Setting*  THOMAS HEBDIGE (Presenter), Controlled Quantum Dynamics Theory Group, Imperial College London, DAVID JENNINGS, School of Physics and Astronomy, University of Leeds — Recently a novel quantum advantage over classical information processing has been developed in the context of randomness processing, under the title of “Bernoulli factories”. Bernoulli Factories find modern application in classical Bayesian statistics, such as in genetics when one encounters intractable likelihood functions. However, since quantum Bernoulli factories are more powerful than their classical counterparts, an open question is if this advantage can be exploited within the classical setting. Here we present work towards an implementation of a quantum Bernoulli factory on near-term quantum devices, and contrast this formalism with the quantum resampling protocol of Webb & Kitaev.

G70.00390: Scaling Hypothesis of Spatial Search on Fractal Lattice Using Quantum Walk  SHOHEI WATABE (Presenter), SHU TAMEGAI, REI SATO, TETSURO NIKUNI, Tokyo University of Science — We investigate a quantum spatial search problem on a fractal lattice. A recent study for the Sierpinski gasket and tetrahedron made a conjecture that the dynamics of the search on a fractal lattice is determined by spectral dimension for the optimal oracle calls, and not by the fractal dimension [A. Patel and K. S. Raghunathan, Phys. Rev. A 86, 012332 (2012)]. We tackle this problem for the Sierpinski carpet, and we find that our simulation result may support the conjecture. We also propose a scaling hypothesis of oracle calls for the quantum amplitude amplification in a fractal lattice, which is given by the Euclidean dimension, fractal dimension, spectral dimension, and the scale factor of a fractal lattice. We have confirmed that our scaling hypothesis holds in the Sierpinski carpet, gasket, and tetrahedron.

G70.00391: Quantum Theory of Entanglement and Brain Physics  SHANTILAL GORADIA (Presenter), Gravity Research Institute, Inc. — Despite decades of hard work by Penrose-Hameroff Hypothesis (ORCH OR) about consciousness, the hypothesis is not universally accepted. We formulate our hypothesis dubbed as “orchestrated subjective experience (ORCH SE)” based on our theory of quantum gravity (explaining the abundance of dark matter) to address the subject disconnect in our recent article, “Quantum Theory of Entanglement and Brain Physics,” in an open minded, OPEN ACCESS Journal of Clinical Reviews and Case Reports 2018, Volume 3, Issue 7. Since dark matter exists in the universe, there is no reason why it would not be present in the brain, to some extent.

G70.00392: FLUID DYNAMICS  —
G70.00393: Pulsatile Flow Through Multi-Coupled Idealized Renal Tubules: Fluid-Structure Interaction and Dynamics Pathologies

NIKSA PRALJAK (Presenter), Department of Physics, Cleveland State University, ANDREW H RESNICK, Department of Physics, Center for Gene Regulation in Health and Disease, Cleveland State University — Kidney tubules are known to have flow-sensing structures, yet information about the flow itself is very fragmentary. Our aim is to generate a biomechanical model for analyzing fluid flow within an elastic kidney tubule when the driving pressure is pulsatile. We created finite-element numerical models of coupled kidney tubules and determined the flow dynamics and wall stresses over a range of driving frequencies and wall compliances. The results form a basis for including elasto-hydrodynamic coupling by neighboring tubules via the interstitium. As well, the results analyze how elastic tubes interact with different frequency phases that alter the hydrodynamics of the fluid in the interior and exterior. Overall, we are interested in exploring the idea of ‘dynamics pathology’ to better understand the progression of certain kidney diseases, for example, Polycystic Kidney Disease.

*This work was supported by the National Science Foundation Research Experience for Undergraduates grant number 1659641.

G70.00394: Particle Collisions During Multiphase Flow

SURESH AHUJA (Presenter), XEROX CORPORATION — Applications of granular materials range from food grains, ores, and coal to pharmaceutical powders and digital printing. High definition digital imaging is enabled in printers by using small micron and nano toner particles. Use of small particles in a housing presents challenges in particle flow as large particles break and small particles tend to aggregate, clog and impact either on the wall of the housing or on other surfaces. Solids are known to undergo brittle – ductile transition depending on the size of a particle, elastic plastic behavior and strain rates under which they are deformed.

Particulate flow can some cases result in jamming and has been analyzed using Lattice- Boltzmann (LB) or DEM (Discrete Element Methods) involving deformation from collisions resulting from hydrodynamic forces. Consequence of particle impaction on surfaces is a reduction in particle charge with wider distribution causing shortfalls in electro-photographic development and image quality. An elasto-plastic model is developed for particle impaction for a particulate flow that depends on particle radius, incident particle speed and yield stress of the material. The model predictions are compared with experimental data on particle impaction.

G70.00395: Foam films and liquid bridges formed by aqueous sodium naphthenate solutions

CHRYSTIAN OCHOA (Presenter), ELIZABETH JOHN, JELENA DINIC, VIVEK SHARMA, Chemical Engineering, University of Illinois at Chicago — Sodium Naphthenates found in crude oils can act as surfactants and self-assemble in aqueous solutions to form micelles and liquid crystals. Understanding and controlling the drainage kinetics of thin films is an important problem that underlies the stability, lifetime and rheology of petroleum foams and emulsions. Here, we show that foam films formed by aqueous solutions of sodium naphthenates exhibit step-wise thinning or stratification. We utilize Interferometry, Digital, Imaging, Optical Microscopy protocols, previously developed by our group, to investigate the drainage and stratification in micellar foam films (< 100 nm) with high spatial (thickness < 10 nm) and temporal resolution (< 1 ms). We determine how the concentration of added sodium naphthenates influences the nanoscopic topography, stratification kinetics and step size of foam films. Finally, we show that visualization and analysis of capillary-driven thinning and pinch-off dynamics of the columnar neck in an asymmetric liquid bridge created by dripping-onto-substrate (DoS) of sodium naphthenate solutions can be used for characterizing the change in shear viscosity, extensional viscosity and microstructure in such surfactant solutions.

G70.00396: Holographic Rheology of Viscoelastic Fluids in Microfluidic Geometries

SIDDHARTHA GUPTA (Presenter), SIVA A VANAPALLI, Texas Tech University — To explore the kinematics and rheology of viscoelastic flows it is critical to map three-dimensional (3D) velocity fields. The 3D flow information can be used for understanding phenomena such as elasticity-driven instabilities, slip and shear-banding. Digital holography microscopy (DHM) with particle tracking velocimetry (PTV) is an interferometry technique which can provide real-time 3D flow information by recording holograms of the flow. We demonstrate the robustness of holography in characterizing the kinematics of polymeric and Newtonian fluids in rectilinear channels, contraction-expansion and curved microchannels, which provide for shear, extensional and curvilinear flow behavior respectively. Using DHM-PTV, we recover the full 3D velocity field which is in good agreement with analytical results and flow simulations. Additionally, we demonstrate a digital holography driven rheology (DHR) approach for quantifying shear viscosity curves of complex fluids in thin-slit geometries. The DHR approach does not make a-priori assumptions about material properties and is thus independent of slip which has been found to affect narrow gap rheology. In sum, we conclude that digital holography microscopy has powerful applications for investigation of complex fluids in complex geometries.
**G70.00397: Effects of nanoparticles on the stability of polymer fibers**

TAEJIN KWON (Presenter), BONG JUNE SUNG, Sogang University — Soft matters in confinement may deform easily upon small perturbation. Especially, polymer fibers are unstable due to a large surface area. Recent studies showed that the addition of nanoparticles (NPs) could control the stability of polymer fibers. It remains elusive how NPs would affect the disruption of polymer fibers. In this work, we perform molecular dynamics simulations for polymer fibers with NPs of different interaction types. We prepare unstable polymer fibers that disrupt into globules. We find that upon the addition of NPs, the disruption of fibers is hindered and the breakup time ($t_b$) of polymer fibers increases. We find that polymer fibers with NPs are more likely to retain their morphology. The free energy barrier between the fiber and the globule would increase due to NPs. The mechanism for the stability differs for the different interaction types of NPs. When the interaction between polymers and NPs is attractive (non-attractive), $t_b$ increases (decreases) with a decrease in temperature. We show that different spatial arrangement of NPs leads to the different temperature dependence of $t_b$.

**G70.00398: Experimental Investigation of Droplets Impacting on Inclined Heated Surfaces with Varying Wettability**

QIANG MA (Presenter), XIAOMIN WU, Department of Energy and Power Engineering, Tsinghua University — Droplets impacting on heated surfaces is a common phenomenon in spray cooling, which can remove very high heat flux. Since the surface wettability has a significant effect on the heat transfer performance by directly changing the droplet spreading, rebounding and boiling behaviors, it has drawn much attention. However, the surface roughness changes simultaneously when changing the surface wettability in most researches. Thus, the influence factors of wettability and roughness are coupled. In this work, the test surfaces were fabricated by spray-coating a thin film on the aluminum substrates and the roughness of each surface is small enough. Therefore, the influence of wettability on droplets impacting on inclined heated surfaces have been experimentally studied. The experiments were carried out with different inclination of 0°, 30° and 60°, with different surface temperature from 100°C to 400°C and with different surface contact angle of 10°, 78°, 95° and 122°. The droplet spreading, rebounding and boiling behaviors have been observed by a high speed camera. The droplet spreading factors, advancing and receding contact angles have been measured and the droplet boiling regimes have been identified.

*National Natural Science Foundations of China (No.51476084).*

**G70.00399: Simulation of Droplet Impact on a Spherical Surface**

XIN LIU (Presenter), XUAN ZHANG, JINGCHUN MIN, Tsinghua University — Droplet impact phenomenon is widely found in nature, production and life. Due to the complexity of the actual surface structures, the droplet may impact not only on a flat surface but also on surfaces of various shapes and the one typical example is a sphere. In this study, the droplet impact process on a spherical surface is simulated using the VOF multiphase model coupled the dynamic contact angle model, which is compared with our experimental data to verify the model. Based on this model, the impact processes of droplets with different We numbers on spherical surfaces with different diameters and contact angles are simulated. The results indicate that the maximum spreading factor increases significantly with the increase of We and the decrease of contact angle while it is little influenced by the sphere diameter. The droplet may break up at the spreading or receding stage during the whole impact process. Compared with impacting on the flat surface, the droplet is more likely to break up when impacting on a sphere due to the gravity and the critical We number for breaking up is smaller. The droplet breaking-up diagram is obtained, which provides reference for the droplet impact study.

*This work is funded by the National Key Basic Research Program of China (No. 2015CB755800).*
G70.00400: Coalescence Dynamics of Near-Critical Sulfur Hexafluoride in Microgravity*  
CHRISTIAN HAWKINS (Presenter), ANA OPRISAN, College of Charleston, DANIEL A BEYSENS, Université Pierre et Marie Curie, YVES GARRABOS, CAROLE LECOUTRE, Institut de Chimie de la Matière Condensée de Bordeaux — Critical fluids have a variety of applications from manufacturing high-tech materials to industrial lubrication and extracting oils from foods. Phase separation of critical fluids cannot be studied on earth due to the increase in compressibility near the critical point and stratification of fluids by density in gravity. We used direct imaging to record snapshots of phase separation that takes place in sulfur hexafluoride (SF6) in weightlessness conditions on the International Space Station (ISS). The system was at liquid-vapor equilibrium slightly below the critical temperature and further cooled down by a 0.2-mK quench that produced a new phase separation. Both full view and microscopic views of the direct observation cell were analyzed to determine the evolution of the radii distributions. In addition, in microscopic view, we measured the diameter of droplets and bubbles in the system throughout multiple coalescence events leading to further support of the coalescence-induced-coalescence model.

*We would like to thank the College of Charleston School of Science and Mathematics for the Dean's Funding grant which funded this research. Furthermore, Y.G., C.L., and D.B. acknowledge a research grant from CNES, and wish to thank the CNES and NASA teams involved in the DECLIC project.

G70.00401: Strategies for Microparticle Manipulation by Rectified Inertial Forces  
SIDDHANSH AGARWAL, University of Illinois at Urbana-Champaign, BHARGAV RALLABANDI, Mechanical Engineering, University of California, Riverside, SASCHA HILGENFELDT (Presenter), University of Illinois at Urbana-Champaign — Oscillating interfaces in a liquid give rise to inertial effects that manifest as multiple physical phenomena on slower (steady) time scales, including streaming flow and force actuation on immersed particles. While these effects have traditionally been treated separately, we develop a timescale separation formalism that puts streaming motion of fluid elements and rectified motion of particles on the same footing. Using ultrasound-driven microbubble oscillations in microfluidic devices allows for flexible and specific manipulation of particles: depending on parameters, microparticle reaction is selective by size or by density, results in attraction to or repulsion from the bubble, and can be focused on particle trapping or deflection. Thus, a device can be tailored to desired applications by changing easily controlled parameters like flow speed and driving frequency.

G70.00402: Throughput enhancement of parallel step emulsifier devices by shear-free and efficient nozzle clearance  
ELAD STOLOVICKI (Presenter), ROY ZIBLAT, DAVID A WEITZ, Harvard University — Step emulsification is an attractive method for production of monodisperse drops. Its main advantage is the ability to parallelize many step emulsifier nozzles to achieve high production rates. However, step emulsification is sensitive to any obstructions at the nozzle exit. At high production rates, drops can accumulate at nozzle exits, disturb the formation of subsequent drops and impair monodispersity. As a result, parallelized step emulsifier devices typically do not work at maximum productivity. Here a design is introduced that parallelizes hundreds of step emulsifier nozzles, and effectively removes drops from the nozzle exits. The drop clearance is achieved by an open collecting channel, and is aided by buoyancy and does not apply shear on forming drops. The clearance method avoids the use of a continuous phase flow for drop clearance. The method works well for a wide range of drops, sizing from 30 to 1000 µm at production rates of 0.03 and 10 L per hour and achieved by 400 and 120 parallelized nozzles respectively.

G70.00403: WITHDRAWN ABSTRACT

G70.00404: Experimental investigation into a nanoparticle based direct absorption solar oscillating heat pipe  
HAIE YANG (Presenter), HAICHUAN JIN, GUIPING LIN, DONGSHENG WEN, Beihang University — Nanoparticle-based volumetric solar absorption has been shown to be an effective technique to realize efficient solar harvesting. However, most of such systems under study are stationary and cannot realize solar energy transport, which limits their potential applications to a large extent. A novel idea of using directive absorptive nanofluids in oscillating heat pipes (OHP) is investigated in this work, which would achieve efficient solar energy capture and transportation simultaneously without the use of any additional pumping power. The influence of a variety of parameters such as nanoparticle type, nanoparticle concentration, nanofluids filling ratio and solar radiation intensity on the performance of OHPs are investigated. Very high effective thermal conductivity is observed. It is found that strong absorption of solar energy, efficient vapor generation inside the OHP and proper configuration of the OHP should be responsible for the efficient operation of this system.
G70.00405: Fluidic wrench: Precise control over the position and orientation of anisotropic colloids using fluid flow*  
DINESH KUMAR (Presenter), ANISH SHENOY, SONGSONG LI, CHARLES SCHROEDER, University of Illinois at Urbana-Champaign — A grand challenge in the field of directed assembly is to precisely assemble chemically and structurally distinct anisotropic particles into functional hierarchical structures. Such complex assembly schemes will require precise control over both the position and orientation of individual rods. In this work, we demonstrate simultaneous control over the 2D center-of-mass position and orientation of anisotropic colloidal particles using only fluid flow. We use a 4-channel microfluidic device with a model-predictive control scheme to generate a flow pattern that translates and rotates rod-like particles from their initial state to a final desired position and orientation. Unlike alternative techniques that exploit intrinsic material properties of particles (e.g. index of refraction, magnetic properties, surface charge) to control position and orientation, our method imposes no restrictions on the physical or chemical properties of the particles, and hence, can be used for rods of any material and size, assuming they can be imaged. Moving forward, this approach could be further engineered to achieve fluidic-directed assembly of asymmetric objects on a meso- to micro-scale level.

*NSF CBET PMP #1704668 for funding.

G70.00406: Microporosity Evolution and Powder-Powder Interaction in Selective Laser Melting Process  
JIQIN LI (Presenter), LU LI, TAI-HSI FAN, Mechanical Engineering, Univ of Connecticut, Storrs, CT — Additive manufacturing in aerospace and biomedical applications is challenging due to the need of superior quality and liability of end products. A critical concern about the process is the formation of surface defects due to incomplete melting of powders and gas trapping between powders, which significantly weakens the mechanical performance of the raw products. Better understanding of the process dynamics can help to mitigate the defects and determine process control parameters. We present phase-field modeling of the powder-powder interaction and the formation of micropores during selective laser melting of pure titanium powders. The solid-liquid phase transition is coupled with thermal transport, capillary flow, and liquid-gas interfacial deformation. The change of morphology and the evolution of pores highly depend on the interplay of the fusion dynamics, configuration of powders, and laser control parameters.

G70.00407: Gravity and Flow Effects on Coarsening Dynamics in Crystal-Liquid Mixtures  
TAI-HSI FAN (Presenter), JIQIN LI, ELIZABETH SOHA, Mechanical Engineering, Univ of Connecticut, Storrs, CT — Coarsening of crystals can be driven by cooling, Ostwald ripening, or interfacial kinetics in crystal-liquid mixtures. The relevant phenomena appear in many manufacturing processes involving metals and alloys, or nonmetallic materials. The degree of coarsening determines the size of crystals and microstructural pattern, and thus understanding coarsening dynamics is important in controlling the uniformity of microstructure and properties of the end products. We present a phase-field theoretical framework to investigate coarsening dynamics in symmetric and asymmetric binary systems. The phase transition and microstructure evolution are coupled with fluid flow, trajectory motion of the crystals, thermophysical properties of the materials, interfacial energy, and the relevant heat and mass transport phenomena. Specifically, we focus on crystal morphology and the fluid flow induced by density variation and gravity acceleration. The flow and collective motion of crystals also influence the heat and mass transfer around the interstitial space between crystals and should be resolved simultaneously. The theoretical analysis and 2d computational results based on spectral method will be presented.

G70.00408: Geometry and Topology of Collective 2D Vortex Dynamics*  
ALEXANDER BOGATSKII (Presenter), PAVEL WIEGMANN, University of Chicago — We consider the coarse-grained dynamics of many quantized chiral vortices on a 2D surface.

There are two groups of emergent phenomena. First, coupling the incompressible Euler equation to a metric in the presence of point vortices involves important ambiguities reminiscent of spin in quantum 2D systems. We obtain the coarse-grained flow of the vortex fluid, observe the effective negative temperature envisioned by Onsager in 1952, and discuss the curvature effects.

Secondly, vortices can form bounded drops of nonzero vortex density. The quantization of vortices leads to the presence of an "overshoot" in the vortex density at the boundary of the drop, also observed in Quantum Hall droplets. The Euler dynamics generates a remarkable edge wave in the overshoot density that obeys the integrable Benjamin-Ono equation. The mass of the soliton in this equation is quantized in units of one vorticity quantum, representing the topological nature of vortices.

Based on work with prof. Paul Wiegmann.

G70.00409: Ellipsometric Characterization of Monolayer MoSe$_2$ from 31 to 300K

HOANG TUNG NGUYEN, HAN GYEOL PARK, TAE JUNG KIM, VAN LONG LE, Kyung Hee University, FARMAN ULLAH, YONG SOO KIM, University of Ulsan, MAENG-JE SEONG, Chung Ang University, YOUNG-DONG KIM (Presenter), Kyung Hee University — The layered transition metal dichalcogenides (TMDCs) has recently gained significant interest due to their distinctive physical properties. Molybdenum diselenide (MoSe$_2$) is well known as one of transition metal dichalcogenides, which suggests promise as a potential substitute for silicon in state-of-the-art transistors, sensors, and photodetectors. A systematic study on temperature dependence of the dielectric function and critical point energies of MoSe$_2$ is therefore strongly needed.

In this work, we investigate the dielectric function of 2D MoSe$_2$ in 0.74 to 6.42 eV energy range at temperatures from 31 to 300 K by spectroscopic ellipsometry. The CP transitions are observed and their energies are obtained by fitting standard analytic expressions to second energy derivatives of the data. We found six new CPs at low temperature beside another six CPs realized at room temperature. Blue shift and enhancement of most CP energies at low temperatures were observed and understood by the reduced lattice constant and electron-phonon interaction. The temperature dependences of these CPs were determined by fitting the data to the coefficients in a phenomenological expression that contains the Bose-Einstein statistical factor.

G70.00410: Anisotropic Phononic Bandgap Formation of Nano-Dicolloid Crystals

HOJIN KIM (Presenter), ERIC M FURST, Department of Chemical and Biomolecular Engineering, University of Delaware, GEORGE FYTAS, Max Planck Institute for Polymer Research — Self-assembly of colloidal nanoparticles form periodic building blocks and the fabricated crystalline structures exhibit useful photonic and phononic properties because of the periodicity of their structure. Such phononic properties are broadly applicable in technologies such as hypersonic and thermal cloaking materials, heat management systems, and metamaterials. To guide the propagation of acoustic waves to targeted direction, we investigate the potential of self-assembled anisotropic colloidal particles. Colloidal crystals consisted of nano-dicolloids are fabricated using directed self-assembly technique under electric field and their hypersonic phonon spectra are measured by Brillouin light scattering (BLS). The anisotropy of dicolloidal particle shape enables crystals to have different periodicity depending on the direction of phonon propagation. We show that the fabricated crystals have anisotropic phononic bandgaps due to both hybridization and Bragg scattering.

G70.00411: Examining the Feasibility of Room-Temperature Exciton-Polariton Lasers Based on III-V Microcavities

ANIRUDDHA BHATTACHARYA (Presenter), Department of Electrical Engineering and Computer Science, The University of Michigan at Ann Arbor, ALEXEY KAVOKIN, Institute of Natural Sciences, Westlake University, No.18, Shilongshan Road, Cloud Town, Xihu District, Hangzhou, China — Exciton-polaritons are light-matter dressed bosonic quasiparticles. Electrically energized room-temperature GaN-based polariton lasers have been recently demonstrated. Nevertheless, further improvements in the laser characteristics can be brought about by implementing them on state-of-the-art GaAs-based microcavities. In particular, GaAs-based microcavities have vanishingly small values of dislocation densities and extremely high values of intra-cavity photon lifetimes. Demonstration of strong coupling and polariton lasing effects in GaAs-based devices at room temperature is limited mainly by the rather small values of the free excitonic Rydberg energies. To that end, we would give an overview of several strategies for enhancing the binding energy of the excitonic component of the lower-polaritons and comment on their respective merits and demerits. Among others, methodologies for squeezing the spatial extent of the excitonic wavefunctions, such as by application of out-of-plane magnetic fields and in-plane lateral confinement of 2D excitons in quantum wells, respectively, and the stabilization effect of the strong exciton-photon coupling on the excitonic binding shall be discussed. We believe that the latter is, probably, the most promising for future device applications.

Session H01 DCMP: Fermi Surface and Excitations of Weyl Systems

BCEC 106 - Ryo Okugawa, Tohoku University - Tag(s): Focus

2:30PM H01.00001: Semi-Quantized Pumping and Spin-Orbit Torque in Topological Dirac Semimetals

TAKAHIRO MISAWA (Presenter), Institute for Solis State Physics, University of Tokyo, KENTARO NOMURA, Institute for Materials Research, Tohoku University — We study the spin/charge transport phenomena and magnetization switching in a topological Dirac semimetal attached to a ferromagnetic insulator. Topological Dirac semimetals manifest a large inverse spin Hall effect when a spin current is pumped from the attached ferromagnetic insulator with a precessing magnetization, compared to conventional normal metals. We show that the induced charge current is semi-quantized because it originates to topological nature. We also show that an applied electric field in the topological Dirac semimetal generates the spin-orbit torque which reverses the magnetization in the ferromagnet.
2:42PM H01.00002: Disordered fermionic quantum critical points  
HENNADII YERZHAKOV (Presenter), JOSEPH MACIEJKO, University of Alberta — We study the effect of short-range quenched disorder on the semimetal-superconductor quantum phase transition in a model of two-dimensional Dirac semimetal with N flavors of two-component Dirac fermions, using perturbative renormalization group methods at one-loop order in 4-ε spatial and ετ time dimensions. Depending on the value of N, the model is applicable to topological insulators (odd N), graphene (N=4), and possibly other systems and type of transitions. For N≥2 we find that the Harris-stable clean critical behavior gives way, past a certain critical disorder strength, to a finite-disorder critical point characterized by non-Gaussian critical exponents, a noninteger dynamic critical exponent, and a finite Yukawa coupling between Dirac fermions and bosonic order parameter fluctuations. For sufficiently large N the disordered quantum critical point is described by a renormalization group fixed point of stable-focus type and exhibits oscillatory corrections to scaling.

2:54PM H01.00003: Chirality Josephson current in inversion-asymmetric Weyl semimetals  
SONGBO ZHANG (Presenter), JOHANNA ERDMENGER, BJ"ORN TRAUZETTEL, Institute for Theoretical Physics and Astrophysics, University of Würzburg — In this report, I will talk about Josephson junctions based on inversion-asymmetric but time-reversal symmetric Weyl semimetals under the influence of Zeeman fields. Due to distinct spin textures, the Weyl nodes of opposite chirality respond differently to an external magnetic field. Remarkably, a Zeeman field perpendicular to the junction direction results in a phase shift of opposite sign in the current-phase relations of opposite chirality. This leads to a finite chirality Josephson current even in the absence of a phase difference across the junction. In the long junction and zero temperature limit, the chirality Josephson current embodies a novel quantum anomaly at π phase difference which is associated with a Z2 symmetry at low energies. It can be detected experimentally via an anomalous Fraunhofer pattern.

3:06PM H01.00004: Generalized Triple-Component Fermions: Lattice Model, Fermi arcs and Anomalous Transport  
SNEHASISH NANDY (Presenter), Department of Physics, Indian Institute of Technology Kharagpur, SOURAV MANNA, Max Planck Institute for the Physics of Complex System, DUMITRU CALUGARU, Cavendish Laboratory, University of Cambridge, BITAN ROY, Max Planck Institute for the Physics of Complex System — A generalization of time-reversal symmetry-breaking triple-component semimetals, transforming under the pseudo-spin-1 representation, to arbitrary (anti-)monopole charge , with n = 1, 2, 3 in the crystalline environment will be presented. The quasiparticle spectra of such systems are composed of two dispersing bands with pseudo-spin projections and one completely flat band at zero energy with . In this talk we will show simple tight-binding models for such spin-1 excitations in a cubic lattice and address the symmetry protection of the generalized triple-component nodes. In accordance to the bulk-boundary correspondence, triple-component semimetals support branches of topologically protected Fermi arc surface states and accommodate a large anomalous Hall conductivity (in the xy plane), given by . Furthermore, we compute the longitudinal magneto-, planar Hall and magneto thermal-conductivities in this system, which increase as (due to the non-trivial Berry curvature in the medium) with the external magnetic field (B), when it is sufficiently weak. A generalization of our construction to arbitrary integer spin system is also highlighted.

3:18PM H01.00005: Magnetic field induced valley polarization in a Weyl semimetal with tilted cones.*  
SIMON BERTRAND (Presenter), RENE COTE, ION GARATE, Universite de Sherbrooke — We present a theory of the optical conductivity in time-reversal symmetric Weyl semimetals with tilted cones placed under strong magnetic fields. Our theory incorporates long range Coulomb interactions treated within the generalized random phase approximation. Under irradiation by circularly polarized light, we predict a 100% valley polarization for significant intervals of the incident photon frequency. This polarization, which occurs between nodes related by time-reversal, originates from interband transitions involving the chiral Landau level. We propose observable signatures of this polarization in the optical conductivity and comment on its manifestation in TaAs and related materials.

*We acknowledge financial support from Québec’s Réseau Québécois des Matériaux de Pointe and Canada’s National Science and Engineering Research Council.
Thermoelectric transport in torsional strained Weyl semimetals* ENRIQUE MUNOZ (Presenter), Pontifical Catholic University of Chile, RODRIGO SOTO GARRIDO, Universidad San Sebastian — We recently1 studied the electronic transport properties in Weyl semimetals submitted to the combined effects of torsional mechanical strain and magnetic field, showing that this configuration induces a node-polarization effect on the current that can be used to measure the torsion angle from transmission experiments. In this talk, we extend our previous work to study thermoelectric transport in Weyl semimetals2 (WSM) under torsional strain and an external magnetic field. We provide exact analytical expressions for the transmitted heat current, in order to calculate the thermal conductance and the Seebeck coefficient under this configuration. Our results suggest that thermoelectric transport coefficients in these materials can be engineered by appropriately tuning the magnitude of the magnetic field, torsional strain and the applied bias or thermal gradient, leading to a potentially very high figure of merit.

First-Principles Studies of Topological Semimetal Features in the Nonpolar Phase of Ferromagnetic Hexagonal Manganites YXO₃ (X=V-Co) SOPHIE WEBER (Presenter), University of California, Berkeley,CA, SINEAD MAGELLA GRIFFIN, JEFFREY B NEATON, Lawrence Berkeley National Lab, Berkeley, CA — Hexagonal Manganites have garnered much attention in the condensed matter community due to their multiferroic properties. Here, we use first principles calculations to examine the topological properties of their band structures. While the noncollinear antiferromagnetism common in this compound class generally yields insulating states, we find that energetically-nearby ferromagnetic ordering can cause metallic band structures with topological nodal features in the nonpolar P6₃/mmc phase. Starting with YMnO₃ we substitute different 3d transition metals for Mn and examine the resultant trends in band structure as a function of B site cation. In particular we find that YVO₃ and YCrO₃ have nodal lines near the Fermi level due a band inversion which can be tuned via biaxial strain. Based on our findings, stabilizing YXO₃ compounds in the hexagonal ferromagnetic phase, for example via epitaxial growth, can offer a promising platform for studying the interplay of topology and multiferroicity.

Topological nodal phases in non-Hermitian systems with parity-time and parity-particle-hole symmetries RYO OKUGAWA (Presenter), WPI-AIMR, Tohoku university, TAKEHITO YOKOYAMA, Department of Physics, Tokyo Institute of Technology — Exceptional points emerge from band touching in non-Hermitian systems. We study band degeneracy in non-Hermitian systems with parity-time and parity-particle-hole symmetries. When parity-time or parity-particle-hole symmetry is present, it is shown that exceptional lines and surfaces can appear in two-dimensional and three-dimensional non-Hermitian systems, respectively. We also investigate topological properties of the nodal band structures. We demonstrate the non-Hermitian topological nodal phases by using lattice models of a topological semimetal and a superconductor.

Berry curvature and Hall viscosities in an anisotropic Dirac semi-metal FRANCISCO PENA-BENITEZ, KUSH SAHA, PIOTR SUROWKA (Presenter), Max Planck Institute for the Physics of Complex Systems — We investigate parity-odd non-dissipative transport in an anisotropic Dirac semi-metal in two spatial dimensions. The analysis is relevant for interacting electronic systems with merging Dirac points at charge neutrality. For such systems the dispersion relation is relativistic in one direction and non-relativistic in the other. We give a proposal how to calculate the Berry curvature for this system and use it to derive more than one odd viscosities, in contrast to rotationally invariant systems. We observe that in such a model the odd part of stress tensor is parameterised by two independent transport coefficients and one that is identically zero.
the external magnetic field \( B \) and increases as \( B^2 \), at least when it is sufficiently weak (the semi-classical regime). In the longitudinal magnetoconductivity (LMC), bearing the signature of the chiral anomaly, is insensitive to the direction of the magnetic field even though the distribution of the underlying Berry curvature is anisotropic, the corresponding intrinsic component of arbitrary integer charge \( n \), with \( n=1, 2 \) and \( 3 \) in a crystalline environment, will be presented. We will show that for any \( n > 1 \), the anomalous contribution, arising from the chiral anomaly.

4:42PM H01.00010: Magnetotransport in multi-Weyl semimetals: A kinetic theory approach

RENAITO DANTAS (Presenter), FRANCISCO PENABENITEZ, PIOTR SUROWKA, BITAN ROY, Max Planck Institute for the Physics of Complex System — Longitudinal magnetotransport in three-dimensional multi-Weyl semimetals, constituted by a pair of (anti)-monopole of arbitrary integer charge \( n \), with \( n=1, 2 \) and \( 3 \) in a crystalline environment, will be presented. We will show that for any \( n > 1 \), even though the distribution of the underlying Berry curvature is anisotropic, the corresponding intrinsic component of the longitudinal magnetoconductivity (LMC), bearing the signature of the chiral anomaly, is insensitive to the direction of the external magnetic field \( B \) and increases as \( B^2 \), at least when it is sufficiently weak (the semi-classical regime). In addition, the LMC scales as \( B^2 \) with the monopole charge. We demonstrate these outcomes for two distinct scenarios, namely when inter-particle collisions in the Weyl medium are effectively described by (a) a single and (b) two (corresponding to inter-valley and intra-valley) scattering times. While in the former situation the contribution to LMC from chiral anomaly is inseparable from the non-anomalous ones, these two contributions are characterized by different time scales in the later construction. Specifically for sufficiently large inter-valley scattering time the LMC is dominated by the anomalous contribution, arising from the chiral anomaly.

4:44PM H01.00011: Geometric signatures of topological origin in the particle-hole continuum of Weyl semimetals

ANIRUDH CHANDRASEKARAN (Presenter), STEFANOS KOURTIS, Boston University — We present a full geometric description of the particle-hole continuum in Weyl semimetals, emphasizing distinctive features in the joint density of states for particle-hole excitations across nodal points. These are shown to arise as a geometric consequence of the linear effective Hamiltonian around nodal points, and are thus characteristic of Weyl semimetals. We discuss how such geometric characteristics of the particle-hole continuum of Weyl semimetals can be present in resonant inelastic X-ray scattering (RIXS) spectra. Our work provides signatures of the presence of Weyl nodes in bulk band structures, and indicates that RIXS is a promising tool that can potentially be used to identify and characterize nodal points in materials, especially in settings that are difficult to access with other spectroscopies. The calculation presented here also serves as a first checkpoint for comparison with ongoing RIXS experiments.

4:54PM H01.00013: Non-abelian braiding of Weyl points

ADRIEN BOUHON (Presenter), Nordita, ROBERT-JAN SLAGER, Max Planck Institute for the Physics of Complex Systems, TOMAS BDUSEK, Physics Department, Stanford University — We discuss the realization of non-abelian braiding of Weyl points in a two-dimensional crystal. This proposal is based on a refined homotopy characterization of band structures that goes beyond the current classification of crystalline topological phases of matter.

*Nordita, Stockholm.

5:06PM H01.00014: The disordered single Weyl cone

JED PIXLEY (Presenter), JUSTIN WILSON, Rutgers University, New Brunswick, DAVID HUSE, Physics, Princeton University, SANKAR DAS SARMA, Physics, University of Maryland — We numerically study a single Weyl cone in the presence of short-range disorder. By representing the Hamiltonian in a \`mixed\’ way between real and momentum space we are able to invoke fast Fourier transforms to take advantage of efficient numerical routines (such as Lanczos and the kernel polynomial method) that rely on sparse matrix-vector multiplications. As a result, we reach sufficiently large system sizes that are comparable to lattice model simulations. We study the distinctions that arise between lattice models that contain band curvature and multiple Weyl nodes that have internode scattering with the case of a single Weyl node with a perfectly linear dispersion. We will report results on the nature of rare regions and the density of states as a function of the strength of disorder as well as compare and contrast single node and multinode situations.
Tuesday, March 5, 2019 2:30 PM - 5:30 PM

Session H02 DMP: Topological Metamaterials and Functional Nanostructures BCEC 107A -
Yongmin Liu, Northeastern University - Tag(s): Focus

2:30PM H02.00001: Topological Metamaterials [Invited] ANDREA ALU (Presenter), Photonics Initiative, Advanced Science Research Center at CUNY GC — In this talk, I discuss our recent research activity in electromagnetics, nano-optics, acoustics and mechanics, showing how suitably tailored meta-atoms and arrangements of them open exciting venues to induce topological order for light, radio-waves and sound, mimicking the response of electronic topological insulators. Our approaches are based on using suitably tailored mechanical motion, spatio-temporal modulation, large nonlinearities in coupled resonator systems, and bianisotropy in order to induce the required symmetry breaking in periodic systems that yields topologically nontrivial wave propagation. In the talk, I will also discuss the impact of these concepts from basic science to practical technology.

3:06PM H02.00002: Two-dimensional mechanical metamaterials with unusual Poisson ratio behavior* DAVID TOMANEK (Presenter), DAN LIU, ZHIBIN GAO, Michigan State University — We design two-dimensional mechanical metamaterials that may be deformed substantially at little or no energy cost. Examples of such deformable structures are assemblies of rigid isosceles triangles hinged in their corners on the macro-scale, or polymerized phenanthrene molecules forming porous graphene on the nano-scale. In these and in a large class of related structures, the Poisson ratio ν diverges for particular strain values. ν also changes its magnitude and sign, and displays a shape memory effect.

*NSF/AFOSR EFRI 2-DARE grant number EFMA-1433459 and China Scholarship Council grant number 201706260027

3:18PM H02.00003: A programmable modular metamaterial with alterable Poisson's ratio and multi-stability* XIAOYI JIANG, JIAYAO MA, YAN CHEN (Presenter), Mechanical Engineering, Tianjin University — Modular metamaterials are artificially designed materials constructed by linked modules, often with properties surpassing these constituent modules. To achieve certain required deformation modes and mechanical properties, the modules are usually linked to form a mobile mechanism or a deformable structure. Here we present a novel 3D modular metamaterial constructed of hinged blocks, which utilizes both to realize alterable Poisson's ratio and multi-stability. We demonstrate through theoretical analysis and experiments that upon axial compression, a single unit of the new metamaterial has two distinct mechanism motion stages with positive and negative Poisson's ratio, respectively. And in between there exist a structure deformation stage, thereby forming a mechanism-structure-mechanism transition with bi-stability. Both the magnitude of Poisson's ratio and the energy needed to bypass the structure deformation stage is programmable through two design parameters. In addition, the single unit can be stacked axially to form a tubular metamaterial with progressive folding deformation mode and multi-stability.

3:30PM H02.00004: Seeded glancing-angle deposition of nanoparticle-nanowire hybrid structures* KAI TREPKA (Presenter), YE TAO, Harvard University — The controllable handling of an arbitrary single particle of matter < 50 nm is an essential but unsolved technological challenge. Applications are wide, ranging from fabrication of functionalized scanning probe tips and samples to the sorting of biological particles such as enzymes and viruses for research and drug development [1-4]. Here, we demonstrate a method to handle single copies of nanoparticles (NP) with diameters from 10-100 nm. The procedure is based on the production of nanoparticle-nanowire hybrid structures using glancing-angle deposition (GLAD), with arbitrary NP seeds. The result is a nanoparticle tip attached to a silicon oxide nanowire handle for facile manipulation. To showcase the generality and versatility of the process, we demonstrate its applicability to a range of NP sizes and compositions (FeO, Au, and Fe@C NP). Such tip-handle growth using arbitrary NPs enables manipulation and heterostructure creation at nanoscale, with wide-ranging applications.

[4] 10.1038/nnano.2014.140

3:42PM H02.00005: Passive Radiative Thermostat Enabled by Phase-Change Photonic Nanostructures*  WILTON DE MELO KORT-KAMP (Presenter), SHOBHITA KRAMADHATI, ABUL K AZAD, MATTHEW T REITEN, DIEGO A R DALVIT, Los Alamos National Laboratory — A thermostat senses the temperature of a physical system and switches heating or cooling devices on or off, regulating the flow of heat to maintain the system’s temperature near a desired set point. Taking advantage of recent advances in radiative heat transfer technologies, here we propose a passive radiative thermostat based on phase-change photonic nanostructures for thermal regulation at room temperature. By self-adjusting their visible to mid-IR absorptivity and emissivity responses depending on the ambient temperature, the proposed devices use the sky to passively cool or heat during day-time using the phase-change transition temperature as the set point, while at night-time temperature is maintained at or below ambient. We simulate the performance of a passive nanophotonic thermostat design based on vanadium dioxide thin films, showing daytime passive cooling (heating) with respect to ambient in hot (cold) days, maintaining an equilibrium temperature approximately locked within the phase transition region. Passive radiative thermostats can potentially enable novel thermal management technologies, for example, to moderate diurnal temperature in regions with extreme annual thermal swings.

*The authors thank LANL LDRD program and the Center for Nonlinear Studies for support.

3:54PM H02.00006: Quantum electrodynamics of photonic Weyl points  IÑAKI GARCIA-ELCANO, Condensed Matter Theory Department, Universidad Autonoma de Madrid, ALEJANDRO GONZALEZ-TUDELA, Instituto de Fisica Fundamental IFF-CSIC, JORGE BRAVO-ABAD (Presenter), Condensed Matter Theory Department, Universidad Autonoma de Madrid — The recent realization of photonic Weyl points in three-dimensional photonic crystals [1,2] has drawn significant interest due to their potential as highly controllable platforms to explore topological phenomena [3]. In this talk, we present a systematic study of the decay dynamics of quantum emitters embedded in Weyl-point photonic materials. By combining both analytical and numerical approaches [4], we show how the unique dispersion of photonic Weyl points enables the emergence of a novel light-matter bound state, which cannot be described by conventional perturbative treatments. Potential applications of these findings in emerging quantum technologies are also discussed.

4:06PM H02.00007: Control of radiative processes using periodic arrays of plasmonic nanostructures*  YUWARAJ ADHIKARI, Department of Physics and Materials Science, University of Memphis, YING LI, CHRISTOS ARGYROPoulos, Department of Electrical and Computer Engineering, University of Nebraska-Lincoln, THANG HOANG (Presenter), Department of Physics and Materials Science, University of Memphis — The radiative processes of a quantum emitter can be profoundly altered by its surrounding photonic environment. In this report we explore fundamentals of the light-matter interactions between quantum emitters (such as semiconductor quantum dots or organic molecules) and periodic lattices of plasmonic nanostructures. A lattice of metallic nanostructures provide high photonic density of states via local and lattice plasmon resonances. Via computational and experimental studies, we demonstrate the emission rate enhancement of quantum emitters by integrating them with arrays of plasmonic nanostructures. A set of parameters including size, shape, and lattice constant will be discussed. In particular, an array of plasmonic nanostructures operating near their cut-off frequency can exhibit effective epsilon-near-zero which is expected to trigger both enhanced spontaneous emission and superradiance.[1] Control of radiative processes using local and lattice plasmon resonances also benefits from possibilities of leveraging multiple energy bands.

*This work is supported by the National Science Foundation (NSF) (Grant No. DMR-1709612)
4:18PM H02.00008: Topological Phononic Logic* JENNIFER WANG (Presenter), Physics, Wellesley College, HARRIS PIRIE, SHUVOM SADHUKA, JENNIFER HOFFMAN, Physics, Harvard University — Topological metamaterials have protected dissipationless boundary modes engineered from their macroscopic arrangement, rather than their microscopic constituency. They can be designed by breaking either symmetry-enforced or accidental degeneracy in Dirac metamaterials. The latter case provides greater flexibility because a large number of tuning parameters can break the degeneracy to induce a topological phase. However, the design of a topological logic element, a switch that can be controlled by the output of a separate switch, remains elusive. Here we numerically demonstrate a topological phononic logic gate by exploiting the large phase space of accidental degeneracies in a honeycomb lattice. We find that a degeneracy can be broken by six physical parameters, and we tune these parameters to create a topological phononic switch that can be triggered by ultrasonic heating. Our design scheme is directly applicable to photonic crystals and may guide future designs of electronic topological transistors [1].

*This work was supported by the Center for Integrated Quantum materials under NSF grant DMR-1231319 and by the Gordon and Betty Moore foundation under grant GBMF4546.

4:30PM H02.00009: Photonic implementation of algebraic number theory SEAN GORSKY (Presenter), FABRIZIO SGRIGNUOLI, LUCA DAL NEGRO, Boston University — We study the unique spectral and optical features of a new class of aperiodic arrays generated from the distribution of prime numbers in complex quadratic fields as well as quaternion primes. By using a multiple scattering spectral method, we have discovered several unique spectral properties, such as light localization, critical level statistics, and the existence of critical modes, i.e. extended fractal modes with long lifetime that cannot be supported in traditional systems. A systematic analysis based on LDOS calculations unveil the new functionalities of these complex aperiodic platforms for lasing applications. Our results unveil the importance of aperiodic structures characterized by a coexistence of singular and continuous spectral components for the engineering of new photonic architectures based on algebraic number theory.

4:42PM H02.00010: “Fractional Photonics”: designing light transport in complex aperiodic media LUCA DAL NEGRO (Presenter), Boston University — Space-time fractional transport equations are integro-differential equations with power-law kernels that naturally account for the non-local and memory effects that become important in strongly non-homogeneous environments. In this talk I will discuss the applications of fractional calculus methods to photonics, with emphasis on the physics of multiple light scattering in structurally-complex, aperiodic optical structures and metamaterials. I will focus on our recent results on tunable, sub-diffusive photon transport of ultra-short pulses a across deterministic aperiodic media with multifractal energy spectra and critical mode localization. I will discuss fractional photon diffusion in the presence of optically amplifying media, thus generalizing Letokhov’s treatment of non-resonant uniform random structures to disordered media with arbitrary correlations. The concept of a “fractional random laser” will be introduced along with detailed predictions on its laser threshold and dynamical behavior. The combination of fractional calculus with photonic devices represents a novel and effective approach for the engineering of complex optical structures with anomalous photon transport and amplification properties leading to enhanced light-matter interaction across multiple spectral bands.

4:54PM H02.00011: Topological Photonics* [Invited] CHE-TING CHAN (Presenter), Hong Kong University of Science and Technology — We will begin with 1D photonic crystals, in which the Zak phase of the bulk bands can be used to predict the existence of boundary modes. For 2D systems, we show that meticulously designed photonic crystals can achieve the duality condition, enabling the realization of photonic topological insulators which can be regarded as classical wave counterparts of electronic topological insulator. We will also see that symmetry-protected pseudospin states that are guided in air ican be realized simply by imposing certain special electromagnetic boundary conditions. Such systems are unique to EM wave and do not have electronic counterparts. We then discuss the realization of Weyl points in 3D photonic crystals carrying chiral structures. One-way edge modes are found on the boundary of these systems as a result of the synthetic gauge flux emerging from the Weyl nodes. These structures possess single Weyl points, including “type-II” nodes, and Weyl points with topological charges higher then one. Weyl points can also be found in some woodpile photonic crystals. The sign of topological charge will change when the constituent materials change, leading to a topological phase transition and the bands change from topologically trivial to nontrivial. We will see that Weyl-like nodal points can be found in the parameter space of a 1D photonic crystals with complex unit cells. The reflection at the surface of these photonic crystals exhibits phase vortexes, which guarantees the existence of interface states between photonic crystals and any reflecting substrates. In addition, we will see that helical structures that be used to realize three-dimension photonic Dirac points, with four-fold symmetry stabilized by electromagnetic duality symmetry. These systems carry spin-polarized surface arcs that can be realized experimentally.

*Work supported by the Hong Kong Research Grants Council (AoE/P-02/12).
2:30PM H03.00001: Surfaces of axion insulators* NICODEMOS VARNAVA (Presenter), DAVID VANDERBILT, Rutgers University, New Brunswick — Axion insulators (AXIs) are magnetic topological insulators in which the non-trivial \(Z_2\) index is protected by inversion instead of time-reversal (TR) symmetry. The naturally gapped surfaces of AXIs give rise to a half-quantized surface anomalous Hall conductivity (SAHC), but its sign cannot be determined from topological arguments. To be explicit, we construct a minimal tight-binding model on the pyrochlore lattice and investigate the all-in-all-out and ferromagnetic spin configurations. We show that the Wilson loop eigenvalues are not required to wind for an AXI in contrast with their TR-invariant cousin. We also implement a method that lets us calculate the SAHC directly, which allows us to explore how the interplay between surface termination and magnetic ordering determines the sign of the half-quantized SAHC. We find that it is possible to construct a topological state with no protected metallic states on boundaries of any dimension, although chiral hinge modes do occur for many surface configurations. Finally, we find that rotation of the magnetization by an external field offers promising means of control of chiral hinge modes, which can also appear on surface steps or where bulk domain walls emerge at the surface.

*This work was supported by grant NSF DMR-1408838.

2:42PM H03.00002: Failure of Nielsen-Ninomiya theorem and fragile topology in two-dimensional systems with space-time inversion symmetry: application to twisted bilayer graphene at magic angle* JUNYEONG AHN, SUNGJOON PARK (Presenter), BOHM-JUNG YANG, Seoul National University — We examine the band topology of two dimensional real fermions in systems with space-time inversion (STI) symmetry. We show that a two-band system with a nonzero Euler class cannot have STI symmetric Wannier representation. Moreover, a two-band system with the Euler class \(e_2\) has band crossing points whose total winding number is equal to \(2e_2\). Thus the conventional Nielsen-Ninomiya theorem fails in systems with a nonzero Euler class. We propose that the topological phase transition between insulators carrying different Euler classes can be described by pair creation and annihilation of vortices across Dirac strings.

For a multiband system, the \(Z_2\) invariant called the second Stiefel-Whitney class \((w_2)\) can be defined, which is equal to \(e_2 \mod 2\) for a 2-band system. Although \(w_2\) remains robust against adding trivial bands, it does not impose Wannier obstruction when the total number of bands is greater than two. However, when the resulting multi-band system with the nontrivial second Stiefel-Whitney class is supplemented by additional mirror and chiral symmetries, a nontrivial second order topology and the associated corner charges are guaranteed. We discuss the implications to the nearly flat bands of twisted bilayer graphene at magic angle.

2:54PM H03.00003: Topological phase transitions induced by tunable magnetization direction in Chern insulators RUI-AN CHANG (Presenter), CHING-RAY CHANG, National Taiwan University — Quantum anomalous Hall effect (QAHE), the quantum Hall effect without Landau levels, has been widely studied in 2D electron systems for its nontrivial topology and promising applications in future technology. Magnetic topological insulators are very typical systems exhibiting QAHE phase [1].

With recent intense study of spintronics such as spin-orbit torque (SOT) or spin-transfer torque (STT), SOT or STT is anticipated as a proper way to manipulate the magnetization direction and trigger the topological phase transitions [2]. Following the preceding idea, we present a 2D QAHE system, possibly realizable in semiconductor heterostructure, with inversion symmetry breaking and Dresselhaus spin-orbit coupling (SOC). Topological phase diagrams are obtained by the calculation of Chern number in a totally analytical way. We find that this system is topologically trivial with in-plane magnetization and undergoes a topological phase transition that makes this system transform into a topologically nontrivial phase when the magnetization is deviated from the in-plane direction. Therefore, the control of the topological phases and corresponding chiral edge states can be achieved by tuning the magnetization degrees of freedom.

3:06PM H03.00004: Topological Superconductivity and Density Waves on the surface of Topological Kondo Insulator
YI LUO (Presenter), Physics and Astronomy, Johns Hopkins University, PREDRAG NIKOLIC, Physics & Astronomy, George Mason University — We study the weak-coupling instabilities in the particle-particle and particle-hole channels on the surface of a prototype Kondo topological insulator. We draw inspiration from samarium hexaboride (SmB6), and the possible observation of its correlation physics through magnetoresistance hysteresis[1]. We work on the 100-surface, which has square C4v symmetry and contains three Dirac cones (electron or hole pockets) at Γ and two X points in momentum space. For superconducting order, we find phases supporting non-zero magnetization and spin current in the ground state, with certain symmetries broken by the condensates of inter-pocket order parameters. The intra-pocket pairings in general lead to a non-zero Chern number in Bogoliubov band, hinting topological superconductivity and the presence of Majorana zero modes bounded to defects. For exciton pairings, similar symmetry breaking phases are discovered.

3:18PM H03.00005: Higher-Order Topology of Three-Dimensional Strong Stiefel-Whitney Insulators*
JUNYEONG AHN (Presenter), BOHM-JUNG YANG, Seoul National University — The Stiefel-Whitney insulator (SWI) is a two-dimensional topological phase protected by the symmetry under the combination of time reversal and a two-fold rotation C2. This phase has got attention because it shows new aspects of topological crystalline insulators such as fragile topology and higher-order topology. In this talk, we study the three-dimensional generalization of the Stiefel-Whitney insulator. We show that a C2T-symmetric insulator in 3D can have a stable topological invariant, contrary to its two-dimensional counterpart having fragile band topology. To characterize the bulk band topology further, we develop a new method based on the homotopy class of the symmetry representation for C2T in a smooth gauge, instead of examining the obstruction to constructing smooth wavefunctions compatible with the reality condition. By using the new method, we show that the 3D topological insulator, dubbed 3D strong SWI, is characterized by the quantized magnetoelectric polarizability, which induces anomalous chiral hinge states along the edges parallel to the C2 rotation axis and massless Dirac fermions on the surfaces normal to the C2 axis. This establishes that a 3D strong SWI is a second-order topological insulator.

3:30PM H03.00006: Revisiting topological property of a \((t_{2g})^5\) system with a honeycomb lattice
BEOM HYUN KIM (Presenter), School of Computational Sciences, Korea Institute for Advanced Study, KAZUHIRO SEKI, TOMONORI SHRAKAWA, International School for Advanced Studies, SEIJI YUNOKI, Computational Condensed Matter Physics Laboratory, RIKEN Cluster for Pioneering Research — Na2IrO3 is the transition-metal system with a honeycomb lattice in which five electrons per site are occupied in Ir \(t_{2g}\) bands. It was firstly proposed as a candidate to show the quantum spin Hall (QSH) phase because spin-orbital entangled \(J_{\text{eff}} = 1/2\) bands across the Fermi level can be map into the Kane-Mele model. However, its topological phase has not been reported yet. Contrarily, Na2IrO3 and its isostructural systems have turned out to be Mott insulator with antiferromagnetic order. Nevertheless, the possibility of the QSH phase in these systems is still an interesting subject. State-of-the-art structural controlling with high pressure, chemical substitution, or substrate engineering can potentially manipulate their electronic kinetics and correlation effect.

In the study, we revisit the topological property of a \((t_{2g})^5\) system with a honeycomb lattice. We explore the topological phase transition with respect to a relative strength of two types of nearest neighboring hopping channels: the hopping mediated by edge-shared ligands with pdp bonding and the direct hopping between \(t_{2g}\) orbitals with ddσ bonding. Moreover, we investigate topological properties in the presence of Coulomb repulsion with help of variational cluster perturbation theory.
prototypical TI Bi\textsubscript{2}Te\textsubscript{3} films, we find from our angle-resolved photoemission spectroscopy (ARPES) measurements of thickness (3 – 10 quintuple layers) on top of bulk Nb film. Moreover, by carefully controlling the growth conditions of the DU, DOUGLAS NATELSON, Rice University — We report preliminary shot noise measurements in InAs/GaInSb quantum well and for clarifying the pairing in these heterostructures for applications in topological quantum computing.

states in these doped TI/SC thin-film heterostructures. Our study underlines methods for realizing superconductivity in TIs ARPES and STM measurements would clarify the mechanism of coupling between the SC and the topological surface dimensions. We investigate the universal behaviour of a density-driven Chern and Z\textsubscript{2} glass transitions by carrying topological matter. In this work we introduce a scaling theory of amorphous topological phase transitions in two dimensional systems. We investigate the universal behaviour of a density-driven Chern and Z\textsubscript{2} glass transitions by carrying out a finite-size scaling analysis of topological invariants averaged over random geometries. We find that the universal properties of continuum problems can be captured by studying random geometries generated by percolation lattices. Strikingly, our results show that even for short-range hopping the topological phase may persists down to the classical site percolation threshold. Furthermore, our theory suggests that the value of the critical exponent describing the diverging localization length near the critical density is close to that of the exponent of the correlation length of the critical percolation cluster. Our theory supports the conclusion that density-driven amorphous topological transitions have their unique properties not shared by disordered systems and occupy separate universality classes.

3:54PM H03.00008: Current Noise in InAs/GaInSb Corbino structures  LOAH STEVENS (Presenter), TINGXIN LI, RUI-RUI DU, DOUGLAS NATELSON, Rice University — We report preliminary shot noise measurements in InAs/GaInSb quantum well interfaces. The band structure of these composite quantum wells is inverted, and electron and hole densities are equal at the cross point of the valence and conduction bands. The holes in the strained GaInSb layer couple strongly to the electrons in the InAs layer, opening a gap in the spectrum of the 2d bulk. At low temperatures or when gated into the appropriate regime, bulk transport is greatly suppressed as the hybridized gap is opened. Corbino disk devices consist of concentric rings, meaning no edge conduction is present. Therefore, in these structures, noise measurements examine transport through the bulk and the role played by contacting electrodes. We will compare current noise measurements of samples in the nominal Quantum Spin Hall Insulator state and in the lower-resistance, bulk transport state.

4:06PM H03.00009: Superconducting proximity effects and pairing in (Bi\textsubscript{1-x}Sb\textsubscript{x})\textsubscript{2}Te\textsubscript{3} films on niobium  JOSEPH HLEVYACK (Presenter), YANG BAI, MENG-KAI LIN, PENG CHEN, DAVID FLÖTOTTO, RO-YA LIU, Department of Physics, University of Illinois-Urbana-Champaign, AYKHIRO TSUZUKI, KOZO OKAZAKI, SHIK SHIN, Institute for Solid State Physics, The University of Tokyo, JAMES N ECKSTEIN, TAI-CHANG CHIANG, Department of Physics, University of Illinois-Urbana-Champaign — Interfacing a topological insulator (TI) with an s-wave superconductor (SC) can favor the formation of helical-Cooper pairing in the topological surface states. However, realizing this system is often challenging, due to the impracticality of growing TIs on most SCs and possibly defects and Fermi surface/lattice mismatch at the TI/SC interface. By developing a novel cleavage-based “flip chip” approach, we have successfully fabricated single-crystalline (Bi\textsubscript{1-x}Sb\textsubscript{x})\textsubscript{2}Te\textsubscript{3} thin films of a predetermined thickness (3 – 10 quintuple layers) on top of bulk Nb film. Moreover, by carefully controlling the growth conditions of the prototypical TI Bi\textsubscript{2}Te\textsubscript{3} films, we find from our angle-resolved photoemission spectroscopy (ARPES) measurements of Bi\textsubscript{2}Te\textsubscript{3}/Nb that the Fermi level can lie in the band gap, giving rise to a lightly n-doped TI on a SC substrate. Ongoing laser ARPES and STM measurements would clarify the mechanism of coupling between the SC and the topological surface states in these doped TI/SC thin-film heterostructures. Our study underlines methods for realizing superconductivity in TIs and for clarifying the pairing in these heterostructures for applications in topological quantum computing.

4:18PM H03.00010: Theory of topological glass transitions in amorphous topological matter  ISAC SAHLBERG, Department of Physics, Tampere University, ALEX WESTSTRÖM, KIM PÖYHÖNEN, Aalto University, TEEMU OJANEN (Presenter), Department of Physics, Tampere University — Amorphous systems have recently been identified as promising platforms for topological matter. In this work we introduce a scaling theory of amorphous topological phase transitions in two dimensional systems. We investigate the universal behaviour of a density-driven Chern and Z\textsubscript{2} glass transitions by carrying out a finite-size scaling analysis of topological invariants averaged over random geometries. We find that the universal properties of continuum problems can be captured by studying random geometries generated by percolation lattices. Strikingly, our results show that even for short-range hopping the topological phase may persists down to the classical site percolation threshold. Furthermore, our theory suggests that the value of the critical exponent describing the diverging localization length near the critical density is close to that of the exponent of the correlation length of the critical percolation cluster. Our theory supports the conclusion that density-driven amorphous topological transitions have their unique properties not shared by disordered systems and occupy separate universality classes.
4:30PM H03.00011: Anomalous scaling law in the quantum Hall plateau-plateau transitions of topological insulator Sn-Bi$_1$.1Sb$_{0.9}$Te$_2$S devices  
FAJI XIE (Presenter), SHUAI ZHANG, FENGQI SONG, Nanjing University — The surfaces of three dimensional topological insulators are two dimensional electron gases of Dirac fermions without electron-phonon scattering contamination. In the quantum Hall states of the surface states system, the mechanism of transport dispassion change from thermal activation to the variable range hopping at a critical temperature 20K. The quantum Hall plateau-to-plateau transition behavior in the temperature regime below 20K gives with a universal exponent $k=0.20$. It indicates that only electron-electron interaction dominates the inelastic scattering mechanism in the two dimensional topological electron system.

4:42PM H03.00012: Mirror Chern number in the hybrid Wannier representation  
TOMÁŠ RAUCH, University of Jena, Germany, THOMAS OLSSEN, Technical University of Denmark, DAVID VANDERBILT, Rutgers University, USA, IVO SOUZA (Presenter), University of the Basque Country, Spain — We formulate the mirror Chern number (MCN) of a two-dimensional insulator with reflection symmetry $M_z$ in terms of hybrid Wannier functions (the eigenfunctions of $P_zP$, the position operator projected onto the valence bands). Because $P_zP$ and $M_z$ anticommute, the spectrum of "Wannier bands" is symmetric about the mirror plane, and an excess of one mirror eigenvalue over the other in the occupied manifold leads to the appearance of flat bands on the mirror plane. (This structure is reminiscent of the energy bands of a bipartite lattice, where the Hamiltonian anticommutes with the sublattice symmetry operator.) In the absence of flat bands, pairs of dispersive bands may touch at isolated points on the mirror plane. These Dirac cones are protected by symmetry, and the MCN is given by the sum of their winding numbers. When flat bands are present the Dirac cones are no longer protected, and the MCN is related instead to the Chern number of the flat bands. In three dimensions, the present formalism reveals a simple relation between the MCNs and the quantized axion angle $\theta$, whose expression in the hybrid Wannier representation was previously obtained.

4:54PM H03.00013: Strongly enhanced Berry-dipole at topological phase transitions in BiTeI*  
JORGE FACIO (Presenter), DMITRI EFERMOV, KLAUS KOEPERNIK, JHIH-SHIH YOU, IFW - Dresden, INTI SODEMANN, Max Planck Institute for the Physics of Complex Systems, Dresden, JEROEN VAN DEN BRINK, IFW - Dresden — Transitions between topologically distinct electronic states have been predicted in different classes of materials and observed in some. A major goal is the identification of measurable properties that directly expose the topological nature of such transitions. Here we focus on the giant-Rashba material bismuth tellurium iodine (BiTeI) which exhibits a pressure-driven phase transition between topological and trivial insulators in three-dimensions. We demonstrate that this transition, which proceeds through an intermediate Weyl semi-metallic state, is accompanied by a giant enhancement of the Berry curvature dipole which can be probed in transport and optoelectronic experiments. From first-principles calculations, we show that the Berry-dipole --a vector along the polar axis of this material-- has opposite orientations in the trivial and topological insulating phases and peaks at the insulator-to-Weyl critical points, at which the nonlinear Hall conductivity can increase by over two orders of magnitude (arXiv:1805.02680).

5:06PM H03.00014: Contrasting the Surface Phonon Dispersion of the Topological Crystalline Insulator Pb$_{0.7}$Sn$_{0.3}$Se in its Topologically Trivial and Nontrivial Phases*  
SAMUEL KALISH (Presenter), Physics, Boston University, LUIZ SANTOS, Physics, Emory University, RAMAN SANKAR, FANGCHENG CHOU, Center of Condensed Matter Sciences, National Taiwan University, CLAUDIO CHAMON, MAGED MANSOUR EL-BATANOUNY, Physics, Boston University — We report inelastic He atom surface-scattering measurements of the (001) surface phonons dispersion of the topological crystalline insulator Pb$_{0.7}$Sn$_{0.3}$Se. Because this material exhibits a temperature-dependent topological transition, we measure the surface dispersion curves in both the trivial and topological phases. Peculiarly, most surface phonon modes appear as resonances, rather than pure surface states. We find that a vertical shear surface resonance branch around 1.9 THz dramatically changes on going from the trivial to the topological phase. We associate this remarkable change with a strong interaction of the emergent surface Dirac fermions with the modes of this branch. We use the measured dispersion of this resonance branch to determine the corresponding mode-dependent electron-phonon coupling $\lambda_m$.$(q)$.

Localization-Driven Correlated States of Two Isolated Interacting Helical Edges

YANG-ZHI CHOU

Presenter, University of Colorado, Boulder — We study the localization-driven correlated states among two isolated dirty interacting helical edges as realized at the boundaries of two-dimensional $\mathbb{Z}_2$ topological insulators. We show that an interplay of time-reversal symmetric disorder and strong inter-edge interactions generically drives the entire system to a gapless localized state, preempting all other intra-edge instabilities. For weaker interactions, an anti-symmetric interlocked fluid, causing a negative perfect drag, can emerge from dirty edges with different densities. We also study the stability of the inter-edge correlated states against finite size and/or finite temperature corrections. The corresponding experimental signatures are discussed.

Tuesday, March 5, 2019 2:30 PM - 5:30 PM

Session H04 DMP: Dirac/Weyl Semimetals -- Type-II Topological Semimetals

Polar domains and domain walls in MoTe$_2$ with Weyl semimetallic and trivial semimetallic phases

Fei-Ting Huang (Presenter), Seong Joon Lim, Sobhit Singh, Jinwoong Kim, Department of Physics and Astronomy, Rutgers University, New Jersey, Lunyong Zhang, Laboratory for Pohang Emergent Materials and Max Planck POSTECH Center for Complex Phase Materials, Pohang University of Science and Technology, JAE-Wook Kim, David Vanderbilt, Sang-Wook Cheong, Department of Physics and Astronomy, Rutgers University, New Jersey — Quantum materials with non-trivial electronic topologies are one of the most active fields of current condensed matter research. Among them, Weyl semimetal (WSM) behavior can be realized quite generally in a semimetallic crystal with large spin-orbit coupling by breaking either time-reversal or space inversion symmetry. Interestingly, those known WSMs through the space inversion breaking mechanism often crystallize in polar structures, and thus they are polar WSMs. The question that naturally arises is the possible existence of polar domains and domain walls (DWs), which is particularly important because the Weyl points and the surface Fermi-arcs can depend on the domain reorientation and accompany with intriguing properties. Here, we focus on the type-II WSM MoTe$_2$, which has recently drawn an immense attention due to its phase tunability and unique physical properties. Utilizing in-situ cryogenic transmission electron microscopy, we unveil intriguing polar domain structures in MoTe$_2$. We also discover unexpected domain kinetics under electron beams. Using spatially resolved tunneling spectroscopy, we observe distinct electronic responses of those domains and DWs. These findings are a key step toward engineering the Weyl-node-pair-related physical properties in such polar WSMs.

Novel structure in the Mo$_{1-x}$W$_x$Te$_2$ family

Yu Tao (Presenter), John Schneeloch, Chunruo Duan, University of Virginia, Masaaki Matsuda, Sachith Dissanayake, Oak Ridge National Lab, Despina Louca, University of Virginia — Mo$_{1-x}$W$_x$Te$_2$ belongs to the family of 2-dimensional transition metal dichalcogenides that are of wide interest because of their fascinating topological properties. Mo$_{1-x}$W$_x$Te$_2$ undergoes a structural phase transition from the monoclinic 1T' phase at high temperatures, to the orthorhombic T$_d$ phase at low temperatures through a first-order structural phase transition. Both phases consist of nearly-identical layers which differ primarily by the layers' in-plane positioning. With elastic neutron scattering, we study the transition between these two structures on single crystals of MoTe$_2$ with and without W-doping. Structural changes including changes in interlayer disorder were observed from the elastic scattering along (2, 0, L) on cooling and warming through the hysteresis. We observed a thus far unreported unit cell doubling phase, T$_d$*, that emerges without disorder on warming from T$_d$ and deduced its layer stacking pattern as 'AABB' rather than the 'ABAB' and 'AAAA' orders for the 1T' and T$_d$ phases. We describe the transition in terms of a 1-dimensional Ising model whose interaction coefficients change with temperature. These results clarify in microscopic detail the nature of these phase transitions.

*This work is supported by the Department of Energy, Grant number DE-FG02-01ER45927.
Doping dependence of the sliding-layer phase transitions in (Mo,W)Te₂

JOHN SCHNEELOCH (Presenter), YU TAO, DESPINA LOUCA, CHUNRUO DUAN, University of Virginia — The electronic properties of materials composed of weakly-bound layers can change substantially depending on how the layers are stacked. For example, the monoclinic 1T' phase of MoTe₂ is reported to become a Weyl semimetal when cooled below 250 K into its orthorhombic T₉ phase, which differs from 1T' mainly by in-plane displacements of the layers. Substituting Mo for W raises the transition temperature. In this talk, we will focus on the effect of W-doping on Mo₁₋ₓWₓTe₂ crystals up to x=0.5, using neutron scattering to investigate structural changes. The transition temperature continues to increase to at least ~460 K, approximately linearly, as a function of W-doping (as estimated from the c-axis lattice constant). The monoclinic beta angle steadily decreases with doping, from 93.9 to 93.2 degrees. The T₉* phase (a thus far unreported phase which will be discussed in Yu Tao's talk) was present on warming up to x~0.3, but was not seen above this point. Some MoTe₂ crystals had broad transitions, likely due to Te vacancies; the existence of a T₉* phase in these crystals could not be determined. We discuss these tendencies and their implications for finding new phases in materials with weakly-bound layers.

*We acknowledge funding from the U.S. Department of Energy.

Fermi Surfaces and Topological Character of Dirac and Weyl Type-II Semimetals as Revealed by the de Haas-van Alphen Effect

LUIS BALICAS (Presenter), National High Magnetic Field Laboratory — The texture of the Berry phase curvature has led to the observation of novel, but controversial, electrical transport properties in the so-called topological semimetals. Examples include the so-called Weyl orbits that explore the Fermi arcs on the surfaces of Weyl semimetals, the observation a planar Hall-effect in non-magnetic compounds, or the observation of a negative magnetoresistivity ascribed to the axial current between Weyl points resulting from the suppression of their chiral symmetry. We have studied the transport properties of some of these compounds as well as their Fermi surfaces through quantum oscillatory phenomena, finding both marked disagreements with calculations and photoemission (e.g. MoTe₂), as well as good agreements (e.g. PdTe₂). Here, we will focus on the semimetals MAl₃ (where, M = V, Nb and Ta) which were predicted to be candidates for a Dirac type-II state. We find that the angular-dependence of their Fermi surface (FS) crosssectional areas reveals a remarkably good agreement with first-principle calculations. Therefore, dHvA supports the existence of tilted Dirac cones with Dirac type-II nodes located at 100, 230 and 250 meV above the Fermi level for VAl₃, NbAl₃ and TaAl₃ respectively. However, for all three compounds the cyclotron orbits on their FSs, including an orbit nearly enclosing the Dirac type-II node, yield trivial Berry phases. We explain this via an analysis of the Berry phase where the position of this orbit, relative to the Dirac node, is adjusted within the error (of ~10 meV) implied by the small disagreement between our calculations and the experiments.

Chemical Bonding Induced Topological Lifshitz Transition in Type-II Dirac Semimetal VAl₃

YI-YUAN LIU, YU-FEI LIU, Physics, Peking University, GUI XIN, Chemistry, Louisiana State University, CHENG XIANG, HUIBING ZHOU, Physics, Peking University, WEIWEI XIE, Chemistry, Louisiana State University, CHUANG-HAN HSU, Physics, National University of Singapore, HSIN LIN, Institute of Physics, Academia Sinica, TAY-RONG CHANG, Physics, National Tsing Hua University, SHUANG JIA (Presenter), Physics, Peking University — We report a chemical bonding induced Lifshitz transition of Ti₁₋ₓVₓAl₃ in which the compounds evolve from p-type trivial metal to n-type robust Dirac semimetal. This topological transition is concomitant with an anomalous structural distortion which stems from the interplanar V-Al bond formation. The V-Al bonds in Ti₁₋ₓVₓAl₃ are built up as long as the bonding orbitals of V atoms are fully populated by the electrons. In other words, the type-II Dirac semimetal state of VAl₃ is protected by the V-Al bonds whose molecular orbitals are the “gravity center” of the topological electron and hole bands.

3:54PM H04.00006: Fermiology and evidence of conventional superconductivity in the type-II Dirac semimetal PdTe₂ AMIT VASHIST (Presenter), RADHA KRISHNA GOPAL, YOGESH SINGH, Department of Physical Sciences, Indian Institute of Science Education and Research, Mohali — We use electrical transport and heat capacity measurements on high-quality single crystals of the recently discovered superconducting type-II Dirac semimetal PdTe₂, to probe the nature of its superconducting phase. The magnitude of the electronic heat-capacity anomaly at Tc, the low temperature exponential T dependence of the heat capacity, the linear H dependence of the T = 0 electronic Somerfield coefficient, and a conventional H − T phase diagram establish that the superconductivity in PdTe₂ is conventional in nature despite the presence of a topologically nontrivial Fermi surface band, which contributes to the electrical conduction. The Fermi surface of PdTe₂ is investigated by the dHvA oscillations.

4:06PM H04.00007: Topological Nontrivial Surface Plasmon on a Type-II Weyl Semimetal XUN JIA (Presenter), XUETAO ZHU, JIANDONG GUO, Institute of Physics, Chinese Academy of Sciences — Type-II Weyl semimetals (WSMs), with the Lorentz invariance broken and hosting tilted Weyl cones giving rise to non-point-like Fermi surfaces (FSs), have attracted plentiful attention recently. The orthorhombic phase of (W, Mo)Te₂ is predicted to be a prototypical system of Type-II WSM. However, the topological signatures are not clear enough from the single-electron measurements due to its complicated band structure. Meanwhile, measurements of electronic collective excitations (i.e. plasmons) in topological bands may provide more evidence of the topological nature, since they possess some exotic properties distinct from those in standard electron gases. Here, using momentum resolved inelastic electron scattering, we report an observation of a topological nontrivial surface plasmon mode originated from the topological bands of MoTe₂, which displays unique super-linear temperature-dependence matching the predictions for that in a WSM. Moreover, the damping of this nontrivial mode matches well with the boundary of electron-hole particle continuum from Weyl band. These findings provide consolidated evidences of the existence of topological nontrivial bands in MoTe₂.

4:18PM H04.00008: Inversion Symmetry Breaking in the Monoclinic Phase of MoTe₂* CHUNRUO DUAN (Presenter), JOHN SCHNEELOCH, YU TAO, University of Virginia, JUNJIE YANG, Central Michigan Univ, XIAOPING WANG, FENG YE, Oak Ridge National Laboratory, DESPINA LOUCA, University of Virginia — Among the layered material transition metal dichalcogenides, MoTe₂ shows a complex phase diagram and many interesting properties such as magnetoresistance, superconductivity, and potentially Weyl semimetal property. If synthesized by furnace cooling, MoTe₂ is stabilized in a hexagonal phase (2H). Quenching from above 1000 °C results in a metastable monoclinic phase (1T'), which becomes orthorhombic (Td) in a first order phase transition when cooled below room temperature. The phase transition is accomplished through layer shifting along the monoclinic tilting direction, and the structure within each layer is not changed. The reported crystal structures indicate that the layer shifting from 1T' (P2₁/m) to Td (Pnm2₁) breaks the inversion symmetry and allows the Weyl physics to emerge. Single crystal neutron diffraction performed at SNS, ORNL provided evidence on a lower symmetry (P2₁) in the 1T' phase which is non-centrosymmetric. Ab initio calculations and molecular dynamics simulations based on the refined structure will be discussed.

4:30PM H04.00009: Pressure evolution of the low temperature crystal structure of superconducting Weyl semimetal candidate MoTe₂ COLIN HEIKES (Presenter), National Institute of Standards and Technology, I-LIN LIU, Center for Nanoscale and Advanced Materials, University of Maryland, TANER YILDIRIM, NICHOLAS BUTCH, WILLIAM RATCLIFF, National Institute of Standards and Technology — Orthorhombic MoTe₂ has been proposed to be a type II Weyl semimetal. This classification is supported by the observation of rare topological phenomena such as Fermi arcs and Weyl nodes through ARPES measurements. Superconductivity is also observed in this material, with a drastic pressure enhancement of the superconducting transition temperature often associated with a first-order structural transition from the non-centrosymmetric orthorhombic phase to a centrosymmetric monoclinic phase with uncertain band topology. I will discuss the temperature-pressure structural phase diagram of this system as determined by neutron scattering at conditions relevant for superconductivity. I will also comment on possible implications of the structural evolution on the ground state electronic structure.
4:42PM H04.00010: Anomalous Transport Properties in Dirac/Weyl Semimetals [Invited]  TIAN LIANG (Presenter), RIKEN — Topological semimetals, notably Dirac/Weyl semimetals have become one of the central fields in modern physics. In this talk, I will talk about two examples of Dirac/Weyl semimetals, ZrTe5 [1] and PbSnTe under pressure [2]. In ZrTe5, in-situ double-axis rotator was employed to detect the full 4π solid angular dependence of the anomalous Hall signals, or effectively the strength of the Berry curvature. Interestingly, the system shows large in-plane anomalous Hall signals, the direct evidence of the Berry curvature coming from the Weyl nodes. In order to further investigate and manipulate the Weyl nodes in the momentum space, pressure measurements of Pb1−xSnxTe were performed. Using pressure to tune the gap, we have tracked the nucleation of a Fermi surface droplet that rapidly grows in volume with P. In the metallic state, we observe a large Berry curvature, which dominates the Hall effect. The results confirm the existence of a topological metallic phase protected by the Weyl nodes over a finite pressure interval. [1] T. Liang et al., Nat. Phys. 14, 451 (2018) [2] T. Liang et al., Sci. Adv. 3, e1602510 (2017)

5:18PM H04.00011: Electronic structure of the candidate Weyl phase in MoTe2  I-LIN LIU (Presenter), University of Maryland, College Park, COLIN HEIKES, NIST, CHRIS ECKBERG, University of Maryland, College Park, NICHOLAS BUTCH, WILLIAM RATCLIFF, NIST, JOHNPIERRE PAGLIONE, University of Maryland, College Park — Orthorhombic MoTe2 has been proposed to be a type II Weyl semimetal. This classification is supported by the observation of rare topological phenomena such as Fermi arcs and Weyl nodes through ARPES measurements. A first-order structural transition from the centrosymmetric monoclinic phase at room temperature to the orthorhombic phase, without inversion symmetry, was found through both magnetoresistance and neutron scattering measurements. I will discuss quantum oscillations measurements and their ramifications for the electronic band structure, and how this relates to the topological state and corresponding novel quantum phenomena

Tuesday, March 5, 2019 2:30 PM - 5:18 PM

Session H05 DMP: Topological Superconductivity: 2D, Junctions BCEC 108 - Adrian Feiguin, Northeastern University - Tag(s): Focus

2:30PM H05.00001: Emergent two-dimensional superconductivity in few-layer stanene [Invited]  DING ZHANG (Presenter), State Key Laboratory of Low-Dimensional Quantum Physics, Department of Physics, Tsinghua University — The two-dimensional crystalline superconductors possess a variety of exotic properties such as the Griffiths singularity, the quantum metal phase as well as the strongly enhanced in-plane critical field [1]. Here we report the discovery of superconductivity in few layer stanene—ultrathin gray tin (111)—and the complete phase diagram in the magnetic field and temperature plane. The emergence of superconductivity in stanene is unexpected. Bulk gray tin is non-superconductive [1] and stanene attracts attention mostly because of its topological properties. Instead, we found superconductivity by growing few-layer stanene on PbTe/Bi2Te3/Si(111) substrate via molecular beam epitaxy [2][3]. The superconducting properties can be further modulated by varying the substrate thickness. Our experimental studies are further supported by first-principles calculations, which suggest that superconductivity occurs in a doped quantum spin Hall insulator.

References

3:06PM H05.00002: Growth and low temperature STM study of Stanene  JINFENG JIA (Presenter), Shanghai jiao Tong University — Stanene and its derivatives can be 2D topological insulators (TI) with a very large band gap as proposed by first-principles calculations, or can support enhanced thermoelectric performance, topological superconductivity and the near-room-temperature quantum anomalous Hall (QAH) effect. Here, we report a successful fabrication of 2D stanene by MBE. The atomic and electronic structures determined by STM and ARPES agree well with the predictions by first-principles calculations. Bulk band gap and edge states are also observed. On stanene thicker than 2 layers, superconductivity is also observed, which suggests stanene is a good candidate for topological superconductor.
3:18PM H05.00003: Tracking the motion of Josephson vortices and the Majorana fermion states bound to them in S-TI-S junctions networks designed for braiding*  
GILBERT ARIAS (Presenter), ERIK HUEMILLER, CHAD GERMANY, GUANG YUE, JESSICA H MONTONE, DALE J VAN HARLINGEN, Physics, University of Illinois Urbana Champaign — Networks of S-TI-S (Superconductor-Topological Insulator-Superconductor) lateral Josephson junctions provide a potential platform for nucleating, manipulating, and braiding Majorana fermion states (MFs) for quantum information processing. In this system, the MFs are bound to the cores of Josephson vortices where the phase difference across the junction is an odd multiple of \( \pi \) and can be manipulated by moving the vortices. To assist in the design of braiding circuits, we are exploring ways to monitor the position of Josephson vortices in junction networks. A direct approach is to image the location of the vortices via Scanning SQUID Microscopy (SSM), for which we are developing an ultralow temperature SSM with sub-micron resolution based on a pickup coil fabricated by electron-beam lithography and focused ion-beam etching and an optical interferometer approach mechanism. We can also indirectly determine the vortices configuration by measuring the modulation of the supercurrent vs. magnetic field modulation patterns. We report on progress toward implementing these techniques.

3:30PM H05.00004: Electron waiting times in hybrid junctions with topological superconductors*  
SHUO MI (Presenter), INAC/PHELIQS/GT, Grenoble Alpes University, PABLO BURSET, CHRISTIAN FLINDT, Department of Applied Physics, Aalto University — We investigate the waiting time distributions (WTDs) of superconducting hybrid junctions, considering both conventional and topologically nontrivial superconductors hosting Majorana bound states at their edges. To this end, we employ a scattering matrix formalism that allows us to evaluate the waiting times between the transmissions and reflections of electrons or holes. Specifically, we analyze normal-metal--superconductor (NIS) junctions and NISIN junctions, where Cooper pairs are spatially split into different leads. The distribution of waiting times is sensitive to the simultaneous reflection of electrons and holes, which is enhanced by the zero-energy state in topological superconductors. For the NISIN junctions, the WTDs of trivial superconductors feature a sharp dependence on the applied voltage, while for topological ones they are mostly independent of it. This particular voltage dependence is again connected to the presence of topological edge states, showing that WTDs are a promising tool for identifying topological superconductivity.

3:42PM H05.00005: Study of Josephson trijunction constructed on Bi\(_2\)Te\(_3\) surface  
GUANG YANG (Presenter), ZHAOZHENG LYU, JUNJUA WANG, JIANGHUA YING, XIANG ZHANG, GUANGTONG LIU, JIE FAN, ZHONGQING JI, XIUNIAN JING, FANMING QU, LI LU, Institute of Physics, Chinese Academy of Sciences — In 2008, Fu and Kane proposed that Josephson trijunctions constructed on the surface of topological insulators could host Majorana zero modes [1]. Such trijunctions could potentially serve as the basic components in a two-dimensional platform for realizing universal topological quantum computing [2]. In this talk, we will present the results of experimental investigations on trijunctions constructed on the surface of Bi\(_2\)Te\(_3\). And we will compare the experimental results with Fu and Kane's theory as well as with the results of numerical simulations based on a lattice model.

3:54PM H05.00006: Observation of perfect Andreev reflection due to Klein paradox in a topological superconducting state in SmB\(_6\)/YB\(_6\) heterostructures*  
SEUNGHUN LEE (Presenter), VALENTIN STANEV, XIAOHANG ZHANG, JOSHUA S HIGGINS, VICTOR M YAKOVENKO, JOHNPIERRE PAGLIONE, RICHARD L. GREENE, VICTOR GALITSKI, ICHIRO TAKEUCHI, University of Maryland, College Park — Topological insulator, whose boundary states are described by the massless Dirac equation, is of great interest to realize unusual states of quantum matter. We report the observation of perfect Andreev reflection as a manifestation of Klein tunneling (perfect transmission of massless Dirac particles through any potential barrier) at the interface between a normal metal and a SmB\(_6\)/YB\(_6\) heterostructure. We have previously demonstrated proximity-induced superconductivity in the surface state of SmB\(_6\). Conductance spectra of point contact junctions between a Ptn tip and the surface of the superconducting SmB\(_6\) show perfect conductance doubling within the induced superconducting gap (\( \Delta \)). The absence of electron reflection under such finite Z is attributed to the interplay of the Dirac material in Andreev reflection process i.e., Klein tunneling. The observation can be described by a modified BTK theory with Dirac Hamiltonian, Dirac-BTK theory.

4:06PM H05.00007: Meissner screening of Proximity coupled Topological Insulator/Superconductor Heterostructures* SEOKJIN BAE (Presenter), SEUNGHUN LEE, ICHIRO TAKEUCHI, STEVEN ANLAGE, University of Maryland, College Park — Meissner screening of proximity coupled SmB$_6$/YB$_6$ topological insulator-superconductor (TI/SC) thin-film bilayers is studied through the temperature dependence of the effective penetration depth. A microwave resonator technique is used in which the bilayers are exposed to the rf magnetic field. The study is conducted by systematically varying the thickness of the SmB$_6$ layer on top of the YB$_6$ layer. Unconventional thickness dependence of the temperature profile of the effective magnetic penetration depth of the TI/SC bilayer is observed, which is distinctly different from that of the conventional metal/superconductor bilayers. This provides evidence for Meissner screening in the presence of bulk insulating states in the SmB$_6$. Through an electromagnetic screening model, key parameters such as normal screening length, normal coherence length, thickness of the surface states, and Fermi velocity of SmB$_6$ are extracted and found to be in reasonable agreement with previous studies.

4:18PM H05.00008: Experimental evidence of proximity induced odd-frequency superconductivity in a topological insulator* JONAS KRIEGER, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, SEAN GIBLIN, School of Physics and Astronomy, Cardiff University, THOMAS PROKSCHA, ANDREAS SUTER, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, THORSTEN HESJEDAL, Department of Physics, University of Oxford, ZAHER SALMAN (Presenter), Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute — At an interface between a topological insulator (TI) and a conventional superconductor, the topological surface states have been predicted to rearrange in an interesting fashion. The induced superconductivity between an s-wave superconductor and a TI surface state is expected to develop a complex p-wave order parameter which may allow to create a Majorana Fermions inside the core of a vortex. These collective excitations are their own antiparticles and are the basic element in a proposal for fault-tolerant quantum computing. Here we present experimental evidence for proximity induced superconductivity in a thin layer of the TI Bi$_2$Se$_3$ grown on top of Nb. From depth-resolved measurements in the Meissner state, we observe a local enhancement of the magnetic field in Bi$_2$Se$_3$ that exceeds the externally applied field, thus supporting the existence of an intrinsic paramagnetic Meissner effect arising from an odd-frequency superconducting state.

4:30PM H05.00009: How to systematically map out a Majorana island* JIE SHEN (Presenter), FRANCESCO BORSOI, SEBASTIAN HEEDT, Delft University of Technology, BERNARD VAN HECK, Station Q, Microsoft Research, SASA GAZIBEGOVIC, ROY L. M. OP HET VELD, Eindhoven University of Technology, JOHN A LOGAN, MIHIR PENDHARKAR, University of California, Santa Barbara, MARINA QUINTERO PEREZ, Station Q, Microsoft Research, NICK VAN LOO, Delft University of Technology, ALEXANDRA FURSINA, KEVIN VAN HOOGDALEM, Station Q, Microsoft Research, CHRIS PALMSTROM, University of California, Santa Barbara, ERIK P. A. M. BAKKERS, Eindhoven University of Technology, LEO KOUWENHOVEN, Station Q, Microsoft Research — As a high-quality hybrid system, InSb nanowires with epitaxial-grown Al shells reveal ballistic superconductivity and quantized zero-bias conductance peak. This holds great promise for the realization of Majorana-based topological quantum computing. Building block for a topological qubit is a superconductor-semiconductor island hosting a pair of Majorana zero modes (called Majorana island). The state of the topological qubit is the combination of the even/odd parity of such Majorana islands. Therefore, to understand the status of the topological qubit, systematic studies of a Majorana island are crucial. First, by performing tunnelling spectroscopy measurements, we use the ballistic superconductivity and quantized zero-bias peak to support the high-quality and potential ‘Majorana’ properties of the island. Secondly, the even-odd ground state phase diagram as a function of chemical potential is mapped out and provides a guideline for the topological qubit. Thirdly, how the superconducting gap and effective g-factor influence the phase diagram is also studied. Such a systematic mapping of the Majorana island is also suitable for double islands, leading towards topological qubits based on multiple islands.

4:42PM H05.00010: Realization of Majorana Zero Modes within a Topological Hinge State* BERTHOLD JAECK (Presenter), YONGLONG XIE, Princeton University, JIAN LI, Westlake Institute for Advanced Study, SANGJUN JEON, ANDREI B BERNEVIG, ALI YAZDANI, Princeton University — Higher order topological insulators (HOTI) host helical edge modes along its hinges that are protected by crystal and time-reversal symmetry. Proximity induced superconductivity on these hinge states is predicted to be topological in nature and provides a platform for the realization of Majorana zero modes (MZM). Theoretical modeling shows the emergence of MZMs in the hinge states at an interface where they are influenced by superconductivity and magnetism. Recently, bismuth was identified as a HOTI where scanning tunneling microscopy (STM) studies revealed the existence of hinge states on its surface (1). To realize this MZM platform, we grow bismuth thin films and iron clusters on a niobium surface. Using high-resolution spectroscopic mapping and spin-polarized STM, we characterize the influence of superconductivity and magnetism on the hinge states. Our measurements show the presence of localized zero energy states at the interface between superconducting hinge states and the iron clusters. Comparing various measurements with theoretical models, we will discuss how our observations are consistent with the presence of MZM.

4:54PM H05.00011: Radio frequency methods for Majorana based quantum computing: fast charge sensing and phase diagram mapping* DAVYDAS RAZMADZE (Presenter), DEIVIDAS SABONIS, FILIP MALINOWSKI, GERBOLD MENARD, Center for Quantum Devices, Niels Bohr Institute, SEBASTIAN PAУKA, ARC Centre of Excellence for Engineered Quantum Systems, The University of Sydney, HUNG NGUYEN, DAVID VAN ZANTEN, Eoin C O'FARREL, Judith Tabea Suter, Peter Kroegstrup, Ferdinand Kuemmeth, Charles M Marcus, Center for Quantum Devices, Niels Bohr Institute — We employ radio frequency techniques to demonstrate two measurements: first, by embedding an InAs/Al nanowire directly into a resonant circuit, it is possible to map key features of the conductance vs. gate-voltage phase diagram approximately 40 times faster than conventional lock-in methods; second, by capacitively coupling the same nanowire to a radio-frequency single electron transistor, fabricated from another nanowire, we demonstrate detection of single electron inter-island transitions, with signal-to-noise ratios exceeding 5 for an integration time below 1 μs at axial (parallel to nanowire) magnetic fields of 0.6T. Latter results will be the requirements for implementing Majorana based quantum computation in hybrid superconductor-semiconductor nanowire devices, and demonstrates the full compatibility of the high-bandwidth sensing techniques. Presented device geometries are similar to that have previously shown signatures of Majorana-like bound states.

5:06PM H05.00012: Advanced hybrid InSb/Al nanowires devices for topological parity readout (Part 1)* FRANCESCO BORSOI (Presenter), SEBASTIAN HEEDT, JIE SHEN, SENJA RAMAKERS, KUN ZUO, Delft University of Technology, QuTech, KEVIN VAN HOOGDALEM, MARINA QUINTERO PEREZ, Microsoft Station Q Delft, SASA GAZIBEGOVIC, ROY L. M. OP HET VELD, Eindhoven University of Technology, Department of Applied Physics, JOHN A LOGAN, MIHIR PENDHARKAR, University of California Santa Barbara, Materials Engineering, BERNARD VAN HECK, Microsoft Station Q Santa Barbara, CHRIS PALMSTROM, University of California Santa Barbara, Materials Engineering, ERIK P. A. M. BAKKERS, Eindhoven University of Technology, Department of Applied Physics, LEO P KOUWENHOVEN, Microsoft Station Q Delft — Majorana bound states (MBS) in hybrid semi-superconducting systems have been proposed to be the building blocks of the next quantum computers. Quantum information can be stored in the fermionic parity degree of freedom, shared in two well-separated MBS. A promising method to readout such parity is to measure the conductance through an Aharonov-Bohm (AB) interferometer, hosting a pair of MBS in one of the interfering arms. Here, we report our progress in the realization of such device based on InSb/Al islands. We first investigate the electron-phase evolution in a normal quantum dot embedded in an InSb nanowire network by mapping the phase of AB oscillations. Phase lapse and winding are extracted from the shift of these oscillations and from the associated Fano effect. Secondly, we study the energy spectrum of proximitized InSb nanowires in Coulomb blockade revealing gate-dependent ground state parity transitions as a function of magnetic field. Based on these results and on the development of a new nanofabrication technique, interferometric readout can be performed in both nano-networks and single-nanowire architectures.

2:30PM H06.00001: Intermediate gapless phase and topological phase transition of the Kitaev model in a uniform magnetic field* SHUANG LIANG (Presenter), MING-HONG JIANG, WEI CHEN, JIAN-XIN LI, QIANG-HUA WANG, Physics, Nanjing University and National Laboratory of Solid State Microstructures — We study the Kitaev model in a [001] magnetic field employing the mean-field theory(MFT) in the Majorana fermion representation. We discover a robust gapless regime in the intermediate magnetic field for both gapless and gapped antiferromagnetic(AFM) Kitaev models with \( J_x = J_y \) before the system is polarized in a high magnetic field. A topological phase transition connecting two gapless phases with a nodal line phase takes place at a critical magnetic field \( h_{c1} \) in this regime. While the nodal line phase at \( h_{c1} \) disappears when the mirror symmetry \( J_x = J_y \) is broken, the nodal point gapless phase can exist at intermediate fields even without the mirror symmetry. We reveal that the phase evolution of the system in the magnetic field is driven by the competition between the magnetic field and the particle-hole asymmetry of the normal state of the BdG Hamiltonian. For the ferromagnetic case, there is no intermediate phase transition before polarization. The above phase diagrams are confirmed by dynamical MFT results.

2:42PM H06.00002: Majorana representations of spin and an alternative solution of the Kitaev honeycomb model* JIANLONG FU (Presenter), School of Physics and Astronomy, University of Minnesota, JOHANNES KNOLLE, Blackett Laboratory, Imperial College London, NATALIA PERKINS, School of Physics and Astronomy, University of Minnesota — Based on the Dirac spinor representation of the SO(4) group, we discuss the relationship between three types of representation of spin in terms of Majorana fermions, namely the Kitaev representation, the SO(3) representation, and the SO(4) chiral representation. Comparing the three types, we show that the Hilbert space of the SO(3) representation is different from the other two by requiring a pairing of sites, but it has the advantage over the other two in that no unphysical states are involved. As an example of its application, we present an alternative solution of the Kitaev honeycomb model. Our solution involves no unphysical states which enables a systematic calculation of physical observables. Finally, we discuss an extension of the model to a more general exactly soluble \( \mathbb{Z}_2 \) gauge theory interacting with complex fermions.

*We acknowledge the support from NSF DMR-1511768 Grant

2:54PM H06.00003: Algebraic Quantum Spin Liquid from an Exactly Solvable Spin-1/2 Kitaev Model JIAN-JIAN MIAO (Presenter), Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, HUI-KE JIN, Zhejiang University, FU-CHUN ZHANG, Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, YI ZHOU, Zhejiang University — We propose an exactly solvable quantum spin-1/2 model with time reversal invariance on a two dimensional brick-wall lattice, where each unit cell consists of three sites. We find that the ground states are algebraic quantum spin liquid states. The spinon excitations are gapless and the energy dispersion is linear around two Dirac points. The ground states are of three-fold topological degeneracy on a torus. Breaking the time reversal symmetry opens a bulk energy gap and the \( \mathbb{Z}_2 \) vortices obey non-Abelian statistics.
3:06PM H06.00004: Topological superconductivity in the Kondo-Kitaev model*  WONJUNE CHOI (Presenter), Physics, University of Toronto, PHILIPP WILHELM KLEIN, ACHIM ROSCH, Physics, University of Cologne, YONG-BAEK KIM, Physics, University of Toronto — We investigate possible topological superconductivity in the Kondo-Kitaev model on the honeycomb lattice, where the Kitaev spin liquid is coupled to conduction electrons via the Kondo coupling. The self-consistent mean-field theory gives three distinct quantum phases as the Kondo coupling is increased: the fractionized Fermi liquid, where the Kitaev spin liquid and conduction electrons remain decoupled, the ferromagnetic topological superconductor with a single chiral Majorana edge mode, and the paramagnetic topological superconductor with a single pair of helical Majorana edge modes. In this talk, we discuss the connection between topological nature of the Kitaev spin liquid and two emergent topological superconductors obtained in this model. These findings offer a novel route to topological superconductivity in the Kondo lattice system.

3:18PM H06.00005: Emergent interacting two-fluids in a disordered Hubbard model*  KYUNGMIN LEE (Presenter), Ohio State University, AAVISHKAR PATEL, Harvard University, NANDINI TRIVEDI, Ohio State University, SUBIR SACHDEV, Harvard University — Recently a number of theoretical studies of models containing lattices of Sachdev-Ye-Kitaev (SYK) islands have brought in a fresh perspective on the problem of non-Fermi liquids. Motivated especially by a two-fluid model, with localized SYK islands and itinerant fermions, that captures the physics of the ‘‘strange’’ metal state of high temperature superconductors, here we discuss the possibility of such a separation of fermionic degrees of freedom starting from a disordered Hubbard model. Our numerical studies indicate that a disordered Hubbard model can lead to the emergence of localized SYK-like islands that interact with itinerant fermions. We also discuss the implications of disorder of the temperature-dependent transport properties.

3:30PM H06.00006: Many-body localization in a modified SYK model  HANTENG WANG (Presenter), ALEX KAMENEV, University of Minnesota — We investigate the many-body spectrum and eigenfunctions of Sachdev-Ye-Kitaev model with additional random hopping terms. To preserve the symmetry class of the original model, the additional term we add is the square of standard two Majorana hopping which is integrable on its own. We examine the level statistics of the many-body energy spectrum of this model numerically and find the crossover from Poisson statistics to Wigner-Dyson statistics when tuning the total energy of the system with finite number of Majorana. We study relations of the transition in level statistical transition to Anderson localization in the Fock space by examining the inverse partition ratios (IPR) and information entropy of the eigenstates with different total energy. Fitting IPR and information entropy with a scaling ansatz, one can access degree of the Fock space localization of the many-body eigenstates. We found that there exist three different regimes: ergodic delocalized, non-ergodic delocalized and localized, which closely resembles findings for the Anderson model on Bethe lattice and random regular graphs.

3:42PM H06.00007: Strong impact of all-in all-out magnetic order on magnetic and lattice dynamics in pyrochlore iridates studied by Raman spectroscopy*  KENTARO UEDA (Presenter), RYOMA KANEKO, University of Tokyo, ALASKA SUBEDI, Universite Paris-Saclay, MATTEO MINOLA, Max-Planck-Institut, BUMJOON KIM, Pohang University, JUN FUJIOKA, University of Tsukuba, YOSHINORI TOKURA, University of Tokyo, BERNHARD KEIMER, Max-Planck-Institut — We perform Raman spectroscopy on pyrochlore Eu2Ir2O7 which undergoes a paramagnetic-to-antiferromagnetic transition, as well as paramagnetic counterpart Pr2Ir2O7. The first polarization analysis combined with density functional theory allows us to assign all observed peaks to six optical phonons without any ambiguity. An additional peak clearly shows up below the transition temperature TN at 210 cm-1 which is reasonably close to the single-magnon excitation energy estimated from the resonant inelastic x-ray scattering. Simultaneously, the Eg phonon, involving Ir-O-Ir bond bending motion, exhibits a remarkable softening by 35 cm-1 that is by one order of magnitude larger than those in 3d magnets. These findings imply that the magnon-phonon coupling is unconventionally strong in this system, and intriguingly, the combination of the antiferromagnetic super-exchange and Dzyaloshinskii-Moriya interaction can play a vital role in the all-in all-out magnetic order, providing an important insight into the exotic phase transition in 5d transition metal oxides.

*This work is supported by JSPS Grant-in-Aid for Scientific Research (No. 26103006, No. 24224009, 18H04214, and 16H00981) and by PRESTO (No. JPMJR15RS) and CREST (No. JPMJCR16F1 and JPMJCR1874) in Japan.
3:54PM H06.00008: Linear magnetoresistance in the all-in-all-out antiferromagnet Cd$_2$Os$_2$O$_7$  
YISHU WANG (Presenter), The Johns Hopkins University, YEJUN FENG, Okinawa Institute of Science and Technology Graduate University, FELIPE GOMEZ, DANIEL SILEVITCH, California Institute of Technology, JIAQIANG YAN, Oak Ridge National Lab, DAVID GEORGE MANDRUS, University of Tennessee, Knoxville, PATRICK LEE, Massachusetts Institute of Technology, THOMAS F ROSENBAUM, California Institute of Technology — The pyrochlore Cd$_2$Os$_2$O$_7$ undergoes a metal-insulator transition at 227 K, concomitant with a formation of all-in-all-out magnetic ordering. Here, we explore the magnetoresistance associated with this magnetic order, which manifests an odd-parity linear functional form. This form, recently reported in the related compounds Eu$_2$Ir$_2$O$_7$, is allowed by the Onsager relationship for antiferromagnetic materials; however the microscopic origin is still unclear. By systematically studying a range of galvanomagnetic measurement configurations, we are able offer potential mechanisms for understanding this linear magnetoresistance involving transport both in the bulk and along the magnetic domain walls.

4:06PM H06.00009: Visualizing Kondo lattice behavior in the frustrated pyrochlore iridate Pr$_2$Ir$_2$O$_7$ using scanning tunneling spectroscopy and machine learning*  
MARIAM KAVAI (Presenter), KYLE G SHERMAN, JUSTIN LESHEN, JOEL FRIEDMAN, IOANNIS GIANNAKIS, Binghamton University, SATORU NAKATSUJI, Advanced Materials Science, The University of Tokyo, MICHAEL J LAWLER, PEGOR AYNAJIAN, Binghamton University — Pyrochlore iridates have attracted great interest due to their geometrically frustrated lattice with potential for realizing metallic spin liquid behavior. Pr$_2$Ir$_2$O$_7$ is uniquely located near the quantum critical point of antiferromagnetic metal to insulator transition. We carried out STM experiments on the [111] Kagome surface of the pyrochlore iridate Pr$_2$Ir$_2$O$_7$. STM topographs show the six-fold atomic structure expected from the [111] surface demonstrating atomic resolution STM images on a pyrochlore iridate. At low temperature, the tunneling density of states reveal Kondo behavior with Fano lineshape near the Fermi energy that exhibit strong electronic inhomogeneity. The large quantity of generated data and the intrinsic electronic inhomogeneity in this system introduce enough complexity to render conventional data analysis inadequate. Using machine learning of large data, we discover these rather seemingly random spectra to form nanoscale patterns, which may be related to electronic entanglement.

*We acknowledge support from the U.S. National Science Foundation (NSF) CAREER under award No. DMR-1654482

4:18PM H06.00010: Using quantum typicality to compute the thermodynamics of the frustrated spin compound SrCu$_2$(BO$_3$)$_2$  
ALEXANDER WIETEK (Presenter), Flatiron Institute, Simons Foundation, ANDREAS HONECKER, Laboratoire de Physique Théorique et Modélisation, Université de Cergy-Pontoise, PHILIPPE CORBOZ, Institute for Theoretical Physics and Delta Institute for Theoretical Physics, Universiteit van Amsterdam, STEFAN WESSEL, Institut für Theoretische Festkörperphysik, RWTH Aachen University, FREDERIC MILA, Institute of Physics, École Polytechnique Fédérale de Lausanne, BRUCE NORMAND, Neutrons and Muons Research Division, Paul Scherrer Institute — The concept of quantum typicality presents a novel route to computing finite temperature properties of quantum many-body systems. We demonstrate, how to use the Lanczos method in conjunction with quantum typicality to extract thermodynamic quantities at arbitrary temperatures without a full diagonalization of the Hamiltonian. This technique is applied to compute the thermodynamics of the frustrated spin compound SrCu$_2$(BO$_3$)$_2$, where recently a pressure-induced quantum phase transition has been observed. Our results are compared to Quantum Monte Carlo and iPEPS simulations.
4:30PM H06.00011: Partial order in the extended Hubbard model on a triangular lattice  MATTHEW ENJALRAN  
(Presenter), Physics, Southern Connecticut State University — The list of new materials which possess charge, spin, and orbital degrees of freedom all competing within a geometrically frustrated environment continues to grow. Such systems are intriguing because they are apt to exhibit new collective phases of matter. Theoretical work in this area has increased too, but theoretical and numerical studies of frustrated models of interacting fermions are difficult for a host of reasons. The application of mean-field theory is typically a good starting point for the study of the phase diagram of a strongly correlated many-body model. Hence, focusing on charge and magnetic degrees of freedom of fermions, we present results from Hartree-Fock calculations of the extended Hubbard model on the triangular lattice. We emphasize the case of $1/3$ filling where a finite temperature metal-insulator transition can be induced for select values of the on-site ($U$) and nearest-neighbor ($V$) Coulomb repulsions, including a phase with partial order confined to the honeycomb substructure of the parent triangular lattice.

4:42PM H06.00012: Supersymmetry in an interacting Majorana model on the kagome lattice*  CHENGSHU LI  
(Presenter), ÉTIENNE LANTAGNE-HURTUBISE, MARCEL FRANZ, University of British Columbia — We construct a supersymmetric model of interacting Majorana modes on the kagome lattice. The supersymmetry is manifest in the infinite-coupling limit, which exhibits an exponential ground state manifold separated in two parity "supersectors". An exact solution for thin torus geometries allows us to analytically construct the entire ground state manifold. Upon inclusion of weak two-fermion terms, the supersymmetry is broken for finite systems but recovered in the thermodynamic limit. We also briefly discuss the non-interacting limit of the model, which exhibits a zero-energy flat band and Majorana Chern bands.

*The work described in this article was supported by NSERC and CifAR. C. L. and É. L.-H. were also supported by the QuEst scholarship at the University of British Columbia.

4:54PM H06.00013: Majorana-Hubbard model on the triangular lattice  TARUN TUMMURU (Presenter), ALBERTO NOCERA, IAN AFFLECK, University of British Columbia — Majorana fermions are known to arise as emergent particles in certain condensed matter systems. One such realization involves inducing superconductivity on the surface of a 3-dimensional topological insulator, in the presence of a magnetic field. The resulting Abrikosov lattice has a Majorana zero mode (MZM) localized at the core of each vortex. It has been shown that the interaction between MZMs falls off exponentially with the superconducting coherence length. This enables one to write a tight-binding model to describe the system and some of these models have rich phase diagrams that exhibit emergent supersymmetry. Given that in experiments the vortex lattice usually has a triangular geometry, we construct a model for interacting MZMs in this setup. With the interaction strength as a tunable parameter, we study the phase diagram numerically using the density-matrix renormalization group.

5:06PM H06.00014: Possible gapless spin liquid in a rare-earth kagome lattice magnets Tm$_3$Sb$_3$Zn$_2$O$_{14}$*  ZHAOFENG DING  
(Presenter), YANXING YANG, JIAN ZHANG, CHENG TAN, ZIHAO ZHU, GANG CHEN, LEI SHU, Fudan University — We report the thermodynamic and muon spin relaxation ($\mu$SR) evidences for a possible gapless spin liquid in Tm$_3$Sb$_3$Zn$_2$O$_{14}$, with the rare-earth ions Tm$^{3+}$ forming a two-dimensional kagome lattice. We extract the magnetic specific heat of Tm$_3$Sb$_3$Zn$_2$O$_{14}$ by subtracting the phonon contribution of the non-magnetic isostructural material La$_3$Sb$_3$Zn$_2$O$_{14}$ and obtain a clear linear-T temperature dependence of magnetic specific heat at low temperatures. The absence of magnetic order is confirmed by specific heat, A.C. susceptibility and $\mu$SR measurements down to 20 mK. We find that the spin-lattice relaxation time remains constant down to the lowest temperature. The possibility of disorder induced effect could not be excluded due to the possible Tm/Zn site-mixing disorder in Tm$_3$Sb$_3$Zn$_2$O$_{14}$.

Tuesday, March 5, 2019 2:30 PM - 5:18 PM
**Session H07 DCMP: Ruthenates and Nickelates** BCEC 109B - David Parker, Oak Ridge National Laboratory

**2:30PM H07.00001: Current-controlled switching of diamagnetism in Ca$_3$(Ru$_{1-x}$Ti$_x$)$_2$O$_7$**

*YOSHITERU MAENO (Presenter), CHANCHAL SOW, RYO NUMASAKI, GIORDANO MATTONI, SHINGO YONEZAWA, Department of Physics, Kyoto University, Kyoto 606-8502, Japan, NAOKI KIKUGAWA, SHINYA UJI, Quantum Transport Properties Group, National Institute for Materials Science (NIMS), Tsukuba 305-0003, Japan — It was recently shown that a strong Landau diamagnetism may emerge in strongly correlated electron systems (SCES) under nonequilibrium steady state (NESS) conditions. However, due to high resistivity of the insulating state, in situ sign-switching of magnetism was not possible in the previous study. Here, we demonstrate that DC current can trigger in situ switching between the impurity-induced Mott insulating state and diamagnetic semimetallic state of the bilayered ruthenate Ca$_3$Ru$_2$O$_7$. By performing simultaneous magnetic and resistive measurements, we map out the temperature vs current-density phase diagram in the NESS of this material. The present results open up the possibility of creating novel electronic states in a variety of SCES by NESS conditions under DC current.*

**2:42PM H07.00002: How does optical response of SrRuO$_3$ and CaRuO$_3$ thin films deviate from Fermi liquid predictions?**

YOUCHENG WANG (Presenter), GRACE BOSSÉ, Department of Physics, Institute for Quantum Matter, Johns Hopkins University, HARI NAIR, Department of Materials Science and Engineering, Kavli Institute at Cornell for Nanoscale Science, Cornell University, JACOB P RUF, Department of Physics, Laboratory of Atomic and Solid State Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell University, BING CHENG, Department of Physics, Institute for Quantum Matter, Johns Hopkins University, DARRELL G. SCHLOM, Department of Materials Science and Engineering, Kavli Institute at Cornell for Nanoscale Science, Cornell University, KYLE M SHEN, Department of Physics, Laboratory of Atomic and Solid State Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell University, NORMAN ARMITAGE, Department of Physics, Institute for Quantum Matter, Johns Hopkins University — Orthorhombic perovskites SrRuO$_3$ and CaRuO$_3$ are strongly correlated metals with unusual transport properties. Previous optics studies in the infrared and terahertz range shows non-Drude dynamics and fractional scattering rates at low temperatures which seems to contradict a Fermi-liquid picture with long-lived quasiparticles. Here we present time domain THz measurements of clean thin films of SrRuO$_3$ and CaRuO$_3$. Our results demonstrate for both materials the low temperature conductivity shows a narrow Drude-like peak and can be fitted with two Drude terms. The conductivity crosses over to become less coherent at higher temperatures. Comparison with Fermi liquid scaling theories shows that CaRuO$_3$ is more anomalous than SrRuO$_3$ probably owing to spin fluctuations in the paramagnetic phase.

**2:54PM H07.00003: $^{17}$O NMR Studies Applied to the Uniaxial Stress-Tuned Fermi-Liquid Crossover in Sr$_2$RuO$_4$**

AARON CHRONISTER (Presenter), ANDREJ PUSTOGOW, YONGKANG LUO, University of California, Los Angeles, NAOKI KIKUGAWA, National Institute for Materials Science, DMITRY SOKOLOV, FABIAN JERZEMBECK, ANDREW MACKENZIE, CLIFFORD HICKS, Max Planck Institute for Chemical Physics of Solids, ERIC BAUER, Los Alamos National Laboratory, STUART E BROWN, University of California, Los Angeles — Application of in-plane uniaxial stress to the quasi two-dimensional strongly correlated system Sr$_2$RuO$_4$ results in substantial changes of the physical properties, including a more than doubled superconducting transition temperature as well as normal state transport properties deviating from conventional Fermi-liquid behavior. Both observations are attributed to a nearby Lifshitz transition, associated with moving the Fermi energy through a van Hove singularity (vHs). $^{17}$O NMR measurements reveal that the Lifshitz point is accompanied by strong field and temperature dependence of the spin susceptibility, persisting to temperatures less than 100 mK. Our NMR measurements indicate that the non-Fermi-liquid behavior is strongly influenced by the proximity of the Lifshitz transition and a large Stoner enhancement, in a system where three energy scales are nearly balanced: width of vHs, as well as Zeeman and thermal energies.

*This work was supported by the National Science Foundation (DMR-1709304) and Los Alamos Laboratory Directed Research and Development (LDRD) program.
3:06PM H07.00004: Collective modes in Sr$_2$RuO$_4$ measured with momentum-resolved EELS (M-EELS)* ALI HUSAIN
(Presenter), MATTEO MITRANO, MELINDA RAK, SAMANTHA RUBECK, Department of Physics and Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, FUMIHIKO NAKAMURA, Department of Education and Creation Engineering, Kurume Institute of Technology, CHANCHAL SOW, YOSHITERU MAENO, Department of Physics, Graduate School of Science, Kyoto University, PETER ABBAMONTE, Department of Physics and Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign — Measurements of the charge susceptibility $\chi(q,\omega)$ of the high-$T_c$ cuprate Bi-2212 using Momentum-resolved inelastic electron scattering (M-EELS) have shown that bad-metallic behavior can be characterized by a continuum of non-propagating density fluctuations, in stark contrast to the plasmons of simple metals [1]. Here, we report on M-EELS measurements of Sr$_2$RuO$_4$, a bad metal which crosses over to a Fermi Liquid at $T=40$K. Like Bi-2212, we find that the bad metal phase of Sr$_2$RuO$_4$ exhibits a continuum of density fluctuations. However, below 40K, spectral weight is redistributed to form a plasmon-like excitation around 1.4 eV. Surprisingly, we also discover a coherent low-energy (sub-80meV) 2D acoustic plasmon in the bad metal phase, whose velocity is strongly renormalized from 0.7 to 0.4eV Å below the Fermi liquid crossover, indicating a coupled 2D Fermi Liquid and 3D bad metal in a single solid. We will contrast this coupled system to a closely related ruthenate, the Mott-insulator Ca$_2$RuO$_4$.

*This work was supported by the Gordon and Betty Moore Foundation's EPiQS Initiative through Grant GBMF-4542. An early prototype of the M-EELS instrument was supported by the DOE CES under award DE-AC02-98CH10886.

3:18PM H07.00005: Magnetisation density and electronic structure of Sr$_3$Ru$_2$O$_7$.* JONATHAN DUFFY (Presenter), University of Warwick, STEPHEN DUGDALE, University of Bristol, SEAN GIBLIN, University of Cardiff, JONATHAN TAYLOR, European Spallation Source, ROBIN S. PERRY, UCL, YOSHITERU MAENO, Kyoto University, MATTHEW BUTCHERS, University of Bristol, TED FORGAN, University of Birmingham — Sr$_3$Ru$_2$O$_7$ is itinerant metamagnet, exhibiting a sharp increase in magnetisation in a field of 5.5 – 7.7 T (depending on the applied field direction) at temperatures around 1 K. This metamagnetic transition is thought to be related to the behaviour of the density of states near the Fermi level. We have performed a study of the magnetisation density in the metamagnetic state combining a magnetic Compton scattering experiment with electronic structure calculations. Our initial density functional calculations were fixed to reproduce the value of the experimentally determined spin moment, but do not agree well with the experimentally measured spin density. In the talk, we will show how it is possible to gain a good agreement with the experimental spin densities from the calculations and the consequences of this in relation to the electronic structure and underlying physics.

*We are very grateful to the Japan Synchrotron Radiation Institute (JASRI) for providing beamtime at SPring-8 via projects 2012B00045 and 2016A0131.

3:30PM H07.00006: DMFT+NRG study of orbital differentiation in three-orbital Hubbard models FABIAN B. KUGLER (Presenter), SEUNG-SUP B. LEE, Ludwig-Maximilians-Universität München, Munich, Germany, MANUEL ZINGL, ANTOINE GEORGES, Flatiron Institute - Simons Foundation, New York, USA, GABRIEL KOTLIAR, Rutgers University, New Jersey, USA, JAN VON DELFT, Ludwig-Maximilians-Universität München, Munich, Germany, ANDREAS WEICHSELBAUM, Brookhaven National Laboratory, New York, USA — The orbital-selective Mott phase (OSMP) in multi-orbital Hubbard models has been of high interest for a long time. While it has early been understood [1] that different bandwidths of the orbitals can lead to different critical interaction energies, the OSMP solely driven by crystal-field splitting (CFS) is more intricate. Here, we present a real-frequency dynamical mean-field theory and numerical renormalization group (DMFT+NRG) analysis of the OSMP driven by CFS in a three-orbital model and illustrate the singular Fermi-liquid properties of this phase [2]. On the example of Sr$_2$RuO$_4$, we show how our method can be used to study low-energy physics in a real-materials framework.

Multi-Wavelength Near-Field Imaging of the Temperature & Current Induced Metal to Insulator Transitions in Ca$_2$RuO$_4$

ROCCO VITALONE (Presenter), BENJAMIN AARON FOUTTY, ALEXANDER SWINTON MCLEOD, JEDRZEJ WIETESKA, Department of Physics, Columbia University, CHANCAL SOW, Department of Physics, Kyoto University, FUMIHIKO NAKAMURA, Department of Education and Creation Engineering, Kurume Institute of Technology, YOSHITERU MAENO, Department of Physics, Kyoto University, ABHAY PASUPATHY, DIMITRI BASOV, Department of Physics, Columbia University — Ca$_2$RuO$_4$, a strongly correlated metal oxide and Mott Insulator, exhibits an insulator to metal transition and a large structural distortion along the c-axis concurrently at 365K with a hysteresis of about 30K. In this study, we examine the temperature driven insulator-metal transition (IMT) in single crystals of Ca$_2$RuO$_4$ at the nanoscale with wavelengths ranging from 10 µm to 16 µm, where a strong phonon resonance characterizes the insulating phase. Through this study, we clearly resolve the phonon mode at 16 µm among insulating domains coexisting with the metallic phase, in accord with the far-field optical response of this material. We also resolve a novel pattern of striped phase coexistence emerging on the sub-micron scale that we attribute to the large strain induced by the structural difference between the metallic and insulating phases. We discuss how the development of this stripe pattern spontaneously minimizes strain energy within the crystal. Our interrogation of the metallic and phonon responses of these coexisting phases provides nano-imaging evidence that the temperature and current driven IMTs proceed through fundamentally different microscopic mechanisms.

Effect of uniaxial strain on the metal-insulator transition in Ti-substituted Ca$_3$Ru$_2$O$_7$

JEDRZEJ WIETESKA (Presenter), ALEXANDER SWINTON MCLEOD, BEN FOUTTY, ROCCO VITALONE, Columbia University, JIN PENG, Physics, Tulane University, YU WANG, ZHIQIANG MAO, Physics, Pennsylvania State University, DIMITRI BASOV, ABHAY P NARAYAN, Columbia University — We present results of electrical transport studies on the metal-insulator transition (MIT) in 10% Ti-substituted Ca$_3$Ru$_2$O$_7$ under uniaxial strain. We observe a large (~10K) modulation of the Mott transition temperature under application of high (<1%) ab-plane uniaxial strain. For low strains we find an anomaly across $T_{MIT}$ in the linear response elastoresistive susceptibility. Complementary scanning near-field optical microscopy measurements have been performed on the same samples.

Novel uniaxial strain device for transport and scanning probe experiments

BEN FOUTTY (Presenter), JEDRZEJ WIETESKA, DREW A EDELBERG, ALEXANDER SWINTON MCLEOD, ROCCO VITALONE, SIMON TURKEL, ABHAY P NARAYAN, DIMITRI BASOV, Physics, Columbia University — In recent years uniaxial strain has emerged as an important probe of condensed matter systems, coupling to phenomena such as nematicity [1], superconductivity [2], magnetism [3], and metal insulator transitions [4]. Existing methods for in-situ application of high strains generally have been based off of extension piezoelectric actuators [5]. We present a method of strain application that relies on stacks of shear piezoelectric actuators to apply up to 1% uniaxial extension and compression at cryogenic temperatures homogeneously to up to 100 um square regions of materials ranging from transition metal dichalcogenides to ruthenates. Our method has been successfully applied to electrical transport, scanning tunneling microscopy, and scanning near-field optical microscopy measurements. Some early results using this device include measurement of a large strain effect on superconductivity in 2H-NbSe$_2$, the formation of solitons in 2H-MoSe$_2$, and the insulator-metal transition in 10% Ti-doped Ca$_3$Ru$_2$O$_7$.

4:18PM H07.00010: Nano-resolved strain control and polar modulation of the Mott transition in a bilayer ruthenate  
ALEXANDER SWINTON MCLEOD (Presenter), RAN JING, JEDRZEJ WIETESKA, BENJAMIN AARON FOUTTY, Physics, Columbia University, SHIMING LEI, RUI ZU, LEIXIN MIAO, KLEYSER E AGUEDA LOPEZ, JIN PENG, ZHIQIANG MAO, Physcis, Pennsylvania State University, DANIO PUGGIONI, JAMES M RONDINELLI, Materials Science and Engineering, Northwestern University, NASIM ALEM, VENKATRAMAN GOPALAN, Physics, Pennsylvania State University, DIMITRI BASOV, Physics, Columbia University — The 4d transition metal oxides of the Ca_{n+1}Ru_{n}O_{3n+1} perovskite family have recently garnered interest for their correlated electron physics and strong sensitivity to external stimuli like strain, temperature, and even electric current. These place the n=1,2 members in a rich phase diagram of competing and tunable metallic, magnetic, and insulating phases. The bilayer ruthenate Ca_{2}Ru_{2}O_{7} exhibits a structural distortion producing a polar metal and, under Ti substitution for Ru, a polar Mott insulator. We report cryogenic (T<100K) infrared nano-imaging (nano-IR) of 5% and 10% Ti-doped crystals revealing spontaneous patterns of striped phase coexistence through the thermal first-order Mott transition, and demonstrate nucleation and manipulation of metallic stripes through in situ uniaxial strain. Energy-resolved nano-IR imaging combined with surface work function mapping reveal suppression or enhancement of the Mott insulating state at polar domain boundaries in the crystal. Verified by second-harmonic polarimetry and transmission electron microscopy, we find the polar orientation and state of charge at these polar domain walls can selectively modulate the Mott transition, thus opening new routes towards manipulation of this canonical insulator-metal transition at sub-micron scales.

4:30PM H07.00011: Ionic gating of correlated perovskite nickelates  
YIFEI SUN (Presenter), ZHEN ZHANG, Purdue University - USA, HUA ZHOU, Argonne National Lab, SHIRIYAM RANAMATHAN, Purdue University - USA — In this work, we demonstrate that an ionic liquid gate can drive the fast motion of Li+ into and out of correlated perovskite nickelates such as SmNiO_{3} and NdNiO_{3}. This modulation effect can successfully engineer the phase of the material and tune the effective gap by nearly 3 eV. X-ray absorption spectra characterization showed that the Ni-site orbital occupancy control upon the gate modulation is the primary reason for the phase transition. Electrical transport measurements illustrated that such liithiation behavior induced the drastic change in electronic transport by several orders of magnitude and is independent of temperature. The lattice dilatation can be monitored as a function of Li+ doping concentration via synchrotron spectroscopy and provides structural insights during the phase transition. We will discuss hydrogen versus lithium doping of the nickelates and discuss the strain-orbital filling relationships.

ABRAHAM LEVITAN (Presenter), JARUI LI, Massachusetts Institute of Technology, KEVIN MERTES, Los Alamos National Laboratory, MARC ALLAIN, Institut Fresnel, ASH TRIPATHI, Los Alamos National Laboratory, WEN HU, Brookhaven National Laboratory, RICHARD L SANDBERG, Los Alamos National Laboratory, CLAUDIO MAZZOLI, Brookhaven National Laboratory, RICCARDO COMIN, Massachusetts Institute of Technology — Cubic perovskite nickelates with a rare earth ion (ANiO_{3}) exhibit both a metal to insulator transition and a transition to antiferromagnetic order, which coincide in the case of NdNiO_{3}. The many-body nature of these oxides and the interplay between antiferromagnetic order and charge disproportionation leads to a complex landscape involving significant inhomogeneity at the nanoscale. This is exhibited in the form of phase segregation near both the antiferromagnetic and metal to insulator transitions [1]. We report on a first step towards fully characterizing that nanoscale texture using resonant soft x-ray coherent Bragg ptychography at the CSX beamline of NSLS-II. In addition, our work demonstrates for the first time the feasibility of Bragg ptychography in the soft x-ray regime using the weak resonant scattering signals associated with electronic ordering wavevectors.

4:54PM H07.00013: Similarities and Differences Between the Nickelate LaNiO_{2} and Isoelectronic Cuprate Superconductors*  
MATTHIAS HEPTING (Presenter), DANFENG LI, HAIYU LU, CHUNJING JIA, XIAO FENG, YASUYUKI HIKITA, BRIAN MORITZ, SIMES, SLAC National Accelerator Lab, EUGENIO PARIS, YI TSENG, Paul Scherrer Institut, ZAHID HUSSAIN, YI-DE CHUANG, Advanced Light Source, Lawrence Berkeley National Laboratory, ZHIXUN SHEN, SIMES, SLAC National Accelerator Lab, SCHMITT THORSTEN, Paul Scherrer Institut, THOMAS DEVEREAUX, HAROLD HWANG, WEI-SHENG LEE, SIMES, SLAC National Accelerator Lab — It is an open question whether layered nickelate compounds and derived heterostructures could mimic a set of distinct properties which are suspected to invoke high-temperature superconductivity in cuprates, that is, a 2D layered crystal structure, spin 1/2 and strong antiferromagnetic correlations in the parent compound, absence of orbital degeneracy, and hybridization with oxygen ligands. To address this issue, we have investigated LaNiO_{2} and isostructural SrCuO_{2} thin films by x-ray absorption spectroscopy (XAS) and resonant inelastic x-ray scattering (RIXS) at the O K -and Ni L-edges. Despite several formal similarities between the nickelate and the cuprate, our study unveils severe differences in orbital configuration, antiferromagnetic order, and ligand-hybridization.

5:06PM H07.00014: On the mysterious magnetic susceptibility of LaNiO$_3$  
OLEKSANDR FOYEVTSOV (Presenter), Physics, 
University of British Columbia, JOHN MITCHELL, Argonne National Lab, GEORGE ALBERT SAWATZKY, Physics, University of British Columbia — Ever since Mott's time, understanding of the enhanced Pauli susceptibility observed in many metallic compounds has remained a great challenge[1]. This, in particular, holds in regard to the temperature dependence of the magnetic susceptibility of LaNiO$_3$, which, up until recently, was thought to be greatly enhanced yet almost temperature independent. However, recent advances in growth of highly stoichiometric LaNiO$_3$ single crystals have revealed that the magnetic susceptibility of LaNiO$_3$ has in fact a much more complex temperature dependence[2,3], which has invoked a renewed theoretical interest in the basic electronic structure of this material. In this talk, we propose an explanation of the recent data assuming temperature dependent disproportionation of localized magnetic moments.

Tuesday, March 5, 2019 2:30 PM - 5:30 PM

Session H08 DCMP: Superconductivity: Copper Oxide - Stripes, CDW and local probes BCEC

2:30PM H08.00001: Doping-dependent precursor charge density wave correlations in La$_{2-x}$Ba$_x$CuO$_4$*  
HU MIAO (Presenter), Brookhaven National Laboratory, GIACOMO GHiringHELLI, Dipartimento di Fisica, Politecnico di Milano, MARK DEAN, Brookhaven National Laboratory — Recently using resonant inelastic x-ray scattering (RIXS), we discovered, in La$_{2-x}$Ba$_x$CuO$_4$ x=0.125, precursor charge density wave (CDW) correlations that exist above the CDW transition temperature and observed that its wavevector varies with temperature and becomes unlocked from the spin wavevector [1]. This observation may help to reconcile the distinct doping-dependence of CDW wavevector in different cuprates families [1,2]. Here we show our new RIXS study that reveals the doping-dependent evolution of precursor CDW in La$_{2-x}$Ba$_x$CuO$_4$.

*This material is based upon work supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Early Career Award Program under Award No. 1047478. Work at Brookhaven National Laboratory was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Contract No. DE-SC0012704.

2:42PM H08.00002: Temperature Dependence of CDW phenomena in optimally-doped Bi2212 via RIXS*  
WEI-SHENG LEE (Presenter), MATTHIAS HEPTING, SLAC National Accelerator Laboratory, JIEMIN LI, ABHISHEK NAG, ANDREW WALTERS, MIRIAN GARCIA-FERNANDEZ, Diamond Light Source, MAKOTO HASHIMOTO, SLAC National Accelerator Laboratory, YOSHIYUKI YOSHIDA, HIROSHI EISAKI, AIST, BRIAN MORITZ, SLAC National Accelerator Laboratory, EDWIN HUANG, Stanford University, ZHIHUN SHEN, SLAC National Accelerator Laboratory, KEJIN ZHOU, Diamond Light Source, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory — Charge density wave (CDW) in double-layered Bi-2212 copper oxide superconductor has long been studied by STM; yet the questions of how the CDW's origin and how it interacts with other degrees of freedom as a function of temperature still remain largely unexplored. Here we utilize high-resolution resonant inelastic x-ray scattering (RIXS) at the Cu L-edge to investigate the CDW in optimally-doped Bi2212. A CDW scattering in the quasi-elastic region can be clearly observed, unambiguously demonstrating that CDW is a bulk property and exist in the optimally-doped Bi2212. Its temperature dependence and interaction with the phonon degrees of freedom will also be discussed.

Orbital symmetries of charge density wave order in \( \text{YBa}_2\text{Cu}_3\text{O}_{6+x} \)

2:54PM H08.00003: CHRISTOPHER M. MCMAHON, ANDREW ACHKAR, Physics and Astronomy, University of Waterloo; EDUARDO H. DA SILVA NETO, Stuart Blussom Quantum Matter Institute, University of British Columbia; ISAIAH DJIANTO, YLER MENARD, Physics and Astronomy, University of Waterloo; FEIZHOU HE, RONNY SUTARTO, Canadian Light Source; RICCARDO COMIN, RUIXING LIANG, DOUGLAS ANDREW BONN, WALTER N HARDY, ANDREA DAMASCELLI, Stuart Blussom Quantum Matter Institute, University of British Columbia; DAVID G. HAWTHORN (Presenter), Physics and Astronomy, University of Waterloo — Charge density wave (CDW) order has been shown to compete and co-exist with superconductivity in underdoped cuprate superconductors. Moreover, the CDW order has been proposed to exhibit a novel \( d \)-symmetry form factor—a quadrupolar modulation of the charge on oxygen sites surrounding each Cu site — evidence for which has emerged from STM measurements in BSCCO, NCCOC and from resonant x-ray scattering measurements of \( \text{YBa}_2\text{Cu}_3\text{O}_{6+x} \) (YBCO). Here, we revisit resonant x-ray scattering measurements at the Cu \( L \) edge of the CDW form factor in YBCO, utilizing a variation in the measurement geometry to provide enhanced sensitivity to the CDW orbital symmetry. Contrary to previous reports, the (0 0.31 \( L \)) peak measured at the Cu \( L \) edge is dominated by a simple \( s \) form factor, revealing no evidence for a dominant \( d \) form factor CDW. However, by measuring the CDW orbital symmetry at both the (0.31 0 \( L \)) and (0 0.31 \( L \)) peaks, we identify a pronounced difference in the orbital symmetry of the CDW order propagating along the \( a \) and \( b \) axes, with the CDW propagating along the \( a \)-axis exhibiting some form of orbital order in addition to charge order. Model calculations indicate that a candidate for the unusual orbital symmetry of the \( a \)-axis CDW to break \( ac \) and \( ab \) plane mirror symmetries.

Ground states of striped cuprates at high magnetic fields (\( H \))*

3:06PM H08.00004: PAUL G. BAITY (Presenter), ZHENZHONG SHI, DRAGANA POPOVIC, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State Univ.; TAKAO SASAGAWA, Tokyo Inst. of Tech. — The interplay of superconductivity and charge orders found in all hole-doped cuprates remains an open question in the limit of high \( H \). To address this issue, we have investigated the \( H \)-tuned superconducting-normal phase transitions in ultra-high-quality single crystals of \( \text{La}_{1.7}\text{Eu}_{0.2}\text{Sr}_{0.1}\text{CuO}_4 \) and \( \text{La}_{1.48}\text{Nd}_{0.4}\text{Sr}_{0.12}\text{CuO}_4 \), which have a striped charge order, under extreme conditions (temperatures \( T \) down to 0.016 K and \( H \) up to 45 T). A variety of linear and non-linear transport measurements have been performed, and the results reveal a full sequence of states in the \( T=0 \) limit as a function of \( H \): a superconductor, a wide regime of 2D superconducting phase fluctuations, and a high-\( H \) normal state. Within the phase-fluctuations regime, an unanticipated insulatinglike region emerges that is consistent with a novel type of ordering of localized Cooper pairs within the charge stripes in \( \text{CuO}_2 \) planes. This regime appears to compete with the \( H=0 \) superconductivity. We will present our results and discuss the role of disorder, as well as the similarities to other 2D systems and materials with competing orders that undergo superconducting phase transitions.

Stripes and superconductivity in the two-dimensional Hubbard model

3:18PM H08.00005: CHIA-MIN CHUNG (Presenter), Department of Physics, Ludwig-Maximilians-Universität München (LMU); MINGPU QIN, Department of Physics, College of William and Mary; HAO SHI, Center for Computational Quantum Physics, Flatiron Institute; ETTORE VITALI, Department of Physics, College of William and Mary, CLAUDIUS HUBIG, Max-Planck-Institut für Quantenoptik, ULRICH JOSEPH SCHOLLWOECK, Department of Physics, Ludwig-Maximilians-Universität München (LMU), STEVEN ROBERT WHITE, University of California, Irvine; SHIWEI ZHANG, Department of Physics, College of William and Mary — The stripes have been shown the ground state in the doped two-dimensional Hubbard model for a particular interaction. In this work we discuss the superconductivity in the stripes. We employ two of the most powerful methods, density matrix renormalization group and constrained-path auxiliary-field Monte Carlo to study the superconductivity in the stripes on finite-size cylinders and in the thermodynamic limit. By studying the pair-pair correlation and the local pairing order, we show that no long-range superconductivity exists in the ground-state stripes. In addition we discuss the mixture of stripes with different stripe fillings, and the effect on the superconductivity.
3:30PM H08.00006: Temperature and field dependence of the intrinsic tunneling structure in overdoped Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$

TIMOTHY BENSEMAN (Presenter), Physics, CUNY Queens College, JOHN ROBERT COOPER, Cavendish Laboratory, University of Cambridge, GEETHA BALAKRISHNAN, Physics, University of Warwick — Tunneling in stacked ‘intrinsic’ junctions in the high-$T_c$ superconductor doped Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ is a bulk probe of the quasiparticle density of states, which can be used to complement surface spectroscopic techniques such as ARPES and scanning tunneling microscopy. However, in order for this technique to give useful data above the superconducting sum-gap voltage, stacks with area of less than 1 $\mu$m$^2$ and containing approximately 10 or fewer intrinsic junctions must be used in order to ensure negligible self-heating.

Here we present intrinsic tunneling data for mesa structures fabricated on three over- and optimally-doped Bi$_{2+\delta}$Sr$_{1+\delta}$CaCu$_2$O$_{6+\delta}$ crystals, with 0.16–0.19 holes per CuO$_2$ unit, for a wide range of temperature ($T$) and applied magnetic field ($H$). The differential conductance above the gap edge shows a clear dip structure which is highly suggestive of strong coupling to a narrow boson mode. Data below the gap edge gives clear evidence for strong $T$-dependent pair breaking. These findings could help theorists make a detailed Eliashberg analysis and thereby contribute towards understanding the pairing mechanism.

3:42PM H08.00007: Bosonic Mode in the Tunneling Spectra of Fe-based and Cuprate Superconductors

JOHN ZASADZINSKI (Presenter), NOAH SAMUELSON, Physics, Illinois Institute of Technology, BEVERLY LOWELL, Physics, Northwestern University, MARIA IAVARONE, Physics, Temple University — The above-gap, SIN tunneling spectral dip feature in the bilayer cuprate Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ (Bi2212) is highly reproducible and unambiguously linked to the resonance spin excitation. The search for similar bosonic mode features in the tunneling spectra of Fe-based and other cuprate superconductors is presented. The single-layer cuprate Hg1201Tc (94K) exhibit sharp spectra and a well resolved bosonic mode feature similar to Bi2212. STS data on FeSe (Tc = 8.9K) reveal a bosonic mode feature quite similar to Bi2212, also linked to the neutron resonance mode. It is demonstrated that SIS break junctions or intrinsic c-axis junctions reveal a strongly enhanced dip feature allowing the observation of a bosonic mode in strongly disordered Bi2201 with Tc values ≤ 5K. Over a wide range of Tc values the mode energy $\Omega$ remains inside the superconducting gap $2\Delta$ as found in high Tc cuprates. The conclusion is that irrespective of Tc, composition and degree of disorder, the bosonic mode $\Omega$ retains its character as a spin exciton and appears to be a universal signature of unconventional superconductivity.

3:54PM H08.00008: Can Short-Range CDW Order Cause the Fermi Surface Reconstruction in the Cuprates?*

YUVAL GANNOT (Presenter), STEVEN KIVELSON, Stanford University — In the cuprates, short-range charge density wave (CDW) order is generally thought to account for the reconstructed Fermi surface apparent in quantum oscillation (QO) experiments. However, since the measured CDW correlation length may sometimes be shorter than the cyclotron radius, it is unclear whether sharp QOs reflecting the reconstructed Fermi surface are theoretically expected. In this work, we derive a simple quantization rule appropriate for disordered CDWs and show that it involves a random Berry phase. We demonstrate that under most circumstances, the predicted QO amplitude is not easily reconciled with observations in the cuprates.

*This work supported by NSF award number DMR-1608055.

4:06PM H08.00009: Visualizing the electronic structure of infinite-layer cuprate by scanning tunnelling spectroscopy*

YONG ZHONG (Presenter), RUIFENG WANG, ZIYUAN DOU, CANLI SONG, XUCUN MA, QIKUN XUE, State Key Laboratory of Low-dimensional Quantum Physics, Department of Physics, Tsinghua University — Infinite layer Sr$_{1-x}$La$_x$CuO$_{2+\delta}$ is a prototype to study the high-$T_c$ superconductivity in cuprates. Using oxide-MBE technique, we fabricate Sr$_{1-x}$La$_x$CuO$_{2+\delta}$ films with different doping levels. Mottness has been observed in lightly electron-doped Sr$_{1-x}$La$_x$CuO$_2$ by in-situ STM. We also find a phase transition to hole-doped Sr$_{1-x}$La$_x$CuO$_{2+\delta}$ when $x$ exceeds 0.1. Apical oxygens are responsible for this electron- to hole-cuprate transition, which is supported by transmission electron microscope measurements. By comparing the electronic structures in electron- and hole-doped Sr$_{1-x}$La$_x$CuO$_{2+\delta}$, we give some clues to understand the e-h asymmetry in cuprates.

*This work is financially supported by the Ministry of Science and Technology of China (Grants No. 2017YFA0304600, 2015CB921001, 2016YFA0301004), the National Natural Science Foundation of China (Grants No. 11427903, 11504196, 11634007, 11774192), and in part by the Beijing Advanced Innovation Center for Future Chip (ICFC).
4:18PM H08.00010: Real-Space Characterization of Charge Ordering in Epitaxial La_{2-x}Sr_xCuO_4 films  YANG WANG (Presenter), YONG ZHONG, ZHILING LUO, MENGHAN LIAO, RUIFENG WANG, ZIYUAN DOU, DING ZHANG, CANLI SONG, XUCUN MA, QIKUN XUE, Tsinghua University — Injection of charge carriers into the parent Mott insulator gives rise to a plethora of electronic orders in cuprates. Investigation of the behaving and relationship of these exotic orders with high-T_c is of pivotal importance in solving the cuprate conundrum. For this, we present a detailed study of the doping dependent charge orderings in the canonical La_{2-x}Sr_xCuO_4 cuprate thin films. By in-situ STM, we unveil a 4a_0-modulated stripe phase in the vicinity of 0.125 doping, whose commensurability is lost with decreasing Sr concentration. When heavier doped, a grid phase appears whose size is averaged to 4 nm. In the lightly doped regime, on the other hand, a Wigner crystal phase with a distorted-hexagonal patterned electronic structure is captured. Our results contribute to the construction of electronic landscape in the cuprate doping phase diagram, and is of help in illuminating its interplay with superconductivity.

4:30PM H08.00011: Charge trapping and super-Poissonian noise centers in a cuprate superconductor  KOEN BASTIAANS (Presenter), DOOHEE CHO, TJERK BENSCHOP, IRENE BATTISTI, DAMIANOS CHATZOPoulos, Leiden University, YINGKAI HUANG, MARK GOLDEN, University of Amsterdam, QUAN DONG, YONG JIN, C2N, University Paris-Saclay, JAN ZAANEN, MILAN P ALLAN, Leiden University — We present new insight into the mystery of highly anisotropic transport in the cuprates and how they can trap additional charges. Above the superconducting transition these materials are perfectly metallic along the crystal planes (ab-plane), but are insulating in the c-axis, with ratios between in-plane and perpendicular resistance exceeding 10^4. This anisotropy has been identified as one of the key mysteries in the cuprates and has been connected to the mechanism of high-temperature superconductivity. Here, we employ our newly developed scanning noise spectroscopy technique, for which we combined a scanning tunneling microscope (STM) with a novel MHz frequency amplifier to bring noise-spectroscopy measurements to the atomic scale [1]. We discover surprising deviations from the expected Poissonian noise of uncorrelated electrons. A behavior that can only happen in highly polarizable insulators and represents strong evidence for trapping of charge in the charge reservoir layers of the cuprates. We will show how these new observations connect to the mystery of anisotropic transport in high-temperature superconductors and shed new light onto this issue [2].

4:42PM H08.00012: Towards the development of YBa_2Cu_3O_7-based S-I-S tunneling Josephson junction device  HOM KANDEL (Presenter), Physics, University of Wisconsin-Parkside, ZHONGRUI LI, University of Michigan, Ann-Arbor, TARPIN CHEN, University of Arkansas — Josephson junctions are used to fabricate superconductor quantum interference devices (SQUIDs), qubits, and terahertz frequency devices. YBa_2Cu_3O_7 (YBCO)-based S-I-S tunneling Josephson junctions offer many advantages over the conventional low temperature superconductor-based Josephson junctions including low cost, cryogenic system simplicity, and high J_cR_n product value (with J_c being the junction critical current and R_n the normal resistance). However, the development of a well-controlled and reproducible YBCO based S-I-S tunneling Josephson junction is very challenging since the thickness of the electrical insulation layer (I) on the junction has to be only about a nanometer and it must provide a very high potential barrier in the junction.

Here, we present our work towards the development of the YBCO based S-I-S tunneling Josephson junction device by discussing growth, structure, and electrical transport properties of (110)-YBCO, various metals (M) doped PrBa_2(Cu_0.8M_0.2)O_7 (PBCMO), and heterostructures of YBCO and PBCMO. In particular, we discuss thin film deposition of (110)-oriented YBCO, PBCMO, and heterostructures of YBCO and PBCMO and their electrical transport properties including the electrical resistivity, conduction mechanism, and proximity effects.

4:54PM H08.00013: Quantum Sensing of Layered Superconductor at the Nanoscale  CHUNHUI DU (Presenter), RUOLAN XUE, MARK KU, FRANK ZHAO, NICOLA POCCIA, Harvard University, RUIDAN ZHONG, Brookhaven National Laboratory, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, GENDA GU, Brookhaven National Laboratory, PHILIP KIM, RONALD L WALSWORTH, AMIR YACOBY, Harvard University — We introduce single spin magnetometry based on nitrogen-vacancy (NV) centers in diamond as a new platform to probe the microwave response of a two-dimensional layered high Tc superconductor Bi_2Sr_2CaCu_2O_{8+x} (BSCCO) flake at the nanoscale. We observed a temperature-dependent spatial profile of the microwave field around the BSCCO flake, which can be attributed to the variation of the conductivity in BSCCO. Our technique provides a novel method to characterize the superconducting phase transitions without making electrical contacts and opens up new possibilities for nanoscale imaging of the charge dynamics in layered materials.
5:06PM H08.00014: High temperature superconducting oxychlorides: a light element model for cuprates  BLAIR LEBERT (Presenter), University of Toronto, MATTEO D’ASTUTO, Institut Néel — The copper oxychloride cuprate Ca$_2$CuO$_2$Cl$_2$ (CCOC) system, with vacancy or Na doping on the Ca site, is unique among the high temperature superconducting cuprates (HTSCs) since it: lacks high Z atoms; has a simple I4/mmm 1-layer structure at all doping and temperatures; and has a strong 2D character due to its apical chlorine. Due to the reduced number of electrons, advanced calculations that incorporate correlation effects, such as quantum Monte Carlo [1], are now feasible which makes CCOC a model system to gain insight into the 30-year-old mystery of HTSCs. But relatively little is known about CCOC so we are now filling this gap by a comprehensive experimental study covering the whole phase diagram, in particular the (para)magnon dispersion using RIXS [2] and the phonon dispersion using IXS [3]. We are also investigating the electron-phonon coupling using RIXS and searching for a bulk signature of the charge modulation (stripes) from x-ray resonant scattering close to the 1/8 doping.

5:18PM H08.00015: Emergent superconductivity upon disordering a charge density wave ground state  ANURAG BANERJEE (Presenter), Indian Institute of Science Education and Research, Kolkata, ARTI GARG, Theoretical Condensed Matter Physics Division, Saha Institute of Nuclear Physics, Kolkata, AMIT GHOSAL, Indian Institute of Science Education and Research, Kolkata — We explore the interplay of a charge density wave (CDW) order and s-wave superconductivity in a disordered system. Recent experiments on 1T-TiSe$_2$, where the pristine sample has a commensurate CDW order and the superconductivity appears upon copper intercalation, motivates our study. Starting with an extended Hubbard model, with parameters which yield a CDW ground state within Hartree-Fock-Bogoliubov formalism in pure systems, we show that the addition of disorder quickly wipes out the global charge order by disrupting periodic modulation of density at some (low) strength of disorder. Along with this, the subdominant superconducting order emerges in regions that spatially anticorrelate with islands of strong local CDW order. The short-range density modulations, however, continue to persist and show discernible effects up to a larger disorder strength. The local CDW puddles reduce in size with increasing disorder and they finally lose their relevance in effecting the properties of the system. Implication of our model calculations on the experimental findings of transition-metal-dichalcogenides will also be discussed.

Session H09 DCOMP: Superconductivity: Sr$_2$RuO$_4$ and other Triplet Candidates  Liuyan Zhao, University of Michigan

2:30PM H09.00001: Investigating the Pairing Symmetry in Uniaxially Strained Sr$_2$RuO$_4$ by $^{17}$O NMR Shifts* ANDREJ PUSTOGOW (Presenter), YONGKANG LUO, AARON CHRONISTER, YUE-SHUN SU, University of California, Los Angeles, NAOKI KIKUGAWA, National Institute for Materials Science, Tsukuba, DMITRY SOKOLOV, FABIAN JERZEMBECK, ANDREW MACKENZIE, CLIFFORD HICKS, Max Planck Institute for Chemical Physics of Solids, ERIC BAUER, Los Alamos National Laboratory, STUART E BROWN, University of California, Los Angeles — The unconventional superconductor and Fermi liquid Sr$_2$RuO$_4$ exhibits clear effects of electronic correlations associated with Hund’s Rule coupling. In the superconducting (SC) state, several experiments produced evidence for time reversal symmetry breaking, and nuclear magnetic resonance (NMR) Knight shift measurements were consistent with an equal-spin pairing triplet state. To that end, Sr$_2$RuO$_4$ is widely considered as a potential candidate for a chiral $p$-wave pairing with an order parameter of $p_x \pm ip_y$ symmetry - a solid state analog to $^3$He-$^3$He. Motivated by the recent observation of a strong peak in $T_c$ across a strain-induced Lifshitz transition associated with a van Hove singularity, we studied the $^{17}$O NMR shifts in the SC state of Sr$_2$RuO$_4$. Our low-temperature experiments at high strain reveal a drop of spin susceptibility below $T_c$ evidenced by unambiguous reduction of Knight shifts for the in-plane O sites. Most pronounced at the Lifshitz point, the loss of spin susceptibility on entering the SC state is reduced on lowering the strain, while no evidence for a phase transition between distinct SC states is observed.

*This work was supported by the National Science Foundation (DMR-1709304) and Los Alamos Laboratory Directed Research and Development (LDRD) program.
2:42PM H09.00002: Microscopic model of the Knight shift in an anisotropic type-II superconductor  RICHARD KLEMM (Presenter), AIYING ZHAO, physics, University of Central Florida, JINGCHUAN ZHANG, QIANG GU, physics, University of Science and Technology Beijing, Beijing, PR China — We have simplified our model of the Knight shift in an anisotropic metal and superconductor by forcing the Hamiltonian for an electron in the Landau orbits for an ellipsoidal anisotropic single electron Hamiltonian and the Zeeman interaction to be relativistically consistent. The resulting Hamiltonian with three effective masses in the three directions of an orthorhombic crystal is invariant under the most general proper Lorentz transformation involving general rotations about all three crystal axes and general boosts in all three directions. The non-relativistic limit then has the following general properties: there is no Zeeman interaction for a one-dimensional metal, and for a two-dimensional metal, the Zeeman interaction is only present for the magnetic field applied perpendicular to the conducting plane. These exact results show that for the field parallel to the layers of a highly layered superconductor or for any field direction in a quasi-one-dimensional superconductor, the temperature dependence of the Knight shift in the superconducting state should either vanish or be very weak. Hence, many Knight shift measurements on such superconducting materials, while correct, have been misinterpreted in the literature.

2:54PM H09.00003: Possible three-dimensional nematic odd-parity pairing in Sr$_2$RuO$_4$ evidenced by uniaxial strain measurements  WEN HUANG (Presenter), Institute for Advanced Study, Tsinghua University, YI ZHOU, Department of Physics, Zhejiang University, HONG YAO, Institute for Advanced Study, Tsinghua University — In the presence of a nontrivial three-dimensional (3D) spin-orbital entanglement, the superconducting pairing in Sr$_2$RuO$_4$ is inherently 3D, consisting both in-plane and out-of-plane channels: $(k_x, k_y)\hat{z}$ and $(k_x, k_y)\hat{z}$. When the latter dominates, the system may develop a time-reversal invariant nematic pairing. We show that, as the out-of-plane pairing lacks a linear-order coupling to certain symmetry-lowering perturbations such as in-plane uniaxial strains, the nematic state may observe a superconducting $T_c$ enhancement indistinguishable from a quadratic function of the strain. Further, in contrast with the chiral pairing, the nematic pairing shall exhibit only a single phase transition or a comparatively less robust secondary transition under the stated perturbations. In combine these may be consistent with several recent experiments on uniaxially-strained samples of Sr$_2$RuO$_4$, thereby providing stronger support for the 3D nematic $p$-wave pairing in this material.

3:06PM H09.00004: Upper critical field of Sr$_2$RuO$_4$ under uniaxial stress  FABIAN JEREMBECK (Presenter), ALEXANDER STEPPKE, YOU-SHENG LI, DMITRY SOKOLOV, Max-Planck-Institut for Chemical Physics of Solids, NAOKI KIKUGAWA, National Institute for Material Science, Tsukuba, Ibaraki, ANDREW MACKENZIE, CLIFFORD HICKS, Max-Planck-Institut for Chemical Physics of Solids — Through application of in-plane uniaxial stress, the unconventional superconductor Sr$_2$RuO$_4$ can be driven through a Lifshitz transition and associated Van Hove singularity (VHS) in the density of states. At this point, its $T_c$ is enhanced by a factor of about 2.5, and $H_{c2}$ by about twenty. Here, we present data on $H_{c2}$ at intermediate strains, and observe that the peak in $H_{c2}$ is much sharper than that in $T_c$. The ratio $H_{c2}/T_c^2$ increases in the close vicinity to the VHS, providing information on the evolution of the superconducting gap as the VHS is approached.

3:18PM H09.00005: Superconducting penetration depth measurement and zero field muon spin relaxation experiments on Sr$_2$RuO$_4$ under uniaxial strain*  SHREENANDA GHOSH (Presenter), VADIM GRINENKO, RAJIB SARKAR, FELIX BRÜCKNER, Institut für Festkörper- und Materialphysik, Technische Universität Dresden, JEAN-CHRISTOPHE ORAIN, HUBERTUS LUETKENS, NIKITIN ARTEM, MATTHIAS ELENDER, Paul Scherrer Institute, Villigen, Switzerland, JOONBUM PARK, MARK E BARBER, NAOKI KIKUGAWA, DMITRY SOKOLOV, ANDREW MACKENZIE, CLIFFORD HICKS, Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany, YOSHITERU MAENO, Department of Physics, Graduate School of Science, Kyoto University, Kyoto, Japan, HANS-HENNING KLAUSS, Institut für Festkörper- und Materialphysik, Technische Universität Dresden — To probe its superconducting order parameter, we have performed muon spin relaxation (muSR) measurements on samples of Sr$_2$RuO$_4$ placed under uniaxial stress. Previous studies on unstressed Sr$_2$RuO$_4$ have revealed enhanced relaxation in the superconducting state, which is interpreted as evidence for a chiral $px \pmipy$ order parameter. With this order parameter, uniaxial stress is expected to induce a splitting between $T_c$ and the onset of chirality. muSR requires large samples, so to perform these measurements, we have developed piezoelectric-based apparatus capable of applying forces of up to ~ 500 N.

*We are grateful to the Deutsche Forschungsgemeinschaft through grants GRK 1621 and SFB 1143, GR 4667 and to the Max Planck Society.
Electronic correlations and enhanced spin-orbit coupling in Sr$_2$RuO$_4$ determined from high-resolution laser-based ARPES.  

**ANNA TAMAI (Presenter), Department of Quantum Matter Physics, University of Geneva, MANUEL ZINGL, Center for Computational Quantum Physics, Flatiron Institute, MINJAE KIM, College de France, ANTOINE GEORGES, Center for Computational Quantum Physics, Flatiron Institute, FELIX BAUMBERGER, Department of Quantum Matter Physics, University of Geneva —** We combine laser-based angle-resolved photoemission and dynamical mean-field theory calculations to study the interplay of electron-electron correlations and spin-orbit coupling (SOC) in the model Fermi liquid Sr$_2$RuO$_4$. Analyzing the experimental Fermi surface, we show that correlations enhance SOC by a factor of $\sim 2$ over the bare value. We further reveal that the real part of the self-energy of the $\beta$ and $\gamma$ sheet is momentum dependent and strongly non-linear down to low energies, in contrast to widely held believes about the phenomenology of Fermi liquids. Introducing a new method to determine orbital self-energies from quasiparticle states with multi-orbital composition, we demonstrate that the anisotropy of the self-energy does not imply momentum dependent many-body interactions. The non-linearity of the self-energy is reproduced by single-site dynamical mean field theory, which provides strong evidence for a dominantly electronic origin of ‘kinks’ in the quasiparticle dispersion of Sr$_2$RuO$_4$.

Sr$_2$RuO$_4$ Josephson junctions built in epitaxial films  

**MASAKI UCHIDA (Presenter), IKKEI SAKURABA, University of Tokyo, MINORU KAWAMURA, RIKEN CEMS, MOTOHARU IDE, University of Tokyo, KEI TAKAHASHI, YOSHINORI TOKURA, RIKEN CEMS, MASASHI KAWASAKI, University of Tokyo —** A layered-perovskite superconductor Sr$_2$RuO$_4$ has attracted continuing interest as a leading candidate with chiral $p$-wave symmetry, which is one of topological superconductors potentially hosting Majorana fermions. For further investigation and possible applications of the unique state, the use of Sr$_2$RuO$_4$ thin films for junctions has been increasingly demanded. While growth of the superconducting Sr$_2$RuO$_4$ films had been extremely difficult over the past decades [1,2], the reproducible and controllable growth has been recently achieved by refining molecular beam epitaxy techniques [3]. In this talk, we report fundamental superconducting properties of Sr$_2$RuO$_4$ thin films and also Josephson junctions as revealed by systematic ultralow-temperature transport measurement. The Sr$_2$RuO$_4$-Sr$_2$RuO$_4$ Josephson junctions built in the epitaxial films have some advantages in investigating the possible multicomponent order parameter. The observed $I_cR_n$ product is as high as 2 $\mu$eV and its temperature dependence shows clear deviations from the conventional Ambegaokar-Baratov model.

**[3] M. Uchida et al., APL Mater. 5, 106108 (2017).**

Spontaneous emergence of Josephson junctions in homogeneous rings of single-crystal Sr$_2$RuO$_4$  

**YUUKI YASUI, Dept. of Physics, Kyoto University, KAVEH LAHABI, Huygens-Kamerlingh Onnes Laboratory, Leiden University, VICTOR FERNANDEZ BECERRA, Dept. of Physics, University of Antwerp, MUHAMMED SHAHBAZ ANWAR, Dept. of Materials Science and Metallurgy, University of Cambridge, SHINGO YONEZAWA, TAKAHITO TERASHIMA, Dept. of Physics, Kyoto University, MILORAD MILOSEVIC, Dept. of Physics, University of Antwerp, YOSHITERU MAENO, Dept. of Physics, Kyoto University, JAN AARTS (Presenter), Huygens-Kamerlingh Onnes Laboratory, Leiden University —** Sr$_2$RuO$_4$ is expected to be a spin-triplet chiral $p$-wave superconductor, where the chirality means that the ground state is two-fold degenerate, with two different directions of the Cooper-pair orbital angular momentum. We fabricated Sr$_2$RuO$_4$ microrings and performed resistance ($R$) and critical-current ($I_c$) measurements in an axial magnetic field. In some such rings, Little-Parks magnetoresistance oscillations are observed close to the transition temperature $T_c$ as recently reported [1]. In other rings, however, we find that $I_c$ oscillates with a period corresponding to the fluxoid quantization down to temperatures far below $T_c$. This behavior resembles that of a superconducting quantum interference device (SQUID) and suggests that a pair of weak links of an intrinsic origin is spontaneously formed in the arms of the ring. Such weak links are most naturally attributable to domain walls separating domains with different chirality, which is also the outcome of order parameter calculations. We believe this to be strong new evidence for the chiral superconducting state in Sr$_2$RuO$_4$.

4:06PM H09.00009: Signature of Unconventional Superconductivity in a Metal-Organic Framework with a Perfect Kagome Structure  
TAKAAKI TAKENAKA (Presenter), KOTA ISHIHARA, YIJIE MIAO, Department of Advanced Material Science, University of Tokyo, XING HUANG, WEI XU, DAOBEN ZHU, Institute of Chemistry, Chinese Academy of Sciences, NA SU, JINGUANG CHENG, Institute of Physics, Chinese Academy of Sciences, TAKASADA SHIBAUCHI, Department of Advanced Material Science, University of Tokyo — Recently, the superconductivity in a Metal-organic framework (MOF) has been discovered for the first time in copper(II) benzenehexathiolate ([Cu₃(C₆S₆)]ₙ, Cu-BHT). A theoretical study predicts that the electron-phonon coupling constant of 0.51 for bulk Cu-BHT can lead to superconductivity at $T_c \sim 1.58$ K, thus conventional s-wave superconducting state has been proposed as a candidate of the pairing state. Meanwhile, recent measurements revealed strong quantum spin fluctuation possibly related to the 2D Kagome lattice of Cu atoms with $S = 1/2$ spin. Quantum spin fluctuations can promote unconventional superconducting pairing states, and it is therefore important to experimentally determine whether the superconductivity in Cu-BHT has conventional or unconventional nature. Here we present measurements of in-plane magnetic penetration depth $\lambda$ in Cu-BHT films down to 40 mK. The temperature dependence of $\lambda$ shows a non-exponential, quasi-linear behavior at low temperatures. Our finding suggests that not only unconventional superconductivity with low-energy quasiparticle excitations is realized in this system but also MOFs can provide a flexible platform to investigate the superconducting pairing mechanisms in the presence of spin frustration and strong quantum fluctuations.

4:18PM H09.00010: Spin Polarized Triplet Supercurrent in Ferromagnetic-Superconducting Josephson Junctions*  
MADISON SUTULA (Presenter), Physics, Materials Science and Engineering, Massachusetts Institute of Technology, MIRKO ROCCI, Francis Bitter Magnet Laboratory, Plasma Science and Fusion Center, Massachusetts Institute of Technology, NILADRI BANERJEE, Physics, Loughborough University, CUI-ZU CHANG, Physics, Penn State University, F. SEBASTIAN BERGERET, Centro de Fisica de Materiales CFM, Centro Mixto CSIC-UPV/EHU, JAGADEESH MOODERA, Physics, Francis Bitter Magnet Laboratory, Plasma Science and Fusion Center, Massachusetts Institute of Technology — Proximity coupling across superconductor-ferromagnet bilayers can give rise to the triplet component of the superconducting condensate [1]. Superconductivity and ferromagnetism have been reported to coexist in a Ni/Bi bilayer system [2]. We investigated Josephson and quasiparticle tunneling across such ferromagnetic-superconducting layers in Bi/Ni/Insulator/Ni/Bi junctions. The superconductivity in the Ni/Bi bilayer is expected to be topological [3]. Moreover, the observed Josephson current could be spin polarized, as superconducting quasiparticles originating from Ni in the Ni/Bi bilayer have been shown to also exhibit spin polarization [2]. The occurrence of conductance at zero bias in these junctions points to odd-frequency symmetry in the superconducting condensate, supporting the presence of a non-zero component associated with a triplet pair superconductivity insensitive to disorder.  
*We acknowledge funding from NSF (DMR-1700137) and ONR (N00014-16-1-2657) as well as MIT UROP funding.

4:30PM H09.00011: Unconventional superconductivity near frustrated orders in quasi-one-dimensional CrAs based systems  
KEITH TADDEI (Presenter), Oak Ridge National Laboratory, GUANGZONG XING, JIFENG SUN, YUHAO FU, YUWEI LI, Physics, University of Missouri, QIANG ZHENG, ATHENA S. SEFAT, Oak Ridge National Laboratory, DAVID SINGH, Physics, University of Missouri, CLARINA DELA CRUZ, Oak Ridge National Laboratory — Even in the absence of a microscopic theory, a generalized recipe has emerged for unconventional superconductivity. In the common scenario, some ordered phase in a strongly-ish correlated material is suppressed giving rise to quantum fluctuations which can act as a possible pairing mechanism. The nature of these fluctuations – whether they are of the ordered phase, resultant of a quantum critical point or some more exotic pair density wave – is still hotly debated. Therefore, it is useful to find new unconventional superconductors which can provide further insight into the most relevant components of this recipe. The recently discovered family of $A_xTM_3As_3$ ($A = \text{Alkali, } x = 1,2 \text{ and } TM = \text{Cr, Mo}$) superconductors provides such an opportunity in a system with a novel quasi-one-dimensional structure. In this presentation the latest results of joint $\text{ab initio}$ and neutron scattering studies will be discussed which reveal a frustrated structural instability in $K_2\text{Cr}_3\text{As}_3$. Together with our previous reports of spin-fluctuations, this observation indicates a rich phase diagram for this system analogous to the traditional unconventional superconductors.
4:42PM H09.00012: Spontaneous magnetisation in the superconducting state of LaNiGa2*  
GABOR CSIRE, Physics, University of Bristol, SUDEEP GHOSH, PHILIP WHITTLESEA, JORGE QUINTANILLA, Physics, University of Kent, BALAZS UJFALUSSY, Wigner Research Center for Physics, KAZUMASA MIYAKE, Ctr Adv High Maget Field Sci, Osaka University, JAMES ANNETT (Presenter), Physics, University of Bristol — Muon spin relaxation shows spontaneous magnetism in the superconducting state of LaNiGa2. Symmetry analyses imply nonunitary triplet pairing with line nodes and predict a sub-dominant magnetisation consistent with SQUID measurements. In contrast, there is evidence from penetration depth and specific heat for two-gap, nodeless superconductivity. It was proposed to reconcile this by assuming equal-spin inter-orbital pairing. Here we show within a mean-field framework, that this gives rise to a nodeless, two-gap spectrum. We probe the state's stability in the presence of finite inter-orbital energy splitting and derive an analytical expression for the resulting spontaneous magnetisation. Furthermore, we present a detailed calculation combining a realistic first-principles band structure with a phenomenological pairing interaction. We find that equal-spin pairing between certain Nickel d-orbitals can describe the specific heat quantitatively. We predict the two-gap structure in differential tunnelling conductance and the size of the spontaneous magnetic moment.

*We acknowledge support from EPSRC (EP/P007392/1, EP/P00749X/1) and the Hungarian National Research, Development and Innovation Office (contract K115632).

4:54PM H09.00013: Nodeless bulk superconductivity in the time-reversal symmetry breaking Bi/Ni bilayer system*  
PRASHANT CHAUHAN (Presenter), FAHAD MAHMOOD, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, MD, United States, DI YUE, PENGCHAO XU, XIAOFENG JIN, Department of Physics, Fudan University, Shanghai, China, PETER ARMITAGE, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, MD, United States — Epitaxial bilayer films of Bi(110) and Ni host a time-reversal symmetry (TRS) breaking superconducting order with an unexpectedly high transition temperature Tc = 4.1K. Using time-domain THz spectroscopy, we measure the low energy electrodynamic response of a Bi/Ni bilayer thin film from 0.2THz to 2THz as a function of temperature and magnetic field. We analyze the data in the context of a BCS-like superconductor with a finite normal-state scattering rate. In zero magnetic field, all states in the film become fully gapped, providing important constraints into possible pairing symmetries. Our data appears to rule out the odd-frequency pairing that is natural for many ferromagnetic-superconductor interfaces. By analyzing the magnetic field-dependent response in terms of a pair-breaking parameter, we determine that superconductivity develops over the entire bilayer sample which may point to the p-wave like nature of unconventional superconductivity.

5:06PM H09.00014: Nontrivial effects of point-like disorder on critical fields and pinning in s± superconductors*  
RUSLAN PROZOROV (Presenter), Ames Laboratory, MARCIN KONCZYKOWSKI, Ecole Polytechnique, VLADIMIR G. KOGAN, MAKARIY TANATAR, Ames Laboratory — In most superconductors non-magnetic point-like defects enhance pinning and upper critical field. However, in s± superconductors, for example iron-based compounds, point-like disorder influences not only intra-band potential scattering, but also inter-band pair-breaking scattering rates. The latter leads to suppression of Tc, Hc2 and the condensation energy. The balance between these opposite effects leads to an increase of (dHc2/dT)T=Tc slope with the decrease of Tc, opposite to what is observed as a function of doping. Even more unusual, it may also lead to a suppression of strong pinning believed to be responsible for a sharp peak in magnetization near H=0. In our experiments controlled disorder was induced by 2.5 MeV electron irradiation.

Session H10 DMP: Fe-based Superconductors IV
2:30PM H10.00001: Pairing mechanisms in iron-based superconductors: variations on the s+- theme*  [Invited]  PETER HIRSCHFELD (Presenter), University of Florida — I will review some of the recent developments in the theory of superconductivity of iron-based systems that go beyond the s+- paradigm established in the early days of the field. These include: a) prediction of and evidence for T-breaking mixed symmetry pair states; b) influence of orbital selective correlations on pairing; c) competition and cooperation of nematic order and superconductivity; and d) new pair states possibly stabilized by spin-orbit coupling. A main focus will be a critical look at the of whether Fe-pnictide based materials are fundamentally different from Fe-chalcogenides.

*Research supported by the Department of Energy under Grant No. DE-FG02-05ER46236.

3:06PM H10.00002: Fermi surface pockets in iron pnictides revised by screened exchange dynamical mean-field theory*  STEFFEN BACKES (Presenter), Ecole Polytechnique, AMBROISE VAN ROEKEGHEM, LITEN, CEA, SILKE BIERMANN, Ecole Polytechnique — Until today our understanding of iron based superconductors is hampered by a persistent systematic discrepancy between theory and experiment: the size of the Fermi surface pockets consistently turn out too large in theoretical calculations[1]. Here we show that this puzzle can be solved when taking into account the effect of nonlocal exchange beyond the Density Functional Theory plus dynamical mean-field theory(DFT+DMFT) approach. As it turns out, the nonlocal exchange properties in DFT+DMFT are rather poorly described, leading to an overestimation of the size of Fermi surface pockets. We show that an approximative treatment within screened exchange dynamical mean-field theory gives rise to momentum dependent Fermi surface modifications leading to a significant improvement with experiment. Additionally, we observe a Fermi surface modification in paramagnetic BaFe2As2, where the Fe 3d_{xy} hole pocket in the Brillouin zone center vanishes completely. Reinterpreting existing angle-resolved photoemission (ARPES) experiments, we propose that indeed the Fe 3d_{xy} states are located below the Fermi level, in contrast to previous belief[2].

3:18PM H10.00003: Doping dependence of the electronic structure and superconductivity of FeSe thin films by Cobalt dopant  SHIYONG TAN (Presenter), XINGYU JI, XINCHUN LAI, China Academy of Engineering Physics — Both superconductivity and structural transition/orbital order are found to be suppressed by Co doping in FeSe single crystal. We have grown FeSe thin films on STO substrates using MBE, and studied the doping dependence of the electronic structure and superconductivity of FeSe thin films by Cobalt dopant. For single layer FeSe, the electron pockets at M point are enlarged when doped with cobalt, and the Tc is slightly increased. When the 2.5 UC, 3.25 UC and 4 UC FeSe sample are electron doped by cobalt, the nematic order is suppressed and superconductivity can be detected. For the multi-layer FeSe thin films, the electronic structure turns out to be alike of single layer FeSe when they are effectively Co doped. But it is not superconducting at the largest doping level, which indicates that the interface effect plays an important role for the high Tc in 1UC FeSe/STO system.

3:30PM H10.00004: Phase diagram of compressed RbEuFe₄As₄ and CsEuFe₄As₄: Coexistence of superconductivity and magnetism∗

DANIEL JACKSON (Presenter), Pulsed Field Facility, National High Magnetic Field Laboratory, Los Alamos National Lab, DERRICK VANGENNEP, Department of Physics, University of Florida, WENLI BI, Advanced Photon Source, Argonne National Laboratory, DONGZHOU ZHANG, Hawaii Institute of Geophysics and Planetology, University of Hawaii at Manoa, PHILIPP MATERNE, Advanced Photon Source, Argonne National Laboratory, YI LIU, GUANG-HAN CAO, Department of Physics, Zhejiang University, SAMUEL T WEIR, Physics Division, Lawrence Livermore National Laboratory, YOGESH KUMAR VOHRA, Department of Physics, University of Alabama at Birmingham, JAMES HAMLIN, Department of Physics, University of Florida — RbEuFe₄As₄ and CsEuFe₄As₄ are members of the recently discovered 1144 superconducting family, they exhibit the unusual combination of superconductivity (Tc ~ 35 K) and ferromagnetism (Tm ~ 15 K). We performed a series of measurements under compression including x-ray diffraction, magnetic susceptibility, and electrical resistivity. Compression monotonically suppresses Tc and enhances Tm. Near 7 GPa, Tc onset and Tm become comparable, at higher compression evidence of bulk superconductivity gradually disappears. Room-temperature x-ray diffraction measurements provide evidence of a transition from tetragonal to a half-collapse-tetragonal structure near 10 GPa for RbEuFe₄As₄ and near 12 GPa for CsEuFe₄As₄. The cross-over from ferromagnetic superconductor (Tc > Tm), to superconducting ferromagnet (Tm > Tc) occurs before the structural transition, suggesting that RbEuFe₄As₄ and CsEuFe₄As₄ are an ideal system for studying the interplay between superconductivity and magnetism.

3:42PM H10.00005: Specific heat under pressure on selected iron-pnictide superconductors∗

ELENA GATI (Presenter), GIL DRACHUK, LI XIANG, ANNA BOEHMER, SERGEY BUDKO, PAUL CANFIELD, Ames Laboratory/Iowa State University — The phase diagrams of iron-pnictide superconductors manifest a complex interplay of superconductivity, magnetism and structure which can typically be tuned by external tuning parameters, such as pressure. In this contribution, we report a study of the specific heat under pressure on selected iron-pnictide superconductors, such as FeSe, as well as pure and Co-doped BaFe₂As₂. We will compare pressure-dependent phase diagrams, as well as provide further characterization of the superconducting properties. The latter will, in particular, include a discussion of the evolution of the specific heat jump sizes at the superconducting transition with pressure.

∗This work was carried out at Iowa State University and supported by Ames Laboratory, US DOE, under Contract No. DE-AC02-07CH11358. L. X. was supported, in part, by the W. M. Keck Foundation.

3:54PM H10.00006: Specific heat evidence for rotational symmetry breaking in RbFe₂As₂

OHEI TANAKA (Presenter), YUTA MIZUKAMI, KOUSUKE ISHIDA, MASAYA TSUJII, Department of Advanced Materials Science, University of Tokyo, SHIGEYUKI ISHIDA, AKIRA IYO, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, THOMAS WOLF, KAI GRUBE, HILBERT LOEHNEYSEN, Karlsruhe Institute of Technology, TAKASADA SHIBAUCHI, Department of Advanced Materials Science, University of Tokyo — RbFe₂As₂ has the 3d⁵.₅ electronic configuration, which corresponds to the most heavily hole-doped system among 122-type iron-based superconductors. In this system, a large mass enhancement has been observed, and the importance of the vicinity to the Mott insulator phase at 3d⁵ configuration has been suggested [1]. Recently, we have observed nematic fluctuations along the Fe-As direction, 45° tilted from the nematic direction usually found in other iron-based superconductors. Although the two-fold symmetry along the Fe-As direction has also been suggested from STM measurements [2], the bulk evidence for nematic ordering has not been reported. Here, we perform field-angle-resolved specific heat measurements in RbFe₂As₂ single crystals by using a high-resolution long-relaxation calorimeter. We choose tiny crystals of about 10 μg to avoid cancellation effect of multiple nematic domains. We find clear two-fold oscillations as a function of in-plane field angle near the superconducting transition. This provides bulk evidence for long-range nematic ordering along the Fe-As direction in RbFe₂As₂.

4:06PM H10.00007: Specific heat in strongly hole-doped Iron-based superconductors  DMITRY CHICHINADZE (Presenter), ANDREY CHUBUKOV, University of Minnesota — In our work we compute the specific heat $C(T)$ in an Fe-based superconductor with only hole pockets. We use a three orbital/three pocket model with two smaller hole pockets made out of $d_{xz}$ and $d_{yz}$ orbitals and a larger pocket made out of $d_{xy}$ orbital. We use the experimental fact that the mass of $d_{xy}$ fermion is much heavier than that of $d_{xz}/d_{yz}$ fermions as an input. We argue that the heavy $d_{xy}$ band contributes most to the specific heat in the normal state, but the superconducting gap on the $d_{xy}$ pocket is parametrically smaller than that on $d_{xz}/d_{yz}$ pockets. We also argue that in this situation the jump of $C(T)$ at $T_c$ is determined by $d_{xz}/d_{yz}$ fermions, and the ratio $(C_s - C_n)/C_n$ is a fraction of that in a one-band BCS theory. Below $T_c$, $C(T)$ remains relatively flat down to some $T^*$, below which $C(T)$ rapidly drops. This behavior is consistent with the data for KFe$_2$As$_2$ and related materials. We claim that the data on $C(T)$ can be reproduced without assuming that the quasiparticle residue $Z$ on $d_{xy}$ band is small. We further argue that the very existence of a finite $T^* < T_c$ favors $s^+$ gap structure over $d$-wave, because in the latter case $T^*$ would vanish.

4:18PM H10.00008: Coexistence of superconductivity and magnetism in CaK(Fe$_{1-x}$Ni$_x$)$_4$As$_4$ as probed by $^{57}$Fe Mössbauer spectroscopy* SERGEY BUDKO (Presenter), VLADIMIR G. KOGAN, RUSLAN PROZOROV, WILLIAM MEIER, MINGYU XU, PAUL CANFIELD, Ames Laboratory, Iowa State University — Temperature dependent $^{57}$Fe Mössbauer spectroscopy and specific heat measurements for CaK(Fe$_{1-x}$Ni$_x$)$_4$As$_4$ with $x = 0$, 0.017, 0.049 are presented. No magnetic hyperfine field (i.e. no static magnetic order) was detected down to 5.5 K for $x = 0$ and 0.017 in agreement with the absence of any additional feature below superconducting transition temperature, $T_c$, in the specific heat data. The evolution of magnetic hyperfine field with temperature was studied for $x = 0.033$ and 0.049. The long-range magnetic order in these two compounds coexists with superconductivity. The magnetic hyperfine field, $B_{hf}$, ordered magnetic moment) below $T_c$ in CaK(Fe$_{0.967}$Ni$_{0.033}$)$_4$As$_4$ is continuously suppressed with the developing superconducting order parameter. The $B_{hf}(T)$ data for CaK(Fe$_{0.967}$Ni$_{0.033}$)$_4$As$_4$, and CaK(Fe$_{0.951}$Ni$_{0.049}$)$_4$As$_4$ can be described by Machida’s model for coexistence of itinerant spin density wave magnetism and superconductivity [K. Machida, J. Phys. Soc. Jpn. 50, 2195 (1981)].

4:30PM H10.00009: Nuclear magnetic resonance techniques for in-situ strain measurements using surface coils CHARLES SNIDER (Presenter), ERICK GARCIA, Brown University, JOHANNA PALMSTROM, IAN R FISHER, Stanford University, VESNA F MITROVIC, Brown University — Widespread efforts have been made to study the role of nematic order in the high temperature superconductivity of iron-based pnictides. This includes the increasing use of strain to explore the anisotropies in electronic states and the nematic susceptibility. Nuclear magnetic resonance (NMR) is the ideal probe to explore such properties because it is sensitive to spin and charge degrees of freedom while allowing the measurement of nematic properties in the superconducting state. It has been shown that strain can be fully transmitted to samples up to approximately 100 μm thick using piezoelectric stacks [J.H. Chu et al. Science 2012], but there are practical limitations in the application of such techniques in NMR. The nontrivial issue of probing such small samples can be overcome by the novel use of surface coils that enhance the signal to noise ratio [W. Liu et al. Rev. Sci. Instrum. 2017] and allow for in-situ sample rotations and controllable application of strain. In this talk, we demonstrate how to simultaneously implement such techniques in NMR experiments.

4:42PM H10.00010: Switching effect in metal-superconductor-metal Fe(0.7Se0.3) nanojunction* YUN LING (Presenter), Suzhou University of Science and Technology, ANDREW STEELEY, ABIN JOSHY, Tulane University, ZHIQIANG MAO, Pennsylvania State University, JIANG WEI, Tulane University — We report our transport study on the metal-superconductor-metal (MSM) device based on Fe(0.7Se0.3) nanoflakes. An unusual switching behavior in I-V characteristics for flakes with a thickness below 10nm has been observed. Furthermore, we discovered that such switching behavior could be controlled by an external magnetic field and bias voltage. Given the traditional understanding that superconductivity in Fe(0.7Se0.3) manifests as the collective effect from clusters of nanoscale superconducting domains, we proposed a self-heating model to explain such switching behavior. Our work demonstrates that nanoscale junction between superconducting and normal metal naturally exists in thin Fe(0.7Se0.3) nanoflakes, which provides an opportunity to study transport behavior MSM junction in nanoscale.

4:54PM H10.00011: Nodeless superconductivity with broken time reversal symmetry*  HUIQIU YUAN (Presenter),
Center for Correlated Matter/ Department of Physics, Zhejiang University — In unconventional superconductors, additional
symmetries, e.g., rotational symmetry and time reversal symmetry (TRS), may be broken below the superconducting
transition temperature. In the past, evidence for TRS breaking was observed in a few nodal superconductors with a
possible triplet pairing state. Recently, there are a growing number of compounds which behave like a simple s-wave BCS
superconductor, but break TRS below $T_c$. How to reconcile these seemingly contradictory feature is currently an
interesting problem. In this presentation, we will present our recent results on a few Re- and La-based nodeless
superconductors with broken TRS at $T_c$, including a few new examples. We will try to summarize their common features
and discuss the possible pairing states and origin of the TRS breaking.

This work is in collaboration with M. Smidman, A, Wang, P. R. Zhang, Z. Y. Nie, W. Xie, G. M. Pang (Zhejiang University), T.

Cyrus Dreyer, Stony Brook University - Tag(s): Focus

2:30PM H11.00001: Scaling Study of Disordered Antiferromagnetic Systems of Acceptors in p-Type Semiconductors
ADAM DURST (Presenter), ALI HYDER, Hofstra University — We consider the low temperature magnetic properties of a system
of randomly-distributed interacting acceptor atoms in a p-type semiconductor. For the equivalent n-type system, where
donor interactions are well described by a spin-1/2 Heisenberg model with a single antiferromagnetic exchange coupling
that varies exponentially with donor separation, the classic work of Bhatt and Lee [Phys. Rev. Lett. 48, 344 (1982)] provides
an iterative numerical procedure for discarding irrelevant high energy excitations of strongly interacting donor pairs while
renormalizing the remaining donor couplings. Due to valence band degeneracy and spin-orbit coupling, acceptor
interactions are known to be more complex. Recent computations thereof suggest a six-level energy spectrum
characterized by five distinct coupling parameters and a nontrivial degeneracy structure. By employing an interaction
model that respects this degeneracy structure, we extend the Bhatt-Lee renormalization procedure to the acceptor case,
studying the evolution of the distribution of exchange couplings, and calculating magnetic susceptibility, as a function of
decreasing temperature. Results are compared with that of spin-1/2 and spin-3/2 Heisenberg models.

2:42PM H11.00002: Theory of Hyperfine Interactions and Electrically Detected Magnetic Resonance (EDMR) for
Phosphorus-Doped Silicon*  NICHOLAS HARMON (Presenter), MICHAEL FLATTÉ, Physics and Astronomy, University of Iowa —
EDMR is a useful tool to sensitively study a spin pair's local environment as well as spin-dependent recombination.
Theoretical treatments have focused on resonances originating from differences between g-factors of two recombining
spins [1]. Recently hyperfine interactions were included but in a classical manner [2]. We present a theory of EDMR where
transitions take place via differences in g-factor or hyperfine interactions. The stochastic Liouville formalism is suited to
account for hyperfine interactions involving multiple nuclei where each nuclear spin is a quantum spin. For a single spin-
1/2 nucleus, expressions for resonances at any field are determined and agree with most measured resonances in
phosphorus-doped silicon [3]. Comparisons between the model and observations lead to new understandings of the
defect-induced recombination pathways.

2:54PM H11.00003: The Interplay among Localization Spin-Orbit Coupling and Ferromagnetism in the Diluted Magnetic Semiconductor (Ga,Mn)As* YI ZHANG (Presenter), Louisiana State University, UNJONG YU, Department of Physics and Photon Science, GIST, HANNA TERLETSKA, Middle Tennessee State Univ, KA-MING TAM, MARK JARRELL, Louisiana State University — We combine the typical medium analysis and dynamical mean field approximation to study the electronic and magnetic properties of the diluted magnetic semiconductor Ga$_{1-x}$Mn$_x$As. We use the $k$-$p$ model to describe the electronic structure of GaAs with spin-orbit coupling. By using the typical medium analysis, localization due to disorder induced by the Mn doping is appropriately captured, which allows us to study the interplay among the localization, spin-orbit coupling and ferromagnetism. This study can serve as a guidance to the more realistic first-principles calculation of Ga$_{1-x}$Mn$_x$As.

3:06PM H11.00004: Spontaneous defect formation on the polar surface of giant Rashba semiconductors BiTeX*

[Invited] WEIDA WU (Presenter), WENHAN ZHANG, Physics and Astronomy, Rutgers University, New Brunswick, DAMIEN WEST, Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, CHEN CHEN, JINWOONG KIM, SANG-WOOK CHEONG, DAVID VANDERBILT, Physics and Astronomy, Rutgers University, New Brunswick, SHENGBAI ZHANG, Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute — Defects in semiconductors are crucial for the performance of modern electronics. Although there are tremendous progress on theoretical understanding of defect formation and kinetics in functional materials, visualizing the kinetics of the defect formation remains a great challenge. Herein, we report an exciting discovery of spontaneous formation of point defects below room temperature on the surface of polar semiconductors BiTeX (X=Cl, Br and I), where giant Rashba splitting of bulk bands was reported. The defect density increases over three order of magnitudes when the surface temperature increases from ~10 K to room temperature. Our scanning tunneling microscopy studies reveal formation of Frenkel pairs of Bi vacancies and interstitial Bi atoms, followed by the formation of BiTe antisites. Combined with first principle calculations, our results reveal a significant reduction of formation energy of Frenkel pairs due to surface band bending of polar surface. Our results demonstrate a dramatic modulation of defect formation via surface bending of polar surface, which is crucial for the potential technological application of giant Rashba systems.

3:42PM H11.00005: 3D imaging and manipulation of subsurface selenium vacancies in PdSe$_2$* GIANG NGUYEN, LIANGBO LIANG, QIANG ZOU, MINGMING FU, AKINOLA OYEDELE, BOBBY G SUMPTER, Oak Ridge National Laboratory, ZHENG LIU, Nanyang Technological University, ZHENG GAI, KAI XIAO, AN-PING LI (Presenter), Oak Ridge National Laboratory — We report 3D imaging and manipulation of individual Se vacancies in PdSe$_2$ using a STM. By imaging the characteristic charge rings of defects arising from a tip-induced band bending effect, we first determine the lateral and depth location of V$_{Se}$ precisely in the 3D lattice. We then use a STM tip as a movable electrostatic gate to manipulate V$_{Se}$ by reversibly switching the charge states of defects between neutral and negative states. We find a slightly higher bias voltage (~2.0 V) can trigger vacancy migrations, which allows us to demonstrate both direct "writing" and "erasing" of atomic defects from a particular lattice site in PdSe$_2$. The results are corroborated by first-principles calculations that unveil the formation energy and diffusion barriers of Se vacancies in PdSe$_2$. This work opens an opportunity for defect engineering at the atomic level to achieve controlled phase transformations, or on-demand switchable states for such as neuromorphic computing and quantum bits.

*This research was performed at the Center for Nanophase Materials Sciences which is a DOE Office of Science User Facility.
**3:54PM H11.00006: Colossal thermopower from defect-induced in-gap states in FeSb$_2$**  
QIANHENG DU (Presenter), Department of Materials Science and Chemical Engineering, Stony Brook University, CEDOMIR PETROVIC, Brookhaven National Laboratory — The thermoelectric properties of FeSb$_2$ are attracting attention due to its colossal thermopower and record-high thermoelectric power factor. Although this colossal thermopower was attributed to phonon-drag effect, the factors that affect the phonon-drag effect remains unclear and further. By changing the amount of defects in different FeSb$_2$ crystals we show that thermopower maxima around 10 K change between relatively small 14 μV/K and colossal values of about 20 mV/K. The effect of crystallographic defects and impurities on the colossal thermopower coefficient is studied in single crystals of FeSb$_2$. From the Hall effect, all the crystals show clear two-bands behavior. Defect-induced vacancy band with low Hall mobility dominates the thermal transport. Defects influence considerably phonon mean free path and low mobility band carrier concentration, revealing the source of the in-gap states that govern thermopower size. Our results explain the strong sample dependence of Seebeck coefficient in FeSb$_2$ crystals and give a possible way to furtherly improve the thermal performance of this correlated semiconductor.

**4:06PM H11.00007: Anisotropic defects and assisted scattering in InAs/GaSb superlattices**  
FRANCESCA CAROSELLA (Presenter), Ecole Normale Superieure, HERMANN DETZ, CEITEC, Brno University of Technology, GÉRALD BASTARD, ROBSON FERREIRA, Ecole Normale Superieure — Heterostructures containing antimonide-based compounds received in the last decade much attention because of their potential for designing new devices. Moreover, some InAs/GaSb heterostructures are also topological insulators thus attracting interest for fundamental research. We performed a thorough multi-scale study of the structure and electronic states of InAs/GaSb superlattices (SL). We have implemented the envelope function formalism for the calculation of the electronic states in these SL, taking into account the strong coupling between conduction and valence states. To improve the description of interface roughness, we performed atomistic simulations (using empirical interaction potentials as well as a Monte Carlo based algorithm) of the growth of InAs/GaSb short-period SL. In particular, we found that the simulated growth of InAs on GaSb along the usual [0,0,1] axis leads to the formation of elongated islands, one ML height, one ML thick, but with a much bigger average length along the direction [1,1,0]. Finally, we tackled the effect of the interface disorder on the electronic properties of these heterostructures. To this end, we present a model to perturbatively evaluating scattering rates by an inhomogeneous ensemble of defects with such a particular aspect ratio.

**4:18PM H11.00008: Scanning Tunneling Microscopy Studies of Er Adatoms on GaAs (110)***  
REBEKAH SMITH (Presenter), ANNE BENJAMIN, KEVIN WERNER, ENAM CHOWDHURY, JAY A GUPTA, Ohio State University — Rare earth dopants in III-V semiconductors are of interest as high quality optical sources due to the preservation of sharp intra-$f$-shell transitions. Here we investigate Er interactions with host GaAs (110) surface with atomic resolution using STM. Er atoms were deposited via electron beam evaporation onto the GaAs surface at 5 K. We find three different Er$_{\text{ad}}$ configurations with varying abundance upon deposition, each with a different surface site location. All three configurations exhibit long-range depressions in STM topographic images, attributed to band bending associated with a positive adatom charge state. Individual Er adatoms can be switched between these states by applying a positive voltage pulse with the STM tip. Tunneling spectroscopy on Er adsorbed at the interstitial sites reveals prominent states within the GaAs bandgap, but no evidence of sharp $f$-shell transitions inferred from bulk optical studies. We also form substitutional Er$_{\text{Ga}}$ by applying a larger positive voltage pulse. Substitutional Er appears neutral, which we attribute to it being isoelectronic with Ga. We will also present preliminary studies with concurrent optical excitation. Shifts in Er defect states are interpreted as a surface photovoltage effect.

*We acknowledge funding from DOE-DE-SC0016379.
We propose a self-consistent site-dependent (SCSD) DFT+U approach for calculations of defects in transition-metal oxides. Defect formation in these materials induces local perturbations in the chemical environment of Hubbard sites around the defect that may not be properly described by applying a global U value on all sites as done in conventional DFT+U. Here, U is treated as an intrinsic response property of the material and computed from first principles using density-functional perturbation theory. SCSD U values are obtained starting from a DFT ground state by an iteration of perturbing all inequivalent Hubbard sites followed by geometry relaxation with the determined U values until convergence of the geometry and U. Changes in U due to excess charge localization and lattice relaxation in defective structures are hence properly accounted for.

After discussing the approach, we highlight some results, showing that U values depend on the distance of the Hubbard site from the defect, its coordination number, its oxidation state, and on the magnetic properties of the material. This site-dependence is particularly important in the case of semiconductors, where filled localized defect states may form in the band gap, and strongly influences all properties related to defect energetics.

**Novel II-VI compound based organic-inorganic hybrid semiconductors: intrinsic properties, defects, and long-term stability**

TANG YE (Presenter), MARGARET KOCHERGA, ANDREI NESMELOV, THOMAS A. SCHMEDAKE, YONG ZHANG, University of North Carolina at Charlotte — The hybrid structures in this study are a family of sub-nanoscale II-VI layers or chains interconnected or coordinated with smaller organic linkers.[1] They were shown to exhibit a very high degree of structural ordering (e.g., the most perfect man-made semiconductor superlattices), and a number of extraordinary properties such as much-greater-than-kT exciton binding energy, exceedingly strong excitonic absorption, and zero thermal expansion.[2,3] Comparison between Raman, PL and XPS spectra of freshly made and approximately 15-year old samples of a prototype hybrid structure β-ZnTe(en)0.5 have revealed defect related spectroscopy signatures that appear in both newly made defective samples and aged samples. Although the old samples typically show varying degree of degradation, some are found to be as pristine as high-quality freshly made samples. The study suggests that the initial state of the defect level is pertinent to the material's long-term stability. This is a rare example of hybrid materials exhibiting recorded long-term stability. This study has a broad impact on the long-term stability of a wide range of hybrid materials, including perovskites.

**2:30PM H12.00001: Theory of 2D Materials: Excitons, Valley-Spin Physics, and Magnetism.** [Invited] TING CAO (Presenter), Physics Department at UC Berkeley and Geballe Laboratory for Advanced Materials at Stanford University — Recent advances in the experimental and theoretical studies of atomically thin two-dimensional (2D) materials have opened up opportunities in exploring new phenomena and properties as well as related applications absent in conventional bulk materials. In the first part of my talk, we will present theoretical studies on the optical responses of monolayer transition metal dichalcogenides. By ab initio GW-BSE calculations, we demonstrate a previously unrecognized valley-spin character of bright excitons, which leads to interesting ultrafast phenomena in monolayer transition metal dichalcogenides [1]. We then discuss the theory of dark excitons and trions, and how they could be brightened by applying an external magnetic field [2] or using other approaches. In the second part of my talk, we will discuss theoretical studies of magnetism in 2D materials. We discuss the physical origins and control of ferromagnetism in materials with different chemical species and structural configurations. We further connect our theoretical discoveries to experimental results and explore their potential applications.

3:06PM H12.00002: A theoretical proposal of gate-induced quantum anomalous hall effect in 2D ferromagnetic multilayers  
YUAN GAO (Presenter), Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, DI XIAO, Department of Physics, Carnegie Mellon University, WENGUANG ZHU, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China — The quantum anomalous hall effect (QAHE) is the manifestation of topological electronic structure characterized by a finite Chern number and helical edge electron states and may have potential applications in future electronic devices with low energy consumption. However, the QAHE so far can only be achieved at very low temperatures. Thus, the search for new quantum anomalous hall systems with elevated temperature is in demand. Here we propose a new design based on recently discovered 2D ferromagnetic semiconductors. Using first-principles calculations, we demonstrate that by applying a moderate electric field a 2D ferromagnetic multilayer can be converted into the quantum anomalous hall state. The topological nature and band gap as a function as the applied electric field and film thickness are systematically investigated in details.

3:18PM H12.00003: Simulating the nanomechanical response of cyclooctatetraene molecules on a graphene device*  
SEHOON OH (Presenter), MICHAEL F CROMMIE, MARVIN L COHEN, Department of Physics, University of California at Berkeley — We have investigated the atomic and electronic structures of cyclooctatetraene molecules on graphene and analyzed their dependence on external gate voltage using first-principles calculations. The external gate voltage is simulated by adding or removing electrons using density functional theory calculations. This allowed us to investigate how changes in carrier density modify the molecular shape, orientation, adsorption site, diffusion barrier, and diffusion path. The results of the calculation imply that the shape and mobility of the adsorbed molecules can be controlled by externally gating graphene devices.

3:30PM H12.00004: Universal scaling laws of electron emission phenomena in two-dimensional material electrical contacts*  
YEE SIN ANG (Presenter), Science and Math, Singapore University of Technology and Design, HUI YING YANG, SUTD-MIT International Design Center, Singapore University of Technology and Design, LAY KEE ANG, Science and Math, Singapore University of Technology and Design — Electrically contacting two-dimensional (2D) material with another material often leads to the formation of an interfacial Schottky barrier. Charge injection across such barrier is commonly analysed using the classic Richardson-Dushman (thermionic emission) and Fowler-Nordheim (field emission) models despite the fact that the assumptions underlying such models are often inconsistent with the physical properties of most 2D materials. Here we formulate generalized models of electron injection across 2D material interfaces. We show that the thermionic transport across a 2D material Schottky contact is governed by universal scaling laws broadly applicable for large classes of 2D systems. We further uncover a new universal scaling behavior in the vertical electron tunneling across 2D material van der waals heterostructures. Our models signal the breakdown of century-old classic electron emission models in 2D materials, and paves the way towards the better understanding and design of 2D material electronic devices.

Design of Atomically Precise GNR-Based Negative Differential Resistance Device

ZHONGCAN XIAO (Presenter), North Carolina State University, CHUANXU MA, JINGSONG HUANG, LIANGBO LIANG, Oak Ridge National Laboratory, WENCHANG LU, North Carolina State University, KUNLUN HONG, BOBBY G SUMPTER, AN-PING LI, Oak Ridge National Laboratory, JERRY BERNHOLC, North Carolina State University — Down-scaling device dimensions to the nanometer range raises significant challenges to traditional device design, due to potential current leakage across nanoscale dimensions and the need to maintain reproducibility while dealing with atomic-scale components. Here we investigate negative differential resistance (NDR) devices based on atomically precise graphene nanoribbons. Our computational evaluation of the traditional double-barrier resonant tunneling diode NDR structure uncovers important issues at the atomic scale, concerning the need to minimize the tunneling current between the leads while achieving high peak current. We propose a new device structure consisting of multiple short segments that enables high current by the alignment of electronic levels across the segments while enlarging the tunneling distance between the leads. The proposed structure can be built with atomic precision using a scanning tunneling microscope (STM) tip during an intermediate stage in the synthesis of an armchair nanoribbon. An experimental evaluation of the band alignment at the interfaces and an STM image of the fabricated active part of the device are also presented. This combined theoretical-experimental approach opens a new avenue for the design of nanoscale devices with atomic precision.

Deep Learning Assisted Optical Identification of Exfoliated Two-Dimensional Crystals

BINGNAN HAN, School of Astronautics, Beihang University, YUXUAN LIN (Presenter), Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, WENYUE LI, School of Astronautics, Beihang University, NANNAN MAO, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, YAFANG YANG, Department of Physics, Massachusetts Institute of Technology, HAOZHE WANG, WEI SUN LEONG, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, PABLO JARILLO-HERRERO, Department of Physics, Massachusetts Institute of Technology, TOMAS PALACIOS, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, JIHAO YIN, School of Astronautics, Beihang University, JING KONG, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology — Up to now, hundreds of two-dimensional materials are being studied in the fields of condensed matter physics, material sciences and electrical engineering. The overwhelming approach to obtain 2D crystals in laboratory is a combination of the mechanical exfoliation and the exhaustive search under an optical microscope by a well-trained researcher. Here we report a generic flake-hunting approach assisted by deep learning that can achieve the automatic, real-time, accurate, and robust optical identification of the type and the thickness of various 2D crystals. A semantic segmentation method using the encoder-decoder convolutional neural networks (SegNet) was developed and trained to identify the type and the thickness of the mechanically exfoliated 2D crystals on a SiO2/Si wafer. Besides the commonly used parameters such as the optical contrasts of the 2D crystals, deep graphical features can also be extracted and harnessed by the SegNet for accurate and robust identification. Our proposed method can be used for a wide range of research topics where initial screening and identification of nanomaterials are necessary.

Ab Initio Study of the Mechanisms of Nitrogen Functionalization of Graphene*

OLIVIER MALENFANT-THUOT (Presenter), MICHEL COTE, Universite de Montreal — Our research aims to better understand the process of nitrogen functionalization of graphene, at the atomic level. We conducted electronic structure calculations, in the Density Functional Theory framework, to study the dynamics of different incorporation mechanisms of nitrogen atoms. We used the Nudged Elastic Band module, available in the BigDFT ab initio code, to calculate reaction pathways and energy barriers for a diverse set of migration and incorporation reactions, with or without the presence of native defects in the graphene sheet. By analyzing these results, we can predict which processes and functionalization configurations are more likely to be obtained in particular conditions.

*This research was enabled in part by support provided by Calcul Québec (www.calculquebec.ca) and Compute Canada (www.computecanada.ca) and has been supported by the Natural Sciences and Engineering Research Council of Canada (NSERC) under grants RGPIN-2016-06666.

Model for the metal-insulator transition in graphene superlattices and beyond

NOAH YUAN (Presenter), LIANG FU, Massachusetts Institute of Technology — We propose a two-orbital Hubbard model on an emergent honeycomb lattice to describe the low-energy physics of twisted bilayer graphene. Our model provides a theoretical basis for studying metal-insulator transition, Landau level degeneracy lifting, and unconventional superconductivity that are recently observed.
may lead to important electronic and spintronic devices. The coupling condition provides important insights in the design and manufacture of two-dimensional heterostructures where no significant p-d coupling exist. This discovery largely widens the scope of periodic structures and the general coupling with substrate and explains why the incommensurate bilayer is even more stable than an AB stacking bilayer, where the top layer to couple and form a gap at the M point of the lower layer. This mechanism also enhances a p-d orbital.

On our first principles calculations, we found that such a coupling mechanism allows a coupling of K and K’ wave vectors of any two vectors of one layer, if their difference equals the difference between the reciprocal vectors of the two layers, for any two vectors of one layer, if their difference equals the difference between the reciprocal vectors of the two layers. Based on our first principles calculations, we found that such a coupling mechanism allows a coupling of K and K’ wave vectors of the top layer to couple and form a gap at the M point of the lower layer. This mechanism also enhances a p-d orbital coupling with substrate and explains why the incommensurate bilayer is even more stable than an AB stacking bilayer, where no significant p-d coupling exist. This discovery largely widens the scope of periodic structures and the general coupling condition provides important insights in the design and manufacture of two-dimensional heterostructures that may lead to important electronic and spintronic devices.

Since the advent of exfoliated graphene on SiO2/Si substrates, the identification process of graphene has relied on the feature extraction algorithm, enabling highly accurate classification of monolayer, bilayer, and trilayer graphene. The analysis can be applied to substrates with differing SiO2 thickness, which demonstrates the generality of the approach.

4:54PM H12.00011: Theoretical investigation of 30 degree twisted bilayer graphene* KEJIE BAO (Presenter), YIOU ZHANG, JUNYI ZHU, Physics, Chinese University of Hong Kong, SHUYUN ZHOU, Physics, Tsing Hua University — To understand the unique stability and coupling mechanism in the interesting incommensurate bilayer graphene on top of Pt substrate with 30 degree twisting angles, we performed theoretical derivations and discovered a general interlay scattering mechanism: for any two vectors of one layer, if their difference equals the difference between the reciprocal vectors of the two layers, they can be coupled via a scattering of another layer. This scattering condition is general for any bilayer structures. Based on our first principles calculations, we found that such a coupling mechanism allows a coupling of K and K’ wave vectors of the top layer to couple and form a gap at the M point of the lower layer. This mechanism also enhances a p-d orbital coupling with substrate and explains why the incommensurate bilayer is even more stable than an AB stacking bilayer, where no significant p-d coupling exist. This discovery largely widens the scope of periodic structures and the general coupling condition provides important insights in the design and manufacture of two-dimensional heterostructures that may lead to important electronic and spintronic devices.

5:06PM H12.00012: Unconventional superconductivity and density waves in twisted bilayer graphene* HIROKI ISOBE (Presenter), NOAH YUAN, LIANG FU, Massachusetts Institute of Technology — We study electronic ordering instabilities of twisted bilayer graphene with n=2 electrons per supercell, where correlated insulator state and superconductivity are recently observed. Motivated by the Fermi surface nesting and the proximity to Van Hove singularity, we introduce a hotspot model to study the effect of various electron interactions systematically. Using the renormalization group method, we find d/p-wave superconductivity and charge/spin density wave emerge as the two types of leading instabilities driven by Coulomb repulsion. The density wave state has a gapped energy spectrum at n=2 and yields a single doubly-degenerate pocket upon doping to n=2. The intertwine of density wave and superconductivity and the quasiparticle spectrum in the density wave state are consistent with experimental observations.

5:18PM H12.00013: Twisted bilayer graphene as a phononic metamaterial* WILLIAM DORRELL (Presenter), HARRIS PIRIE, BOWEI LIU, YU LIU, NATHAN DRUCKER, ALEX J KRUCHKOV, JENNY HOFFMAN, Harvard University — The twist angle within stacked van der Waals materials represents a novel degree of freedom to tune electronic properties. In bilayer graphene, varying the twist angle hybridizes the Dirac cones from each layer, resulting in flat bands that localize charge and induce unconventional superconductivity. Recently, graphene-like Dirac cones were observed in the phononic band structure of a metamaterial consisting of a honeycomb lattice of steel pillars in air. However, varying the twist angle has not been explored in metamaterials, due to the difficulty in coupling two macroscopic layers. Here we develop a method to couple layered phononic metamaterials using intermediary membranes, and we numerically demonstrate a classical system with flat phononic bands analogous to the electronic structure at magic angle twisted bilayer graphene. Our results provide a more tangible route to comprehending the behavior of quantum materials and may yield applications in super-resolution imaging.

Session H13 DMP: 2D Materials (General) -- Defects BCEC 153B - Victor Brar, Caltech - Tag(s): Focus

2:30PM H13.00001: Combining nitrogen substitutional defects and oxygen intercalation to control corrugation and doping level in graphene on Rh(111) JOSE-MARIA GOMEZ-RODRIGUEZ (Presenter), ANA MARTIN-RECIO, Dept. Fisica de la Materia Condensada, Universidad Autonoma de Madrid, Spain, CARLOS ROMERO-MUÑIZ, PABLO POU, RUBEN PEREZ, Dept. Fisica Teorica de la Materia Condensada, Universidad Autonoma de Madrid, Spain — By means of STM experiments and first-principles calculations, we demonstrate the synergetic effect of combining two different strategies to modify the properties of graphene supported on a strongly interacting substrate. A complete control of the corrugation and doping level is achieved by the introduction of nitrogen defects and oxygen intercalation. First, we use ion bombardment to obtain purely-substitutional N-doped graphene on Rh(111) with tunable dopant concentration. Second, the interaction with the substrate is controlled by the amount of intercalated oxygen atoms. Unlike weakly interacting substrates, the highly corrugated structure of G/Rh(111) leads to remarkable variations of the electronic properties associated with N defects created in the high and low areas of the moire. After oxygen intercalation, the N-doped graphene layer decouples from the substrate preserving the incorporated N atoms, which display a subtle dependence of the STM contrast. First principles calculations confirm the identification of substitutional N defects and the recovery of the Dirac cone with a tunable shift governed by N concentration. Our results support the combination of different modification techniques to tailor structural and electronic properties of graphene and other 2D materials.

2:42PM H13.00002: Observation of superlattice periodicity on the surface of highly-doped MoS2 STEVEN SCHOFIELD (Presenter), MOHAMMED BIN SUBHAN, ASIF SULEMAN, GARETH MOORE, PETER PHU, HIDEKAZU KUREBAYASHI, CHRIS A. HOWARD, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London — We have used low temperature (~5 K) scanning tunnelling microscopy (STM) and spatially-resolved tunnelling spectroscopy (STS/CITS) to investigate the surface of highly-doped molybdenum disulphide (MoS2). In agreement with previous STM investigations of intrinsic MoS2 we find the surface exhibits a large density of charged point defects [e.g., ACS Appl. Mater. Interfaces, 9, 19278 (2017)]. Fourier analysis of our atomic-resolution imaging and spectroscopy data from the doped MoS2 surface reveals two separate superlattice periodicities in addition to the 1x1 sulphur lattice, one of which is enhanced in the vicinity of the charged defects. We present an interpretation of the observed superlattices consistent with prior DFT and ARPES data.
In this work, we employ a combination of theoretical calculations to explore the electronic properties of donor and acceptor states of substitutional impurities in h-BN, a wide-gap 2D insulator. We find that the structure of the impurity levels that appear inside the electronic gap strongly depends on the atom replaced by the impurity. For instance, when an acceptor replaces a N atom, the intervalley interaction induced by the impurity is found to be strong and the resulting level structure consists only of non-degenerate levels with strong valley and spin splittings. On the other hand, when an acceptor replaces a B atom, the intervalley interaction is much weaker and a near-valley-degenerate ground state is found. Donor impurities behave on a similar fashion. We show that the differences between these level structures can be traced to the peculiar sublattice-resolved electronic structure of pristine h-BN. In fact, these exotic impurity levels may also be present in other 2D semiconductors and insulators with similar bandstructures, such as other hexagonal III-V compounds, and their optical properties may be engineered for applications in future optoelectronic devices.

3:54PM H13.00006: Point defects in 1T'-MoS2 from first principles  MICHELE PIZZOCHERO (Presenter), OLEG YAZYEV, Institute of Physics, École Polytechnique Fédérale de Lausanne (EPFL), Switzerland — Monolayers of group VI Transition Metal Dichalcogenides (TMDs) exist in either the semiconducting 2H phase or semimetallic 1T' phase. While the stable 2H phase has been extensively investigated due to prospective optoelectronic applications, the metastable 1T' phase has appeared in the spotlight only recently, mainly due to its topological properties. In this talk, I will provide an overview on the formation of point defects in 1T'-MoS2 within two experimentally-relevant situations, i.e. under thermodynamic equilibrium and under electron beam irradiation. First, I will address the stability of point defects, exploring several configurations of vacancy, adatom and antisite defects. All considered defects exhibit lower formation energies in the 1T' phase compared to the 2H phase, suggesting that the 1T' polymorph is more susceptible to lattice imperfections. Next, the response of 1T'-MoS2 to the electron irradiation will be examined. The range of electron beam energies needed to carry out imaging without inducing any damages in the sample and some guidelines for the controlled creation of defects in the electron microscope are discussed. Throughout my talk, I will draw comparisons between local disorder in the two phases to portray a complete picture of the role of defects in TMDs.

4:06PM H13.00007: Correlating Microscopic Electronic Features with Macroscopic Transport in Defective Graphene* JAKE RIFFLE (Presenter), CAITLYN MEDITZ, ALANA GUDINAS, SHAWNA HOLLEN, University of New Hampshire — Past studies on graphene show that intervalley and intravalley scattering off atomic defects and impurities change the electronic transport properties and give rise to weak Anderson localization at low temperatures. We will present our studies on the interactions and correlations between electron-hole charge puddles and the weakly localized regions. Using a low temperature scanning tunneling microscope (STM) on graphene field effect transistors, we present experiments which aim to study the effects of point defects and to employ simultaneous STM and electronic transport measurements to directly associate microscopic electronic interactions with macroscopic transport. These experiments will show strides toward mapping out the phase space of defect-populated graphene in our investigation of the prospect of a metal-insulator quantum phase transition.

4:18PM H13.00008: Atomic manipulation of defects in the layered semiconductor 2H-MoTe2* SARA MUELLER (Presenter), Ohio State University, BENJAMIN ST. LAURENT, University of New Hampshire, YAXIAN WANG, WOLFGANG E WINDL, Ohio State University, SHAWNA HOLLEN, University of New Hampshire, JAY A GUPTA, Ohio State University — Here we demonstrate control over the charge state and layer position of individual defects in the layered semiconductor, 2H-MoTe2. Pristine surfaces were revealed at room temperature in ultrahigh vacuum by cleaving the top few layers from the crystal. STM images and spectroscopy were performed with a cut PtIr tip at 9K. Two classes of native defects were observed in large area STM images, appearing in both near-surface and sub surface layers with progressively fainter contrast. One class of defect images as a bright protrusion with a nm-scale fall-off in STM topography, indicative of band bending associated with a charged defect. Spectroscopic imaging reveals a ring-shaped feature associated with these defects, consistent with tip-induced ionization between two defect charge states. Consistent with studies in other semiconductor systems, the rings depend on the STM imaging conditions and tip apex. We find that subsurface defects exhibit discrete increases in apparent height following large positive voltage pulses, suggesting migration between layers near the surface. We compare with DFT calculations to identify these defects and estimate the energy barriers for inter-layer migration.

4:30PM H13.00009: Defect Characterization and Engineering in Black Phosphorus  BEN ST LAURENT (Presenter), JAKE RIFFLE, CAMERON C FLYNN, Physics, University of New Hampshire, CHARLIE AYOTTE, CHRISTINE CAPUTO, Chemistry, University of New Hampshire, SHAWNA HOLLEN, Physics, University of New Hampshire — A tunable band gap and high carrier mobility make black phosphorus (BP) attractive for device applications. To effectively engineer micron scale BP devices, it is essential to understand defects down to the atomic level. The most prominent defects on the surface of BP exhibit a large electronic signature in scanning tunneling microscopy (STM) images. We previously found that the predominant defects in BP are vacancies and are the source of p-doping in the material. These studies demonstrate the need for vacancy formation control during synthesis. Here, we will describe STM experiments of BP that further characterize the defects and explore defect control and creation through ultra high vacuum annealing.
4:42PM H13.00010: Direct correlation of defects with photoluminescence and electrical conductivity in monolayer transition metal dichalcogenides*  MATTHEW ROSENBERGER (Presenter), HSUN-JEN CHUANG, KATHLEEN MCCREARY, SAUJAN SIVARAM, CONNIE LI, BEREND JONKER, Materials Science and Technology Division, U.S. Naval Research Laboratory — Transition metal dichalcogenides (TMDs) are promising candidates for emerging applications such as transparent and flexible optoelectronics and electronics. Understanding the impact of defects on TMD properties is essential for the advancement of these materials. Here, we demonstrate the ability to observe electronically active defects in monolayer TMDs using conductive atomic force microscopy in ambient conditions, and we correlate defect density with local potential gradients, corresponding to high resistivity. This suggests that the defects responsible for decreased PL intensity are also responsible for decreased electrical conductivity.

*M.R. and S.S. hold NRC fellowships, H.C. holds an ASEE fellowship

4:54PM H13.00011: Spatially Selective Enhancement of Photoluminescence in MoS2 by Photo-mediated Adsorption and Defect Passivation  SAUJAN SIVARAM (Presenter), AUBREY HANBICKI, MATTHEW R. ROSENBERGER, HSUN-JEN CHUANG, KATHLEEN MCCREARY, BEREND T. JONKER, United States Naval Research Laboratory — Monolayers of transition metal dichalcogenides (TMD) are promising components for optoelectronic devices due to their direct band gap and atomically thin nature. Their photoluminescence (PL) is strongly dependent on mid-gap defects which serve as non-radiative recombination sites for excitons. We demonstrate up to a 200x increase in PL intensity by exposing MoS2 synthesized by chemical vapor deposition (CVD) to laser light in ambient. This spatially resolved passivation treatment is air and vacuum stable, which indicates strong bonding of moieties from ambient. A wavelength dependent study confirms that this PL brightening is concomitant with exciton generation in the MoS2; laser light below the optical band gap of MoS2 fails to brighten the TMD. We highlight the photo-sensitive nature of the process by successfully brightening with a broadband white light source (< 10 nW/mm²). We decouple changes in absorption from defect passivation by examining the degree of circularly polarized PL. This measurement, which is independent of exciton generation, confirms that the laser brightening reduces non-radiative recombination sites in the MoS2. We propose that H2O molecules passivate sulfur vacancies in the MoS2 but requires photo-generated excitons to overcome the adsorption barrier.

5:06PM H13.00012: Defect-related photoluminescence from networks of suspended 2D crystal membranes*  ANDREW L YEATS (Presenter), JOSE FONSECA VEGA, JOEL Q GRIM, SAMUEL CARTER, CORY D CRESS, JAMES CLIFFORD CULBERTSON, MAXIM ZALALUTDINOV, JEREMY T ROBINSON, Naval Research Laboratory — Luminescent defects in 2D semiconductors hold promise for applications in photonics and quantum communication. For instance, strain-induced defects in WSe2 have attracted attention as narrow line-width single photon sources. We present a series of low-temperature photoluminescence (PL) microscopy studies on networks of suspended 2D crystal membranes formed by controlled dewetting and recrystallization of an underlying metal film. For monolayer membranes of WSe2 and heterojunctions of WSe2/MoS2 formed on a porous Au film, we find a strong (1000x) enhancement of PL intensity from the suspended regions, as well as the appearance of relatively sharp (< 1 meV) emission lines. The crystallographic texturing of the metal under-layer may also lend itself to low-loss propagation of surface plasmon polaritons (SPP), offering a means for energy transfer between discrete luminescent centers. We use a split excitation/collection imaging approach to characterize nonlocal luminescence in this unique material system, and discuss the outlook for studying networks of interconnected defects in 2D materials.

5:18PM H13.00013: Nano-imaging of local strain in hexagonal boron nitride  BOSAI LV (Presenter), HONGYUAN LI, Shanghai Jiao Tong University, LILI JIANG, UC Berkeley, WANFEI SHAN, Shanghai Jiao Tong University, HANS BECHTEL, MICHAEL CROCKER MARTIN, Lawrence Berkeley National Laboratory, WEIDONG LUO, Shanghai Jiao Tong University, FENG WANG, UC Berkeley, ZHIWEN SHI, Shanghai Jiao Tong University — Strain plays an important role in condensed matter physics. Strain effect becomes more interesting in two-dimensional materials, both because an unusually large strain can be achieved without breaking the material, and because the strain can lead to novel behavior such as the generation of pseudomagnetic field in graphene. Here, we report an ultra-sensitive nanometer scale mapping and a quantitative analysis of local strain field in atomically thin hexagonal boron nitride.
2:30PM H14.00001: Shape of the zeroth Landau level in graphene with non-diagonal disorder* RAJESH MALLA (Presenter), MIKHAIL RAIKH, University of Utah — Non-diagonal (bond) disorder in graphene broadens Landau levels (LLs) in the same way as random potential. The exception is the zeroth LL, n=0, which is robust to the bond disorder, since it does not mix different n = 0 states within a given valley. The mechanism of broadening of the n = 0 LL is the inter-valley scattering. Several numerical simulations of graphene with bond disorder had established that n = 0 LL is not only anomalously narrow but also that its shape is very peculiar with three maxima, one at zero energy, E = 0, and two others at finite energies ± E. We study theoretically the structure of the states in n = 0 LL in the presence of bond disorder. Adopting the assumption that the bond disorder is strongly anisotropic, namely, that one type of bonds is perturbed much stronger than other two, allowed us to get an analytic expression for the density of states which agrees with numerical simulations remarkably well. On the qualitative level, our key finding is that the delocalization of E = 0 state has a dramatic back effect on the density of states near E = 0. The origin of this unusual behavior is the strong correlation of eigenstates in different valleys.

2:42PM H14.00002: Measuring Hall Viscosity of Graphene's Electron Fluid* ALEXEY BERDYUGIN (Presenter), School of Physics & Astronomy, University of Manchester, SHUIGANG XU, National Graphene Institute, University of Manchester, FRANCESCO PELLEGRINO, Dipartimento di Fisica e Astronomia, Università di Catania, ROSHAN KRISHNA-KUMAR, ALESSANDRO PRINCIPI, School of Physics & Astronomy, University of Manchester, IACOPO TORRE, ICFO - Institut de Ciencies Fotoniques, The Barcelona Institute of Science and Technology, MOSHE BEN SHALOM, School of Physics & Astronomy, University of Manchester, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, IRINA GRIGORIEVA, MARCO POLINI, ANDRE GEIM, DENIS BANDURIN, School of Physics & Astronomy, University of Manchester — In this work, we report the violation of the conventional Hall Effect (HE) in a viscous electron fluid. We show that the latter reacts to oppose the HE, producing an opposite electric field, which is proportional to the so-called Hall viscosity, a dissipationless transport coefficient emerging as a result of time-reversal symmetry breaking. By studying the response of a viscous electron fluid in monolayer (MLG) and bilayer (BLG) graphene to a weak (not quantizing) magnetic field in a suitable measurement geometry we were able to identify the anomalous contribution to the measured Hall signal arising from viscous electron flow. We probe this anomaly over a wide range of temperatures and carrier densities and compare it with theoretical calculations based on magnetohydrodynamic equations, which allows us to extract the Hall viscosity from our measurements. Our findings pave the way for investigations of magnetohydrodynamic of viscous electron fluids in two dimensions.

2:54PM H14.00003: The role of edge effects in magnetotransport measurements of graphene hall bars OLIVIA GHOSH (Presenter), YI-HANG ZENG, J.I.A. LI, Department of Physics, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, CORY DEAN, Department of Physics, Columbia University — The development of the Van der Waals (VdW) assembly technique has led to greatly improved bulk quality of graphene devices. However, little is known about the quality of the sample edge. Here we investigate how the nature of the sample edge affects transport measurements, particularly for the case of the quantum Hall effect regime where the chiral edge modes are presumed to be topologically protected and therefore insensitive to details of the edge. We compare in a single device the transport response along electrostatically-defined versus naturally occurring boundaries, and discuss possible implications for the measurement of boundary edge modes more generally.
3:30PM H14.00006: Extraordinary magnetoresistance in encapsulated monolayer graphene  BOWEN ZHOU (Presenter), Washington University, St. Louis, TAKASHI TANIGUCHI, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, Japan, ERIK HENRIKSEN, Washington University, St. Louis — We report a study on the phenomenon of extraordinary magnetoresistance (EMR) in boron nitride encapsulated monolayer graphene devices. Each device is circular, with an internal circular metal shunt made by edge contact to the graphene. Extremely large EMR values—calculated as (R(B) - R(0)) / R(0), can be found in these devices due to the vanishingly small resistance values at zero field. In many devices the zero-field resistance can become negative, likely due to ballistic carrier transport. This enables R(0) to be chosen arbitrarily close to zero depending only on measurement precision, resulting in very large EMR; conversely, small values of R(0) can have large uncertainty in short term measurements, leading to very large error bars on the EMR. We critically discuss the dependence of EMR on measurement precision and device asymmetry. Finally, the gate-voltage-dependent resistance at zero field also shows a strong electron-hole asymmetry, which we trace to the nature of the metal-graphene edge contact: as in the well-studied case of metals deposited on graphene, the graphene at one-terminal contacts also appears to be heavily electron-doped ~100s of nm away from the contact. We also report measurements on the Landau level energy gaps of bilayer graphene adjacent to 1-2 layer WSe₂ through van der Waals stacking. In comparison to pristine samples, a significant enhancement of the orbital splitting between the N=0 and N=1 levels was observed. The coincidence point of the ν=0 gap splits at field as low as 4 T. Meanwhile, the magnitude of the large ν=2 gap was reduced to roughly half of its value in pristine bilayer. Using thermally activated transport and a pair of top and bottom gates, we performed a set of gap measurements at ν=1, 2, 3 as a function of the carrier density and the applied perpendicular electric field D. We analyze the dependences, compare to the results in pristine bilayer and discuss the impact of WSe₂.

3:54PM H14.00008: Observation of Cyclotron Resonance in Dual-Gated Bilayer Graphene* JORDAN RUSSELL (Presenter), JORDAN PACK, YASHIKA KAPOOR, Physics, Washington University, St. Louis, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ERIK HENRIKSEN, Physics, Washington University, St. Louis — We present measurements of the cyclotron resonance in boron nitride encapsulated, dual-gated bilayer graphene by way of infrared transmission magnetospectroscopy. We have observed both intra- and inter-band resonances, and study these as a function of the Landau level filling factor, $\nu - n/B$, for zero electric displacement field, $D$, and constant magnetic field, $B$. The magnetic field dependence and effects of nonzero displacement field on the Landau level resonances will also be discussed.

4:06PM H14.00009: Graphene Quantum Point Contact for Quantum Hall Interferometry THOMAS WERKMEISTER (Presenter), Applied Physics, Harvard University, YUVAL RONEN, SI YOUNG LEE, YOUNG JAE SHIN, Physics, Harvard University, DANIAL HAEI NAJAFABADI, University of Massachusetts Lowell, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, PHILIP KIM, Physics and Applied Physics, Harvard University — Anyons are particles which possess exchange properties beyond the typical bosonic and fermionic quantum statistics. Several varieties of anyons are expected to emerge as quasi-particles in the regime of the fractional quantum Hall effect (FQHE) where strong magnetic fields are applied on a 2-dimensional electron gas with strong electron-electron interactions. Traditionally, experiments in GaAs heterostructures have attempted to demonstrate anyonic exchange properties via quantum Hall interferometry, but results remain inconclusive. Recently, graphene based heterostructures have emerged as an alternative platform for studying these exotic anyonic quasi-particles within several robust FQHE phases that show larger gaps, particularly in even-denominator states. Here we present preliminary results utilizing hBN-encapsulated monolayer graphene with top and bottom graphite gates to electrostatically define interferometers in the FQHE regime. We will present a quantum point contact (QPC) that functions in the quantum Hall regime, a necessary ingredient for interferometers, and several devices that we characterize through transport measurements at cryogenic temperatures and strong magnetic field.

4:18PM H14.00010: Aharonov-Bohm Phase and Valley Splitting in Strained Graphene P-N Junction* RABINDRA NEPAL (Presenter), SANJAY PRABHAKAR, University of Nebraska - Lincoln, RODERICK MELNIK, The MS2Discovery Interdisciplinary Research Institute, Wilfrid Laurier University, ALEXEY KOVALEV, University of Nebraska - Lincoln — Veselago lens focusing on a graphene P-N junction is promising for the realizations of electron-optical devices such as electron lenses and electron beam splitters. We study two effects in a strained graphene layer with P-N junction: the Lorentz force due to fictitious magnetic fields and Aharonov-Bohm (AB) phase. In a strained P-N junction graphene layer, the strain induced magnetic field modifies the electron trajectories. Furthermore, the Lorentz force on electrons engenders the valley-splitting of electron beams as well as the shifting of caustics formed by refracted electron waves. We also calculate a non-zero AB phase associated with the electron beams due to a localized in-plane strain produced by a ripple. This non-zero phase is accumulated from the electrons that avoid traversing through the locally strained region and experience a non-vanishing vector potential associated with the fictitious magnetic field induced by the localized strain. We believe that these effects can be realized in a simple ballistic experiment and might be useful for mapping strain profiles by analyzing the interference pattern observed in electron-optical devices.
