CHRISTOPHER CONNER (Presenter), Institute for Molecular Engineering, University of Chicago, KEVIN SATZINGER, Department of Physics, University of California, Santa Barbara, YOUPENG ZHONG, HUNG-SHEN CHANG, Institute for Molecular Engineering, University of Chicago, GREGORY A PEAIRS, Department of Physics, University of California, Santa Barbara, AUDREY BIENFAIT, MING-HAN CHOU, AGNETTA CLELAND, ETIENNE DUMUR, JOEL GREBEL, RHYS G POVEY, SAMUEL WHITELEY, DAVID AWSCHALOM, Institute for Molecular Engineering, University of Chicago, DAVID SCHUSTER, Department of Physics, University of Chicago, ANDREW N CLELAND, Institute for Molecular Engineering, University of Chicago — The flexibility and scalability of solid-state qubit systems can be greatly improved with the use of flip-chip geometries, as these provide a third dimension for interconnects and allow coupling of systems on different substrates [1,2]. Indium bump-bonded flip-chips can be prohibitively costly for a university lab, and do not offer a means to re-use the substrates. Here, we describe a simple, low cost, non-galvanic approach to flip-chip bonding, demonstrated using superconducting qubits coupled to other quantum systems, including acoustic and electromagnetic resonators. We achieve less than two microns of placement error, and provide a cryogenically-compatible bonded structure that can be disassembled using acetone. We have tested the approach using inductively coupled coplanar waveguide resonators, and we have designed a multi-qubit experiment with direct inductive coupling between qubits on separate substrates.

High Temperature Superconducting nano-meanders made by ion irradiation

PAUL AMARI (Presenter), C FEUILLET-PALMA, FRANÇOIS COUËDO, NICOLAS BERGÉAL, J LESUEUR, LPEM, Sorbonne Université, ESPCI, CNRS, PSL — Low temperature Superconducting single photon detectors (SSPD) are suitable for quantum information and space communications applications. They show unrivaled performances from visible wavelength to 10μm that require complex cryogenics at 4K that limit applications. In this respect, high temperature superconductors (HTS) are attractive materials to design SSPDs operating at 40K.

We report the fabrication of YBa2Cu3O7-x nano-meanders showing the highest aspect ratios ever reported so far (30nm thick, 100nm wide, 450μm long) by e-beam lithography and high-energy ion implantation [Amari et al. SUST (2018)]. DC measurements prove that superconducting properties in nanowires are preserved with respect to raw YBCO thin-film. We report large hysteretic IV curves in our nanowires, which is a key requirement for hot-spot creation in SSPD. The inductive part of the nanowires plays an important role in the dynamics of the detector. We study the nanowire's inductance using a resonant method over a wide range of temperature up to Tc. The London penetration depth around 190nm extracted from the microwave measurement confirms that superconducting properties are conserved. Our ion irradiation technique paves the way for a suitable nanofabrication process of robust SSPDs made of HTS materials.

Session L12 DMP: 2D Materials (Metals, Superconductors, and Correlated Materials) -- TMDC Theory

BCEC 153A - Ting Cao, University of California, Berkeley - Tag(s): Focus
**11:15AM L12.00001: Transport, Interactions, and Flavortronics in 2D Transition Metal Dichalcogenides**

FAN ZHANG (Presenter), Department of Physics, University of Texas at Dallas — Transition metal dichalcogenides (TMDs) provide a unique 2D material platform for discovering novel physics. First, I will briefly discuss our original predictions on the unconventional quantum Hall effect and “topological” valley Hall effect of massive Dirac fermions in monolayer TMDs, which have been confirmed by optical spectroscopy, quantum transport, and local compressibility measurements. Next, I will introduce our recent theories and experiments that have discovered the G-valley holes and Q-valley electrons in the quantum transport of few-layer TMDs. Particularly, the G-valley holes have an extremely large effective mass that produces an odd-integer predominated quantum Hall effect with giant spin susceptibility and extreme density sensitivity, prerequisites for the Wigner crystal phase. Finally, I will elucidate that the TMD Q valleys offer an unprecedented opportunity to realize the solid-state version of SU(3) flavor symmetry that is rare in electron systems. In the quantum-Hall regime, we have predicted that the spontaneous flavor symmetry breaking yields ferroelectric valley nematics tunable by an in-plane electric field. In the quantum-dot geometry, we have predicted flavor enforced irrational Coulomb peaks and fractional Kondo peaks. These effects lead to a new concept—flavortronics.

**11:51AM L12.00002: Mott metal-insulator transitions in pressurized layered trichalcogenides**

HEUNG SIK KIM (Presenter), KRISTJAN HAULE, DAVID VANDERBILT, Rutgers University, New Brunswick — Transition metal phosphorous trichalcogenides, $\text{MP}_X_3$ ($M$ and $X$ being transition metal and chalcogen elements respectively), have been the focus of substantial interest recently because of their possible magnetism in the two-dimensional limit. Here we investigate material properties of the compounds with $M = \text{Mn}$ and $\text{Ni}$ employing *ab-initio* density functional and dynamical mean-field calculations, especially their electronic behavior under external pressure in the paramagnetic phase. Mott metal-insulator transitions (MIT) are found to be a common feature for both compounds, but their lattice structures show drastically different behaviors depending on the relevant orbital degrees of freedom, i.e., $t_{2g}$ or $e_g$. MnPS$_3$ undergoes an isosymmetric structural transition by forming Mn-Mn dimers due to the strong direct overlap between the neighboring $t_{2g}$ orbitals, accompanied by a significant volume collapse and a spin-state transition. In contrast, NiPS$_3$ and NiPSe$_3$, with their active $e_g$ orbital degrees of freedom, do not show a structural change at the MIT pressure or deep in the metallic phase. Hence NiPS$_3$ and NiPSe$_3$ become rare examples of materials hosting electronic bandwidth-controlled Mott MITs, thus showing promise for ultrafast resistivity switching.

*Supported by NSF DMR-1629059.

**12:03PM L12.00003: Giant spin Hall effect in two-dimensional monochalcogenides**

JAGODA SLAWINSKA (Presenter), FRANK T CERASOLI, HAIHANG WANG, Department of Physics, University of North Texas, SARA POSTORINO, Dipartimento di Fisica, Università di Roma Tor Vergata, ANDREW SUPKA, Department of Physics and Science of Advanced Materials Program, Central Michigan University, STEFANO CURTAROLO, Department of Mechanical Engineering and Materials Science, Duke University, MARCO FORNARI, Department of Physics and Science of Advanced Materials Program, Central Michigan University, MARCO BUONGIORNO NARDELLI, Department of Physics, University of North Texas — One of the most exciting properties of two dimensional materials is their sensitivity to external tuning of the electronic properties, for example via electric field or strain. Recently discovered analogues of phosphorene, group-IV monochalcogenides (MX with $M = \text{Ge}$, Sn and $X = \text{S}$, Se, Te), display several interesting phenomena related to the in-plane strain, such as giant piezoelectricity and multiferroicity, which combines ferroelastic and ferroelectric properties. Here, using calculations from first principles, we predict for the first time giant spin Hall effect (SHE) in these materials which suggests their high potential for 2D spintronics. We reveal that the spin Hall conductivity is tunable via combinations of external strain and doping. In some configurations, the strain-induced semiconductor to metal transition enables the logic functionality of switch on/off control of spin currents indicating a new route for the design of multi-tunable spintronics devices.

12:15PM L12.00004: Evolution of Weyl fermions along the polarity reversal paths in MoTe$_2$  SOBHIT SINGH (Presenter), JIUNWOONG KIM, KARIN RABE, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ-08854, USA — MoTe$_2$ is a layered material with rich physics arising from structural and electronic phase competition. The three observed crystal phases - 2H, 1T', and T$_d$ - have distinct electronic properties. The non-centrosymmetric T$_d$-MoTe$_2$ is particularly fascinating due to the presence of type-I and type-II Weyl nodes in this system. In this study, we investigate the energetics of the possible structural phase transitions in MoTe$_2$, and explore the possibility of controlling the dynamics of Weyl fermions in MoTe$_2$. Our first-principles calculations reveal that one can systematically tune the location and chirality of Weyl nodes by exploiting the connection between polar distortions and spin-orbit coupling effects in T$_d$-MoTe$_2$. By restoring the broken inversion symmetry, we locate a highly symmetric saddle point structure (T$_d^0$) on the energy landscape of MoTe$_2$, establishing a polarity reversal path connecting up and down variants of T$_d$. The T$_d^0$ phase resembles a paraelectric phase of a ferroelectric compound, and it is dynamically and elastically unstable leading to structural phase transitions into the T$_d$ and 1T' phases. We study the evolution of Weyl nodes as a function of structural distortions in the vicinity of T$_d^0$.

12:27PM L12.00005: Statistical mechanics of anisotropic 2D sheets*  MOHAMED EL HEDI BAHRI (Presenter), ANDREJ KOSMRLJ, Princeton University — Atomically thin 2D sheets are now routinely produced and are used in a variety of electronic applications as well as in self-folding origami structures. The majority of 2D sheets, such as graphene, hexagonal boron nitride and the H phase of Transition Metal Dichalcogenides (TMDs), are isotropic. However, there also exist anisotropic 2D sheets, such as the T' phase of TMDs. Note that in equilibrium most are in the isotropic H phase, however the T' phase is stable for WTe$_2$. This motivated us to investigate the statistical mechanics of freely suspended anisotropic 2D sheets. Similar to isotropic sheets, thermal fluctuations effectively renormalize elastic constants for anisotropic sheets and make them scale dependent. Thermal fluctuations effectively increase flexural rigidities, while the in-plane elastic constants are reduced. We found 3 different universality classes (isotropic, orthorhombic and monoclinic) that are characterized with different power-law exponents of the renormalized elastic constants. The T' phase of TMDs falls in the orthorhombic universality class. Therefore, the elastic constants for WTe$_2$ are expected to scale differently than for other isotropic 2D sheets.

12:39PM L12.00006: Dynamical synchronization transition in interacting electron systems*  TANAY NAG (Presenter), condensed matter theory, Max Planck Institute for Physics of Complex Systems (MIPPKS) — Synchronization processes are a ubiquitous phenomenon in nature. We propose a new perspective centered around the topic of a novelly introduced dynamical synchronization transition (DST) in interacting electron systems. In particular, using graphene irradiated by an intense bi-circular pulse laser as a prototypical and experimental viable example, we theoretically investigate how to selectively generate a coherent oscillation of electronic order such as charge density waves (CDW), where the key is to use tailored fields that match the crystalline symmetry broken by the target order. After the pump, a macroscopic number of electrons start oscillating and coherence is built up through a transition. Using an analogy to the celebrated Kuramoto model, describing the classical synchronization of coupled pendulums, we formulate a general framework to encapsulate the induced coherent electronic order. The resulting physics is detectable as a coherent light emission at the synchronized frequency and may be used as a purely electronic way of realizing Floquet states respecting exotic space time crystalline symmetries. In the process, we also explore possible flipping of existing static CDW orders and generation of higher harmonics.

1:27PM L12.00007: Symmetry, spin-texture, and tunable quantum geometry in WTe2 monolayer* LI-KUN SHI, Institute of High Performance Computing, JUSTIN SONG (Presenter), Nanyang Technological University Singapore and Institute of High Performance Computing Singapore — The spin orientation of electronic wavefunctions in crystals is an internal degree of freedom, typically insensitive to electrical knobs. We argue from a general symmetry analysis and a k.p perspective, that monolayer 1T'-WTe2 possesses an electrically tunable bulk band quantum geometry arising from a gate-activated canted spin texture. In particular, we find that due to its out-of-plane asymmetry, an applied out-of-plane electric field breaks inversion symmetry to induce both in-plane and out-of-plane electric dipoles. These in-turn generate spin-orbit coupling to lift the spin degeneracy and enable a bulk band Berry curvature and magnetic moment distribution to develop. Further, due to its low symmetry, Berry curvature and magnetic moment in 1T'-WTe2 possess a dipolar distribution in momentum space, and can lead to unconventional effects such as a current induced magnetization and quantum non-linear anomalous Hall effect. These render 1T'-WTe2 a rich two-dimensional platform for all-electrical control over quantum geometric effects.

1:03PM L12.00008: Edge photocurrent response of type-II Weyl semimetal WTe2* QINSHEGNG WANG (Presenter), JIN CAO, JINGCHUAN ZHENG, YUAN HE, Physics, Beijing Institute of Technology, DONG SUN, ICQM, Peking University, YUGUI YAO, Physics, Beijing Institute of Technology — Photodetectors based on new materials or new structures are of great potentials to promote the performance limits of existing photo detection devices. As topological nontrivial materials, Weyl semimetals were reported to have novel optoelectronic properties and potential applications arising from their gapless linear dispersion near Weyl nodes, berry curvature divergence of Weyl nodes, internal broken of inversion or time reversal symmetry, robust fermi-arc type surface states. These unique properties lead to extraordinary optoelectronic response of Weyl semimetals. Here, using scanning photocurrent microscopy, we demonstrate that robust photocurrent will generate on edges with certain crystal direction in type-II Weyl semimetal WTe2, this photocurrent persists under a wide excitation photon energy range from near Weyl point region to high above Weyl point region. We show that the direction of photocurrent did not change with the polarization of excitation photon and a photon energy range from 0.12 eV to 1.96 eV, this edge photocurrent was determined by the symmetry of edges and may come from the nontrivial Fermi-arc type edge state of Weyl semimetal, and may result in a new type of photodetector based on it.

1:15PM L12.00009: Quantum Mechanical Calculations of the Dielectric Properties of Metallic 2D Transition Metal Dichalcogenides XIAO SHEN (Presenter), University of Memphis — 2D materials are widely studied for their optical properties due to their reduced dimensionality. The key optical properties are reflectivity and absorption coefficients, which can be determined from the complex dielectric function obtained from first-principles quantum mechanical calculations based on time-dependent current-density functional theory (TDCDFT) [1]. Here we focus on the metallic phases of 2D transition metal dichalcogenides (TMD), including MoS2, MoSe2, and WSe2. We reveal their unique optical properties and discuss how the optical properties change upon the change of the chemical composition.

1:27PM L12.00010: First-Principles Prediction of Stable Transition Metal Dichalcogenide Alloys* JOHN CAVIN (Presenter), Physics Department, Washington University in St. Louis, SUNG BEOM CHO, Virtual Engineering Center, Korea Institute of Ceramic Engineering and Technology, ROHAN MISHRA, Department of Mechanical Engineering and Material Science, Washington University in St. Louis — Quasibinary alloying among pairs of 2-dimensional (2D) transition metal dichalcogenides (TMDs) is an attractive method for tuning properties for applications such as optoelectronics and catalysis. Of the many possible combinations of TMDs, the small subset of semiconducting alloys have garnered widespread attention. Outside this limited subset, the synthesizability of alloys remains largely unknown. In order to the guide synthesis of such alloys, we present ab initio calculations of equilibrium phase diagrams with regions of stability for 27 TMDC alloys: $M_{1-x} M'_{x} X_2$ and $M_{2(1-x)} X_{2x}$ ($M, M' = V, Nb, Ta, Mo, or W; XX' = S or Se$) and two heterostructural alloys, $M_{0.1-x} W_{x}Te_{2}$ and $W_{2(1-x)}Te_{2x}$. We predict four new alloys that are miscible at all temperatures: $Nb_{1-x}Ta_{x}S_{2}$, $Nb_{1-x}Ta_{x}Se_{2}$, $VS_{2(1-x)}Se_{2x}$, and $TaSe_{2(1-x)}$. For the rest of the alloys, we present a qualitative analysis of synthesizability based on miscibility temperatures. We relate TMDC size mismatch with a mixing asymmetry that indicates the synthesizability of low concentration alloys. Our results open new compositional spaces that can be used to design and synthesize TMDC alloys for various applications.

*This work was funded by NSF DMREF-1729787.
minimize electron leakage. 2D oxide nanosheets such as Ca$_2$Nb$_3$O$_{10}$ exhibit both high dielectric constants and good thermal stability, suggesting their potential for use in 2D-material-based FETs. In this work, we perform quantum mechanical calculations using density functional theory in order to model interface and defect properties of Ca$_2$Nb$_3$O$_{10}$. Calculations of interface band alignments of Ca$_2$Nb$_3$O$_{10}$ and various candidate 2D semiconductors allow for the determination of suitable material pairings for p- or n-type transistors. Atomic defects that arise during material fabrication and preparation, like oxygen vacancies, can create defect levels within the oxide band gap. Therefore, we calculated the position of these defect energy levels and how they align relative to the semiconductor band edges to provide insights into potential sources of electron leakage and device degradation in the proposed structures.

11:27AM L13.00002: Unified Dielectric Nature of Two-Dimensional Materials* ELTON SANTOS (Presenter), School of Mathematics and Physics, BT71NN, United Kingdom, Queen’s University Belfast — Dielectric constant, which defines the polarization of the media, is a key quantity in condensed matter. It describes to a large degree the electron-electron interaction, which has a crucial effect on band gaps, optical excitations, and screening. Here we show that instead of the dielectric constant ε, the 2D polarizability α correctly captures the dielectric nature of a 2D material for both in-plane and out-of-plane polarizations. We reveal that the long-sought universal dielectric-scale relationships in the 2D world: the in-plane polarizability α|| is inversely proportional to the minimal bandgap Eg, while the out-of-plane polarizability α⊥ is directly related to intrinsic thickness of the 2D material. An analytical quantum-mechanical model is developed which give a sound background to the dielectric-scale relationships, which is supported by a broad high-throughput screening over thousands of materials. Moreover, such relations unify the dielectric properties between the 2D materials and their 3D counterparts in a natural manner, which ultimately pushes the boundary of the understanding of electronic screening in both dimensions.

11:39AM L13.00003: Synthesis and structural characterization of the single chain limit of van der Waals materials THANG PHAM (Presenter), SEHOON OH, SCOTT MEYER, BRIAN SHEVITSKI, KYUNGHOON LEE, JEFFREY CAIN, University of California, Berkeley, CHENGYU SONG, PETER ERCIUS, CHRISTIAN F. KISIELOWSKI, Lawrence Berkeley National Laboratory, MARVIN L COHEN, ALEX ZETTL, University of California, Berkeley — The successful isolation of a single layer of van der Waals (vdW) materials, such as graphene and transition metal dichalcogenides (TMDs), and the renewed interests in their emergent properties in the atomically thin limit have motivated the exploration of other vdW materials. Transition metal trichalcogenides (TMTs), such as niobium triselenide (NbSe3), are closely related quasi one-dimensional (1-D) vdW materials consisting of trigonal prismatic chains binding together by weak vdW interaction. The bulk TMTs abound with peculiar properties, such as sliding charge density wave and superconductivity.

In our talk, I will present our recent effort in isolation and study of the single chain of these 1-D vdW materials encapsulated within carbon and boron nitride nanotubes. In the single chain limit of NbSe3, we found an unusual structural helical torsional wave not seen in bulk NbSe3 crystal, by aberration-corrected transmission electron microscopy (TEM). Density functional theory (DFT) calculation shows that the charge transfer from the encapsulating nanotubes to the single chain induces such torsional wave. We term the phenomenon Charge-induced Torsional Wave (CTW). I will also discuss our efforts in synthesis of other TMTs, beyond NbSe3, in the single chain limit.

11:51AM L13.00004: Revealing the Full Spectrum Layered Materials with Super-Human Predictive Abilities [Invited] GOWOON CHEON, EKIN DOGUS CUBUK, EVAN ANTONIUK, Stanford University, JOSHUA E. GOLDBERGER, Ohio State University, EVAN REED (Presenter), Stanford University — We have utilized data mining approaches to elucidate over 1000 2D materials and several hundred 3D materials consisting of van der Waals bonded 1D subcomponents, or molecular wires. We find that hundreds of these 2D materials have the potential to exhibit observable piezoelectric effects, representing a new class of piezoelectrics. A further class of layered materials consists of naturally occurring vertical hetero structures, i.e. bulk crystals that consist of stacks of chemically dissimilar van der Waals bonded layers like a 2-D super lattice. We further combine this data set with physics-based machine learning to discover the chemical composition of an additional 1000 materials that are likely to exhibit layered and two-dimensional phases but have yet to be synthesized. This includes two materials our calculations indicate can exist in distinct structures with different band gaps, expanding the short list of two-dimensional phase change materials. We find our model performs five times better than practitioners in the field at identifying layered materials and is comparable or better than professional solid-state chemists. Finally, we find that semi-supervised learning can offer benefits for materials design where labels for some of the materials are unknown.
12:27PM L13.00005: A Defect-Enabled Reconfigurable Surface* BENJAMIN KATZ (Presenter), VINCENT HENRY CRESPI, Pennsylvania State University — A novel class of surfaces holds the possibility of reversible reconfiguration into dramatically distinct, stable shapes. This property stems in part from their defects—they have equal numbers of pentagon and heptagon disclinations. Exploring these surfaces with an example constructed out of a graphene monolayer with the disclinations arranged in a kagome-like superlattice, we model its mechanical response with semiclassical molecular dynamics. The pentagon disclinations form cones with a two-fold degree of freedom in their up/down orientation, yielding a reconfigurable surface with a large number of stable shapes. Enumerating a complete ‘zoo’ of such shapes for a small patch of this material reveals that not only are the interactions between these degrees of mechanical freedom long-range enough to produce a gaussian-like ‘density of states’ for given cone orientations, but also that the surface possesses other hidden degrees of freedom in certain orientations—further increasing the number of stable shapes it can hold. These shapes cover a broad range of physical forms and a scale comparable to important biomolecules, raising the possibility of biological applications.

*Research performed under a training fellowship for CoMET, an NRT at Penn State funded by NSF.

12:39PM L13.00006: Fabrication of atomically thin nanowire for mesoscopic transport study* ABIN JOSHY (Presenter), YUN LING, Tulane University, XUE LIU, Physics and Applied Physics, Nanyang Technological University, ANDREW STEELY, Tulane University, JINYU LIU, Physics and Astronomy, University of California, Los Angeles, LIUBOV YU. ANTIPINA, PAVEL B. SOROKIN, Structural Research, Technological Institute for Superhard and Novel Carbon Materials, ANA M. SANCHEZ, University of Warwick, ZHIQIANG MAO, Pennsylvania State University, JIANG WEI, Tulane University — Layered transition metal chalcogenides(TMC) have attracted tremendous attention owing to their weak van der Waals(vdW) interactions between chalcogens, allowing easy mechanical exfoliation of single atomic layer from the bulk. We extend this idea of “exfoliating layers” to “exfoliating atomic chains” in Ta2(Pd or Pt)3Se8, which is a vdW bonded stack of molecular strands. In this work, we succeeded to achieve Ta2Pd3Se8 single and few molecular thin (0.7nm, 1.3nm, 2nm) wires through micromechanical exfoliation. High-resolution TEM confirms 1D chain like morphology of these wires. In addition, we also demonstrated that this method can be applied to other isostructures, such as Ta2Pt3Se8. We also discovered that intrinsic semiconducting properties can be largely preserved in the Ta2Pd3Se8 nanowire transistor as evidenced by high on/off ratio (up to 10⁴) and mobility (up to 80 cm²V⁻¹s⁻¹). Finally, our work provides a new strategy for obtaining air-stable and strictly 1D material system, which offers excellent opportunities for the study of 1D physics.

*This work is supported by National Science Foundation under grant #1752997

12:51PM L13.00007: Linking interlayer twist angle to geometrical parameters of self-assembled folded graphene structures* DAWEI ZHAI (Presenter), Ohio University, JOHANNES RODE, CHRISTOPHER BELKE, SUNG J. HONG, HENNRIK SCHMIDT, Leibniz Universität Hannover, NANCY PATRICIA SANDLER, Ohio University, ROLF J. HAUG, Leibniz Universität Hannover — Previous studies have shown the possibility of obtaining folded bilayer graphene ribbons through spontaneous self-tearing and peeling from a substrate [1]. However, the effect of interlayer twist angle has been neglected. Here we investigate the morphology of spontaneously self-grown nanoribbon structures using AFM. Data reveal similar twist angle dependence of the width and interlayer separation, as well as a width-dependent fold radius. As the self-growth involves bilayer formation, bending, tearing and substrate peeling processes, these observations are well described by an energy minimization model that includes the bilayer adhesion energy density as represented by a distance dependent Morse potential. We obtain an explicit expression for the radius-width dependence that predicts a renormalized bending rigidity and stand in good agreement with experimental observations. The newly found relations between these geometrical parameters suggest a mechanism for tailored growth of folded twisted bilayer graphene- a platform for many intriguing physics phenomena.

*We acknowledge support from the DFG within the priority program SPP 1459 and the "Fundamentals of Physics and Metrology" initiative (Germany), NSF-DMR 1508325 (USA).
1:03PM L13.00008: First principles prediction of 2D lattice coherency in van der Waals heterostructures  BENOIT VAN TROEYE (Presenter), JEAN-CHRISTOPHE CHARLIER, XAVIER GONZE, SIMON DUBOIS, AURÉLIEN LHERBIER, Université catholique de Louvain — Beginning with graphene-hBN van der Waals (vdW) heterostructures [1], many Moiré patterns between 2D materials have been observed [2,3]. Still, predicting the coherent, semi-coherent (Moiré) or incoherent matching of 2D lattices at their interface is a challenge for Density Functional Theory (DFT), due to the very large size of the supercells needed in such studies. We introduce a first-principles-based model that bypass the need for large supercells. It generalizes the well-known Frenkel-Kontorova model [4] by including physical effects present in real materials, as derived from a perturbative approach to the problem. In particular, a mean-field modification of the 2D lattice parameters and elastic constants appears, even if the matching of the lattices is incoherent. The results are compared to plain DFT computations and to experimental observations of lattice accommodation in vdW-heterostructures. Then, we predict lattice (in)coherency for a set of 36 vdW-heterostructures based on graphene, phosphorene and different transition metal dichalcogenides.

1:15PM L13.00009: Modeling mechanical relaxation in misaligned 2D heterostructures*  ZIYAN ZHU (Presenter), STEPHEN CARR, SHIANG FANG, STEVEN TORRISI, Harvard University, PAUL CAZEAUX, Department of Mathematics, University of Kansas, MITCHELL LUSKIN, School of Mathematics, University of Minnesota, EFTHIMIOS KAXIRAS, Harvard University — Two-dimensional van der Waals layered materials (e.g., twisted bilayer graphene) provide a platform to study correlated many-body physics and have potential device applications. However, these layered systems are computationally challenging to model by conventional methods due to their large supercells. Here, we present a multi-scale model to efficiently calculate the mechanical relaxation pattern in incommensurate van der Waals heterostructures at arbitrary twist angles and lattice mismatch. We adopt a continuum model to describe lattice relaxation and a generalized stacking fault energy, computed from the density functional theory, to account for interlayer couplings. We obtain the optimized structure by minimizing the total energy. Our model extends the computationally accessible regime to layered systems with relatively small twist angles and large moiré patterns. This model can be applied to a wide range of materials, including those with no empirical interlayer coupling potential available, such as graphene and the transition metal dichalcogenides.

1:27PM L13.00010: Evidence of Moiré Excitons in van der Waal(vdW) Heterostructure*  KHA TRAN (Presenter), University of Texas at Austin, GALAN MOODY, NIST, FENGCHENG WU, Argonne National Lab, XIAOBO LU, Physics, Washington University in St. Louis, JUNHO CHOI, JIAMIN QUAN, University of Texas at Austin, AKSHAY SINGH, Massachusetts Institute of Technology, JACOB S EMBLEY, ANDRÉ ZEPEDA, MARSHALL CAMPBELL, KYOUNGHWAN KIM, AMRITESH RAI, University of Texas at Austin, TRAVIS AUTRY, NIST, DANIEL SANCHEZ, University of Texas at Austin, TAKASHI TANIGUCHI, KENJI WATAÑABE, National Institute of Material Science, NANSHU LU, SANJAY BANERJEE, EMANUEL TUTUC, University of Texas at Austin, SUENNE KIM, Hanyang University, LI YANG, Physics, Washington University in St. Louis, KEVIN SILVERMAN, NIST, ALLAN MACDONALD, XIAOQIN (ELAINE) LI, University of Texas at Austin — We report spectroscopy evidence of interlayers excitons confined by a moire superlattice in hBN encapsulated MoSe2/WSe2 heterostructures with small twist angles. Low temperature photoluminescence(PL) measurement shows that interlayer exciton splits into multiple peaks with alternating circular polarization. We assign these peaks to the ground state and excited state excitons localized within a Moiré supercell and explain how the spatial variation of optical selection rule can give rise to multiple peaks with alternative circular polarization. Temperature dependence PL, twist angle dependence, and recombination dynamics all agrees with the localized exciton picture. Our results suggest the feasibility of engineering artificial excitonic crystal using vdW heterostructures for nanophotonics and quantum information applications.

1:39PM L13.00011: Plate Theory for 2D Crystal Flakes on Curved Surfaces  HENRY YU (Presenter), NITANT GUPTA, KSENIA V. BETS, BORIS YAKOBSON, Rice University — Recent studies demonstrated the use of substrate topography as means to engineer strain patterns in 2D materials. These strain motifs further impart interesting electronic/optical properties in materials. Although there exist theories on the elasticity of layered materials on curved surfaces, these theories rely on 2 restrictive assumptions: 1) gradually varying surfaces and 2) infinite flakes absent of edges. Recent experimental works have shown the capability of creating surfaces with sharp features such as pyramids and tori, crucial for pronounced property modulation, and invalidating the first assumption. Further, in nanoscale growth conditions finite-size and edge effects cannot be ignored due to different strain distribution compared to the infinite case. In this work, we present the exact elastic equations to calculate strain in 2D crystal flakes on curved surfaces. We also show numerical solutions to the strain configurations for graphene and MoS$_2$ flakes on various topographies, with elastic moduli parametrized from atomic simulations; further, we calculate the resulting band-gap modulation or pseudo-magnetic field. Presented formulation allows for the design of the substrate topography to achieve desired strain pattern and associated properties of the 2D materials.

1:51PM L13.00012: First-Principles Study of Chemical doping in WSe$_2$  MAOHUA DU (Presenter), Oak Ridge National Laboratory, DAN HAN, East China Normal University, WENMEI MING, Oak Ridge National Laboratory, HAIXUAN XU, University of Tennessee, SHIYOU CHEN, East China Normal University — 2D transition metal dichalcogenides (TMDs) are promising nano-electronic materials. The ability to dope 2D TMDs both n- and p-type with high carrier concentration and mobility is essential to the development of MOSFET and CMOS technologies. WSe$_2$ has been shown to exhibit both p- and n-type conductivities after chemical doping; however, the n-type doping is much less efficient than the p-type doping. We have carried out density functional theory calculations of a wide range of transition metal dopants in WSe$_2$ with the goal to understand the different dopant behaviors and to design new n-type dopants with improved doping efficiency. We have also studied in details the native defect properties since defects can potentially compensate the dopants. The calculated trend of dopant formation energies is consistent with the available experimental results. We will discuss the underlying mechanisms that are responsible for the different dopant formation energies based on the local symmetries of the dopants in WSe$_2$ and in competing secondary phases, which affect the crystal field splitting and the relative chemical stability of dopants in different crystal environments. We will also suggest new dopants based on our calculations.

2:03PM L13.00013: Ab Initio Calculations of Bonding and Charge Transfer in Borophene Sheets on a Cu(111) Substrate*  STEPHEN ELTINGE (Presenter), Department of Physics, Yale University, New Haven, CT 06520, USA, RONGTING WU, Department of Applied Physics, Yale University, New Haven, CT 06520, USA, ILYA K. DROZDOV, PERCY ZAHL, IVAN BOZOVIC, Brookhaven National Laboratory, Upton, NY 11973, USA, ADRIAN GOZAR, SOHRAB ISMAIL-BEIGI, Department of Applied Physics, Yale University, New Haven, CT 06520, USA — Borophene, the two-dimensional hexagonal lattice form of boron, is predicted to have technological uses in flexible electronics and as a precursor to metallic boron nanotubes. Boron's electron deficiency leads to borophene sheets that have both hexagonal and triangular bonding, and different arrangements of these motifs lead to a wide range of nearly isoenergetic phases. Previous work has grown boron on Ag(111) substrates and reported the striped $\beta_{12}$ and $\chi_3$ borophene phases, but more recent growth on a Cu(111) substrate by our team describes a more complex sheet structure with a much larger unit cell. We describe ab initio density functional theory simulations of borophene sheets on the Cu(111) surface to understand and explain this observed lattice structure. We discuss the bonding structure within the borophene sheet, paying special attention to electron doping via charge transfer from the Cu substrate. In addition, we compare our results to calculations of free-standing borophene sheets and discuss implications for practical growth of borophene on substrates.

Session L14 DCMP: Electronic Interactions in Twisted Bilayers  BCEC 153C - Cory Dean
11:15AM L14.00001: Chiral SDW and d + id superconductivity in the magic-angle twisted bilayer-graphene  
CHENG-CHENG LIU (Presenter), LI-DA ZHANG, School of Physics, Beijing Institute of Technology, Beijing, China, WEI-QIANG CHEN, Department of Physics, Southern University of Science and Technology, Shenzhen, China, FAN YANG, School of Physics, Beijing Institute of Technology, Beijing, China — We model the newly synthesized magic-angle twisted bilayer-graphene superconductor with two px,y-like Wannier orbitals on the superstructure honeycomb lattice, where the hopping integrals are constructed via the Slater-Koster formulism by symmetry analysis. The characteristics exhibited in this simple model are well consistent with both the rigorous calculations and experimental observations. Van-Hove singularity and Fermi-surface nesting are found in the doping levels relevant to the correlated insulator and unconventional superconductivity revealed experimentally, base on which we identify the two phases as weak-coupling FS instabilities. Then, with repulsive Hubbard interactions turning on, we performed random-phase-approximation (RPA) based calculations to identify the electron instabilities. As a result, we find chiral d + id topological superconductivity bordering the correlated insulating state near half-filling, identified as noncoplanar chiral spin-density wave (SDW) ordered state, featuring quantum anomalous Hall effect. The phase-diagram obtained in our approach is qualitatively consistent with experiments.

11:27AM L14.00002: Multiple topological transitions in magic angle twisted bilayer graphene I  
KASRA HEJAZI (Presenter), CHUNXIAO LIU, University of California, Santa Barbara, HASSAN SHAPOURIAN, University of Chicago, XIAO CHEN, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara — The physics of twisted bilayer graphene (TBG) structures has attracted a lot of interest experimentally and theoretically. Attention was drawn to these systems largely by recent experimental works, which showed strong correlation effects in bilayer graphene systems with a twist angle of roughly 1°, the so-called magic angle. A continuum model for describing such systems is used in our study, and instead of observing flat bands only at the magic angle, we notice that the bands remain almost flat within a small range around the magic angle, where multiple topological transitions occur. The topological transitions are caused by creation and annihilation of Dirac points, which are transported within the moire Brillouin zone as the angle is varied around the magic angle. Furthermore, we propose an effective low energy six-band model near the Γ point, which we argue is the minimal model to explain the motion of the Dirac points around Γ as the angle is varied. These observations can also be exploited for explaining the experimental results regarding the response of the magic angle TBG systems to external magnetic field.

11:39AM L14.00003: Electron-phonon superconductivity and Landau levels in twisted bilayer graphene  
BIAO LIAN (Presenter), ZHIJUN WANG, FANG XIE, ANDREI B BERNEVIG, Princeton University — In the first half of the presentation, we show the analytical calculation of the electron-phonon coupling in twisted bilayer graphene (TBG), which was recently experimentally observed to exhibit superconductivity around the magic twist angle θ ≈ 1.05°. We show that phonon-mediated electron attraction at the magic angle is strong enough to induce a conventional intervalley pairing between graphene valleys K and K′ with a superconducting critical temperature T_c ~ 1K, in agreement with the experiment. In the second half of the talk, we show the existence of topological Landau levels at large magnetic fields due to nontrivial topology of the flat bands.

11:51AM L14.00004: Magic angle twisted bilayer graphene: strong correlations and Landau level  
GAURAV CHAUDHARY (Presenter), ALLAN MACDONALD, University of Texas at Austin — The electronic structure of twisted bilayer graphene (TBLG) features a peculiar Fermi velocity renormalization property which leads to vanishing Fermi-velocities near neutrality at certain “magic” twist angles. At the magic angle the system has strong correlations which have been shown experimentally to lead to Mott insulator and superconducting phases. I will discuss the Landau level structure of TBLG near magic angles, the relationship between electronic structure and experimentally observed Landau levels, and the relationship between magic angle behavior and the system's response to external magnetic fields. We show that the Landau level structure near neutrality is highly sensitive to self-energy modifications of magic angle electronic structure.
**12:03PM** L14.00005: High temperature quantum transport in 2D moiré superlattices  
ROSHAN KRISHNA KUMAR (Presenter), JOHN WALLBANK, XI CHEN, GREGORY AUTON, MATTHEW HOLWILL, ARTEM MISHCHENKO, Konstantin S. Novoselov, Vladimir Falko, Andre Geim, School of Physics & Astronomy, University of Manchester — Van der Waals heterostructures based on moiré superlattices have become increasingly popular due to their large tunability unprecedented by any other solid-state system. In this talk, we review recent experimental results on high-temperature electron transport studies in heterostructures based on 2D moiré superlattices. Our experiments describe two fundamental phenomena of electron transport that manifest profoundly at high temperatures and are extremely sensitive to the twist-angle. First, we show that electron-electron collisions in graphene superlattices are dominated by umklapp processes [1]. They cause a giant increase in resistivity that grows rapidly upon decreasing the twist-angle between 2D layers, degrading the intrinsic mobility of graphene by more than an order of magnitude. Second, we show that moiré superlattices feature a novel class of quantum magnetoresistance oscillations [2] that differ fundamentally from the Shubnikov de Haas effect and all known quantum oscillatory phenomena.

MAREC SERLIN (Presenter), CHARLES TSCHIRHART, HRYHORIY POLSHYN, JIACHERG ZHU, University of California, Santa Barbara, Martin E HUBER, University of Colorado, Denver, Andrea Young, University of California, Santa Barbara — Bilayer graphene, rotationally faulted to ~1.1 degree misalignment, has recently been shown to host superconducting and resistive states associated with the formation of a flat electronic band. While numerous theories exist for the origins of both states, direct validation of these theories remains an outstanding experimental problem. Here, we focus on the resistive states occurring at commensurate filling (1/2, 1/4, and 3/4) of the two lowest superlattice bands. We test theoretical proposals that these states arise due to broken spin—and/or valley—symmetry by performing direct magnetic imaging with nanoscale SQUID-on-tip microscopy. This technique provides single-spin resolved magnetometry on sub-100nm length scales. I will present imaging data from our 4.2K nSOT microscope on graphite-gated twisted bilayers near the flat band condition and discuss the implications for the physics of the commensurate resistive states.

**12:27PM** L14.00007: Multiple topological transitions in magic angle twisted bilayer graphene II  
CHUNXIAO LIU (Presenter), Kasra Hejazi, Leon Bales, Kavli Institute for Theoretical Physics, University of California, Santa Barbara — Recent experiments have observed strongly correlated physics in twisted bilayer graphene (TBG) at very small angles $\theta_0 = 1.05$, along with nearly flat electron bands (FBs) at certain fillings. A good starting point to understand this is a continuum model [PNAS 108, 12233 (2011)] which successfully predicts the formation of FBs at $\theta_0$. Following this work, we investigate the low energy FB structure in the entire moiré Brillouin zone (mBZ) as twisting angle is changed; the effect of transverse lattice distortion is also considered. We notice that the bands remain almost flat within a small range around $\theta_0$, where multiple topological transitions occur. In addition to the previous understanding that the FBs are caused by the highly renormalized dispersion at K, we propose that there are other mBZ regions responsible for the low energy physics and the FBs. We trace the evolution of the Dirac points (DPs), which are very sensitive to the twist angle, and specify several processes of DP transfer within the mBZ. Furthermore, we study the effect of magnetic field to the system; comparison to the experimental results is given.

**12:39PM** L14.00008: Role of lattice relaxations in magic angle twisted bilayer graphene  
STEPHEN CARR (Presenter), Shiang Fang, Ziyan Zhu, Efthimiios Kaxiras, Harvard University — Understanding the origin of correlated effects in twisted bilayer graphene (tBLG) first requires a complete single-particle picture of its low-energy electronic states. Previous models of tBLG have had either high accuracy (e.g. DFT, tight-binding supercells), or high twist angle resolution (e.g. continuum or k-dot-p models), but not both. We introduce an ab initio k-dot-p model that includes lattice relaxations which can exactly reproduce DFT tight-binding electronic band-structures, but with the ability to continuously tune the twist angle. Inclusion of relaxation significantly changes the bandstructure near tBLG's first magic angle, and suppresses the appearance of the second magic angle. We find that a geometric interpretation of tBLG's relaxed atomic structure extends to its low-energy electronic states, creating a comprehensive picture of both mechanical and electronic effects at small twist angle.

12:51PM L14.00009: Localized eigenstates in dodecagonal twisted bilayer graphene  MOON JIP PARK (Presenter), HEESEUNG KIM, SUNGBIN LEE, Physics, KAIST — Dodecagonal quasicrystalline order has been experimentally demonstrated in twisted bilayer graphene systems. In this talk, we report emergence of localized eigenstates in the dodecagonal quasicrystals without additional random disorder. That is to say, the non-periodic quasicrystalline order causes the localization. These localized states are evidenced by the scaling behaviors of inverse participation ratio and energy level statistics, which have been used to characterize Anderson localization phenomena. Using exact diagonalization method, we show that the localization can be driven by increasing the interlayer coupling strength. In addition, we will compare our result with the conventional two-dimensional Anderson localization transitions.

1:03PM L14.00010: Atmospheric Pressure Chemical Vapor Deposition of Twisted Bilayer Graphene on Copper Foil Substrates*  LUCAS HANSON (Presenter), NIKHIL M TILAK, MICHAEL ALTVATER, BRIAN J ELLSWORTH, EVA ANDREI, Rutgers University, New Brunswick — Atmospheric pressure chemical vapor deposition (APCVD) of graphene bilayers on copper foil substrates represents a promising paradigm for the fabrication of Bernal stacked and twisted bilayer graphene samples. Large scale growth techniques will be essential in developing the potential applications of bilayer graphene, such as ultra high frequency field effect transistors or novel photonic devices. Using a quartz tube and tube furnace, copper foil substrates, argon and hydrogen forming gas, and a methane carbon feedstock, we studied a variety of different APCVD recipes to determine the optimal growth parameters for depositing graphene bilayers. Additionally, various copper substrate pretreatment techniques were tested, including surface etching, electrochemical polishing, wet oxidation, and argon annealing. Preliminary results suggest that increased bilayer grain sizes can be achieved by flowing higher methane concentrations for longer time periods during the growth stage, and optical microscopy of single and bilayer grain alignment suggest that small twist angles can be achieved using our APCVD method.

1:15PM L14.00011: Strong Correlations in Magic Angle Twisted Bilayer Graphene Investigated by Scanning Tunneling Microscopy  ALEXANDER KERELSKY (Presenter), LEO MCGILLY, Physics Department, Columbia University, SHAOWEN CHEN, Applied Physics and Math Department, Columbia University, MATTHEW YANKOWITZ, Physics Department, Columbia University, LEDE XIAN, DANTE KENNES, Max Planck Institute for the Structure and Dynamics of Matter, ANGEL RUBIO, Max Planck Inst Structure & Dynamics of Matter, CORY R DEAN, ABHAY PASUPATHY, Physics Department, Columbia University — Recent results on twisted bilayer graphene near the “magic” angle of 1.1 degrees reveal gate-tunable superconducting and correlated insulating states generally attributed to the flat band emerging from the moire superlattice and hybridization between the two layers. To date, the investigation of these states has been limited to bulk probes, inherently hindered by overall sample disorder and inhomogeneity. Using gated scanning tunneling microscopy and spectroscopy (STS), we directly locally investigate twisted bilayer graphene around the magic angle. Many theories have been proposed as to the precise band structure which causes the insulating and superconducting states to emerge, but the question remains for instance as to the size of the gap at charge neutrality and at half filling of the moire superlattices. We show the real experimental L-DOS probed by STS at and near the magic angle with gate tunable doping. Our results show the size of the gap at charge neutrality as well as the half filling state which enables a better understanding of the correlation effects leading to the insulating and superconducting states. Additionally, we study the effects of the local inhomogeneity which likely leads to the variable results observed in transport.

1:27PM L14.00012: Scanning tunneling microscopy of gated twisted bilayer graphene: Suppression of tunneling density of states due to electronic correlations*  YOUNGJOON CHOI (Presenter), JEANNETTE KEMMER, HARPREET SINGH ARORA, ROBERT POLSKI, YIRAN ZHANG, HECHEN REN, Caltech, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, STEVAN NADJ-PERGE, Caltech — ‘Magic’ angle(~1.1°) twisted bilayer graphene(TBG) is predicted to host narrow, non-dispersive electronic bands, where the kinetic energy of electrons becomes much smaller than Coulomb interactions. Recent transport measurements in this system showed insulating behavior and superconductivity around half filling of the bands, key signatures of the strongly correlated electronic systems. But the detailed electronic structure and the many-body properties of this system are still not well-understood. We used scanning tunneling microscopy and spectroscopy to measure gated TBG with angles ranging from 0.9° to 2°. When the twist angle was close to the magic angle, at certain carrier densities, we observed strong suppression of the tunneling density of states at the Fermi level associated with electron-electron interactions. Our results may deepen the understanding of strongly correlated behavior in magic angle TBG.

1:39PM L14.00013: Constructing low-energy models for the electronic structure of twisted bilayer graphene
ZACHARY GOODWIN (Presenter), Materials, Imperial College London, ARASH A MOSTOFI, JOHANNES LISCHNER, Materials and Physics, Imperial College London — The recent, unexpected discovery of insulating and superconducting behaviour in magic angle twisted bilayer graphene (tBLG) has generated tremendous interest in theoretical communities to rationalise these observations. To study the angle dependent electronic properties, we have developed a tight binding model for tBLG. Importantly, the developed tight binding model accounts for atomic corrugation, and therefore, different interactions between AA and AB regions. Such asymmetry has been attributed to the isolation of bands near the Fermi energy, which has been experimentally observed. From the tight binding model, the Wannier orbitals and interaction matrix of these orbitals can be obtained. These calculations permit the construction of simplified Hamiltonians with no free parameters. Such downfolded Hamiltonians can be used in state-of-the-art functional renormalisation group methods to calculate the electronic phase diagram. The developed methodology naturally lends itself to systematic improvements and to other bilayer materials.

1:51PM L14.00014: Intralayer and interlayer electron-phonon interactions in twisted bilayer graphene
MARCOS PIMENTA (Presenter), ARIETE RIGHI, ELIEL GOMES DA SILVA NETO, ANDREIJ DE CARVALHO GADELHA, LEONARDO CRISTIANO CAMPOS, Departamento de Física, UFMG, Brazil, MARCUS MOUTINHO, Núcleo Multidisciplinar de Pesquisas em Computação - NUMPEX-COMP, Unifed. do Rio de Janeiro, PEDRO VENEZUELA, Instituto de Física, Universidade Federal Fluminense, PO-WEN CHIU, EE, National Tsing Hua University — In this work we report on the possibility of using resonance Raman spectroscopy to distinguish intralayer and interlayer electron-phonon (el-ph) interactions in twisted bilayer graphene (TBG). This is experimentally attained by tuning the energy of the excitation photon and observing the resonances of the Raman modes in different samples of TBGs. In the intralayer process, the el-ph scattering occurs in a single graphene layer and the other layer imposes a periodic potential that back scatters the excited electron, whereas for the interlayer process the el-ph scattering occurs between states in the Dirac cones of adjacent graphene layers. Our methodology can be extended to study any kind of graphene-based heterostructure. [Eliel et al., Nature Comm. 9, 1221 (2018)]

2:03PM L14.00015: Lattice relaxation and energy band modulation in twisted bilayer graphene
NGUYEN NAM (Presenter), National Institute of Advanced Industrial Science And Technology (AIST), MIKITO KOSHINO, Physics, Osaka University — We theoretically study the lattice relaxation in the twisted bilayer graphene (TBG) and its effect on the electronic band structure. We develop an effective continuum theory to describe the lattice relaxation in general TBGs and obtain the optimized structure to minimize the total energy. At small rotation angles < 2 degrees, in particular, we find that the relaxed lattice drastically reduces the area of the AA stacking region and forms a triangular domain structure with alternating AB and BA stacking regions. We then investigate the effect of the domain formation on the electronic band structure. The most notable change from the nonrelaxed model is that an energy gap of up to 20 meV opens at the superlattice subband edges on the electron and hole sides. We also find that the lattice relaxation significantly enhances the Fermi velocity, which was strongly suppressed in the nonrelaxed model.

Wednesday, March 6, 2019 11:15 AM - 2:15 PM

Session L15 DMP: 2D Materials (Semiconductors) -- Quantum Interactions in Transport and Optical Phenomena BCEC 154 - Jifa Tian, U. Wyoming

11:15AM L15.00001: Transport theory of quantum dots based on transition metal dichalcogenides
ZHI-QIANG BAO (Presenter), PATRICK CHEUNG, FAN ZHANG, University of Texas at Dallas — Atomically thin transition metal dichalcogenides (TMDs) represent a conceptually new class of materials that have large bandgaps, strong spin-orbit couplings, and multiple valley degrees of freedom. One particular characteristic of TMDs is their even-odd layer-dependent band structures that have been theoretically predicted and experimentally observed. We study the transport properties of few-layer TMDs in the quantum dot geometry and predict unconventional Coulomb peaks and Kondo resonances when such a dot is tunnel coupled to two normal leads. The irrational peak ratios and fractional resonance conductances found in our study suggest that TMDs provide a unique platform for novel quantum dot physics.

*Research is sponsored by the Army Research Office and was accomplished under Grant Number W911NF-18-1-0416.
11:27 AM  L15.00002: Single photon-phonon entanglement in WSe$_2$ quantum dots*  XIAOTONG CHEN (Presenter), XIN LU, SUDIPTA DUBEY, QIANG YAO, Emory University, SHENG LIU, XINGZHI WANG, QIHUA XIONG, Nanyang Technological University, LIFA ZHANG, Physics, Nanjing Normal University, AJIT SRIVASTAVA, Emory University — We study photoluminescence of optically active quantum dots (QDs) in monolayer WSe$_2$ FET at low temperature (4K) and magnetic fields up to 8T. In addition to the neutral QD emission, a 21.8 meV red-shifted peak is observed. This replica peak shows correlated spectral jitters identical to the parent peak and exhibits similar excitation power dependence and magnetic field induced Zeeman splitting. Raman spectroscopy and phonon dispersion calculations are used to assign this peak to doubly-degenerate chiral phonons. Different to linearly polarized neutral QD, the phonon replica is completely unpolarized. This unusual behavior is not expected in a coherent phonon scattering. We understand it as a result of phonon-phonon entanglement resulting from two indistinguishable paths in the phonon scattering process. As the phonon part of the entanglement is never measured, the photon part gets fully unpolarized. Under magnetic field this indistinguishability is lost and the replica peak recovers its polarization, corroborating our claim. Our results highlight an intriguing feature of 2D honeycomb lattice which can host chiral phonons. This single photon-phonon entanglement can be further explored for non-reciprocal light propagation at the quantum level.

*NSF EFRI NewLAW grant #EFMA-1741691

11:39 AM  L15.00003: Control of spin-valley state in a charged WSe$_2$ quantum dot by optical helicity*  XIN LU (Presenter), XIAOTONG CHEN, SUDIPTA DUBEY, QIANG YAO, Department of Physics, Emory University, XINGZHI WANG, QIHUA XIONG, Division of Physics and Applied Physics, Nanyang Technological University, AJIT SRIVASTAVA, Department of Physics, Emory University — We present low temperature (~4 K) photoluminescence study of positively charged quantum dots (QDs) in an ambipolar WSe$_2$ field effect transistor. At a negative gate voltage when the monolayer sample is lightly hole-doped, a single peak (S-peak) and a doublet (D-peak) appear simultaneously and spectrally wander in an identical manner. We thus assign S- and D-peaks originate from the same QD. D-peaks are the neutral ($X^0$) QD with fine structure splitting of ~600 µeV resulting from the e-h exchange interaction. While the exchange interaction in a singly, positively charged ($X^+$) QD is expected to vanish due to holes forming a singlet and Pauli blocking. We assign S-peaks to be $X^+$ QD which has a binding energy of -10 meV with respect to $X^0$. $X^+$ QD is doubly degenerate at $B = 0$ T. The degeneracy of $X^+$ is lifted in finite $B$ field, allowing us to spectrally distinguish between the spin-valley states (with excess hole spin up in -K valley or spin down in K valley). By controlling the helicity of the excitation laser, we observe selective initialization of spin-valley of excess hole in $X^+$ QD under small $B$ field. Our results show that spin-valley degree is robust in charged WSe$_2$ QDs and enables valleytronics on single localized charge carriers.

*NSF EFRI NewLAW grant #EFMA-1741691

11:51 AM  L15.00004: Potential landscape engineering in two-dimensional transition metal dichalcogenides: towards hybrid optical-electrical quantum dots*  ANDREY SUSHKO (Presenter), KRISTIAAN DE GREVE, LUIS JAUREGUI, Physics, Harvard University, KE WANG, School of Physics and Astronomy, University of Minnesota, KATERNYA PISTUNOVA, ANDREW Y JOE, DOMINIK S WILD, GIANNI SCURI, Physics, Harvard University, ALEXANDER A HIGH, Institute for Molecular Engineering, University of Chicago, YOU ZHOU, Chemistry and Chemical Biology, Harvard University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, PHILIP KIM, Physics, Harvard University, HONGKUN PARK, Chemistry and Chemical Biology, Harvard University, MIKHAIL LUKIN, Physics, Harvard University — Monolayer transition metal dichalcogenides (TMDCs) have attracted recent interest due to their unique excitonic and electronic properties. As gapped, semiconducting counterparts to graphene, they show particularly strong excitonic effects, which can be exploited both in pure monolayer devices, as well as in van der Waals heterostructures where the TMDC is encapsulated between layers of insulating hexagonal boron nitride (hBN). In this work, we discuss progress towards a unique platform that exploits the strong excitonic binding energies of the TMDCs to create a hybrid, electrically controlled yet optically active quantum dot device. Further, we report on recent experiments showing optically induced current from hole-doped molybdenum diselenide to graphite or metal electrodes across over 90nm of hBN, indicating a limitation of hBN encapsulation for hybrid optical-electronic devices in TMDCs along with a method for unipolar charge injection into uncontacted TMDC layers. Finally, we discuss methods for making tunable excitonic potential landscapes in TMDC heterostructures via modulation of the dielectric environment in reconfigurable moiré structures.

*Hertz, PD Soros fellowships
**12:03PM L15.00005: Spontaneous emission enhancement of single-layer WSe$_2$ coupled to a microcavity**

HYUNSEUNG LEE (Presenter), JIEUN LEE, Physics and Energy System Researches, Ajou University — Atomically thin layers of transition metal dichalcogenides such as single-layer WSe$_2$ have recently attracted much attention as promising material candidates for optoelectronic applications. Engineering the spontaneous emission rate in these materials is expected to improve the performance and functionalities of optoelectronic devices. In this talk, we show the photoluminescence (PL) enhancement of mechanically exfoliated single-layer WSe$_2$ integrated to a microcavity. We directly contact silicon dioxide microspheres with diameters ranging from 2 to 7 μm on single-layer WSe$_2$ to control the enhancement rate. We found that the experimentally obtained Purcell factor agrees well with that calculated by the finite-difference time-domain (FDTD) simulation. The Purcell enhancement is further supported by the direct measurement of the radiative decay rate of WSe$_2$ with and without microspheres. Our finding provides a way to manipulate optical properties of single-layer semiconductors for optoelectronic applications and integrated nanophotonics.

**12:15PM L15.00006: Room Temperature Control of Valley Coherence in Microcavity Bilayer WS$_2$ Exciton-Polariton**

MANDEEP KHATONIAR (Presenter), Physics, Graduate Center, City University of New York, New York, NY 10016, NICHOLAS YAMA, Physics, University of Hawaii, Honolulu, HI 96822, SRIRAM GUDDALA, AREG GHAZARYAN, POUYAN GHAEMI MOHAMMADI, VINOD M MENON, Physics, City College of New York, New York, NY 10031 — Transition metal Dichalcogenides (TMD) have emerged as promising candidate for many optoelectronic and photonic applications. Their lack of inversion symmetry, presence of strong spin-orbit coupling and spin-valley locking make them ideal for realizing “Valleytronics”, a valley counterpart of spintronics. An important aspect of using the valley degree of freedom for information technology is manipulating the coherent circularly polarized photoluminescence (PL) from both valleys which is realized in experiment via the retention of linear polarization of the PL. Bare TMD however suffer from many dephasing mechanisms with electron hole exchange being the dominant one. Embedding these TMD’s in microcavities allow us to form polaritons in the strong coupling regime which is a hybrid light-matter system. We thus earn additional control knobs provided by the photon component of the quasiparticle. Also, the lifetime of the polariton species, dictated by the quality factor can be made comparable to that of the dephasing mechanisms to ease their effects. Here we report robust room temperature valley coherence from bilayer WS$_2$ exciton polaritons and show control of the valley coherence without the application of external magnetic field.

*NSF DMR 40G70 , NANO-NY Program NSF award EEC-1659808

**12:27PM L15.00007: Tracking the origin of single photon emitters in WSe$_2$**

LUKAS LINHART (Presenter), Institute for Theoretical Physics, TU Vienna, MATTHIAS PAUR, Institute of Photonics, TU Vienna, VALERIE SMEJKAL, Institute for Theoretical Physics, TU Vienna, THOMAS MUELLER, Institute of Photonics, TU Vienna, JOACHIM E BURGDOERFER, FLORIAN M LIBISCH, Institute for Theoretical Physics, TU Vienna — Single photon emitters (SPE) in WSe$_2$ have been investigated in several recent publications [1, 2], receiving considerable attention in the field of two-dimensional materials. Although the origin of these emitters is generally attributed to defects and/or local strain, an exact microscopic explanation has proven elusive. Using a multiscale approach we established a tight-binding model capturing non-uniform strain, defects and coulomb-interactions we elucidate this mystery. Tight-binding calculations with local strain patterns and open boundary conditions for a large WSe$_2$ flake yield quantum-dot-like localization. Including defects we can reproduce and explain the large g-factor (≈ 9) as well as the zero field splitting, the linear polarization and the electric field dependence. We conclude that local strain shifts excitonic energy levels into an energy of otherwise unoccupied inter-gap defect states, acting as a doorkeeper to fill these states. Together with localized valence bands, this leads to sharp SPE.

SON T. LE (Presenter), Theiss Research & NIST, NICHOLAS GUROS, University of Maryland, College Park, ROBERT C. BRUCE, Virginia Tech University, ANTONIO CARDONE, National Institute of Standards and Technology, NIRANJANA D. AMIN, National Institutes of Health, SIYUAN ZHANG, Theiss Research & NIST, JEFFERY B. KLAUDA, University of Maryland, College Park, HARISH C. PANT, National Institutes of Health, ARVIND BALIJEPALLI, CURT A RICHTER, National Institute of Standards and Technology — We have fabricated and characterized ionic liquid-gated 2D-MoS2 field effect transistors (2D-ILFETs) that operate at the quantum capacitance limit of the 2D channel material. These devices were used to measure pH with high sensitivity (~75 times higher than the Nernst value of 59 mV/pH) and low noise (~2 orders of magnitude higher signal-to-noise ratio over ion-sensitive FETs) at room temperature. This high device performance in pH sensing is attributed to the large asymmetric capacitive coupling between the top ionic liquid gate and bottom silicon gate to the 2D semiconducting channel. This behavior is fundamentally different from dual-gate silicon FET pH sensors that control two coupled channels. To demonstrate the usefulness of ultra-sensitive pH measurements based on 2D-ILFETs, we experimentally quantified the function of enzymes implicated in Alzheimer's disease at physiological concentrations and with sufficient time-resolution to allow the estimation of both steady-state and kinetic parameters in a single experiment.

ELYSE BARRÉ (Presenter), Stanford University, JEAN ANNE INCORVIA, University of Texas at Austin, SUK HYUN KIM, CONNOR MCCLELLAN, ERIC POP, H. S. PHILIP WONG, Stanford University, TONY F. HEINZ, Stanford University and SLAC — Monolayers of semiconducting transition metal dichalcogenides (TMDCs) exhibit a valley Hall effect (VHE) in which the carriers in the K (K') valley acquire a velocity, \( \mathbf{v}(\mathbf{v}) \) perpendicular the applied electric field, \( \mathbf{E} \) [1,2,3]. As the K and K' bands split by spin, the resulting valley current is also a spin current. For a sample of finite width perpendicular to the direction of an applied electric field \( \mathbf{E} \), this leads to a steady-state accumulation of spin and valley polarized carriers at the edges. We have investigated the VHE in ambipolar WSe2 field-effect transistors in both n- and p-type regimes using spatial imaging of the spin and valley polarization by the optical Kerr rotation (KR) at 20 K. Here we quantitatively interpret the magnitude of the measured KR through a model of the optical response for unequal carrier populations in the valleys to obtain an estimate of the experimental spin/valley imbalance. We compare our findings to predictions of a spin diffusion model. This allows us to infer a spin and valley lifetime compatible with previous time-resolved measurements of spin-polarized carriers [4].

MAXIM TRUSHIN (Presenter), Centre for Advanced 2D Materials, NUS — The standard theory of thermionic emission developed for three-dimensional (3D) conductors does not apply to two-dimensional (2D) materials even for making qualitative predictions because of the vanishing out-of-plane quasiparticle velocity [1]. Here, we focus on two mechanisms possibly responsible for out-of-plane quasiparticle transport in 2D-3D and 2D-2D heterojunctions. First, we consider the fundamental origin of the out-of-plane charge carrier motion in a perfect 2D conductor due to the finite quasiparticle lifetime and huge uncertainty of the out-of-plane momentum. The theory is applied to a Schottky junction between graphene and a bulk semiconductor to derive a thermionic constant, which, in contrast to the conventional Richardson constant, depends on the barrier height and Fermi level [2]. Second, we focus on electron transport from a 2D conductor to a 2D semiconductor assuming some short-range interface disorder that results in momentum randomization and interlayer hopping. The model is applied to electron transport in graphene-MoS2 heterostructures [3].

*Supported by the Director's Senior Research Fellowship from CA2DM at NUS.
1:15PM L15.00011: Hall and thermoelectric measurement of Type-II Weyl semimetal TaIrTe₄

(Presenter), YU JIAN, QINSHENG WANG, YUGUI YAO, Beijing Institute of Technology — Weyl semimetal has gapless band structures protected by topology and symmetry which possess many interesting properties, like Fermi arc surface states, chiral anomaly etc. Without the constraint from the Lorentz invariance, type-II Weyl semimetal has a tilted Weyl cone that electron and hole pockets exist at the node energy. TaIrTe₄ is theoretically predicted to be a type-II Weyl semimetal hosting four well-separated Weyl points which is the minimum required by the symmetry. Here, we present our study of TaIrTe₄ with Hall and thermoelectric measurement. In the Hall measurement, two pairs of electron-hole pockets with quite different mobility could be identified by fitting the Hall curves. The temperature dependence of the carrier density shows an obvious movement of the Fermi level which is quite similar to the reported temperature-induced Lifshitz transition in WTe₂. The Hall result suggests that hole-type carrier dominate the transport properties which is in the opposite to the negative Seebeck coefficient. The Nernst coefficient has the same temperature dependence as the mobility of the dominate hole band.

1:27PM L15.00012: Quantum Oscillation in WTe₂ Flakes

XURUI ZHANG (Presenter), XIAOYAN SHI, Department of Physics, University of Texas at Dallas — WTe₂ is theoretically predicted to have two pairs of electron and hole pockets along Γ-X direction, which have been observed in ARPES. However, ARPES also revealed an additional hole pocket which is very closed to Γ point, the center of Brillouin zone. The two predicted pairs of Fermi pockets have already been verified in transport measurements but there’s few evidence of the existence of the hole pocket at Γ point. Here we report the quantum oscillations study in semimetallic WTe₂ flakes with different thickness. An oscillation signal from the hole pocket at Γ point is very likely to be observed.

1:39PM L15.00013: Quantum Transport in N-doped 2D Tellurene

CHANG NIU (Presenter), GANG QIU, YIXIU WANG, WENZHUO WU, PEIDE (PETER) YE, Purdue University — Tellurium (Te) is a p-type narrow-bandgap high-mobility semiconductor with one dimensional van der Waals (vdW) structure. It has a unique chiral-chain crystal lattice in which individual helical chains of Te atoms are stacked together by vdW type bonds and spiral around c-axis. With recently developed solvent-based growth method, we are able to probe the magneto-transport of Te in its 2D limit, coined as tellurene. In this work, we demonstrate an effective dielectric doping technique to realize n-type tellurene. We report on the pronounced weak anti-localization, quantum Hall effect, strong Shubnikov-de Haas oscillations on n-doped tellurene with temperature down to tens of mK and magnetic fields up to 31 Tesla. Angle, electron density and temperature dependence of the oscillations were systematically measured and analyzed.

1:51PM L15.00014: Substrate Renormalization of Quasiparticle Band Gaps, Exciton Binding Energies and Transport Properties of Quasi-2D Materials

CHIN SHEN ONG (Presenter), FELIPE DA JORNADA, DIANA QIU, STEVEN G. LOUIE, Physics, University of California at Berkeley — Electrons in atomically thin quasi-2D materials, such as monolayer transition-metal dichalcogenides, are spatially confined in the out-of-plane direction and are also more weakly and differently screened than in bulk materials. Consequently, electron-electron and electron-hole interactions in quasi-2D materials are stronger and different compared to the bulk. Similarly, owing to the atomic dimension of layer thickness, quasi-2D materials are sensitive to screening environment produced by substrates, allowing one to dramatically tune their quasiparticle and optical properties. Here, we discuss a method recently developed in our group to incorporate substrate screening into the calculation of quasiparticle and optical properties of quasi-2D materials. We perform ab initio GW and GW-Bethe Salpeter equation (GW-BSE) calculations to quantify this effect on electronic and optical gaps of these systems. We will also discuss a theoretical upper bound of the screening effect. Lastly, we will show how substrate screening can be used to engineer a lateral heterojunction within homogeneous MoS₂ monolayer.

Multiscale Modeling of 2D Materials with the Phase-Field Crystal Model

TAPIO ALA-NISSILA

(Presenter), Applied Physics & Mathematical Sciences, Aalto and Loughborough University — Novel 2D materials have unusual properties, many of which are coupled to their large scale mechanical and structural properties. Modeling is a formidable challenge due to a wide span of length and time scales. I will review recent progress in structural multiscale modeling of 2D materials and thin heteroepitaxial overlayers [1], and graphene and h-BN [2,3], based on the Phase Field Crystal (PFC) model combined with Molecular Dynamics and Quantum Density Functional Theory. The PFC model allows one to reach diffusive time scales at the atomic scale, which facilitates quantitative characterisation of domain walls, dislocations, grain boundaries, and strain-driven self-organisation up to micron length scales. This allows one to study e.g. thermal conduction and electrical transport in realistic multi-grain systems [3,4].

11:15AM L16.00001: Unraveling correlation effects in water from microscopic response functions* [Invited] DEYU LU

(Invited) DEYU LU

(Presenter), Center for Functional Nanomaterials, Brookhaven National Laboratory — Electronic correlation effects play a crucial role in determining the structural and chemical properties of water. Over past decades, first-principles theory has been widely used to obtain physical insights of water and interpret experimental results. However, direct analysis of the electronic correlation in water from first principle is non-trivial, which motivates the development of new descriptors based on the microscopic response functions and formal methodologies to efficiently evaluate them. Recently, we have developed an ab initio local dielectric response theory [Phys. Rev. B 92, 241107, 2015] that partitions the microscopic electric susceptibility in real space based on the Wannier representation. Several applications of the local dielectric response theory are discussed. We demonstrate how to compute the molecular polarizability of water in the condensed phase and analyze the effects of the hydrogen-bonded network resulting from the crystal field and charge transfer. In another example, we studied the non-local correlation behaviors between water and solvated ions, and identified different screening characteristics of longitudinal and transverse modes.

*This research used resources of the Center for Functional Nanomaterials, which is a U.S. DOE Office of Science Facility at Brookhaven National Laboratory under Contract No. DE-SC0012704, and the National Energy Research Scientific Computing Center, a DOE Office of Science User Facility supported under Contract No. DE-AC02-05CH11231.

11:51AM L16.00002: Tracking holes and their reactivity in photon-driven reactions using Real-Time Time-Dependent Density Functional Theory (RT-TDDFT)* VIDUSHI SHARMA (Presenter), MARIVI FERNANDEZ SERRA, Department of Physics and Astronomy, and Institute for Advanced Computational Science, Stony Brook University — Photocatalytic reactions on semiconductor surfaces that produce hydrogen have the potential of addressing our growing energy needs. However, the possible reaction intermediates and trajectories associated with such photon-driven reactions are currently not well understood. Our aim is to study the response of molecular systems upon photoexcitation. We are particularly interested in the evolution of a system on the excited-state potential energy surface and the interaction of the molecular intermediates with its surroundings after excitation which leads to the desired reaction. We use ab initio nonadiabatic simulations to study the time evolution of photoexcited states, and we simulate the coupled electron-ion dynamics using RT-TDDFT-based Ehrenfest dynamics. This is a promising nonadiabatic dynamics scheme given the considerable sizes of the molecular systems of interest. We compare the ultrafast dynamics of the "photogenerated-hole" as captured by RT-TDDFT Ehrenfest dynamics with the commonly used Born-Oppenheimer dynamics at similar time scales and identify the key physical characteristics that differentiate one from the other, thereby empirically testing a more computationally intensive nonadiabatic scheme for elucidating the physics of photoexcited systems.

Energy fluctuations in water: How are they coupled to protein dynamics and vice versa?*
SAUMYAK MUKHERJEE, SAYANTAN MONDAL, BIMAN BAGCHI (Presenter), Indian Institute of Science — The exotic properties of water have intrigued researchers over a long time. Aqueous solutions of complex biomolecules like proteins trigger further interest. Several theories address the complexity of protein-water interactions. Frauenfelder et al. hypothesized the solvent slaving of protein dynamics. In this work, for the first time, we propose a mechanistic pathway of such protein-water coupling. Using atomistic molecular dynamics simulations on five proteins, we find that water dipoles efficiently interact with polar groups at the protein core. The forces thus experienced are comparable to the forces of interaction with other protein atoms. We also find that the fluctuations in self-energy of protein are significantly anti-correlated to the fluctuations in protein-water interaction energy. This signifies a microscopic channel of energy flow between protein and water. This coupling is also manifested in the total energy spectrum of protein which shows bimodal $1/f$ noise characteristics. The additional slope in the spectrum shows signature of perturbation from water as shown by Ohmine et al.

Ohmine et al. Chem. Rev. 93, 2545 (1993)

Multiscale modeling of systems with confined electrolytes FRANCISCO SOLIS (Presenter), Arizona State University — Macroscopic models of physiological materials describe often tissues as passive homogeneous electric materials. At the mesoscopic level, these materials are typically composed of cells or other structures of similar scale which can be considered as confined electrolytes. Conduction and polarization of these structures can be effectively described by means of density functional theories. In this presentation it will be shown how computations for confined electrolytes can be used to build effective macroscopic models. In particular, we interpret the macroscopic conductivity and polarizability in terms of the properties of the confined electrolytes, analyzed by means of dissipative dynamics.

Salt Ion Transport Through Carbon Nanotubes: Insights from Polarizable Force Field-Based Molecular Dynamics Simulations RAHUL PRASANNA MISRA (Presenter), DANIEL BLANKSCHTEIN, Department of Chemical Engineering, Massachusetts Institute of Technology — Carbon Nanotubes (CNTs) which are cylindrical 1D allotropes of carbon are emerging as promising materials for membrane-based applications, including seawater desalination and osmotic power harvesting. For the rational design of CNTs in membrane-based applications, it is imperative to develop a fundamental understanding of the interactions of salt ions such as Na$^+$ and Cl$^-$ with the carbon atoms of CNTs. Given the large polarizability tensors of CNTs, salt ions inside CNTs can exert strong electric fields which can result in a significant polarization of the CNTs. Although the ion - CNT polarization energy is high (e.g., 27 kcal/mol inside a 0.8 nm diameter CNT) and makes the dominant contribution to the ion - CNT binding energy, previous MD simulation studies have neglected the polarization of CNTs in the presence of water molecules and salt ions. In this talk, we discuss our formulation of polarizable force fields parameterized using quantum chemical simulations which can self-consistently model the anisotropic polarizability tensors of CNTs, as well as reliably model water-CNT and ion-CNT interactions. Finally, by performing classical MD simulations with polarizable force fields, we carry out a comprehensive investigation of salt ion transport through 0.8 – 2 nm diameter CNTs.

Cation-specific effects on the attraction of anions to a hydrophobic surface TRAVIS DOUGLAS (Presenter), Department of Physics and Astronomy, Northwestern University, MIAOQI CHU, X-Ray Science Division, Argonne National Laboratory Advanced Photon Source, SANGJUN YOO, Department of Physics and Astronomy, Northwestern University, CHUNG-JONG YU, Pohang Accelerator Laboratory, Pohang University of Science and Technology, PULAK DUTTA, Department of Physics and Astronomy, Northwestern University — Halides such as bromide and iodide are known to accumulate near the free surface of an electrolyte solution. Solid hydrophobic surfaces in contact with water induce a density-depleted gap near the interface, creating a water density profile similar to the free surface. It is therefore possible that polarizable ions like halides are also attracted to hydrophobic surfaces, a notion that is supported by MD simulations. However, the buried solid-liquid interface is more difficult to access experimentally than the free surface of water and is thus much less studied. We present results of an x-ray reflectivity study of aqueous alkali metal-iodide solutions in contact with a hydrophobic self-assembled monolayer. A layer of enhanced anion density is observed at the SAM-water interface, but with an unexpected strong dependence on the cation present in the solution. This experiment attempts to provide insight into the less understood yet ubiquitous interactions between ions and real hydrophobic/non-polar materials, such as proteins and organic materials present in the atmosphere and soil.
coordinated by two G4 molecules and not in direct contact with TFSA− anions at a low concentration of the Li salt. The case of equimolar Li salt concentration, a positive correlation between the total coordination number of Li+ ions and the simulation to study the lithium bis(trifluoromethylsulfonyl)-amide (LiTFSA) and tetraglyme (G4) electrolyte system. For the oxidative stability, low vapor pressure, and non-flammability. Here we employ the first-principles molecular dynamics significantly increased probability of pairing between the Li-G4 complexes and TFSA− anions at the equimolar ratio could phase stability is clearly established. At the ground state of equimolar LiTFSA-G4 electrolyte, most of Li+ ions are

Materials Science, IKUTARO HAMADA, Department of Precision Science and Technology, Graduate School of Engineering, Osaka University — Glyme based electrolytes for rechargeable Li secondary batteries are of great interest, due to the high oxidative stability, low vapor pressure, and non-flammability. Here we employ the first-principles molecular dynamics simulation to study the lithium bis(trifluoromethylsulfonyl)-amide (LiTFSA) and tetraglyme (G4) electrolyte system. For the case of equimolar Li salt concentration, a positive correlation between the total coordination number of Li+ ions and the phase stability is clearly established. At the ground state of equimolar LiTFSA-G4 electrolyte, most of Li+ ions are coordinated to four O atoms of a curled G4 molecule and one O atom of a TFSA− anion. By contrast, Li+ ions prefer to be coordinated by two G4 molecules and not in direct contact with TFSA− anions at a low concentration of the Li salt. The significantly increased probability of pairing between the Li-G4 complexes and TFSA− anions at the equimolar ratio could be highly relevant to its ionic-liquid-like properties [1].

**1:03PM L16.00008: First-Principles Study of the Solvation Structure of Tetruglyme based Electrolytes** YANG SUN (Presenter), Global Research Center for Environment and Energy based on Nanomaterials Science (GREEN), National Institute for Materials Science, IKUTARO HAMADA, Department of Precision Science and Technology, Graduate School of Engineering, Osaka University — Glyme based electrolytes for rechargeable Li secondary batteries are of great interest, due to the high oxidative stability, low vapor pressure, and non-flammability. Here we employ the first-principles molecular dynamics simulation to study the lithium bis(trifluoromethylsulfonyl)-amide (LiTFSA) and tetraglyme (G4) electrolyte system. For the case of equimolar Li salt concentration, a positive correlation between the total coordination number of Li+ ions and the phase stability is clearly established. At the ground state of equimolar LiTFSA-G4 electrolyte, most of Li+ ions are coordinated to four O atoms of a curled G4 molecule and one O atom of a TFSA− anion. By contrast, Li+ ions prefer to be coordinated by two G4 molecules and not in direct contact with TFSA− anions at a low concentration of the Li salt. The significantly increased probability of pairing between the Li-G4 complexes and TFSA− anions at the equimolar ratio could be highly relevant to its ionic-liquid-like properties [1].

**1:15PM L16.00009: Ionic Structure in Highly-Concentrated Confined Electrolytes** NASIM ANOUSHEH (Presenter), Intelligent Systems Engineering, Indiana University Bloomington, FRANCISCO SOLIS, School of Mathematical and Natural Sciences, Arizona State University Glendale, VIKRAM JADHAO, Intelligent Systems Engineering, Indiana University Bloomington — Recent surface force measurements have shown that the effective force between mica surfaces does not decay as sharply as predicted by mean-field models such as the Debye-Huckel theory when the concentration of the confined electrolytes is high (around 2 M for NaCl). In other words, the interaction between charged surfaces is “under-screened” at high electrolyte concentrations. Motivated by these experiments, we use molecular dynamics simulations and strong coupling theory to extract the ionic structure in aqueous NaCl electrolytes confined by two interfaces. Ionic density profiles, effective force (pressure) between surfaces, and pair correlation functions are extracted for electrolytes confined between uncharged, charged, and polarizable interfaces at different concentrations (0.1 M to over 2 M). Effects of varying ion sizes, surface separation, and dielectric properties of the solvent are outlined. Simulation results are correlated with strong coupling theory calculations where “underscreening” behavior is associated with the formation of highly correlated groups of ions that act as individual entities.

**1:27PM L16.00010: Examining Electronic Excitations in Liquid Water under Proton and Photon Irradiation** CHRIS SHEPARD (Presenter), DILLON C. YOST, YI YAO, YOSUKE KANAI, University of North Carolina at Chapel Hill — Proton and Photon irradiation of liquid water is important in many areas of modern technology, including cancer beam therapies. However, understanding the molecular level details of induced electronic excitation has been elusive. Using real-time time-dependent density functional theory, we study the dynamics of electron excitation in liquid water through the propagation of maximally-localized Wannier functions (MLWFs). The MLWF dynamics provide a convenient “molecular orbital” picture of the electronic structure, to understand electronic excitation in terms of localized electrons. We examine the extent to which photo-excitation and electronic stopping excitation differ at the molecular level.

1:39PM L16.00011: TDDFT approach on laser field enhancement by carbon nanotube and photo-decomposition of water
Hong Zhang¹, Yoshiyuki Miyamoto², Xinlu Cheng¹, Angel Rubio³ ¹College of Physical Science and Technology, Sichuan University, Chengdu 610065, China   HONG ZHANG (Presenter), Physics, Sichuan University, China —
In this presentation, we discuss field enhancement of femtosecond laser by carbon nanotubes and application to accelerating water photo-decomposition. The real-time time-dependent density functional theory (TDDFT) was employed for simulating water photo-decomposition near (8,0) semiconducting carbon nanotube. A short pulse with full-width of half-maximum 10fs was considered. When optical field is perpendicular to the tube axis, we found significant laser field enhancement corresponding to laser-power enhancement by factor 2 with laser wavelength 800 nm, and by factor around 8 with wavelength 400 nm. The enhancement is due to polarizability and wall-curvature of carbon nanotube that helps to reduce threshold power for photo-decomposition of water.

1:51PM L16.00012: A Molecular Dynamics Study of Ion Separation and Water Purification Using Graphene/Carbon Nanotube Filter
SAMANEH RIKHTEHGARAN (Presenter), LUC T WILLE, Physics, Florida Atlantic University — Molecular dynamics (MD) simulations have been used to design a graphene carbon nanotube (CNT) filter with an efficiency greater than 90% to separate Na⁺ and Cl⁻ ions from water molecules. The results show that the magnitude of the charge density that covers the surface of the CNT can noticeably influence the performance of ion separation and water purification. Therefore, the ion separation is improved by increasing the magnitude of the surface charge density enormously. In addition, it is observed that the velocity of the piston can have a huge impact on the filter's performance. This work establishes an atomic-level understanding of the effects of graphene and nanostructures on desalination and can be helpful for designing new nanofilter.

2:03PM L16.00013: K-shell Core Electron Excitations in Electronic Stopping of Protons in Water from First Principles*
YI YAO (Presenter), DILLON C. YOST, YOSUKE KANAI, Department of Chemistry, University of North Carolina at Chapel Hill — Understanding the role of core electron excitations in liquid water under proton irradiation has become increasingly important due to the growing use of ion beams in radiation oncology as an alternative to the X/γ-ray photon radiation. Using a first-principles, non-equilibrium simulation approach based on real-time TDDFT, we accurately determine the electronic stopping power over a wide range of proton velocities. The result agrees with available experimental data and also with the SRIM model. Explicit treatment of the K-shell, 1s electrons of oxygen atoms in water was found to be necessary to accurately predict the electronic stopping power for large velocities. The simulations also reveal that excitations of K-shell core electrons influence the valence electron excitation itself, and the separate treatment of valence and core electron excitation is not satisfactory for large velocities.

*This work is supported by the National Science Foundation under Grants No. OAC-1740204. Computer time was provided by the INCITE program with resources of the Argonne Leadership Computing Facility, a DOE Office of Science User Facility supported under Contract DE-AC02– 06CH11357.

Session L17 DCOMP: Matter in Extreme Environments: Planetary Materials BCEC 156A - Thomas Duffy, Princeton University - Tag(s): Focus

11:15AM L17.00001: Material Properties of Super-Earths and mini-Neptunes* [Invited] DIANA VALENCIA (Presenter), University of Toronto — The most common planets in the galaxy are now known to be low-mass exoplanets that either are rocky, known as super-Earths or may have an incipient envelope, the so-called mini-Neptunes. As the data grows for measured masses and radius for these planets the types of questions that we aim to answer have moved from discovery to characterization. I will talk about synergies between the study of material properties in the PT regime of these planets and the inferences we are able to make now in terms of composition and structure.

*DV thanks the Natural Sciences and Engineering Research Council of Canada
**11:51 AM L17.00002: Ab initio study of water speciation in forsterite**  KOICHIRO UMEMOTO (Presenter), Earth-Life Science Institute, Tokyo Institute of Technology, TIAN QIN, Department of Earth Sciences, University of Minnesota, RENATA WENTZCOVITCH, Department of Applied Physics and Applied Mathematics, Columbia University — The Earth's interior contains 0.5 to 100 times of water on the Earth's surface based on different studies. Water or hydrogen (in hydroxyl form) can be stored as hydrous defects in nominally anhydrous minerals (NAMs) in the Earth's mantle. Although in modest concentrations, these defects change the physical properties of their hosts, including electrical conductivity and viscosity, properties that affect mantle processes such as convection. The most likely incorporation mechanism of hydrogen in mantle minerals is the substitution of Mg and Si cations by hydrogens. However, a long-standing debate remains concerning the relative thermodynamic stability of these defects. Using *ab initio* calculations we investigate the energetics of these defects, $(4H)^{\chi}$ Si and $(2H)^{\chi}$ Mg, in forsterite, the Mg end-member of olivine, the most abundant upper mantle phase. We address the role of vibrational free energy and lattice and internal defect configurational entropy in the relative stability of these defects. We conclude that entropic effects are key to the stabilization of the hydrous Mg defect, which should predominate over the hydrous Si defect at typical upper mantle conditions.

*NSF/EAR grant 1161023

**12:03 PM L17.00003: First-principles studies of oxidized carbon in water under extreme conditions**  NORE STOLTE, Department of Physics, Hong Kong University of Science and Technology, DING PAN (Presenter), Department of Physics and Department of Chemistry, Hong Kong University of Science and Technology — The properties of oxidized carbon and water mixtures at high pressure (HP) and high temperature (HT) are of great importance to the deep carbon cycle, which involves more than 90% of Earth's carbon and substantially impacts the carbon budget near Earth's surface. We studied CO$_2$ in supercritical water up to ~13 GPa and 1400 K using *ab initio* molecular dynamics, and found that while the major form of dissolved carbon is CO$_2$(aq) at ambient conditions, carbonic acid (H$_2$CO$_3$(aq)) can be more abundant than CO$_2$(aq) at HP-HT when the total mole fraction of carbon is below 40%. We investigated the aqueous reaction mechanisms of H$_2$CO$_3$(aq) formation and dissociation at HP-HT at the molecular scale. We will discuss the possible P-T range for the stability of H$_2$CO$_3$(aq). Our study suggests that H$_2$CO$_3$(aq) may be an important carbon transport host in the deep carbon cycle.

*The work is supported by the Alfred P. Sloan Foundation through the Deep Carbon Observatory, Hong Kong Research Grants Council (Project No. ECS-26305017), the National Natural Science Foundation of China (Project No. 11774072), and the Croucher Foundation through the Croucher Innovation Grant.

**12:15 PM L17.00004: First-principles prediction of new gas hydrates**  LEWIS CONWAY (Presenter), ANDREAS HERMANN, University of Edinburgh — Gas hydrates can form under low temperature and high pressure (~kbars) conditions and as a result occur naturally on Earth and within the solar system. They have applications in industry in storage and transport of gases. We explore computationally the stability of new gas hydrates, with a focus on the chiral water network S$_X$, the metastable ice structure ice XVII, associated with the C$_0$ hydrogen hydrate and the CO$_2$ HP-hydrate [1]. S$_X$ has been shown experimentally to be readily emptied [2]. Computationally, S$_X$ has been shown to form at least metastable hydrates with He, Ne and Ar [3]. Here we present a density functional theory (DFT) study of molecular N$_2$ and O$_2$ gas hydrates based on filled S$_X$ and analyse the phase evolution in the ground state, which shows a strong dependance on pressure and filling ratio. O$_2$ gas hydrate has the curious potential to form a magnetically ordered structure.

*UK Materials and Molecular Modelling Hub and the UK national HPC service, ARCHER, via the UKCP. EPSRC grants EP/P020194 (partial), EP/P022561/1 and EP/L015110/1 (studentship).
crystals, ammonia (\(\text{NH}_3\)) and ice (\(\text{H}_2\text{O}\)) by density functional theory calculations. We found that \(\text{NH}_3\) and He can form electrostatic energy under high pressure. In this work, we explore and show the reactivity of He with two molecular elements are usually quite inert to chemical reactions due to their closed shell configurations. He is the most stable noble gas since its ionization energy is almost twice as large as that of Xe. It was recently demonstrated that He could react with a large number of ionic compounds with unequal number of cations and anions due to the substantial change of the electrostatic interaction is the driving force for the He insertion under high pressure. In this work, we explore and show the reactivity of He with two molecular crystals, ammonia (\(\text{NH}_3\)) and ice (\(\text{H}_2\text{O}\)) by density functional theory calculations. We found that \(\text{NH}_3\) and He can form stable structure above 50 GPa with a \(\text{NH}_3\):He ratio of 1:1, while \(\text{H}_2\text{O}\) and He can form stable structure above 300 GPa with a \(\text{H}_2\text{O}:\text{He}\) ratio of 2:1. Although change of the electrostatic interaction is the driving force for the He insertion under high pressure, the mechanism is very different between ammonia and ice. This work extends the reactivity of He into a new area of molecular crystals, showing the richness of the chemistry of this most inert element in the periodic table. Since He, \(\text{NH}_3\) and \(\text{H}_2\text{O}\) are the major components of giant gas planets, the new chemistry revealed in our work is important for the understanding of the structure and the evolution of these planets.

**Predicted novel helium compounds under high pressure via CALYPSO**

HANYU LIU (Presenter), JURONG ZHANG, Innovation Center for Computational Physics Method and Software, College of Physics, Jilin university, YINWEI LI, School of Physics and Electronic Engineering, Jiangsu Normal University, JIAN LV, Innovation Center for Computational Physics Method and Software, College of Physics, Jilin university, YANSUN YAO, Department of Physics and Engineering Physics, University of Saskatchewan, XIAOLEI FENG, SIMON REDFERN, Department of Earth Sciences, University of Cambridge, Downing Street, Cambridge CB2 3EQ, CHANGFENG CHEN, Department of Physics, University of Nevada, Las Vegas, YANMING MA, Innovation Center for Computational Physics Method and Software, College of Physics, Jilin university — The knowledge of the structures that can exist in compounds containing helium is of interest for understanding the conditions where and if this inert element can form structures where closed shell electrons of helium can participate in bonding that is not describable exclusively by van der Waals interactions alone. In this work, we examine some mixtures of He and \(\text{H}_2\text{O}\), \(\text{N}_2\) or some minerals at high pressures using a first-principles structure searching method (CALYPSO). We find some thermodynamically stable structures under pressure. These mechanically and dynamically stable structures are found at pressures that are now becoming accessible to high-pressure technique. The present results offer insights for the understanding of the plausible reaction between helium with minerals in the Earth's or other exoplanetary interiors.

**Helium insertion reactions with ammonia and water under pressure**

YIHONG BAI (Presenter), Department of Physics, Beijing Normal University, ZHEN LIU, JORGE BOTANA, Beijing Computational Science Research Centre, DADONG YAN, Department of Physics, Beijing Normal University, HAI-QING LIN, Beijing Computational Science Research Centre, JIAN SUN, School of Physics and Collaborative Innovation Center of Advanced Microstructures, Nanjing University, CHRIS PICKARD, Department of Materials Science and Metallurgy, University of Cambridge, RICHARD NEEDS, Cavendish Laboratory, University of Cambridge, MAOSHENG MIAO, Department of Chemistry and Biochemistry, California State University Northridge — The noble gas elements are usually quite inert to chemical reactions due to their closed shell configurations. He is the most stable noble gas since its ionization energy is almost twice as large as that of Xe. It was recently demonstrated that He could react with a large number of ionic compounds with unequal number of cations and anions due to the substantial change of the electrostatic energy under high pressure. In this work, we explore and show the reactivity of He with two molecular crystals, ammonia (\(\text{NH}_3\)) and ice (\(\text{H}_2\text{O}\)) by density functional theory calculations. We found that \(\text{NH}_3\) and He can form stable structure above 50 GPa with a \(\text{NH}_3\):He ratio of 1:1, while \(\text{H}_2\text{O}\) and He can form stable structure above 300 GPa with a \(\text{H}_2\text{O}:\text{He}\) ratio of 2:1. Although change of the electrostatic interaction is the driving force for the He insertion under high pressure, the mechanism is very different between ammonia and ice. This work extends the reactivity of He into a new area of molecular crystals, showing the richness of the chemistry of this most inert element in the periodic table. Since He, \(\text{NH}_3\) and \(\text{H}_2\text{O}\) are the major components of giant gas planets, the new chemistry revealed in our work is important for the understanding of the structure and the evolution of these planets.

**Helium reaction with sodium halides under pressure**

ZHENG LIU (Presenter), Division of Simulation of Physical Systems, Beijing Computational Research Center, YIHONG BAI, Department of Physics, Beijing Normal University, ORTEGA FERNANDO, Department of Chemistry and Biochemistry, California State University, Northridge, CHRIS PICKARD, Department of Materials Science and Metallurgy, University of Cambridge, DADONG YAN, Department of Physics, Beijing Normal University, HAI-QING LIN, Division of Simulation of Physical Systems, Beijing Computational Research Center, MAOSHENG MIAO, Department of Chemistry and Biochemistry, California State University, Northridge — The noble gas elements are usually quite inert to chemical reactions due to their closed shell configurations. He is the most stable noble gas since its ionization energy is almost twice as large as that of Xe. It was recently demonstrated that He could react with a large number of ionic compounds with unequal number of cations and anions due to the substantial change of the electrostatic energy under high pressure. Unexpectedly, we found in the current work that He can react with NaX (X=Cl, Br, I) under high pressure also with considerable formation energy. The pressure needs to form stable NaXHe compounds decreases with increasing size of the halogen atoms. By analyzing the enthalpy components, the geometry change, and the electronic structures, we find the driving force of the He insertion reaction with AB type compound is the transformation of the structures that disproportionate the interstitial sites, making them ready to accommodate He atoms under high pressure. With the previous work, we greatly extend the reactivity of He with compounds under high pressure.

*We thank the computational resources from Beijing CSRC, National Natural Science Foundation of China (NSFC) for the grants under Nos. 21434001 and 21374011, and China Postdoctoral Science Foundation (No. 2018M630064).
1:03PM L17.00008: Phase relations in δ-AlOOH investigated with ab-initio calculations  
TIANQI WAN, ZIYU CAI, CHENXING LUO (Presenter), Department of Applied Physics and Applied Mathematics, Columbia University in the City of New York, TIAN QIN, Department of Earth Sciences, University of Minnesota, RENATA WENTZCOVITCH, Department of Applied Physics and Applied Mathematics, Columbia University in the City of New York — As a high-pressure phase of diaspore and boehmite, δ-AlOOH is a crucial hydrous phase that can transport water in subducted slabs to the Earth's interior. Knowledge of phase relations in AlOOH is vital to understanding the state of water and the mechanisms of water transportation to the deep mantle. Most previous theoretical studies focused on the low-pressure static behavior of δ-AlOOH, leaving not only issues such as hydrogen-bond symmetrization under pressure unresolved but also high-temperature high-pressure phase boundaries not fully discussed. Recent experiments [1] show that the stability field of δ-AlOOH covers the entire pressure range of the Earth's lower mantle and this phase could remain stable in colder slabs down to the core-mantle boundary. We present an ab initio study of the structural and thermodynamic stability of δ-AlOOH and its related polymorphs to multi-Mbar pressures. We address hydrogen-bond symmetrization in AlOOH and the phase boundaries between its well-known phases. Moreover, we are also interested in assessing the dehydration boundary up to pressures exceeding those of the Earth's mantle as well as the possibility of alternative polymorphs at pressures relevant to terrestrial exoplanets.

1:15PM L17.00009: Proton dynamics in high-pressure ice-VII from density functional theory*  
FLORIAN TRYBEL (Presenter), GERD STEINLE-NEUMANN, THOMAS MEIER, Bavarian Research Institute of Experimental Geochemistry and Geophysics (BGI) — Recent Nuclear Magnetic Resonance (NMR) data on high-pressure ice-VII (Meier et al., Nature Comm., 2018) have revealed significant mobility of protons in the pressure range of 20-95 GPa at room temperature. Using a density-functional-theory-based approach, we explore the compression-dependent proton dynamics in ice-VII by directly sampling the proton potential along the diagonal O-O direction in the disordered body centered cubic configuration. We describe a configuration showing a double-well potential with a barrier that permits tunneling at compressions corresponding to 20 GPa. The double-well character disappears near 45 GPa, but a broad minimum indicates significant proton mobility to persist to 95 GPa. Tunneling frequencies are computed using the approximation of Wentzel, Kramers and Brillouin, with frequencies in the THz range.

1:27PM L17.00010: Role of hydrogen bonding in the phase transformation of bulk liquid water to ice VII under shock loading*  
NILANJAN MITRA (Presenter), DIPAK PRASAD, Indian Institute of Technology Kharagpur — It has been widely reported both through experimental and theoretical investigations that bulk liquid water under shock loading partially transforms into Ice VII – one of the densest forms of ice. It is also known from literature that hydrogen bonding plays the main role in conversion of random arrangement of water molecules in bulk liquid water to that of periodic crystalline arrangement of ice in the event of conventional freezing. Thereby, it can be quite anticipated that the hydrogen bond plays the main role in phase transformation of bulk liquid water to that of ice VII on shock compression. The current manuscript describes the changes in the spectra of water in the 0-1000 cm^{-1} wavenumber regimes as bulk water is shock compressed to form ice VII. The molecular dynamic simulations carried out for this study also compares between different commonly used force potentials that are used to define water.

First-principles modelling of hydrogen-rich planetary materials

ANDREAS HERMANN

Accurate models of the interior structure of planetary bodies, in our or other solar systems, are key to understanding their formation, their evolution to the present day, and many of their properties. The stratification (or lack thereof) of molecular mixtures inside icy planets’ mantles influences their luminosity and cooling rates; and the presence (or not) of water stored inside rocky planets’ mantles influences their convection rates, the magnitude of plate tectonics and presence of surface water. In my talk I will give an overview of our ongoing research aimed at a better understanding of planetary materials using electronic structure calculations, focussing on hydrogen-containing systems on several different pressure scales. For molecular gas hydrates stabilized in the kbar range, crucial in the formation of icy moons and planets, I will show how wave-function based calculations can overcome density functionals’ ambiguities in capturing weak host-guest interactions [1]. For hydrous minerals, which store water inside Earth’s mantle in the GPa range, I will illustrate how crystal structure prediction methodology can help develop a more complete picture on their formation and internal phase transformations [2]. Lastly, I will discuss the properties of mixtures of planetary ices at conditions found in the mantle of Neptune-like bodies, at pressures beyond 1 Mbar and high temperatures [3,4].

Funding from the UK’s EPSRC (EP/L015110/1) and computational resources provided through the UKCP consortium (EP/P022561/1), the UK Materials and Molecular Modelling Hub (EP/P020194) and the Royal Society (RG-150247) are gratefully acknowledged.

Session L18 DCOMP: Quantum Manybody Systems: Theory and Computation I

Entanglement Entropy from Nonequilibrium Work

JONATHAN D’EMIDIO

The Rényi entanglement entropy of quantum many-body systems can be viewed as the difference in free energy of partition functions with different trace topologies. We introduce an external field that controls the partition function topology, allowing us to define a notion of nonequilibrium work as is varied smoothly. Nonequilibrium fluctuation theorems of the work provide us with statistically exact estimates of the Rényi entanglement entropy. We put these ideas to use in the context of quantum Monte Carlo simulations of SU(N) symmetric spin models in one and two dimensions. In both cases we detect logarithmic violations to the area law with high precision, allowing us to extract the central charge for the critical 1D models and the number of Goldstone modes for the magnetically ordered 2D models.

Entanglement Entropy and Negativity in Inhomogeneous (1+1)D Systems: The Rainbow Chain, the SSD and their Holographic Dual

IAN MACCORMACK

Starting with a system described by a conformal field theory (e.g. a critical spin chain or free fermions), one can find interesting violations to the typical logarithmic behavior of the bipartite entanglement entropy by introducing an inhomogeneous kinetic term in the Hamiltonian. Two examples of recent interest are the rainbow chain and the sine-squared deformed (SSD) model. Such systems can be equivalently described by placing the original CFT on a curved background manifold. Using the AdS/CFT correspondence, we develop a holographic dual description of inhomogeneous (1+1) dimensional systems by foliating the bulk spacetime with curved surfaces. Extending these foliations to the BTZ spacetime allows us to describe inhomogeneous systems at finite temperatures. Using field-theoretic, holographic, and numerical techniques, we are able to compute the entanglement entropy and negativity, for various configurations of intervals, both at zero and finite temperatures, for the rainbow chain and the SSD.

11:39AM L18.00003: Crossover Behavior of Entanglement Entropy for Energy Eigenstates of 1d and 2d Fermionic Systems  QIANG MIAO (Presenter), THOMAS BARTHEL, Physics Department, Duke University — The entanglement entropy in ground states of typical condensed matter systems obeys the area law or a log-area law for critical systems. Subsystem entropies in random and thermal states obey a volume law. Here, we discuss the distribution of entanglement entropy in energy eigenstates of quasi-free fermionic systems as a function of energy and subsystem size. Numerical results are obtained with a Monte Carlo approach. We characterize the crossover behavior from the area or log-area law in the vicinity of the ground state and for small subsystem size to the volume law at higher energy and larger subsystem size. The coefficients of the volume law scaling can be matched to entropy densities in equilibrium thermal ensembles. For critical 1d systems at low energies, the universal crossover function matches the prediction from 1+1d conformal field theory for systems at nonzero temperatures. For 2d systems, we find a similar crossover behavior.

11:51AM L18.00004: Relating different localization lengths via non-perturbative construction of local integrals of motion in the many-body localized phase  PAI PENG (Presenter), XUAN WEI, ZEYANG LI, HAOXIONG YAN, PAOLA CAPPELLARO, Massachusetts Institute of Technology — Many-body localization (MBL) is characterized by the absence of thermalization and the violation of conventional thermodynamics. The phenomenological model, which describes the system using a complete set of local integrals of motion (LIOMs), provides a powerful tool to understand MBL. We explicitly compute a complete set of LIOMs non-perturbatively by maximizing the overlap between LIOMs and physical spin operators. This method enables a direct mapping from real space Hamiltonian to the phenomenological model. We demonstrate the exponential decay of weight of LIOMs in real-space and interaction strength of LIOMs in range. We further compare the localization lengths extracted from LIOMs, their interactions and dynamics. Our scheme is immune to accidental resonances and can be applied even at the phase transition point, providing a novel tool to study the microscopic features of the phenomenological model of MBL.

12:03PM L18.00005: A numerical procedure for non-integrable many-body quantum systems*  PAVAN HOSUR (Presenter), University of Houston — Numerical computations of properties of quantum many-body systems generally get drastically simplified by the presence of conserved quantities. Non-integrable quantum systems are those that lack, or have very few, conserved quantities and hence, are invariably intractable numerically. However, the eigenstate thermalization hypothesis postulates certain properties that non-integrable quantum systems must have and so far, computations on small systems have validated these properties. In this talk, a numerical procedure will be described that exploits the eigenstate thermalization hypothesis to discard, at the outset, vast amounts of useless quantum information and extract useful information about a non-integrable system more efficiently. The utility of the algorithm will be demonstrated via comparisons with exact diagonalization studies on prototypical non-integrable models.

12:15PM L18.00006: Product Spectrum Approximation  JOHN MARTYN (Presenter), BRIAN SWINGLE, University of Maryland, College Park — Calculating the physical properties of quantum thermal states is a difficult problem for classical computers, rendering it intractable for most quantum many-body systems. To address this problem, we propose a variational scheme to prepare approximate thermal states on a quantum computer by applying a series of two-qubit gates to a product state. We apply our method to a non-integrable region of the mixed field Ising chain and the Sachdev-Ye-Kitaev model. We demonstrate how our method can be easily extended to large systems governed by local Hamiltonians and the preparation of thermofield double states. By comparing our results with exact solutions, we find that our construction enables the efficient preparation of approximate thermal states on quantum devices. Our results imply that the details of the many-body energy spectrum are not needed to capture simple thermal observables.

12:27PM L18.00007: Non-Markovian Quantum Dynamics via General Quantum Master Equation and Tensor Networks*  ERIKA YE (Presenter), AUSTIN MINNICH, GARNET CHAN, Caltech — Computing real-time dynamics of a quantum many-body system is challenging due to the exponential growth of entanglement. While many different approaches have been investigated, how to compute the real-time dynamics of generic condensed matter systems, or how to best classify for which systems the dynamics cannot feasibly be computed on a classical computer, remain open questions. In this work, we treat the Nakajima-Zwanzig general quantum master equation with tensor network methods to identify the limits of classical time evolution algorithms. Though the memory kernel is difficult to compute even numerically, tensor networks provide a systematic means of obtaining the kernel for diverse complex systems, such as the spin-boson model with anharmonic bath sites. In this work we focus on the spin-boson model and analyze how the types and strengths of interactions affect the lifetime of the memory kernel. Our work provides general insight into the classical simulatability of quantum dynamics.

*2018 Google PhD Fellowship
12:39PM L18.00008: Collective Excitations in a Landau-Majorana Liquid  
JOSHUAH HEATH (Presenter), KEVIN BEDELL, Boston College — Landau-Fermi liquid theory is one of the foundational theories of interacting many-body fermions. Its simplicity has led to its continued application to real materials, and the rare instances where it fails (e.g., the case of a non-Fermi liquid) have become a major concern in the condensed matter community. In this study, we apply the formalism of Landau-Fermi liquid theory to describe a quantum liquid of interacting Majorana fermions. As opposed to Majorana zero modes, which characterize topologically non-trivial materials and obey anyonic statistics, Majorana fermions are spin-1/2 particles that experience mutual pairwise annihilation. Drawing on a previous work (arXiv:1709.04483), we describe the quasiparticles in such a system and construct the Landau-Silin kinetic equation. The presence of a robust Fermi surface in the screened Majorana system leads to a Lifshitz transition in the limit of large driving frequency. In addition, a calculation of the zero sound leads to the presence of an enhanced stability of the Landau-Majorana liquid against Pomeranchuk instabilities. These results lead to important differences in the fundamental physics of interacting Majorana fermion ensembles that has potential applications in various condensed matter systems and astrophysical phenomena.

12:51PM L18.00009: Divergences of the irreducible vertex functions in correlated metallic systems: Insights from the Anderson Impurity Model  
PATRICK CHALUPA (Presenter), PATRIK GUNACKER, TU Wien, THOMAS SCHAEFER, College de France, KARSTEN HELD, ALESSANDRO TOSCHI, TU Wien — We analyze the occurrence of divergences in the irreducible vertex functions of the Anderson impurity model (AIM) [1]. These divergences — a surprising hallmark of the breakdown of many-electron perturbation theory [2] — have been recently observed [3,4] in several contexts, including the dynamical mean-field solution of the Hubbard model. Hitherto, however, a clarification of their origin could be obtained only in the limit of high temperatures and/or large interactions, where the underlying physics is greatly simplified by the absence of low-energy quasiparticle excitations. In this respect, our numerical calculations for the AIM, as well as their comparison with the corresponding results for the Hubbard model, allow us to clarify several open questions about the origin and the properties of vertex divergences occurring in a more interesting context, the correlated metallic regime at low-temperatures.

1:03PM L18.00010: Kondo impurities at the edges of a quantum wire*  
PARAMESHWAR PASNOORI (Presenter), Physics, Rutgers University, COLIN RYLANDS, Joint Quantum Institute, University of Maryland, NATAN ANDREI, Physics, Rutgers University — Quantum impurity systems, where a localized impurity is coupled to a large bath of particles appear naturally in many fields from mesoscopic physics and quantum dot systems to the Kondo lattice of Heavy fermion materials. In this talk we study a miniature Kondo lattice consisting of a one dimensional quantum wire coupled to Kondo impurities at either end. We show that it is exactly solvable by means of Bethe Ansatz for arbitrary values of bulk spin exchange interaction and of the Kondo coupling. The model exhibits both gapped and gapless phases depending on the sign of the bulk interaction and a competition between dynamical mass generation and the Kondo effect. We construct the ground state in all regimes and study the excitations and their finite size corrections as well as the impurity magnetization as function of an applied field.

Dynamics of Densities and Currents in Spin Ladders

JONAS RICHTER (Presenter), Department of Physics, University of Osnabrück, FENGPING JIN, Institute for Advanced Simulation, Forschungszentrum Jülich, LARS KNIPSCHILD, Department of Physics, University of Osnabrück, JACEK HERBRYCH, Department of Physics and Astronomy, The University of Tennessee, HANS DE RAEDT, Zernike Institute for Advanced Materials, University of Groningen, KRISTEL MICHIELSEN, Institute for Advanced Simulation, Forschungszentrum Jülich, JOCHEN GEMMER, ROBIN STEINIGEWEG, Department of Physics, University of Osnabrück — The impact of integrability or nonintegrability on the dynamics of isolated quantum systems is a longstanding issue. For integrable models, a macroscopic set of (quasi)local conservation laws can lead to partially conserved currents and ballistic transport. In generic situations, however, integrability is lifted due to various perturbations and currents are expected to decay. Still, since the dynamics of interacting quantum many-body systems poses a formidable challenge to theory and numerics, it remains open whether nonintegrability as such already implies the emergence of diffusion.

In this context, we study the dynamics of spin and energy in the two-leg spin-1/2 ladder with up to 40 lattice sites, using an efficient pure-state approach based on the concept of typicality. We discuss correlation functions in real and momentum space, and in the time and frequency domain, providing a comprehensive picture of high-temperature dynamics in this archetypal nonintegrable quantum model. Particularly, we unveil the occurrence of diffusion for both spin and energy.

Semiclassical echo dynamics in the Sachdev-Ye-Kitaev model

MARKUS SCHMITT (Presenter), University of California, Berkeley, DRIES SELS, Harvard University, STEFAN KEHREIN, Georg-August-Universität Göttingen, ANATOLI S POLKOVNIKOV, Boston University — The existence of a quantum butterfly effect in the form of exponential sensitivity to small perturbations has been under debate for a long time. Lately, this question gained increased interest due to the proposal to probe chaotic dynamics and scrambling using out-of-time-order correlators. In this work we study echo dynamics in the Sachdev-Ye-Kitaev model under effective time reversal in a semiclassical approach. We demonstrate that small imperfections introduced in the time-reversal procedure result in an exponential divergence from the perfect echo, which allows to identify a Lyapunov exponent \( \lambda \). In particular, we find that \( \lambda \) is twice the Lyapunov exponent of the semiclassical equations of motion. This behavior is attributed to the growth of an out-of-time-order double commutator that resembles an out-of-time-order correlator.

This talk is based on arXiv:1802.06796.

Generalized Hydrodynamics Revisited

JAMES DUFTY (Presenter), JEFFREY WRIGHTON, KAI LUO, Physics, University of Florida — A number of attempts to formulate a continuum description of complex states have been proposed to circumvent more cumbersome many-body and simulation methods. Typically these have been quantum systems and the resulting phenomenologies frequently called “quantum hydrodynamics”. This objective is placed in a formally controlled context using the exact macroscopic conservation laws for number density, energy density, and momentum density, together with standard tools of non-equilibrium statistical mechanics. These continuum equations entail perfect fluid fluxes that are functional of the chosen fields, plus unknown irreversible energy and momentum fluxes. Typically, the latter are obtained from a solution to the Liouville-von Neumann equation for small space and time variations. Instead, here we avoid that restriction by requiring that the unknown irreversible fluxes deliver the exact linear response functions for the fields. In this way, a non-linear generalized hydrodynamic description is obtained, valid across a broad range of length and time scales. The example of electrons in a given ion configuration is described to make contact with current phenomenological "quantum hydrodynamics".

*Research supported by US DOE Grant DE-SC0002139
1:51PM L18.00014: Quantum Fluid Dynamics (QFD) or Bohmian Representation of Schrödinger Equation with Navier–Stokes Type Dissipation Attila Askar Koc University, Sariyer, Istanbul 34450, Turkey  
(Presenter), Koc University — The Quantum Fluid Dynamics (QFD) representation has its foundations in the works of Madelung, De Broglie and Bohm. It is an interpretation of quantum mechanics with the goal to find classically identifiable dynamical variables at the sub-particle level. The approach is partly motivated by Einstein's questioning of the completeness of the quantum theory. Einstein expected the complete theory to have nonlinearity and admit solutions with "particle" nature, similar to solitons in contemporary terminology.

The QFD approach leads to two conservation laws, for "mass" and "momentum", similar to those in fluid-dynamics for a compressible fluid as a set of nonlinear partial differential equations. The QFD formalism is utilized advantageously for solving the time dependent Schrödinger equation for scattering problems.

This paper extends the QFD formalism to include dissipation in the form of Navier–Stokes term in classical fluid dynamics. The introduction of dissipation in the Navier–Stokes sense transform the differential equations from hyperbolic to parabolic type, with nonlinear and dispersive terms. These offer a natural framework for fundamentally new phenomena, in particular possibility of dissipation in quantum mechanics, solitons, vortices and chaos.

Wednesday, March 6, 2019 11:15 AM - 2:03 PM

Session L19 DCMP DAMOP DCMP: Precision Many Body Physics VIII  
BCEC 156C - Olga Goulko, Boise State University

11:15AM L19.00001: Entanglement production and information scrambling in a noisy spin system*  
MICHAEL KNAP (Presenter), Department of Physics, Technical University of Munich — We study theoretically entanglement and operator growth in a spin system coupled to an environment, which is modeled with classical dephasing noise. Using exact numerical simulations we show that the entanglement growth and its fluctuations are described by the Kardar-Parisi-Zhang equation. Moreover, we find that the wavefront in the out-of-time ordered correlator (OTOC), which is a measure for the operator growth, propagates linearly with the butterfly velocity and broadens diffusively with a diffusion constant that is larger than the one of spin transport. The obtained entanglement velocity is smaller than the butterfly velocity for finite noise strength, yet both of them are strongly suppressed by the noise. We calculate perturbatively how the effective time scales depend on the noise strength, both for uncorrelated Markovian and for correlated non-Markovian noise.

*We acknowledge support from the Technical University of Munich - Institute for Advanced Study, funded by the German Excellence Initiative and the European Union FP7 under grant agreement 291763, from the DFG grant No. KN 1254/1-1, and DFG TRR80 (Project F8).

11:51AM L19.00002: Real time correlations and spectral functions in numerical linked-cluster expansions*  
EHSAN KHATAMI (Presenter), San Jose State University — Highly precise static properties of strongly correlated fermions at finite temperatures from numerical linked-cluster expansions have been widely used to characterize systems of ultracold atoms in optical lattices. Here, I will discuss how dynamical properties such as various spectral functions of quantum lattice models can be obtained using the method through real time, as opposed to imaginary time, correlation functions at temperatures relevant to current optical lattice experiments. Nichols et al., arXiv:1802.10018

*I acknowledge support from the NSF under Grant No. DMR-1609560.
Interplay of disorder and strong correlations in quantum many-body systems remains an open question despite much progress that has been made in recent years with ultracold atoms in optical lattices to better understand phenomena such as many-body localization or the effect of disorder on Mott metal-insulator transitions. Here we utilize the numerical linked-cluster expansion technique, extended to deal with disordered quantum lattice models in the thermodynamic limit, and study exact thermodynamic properties of the disordered Fermi-Hubbard model on the square lattice. We consider box distributions for the disorder in the hopping amplitude as well as in the onsite energy or the interaction strength and explore how the system properties evolve as the strength of the disorder changes. We compare our results with those obtained from determinant quantum Monte Carlo simulations on finite clusters and discuss the potential applications of the results to experiments with cold fermionic atoms on optical lattices.

*This work is supported by the NSF under Grant No. DMR-1609560.

Computations are performed on the Spartan high-performance computing facility at San Jose State University provided by the NSF under Grant No. OAC-1626645.

Low-energy physics of the bilinear-biquadratic spin-1 chain

Moritz Binder (Presenter), Thomas Barthel, Duke University — The bilinear-biquadratic spin-1 chain features various interesting quantum phases, including the Haldane phase, a dimerized phase, and an extended critical phase. Here, we apply an efficient density matrix renormalization group (DMRG) algorithm utilizing infinite boundary conditions to compute precise dynamic spin structure factors for a comprehensive set of points in the phase diagram. Analyzing both dynamic spin and quadrupolar correlations, we gain detailed insights into the nature of low-lying excitations of the model. We compare our results to Bethe ansatz solutions at the SU(3)-symmetric ULS point and the TB point as well as at the pure biquadratic point, which can be mapped to an anisotropic spin-1/2 XXZ chain in the gapped Néel phase. In the Haldane phase, we relate our results to the approximate description in terms of the non-linear sigma model.
12:27 PM L19.00005: Ground states of a J-Q model with long-range antiferromagnetic interactions*  
SIBIN YANG (Presenter), Boston University, DAO-XIN YAO, Physics, Sun-Yat sen University, ANDERS W SANDVIK, Boston University — We employ large-scale sign-free quantum Monte Carlo and Lanczos exact diagonalization to study the 1D J-Q model (a Heisenberg antiferromagnet with multi-spin couplings added) with long-range interactions. Three phases, an ordered anti-ferromagnet (AFM), a quasi long-range ordered (QLRO state), and a valence bond solid (VBS), are identified by applying Binder-cumulant and level-crossing methods. We investigate different characteristics of these phases and their quantum phase transitions. From our numerical data and for the model we studied, the Binder-cumulant method has advantages in determining the quantum critical AFM-QLRO point and a certain range of the QLRO-VBS transition line, while the level crossing method is more suitable for the other region of QLRO-VBS transition. In addition, there could be a direct quantum phase transition between the AFM and VBS phases, possibly an analog of the 2D deconfined quantum critical point (DQCP) in one dimension.

*S.Y. and D.X.Y. are supported by Grants No. NKRDPC-2017YFA0206203 and No. NSFC-11574404; A.W.S. is supported by NSF DMR-1710170 and the Simons Foundations.

TIGRAN SEDRAKYAN (Presenter), University of Massachusetts Amherst, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, ALEX KAMENEV, University of Minnesota — We study the stability of ordered states in a two-dimensional quantum spin-1/2 J_1-J_2 XY antiferromagnet on a frustrated triangular lattice using composite fermion representation of spins. In the presence of next-nearest-neighbor antiferromagnetic coupling, J_2, the model is shown to undergo a continuous transition from 120° ordered state to a quantum U(1) Dirac spin-liquid (QED_3) at J_2/J_1 \sim 0.089, in accordance with previous variational Monte-Carlo and DMRG studies. In the XY limit, the U(1) gauge field emerges in a narrow parameter interval of 0.089 \lesssim J_2/J_1 \lesssim 0.116, that stabilizes the spin liquid. The transition to the tripe phase at J_2/J_1 \sim 0.116 is found to be of first order. Finite Ising interaction, J_z, pushes the boundaries of the phase transitions to 120° state and the stripe ordered state apart, thus opening a wider interval for the spin-liquid. Our results show an interesting interplay of ordering and the emergence of the gauge field in the vicinity of unconventional criticality.

12:51 PM L19.00007: Anomaly matching and symmetry-protected critical phases in SU(N) spin systems in 1+1 dimensions  
YUAN YAO, CHANG-TSE HSIEH (Presenter), MASAKI OSHIKAWA, Univ of Tokyo-Kashiwanoha — We study (1+1)-dimensional SU(N) spin systems in the presence of the global SU(N) rotation and lattice translation symmetries. By matching the mixed anomaly of the PSU(N)×Z in the continuum limit, we identify a topological index for spin model evaluated as the total number of Young-tableaux boxes of spins per unit cell modulo N, which characterizes the "ingappability" of the system. A nontrivial index implies either a ground-state degeneracy in a gapped phase, which can be regarded as a field-theory version of the Lieb-Schultz-Mattis theorem, or a restriction of the possible universality classes in a critical phase (symmetry-protected critical phase) -- only a class of SU(N) Wess-Zumino-Witten theories can be realized in the low-energy limit of the given lattice model in the presence of the symmetries. Similar constraints also apply when a higher global symmetry emerges in the model with a lower symmetry. Our prediction agrees with several examples known in previous studies of SU(N) models.

1:03 PM L19.00008: Efficient generation of many-body entangled states by multilevel oscillations  
PENG XU (Presenter), Wuhan University — We propose a fast method utilizing multilevel oscillations to generate high-fidelity massive entangled states in an antiferromagnetic spin-1 Bose-Einstein condensate (BEC). Combing the multilevel oscillations with additional adiabatic drives, we greatly shorten the necessary evolution time and relax the requirement on the control accuracy of quadratic Zeeman splitting, from micro-Gauss to milli-Gauss, for a 23Na spinor BEC. The achieved high fidelities over 96% show that two kinds of massively entangled states, the many-body singlet state and the twin-Fock state, are almost perfectly generated. The generalized spin squeezing parameter drops to a value far below the standard quantum limit even with the presence of particle number fluctuations and stray magnetic fields, illustrating the robustness of our protocol under real experimental conditions. The generated many-body entangled states can be employed to achieve the Heisenberg-limit quantum precision measurement and to attack nonclassical problems in quantum information science.
Efficient Two Dimensional Tensor Network Algorithms for Systems with Long-Range Interactions* MATTHEW O’ROURKE (Presenter), ZHENDONG LI, GARNET CHAN, California Institute of Technology — Current state-of-the-art tensor network algorithms in two dimensions, the most predominant being infinite projected entangled-pair states (iPEPS), have not yet advanced beyond the study of local lattice models. In order to utilize the power of these methods to study systems with physically realistic long-range interactions, we discuss a practical and efficient representation of the Hamiltonian of such systems as a projected entangled-pair operator (PEPO). We express the long-range interaction as a linear combination of correlation functions of an auxiliary system with only nearest neighbor interactions. This construction yields a long-range PEPO as a sum of ancillary PEPOs, each of small, constant bond dimension. Applications of this PEPO formulation to iPEPS simulations of model systems will be discussed.

Solving constrained counting problems with tensor networks STEFANOS KOURTIS (Presenter), Boston University — In this talk, I will present newly developed physics-inspired methods for the solution of counting constraint satisfaction problems (#CSPs). #CSP instances can be reformulated as models of interacting degrees of freedom, whose zero-temperature partition function represents the volume of the solution manifold. I will introduce practical methods to compute such partition functions based on tensor network contraction. In this formulation, computational complexity can be viewed as a manifestation of quantum entanglement, and controlling the growth of entanglement throughout tensor network contraction can yield a significant computation speedup. Using some hard counting problems as benchmarks, I will demonstrate that tensor network methods can be a useful tool for solving some hard classes of #CSPs. I will conclude with an outline of ongoing work on extensions of this framework.

Non-Abelian symmetries in thermal tensor network states* BIN-BIN CHEN (Presenter), Ludwig Maximillians University, Munich, Germany, WEI LI, Beihang University, ANDREAS WEICHSELBAUM, Brookhaven National Laboratory — The implementation of non-Abelian symmetries in the tensor networks greatly improves efficiency and thus also precision of quantum many-body simulations in quasi-1D systems. Here, in particular, we discuss our general implementation of the SU(2) spin together with U(1) charge symmetry based on the QSpace [1] tensor library in the recently developed thermal tensor network simulations including the series expansion thermal tensor network (SETTN) [2], and exponential thermal renormalization group (XTRG) [3]. We will also show benchmarks of the fermionic Hubbard model on both square and triangular lattice.

*This work is supported by the German Research Foundation, DFG WE4819/3-1.

Exponential Thermal Tensor Network Approach for Quantum Lattice Models ANDREAS WEICHSELBAUM (Presenter), Brookhaven National Laboratory, BIN-BIN CHEN, Ludwig Maximilians University, Munich, Germany, LEI CHEN, ZIYU CHEN, WEI LI, Beihang University, Beijing, China — We speed up thermal simulations of quantum many-body systems in one- (1D) and two-dimensional (2D) models in an exponential way by iteratively projecting the thermal density matrix ρ=e^{-βH} onto itself. We refer to this approach as the exponential tensor renormalization group (XTRG) [1]. It is in stark contrast to conventional Trotter-Suzuki-type methods which employ a linear quasi-continuous grid in inverse temperature β=1/T. By avoiding Trotterization altogether, XTRG can also deal with longer-range interactions in a straightforward algorithmic way. By construction, XTRG can reach exponentially low temperatures by a linear number of iterations, and thus not only saves computational time but also merits better accuracy due to significantly fewer truncation steps. More fine-grained temperature resolution can be achieved via simple interleaving of data sets. We work in an (effective) 1D setting exploiting matrix product operators (MPOs) which allows us to fully and uniquely implement non-Abelian and Abelian symmetries to greatly enhance numerical performance. We show exemplary XTRG results for Heisenberg models on 1D chains and 2D lattices with a finite temperature phase transition down to low temperatures approaching ground state properties. [1] Phys. Rev. X 8, 031082 (2018)
11:15AM L20.00001: Getting to the core of valence excitations from first principles* [invited] DAVID PRENDERGAST (Presenter), Molecular Foundry, Lawrence Berkeley National Laboratory — Excited-state processes in molecules, materials, and at interfaces can reveal intricate details of energy transfer between electronic and nuclear degrees of freedom: photo-induced chemistry, charge transfer, nonthermal melting, etc. Accurate theoretical methods can hypothesize on the ultrafast evolution of these excited states and advanced pump-probe characterization can reveal spectral signatures of the same, however, combining prediction and interpretation of ultrafast phenomena works best when we can simulate both pump and probe to directly connect experiment and theory. To this end, we focus on simulating core-level spectroscopy of ground and excited valence states from first principles. Valence excited states can be modeled in different ways, depending on the context, but here we focus on two approaches based on density functional theory (DFT): constrained-DFT and real-time time-dependent (TD) DFT. Core-excited states are generally modeled with Delta-SCF or linear-response TDDFT, and we outline our approach to combine valence and core excited states for direct interpretation of ultrafast X-ray and XUV probes. An abundance of local physical and chemical detail on valence excitations is evident through probing core-excitations, which we explore, atom by atom, in a predictive fashion.

11:51AM L20.00002: Ab Initio Simulation of Carrier Dynamics in Electric Fields in Bulk Semiconductors WILLIAM MCCORKINDALE (Presenter), Cavendish Laboratory, University of Cambridge, JIN-JIAN ZHOU, MARCO BERNARDI, Applied Physics and Materials Science, Caltech — Carrier dynamics in the presence of electric fields governs the performance of semiconductor devices. The carrier drift velocity as a function of electric field (so-called velocity-field curve) has been a key material property since the early days of semiconductor physics. Yet, velocity-field curves cannot be computed from first principles, and their simulation still relies on decade-old semiempirical Monte Carlo approaches. We present a first principles method for solving the Boltzmann Transport Equation (BTE) in the presence of electric fields, which allows us to accurately compute velocity-field curves. The approach extends an efficient scheme we recently developed to solve the BTE with ab initio electron-phonon scattering. Including the electric field is nontrivial – it makes the equations computationally ‘stiff’, a challenge we solve by developing an implicit numerical method to time-step the BTE. We demonstrate the stability of the algorithm, and simulate the relaxation of carriers to steady-state distributions in an electric field. Using GaAs as a case study, we obtain the first fully ab initio velocity-field curves, which correctly exhibit the Gunn effect (negative differential resistance at moderate E-fields) and the drift velocity saturation at high field.

12:03PM L20.00003: Ab Initio Radiative Lifetimes in Gallium Nitride VATSAL JHALANI (Presenter), Applied Physics and Materials Science, Caltech, HSIAO-YI CHEN, Physics, Caltech, MAURIZIA PALUMMO, Physics, University of Rome, Tor Vergata, MARCO BERNARDI, Applied Physics and Materials Science, Caltech — Wurtzite GaN is the primary semiconductor for efficient solid state lighting. The radiative recombination and excited carrier dynamics are challenging to measure in GaN due to the ultrafast (fs – ps) timescales at play and the presence of defects and interfaces in devices. Here, we present ab initio calculations of the radiative lifetime as a function of temperature in bulk GaN. We compute the exciton energies and wavefunctions using a combination density functional theory and GW-Bethe Salpeter equation (BSE) method. We derive an equation for the temperature dependent radiative lifetime for an anisotropic bulk crystal within the ab initio BSE framework. The radiative lifetimes in GaN obtained with this approach are in excellent agreement with experiment. We discuss the importance of including spin-orbit coupling, which, though weak in GaN, is essential to obtaining accurate radiative rates. Combined with our previous calculations of excited carrier relaxation in GaN [1], we can obtain from first principles key device parameters such as the hot carrier cooling time and the carrier diffusion lengths, with important technological implications.

12:15PM L20.00004: First-Principles Study of Hot Electron Dynamics on Silicon Quantum Dot-Molecule System*
JIAN CHENG WONG (Presenter), University of North Carolina at Chapel Hill, LESHENG LI, Princeton University, YOSUKE KANAI, University of North Carolina at Chapel Hill — Controlling hot carriers in nanomaterials is an active area of research, central to various optoelectronic applications. In our previous work¹, a short-lived hot electron transfer from a hydrogen-terminated Si(111) surface to the cyanidin molecule was observed during hot electron relaxation within the conduction manifold of the silicon, followed by interfacial electron transfer of picosecond timescale. We expand this study onto a silicon quantum dot attached to a cyanidin molecule to investigate the extent to which these observations change. Hot electron dynamics are investigated using first-principles simulation based on fewest switches surface hopping method combined with first-principles molecular dynamics and GW calculation.

12:27PM L20.00005: Rashba effect on spin-resolved carrier dynamics excited by circularly-polarized light from first-principles
SUSHANT KUMAR (Presenter), Rensselaer Polytechnic Institute, FENG WU, University of California, Santa Cruz, ADELA HABIB, Rensselaer Polytechnic Institute, YUAN PING, University of California, Santa Cruz, RAVISHANKAR SUNDARARAMAN, Rensselaer Polytechnic Institute — Recent optical pump/X-ray probe experiments have shown that circularly polarized light can be used to manipulate spin states in materials exhibiting strong Rashba splitting like organo-metallic halide perovskites (OMHPs) and transition metal dichalcogenides (TMDs). The ability to exploit the dynamics of spin makes these materials lucrative candidates for spin-optoelectronic applications [1]. While considerable experimental work has been performed on probing the spin dynamics in TMDs and OMHPs, efforts to model this ultrafast spin-dependent dynamics of charge carriers have so far been limited primarily to effective model Hamiltonians. A key challenge is accounting for electron-phonon scattering effects on the spin dynamics explicitly, due to the requirement of ultra-fine Brillouin-zone sampling arising from the disparate energy scales of electrons and phonons. We present a completely parameter-free ab initio approach to study spin and carrier dynamics, using Wannier functions to facilitate efficient calculation of electron-phonon scattering. Using this approach, we present calculations of spin-resolved photo-excited carrier distributions and phonon-assisted spin relaxation times for TMDs and ferroelectric oxides.

12:39PM L20.00006: Spin-dependent electron transfer dynamics: key role of bandstructure*
DANIEL SANCHEZ-PORTAL (Presenter), MORITZ MÜLLER, Centro de Física de Materiales CSIC-UPV/EHU and DIPC — We investigate theoretically the charge transfer dynamics of core-excited Ar on Co(001) and Fe(110). For these systems, recent core-hole-clock measurements [1] of the lifetime of the photo-excited 4s level of Ar⁺ have shown a clear dependence on the spin of the excited electron. Minority electrons decay significantly faster than majority electrons. We investigate such processes using Green's functions techniques on top of density functional theory calculations, explicitly including the effect of the coupling to the semi-infinite substrate [2, 3]. Our results agree with the observed behavior and allow analyzing in detail the origin of this phenomenon. The key ingredient is the spin-depence of the bandstructure of the substrate and, in particular, the different positions of the Ar⁺ 4s level within the projected band gap appearing around Gamma in the dispersive bands of Co(001) and Fe(110) for both spin channels. A simple model incorporating this effect successfully describes most of the observed phenomenology.

Ultrafast Excited State Dynamics of Coupled Carriers and Phonons from Ab Initio Calculations

XIAO TONG (Presenter), JIN-JIAN ZHOU, MARCO BERNARDI, Caltech — The out-of-equilibrium dynamics and equilibration processes of excited states in materials are crucial to understanding time-resolved spectroscopies. Several ultrafast phenomena occurring on a sub-picosecond time scale are governed by the coupled dynamics of electrons and atomic vibrations (phonons), including transient structural distortions and excited electron thermalization due to the competing electron-phonon (e-ph) and phonon-phonon (ph-ph) interactions. Here, we show ab initio calculations of the coupled ultrafast dynamics of carriers and phonons. We develop an efficient algorithm to time-step the coupled electron and phonon Boltzmann transport equations, which include both the e-ph and ph-ph scattering on the same footing. Our approach allows us to study the time evolution of the excited electron populations as well as the out-of-equilibrium phonons together with the transient structural distortions they induce. We apply our method to silicon and graphene, and compare the results with time-resolved spectroscopies probing both the structural and the electron dynamics, such as free-electron laser and time-resolved electron diffraction experiments.

Electron-defect interactions and low temperature carrier mobility from first principles

I-TE LU (Presenter), JIN-JIAN ZHOU, MARCO BERNARDI, Caltech — Electron-defect (e-d) interactions control charge and spin transport at low temperature and induce well-known conductance fluctuation and weak localization effects. While established ab initio methods and code exist for treating electron-phonon (e-ph) interactions, ab initio e-d calculations are still in their infancy, mainly due to the formidable computational cost of computing e-d matrix elements and self-energies from calculations on supercells containing the defect. In this talk, we formulate an efficient approach for computing e-d matrix elements using mainly unit cell quantities, and demonstrate its numerical implementation in the PERTURBO code. Using this approach, we can compute and systematically converge the e-d scattering rates for neutral defects such as vacancy and interstitial atom in silicon, and obtain the corresponding defect-limited low temperature mobility. The results deviate in important ways from broadly used empirical approaches to treat e-d interactions, highlighting the shortcomings of these simple models. Efforts on interpolating e-d matrix elements, computing higher-order e-d processes, and releasing the e-d routines in PERTURBO will be discussed.

Simulating Electron Beam – Materials Interactions with Real-Time Electron Dynamics*

JACEK JAKOWSKI (Presenter), DAVID LINGERFELT, PANCHAPAKESAN GANESH, BOBBY G SUMPTER, Oak Ridge National Laboratory — Time-dependent electron dynamics is used to model interaction of electron beam with materials for beam energy and positions relevant to scanning transmission electron microscopy. We investigate the real-time and linear response framework for simulating the response of small molecular systems including benzene and pyrene. The position dependence of selection rules for electron beam induced electronic excitations is discussed. Higher order terms in the multipolar expansion of the electrostatic potential are shown to contribute significantly to the energy loss probability except in the high impact parameter regime where the electric fields emanated by the electron beam are essentially homogeneous over the volume of the material. Results of this study have implications for the prediction of electron energy loss spectra from first principles, and can lead to a more complete understanding of mechanisms underlying both directed nanoscaled materials manipulations and accidental radiation damage sustained by materials subjected to electron beams with energies below the material’s knock-on threshold.

*This work was conducted at the Center for Nanophase Materials Sciences, a US Department of Energy Office of Science User Facility.
Coherent exciton-vibrational dynamics and energy transfer in conjugated organics

TAMMIE NELSON (Presenter), Los Alamos National Laboratory, DIANELYS ONDARSE-ALVAREZ, NICOLAS OLDANI, BEATRIZ HERNANDEZ, LAURA ALFONSO-HERNANDEZ, Universidad Nacional de Quilmes, JOHAN GALINDO, Universidad Nacional de Colombia, VALERIA D KLEIMAN, University of Florida, SEBASTIAN FERNANDEZ-ALBERTI, Universidad Nacional de Quilmes, ADRIAN E ROITBERG, University of Florida, SERGEI TRETIAK, Los Alamos National Laboratory — Excited state dynamics simulations reveal a ubiquitous pattern in the evolution of photoexcitations for a broad range of molecular systems. Symmetries of the wavefunctions define a specific form of the non-adiabatic coupling that drives quantum transitions between excited states, leading to a collective asymmetric vibrational excitation coupled to the electronic system. This promotes periodic oscillatory evolution of the wavefunctions, preserving specific phase and amplitude relations across the ensemble of trajectories. The simple model proposed here explains the appearance of coherent exciton-vibrational dynamics due to non-adiabatic transitions. We demonstrate universality of these phenomena by inspecting photo-induced dynamics in several common cases for organic conjugated materials. These include a linear oligomer, nano-hoop, tree-like dendrimer, and molecular dimer. In all these molecules, ultrafast dynamics and exciton transport is directly simulated using our atomistic nonadiabatic excited-state molecular dynamics (NEXMD) package. Coherent dynamics observed in these systems persists on the timescale of 100s of fs at room temperature and in the presence of a bath, which agrees with experimental spectroscopic reports on various materials.

Modification of excitation and charge transfer in cavity quantum-electrodynamical chemistry*

CHRISTIAN SCHÄFER (Presenter), MICHAEL RUGENTHALER, HEIKO APPEL, ANGEL RUBIO, Max-Planck Institute for the structure and dynamics of matter — Energy transfer in terms of excitation or charge is one of the most basic processes in nature and understanding and controlling them is one of the major challenges of modern quantum chemistry. In this work, we highlight that these processes as well as other chemical properties can be drastically altered by modifying the vacuum fluctuations of the electromagnetic field in a cavity. By using a real-space formulation from first principles that keeps all the electronic degrees of freedom in the model explicit and simulates changes in the environment by an effective photon mode, we can easily connect to well-known quantum-chemical results such as Dexter charge- and Förster excitation-transfer reactions taking into account the often disregarded Coulomb and self-polarization interaction. We find that the photonic degrees of freedom introduce extra electron-electron correlations over large distances, that the coupling to the cavity can drastically alter the characteristic charge-transfer as well as the excitation energy transfer behavior. Our results highlight that changing the photonic environment can redefine chemical processes, rendering polaritonic chemistry a promising approach towards the control of chemical reactions.

Non-equilibrium dynamics of spin and charge correlation in strongly correlated systems from pump-probe spectroscopy

CHEN-YEN LAI (Presenter), JIAN-XIN ZHU, Los Alamos National Laboratory — The ultrafast pump-probe techniques are used to probe the elementary excitations in materials. We study the non-equilibrium process of the one-dimensional extended Hubbard model under transient laser pump pulse. In non-polarized cases, the competition between charge and spin results in bond-order-wave between spin-density-wave and charge-density-wave phases in equilibrium. We focus on the regime near the phase boundaries and how those spin and charge correlations affected by different pump pulse frequency and strength. Furthermore, in the spin-polarized systems, the Bethe strings state emerges and the non-equilibrium dynamics of the fractional excitation are investigated. The effects from photoinduced charge carriers near the phase boundaries are investigated by time evolving black decimation. These effects should be measurable by time-resolved angle-resolved photoemission spectroscopy. (LA-UR-18-30001)
Ultrafast decay of low-symmetry photo-induced atomic forces.*

SHANE O’MAHONY (Presenter), JOSE QUERALES-FLORES, IVANA SAVIC, Materials Theory, Tyndall National Institute, ÉAMONN MURRAY, Department of Materials and Department of Physics, Imperial College London, FELIPE MURPHY-ARMANDO, STEPHEN B FAHY, Materials Theory, Tyndall National Institute — Generation and control of atomic forces in optically excited systems is crucial to understanding photocatalysis, renewable energy and laser annealing. Eg-symmetry coherent phonons are excited in group-V semimetals by ultrafast (<100 fs) optical pulses when the radiation is polarised perpendicular to the 3-fold symmetry axis of the crystal. The phonon driving force is consistent with an initially unbalanced occupation of electronic states in symmetry-equivalent regions of the Brillouin zone, which decays to fully-symmetric occupation of the zone on fs timescales. Measured temperature-dependence of the force decay time in Bi and Sb [1] suggests relaxation of the excited electronic distribution by electron-phonon (el-ph) scattering.

We calculate the decay of the Eg-symmetry driving force in Bi, Sb and As within the framework of density functional perturbation theory. We compute the initial excited electronic distribution [2], evolve using el-ph rate equations and calculate the atomic forces at each time-step. We obtain good agreement with experiment, showing that el-ph scattering is a dominant relaxation mechanism for the Eg force.

Session L21 DCOMP: Emerging Trends in Molecular Dynamics Simulations and Data Analytics II

11:15AM L21.00001: Overcoming the Time Limitation in Molecular Dynamics Simulation of Crystal Nucleation: A Persistent-Embryo Approach* [Invited] YANG SUN (Presenter), FENG ZHANG, HUAJING SONG, MIKHAIL MENDELEV, Ames Laboratory, ALEX TRAVESSET, Iowa State University, CAI-ZHUANG WANG, Ames Laboratory, KAI-MING HO, Iowa State University — The nucleation of a crystalline phase in liquid is a typical rare event and is usually inaccessible within the limited timescales of conventional molecular dynamics (MD) simulations under experimental conditions. In this talk, we present a “persistent embryo” method to facilitate crystal nucleation in MD simulations, in which a small crystal embryo is inserted into the liquid, with spring forces applied to keep the embryo from melting. The springs are gradually weakened as the embryo grows and are completed removed when the nucleus size remains significantly smaller than the critical size. In this way, one can observe the spontaneous fluctuations of a critical nucleus in an unbiased environment, without any assumptions on the shape of the critical nucleus. We applied this method to simulate crystal nucleation under realistic experimental conditions and obtained results that compare favorably with experiments and other simulation methods. We will show this accelerated dynamic approach provides ample statistics for the critical sampling of the nucleation.

*The work at Ames Laboratory was supported by the US Department of Energy, Basic Energy Sciences, Materials Science and Engineering Division, under Contract No. DEAC02-07CH11358, including a grant of computer time at the National Energy Research Supercomputing Center (NERSC) in Berkeley, CA.

11:51AM L21.00002: TBD [Invited] KLAUS-ROBERT MÜLLER (Presenter), Technical University of Berlin — tbd

12:27PM L21.00003: Cavitation in Water Induced by a SnO2 Nanoparticle and a Strong Electric Field* SHANE JACKSON (Presenter), AIICHIRO NAKANO, PRIYA VASHISHTA, RAJIV KALIA, Physics, University of Southern California — Molecular dynamic simulations are performed to examine the effect of an electric field on a system consisting of a SnO2 nanoparticle embedded in water under ambient conditions. Cavitation is observed in the presence of uniform electric fields ranging from 0.042 to 0.25 V/Angstrom in both the SPCE and the Hydrogen-Bonding Polarizable (HBP) force field models for water. Over at least one order of magnitude, the cavity onset time t is related to the electric field through the Kohlrausch-Williams-Watts form E(t) = E_0 exp(-(t/τ)^β), with b = d^*(d^* + 2) = 3/7, where d^* = d/2, d being the dimensionality of the system. The bubbles are found to rapidly collapse upon removal of the electric field. Results for the structure and dynamics of water along with the electric field distributions in the system will be presented.

* The work was supported by the grant DE-SC0018195 funded by the U.S. Department of Energy, Office of Science. Simulations were performed at the Center for High Performance Computing of the University of Southern California.
12:39PM L21.00004: Interaction Potential for Faceted Nanoparticles.  BRIAN LEE (Presenter), GAURAV ARYA, Duke University — There is a growing interest in studying the assembly of faceted nanocrystals due to the potential of such anisotropic particles to yield unconventional structures with unique electrical, optical, and mechanical properties. While the van der Waals (vdW) interactions between spherical particles can be well-described by analytical functions, no such closed-form expressions are available to describe the vdw interactions between faceted particles. This is especially problematic in molecular simulations of particle assembly, where exact descriptions of interparticle energies in terms of interatomic interactions become computationally prohibitive, requiring a polynomial time algorithm. In this work, we formulate analytical expressions for vdw interactions between faceted particle by taking advantage of available expressions for macroscopic body interactions and by converting the energy integration over the particles' bodies to integration over the particles' facets. We show that the expressions provide reasonably accurate descriptions of the position and orientation dependence of vdw interactions. Since this method is a constant time algorithm, O(1), it could improve the computational efficiency of simulating faceted particles by several orders of magnitude.

12:51PM L21.00005: Atomic Structure of Supported Metal Nano Clusters on MoS2 Monolayer Using Deep Potentials*  WISSAM SAIDI (Presenter), University of Pittsburgh, YONGLIANG SHI, University of Science and Technology of China, LINFENG ZHANG, Princeton University, HAN WANG, Institute and Applied Physics and Computational Mathematics, WEINAN E, Princeton University, JIN ZHAO, University of Science and Technology of China — In nanometer clusters (NCs), the specific arrangement of metal atoms determines the unique size-dependent functionalities of the NCs and hence their potential applications. Here we employ a combined approach utilizing a genetic algorithm and a deep potential (DP) to determine the lowest energy configurations of the NCs including metastable structures. The DP is trained using density functional theory calculations. We discuss the strengths and shortcomings of the DP approach compared to a standard method utilizing density functional theory calculations.

*This work is supported by National Science Foundation (DMR-1809085)

1:03PM L21.00006: Large-Scale Atomistic Simulations of Materials using SNAP Potentials*  AIDAN THOMPSON, MITCHELL A WOOD, MARY ALICE CUSENTINO (Presenter), Sandia National Laboratories — Molecular dynamics (MD) is a powerful materials simulation method whose accuracy is limited by the interatomic potential (IAP). SNAP is an automated quantum data-driven approach to IAP generation that balances accuracy and computational cost. The energy is formulated in terms of a very general set of geometric invariants that characterize the local neighborhood of each atom. The SNAP approach has been used to develop potentials for studying plasticity in tantalum, intrinsic defects in indium phosphide, and plasma surface interactions in tungsten and beryllium. In each case, large quantum-mechanical data sets of energy, force, and stress are accurately reproduced and cross-validation on additional test data is performed. The resultant potentials enable high-fidelity MD simulations with thousands to millions of atoms. The relatively large computational cost of SNAP is offset by the LAMMPS implementation, enabling the efficient use of large CPU and GPU clusters.

1:15PM L21.00007: A mean-field algorithm with decoherence and detailed balance for nonadiabatic molecular dynamics  JUN KANG (Presenter), LIN-WANG WANG, Lawrence Berkeley National Laboratory — Decoherence and detailed balance are two major issues for mixed quantum/classic nonadiabatic molecular dynamics (NAMD) simulations. In this work we introduce a new mean-field dynamics approach with decoherence and detailed balance (MF-DD) for NAMD. This method is able to explicitly treat the decoherence between different pairs of electronic states. Moreover, the energy-increasing and energy-decreasing electronic transitions are distinguished by dividing the density matrix into two parts. The detailed balance correction is then included by a Boltzmann factor applied to the energy-increasing transitions. The MF-DD is applied to study hot-hole cooling and transfer processes in Si quantum dot (QD) systems. The calculated hot carrier relaxation time is in consistent with experiments. In the QD-pair systems, the cooling time shows weak dependence with the QD spacing. However, the charge transfer rate between QDs is found to decreases exponentially as the QD spacing increases, which is attributed to the decreased state anticrossing strength. When the QD spacing is smaller than 1.1 nm, the hot-carrier transfer between two QDs can be quite efficient. It is also shown that the explicit treatment of decoherence time is important.
Multi-Resolution Simulations using the Integral Equation Coarse-Graining Method*

MOHAMMADHASAN DINPAJOOH (Presenter), MARINA GIUSEPPINA GUENZA, University of Oregon — We use the variable-level coarse-grained (CG) description of polymer melts to obtain the effective CG potentials (ECGPs) for multi-resolution simulations of pure polymer melts represented at various CG resolutions. Starting from the Integral Equation Coarse-Graining approach, we obtain the numerical and analytical ECGPs in the multi-resolution simulations that are different from the ECGPs in single-resolution simulations. Therefore, the composition, temperature, and density dependences of such ECGPs can be investigated. In particular, the ECGPs between the polymer melts, represented by $n_{ba}$ blobs, decay slowly with a long tail characteristic scaling exponent of $N_{ba}^{1/4}(\phi_\alpha + (\phi_\alpha - (n_{ba}/n_{b\beta})^3))^{1/4}$, where $\phi_\alpha$ is the volume mole fraction of species $\alpha$, $N_{ba}$ is the number of monomers in a given blob of type $\alpha$, and $\beta$ shows the other species. The ECGPs allow one to avoid any hybrid region in multi-resolution simulations while quantitatively producing the structural and thermodynamical properties of the related atomistic systems such as radial distribution function and pressure.

Development of a universal Electron Force Field*

ISIDRO LOSADA LÓPEZ (Presenter), Condensed Matter Physics, Autonomous University of Madrid, MICHELLE FRITZ, Slalom, Philadelphia, PAULA MORI-SANCHEZ, Chemistry, Autonomous University of Madrid, MARIVI FERNANDEZ SERRA, Department of Physics and Astronomy, Institute for Advance Computational Science, Stony Brook University, JOSE M SOLER, Condensed Matter Physics, Autonomous University of Madrid — In many cases, the unavailability of an adequate classical force field is a major barrier for molecular dynamics simulations. In these cases, density functional theory (DFT) provides a universal but expensive option. We propose an intermediate approach based on an ‘electron force field’ (eFF) [Su and Goddard, PRL 99, 185003 (2007)]. Inspired by VSEPR theory, we expand the electron density as a sum of overlapping spherical electron ‘balls’ (e-balls). The e-balls interact through electrostatic forces, Pauli repulsion, and exchange-correlation. The electronic total energy is calculated as a universal function of the e-ball positions and widths. As in DFT, it is independent of the nuclei, which interact only electrostatically. We parameterize this universal, many-body function by fitting to DFT calculations of a large number of molecules and solids at equilibrium, distorted, and reaction geometries.

*Funded by Spain's MINECO grant FIS2015-64886-C5-5-P

Modeling of La$^{3+}$ doping segregation in nanocrystalline yttria-stabilized zirconia using a combintaion of atomistic MD, Monte Carlo and Nudged Elastic Band calculations*

SHENLI ZHANG, ROLAND FALLER (Presenter), University of California, Davis — The effect of La$^{3+}$ doping on the structure and ionic conductivity change in nanocrystalline yttriasitabilized zirconia (YSZ) was studied using a combination of Monte Carlo and molecular dynamics and Nudge Elastic Band simulations. Simulations of specific grain boundary configurations are developed. Systems with and without La doping are studied and equilibrated using a combintaion of techniques and eventually anaylzed using Voronoi tessellation analysis for the density of the dopants.

The simulation revealed the segregation of La$^{3+}$ at eight tilt grain boundary (GB) structures and predicted an average grain boundary (GB) energy decrease of 0.25 J m$^{-2}$, which is close to the experimental values reported in the literature. Cation stabilization was found to be the main reason for the GB energy decrease, and energy fluctuations near the grain boundary are smoothed out with La$^{3+}$ segregation. Both dynamic and energetic analysis on the S13(510)/[001] GB structure revealed La$^{3+}$ doping hinders O$^2$- diffusion in the GB region, where the diffusion coefficient monotonically decreases with increasing La$^{3+}$ doping concentration. T

Ultrafast detonation of hydrazoic acid: a case study of the ChIMES model

HUY PHAM (Presenter), NIR GOLDMAN, LAURENCE FRIED, Lawrence Livermore Natl Lab — Understanding the chemical evolution and states of matter of an energetic material under detonation is challenging due to the short time scales of chemical reactions and risk of experimental work. First-principle molecular dynamics simulations can provide valuable insights into such systems. However, the computational cost associated with those simulations limits their applicability to relatively small systems and short time scales. We have developed the Chebyshev Interaction Model for Efficient Simulation (ChIMES), a reactive force field, using force matching to trajectories from density functional theory (DFT). This force field has been shown to be capable of retaining the accuracy of DFT simulation while increasing orders of magnitude in computational efficiency. In this work, we use ChIMES to study hydrazoic acid, an azide energetic material that exhibits an ultrafast detonation during a shock wave. We find that our models are able to accurately reproduce the structural and dynamic properties computed from DFT at different thermodynamic states. The ability to describe charge transfer and chemical reactions is also discussed.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

Session L22 DCOMP DMP: Electrons, Phonons, Electron-Phonon Scattering and Phononics III

Electron-phonon coupling and electronic transport in n-type PbTe: Insights from first principles calculations*

IVANA SAVIC (Presenter), Tyndall National Institute, Cork, Ireland — Exploiting the fascinating properties of materials near soft mode phase transitions is an emerging concept in the quest to increase thermoelectric efficiency [1]. Soft phonons may lead to low lattice thermal conductivity, while preserving high electronic conductivity. Here I will focus on the unusual electronic transport properties of n-type PbTe, which is a classic thermoelectric material that exists near a soft optical mode phase transition. Our first principles calculations show that longitudinal optical phonon scattering dominates electronic transport, while acoustic phonon scattering is relatively weak [2,3]. We find that scattering due to soft transverse optical phonons is by far the weakest scattering mechanism, due to the symmetry-forbidden scattering between the conduction band minima and the zone center soft modes [3]. Soft phonons thus play the key role in the high thermoelectric figure of merit of n-type PbTe: they do not degrade its electronic transport properties although they strongly suppress the lattice thermal conductivity [1].

11:51AM L22.00002: Predictive calculations of phonon-limited carrier mobilities in semiconductors*  
SAMUEL PONCE (Presenter), Department of Materials, University of Oxford, ELENA ROXANA MARGINE, Department of Physics, Binghamton University-SUNY, MARTIN SCHLIPF, FELICIANO GIUSTINO, Department of Materials, University of Oxford — In this talk, we will probe the accuracy limit of ab initio calculations of carrier mobilities that relies on the electron-phonon coupling, within the framework of the Boltzmann transport equation. In particular, we will show that predictive calculations of electron and hole mobilities require many-body quasiparticle corrections to band structures and electron-phonon matrix elements, the inclusion of spin-orbit coupling, and an extremely fine sampling of inelastic scattering processes in momentum space [1].

Such fine sampling calculation is made possible at an affordable computational cost through the use of efficient Fourier-Wannier interpolation of the electron-phonon matrix elements as implemented in the EPW code [2].

We will discuss recent findings on the mobility of silicon, wurtzite GaN and halide perovskites [3].

12:03PM L22.00003: Stochastic properties of a hot electron gas in a semiconductor from first-principles*  
ALEXANDER CHOI (Presenter), AUSTIN MINNICH, Caltech — Recent advances in ab-initio methods have enabled the routine calculation of the electronic transport properties of crystals. Analogous calculations of stochastic properties, such as the spectral noise power of an electron gas driven by an electric field, have not yet been reported despite their importance in setting fundamental detection limits of microwave electronics. Here, we report an ab-initio treatment of the noise of a driven electron gas using a Boltzmann-Green's function approach. Our approach combines electronic structure and scattering rates from first-principles with a numerically exact solution of the Boltzmann equation, providing a parameter-free description of stochastic transport processes in a semiconductor. The insights derived our ab-initio approach will facilitate the realization of semiconductor devices operating near the quantum noise limit.

12:15PM L22.00004: Probing electron-phonon interactions in Weyl semimetal using Raman spectroscopy and anharmonic phonon calculations  
KUNYAN ZHANG (Presenter), Electrical Engineering, Pennsylvania State University, FEI HAN, Nuclear Engineering, Massachusetts Institute of Technology, SHUN-LI SHANG, ZI-KUI LIU, Materials Science and Engineering, Pennsylvania State University, MINGDA LI, Nuclear Engineering, Massachusetts Institute of Technology, SHENGXI HUANG, Electrical Engineering, Pennsylvania State University — TaP, a type of Weyl semimetal (WSM) with noncentrosymmetric space group \( I4_1md \), is a special type of quantum materials that have attracted strong recent interests. The gapless band structure of TaP allows unique optical response and transport phenomena. Although electrical and photoemission characterizations such as Hall measurement and angle-resolved photoemission spectroscopy (ARPES) have been performed on various WSMs, there is insufficient research on the electronic and optical properties using optical spectroscopies as probes. In the present work, the light-matter interactions, including electron-phonon and electron-photon interactions, have been studied comprehensively through phonon-based Raman spectroscopy and first-principles calculations. We demonstrate how the optical spectroscopic responses, such as Raman and absorption, of TaP change under various physical parameters including crystal orientation, temperature, and excitation laser energies. Advanced first-principles calculations of electronic and especially anharmonic phonon properties have been employed to unveil the measured optical spectroscopic responses and their relationship with electronic performance of WSMs.
High Temperature Charge Transport In Strontium Titanate*  
CLEMENT COLLIGNON (Presenter), BENOIT FAUQUE, Institut de Physique, College de France, KAMRAN BEHNIA, LPEM, ESPCI — Strontium titanate quickly becomes metallic upon doping, but while the ferromagnetism of this metallic phase is well understood its transport properties remain elusive [1]. At low temperature, even though the scattering mechanism is not known, the resistivity exhibits a $T^2$ behavior typical of Fermi liquids [1]. With increasing temperature, resistivity rapidly grows and follows an unusual $T^3$ power law [1,2]. At room-temperature, the magnitude of resistivity combined with the effective mass, $m^*$, obtained from quantum oscillations, implies strikingly short mean-free-path and scattering time. The Mott-Ioffe-Regel limit is exceeded, and the scattering time decreases faster than the planckian time ($\tau_P = \frac{h}{2\pi k_B T}$). Nevertheless, the resistivity does not show any sign of saturation.

In this talk, we present new charge transport data extended up to 850 K to follow the fate of this enigmatic metallicity at high temperatures. The system continues to display a metallic behavior without saturation in resistivity and the apparent scattering time (assuming a temperature-independent $m^*$) becomes 10 times lower than $\tau_P$.

Band structure and optical properties of boron arsenide (BAs): effects of quasiparticle corrections, spin-orbit coupling, and phonon-assisted optical transitions*  
KYLE BUSHICK (Presenter), KELSEY MENGLE, NOCONA SANDERS, EMMANOUIL KIOUPAKIS, Materials Science and Engineering, University of Michigan — The III-V semiconductor BAs is best known for its high thermal conductivity, which was computationally predicted and recently experimentally validated. However, due to a lack of high-quality samples, the electronic and optical properties have not been systematically explored. We use density functional and many body perturbation theory including quasiparticle and spin-orbit coupling corrections to systematically characterize the electronic and optical properties of BAs. Accurate calculations of band gap values, carrier effective masses, and dielectric functions yield insights into the fundamental properties of this new material. We further explore the effect of phonon-mediated transitions across the indirect band gap on the optical properties. We will discuss the implications of our findings on potential applications of BAs to semiconductor technologies.

Ab initio studies of electron-phonon coupling to the electron self-energy in organic crystals*  
FLORIAN BROWN-ALTVATER (Presenter), UC Berkeley/Lawrence Berkeley Natl Lab, GABRIEL ANTONIUS, University of California, Berkeley, TONATIUH RANGEL GORDILLO, Lawrence Berkeley Natl Lab, MATTEO GIANTOMASSI, Université catholique de Louvain, CLAUDIA DRAXL, Humboldt-Universität zu Berlin, XAVIER GONZE, Université catholique de Louvain, STEVEN G. LOUIE, University of California, Berkeley, JEFFREY B NEATON, UC Berkeley/Lawrence Berkeley Natl Lab — Organic crystals combine properties of individual molecules and extended periodic systems. They garner much scientific interest due to their high charge carrier mobilities, and because their unique electronic and vibrational properties challenge our understanding of fundamental optoelectronic processes. In this work we use density functional perturbation theory to study the phonon-scattering lifetimes, as well as the temperature dependence of the band structure. We find that a self-consistent approach to the electron self-energy due to electron-phonon coupling yields qualitative differences compared to a conventional approach, and shows much better agreement with experimental results. We discuss efficient methods for self-consistency in organic crystals, and implications on calculating band gap renormalization and quasiparticle lifetimes of these systems.

*This work is supported by DOE and computational resources are provided by NERSC.
The interest in the properties of transition metal dichalcogenides (TMDs) has increased due to the discovery of the coupling between spin and valley degrees of freedom, which can be seen experimentally using a circularly polarised laser. After excitation the newly formed carrier populations must move towards the other valley until balance is reached. However, this relaxation process is not entirely understood in the literature, where the relative importance of the electron-electron (e-e) or electron-phonon (e-p) interactions is still a subject of debate. Previous works on WSe₂ [A. Molina-Sánchez, et al - Nano letters, 2017] have shown that the e-p interaction is a good candidate to describe the relaxation process. Using a fully ab-initio framework based on the Baym-Kadanoff equations [P. M. M. C. de Melo and A. Marini, Phys. Rev. B 93, 155102 (2016)] we study the influence of the e-p interaction on MoSe₂ after its excitation by a laser field. We show how phonons allow carrier relaxation and how the Kerr signal and total magnetisation are affected at different temperatures, with the latter exhibiting a non-monotonic behaviour as the temperature increases.

1:15PM L22.00009: Ab Initio Electronic $T_1$ Spin Relaxation Times in Silicon and Diamond  JINSOO PARK (Presenter), JINJIAN ZHOU, MARCO BERNARDI, Applied Physics and Materials Science, California Institute of Technology — Spin relaxation in inversion-symmetric crystals primarily occurs through the Elliott-Yafet mechanism, in which the injected spins are scattered by impurities at low temperatures and phonons at higher temperatures. We present an efficient first-principles approach for computing the phonon-limited Elliott-Yafet electronic spin relaxation time $T_1$ in materials ranging from metals to semiconductors and insulators. Our scheme combines fully-relativistic ab initio electron-phonon scattering with a novel approach to correctly treat Kramers degenerate electronic states. Application of our approach to silicon and diamond is discussed in this talk, where we analyze the temperature dependence of the spin relaxation times together with the contributions from intravalley and intervalley processes. The computed spin relaxation times in silicon are in excellent agreement with experiment above 50 K. Our work enables accurate ab initio calculations of the $T_1$ spin relaxation time in a range of materials, including topological ones, providing new microscopic insight into spin relaxation.

1:27PM L22.00010: Quantum-kinetic theory for electron-diffusion and phonon-drag thermoelectric powers from drifting electrons in a quantum wire* RICHARD ZHANG (Presenter), Department of Mechanical & Energy Engineering, University of North Texas, DANHONG HUANG, Space Vehicles Directorate, Kirtland AFB, Air Force Research Laboratory — Thermal conditions during an ultrafast femtosecond-scale laser pulse are difficult to resolve due to phonon vibration drag behind an electron excitation. The motivation behind this study is to establish a ground-up quantum dynamics model to predict elastic wave effects in a confined electron-phonon state. We established transient collision equations from three-phonon coupled anharmonic interactions to obtain the evolution of hot phonon species distribution and thermoelectric response in a confined-size semiconductor material, such as a GaAs nanowire subjected to a spatially uniform DC electric field. A simplified diatomic chain model was chosen to represent longitudinal phonon dispersion. A quasi-steady state was observed in electron-phonon drift-drag response and settling of low frequency phonon-phonon scattering. We also studied the effects from phonon-surface boundary parameters, such as fluctuation strength and interaction length. As new materials with surprising measured transport properties are being found, further development of this unifying theory of carrier-lattice dynamics has potential for capturing ephemeral excitations in various solids.

1:39PM L22.00011: Electron-phonon coupling from ab initio linear-response theory within the GW method: Method and applications to oxide superconductors*  ZHENGLU LI (Presenter), GABRIEL ANTONIUS, MENG WU, FELIPE DA JORNADA, STEVEN G. LOUIE, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — We present a first-principles linear-response theory of changes due to perturbations in the quasiparticle self-energy operator within the GW method. This approach, named GW perturbation theory (GWPT), is applied to calculate the electron-phonon (e-ph) interactions with the full inclusion of the GW non-local, energy-dependent self-energy effects, going beyond density-functional perturbation theory. Unlike the frozen-phonon approach, GWPT gives access to e-ph matrix elements at the GW level of all phonons, and the computational cost scales linearly with the number of phonon modes (wavevectors and branches) investigated. We present results of correlation-enhanced superconductivity in Ba$_{0.6}$K$_{0.4}$BiO$_3$ and of e-ph physics in other oxide superconductors where many-electron effects are strong.

1:51PM L22.00012: First-principles study of electron-phonon interactions in SrTiO3*  NIKOLAUS KANDOLF (Presenter), CARLA VERDI, FELICIANO GIUSTINO, Department of Materials, University of Oxford — The discovery of a two-dimensional electron liquid on the surface of doped SrTiO3 (STO) and the confirmation of high-temperature superconductivity at the FeSe/SrTiO3 interface have attracted considerable interest in the electron-phonon physics of STO. In this work we focus on the polaron satellites observed in the angle-resolved photoelectron spectra of STO, and investigate their origin using the many-body electron-phonon self-energy in the Migdal approximation, augmented with the cumulant expansion formalism. By comparing our first-principles calculations with experiments we investigate the microscopic mechanisms that give rise to the observed polaron satellites.

2:03PM L22.00013: Exciton-phonon interactions in organic crystals from first principles many-body perturbation theory*  JONAH HABER (Presenter), Department of Physics, University of California, Berkeley, SIVAN REFAELY-ABRAMSON, Department of Materials and Interfaces, Weizmann Institute of Science, GABRIEL ANTONIUS, Département de Chimie, Biochimie et Physique, Université du Québec à Trois-Rivières, FELIPE DA JORNADA, STEVEN G. LOUIE, JEFFREY B NEATON, Department of Physics, University of California, Berkeley — Molecular crystals are attractive candidates for solar energy conversion applications due to their strong light-matter interactions, nearly endless structural tunability, and the relative inexpense with which they can be synthesized and processed. Acene crystals, such as tetracene and pentacene, possess both strong electron-hole and significant electron-phonon interactions, and a thorough understanding of the photophysics of these materials requires a careful analysis of the interplay between the ionic and excitonic degrees of freedom. In this talk, we present our linear response framework for computing exciton-phonon matrix elements, using ab initio density functional perturbation theory and many-body perturbation theory within the GW plus Bethe-Salpeter equation approach. We apply this method to compute exciton-phonon scattering rates for spin-singlet and spin-triplet excitons in prototypical acene crystals and compare with experimental linewidths. Finally, we discuss the implications of our calculations for exciton diffusion and multiexciton generation in these extended organic systems.

11:15AM L23.00001: Cryogenic Nitrogen-Vacancy Scanning Microscope  URI VOOL, ASSAF HAMO (Presenter), ZIWEI QIU, TONY ZHOU, AMIR YACOBY, Harvard University — The Nitrogen-Vacancy (NV) electron spin is a quantum sensor of magnetic field, with high sensitivity in a wide range of frequencies and extremely high spatial resolution. Most NV magnetometry experiments are performed by stationary NVs in a bulk crystal measuring a nearby sample. This limits the spatial resolution to the optical diffraction limit and strongly limits the sample which can be measured. Recently, a scanning technique was developed to overcome these issues, in which the NV is located on a tip that can be scanned over a sample. In addition, most NV experiments are performed at room temperatures, while many of the unexplored phenomena in condensed matter physics occur at cryogenic temperatures.

Our lab has been working on a setup which aims to address both issues, implementing a cryogenic scanning NV setup. This setup allows us to work in a variable temperature from ~1.7K up to room temperature. In this talk we describe the details of our scanning microscope and its advantages in measuring condensed-matter phenomena, and present preliminary scanning results.

11:27AM L23.00002: Nanoscale CVD Graphene Hall Probes for high resolution Scanning Probe Microscopy* DAVID COLLOMB (Presenter), PENGLEI LI, SIMON BENDING, DANIEL WOLVERSON, University of Bath — Advances in magnetic imaging are one of many improvements in instrumentation which have enabled scientists to pioneer and develop their next big research ideas. One important technique, scanning Hall probe microscopy (SHPM), involves rastering a Hall sensor over a surface to create a magnetic field map across the sample. However, SHPM has typically relied on the low temperature performance of GaAs-based Hall probes, whose figures-of-merit become much worse at room temperature. This tends to exclude SHPM from numerous applications under ambient conditions such as susceptibility for non-destructive evaluation and characterisation of ferromagnetic data storage media. Making use of graphene’s high carrier mobility and facile CVD growth techniques, we have fabricated graphene Hall devices with nanoscale lateral dimensions for sub-100nm spatial resolution imaging while maintaining excellent room temperature minimum detectable fields in the μT/√Hz range. We will illustrate the imaging performance of such probes, including; low frequency noise performance and magnetic sensitivity, for devices with different active areas, carrier densities and drive currents.

*Funding was provided by the Lloyds Register Foundation and the UK EPSRC, with award numbers G0086 and EP/R007160/1 respectively.

11:39AM L23.00003: Near-field correlative nanoscopy accesses physical constants in complex functional materials STEFAN MASTEL (Presenter), TOBIAS GOKUS, ALEXANDER GOVYADINOV, ANDREAS HUBER, Neaspec GmbH — Nanoscale characterization methods play a key role in the analysis, development and optimization of nanoscopic materials and devices. Often several characterization techniques are required to gain a comprehensive understanding of the various material properties of complex functional materials. Here we introduce the combined nanoscale analysis of complex material systems by correlating infrared scattering-type Scanning Near-field Optical Microscopy (s-SNOM) with information obtained by other Scanning Probe Microscopy (SPM) based techniques. For example near-field reflection/absorption imaging at 1500 cm⁻¹ of a only 50 nm thin phase-separated PS/LDPE polymer film allows to selectively highlight the distribution of PS in the blend, while atomic force microscopy modes simultaneously map the mechanical properties like adhesion. Further, results will be presented that correlate the nanoscale near-field optical response of semiconducting samples like SRAM devices in different frequency ranges (mid-IR & THz) to Kelvin Probe Force Microscopy and Electrostatic Force Microscopy measurements. Thus, neaspec s-SNOM systems represent an ideal platform to characterize complex material systems by different near-field optical and SPM-based mechanical and electrical methods at the nanoscale.
11:51AM L23.00004: Magnetic force sensing using a self-assembled GaAs nanowire with a MnAs tip

NICOLA ROSSI (Presenter), BORIS GROSS, University of Basel, FLORIAN DIRNBERGER, DOMINIQUE BOUGEARD, Physics, Universität Regensburg, MARTINO POGGIO, University of Basel — We present a scanning magnetic force sensor based on an individual magnet-tipped GaAs nanowire (NW) grown by molecular beam epitaxy [1]. Its magnetic tip consists of a final segment of single-crystal MnAs formed by sequential crystallization of the liquid Ga catalyst droplet [2]. We characterize the mechanical and magnetic properties of such NWs by measuring their flexural mechanical response in an applied magnetic field [3]. Comparison with numerical simulations allows the identification of their equilibrium magnetization configurations, which in some cases include magnetic vortices. We determine a NW’s performance as a scanning probe [4], by measuring its dynamical response to the magnetic field of a micrometric current-carrying wire. The NWs’ tiny tips and their high force sensitivity make them promising for imaging weak magnetic field patterns on the nanometer-scale, as required for mapping mesoscopic transport and spin textures or in nanometer-scale magnetic resonance.

*Swiss NSF (200020-178863); ERC Starting Grant NWScan (334767); Swiss Nanoscience Institute; Kanton Aargau; NCCR QSIT.

# MICHELLE YOTHERS (Presenter), SOUMYA BHATTACHARYA, LLOYD BUMM, Homer L Dodge Department of Physics and Astronomy, University of Oklahoma — Accurate measurements of structures at the nanoscale are of fundamental importance for nanofabrication. Using alkanethiol self-assembled monolayers (SAMs) as a model system, we demonstrate a way to measure the alkanethiol chain tilt direction from constant-current scanning tunneling microscope (STM) images. These measurements are made with a real-space image post-processing technique that compensates for image distortion using a physical model. Using this measurement, we are also able to establish the chain tilt direction without guest molecules, by using the position uncertainty of molecules about their expected lattice site position. In particular, we will show the direction of maximum position uncertainty is anticorrelated with the alkanethiol chain tilt direction. This anticorrelation is consistent across different STM tips and alkanethiol chain lengths.

*Financial support from the National Science Foundation (CHE-1710102), the Homer L. Dodge Department of Physics, and the OU College of Arts and Sciences, the Carl. T. Bush Fellowship (MPY), and NVIDIA Corporation (donation of a Tesla K-40 GPU) is gratefully acknowledged.

12:15PM L23.00006: A differential photon-rate meter for real-time peak tracking in optically detected magnetic resonance at low photon-count rates

KAPILDEB AMBAL (Presenter), National Institute of Standards and Technology — The optically detected magnetic resonance of the NV− center in diamond provides a mechanism for precise, nanoscale magnetometry. As an alternative to measuring and fitting complete resonance spectra, resonance peak locking and tracking methods provide real-time and continuous measurements of the magnetic field. But the weak photoluminescence from small ensembles of NV− center including single NV− centers poses a problem for peak tracking. The emitted light requires single-photon detection which produces a narrow (≈ 20 ns) voltage pulse per detected photon. The discrete voltage pulses are not amenable for demodulation by regular lockin amplifiers. Here, we address active feedback control and real-time field tracking with photon detection rates in the range of $4 \times 10^3$ s$^{-1}$ to $1 \times 10^6$ s$^{-1}$, which are typical of single NV− centers, and we present a custom differential rate meter with phase sensitive detection. Without compromising signal-to-noise, this real-time data processing scheme provides all the typical functionalities of a lock-in amplifier needed for real-time peak locking and tracking. We demonstrate continuous field measurements at sweep rates exceeding 50 μT/s. This scheme covers a broad magnetic field range, limited by the frequency range of the microwave generator.
The tip shape dependence of the STM-induced luminescence* Songbin Cui (Presenter), Physics, Pohang University of Science and Technology (POSTECH), Ungdon Ham, Caldes, Institute for Basic Science (IBS), Taehwan Kim, Physics, Pohang University of Science and Technology (POSTECH) — Photon signal enhancement due to surface plasmon coupling becomes an important issue in high-resolution microscopy/spectroscopy, such as scanning tunneling microscopy (STM) induced luminescence, surface/tip enhanced Raman spectroscopy, and so on. Such enhancement is significantly varied by modifying the plasmonic nanocavities. The gap-mode plasmonic nanocavity between an STM tip and surface realizes sub-molecular photon spectroscopy. The plasmonic resonant modes are known to be modified by tip indentation. However, the tip shape dependence of the plasmonic nanocavity remains unclear. In this work, we experimentally present the role of tip shape in surface plasmonic light emission. We have used Ag tips and a Ag(100) substrate, and STM-induced photon signals have been measured from the two opposite sides of the STM tip simultaneously. We found that changing small parts of the tip can differ the photon spectrum significantly due to tip shape asymmetry. This finding can help us to tune the plasmonic photon emission spectra more efficiently and give a new insight by using the symmetric or asymmetric STM tip induced luminescence.

Session L24 DAMOP: Precision spectroscopy of molecules: status and perspectives BCEC 159
- Sergiy Bubin, Nazarbayev University - Tag(s): Focus

11:15AM L24.00001: Precision spectroscopy in few-electron molecules [Invited] Maximilian Beyr, Nicolas Hölisch, Paul Jansen, Luca Semeria, Frederic Merkt (Presenter), ETH Zurich — Few-electron molecules are attractive systems for precision spectroscopy because their properties can be calculated with high accuracy by quantum-chemical methods.\(^1\)\(^2\)\(^3\) The measurements serve to test theoretical predictions, ideally at the level where their accuracy is limited by the uncertainties of the fundamental constants or by unrecognized physical effects. We report on precision measurements of energy intervals in cold samples of H\(_2\) and metastable He\(_2\). In the case of H\(_2\), we determine the ionization energy with a precision (\(\Delta \nu/\nu\)) of 10\(^{-10}\) from high-resolution Rydberg spectra\(^4\)\(^5\) and derive the dissociation energy with an accuracy of 350 kHz, approaching the level where the size of the proton and the uncertainty in the proton-to-electron mass ratio would limit the accuracy of otherwise exact calculations. Comparison will be made to recent theoretical results in the context of a more-than-100-year-long series of experimental and theoretical determinations of the dissociation energy of H\(_2\). In the case of the He\(_2\), we use multistage Zeeman deceleration to prepare slow, cold metastable molecules in selected spin-rotational components of the metastable \(a\) state. We exploit the long transit times of these molecules through microwave and laser fields to measure fine-structure intervals in the \(a\) state, the Rydberg spectrum of He\(_2\), and the energy-level structure of He\(_2^+\).\(^6\)

11:51AM L24.00002: Precision spectroscopy of molecular hydrogen and its ion through molecular Rydberg states and MQDT-assisted extrapolation of Rydberg series  MAXIMILIAN BEYER (Presenter), Department of Physics, Yale University, NICOLAS HOLSCHE, ETH Zurich, CHRISTIAN JUNGEN, Department of Physics and Astronomy, University College London, FREDERIC MERKT, ETH Zurich — H$_2^+$ and H$_2$ are the simplest of all ionic and neutral molecules and as such important systems for the development of molecular quantum mechanics.

The energy-level structure of H$_2^+$ can be calculated extremely precisely and by comparison with the results of precise spectroscopic measurements, fundamental constants or particle properties, such as the proton-to-electron mass ratio or the proton size, may be determined.

Spin-rovibrational intervals in H$_2^+$ are determined with sub-MHz accuracy from high-resolution measurements of Rydberg series of H$_2$ followed by Rydberg-series extrapolation using multichannel quantum defect theory.

For the excitation of Rydberg states, a resonant three-photon excitation scheme was employed, using pulsed VUV and VIS laser sources to reach the intermediate double-well GK state and a continuous-wave near-infrared laser source for the excitation to the Rydberg states. The valence state - Rydberg state intervals could be measured with a relative accuracy of 3E-10 using an optical frequency comb for the frequency calibration of the cw laser and employing a procedure to minimize systematic uncertainties. The measurements were used to determine the spin-rotational intervals of the first three rotational levels of para H$_2^+$ and the fundamental vibrational interval.

12:03PM L24.00003: Geminal-based high-accuracy quantum mechanics for few-body systems*  MARKUS REIHER (Presenter), ETH Zurich — We elaborate on the variational solution of the Schrödinger and Dirac equations of few-body atomic and molecular systems without relying on the Born-Oppenheimer paradigm [1]. The wavefunction is expanded in terms of parameterized explicitly correlated Gaussians with polynomial prefactors. We developed a simple strategy for the elimination of the translational kinetic energy of the total energy carried out in laboratory-fixed Cartesian coordinates [2].

For semi-classical relativistic calculations we devised a kinetic-balance condition for explicitly correlated basis functions [3]. The resulting form of kinetic balance establishes a relation between all spinor components of an N-fermion system to the non-relativistic limit, which is in accordance with modern exact-decoupling methods. In my talk, I will discuss these developments in the light of spectroscopic results.

*Financial support from the Swiss National Science Foundation is gratefully acknowledged.

12:15PM L24.00004: Optical angular momentum induced molecular switching  HAI BI (Presenter), ERIC MAZUR, SEAS, Harvard University — Molecular electronics is a promising route for downscaling electronic devices since organic molecules can play a role in reconfigurable logic operations. The organic molecule can also strongly interact with optical fields provided that the fields are highly concentrated, for instance by the presence of plasmonic nanostructures.

Simultaneously, the plasmonic nanostructures have been demonstrated recently the ability to produce localized angular momentum (LAM), which could further be coupled to a molecular device. By optically transferring angular momentum to a molecular junction, we demonstrate different logic operations. These molecular-scale operations result from the interaction of conducting molecular junction and the plasmonically enhanced electromagnetic field near the tip of the junction. Importantly, this novel investigation of the LAM in the near-field opens the door for characterization of molecular electronics with near-field optical methods.
**12:27PM L24.00005: Positronic beryllium: accurate energies and leading relativistic corrections in the ground and lowest excited states**  
ISTVAN HORNYAK (Presenter), SERGIY BUBIN, Department of Physics, Nazarbayev University, Astana, Kazakhstan — One of the long standing questions of positron physics and chemistry is the existence of electronically stable positron-atom and positron-molecule complexes. From the theoretical and computational viewpoint, reliable identification of states, especially metastable ones, in which a positron can be attached to an atom, is challenging due to very weak binding energies and nontrivial structure of the complexes. A few years ago we predicted the stability against dissociation of an excited P-state of Be. The fact that both the ground and excited states are stable against dissociation in conjunction with their notably different lifetimes opens up an interesting possibility of measuring resonant positron-atom annihilation and providing experimental evidence for the existence of positron-atom complexes. In this work we have undertaken another, more comprehensive study of this system. We have performed considerably more accurate calculations of the binding energies and other relevant properties, such as the electron-positron annihilation rates. In particular, we have computed the leading relativistic corrections and show how they change the tiny binding energies of the ground and first excited states of the $e^+\text{-Be}$ complex.

**12:39PM L24.00006: Precision calculations for four- and five-particle molecular systems**  
EDIT MATYUS (Presenter), Eotvos Lorand University — Solution methods for the few-particle molecular Schrödinger equation are elaborated relying on both the full electron-nucleus Hamiltonian [1] as well as on a perturbative treatment resulting in effective non-adiabatic Hamiltonians for the atomic nuclei [2]. Numerical results are presented for the hydrogen molecule ($\text{H}_2$) and for the helium molecular ion ($\text{He}_2^+$).

*Financial support of the Swiss National Science Foundation through a PROMYS Grant (no. IZ11Z0_166525) is gratefully acknowledged.

**12:51PM L24.00007: Long Baseline Molecular Interferometry**  
YAAKOV FEIN (Presenter), STEFAN GERLICH, PHILIPP GEYER, FILIP KIALKA, LUKAS MAIRHOFER, University of Vienna, KLAUS HORNBERGER, Physics, University of Duisburg-Essen, MARKUS ARNDT, University of Vienna — Interferometry of massive particles can be used to rule out modifications to quantum mechanics [1], test the equivalence principle [2], and measure molecular properties [3].

I present results from the new Long Baseline Universal Matter-wave Interferometer (LUMI) in Vienna. LUMI is a near-field three-grating interferometer with a baseline of two meters. The long baseline makes the experiment compatible with particles beyond 100,000 amu and makes it particularly sensitive for metrology.

LUMI has shown interference and electric deflection of particles ranging from atoms to tailored biomolecules. I will discuss the techniques required to see interference at this scale, such as compensating the Coriolis effect. I will also outline the efforts underway to break the current mass record of matter-wave interferometry [4].

Counterpropagating light as a means for all-optical phase matching

JEFFERSON MARCIO SANCHES LOPES, Graduate Program in Physics, Federal University of Para, Belem, PA, Brazil — We present novel results on the free base 5,10,15,20-meso-tetrapyridyl-porphyrin (H$_2$TPyP). This molecule presents complex electronic and vibrational properties and in spite of the vast literature reporting the transitions observed in its absorption and fluorescence spectra, a more accurate interpretation has been kept elusive. In particular, we show that the molecule's Q-band is clearly developed into many electronic and vibronic transitions, whose the well-known "four orbital model" finds it difficult to reconcile. Using distinct spectroscopy techniques, we conclude that both $Q_x$- and $Q_y$-bands comprise, in fact, two quasi-degenerated electronic states together with their respective vibronic progressions each. The analysis of the Huang-Rhys factors and complementary time- and polarization-resolved measurements reinforce the need for the proposed Q-band multi features remodeling.

*The authors are grateful to the Professors Waldeci Paraguassu and Sanclayton Moreira, from the Graduate Program in Physics of the Federal University of Para and Prof. Gerard J. Meyer from Department of Chemistry of The University of North Carolina at Chapel Hill, for granting the access to their experimental facilities.

All-optical measurement of molecular spinning dynamics with high-harmonic spectroscopy

PEIXIANG LU (Presenter), LIXIN HE, PENGFEI LAN, Huazhong University of Science and Technology — We demonstrate an all-optical measurement of the spinning dynamics of molecular rotational wave packet (RWP) with an angular high-harmonic spectroscopy. By using a double-pulse excitation scheme, unidirectional rotations (UDR) of the sample molecules are created in experiment. By measuring the time-dependent angular distributions (ADs) of high harmonic generation (HHG), the spatiotemporal evolution of molecular RWP is intuitively visualized. The harmonic ADs also reveal the electronic structure of the sample molecules. Moreover, due to the correlation of HHG and molecular UDR, HHG from the spinning molecules shows obvious nonadiabatic frequency shift at the rotation revivals. The spinning dynamics of molecular RWP can also be revealed from the angle-dependent frequency shift of HHG.

Electronic and Vibrational Anisotropy in Molecular Wavepacket Dynamics

VARUN MAKHIJA (Presenter), Physics and Astronomy, Bowdoin College, ALBERT STOLOW, Physics and Chemistry, University of Ottawa — Resonant excitation of an isolated molecule typically results in an anistropic distribution of molecular axes in the excited state - alignment or orientation of the molecules in the laboratory frame. Femto- or attosecond laser pulses with broad enough bandwidths can potentially excite several electronic and vibrational states in a molecule. By appropriately coupling the angular momentum of these states, we find that an evolving anisotropy (alignment or orientation) develops in the electronic and vibrational probability distributions, in addition to axis alignment. The evolution of the electronic and vibrational alignment is synchronized with vibronic dynamics occurring in the molecular frame, and can be orders of magnitude faster than molecular rotation. This anisotropy can in principal be measured by time and angle resolved scattering. A measurement of the evolving electronic anisotropy in resonantly excited ammonia by time and angle resolved photoelectron spectroscopy confirms the theoretical analysis.
Solving the Helmholtz equation in a fiber with a small axial refractive index variation.* AMALIA SANABRIA (Presenter), PABLO BIANUCCI, Physics, Concordia University — Optical dielectric resonators supporting Whispering Gallery Mode (WGM) represent a class of cavity devices with exceptional properties, like small mode volume, very high power density, and very narrow spectral linewidth [1]. These properties have made them a well-established platform for highly sensitive physical, chemical, and biological sensors [2]. They exist in several geometric structures like cylindrical optical fibers and microspheres, which are the simplest and most common. In this paper we analyze the case of a cylindrical microresonator with a small refractive index variation in the axial direction. We solve the Helmholtz equation assuming a parabolic variation of the refractive index, which allows to obtain harmonic oscillator solutions for the axial component. We derive general transcendental equations to obtain the resonance wavevectors for transverse electric (TE) and transverse magnetic (TM) modes.

Session L26 DQI: Superconducting Qubits: Noise and Decoherence II

11:15AM L26.00001: Correlating decoherence in transmon qubits: Low frequency noise by single fluctuators* STEFFEN SCHLÖR (Presenter), JÜRGEN LISENFELD, Institute of Physics, Karlsruhe Institute of Technology, CLEMENS MÜLLER, Institute for Theoretical Physics, ETH Zürich, ANDRE SCHNEIDER, ALEKSEY USTINOV, Institute of Physics, Karlsruhe Institute of Technology, MARTIN WEIDES, School of Engineering, University of Glasgow — We report on long-term measurements of a high-coherent, non-tunable transmon qubit, revealing low frequency burst noise in coherence and transition frequency. We present a simultaneous measurement of the qubit’s relaxation and dephasing rates as well as resonance frequency fluctuations, and analyze their correlations. These yield information about the microscopic origin of the intrinsic decoherence mechanisms in Josephson qubits and their fluctuation dynamics. From a spectral noise analysis we obtain further evidence for our presented model of a small number of dominant fluctuators.

*This work is supported by Deutsche Forschungsgemeinschaft (DFG) within Project INST 121384/138-1 FUGG and by the European Research Council (ERC) under the Grant Agreement 648011. We acknowledge financial support by the Helmholtz International Research School for Teratronics.

11:27AM L26.00002: Correlation of Lifetime Fluctuations in Superconducting Qubits* DARIO ROSENSTOCK (Presenter), JOSHUA CAREY, CHEN WANG, University of Massachusetts Amherst — While the energy relaxation times (T1) of superconducting qubits have improved greatly since the birth of the field, much work remains to better understand the limitations on lifetimes and how best to extend them. It is widely observed that qubits exhibit time-dependent fluctuations of their T1 times, but the main sources of this process remain a mystery. Among the leading candidates are spurious resonant two-level systems in the dielectric surrounding the device, which are frequency-specific, and excess quasiparticles near the junction, which are not. We monitor the T1 fluctuations for the first two excited states of 3D flux-tunable transmon and fluxonium qubits and examine correlations between the decay rates. We measure T1 of the |e> state at a flux bias such that the |g> - |e> transition frequency matches that of the unbiased |e> - |f> transition. This allows us to resolve frequency dependence of the T1 fluctuations. We believe this is a helpful general tool to distinguish between the effects of dielectric and quasiparticle loss across a range of devices.

Cross-correlation noise measurements of a graphene-based SQUID magnetometer

JONATHAN PRANCE (Presenter), MICHAEL THOMPSON, RICHARD HALEY, YURI PASHKIN, Department of Physics, Lancaster University, MOSHE BEN SHALOM, VLADIMIR FALKO, School of Physics and Astronomy, University of Manchester, HARRIET VAN DER VLJET, ANTHONY MATTHEWS, ZIAD MELHEM, Oxford Instruments Nanoscience — Lateral superconductor/graphene structures can be used to make Josephson junctions with low contact resistances and gate-tuneable critical currents [1]. These junctions have the potential to provide new functionality for superconducting devices. For most devices, e.g. transmon qubits and SQUID sensors [2], it is important to quantify the intrinsic noise of the junctions. The voltage noise of low resistance junctions is typically below the noise floor of room temperature amplifiers. By cross-correlating the signals from two parallel amplifiers, we can detect signals down to ~100 pV/√Hz, well below the noise floor of each amplifier.

Using this technique, we characterise the voltage noise of a NbTi DC SQUID with graphene junctions in a frequency range from ~Hz to ~kHz. Combined with measurements of the SQUID's gain, we map its sensitivity across a range of operating conditions and find that the best-case sensitivity of the device is similar to traditional low temperature SQUIDs with oxide tunnel junctions.

*This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 785219.

Reducing energy loss at the interface of superconducting devices

IGOR DINIZ, Instituto de Ciências Exatas, Universidade Federal Rural do Rio de Janeiro, Seropédica, Brazil, ROGÉRIO DE SOUSA (Presenter), Dept. of Physics and Astronomy, University of Victoria, BC, Canada — We present a quantum theory of dielectric energy loss due to the interaction of photons, tunneling two level systems (TTLSs), and phonons in superconducting devices. As each TTLS couple to photons and phonons, it induces a photon-phonon interaction that can be described as an effective piezoelectric effect. We show that most energy loss occurs at the interface, with phonon interference playing an important role, leading to several predictions that can be tested in current experiments. Explicit numerical calculations of the loss tangent in devices demonstrates that dielectric energy loss can be reduced by exploiting destructive interference of the phonon radiation emitted from different interfaces.

*We acknowledge support from NSERC (Canada), through its Discovery (RGPIN-2015-03938) and Collaborative Research and Development programs (CRDPJ 478366-14).

Magneto-Electric Coupling of Noise and Loss-Generating Paramagnetic Spins in Superconducting Circuits

KEITH RAY (Presenter), JONATHAN L DUBOIS, VINCENZO LORDI, Lawrence Livermore Natl Lab — Noise and loss in superconducting circuits caused by fluctuating charge and magnetic flux represent significant challenges for the realization of large-scale quantum computing architectures. Previous experimental [Phys. Rev. Applied 6 041001 (2016), Phys. Rev. Lett. 118, 057703 (2017)] and theoretical [PRL 112 017001 (2014)] work has identified O2, OH, and atomic H surface adsorbates as possible sources of flux noise in superconducting circuits. We report here on an extension to our model for the flux noise generated by the dynamics of an ensemble of paramagnetic spins on adsorbed O2 molecules to include electric charge density differences associated with spin flips. This model combines a thermodynamic ensemble generated with Monte Carlo simulations with Landau-Lifshitz-Gilbert equation simulations for the dynamics and is parametrized with vdW-corrected density functional theory calculations. From this model we evaluate the effects of external electric and magnetic fields on the phases of the spin system, its dynamics, and the charge and flux noise generated.

**12:15PM L26.00006: Non-Gaussian Noise Spectroscopy with a Superconducting Qubit**

YOUNGKYU SUNG (Presenter), Research Laboratory of Electronics, Massachusetts Institute of Technology, FELIX BEAUDOIN, LEIGH NORRIS, Department of Physics and Astronomy, Dartmouth College, FEI YAN, Research Laboratory of Electronics, Massachusetts Institute of Technology, DAVID K KIM, MIT Lincoln Laboratory, JACK YANJIE QIU, UWE VON LUEPKE, Research Laboratory of Electronics, Massachusetts Institute of Technology, JONILYN L YODER, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, Research Laboratory of Electronics, Massachusetts Institute of Technology, LORENZA VIOLA, Department of Physics and Astronomy, Dartmouth College, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, WILLIAM D OLIVER, Department of Physics, Massachusetts Institute of Technology — Most quantum control and quantum error-correction protocols assume that the noise causing decoherence is described by Gaussian statistics. However, the Gaussianity assumption breaks down when a qubit is strongly coupled to a sparse environment or has a non-linear response to environmental degrees of freedom. Here, we experimentally validate an open-loop quantum control protocol that reconstructs the higher-order spectrum of injected non-Gaussian phase noise using a superconducting qubit as a noise spectrometer. This first experimental demonstration of non-Gaussian-noise spectroscopy represents a major step toward the goal of demonstrating a complete noise spectral characterization of quantum devices.

**12:27PM L26.00007: Sources of decoherence in fixed frequency transmon qubits.**

ANDREAS FUHRER (Presenter), MATTHIAS MERGENTHALER, PETER MUELLER, STEPHAN PAREDES, CLEMENS MÜLLER, MARC GANZHORN, STEFAN FILIPP, THILO STOEFERLE, GIAN SALIS, IBM Research - Zurich — Significant advances in the coherence of superconducting qubits were made possible by clever microwave engineering. For the transmon qubit this was mainly the reduction of its charge dispersion by capacitively shunting the Josephson junction, the increased size of its capacitor pads, filtering of the microwave controls and operation at noise insensitive points. More recently, efforts were made to disentangle the contributions of various material interfaces by engineering participation ratios of the electromagnetic field with different geometries of resonators and qubits in order to pinpoint the sources of noise.

We report on our efforts to measure and understand the noise sources that effect high coherence fixed frequency transmon qubits in a bottom loading dilution refrigerator. We study the effect of various shielding and filtering strategies using fast noise spectroscopy techniques. Furthermore, we present coherence data from devices that were cooled in a UHV package with a controlled atmosphere and discuss the effect of surface adsorbates on qubit performance.

**12:39PM L26.00008: TLS induced decoherence instabilities in superconducting qubits**

ANDREAS BENGTSSON (Presenter), JONATHAN BURNETT, MARCO SCIGLIUZZO, DAVID NIEPCE, MARINA KUDRA, PER DELSING, JONAS BYLANDER, Chalmers University of Technology — We study the temporal stability of relaxation and dephasing in superconducting transmon qubits. By collecting statistics during measurements spanning multiple days, we reveal large fluctuations of qubit lifetimes and find that the main cause of T1 fluctuations is interacting parasitic two-level-systems (TLS). Our statistical analysis also provides useful information about dynamics of TLS which could help identify possible microscopic sources of TLS, which still remain elusive. Moreover, interacting TLS also cause capacitance fluctuations, ultimately leading to frequency noise and dephasing of the qubit state. These discoveries are important for manufacturing stable superconducting circuits suitable as a scalable quantum computing platform where drift and fluctuations lead to unnecessary calibration and downtime.

**12:51PM L26.00009: Charge noise, fluxonium, and all that**

ARI M MIZE (Presenter), YARIV YANAY, Laboratory for Physical Sciences — Fluxonium qubits were designed to eliminate charge offsets. We consider the theory of fluxonium qubits and distill crucial features that reduce vulnerability to charge noise. Our observations prompt a new superconducting qubit design with some attractive features.
Simulations of Magnetic Noise in Classical XY and Heisenberg Spin Models

DANIEL MICKELSEN (Presenter), HUI WANG, Department of Physics and Astronomy, University of California, Irvine, CA, United States, ZHE WANG, Department of Physics, Fudan University, Shanghai, China, RUQIAN WU, CLARE C YU, Department of Physics and Astronomy, University of California, Irvine, CA, United States — Superconducting qubits show great promise but continue to be plagued by flux noise. Experiments show that surface spins are the source of this flux noise, and the noise has a power spectral density of the form $1/f^\alpha$ with the noise exponent $\alpha \approx 1$. Experiments also provide evidence for ferromagnetic exchange. We investigate to what extent ferromagnetic exchange is consistent the observed flux noise exponents. With input from density functional theory calculations of magnetic impurities, we present the results of Monte Carlo simulations of the magnetic noise produced by coupled classical XY and Heisenberg spins in 2D lattices. We find the parameters of the models that result in a noise exponent near 1.

Experimental study of flux noise in nanowire transmons subject to an applied magnetic field

THIJS STAVenga (Presenter), FLORIAN LUTHI, JOEP ASSENDELFT, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, DAVID THOEN, AKIRA ENDO, Department of Microelectronics and Kavli Institute of Nanoscience, Delft University of Technology, PETER KROGSTRUP, Center for Quantum Devices and Station Q Copenhagen, University of Copenhagen, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — Flux noise is generally the dominant dephasing mechanism in transmon qubits using SQUID loops as a tunable inductive element. Continuing experimental research ambitions to elucidate the microscopic origin and mitigation of flux noise. In this work, we experimentally investigate flux noise using an unconventional knob for circuit QED: an applied in-plane magnetic field. We first present various changes introduced to our circuit QED system and setup to further extend the field compatibility of resonators and nanowire transmons beyond 70 mT and to reduce extrinsic noise. Next, we use standard coherence measurements and sensitivity analysis on and off flux sweetspots to investigate the dependence of flux noise on field applied along the axis of the two constituent nanowire junctions.

Measuring Quantum Noise Limits in Superconducting Digital Circuits

AARON LEE (Presenter), MICAH STOUTMORe, JOHN X PRZYBYSZ, AARON PESETSKi, OLIVER OBERG, NATHAN MUNGO, JAMES MEDFORD, LEWIS GRANINGER, Mission Systems, Northrop Grumman — A fundamental question in Josephson junction physics is the temperature at which quantum tunneling becomes the dominant source of junction escape as opposed to thermal excitation. This quantum crossover temperature is important to the design of classical superconducting circuits, as it dictates the minimum error rate that can be achieved for a given junction size. This property has been previously described and measured for over forty years, but the measurement technique is limited to single junctions and not extensible to junctions embedded in a larger circuit. Here we demonstrate a technique for measuring the quantum crossover temperature for a superconducting digital circuit by examining the width of the transition from operation to failure in a basic Reciprocal Quantum Logic digital circuit. This transition width is extracted from the broadband noise generated from the circuit errors and further, disambiguates from spectral noise, such as line noise, that can broaden this transition and artificially increase the crossover temperature. Application of this technique to a medium sized circuit demonstrates that the quantum crossover temperature of a junction embedded in a larger circuit is indistinguishable from the crossover temperature extracted from an isolated junction.

Session L27 DQI: Quantum Error Correction Theory and Experiment

Tag(s): Focus

Fault-tolerant magic state preparation with flag qubits

CHRISTOPHER CHAMBERLAND (Presenter), ANDREW CROSS, IBM Thomas J. Watson Research center — Despite considerable effort, magic state distillation remains one of the leading candidates to achieve universal fault-tolerant quantum computation. However, when analyzing magic state distillation schemes, it is often assumed that gates belonging to the Clifford group can be implemented perfectly. In many current quantum technologies, two-qubit Clifford gates are amongst the noisiest components of quantum computers. In this talk I will present a new scheme for preparing magic states with very low overhead that uses flag qubits. I will then compare our scheme to leading magic state distillation methods and show that the overhead can be reduced by orders of magnitude.
Error correcting Bacon-Shor code with continuous measurement of non-commuting operators*  JUAN ATALAYA (Presenter), Univ of California - Berkeley, ALEXANDER N. KOROTKOV, Univ of California - Riverside, BIRGITTA K WHALEY, Univ of California - Berkeley — We analyze the nine-qubit Bacon-Shor code (smallest Bacon-Shor code capable of correcting any single-qubit error) with simultaneous continuous measurement of non-commuting gauge operators. Error syndromes are determined by cross-correlations of three measurement signals. During continuous operation of the code, such error syndromes can be monitored via running time averages of the measurement signals with a certain weighting function. We investigate how various parameters of the latter affect the performance of the code operation. We calculate the logical error rates due to environmental decoherence, and compare the performances of the continuous and discrete implementation of the nine-qubit Bacon-Shor code.

* This work is supported by IARPA and ARO grant No. W911NF-17-C-0050.

Quantum Error Correction with the Semion Code  GUILLAUME DAUPHINAIS (Presenter), LAURA ORTIZ, SANTIAGO VARONA, MIGUEL ANGEL MARTIN-DELGADO, Complutense University — We present a full quantum error correcting procedure with the semion code: an off-shell extension of the double semion model. We construct open strings operators that recover the quantum memory from arbitrary errors and closed string operators that implement the basic logical operations for information processing. Physically, the new open string operators provide a detailed microscopic description of the creation of semions at their end points. Remarkably, topological properties of the string operators are determined using fundamental properties of the Hamiltonian, namely the fact that it is composed of commuting local terms squaring to the identity. In all, the semion code is a topological code that, unlike previously studied topological codes, it is of non-CSS type and fits into the stabilizer formalism. This is in sharp contrast with previous attempts yielding non-commutative codes.

Disjointness in quantum error correction: Imposing limitations on logical gates [Invited]  TOMAS JOCHYM-O’CONNOR (Presenter), Caltech, THEODORE YODER, IBM, ALEKSANDER M KUBICA, Perimeter Institute — I will introduce the notion of disjointness for stabilizer codes in quantum error correction and discuss its implications for implementing fault-tolerant logical gates. The disjointness, an algebraic quantity, can be used to characterize which level of the Clifford hierarchy is naturally attainable by simple fault-tolerant logical gates such as constant-depth circuits. While the results are applicable to any stabilizer code, when addressing topological code families one can reproduce known bounds on the level of the hierarchy attainable by constant depth circuits, with the addition that the circuits are unconstrained by geometric locality. For instance, symmetric 2D surface codes cannot have non-local constant depth circuits resulting in non-Clifford logical gates.

Stabilizer Slicing: Coherent Error Cancellations in LDPC Codes*  DRIPTO DEBROY (Presenter), Physics, Duke University, MUYUAN LI, School of Computational Science and Engineering, Georgia Institute of Technology, MICHAEL NEWMAN, KENNETH R BROWN, Physics, Chemistry, and Electrical and Computer Engineering, Duke University — In this paper we propose a scheme to cancel coherent overrotation errors when implementing quantum error correcting codes. These are considered to be among the most damaging errors due to the way they grow rapidly when combined. Due to their unitary nature, these errors have inverse operations and through our technique the errors due to different parts of the circuit create pairs of errors which cancel over the logical subspace. When considering a simplified error model and allowing native 3 qubit gates we can completely eliminate error in the purely coherent case for Surface-17, and show 135-fold improvement at 0.99 unitarity. For an ion trap gate set and only two qubit interactions, we can observe an 89-fold improvement in Bacon-Shor-13. This second implementation takes advantage of the prepared gauge of the code, and is the first implementation to our knowledge in which the state of the gauge affects the robustness of our memory.

Continuous Quantum Error Correction with two-qubit Annealing Hamiltonian*

ARMAN BABAKHANI, HERMAN CHAN, JEFFREY EPSTEIN, SONG ZHANG (Presenter), JUAN ATALAYA, BIRGITTA K WHALEY, Berkeley Quantum Information & Computation Center, University of California, Berkeley — Adiabatic quantum computation (AQC) is expected to be robust against dephasing and control errors. Nevertheless, environmental noise on the qubits can cause transitions out of the ground state. Error suppression and correction techniques are needed to remedy this. Using an open quantum system approach, we study the effects of different noise models such as bit-flip errors and more realistic thermal noise on a two-qubit system evolving under an annealing Hamiltonian. By encoding each logical qubit using stabilizer codes, we develop a continuous error correction scheme based on the weakly measured error syndromes and analyze the efficiency of this protocol with different physical parameters. We compare the effectiveness of such error correction with known error suppression techniques.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050. Neural Belief-Propagation Decoders for Quantum Error-Correcting Codes*

YE-HUA LIU (Presenter), DAVID POULIN, University of Sherbrooke, Institut Quantique — Belief-propagation (BP) decoders are responsible for the success of many modern coding schemes. While many classical coding schemes have been generalized to the quantum setting, the corresponding BP decoders are flawed by design in this setting. Inspired by an exact mapping between BP and deep neural networks, we train neural BP decoders for quantum low-density parity-check codes, with a loss function tailored for the quantum setting. Training substantially improves the performance of the original BP decoders. The flexibility and adaptability of the neural BP decoders make them suitable for low-overhead error correction in near-term quantum devices.

Demonstration of Channel-Optimized Quantum Error Correction on Cloud-Based Quantum Computers*

HAIMENG ZHANG (Presenter), HANNES LEIPOLD, University of Southern California, ROBERT KOSUT, SC Solutions, Inc., DANIEL A LIDAR, University of Southern California — With the introduction of several cloud-based quantum computers, for example, from IBM and Rigetti, there is a growing interest in experimenting with quantum algorithms and protocols on such platforms. We are specifically interested in testing quantum error correction protocols since noise is an important factor that limits their performance. We demonstrate the channel-optimized quantum error correction protocol [R.L. Kosut, A. Shabani, and D.A. Lidar, PRL 100, 020502 (2008)] on the IBM and Rigetti machines. Our goal is to protect quantum states from noise. The noise on the IBM machine is characterized by standard process tomography. The optimal encoding and recovery map are found numerically by solving a bi-convex optimization problem which maximizes the average channel fidelity. We implement the optimal encoding and recovery maps by decomposing them into directly implementable gate operations. This error correction protocol does not require post-selection and is designed specifically for the physically relevant noise to the platform.

*This work was supported by Oracle Labs and the Lockheed Martin Corporation, and was made possible thanks to the IBM and Rigetti cloud quantum computing platforms.

Demonstration of fidelity improvement using dynamical decoupling with superconducting qubits*

BIBEK POKHAREL (Presenter), NAMIT ANAND, BENJAMIN FORTMAN, DANIEL A LIDAR, University of Southern California — Quantum computers must be able to function in the presence of decoherence. The simplest strategy for decoherence reduction is dynamical decoupling (DD), which requires no encoding overhead and works by converting quantum gates into decoupling pulses. Here, using the IBM and Rigetti platforms, we demonstrate that the DD method is suitable for implementation in today's relatively noisy and small-scale cloud-based quantum computers. Using DD, we achieve substantial fidelity gains relative to unprotected, free evolution of individual superconducting transmon qubits. To a lesser degree, DD is also capable of protecting entangled two-qubit states. We show that dephasing and spontaneous emission errors are dominant in these systems, and that different DD sequences are capable of mitigating both effects. Unlike previous work demonstrating the use of quantum error correcting codes on the same platforms, we make no use of post-selection and hence report unconditional fidelity improvements against natural decoherence.

*This work was supported by Oracle Labs and the Lockheed Martin Corporation, and was made possible thanks to the IBM and Rigetti cloud quantum computing platforms.
1:27PM L27.00010: A family of subsystem codes with only weight two operators  MILAD MARVIAN (Presenter), Massachusetts Institute of Technology — We introduce a family of subsystem codes with the property that their gauge operators, single qubit logical operators and also the product of any two logical operators of the same type can all be implemented using two-local interactions. We discuss their potential applications in error suppression techniques.

1:39PM L27.00011: Higher-dimensional quantum hypergraph-product codes* WEILEI ZENG, LEONID PRYADKO (Presenter), University of California, Riverside — We describe a family of quantum error-correcting codes which generalize both the quantum hypergraph-product (QHP) codes by Tillich and Zémor, and all families of toric codes on m-dimensional hypercubic lattices. Similar to the former, our codes can have finite rates and power-law distance scaling with bounded-weight stabilizer generators. Similar to the toric codes, our codes form m-complexes $K_m$, with $m \geq 2$. These are defined recursively, with $K_m$ obtained as a tensor product of a complex $K_{m-1}$ with a 1-complex parameterized by a binary matrix. Parameters of the constructed codes are given explicitly in terms of those of binary codes associated with the matrices used in the construction.

*This research was supported in part by the NSF Division of Physics via Grants No. 1416578 and 1820939.

1:51PM L27.00012: Continuous parity measurement and error correction* WILLIAM LIVINGSTON (Presenter), MACHIEL BLOK, JUAN ATALAYA, Univ of California - Berkeley, JING YANG, Univ of Rochester, RAZIEH MOHSENINIA, Chapman University, ANDREW N JORDAN, Univ of Rochester, JUSTIN G. DRESSEL, Chapman University, ALEXANDER N. KOROTKOV, Univ of California - Riverside, IRFAN SIDDIQI, Univ of California - Berkeley — In a multi-qubit system, performing continuous measurements of joint properties such as parity permits the study the quantum dynamics of multipartite state evolution and collapse. By performing simultaneous parity measurements in a three qubit system, we can also observe a single qubit flip in real time, providing the basis for quantum error correction. The parity of two superconducting transmons may be directly measured without qubit ancilla by coupling them to a single readout resonator, using identical dispersive couplings much larger than the resonator bandwidth. Using a chip with three qubits and connecting each pair of two to a parity readout resonator, we implement the two parity measurements needed to perform the conventional three-qubit bit-flip code. We control the qubits from a field programmable gate array while continuously monitoring the parity, allowing for low latency correction pulses to be applied when a qubit flip occurs.

*This work was supported by the Army Research Office.

2:03PM L27.00013: Cellular Automaton Decoder for Topological Codes with Boundaries* MICHAEL VASMER (Presenter), DAN BROWNE, Physics & Astronomy, University College London, ALEKSANDER M KUBICA, Perimeter Institute for Theoretical Physics — Topological codes are some of the most widely-studied examples of quantum error-correcting codes. These codes have desirable properties such as low weight stabiliser generators and high error thresholds. To correct errors using a quantum error-correcting code, we must use a classical algorithm (a decoder) to find a correction operator. Recently, a cellular automaton decoder was proposed for a broad family of topological codes defined on lattices without boundaries. This decoder is a local decoder and does not require multiple rounds of syndrome extraction to deal with measurement errors. In this work, we extend this cellular automaton decoder to topological codes defined on lattices with boundaries and compare its performance to other decoding algorithms.

Session L28 DQI: Distributed Quantum Computation, Networking and Information Security I BCEC 161 - Stephanie Wehner, Delft Univ of Tech - Tag(s): Focus
11:15AM L28.00001: Linking trapped-ion quantum nodes* [Invited] TRACY NORTHUP (Presenter), Institute for Experimental Physics, University of Innsbruck — Future quantum networks offer a promising route to quantum-secure communication, distributed quantum computing, and quantum-enhanced sensing. The applications of a given network will depend on the capabilities available at its nodes, which may be as simple as quantum state generation and measurement or as advanced as a universal quantum computer. Here, we focus on quantum nodes based on calcium ions confined in a linear Paul trap, an experimental platform with which high-fidelity state preparation, gate operations, and readout have been demonstrated.

By coupling trapped ions to the mode of an optical resonator, we construct a coherent interface between single ions and single photons. I will present ongoing work to transfer photonic quantum states between two remote trapped-ion systems, highlighting the experimental challenges and identifying the key components for scaling up such links into networks.

*This work was supported by the Army Research Laboratory Cooperative Agreement No. W911NF15-2-0060, the Austrian Science Fund (FWF) Project F4019, and the EU Horizon 2020 Project DLV-820445.

11:51AM L28.00002: Diamond quantum networks for distributed quantum computation TIM HUGO TAMINIAU (Presenter), QuTech and Kavli Institute of Nanoscience, Delft University of Technology — A promising approach for quantum computations is to distribute logical qubits and error correction over a quantum network. This approach is naturally extendable to larger sizes by adding independent modules and enables exploring a large variety of error correction codes over different network topologies, including three-dimensional structures and non-nearest neighbor connections.

The NV center in diamond provides a powerful platform to realize such quantum networks. It combines optical entanglement links [Nature 526, 682, 2015] and long-lived multi-qubit nodes that can store and process quantum information [Nature Comm. 7:11526, 2016; Nature Comm. 9:2552, 2018]. In this talk I will present our recent experimental progress towards quantum networks for distributed quantum computations and argue that we are getting close to the point where imperfections can be overcome by quantum error correction, so that logical qubits encoded over the network become increasingly more stable as the network is made increasingly larger.

12:03PM L28.00003: Distributed Quantum Computing Architectures MARTIN SUCHARA (Presenter), YURI ALEXEEV, JOAQUIN CHUNG MIRANDA, RAJKUMAR KETTIMUTHU, Argonne National Laboratory — Despite dramatic improvements in quantum gate fidelities, coherence times and qubit counts, the capabilities of quantum processors will remain modest in the near future. We compare two approaches that use small unreliable quantum processors to solve large computational problems. The first approach uses hybrid quantum-classical architectures where larger quantum circuits are broken into smaller sub-circuits that are evaluated separately, either using small quantum processors or a quantum simulator running on a classical supercomputer. The second approach leverages quantum networks to teleport shared qubits between quantum processors. We compare the suitability of these techniques for various quantum circuits, describe optimizations that enable mapping quantum circuits into sub-circuits, and compare the hardware requirements of the two approaches.

12:15PM L28.00004: Numerical finite-key analysis of quantum key distribution* DARIUS BUNANDAR (Presenter), DIRK R. ENGLUND, Massachusetts Institute of Technology — Quantum key distribution (QKD) is still the only quantum-resistant method of sending secret information at a distance. However, accurate theoretical analysis of QKD that accounts for device imperfections is usually challenging. To circumvent this problem, we have developed an efficient numerical approach to calculate the secret key rates of any QKD protocol. Our approach takes only a brief description of the protocol and the measurement results as inputs. The method outputs the secret key rates by solving a semidefinite program which includes not only practical device imperfections but also statistical fluctuations typically observed in QKD experiments.

Distributed Routing in a Quantum Internet

The aim of Quantum Internet is to enable the transmission of qubits between distant quantum devices, in order to achieve tasks that are impossible using classical information. Due to the losses in communication channel, routers are necessary for long distance quantum communication. In such a network, two distant parties share entanglement using the repeaters and transmit qubits using teleportation. However, due to the technological limitation, establishing long distance entanglement takes time and it increases waiting time. This raises the question whether an advantage can be achieved by distributing entanglement ahead of time. In this article we study distribution of entanglement in advance in a network vs producing it on demand. Here we model this problem as a distributed routing in an undirected simple graph. The nodes and edges in the graph denote the routers and communication links. To share an entangled state, two nodes first find a path in the graph and then use the pre-shared entanglement to perform entanglement swapping along that path. To find a path in the graph we use greedy location based routing algorithms. We have done a comparative study of the waiting time for all of the models.

Quantum Network Simulations

Network simulations are extensively used in the design, operation, and evolution of large-scale classical networks. We expect that simulations will also play a significant role in developing and evolving quantum networks. Our work focuses on developing quantum network simulators at various network layers ranging from the physical layer to applications. We envision the need for three simulators. The lowest-layer simulator allows us to study the physics of optical networks; an intermediate-layer simulator studies quantum networking protocols and the classical control network; and the highest-layer one simulates behavior of distributed quantum systems. The lowest-layer simulator uses Monte Carlo methods to evaluate the effects of Pauli errors and investigate the effectiveness of entanglement purification or error correction in the presence of realistic noise. The intermediate-layer simulator uses traditional techniques such as discrete event simulation to investigate scalability of network topologies and ability to communicate between arbitrary pairs of network nodes. Finally, the highest-layer simulator emulates both quantum computing and quantum networking by using HPC. It can be used for testing and developing new distributed quantum algorithms and applications.

Anonymous transmission in a noisy quantum network using the W state

We consider the task of anonymously transmitting a quantum message in a network. In this task, we are concerned with hiding the identities of the sender and receiver of the message from other nodes of the network. We present a protocol that accomplishes this task using the W state. We analyze its performance in a quantum network where common forms of noise are present, and then compare the performance of our protocol with some of the existing protocols developed for the task of anonymous transmission. We show that, in many regimes, our protocol tolerates more noise and achieves higher fidelities of the transmitted quantum message than the other ones. Furthermore, we demonstrate that our protocol tolerates one non-responsive node, as opposed to other considered protocols. Finally, we prove the security of our protocol in a semi-active adversary scenario, i.e. when the adversary is active and the source of a quantum state is trusted.

Anonymous transmission in a noisy quantum network using the W state

Towards a multi-node network with NV centres in diamond

Quantum networks are expected to deliver definitive security for communication, blind quantum computation, improved clock synchronization and more exotic applications such as connecting far apart telescopes. A node of such a network must be capable of running small quantum computations, storing quantum information in memory qubits and generate entanglement with neighbouring nodes.

The nitrogen-vacancy (NV) in diamond is a strong candidate to act as node, as it combines all the mentioned requirements in a solid-state system. Deterministic generation of entanglement between two distant NV centres has been recently shown by our group.

We present our recent progress on the ongoing effort to generate genuine multipartite entanglement between three distant NV centres, as we overcome the obstacles to move beyond two node networks.
Impact of qubit connectivity on quantum algorithm performance

Adam Holmes, Sonika Johri, Gian Giacomo Guerreschi, Jim Clarke, Anne Matsuura (Presenter), Intel — Quantum computing hardware is undergoing rapid development from proof-of-principle devices to scalable machines that could eventually challenge classical supercomputers on specific tasks. On platforms with local connectivity, the transition from one-to-two-dimensional arrays of qubits is seen as a natural technological step to increase the density of computing power and to reduce the routing cost of limited connectivity. Here we map and schedule representative algorithmic workloads - the Quantum Fourier Transform (QFT) relevant to factoring, the Grover diffusion operator relevant to quantum search, and Jordan-Wigner parity rotations relevant to simulations of quantum chemistry and materials science - to qubit arrays with varying connectivity. In particular we investigate the impact of restricting the ideal all-to-all connectivity to a square grid, a ladder and a linear array of qubits. Our schedule for the QFT on a ladder results in running time close to that of a system with all-to-all connectivity. Our results suggest that some common quantum algorithm primitives can be optimized to have execution times on systems with limited connectivities, such as a ladder and linear array, that are competitive with systems that have all-to-all connectivity.

Time-bin and Polarization Superdense Teleportation for Space Applications*

Joseph Chapman (Presenter), University of Illinois at Urbana-Champaign, Trent Graham, Univ of Wisconsin, Madison, Christopher Zeitler, Paul G Kwiat, University of Illinois at Urbana-Champaign —

To build a global quantum communication network, low-transmission, fiber-based communication channels can be supplemented by using a free-space channel between a satellite and a ground station on Earth. We have constructed a system that generates hyperentangled photonic "ququarts" and measures them to execute multiple quantum communication protocols of interest. We have successfully executed and characterized superdense teleportation---our measurements show an average fidelity of 0.94±0.02, with a phase resolution under 7° allowing reliable transmission of >10^5 distinguishable quantum states. Additionally, we have demonstrated the ability to compensate for the Doppler shift, which would otherwise prevent sending time-bin encoded states from a rapidly moving satellite, thus allowing the low-error execution of phase-sensitive protocols during an orbital pass.

Simulation of a 1025-node quantum repeater chain of NV centres with NetSquid, a new discrete-event quantum-network simulator

Tim Coopmans (Presenter), Axel Dahlberg, Matthew Skrzypczyk, Filip Rozpedek, Roeland Ter Hoeven, Leon Wubben, Delft University of Technology, Rob Knegjens, Julio de Oliveira Filho, Netherlands Organization for Applied Scientific Research (TNO), David Elkouss, Stephanie Wehner, Delft University of Technology — We simulate quantum repeater chains of up to 1025 nodes holding nitrogen-vacancy (NV) centres as quantum processors. We model qubit decoherence, timing and fidelity of both gates and readout according to experimental data. The model also incorporates scheduling operations on the quantum state as imposed by the physics of NV centres. For example, the presence of a single communication qubit, the electron spin, only allows for entanglement generation with one remote node simultaneously. As a consequence of the accurate modelling, the numerical results indicate directions for future hardware development. In particular, we analyse the sensitivity of hardware parameters on the performance of the entire repeater chain. We also perform optimisation over several parameters and configurations, such as the number of NV centres in a single node and the scheduling for entanglement purification steps.

For these simulations, we have developed a generic quantum-network discrete-event simulator called NetSquid, which is capable of simulating decoherence together with imperfect quantum-state operations and stochastic feedback loops.
11:15AM L29.00001: Fast Parametric Gates with Superconducting Qubits  
X. Y. JIN (Presenter), SHLOMI KOTLER, KATARINA CICAK, FLORENT LECOCQ, JOHN TEUFEL, JOSE AUGMENTADO, RAYMOND SIMMONDS, National Institute of Standards and Technology Boulder — We discuss a system with two transmon qubits coupled parametrically through a shared dc-SQUID coupler. The coupling can be tuned from nominally zero to up to more than 100 MHz. This coupling mechanism can be used to perform a two-qubit controlled Z-gate. We present the latest experiment results on the gate operation.

WEN-LONG MA (Presenter), KYUNGJOO NOH, PHILIP REINHOLD, SERGE ROSENBLUM, STEVEN GIRVIN, ROBERT J SCHOELKOPF, LIANG JIANG, Department of Applied Physics and Physics, Yale University — In circuit quantum electrodynamics (QED), it has been demonstrated that universal control of the cavity states can be realized by quantum control of a transmon coupled to the cavity in the strongly dispersive regime. An important class of quantum gates are the selective number-dependent arbitrary phase (SNAP) gates, which impart arbitrary phases to the different Fock states of the cavity by cyclically driving the transmon. However, the SNAP gate fidelity is limited by the transmon relaxation and dephasing. Here we show that by using a multi-level transmon and conditional evolution on the transmon state after the gate, the SNAP gate can be made fault-tolerant to the dominant transmon relaxation and dephasing errors. The simulations show that the SNAP gate infidelity can be reduced compared to that of non-fault-tolerant SNAP gate. The fault-tolerant SNAP gates combined with the displacement operations on the cavity can realize fault-tolerant quantum computation in circuit QED.

11:39AM L29.00003: High-fidelity conditional two-qubit swapping gate using tunable ancillas*  
NIELS JAKOB LOFT (Presenter), Aarhus University, MORTEN KJÆRGÅRD, Massachusetts Institute of Technology, LASSE BJØRN KRISTENSEN, Aarhus University, CHRISTIAN KRAGLUND ANDERSEN, ETH Zürich, THORVALD W LARSEN, Niels Bohr Institute, Univ of Copenhagen, SIMON GUSTAVSSON, WILLIAM D OLIVER, Massachusetts Institute of Technology, NIKOLAJ T ZINNER, Aarhus University — Scalable quantum computing relies crucially on high-fidelity entangling operations. Here we demonstrate that four coupled qubits can operate as a high-fidelity two-qubit entangling gate that swaps two target qubits and adds a relative sign on the $|11\rangle$ state (ZSWAP). The gate operation is controlled by the state of two ancilla (control) qubits. The system is readily implementable with superconducting qubits, using capacitively coupled qubits arranged in a diamond-shaped architecture. By using realistic device and noise parameters from state-of-the-art superconducting qubits, we show that the conditional ZSWAP operation can be implemented with a fidelity above 0.99 in a time of about 65 ns.

11:51AM L29.00004: Implementation of a Walsh-Hadamard gate in a superconducting qutrit*  
MUHAMMET ALI YURTALAN (Presenter), Institute for Quantum Computing, Department of Electrical and Computer Engineering, and Waterloo Institute for Nanotechnology, University of Waterloo, JIAHAO SHI, ADRIAN LUPASCU, Institute for Quantum Computing, Department of Physics and Astronomy, and Waterloo Institute for Nanotechnology, University of Waterloo, SAHEL ASHHAB, Qatar Environment and Energy Research Institute (QEERI), Hamad Bin Khalifa University (HBKU), Qatar Foundation, Qatar — We present the experimental demonstration of a generalized Walsh-Hadamard gate, which is a Quantum Fourier Transform gate, for a qutrit embedded in the lowest three energy levels of a superconducting circuit. This circuit is a three Josephson junction flux qubit in which all three junctions are shunted by large coplanar capacitors. We use a decomposition of the quantum gate into two unitary operations, one implemented by an off-diagonal Hamiltonian and the other implemented by a diagonal Hamiltonian. The off-diagonal Hamiltonian is obtained by the simultaneous driving of the transitions between levels 0-1, 1-2, and 0-2, with the latter being a two-photon process. The diagonal Hamiltonian is effectively implemented by appropriately shifting the phases of the driving fields. We find that multi-level ac-Stark shifts play an important role in the dynamics, and we adjust the pulse parameters to correct for these shifts. The gate is characterized using tomography of the generated output states corresponding to a set of input states. The average fidelity exceeds 90%, in good agreement with numerical simulations that take into account the multi-level structure of the system.

12:03PM L29.00005: Microwave-based CPHASE gates for transmon qubits*  GEORGE BARRON (Presenter), FERNANDO CALDERON-VARGAS, SOPHIA ECONOMOU, Department of Physics, Virginia Tech — Superconducting transmon qubits are of great interest for quantum simulation of quantum chemistry. A key component of these algorithms is breaking up the evolution into small steps, which naturally leads to the need for non-maximally entangling, arbitrary CPHASE gates. Here we design such microwave-based gates using an analytically solvable approach leading to smooth, simple pulses. Our protocol allows for the continuous tuning of the phase. We find CPHASE fidelities of more than 0.999 and typical gate times less than 100ns.

*This research is supported by the Department of Energy, Advanced Scientific Computing Research Quantum Testbed Pathfinder Program under FWP ERKJ332.

12:15PM L29.00006: Limitations and improvements of two qubit gates in superconducting circuit QED*  RAVI NAIK (Presenter), BRADLEY MITCHELL, UNPIL BAEK, DAR DAHLEN, JOHN MARK KREIKEBAUM, VINAY RAMASESH, MACHIEL BLOK, IRFAN SIDDIQI, Physics, Univ of California – Berkeley — Remarkable progress has been made towards creating and operating processors for quantum computation and simulation with superconducting circuits, with respect to qubit count and coherence time. This has allowed for the implementation of a variety of quantum algorithms on small quantum processors, with promising results thus far. However, significant limitations on the fidelity of multi-qubit entangling gates remain, placing constraints on the scalability of current processors with respect to algorithmic circuit depth. We explore the sources of errors in these gates, include designs with employ cross-resonance and parametric interactions, and attempt to correct and/or mitigate the errors with hardware improvements, control sophistication, and algorithmic error suppression.

*This work was supported by the Army Research Office.

12:27PM L29.00007: Novel Two-qubit Gate Through Raman-type Transition  BAPTISTE ROYER (Presenter), Universite de Sherbrooke, SEBASTIAN KRINNER, PHILIPP KURPIERS, PAUL MAGNARD, ANDREAS WALLRAFF, ETH Zürich, ALEXANDRE BLAIS, Universite de Sherbrooke — Two-qubit gates are essential for quantum computing. Presently, the low fidelity of these operations is a major factor limiting the physical implementation of long quantum algorithms. In this talk, we propose an entangling gate for directly coupled superconducting qubits based on a Raman-type transition and numerically show that it is fast and high fidelity. This gate is all-microwave and does not require additional hardware compared to standard cQED experiments.

12:39PM L29.00008: Operation and error budget of the Cross-Resonance gate*  VINAY TRIPATHI (Presenter), University of California, Riverside, MOSTAFA KHEZRI, University of Southern California, ALEXANDER N. KOROTKOV, University of California, Riverside — We analyze operation of the Cross-Resonance (CR) gate, in which control qubit is driven at the frequency of target qubit to realize the CNOT gate after additional single-qubit rotations. Numerical simulations for multi-level transmons and particular pulse shapes are used to find the CNOT time and parameters of single-qubit rotations as functions of the drive amplitude $\epsilon$. To understand these dependences, including saturation of the CNOT time at large $\epsilon$, we develop analytical and semi-analytical theories, which agree well with the numerics. We also calculate intrinsic infidelity of the CR gate as a function of $\epsilon$ and find a minimum, created by the interplay between leakage and imperfect unitary evolution. The error budget of the CR gate can be approximately described analytically or semi-analytically.

*This work was supported by ARO grant No. W911NF-18-1-0178.

12:51PM L29.00009: DEMUXYZ Gate Using Single Microwave Drive Line for Multiple Qubits*  CAROLYN EARNEST (Presenter), JEREMY BEJANIN, EVAN PETERS, MATTEO MARIANTONI, Physics & IQC, University of Waterloo — Superconducting qubits have the potential to lead to large-scale quantum computers with $10^5$ or more qubits in 2D arrays. As the number of qubits increases, finding methods to connect all the necessary control lines to each qubit can become a serious challenge. In this talk, we introduce a new one-qubit gate: DEMUXYZ. This gate makes it possible to decrease the number of microwave control lines from $N^2$ to 1 by allowing multiple qubits to share a single microwave line. The shared line carries a continuous wave (CW) microwave tone, which is initially detuned from the qubits' idle frequency. When a qubit must undergo an arbitrary rotation on the Bloch sphere, the qubit is tuned on resonance with the CW tone and allowed to interact with the drive for the duration required to achieve the desired rotation. The rotation phase is tuned by detuning the qubit frequency away from the drive and idle frequency for the required time length. We demonstrate a first proof of concept for this gate performing experiments on two Xmon transmon qubits.

*This research was undertaken thanks in part to funding from the Canada First Research Excellence Fund (CFREF) and the Discovery and Research Tools and Instruments Grant Programs of the Natural Sciences and Engineering Research Council of Canada (NSERC).
1:03PM L29.00010: Realistic simulations of flux-pulse-based controlled-phase gates in superconducting qubits*  
FRANCESCO BATTISTEL (Presenter), QuTech, Delft University of Technology, MICHEL ADRIAAN ROL, FILIP K MALINOWSKI, BRIAN M TARASINSKI, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, BARBARA TERHAL, QuTech, Delft University of Technology — We study the performance of the controlled-phase gate in flux-pulsed transmons by running extensive numerical simulations. We include thermal relaxation, dephasing due to fast and quasi-static components of the noise, leakage, and pulse-shape distortions, validating our model with experimental data. We first consider the conventional Geller-Martinis pulse and find that the leakage strongly depends on the dephasing times and that there is an optimal tradeoff between fidelity, leakage and pulse length. Also, we show that state-of-the-art distortion correction techniques can sufficiently reduce pulse distortions so that they are not a limiting factor. Finally, we compare the Geller-Martinis pulse with a novel double-sided pulse that we call net-zero, which has a built-in echo effect. We find better performance for net-zero than for the conventional pulse with respect to the same noise parameters.  
*This research is supported by ERC grant EQEC No. 682726 and IARPA (U.S. Army Research Office grant W911NF-16-1-0071).

1:15PM L29.00011: Toward a Universal Gate Set on a Qubit Encoded in Superconducting Cavities*  
JACOB CURTIS (Presenter), BRIAN J LESTER, CHRISTOPHER WANG, YVONNE GAO, YAXING ZHANG, LUIGI FRUNZIO, MICHEL H. DEVORET, LIANG JIANG, STEVEN GIRVIN, ROBERT J SCHOELKOPF, Yale Univ — Superconducting microwave cavities coupled to transmon ancillae are an attractive platform for the storage and manipulation of continuous variable (CV) quantum states. Each cavity is a bosonic mode that provides a long coherence time and a large Hilbert space that can be used to redundantly encode quantum information. The coupled transmon ancilla enables nearly arbitrary control over the state of each mode and can be used to perform high quality quantum nondemolition (QND) measurements of the cavity state. Further, it has been demonstrated that the nonlinearity of these ancilla transmons can be driven to enact parametric operations on the system, such as a bilinear coupling between two modes (Gao, et al., PRX 2018). Performing these operations with high fidelity requires mitigating dephasing effects arising from intrinsic properties of the transmon-cavity system as well as external drives. Here, we present our experimental progress towards mitigating these effects and enabling successive, high-fidelity pumped operations on states stored in these cavities.  
*We acknowledge support from the ARO (W911NF-14-1-0011) and AFOSR (FA9550-15-1-0015); BJL from Yale QIMP Fellowship; SMG from NSF (DMR-1609326); LJ from the Sloan (BR 2013- 049) and the Packard Foundations (2013-39273).

1:27PM L29.00012: Two-Qubit Gates with Fluxonium Circuits.*  
YINQI CHEN (Presenter), KONSTANTIN NESTEROV, University of Wisconsin - Madison, IVAN PECHENIZHSKIY, University of Maryland - College Park, ZHENYI QI, University of Wisconsin - Madison, LONG NGUYEN, YEN-HSIANG LIN, AARON SOMOROFF, RAY MENCIA, VLADIMIR MANUCHARYAN, University of Maryland - College Park, MAXIM VAVILOV, University of Wisconsin - Madison — Among superconducting qubits, the fluxonium offers a unique advantage of the possibility to use different transitions for memory storage and gate realizations [1]. In this talk, we discuss various ways to make entangling gates between fluxoniums using noncomputational levels of the two-qubit system. In one example, a controlled-Z gate is activated by driving a transition leading out of the computational subspace while two qubits are kept at fixed frequencies at their sweet spots [2]. The second example is based on adiabatic tuning of one or both of the qubits away from their sweet spots towards the avoided level crossing between a computational and noncomputational levels [3]. One more possible gate is mediated through a common resonator mode. We compare all the techniques and discuss their advantages and limitations.  
*We acknowledge funding from the U.S. Army Research Office (Grant No. W911NF-18-1-0146).
Superadiabatic Stimulated Raman adiabatic passage in a three-level transmon* ANTTI VEPSÄLÄINEN (Presenter), SERGEY DANILIN, SORIN PARAOANU, Department of Applied Physics, Aalto University — Quantum control by adiabatic pulses presents the advantage of robustness under errors in the control parameters, yet it is inherently slow. Here I present an implementation of the superadiabatic protocol in a three-level system realized with a transmon superconducting circuit, where an additional control pulse is used to cancel the non-adiabatic evolution of the system. This enables the transfer of population from the ground state to the second excited state by stimulated Raman adiabatic passage in only a few tens of nanoseconds, approaching the quantum speed limit. As a bridge between adiabatic and direct methods, superadiabatic concept allows a continuous interpolation between the speed and robustness of the population transfer. As a result, it is possible to choose an optimal protocol speed that meets the given robustness criteria. This is particularly important in the field of circuit quantum electrodynamics, where the acceptable duration of the protocol is limited by the coherence time. Additionally, combination of two superadiabatic passages can be used to form a robust rotation gate in the \(|0\rangle - |2\rangle\) subspace.

*We acknowledge financial support from Väisälä Foundation and the Academy of Finland.

Realization of two-qubit gates with tunable couplers in superconducting circuits* MICHELE COLLODO, JOHANNES HERRMANN, ANTS REMM, JEAN-CLAUDE BESSE, CHRISTIAN KRAGLUND ANDERSEN, SEBASTIAN KRINNER, ANDREAS WALLRAFF, CHRISTOPHER EICHLER (Presenter), ETH Zurich — The realization of two-qubit gates with high fidelity and low crosstalk is a key requirement for the scale-up of quantum processors based on superconducting circuits. Two-qubit gates are typically based on either microwave-controlled interactions or on the in-situ tunability of qubit frequencies. Alternative approaches using tunable coupling elements have also been investigated more recently. Here, we report on the design and implementation of a flux-tunable coupler, featuring small residual qubit-qubit interactions when gates are idle. We study gate operations based on both fast DC flux control and parametric flux modulation.

*We acknowledge support by the US ARO grant W911NF-16-1-0071 and by NCCR QSIT.

Wednesday, March 6, 2019 11:15 AM - 2:03 PM

Session L30 GMED: Novel Acquisition Geometries, Radiation Sources, Hardware, and Algorithms for Medical Imaging

The potential of stationary digital tomosynthesis [Invited] EMILIO QUAIA (Presenter), Department of Radiology, University of Padova (Italy) — Digital Tomosynthesis (DT) as a limited angle 3D imaging technique has already demonstrated its clinical superiority compared to planar 2D X-ray. Current systems however, are expensive, lack mobility and are often susceptible to motion breath artifacts due to long acquisition times. Innovative solutions to miniaturize and basically reinvent the X-ray source such as cold-cathode field emitters, allow for the creation of compact array of individual addressable emitters in the form of a flat panel source (FPS). The advantages of a device using an FPS compared to conventional X-rays and DT systems include the ability to acquire images from different angles without any physical movement, the option to create small and compact devices that can be used for bedside imaging and faster acquisition times that will likely reduce the number and severity of motion artefacts. These advantages will likely result in several clinical benefits that will also be discussed. Potential concerns will also be discussed such as a reduced stand-off-distance of the source to the detector, large incidence angles of x-rays and low signal-to-noise ratio of the individual frames which can lead to various effects such as magnification, scattering, and Poisson noise.
11:51AM L30.00002: Cellulose-Based Photonic Nanoparticles for Biomedical Imaging* BERNEY PENG (Presenter), MOHAMMAD ALMEQDADI, Tufts University, FABRICE LAROCHE, Boston University, SHAJESH PALANTAVIDA, MAXIM E DOKUKIN, Tufts University, JATIN ROPER, OMER YILMAZ, MIT, HUI FENG, Boston University, IGOR SOKOLOV, Tufts University — Here we present a fluorescent targeting nanoparticle contrast agent that can serve as an effective companion solution for biomedical imaging and diagnostics of cancer. Particles can be used to label intra- and extracellular biomarkers and provide key information for clinical decisions based on high resolution, real-time optical imaging while mitigating off-target immunogenic effects. We utilize cellulose acetate to develop a class of benign, natural, and chemically inert fluorescent nanoparticles possessing well-defined safety profiles. Particles are generated from supramolecular assemblies of cellulose acetate and guest polymers, producing composite materials with good biocompatibility, tunable morphology, physical encapsulation ability, and excellent luminescence. We demonstrate effective in vivo targeting of sub-mm tumors in zebrafish cervical cancer xenografts as well as topical targeting of colon cancer tumors in mice. We expect a topically administered contrast agent can provide great clinical value especially in the realm of colorectal endoscopies.

*NSF CBET 1745530 is acknowledged by I.S. H.F. acknowledges NIH CA215059 and the St. Baldrick's Foundation. F.J.F.L. acknowledges fellowship from Boston University Innovation Center in Nanotechnology for Cancer.

12:03PM L30.00003: Deformable motion correction for interventional cone-beam CT* SARAH CAPOSTAGNO (Presenter), ALEJANDRO SISNIEGA, Department of Biomedical Engineering, Johns Hopkins University School of Medicine, TINA EHTIATI, Siemens Medical Solutions USA, Inc., J. WEBSTER STAYMAN, Department of Biomedical Engineering, Johns Hopkins University School of Medicine, CLIFFORD R WEISS, Department of Radiology, Johns Hopkins University School of Medicine, JEFFREY SIEWERDSEN, Department of Biomedical Engineering, Johns Hopkins University School of Medicine — Cone-beam CT (CBCT) is a valuable tool for guiding interventional procedures, including embolization and ablation of soft-tissue targets. However, long scan times (5-30 s) make CBCT susceptible to artifacts arising from involuntary motion. This work reports a method to estimate deformable motion from scan data without additional patient monitoring. A motion vector field (MVF) is computed that minimizes a gradient entropy objective function for image sharpness. MVFs describing deformable motion were estimated as a spatial interpolation of M rigid motion trajectories, each with temporal motion modeled by an N-point spline. Abrupt changes were penalized via spatial-temporal regularization, and a modified 3D filtered backprojection approach was used for motion-corrected image reconstruction. The method was evaluated in digital simulation, cadaver, and retrospective clinical studies. Sharpness of edges at soft-tissue boundaries improved by 75% (4.4±1.1 to 1.1±0.1 mm), 77% (2.2±0.1 mm to 0.5±0.0 mm), and 33% (0.9±0.1 to 0.6±0.1 mm), respectively. These initial studies demonstrate feasibility of correcting deformable organ motion, which will increase the utility and precision of CBCT guidance.

12:15PM L30.00004: Quantitative vs qualitative evaluation of automatic segmentation JENNIFER PURSLEY (Presenter), GENEVIEVE MAQUILAN, GREGORY SHARP, Radiation Oncology, Massachusetts General Hospital and Harvard Medical School — Automatic segmentation of anatomic regions in medical images has the potential to improve treatment efficiency for image-guided interventions. While many algorithms for automatic segmentation have been developed, evaluation of their clinical usability is largely limited to quantitative metrics such as measures of region overlap (Dice coefficient) or surface distance (Hausdorff distance). Quantitative metrics only tell part of the story; an auto-segmented contour of a small organ, such as an optic nerve, may have a low Dice coefficient but still be clinically acceptable, while a large organ, such as a prostate, may have a high Dice coefficient but be clinically unacceptable. The goal of this work is to explore the use of a qualitative evaluation system for rating the clinical acceptability of auto-segmented contours, and establish the relation between quantitative and qualitative metrics. The qualitative system is designed with 5 levels ranging from “clinically acceptable” to “completely unacceptable” and evaluated by multiple expert observers for pelvic and abdominal structures. If correlation between quantitative and qualitative metrics are found, it would establish scientific basis for the use of quantitative metrics in the evaluation of medical image segmentation.
A Statistical Model Relating Image Quality to Image Registration Accuracy in Image-Guided Surgery

**MICHAEL KETCHA** (Presenter), THARINDU DE SILVA, RUNZE HAN, ALI UNERI, Johns Hopkins University, SEBASTIAN VOGT, GERHARD KLEINSZIG, Siemens Healthineers, JEFFREY SIEWERDSEN, Johns Hopkins University — Image-guided procedures often rely on the ability to accurately register (i.e., align the coordinate systems of) a preoperative image and an intraoperative image. While the accuracy of this registration step is generally thought to increase with improved image quality (in x-ray CT, for example, achieved at the cost of higher dose), there is little quantitative understanding of how registration accuracy relates to image quality. We present a statistical model that relates factors of spatial resolution, noise, and dose to image registration accuracy (viz. root-mean-squared error in the transform parameters). We further show how this framework may be extended to model how rigid registration of bone structures is affected by deformation of surrounding soft-tissue structures. The model is tested in comparison to experiments performed over a range of dose and deformation magnitude showing accurate agreement in general trends and prediction of optimal registration similarity metric. A statistical foundation for understanding the effect of image quality and soft-tissue deformation is an important step in physics-based modeling of imaging systems and guiding the development of new systems for image-guided procedures.

Neural network-based delineation of clinical target volumes for glioma patients

**NADYA SHUSHARINA** (Presenter), DAVID EDMUNDS, Harvard Medical School, JONAS SÖDERBERG, FREDRIK LOFMAN, Raysearch Laboratories, HELEN SHIH, THOMAS BORTFELD, Harvard Medical School — Outlining the clinical target volume (CTV) in radiotherapy can be time-consuming and error-prone. We propose a convolutional neural network (CNN)-assisted delineation of the CTV for glioma, aiming to reduce inter- and intra-observer variability and decrease treatment planning time. Microscopic disease spread in the brain is restricted by anatomical barriers that are impenetrable by tumor cells. These brain barrier structures were automatically segmented using a 3D CNN trained on 25 datasets of registered planning CT and diagnostic MR images. Satisfactory results were obtained for segmentation of skull, brainstem, corpus callosum, cerebellum, falx cerebri, brain sinuses, tentorium, and ventricles. Segmentation quality was assessed by comparing CNN-derived and manually drawn structures using an independent dataset. The Dice score ranged from 73% to 96% and did not improve after more patients were added to the training dataset. After segmentation, the CTV was generated by expanding the gross tumor volume (GTV) by a fixed radius, excluding voxels contained in other segmented structures. We will compare CNN-derived CTV quality with manually delineated CTVs for a large set of 100 patients.

Deep Learning Vessel Segmentation for Microsurgical Free Tissue Transfer

**KATHARINA HOEBEL** (Presenter), Harvard-MIT Division of Health Sciences and Technology, BRANISLAV KOLLAR, Plastic Surgery, Brigham and Women's Hospital, KEN CHANG, Harvard-MIT Division of Health Sciences and Technology, ANDREW BEERS, JAMES BROWN, Athinoula A. Martins Center for Biomedical Imaging, JAY PATEL, Harvard-MIT Division of Health Sciences and Technology, BOHDAN POMAHAC, Plastic Surgery, Brigham and Women's Hospital, JAYASHREE KALPATHY-CRAMER, Athinoula A. Martins Center for Biomedical Imaging —

**Introduction:** Free autologous tissue techniques like DIEP (deep inferior epigastric perforator) are regarded as state-of-the-art for patients undergoing breast reconstruction after oncological mastectomy. However, surgeons have to rely on their experience in the identification of the vascular perforators suitable for flap harvest as there exists no standardized approach to this problem.

**Objective:** To develop a deep-learning method to autonomously segment vessels in the abdominal wall of patients undergoing autologous breast reconstruction to guide pre-surgical planning.

**Methods:** Manual segmentation of vessel perforators was performed on abdominal CTAs of 24 patients (20 training, 4 validation) undergoing autologous breast reconstruction at the Brigham and Women's Hospital by an expert rater. A 3D U-net model implemented in DeepNeuro with Keras backend (Beers et al. 2018) was trained to automatically segment vessels in CTAs.

**Results:** Sensitivity and specificity of the trained model was 0.70/0.70 (training/validation) and 0.99/0.98 (training/validation), respectively.

**Conclusion:** The described model can reliably perform automatic vessel segmentation in CTA. We will further evaluate this result for guidance of pre-surgical decision making.

1:03PM L30.00008: A Deep Learning Approach to Early Cancer Detection using Near-Infrared Laser Scattering Profiles

MASON ACREE (Presenter), CHRISTOPHER BERNEAU, PORTIA DENSLEY, GUNNAR JENSEN, VERN HART, Utah Valley University — In the early stages of most cancers, before lesions are visible on a CT or MRI, changes begin to occur at the cellular level as nuclei elongate and mitochondria cluster unevenly. As these organelles are responsible for much (>40%) of the optical scattering which occurs in a cell, changes in cell morphology and structure can largely affect the resulting optical signature. Variations in the physical properties of different cancer types leads to a distinct scattering profile unique to each disease. In this study, optical scattering patterns were investigated from five different cancer cell lines, which were irradiated in vitro with a NIR (854 nm) diode laser. The resulting patterns were collected with a CMOS beam profiler and used to train a convolutional neural network. Differences in these profiles were subtle yet significant enough to allow successful classification by the neural network. After being trained with a set of augmented images from each cancer type, the network was able to distinguish cell lines with an accuracy of up to 98.5%. The accurate classification of these patterns at low concentrations could contribute to the early detection of cancerous cells in otherwise healthy tissue. Current methods will also be discussed such as semantics and instance segmentation.

1:15PM L30.00009: Quantitative Cone-Beam CT with High-fidelity Modeling of Imaging Physics

QIAN CAO (Presenter), SISNIEGA ALEJANDRO, MICHAEL BREHLER, SHALINI SUBRAMANIAN, J. WEBSTER STAYMAN, JEFFREY SIEWERDSEN, WOJCIECH ZBJEWSKI, Johns Hopkins University — Bone mineral density (BMD) and bone microstructure are key biomarkers of orthopedic health. Quantitative assessment of these parameters requires high accuracy of reconstructed attenuation values and high spatial resolution. We employ advanced models of x-ray propagation to optimize performance of specialized orthopedic Cone-Beam CT systems in quantitative bone imaging. To achieve accurate measurements of BMD, a model-based reconstruction (MBR) framework utilizing polyenergetic spectral models is used in concert with fast Monte Carlo scatter correction. To advance spatial resolution to a level consistent with trabecular detail (~100 μm), we adopt a customized low-noise CMOS x-ray detector with 400 μm-thick scintillator, optimized through cascaded systems modeling of task-based imaging performance. Studies of BMD accuracy indicate that MBR is able to estimate CaCO₃ concentration with <20 mg/mL error, irrespective of object size and position. The use of optimized CMOS sensor yielded improved correlation with gold-standard micro-CT measurements of bone microstructure compared to current-generation flat-panel detector CBCT, e.g. correlation for trabecular thickness increased from 0.84 with a flat-panel CBCT to 0.96 with CMOS.

1:27PM L30.00010: Quantitative evaluation of inflammatory response dynamics in the lung following proton and photon irradiation

YANJING LI (Presenter), MICHAEL DYKSTRA, Department of Radiation Oncology, Massachusetts General Hospital, Harvard Medical School, TILL BEST, Department of Radiology, Division of Thoracic Imaging and Intervention, Massachusetts General Hospital, Harvard Medical School, JENNIFER PURSLEY, NITISH CHOPRA, HARALD PAGANETTI, HENNING WILLERS, Department of Radiation Oncology, Massachusetts General Hospital, Harvard Medical School, FLORIAN Fintelmann, Department of Radiology, Division of Thoracic Imaging and Intervention, Massachusetts General Hospital, Harvard Medical School, CLEMENS GRASSBERGER, Department of Radiation Oncology, Massachusetts General Hospital, Harvard Medical School — We analyzed lung density changes in lung cancer patients receiving stereotactic body radiation therapy with protons (SBPT) or photons (SBRT). Follow-up computer tomography (CT) scans were registered to pre-treatment scans using B-spline based deformable image registration. Dose response curves (DRC) were used to correlate the radiographic change in Hounsfield Units (HU) to the radiation dose and fitted using linear regression to provide a quantitative measure of normal lung response. CTs were also evaluated by a thoracic radiologist. 46 patients (23 SBPT/SBRT) were matched based on patient characteristics, quantitative assessment correlated highly with expert evaluation (p<10⁻¹³, rho=0.6). The maximum response averages 3.8±3.0 (SBPT) versus 3.2±2.4 HU/Gy (SBRT). The lung response after SBRT significantly increases over the observation period (p=0.003), but not after SBPT, indicating an accelerated acute response after SBPT. We demonstrate that quantitative normal lung response evaluation correlates well with established grading systems and differences in response dynamics after SBPT compared to SBRT, that warrant further investigation into their mechanisms of inflammation.

*National Cancer Institute U19CA21239 (PI: Paganetti), American Lung Association LCD-400286 (PI: Willers)
Measurement of In vitro Cancer Tumor Hypoxia* YIHUA ZHAO, Key Laboratory of Optoelectronic Devices and Systems of Ministry of Education and Guangdong Province, College of Optoelectronic Engineering, Shenzhen University, Shenzhen 518, ROBERT AUSTIN (Presenter), KE-CHIH LIN, JAMES STURM, Princeton University, JUNLI QU, Key Laboratory of Optoelectronic Devices and Systems of Ministry of Education and Guangdong Province, College of Optoelectronic Engineering, Shenzhen University, Shenzhen 518 — Tumors are characterized as swamps: abnormal and disordered tissue masses with highly stressful conditions of hypoxia, low pH, low nutrient conditions due to a combination of rapid cell growth, lack of vasculature and altered metabolism. While for normal cells that combination would be lethal, for cancer cells it provides a genotoxic environment they are adapted to. We show here using a phosphorescence lifetime imaging (PLIM) technology based oxygen sensor to monitor the local \(O_2\) level in a extended two dimensional array of cancer cells with strong and mixed gradients to nutrients and \(O_2\) using a novel pure diffusional three dimensional microfabricated technology the emergence of highly hypoxic dormant cell metapopulations.

Novel X-ray Sources for Medical Imaging: Making Old Physics Do New Tricks GIL TRAVISH (Presenter), AQUILA MAVALANKAR, Adaptix Ltd — The diagnosis of medical conditions often relies on medical imaging. Imaging applies basic physics and the techniques deployed have often found their origin in experimental methods. While some of these imaging modalities are new and have rapidly evolved, x-ray imaging has remained relatively stagnant since the introduction of Computed Tomography (CT) and more recently digital x-ray detectors. The availability of low-noise detectors, high speed desk-top computers and new algorithms offers incremental improvements on established x-ray imaging, but also challenges the practitioners in optimally deploying these resources as a primary concern is patient lifetime dose. New x-ray sources are often needed for advanced imaging approaches such as digital tomosynthesis, phase contrast imaging or improved interventional radiology. These novel sources often rely on field enhanced emission and carry new challenges into clinically deployed devices including ultra high vacuum, high voltage switching and the need for active feedback controls. I will describe some of these challenges, the regimes of operation under consideration by various groups, and the practical implications of the physics parameters to radiology.

Room-Temperature Magnetoresistance in Single-Molecule Devices [Invited] ELISEO RUIZ (Presenter), Universitat de Barcelona, ISMAEL DÍEZ-PÉREZ, King's College London — The goal of this communication is to present a well-defined experimental/theoretical route map to reach single-molecule devices based on porphyrin systems showing magnetoresistance at room temperature. We have already reported that STM measurements of deposited metal thiocyanate (and selenocyanate) complexes on heavy metal surfaces that have large spin-orbit contributions allows to detect magnetoresistance.[1,2] Such magnetoresistance effect is similar to that reported by Fert and Grünberg in magnetic metal layers used in hard disk heads, just the inversion of the magnetization of the magnetic tip results in an important change in the transport properties of the device and more recently, in magnetic RAM memories as STT-MRAM devices.

In this study, we also provide results for empty porphyrin and metalloporphyrins based devices attached to the electrodes through thiol-pyridine axial ligands. Our study shows a theoretical analysis and the practical implementation through two-terminal devices using STM equipment to achieve the room temperature molecular-based spintronic nanodevices. It is worth noting that such metalloporphyrin devices show larger complexity than the previously studied systems[1,2]: (i) three peaks in the STM conductance histograms (only one in the metal thiocyanate complexes); (ii) magnetoresistance effect was also found if the electrons are injected from the magnetic nickel tip (for the thiocyanate systems only the effect was detected injecting from the gold substrate); (iii) magnetoresistance effect is smaller than in the thiocyanate systems. Non-equilibrium Green functions combined with DFT calculations have been employed in order to rationalize such results.

Problems in the treatment of transition metal magnetism with the SCAN meta-GGA functional* DAVID SINGH (Presenter), YUHAO FU, University of Missouri — We test the SCAN functional for magnetic transition metals including Fe, Co and Ni and the near magnetic elements, V and Pd. We find that while SCAN modestly enhances magnetic moments it very strongly enhances magnetic energies leading to qualitatively incorrect predictions for technologically important systems including steel. The origin of these large errors is discussed.

*The work was supported by grant DE-SC0019114, funded by the U.S. Department of Energy, Office of Science

The calculation of accurate core electron binding energy shifts and absolute core electron binding energies using the SCAN exchange-correlation functional JUHAN MATTHIAS KAHK (Presenter), Department of Materials, Imperial College London, JOHANNES LISCHNER, Department of Materials and Department of Physics, Imperial College London — Core electron X-ray Photoelectron Spectroscopy (XPS) is often used to characterize the elemental as well as the chemical composition of surfaces. However, as experimental practice moves towards the study of increasingly complex systems, the analysis of recorded spectra becomes ever more challenging. First principles calculations of core electron binding energies can substantially alleviate the problems that are commonly encountered in “peak assignment”. Recently, we have found that the SCAN density functional is particularly well suited for the calculation of core electron binding energies using the ΔSCF method. In comparison to gas phase reference data, SCAN yields absolute core electron binding energies that are accurate to within ~0.2 eV for the 1s and 2p core levels of C-F and Si-Cl respectively, without any empirical adjustments.

For calculations of adsorbates on metal surfaces, we have devised a two-step approach in which the geometry of the adsorbate is first relaxed using a slab model of the surface, and then a ΔSCF calculation is performed on a cluster cut from the slab. Analysis of the results for various cluster sizes shows that finite size effects can be minimized to the point where they are smaller than the error due to the DFT functional.

A new generation of effective core potentials from correlated calculations: 3rd row main group GUANGMING WANG (Presenter), ABDULGANI ANNABERDIYEV, CODY MELTON, MICHAEL BENNETT, LUBOS MITAS, North Carolina State University — Recently, we have developed a new generation of effective core potentials (ECP) using valence energy isospectrality with explicitly correlated all-electron excitations and norm-conservation criteria. We extend our correlation consistent effective core potentials (ccECP) to 3rd row main group elements. For K and Ca, we use a Ne core and for the 4p elements we utilize large core potentials with 3d-electrons included in the core and with 4s and 4p in the valence shell. We also incorporate relativity including averaged spin-orbit effects. Our ccECPs reproduce all-electron spectra within about chemical accuracy ≈ 0.05 eV. The transferability of ccECPs is tested on corresponding monohydride and monoxide molecules in a wide range of binding geometries. The ccECPs include also optimized valence basis sets and additional comparisons with previously constructed ECPs.

The Schrödinger-Pauli Theory of Electrons: New Perspectives VIRAHT SAHNI (Presenter), Brooklyn College and The Graduate Center, CUNY — The Schrödinger-Pauli (SP) equation corresponds to a system of $N$ electrons in an electrostatic $E(\mathbf{r}) = -\nabla \nabla \phi(\mathbf{r})$ and a magnetostatic field $B(\mathbf{r}) = \nabla \times A(\mathbf{r})$ in which the interaction of the latter with both the orbital and spin angular momentum is incorporated. The ’Quantal Newtonian’ first law for the SP equation is derived: the sum of the external $F_{\text{ext}}(\mathbf{r})$ and internal $F_{\text{int}}(\mathbf{r})$ fields acting on each electron vanishes. The external field is the sum of the electrostatic and Lorentz fields. The internal field is a sum of fields representative of the Pauli exclusion principle and Coulomb repulsion, kinetic effects, the density, and the magnetic field. From the law, it is shown that the SP equation is intrinsically self-consistent. A Quantal Density Functional Theory of the mapping from the interacting system to one of noninteracting fermions possessing the same density and physical current density is developed.
12:39PM L31.00006: Local embedding/downfolding auxiliary-field quantum Monte Carlo (AFQMC)*

BRANDON ESKRIDGE (Presenter), HENRY KRAKAUER, SHIWEI ZHANG, Department of Physics, William & Mary — A local embedding and effective downfolding scheme has been developed and implemented in the auxiliary-field quantum Monte Carlo (AFQMC) method (Shiwei Zhang and Henry Krakauer, Phys. Rev. Lett. 90, 136401 (2003)). Local embedding in the occupied space (Yudis Virgus, Wirawan Purwanto, Henry Krakauer, and Shiwei Zhang, Phys. Rev. Lett. 113, 175502 (2014)) and local effective downfolding in the virtual space are employed to treat strongly correlated local clusters with an effective Hamiltonian. The accuracy is controlled by two geometric cutoff parameters that define the occupied space embedding and virtual downfolding regions. The systematic cutoff dependence of relative energies of physical and chemical interest is found to converge rapidly to the full AFQMC treatment. Thus, significant computational savings is achieved while maintaining a high degree of accuracy. This significantly increases the system size which can be accurately treated with AFQMC. Applications to transition metal atoms in 1D and in graphitic environments are presented. (Shiwei Zhang also acknowledges the Center for Computational Quantum Physics, Flatiron Institute).

12:51PM L31.00007: Benchmark studies for adsorption bond energies to transition metal surfaces*

MANISH KOTHAKONDA (Presenter), JINLIANG NING, YUBO ZHANG, JAMES FURNESS, JIANWEI SUN, Tulane University — The accurate prediction of adsorption energies for molecules on metal surfaces is a challenging subject in condensed matter physics, applied catalysis and physical chemistry research. The use of computational methods such as density functional theory (DFT) calculations to describe surface-adsorbate bond strength is increasing. Often these adsorption energies are used to study heterogeneous catalysis in thermal and electrochemical reactions. Here, we compare the structures and energetics for small gaseous molecules adsorbed to various transition-metal surfaces from density functionals with experimental results [1], with focus on MetaGGAs such as the strongly constrained and appropriately normed (SCAN) [2] density functional that recognizes the different chemical bonds.

1:03PM L31.00008: An exchange-correlation functional capturing bulk, surface, and confinement physics*

ATTILA CANGI (Presenter), Sandia National Laboratories, FRANCISCA SAGREDO, Chemistry, University of California, Irvine, ANN E MATTSSON, Los Alamos National Laboratory — We present the construction of an exchange-correlation functional which enables us to capture bulk, surface, and confinement physics with a single functional. Using the subsystem functional formalism[1,2,3] and the electron localization function, we interpolate between reference systems representing different physical regimes (homogeneous electron gas, the Airy gas, and the harmonic oscillator gas)[4,5]. The resulting functional can be viewed as a meta-GGA on the Jacob's ladder classification scheme. We report on the initial assessment of this functional, as tested on various materials.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.
A first-principles study of insulating La$_2$CuO$_4$ and its transition to the metallic state with Sr-doping

KANUN POKHAREL (Presenter), JAMES FURNESS, Tulane University, CHRISTOPHER LANE, Northeastern University, RUIQI ZHANG, Tulane University, BERNARDO BARBIELLINI, Lappeenranta University of Technology, YUBO ZHANG, Tulane University, ARUN BANSIL, Northeastern University, JIANWEI SUN, Tulane University, ROBERT MARKIEWICZ, Northeastern University

Correct prediction of the electronic structure of La$_2$CuO$_4$(LCO), an exemplar half-filled cuprate, has been a long-standing problem where the commonly used exchange-correlation functionals fail to reproduce the experimentally observed insulating state. In contrast, Strongly-Constrained-and-Approximately-Normed (SCAN) functional properly captures not only the ground state antiferromagnetic insulator character of LCO but also its transition to metallic state with Sr doping. We compare and contrast our SCAN-based results with the corresponding results obtained using other meta-GGA's and hybrid functionals. Our analysis suggests that the SCAN functional can provide a new pathway for first-principles modeling of cuprates and other correlated materials.

The Wilson basis applied to electronic structure

JAMES BROWN (Presenter), JAMES WHITFIELD, Department of Physics and Astronomy, Dartmouth College — We present a method to calculate electronic energies using a pruned phase-space grid of Wilson basis functions. Computational scaling of O(N$^{8/3}$) is realized by representing the Coulomb potential in a sum-of-products form and calculating energies using iterative methods. Convergence of the Wilson basis is analyzed in detail for multiple states of H$_2$ and He with and without a strong magnetic field.

Verification of acoustic mismatching model for sub-THz acoustics in glass

FAN JUN WEI (Presenter), Institute of Physics, Academia Sinica, RICHARD A. MOLE, Bragg Institute, Australian Nuclear Science and Technology Organisation, SUNIL KARNA, Department of Physics & Astronomy, Louisiana State University, JIN-WEI SHI, Department of Electrical Engineering, National Central University, JINN-KONG SHEU, Department of Photonics, National Cheng Kung University, KUNG-HSUAN LIN, Institute of Physics, Academia Sinica — Because of high acoustic attenuation of glass in sub-THz regime, it is difficult to measure the highly damped acoustic waves passing through the media. In theory, the acoustic properties of the media could be experimentally studied by reflection of acoustic waves which do not propagate into the media. Complex acoustic impedance, which includes the information of dispersion relation and frequency-dependence of attenuation, is a parameter in the acoustic mismatching model to describe the phenomena when acoustic waves encounter the interface of media. The mismatch of acoustic impedance results in reflection and transmission of acoustic waves at the interfaces. We report the verification experiments for this model in sub-THz regime. We generated coherent THz acoustic phonons and measured the amplitude and phase of the reflected acoustic phonons from the interface of GaN and silica. Based on the acoustic mismatching model, the frequency dependence of sound speed and the attenuation were obtained up to 0.3 THz. These values were compared with the results from typical method. This verified technique enables the measurement of sub-THz acoustic properties of thick and highly damped materials.

Modulated order and unconventional phase coexistence in a model for lattice mismatched solids

LAYNE FRECHETTE (Presenter), University of California, Berkeley, CHRISTOPH DELLAGO, University of Vienna, PHILLIP L GEISSLER, University of California, Berkeley — Lattice mismatch is a common occurrence in modern materials, but just how it influences the arrangement of atoms in materials is incompletely understood. Here we consider a simple microscopic model for lattice mismatch, in which the difference in natural bond lengths between atoms produces interactions mediated by elastic strain. Monte Carlo simulations reveal that the model exhibits rich phase behavior, supporting structures with modulated order and unusual coexistence scenarios. To explain this phase behavior, we derive an effective pair potential between atoms, revealing preferred spatial arrangements of atoms driven by spatial variations in the interaction energy. Based on this effective interaction, we then develop a mean field theory, which captures the modulated structures observed in our simulations. Finally, we explain the observed coexistence scenarios using a modified Maxwell construction, which is based on the realization that the free energy cost of phase separation in elastic systems is extensive. These results clarify the equilibrium effects of lattice mismatch in macroscopic solids and suggest a role for lattice mismatch in creating spatially heterogeneous compositions in nanoscale materials.

11:51AM L32.00004: Fundamental Link between β Relaxation, Excess Wing, and Cage-Breaking in Metallic Glasses* MENGHAO YANG (Presenter), Ames Laboratory, HAIBIN YU, Huazhong University of Science and Technology, YANG SUN, FENG ZHANG, Ames Laboratory, JIANBO LIU, Tsinghua University, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory, RANKO RICHERT, Arizona State University, KONRAD SAMWER, Universität Göttingen — In glassy materials, the Johari-Goldstein secondary (β) relaxation is crucial to many properties, as it is directly related to local atomic motions. However, a long-standing puzzle remains elusive: why some glasses exhibit β relaxations as pronounced peaks while others as unobvious excess wings? Using microseconds atomistic simulation of two model metallic glasses (MGs), we demonstrate such a difference is associated with the amount of string-like collective atomic jumps. Relative to that of excess wings, we find that MGs having pronounced β relaxations contain larger numbers of such jumps. Structurally, they are promoted by the higher tendency of cages-breaking events of their neighbors. Our results provide atomistic insights for different signatures of the β relaxation that could be helpful for understanding the low-temperature dynamics and properties of MGs.

*Work conducted at Ames Laboratory was supported by the U.S. Department of Energy, Basic Energy Sciences, Materials Science and Engineering Division, under Contract No. DEAC02-07CH11358, including a grant of computer time at the National Energy Research Supercomputing Center (NERSC) in Berkeley, CA.

12:03PM L32.00005: Ultrafast Conformer Relaxation of Provitamin D Analogs in Lipid Bilayers DANIELLE SOFFERMAN (Presenter), ROSEANNE J SENSION, University of Michigan — Ultrafast photochemical transformations of 7-Dehydrocholesterol (DHC, Provitamin D3), DHC-Acetate and Ergosterol (Ergo, Provitamin D2) to previtamin (D3, D3-acetate and D2) occurs upon a ring-opening reaction in the excited state where a cyclohexadiene (CHD) chromophore embedded within the molecules opens to form a hexatriene previtamin D species. Conformer relaxation back to the ground state of isolated CHD happens on the time scale of picoseconds, therefore it is necessary to use ultrafast techniques such as transient absorption to capture the relaxation. Here we are studying conformer relaxation of DHC and its analogs in liposomes as a simple model for biologically relevant skin membranes. DHC has been studied extensively in isotropic solvents where the molecule is free to relax down to the ground state to form a stable previtamin D3 species. However in the cell membrane the molecule is hypothesized to be locked in an unstable previtamin D3 conformation that thermally relaxes down to form Vitamin D3. To understand the conformer relaxation that takes place in biological membranes we extend our studies to DHC analogs, DHC-Acetate and Ergo in isotropic solvents and in simple lipid bilayers.

12:15PM L32.00006: Probing the Molecular Interactions of Small Molecules with Sapphire* NITYANSHU KUMAR (Presenter), SUKHMANJOT KAUR, The University of Akron, RAJAT KUMAR, Department of Biomedical Engineering, Stony Brook University, SELEMON BEKELE, MESFIN TSIGE, ALI N DHINOJWALA, The University of Akron — Numerous challenges in the field of adhesion, biocompatibility, and purification thrives a persistent need to better understand the interactions of small molecules at any interface. The interaction energy of small molecules at a solid/liquid interface is governed by the surface structure of the solid substrate, the interfacial molecular orientation of the small molecules and their chemical nature. Sometimes, the interaction could be driven by the presence of hydrogen bonding leading to a specific molecular orientation. Here, we seek to understand how small molecules compete for interaction sites, orient and interact at the solid/liquid interface. Using MD simulations, we contemplate and present a model to visualize the interaction of acetone and chloroform molecules on the sapphire. Further, combining the simulation results with experimental data obtained using sum frequency generation (SFG) spectroscopy, we attempt to understand the spectroscopic features and their hidden correlations. This work paves the way for understanding the interaction of molecules at the solid/liquid interface with potential applications in the field of adhesives, coatings, medicines, and water purification.

12:27PM L32.00007: Shock Compression Microscopy for Tabletop Detonations in PETN-based Explosives*  
WILL BASSETT (Presenter), Lawrence Livermore Natl Lab, DANA DLOTT, BELINDA PACHECO, LAWRENCE SALVATI, Chemistry, University of Illinois — We have developed a microscope system for performing shock compression experiments with km s⁻¹ impactors and nanosecond-duration shock waves. In the present work, this system is used to study polymer-bound explosive charges (PBXs) 1 mm in diameter and tens to hundreds of microns thick. The microscope diagnostics include particle velocity (Photon Doppler velocimetry) measurements, fast imaging, and optical pyrometry. The PBX under study is a pentaerythritol tetranitrate (PETN)-based PBX (80% PETN, 20% elastomer binder) and has been characterized using x-ray tomography and scanning electron microscopy. At lower shock-pressures we observed sub-detonative behavior and hot spots have structures which evolved over 20 ns and cooled relatively slowly. At higher shock-pressures, the shock wave was supported by fast chemical reactions and the particle velocity remained constant. In this regime the shock wave is detonation-like and the hot spot cooling rate increased dramatically.

1:15PM L32.00009: COARSE-GRAINED SIMULATIONS OF DENDRITIC CARBOHYDRATE NANOPARTICLES*  
EDUARDO MENDEZ (Presenter), MOHAMMAD HASSAN KHATAMI, HENDRICK W DE HAAN, Faculty of Science, University of Ontario Institute of Technology — PhytoSpherix are naturally occurring carbohydrate-polymer dendritic nanoparticles extracted from sweet corn, with branching points at regular intervals. We investigate the structural details of model Px particles via coarse grained strategies (MARTINI forcefield and GROMACS molecular dynamics simulations), and also employ knowledge gathered from small atomistic models to build large structures many thousands of carbohydrate units in size, beyond the typical scales reached by standard atomistic simulations. The scheme used here may be employed to build structures with branched motifs that may not be regular. These structures are produced by other plant species and have a wide degree of applicability due to their sponge-like properties. We present an analysis of various morphologies of these objects and explore their variability depending on the scheme used in their assembly, and thus provide a way to compare models to theories of regular branched dendritic nanoparticles.

1:27PM L32.00010: Designing Interdisciplinary Undergraduate Research Experiences to Increase Diversity in STEM*  
SOLOMON BILILIGN (Presenter), North Carolina Agricultural and Technical State University — The recruitment of undergraduate students, especially minorities, into STEM career paths and in particular into majors in physics continues to be a challenge. One approach for addressing this issue provides an interdisciplinary research opportunity that has societal relevance and uses basic concepts in physics. The program design involves year-round research combined with summer or short visits to major university, national lab, or private research facilities. Other program components include (1) cohort-building activities and effective mentoring; (2) short-course professional development modules focused on research ethics, literature survey, writing, and data management; and (3) student engagement in the creation of personalized professional development plans.

*The Author Acknowledges the funding from NSF under grant number 1600415

1:39PM L32.00011: QPython as mobile computational physics laboratory anywhere, anytime and anyhow  
GODFREY AKPOJOTOR (Presenter), Theoretical and Computational Condensed Matter Physics, Physics Department, Delta State University, Abraka, GODWIN IBEH, Department of Physics, Nigerian Defence Academy, FAMOUS AKPOJOTOR, Department of Physics, University of Benin, SHARON ASEGHELEME EGBORO, Theoretical and Computational Condensed Matter Physics, Physics Department, Delta State University, Abraka — Computational physics (CP) has become an integral part of physics. However, an important choice in deciding the computational approach is accessibility to both the computing device and the programming language. The continuous growth of smartphones in Africa and the availability of the free and open source Python programming capabilities in QPython (QP) meet the accessibility requirement to make them mobile computational physics laboratory (MCPL). We present here one of our current projects under the Python African Computational Science and Engineering Tour Project (PACSETPro) of using QP as MCPL for teaching CP and development of physics Apps to students, new beginners as well as expert programmers anywhere, anytime and anyhow. We examine the third party libraries especially the future of matplotlib in QP.
The triplet state of a two-electron quantum dot in a magnetic field is studied from the perspective of the ‘Quantal Newtonian’ first law. The exact analytical wave function solution of the corresponding Schrödinger-Pauli equation is derived. The anti-symmetric nature of the spatial part of the wave function, and the satisfaction by it of the node electron-electron coalescence constraint is displayed. The quantal sources of the density, pair-correlation density, the Fermi-Coulomb hole charge, the single-particle density matrix, and the current density, and from these the corresponding Hartree, electron-interaction, Pauli-Coulomb, Differential Density, Kinetic, and Effective Magnetic fields are determined. The total energy, and both its external and internal components are obtained from the various fields. The intrinsic self-consistent nature of the Schrödinger-Pauli equation, and thereby the satisfaction of the ‘Quantal Newtonian’ first law is shown.

Session L33 FIAP: Quantum Devices and 2D Materials

11:15AM L33.00001: Quantum Surfing - Pushing a Particle through a Rough Potential*  
DANIEL MARK (Presenter), SAMUEL F SAVITZ, Physics, Caltech, GIL REFAEL, Institute for Quantum Information and Matter, Caltech — Quantum machines rely on our ability to manipulate the motion of electrons. We investigate the transport of particles by a travelling potential pulse in a one-dimensional system with quenched disorder, dissipation, and thermal noise. We simulate finite temperature and dissipation by applying the Schrödinger-Langevin equation to a single-particle hopping model. The transport is understood as a semiclassical Fokker-Planck diffusion process in the pulse frame. The semiclassical behavior arises from decoherence due to the dissipation and thermal noise. We predict that the “surfing length”, our measure of transport, is exponential with pulse width. Measurements agree with drift velocities and diffusivities from simulations with a constant DC field, in the regime of high disorder and thermal noise. We also introduce an alternative nonlinear dissipative term which allows for generalization to higher dimensions and many-body systems.

*Funding for this research was provided by the Institute for Quantum Information and Matter, a National Science Frontier center partially funded by the Gordon and Betty Moore Foundation. DM was funded by the David L. Goodstein SURF Fellowship, Caltech SFP. SS was funded by a National Science Foundation Graduate Research Fellowship under Grant No. DGE-1745301.

11:27AM L33.00002: Electrical initialization of electron and nuclear spins in a single quantum dot at zero magnetic field  
PIERRE RENUCCI (Presenter), LPCNO, Institut National des Sciences Appliquees de Toulouse, FABIAN CADIZ, Ecole Polytechnique, ADBELHAK DJEFFAL, Institut Jean Lamour, UMR 7198-CNRS-Nancy Université, DELPHINE LAGARDE, ANDREA BALOCCHI, LPCNO, Institut National des Sciences Appliquees de Toulouse, BINGSHAN TAO, Institut Jean Lamour, UMR 7198-CNRS-Nancy Université, BO XU, Institute of Semiconductors Beijing, SHIHENG LIANG, MATHIEU STOFFEL, XAVIER DEVAUX, Institut Jean Lamour, UMR 7198-CNRS-Nancy Université, HENRI JAFFRES, JEAN-MARIE GEORGE, Unité Mixte de Physique CNRS-Thales, MICHEL HEHN, STEPHANE MANGIN, Institut Jean Lamour, UMR 7198-CNRS-Nancy Université, HÉLÈNE CARRERE, XAVIER MARIE, THIERRY AMAND, LPCNO, Institut National des Sciences Appliquees de Toulouse, XIUFENG HAN, Institute of Physics, Beijing, ZHANGUO WANG, Institute of Semiconductors Beijing, BERNHARD URBASZEK, LPCNO, Institut National des Sciences Appliquees de Toulouse, YUAN LU, Institut Jean Lamour, UMR 7198-CNRS-Nancy Université — We demonstrate single quantum dot (p-type InGaAs quantum dot) electroluminescence (EL) with a circular polarization degree up to 35% at zero applied magnetic field, proving highly efficient electrical injection of spin polarized electrons [1]. It is achieved thanks to an ultrathin CoFeB electrode presenting Perpendicular Magnetic Anisotropy on top of a spin-LED. In addition, we measure an Overhauser shift of several micro-eV at zero magnetic field for the positively charged exciton (trion X+) EL emission, which changes sign as we reverse the injected electron spin orientation. This is a signature of dynamic polarization of the nuclear spins [1] in the quantum dot induced by the hyperfine interaction with the electrically injected electron spin. Both EL circular polarization and Overhauser shift follow the hysteresis cycle of the magnetic electrode. This study paves the way for electrical initialization of electron and nuclear spins in a single quantum dot without any external magnetic field. [1] F. Cadiz et al, Nano Letters 18 (4), 2381-2386 (2018)
11:39AM L33.00003: Colloidal Quantum Dot Tandem Photovoltaics Employing a Novel Hole-blocking Injection Layer Concept*  
SUE SHI (Presenter), YIJIN GUO, GILLIAN HAGEN, BENJAMIN A ZANK, ALEXI C ARANGO, Mount Holyoke College — Colloidal quantum dot (CQD) tandem photovoltaics (PV) are of interest as candidates for next-generation PV due to their potential for low-cost fabrication and compatibility with lightweight flexible packaging. In this work, we present a CQD tandem PV device that employs indium tin oxide (ITO) as interconnection layer and a novel injection layer with hole-blocking functionality. A lead sulfide (PbS) CQD heterojunction is formed with C60 in each subcell, yet the traditional BPhen/Ag contact is replaced with ITO. We demonstrate that a hole-blocking injection layer must be inserted between C60 and interconnection layer ITO in order to achieve excellent electrical contact between the two. We obtain a doubling in open-circuit voltage and maintain the high fill factor of the single-junction device. This device structure is particularly suited to multiple-cell tandem PV.

11:51AM L33.00004: 0.7 Anomaly, Spin-Mixing and Emergent Spin Gap in Quantum Point Contacts with Strong Spin-Orbit Interaction  
KARINA HUDSON (Presenter), ASHWIN SRINIVASAN, Univ of New South Wales, OLGA GOULKO, Physics, Boise State University, JARROD ADAM, QINGWEN WANG, LAREINE YEOH, OLEH KLOCHAN, Univ of New South Wales, IAN FARRER, Electronic and Electrical Engineering, University of Sheffield, DAVID A RITCHIE, Semiconductor Physics, University of Cambridge, JAN VON DELFT, Arnold Sommerfeld Centre for Theoretical Physics, Ludwig-Maximilians University, ALEX R HAMILTON, Univ of New South Wales — Quantum point contacts (QPCs) are 1D charge constrictions where ballistic conductance through the channel is quantised in integer units, with the exception of the 0.7(2e^2/h) anomaly. The microscopic origin of the 0.7 anomaly remains contentious after over 20 years of study, and the additional influence of spin-orbit interaction (SOI) is even more poorly understood. Here we characterise the 0.7 anomaly for 1D holes with strong interactions and strong SOI. Similarly to electrons, the 0.7 anomaly in 1D holes shares the signature behaviour of evolving to 0.5(2e^2/h) in applied magnetic field. However, while the electron 0.7 anomaly isotropically Zeeman spin-splits in magnetic field, the hole 0.7 anomaly exhibits a weak anisotropic response in in-plane magnetic field. We show the magnetic field orientation dependence of the first 1D hole subband, and demonstrate a new and robust signature for the opening of a spin gap. We compare our measurements to recent theory where the Rashba SOI term predicts the correct anisotropy of the Zeeman spin-splitting in the first hole subband as well as the opening of a spin gap in magnetic field. The opening of a spin gap in 1D hole semiconducting systems has significant implications for the formation of helical spin gaps and Majorana excitations.

12:03PM L33.00005: Ultrasensitive displacement noise measurement of carbon nanotube mechanical resonators  
CHANDAN SAMANTA, SERGIO LUCIO DE BONIS (Presenter), CARLES FLORES, WEI YANG, ICFO, ADRIEN NOURY, CNRS/L2C, QUAN DONG, YONG JIN, Department of Nanoelectronics, CNRS/C2N, ADRIAN BACHTOLD, ICFO — Mechanical resonators based on a single carbon nanotube are exceptional sensors of mass and force. The force sensitivity in these ultra-light resonators is often limited by the noise in the detection of the vibrations. Here, we report on an ultra-sensitive scheme based on a RLC resonator and a low-temperature amplifier to detect nanotube resonators. These advances in detection allow us to reach 0.5 pm/ displacement sensitivity [1]. Thermal vibrations cooled cryogenically at 300 mK are detected with a signal-to-noise ratio as high as 17 dB. We demonstrate 4.3 zN/ force sensitivity, which is the best force sensitivity achieved thus far with a mechanical resonator. This is an important step towards imaging individual nuclear spins and studying the coupling between mechanical vibrations and electrons in different quantum electron transport regimes. We will also present our recent measurements on the coupling between mechanical vibrations and electrons in the Coulomb blockade regime.

Large-area graphene quantized Hall resistance arrays using superconducting interconnections

MATTIAS KRUSKOPF (Presenter), ALBERT RIGOSI, HANBYUL JIN, DINESH PATEL, SHAMITH PAYAGALA, ALIREZA PANNA, DEAN G. JARRETT, DAVID B NEWELL, RANDOLPH E ELMQUIST, Quantum Measurement Division, National Institute of Standards and Technology — Next generation quantum resistance standards based on multiple quantized Hall resistance (QHR) elements will allow tailoring the fundamental value to the needs of a given application. However, scalable resistance networks often suffer from accumulated resistances at metallic interconnections that lead to a deviation from the theoretical value.

This work shows the first results of epitaxial graphene-based, QHR array devices using superconducting contacts and interconnections to minimize parasitic resistances. The applied contact design is optimized for reduced contact resistances and circumvents any possible alteration of the QHR caused by Andreev reflections. For homogenous charge carrier concentrations and high monolayer quality, optimized growth and doping techniques were developed to allow for the realization of complex chip designs on the centimeter scale.

The results show different QHR array devices at exceptionally high currents in the mA range that are utilized to improve the measurement uncertainty of relatively simple, room temperature resistance bridges. To ensure the applicability in quantum resistance metrology, we apply and test new global criteria of quantization and verify the precision using direct current comparators and cryogenic current comparator bridges.

A Metalens Device for Applications of Nitrogen-Vacancy Centers in Diamond

HOPE MCGOVERN (Presenter), JUAN LIZARAZO FERRO, RASHID ZIA, Brown University — There is much interest in using nitrogen-vacancy (NV) centers in diamond for future quantum communication networks. Prerequisite to such advances is a scalable method of focusing light and collecting the resulting emission spectra from the NV centers. Here, we propose a fiber-coupled device that integrates metalenses to excite and collect the photoluminescence from NV centers in diamond. We discuss the design challenges involved in achieving a high numerical-aperture, off-axis metalens and provide detailed simulations evaluating the performance of various optimized metalens systems.

Effects of Wet Transfer on Photoluminescence of WS2*

XIAOTIAN WANG, KYUNGNAM KANG, SHICHEN FU, KYLE GODIN, SIWEI CHEN (Presenter), EUI-HYEOK YANG, Stevens Institute of Technology — Chemical vapor deposition (CVD)-grown transition metal dichalcogenides (TMDs) are often required to be transferred onto another substrate for device applications. The KOH-based wet transfer is the most popular method to transfer TMDs. However, after transfer, PL intensity is heavily quenched due to a combination of trapped water, substrate dope and solvent effects which are introduced during transfer process.

Here, we evaluated the effects of solvents and polymers involved in the wet etching transfer on the PL property of WS2. We used CVD-grown WS2 sample and simulate the transfer process by applying each solvent and polymer to WS2 respectively. The PL mapping results showed there is no significant reduction of PL intensity of WS2 before and after acetone, IPA, DI water and PMMA treatment. We then studied the effect of KOH on the PL intensities by transferring WS2 onto PDMS substrate using the Cu-based transfer method [1]. After 30% KOH solution treatment, the sample showed significant reduction of PL intensity compared to it before KOH treatment. We attribute that KOH molecules are physically adsorbed onto WS2, which can be removed through acid neutralization or high vacuum annealing.

12:51PM L33.00009: Optical verification of H-point exciton in bulk transition metal dichalcogenides*  
SO YEUN KIM (Presenter), Depart of Physics and Astronomy, Seoul National University, HUYEN THI NGUYEN, BYUNG CHEOL PARK, TAE WON NOH, Center for Correlated Electron Systems (CCES), Institute for Basic Science (IBS) — During last decades, transition metal dichalcogenide (TMDC) compounds has been studied extensively. TMDCs provide an excellent platform to investigate many-body physics of exciton, and exciton binding energy increased significantly by reducing thickness. Mostly hydrogen models are used to obtain band gap and exciton binding energy from absorption spectra. On the other hand, recent reports on bulk TMDC claimed an peak previously assigned as \( n=2 \) state of A exciton at K-point is not true, but is an independent \( n=1 \) exciton arising at H-point [J. Kopaczek et al., Jour. Appl. Phys. 119, 235705 (2016)]. Following the argument, previous method to obtain binding energy of bulk TMDC may be incorrect. To verify the existence of H-point, we performed an ellipsometry measurements and two-dimensional correlation spectroscopy on TMDC compounds. We analyzed thermal sequential order of exciton peaks, which may be used to distinguish exciton states that arise from K-point and H-point. In this work, we will discuss on analysis and possible impact in future studies.

*This work was supported by Institute for Basic Science in Korea (Grant No. IBS-R009-G1). S. Y. Kim was supported by Global PH. D Fellowship Program funded by the Ministry of Education (Grant No. NRF-2015H1A2A1034943).

1:03PM L33.00010: Precursor Free Growth of MoS2 Monolayer Devices With Naturally Formed Contacts  
THUSHAN WICKRAMASINGHE (Presenter), GREGORY JENSEN, RUHI THORAT, ERIC A STINAFF, Ohio University — Interest in two dimensional Transition Metal Dichalcogenides (TMDDs) has remained robust due to properties such as their direct band gap, large exciton binding energies, sizeable spin-orbit couplings, and spin-valley interactions. While there are several techniques for developing TMD based devices, in this work we propose a unique, precursor free, Chemical Vapor Deposition (CVD) method in which the device in grown \textit{in situ} with naturally formed contacts. A molybdenum metal pattern, which will form an electrical contact with the TMD, is sputtered on to the substrate prior to the growth. The oxide layer that then naturally forms on the metal surface serves as the precursor for the subsequent growth. In contrast to completely sulfurizing an ultrathin Mo layer, the TMD material grows on, and away from, the thick molybdenum patterns across the Si substrate. Photoluminescence and Raman studies show that the growth can be tuned to produce monolayer and bi-layer Molybdenum Disulfide (MoS2). We also study the self-limiting nature of the growth process and compare it to the growths with the MoO3 precursor.

1:15PM L33.00011: \textit{Ab-initio} Calculations of Electronic Properties of Orthorhombic Tin Selenide (SnSe).*  
YURIY MALOZOVSKY (Presenter), SHAIBU MATHIAS, LASHOUNDA FRANKLIN, DIOLA BAGAYOKO, Southern University — We present results from \textit{ab-initio}, self-consistent density functional theory (DFT) calculations of electronic properties of tin selenide (SnSe) in the \textit{orthorhombic} \textit{B16} crystal structure. We utilized a local density approximation (LDA) potential and the linear combination of atomic orbital (LCAO) formalism. Our calculations minimized the energy down to the ground state, as required by the second DFT theorem. This process ensures the full, physical content of our findings that include electronic energy bands, total and partial densities of states, and electron and hole effective masses.

*This work was funded in part by the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award No. DE- NA0003679), the National Science Foundation (NSF) (Award No. HRD-1503226), LaSPACE, and LONI-SUBR.

1:27PM L33.00012: Microscopic polarization and magnetization fields in extended systems*  
PERRY MAHON (Presenter), Physics, University of Toronto, RODRIGO A. MUNIZ, Electrical Engineering and Computer Science, University of Michigan, JOHN EDWARD SIPE, University of Toronto — We introduce microscopic polarization and magnetization fields at each site of an extended system, as well as free charge and current density fields associated with charge movement from site to site, by employing an approach based on a set of orthogonal orbitals at each site. These microscopic fields are defined using a single-particle electron Green function. For an infinite crystal we choose the orbitals to be maximally-localized Wannier functions, and in the longwavelength limit we recover the expected linear response of an insulator, including the zero frequency transverse conductivity. For a topologically trivial insulator we recover the expected expressions for the microscopic polarization and magnetization in the ground state, and find that the linear response to excitation at arbitrary frequency is described solely by the microscopic polarization and magnetization fields. For very general optical response calculations the microscopic fields automatically satisfy charge conservation, even under basis truncation, and do not suffer from the false divergences at zero frequency that can plague response calculations using other approaches.

*We thank the Natural Sciences and Engineering Research Council of Canada for funding.
Carbon nanotube-quantum dot paper for radiation sensitive Electro-mechanical system

SUKANTA NANDI (Presenter), BUDDHA DEKA BORUAH, ABHA MISRA, Indian Institute of Science — Hybrid nanostructures offer unparalleled properties by coupling different functionalities. Surface modification of multiwalled carbon nanotubes (MWCNTs) by in-situ decoration of zinc oxide quantum dots (ZnO QDs) i.e. ZnO QDs@MWCNTs induces highly sensitive opto-electro-mechanical response. Freestanding paper of ZnO QDs@MWCNTs demonstrated an enhancement of ~122% in the response current upon infrared (radiation) illumination as compared to only MWCNT paper. Moreover, the radiation interaction revealed a comparatively quicker response and recovery time of ~42.4% and ~19.4% respectively. Electro-mechanical measurements revealed a ~349% increment in actuation at 3 V bias owing to increase in net polarization enhancement. Radiation induced actuation further revealed a ~111 ± 4% actuation compared to the electro-mechanical actuation. Through this work we demonstrate MWCNT coupled with dielectric QDs paves extraordinary functionalities altogether for the development of smart micro-opto-electro-mechanical systems.

Wednesday, March 6, 2019 11:15 AM - 2:15 PM

Session L34 FIAP: Future of Transportation BCEC 205A - Michael Gordon, IBM Thomas J. Watson Research Center - Tag(s): Invited, Undergraduate

11:15AM L34.00001: Findings of the Governor's Commission on the Future of Transportation in the Commonwealth of Massachusetts [Invited] STEVEN KADISH (Presenter), Harvard Kennedy School — TBD

11:51AM L34.00002: Crowdsourcing inclusive, accessible last-mile transportation with self-driving #AccessibleOlli* [Invited] JOE SPEED (Presenter), IoT Solutions & Technology, ADLINK Technology — #AccessibleOlli is a crowdsourced, open source effort to create the world's most accessible transportation for all including the elderly and those with disabilities. #AccessibleOlli's precursor, Olli developed by Local Motors is an autonomous vehicle enabled by IBM Watson cognitive assistant. Olli can ‘hear’ spoken questions and instructions and respond in familiar conversational language to take people where they need to go. Using a network of embedded sensors, devices, robotics and AI technology, #AccessibleOlli seeks to transform the lives of the world's growing aging population and persons with disabilities. Contributors to #AccessibleOlli include ADLINK Technology, IBM, CTA Foundation, Local Motors, AARP, MIT, PTECH schools, ASU, Local Motors, Ultrahaptics, what3words, Mapbox, Front Porch, LG, Panasonic, BestMile, Mayo Clinic, City of Rochester MN and a worldwide community of volunteer SMEs, designers, developers and engineers.

Why do we need inclusive mobility that is accessible for all? Urban mobility is a $1.5T a year market serving 4 billion people. Existing public transport options don’t serve the elderly or disabled well enough. Currently 1 billion people, around 15 percent of the world's population, experience some form of disability. In the US, over 560,000 people with disabilities never leave home due to transportation difficulties. According to the Journal of Gerontology, seniors outlive their ability to drive safely by an average of 7 to 10 years. By 2050, around 22 percent of the global population will be aged 60 years or older.

Here is a video overview of the program with Joe Speed of ADLINK Technology and IBMers https://youtu.be/KjP6aRtuEv4

*Funding and/or technology has been provided for this program by Local Motors, IBM, ADLINK Technology, CTA Foundation, MIT, Princeton University, Ultrahaptics, Panasonic, LG, what3words, BestMile.

12:27PM L34.00003: State of the art for drone technology [Invited] TIM MEYER (Presenter), IBM — TBD

1:03PM L34.00004: Self-Driving Cars and Lidar [Invited] SIMON VERGHESE (Presenter), Waymo — TBD

1:39PM L34.00005: The Future of Flight [Invited] BRIAN TILLOTSON (Presenter), Boeing — Air and space transportation are advancing in many ways. We describe current and foreseeable advances; their benefits to comfort, capability, and the environment; and the physics challenges that arise in each. Highlights include urban mobility, hypersonic travel, and settling the solar system. Major challenges include acoustics, lightning, thermal control, cosmic radiation, and the short lifetimes of G-type stars.

Wednesday, March 6, 2019 11:15 AM - 2:15 PM
11:15AM L35.00001: Quantum control and entanglement of 6+ spin qubits in diamond  
**CONOR BRADLEY (Presenter), JOE RANDALL, REMON BERREVOETS, MOHAMED ABOBEIH, MAARTEN DEGEN, VIATCHESLAV DOBROVITSKI, TIM HUGO TAMINIAU, QuTech and Kavli Institute of Nanoscience, Delft University of Technology** — The nitrogen vacancy (NV) centre in diamond is a promising candidate for quantum networks. NVs can be entangled remotely [1], and coupling to $^{13}$C nuclear spins in the environment provides qubits for the storage and processing of quantum information [2]. In recent years, basic building blocks for a quantum network have been demonstrated, including quantum error correction [2] and entanglement distillation [3]. A key challenge is to realise high-quality control over multiple $^{13}$C spin qubits.

In this talk, I will show how a novel two-qubit gate - based upon radio frequency driving interleaved with dynamical decoupling - enables quantum entanglement of 6+ spins. The results are the largest entangled state realised on this platform, and are a key step for error correction and larger quantum networks with NV centres.

11:27AM L35.00002: High-fidelity control of a multi-qubit network node in diamond  
**JOE RANDALL (Presenter), CONOR BRADLEY, REMON BERREVOETS, MAARTEN DEGEN, MOHAMED ABOBEIH, VIATCHESLAV DOBROVITSKI, TIM HUGO TAMINIAU, QuTech and Kavli Institute of Nanoscience, Delft University of Technology** — A powerful approach to realise large-scale quantum computations and simulations is to use quantum networks, which are comprised of a number of multi-qubit nodes connected together by photonic links [1]. The nitrogen vacancy (NV) centre in diamond is a promising platform for building such networks, as it combines optical entanglement links through its electron spin [2,3] with long-lived nuclear spin qubits that can store and process quantum information [4,5]. A key requirement is to realise high-fidelity control over multi-qubit nuclear spin registers within each node.

I will present our experimental demonstration of a novel method to perform selective electron-nuclear two-qubit gates. The method uses radio frequency pulses resonant with the target nuclear spin interleaved with dynamical decoupling pulses on the electron spin. This has several key advantages compared to previous control methods, allowing more nuclear spins to be addressed and higher gate fidelities to be reached.

11:39AM L35.00003: Room-Temperature Quantum Error Correction with Nitrogen-Vacancy Centers  
**MO CHEN (Presenter), DAVID LAYDEN, PAOLA CAPPELLARO, Massachusetts Institute of Technology** — In pursuit of near-term quantum devices that either demonstrate a `quantum supremacy' or perform a meaningful algorithm, quantum error correction (QEC) is required. Arguably, fault-tolerance (FT) is not mandatory at this stage. Therefore, instead of traditional FT QEC, we focus on hardware-efficient QEC that demands less redundancy and imposes less overhead penalty. The system of interest is a room-temperature solid-state quantum register consisting of qubits and one ancilla, respectively given by the nuclear spins and the electronic spin associated with the NV center in diamond.

We first studied the decoherence process of the nuclear spins to better characterize the system. The errors on the nuclear spins turn out to be caused by the same source and are thus strongly correlated. We can then proceed to design custom QEC codes for this system, and develop experimental tools for realizing hardware-efficient QEC.
Laser Written Diamond Optoelectronic Devices for use in Quantum Computing*

YASHNA LEKHAI (Presenter), COLIN STEPHEN, Department of Physics, University of Warwick, YU-CHEN CHEN, LAIYI WENG, Department of Materials, University of Oxford, PAUL HILL, Institute of Photonics, University of Strathclyde, SAM JOHNSON, Department of Materials, University of Oxford, ANGELO FRANGESKOU, PHIL DIGGLE, Department of Physics, University of Warwick, MICHAEL STRAIN, ERDAN GU, Institute of Photonics, University of Strathclyde, BEN GREEN, MARK NEWTON, Department of Physics, University of Warwick, JASON M SMITH, Department of Materials, University of Oxford, PATRICK SALTER, Department of Engineering, University of Oxford, GAVIN MORLEY, Department of Physics, University of Warwick — The nitrogen-vacancy (NV) defect within a diamond lattice has been shown as a viable candidate for a quantum register. Using laser writing, these defect centres can be placed with high precision at any depth through a sample, without inducing significant damage to the surrounding lattice [1-3], to create deep solid state qubit arrays. These sites have shown coherence times of 700 µs, as long as the longest achieved for room-temperature spin-echo coherence measurements in non-^{12}C enriched diamond [1]. Additionally, the technique can be used to create conductive graphitic tracks, which are the subject of current investigation for their potential to act as DC circuitry within the diamond. Configuring the wires such that NVs lie between ends of two wires may allow charge state transfer, bringing greater control of defects, and enable sites to be tuned precisely. It is hoped that, combining these aspects, a single diamond could hold many individually addressable qubits leading to a compact quantum processor.

*We acknowledge funding from the UK EPSRC (EP/M013243/1) and the Royal Society.

Nitrogen vacancy (NV) centres in diamond for fun and profit*

COLIN STEPHEN, University of Warwick, SOUGATO BOSE, University College London, ANGELO FRANGESKOU, University of Warwick, ATM ANISHUR RAHMAN, PETER F BARKER, University College London, LAIA GINES, SOUMEN MANDAL, University of Cardiff, MATTHEW W DALE, YASHNA LEKHAI, University of Warwick, LAIYI WENG, University of Oxford, PAUL HILL, University of Strathclyde, SAM JOHNSON, University of Oxford, PHIL DIGGLE, University of Warwick, MICHAEL STRAIN, ERDAN GU, University of Strathclyde, MARK NEWTON, BEN GREEN, University of Warwick, OLIVER A WILLIAMS, University of Cardiff, JASON M SMITH, PATRICK SALTER, University of Oxford, GAVIN MORLEY (Presenter), University of Warwick — We have proposed [1] and begun developing [2-4] an experiment in which a 1 μm diamond containing an NV centre would be put into a superposition of being in two places at once with a superposition distance of 1 μm. This builds on our previous proposals [5-7] and others [8].

Separately, we have shown that laser-writing allows NV centres to be created in chosen locations inside of a diamond, deep enough to allow solid immersion lenses to be made around them, and with spin coherence times at least as long as naturally occurring NV centres [9].

We are also developing a fibre-coupled magnetometer with an NV ensemble towards possible medical applications [10].

*We acknowledge funding from the Royal Society and the EPSRC.
Near-term protocols for deterministic photonic graph state generation*  
ANTONIO RUSSO (Presenter), EDWIN BARNES, SOPHIA ECONOMOU, Virginia Tech — Highly entangled "graph" states of photons have applications in universal quantum computing and in quantum communications. Here we present near-term experimentally realizable protocols for the deterministic production of graph states, with explicit recipes for nitrogen-vacancy centers in diamond and self-assembled quantum dots. We address the scalability of the approach, focusing on arbitrary size "cluster" states, which can support universal quantum computation.

*This research was supported by a NSF (grant nr: EFRI ACQUIRE 1741656).

Mechanical driving of nitrogen-vacancy centers in diamond*  
DOMINICA LYZWA (Presenter), PAOLA CAPPELLARO, Massachusetts Institute of Technology — We theoretically investigate high-frequency phonon-mediated dynamic mechanical driving of spin transitions in nitrogen-vacancy centers in diamond (NV). Mechanical driving is parity non-conserving and can allow quantum control of spin |−1⟩ ↔ |+1⟩ transitions that cannot be addressed using magnetic resonant fields [1,2]. By applying high-frequency mechanical stress, the electronic and nuclear spin interaction is averaged out in the manifold of the |−1⟩ ↔ |+1⟩ spin transition. This dynamic decoupling yields an increase in the nuclear dephasing time. Experimentally, fivefold longer times were demonstrated using a.c. stress generated by a diamond mechanical resonator [1]. We develop a theoretical framework for this increase in the dephasing time for dynamic mechanical driving. Exploring mechanical driving to induce entanglement aims to engineer NV ensemble entanglement at room temperature to increase sensitivity in quantum metrology.

Engineering nitrogen-vacancy center electron-phonon coupling with a semi-confocal diamond acoustic resonator*  
HUIYAO CHEN (Presenter), CORNELL UNIVERSITY, ALEX JIANG, NOAH F ONPOONDO, SUNIL BHAVE, Purdue University, GREGORY FUCHS, Cornell University — Diamond-based microelectromechanical systems (MEMS) provide direct coupling between quantum states of nitrogen-vacancy (NV) center and the phonon modes inside the resonator. As a prime example, diamond thin film bulk acoustic resonators (BARs) feature integrated piezoelectric transducer and high-quality factor resonance modes up to the GHz frequency range. The bulk acoustic modes allow mechanical manipulation of deeply imbedded NV centers with long spin/orbital coherence, as recently demonstrated in experiments. Limited by the resonator size, ~100 um, coherent NV electron-phonon interaction is still scarce in current diamond BAR devices. In this talk, we present the design and fabrication of a semi-confocal diamond BAR device with f*Q product >10^14 [13]. The semi-confocal geometry confines the phonon mode laterally below 10 um. This drastic modal size reduction offers a boost in the NV center electron-phonon coupling with potential applications in spin-mediated resonator cooling and quantum resonator state control.

Fabrication of High Quality Quantum Emitters in Diamond Nanostructures*  
MICHAEL WALSH (Presenter), ERIC BERSIN, SARA MOURADIAN, NOEL WAN, DIRK R. ENGLUND, Massachusetts Institute of Technology — As the field of solid-state quantum engineering matures, it is increasingly necessary to produce quantum emitters with narrow optical transitions and long spin coherence times aligned to nanophotonic structures. We demonstrate an emitter-device alignment technique enabling fabrication of photonic devices registered to nitrogen-vacancy centers (NVs). The alignment method relies on autonomously imaging emitters and registering them relative to an on-chip coordinate system. This technique can be performed on a large variety of emitters. The repeatability of this method suggests an accuracy down to 50 nm.

The ability to navigate a sample autonomously while collecting data on a large number of NVs enables statistical analyses. We demonstrate the utility of this by correlating the NVs host nitrogen isotope with the optical linewidth of the emitter to understand the effect of implantation. This technique has implications for investigating the effect on NVs as they go through fabrication processes to understand how the local environment may change.

1:03PM L35.00010: Spectral stabilization and indistinguishable photon generation by electromechanical tuning of diamond color centers in nanophotonic devices∗ BARTHOLOMEUS MACHIELSE (Presenter), STEFAN BOGDANOVIC, SRUJAN MEESALA, MICHAEL J BUREK, CLEAVEN CHIA, GRAHAM JOE, Harvard University, SCARLETT GAUTHIER, University of Waterloo, MICHELLE V CHALUPNIK, JEFFREY HOLZGRAFE, LINBO SHAO, HAIG ATIKIAN, MIKHAIL LUKIN, MARKO LONCAR, Harvard University — Silicon-vacancy (SiV) color centers in diamond have excellent optical properties and spin coherence properties, making them ideal candidates for integration into quantum networks. However, their applications are limited by their spectral inhomogeneity and diffusion when implanted within nanophotonic devices. We present a platform for nano-electromechanically stabilizing and tuning the SiV spectral lines inside waveguides and cavities with emitter tuning range 3 times larger than the SiV inhomogeneous distribution. As demonstration of this platform’s capabilities, we tune two, waveguide coupled SiV color centers into resonance using strain and generate an entangled superradiant state between them. We demonstrate that this technique can be used for broad bandwidth suppression of spectral diffusion and to drive spectral lines with 10s of MHz bandwidth. Our platform for cavity coupled, individually tunable solid state quantum emitters with long coherence times should allow for controllable interactions between emitters and is a step towards the creation of a quantum repeater network.

1:15PM L35.00011: Optical Characterization of Single Tin-Vacancy Centers in Diamond∗ ALISON RUGAR (Presenter), SHUO SUN, CONSTANTIN DORY, JELENA VUCKOVIC, Stanford University — Atom-like defects in diamond have emerged in recent years as candidates for solid-state, optically active qubits. Inversion-symmetric color centers based on group-IV impurities in diamond are of particular interest because of their strong optical properties and relatively good immunity to electric field noise. Phonon-induced transitions resonant with the ground-state (GS) splitting are a major cause of spin decoherence for these color centers but can be mitigated with an increased GS splitting. With a relatively large GS splitting of 850 GHz, the tin-vacancy (SnV) center in diamond holds potential for longer spin coherence times while also possessing good optical properties. In this talk, we will present our recent experimental characterization of the optical and spin properties of single SnV color centers in diamond nanopillars. We measure linewidths <30 GHz, observe a clear polarization dependence of the emission, and experimentally investigate the Zeeman splitting of the SnV. Our results match well the predictions of previous theoretical work.

1:27PM L35.00012: All-electron calculation of spin-spin interactions∗ KRISHNENDU GHOSH (Presenter), Mechanical Engineering, University of Michigan-Ann Arbor, HE MA, Chemistry, University of Chicago, VIKRAM GA VINI, Mechanical Engineering, University of Michigan-Ann Arbor, GIULIA GALLI, University of Chicago and Argonne National Laboratory — The decoherence time of defect-spin qubits is controlled by the interaction of nuclear and electronic spins and by that between electronic spins. A key quantity determining these interactions is the value of the electronic spin density at the nucleus, which in turn is a crucial ingredient to evaluate the hyperfine interaction (HF) and zero-field splitting (ZFS) tensors of a defect-spin qubit. Here we report all-electron calculations of the HF and ZFS tensors using real space density functional theory (DFT) calculations based on finite elements. While all-electron DFT calculations using localized basis sets (e.g. Gaussians) can be conveniently performed to determine HF and ZFS tensors of molecules and clusters, they become much more demanding for periodic solids, and plane-wave based calculations are prohibitively difficult to converge. We show that real-space, finite element DFT calculations provide robust estimates of ZFS and HF for both molecules and solids and we present results for molecules and the nitrogen-vacancy center in diamond. We also show that coarse-graining capabilities of the real space mesh included in our formulation enable efficient computations, by avoiding redundant mesh refinements far from the nuclei.

∗We acknowledge funding from NSF-MRSEC.
1:39PM L35.00013: Deep-center defects in semiconductors  MARIYA ROMANOVA (Presenter), JELENA SJAKSTE, NATHALIE VAST, Ecole Polytechnique, Laboratoire des Solides Irradiés, CEA-DRF-IRAMIS, CNRS UMR 7642, France — A renewed interest has been recently devoted to the study of deep-center defects in materials for applications in emergent quantum technologies such as quantum sensing. The typical example of a deep-center defect is the nitrogen-vacancy (NV) center in diamond. The spin states of this defect can be optically manipulated at room temperature, which makes it attractive for magnetic sensing [1].

The aim of this work is to obtain a reference method to model the electronic properties of the NV-center in diamond for the purpose of magnetic sensing. Density Functional Theory (DFT) is widely used for the calculation of the electronic structure of defects [2]. However, the single Slater determinant nature of the DFT wavefunctions does not allow for the calculations of the many-body levels of some defects. In the present work I develop a Hubbard model for the NV-center with the model parameters calculated by wannierization of defect levels computed with DFT-GGA and HSE06 calculations in large supercells. I will show that the model enables access to the multideterminant defect levels.

1:51PM L35.00014: Manipulation of electronic defects in hexagonal boron nitride*  ELANA URBACH (Presenter), TAMARA SUMARAC, HELENA KNOWLES, Harvard University, JAVIER D SANCHEZ-YAMAGISHI, University of California Irvine, SOONWON CHOI, University of California Berkeley, BO DWYER, TROND I ANDERSEN, MIKHAIL LUKIN, Harvard University — Hexagonal boron nitride (hBN) provides a regular nuclear spin lattice, which makes it a promising platform for studying models of spin dynamics. This material also hosts numerous electronic defects that have been well-characterized in bulk electron paramagnetic resonance (EPR) spectroscopy. Nitrogen vacancy (NV) centers in diamond are very sensitive local magnetic field probes that can polarize and control single electronic spins and nanoscale volumes of nuclear spins. In this experiment we use an NV center to manipulate electronic defects in and near hBN, and we are working towards utilizing these defects for better initialization and control of local nuclear spins.

2:03PM L35.00015: Auto-Locking Overhauser Field to the Sweet Point for an Electron Spin by Quantum Weak Measurement of Nuclear Spins*  GENGLI ZHANG (Presenter), Physics, The Chinese University of Hong Kong, VINCENT JACQUES, Laboratoire Charles Coulomb, Université de Montpellier and CNRS, PATRICE BERTET, Quantronics group, Université Paris-Saclay, RENBAO LIU, Physics, The Chinese University of Hong Kong — The sweet points such as the clock transitions (CTs) are important for quantum information processing (QIP) and quantum sensing technologies. Being inherently robust to the fluctuations of the environment, they provide almost the best options to counteract the decoherence of the electron spin. The random fields from the environment (Overhauser fields) that lead to the decoherence of the electron spin, however, can also destroy the sweet points, which sets up a big obstacle to the applications. Here we propose a new dynamical nuclear polarization (DNP) scheme that can auto-lock the Overhauser field to the sweet point of the nitrogen vacancy (NV) center. The DNP channel is established by combining the bath state dependent microwave (MW) control, the conditional flipping of the nuclear spins and the optical pumping of the NV center electronic spin. The mechanism can also be understood as sequential weak measurements of the nuclear spins followed by entropy dumping through initialization of the electron spin.

Session L36 DMP: Physics of Natural Phenomena  BCEC 205C - Antoinette Taylor, Los Alamos National Laboratory -  Tag(s): Invited, Undergraduate
11:15AM L36.00001: Fire/atmosphere Feedbacks that Control Wildland Fire [Invited] RODMAN RAY LINN (Presenter), Los Alamos National Laboratory — Wildfires pose a threat to life, property and critical infrastructure, but wildland fire is an unavoidable part of the nature. In order to improve our ability to cope with wildfires and anticipate their evolving roles on the earth system we need to better understand how they interact with their environment. Recent fire behavior research illustrates the importance of the two-way feedbacks between fires and the surrounding atmosphere, which is influenced by the vegetation structure and topography as well as ambient winds. The effectiveness and consequences of fuels management activities are tied not only on the removal of combustible fuel, but also on the changes in the ventilation induced by decreased vegetation drag, which can potentially increase fire spread. Safe use of prescribed fires to reduce fire risk while accomplishing ecologic objectives typically depends on fire practitioner's ability to anticipate the interaction of multiple fires. This interaction is controlled by the competition between their fire-induced indrafts. Topographic influences on fire behavior are dominated by terrain-induced changes in entrainment patterns that control the patterns of heat transfer to unburned fuel. Multi-scale two-way fire/atmosphere feedbacks determine heterogeneous fire line dynamics and thus fire spread, the effects of fires on ecology and the near-field lofting and transport of the smoke. Unfortunately, deciphering the complex interaction between fires and surrounding atmosphere through field and laboratory experiments alone has been challenging, but recent advancements in computing power have created new opportunity for the complimentary use of numerical models to provide additional perspectives concerning fire/atmosphere feedbacks that have previously been challenging to explore. Examples of ways that the interactions between fire and surrounding atmosphere dictate fire behavior and the use of numerical models to investigate this coupling will be discussed.

11:51AM L36.00002: The Physics of Climate and Climate Change [Invited] KERRY EMANUEL (Presenter), Massachusetts Institute of Technology — The talk will begin with a broad overview of climate science, including the history of the science itself, and what we have learned about the Earth's climate system through analysis of paleoclimate data, the instrumental record, and, most importantly, the fundamental physics, chemistry, and biology underlying the climate system. Projections of future climates, made using both simple and complex models, will be discussed, with an emphasis on sources of uncertainty together with an assessment of whether and to what extent the level of uncertainty can be reduced. I will end the talk with reflections on how physicists might help find solutions for mitigating climate change.

12:27PM L36.00003: Mixed signals in future climate extremes: understanding counterintuitive results* [Invited] SARAH KAPNICK (Presenter), Geophysical Fluid Dynamics Laboratory, NOAA — If temperatures warm in the future, if everything else remains constant, there should be less snowfall since temperatures will rise above freezing more often. If we know a region will become drier on average in the future, and storms have constant rainfall amounts, the likelihood of extreme events should decline. But these stationarity assumptions do not hold true, resulting in what can appear to be counterintuitive changes in climate phenomena and extremes. We will discuss where snowfall accumulation and blizzards may actually increase and why some glaciers have been expanding. We will also discuss why a region may become drier overall, but also have increased risk for extreme precipitation events. While these regional changes may seem counterintuitive, they can actually be explained by unique conditions, seasonality, and changes in atmospheric moisture.

1:03PM L36.00004: Physics of Earthquakes: The Real Earthshaking Science [Invited]  RACHEL E ABERCROMBIE (Presenter), Department of Earth & Environment, Boston University — The study of earthquakes is driven by the desire to understand our dynamic planet and to minimize the devastation that earthquakes can cause. Earthquake science spans a huge range of temporal and spatial scales. The largest earthquakes rupture faults that are 100s to 1000s of kilometers long but start from nucleation regions so small that they have never been reliably observed. Earthquake faults move at only millimeters to centimeters a year but earthquake ruptures propagate at speeds of kilometers a second, and most earthquakes last less than a minute.

I will begin by introducing the basic concepts and observations of earthquake occurrence, and the widely-accepted, friction-based physical understanding of fault failure and rupture. I will then discuss how more recent observations and modeling are providing improved insights into this earthshaking science.

Fault rocks obtained from drilling through the San Andreas Fault and other major earthquake ruptures are providing evidence of the frictional strength of these plate boundary faults. Great earthquakes are being recorded by more, better instruments than ever before providing unprecedented resolution of the rupture process. The increase in anthropogenically-induced earthquakes forms an unintentional semi-controlled experiment to probe the triggering process. Improved geodetic observations are revealing that earthquakes are only part of a continuum of fault rupture types, with durations varying from seconds to minutes, days and even months.

Dynamic modeling of individual earthquakes on super computers can now produce realistic simulations of earthquake rupture and shaking. Earthquakes do not occur in isolation but interact as a consequence of both the dynamic and static stress changes they cause. Progress is also being made on modeling earthquakes as part of a complex system of deformation.

1:39PM L36.00005: The mechanics of hydraulic fractures in glaciers, volcanoes, and reservoirs [Invited]  BRAD LIPOVSKY (Presenter), Earth and Planetary Sciences, Harvard University — Fractures that interact with fluid are ubiquitous in Earth systems. In the floating ice shelves that fringe the grounded Antarctic Ice Sheet, hydraulic fractures pose a threat to ice sheet stability. Hydraulic fractures in volcanoes transport magma and other fluids through Earth's crust. And hydraulic fractures may be engineered to improve the performance of geothermal energy resources. The mechanical analysis of hydraulic fractures may take several viewpoints, of which I focus on two. First, linear elastic fracture mechanics provides insight into the dynamics of hydraulic fractures at shallow depths above the brittle–ductile transition. Second, active hydraulic fractures may create mechanical vibrations that are observable at distant seismometers. In both instances, geophysical data and mechanical analyses together provide insights into stunning natural phenomena that have direct bearing on human civilization.

Session L37 GMAG DCMP DMP: Iridates -- Honeycomb Lattice and Other Geometries BCEC 206A - Stuart Calder, Oak Ridge National Laboratory - Tag(s): Focus

11:15AM L37.00001: Anomalous Magnetic Torque Signal in a Kitaev Spin Liquid Candidate [Invited]  VIKRAM NAGARAJAN (Presenter), ALEJANDRO RUIZ, MAYIA VRANAS, GILBERT LOPEZ, Department of Physics, University of California, Berkeley, GREGORY T. MCCANDLESS, Department of Chemistry and Biochemistry, The University of Texas at Dallas, JULIA Y. CHAN, Department of Chemistry, University of Texas at Dallas, NICHOLAS BREZNAY, Department of Physics, Harvey Mudd College, ITAMAR KIMCHI, Center for Theory of Quantum Matter, University of Colorado, Boulder, JAMES G. ANALYTIS, Department of Physics, University of California, Berkeley — The honeycomb iridates have received much attention as potential material realization of Kitaev's exactly solvable honeycomb model, which predicts a quantum spin liquid ground state with fractionalized Majorana excitations. While the presence of magnetic order at low temperature makes the Kitaev nature of the iridates less apparent, it may still be possible to detect high-temperature signatures of the spin liquid state. In this study, we present data on a unique high-temperature phase of lithium iridate as measured by torque magnetometry.

*Supported by the Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract No. DE-AC02-05CH11231.
A unique feature of 5d materials is the fact that spin-orbit coupling, Coulomb interactions, and crystal electric field effects are of comparable strength. In the edge-sharing honeycomb iridates, this competition of energy scales leads to a strongly anisotropic, Ising-like exchange between neighboring isospin-1/2 moments. Such interactions couple each spin to orthogonal components of the three neighboring spins and, as a consequence, no single exchange direction can be simultaneously satisfied, leading to strong frustration closely approximated by the Kitaev Hamiltonian. So far, most potential Kitaev materials have been found to order at low temperatures, eluding the sought-after QSL state. Nonetheless, experiments suggest that Kitaev exchange is the dominant spin interaction in these systems, with additional small contributions from a direct Heisenberg and a symmetric off-diagonal exchange term. We previously showed that a magnetic field completely suppresses the complex incommensurate spiral order in β-Li2IrO3, while stabilizing a commensurate zig-zag component similar to the ground state observed in Na2IrO3. In this work, we present the magnon excitation spectra of β-Li2IrO3 in zero and finite magnetic field, at zone centers corresponding to both coexisting states.

Spin-Glass Behavior in Hole-Doped Lithium Iridates

Kitaev iridates in 3D: magnetic and structural instabilities

Here, I will present recent results on the pressurized hyperhoneycomb iridate β-Li2IrO3 and argue that this compound can be tuned to a classical spin liquid state triggered by the reduction in the nearest-neighbor Kitaev term K and the enhancement of the off-diagonal anisotropy Γ. We find that above 1.4 GPa pressurized β-Li2IrO3 separates into a mixture of dynamic and frozen spins representing a partially frozen spin liquid, as expected in a system where spin dynamics is supported by thermal rather than quantum fluctuations.

I will further show how Kitaev magnetism is realized in three-dimensional frameworks of Ir4+ hexahalides that can be chemically tuned even at ambient pressure, thus giving rise to a variety of intertwined structural and magnetic instabilities.

*Financial support by the Alexander von Humboldt Foundation and German Science Foundation (TRR80) is acknowledged.
**12:27PM L37.00005: NQR investigation of low frequency spin dynamics in Kitaev spin liquid candidate material Cu$_2$IrO$_3$ in zero magnetic field**

SEAN K S TAKAHASHI, JIAMING WANG, ALEXANDRE ARSENAULT, Dept. of Physics and Astronomy, McMaster University, MYKOLA ABRAMCHUK, FAZEL FALLAH TAFTI, Dept. of Physics, Boston College, PHILIP SINGER, Dept. of Chemical and Biomolecular Engineering, Rice University, SUNG-SIK LEE, TAKASHI IMAI (Presenter), Dept. of Physics and Astronomy, McMaster University — Cu$_2$IrO$_3$ [1] is a Kitaev spin liquid candidate material with nearly ideal honeycomb planes consisting of Ir magnetic moments, and does not exhibit a bulk magnetic long range order. We report $^{63,65}$Cu Nuclear Quadrupole Resonance (NQR) investigation of Cu$_2$IrO$_3$ in zero external magnetic field [2]. Unlike the case of the celebrated sister compound Na$_2$IrO$_3$ or $\alpha$-RuCl$_3$ with a bulk antiferromagnetic ground state below $T_N$, spin dynamics reflected on the NMR relaxation rate $1/T_1$ does not show a divergent behavior caused by conventional magnons. We can therefore probe the intrinsic low energy spin excitations of the Kitaev planes using NQR in zero magnetic field in a broad window of temperature.

*The work at McMaster was supported by NSERC and CIFAR. The work at Boston College was supported by NSF DMR-5104811.

**12:39PM L37.00006: NMR investigation of Kitaev spin liquid candidate material Cu$_2$IrO$_3$**

JIAMING WANG (Presenter), SEAN K S TAKAHASHI, ALEXANDRE ARSENAULT, Dept. of Physics and Astronomy, McMaster University, MYKOLA ABRAMCHUK, FAZEL FALLAH TAFTI, Dept. of Physics, Boston College, PHILIP SINGER, Dept. of Chemical and Biomolecular Engineering, Rice University, SUNG-SIK LEE, TAKASHI IMAI, Dept. of Physics and Astronomy, McMaster University — Cu$_2$IrO$_3$ is a Kitaev spin liquid candidate material [1]. In this talk, we report $^{63,65}$Cu high-field Nuclear Magnetic Resonance (NMR) measurements of Cu$_2$IrO$_3$ [2]. We probed the intrinsic spin susceptibility based on $^{63,65}$Cu Knight shift, and the magnetic field effects on paramagnetic spin dynamics based on NMR relaxation rate $1/T_1$.

*The work at McMaster was supported by NSERC and CIFAR. The work at Boston College was supported by NSF DMR-5104811.

**12:51PM L37.00007: Competition between static and dynamic magnetism in the Kitaev spin liquid material Cu$_2$IrO$_3$**

ERIC KENNEY (Presenter), Department of Physics, Boston College, CARLO SEGREG, Department of Physics, Illinois Institute of Technology, WILLIAM LAFARGUE-DIT-HAURET, Institut des Sciences Chimiques de Rennes, OLEG I. LEBEDEV, Laboratoire CRISMAT, Ensicaen-CNRS, MYKOLA ABRAMCHUK, Department of Physics, Boston College, ADAM BERLIE, STEPHEN P. COTTRELL, Rutherford-Appleton Laboratory, ISIS Neutron and Muon Source, GEDIMINAS SIMUTIS, Laboratory of Muon Spin Spectroscopy, Paul Scherrer Institute, FARANAK BAHRAMI, Department of Physics, Boston College, NATALIA E. MORDVINOVA, Laboratoire CRISMAT, Ensicaen-CNRS, JESSICA L MCCHESNEY, GILBERTO F L FABBRI, Advanced Photon Source, Argonne National Laboratory, XAVIER ROCQUEFELTE, Institut des Sciences Chimiques de Rennes, MICHAEL JOHN GRAF, FAZEL FALLAH TAFTI, Department of Physics, Boston College — Cu$_2$IrO$_3$ is a new honeycomb iridate without thermodynamic signatures of long-range order. Here, we use muon spin relaxation to uncover the magnetic ground state of Cu$_2$IrO$_3$. We find a two-component depolarization with slow and fast relaxation rates corresponding to distinct regions with dynamic and static magnetism, respectively. X-ray absorption spectroscopy and first principles calculations identify a mixed copper valence as the origin of this behavior. Our results suggest that a minority of Cu$^{2+}$ ions nucleate regions of static magnetism whereas the majority of Cu$^{+}$/Ir$^{4+}$ on the honeycomb lattice give rise to a Kitaev spin liquid.
1:03PM L37.00008: Neutron Scattering Study of Kitaev Spin-Liquid Candidate H$_3$LiIr$_2$O$_6$ — THOMAS HALLORAN (Presenter), COLLIN BROHOLM, Johns Hopkins University, KEMP PLUMB, Physics, Brown University, TOMOHIRO TAKAYAMA, Max Planck Institute for Solid State Research, HIDENORI TAKAGI, Physics, University of Tokyo — A central theme of condensed matter physics in recent years has been the realization of materials that exhibit a quantum spin-liquid state beyond one dimension. The exactly solvable Kitaev model of a quantum spin liquid consists of a 2D honeycomb lattice of $J_{eff} = \frac{1}{2}$ magnetic ions with bond dependant interactions. NMR and bulk sample characterization has suggested that H$_3$LiIr$_2$O$_6$ could be a spin-liquid [1]. The structure consists of a honeycomb lattice of Ir$^{4+}$ ions with strong spin-orbit coupling to support the bond dependent exchange interactions required in the Kitaev model. While previous lithium iridates have all been found to magnetically order at low temperature, specific heat and magnetization measurements show no order in this material down to low temperature. Using inelastic neutron scattering on SEQUOIA at ORNL, we probed the material magnetic excitations in D$_3$Li$^{193}$Ir$_2$O$_6$. We describe features in neutron scattering which are consistent with those of a KSL. Through a first moment analysis of the scattering data we determine the range of interactions and an estimate for the ground state energy.

1:15PM L37.00009: Crystal electric field and structural study of $J_{eff} = 1/2$ K$_2$IrX$_6$ (X = Cl, Br) — DALMAU REIG-I-PLESSIS (Presenter), SANGJUN LEE, University of Illinois at Urbana-Champaign, L. HOZOI, MOHAMED SABRY ELDEEB, IFW Dresden, ADAM ACZEL, Oak Ridge Nat. Lab., MARY UPTON, Argonne Nat. Lab., PATRIC CLANCY, McMaster University, JACOB RUFF, Cornell University, JEROEN VAN DEN BRINK, IFW Dresden, PETER ABBAMONTE, GREG MACDOUGALL, University of Illinois at Urbana-Champaign —

Strong spin orbit coupling in 5d materials has been a focus of research due to the wide variety of exotic phases which can exist in these systems. Of particular interest are systems with octahedral coordination, the triply degenerate $t_{2g}$ state will split into the occupied $J_{eff} = 3/2$ and the partially occupied $J_{eff} = 1/2$ states. It is this $J_{eff} = 1/2$ state that can host a large range of exotic phases such as quantum spin liquids and superconductivity. Here we present detailed data on two Iridium halide materials, K$_2$IrX$_6$, X = Cl, Br, which have the antifluorite structure and the Ir atom inside separated halide octahedra. Powder X-ray scattering study show a newly observed structural transition in the Br compound at T$_c$=180K. Resonant inelastic X-ray scattering data and X-ray absorption data are combined with quantum chemistry calculations to study the crystal electric field levels, and show that these materials show record proximity to the ideal $J_{eff} = 1/2$ state at all temperatures down to T=5K.

1:27PM L37.00010: Multi-scale Quantum Criticality driven by Kondo-lattice Coupling in Pyrochlore Systems — HANBIT OH (Presenter), EUN-GOOK MOON, KAIST, YONG-BAEK KIM, Department of Physics, University of Toronto, SANGJIN LEE, KAIST —

Pyrochlore systems with local moments and 5d conduction electrons offer excellent material platforms for the discovery of exotic quantum many-body ground states. Notable examples include U(1) quantum spin liquid (QSL) and semimetallic non-Fermi liquid state. Here we investigate emergent quantum phases and their transitions driven by the Kondo-lattice couplings. Using the renormalization group method, we show that weak Kondo-lattice coupling is irrelevant, leading to a fractionalized semimetal phase with decoupled local moments and conduction electrons. Upon increasing the Kondo-lattice coupling, this phase is unstable to the formation of broken symmetry states. The important thing is the opposing influence of the Kondo-lattice coupling and long-range Coulomb interaction. The former prefers to break the particle-hole symmetry while the latter tends to restore it. The characteristic competition leads to multiple phase transitions, first from a fractionalized semimetal phase to a fractionalized Fermi surface state with particle-hole pockets, followed by the second transition to a fractionalized ferromagnetic state. Multi-scale quantum critical behaviors appear at non-zero temperatures and with the external magnetic field near such quantum phase transitions.
1:39PM L37.00011: Observing spin fractionalization of the Kitaev spin liquid via temperature evolution of the K-edge RIXS response

GABOR HALASZ, Oakridge National Laboratory, STEFANOS KOURTIS, Physics, Boston University, JOHANNES KNOELLE, Physics, Imperial College London, NATALIA PERKINS (Presenter), University of Minnesota — A prominent feature of the Kitaev quantum spin liquid is fractionalization of the spin degree of freedom. Here we propose that the temperature evolution of the fractionalization in the Kitaev honeycomb model can be studied by the resonant inelastic X-ray scattering (RIXS). We calculate the RIXS response of the Kitaev honeycomb model and show how the momentum-energy map of the fractionalization varies with temperature. We also suggest that the indirect RIXS process at Ru K-edge which allows for sub-meV resolution can provide important insights about the structure of the excitation spectrum in α-RuCl₃.

1:51PM L37.00012: Understanding counter-rotating spiral ordering in three dimensional Kitaev materials

PANAGIOTIS PETER STAVROPOULOS (Presenter), ANDREI CATUNEANU, HAE-YOUNG KEE, University of Toronto — The counter-rotating spiral ordering found in three-dimensional (3D) iridate Kitaev candidates suggest frustration of spin interactions and raise a possibility of nearby spin liquid phases. Understanding the microscopic mechanism of this ordering may provide routes to 3D Kitaev spin liquids. We study a minimal 3D model including Kitaev K and a symmetric off-diagonal bond-dependent Γ interaction on the hyperhoneycomb lattice by using exact diagonalization (ED). An ED cluster was chosen to satisfy a hidden SU(2) symmetry. The magnetic ordering in the transformed basis then generically maps to the counter-rotating noncoplanar spiral order of the original spin when the moment is pinned along a certain direction. When K and Γ are negative, a small positive Heisenberg interaction favours the (1,1,0) direction consistent with the reported spiral order in β-Li₂IrO₃. Our findings offer a relevant set of microscopic parameters, which in turn guides a way to approach possible Kitaev spin liquids.

Session L38 GMAG DMP: Spin Chains, Criticality and QPT

11:15AM L38.00001: Magnetic-field induced quantum phase transitions in spin-1/2 XXZ chain materials

THOMAS LORENZ (Presenter), Institute of Physics II, University of Cologne, Germany — Low-dimensional quantum spin systems offer an ideal playground to study the generic behavior close to magnetic-field induced quantum phase transitions. Of particular interest is the XXZ spin-1/2 chain model with anisotropy parameter Δ=Jz/Jxy of the exchange couplings acting either on the z- or the xy-spin components. For Δ=0, 1 and ∞, respectively, the exactly solvable XY, Heisenberg and Ising chain models are covered, but real materials are typically located in between these models and there are additional intra- and/or inter-chain couplings. In this contribution, our recent experimental studies of model materials with field-induced quantum phase transitions will be presented. Cu(C₄H₄N₂)(NO₃)₂, is an almost ideal realization of the Heisenberg chain with weak intra-chain coupling, such that we could study its field induced quantum phase transition in great detail. The experimental data are almost perfectly reproduced by Bethe-Ansatz calculations over a wide temperature and field range and on approaching the quantum critical field the systematic evolution of the generic quantum critical behavior is clearly observed in the experimental data [1]. In BaCo₂V₂O₈, the Co²⁺ ions realize effective spin-1/2 chains with pronounced Ising anisotropy. Here, sizable inter-chain couplings cause long-range, 3D antiferromagnetic order with complex magnetic-field temperature phase diagrams [2]. For a particular transverse-field direction, however, the field-induced suppression of the 3D magnetic order is well separated from the region where we observe the characteristic quantum critical behavior expected for the one-dimensional Ising spin chain in transverse magnetic field [3].

**11:51AM L38.00002: Impact of pressure on the magnetic order in an S=1/2 quantum antiferromagnet**

TAO HONG (Presenter), Neutron Scattering Division, Oak Ridge National Laboratory, QING HUANG, Department of Physics and Astronomy, University of Tennessee, SACHITH DISSANAYAKE, Department of Physics, Duke University, YIMING QIU, National Institute of Standards and Technology, YAN WU, HUIBO CAO, WEI TIAN, Neutron Scattering Division, Oak Ridge National Laboratory, HAI DONG ZHOU, Department of Physics and Astronomy, University of Tennessee, MARK M. TURNBULL, Carlson School of Chemistry and Biochemistry, Clark University — Here we present a neutron scattering study on a spin-1/2 two-leg ladder antiferromagnet C9D18N2CuBr4 (DLCB for short) under applied hydrostatic pressure. In DLCB, the inter-ladder coupling is sufficiently strong to drive the system to the Néel antiferromagnetic ordering phase below $T_N=2$ K and the analysis of the spin Hamiltonian reveals that DLCB is close to the quantum critical point in two dimensions at zero field and ambient pressure [1]. Single-crystal neutron diffraction measurements under pressures up to 1.3 Gpa suggest that size of the staggered moment becomes suppressed with increase of pressure and the magnetic order breaks down above pressure ~1.0 Gpa.

**12:03PM L38.00003: High pressure and high magnetic field tuning of the S = 1 quantum antiferromagnet system**

DAN SUN (Presenter), Los Alamos National Laboratory, SAM CURLEY, PAUL GODDARD, Warwick University, JACQUELINE VILLA, JAMIE MANSON, Eastern Washington University, JOHN SINGLETON, FEDOR BALAKIREV, Los Alamos National Laboratory — [Ni(HF$_2$)(pyz)$_2$]SbF$_6$ is a quasi-one-dimensional S = 1 antiferromagnet in which the magnetic ground state can be tuned by changing the single-ion anisotropy (D) and the intrachain (J) and interchain (J') exchange interactions, allowing exploration of the Haldane phase diagram close to quantum criticality. With a newly developed pressure cell designed for pulsed magnetic fields of up to 100 T, we tune the above interactions in [Ni(HF$_2$)(pyz)$_2$]SbF$_6$ using hydrostatic pressures of up to 5.4 GPa. The characteristic form of the magnetic susceptibility was measured in pulsed fields of up to 65 T using a Proximity Detector Oscillator (PDO), allowing values of D, J and J' to be inferred at each pressure.

*The National High Magnetic Field Lab Pulsed Field facility is supported by the National Science foundation under cooperative Grant Nos. DMR-1157490 and DMR-1644779, the U.S. DOE, and the State of Florida.

**12:15PM L38.00004: Pressure-Tuning through the $D/J \approx 1$ Quantum Critical Point in an $S = 1$ Antiferromagnetic Chain**

MARCUS K. PEPRAH, PAUL S. EDWARDS, Dept. of Physics and NHMFL, University of Florida, JOHN CAIN, Dept. of Chemistry, University of Florida, ORLANDO TREJO, JAYNISE M. PEREZ, PEDRO A. QUINTERO, Dept. of Physics and NHMFL, University of Florida, JAREDS SINGLETON, LARRY PAUL ENGELHARDT, Dept. of Physics and Astronomy, Francis Marion University, SC, SAUL H. LAPI DUS, X-ray Science Division, Argonne National Laboratory, ERIK CIZMAR, Dept. of Condensed Matter Physics, Institute of Physics, P. J. Safárik University, Košice, Slovakia, JAMIE MANSON, Dept. of Chemistry and Biochemistry, Eastern Washington University, MARK MEISEL (Presenter), Dept. of Physics and NHMFL, University of Florida — Properties of [Ni(HF$_2$)(3-Clpy)$_4$]BF$_4$ (py = pyridine), or NBCT, suggest this S = 1 chain is near the $D/J \approx 1$ quantum critical point with easy-plane anisotropy $D = 4.3$ K, intrachain antiferromagnetic interaction $J = 4.86$ K, and no long-range order to 25 mK [1]. To clarify other work [2], the low field (0.1 T) susceptibility $\chi(2$ K $< T < 300$ K) was studied as a function of pressure ($P < 1.5$ GPa). These data are contrasted with isothermal (300 K) powder XRD studies made with $P < 2.5$ GPa. The pressure evolution of $\chi(T)$ correlates with structural modifications. With no evidence of a structural transition, the $\chi(T)$ data can be simulated by changes of $J$ and $D$ [3]. Complemented by inelastic neutron studies ($P$ and $B = 0$ and $T > 300$ mK) [4], NBCT appears to be the first S = 1 antiferromagnetic chain that can be pressure-tuned from the Haldane phase to the Large-D regime by traversing the $D/J \approx 1$ quantum critical point.

12:27PM L38.00005: z=2 quantum critical dynamics in spin chain and spin ladder compounds

DOMINIC BLOSSER (Presenter), VIVEK BHARTIYA, ETH Zurich, NOAM KESTIN, Department of Theoretical Physics, Université de Genève, KIRILL POVAROV, ETH Zurich, DAVID J. VONESHEN, ROBERT BEWLEY, ISIS Facility, Rutherford Appleton Laboratory, EMANUELE COIRA, THIERRY GIAMARCHI, Department of Theoretical Physics, Université de Genève, ANDREY ZHELUDEV, ETH Zurich — By means of high resolution inelastic neutron scattering, we investigate finite temperature critical dynamics near the magnetic field induced quantum critical point with dynamical exponent \( z = 2 \) in one dimension.

In the \( S=1/2 \) Heisenberg spin chain compound \( K_2CuSO_4Cl_2 \) at saturation, we find correlations characteristic of the \( z=2, d=1 \) quantum critical point. At the same time we find a novel thermally activated longitudinal mode that remains underdamped across most of the Brillouin zone. By comparison to finite temperature density matrix renormalization group (DMRG) calculations we quantitatively explain the experimental data [1].

In the strong rung quantum spin ladder \( (C_5H_{12}N)_2CuBr_4 \) (BPCB), at the same \( z=2, d=1 \) critical point, as expected we find a similar low energy excitation spectrum. However, making use of the additional symmetry of the spin ladder, here we can separate universal critical and non-universal structure factor contributions. We find universal finite-temperature scaling of the transverse local dynamic structure factor in spectacular quantitative agreement with long-standing theoretical predictions. Already at rather low temperatures, we again observe strong non-universal longitudinal fluctuations [2].

12:39PM L38.00006: The Magnetocaloric Effect in Exotic Spin Chain Compounds

ROBERT WILLIAMS (Presenter), PAUL GODDARD, SAM CURLEY, Physics, University of Warwick, YOSHIMITSU KOHAMA, AKIRA MATSUO, The Institute for Solid State Physics, University of Tokyo, SYDNEY KAECH, ZACHARY MANSON, JAMIE MANSON, Chemistry, Eastern Washington University — The seminal \( S=1/2 \) chain model is highly sensitive to deviations from the ideal Hamiltonian which, together with the intrinsic quantum fluctuations due to low-dimensionality, can induce a range of exotic behaviours. One such perturbation is an alternating local crystal structure, which produces a field-induced gap to solitonic excitations and promotes non-collinear spin structures. The sine-Gordon (SG) model captures this behaviour at low fields, but breaks down as systems approach saturation. We report the results of pulsed-field adiabatic measurements of the magnetocaloric effect in the archetypal SG chain material \( [(pym)-Cu(NO_3)_2(H_2O)_2] \), plus the novel chiral spin-chain compound with four-fold periodicity along the chain axis: \( [Cu(pym)(H_2O)_2]SiF_6.H_2O \), \( (pym=N_2C_4H_4) \). The chiral system displays a rich variety of excitations above a gap which, in contrast to the SG model, has a linear field-dependence and suppressed magnitude. These measurements provide a powerful means of probing both the magnetic entropy across phase diagrams, and the quantum critical behaviour near saturation. Our results highlight similar underlying physics in the compounds, but also indicate intriguing qualitative differences in the quantum phase transitions at high field.

*We thank the ERC and ISSP for funding
Pressure induced magnetic order in the novel 1D magnet K$_2$Cr$_8$O$_{16}$

OLA KENJI FORSLUND (Presenter), ELISABETTA NOCERINO, Royal Institute of Technology, DANIEL ANDREICA, Babes-Bolyai University, YASMINCE SASSA, Uppsala University, HIROSHI NOZAKI, IZUMI UMEGAKI, Toyota Central Research and Development Laboratories Inc., VIKTOR JONSSON, Royal Institute of Technology, ZURAB GUGUCHIA, ZURAB SHERMADINI, RUSTEM KHASANOV, Paul Scherrer Institut, MASAHIKO ISOBE, Max Planck Institute for Solid State Research, YUTAKA UEDA, oyota Physical and Chemical Research Institute, JUN SUGIYAMA, Toyota Central Research and Development Laboratories Inc., MARTIN MÅNSSON, Royal Institute of Technology, HIDENORI TAKAGI, Max Planck Institute for Solid State Research — The title compound, K$_2$Cr$_8$O$_{16}$, belongs to a series of quasi-1D compounds synthesised using a high-pressure/-temperature technique. The channels are formed by zig-zag Cr$_2$O$_4$ chains parallel to the c-axis and K cations occupying the center. Intriguingly, the compound undergoes a metal to insulator transition while maintaining the ferromagnetic order [1, 2], established by a Peierls transition [3]. Pressure dependent studies on this compound is fairly limited and the complete phase diagram of this compound is not fully resolved, especially the low temperature / high pressure region [4]. Here, pressure dependent muon spin rotation/relaxation (μSR) data is presented, which uniquely allow us perform measurements in zero applied field and hereby access the true intrinsic material properties. Finally, neutron diffraction has recently been conducted in order to elucidate the detailed nature of the complex phase diagram.

Magnetic exchange interactions in the BaM$_2$Si$_2$O$_7$(M= Cu, Co, Mn) system

WEIDONG LUO (Presenter), CHENGYANG XU, GUOHUA WANG, JIE MA, Shanghai jiao Tong University — A quasi 1D system with weak exchange coupling between the magnetic chains will exhibit a crossover from 1D magnetic behavior at high temperatures to a 3D ordered state at low temperatures. The BaM$_2$Si$_2$O$_7$(M = Cu, Co, Mn) with layered structure is an excellent system to study low-dimensional magnetic behaviors. BaCu$_2$Si$_2$O$_7$ has an orthorhombic structure with CuO$_4$ plaquettes, while BaCo$_2$Si$_2$O$_7$ and BaMn$_2$Si$_2$O$_7$ have a monoclinic crystal structure with CoO$_4$ and MnO$_4$ tetrahedrons. We have performed local spin-density approximation with onsite Coulomb interaction (LSDA + U) calculations to study the exchange interactions. By computing the total energies of various magnetic configurations and mapping these energies to a Heisenberg model, we extract the magnetic exchange interactions in the three materials. We also discuss the relations between the magnetic exchange interactions with their crystal and electronic structures. In the end, we make comparisons with experimental studies such as single crystal neutron diffraction measurements.

First-principles calculations of the magnetic properties for one-dimensional chains of dihydrated transition-metal oxalates

JUAN HERNÁNDEZ-TECORRALCO (Presenter), Instituto de Física, Benemérita Universidad Autónoma de Puebla, MIGUEL EDUARDO CIFUENTES QUINTAL, Departamento de Física Aplicada, Centro de Investigación y de Estudios Avanzados del IPN, LILIA MEZA-MONTES, Instituto de Física, Benemérita Universidad Autónoma de Puebla, ROMEO DE COSS, Departamento de Física Aplicada, Centro de Investigación y de Estudios Avanzados del ipN — Dihydrated transition metal oxalates are crystals composed of quasi one-dimensional (1D) chains which could grow in orthorhombic or monoclinic phases. Their dominant magnetic behavior is a long-range antiferromagnetic order along the metal-oxalate chains. In this work, we have studied the magnetic properties of 1D chains of Co- and Ni-oxalate by means of density functional theory calculations. The intra-chain magnetic interaction is analyzed for ferromagnetic (FM) and antiferromagnetic (AF) orders. The calculated structural parameters along the chain direction are in good agreement with the experimental values for the bulk cases. The magnetic ground state of these systems corresponds to the AF configuration, in agreement with the experimental observations for the bulk. For the Co-oxalate, the calculated local magnetic moment of Co atom is 2.6 μ$_B$ which is in accord with the value obtained from neutron diffraction experiments (2.3 μ$_B$). Thus, 1D chains of transition metal oxalates may be useful systems to implement spin chains for applications in spintronics and quantum computing.

Quantized magnon-excitation continuum in quasi one-dimensional antiferromagnetic S=1 Heisenberg systems
TAKAFUMI SUZUKI (Presenter), SEI-ICHIRO SUGA, University of Hyogo — In recent inelastic neutron scattering measurements on (Ba/Sr)CO_2V_2O_8[1,2], quantization of spinon-excitation continuum has been observed below the Néel temperature. The interesting point is that the excitation energies of the quantized spectra are well explained by negative zeros of the Airy functions (NZAF)[3]. In this study, we investigate the possibility of quantized magnon-excitation continuum in quasi-one-dimensional antiferromagnetic S=1 Heisenberg chains with the single-ion anisotropy, D. We use the infinite time-evolving-block-decimation method to compute dynamical spin structure factors and show that the magnon-excitation continuum is also quantized by the weak inter-chain interaction[4]. We find that the excitation energies agree with NZAF when D is quite large negatively. Although the quantization spectra survive up to D ~ 0, the excitation energies deviate from NZAF. [1] Z. Resonant second-order optical resonances in quantum magnets
SHUNSUKE FURUYA (Presenter), RIKEN — Recently, laser control of materials has attracted much attention in various fields of condensed-matter physics. In 2016, Sato, Takayoshi, and Oka proposed an ultrafast way to add to a quantum magnet an effective Dzyaloshinskii-Moriya interaction dynamically. They confirmed their theoretical proposal by calculating the vector chirality to which the Dzyaloshinskii-Moriya interaction is coupled. They also pointed out numerically that there exists a resonance of the dynamically generated vector chirality when the frequency of the applied laser equals to the Zeeman energy of the quantum magnet. This resonance is interesting because the dynamical generation of the vector chirality is the second-order response to the laser but its resonance resembles another linear-response phenomenon to the laser, that is, electron spin resonance. Unfortunately, the resonant second-order response to the laser is yet to be understood. In this presentation, I discuss the origin of the resonant second-order resonance and exemplify it in quantum spin chain systems. I also show that the resonant second-order response can be found in quite a general situation of quantum magnets. For example, the magnetization also exhibits the same resonant second-order optical response.

Lukas Weber (Presenter), Institut für Theoretische Festkörperphysik, RWTH Aachen University, Francesco Parisen Toldin, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Stefan Wessel, Institut für Theoretische Festkörperphysik, RWTH Aachen University — Based on large-scale quantum Monte Carlo simulations, we examine the correlations along the edges of two-dimensional semi-infinite quantum critical Heisenberg spin-1/2 and spin-1 systems. In particular, we consider coupled quantum spin-dimer systems at their bulk quantum critical points, including the columnar-dimer model and the plaquette-square lattice. The alignment of the edge spins strongly affects these correlations and the corresponding scaling exponents, with remarkably similar values obtained for various quantum spin-dimer systems. We furthermore observe subtle effects on the scaling behavior from perturbing the edge spins that exhibit the genuine quantum nature of these edge states.

Spin-current diode with a monoxial chiral magnet
SHUN OKUMURA (Presenter), HIROAKI ISHIZUKA, YASUYUKI KATO, Department of Applied Physics, University of Tokyo, JUNICHIRO OHE, Department of Physics, Toho University, YUKITOSHI MOTOME, Department of Applied Physics, University of Tokyo — Chiral magnets often show interesting magnetic and transport properties associated with their peculiar spin textures. For instance, a monoxial chiral magnet CrNb_3S_6 shows a chiral soliton lattice in a magnetic field, accompanied by peculiar temperature and field dependence of resistivity [1]. Such chiral spin textures potentially give rise to nonreciprocal transport phenomena, as they break spatial inversion and time reversal symmetries simultaneously [2]. However, nonreciprocal transport in the monoxial chiral magnets has not been fully understood, especially for spin currents. Here, we investigate the spin-dependent transport properties in a chiral conical magnetic state using a one-dimensional Kondo lattice model. We calculate the conductance of spin current numerically by using the Landauer method based on Green's functions. We show that the system exhibits nonreciprocal spin transport, which depends on the conical angle, the chirality of the magnetic structures, and the polarized direction of the spin current. We discuss the origin of the nonreciprocity by analyzing the spin states near the edges.

Session L39 GMAG DCMP DMP: Defect Spins in Semiconductors  BSEC 207 - Gregory Fuchs, Cornell University  - Tag(s): Focus

11:15AM L39.00001: Understanding quantum materials using strain-sensitive x-ray diffraction imaging*  [Invited]
JOSEPH HEREMANS (Presenter), Argonne National Laboratory — Understanding the local crystalline strain around point defects, such as the nitrogen vacancy center in diamond and divacancy complexes in SiC, is a critical step toward improving spin coherence and optical properties. These lattice perturbations affect both the charge and the optical transition frequency stability of the defect, limiting their use as nanoscale sensors and quantum bits for quantum communication applications. While local strain can be mitigated using applied electric fields and external static strain, direct observation of inhomogeneous strain fields around these defects at the nanometer length scale remains challenging. Here we present work on the development of synchrotron-based, strain-sensitive x-ray imaging techniques which we use to map the local lattice perturbations within diamond and SiC crystals. These tools can help understand the interaction of defects with dynamically driven strain fields as well as probe the defect creation process to help improve the basic properties of quantum materials. We show two separate techniques: strain-sensitive Bragg coherent diffraction imaging (BCDI) that can measure the three-dimensional lattice strain of individual diamond and SiC nanoparticles as a function of annealing temperature [1,2], and a stroboscopic scanning x-ray diffraction microscopy (s-SXDM) imaging approach that can spatially map acoustic waves in SiC [3] and probe the local strain around crystalline defects. Combining these techniques with growth and implantation protocols could provide a direct means to understand the local crystalline environment surrounding point defect as well as a pathway towards improving their spin properties.

In collaboration with S. J. Whiteley, S. O. Hruszkewycz, M. V. Holt, & D. D. Awschalom.

ANNEMARIE L EXARHOS (Presenter), Lafayette College — Optically-addressable spins associated with localized defects in wide-bandgap semiconductors are the basis for rapidly expanding quantum technologies in nanoscale sensing and quantum information processing. Whereas most research has focused on three-dimensional host materials such as diamond, the van der Waals material hexagonal boron nitride (hBN) has emerged as a robust host for bright, stable, room-temperature quantum emitters (QEs). However, many questions persist regarding the chemical and electronic structure of the defects responsible for emission as well as the potential role of spin-related effects. Significantly complicating the identification are the heterogeneity of optical characteristics observed for these QEs.

In this talk, I will describe the optical and magnetic properties of QEs in hBN characterized using confocal fluorescence microscopy on suspended hBN films. Qualitative similarities in excitation and emission polarization, spectral shape, and emission statistics are evident among QEs in hBN, even for large variations in emission energy [1]. Significantly, a small percentage of observed QEs exhibit strongly anisotropic photoluminescence modulation in response to an applied magnetic field in ambient conditions [2]. The magnetic-field-induced modulation is consistent with an electronic model featuring a spin-dependent inter-system crossing between triplet and singlet manifolds, suggesting that these defects host optically addressable spin states. This discovery enables the realization of spin-based quantum technologies with van der Waals heterostructures.

12:27PM L39.00003: Diamond Nanomechanical Resonators with Narrow Linewidth NVs* IGNAS LEKAVICIUS (Presenter), THEIN OO, MARK KUZYK, HAILIN WANG, University of Oregon — Nitrogen vacancy centers in diamond are promising qubit candidates which have had recent work focusing on interfacing NVs with acoustic fields. One approach, which is monolithic and doesn't require external driving of phonons, is coupling NVs to high quality factor mechanical resonators in diamond. This approach necessitates low mass, thin membranes which are generally fabricated by thinning down a thicker diamond sample with a plasma etch. However, plasma damage to the diamond results in deep charge defects and poor surface termination which affects the spin and optical properties of the NV center. Here we report on the fabrication of thin mechanical resonators imbedded in a phononic crystal and the measurement of improved optical properties of NVs in those membranes.

*NSF under grant No. 1719396 and AFOSR

12:39PM L39.00004: Mechanical rotation via optical pumping of paramagnetic impurities* PABLO ZANGARA, Physics, City College of New York- CUNY, ALEXANDER A WOOD, Physics, Centre for Quantum Computation and Communication Technology, School of Physics, The University of Melbourne, Melbourne, MARCUS DOHERTY, Physics, Laser Physics Centre, Research School of Physics and Engineering, Australian National University, Canberra, CARLOS MERILES (Presenter), Physics, City College of New York-CUNY — The microscopic understanding of magneto-mechanical processes — involving the inter-convertion between magnetization and angular momentum in a solid — has long been hampered by the complex dynamics governing the spin polarized electrons of a ferromagnetic material, collectively coupled via quantum exchange. Here we use a rotationally invariant Hamiltonian to study the spin dynamics of a pair of paramagnetic centers in an insulator — namely, the so-called P1 and NV centers in diamond — close enough to each other to interact via the dipolar coupling. We examine the interplay between magnetic and mechanical degrees of freedom, and theoretically show that in the presence of continuous optical illumination, cross-relaxation between the NV and P1 spins leads to a rigid rotation of the diamond crystal along with the generation of spin-polarized phonons. The effect should be observable using state-of-the-art torsional oscillators.

*C.A.M. acknowledges support from the National Science Foundation through grants NSF-1619896, NSF-1547830, and from Research Corporation for Science Advancement through a FRED Award. 12:51PM L39.00005: Observing the charge state of substitutional nitrogen via nitrogen vacancy magnetometry ARTUR LOZOVOI (Presenter), DAMON DAW, JACOB HENSHAW, HARISHANKAR JAYAKUMAR, PABLO ZANGARA, City College of New York, SIDDHARTH DHOMKAR, University College London, HELMUT FEDDER, Swabian Instruments, Germany, MARCUS DOHERTY, Australian National University, CARLOS A. MERILES, City College of New York — Defects in diamond have been widely explored as a potential system for quantum information processing. The negatively charged Nitrogen Vacancy (NV) center is of particular interest because its spin can be operated at ambient conditions and addressed optically with the help of low frequency microwave. It has been suggested that the spin state of the donor electron of the substitutional nitrogen defect (N\textsubscript{s}) can be utilized as a quantum register for a spintronics bus [1]. Here, we use the NV center as a local probe to examine the ionization of small N\textsubscript{s} ensembles in type 1b diamond. To this end, we implement double electron-electron resonance (DEER), [2] which we articulate with multi-color laser excitation to prepare and subsequently probe the local charge state in the N\textsubscript{s} ensemble. We will also discuss the use of polarization transfer techniques from the NVs as a route to probe the spin resilience of photo-generated carriers throughout cycles of ionization from and re-trapping by N\textsubscript{s}.

Polarization transfer between electric and nuclear spins at the level anti-crossing of the NV center in diamond

VIKTOR IVADY (Presenter), Wigner Research Centre for Physics, IGOR ABRIKOSOV, Linkoping University, ADAM GALI, Wigner Research Centre for Physics — Point defect qubits in semiconductors offer new, highly polarizable and controllable electron spin resources to be utilized in nuclear spin polarization experiment. The NV center in diamond holds a great promise for implementing various dynamic nuclear polarization (DNP) mechanisms to achieve high degree of hyperpolarization at elevated temperatures. For example, the level anti-crossing of the electron spin states at moderate magnetic field allows all-optical DNP processes [1] with a mechanism of microwave-free polarization inversion [2]. In my talk, I summarize our most recent theoretical results on all-optical DNP at the level anti-crossing of NV center in diamond of different $^{13}$C nuclear spin concentrations. We demonstrate that the increasing nuclear spin concentration has a negative impact on the efficiency of nuclear polarization transfer that explains the lack of hyperpolarization in $^{13}$C enriched samples. Additionally, I assess the requirements and discuss possible layouts for hyperpolarizing external nuclear spins for sensitivity enhanced NMR and MRI measurements.

First-principle study of spin-strain coupling in defect spin qubits* HE MA (Presenter), Institute for Molecular Engineering and Department of Chemistry, University of Chicago, MENG YE, Institute for Molecular Engineering, University of Chicago, SAMUEL WHITELEY, Institute for Molecular Engineering and Department of Physics, University of Chicago, GARY WOLFOWICZ, DAVID AWSCHALOM, Institute for Molecular Engineering, University of Chicago, GIULIA GALLI, Institute for Molecular Engineering and Department of Chemistry, University of Chicago — Spin defects in semiconductors are promising platforms for quantum information processing and are useful components of hybrid quantum devices. Transition energies between different defect states are sensitive to external perturbations and hence lattice strains can be utilized for mechanical control of qubits. In this work, we use density functional theory to predict the coupling strength between spin and mechanical degrees of freedom for prototypical defect spin qubits including the nitrogen-vacancy centers in diamond and divacancies in silicon carbide, and we compare our results with recent experiments [1].

*This work was supported by the National Science Foundation (NSF) through the University of Chicago MRSEC under award number DMR-1420709.

Exploring solid-state defects with a microwave-modulated spectroscopy technique* DIANA PRADO LOPES AUDE CRAIK (Presenter), PAULI KEHAYIAS, ANDREW GREENSPON, MINA GADALLA, RONALD L WALSWORTH, EVELYN L HU, Harvard University — We have developed a microwave-based spectroscopy technique to determine charge state of nitrogen-vacancy ensembles in diamond. The technique isolates, in situ, the spectral shape of the fluorescence contribution from neutral and negatively-charged defects, producing sample-specific results which take into account the effects of experimental conditions (e.g. illumination intensity and wavelength) and material properties (such as local strain and electric fields). Here, we use this technique to explore how ensemble charge state is affected by experimental and material parameters, and to study the physics of NV ionization from the negative charge state. We also apply a variation of our technique to silicon vacancies (SiV) in 4H silicon carbide. The technique may be used to isolate the spectra of V1 and V2-type defects at room temperature -- these are two silicon vacancies that occur at inequivalent lattice sites but have closely-spaced spectral signatures. We explore the modulation of the SiV signals in both bulk SiC and in nanobeam optical resonators that include the vacancies.

Coherent electrical driving of quantum spins via localized magnons

AVINASH RUSTAGI (Presenter), Electrical and Computer Engineering, Purdue University, SHIVAM KAJALE, Electrical Engineering, Indian Institute of Technology Bombay, PRAMEY UPADHYAYA, Electrical and Computer Engineering, Purdue University — Spin-spin interactions in quantum-classical spin hybrids are promising enablers of quantum spintronics. For example, dipolar interactions between classical magnets and quantum dot (QD) spins have enabled electrically driven high-fidelity quantum processors [Nat. Nano 13, 102 (2018)]. Motivated by higher operating temperatures, dipolar interactions in quantum impurity (QI) spin [like Nitrogen vacancy (NV) center]-classical magnet hybrids have been used for quantum sensing of ground state configurations-solitons [Nature 549, 252 (2017); Nat. Commun. 9, 2712 (2018)], as well as, excitations-magnons [Science 357, 195 (2017)]. In addition, magnons have mediated long-distance coherent coupling between NVs and microwave antennas [npj Quantum Info. 3, 28 (2017)]. In contrast to QD spin-magnet hybrids, coherent electrical driving of QI spins is, however, missing. Here, we propose to utilize spin-orbit induced electrical driving of magnons [Nano Lett. 2017, 17, 1, 572], to mitigate this challenge. Specifically, we study coherent and incoherent coupling of QI spins in proximity to electrically controlled localized magnons in nanomagnets-showing coherent electrical driving of QI spins.

*We acknowledge NSF grant DMR-1838513.

Modeling the Quantum Dynamics behind Charge Transport in Photosynthetic Reaction Centers beyond the Spin-Boson Model

KRISTINA LENN (Presenter), EITAN GEVA, University of Michigan — Silicon is one of the most common solar cell materials due to its availability, ideal band gap, and high efficiency but needs to be processed onto glass substrates. Research has turned its attention towards organic materials, which can be processed relatively cheaply onto plastic substrates but are not nearly as efficient as silicon. Modeling the quantum dynamics behind the charge transport process will help elucidate methods to enhance the material’s efficiency. This model can be extrapolated from the transport process in the Fenna-Matthews-Olson complex in green sulfur bacteria.

The photosynthetic process observed in the FMO complex utilizes quantum coherence during electron energy transfer, which has been shown to increase efficiency by offsetting radiative recombination. To model the dynamics of this process, we are using a combination of the Ehrenfest method, which has already been tested on the two-state Spin-Boson model, and Multi-Configuration Time-Dependent Hartree for an eight-state system. However, one of the major drawbacks of quantum calculations is the high computational cost. To circumvent this, we plan to implement the Generalized Quantum Master Equation, which has a much more efficient memory kernel, thus cutting the computational cost of quantum calculations.

Probing Coherent Spin Dynamics of Isolated Exchange Coupled Defects in III-V Semiconductors

STEPHEN MCMILLAN (Presenter), NICHOLAS HARMON, MICHAEL FLATTÉ, University of Iowa — Individual magnetic impurities or small collections of magnetic impurities in III-V semiconductors can be identified via scanning tunneling microscopy (STM) [1,2]. Their exchange interaction can be measured [3], and they can have remarkably long spin coherence times [4]. Through low-field magnetoresistance calculations we find that exchange coupled defects generate a resonance feature in the current at critical values of the applied magnetic field, termed “exchange resistance”. Using a single site approximation [5,6], the signatures of hyperfine interaction and the influence of g-factor fluctuation on exchange resistance are examined. By including a non-trivial spin manifold as the ground state this work becomes applicable to defects like divacancies in silicon carbide and Mn+hole complexes in gallium arsenide.

Session L40 GMAG DMP: Magnetism and Domain Structures in Complex Oxides
11:15AM L40.00001: Titanate pyrochlores: Growth of stoichiometric crystals below their melting points* [Invited]
SEYED KOOHPAYEH (Presenter), Johns Hopkins University — The pyrochlore rare earth titanates (RE₂Ti₂O₇) have been intensively studied experimentally and theoretically over the past two decades. In the field of magnetism, this class of materials is considered to be ideal hosts for archetypal geometrical frustration, which consists of the quantum spin ice, classical spin ice, and spin liquid behaviors. The energy scales for such magnetic interactions are low; therefore, these systems are expected to be very sensitive to small perturbations of all kinds, including non-stoichiometry and structural defects. In this talk, we report the effects that synthesis and growth conditions can have on the stoichiometry, defect formation, and physical properties. We also describe the process to grow high-quality and stoichiometric pyrochlore titanate single crystals at temperatures below their melting points by changing their composition using the traveling solvent floating zone technique (TSFZ).

11:51AM L40.00002: Topological structural defects and exotic magnetic behaviors in hexagonal TbInO₃ and GdInO₃
JAE WOOK KIM (Presenter), XUEYUEN WANG, FEI-TING HUANG, YAZHONG WANG, Y LI, SANG-WOOK CHEONG, Rutgers University, New Brunswick, XUAN LUO, Pohang University of Science and Technology, EUNDEOK MUN, XIAXIN DING, VIVIEN ZAPF, Los Alamos National Laboratory — Geometrical frustration may induce highly degenerate ground states, complex spin configurations, or exotic ground states. One extreme example is the spin liquid, where magnetic ordering is suppressed even at zero temperature by quantum fluctuations. Spin liquids may host novel properties such as spinon excitations, majorana edge states, etc. Here, we report intriguing examples of coexisting topological ferroelectric domains and exotic magnetism in hexagonal rare-earth (R) indates such as TbInO₃ and GdInO₃. Geometric ferroelectricity is realized in hexagonal RInO₃ and we have unveiled Z₆ vortex domains associated with geometric ferroelectricity in TbInO₃ and GdInO₃, as similar to what has been observed in hexagonal manganites. On the other hand, magnetic properties vary upon different R ions. For example, GdInO₃ shows a phase transition at low temperatures below 2.5 K whereas no signature of phase transition is observed for TbInO₃. We suggest that the topological defects and ferroelectric domain walls serve as an intrinsic playground for the edge states that may exist in frustrated magnets.

12:03PM L40.00003: Imaging antiferromagnetic antiphase domain boundaries using magnetic Bragg diffraction phase contrast*
VALERY KIRYUKHIN (Presenter), MIN GYU KIM, BIN GAO, SANG-WOOK CHEONG, Rutgers University, New Brunswick, HU MIAO, CLAUDIO MAZZOLI, ANDI BARBOUR, STUART B WILKINS, IAN KEITH ROBINSON, MARK DEAN, BNL — Manipulating magnetic domains is essential for many technological applications. Recent breakthroughs in Antiferromagnetic Spintronics brought up novel concepts for electronic device development. Imaging antiferromagnetic domains is of key importance to this field. Unfortunately, some of the basic domain types, such as antiphase domains, cannot be imaged by conventional techniques. Herein, we present a new domain projection imaging technique based on the localization of domain boundaries by resonant magnetic diffraction of coherent x rays. Contrast arises from reduction of the scattered intensity at the domain boundaries due to destructive interference effects. We demonstrate this approach by imaging antiphase domains in a collinear antiferromagnet Fe₂M₀₂O₈, and observe evidence of domain wall interaction with a structural defect. This technique does not involve any numerical algorithms. It is fast, sensitive, produces large-scale images in a single-exposure measurement, and is applicable to a variety of magnetic domain types.

*Supported by the DOE, Grant No. DOE: DE-FG02-07ER46382.
12:15PM L40.00004: Imaging scale-invariant magnetic textures in a strongly correlated oxide  JIARUI LI (Presenter), JONATHAN PELLICIANI, ABRAHAM LEVITAN, Department of Physics, Massachusetts Institute of Technology, CLAUDIO MAZZOLI, National Synchrotron Light Source II, Brookhaven National Laboratory, SARA CATALANO, Department of Quantum Matter Physics, University of Geneva, FORREST SIMMONS, Department of Physics and Astronomy, Purdue University, JERZY T. SADOWSKI, Center for Functional Nanomaterials, Brookhaven National Laboratory, MARTA GIBERT, Department of Quantum Matter Physics, University of Geneva, ERICA CARLSON, Department of Physics and Astronomy, Purdue University, JEAN-MARC TRISCONE, Department of Quantum Matter Physics, University of Geneva, STUART B WILKINS, National Synchrotron Light Source II, Brookhaven National Laboratory — The electronic ground state of correlated electron systems, often manifests a granular texture across a broad range of length scales. Antiferromagnetic order is a common instability of these materials, however, its nanoscale spatial organization has not been systematically studied. In this talk, I will present our recent result using a resonant soft X-ray scattering nanoprobe to image the bulk magnetic landscape in NdNiO₃ thin films. Our measurements provide direct evidence for a highly textured magnetic fabric, that further exhibits return memory effects across the Neel transition. The scale-free distribution of antiferromagnetic domains and its non-integral dimensionality, together reveal an unprecedented magnetic fractal geometry near criticality, which reflects the interplay between electronic correlations and an intrinsic local parameter. Our observations expose new essential details of the nanoscale anatomy of strongly correlated electronic systems.

12:27PM L40.00005: Capturing Dynamics of Incommensurate Antiferromagnetic Domains with Coherent Soft X-ray Scattering  JOHN BOWLAN (Presenter), Physical Chemistry and Applied Spectroscopy, Los Alamos National Laboratory, RICHARD L SANDBERG, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, VIVIEN ZAPF, XIAXIN DING, National High Magnetic Field Laboratory, Los Alamos National Laboratory, SHIZENG LIN, Theoretical Division, Los Alamos National Laboratory, COLBY WALKER, BENJAMIN A POUND, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, NARA LEE, YOUNG JAI CHOI, Yonsei University, ANDI BARBOUR, WEN HU, STUART B WILKINS, CLAUDIO MAZZOLI, NSLS-II, Brookhaven National Laboratory — The observation of antiferromagnetic (AFM) domains and the dynamics of their interfaces remains an elusive problem. The physical origin and dynamics of AFM domains are different from ferromagnetic domains and are largely unexplored. In this work, we have studied the frustrated AFM, Lu₂CoMnO₆, with the brilliant, coherent, soft X-ray flux of the 23ID-1 beamline at NSLS-II [1]. Lu₂CoMnO₆ is a double perovskite with frustrated AFM order leading to incommensurate ordering and dynamic time scales ranging from seconds to days [2-4]. We have probed the AFM domain structure and dynamics of this material with X-ray photon correlation spectroscopy (XPCS). The motion of the domains is revealed by the motion of a speckle pattern in the scattered X-ray beam. We observed faster domain fluctuations below onsets of hysteresis at (35K) and explained these observations within the Axial Next-Nearest-Neighbor Ising (ANNNI) model.

12:39PM L40.00006: Magnetic Domain wall resistance in Half-metallic CrO2*  LIJUAN QIAN (Presenter), WENZHE CHEN, GANG XIAO, Brown University — The half-metallic CrO₂ is experimentally confirmed to have the highest spin polarization of nearly 100%. It is an ideal system to study magnetic domain-wall resistance (DWR), which differs from the resistance (or resistivity) inside a single-domain. We design and prepare a CrO₂ epitaxial nanostructure with an asymmetrical weak link to localize a single DW, using the techniques of chemical vapor deposition and selective-area growth. The weak link design provides us the capability to generate /annihilate a single DW by applying a moderate/strong reversing magnetic field. By contrasting the resistance between a single-domain state and a DW state under zero field, we obtain the domain wall resistance in half-metallic CrO₂. Using the Levy-Zhang model of DWR and simulated domain wall contour, we further obtain the spin asymmetry ratio between resistivities in the two spin channels. The ratio, 4256 ± 388 at 5.0 K, is 2 to 3 orders larger than that of conventional ferromagnetic metals, attesting the half-metallicity of CrO₂.

12:51PM L40.00007: Domain reversal dynamics and avalanches in a model insulating Ising ferromagnet  
DANIEL SILEVITCH (Presenter), CHRISTOPHER TANG, THOMAS F ROSENBAUM, Caltech — 100 years ago, Barkhausen's noise experiments provided evidence for discrete domains within ferromagnets and magnetization reversal occurring as a set of discrete events. By characterizing individual avalanche events, the underlying mechanisms for domain reversal can be studied. Many materials show a drag effect which appears in the statistical distribution of avalanche event shapes. In typical metallic ferromagnets, this drag is believed to be due to eddy currents induced during magnetization reversal. Whether this is only significant source of drag is an open question which we address by studying the model Ising system LiHo$_{0.65}$Y$_{0.35}$F$_4$, an insulating rare-earth, dipole-coupled ferromagnet with $T_C$ of 0.98 K. The LiHo$_{x}$Y$_{1-x}$F$_4$ family combine strong quantum fluctuations, random-field pinning, and a lack of eddy currents, extending the study of domain dynamics to an entirely new regime. We find symmetrical scaled distributions near $T_C$, indicative of a drag-free environment. By contrast, strong asymmetries appear for long-duration events at lower temperatures, suggesting the presence of drag without eddy currents. A thermal-driven crossover between random-field effects and a quantum-fluctuation regime suggests that the latter act as the source of this additional drag mechanism.

1:03PM L40.00008: Domain Structure and Reversal Dynamics of Magnetoelectric Antiferromagnets*  
ARUN PARTHASARATHY (Presenter), SHALOO RAKHEJA, Electrical and Computer Engineering, New York University — The single domain state of magnetoelectric (ME) antiferromagnet like Cr$_2$O$_3$ can be switched isothermally at room temperature by simultaneous application of electric and magnetic fields (He, et al., Nat. Comm. 2010; Kosub, et al., Nat. Comm. 2017). However, studies pertaining to switching dynamics, especially in thin-film systems, have been limited.

Domain reversal involves switching between saturated single-domain states. This constraint does not limit the dynamic process of reversal, which can exhibit single or multi-domain switching mechanisms, or a mix of both. In general, the mechanism of domain reversal depends on material parameters like the exchange interaction and magnetic anisotropy, size and shape of the sample, structure of defects, and strength of the excitation including thermal fluctuations.

In this work, we theorize the spatial and temporal limits of ME-induced reversal of antiferromagnet domain for nucleation, domain wall propagation and coherent rotation. We also address the formation of non-trivial domain structures in equilibrium in thin film Cr$_2$O$_3$ (Wu, et al., Phys. Rev. Lett. 2011), despite the absence of magnetostatic interaction in the bulk.

1:15PM L40.00009: Non-Reciprocal Directional Dichroism of THz Radiation in LiCoPO$_4$: Read-out of Magnetoelectric Domains*  
TOOMAS ROOM (Presenter), URMAS NAGEL, National Institute of Chemical Physics and Biophysics, SANDOR BORDACS, JAKUB VIT, Department of Physics, Budapest University of Technology and Economics and MTA-BME, ISTVAN KEZSMARKI, Experimental Physics 5, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, Germany, JUDIT ROMHANYI, Okinawa Institute of Science and Technology, Okinawa, Japan, KARLO PENC, Institute for Solid State Physics and Optics, Wigner Research Centre for Physics, Hungarian Academy of Sciences, Budapest, Hungary, VILMOS KOCSIS, YUSUKE TOKUNAGA, YASUJIRO TAGUCHI, YOSHINORI TOKURA, RIKEN Center for Emergent Matter Science (CEMS), Wako, Japan — Magnetoelectric (ME) effect in multiferroic materials is the cornerstone of new electronic devices allowing the electric field control of magnetization. Here we demonstrate the optical read-out of magnetoelectric domains in LiCoPO$_4$ exploiting the absorption difference between ME domains [Kocsis et al., PRL 121, 057601 (2018)]. Domains absorb differently because of non-reciprocal directional dichroism of spin wave resonances coupled to electric polarization. Single ME domain can be selected by poling with crossed electric and magnetic fields from the magnetically disordered state. LiCoPO$_4$ is the realization of a ME memory effect in an insulator with coupled anti-ferroelectric and anti-ferromagnetic orders.

1:27PM L40.00010: Inhomogeneous magnetic order in T'-La$_4$Ni$_3$O$_8$* OSCAR BERNAL (Presenter), Physics and Astronomy, California State University, Los Angeles, Los Angeles, CA 90032, DOUGLAS E. MACLAUGHLIN, Physics and Astronomy, University of California, Riverside, Riverside, CA 92521, GERALD D MORRIS, Center for Molecular and Materials Science, TRIUMF, Vancouver, BC V6T 2A3, Canada, LEI SHU, CHENG TAN, JIAN ZHANG, ZHAOFENG DING, State Key Laboratory of Surface Physics, Department of Physics, Fudan University, Shanghai 200433, China, KEVIN HUANG, National High Magnetic Field Lab, Florida State University, Tallahassee, Florida 32310, VIKTOR V. POLTAVETS, Department of Chemistry and Advanced Materials Research Institute, University of New Orleans, New Orleans, Louisiana 70148 — We report a muon spin rotation (μSR) study of the magnetic properties of the cuprate-analog nickelate La$_4$Ni$_3$O$_8$. The crystal structure of this compound involves square planar NiO$_2$ layers, potentially isoelectronic (Ni$^{1+}$) to the Cu$^{2+}$O$_2$ layers of the cuprates. The material has a magnetic phase transition at 105 K, the structure of which has remained elusive. Zero-field μSR confirms the antiferromagnetic nature and commensurate character of this transition, and sheds light on the most likely configuration of Ni spins below the Néel temperature. Comparison of spectra of observed muon precession frequencies to lattice calculations of Ni dipolar fields at candidate muon stopping sites suggests a spin configuration consistent with the stripe charge order observed previously by x-ray diffraction [1]; in particular, the number of observed frequencies is greater than calculated for homogeneous spin structures without stripes. The frequency magnitudes suggest reduced Ni ordered moments of less than or about 0.5μB. We briefly discuss models of magnetic-stripe order based on alternative charge stripe configurations (cf. Ref. [1]).

1:39PM L40.00011: Unravelling Giant Exchange bias in the single layered Ruddlesden-Popper compound SrLaCo$_{0.5}$Mn$_{0.5}$O$_4$: A combined studies of Experimental and Density Functional Theory* RANJANA RANI DAS, PRIYADARSHINI PARIDA, Indian Institute of Technology Madras, A.K. BERA, Solid State Physics Division, Bhabha Atomic Research Centre, T. CHATTERJII, Institut Laue-Langevin, B.R K NANDA, SANTHOSH NAGAPPAN NAIR (Presenter), Indian Institute of Technology Madras — Discovering exotic magnetism due to competing magnetic interactions in layered perovskites with 3d hetero-species B-site ions has remained an intriguing topic with many unexplained features. Here we study Exchange bias (EB) phenomena in a single layered Ruddlesden-Popper SrLaCo$_{0.5}$Mn$_{0.5}$O$_4$ using state of art measurement such as susceptibility, neutron diffraction and training effect along with density functional calculations. EB as large as ~5.5 kOe is observed in SrLaCo$_{0.5}$Mn$_{0.5}$O$_4$ which is the highest ever found in any layered transition metal oxides including Ruddlesden-Popper series. Neutron diffraction measurements and together with dc magnetic measurements suggest formation of short range magnetic domains. By carrying out density functional calculations on several model configurations we propose that EB is originated at the boundary between Mn rich antiferromagnetic and Co rich ferromagnetic domains at the sub-nanoscale. Our analysis infers that presence of competing magnetic interactions is sufficient to induce exchange bias and thereby a wide range of materials exhibiting EB can be engineered.

1:51PM L40.00012: Potts transition in coupled XY models* VICTOR DROUIN-TOUCHETTE (Presenter), Rutgers University, New Brunswick, PETER ORTH, Physics, Iowa State University, PREMALA CHANDRA, PIERS COLEMAN, Rutgers University, New Brunswick, TOM CARL LUBENSKY, Physics, University of Pennsylvania — Motivated by the long standing experimental mystery of the observation of a melting transition seemingly in the 3-state Potts universality class in thin films of liquid crystals, we revisit a model of coupled XY models. In these compounds, the interplay of the bond-orientational and herring-bone packing degrees of freedom, respectively invariant under rotation by π and by π/3, may lead to emergent discrete variables through the resulting anisotropic coupling. Using both large scale Monte-Carlo algorithms, with an adapted Wolff step and parallel tempering, and analytical methods, such as RG, we study the phase diagram of such a coupled XY model with global U(1) × Z$_3$ symmetry. The presence of the discrete order can highly frustrate the possible binding of vortices, and we investigate how this non-trivial interaction can lead to unconventional arrangements of the vortices. Our extensive numerical study focuses on the regime where both XY variables are equally present, and we discuss the possibility of a 3-state Potts transition at higher temperature than the BKT transition, as well as the nature of the meeting point between the BKT and Potts phase transition.

2:03PM L40.00013: Inelastic Neutron Scattering Investigation of Quantum Order-by-disorder in Bi$_2$CuO$_4$  BO YUAN (Presenter), Physics, University of Toronto, NICHOLAS BUTCH, GUANGYONG XU, National Institute of Standards and Technology, YOUNG-JUNE KIM, Physics, University of Toronto —

Order by disorder (ObD), where ground state is selected from a continuous manifold of classically degenerate states by either thermal or quantum fluctuation has been intensively studied theoretically. However, experimental realizations of ObD in real materials are still very rare. In this talk, we present strong evidence from neutron scattering for quantum ObD in tetragonal cuprate Bi$_2$CuO$_4$. With high resolution inelastic neutron scattering, we observed a gapless and a gapped magnon mode due to in-plane and out-of-plane spin fluctuation. By studying field dependence of the in-plane mode and magnetic Bragg peak, we directly observed a spin-flop transition at $\sim 0.4T$ and demonstrated the existence of a small magnetic anisotropy within the ab plane. Since any in-plane anisotropy is prohibited by symmetry in Bi$_2$CuO$_4$ on a classical level, we attribute its existence to quantum ObD. We investigated quantum ObD in Bi$_2$CuO$_4$ theoretically by spin-wave analysis. By taking into account quantum zero-point fluctuation of the spin wave modes in Bi$_2$CuO$_4$, we found a small in-plane anisotropy favouring an ordered moment 45 degrees from the crystallographic a and b directions. Our model quantitatively explained the size of critical field for spin-flop transition in our data.

Session L41 GMAG DMP: Heterostructures and Thin Films for Skyrmions  BCEC 209 - Andrew Kent, New York Univ NYU - Tag(s): Focus

11:15AM L41.00001: Hybrid chiral domain walls and skyrmions in magnetic multilayers* [Invited] WILLIAM LEGRAND (Presenter), Unité Mixte de Physique CNRS/Thales, Univ. Paris-Sud, Université Paris-Saclay, 91767 Palaiseau, France, NATHAN RONCERAY, Ecole Polytechnique, 91128 Palaiseau, France, JEAN-YVES CHAULEAU, Synchrotron SOLEIL, L'Orme des Merisiers, 91192 Gif-sur-Yvette, France, DAVIDE MACCARIELLO, FERNANDO AJEJAS, SOPHIE COLLIN, K BOUZEHOUANE, NICOLAS REYREN, Unité Mixte de Physique CNRS/Thales, Univ. Paris-Sud, Université Paris-Saclay, 91767 Palaiseau, France, NATHAN RONCERAY, Ecole Polytechnique, 91128 Palaiseau, France, JEAN-YVES CHAULEAU, Synchrotron SOLEIL, L'Orme des Merisiers, 91192 Gif-sur-Yvette, France, VINCENT CROS, ALBERT FERT, Unité Mixte de Physique CNRS/Thales, Univ. Paris-Sud, Université Paris-Saclay, 91767 Palaiseau, France — Aiming at reducing the radius of individual magnetic skyrmions below 10 nm without making compromises between room-temperature stability and current-induced mobility, a multilayered magnetic system is often privileged. However, dipolar interactions can overcome the essential chiral properties of magnetic skyrmions stemming from the Dzyaloshinskii-Moriya interaction (DMI), for multilayers with too large magnetization or number of layers. Using circular dichroism in X-ray Resonant Magnetic Scattering, we demonstrate a reorientation of chirality along the vertical direction of magnetic domain-walls and skyrmions, leading to the formation of hybrid chiral skyrmions. We next establish an extensive micromagnetic model of magnetic skyrmions, which allows obtaining their equilibrium profiles with an accurate and layer-resolved description of both size and chirality. The resulting magnetization profiles allow predicting, within the Thiele formalism, the expected velocity of skyrmions under current-induced spin-orbit torques in different spin injection geometries. We find the requirements on the DMI magnitude to ensure an efficient motion, and observe a regime of compensation of the skyrmion Hall effect for hybrid chiral skyrmions. Beyond such issues related to the chirality of ferromagnetic skyrmions, we finally present our recent progresses in the study of multilayers hosting synthetic antiferromagnetic skyrmions, whose alternation of polarity enables a way to circumvent all issues related to dipolar interactions in skyrmion multilayers.

*French ANR grant TOPSKY (ANR-17-CE24-0025), DARPA TEE program grant (MIPR#HR0011831554) and EU grant MAGicSky (FET-Open-665095) are acknowledged.
Surprisingly, they were all at least several tens of nanometer in diameter. Their large size has a fundamental origin: these skyrmions are stabilized by a competition of classical long range fields, namely stray fields and externally applied fields. Based on accurate analytical modeling, we could show that this is a general property of ferromagnets due to their overwhelming stray fields [5].

In ferri- and antiferromagnetic materials, stray fields play no significant role. We predicted theoretically [5] and confirmed experimentally [6] that a different type of skyrmion can exist in these materials at room temperature, stabilized by all-quantum interactions. These skyrmions are insensitive to classical fields, exist even at zero external field, and can be as small as ~10 nm in diameter. Finally, they are also created by quantum spin-orbit torques [7].

12:03PM L41.00003: Structural Imprinting of Target Skyrmions in Magnetic Multilayers* NOAH KENT (Presenter), UC Santa Cruz/ LBNL, ROBERT STREUBEL, MSD, Lawrence Berkeley National Laboratory, CHARLES-HENRI LAMBERT, ETH Zurich, SCOTT DHUEY, MI-YOUNG IM, MSD, Lawrence Berkeley National Laboratory, FELIX BUETTNER, Massachusetts Institute of Technology, PETER FISCHER, UC Santa Cruz/ LBNL — We will report on a recent study of topological spin textures that were imprinted due to coupling between a 30nm thin permalloy (Py) nanodisk with diameters from 250-1000nm and a multilayer Ir/Co/Pt film with strong DMI. Using element-specific magnetic soft x-ray microscopy we were able to image the magnetic structure of the Py nanomagnets and the spin texture in the DMI film independently. We found a significant increase of the imprinted domain period (240nm) in the film under the disks compared to the free film (180nm), which can be traced back to a locally varying stray field energy. We stabilize extended target skyrmions in the film with up to four \( \pi \) rotations of the z component of magnetization. This is due to the reduced stray field energy and enforced radial symmetry caused by the Py disk. We confirm that these structures have a uniform chirality enforced by the DMI of the thin film by observing an asymmetric expansion of the domain walls as a function of applied magnetic field pulses. We also observe the overall structural stability of target skyrmions in an external magnetic field has no dependence on topological charge.

*Work supported by DOE MSE BES DE-AC02-05-CH11231, Non-Equilibrium Magnetic Materials Program

12:15PM L41.00004: Realization of magnetic skyrmions in thin films at ambient conditions* LISA DEBEER-SCHMITT (Presenter), RYAN DESAUTELS, Oak Ridge National Laboratory, SERGIO MONTOYA, Space and Naval Warfare Systems Center Pacific, JULIE BORCHERS, NIST Center for Neutron Research, National Institute of Standards and Technology, SOONG-GEUN JE, MI-YOUNG IM, Center for X-ray Optics, Lawrence Berkeley National Laboratory, MICHAEL R. FITZSIMMONS, Oak Ridge National Laboratory, ERIC FULLERTON, Center for Memory and Recording Research, University of California, San Diego, DUSTIN GILBERT, Department of Materials Engineering, University of Tennesse, Knoxville — Magnetic skyrmions present interesting physics due to their topological nature and hold significant promise for future informational technologies. A key barrier to realizing skyrmion devices has been stabilizing these spin structures in ambient conditions. I will discuss how we exploited the tunable magnetic properties of amorphous Fe/Gd films to realize, for the first time, skyrmion lattices in continuous amorphous thin-films, stable at room temperature and zero magnetic field. These Bloch-type skyrmions are stabilized by dipolar interactions rather than traditional Dzyaloshinskii-Moriya interactions. Small angle neutron scattering was used in combination with soft x-ray microscopy providing a unique, multi-scale probe of the local and long-range order of these structures. Key to this work was to prepare an artificial stripe phase, which evolves into the hexagonally ordered skyrmion lattice structure under increasing magnetic field. These results identify a pathway to engineer controllable skyrmion phases in thin film geometries which are stable at ambient conditions.

*This research used resources at the High Flux Isotope Reactor, a DOE Office of Science User Facility operated by the Oak Ridge National Laboratory.
12:27PM L41.00005: SP-STM Studies of B20 MnGe* JACOB REPICKY (Presenter), JOSEPH CORBETT, TAO LIU, ADAM AHMED, Ohio State University, JONATHAN GUERRERO-SANCHEZ, National Autonomous University of Mexico, ROLAND KAWAKAMI, JAY A GUPTA, Ohio State University — Materials in the B20 crystal structure have broken bulk inversion symmetry, which can lead to the formation of chiral magnetic textures. MnGe is an example with the smallest magnetic period (~3 nm) and largest topological Hall signals observed among B20 chiral magnets. Here, we present spin-polarized scanning tunneling microscopy (SP-STM) characterization of thin MnGe(111) films grown by molecular beam epitaxy. Atomic resolution images show a triangular lattice with a lattice parameter of 6.85 Å in good agreement with the bulk. Three of four possible surface terminations are observed in STM images of different terraces on the surface. Tunneling spectroscopy with a bulk Cr tip shows a pronounced dependence on magnetic field, which we compare to the spin-resolved local density of states calculated by DFT. Counter-intuitively, we observe the largest spin signal from one of the Ge-terminated surfaces, due to their antiferromagnetic coupling to the underlying Mn layer. We also examine magnetic field dependence in topography and spectroscopic maps to probe for surface magnetic structures.

*Funding for this research was provided by the Defense Advanced Research Projects Agency Grant No. 18AP00008

12:39PM L41.00006: Stability of Skyrmions and Topological Hall Effect in Mn2CoAl thin films GUY DUBUIS (Presenter), YAO ZHANG, SIMON GRANVILLE, Victoria University of Wellington — Skyrmions are magnetic quasi-particles that have the potential to help resurrect Moore’s Law.[1] Due to their topological protection, they could be used as non-volatile memory,[2] while also allowing the design of logic gates[3] that could be used in magnonic devices. The presence of skyrmions can be detected by observing the topological contribution to the Hall resistance, due to the time-varying magnetic field experienced by an electron travelling through a material hosting skyrmions. We observe skyrmions in thin films of the ferromagnetic spin-gapless semiconductor Heusler alloy Mn2CoAl capped by Pd.[4] We can engineer our thin films to make the skyrmions stable from 3K to above room temperature. By careful control of the magnetic and thermal history of the sample, we can condition various forms of skyrmions in this material. In order to understand their stability, we have measured time dependent Hall resistance and magnetization in the skyrmion regions. We observe skyrmions that are stable for at least hours at room temperature in the absence of a magnetic field.

12:51PM L41.00007: Determining Chirality of Non-Centrosymmetric FeGe and MnGe Thin Films via STM JOSEPH CORBETT (Presenter), JACOB J REPICKY, Department of Physics, Ohio State University, JONATHAN GUERRERO-SANCHEZ, Centro de Nanociencias y Nanotecnologia, Universidad Nacional Autónoma de México, TIANCONG ZHU, ADAM S AHMED, STEVEN TJUNG, TAKAHIRO TAKEUCHI, ROLAND KAWAKAMI, JAY A GUPTA, Department of Physics, Ohio State University — Recent interest in the 'B20' phase of FeGe and MnGe stems from noncollinear magnetic states, such as magnetic Skyrmions. Here we present a joint STM and DFT study of FeGe and MnGe films grown by molecular beam epitaxy. An average surface lattice constant of ~6.8 Å (FeGe) and of ~6.9 Å (MnGe), in agreement with the bulk values, was observed via LEED, as well as in situ RHEED during the MBE growth. Atomic resolution images of each of the four possible chemical terminations in the FeGe films were characterized by distinct image contrast and corrugation, as well as local density of states in tunneling spectra. Likewise, three of the four possible chemical terminations of MnGe were identified in atomic resolution STM images. These assignments were confirmed by the good agreement between the STM images and DFT-simulated images using the Tersoff-Hamann approximation. Having determined the surface terminations, STM images of the atomic layering order and registry across step edges allows us to uniquely determine the stacking order, and hence chirality of these films, which is difficult with conventional crystallography techniques.
1:03PM L41.00008: Skyrmions in Monolayer van der Waals 2D Magnets*  
AROOP BEHERA (Presenter), Kansas State University, SUGATA CHOWDHURY, Physical Measurement Laboratory, NIST, SUPREM DAS, Kansas State University — In this work, using Landau-Lifshitz Gilbert (LLG) model and first-principle calculations we demonstrate the occurrence of skyrmions in monolayer CrI$_3$. We considered a paramagnetic state and apply a range of magnetic fields from 0 T to 1.5 T. We found the system evolves under normal conditions (i.e., the time evolution under the influence of exchange and anisotropic interactions) to energetically favourable skyrmionic ground state. We derive the Heisenberg exchange ($J$), uniaxial magnetocrystalline anisotropy ($K$) and Dzyaloshinskii-Moriya interaction (DMI) parameters for monolayer CrI$_3$. Our calculations revealed that the isolated skyrmionic spin textures evolved in the order of a few picoseconds for a wide range of magnetic field. We found the chiral domain walls or helical states in the 2D monolayer CrI$_3$ along with the presence of skyrmions at low magnetic field strengths. However, with increasing strength of the magnetic field, the density of occurrence of chiral domains reduces converging and forming skyrmions. It is also observed that with the increase in the field strength the size of stable skyrmions reduces.

1:15PM L41.00009: Large terahertz resonance in MnGe thin films  
YOSHIHIRO OKAMURA (Presenter), YUDAI HAYASHI, NAOYA KANAZAWA, University of Tokyo, ATSUSHI TSUKAZAKI, Tohoku University, MASASHI KAWASAKI, MASAKAZU ICHIKAWA, University of Tokyo, YOSHINORI TOKURA, RIKEN CEMS, YOUTAROU TAKAHASHI, University of Tokyo — Topological nature of matters often plays an important role in transport phenomena such as Hall effect. For example, the large anomalous Hall effect (AHE) and topological Hall effect (THE) have been observed in bulk MnGe [1]. In this study, we investigate the optical Hall conductivity by means of terahertz time domain spectroscopy in MnGe thin films. While the diagonal conductivity can be well described by the conventional Drude model, the Hall conductivity spectra show the large resonance structure at ~1.2 meV, which is significantly enhanced and dominates the DC Hall conductivity at low temperatures. We further analyze the Hall conductivity spectra based on the Karplus-Luttinger model, which indicates that the resonance structure consists of two interband transitions corresponding to AHE and THE.

1:27PM L41.00010: Detecting Crystallographic Lattice Chirality using Resonant Inelastic X-ray Scattering  
TRINANJAN DATTA (Presenter), SEAN KEVIN MONGAN, Chemistry and Physics, Augusta University, GA, ZENGYE HUANG, School of Physics, Sun Yat-Sen University, China, TAKUJI NOMURA, Synchrotron Radiation Research Center, National Institutes for Quantum and Radiological Science and Technology, SPring-8, Japan, DAO-XIN YAO, School of Physics, Sun Yat-Sen University, China — The control and detection of crystallographic chirality is an important and challenging scientific problem. Chirality has wide ranging implications from medical physics to cosmology including an intimate but subtle connection in magnetic systems, for example Mn$_1-x$Fe$_x$Si. We demonstrate using theoretical calculations the feasibility of indirect K-edge bimagnon resonant inelastic X-ray scattering (RIXS) spectrum as a viable experimental technique to distinguish crystallographic handedness. We apply spin wave theory to the recently discovered $\sqrt{5} \times \sqrt{5}$ vacancy ordered chalcogenide Rb$_{0.89}$Fe$_{1.58}$Se$_2$ for realistic X-ray experimental set up parameters (incoming energy, polarization, and Bragg angle) to show that the computed RIXS spectrum is sensitive to the underlying handedness (right or left) of the lattice. A Flack parameter definition that incorporates the right- and left- chiral lattice RIXS response is introduced. It is shown that the RIXS response of the multiband magnon system RbFeSe arises both from inter- and intra- band scattering processes. The extinction or survival of these RIXS peaks are sensitive to the underlying chiral lattice orientation. This in turn allows for the identification of the two chiral lattice orientations.

1:39PM L41.00011: Numerical study of skyrmion-string dynamics  
WATARU KOSHIBAE (Presenter), NAOTO NAGAOSA, RIKEN CEMS — Magnetic skyrmion is a swirling emergent particle in two-dimensions characterized by the topological index called skyrmion number. The skyrmion in three dimensional chiral magnets forms a string, end points of which are monopole and antimonopole. This meandering one-dimensional object has many internal degrees of freedom including the rotation and breathing. The skyrmion string is driven by the current through the spin transfer torque effect, and the collision with the disorder induces a variety of phenomena. Here we show theoretically by the numerical simulation of a skyrmion string under current that the four distinct behaviors: (i) pinned string, (ii) depinned motion with the excitation of breathing mode, (iii) resonant excitation of breathing mode leading to the creation of monopole and antimonopole, and (iv) motional narrowing to recover the straight string, as the current density increases.
1:51PM L41.00012: Skyrmions Driven by Intrinsic Magnons  CHRISTINA PSAROUDAKI (Presenter), DANIEL LOSS, Department of Physics, University of Basel — We study the dynamics of a Skyrmion in a magnetic insulating nanowire in the presence of time-dependent oscillating magnetic field gradients [1]. These ac fields act as a net driving force on the Skyrmion via its own intrinsic magnetic excitations. Making use the generalized micromagnetic equations of motion for the quantum propagation of a skyrmion in a magnetic insulator [2], we include the unavoidable coupling of the external field to the magnons, which gives rise to time-dependent dissipation for the Skyrmion. We demonstrate that the magnetic ac field induces a super-Ohmic to Ohmic crossover behavior for the Skyrmion dissipation kernels with time-dependent Ohmic terms. The ac driving of the magnon bath at resonance results in a unidirectional helical propagation of the Skyrmion in addition to the otherwise periodic bounded motion.

2:03PM L41.00013: Relaxation dynamics in magnetic skyrmions with quenched disorder*  BART J BROWN (Presenter), UWE CLAUS TAUBER, MICHEL PLEIMLING, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — Magnetic skyrmions are topologically protected spin textures of nanometer size found in certain chiral magnets. Skyrmions can be moved by very low current densities which makes them ideal for applications in spintronics such as data storage devices and logic gates. A thorough understanding of the relaxation processes for systems of interacting skyrmions far from equilibrium could prove invaluable in real world applications. We use a particle based model derived from Thiele’s approach to study the relaxation dynamics of thin film skyrmions in the presence of randomly distributed defects. The particle model differs most notably from similar models which describe vortices in type-II superconductors by the addition of the Magnus force which always acts perpendicular to the forces in the plane. The interplay between the Magnus force, repulsive skyrmion-skyrmion interaction and Gaussian noise yields different regimes during non-equilibrium relaxation depending on the strength of the defects.

Session L42 DQI: Quantum Annealing: Algorithms and Applications  BCEC 210A - Lin Tian, University of California, Merced - Tag(s): Focus

11:15AM L42.00001: Benchmarking coherent Ising machines and quantum annealers with MAX-CUT and SK problems*  RYAN HAMERLY (Presenter), Research Laboratory of Electronics, Massachusetts Institute of Technology, TAKAHIRO INAGAKI, NTT Basic Research Laboratories, PETER MCMAHON, E. L. Ginzton Laboratory, Stanford University, DAVIDE VENTURELLI, Quantum Artificial Intelligence Laboratory (QuAIL), NASA Ames Research Center, ALIREZA MARANDI, TATSUHIRO ONODERA, EDWIN NG, E. L. Ginzton Laboratory, Stanford University, ELEANOR RIEFFEL, Quantum Artificial Intelligence Laboratory (QuAIL), NASA Ames Research Center, MARTIN FEJER, HIDEO MABUCHI, E. L. Ginzton Laboratory, Stanford University, SHOKO UTSUNOMIYA, National Institute of Informatics, HIROKI TAKESUE, NTT Basic Research Laboratories, YOSHIHISA YAMAMOTO, E. L. Ginzton Laboratory, Stanford University — We benchmark the performance of two types of physical annealing machines -- coherent Ising machines (CIMs) built from coupled optical parametric oscillators, and a commercial quantum annealer (QA) by D-Wave Systems -- on a range of NP-hard Ising problems including MAX-CUT and ground-state computation of Sherrington-Kirkpatrick (SK) spin glasses. Connectivity and embeddability play a central role in the performance differences between the machines, as the QA's connections are defined on a Chimera graph while the CIM is all-to-all. The QA outperforms the CIM for MAX-CUT problems on sparse graphs, while for dense-graph MAX-CUT and SK problems, the QA exhibits an exponential performance penalty relative to the CIM. This performance difference persists in an optimal anneal-time analysis. The strong correlation between hardness and graph edge density when solving problems on the QA, which is absent in the CIM, motivates future work to increase the connectivity in quantum annealers. [arXiv:1805.05217]

Benchmarking Portfolio Selection with Adiabatic Quantum Optimization*  
ERICA GRANT  
(Presenter), Bredesen Center, University of Tennessee, TRAVIS HUMBLE, Oak Ridge National Laboratory, NADA WAEL SAMIR ELSOKKARY, FAISAL SHAH KHAN, Khalifa University, GREG QUIROZ, Applied Physics Laboratory, Johns Hopkins University — Portfolio selection is a constrained optimization problem to choose a set of financial assets that maximizes returns while staying under budget and minimizing risk. Markowitz portfolio theory strategically uses correlated behaviors between assets to mitigate financial risk, which we formulate as a quadratic unconstrained binary optimization problem with frustrated stoquastic form. We benchmark the probability of success with the D-Wave 2000Q quantum annealer using problems derived from cryptocurrency market data. We retrieve the lowest energy result from the quantum annealer and compare to the ground truth of a brute force solver. We observe a weakly sub-exponential decay in the probability of success for up to 20 assets, which we extrapolate to estimate the samples required for larger problems. We also find that the relative contributions of the positive diagonal and negative off-diagonal elements have minor influence on the performance as described by the risk. We further investigate performance improvements due to changes in annealing duration, spin-reversal transformations, and reverse annealing post-processing techniques.

*Circuit fault diagnosis using quantum annealing and other spin glass solvers*  
BRENDAN REID  
(Presenter), Information Sciences Institute, University of Southern California, ELIZABETH CROSSON, Department of Physics and Astronomy, University of New Mexico, ITAY HEN, Information Sciences Institute, University of Southern California — In this work we present a novel approach to solving circuit fault diagnosis (CFD) problems using quantum annealers and other spin glass solvers, such as simulated annealing and parallel tempering. The cost function we construct does not minimize the number of faults but rather the distance between real and model circuit outputs: as such it has the attractive property of processing multiple circuit input/output pairs contrary to existing schemes. By showcasing the algorithms' performance through comparison of various metrics, such as time-to-solution, we aim to offer a fresh perspective on using real world-applicable problems in order to understand the nature of quantum annealing optimizers.

*Forward-reverse error mitigation algorithm for quantum annealers*  
NIC EZZELL  
(Presenter), MISSISSIPPI STATE UNIVERSITY — We propose a novel way to try to improve ground-state sampling statistics on quantum annealers with no cost in ancilla qubits—“forward-reverse error mitigation” (FREM) sampling. FREM starts by partitioning a Hamiltonian such that \( H = H_F + H_R \) and proceeds by forward annealing \( H_F \) while backward annealing \( H_R \). While there are no strict requirements on how \( H \) should be partitioned, one should have a good approximation of the ground-state of \( H \) projected onto the qubits in \( H_R \) for the reverse anneal. We study the efficacy of FREM using numerical simulations. In particular, our simulation is modelled after the annealing processes on a D-Wave 2000Q, and we use it to compare the ground-state sampling success of forward, reverse, and FREM annealing by comparing their Kullback-Leibler divergence with respect to direct diagonalization. Overall, this work provides an interesting new method to attempt to mitigate errors on near-term quantum annealers with limited qubit numbers.

12:03PM L42.00005: Minor embedding: an application in quantum annealing*  
YAN-LONG FANG (Presenter), SIMONE SEVERINI, PAUL A. WARBURTON, University College London — Minor embedding is the embedding of a logical graph as a minor of another graph representing a real quantum annealing device. In the embedded graph each logical qubit is represented by a tree of ferromagnetically-coupled physical qubits. Choi's work gives bounds on the magnitude of the ferromagnetic coupling needed to preserve the ground state spin configuration. We have developed a new method for determining tighter bounds on this magnitude, which in turn should result in fewer errors from thermal noise. Moreover, we prove that our bound is the best bound under some conditions. We have confirmed this result by experimenting on the D-Wave annealer. Since this machine is an open quantum system, the probability of finding the ground state of the embedded problem is maximized when the ferromagnetic coupling strength is set to be equal to the calculated best bound. Our result will likely lead to improved performance for a wide variety of optimization problems with higher degree than can be directly implemented on quantum annealing hardware.

12:15PM L42.00006: Performance Improvement of a Quantum Annealer Using Optimized Quantum Control  
GREGORY QUIROZ (Presenter), Johns Hopkins University Applied Physics Lab — Adiabatic quantum computation (AQC) relies on controlled adiabatic evolution to implement a quantum algorithm. Properly designed time-optimal control has been shown to be particularly advantageous for AQC. Grover’s search algorithm is one such example where analytically-derived time-optimal control leads to improved scaling of the minimum energy gap between the ground state and first excited state and thus, the well-known quadratic quantum speedup. Recently, the D-Wave Systems quantum processing unit (QPU) -- a system designed to implement quantum annealing (a non-universal, finite-temperature version of AQC) -- has been upgraded with the ability to manipulate the annealing schedule; thus, enabling an evaluation of the effect of optimized control on computational accuracy. Here, we evaluate the new control features of the device for a range of optimization techniques, assessing the potential benefits of control for enhancing QPU performance for hard problem instances. Specifically, we employ closed-loop control optimization protocols based on stochastic gradient ascent and Bayesian optimization to optimize QPU performance. We focus on engineered hard problem instances for the QPU that exhibit small energy gaps and strong susceptibility to noise.

12:27PM L42.00007: Quantum magnetism on a chip [Invited]  
RICHARD HARRIS (Presenter), D-Wave Systems Incorporated — D-Wave Systems builds superconducting quantum annealing processors that are primarily intended to be used for solving classical computation problems such as optimization and sampling. However, recent publications in Science (Vol. 361, Issue 6398, pp. 162-165) and Nature (Vol. 560, Issue 7719, August 22, 2018) have shown how this computing platform can be used as a programmable quantum magnet that can be used to simulate physical systems relevant to the field of condensed matter physics. This lecture will provide a brief review of the aforementioned results and an update on related experiments.

1:03PM L42.00008: Reverse Quantum Annealing on D-Wave 2000Q*  
DAVIDE VENTURELLI (Presenter), Quantum Artificial Intelligence Laboratory, USRA:RIACS and NASA — We review results to date obtained by the usage of the quantum reverse annealing feature introduced in the latest model of the D-Wave machine - especially comparatively with forward annealing protocols. Results suggest that there is sizable advantage in hybridizing runs with classical initialization algorithms. Particular attention will be devoted in combinatorial optimization problems connected to applications, with examples taken from several different industrial domains, where a large ferromagnetic structure is present in the spin systems due to minor embedding.

1:15PM L42.00009: Quantum Annealing XORSAT on Dilute Square Lattices*  PRANAY PATIL, CLAUDIO CHAMON, STEFANOS KOURTIS, ANDREI E RUCKENSTEIN, Boston University, EDUARDO R MUCCILO (Presenter), Physics, University of Central Florida — Here we show how we can embed the 3-regular 3-XORSAT on a square lattice made out of gates which couple the bits in a manner that recreates the constraints. This system can be annealed to the solution by tuning a transverse field to zero. We explore ways to avoid two potential obstacles that limit how fast one can anneal this system; the first is the nature of the phase transition as we tune the transverse field and the second is the avoided level crossings for small transverse field strength. We discuss how the second pitfall can possibly be avoided in the lattice and other embeddings which have already been studied. We also present Quantum Monte Carlo results on the nature of the phase transition for the embedding of XORSAT on the square lattice. We compare the results to the embedding on a random regular graph, where the phase transition is known to be first order. We also show that different XORSAT problems result in lattice arrangements which exhibit a phase transition whose order is closely related to the classical complexity of the particular problem.

1:27PM L42.00010: Solution planting scheme for fully-connected spin glasses  CHRISTOPHER PATTISON (Presenter), Texas A&M University, FIRAS HAMZE, JACK RAYMOND, D-Wave Systems Inc., HELMUT KATZGRABER, Texas A&M University — The advent of new specialized hardware designed to tackle spin-glass-like problems on dense graphs has resulted in a renewed interest in planted solutions for spin-glass Hamiltonians. Here we present a method for planting solutions in fully-connected spin-glass systems with tunable hardness. In particular, the hardness of the problems undergoes a complexity transition. Using both analytical and numerical techniques, we characterize the behavior of these new planted systems.

1:39PM L42.00011: Testing the D-Wave 2000Q as a quantum Monte Carlo simulator*  ZOE GONZALEZ IZQUIERDO (Presenter), Physics and Astronomy, University of Southern California, ITAY HEN, TAMEEM ALBASH, Information Sciences Institute, USC — With recent advances in quantum annealing technologies allowing for ‘measurement in the middle’ protocols, present-day experimental quantum annealers have been suggested as practical quantum simulators in lieu of quantum Monte Carlo algorithms. To put this assertion to the test, we have studied the prospects of a D-Wave 2000Q device to function as a simulator of simple one-dimensional chains, in particular to measure thermal expectation values. Here we will present the results of our work along with some interesting conclusions.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050

1:51PM L42.00012: Theoretical survey of unconventional quantum annealing methods applied to a difficult trial problem*  ZHIJIE TANG (Presenter), ELIOT KAPIT, physics, colorado school of mines — Adiabatic quantum annealing is a promising method to solve optimization problems. In our work, we define an artificial trial problem inspired by "transverse field chaos" in larger systems where classical and quantum methods are steered toward a local false minimum and the minimum gap to the true ground state is exponentially small. (all N spins must be flipped from the local minimum to the global minimum, which makes the problem exponentially difficult to solve.) We numerically study this problem by using a variety of new methods from the literature: ramping the transverse field down one by one; adding transverse couplers between qubits; adding local oscillating transverse field. We show that the standard adiabatic quantum annealing method can be improved with these methods, and comparison of these methods could help identify the most promising routes to a quantum speedup in future quantum hardware.

Session L43 DCMP: New Developments in the FQHE in Half-filled Landau Levels BCEC 210B -
Tag(s): Invited
The universality of the quantum of measurements not trivial, and inter-mode equilibration is not fully understood.

thermal conductance is more challenging as heat flow is not conserved, accurate and noninvasive temperature measurements not trivial, and inter-mode equilibration is not fully understood.

Unlike the relative ease in determining accurately the quantization of the electrical conductance, measuring accurately the thermal conductance, agreeing in good accuracy with numerical works.

We first focused on the Integer, Laughlin's, and hole-conjugate \((\frac{1}{2} < \nu < 1)\) states \([6]\) - proving the universality of \(k_0\). We extended our studies to the fractional states in the first-excited Landau level \((2 < \nu < 3)\), and in particular on the \(\nu=5/2\) state.

We find in the latter a deviation from the quantization of the thermal conductance, suggesting the non-abelian character of the state \([7]\). This topological order was not expected in previous numerical works.

Even denominator fractional quantum Hall physics in higher order Landau levels of graphene

[Invited] JURGEN SMET (Presenter), Max Planck Institute for Solid State Research — An important development in the field of the fractional quantum Hall effect has been the proposal that the 5/2 state observed in the Landau level with orbital index \( n = 1 \) of two-dimensional electrons in a GaAs quantum well originates from a chiral \( p \)-wave paired state of composite fermions which are topological bound states of electrons and quantized vortices. This state is theoretically described by a `Pfaffian` wave function or its hole partner called the anti-Pfaffian, whose excitations are neither fermions nor bosons but Majorana quasiparticles obeying non-Abelian braid statistics. This has inspired innovative ideas for computation and has also instigated a quest for other states with exotic quasiparticles. Here we report experiments on monolayer graphene that show clear evidence for unexpected even-denominator fractional quantum Hall physics in the \( n = 3 \) Landau level. We numerically investigated the known candidate states for even-denominator fractional quantum Hall effect, including the Pfaffian, the particle-hole symmetric Pfaffian, the 221-parton, and several valley/spin singlet states. We conclude that, among these, the 221-parton state is a possible candidate to explain the experimentally observed state and that this incompressible ground state is distinct from the 5/2 state in GaAs. Like the Pfaffian, this state is also believed to harbour quasi-particles with non-Abelian braid statistics.

This work has been carried out with Youngwook Kim, Ajit Balram, Takashi Taniguchi, Kenji Watanabe and Jainendra Jain.

The Dirac Composite Fermion of the Fractional Quantum Hall Effect

Session L44 DCMP GSNP: Onsager, Kadanoff, Davisson-Germer Prize Session BCEC 210C - Greg Huber - Tag(s): Invited

11:15AM L44.00001: Lars Onsager Prize Talk: Scaling down the laws of thermodynamics [Invited] CHRISTOPHER JARZYNSKI (Presenter), University of Maryland, College Park — Thermodynamics provides a robust conceptual framework and set of laws that govern the exchange of energy and matter. Although these laws were originally articulated for macroscopic objects, it is hard to deny that nanoscale systems also exhibit “thermodynamic-like” behavior – for instance, biomolecular motors convert chemical fuel into mechanical work. To what extent can the laws of thermodynamics be “scaled down” to apply to individual microscopic systems, and what new features emerge at the nanoscale? I will describe some of the recent progress and challenges associated with addressing these questions.

11:51AM L44.00002: Dissertation Award in Statistical and Nonlinear Physics Talk: The emergence of collective modes, ecological collapse and directed percolation at the laminar-turbulent transition* [Invited] HONG-YAN SHIH (Presenter), Department of Physics and Carl R. Woese Institute for Genomic Biology, University of Illinois at Urbana-Champaign — How a laminar flow becomes turbulence has been an unsolved problem for 130 years and is important in various industrial applications. Only since a decade ago, precise measurements in pipe flow experiments showed non-trivial spatio-temporal complexity at the onset of turbulence where lifetime and splitting time of metastable turbulence do not diverge asymptotically as would have been expected in a sharp transition. Based on numerical evidence in the Navier-Stokes equations, we discovered the surprising fact that the fluid behavior at the transition is governed by the emergent predator-prey dynamics of the important long-wavelength mode, leading to the mathematical prediction that the laminar-turbulent transition is a non-equilibrium phase transition in the directed percolation universality class. This prediction explains the universal scaling laws in experimental observations, and provides a unified picture of transition to turbulence emerging in systems ranging from turbulent convection to magnetohydrodynamics.

M CRISTINA MARCHETTI (Presenter), University of California, Santa Barbara — Active matter is the named coined to describe collections of interacting self-driven entities that spontaneously organize in active fluids and solids, with nonequilibrium transitions between ordered and disordered states. Examples include subcellular structures, groups of motile organisms, and chemical and mechanical analogues with life-like properties. The distinguishing property of active systems is that they are driven out of equilibrium by a forcing that acts independently on each unit, breaking detailed balance at the micro-scale and resulting in behaviors that challenge our intuition. For instance, active fluids flow with no externally applied forces and active gases do not fill their container. After highlighting some of these behaviors, I will focus in this talk on the self-sustained flows of active nematics where the proliferation of motile topological defects mediates the transition to spatiotemporal chaotic dynamics. I will conclude by identifying some of the challenges that lie ahead.

*This research has been primarily funded by the Division of Materials Research of the National Science Foundation, most recently under DMR-1609208. Additional support was received by the Simons Foundation Targeted Grant in the Mathematical Modeling of Living Systems Number 342354.

RANDALL FEENSTRA (Presenter), Carnegie Mellon University — Over the past decade, much research world-wide has focused on two-dimensional (2D) materials, in which the electrons are localized within a single atomic plane. Obtaining μm-size flakes of 2D material by “exfoliating” (peeling apart) layers using adhesive tape has been a standard practice for decades, but only recently has this method been applied to produce small, microfabricated electronic devices on the flakes (Geim and Novoselov, Nobel Prize 2010). However, for practical electronics of the future, such devices must be produced on grown (deposited), large-area 2D layers, rather than on flakes. In this talk, studies of the structure of grown 2D layers will be described, focusing on heterobilayers of MoS2 on WSe2. The method of scanning tunneling microscopy is used to obtain detailed, atomic-scale views of the structure of the layers. Additionally, through spectroscopic measurements with the tunneling microscope, band gaps of the materials and band offsets between neighboring layers are determined. We find, in particular, the occurrence of localized electron states associated with the moiré pattern that forms when one layer of a 2D material (MoS2) is placed on another layer (WSe2) with different lattice constant.

*Work performed in collaboration with D. Waters, F. Lüpke, Y. Pan, S. Fölsch, Y. Nie, Y.-C. Lin, B. Jariwala, K. Zhang, K. Cho, and J. A. Robinson, and supported in part by the Center for Low Energy Systems Technology (LEAST, one of six centers of STARnet, a Semiconductor Research Corporation program sponsored by MARCO and DARPA), the National Science Foundation, and the A. von Humboldt Foundation.

Wednesday, March 6, 2019 11:15 AM - 1:51 PM

Session L45 DCMP: Surface Studies of Transition Metal Chalcogenides

GUANNAN CHEN (Presenter), SEAN T HOWARD, SOMESH CHANDRA GANGULI, VIDYA MADHAVAN, WACLAW SWIECH, Physics, University of Illinois at Urbana-Champaign — TMDC provide a unique platform exhibiting ground states from CDW, to ferromagnetism and superconductivity. Among the TMDC family, bulk 1-T VSe2 is known as a typical 3D CDW material with a transition temperature of 105 K. But there have been two interesting observations in a few layers VSe2. First, while bulk VSe2 is paramagnetic, VSe2 a few layers limit was shown ferromagnetism. Second, multiple CDW patterns with different Q-vectors have been observed. In this work, we grow VSe2 thin films at two growth temperatures (Tg) by a home-built MBE and study the samples in a 4K STM. In the samples grown at low Tg, we found different 2D CDW patterns in the first and second layer. The high Tg films show stripe-type topographies in the first and second layer with different periodicity. The STM scans and RHEED images indicate that the second layer grown at high Tg is 1T' phase VSe2. Based on this we conclude that two different Tg produce distinct polymorphs of VSe2. We further compare the dI/dV spectrums of the two polymorphs as a function of layer thickness and discuss the evolution of the electronic properties with thickness.

*The work was supported by the Gordon and Betty Moore Foundation’s EPiQS Initiative through Grant GBMF4860 and NSF-DMREF program through Grants 1629382 and 1629068.
Transport properties of high-mobility InSe in Quantum Hall regime.*

DMITRY SHCHERBAKOV (Presenter), PETR STEPANOV, JIAWEI YANG, Ohio State University, SHAHRIAR MEMARAN, WENKAI ZHENG, National High Magnetic Field Laboratory FSU, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Namiki Tsukuba Ibaraki, Japan, LUIS BALICAS, National High Magnetic Field Laboratory FSU, CHUN NING LAU, Ohio State University — Among the modern two-dimensional (2D) semiconductors, InSe is a promising candidate for future electronics due to its large thickness-dependent bandgap and high mobility. We have fabricated high mobility ultrathin InSe devices, and observed quantum Hall states in high magnetic field. Transport properties of InSe at low temperatures and high magnetic fields will be presented.

*This research was supported by grants NSF-DMR 1807928 (Lau) and NSF-DMR 1807969 (Balicas)

New Mechanical Exfoliation Technique for Preparing Large Area 2D Materials and Special Structures

YUAN HUANG (Presenter), WEN JUAN ZHAO, LIN ZHAO, GUO DONG LIU, National Laboratory for Superconductivity (NLSC), Institute of Physics, CAS, PETER SUTTER, Engineering, University of Nebraska, Lincoln, XINGJIANG ZHOU, National Laboratory for Superconductivity (NLSC), Institute of Physics, CAS — Mechanical exfoliation method has been widely used to study the intrinsic properties of 2D materials. Even though the exfoliated 2D materials show high quality, the size of monolayer samples are usually quite small, which has limited the investigation progress of 2D materials. Recently, we developed a new mechanical exfoliation technique for preparing large area and high quality 2D materials[1]. Many monolayer 2D materials with millimeter to centimeter size have been successfully exfoliated through this method, including graphene, TMDCs et al. The key of this technique is to enhance the van der Waals interaction between the layered materials and the substrates, which can be realized by optimizing the exfoliation process, such as substrate types, temperature and vacuum. Besides, some special structures (like bubble and wrinkle) can be prepared by using different parameters. Therefore, many unique properties can be observed on these structures, e.g., standing wave induced Raman oscillation was first discovered on the exfoliated graphene bubbles[2]. The new mechanical technique will show great potential for exploring new properties of 2D materials.

Epitaxial Growth and Structure Phase Transition of monolayer 1T'-WSe2 thin film*

WANG CHEN, TONG CHEN, DONGJIN LIN, XUEDONG XIE, JUNYU ZONG, FAN YU, SHAOEN JIN, LINGJIE ZHOU, JINGYI ZOU, JIAN SUN, XIAOXIANG XI, YI ZHANG (Presenter), Nanjing University — The emerging two-dimensional (2D) materials are playing more and more important roles in both fundamental research and practical application potentials in recent years. The 2D transition metal dichalcogenides (TMDCs) have attracted extensive interest due to their remarkable fundamental properties distinct from those of their bulk counterparts. Its 2H phase possesses an indirect to direct bandgap transition in 2D limit. The 1T' phase transition can drive the monolayer MX2 to be a 2D topological insulator. Using molecular beam epitaxial (MBE) method, we realized the growth of both the 1T' and 2H phase monolayer WSe2 thin films. The crystalline structure of these two phases was characterized using the in-situ scanning tunneling microscopy (STM) technique. The monolayer 1T'-WSe2 was found to be metastable, and can transform into 2H phase under post-annealing procedure. This thermo-driven crystalline phase transition makes the monolayer WSe2 to be an possible platform for controlling of topological phase transition.

Distinct ultrafast carrier dynamics governed by spin filtering in bulk and single-layer WSe$_2$*

RO-YA LIU (Presenter), Institute of Physics, Academia Sinica, MENG-KAI LIN, PENG CHEN, Physics, University of Illinois at Urbana-Champaign, TAKESHI SUZUKI, Institute for Solid State Physics, University of Tokyo, PHILIPPA CLARK, NATHAN LEWIS, Photon Science Institute, University of Manchester, CEPHISE CACHO, Diamond Light Source, STFC Rutherford Appleton Laboratory, EMMA SPRINGATE, Central Laser Facility, STFC Rutherford Appleton Laboratory, CHIA-SENG CHANG, Institute of Physics, Academia Sinica, KOZO OKAZAKI, Institute for Solid State Physics, University of Tokyo, WENDY FLAVELL, Photon Science Institute, University of Manchester, IWAO MATSUDA, Institute for Solid State Physics, University of Tokyo, TAI-CHANG CHIANG, Physics, University of Illinois at Urbana-Champaign — Carrier dynamics in a semiconductor following pulsed optical excitation is relevant to ultrafast optoelectronic applications. We report herein a comparative study of bulk WSe$_2$ and single-layer (SL) WSe$_2$ grown on bilayer-graphene-terminated SiC. Subtle dimensional effects lead to substantial differences in the transient response as revealed by time-resolved angle-resolved photoemission spectroscopy (TRARPES) measurements. The conduction band minimum in bulk WSe$_2$, populated by optical pumping, decays promptly. The corresponding decay for SL WSe$_2$ is more complex but overall much slower due to spin filtering arising from the lack of space inversion symmetry. Concurrent measurements of the valence bands show longer but different response times arising from lattice excitation, carrier transport, and dissipation. These results illustrate the various time scales and processes at work for carrier and band structure evolution.

A Gate Free Monolayer WSe$_2$ pn Diode

CHUNG-LIN WU (Presenter), JHIH-WEI CHEN, Department of Physics, National Cheng-Kung University, CHIA-HAO CHEN, National Synchrotron Radiation Research Center (NSRRC), YI-CHUN CHEN, TSE-MING CHEN, SHUN-TSUNG LO, SHENG-SHONG WONG, Department of Physics, National Cheng-Kung University — Interest in bringing p- and n-type monolayer semiconducting transition-metal dichalcogenides (TMD) into contact to form rectifying pn diode has thrived since it is crucial to control the electrical properties in two-dimensional (2D) electronic and optoelectronic devices. Usually this involves vertically stacking different TMDs with pn heterojunction or, laterally manipulating carrier density by gate biasing. Here, by utilizing a locally reversed ferroelectric polarization, we laterally manipulate the carrier density and created a WSe$_2$ pn homojunction on the supporting ferroelectric BiFeO$_3$ substrate. This non-volatile WSe$_2$ pn homojunction is demonstrated with optical and scanning probe methods and scanning photoelectron micro-spectroscopy. A homo-interface is a direct manifestation of our WSe$_2$ pn diode, which can be quantitatively understood as a clear rectifying behavior. The non-volatile confinement of carriers and associated gate-free pn homojunction can be an addition to the 2D electron-photon toolbox and pave the way to develop laterally 2D electronics and photonics.

Investigation of charge density wave transitions in a proximally coupled single-layer TiTe$_2$/TiSe$_2$ system

MENG-KAI LIN (Presenter), JOSEPH HLEVYACK, PENG CHEN, RO-YA LIU, TAI-CHANG CHIANG, University of Illinois at Urbana-Champaign — TiSe$_2$, a prototypical charge density wave (CDW) system with a 1T structure in the bulk, undergoes a (2×2×2) CDW transition at 205 K. By comparison, a single layer of TiSe$_2$ prepared on a bilayer-graphene-terminated SiC(0001) undergoes a (2×2) CDW transition at 232 K. The bonding of the single layer to the substrate is expected to be of the van der Waals type. Furthermore, the structures are incommensurate, which makes the interfacial bonding even weaker. A reasonable premise is that the single layer is nearly freestanding with minimal influence from the substrate on its (2×2) CDW. TiTe$_2$, by contrast, shows no CDWs in the bulk or in films grown on the same bilayer-graphene-terminated SiC; the only exception is a (2×2) CDW transition at 92 K in the single layer. The unique behavior of the single layer is an anomaly. To explore the physics further, we have grown a composite system made of a single layer of TiTe$_2$ on a single layer of TiSe$_2$ on a bilayer-graphene-terminated SiC. The crystal structures of TiSe$_2$, TiTe$_2$, and graphene are all incommensurate. Questions abound: Is there a CDW transition in this composite system? Or, are there actually two transitions? Results of band structure mapping by angle-resolved photoemission spectroscopy will be presented to address these issues.
12:39PM L45.00008: Electronic and structural properties of the phase transitions in TaTe$_{2-x}$Se$_x$* CHEN CHEN (Presenter), HEUNG SIK KIM, ALEMAYEHU S ADMASU, WENHAN ZHANG, FEI-TING HUANG, SANG-WOOK CHEONG, KRISTJAN HAULE, DAVID VANDERBILT, WEIDA WU, Department of Physics and Astronomy, Rutgers University — Charge density wave (CDW) is a spontaneous modulation of electron density, which is usually associated with periodic lattice distortion with the same wavelength. Such phenomenon is often observed in layered transition metal dichalcogenides (TMD), although its origin is still under debate. 1T-TMD TaTe$_2$ shows a CDW like phase transition around 170 K where new modulation of 3×3 superstructure forms. Magnetic susceptibility and resistivity show abnormal behavior at the phase transition, which is inconsistent with conventional model or example. Here, we use combination of scanning tunneling microscopy/spectroscopy, low energy electron diffraction, and density functional theory calculations to study the temperature dependence of CDW in undoped and Se doped TaTe$_2$ single crystals. We have observed a hidden phase with a distinct modulation, which can be stabilized by Se doping, and is less metallic than the 3×3 low temperature phase. Our results suggest a possible explanation to the mystery in transport properties, which provides new insight on the electron-lattice coupling associated with CDW phase transitions.

12:51PM L45.00009: Confining electronic states with domain walls in ferroelectric SnTe monolayers* KAI CHANG (Presenter), Max-Planck Institute of Microstructure Physics, BRANDON J MILLER, Department of Physics, University of Arkansas, HAO YANG, Max-Planck Institute of Microstructure Physics, HAICHENG LIN, QIKUN XUE, XI CHEN, SHUAIHUA JI, Department of Physics, Tsinghua University, SALVADOR BARRAZA-LOPEZ, Department of Physics, University of Arkansas, STUART S P PARKIN, Max-Planck Institute of Microstructure Physics — Electronic standing wave patterns at surfaces are usually generated by edges, atomic steps or adatoms that introduce large potential barriers. However, in multi-valley semiconducting 2D materials, quasiparticle confinement and suppressed transmission can be created from mismatched electronic structures through domain walls, with a neglectable built-in bias at the interface. Here, we report the first observation of electronic standing waves near the valence band maximum in a SnTe monolayer that is generated by the reflection from ferroelectric domain walls. Despite of the nearly flat potential barrier at the domain walls, the reflectivity is found to be 68+-9% at 4.7 K, and no sign of transmission was seen. Such a strong confinement of electronic states is due to a large change of valley positions between the neighboring domains arising from a 90 degree rotation of the Brillouin zone. These results show potential for polarization-tuned valleytronics in 2D ferroelectrics.

1:03PM L45.00010: Electrical and Optical Characterization of Ultrathin Tellurium Nanostructures Synthesized by Vapor Phase Deposition* KESHAB SAPKOTA (Presenter), DOUGLAS L. MEDLIN, PING LU, TING-SHAN LUK, TZU-MING LU, GEORGE T. WANG, Sandia National Labs — Tellurium (Te) is a semiconductor with a slightly indirect bulk bandgap of 0.35 eV. The trigonal crystal structure of Te consists of 1D helical chains of Te atoms stacked together by van der Waals type bonds arranged on 2D hexagonal lattice. Each Te atom is covalently bonded with its two nearest neighbors on the same chain. This unique crystal structure allows a stable 1T-MoS$_2$-like α-Te, a metastable tetragonal β-Te, and a 2H-MoS$_2$-like γ-Te structures. The α- and γ-Te phases are expected to have nearly direct band gaps and high carrier motilities suggesting potential applications in electronic and optoelectronic devices. Here we present the vapor phase synthesis and characterization of novel ultrathin Te nanostructures having thickness down to 3.5 nm. Room temperature (RT) electrical measurements exhibit p-type semiconductor with field effect hole mobility of ~350 cm$^2$/V.s. The low-temperature transport properties, RT micro-photoluminescence, and structural properties of the Te nanostructures will also be presented.

1:15PM L45.00011: Biexcitons in Monolayer Transition Metal Dichalcogenides Tuned by Magnetic Fields

CHRISTOPHER E STEVENS, VARUN MAPARA (Presenter), JAGANNATH PAUL, TIMOTHY COX, PRASANA SAHOO, HUMBERTO RODRIGUEZ GUTIERREZ, Dept. of Physics, University of South Florida, VOLODYMYR TURKOWSKI, Dept. of Physics, University of Central Florida, DIMITRY SEMENOV, STEPHEN A MCGILL, National High Magnetic Field Laboratory, Florida State University, MYRON KAPETANAKIS, ILIAS PERAKIS, DAVID J. HILTON, Dept. of Physics, University of Alabama Birmingham, DENIS KARAISKAJ, Dept. of Physics, University of South Florida — Time-Integrated Four Wave Mixing measurements were performed on CVD grown MoSe$_2$ monolayers. The dephasing lifetime was investigated in magnetic fields up to 25T. Additionally, the effects of valley selection on the lifetime was explored through varying polarization schemes. The results were then modeled using time-dependent density function theory revealed the dephasing lifetime is dominated by the inter-valley biexcitons.

1:27PM L45.00012: Controlled and Tunable Light Emission of Heat Treated Black Phosphorus: Towards Tunable Optoelectronic Devices

SARAH ALODAN (Presenter), FADHEL ALSAFFAR, King Abdulaziz City for Science and Technology, JUSTIN M. GORHAM, FRANK W. DELRIO, Material Measurement Laboratory, National Institute of Standards and Technology, MOHAMMED R AMER, King Abdulaziz City for Science and Technology — Layered black phosphorus (BP) has shown exceptional optical properties due to its layer-dependent band gap, which ranges from 0.3 to 1.7 eV for bulk to monolayer, respectively. However, instability of black phosphorus nanosheets can be a major hurdle in controlling this light emission and requires various passivation methods. Moreover, the tunablility of the emitted light can only be controlled by changing the nanosheet thickness, which in turns changes the band gap energy. Here, we show for the first time a well-controlled tunable light emission from heat treated black phosphorous nanosheets. We show tunable wideband photoluminescence (PL) between 590nm to 720nm, with a tunablility resolution of 5nm. This tunable PL is found to be anisotropic and can last for at least 10 days when nanosheets are properly stored. We attribute the origin of this light emission to the formation of stable black phosphorus oxide on the surface of black phosphorus, as confirmed with i-XPS measurements. Our findings unlock doors for optoelectronic applications of layered black phosphorus nanosheets.

1:39PM L45.00013: Reversible Thermally Driven Phase Transformation in Ultrathin Ferroelectric In$_2$Se$_3$ Layers

FAN ZHANG (Presenter), Department of Physics, Virginia Tech, ZHE WANG, Department of Physics, University of Science and Technology of China, ANMIN NIE, JIANYONG XIANG, State Key Laboratory of Metastable Materials Science and Technology, Yanshan University, China, WENGUANG ZHU, Department of Physics, University of Science and Technology of China, ZHONGYUAN LIU, State Key Laboratory of Metastable Materials Science and Technology, Yanshan University, China, CHENGGANG TAO, Department of Physics, Virginia Tech — Phase transformation in emerging two dimensional (2D) ferroelectric materials is crucial for their applications, such as in nonvolatile memory devices. We combined STM, STEM, Raman spectroscopy and first-principles calculation to investigate ultrathin layered In$_2$Se$_3$ syntheszed by chemical vapor deposition (CVD). At room temperature, we observed that ultrathin In$_2$Se$_3$ ranging from ~20 layers to monolayer, stabilized at the $\beta$ phase with a superlattice. Strikingly, at around 210 K the $\beta$ phase converted to a novel and more stable $\beta'$ phase, which has never been revealed in 2D In$_2$Se$_3$ with atomic resolution. The thermally driven kinetics of the reversible $\beta$-$\beta'$ phase transformation was studied with temperature dependent STEM and Raman spectroscopy, which corroborated with the expected minimum-energy pathways for the transformation obtained from our DFT calculation. The calculated energy difference between the $\beta$ phase and the $\beta'$ phase is 0.033 eV/In$_2$Se$_3$, with an energy barrier of 0.006 eV/In$_2$Se$_3$. The DFT calculation further suggested in-plane ferroelectricity in the $\beta'$ phase, and in contrast, both in-plane and out-of-plane ferroelectricity in the $\beta$ phase.

Wednesday, March 6, 2019 11:15 AM - 2:15 PM
11:15AM L46.00001: Shedding light on materials out of equilibrium: Ultrafast control of magnetism in complex oxide thin-films* [Invited] NICOLE BENEDDEK (Presenter), Department of Materials Science and Engineering, Cornell University — The recent development of intense ultrashort mid- and far-infrared laser sources has created an opportunity for functional materials based on the direct excitation of infrared active phonons. Strong excitation of infrared active phonons can produce sizable unidirectional distortions of crystal structure through non-linear couplings between various lattice modes. Complex oxides provide an important test-ground for this experimental approach due to their chemical diversity, strong coupling to optical fields, and demonstrated connection between subtle structural changes and functional properties. Early experiments in complex oxides are intriguing, suggesting that non-linear phonon coupling is responsible for transiently induced insulator-metal phase transitions and enhanced superconductivity in optical experiments. In this talk, I will describe our recent theoretical efforts exploring selective control of functional properties in perovskite oxides that exploit non-linear lattice dynamics. Using first-principles techniques we show that optical control of various properties is experimentally feasible and that, when combined with epitaxial strain, it is possible to transiently stabilize and explore phases inaccessible in the equilibrium phase diagram.

11:51AM L46.00002: Ultrafast Carrier Dynamics in La_{1-x}Sr_xMnO_3/SrTiO_3 Heterostructures* KUN ZHAO (Presenter), JOEL E TAYLOR, Department of Physics & Astronomy, Louisiana State University, RAMI A KHOURY, Department of Chemistry, Louisiana State University, MOHAMMAD SAGHAYEZHIAN, Department of Physics & Astronomy, Louisiana State University, LOUIS H HABER, Department of Chemistry, Louisiana State University, JIANDI ZHANG, E WARD PLUMMER, Department of Physics & Astronomy, Louisiana State University — Transition metal oxide thin films and heterostructures have attracted interest of community due to manifestation of broken symmetry and dimensional confinement, which create new forms of coupling and consequently new functionality. An important challenge is to probe the excited states of these artificially structured materials. Ultrafast reflectivity measurements can be used to study the highly non-equilibrium exited states and observe subsequent dynamical behavior. We grew La_{1-x}Sr_xMnO_3/SrTiO_3(001) heterostructures using different growth conditions, being able to control structural and compositional modulation near the interface, which profoundly changes electronic and magnetic properties of these thin films. Using ultrafast reflectivity measurements, we show novel excited-state relaxation dynamics and phonon oscillations in these heterostructures. The changes in these relaxations will be discussed relevant to the growth conditions. With specific growth condition, we observed the relaxations of electron-phonon coupling and phonon-phonon coupling with larger than expected lifetimes as well as the oscillations of two phonon modes. Furthermore, pump-power dependent reflectivity and lifetimes were also studied.

*Supported by the U.S. Department of Energy under Grant No. DE-SC0002136.

12:03PM L46.00003: Atomic-Resolution Studies of Radiation-Induced Defects In High Conductivity Delafossite Oxide Metals* CELESTA CHANG (Presenter), Cornell University, VERONIKA SUNKO, PHILIPPA MCGUINNESS, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids, DAVID ANTHONY MULLER, Cornell University — Delafossite metals are known for having the highest in-plane conductivity in the oxide family. Room temperature resistivity of PdCoO_2 is 2.6μΩ, and at low temperature it drops down to 0.0075μΩ, with a mean free path of 20μm. Such long mean free path raises the question of the nature of the defects – is the density truly that low, or are defects present but somehow hidden from scattering channels? Using scanning transmission electron microscopy (STEM) we deliberately introduced defects at a specific atomic plane of PdCoO_2 and PtCoO_2 using a high electron dose of 520×10^{-3}C/mm^2, then imaging at lower doses. Our results show that damage from an electron beam focused on the Pd (Pt) atomic layers creates local metallic chains and clusters. A beam placed on the O-Co-O layer damages more dramatically by cutting the Co layers off, resulting in Pd (Pt) layers to be pulled towards the neighboring Co layer position.

*Work supported by the U.S. DOE BES, Award #DE-SC0002334 and PARADIM, an NSF MIP (DMR-1539918). EM Facility support from the NSF MRSEC program (DMR 1120296).
Interfaces of complex oxides can exhibit properties not realized in the constituent materials. The chemistry that occurs at such interfaces has received relatively little attention, yet can be very influential and permit control of interfacial properties, if it is well understood. Here we focus on a dramatic interface chemical effect: the apparent dissolution of an entire atomic plane during WO₃ heteroepitaxy on TiO₂-terminated SrTiO₃(001). Transmission electron microscopy indicates that the first subsurface SrO monolayer is completely removed, resulting in the formation of a TiO₂ bi-layer at the interface. In combination with x-ray photoelectron spectroscopy measurements, these data suggest that at least a fraction of the Sr from this layer dissolves into the WO₃ film. To assist interpretation of the TEM data, we determined the thermodynamic stability of candidate interfacial structures using ab initio (density functional theory) simulations and linked these stabilities to the growth conditions. The analysis of near-interface diffusion pathways suggests ways in which SrO dissolution takes place, and how manipulation with the growth conditions can shift the thermodynamic preference from one structure to another.

*US DOE, BES/MSE Award 10122, Early Career Research Program Award 68278

12:27PM L46.00005: Defects and transport in oxide heterostructures* [Invited] CHRIS VAN DE WALLE (Presenter), University of California, Santa Barbara — Complex oxide heterostructures have been intensively investigated in recent years. However, the widely used transition-metal oxides suffer from low carrier mobility, which limits device applications. For applications in electronics, attention has shifted to materials such as BaSnO₃ and Ga₂O₃. They have large band gaps, rendering them suitable for transparent conductors and high-frequency and power electronics, but can be highly n-type doped and exhibit good transport properties. Better control of dopants and point defects is still needed in order to improve materials quality and enable further applications. I will show how cutting-edge first-principles modeling, using advanced hybrid functional calculations within density functional theory, can shed light on the multiple aspects of this problem: band alignment and confinement of two-dimensional electron gases [1,2,3,4], carrier scattering and mobility [5,6], doping [7,8], point defects and their impact on carrier concentrations [8], energetics and electronic structure of alloys [3,4], and optical properties [9,10].

1:03PM L46.00006: Structural Goldstone modes in 111-strained perovskite SrMnO$_3$*

ASTRID MARTHINSEN,
Department of Materials Science and Engineering, NTNU Norwegian University of Science and Technology, SINEAD MAGELLA
GRIFFIN, Molecular Foundry, Lawrence Berkeley National Laboratory, MAGNUS MOREAU, Department of Electronic Systems, NTNU
Norwegian University of Science and Technology, TOR GRANDE, Department of Materials Science and Engineering, NTNU Norwegian
University of Science and Technology, THOMAS TYBELL, Department of Electronic Systems, NTNU Norwegian University of Science and
Technology, SVERR SELBACH (Presenter), Department of Materials Science and Engineering, NTNU Norwegian University of Science and
Technology — Epitaxial strain has been extensively explored to enhance existing and enable new functional properties in perovskite thin films. While most of this work has been done on 001-oriented heterostructures, 111-oriented films can have very different properties. Here we use DFT calculations to predict structural Goldstone modes in the (111)-strained perovskite SrMnO$_3$. Massless Goldstone modes are found in high energy particle physics as well as in low energy systems like superconductors and superfluid helium, while structural Goldstone modes are rare. Here we predict acoustic Goldstone phonon modes under compressive strain resulting from coupling between two in-plane rotational instabilities, giving the characteristic Mexican hat shaped energy surface. Large tensile strain is found to induce in-plane polar instabilities giving rise to a continuous polar ground state. Such phonon modes with U(1) symmetry could emulate structural condensed matter Higgs modes, where the mass of this boson is given by the shape of the Mexican hat energy surface, which is tunable by epitaxial strain.

1:15PM L46.00007: Designing Optimal Perovskite Structure for High Ionic Conduction*

RAN GAO (Presenter), Materials Science and Engineering, University of California, Berkeley, ABHINAV JAIN, Materials Science and Engineering, University of Illinois, Urbana-Champaign, SHISHIR PANDYA, Materials Science and Engineering, University of California, Berkeley, YONGQI DONG, X-ray Science Division, Advanced Photon Source, Argonne National Laboratory, YAKUN YUAN, Materials Science and Engineering, Pennsylvania State University, HUA ZHOU, X-ray Science Division, Advanced Photon Source, Argonne National Laboratory, LIV R DEDON, Materials Science and Engineering, University of California, Berkeley, VINCENT THORÉTON, WPI international Institute for Carbon-Neutral Energy Research (WPI-I2CNER), Kyushu University, SAHAR SAREMI, RUIJUAN XU, AILEEN LUO, Materials Science and Engineering, University of California, Berkeley, TING CHEN, WPI International Institute for Carbon-Neutral Energy Research (WPI-I2CNER), Kyushu University, VENKATRAMAN GOPALAN, Materials Science and Engineering, Pennsylvania State University, ELIF ERTEKIN, Mechanical Science and Engineering, University of Illinois, Urbana-Champaign, JOHN KILNER, TATSUMI ISHIHARA, WPI International Institute for Carbon-Neutral Energy Research (WPI-I2CNER), Kyushu University, NICOLA PERRY, DALLAS TRINKLE, Materials Science and Engineering, University of Illinois, Urbana-Champaign, LANE MARTIN, Materials Science and Engineering, University of California, Berkeley — There has been an incomplete understanding of the structure-property relationships that would enable the rational design of better ion-conducting electrolytes for SOFC. Here, using epitaxial thin-film growth, synchrotron X-ray diffraction, impedance spectroscopy, and density-functional theory, we delineate the impact of structural parameters (i.e., unit-cell volume and octahedral rotations) on ionic conductivity in La$_{0.9}$Sr$_{0.1}$Ga$_{0.95}$Mg$_{0.05}$O$_{3-\delta}$. As compared to the zero-strain state, compressive strain reduces the unit-cell volume while maintaining large octahedral rotations, resulting in a strong reduction of ionic conductivity, while tensile strain increases the unit-cell volume while quenching octahedral rotations, resulting in a negligible effect on the ionic conductivity. Calculations reveal that larger unit-cell volumes and octahedral rotations decrease migration barriers and create low-energy migration pathways, respectively. The desired combination of large unit-cell volume and octahedral rotations is normally contraindicated, but through the creation of superlattice structures we experimentally realize both expanded unit-cell volume and strong octahedral rotations which result in an enhancement of the ionic conductivity by ~250% at around 600°C.

*NSF Grant OISE-1545907
Epitaxial strain effect on site occupancy and conductivity of titanomagnetite*  
TIFFANY KASPAR (Presenter), Pacific Northwest Natl Lab, STEVE MICHAEL HEALD, Argonne National Lab, MARK BOWDEN, PETER SUSHKO, SCOTT CHAMBERS, Pacific Northwest Natl Lab — Magnetite, Fe$_3$O$_4$, exhibits metallic conductivity via electron hopping between Fe$^{2+}$ and Fe$^{3+}$ occupying octahedral sites in the spinel lattice. As Ti$^{4+}$ is doped into the octahedral sites of magnetite (the titanomagnetite series), an equal fraction of Fe$^{3+}$ is reduced to Fe$^{2+}$ to maintain charge neutrality. The site occupancies of Fe$^{2+}$ and Fe$^{3+}$ determine the transport properties of the titanomagnetite series; the end-member ulvöspinel, Fe$_2$TiO$_4$, exhibits $p$-type semiconducting transport properties. The Fe$^{2+}$/Fe$^{3+}$ site occupancy remains controversial, but is likely in part a function of the lattice strain induced by doping smaller Ti$^{4+}$ into the lattice. Here, we have deposited titanomagnetites and ulvöspinel as well-defined epitaxial thin films on both MgO and MgAl$_2$O$_4$ substrates. We have characterized the Fe valence state and site occupancy with XPS, XANES, and EXAFS, and related them to the epitaxial strain induced by the substrate. The impact of these factors on the electrical transport properties of the films will be discussed.

*U.S. Department of Energy (DOE), Basic Energy Sciences (BES), Division of Materials Sciences and Engineering, under Award No. 10122.

Electronic and Catalytic Behavior of Mn-based Spinels Grown by Molecular Beam Epitaxy*  
MILES BLANCHET (Presenter), SHALINEE CHIKARA, ALEXANDRIA BREDAR, Auburn University, TIFFANY KASPAR, Physical and Computational Sciences Directorate, Pacific Northwest National Laboratory, BYRON FARNUM, RYAN COMES, Auburn University — Previous research on manganese-based spinel structures has shown that some exhibit strong oxygen reduction reaction catalytic behavior for water splitting in hydrogen fuel cells. However, there have been limited efforts to study these materials as epitaxial thin films which can be used for surface catalysis studies. With this in mind, thin films of spinel structures such as MnFe$_2$O$_4$, CoMn$_2$O$_4$, NiMn$_2$O$_4$ and Mn$_3$O$_4$ were synthesized to study the relationship of electronic properties and catalytic behavior. Films were grown using a molecular beam epitaxy system which allowed for precise control of sample stoichiometry. After growth, films were transferred to an in-situ x-ray photoelectron spectroscopy system to be examined without exposure to atmosphere. In addition, measurements characterizing the films’ electronic and catalytic properties such as ellipsometry and cyclic voltammetry were also performed. The combination of these studies allows for a greater understanding of these spinels and how they might be used in future catalytic applications.

*This work is funded by the National Science Foundation, Division of Materials Research, Solid State and Materials Chemistry program under award number 1809847 with additional funding from EPSCOR.

Fluorination of Epitaxial Thin Films of Functional Metal Oxides*  
JOSEPH CARTELLI (Presenter), FRANCIS WALZ, ANTON WIGGINS, DAVID HUSTON, SANEDYA HERNANDEZ, AZRIEL WEINREB, RAJESWARI M KOLAGANI, Towson University — The goal of this project is to investigate the effects of incorporating fluorine into epitaxial thin films of functional metal oxides including Lanthanum Calcium Manganese Oxide (LCMO), Calcium Manganese Oxide (CMO), and Strontium Titanate (STO), with emphasis on electrical resistivity and structural changes. Electrical resistivity is a property of interest for many technical applications of these advanced and emerging materials. Fluorination of similar perovskite oxide materials including SrFeO$_{3-d}$ in thin films has yielded many interesting results. These results include altering the crystal structures and altering the electrical properties. Fluorine alters the anionic composition of these materials thus providing a way for extending the range of functional properties realizable. Fluorine introduction has the potential for charge doping the materials and altering the cation valence states. This would lead to changing structural order and symmetry through ionic size differences in the cation, and changes in the charge carrier concentration and mobility.

*We acknowledge support from the NSF grant DMR 1709781 and support from the Fisher General Endowment grant from the Jess and Mildred Fisher College of Science and Mathematics at Towson University.
2:03PM L46.00011: Nanoscale Visualization of the Au/HfO2/Si(001) Interface Electrostatics with BEEM  
JACK ROGERS (Presenter), DANIEL PENNOCK, HYEONSEON CHOI, STEVEN GASSNER, WESTLY NOLTING, VINCENT LABELLA, Colleges of Nanoscale Science and Engineering, SUNY Polytechnic Institute — Understanding carrier transport through the electrostatic potential of monolayer-thick oxide layers is important for nanoscale devices. Ballistic electron emission microscopy (BEEM) is an STM-based technique which allows for the visualization of nanoscale fluctuations of metal / insulator / semiconductor interface electrostatics [1]. In this work, the electrostatic barrier of an Au/HfO2/Si(001) interface is examined with BEEM to nanoscale dimensions. Thousands of spectra are taken at equally spaced points in a grid over a square micron. Barrier heights consistent with the band offsets for SiO2, HfO2, and the Schottky barrier for gold on p-type silicon are observed. This suggests that the monolayer-thick HfO2 layer is transparent to the ballistic electrons. X-ray photoemission spectroscopy confirms the presence of native SiO2 formation, which is further supported by computational modeling.

Session L47 GERA: Photovoltaics -- Solar Energy Conversion II  
BCEC 213 - John Mintmire, Oklahoma State University-Stillwater - Tag(s): Focus

11:15AM L47.00001: Hybrid functional studies of electronic properties of Cu2MgSnS4 (CMTS) for photovoltaics*  
KIN FAI TSE (Presenter), MAN HOI WONG, JUNYI ZHU, The Chinese University of Hong Kong — Cu2ZnSnS4 (CZTS) is a promising photovoltaic absorber material, efficiency is however largely hindered by potential fluctuation and band tailing problem due to abundance of defect and their complexes. Our previous work has establish CMTS should have a stable chemical potential range and desirable optical properties similar to CZTS. In this work, we examine the electronic properties of CMTS using HSE06 functional, our results shows 1) a general increase in formation energy in most defects except MgSn in CMTS, mainly due to the change of ground state structure, 2) qualitative similarity of defect thermodynamics and electronic properties in CMTS to CZTS and 3) identified CuMg as the main contribution to p-type carrier. These findings suggest CMTS may suppress potential fluctuation due to formation of detrimental CuZn+ZnCu defect complex in CZTS, and alleviate the band tailing near CZTS and CdS interface, and further confirm the feasibility of CMTS as an alternative absorber material to CZTS, suggesting potential for tuning. Implications to alloy with CZTS will be discussed.

*We are grateful for the support from Research Grants Council of Hong Kong (GRF/14319416) and Direct Grant from the Chinese University of Hong Kong (No. 4053233).

11:27AM L47.00002: First-principles structural studies of polythiophene isomeric systems*  
JOHN MINTMIRE (Presenter), Oklahoma State University-Stillwater — Recent experimental work has been reported for the synthesis of poly-ortho-thiophenes, in particular helical poly(5-alkyl-2,3-thiophene)s. These polythiophenes differ from the poly(3-alkyl-2,5-thiophene)s studied over for the past several decades as electroactive polymers similar to the polypyrroles, and which have had application in bulk heterojunction photovoltaics. We have carried out first-principles, density functional simulations for the electronic structure and total energy of a range of polythiophene systems using Gaussian-function-based orbitals in a band structure approach using helical symmetry. We have examined the hydrogen, methyl, ethyl, and propyl substituted poly(5-alkyl-2,3-thiophene)s and poly(3-alkyl-2,5-thiophene)s, optimizing the geometry as a function of twist angle in the helical backbone. We have also looked into other possible polymer conformations such as the poly(5-alkyl-2,4-thiophene).

*This work was supported in part by a sabbatical period at the ORNL Center for Nanophase Materials Science funded through the ORAU ORNL-HERE program.
11:39AM L47.00003: A New Family of Plasmonic Photocatalysts without Noble Metals* DONGYANG WAN (Presenter), BIXING YAN, NUSNNI, National University of Singapore, XIAO RENSHAW WANG, Nanyang Technological University, THIRUMALAI VENKY VENKATESAN, NUSNNI, National University of Singapore — Efficient photocatalysis is important for sustainable energy. Recently, an unconventional photocatalyst based on intrinsic plasmon, called intrinsic plasmonic photocatalyst (IPP), seems promising for higher efficiency in hydrogen evolution. This catalyst seems to benefit from the advantages of visible light absorption, plasmon-assisted hot carrier generation over conventional photocatalysts. Here, we report the relative hydrogen evolution efficiency under visible light irradiation of a family of IPP based on alkaline earth niobates (MxNbOy, where M=Ca, Sr or Ba), with efficiency of CaNbO3 > SrNbO3 > BaNbO3. The contributions of electron-phonon coupling time and solar energy absorption to the hydrogen evolution efficiency are identified as keys based on our comprehensive characterization of carrier density (10²² cm⁻³), plasmon absorption, carrier dynamics and surface area. This study demonstrates a generic approach to create a family of IPP and validates the solar energy absorption of intrinsic plasmon as an additional knob to enhance the photocatalytic efficiency.

*We thanks to Singapore National Research Foundation under the CRP project ‘Oxide Electronics on Silicon beyond Moore’ (NRF-CRP15-2015-01)

11:51AM L47.00004: Influence of microstructure on resistance, photovoltaic response and piezoelectric voltage of Colemanite CHANDRIMA CHATTERJEE, Department of Physics and Astronomy, University of Mississippi, BHASKAR ROY BARDHAN (Presenter), Department of Physics and Astronomy, SUNY Geneseo — Colemanite belongs to the class of prismatic monoclinic crystals. It is a hydrous compound and the water molecules contribute to conduction mechanisms at high temperature. The material contains interstitial and substitutional point defects which form intraband energy levels. These energy levels trap electrons and at high temperature the electrons gain enough energy to move to the conduction band. This phenomenon shows up as peaks in the current-voltage characteristics of colemanite. When excited with near ultraviolet light, colemanite exhibits ohmic resistance. The presence of photovoltaic microstructures such as grain boundaries, ferroelectric domains and others is responsible for this kind of behavior. The results show that colemanite may be used to generate higher photocurrent than conventional semiconductors. This opens up new possibilities of replacing semiconductors in photovoltaic device with colemanite. The piezoelectric response from different positions of colemanite varies in order of magnitude. These variations are due to the presence of point defects. The results may be used in the nondestructive testing of the uniformity of surfaces of piezoelectric crystals in general.

12:03PM L47.00005: Inexpensive Solar Tracking for Developing Regions* BETH PARKS (Presenter), Colgate University — A solar tracking system for photovoltaic cells was built and tested in sub-Saharan Africa. The cell was suspended from a mount, and weights were hung on the two ends. One of the weights was a water bucket with a controllable leak. The water bucket was hung from the east end of the cell, and the weights were adjusted so it was heavier in the morning. Over the course of the day, as it lost water, the cell rotated to track the sun. The system was tested for 20 days, and collected 32% more energy than would have been collected by a horizontal solar cell in the same location. The cost of the frame is less than the savings in purchasing a smaller PV cell, so it has the potential to make solar energy more affordable to households and small businesses in the developing world.

*This project was supported by the Fulbright Scholar program.

12:15PM L47.00006: Simulation-Optimized ZnSₓSe₁₋ₓ Contacts on Si for Photovoltaic Carrier-Selective Contacts* REBECCA GLAUDELL (Presenter), HARRY ATWATER, Caltech — ZnSₓSe₁₋ₓ films are promising materials for front carrier-selective contacts in silicon photovoltaics given their wide bandgaps and low resistivities compared to amorphous silicon, with the potential to capture more photo-generated current than a traditional heterojunction with intrinsic thin layer (HIT) solar cell. X-ray photoelectron and ellipsometric spectra of ZnSₓSe₁₋ₓ (x ranging from 0 to 1) films grown on Si by molecular beam epitaxy were used to measure band offsets of ZnSₓSe₁₋ₓ with respect to Si for purposes of accurate optoelectronic simulations of photovoltaic devices incorporating ZnSₓSe₁₋ₓ carrier-selective contacts. Further experimentally determined parameters including complex refractive index and resistivity were also included in the simulation of a HIT-style cell to determine the ZnSₓSe₁₋ₓ top contact mole fraction x, doping level, and thickness for optimal device performance.

*This material is based upon work supported by the NSF and the DOE under NSF CA No. EEC-1041895, by the DOE under Award Nos. DE-E0006335 and DE-E0004946, and by the NSF Graduate Research Fellowship under Grant No. 1144469.
12:27PM L47.00007: Modeling of PV/TPV devices using analytical solution of generalized Shockley – Queisser model* ANDREI SERGEEV (Presenter), HARRY HIER, CHRISTOPHER MIKE WAITS, US Army Rsch Lab - Adelphi — The generalized Shockley-Queisser (gSQ) model takes into account the frequency dependent absorption (emission), photon trapping and recycling, photocarriers multiplication, and nonradiative recombination processes. Exact analytical solution of gSQ model allows one to present the conversion efficiency and other photovoltaic (PV) and thermophotovoltaic (TPV) characteristics in convenient form via the Lambert W function, which is well approximated by logarithmic functions [1]. Analytical equations for useful energy, emission losses, thermal losses and optimal photocarrier collection time provide effective, convenient, and flexible tool for modeling of modern devices with effective photon trapping and recycling. We discuss analysis of experimental characteristics and optimization of PV/TPV devices based on gSQ solution. [1] Sergeev and Sablon, Exact Solution, Endoreversible Thermodynamics, and Kinetics of the Generalized Shockley-Queisser Model, Phys. Rev. Appl. 2018.

*This work is supported by ORAU (AS) and Army Research Laboratory.

12:39PM L47.00008: Density Functional Theory calculations of optical properties of Hybrid Halide Perovskite Bio-Solar Cells SUBHABRATA DAS (Presenter), Langmuir Center of Colloids and Interfaces, Columbia University, BERNARDO BARBIELLINI, Physics, Lappeenranta University of Technology, PONISSERIL SOMASUNDARAN, Langmuir Center of Colloids and Interfaces, Columbia University, VENKATESAN RENUGOPALAKRISHNAN, Chemical and Chemical Biology, Northeastern University — The photovoltaic performance of hybrid halide perovskite is related to the atomic and electronic structure at the interface between the carrier generating perovskite layer and the electron transport layer (ETL). Based on ab-initio density functional theory (DFT) calculations, we studied the interfacing of the ETL layer, bacteriorhodopsin (bR) protein with Methylammonium lead triiodide CH$_3$NH$_3$PbI$_3$ based organic-inorganic hybrid perovskite to fabricate Perovskite Biosolar Cells, which demonstrated a high ambient stability and an optical bandgap extending into the visible range. The dielectric spectrum of the Perovskite thin films is evaluated and validated with spectroscopic ellipsometry data. We further model the dielectric function according to the established Drude model with coupled harmonic oscillators. Our results agree well with reported data of the optical absorption coefficient and consistent with Kramers–Kronig transformations thus demonstrating band alignment between the protein and the perovskite. Hence, we comment on the structural, electronic, and transport properties at the br/perovskite/ETL interface.

12:51PM L47.00009: The Influence of Imperfect Band-edges on the Maximum Efficiency of a Solar Cell JOESON WONG (Presenter), STEFAN OMELCHENKO, HARRY ATWATER, Caltech — The theoretical maximum efficiency of a solar cell is given by the Shockley-Queisser Limit, which assumes a step-function absorbance near the band-edge. However, real materials always have an imperfect band-edge, which is usually characterized by an Urbach tail. In this work, we utilize optoelectronic reciprocity relations to develop a modified detailed balance limit of solar cells with imperfect band-edges. We find that for band-edges that are not sharper than the thermal energy, an effective renormalized band-gap is given by the quasi-Fermi level splitting within the solar cell. This renormalized bandgap creates a Stokes shift between the onset of absorption and the photoluminescence peak position, which drastically lowers the maximum achievable efficiency. The band-edge density of states therefore has important implications for the performance of photovoltaic devices.

1:03PM L47.00010: Heterocyclic halides as passivating layer improves photovoltaic properties and intrinsic stability in perovskite solar cells* MANUEL SALADO (Presenter), Materials science, BC Materials, ALEXANDER D. JODLOWSKI, University of Cordoba, CRISTINA ROLDAN-CARMONA, EPFL, GUSTAVO DE MIGUEL, University of Cordoba, SAMRANA KAZIM, Materials science, BC Materials, MOHAMMAD KHAJA NAZEERUDDIN, EPFL, SHAHZADA AHMAD, Materials science, BC Materials — Perovskites solar cells have improved in the photovoltaic field with no precedent. Rising from ~4% to 23.2% the power conversion efficiencies (PCE), however long term stability together with the lack of a fully understanding of intrinsic processes are still issues which need to be undertaken. To improve the intriguing challenges, compositional engineering of perovskites as well as molecular engineering of hole transport materials (HTMs) were adopted. Furthermore, an optimized interface between the different layers of the perovskite device is paramount to improve the problems aforementioned. In this regard, an optimized surface passivation layer is seen as an ideal approach to protect the surface from extrinsic factors, without altering the electro-optical properties.

In this work, we present the utilization of a passivation layer, which protect the perovskite layer from atmospheric attack. An improved PCE (20%) was also obtained compare with reference devices (18%), as the passivation layer will restricts the flow of electron towards the HTM layers and reduce recombination processes.

**1:15PM L47.00011:** An *ab-initio* study of water interactions in the hybrid perovskite MAPbI$_3^*$  
ARVIN KAKEKHANI (Presenter), ANDREW RAPPE, Chemistry, University of Pennsylvania — Hybrid (organic-inorganic) perovskites have recently received great attention as candidates for commercially viable and efficient conversion of solar energy. Nevertheless, the performance and stability of these materials gets affected by water and moisture in the environment. Here, using density functional theory (DFT) simulations, and taking MAPbI$_3$ as our case study, we investigate the nature of water interactions in hybrid perovskite MAPbI$_3$. Changing water concentration over 2 orders of magnitude, we study the process of water infiltration and the surface and bulk chemistry that follows and leads to first reversible, and then irreversible changes to the material's structure. We discuss, based on electronic-structure analyses, how water changes the optical properties of the material in different concentrations. Such understanding of the nature of water--hybrid-perovskite interactions, can then be used to design better and more stable solar cells.

*ONR N00014-17-1-2574

**1:27PM L47.00012:** Synthesis and optoelectronic properties of Perovskite nanowire*  
ATIKUR RAHMAN (Presenter), GOKUL M. A., Department of Physics, Indian Institute of Science Education and Research (IISER)-Pune — We have developed a simple solution based synthesis method of CsPbI$_3$ nanowire. This method produces high yield nanowire with controllable length and diameter. We studied in details the effect of various growth conditions, such as temperature and time on the morphology of these nanowires. Single nanowire devices were made to investigate their individual property. To understand different mechanisms that play a major role in determining the performance and stability of these nanowire devices, we studied optoelectronic and noise characteristics under various conditions. These nanowires are structurally stable under ambient condition and show stable photoresponse. We will discuss in details the possible growth mechanism and the observed optoelectronic properties of these nanowires.

*The authors acknowledge funding support from IISER Pune.

**1:39PM L47.00013:** A density functional theory study (GGA+U) of the electronic and optical properties of Sn doped acanthite Cu$_2$S*  
SAJIB BARMAN (Presenter), MUHAMMAD NURUL HUDA, Physics, University of Texas at Arlington — Cu$_2$S is earth abundant, non-toxic and an important semiconductor with many applications. Previously it sought wide attention to scientific community as a promising photovoltaic material since Cu$_2$S based thin film solar cells demonstrated nearly 10% conversion efficiency. Despite excessive Cu vacancy formation tendency, studies on Cu$_2$S based thin film solar cells didn't lose its importance in decades. Our recently published theoretical study (J. Phys.: Condens. Matter 30 165701) on the acanthite phase of Cu$_2$S showed that Cu vacancy formation tendency can be reduced with Ag alloying. Hence, alloying with other materials needs to be studied systematically, as well. Here, we report a systematic first principle study on Sn doped acanthite Cu$_2$S. We have showed that Sn doping in this structure is even thermodynamically more favorable. Even though excessive Sn doping makes the material metallic, the Cu vacancy formation tendency decreases with high doping concentration. With suitable low doping the material undergoes electronic intraband transition which extends the optical absorption to the infrared region. In addition, detail electronic structures and optical properties will be presented for pure and Sn doped cases.

*All the computational work was done at Lonestar5 at TACC in Austin, TX.

**1:51PM L47.00014:** Screening of Metallic Single-Replacements for Lead-free Perovskites with Intrinsic Photovoltaic Functionalities  
CLARK ZHANG (Presenter), XUAN LUO, National Graphene Research and Development Center — Methylammonium lead triiodide perovskites, CH$_3$NH$_3$PbI$_3$ (MAPbI$_3$), are solution-processable materials with photovoltaic properties capable of surpassing those of silicon solar cells. However, concerns over lead toxicity and lack of exploration into transition metal perovskites drove this ab initio Density Functional Theory screening for environmentally friendly perovskite materials by incorporating transition and post-transition metals at the B-site of MAPbI$_3$. This revealed fourteen replacements to be suitable: their band structures are highly dispersive while band gaps of such materials fall within ideal ranges for single-junction and tandem cells. Transition metal monoreplacements are shown to be viable perovskites after reducing the size of the halide, corroborating that tunability of the band gap is observed in halide replacement at the X-site. Strong peaks in the imaginary output of the dielectric function below 3.5 eV indicate high sunlight absorption efficiency for select materials. Excellent carrier mobility is expected of studied materials as their effective mass is low. This work helps gain further insight into the viability of plentiful transition metals for lower toxicity and higher absorption divalent perovskites.

*Wednesday, March 6, 2019 11:15 AM - 2:15 PM*
11:15AM L51.00001: Max Delbruck Prize in Biological Physics Talk: The Physics of Cellular Proteostasis [Invited]  KEN DILL (Presenter), Stony Brook University — In order for cells to function, their proteins must be folded and not aggregated. This healthy state is maintained by a complex energy-expensive system of chaperones, and synthesis and degradation machinery. This is among the most central and complex ‘decision-making’ processes of simple cells. We model proteostasis by combining the dynamics of the chaperone binding and trafficking with the kinetics of protein folding and aggregation. We also explore the rates of evolution of protein sequences and how the chaperones modulate those rates.

11:51AM L51.00002: Max Delbruck Prize in Biological Physics Talk: Exploring the Energy Landscape for Protein Folding and Function: Integrating Structural Models and Sequence Coevolution Information. [Invited]  JOSE ONUCHIC (Presenter), Center for Theoretical Biological Physics, Rice University — Energy landscape theory and the funnel concept have been a powerful approach to study protein folding dynamics and function. The discovery that an accurate estimate of the joint probability distribution of amino acid occupancies in protein families provides insights about residue-residue coevolution and concrete details about protein folding landscapes has also advanced structural biophysics. Our realization that the collection of couplings and local fields as parameters of such distribution is inherently connected with the thermodynamics of sequence selection towards folding and function demonstrates the importance of coevolutionary methods to understand stability and function of biomolecules. The synergy between structure based models and coevolutionary information has spearheaded the field of structure prediction, including protein and RNA, as well as accelerating the discovery of functional structural states and the prediction of protein complexes. Coevolution signals can also be used to create protein recognition metrics, which led to successful experimental efforts, and the uncovering of novel molecular interactions. This idea has opened the door to encode recognition in protein pairs. Coevolved interfaces can also be combined with small molecule hot spot estimation methods to improve the discovery of druggable interfaces. Recently this approach has been used to predict extremely large protein assemblies consisting of structural maintenance of chromosones (SMC) and kleisin subunits which are essential for the process of chromosome segregation across all domains of life. While limited structural data exist for the proteins that comprise the (SMC)–kleisin complex, using an integrative approach combining both crystallographic data and coevolutionary information, we have predicted an atomic-scale structure of the whole condensing complex in prokaryotes.

12:27PM L51.00003: Using evolutionary repair to learn about biological functions [Invited]  MARCO FUMASONI, YU-YING HSIEH, ANDREW MURRAY (Presenter), Harvard University — Although many biological processes, such as DNA replication and chromosome segregation, are universal and many of the proteins that mediate them have persisted since the last common ancestor, other components have appeared and disappeared during evolution. We have removed important, but non-essential components from two different processes, DNA replication and chromosome segregation, allowed cells to accumulate mutations that restore reproductive fitness to nearly wild-type levels, and studied how these mutations affect DNA metabolism. In both cases, mutations alter multiple aspects of DNA metabolism with the effects of the different mutations being approximately additive and at least one of the adaptations is to slow an aspect of DNA replication. We discuss the trade-off between the speed of DNA replication and the accumulation of harmful intermediates in wild-type and mutant cells and how mutations can regulate the trade-off to improve reproductive fitness.

*NIH/NIGMS GM043987

1:03PM L51.00004: Fitness Landscapes of Ribozymes [Invited]  IRENE CHEN (Presenter), Chemistry and Biochemistry, UCSB — Evolutionary outcomes are difficult, if not impossible, to predict, largely because the effect of any possible mutation is unknown. In other words, understanding evolution requires detailed knowledge of the relationship between sequence and activity, or the fitness landscape. Molecules explore the fitness landscape in sequence space during evolution, much as proteins explore the folding landscape in conformational space. Inspired by the RNA World theory of early life, in which RNA would carry information and also perform catalytic functions, we study the emergence and evolution of functional RNAs. Our experimental efforts focus on mapping complete fitness landscapes of ribozyme activity. We also study how confinement in a vesicle affects RNA activity and structure. These studies inform our understanding of the likelihood of emergence of function and the roles of chance vs. natural selection in prebiotic evolution.
1:39PM L51.00005: From Tunneling Pathways to Essential Biological Function* [Invited] DAVID BERATAN (Presenter), Duke University — Energy capture, storage, and conversion in living systems relies, fundamentally, on the flow of electrons and protons. The transport of electrons through proteins uses cofactors, special chemical groups that sequester electrons as they hop among these sites through otherwise insulating proteins. These cofactors trade electrons with one another via electron tunneling. Electrons thus move across membranes, generating a proton gradient, and leading to the synthesis of energy storing chemical bonds. Electron transfer reactions also participate in essential reaction of biosynthesis, damage repair, and signaling. Electrons flow in biology on time scales from picoseconds to seconds, and the trick for insuring that the electrons get to the right places at the right times is to employ electron tunneling pathways between the charge localizing cofactors. I will describe the theoretical framework for describing how proteins control these reactions with tunneling pathways, and will discuss research frontiers in that have become accessible to theoretical analysis as a consequence of the tunneling pathways framework. Examples will include the repair of DNA damage by the protein photolyase, the micrometer length scale flow of electrons through extracellular bacterial nanowires that enable respiration in some aerobic bacteria (when deprived of oxygen) through the use of biotic-abiotic charge exchange (i.e., electron transfer to rocks), and electron bifurcation - a reaction that couples electron flow between two-electron donors and single-electron carriers.

Session L53 GSOFT: Controlling Local Structure With Time-Dependent External Fields BCEC
253C - Craig Maloney, Northeastern University - Tag(s): Invited

11:15AM L53.00001: Symmetric and Asymmetric Time-Varying Magnetic Fields to Control and Drive Paramagnetic Colloidal Assemblies* [Invited] SIBANI BISWAL (Presenter), Rice University — Micron-sized superparamagnetic colloids placed in time-varying magnetic fields can provide us with rich dynamic behavior depending on the magnetic field applied and the particle concentration. In symmetric magnetic fields, a long-range attractive potential is induced resulting in the formation of colloidal clusters, which assemble into circular shapes that exhibit fluid-like behavior at relatively low fields, while becoming crystallized and highly ordered at higher field strengths. These systems exhibit interesting coarsening and spinodal decomposition structural transitions for larger particle systems.

In asymmetric time-varying fields, the colloids assemble into directed collective motion. The simplest case of two bodies by which a smaller arm particle can be driven in an asymmetric orbit in the proximity of a larger torso particle using an eccentric rotating magnetic field (ERM), resulting in both bodies swimming in a directed motion. Furthermore, adding additional particles the arm leads to overlapping orbits and arm synchronization, resulting in faster swimming speeds. This new methodology for being able to achieve nonreciprocal motion at low Re offers insight into directing the motion of collective active systems.

*National Science Foundation CBET-17055703

11:51AM L53.00002: Driving and assembling magnetic particles with incoherent fields* [Invited] RANDY ERB (Presenter), RASAM SOHEILIAN, HAMED ABDI, CRAIG MALONEY, Northeastern University — Magnetic particles in suspension can chain under static applied magnetic fields or be transported to target sites with static magnetic field gradients. This is clear and has led to innovations from magnetorheological fluids to magnetic targeting of tumors to magnetic delivery of drugs. But how do magnetic particles behave in more complicated fields and field gradients? Can we use these complications to our advantage? Can we understand the physics? There has been significant research toward these questions for coherent (simple rotating) fields by many research groups including ours. Dynamically tuning the direction (but not magnitude) of the field will disrupt the simple chaining of particles. For two isolated particles, this disruption is found to be an elegant systematic dance between particle pairs. For large populations of particles, fascinating group dynamics occur. We have looked at these dynamics for chains as well as for multipolar ring formations. In addition, we have been investigating the behavior of magnetic particles under incoherent fields, in which there is a mismatch in the frequency domain for x, y, and z field functions. Surprisingly, we find that incoherent fields can generate coherent assemblies! We apply our findings to the realms of magnetic assembly, magnetic drug delivery and magnetic rheology in an attempt to enhance current practices through complicating the applied fields.

12:27PM L53.00003: A touch of non-linearity in fluid fields: where spheres “think” collectively and swim together*
[Invited] DAPHNE KLOTSA (Presenter), University of North Carolina at Chapel Hill — From crawling cells to orca whales, swimming in nature occurs at different scales. The study of swimming across length scales can shed light onto the biological functions of natural swimmers or inspire the design of artificial swimmers with applications ranging from targeted drug delivery to deep-water explorations. In this talk, I will present experiments and simulations of how oscillating spheres, universally simple geometric objects, can utilize non-linearities to demonstrate complex pattern formation in a granular system, or different swimming behaviors in a spherobot (robot made out of spheres) when placed in a fluid at intermediate Reynolds numbers, 1<Re.

*National Science Foundation, grant award DMR-1753148

1:03PM L53.00004: Deck the walls with tunable energy fields for colloidal particles in nematic liquid crystals*
[Invited] KATHLEEN STEBE (Presenter), University of Pennsylvania — Confined nematic liquid crystals provide new opportunities to direct colloidal motion and assembly. Nematic liquid crystal director fields molded by confinement can present domains of bend, splay or twist with associated elastic energies. Colloidal particles also distort the nematic director field, and are repelled or attracted to these domains to minimize the elastic energy cost in these systems. We have been studying colloids adjacent to a wavy wall in a nematic liquid crystal with a smoothly varying, non-singular director field that features bend and splay distortions. Colloids within this field can have multi-stable states. Wall-colloid equilibrium distances and ranges of interaction can be tuned by varying wavy wall geometry. Colloids move toward and dock at attractive sites and away from repulsive loci; this repulsion can propel objects in the domain. Extensions to anisotropic colloids are discussed. Manipulation by application of external fields to complement the nematic director fields are discussed in the context of reconfigurable systems and microrobotics.

1:39PM L53.00005: Emergent dynamics and self-assembly of colloids in time-dependent magnetic fields*
[Invited] ALEXEY SNEZHKO (Presenter), Argonne National Laboratory — Strongly interacting colloids subject to an external periodic forcing often exhibit nontrivial collective dynamics and self-organization. Driven magnetic colloids proved to be an excellent model system to explore emergent collective behavior and out-of-equilibrium self-assembly. New self-assembled structures emerging in time-dependent magnetic fields are often not accessible under equilibrium conditions. In this presentation I will demonstrate that dispersions of magnetic particles suspended at a liquid-air, liquid-liquid interfaces or in the bulk and driven out-of-equilibrium by an alternating magnetic field develop nontrivial dynamic self-assembled phases and structures. Experiments reveal new types of nontrivially ordered phases and collective dynamics emerging in such systems in a certain range of excitation parameters. These remarkable non-equilibrium structures emerge as a result of the competition between magnetic and hydrodynamic forces. The dynamic phases are reversible and fine-tuned by the parameters of the driving magnetic field. Above certain frequency threshold or on external perturbation some of the dynamic structures spontaneously break the symmetry of self-induced flows and turn into swimmers, spinners or can be used as robotic manipulators at microscale. Furthermore, collective motion of self-assembled dynamic structures at interfaces often generates chaotic fluid flow reminiscent of two-dimensional turbulence - active turbulence. In case of a rotational magnetic field two-dimensional active spinner materials can be realized.

Session L54 DCMP: 2D Heterostructures -- Transport BCEC 254A - Jianhao Chen, Peking University - Tag(s): Focus
11:15AM L54.00001: Perfectly gate-tunable graphene-WSe₂ van der Waal’s heterostructure at the Schottky-Mott limit  
SAMUEL LAGASSE (Presenter), PRATHAMESH DHAKRAS, Colleges of Nanoscale Science and Engineering, SUNY Polytechnic Institute, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, JI UNG LEE, Colleges of Nanoscale Science and Engineering, SUNY Polytechnic Institute — Recently, the Schottky-Mott (SM) limit has been studied through measurements on many metal-semiconductor junctions with various metals [1]. Here, we probe the SM limit using a single, gate-tunable, hexagonal boron nitride encapsulated graphene-WSe₂-graphene heterostructure. One-dimensional edge contacts are made to the graphene and buried split-gates are used to separately tune the electrical properties each graphene-WSe₂ junction. By making one graphene-WSe₂ junction Ohmic, we perform electrical measurements of the Schottky barrier (SB) formed in the other junction. Electrical measurements of the SB show striking agreement with the ideal-diode equation, with over thirteen decades of drain current modulation via the gate voltage. Arrhenius activation energy measurements reveal one-to-one electrical control of the SB height by the gate voltage. These measurements indicate a stark absence of Fermi-level pinning at the graphene-WSe₂ interface, resulting in a tunable SM limited heterojunction. Our findings are of broad significance, enabling fundamental studies of the SM limit and the ability to make superior electrical contact to two-dimensional materials.

11:27AM L54.00002: Naturally formed contacts between assorted metals and 2D TMD materials*  
RUHI THORAT (Presenter), THUSHAN WICKRAMASINGHE, GREGORY JENSEN, MARYAM BIZHANI, ERIC A STINAFF, Ohio University — Novel technologies built on the properties of two dimensional transition metal dichalcogenides (TMD) require the ability to pattern, process, and contact the material in a scalable manner. However, reproducibly making quality contact to 2D materials remains a significant challenge. We have developed a technique which uses bulk transition metal contacts which act as nucleation sites and a source of material for the growth of 2D TMDs. The bulk metal remains after growth, establishing a naturally formed electrical contact with the TMD material. In the original manifestation of this technique, the contact material was limited to the transition metal of the subsequently grown TMD, however, it has been reported that various elemental metal contacts exhibit reduced Schottky barriers. We will present results from a modification of our growth process which allows for different metal contacts to be produced. A comparison between various metal contacts such as Ti-MoS₂ and Mo-MoS₂ will be presented and transport measurements will be discussed. This modification to our technique opens up the possibility of producing more complex device architectures with tailored contact properties.

11:39AM L54.00003: Direct reversible writing of nanoscale doping patterns in van der Waals heterostructures*  
WU SHI (Presenter), SALMAN KAHN, Lawrence Berkeley National Laboratory and UC Berkeley, LILI JIANG, SHENG-YU WANG, HSIN-ZON TSAI, UC Berkeley, DILLON WONG, Princeton University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, FENG WANG, MICHAEL F CROMMIE, ALEX ZETTL, Lawrence Berkeley National Laboratory and UC Berkeley — Spatially controlled modification of charge density is essential to explore exotic physics and enable new device applications. Conventionally, this has been achieved using lithographically defined local gates or by employing molecular self-assemblies on surfaces. However, these methods face limitations in applications necessitating spatial re-writability and complex circuit designs. Recent progress has demonstrated alternative ways to induce rewritable doping patterns in van der Waals (vdW) heterostructures without complex processing masks or resist by optical illumination or applying an STM tip voltage pulse. In this work we introduce a more flexible electron beam doping technique to induce controllable and erasable doping effect in (vdW) heterostructures. With this new doping technique, we can accumulate high carrier density and reversibly write complex doping patterns with nanoscale spatial resolution while preserving the high quality of the vdW heterostructures. The technique can be an ideal approach to study a variety of superlattice physics in vdW heterostructures and to create on-demand circuits for device applications.

11:51AM L54.00004: Effect of Remote Surface Optical Phonon Scattering in Ferroelectric-Gated Single- and Bi-layer Graphene*  
HANYING CHEN (Presenter), ZHIYONG XIAO, ANIL K RAJAPITAMAHUNI, YIFEI HAO, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science - Japan, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln — We investigate the effect of the remote surface optical (RSO) phonon scattering on the transport properties of single and bi-layer graphene gated by ferroelectric Ba$_{0.6}$Sr$_{0.4}$TiO$_3$ (BSTO) thin films. Graphene flakes were exfoliated on epitaxial 100-300 nm BSTO thin films grown on Nb-doped SrTiO$_3$ substrates. Single and bi-layer samples were then identified via optical microscopy and characterized by atomic force microscopy and Raman spectra. Selected flakes were fabricated into field effect transistor (FET) devices via e-beam lithography. At low temperature, these ferroelectric-gated FETs (FeFET) exhibit resistivity hysteresis induced by ferroelectric switching, which evolves to anti-hysteresis at ~40 K. The graphene FETs exhibit high field effect mobility up to $\mu_{FE}$~19,000 cm$^2$/Vs and quantum Hall at 10 K, from which we deduced a dielectric constant of ~60 for BSTO. We examined the temperature dependence of the resistivity, which reveals dominant RSO phonon scattering from the interface with BSTO. We also discuss the effect of capping these samples with a top h-BN layer. Our study facilitates the development of high-performance FeFETs based on graphene.

*This work was primarily supported by the U.S. Department of Energy, BES, under Award No. DE-SC0016153.

12:03PM L54.00005: Quantifying thermal boundary conductance of 2D-3D interfaces  
CAMERON FOSS (Presenter), ZLATAN AKSAMija, Electrical and Computer Engineering, University of Massachusetts Amherst — Heat dissipation in next-generation electronics based on two-dimensional (2D) materials is a critical issue in their development and implementation. A bottleneck for heat removal from the 2D layer into its supporting substrate is the thermal boundary conductance (TBC) of the 2D-3D interface, which is impacted by their structure and composition. Here we investigate the temperature-dependent TBC of 42 interfaces formed between a group of six 2D materials and seven crystalline and amorphous substrates. Our results show that the TBC can be varied by nearly two orders of magnitude, from 0.6 MW.m$^{-2}$.K$^{-1}$ (h-BN on diamond) to 40 MW.m$^{-2}$.K$^{-1}$ (h-BN on SiO$_2$), for the same 2D layer by changing the substrate material. We find that amorphous materials boost the TBC due to the low-frequency Boson peak feature in their vibrational density of states (vDOS) relative to their crystalline counterparts, whose vDOS follows a Debye model at low frequency, assuming the two interfaces have the same adhesion. For crystalline substrates, we correlate constituent material properties with the calculated TBCs and find that TBC depends on a combination of the speed of sound, Debye temperature, density of the substrate, and bandwidth of the flexural branch in the 2D material.

12:15PM L54.00006: Towards the Mechanism of Protonic Transport in Graphene Oxide*  
VLADIMIR SAMUILOV (Presenter), Department of Mat. Sci & Eng., SUNY at Stony Brook, NIKOLAI POKLONSKI, Department of Physics, Belarus State University — Graphene oxide (GO) has been considered as a good ionic conductor and an electronic insulator simultaneously [1,2]. The mechanism of the protonic conductivity in GO has not been studied carefully yet. This report presents new experimental data of the protonic conduction in GO in a wide temperature range with the humidity as a parameter. The activation energy of the protonic transport (approx. 0.7 eV) was obtained from the Arrhenius plots. Applications of GO membranes to the humidity sensors [2] and to solid-state electrolyte energy storage devices [1] have been considered.  

*The work was partially supported by Belarusian Scientific Program “Convergence”, Belarusian Republican Foundation for Fundamental Research (Grant No. F18R-253) and by Sensor CAT at Stony Brook University, NY
12:27PM L54.00007: AC Josephson effect in a capacitively shunted graphene Josephson junction  FAN YU (Presenter), SANDESH S KALANTRE, University of Maryland, College Park, GLEB FINKELSTEIN, Physics, Duke University, FRANCOIS AMET, Physics and Astronomy, Appalachian State University, JAMES R WILLIAMS, University of Maryland, College Park — The AC Josephson effect is being used to detect signatures of novel modes in Josephson junctions. However, complex behavior of these junctions under RF radiation can also from trivial effects, like the presence of a large shunting capacitance. Here we study the AC Josephson effect on a junction made of graphene encapsulated in boron nitride and contacted by electrodes made of a superconducting molybdenum-rhenium alloy. In regions where chemical potential is close to the charge-neutrality point and the RF drive current is comparable with critical current, this device demonstrated a bi-stability between the first Shapiro steps, indicating the Josephson junction is in a chaotic regime. A full description of the chaotic physics observed is presented. These observations cast doubt over arguments that AC Josephson effect in the low RF drive amplitude region would offer the opportunity to observe 4-π current phase relation in topological Josephson junctions.

12:39PM L54.00008: Superconductivity in Graphene NbSe₂ heterostructures* SATRIO GANI (Presenter), Physics Department, College of William & Mary, HADAR STEINBERG, The Racah Institute of Physics, The Hebrew University of Jerusalem, ENRICO ROSSI, Physics Department, College of William and Mary — We study van der Waals heterostructures formed by graphene and monolayer NbSe₂. We show that despite the large mismatch between the lattice constant of graphene and NbSe₂ in these structures a large superconducting pairing can be induced into the graphene layer. In addition, we show how such pairing depends, both in nature and structure, on the stacking configuration. Our results are relevant also to heterostructures formed by graphene and other monolayer of transition metal dichalcogenides such NbS₂, TaS₂, and TaSe₂, that have also been shown to be superconducting at low temperature, and suggest a way to probe the nature of the multiband superconducting gap in these systems.

*Work supported by NSF and BSF.

12:51PM L54.00009: Superconducting contact to 2D transition-metal dichalcogenide superconductors* MICHAEL SINKO (Presenter), SERGIO DE LA BARRERA, Carnegie Mellon University, OLIVIA LANES, MICHAEL HATRIDGE, University of Pittsburgh, BENJAMIN MATTHEW HUNT, Carnegie Mellon University — Two-dimensional transition-metal dichalcogenide superconductors have unique and desirable properties for integration with conventional superconducting circuits. These properties include the ability to form atomically clean and flat interfaces with stable tunnel barriers (such as boron nitride), increased kinetic inductance due to the atomically-thin geometry, and resilience to very high in-plane magnetic fields. Integrating 2D superconductors into superconducting circuits requires a fully superconducting contact be made between the 2D material and a conventional superconductor. By means of an in situ process of etching and angled Al evaporation, we present evidence of robust superconducting edge contact to NbSe₂ fully encapsulated by insulating hBN. A critical current density Jc = 7x10⁸ A/m² is achieved in the contacts. In a second set of samples, two contacts are connected with an Al loop to form a SQUID. A Fraunhofer pattern is observed in each of these samples, whose periodicities can be modeled by using an effective area for the SQUID loop equal to the physical loop area plus an area from the thin NbSe₂ flake that is uniformly penetrated by the applied magnetic field.

*This project was supported by the National Science Foundation PIRE program under award number 1743717

1:03PM L54.00010: Magnetotransport studies in hybrid 2D/0D nanostructures* ETHEL PEREZ-HOYOS (Presenter), YUNQIU (KELLY) LUO, Physics, The Ohio State University, ABHILASHA DEHANKAR, Chemical and Biomolecular Engineering, The Ohio State University, JINSONG XU, ROLAND KAWAKAMI, Physics, The Ohio State University, JESSICA WINTER, Chemical and Biomolecular Engineering, The Ohio State University — We present a device fabrication strategy that takes advantage of stacking techniques developed for van der Waals heterostructures to construct hybrid 2D/0D composite nanostructures, with potential application in the study of spin and charge disorder as well as magnetic-proximity effects. The structures in this study are comprised of superparamagnetic iron oxide nanoparticles (SPIONs) and monolayer graphene. The SPIONs are deposited first using a Langmuir-Blodgett technique, yielding rafts of highly ordered nanoparticles. Characterization via magnetic force microscopy (MFM) reveals magnetic order at multiple length scales and SQUID magnetometry identifies both glassy antiferomagnetic and ferromagnetic response. Single graphene monolayers are mechanically stacked on the SPION layer, and are found to maintain relatively high mobility and gate sensitivity, as indicated by quantum Hall effect (QHE) measurements.

*Funding for this research was provided by the Center for Emergent Materials: an NSF MRSEC under award number DMR-1420451.

1:15PM L54.00011: Transport measurements on 2D material devices [invited] YU HUANG (Presenter), UCLA — Selected by Focus Topic Organizer John Schaibley
Wednesday, March 6, 2019 11:15 AM - 1:51 PM

Session L55 DMP: Devices from 2D Materials -- Optical Spectroscopy BCEC 254B - Nick Vamivakas, University of Rochester

DAVOUD HEJAZI (Presenter), SARAH OSTADABBAS, SWASTIK KAR, Northeastern University — We created a vector of low-cost filters for estimating the wavelength of a light source in the range of 300nm-1100nm using gradually differing mixtures of nano-flakes of semiconducting materials, Molybdenum-Disulfide (MoS2) and Tungsten-Disulfide (WS2). The nano-flakes were produced by method of Liquid-Phase Exfoliation and Sonication. We studied the incident and transmitted intensities of light passing through these filters and derived a statistical model for the behavior pattern of the filters for incident light. By employing machine learning techniques we estimated the wavelength distribution of incident light with accuracy of ≤ %1 using the incident and transmitted sensor readings for intensity of light.

11:27AM L55.00002: Interface-Driven Nonlinear Optical Response at MoS2/Ferroelectric Composite Structures*  
DAWEI LI (Presenter), Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln, XI HUANG, Department of Electrical and Computer Engineering, University of Nebraska - Lincoln, ZHIYONG XIAO, HANYING CHEN, LE ZHANG, DING-FU SHAO, EVGENY Y TSYMBAL, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln, YONGFENG LU, Department of Electrical and Computer Engineering, University of Nebraska - Lincoln, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln — Integrating layered van der Waals materials such as the transition metal dichalcogenides with ferroelectrics offers the opportunity to introduce new functionalities to the 2D platform, including nonvolatile memory and programmable junctions. In this work, we report a novel nonlinear optical response emerged at the interface between monolayer MoS2 and ferroelectric thin films. We have pre-patterned ferroelectric domain structures with polarization up and down domains on epitaxial PbZr0.2Ti0.8O3 (PZT) thin films using piezoresponse force microscopy, and then transferred on the top MoS2 flakes. We then carried out second-harmonic generation (SHG) microscopy studies on the composite structures. In the reflection mode, we find that the SHG intensity on the ferroelectric domain wall (DW) is highly modulated compared with those on both polar domains, either significantly enhanced or suppressed depending on the chirality of the DW. Stacking angle dependence demonstrates that MoS2 also tunes the polarity of the SHG response on the DW. Our study points to a new strategy to achieve tailored light polarity and intensity modulation via nanoscale ferroelectric control.

*This work was primarily supported by the DOE, BES, under Award No. DE-SC0016153.

11:39AM L55.00003: Investigation of Intrinsic Optical Characteristics in MoS2 Phototransistors using Van der Waals Heterostructure  
JINSU PAK (Presenter), Seoul National University, ILMIN LEE, Electronic and Electrical Engineering, Sungkyunkwan University, KYUNGJUNE CHO, WANG-TAEK HWANG, JAE-KEUN KIM, KEEHOON KANG, Seoul National University, WOO JONG YU, Electronic and Electrical Engineering, Sungkyunkwan University, SEUNGJUN CHUNG, Photoelectronic Hybrids Research Center, Korea Institute of Science and Technology, TAKHEE LEE, Seoul National University — Since the photodetectors based on molybdenum disulfide (MoS2) emerged, diverse researches have been conducted to obtain high performance as the photodetectors.[1] However, it is not trivial to study the intrinsic optical properties of MoS2 because of the reflected incident light by the generally used opaque substrate such as SiO2. Here, we report our study of the intrinsic optical characteristics in MoS2 phototransistor through the transparent device structure fabricated by 2D materials-based heterostructure. The internal photo-responses (corresponding to the photo-response generated by absorbed photons in a MoS2 sheet) such as responsivity, detectivity, and quantum efficiency were carefully investigated. The measured results indicated that the internal quantum efficiency was not strongly dependent on the wavelength of the incident light, whereas the external quantum efficiency was. Our study helps to understand the intrinsic optical characteristics of 2D-based photodetectors, and will provide an insight for the realization of 2D-based transparent photodetectors.

11:51AM L55.00004: Nonlinear Plasmonics with 2D Excitons*  
BEKELE BADADA (Presenter), MATTHEW KLEIN, Physics, University of Arizona, Tucson, Arizona 85721, USA, ROLF BINDER, College of Optical Sciences, University of Arizona, Tucson, Arizona 85721, USA, ADAM ALFREY, MAX MCKIE, Physics, University of Arizona, Tucson, Arizona 85721, USA, MICHAEL KOEHLER, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee, 37831, USA, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Tsukuba, Ibaraki 305-0044, Japan, BRIAN LEROY, JOHN SCHAIBLEY, Physics, University of Arizona, Tucson, Arizona 85721, USA — We investigate the interactions between propagating surface plasmon polaritons (SPP) in a metallic waveguide and excitons in WSe2 monolayer. The WSe2 monolayer was encapsulated by few layer thick hBN and transferred onto a lithographically defined gold waveguide using dry transfer technique. SPPs were launched by focusing a tunable laser onto an integrated input grating coupler and scattered out using another grating coupler. Both linear and nonlinear response of SPP-exciton interactions were measured. We report a very large linear absorption of SPP ~ 73% when the SPP is tuned to the exciton energy. For the nonlinear response, we report both optical-pumped and SPP-pumped differential SPP transmission measurements. For the SPP-pumped case, we report a large differential transmission (DT/T) over 4%. These results are highly consistent with a theoretical model of the linear and nonlinear SPP-exciton response. In our model, the SPP-exciton wave is based on an eigenmode analysis in the linear response regime, which is then perturbatively extended to the nonlinear regime. We believe that our device architecture and analysis could pave the road towards all-plasmonic modulators, amplifiers and transistors.

12:03PM L55.00005: Low-frequency Raman signature of Ag-intercalated MoS2: A first-principles study.  
NATALYA SHEREMETYEVA (Presenter), DRAKE NIEDZIELSKI, DAMIEN TRISTANT, Physics, Rensselaer Polytechnic Institute, LAUREN E. KERSTETTER, AMA AGYAPONG, ANNA C. DOMASK, SUZANNE MOHNEY, Materials Science and Engineering, Pennsylvania State University, VINCENT MEUNIER, Physics, Rensselaer Polytechnic Institute — Two-dimensional layered materials (2DMs) are promising candidates for novel electronic devices as their electronic properties can be tuned e.g. by controlling their layer number. Precise characterization of 2DMs' is crucial for exact property control. Raman spectroscopy is a nondestructive technique that can identify even small structural/electronic changes.

Recent advances in Raman spectroscopy hardware made resolution of low-frequency (LF) Raman response in 2DMs possible. This response has a low intensity compared to the high-frequency (HF) Raman signature and is located close to the strong Rayleigh line making the detection challenging. However, as LF interlayer modes are rigid motions of each layer as a whole unit within the 2DM with restoring forces governed by the weak interlayer interactions, they are more sensitive to structural parameters than their HF intralayer counterparts (Liang L. et al., ACS Nano Article ASAP, DOI:10.1021/acsnano.7b06551).

Motivated by experiment, we present a Density Functional Theory based study of LF Raman modes of few-layer MoS2 intercalated with silver. We predict a noticeable red shift of LF modes with increasing Ag concentration. This shift is confirmed experimentally and can be used for confirmation of successful silver diffusion into MoS2.

12:15PM L55.00006: Tailoring the electroluminescence of dual-gated monolayer p–n diodes*  
ERIK LENFERINK (Presenter), Physics and Astronomy, Northwestern University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, NATHANIEL STERN, Physics and Astronomy, Northwestern University — Owing to their direct bandgaps and atomic-scale thickness, monolayer transition metal dichalcogenides have been heavily investigated for optoelectronic applications. Their potential for atomically-thin visible frequency light sources can be realized by lateral monolayer p–n diodes defined by local electrostatic gates. Control over the spectral distribution and polarization of the electroluminescence is desirable for integrating these prototypical monolayer LEDs into optoelectronic and nanophotonic devices with tunable coupling. The high electric fields near the p–n interface in these single-monolayer devices provide a route for in situ control of emission. Here, we discuss electrical tuning of the electroluminescence from the electrostatically-induced interface of gate-defined monolayer WSe2 p–n diodes. We observe strong linear polarization (~50%) of the electrically-pumped luminescence and a gate-tunable emission energy shift originating at this interface. Current-induced valley polarization, a possible avenue to achieving electrically-controlled circularly polarized emission, is also investigated with spatially-resolved Kerr rotation at cryogenic temperatures.

*Work supported by the Office of Naval Research (N00014-16-1-3055).
12:27PM L55.00007: Characterizing the low doping regime and charge fluctuation in graphene using Raman spectroscopy.*  
ZHUOFA CHEN (Presenter), NATHAN JEAN CARL ULLBERG, DAVID BARTON, ANNA K SWAN, Department of Electrical and Computer Engineering, Boston University — Graphene without charge impurities is essential for high-quality transport-based devices. Here we propose using Raman spectroscopy, as opposed to labor-intensive transport measurements, to monitor low-level accidental doping and charge fluctuation in graphene. At low doping level, monitoring the 2D band splitting reveals a whole host of information on charge density screening in graphene [1]. This method provides orders of magnitude higher precision than the reported results using the G-band shift. Our work provides a simple, noninvasive way to explore doping levels and charge fluctuation in graphene, which is important to evaluate the quality of graphene before fabricating graphene-based devices.

*This work is supported by NSF DMR grant 1411008

12:39PM L55.00008: Low-Temperature Interfacial States of MoS2-Pentacene Heterojunctions*  
TEODOR STANEV (Presenter), TREVOR LAMOUNTAIN, VINOD SANGWAN, HADALLIA BERGERON, MARK HERSAM, NATHANIEL STERN, Northwestern University — Layered 2D materials such as transition metal dichalcogenides are fundamental components for building more complex heterostructures using organic molecules, nanostructures, or other layered materials. Organic thin film solids of pentacene, a well understood polycyclic aromatic hydrocarbon used commonly for photovoltaics and thin-film FETs, has been used to form mixed dimensional p-n heterojunctions with 2D MoS2, wherein the type II band alignment leads to ultrafast hole transfer across the junction. Here, we report low temperature optical spectroscopy showing distinct optical features that emerge in the pentacene-MoS2 heterostructure. We observe the quenching of pentacene singlet/triplet-emission and of MoS2 defect photoluminescence as well as the emergence of a narrow emission feature at low temperatures. The power dependence and lack of response to local back-gating suggest these effects are not from charge doping or bound excitons. These results demonstrate the diverse control over opto-electronic properties obtainable by combining low-dimensional materials.

*Work supported by the NSF MRSEC program (DMR-1720139).

12:51PM L55.00009: Engineering photoluminescence in thin-layer WSe2 by ionic gating*  
LEI LIU (Presenter), Department of Materials Science and Engineering, College of Engineering, Peking University, ERIK J. LENFERINK, Department of Physics and Astronomy, Northwestern University, GUOHUA WEI, Applied Physics Program, Northwestern University, TEODOR STANEV, NATHANIEL STERN, Department of Physics and Astronomy, Northwestern University — Electron-double-layer gating with ionic liquid introduces extreme doping level, compared with the conventional solid dielectric approach. For transition metal dichalcogenides (TMDCs) atomic crystal, ionic gating has been demonstrated as a powerful tool to tuning the lattice and electronic properties, e.g., the transition between the 2H and 1T’ phase of MoTe2 and Ising superconductivity in MoS21,2. The tuning of TMDCs’ optical properties by ionic liquid gating so far has remained largely unexplored. Here we show the voltage-tunable photoluminescence (PL) of monolayer and bilayer WSe2 in the ambipolar devices. With the Fermi level sweeping from the conductance and valence band, the PL strength varies continuously (down to zero) and the valley polarization can be controlled, while the Raman results reveal no phase transition. The emission from indirect optical transition can be enhanced by applying appropriate gating in bilayer WSe2. The efficient electrical tuning of thin-layer TMDC photoluminescence opens new possibilities for the opto-electronic functional devices.

*This work is supported by the ONR (N00014-16-1-3055), the NSF MRSEC program (DMR-1720139), and the U.S. DOE (BES DE-SC0012130).
1:03PM L55.00010: Rapid and High Sensitivity Imaging of Two-dimensional Materials by Stimulated Raman Scattering Microscopy*  
JIWEI LING (Presenter), XIANCHONG MIAO, MINBIAO JI, Fudan University — 
Raman microscopy has been widely used to characterize phonon vibration in two dimensional materials. It enables us to gain insight into the information of sample thickness, doping and strain effect. However, Raman mapping by spontaneous Raman microscopy is often hindered by limited sensitivity and imaging speed. Here, we bring the stimulated Raman scattering (SRS) for the first time in characterizing two dimensional hexagonal-boron nitride. We found that SRS offers background free and greater sensitivity imaging than spontaneous Raman scattering (SR), second harmonic generation (SHG) and four-wave-mixing(FWM). The SRS signal shows good linearly dependence on layer number. What is more, it enables rapid imaging that is thousand times faster than SR mapping. Our result shows great potential of SRS in the study of two dimensional materials.

1:15PM L55.00011: Electrostatic control of exciton flux in van der Waals heterostructures  
DMITRII UNUCHEK (Presenter), ALBERTO CIARROCCHI, AHMET AVSAR, Ecole polytechnique federale de Lausanne, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, ANDRAS KIS, Ecole polytechnique federale de Lausanne — Large exciton binding energy in recently discovered two-dimensional semiconductors makes exciton physics accessible even at room temperature in these materials. Particular interest has been given to the interlayer excitons in van der Waals heterostructures based on transition metal dichalcogenides (TMDCs) with type-II band alignment. Whereas individual two-dimensional materials have short exciton diffusion lengths, the spatial separation of electrons and holes in different layers in heterostructures increases exciton lifetime and thus helps to overcome this limitation. In addition, this charge separation realizes built-in out-of-plane electric dipole moment, allowing exciton manipulation via an external electric field, showing promise for next-generation photonic devices relying on excitonic effects. Here, we present van der Waals devices made of TMDCs heterostructures encapsulated in h-BN with graphene control gates, which allow us to manipulate exciton dynamics by creating electrically reconfigurable potential profiles for the exciton flux. Our excitonic device demonstrates electrically controlled transistor actions at room temperature, that holds great promise for realizing small and efficient interconnects between optical data transmission and electrical processing systems.

1:27PM L55.00012: Directional coupling of valley exciton emissions from monolayer MoS2 on periodic plasmonic nanostructures  
CHIEN-JU LEE (Presenter), CHIH-LUN WU, LI-SHUAN LU, WEN-HAO CHANG, Department of Electrophysics, National Chiao Tung University — The unique coupled spin-valley physics in two-dimensional (2D) transition metal dichalcogenides (TMDs) has triggered abundant research activities in realizing valleytronic applications. Due to the valley contrast optical selection rule, excitons in monolayer TMDs formed at two degenerate but inequivalent K and K' valleys can couple to light with different helicities. Here, we demonstrate the spatial separation of valley-polarized excitons at room temperature by coupling monolayer MoS2 with the surface plasmon polariton (SPP) of a periodic metallic structures. Due to the spin-orbit coupling of light, the SPP waves excited by exciton emissions with opposite helicities interacting with the periodic metallic structures can be separated into different directions. When the exciton emissions are on resonance with the SPP modes, we observe the valley-dependent directional coupling of exciton emissions in both real and momentum space by polarization-resolved photoluminescence imaging. Our results demonstrate a route for controlling and detecting the valley polarization of TMDs by optical means.
1:39PM L55.00013: Generating Strain in 2D Materials using Microelectromechanical Systems*  MOUNIKA VUTUKURU (Presenter), JASON W CHRISTOPHER, ZHUOFA CHEN, DAVID JOHN BISHOP, ANNA K SWAN, Boston University — 2D materials are unique in that many of their material properties, such as doping and band-gap, are dynamically tunable. Strain engineering is a promising way to access and tune their electronic properties. We integrate 2D materials with MEMS technology which offers tremendous control over the strain field and is readily compatible with modern electronics. We have previously achieved success in straining MoS2 to 1.3% using MEMS [1]. Here we report on the use of electrothermal MEMS actuators to uniaxially strain monolayer graphene, as confirmed through micro-Raman spectroscopy. This was achieved through the development of gold micro-riveting to anchor the 2D material in place. We also examine two terminal electrical transport through MEMS-strained graphene. The application of controlled strain using MEMS therefore allows for the investigation of electrical and mechanical interplay in strained 2D materials, opening the door to the development of strain-based 2D electronics.

Session L60 FED FGSA: Launching a Successful Career as a Physicist  BCEC 258A - Chuhee Kwon, Cal State Unv- Long Beach - Tag(s): Careers, Education , Industry, Invited, Undergraduate

11:15AM L60.00001: Launching a Successful Legal Career as a Physicist?  [Invited]  LARISSA BIFANO (Presenter), DLA Piper — Physics degree holders are highly employable in a variety of settings. With a physics training, a potential hire has acquired a broad problem-solving skill set that translates to almost any environment, as well as an ability to be self-guided and -motivated so that they can learn the skills are needed to achieve. Patent law presents an interesting opportunity for physicists to apply their technical skills to the legal field. As a patent lawyer, you have the opportunity to work with researchers, innovators, start-ups, and large Fortune 500 companies to protect their ideas with patents, and potentially enforce those patents against competitors.

11:51AM L60.00002: Transitioning from Physical Science to Data Science  [Invited]  CHRIS RYAN (Presenter), TrialSpark — In the past decade, data science has emerged as an indispensable part of many engineering organizations at technology companies. Physical scientists have a great background for this kind of work, and this has been appreciated since this still-evolving role was originally defined. Expectations for the role have continued to clarify and can differ from company to company—from product feature experiments, focused analytics work, open-ended research projects, machine learning feature development, to all of the above and more. This talk will focus on how to efficiently overcome the possible hurdles faced when making this transition. I will talk about what to do and what to avoid when leveraging your research experiences, skills to know and learn, resume and interview tips, what to look for in job descriptions, what "data science" means at different kinds of companies, and other topics. I will also discuss examples of recent projects I have worked on as a data scientist at a healthcare startup.

12:27PM L60.00003: Why I Teach: High School Physics Teaching as a Career  [Invited]  AARON OSOWIEKI (Presenter), Science, Boston Latin School — What can you do with a degree in physics? You can teach others about the joy in understanding the world around them. Teach students how to think critically and solve problems. Come to this session to learn why I became a physics teacher and you should to.

1:03PM L60.00004: What do physics students need for career success? Findings from the Phys21 report*  [Invited]  LAURIE MCNEIL (Presenter), University of North Carolina at Chapel Hill — In October 2016 the Joint Task Force on Undergraduate Physics Programs published a report, Phys21: Preparing Physics Students for 21st-Century Careers. Based on information supplied by employers of physics graduates in the private sector and in government laboratories as well as in academia, the report summarizes the knowledge and skills that physicists need to succeed in a wide range of contemporary careers. In this presentation I will discuss those findings as well as ways in which students can prepare themselves for successful careers and how physics departments can help.

*The preparation of the Phys21 report was supported by the NSF under grants DUE-1540570 and -1540574.
1:39PM L60.00005: The Value of Curiosity [Invited] JOSEPH DAY (Presenter), Research, Bridgewater Associates — As physicists we are all driven by a deep curiosity to better understand the world. In this talk I'll share how curiosity has taken me on a journey from a public high school in Los Angeles, to a particle physics PhD, Stanford, the Ivy League, and the world's biggest hedge fund.

Wednesday, March 6, 2019 11:15 AM - 2:15 PM

Session L62 DAMOP: Topological and Non-Hermitian Photonics BCEC 258C - Wladimir Benalcazar, Pennsylvania State University - Tag(s): Invited

11:15AM L62.00001: Topological Photonics [Invited] MARIN SOLJACIC (Presenter), Massachusetts Institute of Technology — TBD

11:51AM L62.00002: Nontrivial topology from simple photonic structures [Invited] SHANHUI FAN (Presenter), Stanford University — Within the emerging area of topological photonics, which seeks to discover novel topological physics effects in photonic systems, much of the efforts have been devoted to discover non-trivial topology in photonic band structures. On the other hand, there are also interesting topological effects in other aspects of photonics. In this talk, as one of the examples, we discuss the non-trivial topology that arises from the dependency of the scattering matrix of a photonic crystal slab on the angles of incidence. We show that these scattering matrices can exhibit non-trivial topology, which leads to complete polarization conversion, as well as the capability for generation of arbitrary polarization by varying only the input angles. Being topological, these effects are robust to frequency variation, and thus is naturally broad-band.

12:27PM L62.00003: Exceptional points, coherent perfect absorption and disorder scattering in non-Hermitian media* [Invited] STEFAN ROTTER (Presenter), Institute for Theoretical Physics, Vienna University of Technology (TU Wien) — In my talk I will discuss the physics of exceptional points (EPs) and how encircling them creates a robust and asymmetric switch between the two resonant modes that meet at such an EP. In particular, I will focus on the topological aspects of this state transfer protocol that has meanwhile been implemented in a number of different experimental setups [1-3]. I will then point out that EPs can not only be obtained by merging two resonant states, but also by the coalescence of two S-matrix zeros giving rise to a perfect chiral absorber [4]. By studying the movement of such perfectly absorbing S-matrix zeros in a disordered system, we recently achieved the first experimental demonstration of a "random anti-laser" - a disordered system that perfectly absorbs a suitably shaped incoming wave state [5]. If time permits, I will also report on scattering states in disordered media with constant intensity and perfect transmission [6]. Implementing these states using several loudspeakers with gain and loss allows us to steer an incoming sound wave across a strongly disordered waveguide without any reflection or variation in its pressure [7].

*We acknowledge funding by the Austrian Science Fund (FWF) through project numbers SFB-NextLite F49-P10 and I 1142-N27 (GePartWave).

1:03PM L62.00004: Topological photonics in open systems [Invited] BO ZHEN (Presenter), University of Pennsylvania — Topological order has raised great research interests in optical systems over the past years, while most of the efforts have been focused on closed and lossless (Hermitian) systems. Here, I will present some of the recent progresses in studying topological states in optical systems with open boundary conditions. On the one hand, radiation losses in these non-Hermitian systems give rise to new topological states that are not possible in Hermitian ones. On the other hand, the concept of topological invariants gives us new means to control the radiation fields, both in their amplitudes and polarization states.
Photonic Topological Insulators in Synthetic Dimensions

Topological phases enable protected transport along the edges of materials, offering immunity against scattering from disorder and imperfections. These phases were suggested and demonstrated not only for electronic systems, but also for electromagnetic waves, cold atoms, acoustics, and even mechanics. Traditionally, the underlying model of these systems is a spatial lattice in two or three dimensions. However, it recently became clear that many lattice systems can exist also in synthetic dimensions which are not spatial but extend over a different degree of freedom. Thus far, topological insulators in synthetic dimensions were demonstrated only in cold atoms, where synthetic dimensions have now become a useful tool for demonstrating a variety of lattice models that are not available in spatial lattices. Recently, efforts have been directed towards realizing topological lattices with synthetic dimensions in photonics, where they are connected to physical phenomena in high-dimensions, interacting photons, and more. We will describe our recent results demonstrating experimentally the first photonic topological insulator in synthetic dimensions. The ability to study experimentally photonic systems in synthetic dimensions opens the door for a plethora of unexplored physical phenomena ranging from PT-symmetry, exceptional points and unidirectional invisibility to Anderson localization in high dimensions and high-dimensional lattice solitons, topological insulator lasers in synthetic dimensions and more. Our study here paves the way to these exciting phenomena, which are extremely hard (if not impossible) to observe in other physical systems.

Session L69 CSWP: Creating Inclusive Environments for Working and Learning

Tag(s): Diversity, Invited

11:15AM L69.00001: Sexual Harassment Reported by Undergraduate Women in Physics*

LAUREN AYCOCK (Presenter), AAAS Science & Technology Policy Fellow, Department of Energy, ZAHRA HAZARI, STEM Transformation Institute, Department of Teaching & Learning, and Department of Physics, Florida International University, ERIC BREWE, Department of Physics and School of Education, Drexel University, KATHRYN B. H. CLANCY, Department of Anthropology, University of Illinois at Urbana-Champaign, THEODORE W HODAPP, RENEE MICHELLE GOERTZEN, American Physical Society APS — Sexual harassment occurs frequently in male-dominated fields including physics which is more male-dominated than most other science, technology, engineering and mathematics (STEM) fields. I will present results on the incidence of sexual harassment and its impact on our sample of women in physics. Our work focused on undergraduate women, who attended a conference for undergraduate women in physics, and took an online post-conference survey. Approximately three quarters (74.3%; 338/455) of survey respondents experienced at least one type of sexual harassment in physics. We find that more frequent/less severe types of sexual harassment predict a negative sense of belonging and exacerbate the imposter phenomenon. Prior work has found that sense of belonging and the imposter phenomenon are related to students' persistence in STEM fields. Our results have implications for understanding and improving persistence in physics. Informing the community about the occurrence of sexual harassment in physics can enable work toward reducing its occurrence and mitigating its impact.

11:51AM L69.00002: An honest look at why women are underrepresented in competitive technical leader roles; strategies to create inclusive environments to bridge the gap

JOANNA PERKINS (Presenter), Intel Corporation — In this talk I will share my insight on key practices that have helped to create inclusive environments at each stage of my career: studying undergraduate Physics at a small liberal arts college, teaching high school Physics in the Mississippi Delta, completing my Physics PhD at a large university, and finally in an extremely competitive Technology Development career in industry. Attendees should walk away with strategies for navigating career opportunities in all sectors and ideas to help build strong communities for women in technical roles.
Inclusion, Equity, and Program Improvement with the APS/AAPT Guide to Effective Practices in Physics Programs (EP3)

Courtney Lannert (Presenter), Smith College — In light of the numerous challenges faced by Physics programs in the United States, along with feedback from the physics community, the Council of the American Physical Society formed a national blue-ribbon task force charged with creating a living guide to equip undergraduate physics programs to address these challenges. Developed in partnership with AAPT, the Effective Practices for Physics Programs (EP3) Guide will assist physics programs nationwide by providing a practical set of practices, approaches, and tools deemed effective by the community or informed by current research. Topics covered by the Guide span the areas of curricula, pedagogy, mentoring, recruitment, retention, career/workforce preparation, resources, and faculty professional development. Considerations of inclusion and equity are woven throughout the Guide and also appear as stand-alone sections within the Guide to motivate broader discussions of inclusion.

The work of the task force is underway and the first release of the Guide is expected in Spring 2020. This talk will outline and introduce the Guide, highlighting how it can be an effective tool for individuals and departments to improve their programs by adopting practices that are inclusive and equitable.

Creating environments where women of color can thrive

Angela Johnson (Presenter), St. Mary's College of Maryland — I have been exploring where women of color complete physics degrees. Despite the fact that women of color (Black, American Indian, Asian and Asian American women and Latinas) are clustered in women's colleges and minority-serving institutions, most women of color nonetheless study physics at large, predominantly White institutions where they are deeply isolated. Thus, it is imperative that all physics professors know how to create departments where women of color can thrive.

I will begin with some theory to help understand the experiences of women of color in physics, including intersectionality and implicit bias. Next I will present data about the extreme under-representation of women of color in physics and patterns in where they are completing physics degrees. I will also present what little is known about these women's typical experiences, which, unfortunately, are often discouraging and alienating.

Next, I will describe the findings from an ethnography I conducted at a physics department where women of color reported a strong sense of belonging. I will describe typical student experiences in this department (for all students, not just the women of color) and then pinpoint the actions taken by physics faculty that I believe created this positive environment. Typical experiences of the women of color (and all students, for that matter) include having a lot of friends among physics majors, feeling comfortable asking other students for help, and trusting their professors for help both with physics and with handling racism and sexism. Typical actions by professors including insisting that students collaborate and support one another during group work and emphasizing that success in physics comes from hard work rather than innate ability.

*This research was funded in part by NSF IUSE grant #1712531, “Centering Women of Color in STEM: Identifying and Scaling Up What Helps Women of Color Thrive.”

Gender Research in PER: A Binary Past and Complex Future

Ramon S Barthelemy (Presenter), EAB — Gender research in physics education research (PER) has become common in the last three decades. This work, however, has focused heavily on the differences between men and women in introductory physics courses. Known as gender gap research, these studies create a deficit model comparing women to men, and do not account for other identities and factors. This talk will present a “gapless” study that upends this trend by focusing on the contextualized experiences of women in graduate physics and astronomy using qualitative interviews. Data will include an exploration of their gendered experiences through the forms of microaggressions and hostile sexism. A concluding vignette will show an example of “gapless” research using quantitative methods, focused on the experiences of transgender physicists.

Session L70 : Poster Session II (11:15am-2:15pm) BCEC Exhibit Hall - Tag(s): Poster

L70.00001: POLYMER PHYSICS —
L70.00002: Thermal Properties of Polyvinyl Alcohol by Fast Scanning Calorimetry

DAVID THOMAS, Physics and Astronomy, Tufts University, EVGENY ZHURAVLEV, ANDREAS WURM, CHRISTOPH SCHICK, University of Rostock, PEGGY CEBE (Presenter), Physics and Astronomy, Tufts University — Polyvinyl alcohol crystallizes from the melt so rapidly that it is difficult to obtain fully amorphous glassy polymer. To study thermal properties of fully amorphous PVA, we use fast scanning calorimetry (FSC) to heat and cool at rates ranging from 1000 K/s up to 600,000 K/s. We determine the critical cooling rate, $\beta_c$, needed to quench PVA from the melt into an amorphous glass as $|\beta_c| = 20,000$ K/s. Using FSC in combination with conventional differential scanning calorimetry (DSC), we evaluate the temperature dependent liquid state heat capacity, $c_p^{\text{Liquid}}(T) = (0.0016 \pm 0.0002^* T + (2.3 \pm 0.2)) J/(gK)$. The specific heat capacity increment at $T_g$ for fully amorphous PVA is $\Delta c_p^{\text{amor}}(T_g) = (1.005 \pm 0.002) J/(gK)$. For the semi-crystalline samples used in this study, PVA obeys a two phase model in which the rigid amorphous fraction, $\varphi_{RA} \sim 0$. The approaches used in this work are applicable to any semicrystalline polymer or biopolymer which degrades upon heating, or crystallizes so rapidly from the melt that a fully amorphous material cannot be realized at conventional DSC rates.

L70.00003: A new concept of electrodes for ambipolar carrier injection in organic semiconductors

KATSUMI TANIGAKI (Presenter), THANGAVEL KANAGASEKARAN, WPI-AIMR, Tohoku University, SYUN ONUKI, TAIKI MIURA, HIDEKAZU SHIMOTANI, Department of Physics, Graduate School of Science, Tohoku University — Organic semiconductors (OSCs) have attracted much attention for low cost, flexible and human friendly optoelectronics. However, achieving high electron injection efficiency is difficult from air stable electrodes and cannot be equivalent to that of holes. Here, we present a novel concept of electrode composed of a bilayer of tetratetracontane (TTC) and polycrystalline organic semiconductors (pcOSC) covered by a metal (M) thin film layer. Field effect transistors of single crystal organic semiconductors (scOSCs) with the new electrodes of M/pcOSC/TTC (M: Ca or Au) show both highly efficient electron and hole injection. Contact resistances of electron and hole injection from Ca/pcOSC/TTC and Au/pcOSC/TTC are fascinatingly lower than those from pure Ca for electrons and Au for holes, respectively. Equivalent high field effect mobilities of holes (22 cm$^2$V$^{-1}$s$^{-1}$) and electrons (5.0 cm$^2$V$^{-1}$s$^{-1}$) can be observed in a rubrene single crystal, which are the highest among field effect transistors so far proposed. Highly efficient light emission will be demonstrated via amipolar carrier injection.

L70.00004: Water-Mediated Mixed Ionic-Electronic Conduction in Polythiophene-Derived Polyelectrolytes

GARRETT GROCKE (Presenter), BAN DONG, SHRAYESH PATEL, Institute for Molecular Engineering, University of Chicago — Conjugated polyelectrolytes that can conduct both ionically and electronically are attractive candidates for next-generation electrochemical devices, yet little is known about the impact of polymer processing and morphology on mixed conduction characteristics. This work reports the influence of water on the structure and conduction of poly[3-(potassium-n-alkanoate) thiophene-2,5-diyl]s (P3KnTs) in thin film. These materials were found to be highly resistive under anhydrous conditions but exhibited mixed ion-electron conduction as a function of increasing relative humidity. UV-Vis-NIR measurements provide evidence for water-assisted formation of alkanoate-anion-stabilized polythiophene bipolaron states and thus electronic conductivity, wherein dissociation of potassium-alkanoate bonds leads to the enhanced ionic conductivity. Additionally, using in-situ humidified scattering experiments, it was shown that increasing side-chain stacking distance coincides with the improvement in ionic conductivity as a function of relative humidity, suggesting that ionic transport occurs through regular pathways formed by the flexible side-chains. Our results show strong influence of water on mixed ion-electron conduction characteristics of conjugated polyelectrolytes in undoped conditions.
In this study, focusing on polymer / fullerene-free type PTB7 / ITIC complex, we obtain the electronic structure of complex and absorption spectrum at donor / acceptor interface using time dependent density functional theory method. In addition, from the viewpoint of electronic structure, absorption spectrum, and HOMO–LUMO gap, we consider the mechanism of charge transfer in polymer / fullerene-free type organic solar cell.

We compared the amounts of D/A transition contribution in absorption spectra, charge transfer (CT) and CT distance of the PTB7/ITIC complex with those of the fullerene PTB7/PC71BM complex. It turns out that any of these quantities were larger for the former. In addition, PCE is reported to be larger for fullerene-free OSC than for fullerene OSC and to be higher when CT distance becomes longer in fullerene OSC. Therefore, we have found that the CT distance is a descriptor for assessing PCE in the fullerene-free type OCS as well.

L70.00007: Excimontec: An Open-Source Software Tool for Kinetic Monte Carlo Simulations of Organic Electronic Devices* MICHAEL HEIBER (Presenter), Center for Hierarchical Materials Design, Northwestern University — Kinetic Monte Carlo (KMC) simulations are a powerful computational tool that have been used in concert with experiments and theory to understand and optimize organic semiconductor devices. However, despite over 30 years of applying KMC simulations to organic semiconductors, no standardized software tools have emerged. Instead, many research groups around the world have maintained private codebases of varying complexity, efficiency, and reliability. As a result, there have been large barriers to entry for new researchers and a lot of repetitious efforts that would be much better off applied to further refining the physical models. Excimontec is a new well-tested, reliable, and accessible open-source software tool for performing KMC simulations of organic electronic devices, and this presentation will highlight some of the main features currently available, including time-of-flight charge transport simulations, excited state dynamics simulations, and internal quantum efficiency simulations.

*Financial assistance award 70NANB14H012 from U.S. Department of Commerce, NIST as part of the Center for Hierarchical Materials Design (CHiMaD).

L70.00008: Variable Resolution Coarse-Graining of Ion-Coupled Electron Transport in Electrochemically Active Polymers BRET SAVOIE (Presenter), Purdue University — Conducting polymers that exhibit reversible mass and ion exchange with aqueous media have potential for sensing applications when implemented in organic electrochemical transistors (OECTs). However, the degree to which ion motion is coupled with electron transport and morphology changes, and the range of polymer chemistries that can exhibit and be optimized for electrochemical response in aqueous media is unknown. To address these challenges we have developed the first variable resolution model of hydrated PEDOT:PSS, the archetypical electrochemically active system, with several simple salts. Using this variable resolution model we are able to characterize both long-timescale morphology reorganizations and the corresponding short-timescale evolution of the conducting polymer electronic structure and develop design rules for optimal doping and hydration levels in PEDOT-based systems. The generality of this approach creates an opportunity to establish to what degree PEDOT:PSS is representative of other OECT polymers and address the lack of materials diversity in OECT applications.
Absorption enhancement in evanescently-coupled waveguides

In this project the main goal is to construct various thin films of different thicknesses of CYTOP and PMMA in a glass substrate using the spin coating. A glass, CYTOP and PMMA substrate was proposed. Although this substrate was bio-imaging oriented in order to enhance resolutions and get better signals when working with bio-samples, is also a good platform for luminescence cooling. In a Matlab simulation, we find that the best thicknesses that will enhance the electrical field on the films surface at a resonant angle between 65-70 degrees are ~600-750 nm and ~350-450 nm, respectively. Then, Glass/CYTOP/PMMA substrate were successfully spin-coated with an optimal thickness achieved between ~700nm (for CYTOP) and ~400nm (for 1wt% of Lumogen Red L305 with PMMA). Photoluminescence (PL) spectra was enhanced and absorption is stronger on thicker films. The reflectivity spectrum shows that the resonant angle was ~47 degrees. The idea of cooling a solid-state optical material by simply shining a laser beam onto it, the advantages of compactness, the absence of vibrations and moving parts or fluids, high reliability and the ability to operate without cryogens is rapidly becoming a promising technology for future cryocoolers.

Optical Super-Resolution Imaging of Block Copolymer Thin Film Surface Morphology Using Fluorescent Silica Nanoparticles

Block copolymers (BCPs) are of tremendous academic and industrial interest, as they exhibit myriad tunable properties useful across a broad range of applications. This is particularly true for BCP thin films. Traditionally, imaging mesostructured BCP surfaces of such films has been dominated by electron and scanning probe microscopies. In recent years, however, high-resolution optical imaging in the far field has provided exciting opportunities for alternative approaches. Here, we report the optical super-resolution imaging of BCP thin film surface mesostructure through stochastic optical reconstruction microscopy (STORM). To that end, we introduce a new class of functionalized silica nanoparticles to enhance the brightness of encapsulated dyes for STORM, offering distinct advantages over conventional sample labeling with organic dyes. These nanoparticles are simply mixed with or attached to specific blocks of the BCPs, thereby enabling selective block staining and optical visualization. This allows for facile imaging of morphological features on the near-molecular scale, thus providing a versatile method for BCP surface morphology assessments using optical imaging.

Ion transport properties of block copolymer electrolytes comprising mixed ionic liquids

Ionic conductivity and mechanical properties of block copolymers comprising various ionic liquids has been extensively studied lately to develop future solid-state polymer electrolytes. It has been found that the independent control of cation and anion in ionic liquid can improve ion transport properties of such materials given that the type of cation and anion determines swelling behavior of ionic domains and interfacial properties of ionophilic/ionophobic phases. In the present study, we investigate ion transport properties of block copolymers comprising different ionic liquids. In particular, by employing mixed ionic liquids, markedly improved ionic conductivity was obtained, far higher than simple sum of known values. The results were understood by dissimilar ion distributions in the substructure of self-assembled morphology, as quantified by combining scattering and spectroscopy techniques.

Nanofabrication for Probing Ionic Conductivity Mechanisms in Thin-Film Polymer Electrolytes

These devices are fabricated so that a percentage of the trenches, which model the conducting pathway of a BCP, are blocked by additional SiO₂. A PEO/LITFSI solution is spincoated and reflowed onto the devices then measured using AC impedance spectroscopy to calculate the conductivity. We report a decrease in conductivity with increasing percent hindered pathways. By eliminating the effects of grain boundaries and interfacial blurring between blocks of a block copolymer, this study elicits a direct relationship between structure and conductivity.
L70.00013: Ion Transport in Polymer Blend Electrolytes* BILL WHEATLE (Presenter), VENKATRAGHAVAN GANESAN, University of Texas at Austin — In conventional small-molecule battery electrolytes, high ionic conductivity is achieved through blending of high polarity and low viscosity components. One may simply assume that the conductivities of these blended electrolytes will be an average of the intrinsic conductivities of each host, each of which is weighted by its volume fraction. However, it has been shown that the ionic conductivity is instead a nonmonotonic function of the volume fraction of each host, maximizing at some intermediate blend composition.

Inspired by these results in small molecule electrolytes, we hypothesize similar nonlinearities may occur in polymeric blend electrolytes. In this work, we seek to examine the effect of blending polymeric hosts by using the Stockmayer polarity model in a coarse-grained molecular dynamics framework, which we have previously used to describe the role of host polarity on ionic conductivity. We first investigate the role of host polarity contrast (measured by the difference in monomeric dipole strength) and blend composition on blend phase stability and segmental dynamics. We then correlate these properties with the resultant ionic conductivities of these electrolytes.

*The authors acknowledge the Welsh Foundation and the National Science Foundations for funding this work.

L70.00014: Simultaneous Transient Gel Behavior and Multivalent Ionic Mobility in Polymeric Ionic Liquid-Ligand Gels* SEAMUS JONES (Presenter), Department of Chemical Engineering, University of California, Santa Barbara, NICOLE MICHENFELDER-SCHAUSER, Materials Department, University of California, Santa Barbara, GLENN FREDRICKSON, RACHEL SEGALMAN, Department of Chemical Engineering, University of California, Santa Barbara — Polymeric ionic liquids form labile metal-ligand bonds with cations to delocalize and conduct multivalent metal ions in the solid state. These multifunctional interactions transiently cross-link the polymer network, leading to dramatic enhancements in the storage modulus on some timescales. Correlating the relationship between metal-ligand interaction energies, timescales, and continuum-level mechanical and conductivity properties leads to design rules for multivalent ion-conductive polymers. Oscillatory rheology experiments are used to elucidate metal-ligand coordination timescales while ionic conductivity measurements are used to both understand the timescale of crosslink motion and the mechanism of ion motion in a telechelic poly(methyl acrylate) with imidazole endgroups.

*This work was supported by the MRSEC Program of the National Science Foundation under Award DMR 1720256 (IRG-2).

L70.00015: Mechanism of pattern formation in polymer ionic liquid blends under the influence of an electric field* VANDANA RAJPUT (Presenter), ANUBHA AGRAWAL, PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology Gandhinagar — Formation of controllable self-assembled patterns in soft materials can be used to design a variety of multifunctional materials with tunable properties. Here, we utilize unique properties offered by the blends of polymers and ionic liquids (PIL) to reveal the mechanism behind the formation of intricate morphological patterns that emerge in these blends in the presence of an external electric field (EF). In particular, we perform stability analyses to identify key parameters that can be used to lock a pattern of a particular wavenumber in PILs. In addition, we reveal that under the effect of an external stimulus, which in our case is the strength of the EF, both ordered and disordered phase morphologies can co-exist. We also show that the increased strength of EF in PIL system results in the formation of alternating layers of polymer-rich and IL-rich phases of different widths. The reason for this behavior is attributed to cation-anion, polymer-anion, and polymer-cation interactions present in the blends. Thus, the effect of EF can drive new patterns and allows the control of these patterns through wavenumber locking. We believe that our approach can be extended to a variety of soft matter blends containing constituents with stark different properties.

*IIT Gandhinagar
Gel polymer electrolyte membranes have many advantages over their liquid counterparts, such as high energy density and flexible geometry. However, one of the major challenges in using the polymer electrolytes is their low ionic conductivity at ambient temperature that limits their practical applications. The development of heterogeneous electrolytes, comprising ion-rich and ion-poor regions, has enabled the decoupling of electrical and mechanical properties. However, ILS possess delocalized charges and are composed of ionic species that are generally large and asymmetric. These characteristics hinder the formation of well-ordered ionic domains and result in low conductivity. The emerging challenge is how to design heterogeneous polymer electrolytes with different shapes of continuous nanochannels to maximize the decoupling of ionic conductivity and mechanical strength. We propose that this challenge can be addressed through the polymerization of mesophases of monomer, ionic liquid, and amphiphilic block copolymers. Our results show that high mechanical strength without sacrificing the ionic conductivity can be obtained by the mesophase templating method.

*This research is funded by NM NASA EPSCoR Research Infrastructure Development (RID), Grant No: NNX15AK41A.
MINJUNG LEE (Presenter), RYAN HAYWARD, Polymer Science and Engineering, University of Massachusetts Amherst — The formation of complex coacervates has been a subject of great interest in the field of charged polymers, with a focus almost exclusively on aqueous systems. Herein, we studied the phase behavior of two polymerized ionic liquids, namely poly(1-ethyl-3-methyl imidazolium (3-sulfopropyl) acrylate) and poly(1-(2-acryloyloxy-ethyl)-3-buthyl-imidazolium bis(trifluoromethane) sulfonimide), representing a polyanion and a polycation, respectively, in non-aqueous solutions. By controlling the concentration of the polymers and added salt composed of the two counterions, we studied the conditions for one vs. two phases, which provides useful information for further applications of polymerized ionic liquids, as well as providing an interesting comparison with the phase behavior of other charged polymers such as polypeptides and polysaccharides in aqueous media.

RITUPARNA SAMANTA (Presenter), VENKATRAGHAVAN GANESAN, University of Texas at Austin — We study the effect of pH of the solution on the structural characteristics of a system of weakly charged spherical particles in oppositely charged, dissociable polyelectrolyte solutions. The pH dependent dissociation of weak polyelectrolytes is known to affect the adsorption and bridging of polymers on the particles. We have used a hybrid method of single chain in mean field theory and the solution of general Poisson’s equation in a semi-grand canonical framework. We study the effect of charge of particles, volume fraction of particles and polymers, concentration of polymers on the structural characteristics of the suspension.

ALAN NAKATANI (Presenter), LYNDASY LEAL, NIHIL FERNANDES, KATHLEEN MICHELS, JENNIFER M KOENIG, CATHRYN JACKSON, Dow Chemical Company — Two sets of Hydrophobically modified Alkali Soluble Emulsion (HASE) polymers were investigated using steady shear viscosity and dynamic frequency measurements. One set of HASE polymers contained a fixed ratio of ethyl acrylate (EA) to methacrylic acid (MAA) and a hydrophobe (C12, C18, or C22) containing monomer (macromonomer). The second set of HASE polymers contained a fixed amount of MAA but the amount of C18 macromonomer was varied (1%, 5%, or 10% by mass). Aqueous solutions of the polymers (1% by mass) were tested at pH = 3, 5, 7 and 10. The neutralization process is known to impact the solution viscosity, therefore, samples “back-titrated” from pH = 10 to pH = 7 were also tested. The samples at pH = 3 and 5 had the lowest viscosities. Samples directly adjusted to pH 7 had a much higher viscosity and a yield stress, which increased with increasing hydrophobe size. The samples at pH = 10 had the highest viscosity and yield stress values. Samples back-titrated to pH = 7, were lower in viscosity than the samples directly adjusted to pH = 7. The dynamic frequency results at pH = 10 show additional characteristic timescales which shift as a function of the hydrophobe size.

SUPRIYA GUPTA (Presenter), PARESH CHOKSHI, Chemical Engineering, Indian Institute of Technology Delhi — Incorporation of nanofillers in polymer melt produces composites with extra-ordinary properties due to enhanced surface to volume ratio of the fillers. Fillers are functionalized by grafting polymeric chains on the surface inducing steric stabilizing preventing particle agglomeration. Here, we address the dispersion of clay nanosheets in polymer matrix. We use self-consistent field theory to theoretically construct the polymer mediated interparticle potential curve. The interaction potential is obtained from the inhomogeneous composition field for the polymer segments. First, we examine the interparticle interaction between two grafted nanosheets immersed in the matrix of polymeric chains of dissimilar chemistry to that of the grafted chains. The interaction potential is repulsive at short separation and shows depletion attraction for moderate separations. Further, we construct the interaction potential between two nanosheets grafted with polymeric chains of varying architectures, like star polymer and diblock copolymer. Nanosheets disperse better in the matrix of star polymer than linear polymer. In surfaces grafted with diblock copolymers, the interplay between the enthalpic and entropic interaction gives rise to a rich behavior in the interparticle interaction potential curve.
L70.00024: Novel Properties of Mesostructured Superconductors Synthesized via Block Copolymer Self Assembled Nanocomposites*  RANDAL THEDFORD (Presenter), SOL MICHAEL GRUNER, ULRICH WIESNER, Cornell University — The effect of mesoscale confinement or ordering on the properties of superconductors is an active area of study, but to date this work has largely been done using 2D materials. Three-dimensionally mesostructured superconductors are expected to behave very differently than their 2D or bulk analogues, but exploration of such materials has been limited by the lack of available methods for their synthesis. We demonstrate multiple routes to superconductors with mesoscale order and porosity though the self-assembly of block copolymer nanocomposites. This represents a versatile, robust, and tunable platform for the investigation of 3D mesostructured superconductors. Our results show changes in the superconducting properties of multiple materials when synthesized in block copolymer derived 3D periodic structures such as the bicontinuous double gyroid and the alternating gyroid, suggesting quantum metamaterials behavior.

L70.00025: In-Situ Monitoring Polymer-graft Functionalization on Gold Nanoparticles and Influences on Assembly Formation  YIWEN QIAN (Presenter), TING XU, Department of Materials Science and Engineering, University of California, Berkeley — Controlled assemblies of polymer grafted nanoparticles can lead to a unique class of material with distinct advantages due to the programmability and diversity endowed from polymer-based-ligands. Surface functionalization of nanoparticles (NPs) with polymer-based ligands plays a critical role in controlling the effective size and ‘interaction softness’. To this end, it is requisite to quantity the attached polymer ligands. Here we present the (in situ) proton nuclear magnetic resonance ($^1$H NMR) study on the ligand exchange of oleylamine by thiol end-functionalized polystyrene as a function of the ligand concentration and particle size on Au NPs. As the extensive overlap of the polymer ligands impede the direct evaluation, we examine the pristine chemical shifts of the oleylamine to characterize the ligand modification. We show that the surface functionalization efficacy depends on the ligand/particle ratio, size of NPs and molecular weight of the polymeric ligands. These quantitative studies enabled us to investigate the influences of the ligand modification and solvent quality on the ordering of the self-assembled polymer grafted nanoparticles with a focus on a polycrystalline assembly to hexagonally ordered superlattice transition.

L70.00026: Fabrication of polymer-brush modified Ba-Ti oxide/poly(vinylidene fluoride) nanocomposites thin film*  MAIKO NISHIBORI (Presenter), KOHEI NOSUE, AYUMI HAMADA, YUKO KONISHI, ATSUSHI TAKAHARA, Kyushu University — Polymer composite with high dielectric constant have attracted attention in the micro-electronic industry due to their easy-processing and low cost. In the composite thin film, the surface properties of the ceramics nanoparticle and the volume fraction of polymer to ceramics particles are quite important in order to increase in their functionality. In this study, the surface modification of Ba-Ti oxide nanoparticles (BT) with high-density poly-methyl methacrylate (PMMA) brushes was conducted to improve its dispersibility in poly(vinylidene fluoride) (PVDF) and the fabrication of nanocomposites thin film of PMMA-BT and PVDF was investigated. PMMA brushes on the surface of BT particles were fabricated by Atom Transfer Radical Polymerization with (2-bromo-2-methyl) propionyloxyhexyltriethxysilane as a silane coupling agent. PMMA-BT particles showed high dispersibility in PVDF-DMF and almost no voids and clacks were observed in the composite film of BT-PMMA mixed with PVDF even if the volume fraction of PMMA-BT particles was high to PVDF. The results indicated that the surface modification by polymer-brush could be a promising method to fabricate the composite film having good quality and high dielectric property.

L70.00027: Morphological behavior of ABC mikto-arm terpolymer with a C60*  
HYEYOUNG KIM, University of Massachusetts Amherst, MATTHIAS ML ARRAS, Oak Ridge National Lab, SERGEY CHERNYY, Technical University of Denmark, DUK MAN YU, University of Massachusetts Amherst, GREGORY S SMITH, Oak Ridge National Lab, THOMAS RUSSELL (Presenter), University of Massachusetts Amherst — We observed the morphological behavior of ABC mikto-arm terpolymer with a C60 additive. ABC mikto-arm terpolymers, consisting of polystyrene, polyisoprene and poly(2-vinylpyridine) (PS-PI-P2VP), with various P2VP volume fractions were examined. The role of C60 on the morphological behavior of mikto-arm terpolymer was studied by small angle X-ray scattering (SAXS) and transmission electron microscopy (TEM). The affinity of C60 to PS or P2VP was examined by neutron reflectivity. C60 can form charge-transfer complexes with electron donating pyridine groups in P2VP blocks. Before and after charge-transfer reaction, C60 showed different effects on the self-assembly of mikto-arm polymers. The domain spacing, interfacial width, and morphology of mikto-arm terpolymers were changed depending on the concentration of C60.

L70.00028: Desorption of Water Collected on Hygroscopic Polymer Nanofibers  
ZHIHAO SHANG, D RENEKER (Presenter), The University of Akron — The high surface area-to-mass ratio make nanofibers an optimal material structure for water absorption from humid ambient air. Water molecules were concentrated on the surface of hygroscopic nanofibers. Strong nanofibers withstood the forces from the flowing air that carried water molecules to within about 100 nm of the fiber surfaces. Nanofiber surfaces became saturated with water molecules. Microwave energy with frequency of 2.45 GHz caused rapid evaporation and formation of a bolus of steam in the air stream. The bolus was collected and the water condensed in an external condenser. Alternatively, high voltage DC was applied to two edges of a thin mat of hygroscopic nanofiber to evaporate water from the nanofiber mat. The apparatus provides a useful method to test water absorption ability of different hygroscopic nanofibers. It also provides other information needed to design large scale water collectors.

L70.00029: A Colloidal Model to describe the effects of mixing time on filler dispersion in industrial nanocomposites*  
VISHAK NARAYANAN (Presenter), KABIR RISHI, GREG BEAUCAGE, Chemical and Materials Engineering, University of Cincinnati, VIKRAM K KUPPA, Nonstructural Materials Division, University of Dayton Research Institute, ALEX MCGLASSON, MICHAEL CHAUBY, Chemical and Materials Engineering, University of Cincinnati — The properties of industrial nanocomposites such as tires depend on the degree of filler dispersion under high-shear mixing. Conventionally, the dispersion is quantified through an index based on the reduction in micron-scale agglomerate size observed in micrographs and bulk electrical conductivity measurements. An alternate nano-scale dispersion technique based on x-ray scattering has been proposed.1 The impact of mixing time on dispersion is investigated taking advantage of the van der Waals equation to describe excluded volume and interaction energy in the dispersion. Herein, an analogy is made between thermally driven true colloidal dispersions and total accumulated strain in nanocomposites. The excluded volume depends only on the filler type and seems insensitive to bound rubber whereas the interaction energy is strongly dependent on viscosity and polymer chemistry. Moreover, the wetting time for nano-scale incorporation of elastomer into filler can be predicted. The description of nano-scale dispersion via a pseudo- second virial coefficient offers the additional possibility of determining the interaction potential that can be used for coarse grained simulations.

Nafion Nanocomposite Fuel Cell Membranes for Improved High Temperature Performance

DONOVAN WEIBLEN (Presenter), KRISTA BIGGS, ALIANGNA MAGUIRE, Materials Science and Engineering, Rensselaer Polytechnic Institute, DENIZ RENDE, Center for Materials, Devices, and Integrated Systems, Rensselaer Polytechnic Institute, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — Proton exchange membranes represent an active area of fuel cell research. Current work seeks a membrane with excellent proton conductivity, minimal permeability of oxygen and fuel, and stable physical properties. At temperatures above 90 °C, traditional Nafion membranes experience decreased proton conduction, decreased water uptake, and softening. Although the performance is still being improved, addition of silica nanoparticles to Nafion membranes is known to improve conduction and water uptake at high temperatures. Recent work shows a new polymer nanocomposite system that stiffens repeatably and reversibly with increasing temperature via interfacial heterogeneous dynamics between a matrix polymer with low glass transition temperature (Tg) and high Tg polymer modifier adsorbed to silica nanoparticles. Studies were completed to investigate the applicability of this phenomena to Nafion using silane coupling agents to achieve improved high temperature performance. The effects of silica nanoparticle and grafted modifier concentration, and grafted chain structure and dynamics on Nafion nanocomposite structure and properties, particularly thermal stiffening, were studied.

Growth and Bulk Effects of Irreversibly Adsorbed Layers in Polymer Nanocomposites

KATELYN RANDAZZO (Presenter), RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — Recent studies have demonstrated that the formation of irreversibly adsorbed layers at the polymer-substrate interface can significantly affect the overall properties in thin films. However, little attention has focused on the polymer nanocomposites, where irreversibly adsorbed layer growth is expected to be an important parameter due to the amount of surface area and high temperature processing. In this work, we characterize the growth of irreversibly adsorbed layers of polystyrene atop silica nanoparticles, which we correlate to the resulting bulk properties of polystyrene-silica nanocomposites. Our approach compares bulk properties measured via traditional means such as DSC with a direct measurement of local properties achieved by fluorescence spectroscopy. We expect the characterization of irreversibly adsorbed layers and their bulk effects to be useful in engineering new polymer nanocomposite materials.

Biomimetic Nanocoatings with Exceptional Mechanical, Barrier, and Flame Retardant Properties from Large Scale One-Step Co-assembly

FUCHUAN DING, JINGJING LIU, LUYI SUN (Presenter), University of Connecticut — Large-scale biomimetic organic/inorganic hybrid nanocoatings with a nacre-like microstructure were prepared via a facile co-assembly process. Different from conventional polymer nanocomposites, such nanocoatings contain a high concentration of nanosheets, which can be well aligned along the substrate surface. Moreover, the nanosheets and polymer matrix can be chemically co-crosslinked. As a result, the nanocoatings exhibit exceptional mechanical properties (high stiffness and strength), barrier properties (to both oxygen and water vapor), and flame retardancy, but meanwhile they are highly transparent (maintaining more than 85% of their original transmittance to visible light). The nanocoatings can be applied to various substrates and regular or irregular surfaces (e.g., films as well as foams). Because of their excellent performance and high versatility, such nanocoatings are expected to find widespread application.
Metal-polymer nanocomposites are an interesting material class, which allows combining the superior plasmonic, electrical and thermal properties of metal-nanoparticles with the good processability of polymers. To achieve stable nanoparticles in a polymer matrix, the nanoparticle surface has to be modified with a polymer brush, which is commonly done by a ligand exchange approach.

By using Brillouin light scattering (BLS), we elucidate the nanomechanical properties of this hybrid material and combine these measurements with finite element modeling and thermography. We found a counterintuitive decrease of the speed of sound with increasing Ag content and a strong influence of the hybrid material composition. The mesoscopic order of this material can be varied drastically by thermal annealing going from a dispersed phase to a clustered state and back. Finally, the strong light absorption and thermalization of the Ag nanoparticles results in a pronounced local heating effect. Consequently, this thermoplasmonic heating can be used to change the acoustic and, therefore, mechanical properties locally.

Coassembly of binary nanoparticle systems  
JIULING WANG (Presenter), BRIAN LEE, GAURAV ARYA, Duke University — The spatial distribution of nanoparticles (NPs) in polymer nanocomposites plays a critical role in governing their mechanical and optical properties. Although there have been many studies focusing on the assembly of uniform-sized NPs in polymers, relatively few studies have investigated the coassembly of NPs of different sizes and surface properties. Using a lattice Monte Carlo approach, we investigated the morphology of heterogeneous NP structures assembled from NPs of different sizes and surface properties. Our results indicate that these particles assemble into networks with different pore sizes, fractal dimensions and local aggregation interfaces depending on the particle sizes and sticking probabilities between them. The effects of the initial distribution of NPs on the assembly will also be discussed. Our findings provide guidance for controlling NP assembly and could help us design nanocomposites with superior mechanical and optical properties.

Hybrid computer simulations of block copolymer/nanoparticle systems  
MARCO PINNA (Presenter), JAVIER DIAZ, Centre for Computational Physics, University of Lincoln, IGNACIO PAGONABARRAGA, Departament de Fisica Fonamental, Universitat de Barcelona, ANDREI ZVELINDOVSKY, Centre for Computational Physics, University of Lincoln — Polymer nanocomposites have been shown to display improved properties over their purely polymeric counterparts. Furthermore, block copolymers (BCP) are perfect candidates to control the localisation of nanoparticles. Nonetheless, the presence of nanoparticles can distort the BCP properties such as morphology and thus colloids act as more than just passive fillers. A systematic study of the co-assembly of block copolymers and nanoparticles is presented. Using a hybrid Cell Dynamic/Brownian Dynamic Simulation method we study the mesoscopic properties of the system. The phase behavior of the block copolymer after the inclusion of nanoparticles is studied, finding phase transitions along with the appearance of new phases due to the effect of colloids in the system [1]. Similarly, the nanoparticles are found to segregate within the block copolymer depending on chemistry, size and anisotropy. The conditions for the formation of aggregates is studied, both in the case of isotropic particles as in the case of anisotropic colloids (Janus, rods, squares, among others).

Influence of PVAc/PMMA/Silica Nanocomposite Structure on Properties

CHEN GONG (Presenter),
Materials Science and Engineering, Rensselaer Polytechnic Institute
DENIZ RENDE, Center for Materials, Devices and Integrated Systems, Rensselaer Polytechnic Institute
RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute —
Rheological properties of poly(vinyl acetate), PVAc, and silica composites were previously studied as a function of silica concentration and silica surface chemistry. In the current work, we investigate the effect of poly(methyl methacrylate), PMMA, coated silica nanoparticles on the properties of PVAc. PVAc and PMMA are known to form a miscible blend, however, the addition of silica nanoparticles, which forms hydrogen bonds with PVAc might alter the blend morphology and therefore, the blend properties. In addition, by selectively adsorbing PMMA onto silica nanoparticles first, and then embedding them into PVAc might lead to a phase separated interface at the nanoparticle surface. The morphology and rheological properties of PVAc/PMMA/silica nanocomposites were investigated as a function of composition and silica nanoparticle surface chemistry.

Energy dissipation of elastomer nanocomposites at large strains and high strain-rates

KEITH DUSOE (Presenter), ALFRED CROSBY, Polymer Science and Engineering, UMass Amherst — Characterization of the mechanical behavior of rubbery materials at high strain rates is a nontrivial challenge. Many of the physical properties of rubbers are strain-rate dependent and therefore necessitates the understanding of the high-strain rate response of rubbery materials. Current methods to characterize the mechanical properties of rubbers typical probe the material response under low strain-rate, quasi-static conditions or dynamic conditions at low strain. A highly strained rubber undergoes free retraction when the material is suddenly released from one end. The resulting speed of the retracting material can be very fast, approaching the speed of sound in the material, and is related to the material's molecular structure, modulus and internal friction. In this work, large strain, high strain-rate mechanical response of elastomer and elastomer-matrix nanocomposite materials are investigated by free retraction of highly-stretched samples. High-speed videos of rubber retraction are acquired and analyzed to characterize the mechanical properties of these materials at high strain rate, large strains. Furthermore, the role of filler-matrix interactions in elastomer nanocomposites in minimizing viscoelastic energy losses at large strain and high strain-rates are considered.

Nanoparticle Diffusion in Athermal And Attractive Entangled Polymer Melts

ERIC BAILEY (Presenter),
RUSSELL JOHN COMPOSTO, KAREN WINEY, Materials Science and Engineering, University of Pennsylvania — Understanding the mechanisms by which nanoparticles (NPs) diffuse in a polymer melt remains an experimental challenge. In this study, we combine Rutherford backscattering spectrometry (RBS) and X-ray photon correlation spectroscopy (XPCS) to probe the diffusion of (i) enthalpically attractive silica (SiO2) NPs in poly(2-vinyl pyridine) melts and (ii) athermal phenyl-capped SiO2 NPs in polystyrene melts. In both systems, RBS shows NP diffusion in reasonable agreement with recent theoretical predictions where the athermal NPs diffuse faster than the attractive NPs. XPCS show quantitative agreement with RBS in weakly entangled polymer melts but in well-entangled polymers, XPCS shows unexpected hyperdiffusive behavior that is not observed in RBS. Our direct comparison of these techniques probes NP diffusion between ~30 and 800 nm, isolates the effect of NP-polymer interaction, and highlights the different sensitivities and observations of these experimental methods.

The Study of Mechanical Property of Block Copolymer Composites Tuned by Nanoscale Polymeric Morphology and Nanoparticles

JUNPYO KWON (Presenter), ROBERT OLIVER RITCHIE, TING XU, University of California, Berkeley — The Understanding of structure-property relationships in block copolymer nanocomposites is one of the main challenges. Especially, the study of mechanical properties tuned by compositional and structural variables is significant to the applications of the nanocomposites. Here, we focus on the fundamental analysis with regard to the mechanical properties changed by the block copolymer morphologies, the volume fractions of nanoparticles and the strength of interactions between the polymeric matrix and fillers. In addition, we studied thermal annealing effects on the nanoscale structural rearrangements which link to the mechanical behavior changes.

L70.00041: Elucidating Synthetic Pathways in the Synthesis of Block Copolymer Self-Assembly Derived Mesostructured Nitrides with in situ Multimodal Synchrotron Characterization  PETER BEAUCAGE (Presenter), FRANCIS J DI SALVO, SOL MICHAEL GRUNER, ULRICH WIESNER, Cornell University — Block copolymer-inorganic hybrid co-assembly has recently emerged as a scalable, tunable route to crystallographically ordered, mesoporous, highly crystalline inorganics relevant to catalysis, energy conversion and storage, and other areas. The successful synthesis of these materials, however, often relies on heavily tuned thermal processing in order to crystallize a functional inorganic material without crystal growth-induced mesostructure collapse. For example, in our recent efforts to produce gyroidal niobium nitride (NbN) superconductors, a two-step thermal treatment process was needed with temperature sensitivity ca. ± 1%. To enable the rapid discovery and optimization of these synthesis routes, we developed an in situ apparatus capable of measuring small- and wide-angle x-ray scattering (SAXS/WAXS) during annealing at temperatures up to 1200°C in reactive gases. In a first application, we have explored the transformation pathways from block copolymer-oxide nanocomposite to nitride, resulting in the first synthesis of a mesostructured nitride from a Pluronics ABA block copolymer. We expect that this system will enable the rapid screening of a variety of block copolymer-derived oxide, nitride, and carbide materials with applications in catalysis, energy, and beyond.

L70.00042: Probing the Morphology of Hydrocarbon-Based Anion-Exchange Membranes via Scattering and Computational Methods*  ERIC SCHIBLI (Presenter), BARBARA J FRISKEN, Department of Physics, Simon Fraser University, STEVEN HOLDCROFT, Department of Chemistry, Simon Fraser University — While perfluorinated polymers dominate the commercial fuel cell industry, hostility to catalysts, difficult and expensive synthetic routes, and challenging disposal hamper wide adoption of fuel cell technology and impede further development. Hydrocarbon-based membranes utilize simple, well-developed synthetic routes that allow for rapid material development. We have investigated a promising series of methylated (benz)imidazole-based ionenes utilizing a combination of lab-scale X-ray scattering and molecular dynamics simulations, based on the united-atom DREIDING model with targeted optimizations to quickly elucidate the morphology of these materials. Derived structure-property relationships may motivate further material development.

This research was enabled in part by support provided by WestGrid and Compute Canada/Calcul Canada.

L70.00043: Investigation of microdomain deformation of thermoplastic elastomer based on in situ synchrotron radiation X-ray scattering  NATTANEE DECHNARONG (Presenter), Chemistry and Biochemistry, Graduate School of Engineering, Kyushu University, KAZUTAKA KAMITANI, Institute for Materials Chemistry and Engineering, Kyushu University, CHAO-HUNG CHENG, SHIORI MASUDA, SHUHEI NOZAKI, CHIGUSA NAGANO, Chemistry and Biochemistry, Graduate School of Engineering, Kyushu University, NOBUHISA TAKAYAMA, Institute for Materials Chemistry and Engineering, Kyushu University, KEN KOJIO, ATSUSHI TAKAHARA, Kyushu University — Microphase separation occurs in polystyrene (PS)-b-poly(ethylene-co-butylene)-b-PS (SEBS), leading PS domains to serve as physical crosslinking points. To investigate behaviors of PS domains, well-ordered SEBS films with low PS content were measured during uniaxial, biaxial and compression testing using in situ SAXS in SPring-8, Japan. After annealing, characteristics of spherical microdomain of PS packed in body-centered cubic lattice were observed in structure and form factors. During uniaxial testing, a shift of structure factor reveals an increase in domain spacing in parallel to stretching direction (SD) while it decreased in the perpendicular to SD. Furthermore, the shift of form factor implies to the deformation of PS spherical domains to egg-like ellipsoidal shape. For biaxial testing, a shift of structure factor indicates an increase in domain spacing as strain increased. In compression testing, the experiment was observed from the edge of sample. It was found that structure factor indicates a decrease in domain spacing in the parallel to compressing direction (CD) while it increased in the perpendicular to CD. The results of form factor observed in biaxial and compression testing suggest the deformation of PS domain, which the sphere became asymmetry in three dimension.
**L70.00044: Quantification of Nanocomposite Dispersion for Weakly Correlated Systems**

ALEX MCGLASSON (Presenter), GREG BEAUCAUGE, MICHAEL CHAUBY, KABIR RISHI, University of Cincinnati, VIKRAM K KUPPA, University of Dayton Research Institute — Nanocomposites such as carbon black dispersions in elastomers can be described by a mean-field approach and the RPA equation. [1,2] However, dispersion of nanoparticles influenced by surface potentials or entropic and steric interactions, such as for surface-grafted nanoparticles, often cannot be described using the mean-field approach since the particles are weakly organized. For these cases it is necessary to consider a discrete correlation function and an associated structure factor in scattering. Recently Oberdisse and Genix [3] have developed an approach to model scattering from nanocomposites of precipitated silica in elastomers. In this talk an approach similar to Oberdisse is used but with a simpler structure factor based on the Born-Green approach of Guinier and Fournet. [4] The result is a simple parameterization of correlations that can be used to determine the second virial coefficient for direct comparison with uncorrelated systems such as fumed silica or carbon black in elastomers.

**L70.00045: Electrospun fiber deposition using the gap method alters fiber moduli**

CHRISTINE HELMS (Presenter), MIMI TRAN, GARRETT LANG, NICOLE BIALICK, University of Richmond — Applications of electrospun nanofibers often require precise mechanical properties and fiber deposition. One common way to control fiber deposition is to use parallel collectors separated by a gap (gap method). In this work, we investigate the effect of gap method deposition on fiber modulus.

We formed electrospun fibers using collectors spaced at various gaps ranging from 2 cm to 10 cm and fiber moduli were measured by AFM using 3-point bending.

The gap between the collector plates had an inverse relationship with the diameter of the fibers; larger gaps produced smaller fibers. In agreement with previous data, the small fibers created by the larger gap distance had higher average moduli (67 +/- 9 GPa for a 10 cm gap) than larger fibers (10 +/- 2 GPa for a 4 cm gap). Therefore, fiber deposition directly influenced individual fiber moduli. Additionally, when we compared fibers of similar diameter we found larger gap distances produces fibers with higher moduli independent of fiber diameter. Fibers with diameters between 150 nm and 250 nm had an average modulus of 18 +/- 3 GPa for an 8 cm gap and 12 +/- 2 GPa for a 4 cm gap. Preliminary data using polarized-FTIR suggest molecular alignment is increased by the gap method.

**L70.00046: Evolution of CTAB/NaSal Micelles: Structural Analysis by SANS**

CHRISTOPHER LAM (Presenter), WEI-REN CHEN, CHANGWOO DO, Oak Ridge National Laboratory — Surfactants self-assemble into micelles in aqueous solution and exhibit structural polymorphism. Under certain conditions, long and flexible structures referred to as wormlike micelles (WLMs) can develop and entangle to form a transient network, leading to spectacular viscoelastic properties. The salt concentration—in particular, the molar ratio of salt (Cs) to surfactant (Cd), Cs/Cd—has been shown to have a significant influence on the viscoelastic properties of WLMs. Salicylate (Sal-) has a strong affinity for the cationic surfactant cetyltrimethylammonium bromide (CTAB) and can promote the growth of WLMs even at very dilute surfactant concentration. We investigate the structure of CTAB/NaSal micelles at relatively low concentration over a wide range of Cs/Cd. Using small-angle neutron scattering and the most advanced scattering function for WLMs, we characterize the development and structural evolution of wormlike micelles both qualitatively and quantitatively, culminating in an understanding of the phase behavior of CTAB/NaSal within this region of phase space.

*The research at the Spallation Neutron Source of Oak Ridge National Laboratory was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.
decorated with a lower frequency component. We will discuss possible mechanistic causes for these distinct patterns.

In the thinnest films (10 nm ~ 50 nm) the high wavenumber mode is throughout the bulk of the pattern. In intermediate thickness films (50 nm ~ 600 nm), the bulk wave mode cascades into wrinkle pattern in three different thickness regimes: In the thickest films (600 nm ~ 1 μm) a single wave number is seen of the floating film. When a large range of film thickness is used (10 nm to 1 μm) we observe a qualitative change in the previously studied, this wrinkle pattern is generated by the capillary force exerted by a water droplet placed at the center polymer (PS, PMMA, and Cytop™ (poly(perfluoro(1-butenyl vinyl ether)) films, floating on an air-water interface. As

MENON, THOMAS RUSSELL, University of Massachusetts Amherst — We investigated capillary force induced wrinkling of MENON, THOMAS RUSSELL, University of Massachusetts Amherst — We investigated capillary force induced wrinkling of polymer (PS, PMMA, and Cytop™ (poly(perfluoro(1-butenyl vinyl ether)) films, floating on an air-water interface. As

neutron scattering. It is demonstrated that structural screening, and the associated virial coefficient, has an increasing impact on scattering with increasing surfactant concentration. A linear relationship between the second virial coefficient, $A_2$, and the salt to surfactant ratio, $\Theta_{s-s}$, is derived based on SANS results. The $\Theta_{s-s}$-dependency is described via association/dissociation kinetics of salt ions between the bulk and an ion cloud surrounding the WLMs. An ion-cloud model for the high ionic strength condition is proposed and verified based on this work. It is also demonstrated that a virial approach can be used to understand and predict WLM stability.

L70.00049: Influence of Side Chain Isomerism on the Conformation of Poly(3-alkylthiophenes) in Solutions Revealed by Neutron Scattering* KUNLUN HONG (Presenter), YANGYANG WANG, CHANGWOO DO, CHRISTOPHER LAM, WEI-REN CHEN, Oak Ridge National Laboratory — Using small angle neutron scattering, we conducted a detailed structural study of poly(3-alkylthiophenes) dispersed in deuterated dichlorobenzene. The focus was placed on addressing the influence of spatial arrangement of constituent atoms of side chain on backbone conformation. We demonstrate that by impeding the π - π interactions, the branch point in side chain promotes torsional motion between backbone units and results in greater chain flexibility. Our findings highlight the key role of topological isomerism in determining the molecular rigidity and are relevant to the current debate about the condition necessary for optimizing the electronic properties of conducting polymers via side chain engineering.

L70.00050: Relaxation behavior of biodegradable aliphatic-aromatic block copolymers as revealed by dielectric spectroscopy I. IRSKA, Institute of Material Science and Engineering, ZUT Szczecin, Poland, A. LINARES, A. NOGALES, IEM-CSIC, Serrano 121, Madrid 28006, Spain, E. PIESOWICZ, S. PASZKIEWICZ, Z. ROSLANIEC, Institute of Material Science and Engineering, ZUT Szczecin, Poland, TIBERIO EZQUERRA (Presenter), IEM-CSIC, Serrano 121, Madrid 28006, Spain — Thermoplastic elastomers are copolymers composed of a hard block, typically a polyester, and a soft block, typically a polyether. Most commercially available poly(ether-ester) thermoplastic elastomers are produced based on petrochemical monomers. The increasing necessity of eco-friendly polymers has driven the interest for the production of thermoplastic elastomers fully or partially based on monomers from renewable sources. Poly(lactic acid) (PLA) is a biodegradable aliphatic polymer which can be obtained from natural products. Here we present dielectric relaxation results of a series of thermoplastic elastomers based on poly(tetramethylene oxide), as soft segment, and on a multiblock of poly(buthylene terephthalate) (PB) and poly(lactic acid) (PLA) as hard segment. The results indicate the existence of a single alpha relaxation, associated to the segmental motions above the glass transition temperature, regardless of the PB/PLA ratio of the hard segment pointing towards an absence of phase segregation between the two blocks within the hard segment. In addition, different local dynamic processes are revealed below the glass transition temperature contributing to a multimodal beta relaxation that can be assigned to different bonds of both hard and soft blocks.
**L70.00051: Polymer Dynamics in Poly(styrene-isoprene-2,vinylpyridine) miktoarm terpolymers**

THOMAS KINSEY (Presenter), EMMANUEL MAPESA, Chemical and Biomolecular Engineering, University of Tennessee, Knoxville, KUNLUN HONG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, JOSHUA SANGORO, Chemical and Biomolecular Engineering, University of Tennessee, Knoxville — In this study we employ broadband dielectric spectroscopy to probe the motion of several poly(styrene-isoprene-2,vinylpyridine) (PS-PI-P2VP, respectively) miktoarm star terpolymers with constant “PS” and “PI” block molecular weights, and we vary the molecular weight of the “P2VP” block. A strong but significantly faster secondary, dipolar relaxation is observed over wide temperature and frequency ranges for the terpolymers compared to homopolymers. This process is attributed to local dynamics of the “P2VP” heterocyclic segments. Additionally, to probe the end-to-end dipole vector timescales of the Type-A polymer chains in the “PI” block, lithium salts were added to suppress the β-process of the “P2VP” block due to coordination of the nitrogen in the heterocycle with the Li+ cation. These data for the “PI” chain relaxation are compared the dynamics of poly(isoprene) in phase separated linear diblock and homopolymer systems. We show that this unique miktoarm star architecture greatly affects the dynamics in these polymers, and discuss the results in terms of polymer dynamics in well-studied phase separated systems.

**L70.00052: Low frequency complex dielectric response of dilute clay suspensions**

LING FENG (Presenter), CHANG-YU HOU, NIKITA SELEZNEV, DENISE FREED, Schlumberger-Doll Res Ctr — In this work, we measured the low-frequency complex dielectric dispersion of dilute clay suspensions using a four-point impedance measurement, which can be reliably calibrated in the frequency range between 0.1 Hz and 10 kHz. Complex dielectric spectra of smectite and illite suspensions in brine with different weight fractions were obtained. The brine salinities ranged from 100 to 3000 ppm. We fit our results to an effective medium model incorporating the dielectric response of a charged oblate spheroid immersed in an electrolyte. We found reasonable agreement between our measurements and the model; they both exhibited the same trends when the brine salinities and weight fractions of the clays were varied. When the clay grains have a narrow size distribution, we expect that the dispersion of the complex conductivity phase exhibits a near-resonance peak associated with the size of the particles. In our case, because the clay grains have a broad size distribution, the phase peak is broadened. The parameters obtained from the fit agree reasonably well with independently measured quantities, including the size distribution and cation exchange capacity of the clays.

**L70.00053: Entanglement Effect on Mechanical Properties in Ultra-thin Glassy Polymer Films**

CYNTHIA BUKOWSKI (Presenter), REED BAY, ALFRED CROSBY, University of Massachusetts Amherst — Entanglement density can influence the large strain and failure responses of ultra-thin glassy polymer films. For model films of high molecular weight polystyrene (PS), recent results show severe embrittlement as film thickness decreases below the average size of an unconfined chain. The hypothesized cause for this effect is the loss of interchain entanglements as polymers statistically interact with themselves more than neighbors in dimensionally-confined geometries. Introducing polymer chains shorter than the entanglement molecular weight can also lower the entanglement density, effectively swelling the entanglement network. Here, we blend short (10 kDa) and long (151.5 kDa) PS chains and measure the changes in mechanical properties using the recently developed TUTTUT (The Uniaxial Tensile Tester for Ultra-Thin films). We measure the complete uniaxial stress-strain response of 100 nm PS films as a function of blend concentration. We observe a decrease in yield stress and strain with increasing diluent concentration. Above a critical diluent concentration, the entanglement density reaches a limit where films are too brittle to manipulate. These results establish the framework of how entanglement density affects mechanical properties of ultra-thin polymer films.

L70.00054: Effect of Topological Constraints on the Glass Transition Behaviors of Polyrotaxanes* KAZUAKI KATO (Presenter), AKIHIRO OHARA, HIDEAKI YOKOYAMA, KOHZO ITO, Department of Advanced Materials Science, Graduate School of Frontier Sciences, The University of Tokyo — We report here peculiar glass transition behaviors attributed to the topological interactions between two different components of a mechanically interlocked polymer. A new class of polymer glasses were recently materialized from polyrotaxanes, which are necklace-like supramolecules composed of a linear polymer and threaded cyclic molecules. Some of the glasses were ductile and extensible to more than four-folds in length because of the slipping of threading chains through the rings in the region where the stress is concentrated. The unique structural change forced by large deformation seems to relate to the molecular dynamics. In the glass transition regime, the relaxation mode is almost an Arrhenius dependence on temperature, suggesting negligible cooperativity of molecular motions. In addition, a new viscoelastic relaxation at slightly slower than the glass transition regime is generated, when the number of rings in a single threaded chain (so-called “coverage”) is increased. The slower relaxation is significantly prolonged by the increase in coverage. It suggests that the increased topological constraints between different components restrict the translational motions of the rings dragging the threading chain.

L70.00055: Alternation of thin film morphology with monomer modifications QIMING HE (Presenter), DEAN MASTROPIETRO, WEI CHEN, MATTHEW TIRRELL, University of Chicago — The morphologies of a group of well-defined fluorine-containing copolymers, poly(methyl methacrylate)-b-poly(perfluoroalkyl methacrylate) (PMMA-b-PFMA) with chemical compositions on silicon substrates have been investigated. Thin polymer coatings were prepared on silicon substrates by spin coating from polymer solutions of varying composition and suspended in varying solvents and characterized using atomic force microscopy (AFM) tapping mode height and phase traces. By varying the chemical compositions slightly in the copolymers, alternation of morphologies can be achieved, which provides a unique way to engineer the polymeric coatings on substrates with varying mechanical and surface properties.

L70.00056: Self-assembled Copolymer Adsorption Layer-Induced Block Copolymer Nanostructures in Thin Films DONG HYUP KIM (Presenter), SO YOUN Y KIM, Ulsan National Institute of Science and Technology — Generally, a very thin adsorption layer originated from the irreversible chain adsorption on solid substrates exists in polymer thin films, which often governs the macroscopic property of the polymer films. Thus, even in microphase separated block copolymer (BCP) films, an adsorption layer can be present playing a critical role in BCP self-assembly. However, understanding on the adsorption layer in BCP films has not yet been elaborated, and therefore its effective control has not been discussed. Herein, we employ self-assembled copolymer adsorption layers (SCALs), transferred from the self-assembly of BCPs at the air/water interface, as an effective way to control adsorption layers in BCP thin films. SCALs are irreversibly adsorbed onto substrates and can replace the natural adsorption layer when other BCP is additionally coated. We further show that SCALs can guide the film nanostructures as it provides topological restrictions and enthalpic/entropic preferences for additionally coated BCP self-assembly. Thus various novel nanostructures of SCAL-induced self-assembly are introduced such as arrays of spacing-controlled hole/dot pattern, dotted-line pattern, dash-line pattern, anisotropic cluster pattern, and etc.

L70.00057: Morphological Evolution of Poly(solketal methacrylate)-block-polystyrene in Thin Films* DUK MAN YU (Presenter), University of Massachusetts Amherst, DARREN SMITH, Univ. at Buffalo, The State Univ. of New York, HYEYOUNG KIM, University of Massachusetts Amherst, JOSE KENNETH D. MAPAS, JAVID RZAYEV, Univ. at Buffalo, The State Univ. of New York, THOMAS RUSSELL, University of Massachusetts Amherst — The morphological evolution of the lamellar microdomains for the thin films of symmetric poly(solketal methacrylate-b-styrene) (PSM-b-PS) copolymers that can be converted into poly(glycerol mono-methacrylate-b-styrene) (PGM-b-PS) copolymers by the hydrolysis reaction was investigated. This simple hydrolysis was performed in the solid state using an acid vapor and markedly improves the segmental interaction parameter (χ) from 0.035 to 0.438 at 25 °C. For the perpendicular orientation of the lamellar microdomains, the hydroxyl-terminated random copolymer (PSM-r-PS) with χ_{PSM} = 0.5 was used to tune the interfacial interactions at the substrate as a neutral and it can also be transformed into PGM-r-PS with the block copolymers. Scanning force microscope (SFM) and grazing-incidence small angle X-ray scattering (GISAXS) measurements as a function of the exposure time to an acid vapor were conducted to characterize the transition from the disordered state as well as the perpendicular orientation and features of the lamellar microdomains. As a result, sub-10 nm full pitch lamellar patterns in the thin films were achieved after full conversion and thermal annealing.

Highly Ordered, Complex Morphologies in Block Copolymer Films Obtained by Spatial Confinement Using Topographical Substrates

ELISHEVA MICHAM, Institute of Chemistry, The Hebrew University of Jerusalem, ROLAND STENGER, MARCEL LANGENBERG, MARCUS MUELLER, Institute for Theoretical Physics, Georg-August-University Göttingen, ROY SHENHAR (Presenter), Institute of Chemistry, The Hebrew University of Jerusalem — Block copolymers microphase separate into periodic arrays of nanostructures. Thin films of these self-assembled BCPs are finding increasing use as platforms for nanofabrication, either as lithography masks or as templates for the patterning of nanowires and particles. Directed self-assembly, using a chemical or topographical pre-pattern, increases the long range order of BCP thin films and can be used to introduce diversity to the BCP morphology. However, the ability to pattern BCPs in a variety of morphologies in close confinement usually requires multiple fabrication steps and is limited in scope.

We present a simple, one-step process for obtaining complex, highly ordered morphologies in ultra-confined films in a controlled fashion. Our approach utilizes topographically patterned silicon substrates to guide the assembly of block copolymer domains. Remarkably, different local morphologies of the block copolymer are observed on the plateaus and inside the trenches. This behavior is explained in terms of the variation in the local film thickness and the selectivity of the substrate towards one of the copolymer domains.

Quasi-Two-Dimensional Assembly of Bottlebrush Block Copolymers with Nanoparticles in Ultrathin Films: Combined Effect of Graft Asymmetry and Nanoparticle Size

YARON AVIV, Institute of Chemistry, The Hebrew University of Jerusalem, ESRA ALTAY ESRAALTA@BUFFALO.EDU, Department of Chemistry, University at Buffalo, LEA FINK, URI RAVIV, Institute of Chemistry, The Hebrew University of Jerusalem, JAVID RZAYEV, Department of Chemistry, University at Buffalo, ROY SHENHAR (Presenter), Institute of Chemistry, The Hebrew University of Jerusalem — Block copolymer guided assembly of nanoparticles leads to the formation of nanocomposites with periodic arrangement of nanoparticles, which are important for applications, such as photonic devices and sensors. However, linear block copolymers offer limited control over the internal arrangement of nanoparticles inside their hosting domains. In contrast, bottlebrush block copolymers possess unique architectural attributes that enable additional ways to control the local organization of nanoparticles. In this work, we studied the co-assembly of 8 and 13 nm gold nanoparticles with three bottlebrush block copolymers differing in the asymmetry of their graft lengths in ultra-confined films, where assembly occurs quasi-two-dimensionally. Our results indicate that graft asymmetry could be used as an additional tool to enhance nanoparticle ordering by forcing them to localize at the center of the domain regardless of their size. This behavior is analyzed in terms of the influence of the graft asymmetry on the average conformations of the blocks.

Kinetic Pathway Dependent Supramolecular Nanocomposite Assembly on Patterned Substrates

KATHERINE EVANS (Presenter), TING XU, University of California, Berkeley — Block copolymer (BCP)-based supramolecular nanocomposites are promising materials to create hierarchically structured materials and incorporate and organize nanoparticles (NPs). Assembling these materials on lithographically patterned substrates combines the advantages of “bottom-up” and “top-down” assembly to yield materials where the exact ordering and placement of NPs can be controlled. However, for traditional BCP self-assembly on patterned substrates, the width of the underlying pattern must be commensurate with the periodicity of the BCP due to thermodynamic constraints. Here, supramolecular nanocomposites are assembled onto several different geometrically patterned substrates, including lines and concentric circles. On these patterns, incommensurability between the pattern and the supramolecule periodicity was not observed. Instead, the supramolecule self-adjusts to a smaller, non-equilibrium periodicity in the trench. This phenomenon is attributed to the kinetic pathway taken during assembly.
L70.00061: Protein-Polymer Block Copolymer Thin Films for Detection of Small Proteins in Biological Matrices via Size-Exclusion*  

JUSTIN PALONI (Presenter), BRADLEY DAVID OLSEN, Massachusetts Institute of Technology — While biosensors have been developed to allow sensitive detection of biomolecules, limit of detection (LOD) is often increased by several orders of magnitude in biological matrices due to nonspecific binding events from off-target molecules. Here, we demonstrate the self-assembly of protein-polymer conjugate thin films into lamellar structures containing alternating domains of proteins and polymer meshes that can exclude molecules based on particle size. By comparing the diffusion of two analytes, streptavidin (52.8 kDa) and monomeric streptavidin (15.6 kDa), it is found that the larger protein streptavidin experiences greater resistance to diffusion into the films and is largely excluded from the film structure. Furthermore, by decreasing the polymer molecular weight and therefore the spacing of the polymer nanodomains, the thin films can be tuned to enhance selectivity for smaller molecules. When compared against a traditional surface-immobilized protein biosensor, the conjugate films achieve a two order of magnitude reduction in LOD when detecting monomeric streptavidin, resulting from both the greater density of binding sites within the thin films as well as the size-based exclusion of larger proteins.

*This work was funded by the NSF.

L70.00062: Interfacial Interaction Effects on Phase Transition Behavior of Block Copolymer Thin Films  
YEONGSIK KIM (Presenter), Yonsei University, DAESEONG YONG, Ulsan National Institute of Science and Technology, HYUNGJU AHN, Pohang University of Science and Technology, JAEUP KIM, Ulsan National Institute of Science and Technology, DU YEOL RYU, Yonsei University — Confined in a film geometry, the preferential interaction of the polymer/air and polymer/substrate interfaces generates cylindrical and lamellar microdomains oriented parallel to the substrate. We presented the thickness dependent phase diagram of BCP films using ex-situ grazing incidence small-angle x-ray scattering (GISAXS) and transmission electron microscopy (TEM). With decreasing film thickness (t) when t < t₀, where t₀ is an onset thickness above which the ODT temperatures (T_ODTs) of the films are independent of film thickness, the T_ODTs of cylinder- and lamella-forming polystyrene-b-poly(2-vinylpyridine) (PS-b-P2VP) films supported on preferential substrates remarkably increase. Consistent between cylinder- and lamella-forming PS-b-P2VP films, this effect is so intense in very thin BCP films.

L70.00063: Top Coats: Control of Orientation, Alignment and Morphologies of Sub-10 nm Block Copolymer Microdomains  
EUNJIN KIM, EUNKYOUNG YOON, IN HYU RYU, JINWOO OH, JEONG GON SON (Presenter), Photo-electronic Hybrids Research Center, Korea Institute of Science and Technology — Achieving sub-10 nm high-aspect-ratio patterns from diblock copolymer self-assembly requires both a high interaction parameter (χ, determined by the incompatibility between the two blocks) and a perpendicular orientation of microdomains. However, these two conditions are extremely difficult to achieve simultaneously because the blocks in a high-χ copolymer typically have very different surface energies, favoring in-plane microdomain orientations. We introduce top coat for the control of orientation, alignment and morphology of a high-χ block copolymer, poly(styrene-block-dimethylsiloxane) (PS-b-PDMS). Using partially hydrolyzed PVA top coats with a solvent annealing, perpendicular orientation of PS-b-PDMS can be obtained despite the large surface energy differences between PS and PDMS. Extremely straight and laterally aligned cylindrical microdomain of BCP films were prepared by simply covering the BCP films with a top coat and dewetting the latter via thermal annealing to generate shear flow in the BCP underlayer. We also observed the gyroid-cylinder phase transition using interfacial-energy-tailored top-coat. At the optimized top-coat composition, gyroid nanostructures with sub-10 nm strut width were achieved down to ~125 nm.
Thin Films of Block Copolymer-Based Supramolecules with Feature Size Over 50 nm

KATHERINE EVANS, EMMA VARGO (Presenter), TING XU, University of California, Berkeley — Block copolymer-based supramolecular self-assembly offers a simple method to overcome issues with incommensurability, surface chemistry, and assembly kinetics to access nanostructures in thin films. Much work has been focused on creating nanostructures with periodicities between 10-50 nm. However, for some applications, including the interaction with visible light, larger periodicity features are necessary. Creating thin films with feature sizes larger than 100 nm is challenging. Large MW nanocomposites have differing kinetic and thermodynamic considerations when compared to the low MW analogs. Thermodynamically, incorporation of particles does not have the same entropic penalty when the polymer chain length increases. Kinetically, the diffusions of nanoparticle and supramolecule may play a more critical role in determining the NP placement and NP packing within supramolecular microdomains. Here, we demonstrate that nanocomposites with controllable morphology can be created with a periodicity of up to ~100 nm. The size and loading of nanoparticles, as well as the solvent annealing condition, determines the final morphology as well as the periodicity, grain size, and packing of nanoparticles.

Influence of salt additives on unconfined melt electrospinning of thermoplastics

NEELAM SHEORAN (Presenter), BRENTON BOLAND, Department of Physics, North Carolina State University, ELNAZ SHABANI, RUSSELL E GORGA, Fiber and Polymer Science Program, North Carolina State University, JASON BOCHINSKI, LAURA CLARKE, Department of Physics, North Carolina State University — Incorporation of ionic or salt additives into thermoplastic melts can effect both viscoelastic properties and ionic conductivity. Such an approach might usefully alter the process of melt electrospinning where jet diameter (and subsequent fiber size) is influenced by melt viscosity as well as ionic motion within the melt under the influence of a strong applied electric field. These changes have the potential of producing mesoscale thermoplastic nanofibers which are important for filtration and biological applications where high strength nanofibrous materials are required. We report ionic conductivity measurements obtained using broad-band impedance spectroscopy of commercial linear low-density polyethylene (ASPUN 6850A) as a function of temperature, salt type, and concentration, along with corresponding information on viscosity changes. The salt-doped melts were electrospun in an unconfined geometry; changes in jet formation time, number of jets, jet and cone widths, and the resulting fiber diameters were determined. We discuss results and current understanding of the changes in melt properties due to salt additives.

A facile route to calculate the effective volume fractions in block copolymers during solvent vapor annealing

SAEED BEHZADINASAB (Presenter), JULIE ALBERT, Chemical & Biomolecular Engineering Department, Tulane University — The nano-scale domains obtained from self-assembly of block copolymers (BCPs) have attracted significant attention. In a BCP system, solvents are oftentimes used to plasticize the polymer molecules and reduce the unfavorable interactions in between to facilitate the microphase separation. However, it is not straightforward to predict the final morphology of a BCP system due to the critical impacts of the annealing condition on the nanostructure. The effective volume fraction of each block remains constant when a neutral solvent is used, while selective solvents can significantly change this parameter and encourage the formation of a distinct morphology. To monitor morphology changes, advanced in-situ techniques, such as X-ray or neutron scattering, which are not readily accessible, are required. In this work, we present a facile route to predict the morphology of BCPs during solvent vapor annealing by simultaneous calculation of the Flory-Huggins theory coupled with mass conservation. This results in the prediction of effective volume fractions of each block, which can significantly reduce the number of required experiments in morphological studies.

**L70.00067: Reactive Processing of 3D Printed ABS Structures Formed by Fused Deposition Modeling to Reduce Structural Anisotropy**  
KAIZHONG GUAN (Presenter), MARK DADMUN, University of Tennessee, Knoxville — Fused deposition modeling (FDM) is one of the most common additive manufacturing methods, which allows the fabrication of complex structures and customization. However, due to its layer-by-layer nature, the resultant structures exhibit anisotropic properties. A primary reason for the anisotropy is weak interactions and poor entanglement between subsequently deposited layers. Methods to increase inter-layer adhesion include post-deposition heating, which results in loss of fidelity of the fabricated shape to the target structure. To address this shortcoming, our group has modified an FDM printer to allow for the reactive processing of the interlayer interface as a part of the deposition. This is realized by adding a UV-LED optical fiber to an FDM 3D printer, which is designed to initiate a reaction at the inter-layer interface. This presentation will present results that examine the success of this novel processing scheme. Samples of ABS that include a photo-initiator and a crosslinker to form covalent bonds across the interlayer interface are printed with this modified printer, and its tensile properties and anisotropy monitored. This presentation will report the impact of the loading of photo-initiator and crosslinker on the mechanical properties of the printed sample.

**L70.00068: Droplet-Jet Shape Parameters Predict Electrospun Polymer Nanofiber Diameter**  
SUQI LIU (Presenter), D RENEKER, The University of Akron — The relationships between observable features of the droplet-jet shape and the diameter of electrospun nanofiber were studied. Three shape parameters were derived from optical images of the jet emerging from a droplet. They are: Left-Right (L-R) curvature, initial jet diameter, and transition slope. Fiber diameter increased as each shape parameter increased. The relation between initial jet diameter and fiber diameter, as well as the relation between transition slope and fiber diameter, were not affected by the variation of voltage or viscosity of the polymer solution. Ambient temperature and humidity were controlled. Day-to-day variations in other ambient conditions that might have occurred in the laboratory do not invalidate these relationships.

**L70.00069: Solvent Effects on the Crystallization Order and Morphology in PEO-b-PCL Copolymers**  
RYAN VAN HORN (Presenter), Lafayette College, COLE TOWER, NATASHA BRIGHAM, KRISTI M ALLEN, ALLISON CARANDANG, Allegheny College — Physical structure of block copolymer films plays an important role in the macroscopic properties of the material. Where applicable, crystallization is one important aspect of the physical structure. PEO-b-PCL copolymer films have two crystalline components that makes for rich hierarchical assembly. Using various solvents for film casting has allowed for the opportunity to control this hierarchical assembly. Films were made using various molecular weight samples at varying drying temperatures in an attempt to manipulate the crystallization process. The crystallization order and morphology was monitored via DSC, FTIR, and optical microscopy. It was determined that the relative solubilities of the two blocks influences the film's final structure.

*This work was supported by funding from NSF (DMR-1606532).*

**L70.00070: Morphology and crystallization kinetics of poly(ethylene brassylate)**  
DAOKUN SONG (Presenter), RUFINA G ALAMO, Chemical and Biomedical Engineering, FAMU-FSU College of Engineering, IRMA FLORES, ALEJANDRO J MÜLLER, POLYMAT and Polymer Science and Technology Department, University of the Basque Country — Poly (ethylene tridecane dioate), also known as poly(ethylene brassylate) (PEB), is a long-spaced aliphatic polyester obtained from a renewable source. PEB in a range of molar mass between 27,000 and 188,000 Dalton crystallize rapidly as single peaks at ~55 C and display two major melting peaks (60 -70 C). The two melting peaks are associated with crystallites that differ in the packing of the crystalline ester layer. Although the WAXD patterns are undistinguishable, differences in the ester layer packing lead to the effect of self-poisoning at the growth front, and hence to a deep depression of the growth rate at temperatures approaching the transition between both forms, from above. This minimum of the rate, first described for n-alkanes, is also observed in the overall crystallization kinetics obtained by DSC, and follows a general behavior of precision polyethylenes that develop different crystalline polymorphs by changing undercooling.

**L70.00071: Tunable Liquid Crystallinity of Graphene Oxide by Polymer Crystallization**  
SOHJIN MUN (Presenter), SO YOUN KIM, Ulsan National Institute of Science and Technology — Graphene oxide (GO) can form liquid crystals (LC) in aqueous solution, which can be a valuable method for many applications using GO. One of the attractive applications is GO based polymer nanocomposites where GO can act as an effective nanofiller in semicrystalline polymer matrix. Previous studies have shown that polymer can be crystallized on GO surface and thus adding GO controls the polymer crystallinity and changes the macroscopic property of GO. However, less attention has been paid to how crystallizable polymers can conversely alter the liquid crystallinity of GO. Herein, we show that GO LC can be correlated with polymer crystallization. We found that the stability and directionality of GO LC can be affected by the rate of polymer crystallization. The microstructure and rheological property of GO LC are extensively investigated with small-angle X-ray scattering and rheometry experiments at a given temperature profile for polymer crystallization.
Controlling of Chain-Level Structure of Polymer via Freeze-Drying

TOSHIKAZU MIYOSHI (Presenter), The University of Akron — Freeze-drying (FD) method may potentially control chain-level structures of polymer with varying entanglement densities. In this work, we investigated phase structure, chain-to-chain distance, \(<R>\) and self-assembled chain structure of \(^{13}\text{C}\) labeled poly(L-Lactic Acid) (PLLA) formed via FD from both good and poor solvents, by solid-state (ss) NMR. It is found that the FD-PLLA from the good solvent adopts an amorphous state while the FD one from the poor solvent forms a semicrystalline state with a crystallinity of \(~40\%\). By comparisons of the \(^{13}\text{C},^{13}\text{C}\) Double Quantum (DQ) experimental and simulated curves, it is demonstrated that i) FD-PLLA chains from both poor and good solvents adopt the same \(<R>\) value of \(6.2\ \AA\), ii) FD-PLLA chains in the latter adopts much larger nanoclusters via folding than those in the former, and is slightly smaller than those in the single crystals. While the FD-PLLA chains obtained from good solvent exhibited similar structure with the bulk glassy state. It is concluded that different solvent-polymer affinities do not affect \(<R>\) and significantly affect self-assembly structure of individual chains.

**NSF DMR 1708999**

Liquids That Freeze When Mixed: Co-Crystallization and Liquid-Liquid Equilibrium in Polyoxacyclobutane-Water Mixtures

JOYITA BANNERJEE, PETER KORONAIOS, ERIC BECKMAN, ROBERT ENICK, JOHN KEITH, SACHIN VELANKAR (Presenter), University of Pittsburgh — We show that liquid polyoxacyclobutane –\([\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{O}]_n\)– when mixed with water at room temperature, precipitates solid co-crystals of the polymer and water. Such co-crystals are formally known as a clathrate hydrate. Hydrate co-crystals can also be formed by simply exposing the liquid polymer to saturated humidity. Outside of metal alloys, this is a rare example of an co-crystal whose melting point exceeds that of the pure species, and the only known example of non-reacting liquids that combine to form a solid co-crystal at room temperature. At high temperatures, the same polymer-water mixtures phase separate into two co-existing liquid phases. This combination of co-crystal hydrate formation and LCST-type liquid-liquid equilibrium (LLE) gives rise to an unusual, possibly unique, type of phase diagram. We examine the effects of polymer molecular weight on the phase behavior and show that at molecular weights exceeding \(~2000\) g/mol, nearly the entire composition-temperature space is split between regions of solid-liquid equilibrium and liquid-liquid equilibrium. Furthermore, this unusual phase diagram produces distinct crystallization pathways depending on whether the mixture is single-phase or two-phase prior to crystallization.

Crystallization behavior, morphology and mechanical properties of copolymers of syndiotactic polypropylene with branched monomers

CLAUDIO DE ROSA, MIRIAM SCOTI (Presenter), FINIZIA AURIEMMA, Chemical Sciences, University of Napoli Federico II — We report a study of the structure and mechanical properties of copolymers of syndiotactic polypropylene (sPP) with different comonomers from ethylene to branched a-olefins. The effect of the presence of short or long branches on the crystallization behaviour and elastomeric properties of sPP has been analyzed. Incorporation of long branched comonomers, as 1-octadecene and 1-eicosene, allows fast decrease of the glass transition temperature and development of interesting elastomeric materials. The relationships between structure and stress-induced phase transformations and mechanical properties have been clarified. In samples with low comonomer content the elastic properties are associated with a reversible polymorphic transition that occurs upon stretching and releasing the tension, which provides an enthalpic contribution to the elasticity. Samples with higher comonomer concentrations show very low crystallinity and a typical thermoplastic elastomeric behavior. The study of the crystal morphology shows the presence of small bundles of rod-like lamellar crystals in all copolymers whose size decreases with increasing content and size of comonomeric units. The small needle-like crystals act as knots of an elastomeric lattice, explaining the development of elastic properties.

Fractionated and confined crystallization of polybutene-1 in immiscible polypropylene/polybutene-1 blends

CHENGUANG LIU (Presenter), YAO XU, HUARONG NIE, AIHUA HE, Qingdao University of Science and Technology — The crystallization of immiscible polypropylene (PP)/polybutene-1 (PB) blends, in particular the effect of crystal morphology of PP (HTC) on the subsequent crystallization behavior of PB (LTC) was studied. We firstly deemed that PP/PB blends are not complete compatibility but characterized as the LCST-like phase diagram above the melting temperature of PP. Crystallization of PP at different crystallization temperatures brought different PP crystal morphologies and PB was segregated and confined at different locations. Much larger-sized domain of PB component appeared in PP spherulites resulting from the effects of non-negligible phase separation and the slower PP crystallization rate as PP crystallized at high temperature. As temperature continued to fall below Tm of PB, the fractionated and confined crystallization of PB occurred in the framework of PP spherulites reflecting as the decreased crystallization temperature (Tc) of PB and the formation of form I beside form II. If PP previously crystallized at high Tc, fractionated crystallization of PB became prominent and confined crystallization of PB became weak due to the much wider droplet-size distribution of PB domains.

L70.00076: Crystallization of trans-1,4-polyisoprene* HUARONG NIE, XIAO HAN (Presenter), AIHUA HE, HUICHENG REN, Qingdao University of Science and Technology — Isothermal crystallization of TPI from its solutions and melt were both studied to attain the kinetic parameters and polymorphic behavior. The solubility curves of TPI in solvents and the conversion temperatures between isothermal and non-isothermal crystallization were supplied to propose the available concentrations and temperatures for TPI isothermal crystallization. In most cases, the kinetics of TPI crystallization was subject to the Avrami-equation though few deviations arising from the influence of non-isothermal crystallization and transient nucleation were also observed under several special conditions. When TPI melt recrystallization was observed, β-TPI (metastable form) exhibited stronger melting memory effect than α-TPI. Irrespective of the pre-existed crystal modification, the reduced energy barrier for nucleation favored the formation of α-TPI. Furthermore, an increase in crystallinity was also observed if recrystallization occurred at low temperatures.

*Authors thank the supports from the National Natural Science Foundation of China (51773105, 51103068), the National Basic Research Program of China (No. 2015CB654700 (2015CB654706)), Major Program of Shandong Province Natural Science Foundation (ZR2017ZA0304) and Taishan Scholar Program.

L70.00077: Thermodynamic Concepts of the First-Order Prefreezing OLEKSANDR DOLYNCHUK (Presenter), MUHAMMAD TARIQ, THOMAS THURN-ALBRECHT, Experimental Polymer Physics, Institute of Physics, Martin Luther University Halle-Wittenberg — An interaction with a solid surface can induce crystallization in liquids by either heterogeneous nucleation or prefreezing. The latter is seen as the crystalline layer formation at an interface to a solid substrate at temperatures higher than that of a bulk crystal. Most recently, it was ascertained that prefreezing is a first-order transition, since the formation of the crystalline phase is abrupt and reversible.

We introduce a phenomenological theory of prefreezing and analyze such equilibrium properties as the temperature dependent crystal thickness, the maximum melting temperature $T_{\text{max}}$, and the mesoscopic jump of thickness during melting or crystallization. The theory enables a clear first-principles explanation of the abrupt formation of a crystalline layer, i.e., the first-order nature of prefreezing and defines the corresponding transition temperature $T_{\text{max}}$ as a function of the interfacial free energies. We show that it is the difference of the interfacial energies that controls $T_{\text{max}}$ and acts as a driving force for prefreezing. The analytical outcomes are congruent with recent experimental results for poly(epsilon-caprolactone) crystallized on graphite via prefreezing.

L70.00078: In Situ Electron Microscopy of Polyethylene Glycol Crystallizing in an Ionic Liquid SATYAM SRIVASTAVA (Presenter), ALEXANDER RIBBE, THOMAS RUSSEL, DAVID HOAGLAND, University of Massachusetts Amherst — In this study, the nonvolatile room temperature ionic liquid (IL) 1-ethyl-3-methylimidazolium ethyl sulfate ([EMIM][ETSO4]) was chosen as a suitable solvent to study the thermally induced solution crystallization and gelation of polyethylene glycol (PEG) by electron microscopy and electron diffraction. For both phenomena, key features occur at the nanoscale. PEG-IL samples were prepared as thin freestanding or supported liquid films on TEM grids, with crystallization observed upon cooling of heated films to room temperature. In free-standing films, crystals predominantly resided at the liquid surface, and in supported films, on the solid substrate, varied by use of different support films on TEM grids. Crystalline morphologies were observed in the form of rods (width <100 nm), fibers, spherulites (80-500 nm diameter), compact faceted single crystals (<100 nm), and interconnected networks. Electron diffraction patterns on the rod- and fiber-like crystals reveal single crystal order at length scales greater than one micron. Electron microscopy and electron diffraction were also performed on fiber-like PEG crystals grown from mixtures of [EMIM][ETSO4] with the less polar ethyltributylphosphonium diethyl phosphate ([P2444] [DEP]).

Tentative results on the MEM analysis for the X-ray powder diffraction data of Polymer crystal will be explained in my poster presentation.

*The synchrotron radiation experiments were performed at BL44B2 in Spring-8 with the approval of RIKEN (Proposal No. 20160041, 20170094, 20180039).
L70.00080: Gelatinization and Gelation Process of Japanese sweets -Warabi-mochi-  
AKANE NAGASAKI, GO MATSUBA  
(Presenter), Grad Sch of Organic Materials Engineering, Yamagata University — Fig. 1 Chemical structure of amylopectin.

"Warabi-mochi" is one of Japanese traditional sweets and is made from mainly starch and water (and sugar and so on). The way to make Warabi-mochi is to heat and stir the mixed suspension of starch and water then to cool down the gelatinized “mixed starch and water”. Fig.1 shows the chemical structure of starch (amylopectin). The amylopectin has a lot of branches because of both \(\alpha(1-4)\) bond and \(\alpha(1-6)\) bond. Warabi-mochi is safe for human and quite significant for our daily life such as boiling rice (making “gohan”), making noodle, baking breads and so many foods. Recently, it has been used as a supporting medicine of swallowing for preventing aspiration in aged persons. It’s well known that a texture and feel of Warabi-mochi depend on various parameters such as the contents (ratio) of starch and water, heating for time and temperature, and cooling process. However, the processes of making Warabi-mochi are unclear from the view point of molecular structure. In order to control these properties, we focus on the structural change during gelatinization and gelation processes with X-ray and viscoelastic measurements.

L70.00081: Mesoscale Simulations for Micellization of Diblock Copolymers*  
CHU-YUN HUANG (Presenter), Chemical Engineering, National Taiwan University, MING-TSUNG LEE, Chemical Engineering and Biotechnology, National Taipei University of Technology, HSIU-YU YU, Chemical Engineering, National Taiwan University — Polymeric filomicelles have been considered as drug carriers in nanomedicine for their structural stability and long circulation time in the blood flow. Literature (Geng, Y., et al., Nat. Nanotechnol. 2007) suggests that filomicelles formed by poly(ethylene oxide)-b-poly(ε-caprolactone) (PEO-PCL) copolymers have high capacity for paclitaxel (TAX) which could suppress tumor growth. We investigate the micellization of PEO-PCL copolymers using a mesoscale method called dissipative particle dynamics (DPD). Force fields are parameterized to best reproduce the equilibrium configurations of micelles. Inter-species parameters are chosen to reproduce the bulk properties of bead components. The stiffness of the bonds that connect copolymer beads is determined to satisfy the average distance of composing monomers at the same system density. The obtained equilibrium micellar morphologies are simulated in relevant blood flow conditions to characterize the corresponding dynamical response of filomicelles.

L70.00082: Anti-biofouling polymer surfaces by a top-down approach  
ZHIXING HUANG (Presenter), DANIEL SALATTO, WEIYI LI, Stony Brook University, LEIO KOGA, Ward Melville High School, YIZHI MENG, MAYA ENDOH, TADANORI KOGA, Stony Brook University — Polymer have been used to develop alternative antifouling coatings against primary protein adsorption. Antifouling polymers have very diverse chemical, structural, and surface topological properties, but they share common physical characteristics: hydrophilic, electrically neutral, or highly hydrated, causing strong interactions with water molecules while reducing interactions with proteins. To stabilize polymer coating under various environmental conditions, chemical end-grafting of polymer chains have been utilized. However, challenges remain in developing a universal non-fouling material that contains the necessary attributes for the next generation of polymer-based anti-biofouling coating technologies. Here we report a radically new paradigm of designing a polymeric coating that is a few nanometers thick (“polymer nanocoating”) with an anti-biofouling property. The nanocoating is composed of homopolymer chains physically adsorbed onto solid surfaces. The results demonstrate that the polymer nanocoatings composed of high surface energy hydrophobic polymers exhibit an antifouling property against a model protein, bovine serum albumin (BSA), while counterpart spin-cast thin films still exhibit adsorption of the protein.

L70.00083: Knot untying in elongational fields*  
BEATRICE SOH (Presenter), ALEXANDER KLOTZ, PATRICK DOYLE, Massachusetts Institute of Technology — Knotting is a prevalent phenomenon which occurs in long polymer chains. We perform Brownian dynamics simulations and single-molecule DNA experiments to investigate knot untying in elongational fields that is induced by the knot being convected off the chain. The change in knot size as the knot moves off the chain and unties causes a change in the effective Weissenberg number, which in turn leads to a change in chain extension. Large-scale chain conformational changes are observed in both simulations and experiments for complex knots at low Weissenberg numbers (Wi). We investigate the knot untying time and untying-induced change in extension for a range of knot types and field strengths.

L70.00084: Polymer Diffusion Under Cylindrical Confinement  JAMES PRESSLY (Presenter), ROBERT RIGGLEMAN, KAREN WINEY, University of Pennsylvania — Measuring the center of mass diffusion of polymers under confinement is critical for understanding polymer dynamics in applications including semiconductor manufacturing, separation membranes, and polymer nanocomposites. Recent simulations of polymers confined to cylindrical pores reveal non-monotonic changes in the polymer diffusion coefficient, D, as the pore size decreases due to competition between increasing disentanglement and chain segregation. In this study, we use elastic recoil detection to examine the diffusion coefficients of linear polystyrene (M_w = 100-800 kg/mol) confined to cylindrical anodic aluminum oxide (AAO) nanopores (diameter, d = 10-80 nm). The experimental results are compared to the previous coarse grained molecular dynamics simulations to interpret the measured diffusion coefficient in terms of the competition between chain disentanglement and segregation.

L70.00085: Theoretical Study of Polymer-Grafted Nanoparticle Translocation*  GABRIELA T JUSTINO (Presenter), MICHAEL HORE, Case Western Reserve University — Typically, translocation -- the movement of polymers or particles from one region through a channel into another -- is studied by observing changes in ionic current through the channel as a function of time. As the particle moves through the channel, blockage of the pore results in a decrease in the current. Here, we combine self-consistent field theory (SCFT) and Poisson-Nernst-Planck (PNP) theory to investigate the translocation of both bare and polymer-grafted nanoparticles as a function of the ratio of channel diameter to nanoparticle diameter, polymer grafting density, and electric field strength by computing the expected ionic current traces that would be observed experimentally.

*This work was supported by an academic partnership between CAPES (Brazil) and Case Western Reserve University.

L70.00086: Prediction of Stable Morphology of Block Copolymers by using SCF Calculation and Deep Learning*  Takeshi Aoyagi (Presenter), Sadato Yamanaka, CD-FMat, National Institute of Advanced Industrial Science and Technology, Japan — Block copolymers show various microphase separated structure depending on the chain architecture, and miscibility (chi parameter) between different segment type. Various stable phase such as lamellar, double gyroid, hexagonal cylinder and bcc sphere are known, and phase diagram has been studied for simple block copolymers by SCF calculation. However, it is not simple to find equilibrated morphologies even by the calculation, because many metastable morphologies are obtained. Usually, it takes large computational resource to obtain stable structure from many possible metastable structures by real space SCF calculation. We applied 3D CNN deep learning technique to predict stable morphology from metastable morphology obtained from the SCF calculation without initial constraint. Metastable morphology of diblock copolymer and stable morphologies derived from well-known phase diagram are used for training sample. The optimized deep learning network can predict stable morphology of diblock copolymers of arbitral volume fraction and chi parameter.

L70.00087: Evaluation of Accelerated Aging of Cross-Linked Polyethylene Pipes by Applying Machine Learning Concepts to Infrared Spectra  Melanie Hiles, Michael Grossutti, John Dutcher (Presenter), University of Guelph — Cross-linked polyethylene (PEX) pipes are emerging as promising replacements for traditional metal or concrete pipes used for water, gas and sewage transport. Infrared (IR) spectroscopy is well suited to the characterization of PEX pipes and additives that are used to achieve long term stability. We have developed a methodology based on IR absorbance peaks to track crystallinity, degree of degradation and the presence of stabilizing additives across the wall thickness of PEX pipes. We observed that, in response to accelerated aging protocols such as heating and UV exposure, the intensities of many IR peaks corresponding to functional groups of both polyethylene and the stabilizing additives are interdependent and highly correlated. We have used principal component analysis to identify and track the IR peaks that are most relevant to pipe degradation. We used these results, together with machine learning techniques such as support vector machines and cluster analysis, to identify and classify different modes of degradation. Our approach highlights the advantages of using machine learning techniques to understand the effects of accelerated aging of PEX pipes, which can be used to refine the pipe manufacturing process to maximize pipe durability.
L70.00088: Mobile Doubly Grafted Polymers and their Interaction  MIN CHU, DIETER HEERMANN (Presenter), Heidelberg University — Doubly grafted polymers can, for example, be found in viral membrane proteins. The interaction between doubly grafted polymers, essentially ring polymers, on a two-dimensional substrate differs from the singly grafted polymer due to the entropic repulsion. What does this entail as the grafting density increases and what are the consequences for the viral membrane proteins? We study various quantities of interest such as the order parameter, density profiles etc. varying the maximal distance between the anchor points in the range \([d_{\text{min}},d_{\text{max}}]\) (otherwise the anchor points are mobile), the chain length and the grafting density. We show that there is no phase transition from the disordered (isotropic) phase to an ordered (nematic) phase. However, due to the interaction of loops, i.e. the entropic repulsion, an increasing tendency for locally orientational order without long range order is observed. As the grafting density is increased, the transition from the mushroom regime to an almost upright conformations is observed.

L70.00089: Non-monotonicity in the knotting probability of semiflexible rings: numerical and analytical prediction  ERICA UEHARA, Physics, Ochanonizu University, Tokyo, LUCIA CORONEL (Presenter), CRISTIAN MICHELETTI, International School for Advanced Studies, TETSUO DEGUCHI, Physics, Ochanonizu University, Tokyo — Polymers in canonical equilibrium are prone to become knotted, and the knotting probability for a specific type of knot depends on several conditions, among these we found interesting to study on the effect of bending rigidity of self-avoiding polymers. We use a simple physical mapping to adapt the known asymptotic expressions for the knotting probabilities of self-avoiding polygons to the case of semiflexible rings of beads. We thus obtain analytical expressions that approximate the abundance of the simplest knots as a function of the length and bending rigidity of the rings. We validate the predictions against previously published data from stochastic simulations of rings of beads showing that they reproduce the intriguing non-monotonic dependence of knotting probability on bending rigidity. The mapping thus provides a useful theoretical tool not only for a physically-transparent interpretation of previous results, but especially to predict the rigidity-dependent knotting probabilities for previously unexplored combinations of chain lengths and bending rigidities. In particular, our mapping suggests that for rings longer than 20,000 beads, the rigidity-dependent knotting probability prole switches from unimodal to bimodal.

L70.00090: Dynamics of Biodegradation*  RYAN SAYKO (Presenter), ZILU WANG, MATTHEW BECKER, ANDREY DOBRYNIN, The University of Akron — Biodegradable polymers are widely used in drug delivery and tissue engineering. However, direct experimental observation of the degradation process of such polymers is limited. To address this issue, we have developed a coarse-grained model to mimic degradation dynamics of L-valine and L-phenylalanine based poly(ester urea)s (PEUs) in vitro. Simulations show that the rates of hydrolysis and chain diffusion control the degradation process. In particular, it is found that PEUs experience a combination of surface and bulk erosions, which both contribute to the degradation of the material. By tuning the reaction parameters in our simulations, we determine the crossover between degradation-controlled and swelling-controlled regimes. Using these results, we established a general framework for modeling competition between degradation and swelling-controlled mechanisms in biodegradable materials. To test model predictions and to map coarse-grained parameters, we compare the time evolution of the molecular weight distributions of the polymer chains obtained in simulations with those obtained experimentally from size-exclusion chromatography.

L70.00091: A Computational Method for Inverse Design Problem in Directed Self-Assembly of Block Copolymers  DANIIL BOCHKOV (Presenter), FREDERIC GIBOU, Mechanical Engineering, University of California, Santa Barbara — Directed Self-Assembly is an important process used in the semi-conductor industry. It uses confinement masks to drive the self-assembly of block copolymers towards targeted nano-templates for subsequent optical or e-beam lithography. The shape of such confinement masks must be carefully designed as it is one of the primary factors determining the final polymeric structures. In this talk, we present a computational approach, within the self-consistent field theory framework, for finding confinement shapes that lead to a-priori chosen self-assembled structures of block copolymers. The method is based on a constrained optimization formulation described by partial differential equations: we define a cost functional that measures the discrepancy between the target and the actual self-assembled configurations, and analytically derive the sensitivity of the functional to changes in shape, which in turn enables an efficient minimization of the functional with respect to the confinement shape. We provide simulation results that demonstrate the ability of our approach to design mask geometries that successfully guide the self-assembly to the desired targets.
L70.00092: Coarse-Grained Simulations to Understand the Effect of Grafting on Methylcellulose* VAIDYANATHAN SETHURAMAN (Presenter), KEVIN DORFMAN, University of Minnesota — Methylcellulose is a biopolymer derived from sugar, and it has a wide range of industrial applications. Recent experiments on methylcellulose solutions showed that they undergo fibril formation above the lower critical solution temperature. However, on grafting the methylcellulose polymer with polyethylene oxide (PEG), experiments show that the fibril structure is destroyed. We use coarse-grained molecular dynamics simulations to provide molecular insights into the effect of grafting on fibril formation. Our results showed that the radius of gyration of the polymer increases with increasing grafting density, in qualitative agreement with the experimental results. We also show that the loss in fibrillar structure arises from a steric repulsion between the grafted PEG monomers and the methylcellulose backbone.

L70.00093: A Coarse-Grain Model for Efficient Simulation of Self-Assembling Amyloidogenic Peptide Systems* MURRAY SKOLNICK (Presenter), ROBERT RIGGLEMAN, ZAHRA FAKHRAAI, University of Pennsylvania — Prior experiments with amyloid forming peptides have demonstrated that short peptides exhibit distinct self-assembly behavior when constrained to a surface resulting in rapid formation of amyloid fibrils. Molecular dynamics simulations of such systems can provide key insights into this self-assembly process. However, the size and time scales associated with such systems is too large for atomistic approaches to study self-assembly. Thus, we are developing an implicit-solvent coarse-grained model of amyloidogenic peptides for the investigation of their surface mediated self-assembly in these systems using MD. The model consists of three CG beads per residue where the central bead has either hydrophobic or hydrophilic character depending on the amino acid it represents. The two side-chain beads form a dipole which replicates that found in an all atom amide backbone. The simulations of initially randomly oriented peptides demonstrate rapid self-assembly into fibrillar structures upon adsorption to a surface. Additionally, the simulations show that fibrillar structures are favored at lower peptide concentrations while surface covering films are favored at high peptide concentrations which is in agreement with experimental evidence.

L70.00094: A Model for Hyaluronan Secretion into Biological Fluids JAN SCRMGEOUR (Presenter), Clarkson University — Hyaluronan (HA) is an essential biopolymer in joint tissues and synovial fluid, and changes in its molecular weight distribution have been linked to debilitating inflammatory joint conditions such as arthritis. Despite this, there is limited understanding of the physical mechanisms behind its secretion into biological fluids. HA is unique among biological polymers, as the polymer is synthesized at, and directly extruded through, the cell membrane. Current models for HA secretion have largely focused on a single enzyme, hyaluronan synthase, although no governing mechanism has been identified. In tissue observations point toward a more complex regulatory system involving additional enzymes, such as cell surface hyaluronidase, which is responsible for HA cleavage. This work presents a simple model for the synthesis and release of HA. The model makes predictions for the equilibrium molecular weight distributions of surface tethered and secreted HA. In addition, it describes the time-dependent growth and degradation of surface tethered HA. The model provides guidance for experimental investigation into rates of HA synthesis and release from the cell surface, and may act as a basis for understanding how the environment in the joint affects HA secretion into synovial fluid.
L70.00095: Predicting the linear stress and dielectric relaxations of polydisperse linear polymers* DANIEL READ (Presenter), CHINMAY DAS, School of Mathematics, University of Leeds — We present a generic algorithm to predict the linear relaxation spectrum for polydisperse linear polymers. As common in the tube theory descriptions of linear polymers, we assume that the stress relaxation is affected by both constraint release and tube escape modes. But unlike most existing descriptions, we consider how these two modes of relaxation affect each other and argue that the proper description for relaxation in an arbitrary blend of linear polymers requires consideration four embedded tubes affecting the different relaxation pathways: the thin tube, the tube for fastest reptation, the constraint release "supertube" and the fully diluted tube. We derive the scaling level descriptions of these relaxation pathways and use a large number of existing experimental results on the stress and dielectric relaxations to validate our model. For the particular case of binary blends of long and short polymers, our model is successful at predicting the linear stress and dielectric response for blends throughout the two dimensional space (constraint release rate and degree of entanglement) mapped by the Viovy diagram.

*Supported by EPSRC grant ref EP/P005403/1

L70.00096: Impact of divalent ions on the rheology and aggregation of semidilute polyelectrolyte solutions CARLOS LOPEZ (Presenter), WALTER RICHTERING, RWTH Aachen University — We report rheology and light scattering data for the Na+, Mg2+, Ca2+, Mn2+, Co2+, Ba2+ salts of carboxymethyl cellulose in aqueous solutions. The viscosity as a function of molar polymer concentration falls into a single curve for all divalent salts. Compared NaCMC, divalent salts display a lower viscosities at low concentrations (in the non-entangled regime), suggesting less expanded chains. Above the entanglement crossover, solutions with divalent counterions display viscosities an order of magnitude larger than NaCMC because interchain crosslinks form by electrostatic bridging.

DLS measurements on semidilute reveal a bimodal decay function, where the relative amplitudes of the two modes vary with counterion valence, size as well as with the filter size employed and the time after filtration. These variables (except for counterion valency) do not affect the solution viscosity, indicating that polyelectrolyte clusters contain a small fraction of the total number of chains in solution.

L70.00097: Viscoelastic Relaxation Behavior of Polyelectrolyte Complexes from Coacervate to Precipitate SAMIM ALI (Presenter), ANAND RAHALKAR, National Institute of Standards and Technology, JUAN DE PABLO, Institute for Molecular Engineering, The University of Chicago, VIVEK PRABHU, National Institute of Standards and Technology — The relaxation dynamics of polyelectrolyte complexes slows down while transitioning from coacervate to precipitate upon decreasing salt concentration. However, knowledge of such changes over full relaxation spectrum is still limited. This presentation will describe the relaxation behavior of complexes probed over a wide timescale by measuring viscoelastic spectra and zero-shear viscosities at varying temperatures, salt concentrations and molecular weights using a set of model polyelectrolytes. Our studies show that the complexes exhibit time-temperature superposition (TTS) at all salt concentrations, while the range of overlapped-frequencies for time-temperature-salt superposition (TTSS) strongly depends on the salt concentration and gradually shifts to higher frequencies as the complex approaches precipitate phase. Further understanding of this transition using the sticky Rouse model and simulations studies will be presented.

L70.00098: Free Surface Flows and Extensional Rheology of Polymer Solutions JELENA DINIC (Presenter), LEIDY NALLELY JIMENEZ, VIVEK SHARMA, University of Illinois at Chicago — Free-surface flows -- jetting, spraying, atomization during fuel injection, roller-coating, gravure printing, several microfluidic drop/particle formation techniques, and screen-printing -- all involve the formation of axisymmetric fluid elements that spontaneously break into droplets by a surface-tension-driven instability. The growth of the capillary-driven instability and pinch-off dynamics are dictated by a complex interplay of inertial, viscous and capillary stresses for simple fluids. Additional contributions by elasticity, extensibility and extensional viscosity play a role for complex fluids. We show that visualization and analysis of capillary-driven thinning and pinch-off dynamics of the columnar neck in an asymmetric liquid bridge created by dripping-onto-substrate (DoS) can be used for characterizing the extensional rheology of complex fluids. Using a wide variety of complex fluids, we show the measurement of the extensional relaxation time, extensional viscosity, power-law index and shear viscosity. Lastly, we elucidate how polymer composition, flexibility, and molecular weight determine the thinning and pinch-off dynamics of polymeric complex fluids.
L70.00099: Electronically excited states in p/p stacking compounds  AYAKA TERAUCHI, ATSUNE MITSUI, AZUSA MURAOKA (Presenter), Japan Women’s University — In particular, p/p stacking compounds have become of interest in new materials for photocatalysis, solar energy and phosphorescent organic light-emitting diodes. We investigate theoretically the photo-induced charge transfer in supramolecular chemistry such as a bowl-shaped polycyclic hydrocarbon and helical ortho-position linked phenylenes (OPs). The electronically excited states and absorption spectra of these materials were first studied by using TD-DFT calculations with various functionals. The functional that best reproduced the experimental results was found to be wB97XD, and the assignment of the experimentally observed UV-Vis absorption spectrum was successfully performed in comparison with the theoretically obtained one. We especially performed spectral assignment of the carbazole (Cz)-modified OP complexes. The results showed that the absorption spectrum of the complexes consisted of (i) an n–p* charge-transfer type transition from Cz to OPs units of longer wavelength at around 290 nm and the p–p* transition of a shorter wavelength at around 230 nm, and (ii) the components of three isomers which coexist with three kinds of substitution of Cz to OPs, such as ortho, meta and para linkage of Cz, to interconnect the aromatic units of the Ops.

L70.00100: Deformation of Hybrid Networks  MICHAEL JACOBS (Presenter), HEYI LIANG, ANDREY DOBRYNIN, The University of Akron — Mimicking the mechanical properties of soft materials and biological tissues is crucial for novel materials development for medical implants, tissue engineering, soft robotics, and wearable electronics. Bottlebrush and comb networks are shown to be able to replicate the required combination of softness, strength and toughness in solvent-free elastomers. Such networks are made by crosslinking the side chains which results in the formation of the hybrid networks which have two types of strands of different rigidity and extensibility. We use a combination of analytical calculations and coarse-grained molecular dynamics simulations of hybrid network deformation to establish universal features. In our approach we first study an idealized system which preserves the network topology and represents the difference in the strands’ bending rigidities by considering the network strands as linear polymer chains with different Kuhn lengths and degrees of polymerization. The developed model is used to describe deformation of bottlebrush and comb networks in the linear and nonlinear network deformation regimes.

L70.00101: Comparison of Mullins Effect between Tough Double Network Hydrogels and Filled Elastomers under Various Types of Deformation  THANH-TAM MAI (Presenter), Kyoto Institute of Technology, TAKAHIRO MATSUDA, TASUKU NAKAJIMA, JIAN PING GONG, Hokkaido University, YOSHIHIRO MORISHITA, Bridgestone Corporation, Tokyo, KENJI URAYAMA, Kyoto Institute of Technology — The distinctive features of the Mullins effect between the double network (DN) hydrogels (Mai et al., Macromolecules 51, 5245–5257, 2018) and filled elastomers (Mai et al., Soft Matter 13, 1966–1977, 2017) are revealed by cyclic stretching measurement with various extension modes, i.e., uniaxial, planar, unequal and equal biaxial stretching. The modulus reduction, energy dissipation (D), and dissipation factor (Δ, the ratio of dissipated energy to input strain energy) in each loading-unloading cycle are evaluated. The result indicates that the cross-effect of strains (λij; ij = x,y,z and i ≠ j) on Δ is pronounced in the DN gels whereas it is minimal in the filled elastomers. Interestingly, the modulus reduction relative to initial modulus and Δ in each cycle almost agree with each other in the DN gels, but they are considerably different in filled elastomers. This discrepancy reflects that the modulus reduction and dissipation factor are different in the main origin for the filled elastomers, while both of them totally stem from the purely elastic fracture of the chains in rigid and brittle DN gels networks.

L70.00102: Effect of miscibility on shape memory characteristics of Polymer Blends  SURBHI KHEWLE (Presenter), PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology, Gandhinagar, Gujarat — Designing programmable shape shifting materials has been a grand challenge for science and engineering. Shape Memory Polymers (SMPs) are smart materials that have the ability to transform back to their intended shape when the external conditions are reversed. One of the strategies for synthesizing SMPs is to bond soft and rigid chemical moieties with one another through polymerization. Although polymer blending offers a simple strategy, it has not been used as a preferred technique to design SMPs. As most of the polymer blends are immiscible, synthesizing SMPs through blending route introduces a new set of challenges. Here, we use the equilibrium phase diagram to examine the role of compatibility of the constituent polymers on the characteristics of SMP blend. Specifically, we use Flory-Huggins theory in conjunction with the phase-field theory to capture the amorphous-amorphous and crystal-amorphous interactions in the SMP blends, respectively. Subsequently, we use the thermo-mechanical constitutive model to demonstrate the effect of miscibility on shape fixity and shape recovery of the SMP blend. Our approach can be utilized to design SMP blends with tunable properties and allows a mechanism to establish structure-property relationships in these systems.

*IIT Gandhinagar
L70.00103: Ion Specific, Odd-Even Glass Transition Temperatures in Precise Network Polymerized Ionic Liquids

CHRISTOPHER EVANS (Presenter), CHENTIAN SHEN, QIUJIE ZHAO, University of Illinois at Urbana-Champaign — Relationships between \( T_g \), fragility, nanostructure, electrostatics and conductivity are investigated in precise network polymerized ionic liquids (n-PILs). These n-PILs contain an exact number of carbon atoms (C\( x \)) between charges in the backbone and can be exchanged to various anionic forms. The \( T_g \) exhibits an odd-even effect with the non-spherical, bulky bis(trifluoromethane sulfonamide) (TFSI) counter ion with a maximum jump of 45 K between C4 and C5 networks. In contrast, the same n-PIL networks with the smaller and spherical BF\(_4\) anion show no odd-even \( T_g \) effect. Small angle X-ray scattering of TFSI networks suggests that ionic aggregation is not the primary cause of the odd-even effect. The amorphous halo exhibits a weak odd-even dependence indicating a minor role of backbone-backbone correlations and packing on the observed effects. However, odd-even effects appear to be largely dynamical in n-PILs with only minor variations in structure. Due to the large changes in \( T_g \), the room temperature ionic conductivities of the TFSI n-PILs exhibit odd-even effects greater than an order of magnitude between adjacent C\( x \) networks. Finally, dynamic fragility shows odd-even fluctuations with higher fragility corresponds to lower \( T_g \) opposite to what is typically observed.

L70.00104: Efficient Shockwave Energy Dissipation in Dynamic Covalent PDMS Rubber

CHRISTOPHER EVANS (Presenter), JAEJUN LEE, BRIAN JING, LAURA E PORATH, NANCY SOTTOS, University of Illinois at Urbana-Champaign — Polymer networks containing transient bonds require some amount of energy to undergo an exchange process. We hypothesize and demonstrate that dynamic bonds in polydimethylsiloxane (PDMS) networks can be used as an effective mechanism for dissipating shockwave energy. By controlling the diol molecular weight, the density of dynamic boronic ester linkages can be controlled while the network chemistry is invariant. Using a classical laser induced shockwave technique, we demonstrate superior energy dissipation in a PDMS boronic ester dynamic rubber (PDMS-B-DR) compared to the benchmark polyurea and covalent PDMS (cured via thiol-ene click chemistry). A monotonic improvement in dissipation performance (monitored as a reduced peak pressure of the shockwave) is observed with increasing density of dynamic boronic ester bonds. In all cases, the Tg is invariant in the different networks (-125 °C) implying a minimal role of segmental dynamics on dissipation in these specific networks. Our results indicate that dynamic networks are a promising route to engineering improved SWED materials which are lightweight, flexible, and able to withstand repeated shocks. X-ray scattering and rheology have also been performed to relate dissipation performance to structure and relaxation of the material.

L70.00105: Approaches to Modification of Maleic Anhydride Copolymers with Applications to Antifouling and Water Purification

STEVEN ZBORAY (Presenter), KIRILL EFIMENKO, JAN GENZER, North Carolina State University — Precise control over structure and tailoring of chemical moieties along the chain are the keys to creating polymeric materials with advanced functionality. We present an approach based on maleic anhydride copolymers allowing facile modification with various chemical groups as embodied in two systems: a polymer network capable of catalytic degradation of organophosphates and antibiofouling coatings. Through the use of crosslinking, which could be controlled via several synthetic pathways, hydrogels containing hydroxamic acid groups were made that allowed the gel to be used for water purification applications. Kinetic studies of the performance of the gels in degrading the model compound dimethyl nitrophenyl phosphate (DMNP) were performed. For antifouling purposes, a systematic study of the structure-property relationships of several sulfobetaines and the ability to resist fouling by fluorescent-labeled proteins was conducted. It was also found that by varying the comonomer in the system, it was possible to control hydrophobic/hydrophilic interactions and adhere the polymers to substrates as thin-layer coatings.

L70.00106: Elastocapillary-driven Deposition of Liquid Drops in Polymer Gels

HONGBO FU (Presenter), CHRISTOPHER BARNEY, XUDONG LIANG, ALFRED CROSBY, University of Massachusetts Amherst — The deposition of a finite volume of liquid at a specific location within an elastic gel offers novel opportunities for device fabrication and materials properties measurement. We present a systematic study of the controlled deposition of liquid droplets within a polymer hydrogel. With parameters, such as pressure and viscosity of the liquid, the size and spacing of deposited liquid droplets can be controlled. To understand this process, we propose an elastocapillary-based mechanism that balances the surface tension and viscosity of the liquid with the elasticity of the gel.

*Human Frontier Science Program (HFSP) RGP0019/2017
L70.00107: Finite element modelling of polymer gels that exhibit temperature induced volume phase transitions*  
PRIYANKA NEMANI (Presenter), Department of Chemical Engineering, Indian Institute of Technology Gandhinagar, RAVI SASTRI AYYAGARI, Department of Mechanical Engineering, Indian Institute of Technology Gandhinagar, PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology Gandhinagar — Temperature-induced volume phase transitions are one of the mechanisms by which large-scale deformations are manifested in biological systems. Polymer hydrogels that undergo spontaneous volume change upon variations in temperature are, therefore, perfect candidates for designing bioinspired self-oscillating materials that can reversibly sustain large deformations. Here, we present a computational framework to design the dynamical system based on chemical reactions, that undergoes large mechanical oscillations via external loading and thermally induced volume phase transitions, simultaneously. Specifically, our model is based on a nonlinear finite element framework that essentially combines reaction-diffusion phenomena with nonlinear elastic deformations of the gel under nonisothermal conditions. Through modelling and simulation, we capture large deformations and volume changes represented by swelling/shrinkage of the gels at varied temperatures. Our major findings not only complement the existing features of polymer gels and facilitates the design of a variety of complex biomimetic systems like thermosensitive actuators but also provides a mechanism to predict their complex nonlinear phenomena.

L70.00108: Diffusion of Gold Nanoparticles in Entangled Poly (vinyl alcohol) Solutions and Gels.  
KAVINDYA SENANAYAKE (Presenter), ASHIS MUKHOPADHYAY, Wayne State University — Dynamical studies of nanoparticles in concentrated polymer solutions have importance in industrial and medical applications. We study the diffusion of gold nanoparticles (AuNPs) in high molecular weight poly (vinyl alcohol) (PVA) entangled solutions and gels. Using fluctuation correlation spectroscopy, diffusion coefficients of different sized AuNPs in different volume fractions above the entanglement volume fraction of PVA were determined. Comparison of results with the recent scaling theories will be presented.

L70.00109: Computational investigation of cavitation phenomena in physically assembled gels*  
SATISH MISHRA (Presenter), Mississippi State University, THOMAS E. LACY, JR, Mechanical engineering, Texas A&M University, SANTANU KUNDU, Mississippi State University — Cavitation rheology is a novel technique to probe local mechanical properties of soft materials. In this experiment, a defect is introduced in the gel by inserting a needle connected to a syringe pump. The growth of defect subjected to a pressure load is recorded. At critical pressure, the defect becomes unstable and suddenly expands into a cavity leading to a drop in pressure. For physically assembled gels, experimental studies demonstrate critical pressure as high as ten times of that calculated analytically using hyperelastic models. We present a finite element modeling approach to capture the coupled effect of material modulus, viscous dissipation, surface tension, and geometry confinement in determining the critical pressure. Our results indicate that a portion of pressure applied to expand the defect dissipates through stress relaxation mechanism, thus, pumping rate influences the critical pressure. Surface tension restricts the expansion of defect while the confinement introduces an artificial stiffening response to the gel, hence, increase the critical pressure. We will also compare the finite element analysis results with that obtained from cavitation experiments.

L70.00110: Polyethylene Cross-link Density Effects on Crystallization and Shape Memory Performance*  
DEAN PENNER (Presenter), CHESTERTON B SCHUCHARDT, AUDREY T YOUNG, DAVID D HSU, Wheaton College — In pursuit of a model of microstructure-property relationships in cross-linked, semi-crystalline Shape Memory Polymers (SMPs), we investigate the effect of cross-link density on thermally-activated SMP performance characteristics. Specifically, we aim to establish a relationship between crystal size distribution and shape fixity, shape recovery rate, and shape recovery temperature. United-atom Molecular Dynamics (UAMD) simulations of the shape memory cycle for cross-linked polyethylene are carried out at varying cross-link densities between 150 and 800 g/mol. Crystal size distribution is investigated as a function of cross-link density using order parameter and a density-based clustering algorithm. Both shape fixity and shape recovery rate are found to increase with lower cross-link density down to 150 g/mol, due to the uniform crystal size distribution resulting from unimpeded crystal growth.

*D.P., C.S., A.Y., and D.H. acknowledge support from the Wheaton College Alumni Association and Wheaton Summer Research Grant.
While plants are traditionally regarded as static, some plants are able to move at accelerations thousands of times the acceleration of gravity. Engineered systems seek to achieve the high accelerations and high speeds observed in nature for use as fast and adaptable materials. Using the inspiration of plant seed pods, we aim to demonstrate that adhesion may act as self-releasing latch when sufficient bending energy is applied to overcome the adhesion of the latch, causing rapid energy release in the form of a bending motion. We prepare a bilayer beam made of polydimethylsiloxane (PDMS) layers with different crosslinking densities, which provides a mechanism for asymmetric swelling and bending when placed in good solvents. Our actuator approaches accelerations 20 times that of gravity and with total response times on the order of 10 ms over cm-scale distances. This work is one step towards increasing the abilities of soft actuators and robots capable of fast motion that are not limited by the requirements of mechanical motors.

**L70.00112: Water Dynamics in Poly(N-isopropyl acrylamide) Solutions at Ambient and High Pressure Probed with Quasi-elastic Neutron Scattering**  
BART-JAN NIEBUUR, Physics Department, TU Munich, WIEBKE LOHSTROH, Heinz Maier-Leibnitz Zentrum (MLZ), TU Munich, MARIE-SOUSAI APPAVOU, Jülich Centre for Neutron Science at MLZ, TU Munich, ALFONS SCHULTE (Presenter), Physics Department, University of Central Florida, CHRISTINE M. PAPADAKIS, Physics Department, TU Munich — We investigate the dynamic behavior of hydration water in a 25 wt% aqueous Poly(N-isopropyl acrylamide) (PNIPAM) solution in dependence on temperature (25 – 50 °C) and pressure (0.1 – 130 MPa) employing quasi-elastic neutron scattering (QENS). The susceptibility spectra span the frequency range from 2 GHz to 2 THz at momentum transfers between 0.7 to 1.7 A⁻¹ and reveal the relaxation peak of the hydration water near 10 GHz, in addition to the known diffusive and effective local and vibrational processes of bulk water. Evaluating the temperature dependence, we find that, at atmospheric pressure, the relative population of (bound) hydration water sharply decreases upon heating from the one-phase to the two-phase state, i.e. the chains dehydrate strongly. In contrast, at 130 MPa, no sharp decrease is observed, i.e. the dehydration takes place over a much broader temperature range. This suggests an enhanced hydrophobic hydration at high pressure.

**L70.00113: Biomimetic wet-applicable adhesive as a stiffness-tunable binding interface for on-skin sensors and self-locking actuators**  
SONG CHEN, South China University of Technology, SONGSHAN ZENG, University of Connecticut, LAN LIU, South China University of Technology, LUYI SUN (Presenter), University of Connecticut — Both stimuli responsive strain sensors and actuators have drawn significant attention because they are promising in a wide span of applications, including wearable devices, stretchable electronics, and soft robotics. However, there are few researches focusing on achieving a wet-applicable, ultra-conformable, and stiffness-tunable interface, which is highly critical in these fields. Herein, we develop a novel wet stretchable adhesive that shows high binding strength to various substrates. Furthermore, by introducing hygroscopic calcium chloride (CaCl₂) into the system, the Young's modulus of the adhesive film can be easily adjusted from higher than 1.5 GPa to lower than 0.01 MPa under ambient environment (ca. 25 °C, 70% relative humidity) because of the water uptake and the corresponding plasticizing effect. We further use this adhesive to fabricate a soft (skin-like modulus, 0.1-10.0 MPa), thin (~50 μm), highly sensitive (a gauge factor of ~2000 under 20% strain), and ultra-compliant on-skin strain sensor and a multi-responsive (heat, near infrared (NIR) light, voltage, and humidity) self-locking actuator. A new avenue has been created to address both sensing and actuating bottlenecks by introducing a wet-applicable adhesive as a versatile and robust binding interface.

**L70.00114: Spinodal Decomposition-Induced Surface Wettability Modification of Thermo-Responsive Nanoemulsion Films**  
HYEMIN SEO (Presenter), JIN WOONG KIM, Hanyang University — Functional polymer thin films with a multilayer structure have been constructed with nanometer scales typically by using the sequential adsorption of oppositely charged polyelectrolytes onto a solid substrate. Tight control over phase separation is essential for providing the film with structured surface heterogeneity as well as surface functionality. Herein, we fabricate nanoscale emulsion thin films by utilizing the layer-by-layer deposition. Their thickness was tunable to micrometer scales by solely changing the number of alternate emulsions and polyelectrolytes layers. Interestingly, the nanoemulsion films exhibited a thermoresponsive heterogeneous phase separation behavior, which is typically referred as Spinodal decomposition. We observed that surface wettability of the Nanoemulsion films was critically dependent upon the pattern of the Spinodal decomposition, which enables development of thin film-based smart drug delivery patches.
L70.00115: Towards Optimizing Synthesis Temperature for Microgels with Large Degree of Deswelling* KIRIL STRELETZKY (Presenter), KRISTA G FREEMAN, JACOB ADAMCZYK, Cleveland State University — Polysaccharide microgels have been synthesized at various temperatures (Tsyn) above the LCST of the parent polymer. Microgel structure and dynamics below and above the corresponding volume phase transition have been studied with light scattering. All microgels were found to undergo a reversible 15-50-fold deswelling in volume. However, the size distribution, structure, dynamics, and deswelling ability of microgels were found to strongly depend on synthesis temperature. In this work, the attempt was made to optimize the synthesis temperature to yield more monodisperse microgels with a larger degree of deswelling. The results suggest that Tsyn influences the density distribution of microgels and, therefore, their structure and dynamics.

*USRA program of CSU and REU Award #1659541

L70.00116: Effect of Elasticity, Viscosity, External Dissipation and Structures on Impulsive Elastic Energy Release in Polymers* XUDONG LIANG (Presenter), ALFRED CROSBY, Polymer Science and Engineering, Univ of Mass - Amherst — Impulsive elastic energy release in materials have been widely adopted in small organisms and engineered micro-robotic devices to achieve high speed motion. The kinematics of impulsive motion are well characterized through high speed camera imaging, but the mechanics of the materials under large deformation and high strain-rate deformation is not yet established. Here, we present a theoretical and experimental study about the effects of material properties, environmental interactions and structures of synthetic polymers for the performance of a free retraction. Building upon the 1D elastodynamics and nonlinear mechanics, we discover that kinematics of impulsive recoiling can be described through a power-law constitutive model, and the residual strain after retraction determines the maximum center-of-mass velocity. The viscous losses in the materials and frictional force in the environment are shown to significantly affect the center-of-mass velocity. Finally, we explore how topologies in mechanical metamaterials can lead to control of impulsive elastic energy release.

L70.00117: Microballistic Deformation Behavior of Carbon Nanotube Mats WALE LAWAL, Eglin Air Force Base, JINHO HYON, Rice University, RAMATHASAN THEVAMARAN, University of Wisconsin, EDWIN THOMAS (Presenter), Rice University — We investigate the energy absorption characteristics of 2D isotropic multiwall carbon nanotube (MWCNT) mats using a micro-projectile impact test at velocities ranging from 300 m/s to 900 m/s. The quasi-static properties of the 2D isotropic network of meandering MWCNT nanofibers are quite modest but at the extreme strain rates and large strains of ballistic impact, the deformation behavior of the mat results in unprecedented energy absorption per unit mass of the target mat. The mat is comprised of a network of ultra high aspect ratio interconnected tubes and tube bundles with many branches and cross-overs leading to increasing retarding forces from the interacting tubes and tube bundles with the silica sphere projectile. As the projectile rotates and moves forward, the MWCNT tubes and tube bundles are straightened and pulled into the impact region. The increased friction associated with the amplified surface interactions occurring between the translating principal tubes raises the load on those portions of the tubes adhering to the sphere surface and the subsequent large back-deflection of the impact region slows the advancing projectile as KE is converted into elastic stretching energy of the network and ultimately fracture of many principal tubes.

L70.00118: Slicing of soft materials STEVEN RHODES (Presenter), ERIC WEEKS, Emory University — We experimentally study the slicing of soft materials. We use a rheometer to press a circular cutting tool into materials (a steel “cookie cutter”). This allows us to measure the normal force required to press the cutter and the torque required to rotate the cutter, while controlling the shear rate. Our soft materials are Styrofoam and PDMS. We find rotating the cutter makes it easier to cut into the material. In particular, without rotation, the cutter only indents the Styrofoam rather than slicing it.

L70.00119: Optimizing random heteropolymers to improve protein folding in cell-free synthesis ZHIYUAN RUAN (Presenter), TAO JIANG, TING XU, Materials Science and Engineering, UC Berkeley — Membrane proteins play key roles in biological activities, and represent one of most prevailing drug targets. Functional and structural analysis of membrane proteins remain intriguing but challenging due to the protein misfolding and aggregation. Here, we show that four-meronmer random heteropolymers (RHPs) can assist membrane protein folding during translation in cell free synthesis. Two types of membrane proteins, Aquaporin Z (water channel, helices) and OmpT (protease, barrel) were examined, and demonstrated tunable polymer performance by controlling the composition of RHPs. The results indicated that the extent of folding assistance of various RHPs for the membrane proteins was different due to the chemical heterogeneity along the length of RHP chains. An in-house program for chemical heterogeneity analysis was developed to investigate the sequences of various RHPs and proteins. The current data suggests that RHPs act as artificial chaperones and that their ability to aid in the proper folding of membrane proteins can be easily tuned by changing their composition.
L70.00120: Thickness-dependent elastic modulus of spin-coated PDMS films*  PAK MAN YIU (Presenter), HAILIN YUAN, OPHELIA TSUI, Department of Physics, Hong Kong University of Science and Technology — Poly(dimethyl siloxane) (PDMS) elastomer is one of the most commonly used substrate materials for stretchable electronics and artificial skin. Many fundamental studies of soft interface mechanics use PDMS. It is therefore important to understand the factors affecting the mechanical properties of this material. A previous study revealed that the elastic modulus, $E$, of spin-coated PDMS increased almost three-fold when the PDMS thickness, $h$, was decreased from 108 to ~30 μm. The enhancement in $E$ had been attributed to the alignment of PDMS chains during spin-coating. In this study, we measured the elastic modulus of spin-coated PDMS with various $h$ from 15 to 110 μm. We found that $E$ increased with decreasing $h$ initially, but on reaching $h \sim 20$ μm, $E$ decreased with decreasing $h$. We verified that this phenomenon was universal regardless of the curing condition. We discuss a possible origin for the phenomenon with supporting measurement data.

*NSF DMR-1624569

L70.00121: Force Balance at Contact Lines of Soft Substrates*  HEYI LIANG (Presenter), Department of Polymer Science, University of Akron, ZHEN CAO, Department of Materials Science and Engineering, Massachusetts Institute of Technology, ZILU WANG, ANDREY DOBRYNIN, Department of Polymer Science, University of Akron — We use coarse-grained molecular dynamics simulations to show that the force balance analysis at the triple-phase contact line formed at an elastic substrate must include a quartet of forces: three surface tensions (surface free energies) and an elastic force per unit length. In the case of the contact line formed by a droplet on an elastic substrate, the elastic force is due to substrate deformation generated by formation of the wetting ridge. The magnitude of this force $f_{el}$ is proportional to the product of the ridge height $h$ and substrate shear modulus $G$. Similar elastic line force should be included in the force analysis at the triple-phase contact line of a solid particle in contact with an elastic substrate. For this contact problem elastic force obtained from contact angles and surface tensions is a sum of the elastic forces acting from the side of a solid particle and an elastic substrate. By considering only three line forces acting at the triple-phase contact line, one implicitly accounts the bulk stress contribution as a part of resultant surface stresses. This “contamination” of surface properties by a bulk contribution could lead to unphysically large values of the surface stresses in soft materials.

*L70.00122: Effects of force on facilitated protein dissociation  JING ZHAO (Presenter), KATELYN DAHLKE, CHARLES E. SING, University of Illinois at Urbana-Champaign — Protein-DNA interactions depend on the conformation of DNA, so binding/unbinding kinetics may be altered by applied forces; classically, protein unbinding is accelerated and binding is inhibited as force increases. Additionally, certain proteins exhibit concentration-dependent dissociation rates, where proteins in solution compete to facilitate protein dissociation from DNA. Together, facilitated dissociation (FD) and force can lead to diverse dissociation behaviors including “slip bonds”, where dissociation rates decrease with force, and “catch bonds”, where dissociation rates increase with force. We investigate these combined effects via coarse-grained simulation. We reproduce concentration-dependent rates that are observed experimentally and explore how force can alter these binding kinetics. We observe catch bonds when protein binding is strongly coupled to the force, while the force dependence of protein unbinding is relatively weak. Slip bonds occur under opposite conditions. Transitions between these different bonds occur when force effects on binding and unbinding compete. Thus, applied force may regulate protein-DNA interactions by inhibiting FD by coupling protein exchange rates to DNA conformations.

L70.00123: Melt-Electrospinning of Poly(ether ether ketone) Fibers to Avoid Sulfonation*  NELAKA DILSHAN GOVINNA (Presenter), THOMAS KELLER, PEGGY CEBE, Department of Physics and Astronomy, Tufts University — We have successfully electrospun un-sulfonated fibers of poly(ether ether ketone), PEEK, from the molten state. A high temperature furnace was used to melt electrically grounded PEEK pellets at 350 °C, and the electric force caused fibers to be deposited onto the high voltage collector. Whereas solution electrospinning of PEEK results in sulfonation of the polymer chain and reduction of thermal stability, direct melt electrospinning produced PEEK fibers which are chemically unaltered from as-received pellets, as shown by their Fourier transform infrared spectra. Thermogravimetry demonstrated electrospun PEEK fibers have similar thermal decomposition temperature, $T_d = 600$ °C as the pellets. Melt electrospun fibers had a large range of diameters, ranging from 1.5 μm to 8.5 μm, and were smooth, defect-free, and round in cross-section. As-spun amorphous fibers, with thicknesses less than 10 μm and masses ~200 ng, were selected for fast scanning calorimetry (FSC) experiments. Using heating and cooling rates from 50 to 2000 K/s, FSC studies were made of the glass transition, melting and crystallization behavior of electrospun PEEK fibers.

*NSF DMR 1608125
L70.00124: Structural differences in regenerated cellulose fibers produced using Viscose and Lyocell techniques*  
AAKASH SHARMA (Presenter), GURUSWAMY KUMARASWAMY, National Chemical Laboratory, SHIRISH THAKRE, Aditya Birla Science and Technology Company Pvt. Ltd. — We compare the structural features of regenerated cellulose fibers manufactured using Viscose and Lyocell processes. It is known that these fibers possess different surface morphologies. However, there is not much information on nanoscale structural features e.g. microvoids, lamellar structure etc. We show using small angle x ray and ultra-small angle neutron scattering that the fibers possess elongated microvoids, oriented in the fiber direction. We analyse 2D SAXS data using Ruland’s equatorial streak method and obtain average length and average misorientation of the microvoids in both fibers. Using Porod’s law and invariant calculated from the combined SAXS and USANS measurement, we evaluate the radius. We show that Lyocell fibers have bigger, better orientated voids than Viscose fibers. There are also differences in the crystal structure of these two fibers. Scattering from Viscose fibers show evidence for lamellar stacking in the fiber direction whereas, that from the Lyocell fibers is qualitatively different and does not show stacking. This shows that process differences strongly affect the microstructure of the fibers at length scales of few nanometres.

*We acknowledge Aditya Birla Science and Technology Company Pvt. Ltd. For funding.

L70.00125: A molecular model for ductility (T< Tg) and drawability (T>Tg) of semicrystalline polymers*  
SHIQING WANG, MASOUD RAZAVI (Presenter), Department of Polymer Science, University of Akron — We make oversimplifications to construct a tractable molecular model for mechanics of semicrystalline polymers that takes into account of the mechanical interplay between crystalline and amorphous regions connected by tie chains. The idea can be reformulated to address the origin of yielding or breaking in semicrystalline polymers that form spherulites. Our goal is to understand the brittle failure of fully crystallized glassy polymers such as PLA and PET and whether or not various semicrystalline polymers are highly drawable above their glass transition temperatures.

*This work is supported, in part, by NSF-DMR 1609977.

L70.00126: Semiflexible Polymers in Spherical Confinement  
ARASH NIKOUBASHMAN (Presenter), Johannes Gutenberg University Mainz, ANDREY MILCHEV, Institute for Physical Chemistry, Bulgarian Academy of Sciences, MIHIR KHADILKAR, Johannes Gutenberg University Mainz, SERGEI EGOROV, Chemistry, University of Virginia, DANIEL VEGA, Physics, Universidad Nacional del Sur-IFISUR-CONICET, KURT BINDER, Johannes Gutenberg University Mainz — Semiflexible macromolecules find various applications as versatile materials, in particular due to their possible liquid crystalline order, and are also important constituents of living matter. We studied the ordering of such stiff macromolecules confined in spheres by molecular dynamics simulations, and found that densely packed semiflexible polymers cannot exhibit uniform nematic order when their contour length is of the same order as the sphere radius. Instead, the confinement leads to the emergence of topological defects on the sphere surface with competing ordering in the interior of the sphere. Each of the configuration variables including chain length, chain stiffness, packing density, and shell thickness uniquely affect the ordering, including the nature and relative orientation of the defects on the surface. For example, at high densities, a thin shell of polymers close to the surface exhibits a quadrupolar tennis ball texture due to the confinement-induced gradual bending of polymer bonds. Systemic trends observed could pave the way for better understanding the links between topological defects and elastic properties of polymers. Further, controlling the defect locations is promising for designing patterned colloids in experiments by functionalizing defect sites.

L70.00127: Replicating Chiral Structures with Common Polymers and the Study of Surface Changes under VOC’s  
THOMAS STOKE (Presenter), PETR SHIBAYEV, Fordham University — Liquid crystals are known to have interesting surface patterns, characterized by focal conic domains patterned across their surface. These chiral structures can be observed through Atomic Force Microscopy, and replicated on the surfaces of common polymers. When exposed to certain Volatile Organic Compounds (VOC’s), the surface structures of chiral polymers are seen to break down. However, on these replica polymers, no such changes can be seen. The applications of these traits are discussed.
L70.00128: Dynamic Relaxation and Glass Transformation of Electrospun Fibrous Membrane with Confined Chain Configuration: for Physical Aging and Shape Function Control and Delivery  BIN XIAO, CHENHONG WANG, NUOZI ZHANG, HERAN WANG, XUHONG CHEN (Presenter), SHANSHAN XU, CHARLES C HAN, Institute for Advanced Study, Shenzhen University — The thermodynamic glass transformation processes of electrospun membranes are firstly introduced to study the dynamic relaxation nature of this not always in equilibrium transformation process. The relaxation modes of the electrospun membrane are slow but measurable in the vicinity of the Tg and even above the Tg due to the stretched chain in long distance. Based on the differential scanning calorimetry (DSC) experiments and the general principle of mode-coupling theory (MCT), the endothermic peak temperature and the relaxation enthalpy were used to analyze the relaxation process by capturing these instantaneous "arrested" structures. With different annealing time and annealing temperatures relative to DSC measured T for E-spun membrane with different molecular weight, the short and long wavelength relaxation modes could be identified. These results clearly show the dynamic nature of the glass transition in polymeric materials which can be explained by the general principle of MCT type of dynamic theory.

L70.00129: Terahertz Dynamics of Carboxymethyl Starch*  WAKANA TERAO, LEONA MOTOJI (Presenter), TATSUYA MORI, Division of Materials Science, University of Tsukuba, KAROLINA KACZMARSKA, BEATA GRABOWSKA, Faculty of Foundry Engineering, AGH University of Science and Technology, YASUHIRO FUJII, AKITOSHI KOREEDA, Department of Physical Sciences, Ritsumeikan University, MIKITOSHI KABEYA, Division of Materials Science, University of Tsukuba, JAE-HYON KO, Department of Physics, Hallym University, SEIJI KOJIMA, Division of Materials Science, University of Tsukuba — We performed terahertz time-domain spectroscopy on microwave-treated sodium carboxymethyl starch (CM-Starch), to detect the boson peak and fracton. Starch is a natural polymer formed by polymerization of a number of D-glucose molecules by glycosidic linkage and CM-Starch is produced by carboxymethylating the starch. The obtained spectral shape of boson peak plot $\alpha(\nu)/\nu^2$ of the CM-Starch, where $\alpha(\nu)$ is the absorption coefficient, is different from vitreous glucose. It suggests the existence of the fracton in the CM-Starch.

L70.00130: Contrasting rubber-toughen mechanisms for glassy polymers*  MASOUD RAZAVI (Presenter), SHIQING WANG, Department of Polymer Science, University of Akron, HAILAN GUO, Dow Chemical — We perform standard pre-yield and post-yield stress relaxation to probe molecular mobility in various rubber-toughened polymer glasses and to differentiate between "apparent" and true yielding. The rubber-toughened PS and SAN, e.g., HIPS and ABS, show apparent yield at high strains whereas a new generation of PMMA based nanocomposites from Dow Chemical is transparent, truly ductile and shows enhanced molecular mobility in post-yield deformation at different draw rates, form a sharp contrast with the conventional materials such as HIPS and ABS.

*This work is supported, in part, by NSF-DMR 1609977.

L70.00131: The morphology and flowing behaviors of TEMPO-oxidized cellulose nanofibers dispersed in non-aqueous solutions*  RUIFU WANG (Presenter), TOMAS ROSEN, CHENGBO ZHAN, BENJAMIN S HSIAO, Chemistry, Stony Brook University — Cellulose nanofibers (CNF), sustainable and possessing good mechanical properties, is a good reinforcement agent for polymer composites. However, pure CNF is hard to disperse in common organic solvents due to the strong interfibrillar H-bondings and $van der Waals$ interactions. In this study, we investigated the dispersion behavior of CNFs having different charged density, prepared by the TEMPO-oxidation and nitro-oxidation methods, in two different non-aqueous solvents: ethylene glycol and propylene glycol. The morphologies of CNF was first characterized by combined AFM, TEM and solution SAXS methods, whereby the results showed that the fiber cross-section dimensions were closely related to the oxidation conditions that also led to different charge density. The rheological results indicated that the overlap concentration of the suspension is solvent independent. Moreover, the CNF/glycol suspensions behave very similarly to polymer solutions, exhibiting shear thinning behavior beyond the overlap concentration. We postulate that the solvent exchanging method could also be used to disperse CNF into other non-aqueous solvent for better mixing with hydrophobic polymers.

*The presenter would like to thank the National Science Foundation (DMR-1409507)
L70.00132: Polymer physics and flow dynamics of thermodynamically pure ring polymers*  
MICHAEL TU (Presenter), CHING-WEI LEE, CHRISTOPHER RUDOLPHI, SIMON ROGERS, CHARLES SCHROEDER, Department of Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign — Ring polymers have fascinated polymer chemists and physicists for decades, yet achieving a complete understanding of the dynamics of pure ring polymer systems has remained elusive due to major challenges in residual linear polymer contamination. Despite recent advances in purification methods, trace amounts of linear polymers are thought to remain in existing ring polymer samples, greatly affecting the mechanical properties of these materials. Here, we study the equilibrium and non-equilibrium flow properties of synthetic rings based on cyclic poly(phtalaldehyde) (cPPA), a low-temperature polymer whose linear chain analogues are thermodynamically unstable at room temperature due to depolymerization at free ends. The polymerization reaction yields high molecular weight cyclic polymers with no free ends, thereby providing highly pure and thermodynamically stable ring polymers. Using this approach, we study the linear viscoelastic properties, zero-shear viscosity, and nonlinear flow response of cPPA samples as a function of polymer molecular weight and weight fraction. Overall, these results give insight into the dynamics of ring polymer systems with unprecedented purity.

*This work is supported by the NSF Grant CBET-1604038 to CMS.

L70.00133: Nonlinear melt rheology explored by molecular dynamics simulations*  
YEXIN ZHENG (Presenter), MESFIN TSIGE, SHIQING WANG, The University of Akron — We apply bead-spring based molecular dynamics simulation to study both shear and extensional responses of entangled melts. Shear creep is carried out to show the emergence of entanglement-disentanglement transition (EDT) previously observed in experiment [1], confirming that EDT can take place in absence of edge instability. At high Rouse-Weissenberg numbers (larger than ca. 5), entangled melt is observed to undergo melt rupture independent of whether Filament stretching rheometry or Sentmanat extensional rheometry is employed. The lack of yielding suggests intriguing lockup of chain entanglement in melt stretching [2]. Such extreme tensile strain localization is observed for the first time in MD simulation, corresponding to the threshold of full chain disentanglement in absence of the chain scission mechanism that in reality triggers the unzipping of chain entanglement.

*This work is supported, in part, by NSF-DMR 1609977.

L70.00134: Melt Blown Cross-linked Fibers from Thermally Reversible Diels-Alder Polymer Networks*  
KAILONG JIN (Presenter), SUNG-SOO KIM, JUN XU, FRANK BATES, CHRISTOPHER ELLISON, University of Minnesota — Melt blowing is a process in which liquid polymer is extruded through orifices and then drawn by hot air jets to produce nonwoven fibers. Melt blown nonwovens constitute more than 10% of the $50 billion global nonwovens market. Thermoplastic feedstock, such as polyethylene, polypropylene, and poly(butylene terephthalate), have dominated melt blown nonwovens because of their combined cost, good chemical resistance and high-temperature performance. Cross-linked nonwovens from other commodity polymers (e.g., (meth)acrylates, styrenics, silicones, etc.) could be attractive alternatives; however, no commercial cross-linked nonwovens currently exist. Here, cross-linked fibers were produced via one-step melt blowing of thermoreversible Diels-Alder polymer networks comprised of furan- and maleimide-functional methacrylate-based polymer backbones. These dynamic networks decross-link and flow like viscous liquids under melt blowing conditions, then revert to a network via cooling-induced cross-linking during/after melt blowing. Finally, the resulting cross-linked fibers can be recycled because of their reversible dynamic nature, which may help address the microfiber pollution problem.

*The authors thank Cummins Filtration for financial support.
L70.00135: Properties of chemically crosslinked methylcellulose gels  PETER SCHMIDT (Presenter), Department of Chemical Engineering and Materials Science, University of Minnesota, Twin Cities, SVETLANA MOROZOVA, Department of Chemistry, University of Minnesota, Twin Cities, MCKENZIE COUGHLIN, Department of Chemical Engineering and Materials Science, University of Minnesota, Twin Cities, S. PIRIL ERTEM, THERESA M. REINEKE, Department of Chemistry, University of Minnesota, Twin Cities, FRANK BATES, Department of Chemical Engineering and Materials Science, University of Minnesota, Twin Cities, TIMOTHY LODGE, Department of Chemistry, University of Minnesota, Twin Cities — Methylcellulose (MC) is used in an impressively wide variety of commercial products due to its ability to reversibly form fibrous networks upon heating. To investigate the effect of crosslinking on these materials, we have prepared two types of gels and compared their thermodynamic and elastic properties. First, crosslinked methylcellulose gels were prepared at room temperature using a thiol-ene click reaction. Allyl methylcellulose was crosslinked with dithiol poly(ethylene glycol) ($M = 1500$ g/mol) and allowed to swell to equilibrium as a function of temperature and strand length. Upon heating, instead of forming fibrous networks, crosslinked methylcellulose gels experience volume change. By measuring the polymer volume fraction and modulus of gels in equilibrium we identify the thermodynamic parameters that drive the gel volume change using a modified Flory-Rehner theory. Second, crosslinked methylcellulose fiber gels were prepared by crosslinking allyl methylcellulose solutions at 80 °C, after the full conversion of chains to fibrils. The swelling and thermodynamic properties of crosslinked chain gels and crosslinked fiber gels will be compared and discussed.

L70.00136: Gel Point Determination of a Diffusive Photopolymer via $^1$H NMR Relaxometry*  CASEY LEE-FOSS (Presenter), ANTHONY V LYNCH, GRETCHEN HOFMEISTER, Dept. of Chemistry, Carleton College, MARTHA-ELIZABETH BAYLOR, Dept. of Physics and Astronomy, Carleton College — Diffusive photopolymers can simplify the fabrication of “lab on a chip” devices. Knowledge of the gel point of the photopolymer, defined as the exposure time when an infinite macromolecule is formed, is required to create complex coplanar features via UV exposure. Because instrumentation for traditional gel point determination techniques is not locally accessible, we sought to develop a locally available method of gel point quantitation for a two-stage methacrylate/thiol-ene formulation. Since methacrylate chain growth and increasing cross-linking during the sol-gel transition reduces the mobility of diluent monomers, we hypothesized that the gel point can be found using NMR inversion-recovery to measure how polymerization affects the mobility-dependent $T_1$ relaxation time of an added “spectator” molecule. We present results showing a correlation between the rheological gel point and the time when the slope of $T_1$ versus exposure time changes, demonstrating $^1$H NMR relaxometry is a feasible method of gel point determination.

L70.00137: Self-Moving Polymer beads*  ANKUR MITTAL (Presenter), PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology Gandhinagar — Self-propelled motion through internalized chemical reaction, a characteristic of living systems, has led to the design of various synthetic bio-inspired systems. Here, we design a self-moving macroscopic system through careful use of self-oscillating chemical reaction inside a polymeric gel. Specifically, we use poly-N-isopropylacrylamide (NIPAAm) gel bead as a miniaturized reactor and harness chemical oscillations of the Belousov Zhabotinsky (BZ) reaction to produce sustained motion. In a typical experiment, the gel beads are charged with BZ reagents and placed on an oil-covered substrate. Due to the porous nature of the gel beads, the intermediates of BZ reaction ooze out of the gel and react with oil, thereby producing spontaneous motion of the bead via Marangoni effect. We further demonstrate that the velocity of the beads can not only be controlled by tuning the kinetics of BZ reaction but also by varying the external stimuli. In particular, we show that by using Ru decorated graphene nanosheets as catalysts the velocity of the beads can be enhanced significantly compared to the traditional solution based catalysts. Our findings can be used to design self-propelled conveyor belts that can deliver cargo from micron to mm length scale.

*DST-SERB (EMR/2016/007778)
Self-oscillating polymer gels that intrinsically utilize Belousov-Zhabotinsky (BZ) reaction have emerged as an interesting class of smart materials due to their biomimetic characteristics. Here, we synthesize polymer gels using imidazolium-based ionic liquid as a precursor and immobilize the catalyst of the BZ reaction onto the backbone of the gel. Further, we replace the protonating agent in the BZ reaction with Ethyl Ammonium Bisulfate (EABS)—a protic ionic liquid. In essence, we demonstrate that through careful replacement of BZ reagents with their ionic liquid counterparts, the chemical oscillations in the BZ system can be manifested into mechanical swelling and deswelling of the polymer gel, just like the conventional BZ gels. Our approach, however, offers significant advantage over the BZ gels synthesized through the conventional route. Specifically, due to the presence of ionic bonds the dynamics of the mechanical oscillations in our self-oscillating ionic gels can be controlled via electric and magnetic fields. Thus, our approach opens up new avenues for designing multi-functional biomimetic systems that can be controlled by application of variety of external stimuli.

*L70.00138: Design of Self Oscillating Ionic Gels*
SAIRAM S (Presenter), Department of Chemical Engineering, Indian Institute of Technology, Gandhinagar, ARNAB DUTTA, Department of Chemistry, Indian Institute of Technology, Gandhinagar, ARVIND KUMAR, Salt and Marine Chemicals Division, Central Salt and Marine Chemicals Research Institute, Council of Scientific and Industrial Research (CSIR), G.B Marg, Bhavnagar 364002, PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology, Gandhinagar —

L70.00139: Salt and Water Diffusivities in Polymer Electrolyte Membranes
DIPAK ARYAL (Presenter), VENKATRAGHAVAN GANESAN, University of Texas at Austin — Motivated by experimental observation where transport properties of salt ions and water in charged polymer membranes exhibit an intriguing dependence on salt concentration, we have probed a series of atomistic molecular dynamics simulations of non-cross linked membranes in aqueous mono and divalent salt solutions along with mesoscale dissipative particle dynamics (DPD) simulations for crosslinked membranes at concentrations ranging from 0.06 to 1 M. We investigate the molecular level understanding the effects of both multi-component salt solutions and crosslinking of polymers on fundamental salt and water transport properties. Our finding shows that the diffusion of salt ions and water are influenced by cation sizes and salt concentrations. Divalent ions are more strongly coupled with ionic groups which reduce their motions as increasing concentration in fixed charged membranes. In crosslinked membranes, diffusion of salt ions and water are reduced significantly relative to non-crosslinked systems. However, the trends exhibited by the salt concentration dependence of diffusivities, and the coordination of the cations with anions, and with the polymer backbone remain qualitatively similar to those observed in non-crosslinked membranes.

L70.00140: Effect of doping ratio on lithium-ion conductivity in nanostructured self-doped block polymer electrolytes
MELODY MORRIS (Presenter), Department of Chemical and Biomolecular Engineering, University of Delaware, THOMAS H EPPS, Department of Chemical and Biomolecular Engineering, Department of Materials Science and Engineering, University of Delaware — Self-doped polymers, in which the salt anions are attached covalently to the polymer, are promising alternatives to salt-doped polymer electrolytes because concentration polarization is reduced and stability is enhanced in the electrolyte. A self-doped diblock terpolymer electrolyte was synthesized such that one block was composed of a high modulus material and the other block consisted of both ion-conducting and self-doping monomer segments. The self-doped block polymers were made with a series of self-doped lithium concentrations (by altering the relative amounts of ion-conducting and self-doping monomer segments). Small-angle X-ray scattering results suggested that all self-doped block polymers exhibited ordered nanostructures. AC impedance spectroscopy and DC polarization were used to evaluate the conducting properties of the electrolyte (ionic conductivity and transference number), and the conductivities increased with self-doping ratio. Thus, with the framework for nanostructured self-doped block polymer electrolytes realized, the ion content can be manipulated to design improved electrolyte systems.

L70.00141: Tailoring Ionic Conductivity of Block Copolymer Electrolytes with End-functionalyzed Homopolymers
JIHOON KIM (Presenter), MOON JEONG PARK, Pohang University of Science and Technology — Block copolymer electrolytes based on poly(ethylene oxide) (PEO) have been regarded as promising candidates of solid electrolyte materials for lithium ion batteries. This is attributed to their ability to dissolve lithium salts and high ionic conductivity of the resultant polymer/salts complexes. However, PEO crystallization below its melting temperature has been tied to a radical reduction in ionic conductivity, especially at room temperature, various attempts have been made to reduce the PEO crystallinity. Herein, we propose a new method to modulate crystallization behavior of PEO-based block copolymers with embedded end-group-functionalyzed PEO homopolymers. Intriguing, the morphology and ionic conductivity of the resultant block copolymer/homopolymer blends were sensitive function of the type of end group in PEO homopolymers at the same blend ratio. Our approach offers a platform for the development of efficient solid-state polymer electrolytes by controlling intermolecular interactions in PEO phases via a simple end-group chemistry.

L70.00142: Ion clustering behavior of “precise” phosphonated polymers
SE JONG KANG (Presenter), MOON JEONG PARK, Pohang University of Science and Technology — Polymers functionalized with phosphonic acid groups are promising candidates of proton exchange membranes for fuel cells that can be operating at high temperatures. This is owing to the amphoteric nature and self-dissociation ability of phosphonic acid groups, unlike sulfonic acid counterparts, thereby allowing acid groups to form hydrogen-bond networks in the absence of moisture. In the present study, we report the synthesis of polymers bearing phosphonic acid groups at the precise position. For this purpose, controlled radical polymerization of styrene phosphonate was carried out, where the substitution positions were varied based on ortho, metal, para directing groups. It has been revealed that polymers tethered with phosphonic acid groups at meta and ortho positions display suppressed ion clustering behavior than those with para position acid group, attributed to the dominant hydrogen bonding interactions of neighboring acid groups.

L70.00143: Self-Assembled Shape-Anisotropic Diblock Copolymer Particles from Evaporative Emulsions: Experiment and Theory*
KANG HEE KU (Presenter), YOUNG JUN LEE, YONGJOO KIM, BUMJOON KIM, KAIST — We report the systematic design of shape-anisotropic diblock copolymer (dBCP) particles based on a new theoretical model that embodies entropic penalty associated with bending of the cylindrical and lamellar dBCP chains upon deformation of the particles. First, we produced the convex-lens shaped (oblate) and football-shaped (prolate) PS-b-PDMS particles, where the aspect ratios (AR) were tunable over a broad range from 1 to 10. Of note, the AR of oblate particle increased almost linearly up to 10 as the particle size increased, whereas the increase of AR for the prolate particle was limited to 2.0. To understand this discrepancy, we developed the theoretical model that includes the bulk elastic and bending energies of dBCP cylinders and lamellae, and the surface energy between the particle/ surrounding medium. For oblate particles, the high excessive bending energy of the curved cylinders at the periphery of particle can be released by increasing the AR of particle. However, the relatively low excessive bending energy of curved lamellae of prolate particles prevents the particles from having a high AR.

*This research was supported by the Korea Research Foundation Grant, funded by the Korean Government (2017M3A7B8065584, 2012M3A6A7055540, and 2018R1D1A1B07040671).

L70.00144: Coupling between mean curvature and texture in thin block copolymer film
GABRIEL CATALINI (Presenter), ALDO DANIEL PEZZUTTI, DANIEL VEGA, Departamento de Física, Universidad Nacional del Sur (UNS), Instituto de Física del Sur (IFISUR), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET) — Using a phase field approach we study the orientational coupling between the pattern developed by a lamellae forming block copolymer thin film and a topographically patterned substrate. Utilizing the Brazovskii free energy functional for a conserved order parameter, we perform a Taylor series expansion on the film thickness to obtain an effective geometric potential that correlates the smectic texture orientation to the curvature of the underlying surface. The results of this expansion are in good agreement with numerical results obtained through a Cahn-Hilliard model and experimental data on curved monolayers of asymmetric diblock copolymers.
L70.00145: Modelling Silica in Aggregates of Block Copolymers

PALLABI HALDAR (Presenter), ALESSANDRO PATTI, FLOR R. SIPERSTEIN, University of Manchester — There is developing interest in the use of Periodic Porous Materials (PPMs) synthesized from silicic acid and amphiphilic block copolymers in drug delivery and catalysis. Existing studies of the formation of PPMs have not drawn a clear conclusion as to the formation mechanism. In the prior studies two formation mechanisms were suggested; Liquid Crystal Template (LCT), where silicic acid plays no active role in the formation, and Cooperative Mechanism, where silicic acid plays a role in the formation.

In this study, we have investigated how the presence of silicic acid affects the self-assembly of these block copolymers by employing molecular dynamics simulations of coarse-grained (CG) models of Polyethyleneoxide-b-polybutylmethacrylate (PEO-b-PBMA) with silicates in water and tetrahydrofuran. An existing CG silicic acid model could not reproduce the water-silicic acid interaction observed experimentally. We have developed a more effective silicic acid CG model by comparing the solvation free energy of silicic acid in solvents with the values obtained from DFT calculations, which will allow for the determination of the correct formation method of PPMs.

*MSCA, MULTIMAT, Horizon 2020

L70.00146: Thermally Induced Phase Transitions in Amorphous-Crystalline Brush Block Copolymers

GAYATHRI KOPANATI (Presenter), BENJAMIN M YAVITT, HUAFENG FEI, University of Massachusetts Amherst, RUIPENG LI, MASAFUMI FUKUTO, Brookhaven National Lab, Upton, JAMES J WATKINS, University of Massachusetts Amherst — Temperature resolved small angle x-ray scattering (SAXS) and wide-angle x-ray scattering (WAXS) were used to investigate the temperature dependent phase transitions of five lamellae forming poly(styrene)-block-poly(ethylene oxide) (PS-b-PEO) brush block copolymers. Asymmetric lamellar morphologies were observed for all the PS-b-PEO series irrespective of their volume fraction and backbone length. The temperature dependent SAXS and WAXS reveal the presence of long-range order up to 140 °C. Unlike their linear counterparts, the primary peak position (q*) and full-width half maximum (FWHM) of q* remain constant, indicating no order-disorder transition (ODT) up to 200 °C. The melting and crystallization of the PEO side chains co-exists within the lamellar morphology. Isothermal crystallization studies were conducted to investigate the crystallization kinetics of the PEO domain. The results indicate a two-stage crystallization process with Avrami exponents of 1 and 2, suggesting a one-dimensional initial stage followed by two-dimensional growth at later times.

L70.00147: The Systematic Study of Porous Monoliths to Measure Diffusion Induced by Hydrochloric Acid

PAOLA LO-EZ (Presenter), Lehigh University — There is the open question of the effect of loaded and non-loaded hydrogels with CaCO3 on diffusion kinetics. Formulations of PEDGA solutions were created containing varying concentrations of CaCO3 since higher concentrations would result in the material to develop yield stresses. The formulation was polymerized into flat monoliths using UV light rays. The 200 µm monoliths were swelled in H2O for 24 hours. Then, were subjected to a diffusive dissolution experiment and submerged into different concentrations of HCl (1 M/L to 0.06 M/L) and CaCO3 (0% to 25%). Time measurements were taken assuming that the longer the hydrogel was soaked in HCl the less CaCO3 and the more porosity. Pictures taken with an SEM of the porous dissolution fronts measured over time show the diffusion reaction scheme fits a model of diffusion of the square root of time. Also, a pH sensitive dye experiment was carried out in the porous hydrogels. The methyl orange soaked hydrogels were put in an aqueous HCl bath, and the movement of the concentration front was measured assuming the dye is trapped and the reaction is limited by diffusion of the acidic front. Rearranging the diffusion equations, diffusion coefficients were retrieved for the reactions.

Solvay, S.A
L70.00148: Effect of Partial Saturation on Thermodynamic Interactions in Polydiene/Polyolefin Blends* JIALIN QIU
(Presenter), MEGAN L ROBERTSON, RAMANAN KRISHNAMOORTI, University of Houston — Polymer blends exhibit properties
that are highly dependent on interactions between components, typically quantified by the Flory-Huggins interaction
parameter, χ. Polyolefins and polydienes are important materials with commercial relevance in elastomer applications.
The majority of previous studies on the thermodynamics in polyolefin and polydiene systems have focused on polymer
pairs within the same class, which generally exhibit a small and weakly temperature dependent χ. There is little
quantitative information on thermodynamic interactions of polydienes and polyolefins. In our previous work, we
characterized the χ parameter in a model polydiene/polyolefin blend based on 1,2-polybutadiene (1,2-PBD) by small angle
neutron scattering (SANS). We observed an unusually large χ parameter in blends of 1,2-PBD and saturated 1,2-PBD that
exhibited a strong temperature dependence. We also studied the impact of partial saturation on χ of polydiene/polyolefin
blends. The χ(T) behavior in blends of fully saturated 1,2-PBD with partially saturated 1,2-PBD, at varying levels of
saturation, was characterized. The applicability of the random copolymer theory to predict χ(T) behavior in these blends
was evaluated.

L70.00149: Temperature-induced coil-globule transition of polypropylene oxide in aqueous solutions* RASIKI
DAHANAYAKE (Presenter), UDAYA R DAHAL, ELENA DORMIDONTOVA, Polymer Program - Institute of Material Science and Physics
Department, University of Connecticut — Polypropylene oxide (PPO) is a biocompatible polymer which is used in a wide range
of industrial to biomedical applications, e.g. as a component of the commercial family of Pluronics. Using all-atom
molecular dynamics simulations with modified OPLS forcefield we study the conformational changes of PPO in aqueous
solutions as a function of temperature. We analyzed the temperature induced change in the PPO radius of gyration and
 correlate it with the polymer hydration properties, such as hydrogen bonding, hydration number, solvent accessible
surface area, etc. We found that the coil-globular transition is accompanied by a noticeable reduction in polymer-water
hydrogen bonding. We also estimate the heat capacity change as a function of temperature, which exhibits a maximum at
the transition point and compare it with experimental data.

L70.00150: Simulating Diblock Copolymer Micelles in Binary Explicit Solvents JING ZONG (Presenter), DONG MENG,
Mississippi State University — Amphiphilic block copolymers form nanoscale assemblies when dissolved in a selective
solvent. Such self-assembled structures have wide-ranging applications as drug delivery vehicles and nanoreactors, etc. A
powerful method to manipulate the assemblies is to vary the composition of solvent mixtures. Unlike single solvent
solution, computational studies of amphiphilic block copolymers in solvent mixtures are rarely reported due to high
computational cost associated with the necessity of treating solvents explicitly. Here, the Field-Accelerated Monte Carlo [1]
simulation is employed in the expanded grand canonical ensemble to study the micelle formation of diblock copolymers in
binary solvent: one selective solvent and one good solvent for both blocks. We investigate effects of molecular weight and
solvent composition on micelle morphology, critical micelle concentration, and micelle size and aggregation number. It is
found that distribution of the good solvent is highly inhomogeneous, concentrating at micelle interface and partitioning
unevenly outside/inside micelle cores. Solvent intake by micelle cores increases with polymer molecular weight, affecting
the way micelle size and aggregation number change with solvent composition.

L70.00151: Local Structure and Relaxation Dynamics in the Brush of Polymer-Grafted Silica Nanoparticles* YUAN
WEI (Presenter), MICHAEL HORE, Case Western Reserve University — Polymer chains are grafted to nanoparticle (NP) surfaces
for a variety of purposes, including altering NP solubility or dispersion within a polymer matrix. At high grafting densities,
high molecular weight polymers adopt two primary conformations on the NP surface. Polymer chains near the NP core are
stretched in the concentrated polymer brush region (CPB). Farther away from the core, polymer chains are less confined
and the conformation becomes more ideal in the semi-dilute polymer brush region (SDPB). Using a combination of small-
angle neutron scattering (SANS) and neutron spin echo (NSE) spectroscopy, we directly characterized both the structure
and dynamics of the CPB and SDPB on poly (methyl acrylate) (PMA) grafted SiO2 NPs by selectively deuterating each region
separately. Analysis of SANS measurements using a new core-chain-chain (CCC) model confirmed that the portion of the
polymer chains in the CPB region are stretched, and transitions to a more ideal conformation in the SDPB region. From
NSE, we found the dynamics in the CPB region were found to be much slower than the SDPB region across all length
scales, and followed the Zimm model.

L70.00152: Thermodynamics of Binary and Ternary Polymer Blend Nanocomposites

SHAWN MAGUIRE (Presenter), NADIA KROOK, University of Pennsylvania, PATRICE RANNOU, MANUEL MARECHAL, CEA-CNRS-University Grenoble Alpes, KOHJI OHNO, Kyoto University, RUSSELL JOHN COMPOSTO, University of Pennsylvania — Polymer nanocomposites (PNC), which are a combination of organic and inorganic fillers and a polymer matrix, have found great scientific interest due to the fact that the material properties of the PNC are largely determined by the chemical composition of the polymer as well as the type of fillers. While the fundamental physics governing the phase space of polymer blends is mature, there is a significant lack of understanding of the thermodynamics and kinetics that govern PNCs. In this work, we investigate model binary and ternary nanocomposites of poly(methyl methacrylate) grafted silica nanoparticles (PMMA NP), poly(styrene-ran-acrylonitrile) (SAN), and poly(methyl methacrylate) as a platform to elucidate the governing thermodynamic contributions. The thermally annealed films were characterized using electron microscopy and x-ray scattering, revealing lower critical solution temperature (LCST) behavior in the binary composite and an increased miscibility window in off-critical compositions for the ternary. These results extend the current understanding of PNC phase behavior and allow for greater control over NP dispersions.

L70.00153: Vinyl Imidazole Sulfonate-based Zwitterionic Copolymers with Tuneable Adsorption on Carbonates

MOHAMMED KAWELAH (Presenter), MARIAM F. ALGHAMDI, S. SHERRY ZHU, AYRAT GIZZATOV, Aramco Research Centre - Boston, Aramco Services Company, YUAN HE, TIMOTHY M SWAGER, Department of Chemistry, Massachusetts Institute of Technology — Polymer injection in hydrocarbon reservoirs has been of great interest in petroleum engineering as an enhanced oil recovery (EOR) method. Injection of aqueous solutions of polymers into reservoirs increases the fluid viscosity and reduces its relative permeability in the reservoir, and hence improves volumetric sweep efficiency for EOR applications. However, the flow of polymeric solutions in porous media is subject to some particular effects such as non-Newtonian flow, degradation (thermal, physical, bacterial, and chemical), retention and inaccessible pore volume that are key to evaluating the success of a polymeric flooding. Significant polymer adsorption on the rock surface under high salinity and high temperature reservoir conditions is one of the most major challenges in polymer flooding EOR. Here we report the dynamic adsorption studies of four brine-soluble zwitterionic copolymers containing vinyl imidazole sulfonate using a Quartz Crystal Microbalance and core flooding at high temperatures. Our results indicate that the dynamic adsorption of the polymers on carbonates correlates to their structure variation and fluid properties, and a small presence of certain functional co-monomers on the polymers dramatically changes their dynamic adsorption.

L70.00154: Nonmonotonic glass transition behavior of polystyrene film in contact with polystyrene brushes

WOOSEOP LEE (Presenter), HOYEON LEE, Yonsei University, VAIDYANATHAN SETHURAMAN, University of Texas at Austin, DU YEOL RYU, Yonsei University, VENKATRAGHAVAN GANESAN, University of Texas at Austin — The interplay between a polymer melt the substrate grafted with 'chemically identical' polymer brushes has attracted attention due to the possible applicability to slip, adhesion, wettability, and lubrication. In this study, we controlled grafting density (σ) and chain length of polystyrene (PS) brushes on substrates to investigate their effect on the glass transition temperature ($T_g$) of overlaying PS films. To our surprise, we observed a nonmonotonic change of the $T_g$ of PS film as a function of $σ$ with the maximum value that exceeds the $T_g$ of bulk PS. A computer simulation supports our experimental results in terms of the local segmental dynamics in overlaying PS film, which is related to the enhanced friction by interpenetration between the melt (PS film) and the grafted layer.

L70.00155: Ion-Conducting Polymers as Interfacial Layers in Solid Electrolytes

ARVIN SOOKEZIAN, PRIYADARSHINI MIRMIRA (Presenter), SHRAYESH PATEL, STUART J ROWAN, Institute for Molecular Engineering, University of Chicago — The development of safe lithium/lithium ion batteries is of interest for large-scale energy storage applications such as electric vehicles. The use of solid-electrolytes (SE) is a promising alternative to commonly used liquid electrolyte based batteries, which have safety and electrochemical stability concerns. Notably, solid-state systems are bottlenecked in performance due to inadequate solid-to-solid contact between the SE and the electrode that leads to high interfacial impedance. To address this challenge, we have developed a class of ion-conducting polymers that can be utilized as thin interfacial layers that help mitigate the poor adhesion between the solid interface while still permitting lithium ion-transfer across the interface. We specifically report on the lithium-ion conductivity, mechanical, and adhesive properties of our materials. Lastly, we report the electrochemical stability and performance of the ion-conducting interfacial layers in normal lithium-ion battery operating conditions.

*Our research is supported through NSF DMR 1609076.
L70.00156: Brushes of Peptide Coiled Coil Bundle Chains  MATTHEW LANGENSTEIN (Presenter), DARRIN POCHAN, University of Delaware — Through solution self-assembly, computationally designed peptide coiled coil bundles (CCBs) have shown the ability to produce 2-D lattices, nanocages, nanotubes, and 1-D supramolecular polymers. However, to date no studies have been performed on the impact of substrate interactions on the structure of CCBs. Successful preservation of the coiled coil motif during surface conjugation could provide a robust pathway towards the computational design of stimuli-responsive latticed self-assembled monolayers and serve as a template for layer by layer growth of complex brushes with exact sequence control. In this poster the use of atomic force microscopy (AFM), angle resolved X-ray photoelectron spectroscopy (ARXPS), and quartz crystal microgravimetry (QCM) to characterize peptide layer thickness, surface topography, orientation, and deposition rate will be discussed. Additionally, the impact of temperature, solvent, and pH on the structure of cysteine terminated CCBs on planar gold substrates will be examined.

L70.00157: Impact of casting conditions on mechanical properties of polynorbornene membranes under typical biobutanol operating conditions. * MEETA TRIVEDI (Presenter), BRYAN VOGT, Department of Polymer Engineering, University of Akron — Poly(butylnorbornene)-ran-poly(hydroxyhexafluoroisopropyl norbornene) (BuNB-r-HFANB) is a promising material for biobutanol membrane with Tg’s for both segments exceeding 300°C to provide the potential for highly stable membranes. During operation, the BuNB-r-HFANB is swollen by the aqueous butanol in the broth that impacts its properties. The membrane performance is dependent on how it is cast. Here we investigated effect of four different casting solvents (THF, Toluene, DMF and Butanol) on the mechanical properties of these membranes using DMA. The change in mechanical properties in the butanol broth was enabled by using a submersion cell with DMA. The effect of temperature in both the dry and swollen state was also examined to provide insights into how the mechanical properties of these membranes would be expected to change during operation.

L70.00158: Oligomeric Cellulose Co-Crystallization with DMSO SEULGI KIM (Presenter), JI EUN KIM, JEONG YI KANG, JIN WOONG KIM, Hanyang University — Oligomeric cellulose nanofibers (BCNFs), known as bacteria-derived celluloses, are attractive biomaterials, since they are biocompatible and can be easily chemically modified for a variety of biomedical treatments. When primary hydroxyl groups on the BCNFs are substituted to carboxylic groups by 2,2,6,6-tetramethylpiperidine-1-oxyl radical (TEMPO)-mediated oxidation, they are able to physicochemically interact with biomolecules. Herein, we propose a new BCNF-based bioadhesion system for dermal therapy. The essence of our approach is that the antibody-conjugated BCNFs are bound to involucrin in the corneocyte of stratum corneum. The BCNF bioadhesives were fabricated by 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC)/N-hydroxysulfosuccinimide (sulfo-NHS) coupling reaction of antibody. Then, the adhesion force between the antibody-conjugated BCNFs and porcine skin was characterized by using the axial rheometer measurement. Finally, we demonstrated that our BCNF bioadhesives exhibited such a strong interaction with the skin tissue even under wet conditions, thus promising a variety of biological applications in the field of dermal therapy.

L70.00159: Oligomeric Cellulose Co-Crystallization with DMSO XIN ZHANG (Presenter), FENG JIANG, YIMIN MAO, DOUG HENDERSON, University of Maryland, College Park, YOSHIHARU NISHIYAMA, CERMAV, CNRS, Grenoble, Isère, France, ROBERT M BRIBER, HOWARD WANG, University of Maryland, College Park — Oligomeric cellulose with a median degree of polymerization of 7 (DP7) is produced by hydrolysis of cellulose in phosphoric acid. DP7 molecular weight distribution was characterized by NMR, MALDI-TOF, and GPC. DP7 is soluble in hot DMSO and crystallizes in the form of spherulites upon cooling. The spherulite morphologies and crystallization kinetics was characterized by polarized optical microscopy. The structure of the crystal has been studied by synchrotron radiation XRD, TEM and MD simulation. The oligomeric cellulose and DMSO co-crystallize. After removing excessive solvent, the crystal is metastable in dry air but transforms into the cellulose II crystal structure when exposed to humidity.

L70.00160: Synthesis and Self-Assembly of Oligomeric Cellulose-block-Poly(ethylene glycol) Diblock Copolymers FENG JIANG (Presenter), XIN ZHANG, DOUG HENDERSON, WONSEOK HWANG, HOWARD WANG, ROBERT M BRIBER, University of Maryland, College Park — Block copolymers containing cellulose have not been well studied or understood partly due to the poor solubility of cellulose in common solvents. In this study, well-defined oligomeric cellulose-block-poly(ethylene glycol) diblock copolymers, Cell1.1k-b-PEG1.7k (Mn = 2.8 kD, PDI = 1.04) and Cell1.1k-b-PEG5k (Mn = 6.1 kD, PDI = 1.02), have been synthesized via coupling reactions. The volume fractions of oligomeric cellulose in Cell1.1k-b-PEG1.7k and Cell1.1k-b-PEG5k diblock copolymers are 0.32 and 0.14, respectively. Due to the incompatibility between the cellulose and PEG, Cell-b-PEG diblock copolymers can separate at a local scale forming cellulose-rich and PEG-rich nano-domains, which further organize into larger scale structures, both in solutions and in the bulk. Small-angle X-ray scattering, atom force microscopy, and electron microscopy show hierarchical structures of Cell-b-PEG from nanometers to microns.

L70.00161: SOFT CONDENSED MATTER —
New coarse grained model for the study of the dynamics of the Worm Like Chain

ANGELO SETARO (Presenter), Rensselaer Polytechnic Institute — Semiflexible polymers display rich and varied behavior, distinct from both their rigid and flexible counterparts. This diversity arises from the interplay between bending energetics and conformational entropy. This energetic balance manifests as correlations between orientations along the polymer backbone, which depend on the flexibility of the polymer. Typically, the Kratky-Porod model is used to study semiflexible polymer systems, however, it is of limited utility when attempting to study non-equilibrium polymer dynamics, particularly over long timescales in flow. Currently, coarse grained models exist which allow for the study of polymers over longer time scales than the Kratky-Porod model, but at the cost of much fine grained information. To address this deficiency and bridge the gap between models, we propose a new coarse grained model for semiflexible polymers that reproduces some key behaviors of the Kratky-Porod model while simultaneously allowing for study of polymeric systems on a longer time scale. In this work, we have used Brownian dynamics to quantify and assess the accuracy of other key features of the model.

Dynamic and Structural Critical-like Behaviors in glassy monolayers of colloidal ellipsoids

ZHONGYU ZHENG (Presenter), Center for Soft and Living Matter, Institute for Basic Science, YILONG HAN, Department of Physics, The Hong Kong University of Science and Technology — Whether the glass transition is a purely dynamic transition or a thermodynamic one is a long-standing debate in condensed matter physics. Critical behaviors have been found in translational degree of freedom in glasses composed of spheres with local polycrystalline structures, but it is not clear if criticality exists in more general glassy systems without crystalline orders or composed of non-spherical particles. Here, we show rich critical behaviors in both translation and rotation in monolayers of monodispersed colloidal ellipsoids lacking crystal-like structures. We found an Ising criticality at the ideal glass transition point $\phi_0$ for the static glassy structures, local structural entropies and dynamic slow-moving clusters. These structural and dynamic quantities sharing the same Ising criticality are a direct evidence of the critical phenomena and thermodynamic nature of the glass transition at $\phi_0$. A different criticality is found at the mode-coupling point $\phi_C$ for the fast-moving clusters reflecting a dynamic glass transition. These results may explain the theoretical puzzles that the dynamic correlation length diverges at two different temperatures and the relaxation mechanism changes around $T_C$.

Measure particle diffusion in cytoskeletal networks with light-sheet and differential dynamic microscopy

CHRISTELLE MATSUDA (Presenter), SYLAS ANDERSON, RAE ROBERTSON-ANDERSON, RYAN J. MCGORTY, University of San Diego — Filamentous actin and microtubules contribute to the crowded environment of the cytoplasm. Modeling the cytoplasm, we create networks of varying crosslinking motifs and varying ratios of actin and microtubules. We crosslink either actin to actin, tubulin to tubulin, or tubulin to actin. We add micron-sized fluorescent beads to the various networks, record videos of the samples using light-sheet microscopy, and perform differential dynamic microscopy (DDM) analysis. We compare DDM and single-particle tracking results to examine differences between ensemble and single-particle transport properties. We find varying degrees of anomalous diffusion and significant heterogeneity in the dynamics, particularly in actin environments.

*National Institutes of Health (1R15GM123420)

Particle-tracking reveals heterogeneous subdiffusion in in vitro cytoskeleton composites

SYLAS ANDERSON (Presenter), CHRISTELLE MATSUDA, RYAN J. MCGORTY, RAE ROBERTSON-ANDERSON, University of San Diego — The diffusion of microscopic particles through the cell, important to processes such as transcription, viral infection, transfection and gene delivery, is largely controlled by the complex cytoskeletal network that pervades the cytoplasm. The cytoskeleton is predominantly made up of thin semiflexible actin filaments and thicker, more rigid microtubules, as well as binding proteins that can crosslink each filament. By varying the relative concentrations of actin and microtubules, as well as the degree to which each filament is crosslinked, the cytoskeleton can display a host of different structural and dynamic properties that in turn impact the diffusion of particles through the network. Here we use single particle tracking methods to quantify the mean-squared displacements of microspheres diffusing in custom-designed in vitro composites of actin and microtubules. We show that particles exhibit subdiffusion, with scaling exponents and transport coefficients that decrease as the relative fraction of actin in composites increases. By evaluating the distributions of bead displacements, we also find that composites induce unique non-gaussian diffusion characteristics and substantial heterogeneities in particle trajectories.

*This work was funded by NIH NNIGMS Grant No. R15GM123420.
L70.00166: Colloidal diffusion and viscoelasticity in blended solutions of supercoiled, ring and linear DNA*  
MEGAN LEE (Presenter), KARTHIK REDDY PEDDIREDDY, SYLAS ANDERSON, RAE ROBERTSON-ANDERSON, University of San Diego — DNA, which has been widely studied as a model polymer system, naturally exists in different topological forms including linear, relaxed circular (ring) and supercoiled. While the reptation model can be used to understand molecular transport and interactions in systems of entangled linear polymers, it is far less successful in describing the dynamics of entangled supercoiled or ring polymers. The properties of entangled polymer blends of different topologies and polymer solutions near the critical entanglement concentration are also still poorly understood. Here, we address these problems by creating blended solutions of (1) entangled linear and ring DNA of varying blend ratios and (2) supercoiled and ring DNA of varying overall concentrations from the semidilute to entangled regime. We use particle-tracking methods to measure the diffusion of colloids embedded in these solutions as well as the corresponding linear viscoelastic properties. We reveal previously unobserved and unpredicted dependences of transport and viscoelasticity on the ratio of linear to ring DNA in blends as well as the overall solution concentration.

L70.00167: Tuning dynamics of moisture responsive wrinkling surfaces  
SONGSHAN ZENG, RUI LI, DIANYUN ZHANG, LUYI SUN (Presenter), University of Connecticut — The wrinkle dynamics (such as reversibility and stability) of human skin are affected by the external stimuli, as well as the skin's structure and mechanical properties. Inspired by these tunable responses, three types of moistureresponsive wrinkle dynamics are achieved, for the first time, through a single film-substrate system. These dynamics include: (1) completely reversible wrinkles formation; (2) irreversible wrinkles formation I: the initially formed wrinkles can be permanently erased and never reappear; and (3) irreversible wrinkles formation II: once the wrinkles form, they can no longer be erased. The key to success is to control the stiffness and thickness ratios of the film and the substrate, and tailor the crosslink degree/gradient of the film to allow for moisture-dependent changes of modulus and swelling degree. These unique responsive dynamics motivate the invention of a series of optical devices triggered by moisture, including anticounterfeit tabs, encryption devices, water indicators, light diffusors, and antiglare films. This study also paves the road for further understanding of the skin wrinkling dynamics and manipulation.

L70.00168: How crosslinking actin filaments influences the microscale viscoelastic properties of actin-microtubule composites*  
MADISON FRANCIS (Presenter), RAE ROBERTSON-ANDERSON, SHEA RICKETTS, University of San Diego, JENNIFER ROSS, Physics, University of Massachusetts Amherst — The strength and mobility of cells is dependent upon the interactions between two protein filaments that comprise the cytoskeleton: actin and microtubules. These proteins form entangled networks that can also be chemically crosslinked to enable a wide range of mechanical properties. Here, we use optical tweezers microrheology to determine how varying concentrations of actin crosslinkers influences the viscoelastic properties of actin-microtubule composites. We create equimolar co-entangled networks of actin and microtubules with varying concentrations of actin crosslinkers. We use optical tweezers to apply both oscillatory and constant speed microscale strains over a range of rates and distances while simultaneously measuring the force the networks exert to resist these strains. We quantify the frequency-dependent complex viscosity, the nonlinear stress response, and the relaxation dynamics following strain. Surprisingly, we find that increasing the concentration of crosslinkers yields a decrease in network elasticity and stiffness.

L70.00169: Mechanism of reinforcement in soft composites: random fiber networks with inclusions*  
MOHAMMAD ISLAM, CATALIN PICU (Presenter), Rensselaer Polytechnic Institute — The mechanical behavior of athermal random fiber networks embedding particulate inclusions is studied in this work. Composites in which the filler size is comparable with the mean segment length of the network are considered. In presence of inclusions, the small strain modulus increases, while the ability of the network to strain stiffens decreases relative to the unfilled network case. The reinforcement induced by fillers is most pronounced in sparse networks of floppier filaments that deform in the bending-dominated mode in the unfilled state. As the unfilled network density or the bending stiffness of fibers increase, the effect of filling diminishes rapidly. Fillers lead to a transition from the soft, bending-dominated, to the stiffer, axial-dominated, deformation mode of the network, transition which is primarily responsible for the observed overall reinforcement. These results provide a justification for the broadly observed difference in reinforcement in sparsely versus densely cross-linked networks at given filling fraction, and provide guidance for the further development of network-based materials.

L70.00170: Characterization of Aqueous Hyaluronate Solutions using Static and Quasielastic Light Scattering*

DAVID WALLS (Presenter), LAUREL HUNTER, VINGNESH VENKATARAMANI, DAVID ROSS, SCOTT FRANKLIN, MOUMITA DAS, GEORGE THURSTON, Rochester Institute of Technology — Human vitreous humor contains a hydrogel made up of a network of dilute collagen and hyaluronic acid. Liquefaction of the vitreous gel with age and in other conditions has been associated with retinal pathologies.

We use static and quasielastic light scattering to study the osmotic compressibility and local dynamics of aqueous hyaluronate solutions, in preparation for studying model vitreous gels. Buffered solutions prepared from commercial sodium hyaluronate were filtered to minimize light scattering heterogeneity. Refractometry was used to assess sample concentration post-filtration. Excess Rayleigh ratios from cleaned low-concentration samples gave molecular weights compatible with manufacturer's data. Higher concentration data give osmotic compressibilities that indicate repulsive intermolecular interactions, which we compare with theoretical models. At all concentrations, quasielastic light intensity autocorrelation functions show two well-separated slower decays and a faster decay. With increasing concentration, the slow component that has a characteristic decay time of tens of microseconds becomes faster as concentration increases, while the slowest component becomes more prominent.

L70.00171: Nonlinear mechanics of composite fiber networks*

SADJAD ARZASH (Presenter), JORDAN SHIVERS, FRED C. MACKINTOSH, Department of Chemical & Biomolecular Engineering, Rice University — Fibrous networks such as collagen are ubiquitous in biological systems. Although the mechanical behavior of single fiber networks has been, both experimentally and theoretically, well studied, understanding the effect of the interplay between different biopolymer networks remains unclear especially under large deformations. In this work, we model a rigid fiber network inside a soft and flexible underlying matrix. This double network model enables us to study the effect of internal interactions of different networks on their overall mechanics. We find that the linear shear modulus of the composite system is greater than the sum of the individual linear shear moduli. Moreover, by calculating the non-affine fluctuations, we see clear suppression of fluctuations in the rigid fiber network. We also find a mechanical phase transition between matrix-dominated and fiber-dominated states.

L70.00172: Classification and prediction of the mesophases of block copolymers*

SADATO YAMANAKA (Presenter), TAKESHI AOYAGI, CD-FMat, National Institute of Advanced Industrial Science and Technology — Self-organization and the resultant mesoscopic structures in block copolymer systems are of great advantage to applications such as nanolithography. Nevertheless, the whole phase behaviors still have not understood well even in ABC triblock copolymers. We study on classification problem on the classical phase diagram of AB diblock copolymers by means of supervised machine learning. We compare three model: kernel support vector machine (SVM), random forest, and k-nearest neighbor method. The prediction accuracy of kernel SVM is 94.5%, which is higher than the other two methods. This indicates that kernel SVM can be a candidate of classification model that is applicable to more complex architectures, such as linear/star ABC triblock copolymers.

L70.00173: Using an autoencoder to reduce experimental noise*

NANCY THOMAS (Presenter), JORDAN HOFFMANN, LISA LEE, PARKER LAMASCUS, SHMUEL RUBINSTEIN, CHRISTOPHER RYCROFT, Harvard University — Experimental noise is ubiquitous in the sciences. Some of this noise is random, however some is systematic. We use machine learning to try to remove the systematic noise in experimentally found scans of crumpled sheets of paper in order to be able to study this classical disordered system. Properties that were previously uncovered using other denoising mechanisms were that crease mileage is a state variable of crumpling, is independent of crumpling history, and has a logarithmic scaling property. Through the use of an autoencoder, we were able to recover the scaling properties of crease mileage while improving the automation of the denoising process. This denoiser is able to outperform other methods on extremely noisy sheets. The removal of noise from our data is essential in order to be able to further explore the characteristics of the crease networks in a crumpled sheet.

L70.00174: Probing mechanical properties of particle shells formed on droplets by electric field-induced wrinkling*  
ALEXANDER MIKKELSEN, Physics, Adam Mickiewicz University, ZBIGNIEW ROZYNEK (Presenter), Harvard University —  
Fabricating curved monolayers that mimic the properties from natural shells can help researchers to develop lighter,  
stronger and more flexible materials, better drug delivery and encapsulation systems, etc. Here we investigate  
synthetically made particle shells formed on droplets in a bulk fluid, in context of their mechanical properties. We used  
induced compressive stress on the particle shells by applying electric fields. In response to the stress, the particle  
monolayers folded and formed wrinkles with characteristic wavelengths. By deriving a simple model for particle shell  
wrinkling, we used these wavelengths to estimate the Young modulus and bending stiffness of the shells. Our results  
indicate that the elasticity of particle shells decreases with particle and shell size. We also show that deformation cycles  
induced by electric fields can be used to increase particle packing of monolayers on droplets and reduce wrinkle  
formation. These results suggest that in addition to probing mechanical properties, our approach can also be used to  
tailor the surface properties of shells, i.e. their permeability and roughness.

L70.00175: Emergent Dynamics of Paramagnetic Suspensions under Toggled Magnetic Fields  
HOJIN KIM (Presenter), ERIC M FURST, Department of Chemical and Biomolecular Engineering, University of Delaware —  
Suspensions of superparamagnetic colloidal particles are subjected to toggled magnetic fields by switching on and off the field repeatedly.  
At sufficiently high field strengths, the microstructure of the suspension begins in a solid, gel-like state and anneals to  
droplet-like domains governed by time-averaged bulk and surface energies. Here, we study the effect of the toggled-field  
duty cycle. At frequencies range investigated in this study (0.33-5Hz) and high duty cycle ratio (0.8), the suspensions form  
column-like microstructures that do not evolve into energetically favorable states. In this case, the period the field is off is  
shorter than the particle characteristic diffusion time scale. As duty cycle decreases, however, microstructures grow to  
ellipsoidal-shape as a result of the sufficient time for particle diffusion. Under a small range of conditions (1.5-3.5 Hz, 0.2  
duty cycle ratio), we observe a new class of wavy-shaped microstructures with dynamics that exhibit a strong and  
continuous process of rotation, coalescence, and breakup. We attempt to understand these dynamics by considering the  
hydrodynamic forces exerted by a collection of thermal ratchets composed of particles in an asymmetric process of  
ballistic approach and diffusive relaxation.

L70.00178: Quantifying the surface tension of non-equilibrium colloidal fluids*  
CAROLINE RIEDSTRA (Presenter), JING  
WANG, RYAN J. MCGORTY, University of San Diego — Through the use of a colloid-polymer system employing temperature-  
sensitive pNIPAM microgel colloidal particles, we observe the nucleation and dissolution of colloid-rich liquid droplets. We  
use light-sheet microscopy to observe the formation and dissolution of colloid-rich droplets in three-dimensions and with  
optical sectioning. Our colloid-polymer system allows us to precisely tune the equilibrium state--mixed or demixed--by  
adjusting the sample temperature. With videos obtained from the light-sheet microscope, we perform image analysis of  
fluctuating droplets to extract the surface tension.

L70.00179: Probing viscoelasticity of dilatant fluid by solid projectile impact*  
KAZUYA EGAWA (Presenter), HIROAKI  
KATSURAGI, Nagoya University — Dilatant fluids offer complex rheological properties such as discontinuous shear  
thickening (DST). In recent years, various solid-impact experiments onto a dilatant fluid have been performed to reveal the  
physical properties of DST. Interesting phenomena such as dynamic jamming[S. R. Waitukaitis & H. M. Jaeger,Nature 487,  
205(2012)] and dynamic fracturing[M. Roche et al., Phys. Rev. Lett. 110 148304(2013)] have been reported in previous  
reserches. In addition, peculiar surface deformation of the vibrated dilatant fluid has also been found[F. S. Merkt et al.,  
Phys. Rev. Lett. 92 184501(2004)]. In this study, we perform a simple solid-projectile impact to a dilatant-fluid target to  
observe the penetration and rebound dynamics. In addition, to investigate the effect of vibration to the rheological  
properties of dilatant fluid, mechanical vibration is also applied to the dilatant fluid. From these results, the rebound  
timescale and restitution coefficient are measured. To characterize the viscoelasticity, we assume a simple attenuating-  
n oscillation model. Using the model, the effects of impact inertia, boundary conditions, and mechanical vibration to the  
rheological properties are systematically studied.

**L70.00180: Cratering and collapse of an inclined granular layer by oblique impact of a spherical projectile**

SHINTA TAKIZAWA (Presenter), RYUSEI YAMAGUCHI, HIROAKI KATSURAGI, Nagoya University — The oblique impact of a solid sphere onto an inclined granular layer is experimentally studied. The inclination angle of the target granular layer is varied from 0 to 33 degrees. The incident angle is also varied from 10 to 170 degrees. The range of impact velocity is 10 - 100 m/s. As a result, we observe following behaviors. When the incident angle is 90±10 degrees (almost normal impact), simple penetration of the projectile is observed. However, rebound or ricochet of the projectile occurs when the incident angle is smaller than 70 degrees (or larger than 110 degrees). When the target granular layer is steep enough, the transient crater produced by the impact is significantly modified by the asymmetric collapse of crater wall. Due to these complex effects, the final crater shape becomes complex. In this study, the characteristic dimensions of the crater (diameter, depth, and cavity volume) are measured and scaled by the effective impact kinetic energy transferred to the target by the projectile impact. While the crater volume can be scaled with a universal exponent, the specific volume value depends on the inclination angle.

*JSPS KAKENHI No. 18H03679

**L70.00181: Granular flow dynamics in a vibrating system from multiple points of view: Laboratory experiments, continuum modeling, and numerical simulations**

DAISUKE TSUJI (Presenter), Department of Earth and Environmental Sciences, Nagoya University, MICHIO OTSUKI, Graduate School of Engineering Science, Osaka University, HIROAKI KATSURAGI, Department of Earth and Environmental Sciences, Nagoya University — This study investigates granular flow dynamics in a vibrating system from multiple directions: laboratory experiments, continuum modeling, and numerical simulations. In the experiment, a conical granular pile is subjected to vertical vibration. Depending on its strength, granular particles are fluidized, and the shape of the pile is gradually relaxed. During the vibration, the relaxing pile is observed by a high-speed laser profiler. Based on those data, we have proposed a continuum model, which can predict how the flux of granular particles is determined. This model has only one fitting parameter that indicates the conversion efficiency from inputted vibration energy into granular transport energy. By comparing the experimental data obtained under various conditions, we have confirmed that the continuum model is satisfied and the conversion efficiency does not change in numerical simulations. We have also found that the velocity decreases exponentially from the surface of a pile, which suggests the presence of shear-band structure.

**L70.00182: Reversible Sol-Gel Transition of Silicone Complex Oils Using Hydrophobically Modified Attractive Hectorite Nanoplatelets as Rheology Modifiers**

DOYEON KIM (Presenter), DAEHWAN PARK, YEONG SIK CHO, JIN WOONG KIM, Hanyang University — Hectorite nanoplatelets (HNPs) have truly intriguing surface properties such as high specific surface area, high cation exchange capacity. Herein, we introduce a facile but robust approach to fabricate attractive hectorite nanoplatelets (AHNPs), in which the surface of HNPs was hydrophobically modified by using a cationic surfactant, dimethyl dioctadecyl ammonium chloride. We could finely disperse the AHNPs in the silicone oil by repeated high pressurized homogenization. The suspension rheological studies revealed that the AHNPs interacted to form a strong gel phase that exhibits the reversible shear stress-responsive sol-gel transition. Based on the chemical and structural characterization of AHNPs by using XRD, FT-IR, AFM, and TEM analyses, we interpreted this is attributed to the weak but long-range edge-to-edge interaction of AHNPs in the silicone oil, which is induced by the hydrogen bonding between small amounts of hydroxy groups at the edge of AHNPs. The AHNPs fabricated in this study are expected to be widely used as rheology modifiers for various oil-based complex fluids.

**Keywords:** Sol-gel transition, hectorite nanoplatelets, suspension rheology, rheology modifiers
L70.00183: Using Pressure Sensors To Characterize Avalanche Dynamics On A Conical Bead Pile*  
KATIE SHIDELER (Presenter), SUSAN LEHMAN, College of Wooster — A system of pressure sensors is used to characterize the dynamics of avalanches as they occur on a conical bead pile. The bead pile is a slowly driven critical system of roughly 20,000 steel beads, 3 mm in diameter, atop a circular base. We slowly drive the pile by dropping one bead at a time on the pile apex, and we record avalanches (the change in mass as beads leave the pile) occurring over the course of 60,000 bead drops. To complement this statistical information about the avalanche size probability distribution, we recently modified the base of the pile to add a system of eight pressure sensors that are monitored continuously during the data run. The sensors respond to shifting of forces within the pile during the avalanche, providing a way for us to characterize the types of bead motions occurring on the pile at different places on the pile and at different stages of the avalanche. With these sensors, we can characterize surface motion of beads on the pile independently from motion of beads off the pile. We are developing analysis techniques to characterize avalanches not just by the number of beads involved but also by the area of the pile participating in the avalanche; we propose an experimental definition for a system-spanning avalanche.

*Supported by NSF DMR 1560093.

L70.00184: Controlling Interactions in Active Matter Systems*  
JOSHUA STEIMEL (Presenter), SAGE MORELAND, University of the Pacific, ALFREDO ALEXANDER-KATZ, MIT — It has been demonstrated in a 2D colloidal monolayer composed of active spinning ferromagnetic and passive colloids that an ultra-long range attractive interaction emerges between active colloids. This interaction was induced by the activity of the spinning particles and mediated by the elasticity of the passive colloidal monolayer. We demonstrate through experiments and simulations that the range and dynamics of this emergent attractive interaction can be tuned or reversed by changing the mode of activity or the composition of the passive monolayer. With a 3D Helmholtz-coil like apparatus we can change the mode of activity from spinning to a top-like motion. These tops exhibit a similar attractive interaction at long-range, however they repel at distances less than four particle diameters, unlike the spinners. The tops also effectively anneal the passive monolayer into almost perfect crystal grains while the tops occupy sites on the grain boundaries effectively functioning as dislocation sources. Additionally, by doping the passive colloidal monolayer with small concentrations of passive particles of different sizes the monolayer behaves more elastically. This increases the range of the interaction but the dopants impede dislocation motion so the rate of attraction decreases.

L70.00185: A Method to Measure Drag Coefficient of An Active Particle  
CHONG SHEN (Presenter), H DANIEL OU-YANG, Lehigh University — The drag coefficient of an active particle is important because it reveals the energy cost of swimming of an active particle, i.e., micro-organisms or swimming colloids. We introduce a method to obtain the drag coefficient for an active particle by separately measuring diffusion and sedimentation. We test this method on an active Brownian particle (ABP) that is driven by induced-charge electrophoresis of Janus particles. The diffusion is measured by tracking the single-particle motion and calculating the slope of mean squared displacement at long times. An effective temperature, $T_{\text{eff1}}$, can be calculated from diffusion. The particle density distribution in sedimentation is measured by counting the number of particles at different heights in the dilute region, where it obeys Boltzmann distribution with an effective temperature, $T_{\text{eff2}}$. With the assumption that the effective temperatures measured from the two methods are the same, the drag coefficient of ABP could be solved.

L70.00186: Macro and Micro Phase Separation in Mixtures of Active and Passive Particles  
RYAN TOLLEFSEN, Oregon State, JONATHAN LU, MIT, JOSHUA STEIMEL, University of the Pacific, ALFREDO ALEXANDER-KATZ (Presenter), MIT — Active spinning particles have been shown to phase separate when mixed with inactive particles. Here we present our work on controlling such phase separation to obtain microphase separation apart from the typical macrophase separation as a function of the reversal of the torque on the particles. Using this technique we can achieve control over the domain size as a function of the activity. We further show that the systems displays hysteresis as one changes the driving force. These results extend our knowledge of phase separation in mixtures of active and passive particles.
L70.00187: Snapping induced by controlled drying of polymer gels: from moving bonito flakes to jumping shells*

YONGJIN KIM (Presenter), University of Massachusetts Amherst, JAY VAN DEN BERG, Delft University of Technology, ALFRED CROSBY, University of Massachusetts Amherst — Dynamic changes in swelling states can induce life-like motions in bonito flakes placed on a hot Okonomiyaki. The shape transitions of these thin polypeptides films not only happen smoothly but also occur abruptly. Inspired by these generally occurring, but random events, we developed novel design principles for inducing self-repeating snapping motions during the drying process of swollen polymer disks that can persist until the depletion of the solvent. We demonstrate the ability to tune the system performance of these polymer devices to achieve either higher jumping kinetics (t ~ 2ms, Power ~ 370W/kg) or greater total energy output (Eout ~ 2J/kg) by controlling the geometry and boundary conditions. The performance of the snapping shells under different conditions was modeled with finite element analysis results. The systematic study on the snapping mechanism and its incorporation into engineered systems will bring great advantages for designing micro-scale, high-efficiency robots.

L70.00188: Temperature-invertible gel for manipulation of colloidal particles*

CATHY ZHANG (Presenter), SEAS, Harvard University, YA LIU, University of Pittsburg, CINDY WANG, University of Waterloo, XIAOGUANG WANG, STEFAN KOLLE, SEAS, Harvard University, ANNA CHRISTINA BALAZS, University of Pittsburgh, JOANNA AIZENBERG, SEAS, Harvard University — We develop an actuatable, responsive gel surface with a set of periodically spaced, temperature-invertible ridges and demonstrate that this surface enables us to create large, dynamic arrays of a range of colloidal particles through multiple physical mechanisms. The surface is constructed from a responsive gel that is spatially patterned on a topographically ridged surface to form gel ridges that collapse to form valleys. Using both experiments and numerical simulations, we show that we can obtain fine-grained control over the amplitude of surface topography, where the exact trajectory of the surface change depends on the rate and direction of temperature change. We then sediment particles on the surface and quantitatively demonstrate how the dynamic features of this gel enable us to pattern colloidal assembly and release under low Reynolds number shear flow. Finally, we introduce biological particles on the surface and show how such a multifunctional surface provides opportunities in creating antifouling surfaces whose properties can be tuned on demand.

*This project was supported by the Office of Naval Research Award number N000141613169 and National Science Foundation Graduate Research Fellowship.

L70.00189: Competition and Cooperation among Chemically Active Sheets and Particles

ABHRAJIT LASKAR (Presenter), OLEG SHKLYAEV, ANNA CHRISTINA BALAZS, University of Pittsburgh — Using theory and simulation, we model the interactions among different, chemically active objects in a fluid-filled microchamber to establish conditions that drive these synthetic objects to display biomimetic competitive or cooperative behavior. The first objects are catalyst-coated, flexible sheets that generate buoyancy-driven fluid flows. The second objects are mobile tracer particles that move via diffusiophoresis towards higher reactant concentrations. We vary the sheets’ size and areal concentration of catalyst to tune the rate of reaction at this layer. Through these studies, we determine regions in phase space that lead to “aggressive” competition or “beneficial” cooperation within this dynamic, non-equilibrium system. As an example of competition, we show that when a low concentration of reactants is introduced into the solution, the larger sheet “catches” more tracers than a smaller sheet with a higher areal concentration of catalyst. Furthermore, we isolate conditions where single sheets acting alone do not capture tracers, but can trap the motile particles through cooperative interactions. These studies illustrate how purely physicochemical factors can promote behavior highly reminiscent of biological systems among active objects in fluidic environments.

L70.00190: Self-propelled Nanoparticles

JOHANNES SACHS (Presenter), PEER FISCHER, Micro Nano and Molecular System, Max Planck Institute for Intelligent Systems — Chemically active particles that self-propel due to catalytic reactions have been demonstrated at various length scales. It has, however, not yet been experimentally established how the propulsion of very small chemical motors scales with size. For this reason, we use a unique physical nanofabrication technique, based on physical vapor deposition, to grow catalytically-active Janus particles. These can be grown at defined lengths ranging from 20nm to 500nm, and can contain photocatalytic materials. This allows us to switch the particle between its passive and active state and thereby potentially from Brownian to enhanced diffusion. The observation of the particles’ motion is, however, far from trivial. We report our latest experimental results from a variety of analytical techniques, some of which can be used in situ.
L70.00191: Seal Zone Mechanics: Mechanical Stability of the Endograft/Aorta Interface  LUKA POCIVAVSEK (Presenter), University of Chicago, ENRIQUE CERDA, Universidad de Santiago de Chile, CHRISTOPHER SKELLY, ROSS MILNER, University of Chicago — Endovascular surgery (EVAR) has nearly replaced open aortic aneurysm repair. The long-term stability of EVAR repairs has come into question especially concerning graft endoleaks. Adhesion between the endograft and aortic wall is poorly understood and differs substantially from the traditional approach of kinematic fastening (suturing) utilized in open reconstructions. We provide a first general computational and theoretical approach to characterize and study seal zone mechanics. Our analysis (computational and analytical) shows that in the limit of no adhesion (or very weak adhesion) the endograft is always unstable relative to its position in the non-aneurysmal aorta. The energy driving graft displacement is the stored elastic energy in the aortic wall that comes from the oversizing of the stent graft. Adhesion between the aorta and endograft balances this stored elastic energy. This balance of adhesive energy to elastic energy is the central control parameter in the stability of the endograft. We develop a toy model for graft stability and apply it to patient specific geometries. Our work provides the first steps towards a robust physical understanding of the mechanics involved in EVAR stability that will allow for more durable future devices.

L70.00192: Controlling the strength of network materials: insights into failure mechanisms of random soft networks and composites*  SAI S DEOGEKAR, MOHAMMAD ISLAM, CATALIN PICU (Presenter), Rensselaer Polytechnic Institute — Fiber networks occur abundantly at all length scales in biological and artificial materials. In most cases, the network has structural role and hence its failure defines the strength of the material. Since these materials are structurally stochastic, heterogeneity plays a major role in determining the dominant failure mechanism. In this work we establish relationships between network strength and various parameters defining the network structure and properties of fibers and bonds [1]. These provide guidelines for network design. Further, we explore the role of heterogeneity in defining the strength and consider structures in which the fluctuations in the mechanical fields are controlled by adjusting various network parameters. Specifically, we consider networks with rigid inclusions (composite networks) and networks with stochastic structural perturbations of increasing amplitude. The results are discussed against insights related to stochastic continua, from the literature.

*L70.00193: In Situ TEM Imaging of Nanoscale Bubble Collapse and the Resulting Damage in Soft Matter*  GARTH EGAN (Presenter), XAVIER LEPRO CHAVEZ, EDMOND LAU, ERIC R SCHWEGLER, Lawrence Livermore Natl Lab — In recent years, it has been suggested that micron and sub-micron scale cavitation can occur in the human brain during explosive pressure wave, blunt trauma, or sports collision type events and that the resulting bubble collapse could be the main cause of damage leading to traumatic brain injuries. However, the behavior of sub-micron bubbles and their damagae potential to soft mater is not yet well understood. This is in part a result of the challenges associated with imaging on the necessary length and time scales. Here, we present the direct imaging of bubble collapse in a liquid cell using the Movie-Mode Dynamic Transmission Electron Microscope (MM-DTEM) at Lawrence Livermore National Laboratory. Bubbles were induced in ~1-3 µm of water using laser heating of 60 nm gold particles and typically found to collapse within 200 ns. Various polymers coated on the liquid cell substrates served as witnesses to potential damage. The experiments were performed in conjuncture with molecular dynamic (MD) simulations to further explore the dynamics of the system.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

L70.00194: Characterization of Novel Surfactant Molecules for Liquid Crystal Phase Triggering*  LINDA OSTER, BENJAMIN STRAIN (Presenter), University of Massachusetts Amherst, JESSICA SLEATOR, Springfield College, JAKE SHECHTER, FNU MANISHA, SANKARAN THAYUMANAVAN, JENNIFER ROSS, University of Massachusetts Amherst — Liquid crystal systems have the potential to produce macroscopic reactions from microscopic stimuli, making them exciting systems for triggered assemblies. Such triggerable systems are a cornerstone of biological systems’ ability to respond to their environment. Here, we use a novel surfactant composed of a trimer of amphiphilic molecules. These trimeric surfactants have three hydrophobic tails, with one tail varying in length. We have characterized the phase of the liquid crystal, 5CB, in spherical droplets as a function of surfactant type, surfactant concentration, and the diameter of the 5CB droplet. We find that small droplets, less than 11 µm in diameter, with high surfactant concentration, are more likely to be in the radial phase. We also find that the concentration and droplet sizes for the phase transition depended on the variable tail length.

*DoD ARO MURI 67455-CH-MUR
L70.00195: A Generalized Interfacial Structure Analysis Model for the Crystal Morphology: β HMX  JUNBEOM CHO (Presenter), WON BO LEE, Seoul National University — We studied the spiral growth mechanism of β-cycloctetramethylenetetranitramine (β-HMX) crystals with (0 2 0), (0 1 1), (1 1 0), and (1 0 1) faces, both experimentally and theoretically. In this work, a generalized interfacial structure analysis model is suggested to elucidate the morphology of β-HMX. There are two significant factors on crystallization procedure; 1) Molecular concentration near the surface of crystal 2) Whether pre-ordering of growth units occur during adsorption on the surface of each crystal faces. We investigated these through the Molecular Dynamic approach and metadynamics simulation, respectively. However, due to high conformational free energy barrier, pre-ordering of the growth unit does not occur and the factor 1 plays critical role in crystal growth, so the result of present work indicates that anisotropic local concentration of the growth units at the interface is the main factor determining relative growth rates, which was consistent with those of previous studies.

L70.00196: Computer simulations of associating liquid crystals*  DIMITRI BAPTISTE (Presenter), ELENA DORMIDONTOVA, Polymer Program Institute of Materials Science and Physics Department, University of Connecticut, Storrs, CT 06269 — Liquid crystals possess a range of interesting properties and are actively used in various technological applications. Reversible association, such as hydrogen bonding or metal-ligand complexation can provide additional mechanisms to control their properties leading to new applications including responsive functional materials. We employ Monte Carlo simulations using a spherocylinder model to predict the phase diagram for formation of the different ordered liquid crystalline phases in the presence of reversible associations. In particular we investigate the inter-relation between the strength of reversible association and the aspect ratio of liquid crystalline mesogens. The effect of confinement on system behavior will be discussed well.

*This work was supported by the Research Excellence Program (REP) of the University of Connecticut

L70.00197: Static and Dynamic properties of self-assembled hybrid wormlike surfactant micelles: Molecular Dynamics Study*  HARI SHARMA (Presenter), ELENA DORMIDONTOVA, Polymer Program, Institute of Material Science, Department of Physics, Storrs CT 06269, USA, University of Connecticut — Self-assembled wormlike surfactant aggregates have attracted considerable interest in both fundamental research and in practical applications due to their rich viscoelastic behavior and dynamic responsiveness to external conditions. Incorporation of polymer within wormlike micelles is shown to have enhanced stability and potentially superior viscoelastic properties. Co-assembly of polymers with surfactants in hybrid micelles is studied using coarse grained MD simulation with MARTINI force field and by united atom MD simulation with GROMOS53a6 force field. Simulations are carried out using GPU accelerated version of GROMACS 4.6.5. The change in micelle properties due to the presence of polymer is analyzed and the results are compared with available experimental data

*This research is supported by the ACS PRF#56803-ND6 and NVIDIA GPU grant.

L70.00198: Simulating the Response of Liquid Crystalline Elastomer Microposts to Light  JAMES WATERS (Presenter), University of Pittsburgh, JOANNA AIZENBERG, Harvard University, ANNA CHRISTINA BALAZS, University of Pittsburgh — Liquid crystalline elastomers (LCEs) represent a realizable physical system that can exhibit a large, non-linear response to an environmental stimulus. By adding light-sensitive moieties to the mesogens responsible for liquid crystalline order, one can create elastomers that will change shape in response to ultraviolet light. This provides a basis for a “write once, read many times” (WORM) memory. Information is encoded in an array of LCE microposts through a magnetic field during cross-linking, and then read out by introducing a light source. The system will return to its initial state upon removal of the stimulus, allowing the reading process to be repeated without altering the system. We developed a finite element simulation code to study components of such a system. Using our simulation method, we can predict the micropost deflection as a function of the preset nematic director and the incident angle of the light. We make comparisons to available experimental results and describe new findings that reveal how light can be used regulate the structure of an array of multiple, interacting LCE microposts. These studies point to new ways of utilizing the LCE arrays for technological applications.
Finally, we construct a phase diagram and correlate it w.r.t various phase diagrams of F127 available in the literature. 

The glass transition behavior is also observed at high temperature during gel melting. This illustrates the rate dependence of glass transition. The temperature associated with the glass transition decreases on increase in F127 concentration. Interestingly, the maxima in tan $\delta$ with $\omega$, followed by a glass transition as characterized by a peak in tan $\delta$. Interestingly, the maxima in tan $\delta$ shifts to lower temperatures with an increase in $\omega$, which illustrates the rate dependence of glass transition. The temperature associated with the glass transition decreases with increase in F127 concentration. The glass transition behavior is also observed at high temperature during gel melting. Finally, we construct a phase diagram and correlate it w.r.t various phase diagrams of F127 available in the literature.

In stationary state, the torque produced by friction force in the contact area balances that due to the external force generated by the active beads and the shell sticks to the substrate. In steady rolling state, rolling friction force balances the driving force, and the shell maintains a constant rolling velocity. Theoretical analysis shows a universal scaling relationship between the magnitude of driving force and shell velocity. This is a manifestation of viscoelastic nature of shell skin deformation dynamics during rolling motion. In accelerating state, energy supplied to the system by active beads exceeds the energy dissipation due to viscoelastic shell deformation in the contact area. Furthermore, the contact area of the shell with substrate decreases with increasing shell instantaneous velocity.

L70.00200: Phase Behaviour of Block Copolymer Pluronic: A Rheological Perspective

KHUSHBOO SUMAN (Presenter), SAGAR SOURAV, YOGESH M JOSHI, Indian Institute of Technology Kanpur — We study temperature induced phase change of a block copolymer Pluronic F127 (PEO$_{100}$-PPO$_{65}$-PEO$_{100}$) over a concentration range of 20-35 wt%. While this temperature dependent phase change visually appears like a liquid-soft solid transition, termed as gel in the literature, there is a debate regarding precise microstructure of the soft solid state. In this work, we conduct frequency ($\omega$) sweep at various temperatures on F127 solution. We observe that irrespective of the concentration, F127 solution shows all the rheological characteristics of sol – gel – glass transition. This suggests the transition of a liquid-like sample to a space spanning percolated network, whose rheological characteristic is increase in tan $\delta$ with $\omega$, followed by a glass transition as characterized by a peak in tan $\delta$. Interestingly, the maxima in tan $\delta$ shifts to lower temperatures with an increase in $\omega$, which illustrates the rate dependence of glass transition. The temperature associated with the glass transition decreases with increase in F127 concentration. The glass transition behavior is also observed at high temperature during gel melting. Finally, we construct a phase diagram and correlate it w.r.t various phase diagrams of F127 available in the literature.

L70.00201: Anomalous apparent Poisson ratios in stiff semiflexible polymer networks

JORDAN SHIVERS (Presenter), SADJAD ARZASH, FRED C. MACKINTOSH, Department of Chemical and Biomolecular Engineering, Rice University — Fibrous networks of stiff athermal biopolymers such as collagen, a major structural component of the extracellular matrix, have been shown to exhibit anomalously large apparent Poisson ratios, i.e. significant transverse contraction under small applied longitudinal extension. Here we show that this effect can be understood in the context of a macroscopic mechanical phase transition from a bending-dominated regime to a stretching-dominated regime at a critical applied extension controlled by the network connectivity. We measure this effect using a variety of 2D and 3D model network structures and propose a phase diagram governing the transition as a function of connectivity and strain.

*This work was supported in part by the National Science Foundation (DMR-1826623 and PHY-1427654).

L70.00202: Computationally modeling the use of digital holographic microscopy to characterize colloidal fractal aggregates

JEROME FUNG (Presenter), Department of Physics & Astronomy, Ithaca College, SAMANTHA HOANG, Department of Physics, Wellesley College — Recent experiments suggest that digital holographic microscopy can be used to determine the average fractal dimension of an ensemble of colloidal fractal aggregates [1]. We present computational results that clarify the range of validity of this approach. In the experiments, an aggregate in solution is illuminated with coherent light, and the interference pattern formed between scattered and unscattered light, or hologram, is recorded. Fitting an effective-sphere scattering model to a hologram allows an effective radius $r_{\text{eff}}$ and effective refractive index $n_{\text{eff}}$ to be determined for each aggregate. Once $r_{\text{eff}}$ and $n_{\text{eff}}$ are determined for an ensemble of aggregates, a scaling relationship between $r_{\text{eff}}$ and $n_{\text{eff}}$ derived from the Maxwell Garnett effective medium theory yields the average fractal dimension. In our study, we computationally generate holograms of aggregates of known geometry (and hence, fractal dimension) and fit effective-sphere models to those holograms. We then determine whether the scaling relationship between $r_{\text{eff}}$ and $n_{\text{eff}}$ correctly determines the fractal dimension. Our results suggest that this approach is useful for loosely-packed aggregates whose extent does not greatly exceed the wavelength of the incident light.

L70.00203: Charge Transport and Electrode Polarization in Phosphonium Ionic Liquids Bearing Sulfonate and Carboxylate Anions*  MATTHEW HARRIS (Presenter), JAMES T COSBY, University of Tennessee, DURGESH WAGLE, GARY BAKER, University of Missouri, JOSHUA SANGORO, University of Tennessee — The impact of chemical structure on mesoscale organization and dynamics in a series of ionic liquids based on the tetradecyltrihexylphosphonium cation with various sulfonate and carboxylate anions has been studied using broadband dielectric spectroscopy and wide-angle X-ray scattering. The effects of anion structure on the mesoscale organization in the liquid and ion transport properties were interpreted based on current theoretical understanding. In addition, the phenomena of electrode polarization arising due to accumulation of ions at the electrode surface was analyzed with regard to mesoscale organization and bulk transport properties. Evidence of slow dynamics at the electrode/ionic liquid interface is observed and attributed to electrosorption.

*The authors acknowledge financial support through the National Science Foundation, Division of Chemistry through grant CHE-1753282.

L70.00204: Charge transport and structural dynamics in deep eutectic mixtures (DEMs)*  STEPHANIE SPITTLE (Presenter), JAMES T COSBY, JOSHUA SANGORO, Chemical and Biomolecular Engineering, University of Tennessee, Knoxville — Charge transport and structural dynamics in choline chloride and glycerol mixtures were studied by broadband dielectric spectroscopy (BDS), dynamic mechanical spectroscopy (DMS), and differential scanning calorimetry (DSC). Slow sub-α relaxations are observed with BDS and DMS spectra. With decreasing choline chloride concentration, the sub-α dielectric relaxation, that is coupled to ion diffusion becomes much slower, while the slower mechanical relaxation is unaffected. This unexpected result is discussed within the framework of recent theories of ion transport and sub-α dynamics in small-molecule liquids.

L70.00205: Charge Transport and Ion Dynamics in Imidazolium-Based Homo- and Tri-Block Poly(Ionic Liquid)s*  ALEXANDRE HORTON (Presenter), EMMANUEL MAPESA, Chemical and Biomolecular Engineering, University of Tennessee, Knoxville, MINGTAO CHEN, Chemistry, Macromolecules Innovation Institute (MII), Virginia Tech University, MAXIMILIAN F HERES, MATTHEW HARRIS, Chemical and Biomolecular Engineering, University of Tennessee, Knoxville, YANGYANG WANG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, TIMOTHY LONG, Chemistry, Macromolecules Innovation Institute (MII), Virginia Tech University, BRADLEY LOKITZ, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, JOSHUA SANGORO, Chemical and Biomolecular Engineering, University of Tennessee, Knoxville — Broadband Dielectric Spectroscopy (BDS) and Differential Scanning Calorimetry (DSC) are used to probe ion dynamics in a series of imidazolium-based tri-block copolymers, and compared to their homopolymer analogues. Two calorimetric glass transitions are observed and assigned to the charged and uncharged (polystyrene) blocks. Exchanging bromide with bis(trifluoromethylsulfonyl)amide counter-ion, a change of the glass transition temperature by over 50 K is realized, bringing forth an increase in the room-temperature dc-ionic conductivity by over six (6) orders of magnitude. By systematically varying the volume fraction of the charged block, we demonstrate that the choice of counter-ion is the key parameter influencing charge transport in these systems.

L70.00206: Charge Transport and Dynamics of 2D-Conﬁned Polymerized Ionic Liquid Blends* KAITLIN GLYNN
(Presenter), THOMAS KINSEY, JOSHUA SANGORO, Chemical and Biomolecular Engineering, University of Tennessee, Knoxville —
The impact of geometrical conﬁnement on ion transport and dynamics in molecular and polymerized is investigated by broadband dielectric spectroscopy. The monomers of ammonium based ionic liquids are ﬁlled into unidirectional silica nanopores with mean diameters of 7 nm and studied by Raman spectroscopy in situ to monitor the progress of monomer conversion. Ionic conductivity is also probed at different degrees of polymerization and compared to bulk blends of molecular and polymerized ionic liquids. In agreement with similar systems recently published, it is found that the ionic conductivity in polymerized ionic liquids in nanopores is enhanced compared to their bulk counterparts. The results are discussed within the current theoretical frameworks for describing dynamics and transport in conﬁned polymers.

*The authors acknowledge ﬁnancial support through the National Science Foundation, Division of Chemistry through grant CHE-1753282.

L70.00207: Molecular Dynamics in Poly(Methyl Methacrylate)/Silica Nanoparticle Composites* EMMANUEL MAPESA
(Presenter), MICHAEL KILBEY, DAYTON STREET, JOSHUA SANGORO, University of Tennessee — Broadband Dielectric Spectroscopy (BDS) and Differential Scanning Calorimetry (DSC) are employed to study molecular dynamics and glass transition temperature (Tg) in poly(methyl methacrylate) (PMMA)/Silica-nanoparticle (NP) composites. By systematically probing the case of bare (non-functionalized) Si-NPs dispersed in PMMA matrix and that of PMMA grafted Si-NPs in PMMA matrix, we isolate the effects of each of these cases on dynamics and Tg. Furthermore, we show – for the structural relaxation process – that in addition to slowed down mobility, which is commonly reported in literature and assigned to dynamics at the NP-matrix interface, faster modes also arise due to conﬁnement effects. Scanning Electron Microscopy (SEM) is used to conﬁrm uniform dispersion of the NPs.

*E.M., and J.S. acknowledge support from the National Science Foundation, Division of Materials Research, Polymers Program, award DMR-1508394.

L70.00208: 3D Printing Water-In-Water GANHUA XIE, University of Massachusetts Amherst, JOE FORTH, YU CHAI, PAUL ASHBY, BRETT HELMS, Lawrence Berkeley National Lab, THOMAS RUSSELL (Presenter), University of Massachusetts Amherst — One of the hallmarks of biology is the ability to compartmentalize and coordinate system functions, which has been difﬁcult to reproduce even in the most sophisticated synthetic mimics. We show how to fabricate ﬂexible, 3D structured water-in-water systems embodying both principles by using the interface of immiscible polymer solutions to generate tubular membranes held in shape by an elastic polyanion-polycation complex. Using a 3D printer, the length, shape, and diameter of printed tubules water-in-water systems can be controlled. We demonstrate directional diffusion and separation of ionic species conﬁned to each liquid phase according to their preferential afﬁnity for the polyelectrolyte in the opposite phase. By coupling compartmentalization with ﬂow-driven directed material transport, continuous molecular separation can be achieved in such water-in-water systems. A layer-by-layer strategy is also used to further strengthen and functionalize the ﬂexible tubules, signiﬁcantly extending the potential applications of these all-aqueous 3D printed tubular systems.

L70.00209: The Manipulation of Granular Media Flow Properties to Produce Stable, Uphill, Low Mass Bipedal Locomotion JONATHAN GOSYNE (Presenter), DANIEL GOLDMAN, Georgia Institute of Technology — Unlike multileg robots which are typically close to the ground and generally statically stable, bipedal robots must maintain balance in potentially shifting terrain. We performed a series of systematic experiments to enable a 7 degree-of-freedom planar biped walker (45cm tall) to robustly traverse granular inclines of 0 to 10 deg of 1 mm poppy seeds. Through gait optimization, center of mass (CoM) variation, and contact-based control, a robust open-loop (OL) system for low mass biped robotic locomotion on granular media (GM) was developed. This was achieved through manipulation of step length, L, and vertical CoM to minimize GM ﬂow at the foot-media boundary. Because of nonlinearities involved in GM deformation, typical body and joint stabilization techniques used in biped robotics over hard ground are insufﬁcient. Thus, we developed a control scheme encompassing static inertial changes through torso position, and contact area variation through dynamic expansion of the feet, to redistribute slip forces (characterized by foot intrusion or material ﬂow). This allows for robust, steady gait over GM, and have found that this scheme enables the robot to remain upright for the duration of a trial (5 gait cycles) 90% of the time, compared to consistent OL failure within 1 gait cycle.

L70.00210: Versatile and Robust Soft Untethered Robots with Tight Integration of Soft Actuators and Flex Circuitry that Navigating Through Unstructured Terrains  
XIAONAN HUANG (Presenter), KITTY KUMAR, Carnegie Mellon University, MOHAMMAD KHALID JAWED, University of Los Angeles, California, ZISHENG YE, CARMEL MAJIDI, Carnegie Mellon University — Soft legged robots require robust walking dynamics and untethered functionality to approach the capability of their natural mammalian and reptilian counterparts to swiftly maneuver through unstructured environments. Achieving a soft robotics platform capable of biologically-relevant locomotion speeds depends on careful selection of actuators and electronics with soft materials and integration of power and control electronics. We demonstrate this with two untethered soft robotic testbeds that are both composed of flexible printed circuit board that integrates power and control electronics and electrically-powered soft limbs. The first implementation is a quadruped that is capable of walking at a maximum speed of 0.56 body length per second (3.2cm/s) and making 90 degree turns in two complete gait cycles (~5s). The second is a caterpillar-inspired robot capable of crawling with multiple gait at a speed of ~10mm/s over 25min. These robots are versatile and robust and have the capability of walking on a variety of surfaces, including up inclines, rocky terrain and poppy seeds, climbing over a half body height step, and maintaining continuous forward locomotion through confined space or after being dropped from an elevated height.

L70.00211: Self-Organization of Confined Binary Active Particles  
WILSON LUO (Presenter), MINGFEI ZHAO, XIN YONG, Mechanical Engineering, Binghamton University — The emergent behavior of active systems with self-propelled particles can be found in nature at many length scales, from bird flocking to bacteria swarming. Most previous studies investigate the collective behavior of systems with uniform morphology. However, many biological systems function via the interactions between multiple distinct organisms, often with differing geometries. In this study, we investigate the interactions between active particles of differing morphology. Our system consists of a mixture of self-propelled rod-like and sphere-like particles which exert pairwise repulsive forces and torques on each other in a 2D confined domain. Segregation of rods and spheres into distinct clusters can be observed without any adhesion. Our study will provide important insight in phase separation and cell sorting in co-cultured organisms.

L70.00212: Stress Localization of Thin Sheets in a Cylindrical Geometry  
NICOLE VOCE (Presenter), KLEBERT B FEITOSA, James Madison University, MARCELO AZEVEDO DIAS, Aarhus University — The ability to manipulate surface elastic instabilities finds many applications in engineering smart interfaces. We study the buckling phenomena of a thin cylindrical shell under axial compression that is constrained to slide onto an inner non-deformable pipe. Surface buckling is induced by immobilizing one end of the cylindrical shell and applying force to the other end. We study the geometry of the surface pattern, which is composed of rhombus shaped unit cells. We characterize the stress localization through shell thickness dependence and the out-of-plane deformation of the pattern after compression. Analysis of the curvature radii around the vertices of the unit cell shows that for thinner shells, the features get sharper suggesting that the stress is becoming more localized. Furthermore, as the thickness decreases, the distribution of the measured Gaussian curvature on the surface narrows around the zero mean indicating that the cylindrical shell is approaching the classical origami Yoshimura pattern.

L70.00213: Crystals and Liquids in Monolayers of Heavy particles  
NISHA LAMA (Presenter), ERIC WEEKS, YIJUN DONG, Physics, Emory University, PEIYAO WU, JAMES T KINDT, Chemistry, Emory University — We use brightfield microscopy to observe a dense monolayer of heavy colloidal particles sedimented to the bottom of a sample chamber. In our system, we control two parameters: particle concentration and Peclet number (Pe). Pe measures the relative importance of the gravitational force over the thermal effects and is directly proportional to the particle diameter. We are trying to find how Pe and particle concentration influence the packing structure of the sedimented monolayer. When we compared our simulation data with our experimental results, we found that our experiments were significantly less ordered than the simulations. This led us to investigate the influence of polydispersity in our samples and experimental issues created by the unintended influence of gravity when the slide has a slight tilt away from the horizontal.
L70.00214: Compressible Colloidal Clusters from Pickering Emulsions and Their DNA Functionalization* IN-SEONG JO (Presenter), School of Chemical Engineering, Sungkyunkwan University, JOON SUK OH, Center for Soft Matter Research, New York University, SHIN-HYUN KIM, Department of Chemical & Biomolecular Engineering, KAIST, DAVID J PINE, Center for Soft Matter Research, New York University, GI-RA YI, School of Chemical Engineering, Sungkyunkwan University — In this study for DNA-mediated colloidal assembly with pre-assembled clusters, DNA sequences, areal density of DNA, particle number density and size ratio are key parameters for determining equilibrium structures. We developed a simple and facile method to produce compressible colloidal clusters were prepared by assembling azide-functionalized non-crosslinked polymer particles using fluorinated oil-in-water emulsion droplets. The particles were adsorbed onto the droplet interface, which were packed to form clusters during slow evaporation of the oil. Because we use non-crosslinked polystyrene particles for colloidal clusters instead, which can be merged partially through solvent annealing, the compression ratio can be precisely controlled. Then, the clusters were coated by DNA using an strain-promoted alkyne-azide cycloaddition reaction. As the particles are not crosslinked, the shape of the DNA-coated clusters can be further modified to control the compression ratio through plasticization.

*We acknowledge support from the National Research Foundation of Korea (NRF-2017M3A7B8065528, NRF-2017R1A5A1070259 and NRF-2014M3A9B8023471). DP acknowledges partial support from the US National Science Foundation under Award Number DMR-1610788.

L70.00215: Tuning the Temperature-Dependent Thermal Conductivity via Complex Colloidal Superstructures* FABIAN NUTZ, MARKUS RETSCH (Presenter), Department of Chemistry, University of Bayreuth, 95447 Bayreuth, Germany — The ability to precisely tune the temperature dependence of the thermal conductivity possess a vital challenge to develop and conceive future heat management devices. In this contribution, we demonstrate the vast potential of polymer colloidal crystals to address and master these challenges. We achieve this goal based on the constriction-controlled thermal transport through well-defined colloidal crystal superstructures. These colloidal superstructures are specifically built by tailor-made latex particles with distinct glass transition temperatures. We exploit their multiresponsive film formation at various temperatures to demonstrate unprecedented control over thermal conductivity at temperatures between 25 °C and 200 °C. Based on the film formation process, we can irreversibly increase the thermal conductivity by a factor of about three. We show how to control:

i) the temperature, where the increase in thermal conductivity happens
ii) the sharpness of the thermal conductivity increase
iii) the height of the increase in thermal conductivity
iv) the incorporation of a multistep increase in thermal conductivity

*This project was funded by the Volkswagen Foundation (Lichtenberg professorship). Additional support was provided by the SFB 840.

L70.00216: WITHDRAWN ABSTRACT

L70.00217: de Gennes Narrowing in Colloidal Discs NAMITA SHOKEEN (Presenter), ASHIS MUKHOPADHYAY, Wayne State University — We studied the wave vector (q) dependence of relaxation time (τ) for different volume fractions of aqueous solutions of microspheres and microdiscs in concentrated regime. We observed characteristic peaks in τ(q) at certain q values. Such peaks indicate slow relaxations of structural rearrangements. These peaks match very well with the peaks in structure factor S(q) and radial distribution function g(r) calculations. This phenomena is called as de Gennes narrowing.

L70.00218: Dynamics of Polydisperse Emulsion Systems in a T-Shaped Chamber KENNY NGUYEN (Presenter), XIN DU, Department of Physics, Aquinas College — Emulsions consist of droplets of one liquid mixed into another immiscible liquid. Our samples are oil-in-water emulsion droplets flowing through a T-shape chamber. By means of microscopy, we studied the influence of the polydispersity on the dynamics of emulsion droplets, analyzed the deformation profile of the droplets and compared the emulsions flow with stratified liquid flow. Our experimental results indicate that (1) monodispersed sample exhibited more jammed behavior than the polydispersed samples; (2) particles near the boundary move differently from those in the middle at the T-junction; (3) The flow of emulsion system exhibit more turbulence comparing with stratified flow; (4) smaller droplets moved faster and are less affected by cooperative motion of neighbor droplets.
Effect of Interfacial Rheology on the Properties of Polymerized High Internal Phase Emulsions

MUCHU ZHOU (Presenter), REZA FOUDAZI, Chemical and Materials Engineering, New Mexico State University — High internal phase emulsions (HIPEs) can be created when the volume fraction of dispersed phase exceeds 74%. Porous polymer materials can be produced through HIPE-templating approach. Polymerized high internal phase emulsions (polyHIPEs) are formed by polymerization of the continuous phase of HIPEs that contains the organic monomers and subsequent extraction of the dispersed phase. The porous interconnected structure of polyHIPE is achieved through the formation of small holes (also known as windows) on the polymer wall between droplets. The polyHIPEs can be used as adsorbents, ion-exchange resins, separation membranes, and scaffolds in tissue engineering due to their high porosity and low density. In order to meet the requirements of the specific applications, strategies to control the pore size and window size of the polyHIPEs are necessary to be investigated. In this study, different surfactant systems and mixing methods are employed to prepare the polyHIPEs with different pore and window sizes. We also study the effect of interfacial rheological properties of different surfactant systems at the interface of the aqueous and oil phases on the morphology, and thus, mechanical properties of final polyHIPEs.

Foam-templated macroporous polymers

RYAN ZOWADA (Presenter), REZA FOUDAZI, Chemical Engineering, New Mexico State University — Foam templates were produced by rapid gas dispersion into an aqueous monomer solution at various dispersion concentrations. Then, the templates were cured through free radical polymerization to obtain polydispersed solid foams. The foams were analyzed for their stability by measuring coarsening rates and drainage times to quantify and compare the effect of gas dispersion concentration. The foams exhibited yield stress with pseudoplastic behavior, so their flow curve was fitted using Herschel-Bulkley model to calculate the required foaming energy. The benefits of using a gas dispersion phase instead of a liquid phase is an increase in starting material efficiency and eliminating typical removal step of the disperse phase in foam-templating compared to emulsion-templating. We investigated the morphological characteristics and mechanical properties of obtained porous polymers from foam- and emulsion-templating methods.

Foamability of Aqueous Solutions of Charged Surfactants and of Surfactant-Polymer Mixtures

CARINA MARTINEZ (Presenter), Chemical Engineering, University of Illinois at Chicago, SOPHIA HOROWICZ, University of Chicago, MATTHEW WAGENER, VIVEK SHARMA, Chemical Engineering, University of Illinois at Chicago — Dynamic adsorption of a freshly created interface is intimately linked with the rate of mass transfer of surfactant from liquid sub-phase to the interface, and this adsorption-limited kinetics is said to impact the stability of the newly formed interface. Addition of polymer to a surfactant solution affects the dynamic adsorption and the rheological response due to the formation of association complexes. Dynamic surface tension refers to the time dependent variation in surface tension, which is related with the rate of mass transfer of a surfactant from liquid sub-phase to the interface. In this study, we apply the method of maximum bubble pressure tensiometry for the measurement of dynamic surface tension effects at extremely short (1-50 ms) timescales. We discuss the overall adsorption kinetics of charged surfactants and the influence of added polymer on dynamic surface tension. Finally, we examine how pinch-off dynamics and rheological properties are modified in the presence of added polymers by including a critical examination of shear and extensional rheological responses.

Viscous fingering in lyotropic chromonic liquid crystals

SHUANG ZHOU (Presenter), University of Massachusetts Amherst, QING ZHANG, IRMGARD BISCHOFBERGER, Massachusetts Institute of Technology — We studied the Saffman-Taylor instability in a Hele-Shaw cell containing nematic lyotropic chromonic liquid crystals. The coupling between the flow field and director field changes the effective viscosity of the liquid crystal, and therefore influences the patterns formed by the injected liquid. In particular, the hugely different viscosities for different distortion modes in chromonic liquid crystals play important roles in determining the patterns. Besides changing the viscosity of injected fluid and the injection rate, we can also control the pattern by changing the concentration of chromonics in water solution, which tunes the anisotropic viscosities. By quantitatively comparing the local director field with flow field, we show that the intrinsic anisotropy of the displaced liquid can lead to rich and controllable patterns in a Hele-Shaw cell setup.

*New faculty start-up fund of UMass Amherst
L70.00223: Omnidirectional optical band gap for circularly polarized light in a nanocomposite cholesteric elastomer. Guillermo Reyes (Presenter), Adrian Reyes, National Autonomous University of Mexico — In recent years, Liquid Crystal Elastomers (LCE) have become very important in research, due to its possible applications to manufacture many optical devices as filters, actuators or transducers.

LCE combine properties of liquid crystals and elastic properties of polymers, these materials are composed by mesogens joined into a chain of polymers, their orientations may be changed by action of mechanical forces. Due to orientation change of mesogens in LCE, optical properties, as reflectance or transmittance can be modified. Reflectance and transmittance in LCE can be substantially modified by the effect of a particulated medium.

In this work we have studied a nano-composite consisting of a chiral elastomer doped with metallic nano spheres. We show that Bragg phenomenon occurs in this chiral media, hence this composite works as a complex circular polarization optical controller handle by the filling factor of nano spheres, incidence angle of light and stretching of the sample.

L70.00224: Fast electro-optical switching of dichroic dye-doped antiferroelectric liquid crystals without polarizers. Veridiana Garcia Guimarães, Department of Physics, Universidade Estadual de Maringá, Junren Wang, Liquid Crystal Institute, Kent State University, Steven Planitzer, Department of Physics, Kent State University, Rafael Soares Zola, Department of Physics, Universidade Estadual de Maringá, Antal Istvan Jakli (Presenter), Liquid Crystal Institute, Kent State University — In this work we investigate alignment and electro-optical properties of a room temperature dye-doped antiferroelectric liquid crystal mixture. We achieved extremely uniform alignment on macroscopic scale of thin cells with the combination of proper surface alignment and electric field treatment. We have also successfully demonstrated that two films of dye-doped antiferroelectric liquid crystals in their antclinic chiral smectic C (SmC*) phase can be used to switch the transmitted light intensity between dark and bright states without the need of polarizer filters. We also demonstrate that one could get either normally dark or bright states. Normally dark states can be useful in number of applications such as in privacy windows or smart refrigerators. A normally transparent display has applications in plethora of other areas, such as navigation systems built in windshields, in goggles, or smart windows.

*This research was supported by Valeo Lightning Systems and by CAPES Foundation – PDSE [88881.133505/2016-01].

L70.00225: Amplification of chirality of lyotropic chromonic liquid crystals confined to capillaries. Sujin Lee (Presenter), Elsa Reichmanis, Jung Ok Park, Mohan Srinivasarao, Georgia Institute of Technology — Lyotropic chromonic liquid crystals (LCLC) molecules are achiral, that have plank-like rigid aromatic cores and hydrophilic ionic groups at the peripheries. Upon confinement of LCLCs in cylindrical capillary, the director adopts a doubly twisted director configuration, due to unusually small twist elastic constants in LCLCs. Since the LCLC is achiral, they possess multi domain with equal probability of both handedness which is separated by Neel walls. In this work, we report that by adding minute amounts of chiral molecules to LCLCs with a doubly twisted director configuration possessing both handedness, the whole system can be transformed into a single handedness. The structure and charge of the chiral molecules were also studied. By investigating the effect of various chiral molecules within this LCLCs in capillary system, we expect to understand chirality amplification mechanisms.

L70.00226: Repeated rehydration of lipid films as a method to mix phospholipids without the use of organic solvents. Eric Oropeza-Guzman (Presenter), Soft & Bio Lab, CINVESTAV Monterrey, México — A technically simple method for mixing phospholipids of different species without using organic solvents or additives has been developed. Based on the reported literature regarding aqueous lamellar systems, phospholipid interaction parameters, and lipid diffusion coefficients, we hypothesized that the repeated drying and rehydration of a multispecies phospholipid sample, using only deionized water, should produce a uniform distribution of phospholipid molecules. Different lipid films of binary mixtures of zwitterionic and anionic glycerophospholipids were prepared using this method. The resulting films were reconstituted in vesicular form and compared to controls prepared with organic solvents by differential scanning calorimetry. The calorimetric scans revealed no significant differences between samples and controls for any of the tested mixtures. This finding suggests that the proposed technique creates a product with equivalent compositional homogeneity than the conventional method. From an environmental, health and safety standpoint, we are confident that this technique can contribute to the implementation of sustainable chemical practices, especially in industrial settings where organic solvents are tightly regulated.
L70.00227: Self-assembly of cyclic polygon shaped fluid colloidal membranes through pinning  

LACHIT SAIKIA (Presenter), PRERNA SHARMA, Department of Physics, Indian Institute of Science, Bangalore, India — An isotropic mixture of rod-like viruses self-assembles into 2D fluid monolayer membranes in presence of non-adsorbing polymer through depletion attraction. These membranes are circular in shape due to surface tension. Surprisingly, cyclic polygon shaped colloidal membranes form when isotropic mixtures of two kinds of geometrically different rods are mixed with depleting polymer. Long rods form faceted core of the cyclic polygon whereas short rods phase separate into lobes that are connected through pinning points. We demonstrate that the origin of this stable out of equilibrium anisotropic shape of the membranes lies in the phenomenon of how one fluid membrane spreads over another in presence of disorder/pinning sites. We show that the pinning sites are not topological defects rather accumulation point of rods that are significantly different. Our results show a unique counter-intuitive scenario where disorder leads to self-assembly of ordered structure.

L70.00228: Structure of Lung-Mimetic Multilamellar Bodies with Lipid Compositions Relevant in Pneumonia*  

DYLAN STEER (Presenter), SHERRY LEUNG, HANNAH MEISELMAN, University of Illinois at Urbana-Champaign, DANIEL TOPGAARD, Division of Physical Chemistry, Lund University, CECILIA LEAL, University of Illinois at Urbana-Champaign — Pneumonia is the leading cause of death amongst captive dolphins. While the pathology of pneumonia is understood at a macroscopic level, recent results show that changes in material chemistry at the lung-air interface plays an important role in symptoms, though the physical basis is unknown.[1] Healthy lungs are coated by a thin, hydrated biological composite composed primarily of amphiphilic lipids and a small amount of proteins. These self-assemble into liquid-crystalline phases which can reduce the fluid-air interfacial surface energy to near 0. In diseased lungs abnormally high concentrations of cardiolipin, a highly charged and highly unsaturated lipid, and Ca^{2+} can be found. Here we observe using small angle X-ray diffraction (SAXS) that addition of cardiolipin dehydrates the lipid membranes, contrary to predictions of pure electric double layer theory. The physical cause for these effects and the influence of Ca^{2+} is studied using wide angle X-ray diffraction (WAXS) and solid state nuclear magnetic resonance (ssNMR).

L70.00229: Colloidal Gelation of Thermo-Responsive Microgel Mixture Suspensions*  

SAORI MINAMI (Presenter), Kyoto Institute of Technology, TAKUMI WATANABE, DAISUKE SUZUKI, Shinshu University, KENJI URAYAMA, Kyoto Institute of Technology — Concentrated suspensions of microgels composed of thermo-responsive polymer such as poly(N-isopropylacrylamide) (PNIPA) exhibit various states, i.e., repulsive glass, dispersion, (attractive) colloidal gel, depending on temperature (T), particle concentration, surface charge density. The heating reduces the volume of the microgels, and also substantially changes the type of interparticle interaction from repulsive to attractive when T across the LCST, resulting in the formation of colloidal gel. Present work focuses on the dense suspensions of the microgel mixtures of PNIPA and the homologue with different LCSTs. We show that the rheological properties of the mixture suspensions are pronouncedly affected by the mixing ratio. The T-dependent viscoelastic properties of the mixture suspensions are interpreted by considering the T-dependence of the volume fraction and the type of interparticle interaction of each component.[1] [1] S. Minami, T. Watanabe, D. Suzuki, K. Urayama, Soft Matter, 14, 1596-1607, 2018

L70.00230: Thermoelastic heterogeneity in a model metallic glass from molecular dynamics calculations*  

BAOSHUANG SHANG (Presenter), Laboratoire Interdisciplinaire de Physique, PENGFEI GUAN, Beijing Computational Science Research Center, JEAN-LOUIS BARRAT, Laboratoire Interdisciplinaire de Physique — It is well known that the elastic properties of amorphous systems are heterogeneous, leading to peculiarities in vibrational spectra and thermal properties. In this work, we investigate the heterogeneity in thermoelastic properties, and more precisely in the thermal expansion coefficient, in a model metallic glass. We find heterogeneities that are similar - in terms of length scales - to those in elastic constants. It has been suggested that such heterogeneities could be the reason for "cryogenic rejuvenation" processes observed under thermal cycling in several experiments. We investigate this hypothesis by comparing the values of the local yield stresses with the stresses generated by heterogeneities in thermal dilation.

**L70.00231: Terahertz Time-Domain Spectroscopy and Low-Temperature Specific Heat Investigation of Vitreous Glucose**

TATSUYA MORI (Presenter), MIKITOSHI KABEYA, Division of Materials Science, University of Tsukuba, SUGURU KITANI, Laboratory for Materials and Structures, Tokyo Institute of Technology, YASUHIRO FUJII, Department of Physical Sciences, Ritsumeikan University, JAE-HYON KO, Department of Physics, Hallym University, AKITOSHI KOREEDA, Department of Physical Sciences, Ritsumeikan University, HITOSHI KAWAJI, Laboratory for Materials and Structures, Tokyo Institute of Technology, SEIJI KOJIMA, Division of Materials Science, University of Tsukuba — The boson peak is a low energy excitation universally observed in the THz region of the amorphous materials. The boson peak of infrared spectra appears in the spectra of $a(v)/v^2$ [$a(v)$ is the absorption coefficient]. In this study, we performed terahertz time-domain spectroscopy on glassy glucose to investigate the boson peak dynamics. Moreover, we determined infrared light-vibration coupling coefficient using the $a(v)$ and vibrational density of states obtained from the low-temperature specific heat measurement.

**L70.00232: Mechanics of filamentous growth in soft materials**

NICOLAS BRUOT (Presenter), NINO KUKHALEISHVILI, Institut de Physique de Nice, CNRS, Université Côte d’Azur, CHARLES PUERNER, D. THOMPSON, Institut de Biologie de Valrose, CNRS, INSERM, Université Côte d’Azur, AGNESE SEMINARA, Institut de Physique de Nice, CNRS, INSERM, Université Côte d’Azur, MARTINE BASSILANA, ROBERT ARKOWITZ, Institut de Biologie de Valrose, CNRS, INSERM, Université Côte d’Azur, XAVIER NOBLIN, Institut de Physique de Nice, CNRS, Université Côte d’Azur — Candida albicans is a yeast that grows in the shape of a filament with a tip continuously moving forward in the nutritious medium. The forces at the tip are driven by the internal pressure of the cell and are strong enough to induce indentation and penetration in materials such as the human tissues. This allows *C. albicans* to invade a host, with possibly lethal consequences, especially in immunodeficient individuals. How the growth rate and direction depend on the material properties provide indications of the internal behaviour and response of the organism to its environment. These can be better understood by growing filaments in controlled substrates, and even reducing experiments to observing the penetration of thin solids in soft materials. We present here experiments of both the indentation of PDMS by a micrometric-sized sphere, and the observation of *C. albicans* growing in PDMS substrates containing fluorescent particles where the deformations of the material can be monitored. We expect with such experiments to improve and develop models of the mechanics of penetration in brittle and elastic materials depending on their mechanical properties such as the Young modulus, the viscosity and the adhesive properties.

*We acknowledge funding from the ANR 2016 project "FORFUNIGO".

**L70.00233: DNA-Functionalized 100 nm Polymer Nanoparticles from Block Copolymer Micelles**

JEONGHOON YOON (Presenter), SAEROM LEE, IN-SEONG JO, School of Chemical Engineering, Sungkyunkwan University, JOON SUK OH, Department of Physics and Center for Soft Matter Research, New York University, DAVID J PINE, Department of Chemical & Biomolecular Engineering, New York University, TAE SOUP SHIM, Department of Chemical Engineering and Department of Energy Systems Research, Ajou University, GI-RA YI, School of Chemical Engineering, Sungkyunkwan University — DNA-mediated self-assembly of colloidal particles is one of the most promising approaches for constructing colloidal superstructures. For nanophotonic materials and devices, DNA-functionalized colloids with diameters of around 100 nm are essential building blocks. Here, we demonstrate a strategy for synthesizing DNA-functionalized polymer nanoparticles (DNA-polyNPs) in the size range of 55~150 nm using block copolymer micelles as a template. Diblock copolymers of polystyrene-b-poly(ethylene oxide) with an azide end group are first formed into spherical micelles. Then, micelle cores are swollen with styrene monomer and polymerized, thus producing PS nanoparticles with PEO brushes and azide functional end groups. DNA strands are conjugated onto the ends of the PEO brushes on the surface of PS particles through a strain-promoted alkyne-azide cycloaddition reaction (SPAAC). The DNA-polyNP with complementary sequences show thermally-responsive association and dissociation behavior.

**L70.00234: Geometry-driven self-assembly of interfacial sheets**  
ZACHARIAH SCHRECENGOST (Presenter), JORDAN V BARRETT, Physics, Syracuse University, VINCENT DÉMERY, Physics, Université de Lyon, JOSEPH D PAULSEN, Physics, Syracuse University —  
When a linear elastic material is made sufficiently thin, the energy required to bend the sheet is orders of magnitude lower than the energy required to stretch it. Placing this sheet on a liquid interface introduces another energy scale. In the case of an inextensible sheet with zero bending cost – an asymptotic limit that is readily achieved in experiments using ultrathin polymer films – the sheet will bend and wrinkle in such a way as to minimize the exposed liquid surface area [1]. However, predicting the overall shape of the film is a nontrivial optimization problem that is highly sensitive to the curvature of the interface or the boundary conditions. We use Surface Evolver simulations and analytic calculations to study the energetic cost of placing an ultrathin elastic disc on an arbitrary local topography of moderate curvature, from spherical to ellipsoidal to saddle-shaped interfaces. We establish scaling laws that relate the system energy to the principal radii of curvature, which capture our measurements spanning nearly three decades in curvature. This work paves the way for designing curved interfacial topographies that promote self-assembly via energy minimization. [1] Paulsen et al., Nat. Mater. 14 (2015).

**L70.00235: Hierarchical Self-assembly, Spongy Architecture and Phase States of Laponite in water-Alcohol mixtures**  
RAVI KUMAR PUJALA (Presenter), Physics, University of Hyderabad —  
We propose an alternative method to tune the electrostatic interactions to obtain a transition from a repulsive to an attractive system of nanoplatelets by increasing the alcohol concentration, i.e. increasing the Bjerrum length. A phase diagram of Laponite® in alcohol solutions has been proposed, which clearly demarcates regions of stable sol, unstable sol, transparent gel, turbid gel, glass, and flocculation. A new class of soft materials, called nanoclay-organogels, was deeply explored using confocal and scanning electron microscopy that depicted spongy architecture and presence of nano and micron size pores inside the gel matrix indicating the hierarchical self-assembly of the nanoplatelets in the binary solvent. Universal power-law scaling of storage modulus and yield stress with alcohol concentration was observed. We have extensively examined the dispersion stability, aggregation and gelation behaviour of Laponite nanoplatelets in different alcohol -water binary solvents, thereby proposing a universal description of nanoclay dispersion in alcoholic solutions, which is poorly probed and marginally understood in the literature.

**L70.00236: Liquid Magnets**  
XUBO LIU (Presenter), Beijing University of Chemical Technology, NOAH KENT, ALEJANDRO CEBALLOS, JOE FORTH, Lawrence Berkeley National Lab, SHAOWEI SHI, DONG WANG, THOMAS RUSSELL, Beijing University of Chemical Technology —  
Dispersions of carboxylated iron oxide magnetic nanoparticle (Fe₃O₄-COOH MNP) with a diameter of 30nm are a type of ferrofluid that is superparamagnetic under normal conditions. Here, we demonstrate a simple approach to reversibly transform a paramagnetic ferrofluid droplet into the ferromagnetic state by immersing it into an immiscible liquid containing ligands, that can interact with the particle to form MNP-surfactants that subsequently are brought into the jammed state. As a result, a novel ferromagnetic liquid device, namely a liquid magnet, is generated in one step. The liquid magnet is a functional core-shell structure, with a superparamagnetic fluid core wrapped by a monolayer shell of jammed ferromagnetic MNPs-surfactants, where the thermal energy of the active MNPs is weakened significantly by anchored ligands. The magnetic dipole moment of the ferrofluid is able to be maintained indefinitely. There is a measurable coercivity and remnant magnetization of the ferromagnetic liquid droplet. Under the influence of a rotating permanent magnet, the liquid droplets are seen to rotate at an angular velocity that increases with decreasing droplet size. The angular velocity is also found to increase with increasing time and reach a limiting velocity.
L70.00237: Dimerization of Annular Sector Particles*  
ELYSE ROOD (Presenter), SCOTT FRANKLIN, Rochester Institute of Technology, THEODORE ANTHONY BRZINSKI, SYKES CARGILE, Haverford College — We study annular sector particles (ASPs), open semi-circular rings characterized by two dimensionless numbers: the subtended opening angle and the ratio of inner and outer radii. The ASPs are placed in an annulus with a rotating, ridged ring above them. Applying a torque to this ring exerts a shear stress on the quasi-2D packing of ASPs. Within the annulus, if two ASPs are within the outer radius distance from each other they have the potential to intersect with each other. This entangled pair of ASPs is defined as a dimer. The movement of ASPs results in the formation as well as annihilation of dimers, known as dimerization and de-dimerization. From images of the annulus and computational analysis, the location and orientation of each ASP is determined. From this information, we can identify dimers and classify them based on the dot product of ASP orientations. Opposite facing dimers, which have the ability to form chains, are defined by a negative dot product; similar facing dimers are defined by a positive dot product. We investigate the distribution of structure types and how they evolve with shear.

L70.00238: STATISTICAL AND NONLINEAR PHYSICS —

L70.00239: Predicting Network Edge Count and Fragmentation under Vertex Percolation Processes*  
NICHOLAS BRUNK (Presenter), Intelligent Systems Engineering, Indiana University Bloomington, WILLIAM BUTSKE, Department of Mathematics, Rose-Hulman Institute of Technology, JAMES ALEXANDER GLAZIER, Intelligent Systems Engineering, Indiana University Bloomington — Network and graph-based percolation theory are applicable to a broad range of disciplines throughout the natural, life, and social sciences. We present a graph-based vertex (site) percolation study empirically quantifying – as a function of vertex occupation fraction – the number of edges (bonds) formed, the extent of fragmentation of the network, and the scaling of percolation thresholds with the mean vertex degree of the graph. The edge count is shown to be quadratically dependent upon the vertex occupation fraction with no unknown fitting parameters, thus applying universally - that is, to all networks - with minimal error. It may be used to predict, for example, the number of nearest neighbor bonds remaining in a lattice (e.g. translational degrees of freedom in a spatial lattice) or the number of friendships remaining as a social network is deconstructed (e.g. due to account closure on social media or mortality). For well-behaved networks with a reasonably low variance in the vertex degree distribution, the latter relations may be used to predict fragmentation: both the percolation threshold and, subsequently, the number of distinct connected components in the network at a given occupation fraction.

L70.00240: Optimal deployment of resources for maximizing impact in spreading processes  
ANDREY LOKHOV (Presenter), Los Alamos National Laboratory, DAVID SAAD, Aston University — The effective use of limited resources for controlling spreading processes on networks is of prime significance in diverse contexts, ranging from the identification of “influential spreaders” for maximizing information dissemination and targeted interventions in regulatory networks, to the development of mitigation policies for infectious diseases and financial contagion in economic systems. Solutions for these optimization tasks that are based purely on topological arguments are not fully satisfactory; in realistic settings, the problem is often characterized by heterogeneous interactions and requires interventions in a dynamic fashion over a finite time window via a restricted set of controllable nodes. The optimal distribution of available resources hence results from an interplay between network topology and spreading dynamics. We show how these problems can be addressed as particular instances of a universal analytical framework based on a scalable dynamic message-passing approach and demonstrate the efficacy of the method on a variety of real-world examples.

L70.00241: Electromechanical Instability of a Dielectric Elastomer Balloon  
SHENQIANG CAI (Presenter), University of California, San Diego — As an electroactive polymer, dielectric elastomer has been recently intensively explored in different engineering applications, ranging from soft robot, haptic devices, artificial muscle to energy harvesting system. In the applications, inflated dielectric elastomer balloons of various shapes have been widely adopted. Some recent experiments have shown unusual instability modes in dielectric elastomer balloon, when it is subjected to an internal pressure and electric voltage. In the talk, I will present our theoretical analysis of electromechanical instability of dielectric elastomer balloons with considering electromechanical coupling effect, hyperelasticity and viscoelasticity of the material. Our theoretical results have indicated that the electromechanical instability of the dielectric elastomer balloon may dramatically affect its performance or even determine its failure mechanism. Our results further show that by controlling the electromechanical loading path, we may achieve or avoid the electromechanical instabilities of the balloon. Our theoretical predictions agree very well with experimental observations.
L70.00242: Cross-Influence of Thermodynamic Driving Forces in Confined Environment  YU QIAO (Presenter), MENG WANG, University of California, San Diego — The second law of thermodynamics dictates that under a certain condition, the cross-influences of thermodynamic driving forces (tdf) must be balanced. For a galvanic cell, it is equivalent to the well-known Nernst equation; for a double-layer supercapacitor, it is consistent with the classic Gouy-Chapman model. In our recent experiment on confined large pivalate ions in carbon nanopores, however, it was measured that the cross-influences of the electromotive force and the chemical potential were different from each other by an order of magnitude. We attribute this remarkable phenomenon to the confinement effect of the electrode inner surfaces, which forbids the formation of diffuse layer. We argue that in general, in a low-dimensional environment, in the large dimension(s), the laws of classic statistical physics can be applied; but in the small dimension(s) wherein two tdf interact, the governing equations can be distinct. With this unique mechanism, the second law of thermodynamics may break down, in a dissimilar manner to “Maxwell's demon”. The concept of unbalanced cross-influence of tdf is further examined through a theoretical analysis on a model system comprising of randomly moving elastic particles restricted in a two-dimensional transition zone in a gravitational field.

L70.00243: Fractional Langevin equation with reflecting barrier* SARAH SKINNER (Presenter), THOMAS VOJTA, Physics, Missouri University of Science and Technology — The Fractional Langevin equation describes a the motion of a particle under the influence of a random force with long-time correlations. This stochastic differential equation is a common model for anomalous diffusion. We investigate the fractional Langevin equation in the presence of a reflecting wall using Monte Carlo simulations. The mean-square displacement shows the expected anomalous diffusion behavior, $x^2 \sim t^{2-\alpha}$, as in the unconfined case. However, the probability density close to the wall shows highly non-Gaussian behavior. For reference, we compare our results to reflected fractional Brownian motion for which the probability density shows a power law singularity at the barrier [1].

*L This work is supported in part by the NSF under Grant No. DMR-1506152 and DMR-1828489.

L70.00244: Fractional Brownian Motion with an Absorbing Wall* ALEX WARHOVER (Presenter), THOMAS VOJTA, Missouri University of Science and Technology — Fractional Brownian motion, a random walk with long-time power-law correlations between its steps, is a prototypical model for anomalous diffusion. We employ large scale Monte Carlo simulations to investigate fractional Brownian motion in the presence of an absorbing wall. In the limit of vanishing correlations, our findings reproduce the well-known results for normal diffusion. In contrast, the interplay between the absorbing wall and the long-range power correlations leads to a singular probability density close to the wall. We compare our results to those of Brownian Motion in the presence of a reflecting wall [1], and we discuss implications of our results. [1] A.H.O Wada and T. Vojta, Phys. Rev. E 97, 020102 (2018)

*L This work was supported in part by the NSF under Grant No. DMR-1506152 and DMR-1828489.

L70.00245: Oscillatory force generation in nonequilibrium systems from peaked energy spectra.* ANTHONY BONFILS (Presenter), WOOSOK MOON, DHRUBADITYA MITRA, Nordic Institute for Theoretical Physics, Sweden, JOHN WETTLAUFER, Yale university — A key to force generation in non-equilibrium systems is encoded in their energy fluctuation spectrum. A non-equipartition of energy, which is only possible in active or forced systems, can lead to a non-monotonic fluctuation spectrum. Recently, it has been shown that for a narrow, unimodal spectrum, the force exerted by a non-equilibrium system on two walls embedded in a system with such a spectrum oscillates between repulsion and attraction as a function of wall separation [1]. These results are consistent with the Maritime Casimir effect, which is driven by wind-water interactions, and with recent simulations of active Brownian particles. The spectrum is believed to be the solution of a specific class of Fokker-Planck equations. Taking a hydrodynamic perspective of Janssen [2], we construct a theory and a numerical basis for the observed Pierson and Moskovitz spectrum, which underlies the Maritime Casimir effect.

*Swedish Research Council Grant No. 638-2013-9243
L70.00246: Counterintuitive asymmetry of transition times in the Brownian asymmetric simple exclusion process
DOMINIK LIPS (Presenter), University of Osnabrück, ARTEM RYABOV, Department of Macromolecular Physics, Charles University, PHILIPP MAASS, University of Osnabrück — Driven diffusion of hard spheres (rods) in a one-dimensional cosine potential under a static bias should reflect properties of the asymmetric simple exclusion process (ASEP) on a lattice, if the amplitude of the cosine potential is considered to be large compared to the particles' thermal energy. For this Brownian asymmetric exclusion process (BASEP) [1], we study transition times of a tagged particle between potential wells against and along the bias direction in non-equilibrium steady states. These transition times exhibit a counterintuitive asymmetry: While one may expect that the mean transition time in bias direction is shorter, the opposite is true. We relate this surprising asymmetry to the collective motion of the particles. Differences in the distributions of the times in and against bias direction depend sensitively on the filling factor (number of particles per potential well) and the rod length. Our analysis sheds light on the transport behavior of the model, which, compared to the ASEP, shows richer properties due to the additional length scale given by the rod length.

L70.00247: Imperfections by Design: Interactive Buckling and postbuckling in Architected Materials*
YINGHAO ZHAO, Department of Civil, Environmental and Geodetic Engineering, The Ohio State University, AMAL JERALD JOSEPH MARIA JOSEPH, Department of Mechanical and Aerospace Engineering, The Ohio State University, CHUNPING MA (Presenter), MEGAN SKIBINSKI, BURAK GUL, ANDREW SCHELLENBERG, NAN HU, Department of Civil, Environmental and Geodetic Engineering, The Ohio State University — Harnessing elastic instabilities in materials has recently enabled new classes of tunable systems and devices, such as gating mechanisms, artificial muscles, and soft robotics, etc. The common feature of those instability-induced smart systems is the amplification of force and motion compared to their traditional stiff counterparts. Achieving these amplifying effects usually relies on harnessing tailor able architected materials as the building block. One of the challenges is how defects change the properties of architected materials to achieve targeted functions with aperiodic materials. In response to such need, we introduce a class of shell structures which undergoes interactive buckling. By combining finite-element simulations and desktop-scale experiments, we found that the interactive buckling can be induced by strategically controlling the number and the distribution of defects, leading to a deterministic actuation response compared to the one without geometric defects. Our study thereby opens avenues for the design of next-generation actuators and robots with high fidelity and low sensitivity over a wide range of length scales.

L70.00248: Scaling Features as Universal Hallmark of Physiological Dynamics across Systems, States and Clinical Conditions*
PLAMEN IVANOV (Presenter), Physics Department, Boston University — We will present a review of linear and nonlinear scaling characteristics in physiological dynamics, their universality across systems, phase transitions across physiological states, relation to underlying control mechanisms and their relevance for diagnosis and prognosis of disease.

*We acknowledge support from W M Keck Foundation, National Institutes of Health (NIH Grant 1R01-HL098437), the Office of Naval Research (ONR Grant 000141010078), the US-Israel Binational Science Foundation (BSF Grant 2012219).

L70.00249: Discrete Bound States in a Floquet-Bloch Active Spinning System
SHAHRZAD YAZDI (Presenter), ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — Inspired by electronic systems, we explore the transport of an active spinning particle in a lattice of posts using a periodic driving protocol akin to a Floquet system. In our 2D Floquet-Bloch system, coupling of hydrodynamic and electrostatic interactions leads to hybridization of localized states of the spinning particle that are able to diffuse through the medium, or in some cases move ballistically. More interestingly, we find a set of discrete localized states at quantized applied frequencies that delimit regions of diffusion. These states have typical orbits much larger than the original localized states. They occur approximately at fractional frequency values of the two frequencies for the localized trivial states. Our results may be an interesting new view on transport in active colloidal systems and their counterparts in solid state physics.
L70.00250: Tunable Failure in Non-periodic Architected Materials Inspired by Slime Mold Growth*  
CHUNPING MA (Presenter), Department of Civil, Environmental and Geodetic Engineering, The Ohio State University, HANQING ZHANG, DAOBO ZHANG, PENG FENG, Department of Civil Engineering, Tsinghua University, BURAK GUL, NAM HU, Department of Civil, Environmental and Geodetic Engineering, The Ohio State University — The field of architected materials has been explored in many disciplines over the past decade, it has yet to be fully explored in civil engineering and architecture. From the perspective of material constitution, most existing efforts on metamaterials primarily use the elastic buckling of soft materials, while common infrastructure materials lack the ability to undergo such large deformation/strain. In addition, most studies to date have maintained the symmetry of material and studied the simple periodic form. Inspired by slime mold growth, we explored a new class of non-periodic cellular materials and conducted proof-of-concept experiments on 3D-printed specimens. We found that simple changes on the architectures of material can lead to significant differences in failure mechanism. Therefore, this study paves the road for the future design of resilient infrastructure involving the ability to rebound from extreme events and the corresponding repair approaches to recover capacity after those events.

*N.H. acknowledges the start-up fund from the College of Engineering at the Ohio State University.

L70.00251: Predicting shear transformation events in glasses via energy landscape sampling*  
BIN XU (Presenter), Beijing Computational Science Research Center, MICHAEL FALK, Johns Hopkins University, JINFU LI, LINGTI KONG, Shanghai Jiaotong University — Shear transformation (ST) events, as the elementary process for plastic deformation of glasses, are of vital importance to understand the mechanical behavior of glasses. Here, by characterizing first-order saddle points in the potential energy landscape, we develop a framework to characterize and to predict the triggering (i.e. locations, triggering strains, and local structural transformations under different shear protocols) of ST events. Verification undertaken with a model Cu-Zr glass reveals that the predictions agree well with athermal quasistatic shear simulations. The proposed framework is believed to provide an important tool for developing a quantitative understanding of the deformation processes that control mechanical behavior of metallic glasses.

L70.00252: Machine Learning on Lithium Sulfur Materials*  
YING LI (Presenter), Argonne National Laboratory — Materials properties are collective phenomena in a nonlinear relationship of compositions and interatomic configurations, which are difficult to acquire from computations. Interactions between the constituent particles (atoms) are so complicated which only the limited scale of the problem is analytically solvable with descriptive theory (e.g., density functional theory, molecular dynamics, etc.) combining with current high-performance computing technology. To generalize materials simulation and properties prediction, data-driven approaches (e.g., machine learning, neural network, etc.) are much needed. Here, we provide an example showing how the cohesive energy, Fermi energy and band structures of lithium-sulfur materials as intrinsic collective behaviors are learned via Machine Learning methods, such as random forest, K-nearest neighbor algorithm, LASSO, Neural Networks, etc, and the performance comparison of the different methods will be demonstrated, which provides a general design guidance for lithium-sulfur batteries.

L70.00253: Behavior of a Non-equilibrium Self-Organizing System: A Potential Means to Enhance Energy Efficiency in Systems with Functional Intelligence*  
GAO(ZACHARY) SUN (Presenter), ZHOU XU, KUN WANG, BUQIN WANG, MARK T. TUOMINEN, University of Massachusetts Amherst — Research and development efforts in so-called artificial intelligence has increased dramatically. However, designing AI with energy efficiency is becoming an important priority. It is not yet clear how this should be done. One possible inspiration is to study the physics of self-organizing systems, both non-living and living, as guidance for future designs with functional intelligence. Irreversible processes at non-equilibrium can drive a system to self-organize and exhibit characteristics shown in systems known as dissipative structures. Our research explores the characteristics of experiments that use electrically conductive beads in an applied electric field. The setup resembles a primitive dissipative structure that can be interpreted as a possible bridge between behaviors in non-living and living systems. Using video and electrical measurements, we investigate the transient and steady-state behavior of self-organizing worm-like behavior under a range of initial and driving conditions. The non-equilibrium processes of a non-living system exhibiting characteristics that also exist within a living system are a possible way to explore biomimetic structures that exhibit intelligence.

*National Science Foundation Center for Hierarchical Manufacturing Award Number CMMI-1025020.

L70.00254: Dynamics of Driven Diffusive Systems with Interactions and with Langmuir kinetics  
TRIPTI MIDHA (Presenter), Department of Mathematics, Indian Institute of Technology Ropar, ANATOLY BORIS KOLOMEISKY, Department of Chemistry and Centre for Theoretical Biological Physics, Rice University, ARVIND KUMAR GUPTA, Department of Mathematics, Indian Institute of Technology Ropar — Driven diffusive system belongs to a special class of nonequilibrium systems that has wide applications in biological and vehicular transport processes. During intracellular transport of vesicles along microtubules, motor proteins interact among each other as well as frequently associate and dissociate from the tracks. Motivated by the above phenomenon, we develop a model that assimilates the interactions along with the nonconserved Langmuir kinetics in a totally asymmetric simple exclusion process [1]. We find that the continuum version of the simple mean-field (SMF) approach fails to handle strong correlations in the system. To incorporate the effect of correlation, we analyze the model using the correlated cluster mean-field theory. We compute the stationary phase diagrams, density, current and correlation profiles along the lattice for the various strength of attractive and repulsive interaction energy. Our results are in excellent agreement with the Monte Carlo computer simulations. For the case of attractions, we find the two-point correlation function to be stronger at the position of localized shocks.

L70.00255: Least Rattling Feedback from Strong Time-scale Separation*  
PAVEL CHVYKOV (Presenter), JEREMY L ENGLAND, Massachusetts Institute of Technology — Many interesting dynamical systems in the world have a hierarchical structure. Here we explore how to leverage this structure to better understand and predict such systems. We assume that the dynamics on different scales can be viewed as independent, except for a clearly defined feedback loop: the slow motion defines the environment that fast dynamics live in, while fast motion maintains the rules governing effective slow dynamics. Focusing on this feedback loop, rather than the details of the fast or slow motion, may pave the way for generalizable insights about hierarchical systems. We illustrate on toy examples.

L70.00256: Janus Colloidal Crystal, a New Model System for Spin Ice and Glass  
MYEONGGON PARK (Presenter), STEVE GRANICK, Ulsan National Institute of Science and Technology — Questions like the dynamics of magnetic monopole in spin ice and the translation -rotation coupling in molecular glass have long puzzled scientists in different communities, mainly because it is hard to monitor the dynamics of these systems on microscopic level. Here we try to address these questions using Janus colloidal crystals, in which both the translational and rotational motions of particles can be tracked by video microscopy and the particle interaction can be finely tuned by electric field. as one of the results, we find that glasslike dynamics for rotational motion appears when the area fraction is so high that the system is crystalline. Our experimental system paves the way for modeling a wide range of phenomenon in spin ice and molecular glasses.
L70.00257: Jamming with Pins: How do different pin geometries affect jamming?*  
BRIAN JENIKE (Presenter), TRISTAN CATES, AMY GRAVES, Physics and Astronomy, Swarthmore College — We simulate two-dimensional, zero temperature systems of soft disks with harmonic repulsive pair potentials. The pin lattices contain disks that employ the same potential, but are of negligible size. We study square, triangular, honeycomb, and random lattices. That is, it has been known for several years that the jamming threshold, $\phi_j$, decreases with pin density, $\rho$. At low pin densities, all lattice geometries produce the same $\phi_j(\rho)$ which decreases linearly with $\rho$, but pin lattice geometry begins to matter as $\rho$ increases further. At low densities, as expected, all lattices are equivalent with a linear dependence on $\rho$. At moderate densities, the square lattice supports jamming better than the random lattice; but interestingly, at higher densities the situation is reversed. We present data on $\phi_j$ parameterized by lattice constant and lattice density; and on structural features such as distributions of contacts and angular ordering of bonds between particles.

L70.00258: Relaxation Dynamics after the Removal of a Static Force: Binary Operators and Impact of Eigenstate Thermalization  
JONAS RICHTER (Presenter), Department of Physics, University of Osnabrück, JACEK HERBRYCH, Department of Physics and Astronomy, The University of Tennessee, JOCHEN GEMMER, ROBIN STEINIGEWEG, Department of Physics, University of Osnabrück — We study the relaxation dynamics of expectation values under unitary time evolution for a certain class of initial states. The latter are thermal states of the quantum system in the presence of an additional static force which, however, become nonequilibrium states when this force is eventually removed. While for weak forces the dynamics is well captured by linear response theory (LRT), the case of strong forces, i.e., initial states far away from equilibrium, is highly nontrivial.

Employing a combination of analytical arguments as well as numerical calculations for interacting quantum lattice models, we unveil that the nonequilibrium dynamics at high temperatures can, in various cases, be universally generated by a single correlation function in the entire regime close to and far away from equilibrium. Specifically, we consider so-called binary operators and study, as an example, the dynamics of spinless fermions in a random potential. In addition, we discuss the role of the eigenstate thermalization hypothesis (ETH) and establish a connection between ETH and LRT.

L70.00259: Disruption and Recovery of Reaction-Diffusion Wavefronts Colliding with Obstacles*  
REBECCA GLASER (Presenter), NATHANIEL SMITH, VINCENT W.H. HUI, JOHN LINDNER, NIKLAS MANZ, The College of Wooster — We study the damage to and restoration of planar reaction-diffusion wavefronts colliding with convex obstacles in narrow two-dimensional channels using finite-difference numerical integration of the Tyson-Fife reduction of the Oregonator model of the Belousov-Zhabotinsky reaction. We characterize the obstacles' effects on the wavefront shape by plotting wavefront delay versus time. Due to the curvature dependent wavefront velocities, the initial planar wavefront (or iso-concentration line) is restored after a relaxation period that can be characterized by a power-law. We find that recovery times are insensitive to obstacle concatenation or to the upstream obstacle shape but are sensitive to the downstream shape, with a vertical back side causing the longest disruption. Delays vary cyclically with obstacle orientations. The relaxation power-laws confirm that larger obstacles produce larger wavefront delays and longer recovery times, and for a given area larger obstacle width-to-length ratios produce longer delays. Possible applications include elucidating the effect of inhomogeneities on wavefront recovery in cardiac tissue.

Many-Body Dynamic Localization Effect in Periodically Driven Finite Clusters of Spins 1/2 without Disorder* BORIS FINE (Presenter), Skolkovo Institute of Science and Technology, KAI JI, Department of Physics, Shanghai Normal University — We investigate numerically and analytically the heating process in ergodic clusters of interacting spins 1/2 subjected to periodic pulses of an external magnetic field. Our findings indicate that many-body dynamic localization manifests itself as a cluster-size-dependent threshold for the pulse strength below which the heating is suppressed. This threshold decreases with the increase of the cluster size, approaching zero in the thermodynamic limit. Nevertheless, it should be observable in clusters with fairly large Hilbert spaces. We obtain the above threshold quantitatively as a condition for the breakdown of the golden rule in the second-order perturbation theory.

The thermodynamics of computing with finite automata* DAVID WOLPERT (Presenter), ARTEMY KOLCHINSKY, Santa Fe Institute — Recent breakthroughs in stochastic thermodynamics have greatly enriched our understanding of the thermodynamics of computation. To date, these analyses have concentrated on the “computation” of erasing a single bit. One of the idiosyncratic characteristics of such computation is that we know ahead of time when it will finish, and so do not need to continually observe it to tell whether it has finished - thereby avoiding the thermodynamic costs of such observation. Here we show how to analyze the thermodynamic costs of running a computer without continually observing it even though its finishing time is random, e.g., because it depends on the random input to the computer. We then use this to analyze the thermodynamics of finite automata (FA), one of the most important types of computational system. In particular, we show that due to the variability in the number of iterations it takes a given FA to finish, the Landauer cost of running that FA is a sum of novel information theoretic quantities, which we call “partial entropies”.

Spatiotemporal tiling of the Kuramoto-Sivashinsky equation* MATTHEW GUDORF (Presenter), PREDRAG CVITANOVIC, Georgia Institute of Technology — Numerical simulations play a very important role in the study of chaotic partial differential equations due to the lack of analytic solutions. In the limit of strong chaos and or turbulence, these computations become very challenging if not completely intractible. In an attempt to circumvent these difficulties, we recast time dynamical systems as purely spatiotemporal problems in (d+1) dimensional spacetime. Specifically, the focus of this study will be on the spatiotemporal Kuramoto-Sivashinsky equation, a (1+1) dimensional system. Our main hypothesis is that spatiotemporal recurrences resultant from shadowing of invariant 2-tori are of critical import. This intuition is a spatiotemporal parody derived from the theory of cycle expansions [1]. By developing a (1+1) dimensional symbolic dynamics with invariant 2-tori as the fundamental building blocks, we hope to quantitatively characterize infinite spacetime solutions.

Propagation of light-sensitive reaction-diffusion waves in inhomogeneously illuminated systems* DANIEL BLAIKIE (Presenter), SPENCER L. KIRN, NIKLAS MANZ, College of Wooster — The propagation dynamics of reaction-diffusion (RD) waves in illuminated quasi-2-dimensional systems was investigated, using various light-sensitive chemical Belousov-Zhabotinsky (BZ) reactions. Illuminating the BZ waves from below with visible light with a checkerboard pattern was used to change the light intensity in a repeating pattern, thus changing the speed of the light-sensitive waves. In our system, BZ waves slow down at higher illumination levels. Using a Ruthenium based catalyst, a light-sensitive BZ solution was made and absorbed by a filter paper to create the quasi-2D system. As the wave propagated over the checkerboard pattern of the illuminated system, the changes in speed would cause the wave to curve forward (dark area) and backward (bright area). The curvature should alternate and increase the overall speed of the wave as shown numerically by Schebesch and Engel in Phys.-Rev.-E 60(6) 1999. We used various catalysts, light intensities, illumination patterns, and BZ-component concentrations to determine how different excitation waves propagate through non-homogeneous excitation pattern.

L70.00264: Structural Vulnerability of Quantum Networks
ANGKUN WU (Presenter), Physics and Astronomy, Rutgers University, New Brunswick, LIANG TIAN, YANG-YU LIU, Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School — Quantum networks allow for the transmission of quantum information between physically separated quantum processors. They play a very important role in quantum computing and quantum communication. Previous studies show clear advantages of establishing long-distance entanglement between two nodes in a quantum network for communication. Yet, the general structural vulnerability of such quantum networks has not been studied. Here we systematically examine two key notions in graph theory: articulation points (APs) and bridges, which ensure the connectivity of a network and naturally represent potential targets of attack if one aims for immediate damage to a network. We offer an analytical framework to calculate the fraction of APs and bridges for quantum networks with arbitrary degree distribution. We find that quantum networks with swap operations have lower fractions of APs and bridges than their classical counterparts. Moreover, we find that quantum networks under low degree swap operations are substantially more robust against AP attacks than their classical counterparts. These results help us better understand the structural vulnerability of such quantum networks.

L70.00265: Human Information Processing in Complex Networks*
ARI E KAHN, CHRISTOPHER LYNN (Presenter), LIA PAPADOPOULOS, DANIELLE BASSETT, University of Pennsylvania — A curious aspect of information is its relativity: the amount of information contained in a message depends not just on its content, but also on the expectations of a receiver. Nowhere is this observation more evident, nor are the implications more important, than in the context of human cognition. Here, we develop an analytical framework for measuring information relative to human expectations, and we demonstrate its utility in two distinct ways. First, we verify that our framework predicts aspects of human behavior that cannot be accounted for by traditional information theoretical measures such as entropy. Second, we apply our framework to characterize the network structure of designed information sources, such as the network topology of natural languages and the structure of note transitions in music. Across a range of real-world networks, we discover that their inherent complexity is high while their divergence from human expectations is low, thereby allowing for the efficient communication of information. We find that this competition between high complexity and low divergence from expectations is driven by hierarchically modular organization, which, interestingly, has been observed in many evolved and designed networks.

L70.00266: Coarse-graining of Dynamics in Weakly Non-linear Processes on Networks
NIMA DEHMAMY (Presenter), YANCHEN LIU, Northeastern University — It is known that if the graph has a hierarchical structure, many dynamical processes exhibit transient states in which the dynamics synchronizes or stabilizes at communities in one level of hierarchy. In linear and weakly non-linear processes these transient states appear at time scales associated with inverse of the so-called community eigenvectors of the quadratic piece of the Hamiltonian. We show that these transient states can be exploited to coarse-grain the network during the dynamics and reduce the time complexity of estimating the outcome of a dynamical process from $O(N^3)$ down to a lower complexity in most hierarchical networks, and possibly to $O(N^2 \log N)$ in tree-like networks. We outline the coarse-graining procedure, which relies on spectral methods and can be computed efficiently. We also discuss potential relations with graph learning and regression on graphs.

L70.00267: Global and microstructural ergodic properties of financial markets*
JACK SARKISSIAN (Presenter), Managing Director, Algostox Trading — In finance everyone is concerned about future expectations. Whether it’s pricing or risk evaluation - current models always involve some form of time averaging. Understanding the ergodic properties of the markets allows to replace the time average with ensemble average. Since calculation of ensemble average requires only one step in time, this approach allows much faster computation, and therefore a much faster reaction to changing market conditions. In this work we will explore market ergodicity from various points of view. First, we will consider market properties as a global dynamic system made of individual securities. Second, we will discuss ergodicity of individual securities represented by a dynamic limit order book. We will show how concepts of ergodicity can be applied to determine current market volatility, and introduce the new eVOL and eVAR indices that measure current volatility as opposed to traditional realized and implied volatilities. We will demonstrate real-life examples highlighting the capabilities of these new indices for trading and asset management.

L70.00268: Classical Dimer Model on the Square Bilayer Lattice*  NISHEETA DESAI (Presenter), University of Kentucky, KEDAR DAMLE, Tata Institute of Fundamental Research, SUMIRAN PUJARI, Indian Institute of Technology, Bombay — We study the Classical Dimer Model (CDM) on the square bilayer lattice with the fugacity of interlayer dimers as a tuning parameter. The square monolayer CDM is one of the paradigmatic model of a “Coulomb” phases whose distinct signatures are a) power law correlations in real space, and b) “pinch points” in the “transverse” form of structure factors in momentum space. Here we find that for low fugacity, the square bilayer CDM again hosts Coulomb phases with power law correlations. The pinch point phenomenology is however crucially different than the monolayer. This is integrally related to presence of longitudinal modes and Coulomb correlations together in the bilayer CDM ensemble. For high fugacity, it hosts a featureless phase with predominantly interlayer dimers and exponentially decaying correlations. Remarkably, even though the two phases are not symmetry related, numerical evidence from system sizes upto 512 × 512 points to a continuous transition rather than first-order. We provide an effective “electrostatic” description of the numerical data for low fugacities with the interlayer dimers interpreted as spontaneously fluctuating charged dipole defects.

L70.00269: Influence of correlated temporal disorder on an extinction phase transition*  MATTHEW SMALL (Presenter), ALEXANDER H ONIWA WADA, THOMAS VOJTA, Missouri University of Science and Technology — We employ large-scale Monte Carlo simulations to investigate the effect of long-range correlated temporal disorder (i.e. external noise) on extinction phase transitions in the logistic evolution equation. Uncorrelated temporal disorder is known to cause an unusual phase transition controlled by an infinite-noise critical point [1]. It features diverging density fluctuations at criticality, implying that the typical population decay is much faster than the ensemble average. Our results demonstrate that correlated temporal disorder enhances these effects; the correlations further accelerate the decay of a typical population while slowing the decay of the ensemble average. We also establish a relation to reflected fractional Brownian motion [2] which yields a conjecture for the critical behavior of the population.

L70.00270: Universal quantum Hawking evaporation of integrable two-dimensional solitons*  CHARLES ROBSON, DI MAURO VILLARI LEONE (Presenter), FABIO BIANCALANA, Heriot-Watt University — In a work published in 1976, Abdus Salam and his student John Strathdee proposed a connection between two different fields, namely general relativity and the theory of nonlinear evolution equations. Their conjecture was simple: a black hole is nothing else than a soliton. We show that any soliton of an arbitrary two-dimensional integrable equation has the potential to evaporate and emit the analogue of Hawking radiation from black holes. From the AKNS matrix formulation of integrability, we show that it is possible to associate a real spacetime metric tensor which defines a curved surface, perceived by the classical and quantum fluctuations propagating on the soliton. By defining proper scalar invariants of the associated Riemannian geometry, and introducing the conformal anomaly, we are able to determine the Hawking temperatures and entropies of the fundamental solitons of the nonlinear Schrödinger, KdV and the sine-Gordon equations. The mechanism advanced here is simple, completely universal and can be applied to all integrable equations in two dimensions, and is easily applicable to a large class of black holes of any dimensionality, opening up totally new windows on the quantum mechanics of solitons and their deep connections with black hole physics.

L70.00271: Exotic quantum statistics from a many-body theory of Majorana fermions  JOSHUAH HEATH (Presenter), KEVIN SHAWN BEDELL, Boston College — Starting with a simple counting argument, we construct a statistical and thermodynamic model of free Majorana fermions at low temperature. Originally defined as a fermion identical to its own antiparticle state, Majorana particles often appear in the contemporary many-body literature as non-Abelian zero energy modes in topological superconductors. We deviate from the usual anyonic description and instead consider a gas of non-interacting, spin-1/2 Majorana fermions as Ettore Majorana first envisioned them. A combinatorial analysis of the many-body Majorana ensemble leads to a configurational entropy which deviates from the fermionic result with an increasing number of available microstates. A Majorana distribution function is derived which shows signatures of a sharply-defined Fermi surface at finite temperatures. The Majorana distribution is then re-derived in the context of a modified Kitaev chain with bosonic pair interaction. The thermodynamics of the free Majorana system is found to be nearly identical to that of a free Fermi gas, except now distinguished by a two-fold ground state degeneracy and, thus, a residual entropy at zero temperature. Experimental realization of the Majorana thermodynamics is then discussed in the context of real materials and cosmological phenomena.

L70.00272: BIOLOGICAL PHYSICS —

L70.00273: A numerical method for detecting and classifying multi-channel and multi-state binding events in single-molecule TIRFM experiments* JOSEPH TIBBS, University of Northern Iowa, ELIZABETH BOEHM, Harvard University, FLETCHER BAIN, COLLEEN CALDWELL, TODD WASHINGTON, MARIA SPIES, University of Iowa, ALI TABEI (Presenter), University of Northern Iowa — Biomolecular binding may be observed using Total Internal Reflection Fluorescence Microscopy. By using multiple channels, which corresponds to different colors of fluorescence, the real-time interaction of multiple proteins can be observed. Although for many of these interactions the bound state is binary, for some the binding is more complex, with discrete states demonstrating intermediate levels of fluorescence. We will explain a numerical method for extracting these fluorescence traces from microscope data and then organizing and classifying traces from single-molecule experiments. With multiple channels and multiple binding states possible, the possible binding patterns are numerous. The data is organized in groups by these binding patterns and the statistics of each interaction is displayed. Which combinations are most likely, the binding duration of each protein or the probable binding/dissociation order of each subunit are all data which can inform on the underlying mechanism behind the interaction. We show how our method determines cooperative or inhibitory binding in multi-protein systems, or observe the construction of protein complexes.

L70.00274: Activity and Effects of Retroelements in Bacteria* DAVNEET KAUR (Presenter), GLORIA LEE, NICHOLAS SHERER, NEIL KIM, ELLIOT URRIOLA, CHI XUE, K. MICHAEL MARTINI, NIGEL GOLDENFELD, University of Illinois at Urbana-Champaign, THOMAS KUHLMAN, Physics, University of California at Riverside — Retroelements (RTEs) are abundant in eukaryotic genomes but less numerous in bacteria as group II introns. It has been hypothesized that eukaryotic spliceosomal introns and retrotransposons may have evolved as a result of invasion by bacterial group II introns. However, it remains unclear what limits RTE proliferation in bacteria and archaea and what enables it in eukaryotes. We quantify the effects of the human RTE LINE-1 and the bacterial group II intron Ll.LtrB in Escherichia coli, Bacillus subtilis and Enterococcus faecalis. We find that RTE expression is detrimental to all species, that LINE-1 successfully integrates into the chromosomes, and that the ability to repair DNA breaks with bacterial non-homologous end joining systems increases retrotransposition efficiency. Our results show that RTEs place a significant burden on organisms poorly equipped to handle their effects, and that the capacity of the last eukaryotic common ancestor for NHEJ may have enabled the proliferation of RTEs and the evolution of eukaryotes.

L70.00275: Understanding protamine-induced DNA folding in sperm  HILARY BEDIAKO (Presenter), ADAM D. SMITH, OBINNA UKOGU, ANDREA BOSKOVIC, MOUMITA DASGUPTA, ASHLEY CARTER, Amherst College — We examine how protamine causes DNA folding within the sperm nucleus. Specifically, we are interested in how protamine loops the DNA into toroids that allow for tight packaging of the paternal genome. The formation of toroids have implications in epigenetics and fertility. Toroids may be formed in a single step (collapse model) or multistep (sequential model) manner. In the collapse model, all loops form along the DNA at once and then collapse into the toroid. In the sequential model, loops stack sequentially into a toroid. To decipher between these two models, we perform an in vitro Tethered Particle Motion (TPM) assay. In a TPM assay, an individual DNA molecule is attached to a bead and tethered to a cover-slip. By observing the position of the bead over time, we can measure the DNA length to a precision of about 10 nm and infer the folding trajectory of our DNA. We observe that as the length of the DNA increases, the number of folding events increases, suggesting that toroid formation is multistep (sequential model). If DNA folding is multistep, the location of nucleation loops is important as they may indicate where histones, and thus epigenetic tags, may be present. Moreover, the ratio of different protamine proteins may affect how toroids form and play a role in fertility.

L70.00276: Characterizing Protamine-Induced DNA Loop Formation Using a Tethered Particle Motion Assay  KYLIE JONES (Presenter), ASHWIN BALAJI, HILARY BEDIAKO, ANDREA BOSKOVIC, ASHLEY CARTER, Amherst College — Protamine is a protein found in sperm cells. It folds DNA into compact toroids by first forming it into loops and then stacking those loops. This compaction plays an important role in reproduction, ensuring that sperm are hydrodynamically efficient and protecting the DNA they carry. We use a tethered particle motion assay to examine the mechanics of loop formation in this process. By tracking the Brownian motion of a bead tethered to a length of DNA, we can detect changes in DNA conformation through changes in the bead’s motion. We find that loop formation is a multi-step process with intermediate states.

*This work was supported by a Research Corporation Cottrell Science Award (23239), a National Science Foundation CAREER Award (1653501), and Amherst College.

L70.00277: Characterizing the Mechanism of DNA Loop Formation by Protamine  ASHWIN BALAJI (Presenter), ASHLEY CARTER, Amherst College — DNA compaction in sperm cells by the protein protamine represents an extreme case of polymer folding, approaching crystalline packing of the molecule. This high compaction is necessary for creating viable sperm, yet the physical mechanism of folding is unknown. In this study, we investigate how protamine folds DNA into a loop. One hypothesis is loop formation occurs through entropic folding where protamine binds and neutralizes the negative charge of the DNA backbone, increasing flexibility and allowing the molecule to fold into a loop. Another hypothesis is loop formation occurs as each protamine binds and bends DNA, changing its enthalpy. Using single-molecule force spectroscopy, we measure force-extension curves and fit them with a worm-like chain model. This model obtains the entropic and enthalpic portions of the folding, allowing us to differentiate between our two hypotheses. Specifically, we pull on DNA tethers biochemically attached on one end to a glass slide and on the other to a polystyrene bead. We then flow protamine over the tethers and measure the force-extension curve. We use a centrifuge force microscope to apply force and to image the tethers to track their extension. Here we report progress in building the instrument and measuring force-extension curves.

L70.00278: Expressing, Purifying, and Characterizing a Flavodoxin from the Solvent-Producing Clostridium Acetobutylicum  ALYSSA ALVAREZ (Presenter), Undergraduate Physics, St. Mary's University, San Antonio, TX, ANDREA PADRON, ANNA GUSEVA, Biochemistry and Cell Biology Graduate Program, Rice University, Houston, TX, JONATHAN SILBERG, Department of Biosciences, Rice University, Houston, TX — Flavodoxins (Fld) are relatively small redox proteins responsible for facilitating the transport of electrons in certain types of bacteria and algae. In order to understand how these proteins control the flow of electrons between different redox partners in organisms with multiple electron transfer proteins, we must understand their structure and partner specificity. While structures have been reported for Flds, we do not understand their structural properties sufficiently enough to predict electron flow in cells. This project aims to overexpress a flavodoxin from Clostridium acetobutylicum (CacFld1) in E. coli cells, purify it using chromatography techniques, screen for conditions that yield CacFld1 crystals, and acquire structural data using the crystals. To express CacFld1, the gene encoding this protein was synthesized and placed under a T7 phage promoter which is inducible by IPTG. Optimal expression conditions of CacFld1 were found and purification of the protein by anion exchange chromatography was attempted. Future studies entail finding the conditions in which CacFld1 crystallizes and analysis of its structure through x-ray crystallography techniques.

L70.00279: A three-dimensional analytical pathway to smoothly connect successive nucleosomes along DNA*
SEYED AHMAD SABOK-SAYR (Presenter), WILMA K OLSON, Rutgers University, New Brunswick — Most DNA in the human genome is wrapped on nucleosomes. The nucleosome is an assembly of eight proteins and about 150 base pairs of DNA. Understanding the biological processing of DNA requires knowledge of how the nucleosomes are arranged in space. We have developed a new analytical model to describe the three-dimensional pathways of long stretches of nucleosome-bound DNA. Given the positions and orientations of a set of nucleosomes, we can find a smooth connector that joins the ends of successive nucleosomes along the DNA. Our studies show that the simplest equation which can smoothly connect any two nucleosomes is a quadric function which is uniquely determined by the position and orientation of each pair of successive nucleosomes. Since the equation for the connector only depends on the boundary conditions, our method can be used to connect either theoretical curves describing the nucleosomal pathway or the protein-bound DNA in known high-resolution structures. This treatment makes it possible to study the effect of elastic and electrostatic energies of the connectors on the stable structure of the nucleosomal arrays and to examine the influence of nucleosomal pathways, such as the length of bound DNA, on the global folding of the arrays.

L70.00280: Effects of Protein Conformation on Charge Regulation  JACOB PALMERIO (Presenter), DAVID ROSS, GEORGE THURSTON, Rochester Institute of Technology — Proteins change charge in response to their electrostatic environments, by changing protonation patterns of titratable residues. This charge regulation is important for modeling protein interactions, including proteins that undergo conformational change, such as intrinsically disordered proteins, and enzymes that are allosterically controlled. We construct grand canonical partition function models that take account of flexibility by incorporating it into the relevant partition functions for each proton occupancy pattern. We use this model to analyze titration data for selected small molecule sequences, including dicarboxylic acids, diamines, and peptides.

L70.00281: Investigating Protamine-Induced Toroid Formation*  ANDREA BOSKOVIC (Presenter), KYLE JONES, HILARY BEDIAKO, ASHWIN BALAJI, ASHLEY CARTER, Amherst College — In somatic cells, DNA is folded by histones, forming chromatin. However, protamine, a small, arginine-rich protein that allows DNA to fold in mammalian sperm cells. Protamine allows DNA to form loops, which are then condensed into toroids that are stacked within the sperm cell. In order to investigate protamine-induced toroid formation in DNA, we performed a tethered particle motion (TPM) assay. Due to the fact that we see multiple states present in our visualizations of standard deviation over time, toroid formation in DNA due to the binding of protamine is a multi-step process. Understanding how DNA folds has applications in biomaterials, epigenetics and infertility.

*I would like to thank the Gregory Call Fund at Amherst College for providing funding to attend this conference.

L70.00282: Improved Molecular Dynamic Simulation of Protein Devices: PEGylated Proteins and Protein Microarrays  ADDISON SMITH (Presenter), THOMAS KNOTTS IV, Brigham Young University — Protein-based devices have great potential to change how we harness the power of biology. PEGylated proteins and protein microarrays are two such devices. PEGylation covalently bonds polyethylene glycol (PEG) chains onto a protein's primary structure to increase a protein's stability in the body. Protein microarrays covalently tether proteins onto a solid surface and has transformative applications for detection assays. However, for both devices, functionalization often renders it inactive.

We have developed a coarse-grain molecular simulation model that has been shown to accurately predict optimal functionalization sites. This presentation explains this model and reports its use on a the commercially-relevent protein β-lactamase. The in silco screen reveals the best candidate sites for PEG and surface attachment. Experiments then validate these results.

The results for both protein devices are presented and indicate that device attachment site strongly affects thermostability and that configurations more stable than wild type are possible. Moreover, by using the same protein for both devices, we show that optimal site locations for one device is not predictive for the other. Finally, PEGylation simulation indicate stabilizing PEG/protein structures contradict current theory
**L70.00283: Effect of substrate viscosity on stick-slip dynamics of migrating cells**  
RUMI DE (Presenter), Department of Physical Sciences., Indian Institute of Science Education and Research Kolkata, Mohanpur 741246, India — Migration is central to many cellular processes such as wound healing, morphogenesis, embryonic development, tissue regeneration to name a few. 'Stick-slip' motion, observed during cell crawling, has been found to be strongly sensitive to the substrate stiffness. The stick-slip behaviour has been investigated before typically using purely elastic substrates. For a more realistic understanding of this phenomenon, we propose a theoretical model to study the dynamics on a viscoelastic substrate. Our model based on a reaction-diffusion framework, incorporates known important interactions such as retrograde flow of actin, myosin contractility, force dependent assembly and disassembly of focal adhesions coupled with cell-substrate interaction. We show that consideration of a viscoelastic substrate not only captures the usually observed stick-slip patterns, but also predicts the existence of an optimal substrate viscosity corresponding to a maximum traction force and minimum retrograde flow which was hitherto unexplored. Moreover, our theory predicts the evolution of individual bond force which provides insights into the stick-slip jumps on soft versus stiff substrates. Our analysis also elucidates the dependence of the duration of stick-slip cycles on various system parameters.

**L70.00284: Actomyosin contractility depends on the load-dependent binding kinetics of myosin motors**  
PASHA TABATABAI (Presenter), DANIEL S. SEARA, IAN LINSMEIER, MICHAEL MURRELL, Yale Univ — Within the cytoskeleton, myosin motor proteins consume chemical energy and generate mechanical work within the filamentous actin network essential for diverse cell functions like migration, division, and shape change. Myosin unbinding kinetics are force dependent exhibiting "catch-bond" behavior which decreases the probability of unbinding under load. Altering the binding kinetics of proteins is prohibitively difficult, thus the impact of load dependent binding kinetics on the dynamics and mechanics of actomyosin contractility are unclear. To this end, we use coarse grained molecular dynamics simulations to explore the effect of catch bonds on the accumulation and dissipation of mechanical energy in the actomyosin cytoskeleton. We find that motor binding that increases under load sensitizes the network to myosin motor concentration, increasing the rate of contractility while simultaneously increasing network toughness, or the storage of mechanical energy.

**L70.00285: Actin-microtubule co-formation inside of a giant unilamellar vesicle**  
SUNGWOO JUNG (Presenter), C. H. KIM, A SETIAWATI, HUONG NGUYEN, Sogang University, M. C. CHOI, KAIST, KWAN SHIN, Sogang University — Microtubule and actin cytoskeletons are physically contacted in a cell, and dynamically coordinated to play vital roles in many cell functions, from migration, growth, and division. These structural dynamics of cytoskeletal proteins are of interest, the physical roles of cross-linking proteins between two filaments have been identified. Yet most studies were performed in a highly controlled interface or a bulk. Recently, we developed to simulate a cytoskeleton formation through ATP-dependent actin polymerization in a giant unilamellar vesicle. Optical stimulation initiated ATP synthesis and induced ATP-dependent actin polymerization, leading to growth of three-dimensional highly curled actin filament network. In this study, we further added the ingredients for microtubule formation into the actin polymerizable GUV system, and initiated the filament formations of those two cytoskeleton proteins simultaneously. We will discuss how these highly curled actin filaments in the single vesicle affects the structural environment in the presence of highly straight microtubule filaments. We will discuss how these two filaments are interacting in a highly confined, cell-like space where they are mutually restricted.

**L70.00286: Building Towards Single Particle Characterization of Nanoparticle Bioconjugates**  
MOHAMMAD ABDULMOQUEET (Presenter), LEEANA TOVAIS, KATHRYN MAYER, Physics and Astronomy, University of Texas at San Antonio — Development of functional nanoparticle bioconjugates has been an important research area for nearly the last decade. Functionalized nanoparticles of various self-assembled monolayers (SAM-layers) have been used for biological and medical applications. Determining the exact spatial distribution of functionalized antibodies on the surface of the nanoparticles will provide necessary information to fully characterize and optimized nanoparticle bioconjugates for the preclinical stages of research. Gold bipyramids have been synthesized and then coated with a SAM-layer of various ligand types. Current and future work consists of conjugating these functionalized nanoparticles with fluorescently labeled anti-EGFR antibodies, which will enable imaging of the number and spatial arrangement of antibodies around the gold bipyramid using Total Internal Reflection Fluorescent (TIRF) Microscopy. EGFR is chosen as the target for future applications in cancer therapy.

*I would like to acknowledge the NIH Score program for supporting this research project.*
Correlation of hatchling mass and egg volume in extant birds from Archilochus colubris to Struthio camelus

JOSHUA THOMAS (Presenter), Clarkson University, SCOTT LEE, MAX COOLEY, RICHARD IRVING, University of Toledo — Observations suggest that birds hatch when they are near the maximum size that can be contained in their egg. In order to test this hypothesis, we have measured the volume of eggs of nineteen bird species from Archilochus colubris (the ruby-throated hummingbird) to Struthio camelus (the ostrich). The hatchling mass of these birds vary by more than three orders of magnitude. The volume of the eggs were measured by using scaled pictures of the eggs. The OpenCV library, and a custom python code was used to detect the edges of the eggs. We assumed the images were taken at right angles to the eggs, and that the eggs have cylindrical symmetry around the long axis. The points along the edges of the egg were fit with a polynomial to avoid resolution-induced calculation issues. The surface area and volume were calculated as if the points were a solid of revolution. Our method reproduces the volumes of ellipsoids with known dimensions with errors of less than 1%. The hatchling mass is found to depend on the egg volume via a power law with an exponent of 1.01 (standard deviation = 0.04), in support of the hypothesis. This relationship predicts a hatchling mass of 8.0 kg for the extinct Aepyornis maximus (the giant elephant bird), the largest known bird for which intact eggs exist.

Humeral bone strength and flight in eumaniraptoran dinosaurs

SCOTT LEE (Presenter), University of Toledo, JOSHUA THOMAS, Clarkson University — Flight requires that the animal be able to generate sufficient lift and thrust to support its weight in air. This requires that the humerus have a sufficiently strong section modulus to withstand the applied stresses. In order to study the possibility of flight in extinct dinosaurs, the humeral section modulus of 17 species of extant volant birds with masses ranging from 5.8 grams in Regulus calendula to 8.959 kg in Cygnus olor has been measured. The humeral section modulus is related to the mass of the animal via a power law with an exponent of 1.14 (standard deviation 0.02). The humeral section modulus is evaluated for 19 extinct dinosaurs from Dromaeosauridae, Troodontidae and Avialae. Comparing to the data for extant volant birds allows for the determination of those dinosaurs whose humeri were too weak to support powered flight. All five species of Avialae are found to have had humeri sufficiently strong for flight. Four dromaeosaurids (Microraptor gui, Graciliraptor lujiahunensis, Buitreraptor gonzalezorum, and Changyuraptor yangi) and one troodontid (Jianianhualong tengi) are also found to have had humeri that were strong enough for flight. This is a necessary, but not necessarily sufficient, condition for flight.

On the kinetics and dynamics of apatite crystallization at amyloid-solution interfaces found during enamel biomineralization

SUSRUT AKKINENI (Presenter), University of Washington, JINHUI TAO, Pacific Northwest National Laboratory, STEFAN HABELITZ, University of California, San Francisco, JAMES J DE YOREO, Pacific Northwest National Laboratory — Mammalian enamel has a remarkable structure made of interwoven apatite filaments. Recent in vivo and in vitro evidence suggests amyloid-like amelogenin nanoribbons act as a scaffold for apatite growth. However, the correlation between amyloid structure and apatite crystallization is unclear. Parts of this relationship are unraveled by the kinetics of calcium phosphate nucleation and growth at the amyloid-solution interface through in situ atomic force microscopy. Using peptide analogs of amelogenin, films of oriented nanoribbons with 3-fold symmetry stabilized by Van der Waals's forces were self-assembled on graphite. They shared similar amyloidal properties even after addition of charged residues at C-terminus or with phosphorylated serine-16. Their role during apatite crystallization was then determined using physiologically-relevant solutions, favorable to heterogenous apatite nucleation. Quantitative analysis reveals that the peptide films, with or without additional charged residues, cannot independently promote apatite nucleation over time, but can provide an interface for growth of nuclei.

ABSTRACT WITHDRAWN
L70.00291: Biomechanics of the peafowl's crest reveals frequencies tuned to social displays*  SUZANNE KANE, DANIEL VAN BEVEREN (Presenter), Physics & Astronomy, Haverford College, ROSLYN DAKIN, Migratory Bird Center, Smithsonian Institute — Feathers can act as vibrotactile sensors of mechanical stimuli during avian flight and tactile navigation, suggesting they may also detect stimuli during social displays. Here we present the first measurements of the biomechanical properties of bird feather head crests. We show that in Indian peafowl (Pavo cristatus), crest feathers are coupled to mechanosensory filoplume feathers. We also determined that peafowl crests are driven at resonance by their main social display frequency, but that other peacock feathers and crest of other birds have resonant frequencies that vary over a wide range (seven times that of the peafowl's crest). Peafowl crests were also driven to vibrate near resonance when we played back audio recordings of their displays in geometries that mimicked the acoustic near-field geometry found during these behaviors in vivo, but not when we played back control audio. These results suggest that mechanosensory stimuli could complement acoustic and visual perception and/or proprioception of social displays in peafowl and other bird species.

L70.00292: Mechanical principles of biofilm formation revealed by single-cell resolution imaging  JING YAN (Presenter), FARZAN BEROZ, HOWARD A STONE, NED WINGREEN, BONNIE BASSLER, Princeton University — Biofilms are surface-associated bacterial communities embedded in an extracellular matrix. Biofilm cells are more resistant to antibiotics than their planktonic counterparts, which is a major problem in the context of chronic infections. We still lack a fundamental biophysical understanding of how bacteria, in time and space, build these three-dimensional structures that attach to surfaces and resist mechanical and chemical perturbations. During this talk, I will present a technique to image living, growing bacterial biofilms from single founder cells to ten thousand cells at single-cell resolution. Using the human pathogen Vibrio cholerae as a model biofilm former, we discovered that the biofilm develops from a disordered, two-dimensional layer of founder cells into a three-dimensional structure with a vertically aligned core. Using computer simulations, we found that verticalization proceeds through a series of localized mechanical instabilities on the cellular scale. By modulating cell lengths and osmotic conditions, we quantitatively tested the predictions made from the agent-based simulations.

L70.00293: Application of RLGC Models in Addressing Hospital Acquired Infections*  JESUS PEREZ (Presenter), California State University, San Marcos, YAW OBENG, National Institute of Standards and Technology — In this presentation, I will discuss the application of RLGC models to extract the electrical(RLGC) properties of modeled pathogens in the context of Hospital Acquired Infections (HAIs). HAIs can occur from antibiotic-resistant pathogen contaminants in either the medical procedures, devices, or from the overall hospital circumstance. It is known that exposure to UV light can prevent bacteria from reproducing. However, there is no reasonable quick-turn metrology for evaluating the efficacy of such treatments. Thus, our project is aimed at providing a module for acquiring the electrical properties of pertinent materials to help quantify the amount or intensity of UV light required kill bacteria. In our study, we investigated the changes in the capacitance and resistance of pertinent thin films in response to broad-band UV light irradiation. The results from this study demonstrate the feasibility of using our RLGC model to interpret the radio frequencies’ response of biological systems.

L70.00294: Myosin V executes steps of variable length via structurally constrained diffusion  DAVID HATHCOCK (Presenter), Cornell University, RIINA TEHVER, Denison University, MICHAEL HINCZEWSKI, Case Western Reserve University, DAVE THIRUMALAI, University of Texas, Austin — Myosin V is a molecular motor that performs intracellular transport by moving along actin filaments and generating energy through ATP hydrolysis. By alternating head detachment, myosin V steps hand-over-hand with the free head executing a random diffusive search for actin binding sites. Recent experiments suggest that the joint between the myosin lever-arms is not freely rotating, as indicated by previous studies, but instead has a preferred angle giving rise to structurally constrained diffusion. We address this controversy by developing a comprehensive model of myosin V, combining a polymeric description of the diffusive search with the kinetic network of states occupied during the stepping cycle. When the joint is constrained, our model predicts diffusion similar to that recently observed, allowing us to estimate bounds on the constraint energy. We also analyze the consistency of constrained diffusion with previous measurements of step distributions and the load dependence of the forward-to-backward step ratio, run length, and velocity, finding good agreement for each. The theory lets us address the biological significance of the constrained joint and provides testable predictions of new myosin behaviors, including a stomp distribution and the run length under off-axis force.
**L70.00295: Label-free visualization of cellular uptake and trafficking of nanoparticles by interferometric scattering microscopy**  
**JIN-SUNG PARK (Presenter), IL-BUEM LEE, Center for Molecular Spectroscopy and Dynamics, Institute for Basic Science, HYEON-MIN MOON, KYOUNG-HOON KIM, SEOK-CHEOL HONG, Department of Physics, Center for Molecular Spectroscopy and Dynamics, Institute for Basic Science, MINHAENG CHO, Department of Chemistry, Center for Molecular Spectroscopy and Dynamics, Institute for Basic Science — Interferometric scattering (iSCAT) microscopy is a new label-free optical imaging technique, recently developed to identify the nano-sized particles beyond a diffraction limit at a high temporal resolution. Here we report on the direct iSCAT visualization for the moment of cellular uptake of nanoparticles which are diffused in the plasma membrane of a live cell. After initial docking onto the plasma membrane, nanoparticles undergo abnormal sub-diffusion, characterized by simple Brownian motion, local confined diffusion, or Hopf diffusion in their long trajectories. During these processes, we sometimes observed that the scattering signals from nanoparticles in the plasma membrane are suddenly disappeared after exhibiting the oscillating motion in the vertical direction of a flat membrane. Such signal loss indicates that these nanoparticles escape from the focal plane of the microscope as they transport rapidly into the cytoplasmic area after cellular uptake. Our experimental results demonstrate that the label-free iSCAT microscopy can be used as a powerful tool to shed interferometric light on dynamic biophysical processes of various intracellular phenomena.

**L70.00296: The Effect of Intracellular Crowding on the Diffusion Dynamics of Neurofilaments and Microtubules**  
PETER JUNG (Presenter), NILAJ CHAKRABARTY, Department of Physics and Astronomy, Ohio University — Neurofilaments are a class of cytoskeletal proteins which are essential for providing structural support for axons and for regulating axon diameter. Neurofilaments are primarily synthesized in the cell body of neurons and are cargoes of slow axonal transport. Several studies have established that neurofilaments are transported as assembled polymers along microtubule tracks driven by motor proteins. The transport kinetics of neurofilaments have been explained by a “Stop-and-go” model where neurofilaments move intermittently in a bidirectional manner. However, the established models do not take into account the intracellular crowding which can severely limit the diffusion kinetics and in turn affect the reaction rates. We model the neurofilament and microtubules as a bi-disperse population of hard disks in a circular domain representing the cross section of the axon. We find that both cellular confinement and steric repulsion play important roles in modulating the diffusion dynamics and in turn the reaction rates. We are also using our model to study whether phase transition effects at high crowding densities can explain the segregated neurofilament and microtubule populations typically found in some neurodegenerative diseases.

**L70.00297: A Nonlinear Dynamical System Approach to Bird Song Analysis**  
**XIAO ZENG (Presenter), EVE ARMSTRONG, VIJAY BALASUBRAMANIAN, University of Pennsylvania — Songbird vocal production is a complex nonlinear phenomenon. However, acoustic studies of bird vocalization have mostly been based on linear spectral analysis. Such analysis methods necessarily fail to capture the information content of song, and for that reason are not effective probes of the means by which songbirds communicate. We present a novel approach to the analysis and classification of songbird vocalization using nonlinear time series analysis techniques. Time-delay embedding is used to construct a new coordinate system in which to view the song time series. The number of coordinates required to unfold the dynamics represents the dimensionality of a new geometric space, wherein the song's attractor can be visualized. We show that the reconstructed phase space representation of bird vocalization can reveal information that is absent in traditional linear approaches.**

**L70.00298: Spots to stripes: using machine learning to navigate pattern formation space**  
**REBECKAH K FUSSELL, AYESHA BHIXHA, SUZANNE KANE (Presenter), Haverford College — Current models of pattern formation (e.g., Turing reaction-diffusion theory) can generate many observed animal pigmentation patterns. However, their dependence on many interacting parameters makes it difficult to explore their full phase space of patterns. This is an important problem because research in cell signaling and developmental biology allows us to generate increasingly accurate pattern formation models. In this study, we first defined a "measure space" using 25 different measures of pattern geometry (e.g., feature circularity, compactness, intensity variance). We mapped photographs of pigment patterns in measure space and classified them using k-means clustering. We found that three measures were sufficient to group patterns into distinct classes (e.g., spots, stripes, labyrinthine, etc.) The next phase involves using this measure space as a guide for navigating the complex parameter space of a new pattern formation theory. For example, all known patterns generated by the model and a new test pattern (for which the model parameterization is unknown) first are mapped onto measure space. To determine the parameters needed to form the test pattern, a guided search can be performed in parameter space using the measure space distance between the test and known patterns.**
**L70.00299: Self-organized Pattern Formation in Bacterial Colonies**

SIYU LIU (Presenter), The Chinese University of Hong Kong — Pattern formation is ubiquitous in living organisms. In bacterial colonies, pattern formation generally relies on chemical signalings, such as in the case of chemotactic ring formation. Here we study how mechanical interactions between cells in a colony may promote self-organized pattern formation in bacterial colonies. The results may provide new insights into the development of structured bacterial communities, such as biofilms.

**L70.00300: Building a Custom Microscope to Study Brownian Motion and Active Matter**

HUNTER SEYFORTH (Presenter), WYLIE AHMED, California State University, Fullerton — Our goal is to build an optical microscope, calibrate it, and make precise measurements of Brownian motion and diffusion using multiple approaches such as mean squared displacement (MSD) analysis and differential dynamic microscopy (DDM). These methods of analysis were applied to quantify the motility of active matter and standardize the process to develop an advanced module for the graduate program. We constructed a microscope based on the design by Kemp et al.(arXiv:1606.03052). Then, the Brownian motion of 1 micron colloidal particles were studied and both single particle tracking and image correlation techniques were implemented to analyze colloidal diffusion. To do this, publicly available matlab codes for particle tracking, MSD analysis, and DDM analysis were applied to calculate the diffusion coefficient. These methods were utilized to quantify the diffusion of two different types of active matter: janus particles and swimming microorganisms. This was done to quantify the motility of active matter. This project is being developed into an advanced lab module to be an introduction to physics research, fortify concepts from optics and statistical physics, and give students experience in building optical systems and analyzing noisy data.

**L70.00301: Analysis and Modeling of Mitochondrial Fission and Fusion Processes in Cells From Healthy and Trisomy Patients**

JOHANNA PAINE (Presenter), California Lutheran University, CARLOS PEREZ, GHANIM ULLAH, Computational Biophysics, University of South Florida, JORGE BUSCIGLIO, Neuroscience, University California Irvine — Mitochondria play a vital role in many cell functions, including ATP production, modulation of Ca2+ signaling and apoptosis. The homeostasis of the fission and fusion of the mitochondrial network allow for healthy cellular function. If the homeostasis of fission and fusion processes becomes unbalanced, the mitochondria can no longer supply enough ATP nor process the calcium ions which leads to apoptosis. Mitochondria’s role in apoptosis makes it a possible target for curing neurodegenerative diseases. The causes behind the progressive degeneration of neurons are not yet understood, beyond a correlation with age, an understanding of the details of mitochondrial function and structure is crucial for better treatments for neurodegenerative diseases. Mitochondrial reticulum structure and function are altered due to conditions like Trisomy 21. We investigate the difference rates of fission and fusion, cluster size and mean degree of healthy and Trisomy mitochondria reticulum. We present a model of the dynamic mitochondrial reticulum, and deduce fission and fusion rates from a single image. This process can be used to deduced the fission and fusion rates of mitochondrial networks with different neurological disease to understand the exact mechanisms these diseases.

*NSF Grant: 1560090*

**L70.00302: Time cells in the mouse dentate gyrus: An apparent instance of traveling waves in the brain**

WEI ZHONG GOH (Presenter), MARC HOWARD, Boston University — The role of standing brain rhythms in cognition has been well investigated, but traveling waves have only recently attracted interest for their potential role in memory and attention. A manifestation of traveling waves in the brain may be "time cells". In animal experiments, a task-relevant event triggers a reliable sequence of neural firing. Each “time cell” fires during a circumscribed period of a delay interval; different events can trigger different sequences. As the time interval since the event increases, the proportion of active time cells decreases. We present evidence of time cells in the mouse dentate gyrus whose activity spans a 20 s delay interval. We describe how information encoded about the time interval since the event is characteristic of a propagating wave traveling in a medium with graduated index of refraction. This framework allows us to characterise how the brain is continually aware of its orientation with respect to events in the world unfolding in time.
L70.00303: Modularity and flexibility quantify unique processing of music and speech stimuli in the human brain*
MELIA BONOMO (Presenter), Department of Physics & Astronomy, Rice University, CHRISTOF KARMONIK, Magnetic Resonance Imaging Core, Center for Performing Arts Medicine, Houston Methodist Hospital, J TODD FRAZIER, Center for Performing Arts Medicine, Houston Methodist Hospital, MICHAEL DEEM, Department of Bioengineering, Department of Physics & Astronomy, Rice University — Music has been shown to have therapeutic benefits for mental health, though few studies have quantified the impact on the brain. We investigated neural network changes from fMRI data while subjects actively listened to a variety of auditory pieces that varied in cultural familiarity and emotivity. We applied theory derived in our group showing that the extent to which modularity and flexibility of the network are selected for depends on the complexity and timescale of the activity being carried out. We found a strong negative correlation between modularity and flexibility while subjects listened to speech; this relationship decreased during self-selected and culturally familiar music, and it became random during culturally unfamiliar music and speech. We also found that modularity during a self-selected song was predictive of the neural network architecture during other pieces. These novel quantifiers of neural activity pave the way for creating individualized predictions of response to music engagement and tailoring therapy interventions to individual patients.

L70.00304: Modelling Axon Growth Using Driven Diffusion
NIMA DEHMAMY (Presenter), YANCHEN LIU, Northeastern University — Axon growth has been studied at small scales using models based on diffusion. An important part of the guidance of axons during their growth is following gradients of concentration of special chemicals called axonal guiders. We show how a model of coupled random walkers in a background potential derived from a the concentration guiders can lead to realistic paths for axons, exhibiting a high level of parallelism and following reasonably short paths. We propose a simple mechanism by which using a handful of axonal guiders, a brain could accurately assign target addresses for hundreds of brain regions and grow axons from any brain region to any other using a small alphabet. We also present some preliminary analysis of axon trajectories in the mouse brain.

L70.00305: Overcome Competitive Exclusion in Ecosystems
XIN WANG (Presenter), YANG-YU LIU, Harvard Medical School — Explaining biodiversity in nature is a fundamental problem in ecology. An outstanding challenge is embodied in the so-called Competitive Exclusion Principle: two species competing for one limiting resource cannot coexist at constant population densities, or more generally, the number of consumer species in steady coexistence cannot exceed that of resources. The fact that competitive exclusion is rarely observed in natural ecosystems has not been fully understood. Here we show that by forming chasing triplets among the consumers and resources in the predation process, the Competitive Exclusion Principle can be naturally violated. Our model can be broadly applicable to explain the biodiversity of many consumer-resource ecosystems and deepen our understanding of biodiversity in nature.

L70.00306: A chemical basis for metabolic cooperation in microbial communities*
AKSHIT GOYAL (Presenter), SANDEEP KRISHNA, Simons Centre for the Study of Living Machines, National Centre for Biological Sciences (NCBS-TIFR) — What distinguishes autonomous and cooperating metabolic networks in microbes? How does the underlying universal chemical network constrain metabolic cooperation between individuals? Answering these questions remains a conceptual roadblock given the dearth of culturable, sequenced microorganisms: only about 1% of the expected diversity. Here, we attempt to sidestep this experimental limitation by algorithmically generating reaction networks from the repertoire of chemical reactions in KEGG. We generate a large set of reaction networks, both autonomous and cooperating (cross-feeding). We survey their size, energy (ATP) and biomass yields, as well as their response to a variety of perturbations. We find that while rare, cross-fed pairs can best even the most productive autonomous networks without an obvious compromise to stability. This central result is robust to changing environmental conditions, biomass compositions and the precise method to calculate yields. As a proof-of-concept that a “productivity boost” is possible by cross-feeding, our study provides a chemical basis for the prevalence of metabolic diversity and cooperation in naturally-occurring microbial communities.

Heterogeneous Absorption of Antimicrobial Peptide LL37 in Escherichia coli Cells Enhances Population Survivability

Paul Talledo (Presenter), Physics and Astronomy, California State University, Northridge, MEHDI SNOUSSE, Nathan Del Rosario, Biology, California State University, Northridge, BAE-YEUN HA, Physics and Astronomy, University of Waterloo, ANDREJ KOSMRLJ, Mechanical and Aerospace Engineering, Princeton University, SATTAR TAHERI-ARAGHI, Physics and Astronomy, California State University, Northridge — Antimicrobial peptides (AMPs) are broad-spectrum antibiotics that selectively target bacteria. Here, we present our recent investigations on the activity of human AMP LL37 against Escherichia coli by integrating quantitative, population and single-cell level experiments with theoretical modeling. Our data indicate an unexpected, rapid absorption and retention of a large number of LL37 by E. coli cells upon the inhibition of their growth, which increases the chance of survival for the rest of the population. Cultures with relatively high cell density exhibit two distinct subpopulations: a non-growing population that absorb peptides and a growing population that survives attributable to the sequestration of the AMPs by other cells. Comparatively, we screened several common antibiotics for their MIC as controls to juxtapose AMPs' effects on E. coli. A mathematical model based on this binary picture reproduces a quite surprising behavior of E. coli culture in the presence of LL37, including the increase of the MIC with cell density—even in dilute cultures—and the extended lag duration of growth introduced by sub-lethal dosages of LL37.

Survival chances of a prey swarm: selfish runaway versus cooperative interaction

Rumi De (Presenter), Department of Physical Sciences, Indian Institute of Science Education and Research Kolkata, Mohanpur 741246, India — Cohesive group formation has been observed in diverse species, for example, flock of birds, school of fishes, herd of zebras, huddle of penguins to name a few. In nature, swarming behaviour has generally been found in search of food, for breeding, or to avoid predators etc. However, swarming could also thought to be unfavourable for preys as the predator could easily track and attack the whole group. Here, we investigate the effect of cooperative interaction within a prey group based on a simple theoretical prey-predator model framework incorporating short range repulsion and long range attraction between preys. Moreover, the range of interaction of preys, as in real scenario, may be limited due to their sensitivity, vision, age, or even physical structure; hence, in our model, we consider that each prey interacts with other neighbouring preys within a certain range of interaction radius. Our analysis shows that varying range of interaction vastly influences the trajectory of preys when chased by a predator and also strongly affects the survival probability of the prey group. Interestingly, we find that the survival of number of preys increases within an intermediate regime of interaction radius. These findings could also be qualitatively mapped with observations in nature.

Consecutive seeding and transfer of genetic diversity in metastasis

Alexander Heyde (Presenter), Harvard University, Johannes Reiter, Stanford University, Martin A Nowak, Harvard University — The transfer of genetic diversity between spatially separated growing populations is relevant to a wide range of biological applications, including clonal diversity in cancer metastasis, clonal hematopoiesis in stem cell biology, and species diversity in ecology. We study a multitype branching process of population growth that originates from a single individual but over time receives additional migrants. We derive a surprisingly simple expression for the fraction of genetic diversity transferred between populations as a function of the immigration rates that connect them. Additionally, we calculate statistics for the fixation index FST between populations. Using this model framework, we analyze single-cell sequencing data from ovarian, breast, and colorectal cancer samples collected from 15 patients. For these genetically diverse cell populations, we find an average seeding rate of 1-10 migrant cells per cellular generation time. Under typical metastasis growth conditions, this estimate suggests that 16-130 cells seeded each metastasis and left surviving lineages. Since primary tumors are often surgically removed, the genetic diversity of these metastases determines the probability for treatment efficacy.

Tracking motion and sleep in Astyanax fish

Adam Patch (Presenter), Yaouen F Fily, Physics, Wilkes Honors College, Florida Atlantic University — Astyanax or tetra fish, as a genus, contain more than 150 species, many of which have migrated into coastal caves around the Gulf of Mexico, convergently evolving sleeplessness, blindness and more sensitive lateral lines. Social behavior is also affected, which may in turn affect sleep patterns. We analyze Astyanax tracking data from the labs of Alex Keene and Erik Duboué at Florida Atlantic University and Wilkes Honors College to characterize motion and sleep patterns and their variations across species.

*Wilkes Honors College of Florida Atlantic University
L70.00311: Directed self-organization through thermoregulation in ant colonies* FAZIL USLU ( Presenter ), Institute of Mechanical Engineering, Ecole polytechnique federale de Lausanne, SEAN MCGREGOR, LAURENT KELLER, Department of Ecology and Evolution, University of Lausanne, MAHMUT SELMAN SAKAR, Institute of Mechanical Engineering, Ecole polytechnique federale de Lausanne — The nest of social insects is a complex architecture housing a multitude of individuals in a highly structured hierarchical network. At the heart of each of these spontaneously organized colonies, are the brood. Given the great lengths that social insects invest in their nest design and the spatial fidelity that individuals present, it stands to reason that the location of brood may regulate the dynamics of the social network and in turn, influence division of labor. We aim to test this prediction in colonies of C. fellah by taking advantage of the inherent thermosensitivity of the colony members. We discovered that the workers repeatedly transport the brood to locations within a certain temperature range. We then developed a robotic heat regulation system that allows us, for the first time, to directly control the position of the brood pile within an ant colony by subtly altering fine thermal gradients under the nest surface floor, while simultaneously, gathering precise behavioral data for all individuals within the colony using automated visual tracking. Analysis of spatial and social interaction network reveals novel insight on how spatial reorganization within the colony drives changes in population dynamics and collective decision making.

*Swiss National Science Foundation

L70.00312: Morphology of interacting proteins (CorA) by a coarse-grained Monte Carlo simulation WARIN JETSADAWISUT, Chemistry, Chulalongkorn University, SUNAN KITJARUWANKUL, Kasetsart University Sriracha Campus, PANISAK BOONAMNAJ, PORNTHEP SOMPORNPIISUT, Chemistry, Chulalongkorn University, RAS PANDEY ( Presenter ), University of Southern Mississippi — A transmembrane protein such as CorA performs selective transport of magnesium across the membrane with specific functions of its inner (iCorA) and outer (oCorA) membrane segments and known to exist as a homo-pentamer. The thermal response of iCorA is found [1, 2] to differ from that of oCorA in both native and denatured phases. Self-organized structures of proteins (CorA and iCorA) are examined by a coarse-grained model as a function of protein concentration at a range of temperatures. The collective structures show clear distinctions in morphology visually in its dilute concentration from that in the crowded (dense) protein matrix both at low and high temperatures. The effective dimension $D$ of CorA assembly is found to be lower ($D \leq 2$) than that of iCorA segments which remain globular ($D \approx 3$) at almost all length scales in its native phase. Based on the higher structural response, (i.e. structure factor and radius of gyration) in its native phase, the inner-segments may be more conducive to transient channel pathways due to cooperative protein-protein interactions.

L70.00313: Exploring the structure of single amylose chains using molecular dynamics* MASON SULLIVAN ( Presenter ), MOHAMMAD HASSAN KHATAMI, HENDRICK W DE HAAN, University of Ontario Institute of Technology — Amylose is a polymeric chain consisting of glucose molecules bound through $\alpha$-1,4 glycosidic linkages. Amylose can assume a variety of conformations in water – the structure and dynamics of which are of primary interest in this research. Despite well-defined secondary structures of amylose chains in experimental studies, the structures obtained through MD simulations lack such well-defined conformations (i.e. helical structures). Presented are results from all-atom MD simulations of single amylose chains (V-amylose) in water. From these simulations, criteria for helix-like structures is developed and the prevalence of these structures is explored. Dynamics such as bond flipping and other structural changes and their effects on helices are also discussed.

*OCE VIP II
NSERC CRD
oscillating swimmer which is capable to chemotax.

In presence of the gradient, the restricted oscillatory motion of the squirmer is altered due to the modification of the slip coefficients of the slip velocity and it starts to move towards the direction of the gradient. Here we have studied, how the net displacement of the body at the end of a complete cycle of oscillation towards the direction of the gradient depends on the strength of the gradient and the frequency of oscillation. This study can be helpful to design an artificial oscillating swimmer which is capable to chemotax.

L70.00318: Collective dynamics of 2D self-propelled semiflexible chains  GIMOON NAM (Presenter), CHANGBONG HYEON, Korea Institute for Advanced Study — Collective behavior is an emergent dynamics in active systems. This behavior often involves a hydrodynamic transition between coherent and turbulent flows, which occurs spontaneously even in the absence of an external driving. While the coherent flow state is theoretically well described as a polar and nematic phase, the turbulent state is rather difficult to describe as a single phase due to the existence of many complex local structural patterns such as vortices and spirals. So far, most of the studies have focused on such transition in self-propelled particles system, but the corresponding polymers system is rarely studied. In recent simulation studies on self-propelled chains, it has been implicated that the transition could take place near the boundary between the coherent flow and spiral phases, where each phase is characterized by different values of the stiffness and Peclet number of a single chain. To reveal the underlying mechanism, we have studied the collective dynamics of 2D active semiflexible chains. By means of coarse-grained modeling and Brownian Dynamics simulation, we modeled self-propelled chains melt and monitored its structural dynamics. In this poster session, we report our recent progress on the collective behaviors of 2D active polymer system.

L70.00319: Compressing a Swarm of Multicellular Magnetotactic Bacteria with an Applied Magnetic Field  ALEJANDRA ROSSELLI (Presenter), CAMERON MITCHELL, BENJAMIN ROQUE, ALEXANDER PETROFF, Clark University — Bacteria of the species Magnetoglobus multicellularis live in spherical colonies composed of 10-50 individual bacteria. The colony swims as a single unit parallel to the Earth's magnetic field. Here we investigate the collective dynamics of a swarm of these colonies under an applied magnetic field. We orient the magnetic field towards a wall and measure the spatial distribution of the colonies. We track the motion of individual colonies as they align with the field and collide with one another and the chamber walls. We show that the distribution of colonies is the same as that of an ideal gas in a harmonic potential. We present a simple model to explain how this similarity arises and how it breaks down.

L70.00320: Control of Multicellular Magnetotactic Bacteria with a Magnetic Field  BENJAMIN ROQUE (Presenter), ALEJANDRA ROSSELLI, CAMERON MITCHELL, ALEXANDER PETROFF, Clark University — Bacteria of the species Magnetoglobus multicellularis form spherical colonies composed of tens of cells. A colony moves as a single unit as each cell rotates its flagella. Magnetic minerals within each cell cause the direction of the colony’s motion to align with the ambient magnetic field. Here we characterize the motion of these large, fast-swimming colonies both individually and collectively in an oscillating magnetic field. First, we observe the dynamics of individual colonies. We measure their swimming speed, magnetic moment, and diffusion coefficient. Next, we observe the collective motion of dense swarms of colonies in a rotating magnetic field. We compare the these observations to the predictions of a simple model. We use these results to propose a method to direct swarms of swimming colonies to perform tasks, such as sorting tracer particles in a fluid.

L70.00321: Mechanism of Reentrant Liquid Condensation in Arginine-rich Low Complexity Domains*  TARANPREET KAUR (Presenter), IBRAHEEM ALSHAREEDAH, PRIYA R. BANERJEE, Department of Physics, University at Buffalo, The State University of New York — Arginine-rich (R-rich) low complexity domains (LCDs) are ubiquitous in eukaryotic RNA binding proteome, act as multi-valent RNA/protein-binding elements for liquid-liquid phase separation, and implicated in c9orf72-related ALS disease etiology. Recently, we showed that RNA mediates a remarkable reentrant liquid condensation of R-rich LCDs1, a phenomenon that is also observed in the cell2. Combining biophysical experiments and polymer physics theories, here we study the mechanism of the reentrant phase behavior of R-rich LCDs in ALS-associated protein FUS. We show that charge regulated electrostatic forces (long range) control condensation and de-condensation thresholds, whereas short-range attractions determine the stability of the condensates. Importantly, conditions promoting homotypic LCD-LCD and/or RNA-RNA interactions result in a more complex phase behavior, such as the formation of distinctive condensates with orthogonal physical properties. Together, our experiments and free-energy surface modeling suggest a highly tunable phase behavior of R-rich LCDs.

L70.00322: Modularity Promotes Adaptation in a Model of Exploratory Evolution* SHUBHAM TRIPATHI (Presenter), MICHAEL DEEM, Rice University — Biological systems are modular. They are composed of distinct components that function almost independently of one another. Studies have shown that modularity can spontaneously emerge in systems evolving under changing environmental conditions if the goals of evolution are varying in a modular manner or if horizontal gene transfer is present. Here, we examine a model that relaxes these constraints. We analyzed the effect of adding modular organization to a previously characterized model of evolution in gene regulatory networks. In this model, the topology of regulatory interactions is fixed while the regulatory strengths evolve to satisfy a linear constraint on the levels of different regulatory factors. We observed that the probability of successful adaptation within a fixed time period was higher when the regulatory topology was modular. The probability varied non-monotonically with the modularity of the regulatory topology. There are neither modularly-varying goals nor horizontal gene transfer in our model. Our model thus represents a previously uncharacterized scenario wherein modularity can be beneficial in evolving biological systems.

L70.00323: Bio-energy Transport as a Dressed Vibrational Exciton in Protein Molecules* PEIGHTON BOLT, THEJA DE SILVA (Presenter), Physics, Augusta University — Following the ideas of Davydov's soliton theory, we study the bio-energy transport in protein molecules. By using a quantum Brownian motion model for a phonon dressed vibrational exciton, we calculate the time-dependence on the mean square distance, diffusion coefficient, and energy of the vibrational exciton. We find the time-dependence by solving the quantum Langevin equation and find oscillatory behaviors due to the super-diffusive non-ohmic dissipation. We find that the vibrational exciton gains an overall energy due to the coupling to the phonon bath, it also dissipates its energy to the environment as it propagates. The amount of energy gain and the oscillatory features depend on both temperature and the phonon-vibron coupling.

L70.00324: Continue study of nano-Co synthesized by pea (Pisum Sativum L.) and lucerne (Medicago Sativa L.). NEREIDA AVENDAÑO GAVIRA (Presenter), ELIZABETH CHAVIRA, GUADALUPE ZAVALA, ADRIANA TEJEDA, National Autonomous University of Mexico — Our research group reports the synthesis on nano-Co using Co3O4 (STREM CHEMICALS) reagent, analyzed by X-ray powder diffraction, (XRD) with concerning a hexagonal unit cell (PDF 43-1003) and 3% of iron oxides (PDF: 8-0097) impurities.

Lucerne oxidizes Co3O4 by its growing process; all vegetables need oxygen to grow (we are working in the mechanism by which lucerne do that). The lucerne is a natural nano-synthesizer; by HRTEM it is visualized Co shape and size of the nano-crystals in lucerne. Co is distributing in small highly symmetric complex similar to virus structure in infected cells. In pea the results are not that clear, we visualized the Co agglomerate by HRTEM in the root.

Due to the interest in the structural properties of nano-cobalt synthesized, the contaminated samples were allowed to dry under room conditions during 29 days. Then plats were grind, and as we know we have metallic Co inside the plat, so using a magnet we separated the organic part which contained it. Finally they were analyzed with XRD, one study for lucerne and other for pea.

Because of in the XRD analysis the proportion of Co were less than 1% (plants were contaminated with 0.05 g of Co3O4) result showed us only the diffraction of the organic part.
Technologies such as microalgae cultures and nanotechnology have been developed for water purification systems. In this work we continue using the silver nanocrystals that were synthesized from garlic (Allium sativum) and onion (Allium cepa) with two different solvents (water and ammonium hydroxide) plus a precursor agent in solution and polycrystals; obtaining a cubic crystalline structure for garlic (Allium sativum) PDF 00-001-1236 of AgCl and onion (Allium cepa) PDF 00-001-1167 obtained with X-ray diffraction analysis (XRD). In addition, a mass loss process of 90% at 100 °C corroborated by thermogravimetric analysis (TGA) and simultaneous analysis (SDT), crystalline cubic conglomerates of silver nanocrystals between 100 and 200 nm with crystal morphology have order diameters of 2-10 nm. Obtained by SEM and HRTEM. To be able to mix the nanocrystals with a microalgae and determine the reactions between them; The first stage is carried out, consisting of the production of microalgae using 10, 20 and 30 ml of liquid humus obtained from the California red worm (eisenia foetida) in 600 ml of water with growth conditions at a temperature of 23-26 °C and a humidity of 45-55% after the first 192 h of diatomaceous microalgae observed at 10x in the optical microscope.

Identification of a Model Organism for Giardia Lamblia by Raman Spectroscopy* JOSEMARIA SORIANO (Presenter), Physics and Environmental Science, St. Mary's University, CHENGLONG ZHAO, FARZIA KARIM, Physics, University of Dayton — Giardia Lamblia is a protozoan parasite which causes Giardiasis, the most common intestinal protozoan infection in the world. Several studies show the presence of blackish pigment granules in retinal layers due to Giardiasis, making of Giardia a pigment-related parasite. In the following work, Raman spectroscopy will be used for the identification of Euglena gracilis, model organism chosen because of its physical similarity, low cost and biosafety. In this study, Euglena samples were excited at 785 nm and signal optimization was performed using Surface-Enhanced Raman spectroscopy (SERS) utilizing gold (Au) nanoparticles as substrate. Our results indicate that SERS provides a four-fold signal enhancement for peaks at 1188 cm⁻¹ and 1530 cm⁻¹, corresponding to the β-carotene conjugated double-bond system present in Euglena, pigment concentrated in the light sensitive eyespot. Thus, we have shown the effectiveness of Raman and SERS Spectroscopy on the identifying of microbial pigments, constituting a robust method to detect and characterize pathogenic microbes such as Giardia, which will have significant downstream diagnostic implications.

*Funded partially by University of Dayton College of Arts and Sciences, Department of Physics, STEM Catalyst Grant and National Science Foundation.

Single Molecule Localization and Orientation Mapping Using a Joint Inversion Technique ANTHONY MAUTINO (Presenter), ABHISHEK KUMAR, University of Maryland, College Park, JAMES M MARR, MARK MCLEAN, STEPHAN STRANICK, Materials Measurement Laboratory, National Institute of Standards and Technology, VERONIKA SZALAI, JAMES LIDDLE, Physical Measurement Laboratory, National Institute of Standards and Technology — For rotationally-constrained molecules, single molecule (SM) localization based super-resolution imaging can incur losses in accuracy when not accounting for the effect of SM orientation on the point spread function. It is important to determine molecular orientation both to maximize localization accuracy and also because orientation provides information about the local molecular environment, which determines features such as chemical reactivity, biomolecular interactions, local polymer mobility, etc. To map the 3D orientation of SMs, we collect the intensity projected onto four different polarization orientations simultaneously and use the intensities in the different channels to reconstruct each dipole's 3D orientation. These data provide 1) information on the SM's local environment, and 2) constraints for image point spread function-fitting and localization. SM images acquired from a second objective positioned on the opposite side of the sample versus the four-channel collection system are utilized for a joint inversion technique for position. We present techniques of registration, localization, and polarization analysis, along with an uncertainty analysis and assessment of the developed methods.
We monitored γ-H2AX formation using ChIP-qPCR after creating a site-specific break on Chromosome III. Experimentally measured γ-H2AX profiles by the two kinases are significantly different from each other suggesting that different mechanisms are used to reach H2A histones around the break. We consider four modes of phosphorylation propagation: (a) 3D diffusion of a kinase initially bound to the break, (b) looping of chromatin to bring a kinase tethered to the break to distant sites along the chromatin, (c) directed sliding of a kinase along the chromatin, and (d) 1D diffusion of a kinase along the chromatin. Using Bayesian model selection, we determined that the activity of Mec1 is best described by looping while Tel1 is best described by directed sliding.

JING XIA (Presenter), School of engineering and applied science, Harvard University, FRED C. MACKINTOSH, Chemical and Biomolecular Engineering, rice university, LIHENG CAI, Materials Science and Engineering, university of virginia, HUAYIN WU, DAVID A WEITZ, School of engineering and applied science, Harvard University — Fibrin are the main constituent during the hemostasis due to its unique mechanical properties resulting from its hierarchy structure, malfunction of fibrin can lead to diseases such as thrombosis. Here we show Zn can tune the fibrin network and its mechanical properties. In the presence of Zn2+, fibrin protofibrils form huge fiber bundles which are intrinsic loosely coupled. By further comparing with theoretical model, we show that under low stress, the mechanical properties of Zn modified fibrin network are contributed by the thermal fluctuation of the network; at high stress, the mechanical properties are contributed by single protofibril mechanics.
Finally, we examine the influence of resulting network structures on dynamics of molecular motor motion. Using tools from graph computational methods utilizing kinetic Monte Carlo and Brownian dynamics simulations to study the organization of such as plant villin influence cytoskeletal organization and intracellular transport in plant cells. In this work, we use hybrid computational methods utilizing kinetic Monte Carlo and Brownian dynamics simulations to study the organization of actin networks as a function of system size, system shape, and density of crosslinking proteins. Using tools from graph theory, we gain insight into cytoskeletal architecture by analyzing graphs characterizing the connectivity of actin networks. We analyze how the connectivity, as described by the Flory-Stockmayer theory, changes as a function of the concentration of non-neuronal microtubules have been evaluated in several reported studies. However, our knowledge about dielectric factors of non-neuronal microtubules is still limited. In our study, we quantified the normalized polarization coefficient of Tau-MCF7 microtubules by implementing the electro-orientation method. The result was then compared with the one we previously reported for MCF7 microtubules in the absence of Tau protein. This study is significant, as MCF7 microtubules are structurally different from neuronal microtubules in terms of the distribution of beta tubulin isotypes. The polarization factor and, consequently, negative charge of those microtubules is smaller than MCF7 polymerized from MCF7 tubulin. This can potentially be an underlying mechanism for many intracellular functions.

Finally we compare this result with actin networks containing Arp2/3. We expect our results to give an insight into how the concentrations of linker and motors than those required to observe contractions in the mechanochemical simulations. We find that the sol-gel transition in the system occurs at lower concentrations of linker and motors than those required to observe contractions in the mechanochemical simulations. Finally we compare this result with actin networks containing Arp2/3. We expect our results to give an insight into how the connectivity of the network affects its dynamic behavior.

Single Wall Carbon Nanotube (SWCNT) as an Intracellular Gene Delivery Cargo*  
(ADEYINKA ADESINA (Presenter), NANOSCIENCE, UNIVERSITY OF NORTH CAROLINA AT GREENSBORO — A SWCNT is truly one-dimensional nanoscale object, possessing unique optical, electronic, and mechanical properties. Earlier works on SWCNT toxicity and size allowed for widespread use of SWCNTs in biological studies. SWCNTs bind to biomolecules, proteins and nucleic acids via Coulomb and other interactions, both on the specific and nonspecific level, this motivated many drug and gene delivery studies which demonstrated that SWCNTs, functionalized with polymers and biological molecules may serve as highly efficient and easily targeted delivery agents.

In this study, ssDNA labeled with Alexa Fluor 546 dye was used to functionalize SWCNT. This hybrid matched a complementary ssDNA which was labeled with Alexa Fluor 488 dye. Double-stranded DNA hybridization on the solvent-exposed sticky ends was monitored by Forster Resonance Energy Transfer technique. The modulation of the SWCNT optical response due to DNA conformational charge motion before and after hybridization was also investigated.

Mining recombination algorithms in modular biosynthetic gene clusters  
(ZHIYUAN LI (Presenter), DONIA MOHAMED, Princeton University — Non-ribosomal peptide synthetases (NRPSs) are ubiquitous in micro-organisms and produce large varieties of metabolites with pharmaceutical potentials. Its modularity structure inspired de-novo designing efforts by recombining desired modules. However, past efforts in this direction are largely unsuccessful. The difficulty in re-engineering new products raise questions on the modulized view: are there unknown functional constraints between different parts of NRPS that favor/disfavor certain combinations of modules or subunits?

In large database, correlations between different subunits of NRPS can be uncovered by statistic techniques. However, as subunits in the same gene cluster are correlated by sharing the same lineage history, the correlation induced by functional constraints usually get blurred.

A unique marine bacteria described in our previous research reveals important design principles of NRPS. In this bacteria, 20 NRPS pathways generate chemical diversity though extremely frequent recombination. Genetic exchange between NRPSs is so intensive that it largely erases the correlation by lineage history, leaving correlation by function clearly observable. In this system, we revealed previously undescribed constraints between different types of subunits of NRPS.

Probing the Cell-Fate Decision During Infection of E. coli by the Virus Lambda  
(SETH COLEMAN (Presenter), RICE UNIVERSITY; IDO GOLDING, BAYLOR COLLEGE OF MEDICINE; OLEG A IGOSHIN, RICE UNIVERSITY — Lambda is a virus which infects E. coli bacteria, and its infection serves as a paradigm for cell-fate decisions, processes where cells select and transition to stable states. Infected cells can proceed along one of two developmental pathways: lysis, characterized by rampant viral replication and eventual cell death, or lysogeny, characterized by viral dormancy. Despite the decades of research done on this system, fundamental questions remain about what factors drive the decision and the mechanisms by which they act.

We are developing models which, calibrated by single-cell resolution experimental data, will be able to shed light on how currently known factors (such as gene copy number, both as an initial condition and as a function of time due to replication, as well as cell volume) influence the decision process, and predict additional factors.  We are also investigating explanations for a surprising observation in lambda – the scaling of the probability of a lysogenic outcome with viral concentration exhibits a complicated structure, which can be understood by positing that viruses independently decide their fates. We are developing simple models to test this hypothesis and propose a possible physical mechanism for this intracellular individuality.
A game-theoretic approach to model the transmission of Chikungunya on Reunion Island.

DAVID FEAGINS (Presenter), Department of Physics and Environmental Science, St. Mary's University, Texas, SYLVIA KLEIN, Department of Mathematics, St. Mary's College of Maryland, Maryland, ALEX FOSTER, Department of Mathematics, Coastal Carolina University, South Carolina, JONATHAN ROWELL, IGOR EROVENKO, Department of Mathematics, University of North Carolina at Greensboro, North Carolina — Chikungunya is a viral infection that is spread by mosquitoes of the genus Aedes. Chikungunya victims experience symptoms similar to those caused by the Dengue and Zika viruses but are less likely to die from it. Chikungunya was not a major research interest up until 2004 when a third of the population on Reunion Island, located in Africa, was infected by the disease. This outbreak inspired the creation of mathematical models to study how Chikungunya is transmitted. Driven by these studies, we constructed a game-theoretic model that considers how rational individuals decide to use mosquito repellent to prevent the disease. In our model, individuals make their decision based on a payoff function that takes into account the consequences of being infected and the perceived cost of using mosquito repellent. We found that the usage of mosquito repellent is negatively correlated with the perceived cost of mosquito repellent while keeping the consequences of contracting the disease constant. However, setting the perceived cost of mosquito repellent to zero does not guarantee the eradication of Chikungunya. With this in mind, governments and disease control programs can better understand how to manage the transmission of this mosquito-borne disease.

Critical level of epistasis separates trajectories toward evolution of mutational or drift robustness in small populations

CHRIS ADAMI (Presenter), Microbiology and Molecular Genetics, Michigan State Univ, DARIYA SYDYKOVA, Department of Integrative Biology, University of Texas at Austin, THOMAS LABAR, Department of Molecular and Cellular Biology, Harvard University, CLAUS WILKE, Department of Integrative Biology, University of Texas at Austin — High mutation rates select for the evolution of mutational robustness, where populations inhabit flat fitness peaks with little epistasis [1]. Recent evidence shows that a different effect shields small populations from fitness declines. In drift robustness [2], populations occupy peaks with steep “flanks”, and positive epistasis. But what happens when mutation rates are high and population sizes are small at the same time? Using a fitness model with both variable epistasis and mutational effect size, we show that the equilibrium fitness has a minimum as a function of the parameter that tunes epistasis, implying that this critical point is an unstable fixed point for evolutionary trajectories. In agent-based simulations of evolution at finite mutation rate, we demonstrate that when mutations can change epistasis, trajectories with a subcritical value of epistasis evolve to decrease epistasis, while those with supercritical initial points evolve towards higher epistasis. These two fixed points can be identified with mutational and drift robustness, respectively.

*Supported by the National Science Foundation under Grant No. DBI-0939454.

Structured Active Fluids via Interfacial Nanoparticle Assembly

PAUL KIM (Presenter), JOE FORTH, Lawrence Berkeley National Laborabory, ZVONIMIR DOGIC, POOJA CHANDRAKAR, University of California, Santa Barbara, THOMAS RUSSELL, Lawrence Berkeley National Laborabory — The transport of ordinary liquids tends to be driven by pressure difference, whereas for active fluids (or biological matters), the transport is autonomous and/or isotropic, governed by the gradient in specific chemical. Wu et al. recently discovered the emergence of spontaneous directional flow of active fluids, consisting of microtubule filaments and kinesin molecular motors, upon their confinement in a variety of microfluidic channels [Science 24 Mar 2017: Vol. 355, Issue 6331]; when confined in loops of toroidal and cylindrical channels, the flow persisted in one direction, either clockwise or counterclockwise. Here, we observed the same active fluid confined in channels of similar geometries, which are made of a thin layer of nanoparticles. By extruding or molding a dispersion of charged nanoparticles in an immiscible solution of oppositely charged surfactants, liquids can be mechanically stabilized (or structured) in an arbitrary shape by jamming of nanoparticle surfactants at the liquid interface. The flow of active fluid and its consequence to overall structures are observed in situ by fluorescent microscopy. The interactions between the liquid interface and active fluid is also studied.
**L70.00343: Emergence of E. coli Critically Buckled Motile Helices Under Antibiotic Stress**

TRUNG PHAN, Princeton University, RYAN MORRIS, Physics, University Edinburgh, ROBERT AUSTIN (Presenter), MATTHEW BLACK, Princeton University, JULIA BOS, Institute Pasteur

— Bacteria under external stress can reveal unexpected emergent phenotypes. We show that the intensely studied bacterium E. coli can transform into long, highly motile helical filaments poised at a torsional buckling criticality when exposed to minimum inhibitory concentrations of several antibiotics. While the highly motile helices are physically either right- or left-handed, the motile helices always rotate with a right-handed angular velocity \( \omega \) which points in the same direction as the translational velocity \( \nu_T \) of the helix. Furthermore, these helical cells do not swim by a 'run and tumble' but rather rather synchronously flip their spin \( \omega \) and thus translational velocity \( \nu_T \) backing up rather than tumbling. By increasing the translational persistence length, these dynamics give rise to an effective diffusion coefficient up to 20 times that of a normal E. coli cell. Finally, we propose an evolutionary mechanism for this phenotype's emergence whereby the increased effective diffusivity provides a fitness advantage in allowing filamentous cells to more readily escape regions of high external stress.

*This work was supported by NSF PHY-1659940.

**L70.00344: Simple Stochastic Simulations for Visualizing and Testing Models of Gene Expression and Proofreading**

KEVIN Y CHEN, Chemistry, University of Cambridge, DANIEL ZUCKERMAN, Biomedical Engineering, Oregon Health & Science University, PHIL NELSON (Presenter), Physics and Astronomy, University of Pennsylvania — To better visualize the stochastic nature of cellular processes and how they unfold over time, we developed a simple Gillespie algorithm to simulate two important non-equilibrium statistical processes, gene expression and translation error correction.

For example, our simulations demonstrate the concept of kinetic proofreading, generating proteins with error fractions predicted by Hopfield's rate-equation analysis, but also providing illustrative time courses for the reaction. Animations derived from simulation help build intuition. Furthermore, our simulations show that a ribosome with only kinetic proofreading, i.e. only a difference in unbinding rates between right and wrong charged tRNA, must sacrifice speed for accuracy. Simulating translation with recently measured rate constants shows how the ribosome combines kinetic proofreading, which relies on sequential, quasi-equilibrium steps, with internal discrimination, which allows for unequal forward rates, to efficiently translate mRNA with few misreadings. The stochastic simulation algorithm used here requires only a few lines of code and can easily be adapted for other biomolecular processes.

**L70.00345: Modeling the collective behaviour of Dictyostelium discoideum under directed migration**

VIKTOR TESHOME BELAY (Presenter), Department of Physics, American University, WOLFGANG LOSERT, Department of Physics, University of Maryland — Cellular migration is a function that is ubiquitous across a vast number of organisms. This phenomenon is observed in many biological functions such as embryogenesis, tissue regeneration, tumor metastasis, muscle contraction, and more. Cellular migration is influenced by various factors; principally, by chemical, mechanical, and electrical cues. We utilize the model organism Dictyostelium discoideum to study the effects of nanotopographical guidance and electrostatic fields on the motion of cells. We develop a cell-scale stochastic model of the influence of nanotopography, electrostatic fields, and chemical signaling by the secondary messenger cyclic adenosine monophosphate on the motion of D. discoideum cells. Model simulations show that unidirectional guidance by nano-ridges allows for D. discoideum streaming and aggregation, while bidirectional nanotopography creates a cell bifurcation in which there is little to no streaming or aggregation. In addition, simulations indicate that D. discoideum cells exhibit directed collective motion when under the influence of a unidirectional electric field.

L70.00346: Designing Compact Microfluidic Structures to study Cancer Cell Metastasis via Flow-less Spatial and Temporal Gradients*  
ARTURO RUBEN DIAZ (Presenter), ILEENE ASHLEY DIAZ, Physics and Astronomy, Georgia Southern University, DWAYNE G. STUPACK, Moores Cancer Center, University of California San Diego, DRAGOS AMARIE, Physics and Astronomy, Georgia Southern University — Metastasis, the migration of cancer cells away from an original tumor to other tissues, is the primary cause of morbidity and mortality in cancer patients. This migration is controlled by complex biomechanical processes and triggered by diverse stimuli. We seek to develop a set of microfluidic tools to investigate metastasis that will allow us to analytically pinpoint triggering factors by studying changes in cell migration as prompted by as few simultaneous stimuli as possible. These devices are microfluidic structures that produce stable, controlled gradient flows across and along a microfluidic gradient chamber. They will allow us to study how extracellular chemical gradients of various compositions and/or concentrations drive ovarian carcinoma cell migration. These tools follow our previous work and use the concept of splitting and recombining flows through a series of bifurcations and trifurcations, while introducing a gradient chamber separate from the cell culture chamber. Bright field and epi-fluorescence microscopy will be used to characterize these devices.

L70.00347: Bacterial Physiology during Intercellular Signaling*  
SHIQI LIU (Presenter), The Chinese University of Hong Kong — Cell-cell communication plays an important role in many biological processes. The communication is often mediated by diffusing chemical signals released by cells. Here we study how the bacterial physiological state responds to the intercellular signals and how individual cells benefit from those signaling-related processes. A better understanding of bacterial physiology during intercellular signaling could enable us to manipulate the behavior of cells and may help to understand biofilm formation.

*This work was supported by the Research Grants Council of Hong Kong SAR (RGC Reference numbers 14303918, 14322316 and 14301915) and the National Natural Science Foundation of China (NSFC 21473152)

L70.00348: Propagation of Wall-Less Bacteria*  
YISEN LI (Presenter), The Chinese University of Hong Kong — Normally bacterial growth relies on the peptidoglycan cell wall. However, cells in a wall-free state can propagate in a wall-independent manner, which remains poorly understood. We will present our recent work on continuous propagation of wall-less bacteria and colony formation. The underlying mechanism is relevant to antibiotic resistance of pathogens.

*This work was supported by the Research Grants Council of Hong Kong SAR (RGC Reference numbers 14303918, 14322316 and 14301915) and the National Natural Science Foundation of China (NSFC 21473152).

L70.00349: Anomalous flip-flop of DMPC in lipid membranes*  
NETI BHATT (Presenter), URSULA PEREZ-SALAS, University of Illinois at Chicago, LIONEL PORCAR, Institut Laue–Langevin, YANGMINGYUE LIU, MICHAEL STANFIELD, University of Illinois at Chicago — Although the study of the passive movement of lipids between and within membranes can give insight into lipid transport regulation by providing a way to gauge the energetic cost on active metabolic pathways, published work on the spontaneous transfer of lipids report a wide variation in the rates of transfer between and particularly within membranes. Non-invasive approaches like time resolved small angle neutron scattering or sum-frequency vibrational spectroscopy have shown that the movement of lipids is extremely sensitive to chemical structures of molecules finding that the transfer rates of unaltered lipid molecules are dramatically different from their chemically tagged counterparts. My group performed Neutron Scattering experiment and found that DMPC flip-flop rates display two Arrhenius states well above DMPC’s melting temperature. I will report on measurements of the flip-flop rates in DMPC using nuclear magnetic resonance spectroscopy and membrane order and fluidity using Laurdan generalized polarization, DPH anisotropy respectively, to reveal the nature of this intriguing behavior.

*We thank CAREER award DMR-1753238 as well as University of Illinois at Chicago Chancellor’s undergraduate award and Honors college research grant for providing funding for the experiment
L70.00350: Deterministic and stochastic analysis of an oncolytic infection model* KARAN BUNTVAL (Presenter), Bard College at Simon’s Rock, HANA M DOBROVOLNY, Departments of Physics and Astronomy, Texas Christian University — Mathematical models of biological processes have had a history of high predictive power of both experimental data and preliminary drug tests. Models that aim to predict the dynamics of oncolytic virus infections have previously focused solely on 3 populations, i.e., the cancer cells, virus-inflicted cancer cells, and the virus itself. Considering that most tumor populations have a substantial proportion of healthy cells, an oncolytic model that rightly adjusts for this increased fraction would provide insight into dual cell dynamics. Our findings elucidated that certain parameter variations with the tumor proliferation, infection, virus replication, and infected cell dissolution rates eventually allowed for the negation of cancer cells while simultaneously keeping the healthy cells alive. A stochastic interpretation of the model was further utilized to more authentically characterize the probabilistic events during an infection. In addition to preventing the oscillatory behavior observed with the deterministic model, it also confirmed the initial denouement of an extinct cancer population and thriving non-cancerous cells.

*This work was supported by NSF REU grants NSF-1358770 & NSF-1659444.

L70.00351: Assessing tumor treatment modalities using an allometric model JENNIFER FIREHAMMER, ALLEN GARNER (Presenter), Purdue University — Allometric growth models apply universal growth laws to predict growth of organisms and structures from very small to very large and have accurately modeled avascular tumor growth. These models have been extended by coupling the allometric growth law to a reaction-diffusion equation for nutrient transport to model necrotic core formation [A. L. Garner, Y. Y. Lau, T. L. Jackson, M. D. Uhler, D. W. Jordan, and R. M. Gilgenbach, J. Appl. Phys. 98, 124701 (2005).] and incorporated vascularization by applying energy arguments to incorporate vascularization [A. B. Herman, V. M. Savage, G. B. West, PLoS ONE 6, e22973 (2011).]. Recent developments of artificial, 3D tumor in vitro models that can incorporate vasculature provide a future means to assess chemical, physical, and combined treatments [R. Michna, M. Gadde, A. Ozkan, M. DeWitt, and M. Rylander, Biotech. Bioeng., https://doi.org/10.1002/bit.26778] for eventual clinical use. In this study, we modify the allometric growth model to assess the implications of dosage profiles on tumor growth. For a constant dosage, we observe that a subthreshold treatment reduces the steady-state tumor size while a suprathreshold amount destroys the tumor. The therapeutic implications of these results and future experiments will be discussed.

L70.00352: Tracking the Kinematics of Zebrafish Startle Responses Following Ablation of Sensory Hair Cells PETER JAEOH CHO (Presenter), MOHAMED AHMED RAMY, YAGMUR I. OZDEMIR, RANA BARGHOUT, JOSEF TRAPANI, ASHLEY CARTER, Amherst College — The survival of a zebrafish depends on its ability to detect and respond to external stimuli. Indeed, to avoid predators, zebrafish startle when subjected to sudden mechanical stimuli. Here our goal is to characterize the kinematic properties of the zebrafish startle response following ablation of sensory hair cells to determine the role of these cells as well as observe whether differences in the neural circuitry lead to measurable physical changes in the kinematic properties. To measure these kinematic properties, we head mounted a single larval zebrafish, induced a startle, and took videos of tail movement with a high-speed camera. Videos were analyzed in MATLAB to find the tail midline, allowing us to measure the kinematic differences in tail angle, velocity, acceleration, and curvature. Further work could observe twist and out of plane motion of the tail. Differences in these kinematic parameters would highlight how zebrafish behavior is affected by an altered neural circuit.

L70.00353: Scale-dependent relationships in human language AAKASH SARKAR (Presenter), MARC HOWARD, Psychological and Brain Sciences, Physics, Boston University — Many models of human language extract statistical regularities of natural language to estimate “meaning”. Mutual information between words in natural language has been shown to decay as a power law (Lin and Tegmark, 2017). Despite this evidence for scale-invariant statistics, statistical models of language typically impose a strong scale. We study the scale-dependence of language using Word2Vec (Mikolov et al., 2013), a shallow neural network model which generates a vector embedding of words by training over a corpus of text. We modify the Word2Vec algorithm to choose neighbors of a target word with an exponentially decaying distribution, and look at the embedding generated for a broad spectrum of scale parameters. It seems to appear that different syntactic and semantic relations (as classified in several tests developed by Mikolov et al.) seem to be best expressed at different word scales. Word similarities between neighbors seem to capture qualitatively different behavior across a range of word-scales, often peaking at distances that would not be captured by an embedding sampled at a single, particular scale. These results point toward the importance of developing scale-free models of semantic meaning.
L70.00354: Temporal contingency and informativeness in Laplace domain  KONSTANTIN TIUREV (Presenter), MARC HOWARD, Boston University — Associative learning in conditioning protocols is traditionally thought to depend on temporal contiguity between the stimuli. However, recent proposals suggest that temporal contingency rather than temporal contiguity is responsible for associative learning. That is, associations to the unconditional stimulus develop whenever it provides meaningful information about the expected time of reinforcement. Such information-theoretic framework has recently been considered in the context of Pavlovian conditioning, operant conditioning, and behavioral neuroscience. Here we develop information-theoretic approach to the long-range temporal credit assignment subject to several cognitively-inspired constraints. First, we assume that the system cannot possibly measure the joint statistics of the past combinations of stimuli. Second, our method assumes that the approximate stimuli history is available in the form of the inverse Laplace transform, which makes the method time-local and scale-invariant and helps to overcome major drawbacks of traditional approaches to the long-range credit assignment problem. The result is a biologically-plausible, computationally efficient model of associative learning, one of the fundamental processes in neural function.

L70.00355: An Electro-Mechanical Model of the Axon*  JOHN LEVENTIS (Presenter), GARY PENNINGTON, Towson University — Recent research into the electro-chemical effects of neural damage have provided evidence for interactions between deformations of the axonal membrane and the flow of charges thru its ion channels. Furthermore, traveling mechanical membrane waves in the axon have been shown to accompany the action potential. It seems possible that a more complete understanding of the true phenomena governing the transmission of an electric signal along a myelinated axon must incorporate more than just the electro-chemical mechanisms. We report simulation of signal transport in neural axons incorporating both electro-chemical and mechanical strain-related membrane deformations. Myelinated axons under normal and abnormal stressed conditions are compared. The results are used to investigate interdependencies between strain-related membrane deformations and electrical signals along the membrane. We model electro-mechanical behavior due to cell damage, disease, and abnormal ionic concentrations around the cell. We hope that making explicit the interdependencies between mechanical waves and electrical signals within the axon will prove useful to further biophysical research.

*We would like to gratefully acknowledge funding support from the Fischer College for Science and Mathematics at Towson University.

L70.00356: Development of a Behavioral Assay using Fluidic Devices to Study Learning and Memory in Cuttlefish Larvae*  COLTON SELLARS (Presenter), Physics and Astronomy, Georgia Southern University, JESSICA BOWERS, VINOTH SITTARAMANE, Biology, Georgia Southern University, DRAGOS AMARIE, Physics and Astronomy, Georgia Southern University — We developed behavioral assays to investigate the behaviors of cuttlefish hatchlings. Despite their behavioral complexity, little is known about cuttlefish behavior due to chemical stimuli. Current work done in 6-well plates shows the need for designing new fluidic device to manipulate chemical flow, delivery times, and allow event recording. Since behavioral assays for aquatic species require a flow-through design, our chip consists of joined channels, while diffusion coefficient calculation allowed us to evaluate flow rates. Our fluidic device provides more control thus creating a complex environment for cuttlefish hatchlings to explore. Using this device and tracking software, we can quantify the movement of cuttlefish in response to different stimuli. In these trials we aim to determine how prey cues have an effect on the cuttlefish navigation throughout the new environment. By providing food rewards for performing tasks, we can determine cuttlefish ability to learn to discriminate specific chemical information. This work presents a novel method for studying animal behavior in a dynamically changing chemical environment.

*This work was supported in part by a COUR award from the College of Science and Mathematics, and FRC Seed funding from the Georgia Southern University.

L70.00357: Investigating material properties of fish schools with dynamic light fields  PRANAV KAYASTHA (Presenter), AAWAZ POKHREL, JAMES PUCKETT, Gettysburg College — Many social animals, such as birds, fish and insects, exhibit complex group behavior. Models have shown that simple local interactions between individuals gives rise to the emergent self-organized macroscopic states such as flocks, swarms, or schools. We investigate the material properties of laboratory fish schools by exploiting the negative phototaxicity of Rummy-Nose Tetra (Hemigrammus blehri) to strain the school using projected dynamic light field. To do this, we use an overhead high speed camera to record individual fish trajectories in a quasi-two-dimensional tank. The strain is generated by projecting two dark regions moving in opposite directions, where fish use both social and environmental information to determine their behavior. We find that schools can undergo large deformations before collapsing back to one of the regions. We show that the school exhibits a linear stress-strain relationship, analogous to the Hooke's law.

L70.00358: CHEMICAL PHYSICS
Quantum Chemical Investigations on Heavy Ligand Atom Induced Large Magnetic Anisotropy in Mn(II) Complexes.*

SABYASACHI ROY CHOWDHURY (Presenter), SABYASHACHI MISHRA, Chemistry, Indian Institute of Technology Kharagpur — In Single Molecule Magnets (SMM) metal ions are considered pivotal towards achieving large magnetic anisotropy barriers. A metal ion with strong spin-orbit coupling constant and low coordination number results in the retention of unquenched metal-orbital angular momentum, produces large magnetic anisotropy (1-2). In this context, the influence of ligands with heavy elements, showing large spin-orbit coupling, on magnetic anisotropy barriers was investigated using a series of Mn(II)-based complexes, in which the metal ion did not have any orbital contribution. The mixing of metal and ligand orbitals was achieved by explicitly correlating the metal and ligand valence electrons with Complete Active Space Self-Consistent Field (CASSCF) calculations. The CASSCF wave functions were further used for evaluating spin-orbit coupling and zero-field splitting parameters for these complexes. For Mn(II) complexes with heavy ligand atoms, such as Br and I, several interesting inter-state mixings occur via the spin–orbit operator, which results in large magnetic anisotropy in these Mn(II) complexes(3).

*IIT Kharagpur

Modeling X-ray Absorption Spectroscopy with Relativistic TDDFT*

XIAOSONG LI (Presenter), University of Washington — X-ray absorption spectroscopy (XAS) is an element specific probe that has been used to understand the local electronic and binding environment around metal centers. Electronic structure theory has become an important aid in interpreting XAS spectra. While K-edge spectra have been investigated in great detail, the modeling of L-edge spectra poses several unique challenges. First, the L-edge spectrum is composed of multiple features: L₁ corresponding to the 2s orbital, and L₂,3 corresponding to 2p orbitals, which are split into 2p₁/₂ and 2p₃/₂ levels by spin-orbit coupling. Additionally, with density functional theory (DFT) it also becomes necessary to make modifications to handle non-collinear spin densities in the presence of spin-orbit coupling. We model the L₂,3 spectra for several molecules with variety of model chemistries using exact two component TDDFT (X2C-TDDFT). With the X2C-TDDFT method we are able to include the one-electron spin-orbit coupling terms variationally from first principles. An analysis of the molecular orbitals involved in the transitions yields valuable theoretical information that can be used to connect the local electronic structure with experimental observables.

Excited State Time-Resolved Vibrational Dynamics: the Challenge of Charge Transfer Complexes

FEDERICO COPPOLA (Presenter), Chemical Sciences, University of Naples Federico II, PAOLA CIMINO, Pharmaceutical Sciences, University of Salerno, UMBERTO RAUCCI, MARIA GABRIELLA CHIARIELLO, NADIA REGA, Chemical Sciences, University of Naples Federico II —

Charge transfer -CT- reactions are ubiquitous processes in nature. Photoexcited systems can be monitored to modulate the process and to rationally design photosensitive materials. Current vibrational spectroscopies provide experimental data with high time resolution, although the interpretation at molecular level requires the help of theory and computation. In this context, the atomistic description provided by theoretical analysis and ab initio molecular dynamics (AIMD) are a valid support. Isolated molecular systems are a good starting point to disentangle the complexity of anharmonicity and for the method's assessment. This contribution focuses on photoinduced CT reactions of benchmark systems showing a complex photophysical behaviour both in ground and excited state. To unravel the vibrational dynamics of key vibrational modes we use a theoretical approach² combining the AIMD simulations to the Wavelet Analysis in both electronic state. We focused vibrational relaxations of several vibrational modes moving towards quantification of the anharmonic coupling especially between high and low frequencies modes.

L70.00362: Speeding-up \textit{Ab Initio} Simulations: Novel Approaches for Extended Lagrangian Molecular Dynamics
FULVIO PERRELLA (Presenter), ALESSIO PETRONE, NADIA REGA, Chemical Sciences, University of Naples Federico II — Modern theoretical chemistry is prompted to give insight into ultrafast phenomena from an atomistic point-of-view and to give an interpretation of the experimental data from time-resolved spectroscopies. \textit{Ab initio} molecular dynamics (AIMD) is the prominent approach to capture both electronic and nuclear relaxation events.\textsuperscript{1} Among different approaches to molecular simulations, the Extended Lagrangian AIMD techniques appear to give best performances with respect to the accuracy/cost ratio. The fictitious electronic mass is a crucial parameter, because it has to ensure an efficient propagation of the electronic degrees of freedom, while keeping a strong degree of adiabaticity.\textsuperscript{2} Current implementations are based on a uniform or an energy-based weighting of atom centered basis functions and often cannot capture their core or valence-like character. A novel mass weighting scheme, based upon a rational classification of the atomic functions, will be proven to be consistently more reliable, while avoiding errors typically occurring with fixed energy thresholds. Such an approach may allow larger time-steps, while ensuring a strong physical soundness to the simulation.

L70.00363: Using geometric phases to separate overall rotation and internal motions in classical and quantum molecular dynamics\textsuperscript{*}
F. J. LIN (Presenter), F. J. Lin Research — In 1959, Aharonov and Bohm pointed out that electrons could be affected by vector potentials without an external magnetic field. To make the wave functions in vector potentials single-valued, an \textit{ad hoc} phase shift is required. This phase shift exemplifies a geometric phase (or Berry's phase). Similarly, Mead and Truhlar described an \textit{ad hoc} phase shift required for nuclear wave functions describing three-body molecular dynamics in the Born-Oppenheimer approximation. In their "molecular Aharonov-Bohm effect," Mead and Truhlar \textit{assumed} decoupled overall rotation and internal motion and considered the effects of a conical intersection. Instead of neglecting coupled overall rotation and internal motion, now this coupling is used to create a frame with \textit{decoupled} overall rotation and vanishing classical and quantum geometric phases. An extension of the classical dynamics describes the quantum dynamics of a three-body molecular system in the Born-Oppenheimer approximation. This theoretical approach agrees with observations of spectra of rare gas-diatomic molecule complexes and observations of triatomic photodissociation dynamics.

L70.00364: Calculations of small molecules using the Highly Accurate N-DEterminant (HANDE) quantum Monte Carlo software package\textsuperscript{*}
HAYLEY PETRAS (Presenter), TINA MIHM, JAMES SHEPHERD, University of Iowa — We use calculations of small molecules and the uniform electron gas to illustrate the capability of HANDE, an open-source software package that calculates stochastic estimates for high accuracy quantum chemistry methods. We choose to focus on full configuration interaction and its finite temperature variant, density matrix quantum Monte Carlo. We describe how strong correlation and other phenomena manifest in the context of this and the initiator approximation to these methods.

\textsuperscript{*}We thank the University of Iowa for funding.

L70.00365: Theoretical Insights into the Mechanisms of Aggregation-Induced Emission of a Tetraphenylethylene\textsuperscript{*}
NORIFUMI YAMAMOTO (Presenter), Chiba Institute of Technology — The aggregation induced emission (AIE) of tetraphenylethylene (TPE) was studied theoretically. The TPE has been known to exhibit the AIE, which is non-emissive in dilute solutions but becomes highly emissive in solid or aggregated state. In this study, the AIE mechanism of TPE was investigated by using electronic structure calculations, together with molecular dynamics (MD) simulations. The results of electronic structure calculations showed that potential energies of TPE for electronic ground (S\textsubscript{0}) and first excited (S\textsubscript{1}) states are degenerated at a conformation with the twist angle of 90° around its ethylenic C=C bond, which can lead the fluorescence quenching of this molecule in dilute solutions. The results of MD simulations revealed that the TPE in aggregated state tends to assemble in close contact, where the ethylenic C=C bond rotation is markedly restricted, preventing the fluorescence quenching via the S\textsubscript{0}/S\textsubscript{1} conical intersection; the TPE in THF solution, however, proceeds the barrierless non-radiative transition. These results gave a clear picture of the AIE mechanism of TPE.

L70.00366: Single-electron excitations from thermally-assisted-occupation reference* SHU-HAO YEH, AADITYA MANJANATH (Presenter), Institute of Chemistry, Academia Sinica, JENG-DA CHAI, Department of Physics, National Taiwan University, CHAO-PING HSU, Institute of Chemistry, Academia Sinica — The linear response time-dependent density functional theory (LR-TDDFT) has been broadly used to investigate excited-state properties of various molecular systems. However, current LR-TDDFT methods heavily rely upon outcomes from ground-state DFT calculations. For systems with small HOMO-LUMO gaps, single-determinant ground-state DFT may be prone to non-dynamical correlation, and hence, LR-TDDFT results can be inaccurate. Traditionally, nearly degenerate orbitals require proper treatment of non-dynamical correlation, which usually involves active-space treatments. Recently, the thermally-assisted-occupation (TAO) DFT scheme was proposed, which explicitly incorporates the non-dynamical correlation effect in the ground-state simulation, but retains the low computational complexity of conventional DFT. The aim of this work is to combine ground-state TAO-DFT with LR-TDDFT framework to study excited-state phenomena. The preliminary simulations successfully capture the dissociation feature of the first triplet excited state of hydrogen molecule, which is not the case for conventional TDDFT.

L70.00367: Bicarbonate charging of hydrophobic/water interfaces* FRANCOIS GANACHAUD (Presenter), COMPASS, JULIEN BERNARD, XIBO YAN, IMP, INSA Lyon, ANTONIO STOCCHO, Institut Charles Sadron, CNRS — Most surfaces in contact with water are negatively charged. The reason for that has long been debated in the physics community as arising either from hydroxide ion adsorption or water reorganization towards a hydrophobic interface. We have recently proposed another explanation coming from the carbonate of water. Bicarbonates, which in distilled water are the most present ions at intermediate pHs (from 5 to 10), are catatropic ions that stick to interfaces. We made use of a combination of interfacial tension measurements of oil droplets in water, and nanoprecipitation assays of polymers in a large range of pH, to show such affinity of HCO3⁻ for hexadecane oil and PMMA. This preferred adsorption of bicarbonate allows also explaining why freeze/thaw cycles contribute to emulsifying oil/water mixtures.

L70.00368: Computational Study of the Intermolecular Interactions Hg and Hg (II) With Thiols in Aqueous Environments. JICLI ROJAS (Presenter), Departamento de Química, Universidad Nacional de Colombia, JUAN CAMILO GALVIS, ALFREDO LORA, CARLOS PINILLA, Departamento de Física y Geociencias, Universidad del Norte, NEIL ALLAN, School of Chemistry, University of Bristol — Hg water contamination is one of the most common problems of gold mining. It is known that Hg has a great capacity to form compounds, especially when it reacts chemically with aquifer sources transforming it into methylmercury [CH₃Hg]⁺; a powerful neurotoxic that tends to accumulate, through the trophic chain, in fish, humans and wildlife that feed on them, causing irreversible effects on health. Currently there are no efficient methods for the treatment of water contaminated by Hg. In this work we systematically study the interaction energies between Hg, Hg (II) and methylmercury species with the -SH (thiol) group of the compounds Cysteine C₃H₇NO₂S (1), 3-mercaptop-3-methylbutan-1-ol C₅H₁₂OS (2), Silanol C₃H₇O₂SSi (3) and Dimercaprol C₃H₈OS₂ (4) in aqueous medium, using DFT in order to identify the compound with the most favorable interactions, which can be used for functionalization and so to produce new materials for the extraction of Hg. The results show that interactions with elemental mercury (Hg) are thermodynamically favored. However, with mercury in its ionic form (Hg II), the interactions that are favored are those when compound (2) and compound (4) were used. Our study hints on the possiblity to use thiols extracted from local vegetables and fruit sources.
A Theoretical Study of Novel Composite Clusters of Platinum Metals*  
AJIT HIRA (Presenter), JOSE PACHECO, RUBEN RIVERA, MATILDA FERNANDEZ, ALEXANDRA VALDEZ, Math and Physics, Northern New Mexico College — Material shell composites of platinum (Pt) and palladium metals have great stability and remarkable physical and chemical properties. In light of our previous work on the small atomic clusters on metallic clusters, we present here an Ab-initio quantum-mechanical study of the Ptn, Irn, and Osn (n = 1-9) clusters, their hybrids MiNj (M= Pt, Ir, Os; N= Pt, Ir, Os; i= 1-6; j= 1-6), and their composites of these metal clusters with palladium (Pd) clusters. Our theoretical approach is to utilize the ab initio methods of quantum chemistry to derive optimal geometries for the clusters of interest. Of particular interest in this research are the Pt6 and Pt8 rectangular parallelepipeds, and the Pt8, Pt9, Pt8Pd8, Pt8Pd9 cubic clusters. We examine the implications of this research for the self-assembly of metallo-supramolecular structures, by the directional bonding approach. Also, of interest here is the recent experimental work that showed that Pt clusters deposited on Pd shell over Au core nanoparticles (Au@Pd@Pt NPs) exhibit unusually high electrocatalytic activity for the electro-oxidation.

Structure and optical properties of In1-xRExTaO4 (RE= Er, Yb) and their oxynitrides, an evaluation as photocatalysts for water splitting*  
JUAN CRUZ PUERTO (Presenter), CRISTINA RAMÍREZ, Facultad de Química, Universidad Nacional Autonoma de Mexico, PABLO DE LA MORA, Facultad de Ciencias, Universidad Nacional Autonoma de Mexico, GUSTAVO TAVIZÓN, Facultad de Química, Universidad Nacional Autonoma de Mexico — Ta2O5 based photocatalysts show a band gap of about 4.0 eV, this implies that they should be used under UV electromagnetic radiation, this condition limits its applications. Zou, Z. et al. [1] prepared visible-light active photocatalyst with formula InTaO4: NiO, with a wolframite structure and a band gap of 2.6 eV; more recently this system was reviewed by Malingowski, A. et al. [2] and they found a direct band gap of 3.96 eV for the nickel doped InTaO4 compound. In this work, we studied the In1-xRExTaO4 (RE= Er, Yb, 0.0≤x≤2.0) solid solution with a wolframite structure and we found that for the Yb case the system it does not exhibit absorption in the visible region of the electromagnetic spectrum, while the Er system it shows a rich absorbance spectrum in the visible region. Probably this absorbance signals are associated to internal f-f electronic transitions and could be active in photocatalysis under visible radiation.

Theoretical modeling of coherent proton transfer dynamics and pump probe spectroscopy simulation*  
LUHAO ZHANG (Presenter), GREG SCHOLES, Princeton University — Proton transfer reaction is ubiquitous in chemistry and biology. Pump probe spectroscopy shows general feature of fast rising and oscillation signal of excited state proton transfer which can only be explained by quantum mechanics. However, due to the interplay of electron rearrangement, nuclear vibrations, skeletal torsion and molecule-solution interaction, it’s difficult to use ab-initial quantum dynamics calculation to illustrate pump probe signal. Here, we adopt the a vibronic coupling Hamiltonian and used methods of open quantum dynamics to simulate pump probe signal of HBT(2-(2’-Hydroxyphenyl)benzothiazole) and compare with experiment. Our method will make a brige between experiment and ab-intial calculation, and also provide a framework to describe a chemical reaction in a wave function(density matrix) perspective. Furthermore, because of the quantum mechanical nature of excited state proton transfer, it’s possible to realize a superposition of two pathways for a dimer molecule with two proton transfer sites, which brings a new mechanism for general chemical reaction. Using similar model Hamiltonian, we found for isolated dynamics, a superposition reaction shows interference pattern of nuclear density while single proton transfer does not.

*Thank Kech’s grant for funding.
L70.00372: Dynamic scaling in stochastic chemical kinetics*  JONAH GREENBERG (Presenter), JASON R. GREEN, University of Massachusetts Boston — Universality classes are often comprised of seemingly dissimilar physical systems. Here, we draw a formal analogy between surface-roughening processes and the stochastic kinetics of fundamental chemical reactions. We simulate the chemical kinetics of several classes of reactions with Gillespie’s exact stochastic simulation algorithm and analyze the dynamic scaling of a quantity analogous to the surface roughness, \(w\). For kinetics at chemical equilibrium considered thus far, the growth exponent is \(\beta=1/2\). The dynamic exponent \(z\), however, depends on the molecularity of the reaction. For simple cases these computational results can be verified analytically through the associated master equations. We observe a richer collection of exponents and scaling relations for nonequilibrium kinetics. Overall, these results suggest, just as in surface-roughening phenomena, that seemingly dissimilar chemical systems may also be partitioned into universality classes, some known and others new.

*This material is also based upon work supported by the U.S. Army Research Laboratory and the U.S. Army Research Office under grant number W911NF-14-1-0359.

L70.00373: Effect of surface morphology on kinetic compensation effect: interactions vs. energetic heterogeneity  NAYELI ZUNIGA-HANSEN (Presenter), Louisiana State University, LEONARDO SILBERT, Central New Mexico Community College, M. MERCEDES CALBI, University of Denver — The kinetic compensation effect, observed in many fields of science, is the systematic variation in the apparent magnitudes of the Arrhenius parameters, the activation energy \(E_a\) and the preexponential factor \(\nu\), as a response to perturbations. In principle, a change in \(E_a\) results in a change in the configurational entropy of the system, which appears as variations in \(\nu\) throughout an activated process. As part of a systematic study, we compare the effects of interactions on these parameters during the thermal desorption of quasi spherical molecules from a 2D glassy surface to the effects of surface energetic heterogeneity. The results of this study show that the decrease in configurational entropy is more pronounced in the presence of interactions. We also explore the role that diffusion plays in the extent to which the parameters offset each other. These results provide a deeper insight into the microscopic events from which compensation effects and isokinetic relations originate in this system, suggesting similar mechanisms may be at play in other systems where compensation effects have been reported, and which can improve our understanding of the mechanisms which control the rates of many activated processes.

L70.00374: Molecular Dynamics Simulations of the Elastic and Structural Properties of Calcium Aluminate Glass: Effects of Low Silica Contents  HICHAM JABRAOUI (Presenter), MICHAEL BADAWI, University of Lorraine, ABDELLATIF HASNIAOUI, Université Hassan 1er, SAID OUASKIT, Université Hassan II de Casablanca, YANN VAILLS, University of Orleans — We have used classical molecular dynamics to investigate the elastic constant behaviors of low silica calcium aluminosilicate glasses where \(\text{SiO}_2=5-25\text{ mol}\%\) and \([\text{CaO}]/[\text{SiO}_2]=2\). To compute the elastic constants, we have used two methods; the minimization energy at zero temperature (Zero-T) and a second one that allows calculating the elastic constants at finite temperature (FT)[1]. To evaluate the reliability of these methods, the obtained results are compared with those already measured by Brillouin light scattering spectroscopy (BLS). To this end, we show that elastic constants decrease with increasing silica content, which can be correlated with some structural features such as oxygen types and short-range order parameters. However, these properties are not easily accessible from experiment [2]. Therefore, our simulations complement well the current knowledge on the influence of low silica contents on the physicochemical properties of calcium aluminate glasses.

L70.00375: Like dissolves like: how like need they be? A statistical field theory for polar liquids and their mixtures*

BILIN ZHUANG (Presenter), Institute of High Performance Computing, ZHEN-GANG WANG, California Institute of Technology — We have been taught the empirical “like-dissolves-like” rule in secondary school chemistry classes, but how like must the solvents be? This question does not yet have a good quantitative answer because of the difficulty in finding a general description for mixture interactions. Here, we present a theory for polar liquids and their mixtures, developed using a statistical field approach. This approach allows us to avoid the use of ad hoc mixing rules, and thus provides a more holistic description of liquid mixtures. The resulting theory consists of simple algebraic expressions for the free energy and the dielectric constant of the liquid, based on just the dipole moments and the sizes of the constituent liquid molecules. Without the use of any adjustable parameters, the theory very well predicts the miscibility for a variety of liquids, thus providing a quantification for the well-known empirical “like-dissolves-like” rule.

*B.Z. gratefully acknowledges the support by an A-STAR fellowship. Acknowledgement is also made to the donors of the American Chemical Society Petroleum Research Fund for partial support of this research.

L70.00376: Determining the role of morphology in the acoustic absorption of materials*

SUMAN KUMARI (Presenter), Department of Chemical Engineering, Indian Institute of Technology Gandhinagar, VINOD NARAYANAN, Department of Mechanical Engineering, Indian Institute of Technology Gandhinagar, PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology Gandhinagar — Development of soundproofing technology that utilizes real-time noise cancellation over a broad range of frequencies has been a challenge in the field of acoustics. In a typical scenario, noise control can be achieved by two approaches, active and passive. In active noise cancellation, the low-frequency sound is sampled and a canceling signal is generated using an external power source. In passive noise cancellation, however, sound absorbing materials, like foams, are used to filter out the unwanted sound mostly at high frequencies. Here, we show that by optimizing the internal structure, or morphology, of the sound absorbing material, the efficiency can be increased. In other words, we demonstrate that the absorption coefficient of polymeric foams, used for passive noise cancellation, increases significantly if the internal morphology of the foam is modified. Using our approach, therefore, it is possible to design thin, lightweight soundproof materials that can absorb noise at a wide range of frequencies and thus, can facilitate the design of miniaturized noise canceling devices.

*DST-SERB (EMR/2016/007778)

L70.00377: Modeling of One-Dimensional Diatomic Molecules through Density Functional Theory

KYLE JONES (Presenter), ANTONIO C CANCIO, Ball State University — We have developed a code to solve the Schrodinger equation of one-dimensional systems of electrons numerically in a plane wave basis. We have tested the accuracy of the code by performing convergence tests versus cell size and plane wave number, for the square-well and the Poschl-Teller well. We use this to calculate numerically accurate electron and kinetic energy densities and compare to simple density functional models for these quantities. We plan to use this code to investigate the results when two potential wells are pulled apart. Density functional theory (the use of only the density to calculate energies) is known to fail in three dimensions as electric bonds are broken and we expect this to be a problem in one dimension as well. Our one-dimensional code will allow for quick testing of new models and theories to see if they are viable avenues for better describing electronic bonding.

L70.00378: WITHDRAWN ABSTRACT

L70.00379: Self-interaction effects in molecular dissociation curves*

KOBLAR JACKSON, ALEXANDER JOHNSON (Presenter), JUAN PERALTA, KAMAL SHARKAS, Central Michigan University — The Fermi-Löwdin Orbital Self Interaction Correction (FLO-SIC) removes unphysical electron self-interaction from Density Functional Theory (DFT), the most widely used first-principles method in condensed matter and chemical physics. Self-interaction errors can be particularly pronounced in situations where bonds are stretched, such as when an atom is dissociated from a molecule. To study the effectiveness of FLO-SIC in this context, we calculated dissociation curves corresponding to removing one H atom from each of the molecules LiH, BeH₂, BH₃, ..., HF, and one F atom from each of LiF, F₂ and FCl. To get a statistical measure of performance, we compare FLO-SIC-DFT and DFT dissociation energies to accurate reference energies at four points along each curve. We find that FLO-SIC improves the performance of the local density approximation (LDA) at all separations, while for the generalized gradient approximation in the Perdew-Burke-Ernzerhof (PBE) form the performance is improved only for large separations. FLO-SIC corrects the tendency of both LDA and PBE to predict charged fragments in the large separation limit.

L70.00380: MD Simulation of Ligand Migration and Substrate Binding in Lipoxygenases*  VIPIN KUMAR MISHRA
(Presenter), SABYASHACHI MISHRA, Indian Institute of Technology Kharagpur —
Lipoxygenases are an important class of enzymes with non-haem, non-sulphur iron-containing protein, whose catalytic action has severe consequences in a range of inflammatory diseases and its associated disease. The lipoxygenases are responsible for catalyzing the activation of poly-unsaturated fatty acids by inserting molecular oxygen at a specific position of the substrate, in a highly stereo-specific and regio-specific manner to yield hydro-peroxide [1]. We are currently investigating the pathways of migration of oxygen molecule into the active site of the enzyme and trying to determine the binding modes of the substrate. We have identified the side chains, such as, Arg185, Tyr181, Phe178, Ala592, Ala623, and Leu434 to play an important role in substrate binding. We are investigating the substrate binding propensity for different mutant systems and their roles towards hydroperoxidation. Further, we are investigating the global dynamic of the protein at atomic level. We are interested in providing a detailed description of the reaction pathway with structural and energetic details of the reactants, products, and intermediates along with the transition states separating them.

L70.00381: Nano-Species Release System Activated by Enzyme-Based XOR Logic Gate*  YAROSLAV FILIPOV (Presenter), MARIA GAMELLA, EVGENY KATZ, Clarkson University — An enzyme-based XOR logic gate was realized at interface of an alginate-modified electrode. The biocatalytic production of H2O2 inside the alginate film was controlled by logically processed input signals. The in situ generated H2O2 was decomposed to yield free radicals in a Fenton-type reaction catalyzed by iron cations, which were present in the alginate film as cross-linkers stabilizing the hydrogel. The produced free radicals (*OH, *OOH) resulted in decomposition/dissolution of the alginate film removing it from the electrode surface and stimulating release process of magnetic nanoparticles (MNPs) functionalized with a fluorescent dye and entrapped in the alginate film. The release of the MNPs was analyzed by following fluorescence appearing in the solution. The release process followed the logic features of the XOR gate. The present system is the first realization of the enzyme-based XOR gate functionally integrated with the downstream actuation process in the form of the signal-stimulated release.

L70.00382: Molecular Modeling of 1-Benzazepine Analogues that bind to the ACh Protein (2PH9) Using Hyperchem and AutoDock  PAOLA COLON, ASTRID SANTIAGO (Presenter), Chemistry, University of Puerto Rico in Humacao — Ligand interactions of the designed analogs to neuronal nicotinic Acetylcholinesterase receptor (nAChR) are being studied to see which one fit into the binding site of an ACh binding protein PDB code (2PH9).1-Benzazepine analogs improve allosteric positive modulation of the nicotinic α-7 acetylcholine receptors.The Heat of Formation, obtained using Schrödinger equations, of 8 benzazepines analogues that were designed in the Hyperchem program were calculated on the PM3 Hyperchem quantum levels. They were pre-optimized using MM + and the PM3 semi-empirical method with the Polak-Ribière conjugate gradient. The protein-ligand binding of these benzazepine analogs to ACh binding protein PDB code is being determined using the Auto Dock Tools and AutoDock Vina programs. The Affinity of the analogues under studies could be calculated using the Command Prompt of the computer, assigning specific x, y and z coordinates with a specific grid box size. It’s obtained that the ligand with the best interaction with the protein was 7-8 dimethoxy-1 BNZ-cinnamic acid with an affinity of -8.6kcal / mol and a Heat of Formation equal to -126.06 kcal / mol. These results, of the 8 ligands, were compared to Galantamine which is the commercial drug used to treat neurodegenerative diseases.

L70.00383: Modeling Circular Current Resonances in a 6-Quantum Dot Ring  YONG JOE (Presenter), Ball State University, ERIC HEDIN, Biola University — A nanoscale ring configuration, modeled as a 6-quantum dot ring, is investigated computationally to study the behavior of circular current resonances. The computational method utilizes the tight-binding approximation to the Schrödinger Equation to solve for the transmission and circular transmission as a function of electron energy, external magnetic flux, and other system parameters. Large amplitude resonances of the circular transmission are found to occur when two poles of the transmission are separated along the imaginary axis. These resonances demonstrate a high degree of flux-sensitivity at specific energy values and flux ranges. Flux-dependent interference between the transmission poles and zeros in the complex energy plane affects the magnitude of the circular transmission resonance amplitudes. The circular transmission and its corresponding current-vs.-voltage characteristics may serve as a nano-sensor, providing a higher degree of correlation with the external flux than is observable with the normal transmission alone.
**L70.00384: Method for the Growth and Stabilization of Rare Earth Nano-Particles**

PATRICK TALBOT (Presenter), PEI-CHUN HO, California State University, Fresno — We are developing a process to create rare-earth metal (REM) nanoparticles (NPs), to the end of studying their magnetic and electrical properties. The large redox potential of REMs hinders the formation and stabilization of these NPs, requiring a strong reducing agent to form the NPs, and their protection from ambient conditions.

Firstly, the ease and efficacy of several organo-metallic reduction compounds, with sodium as an electron source, were compared: 15-crown-5, Benzophenone (anion and dianion), and naphthalene; with naphthalene showing to be the most consistent and convenient due to its: relatively high reduction potential, stability, and singly reduced state.

Secondly, we then compared methods of passivating the NPs; this consisted of looking at the relative stability of NPs using combinations of: ligation with 1-octylamine. Preliminary observations indicate ligation alone provides little protection from oxidation for the pure REM NPs, and is only able to prevent agglomeration.

**L70.00385: Steering of microwave absorption in MxCo(1-x)Fe2O4 (M: Ni2+, Mn2+, Zn2+) based ferrite-Carbon black/PVA composites by engineering the magnetic microstructures**

GOPAL DUTT (Presenter), Department of Metallurgical and Materials Engineering, Defence Institute of Advanced Technology, Pune, India, CHETAN KOTABAGE, Department of Physics, KLS Gogte Institute of Technology, Belagavi, India, ASHUTOSH C. ABHYANKAR, Department of Metallurgical and Materials Engineering, Defence Institute of Advanced Technology, Pune, India — Microwave mitigation property of ferrite nanoparticles (NFs)-Carbon black/PVA composites by tuning magnetic microstructure and spin arrangement of NFs is studied. The annealing of NiCoFe2O4 at 1000°C reveals significant changes in cationic distribution. The NFs were then used to fabricate the NF-CB hybrids and flexible NF-CB/PVA composite films. A comparative study of Ni-NFs composite prepared from non-annealed and annealed NFs indicates better shielding effectiveness for non-annealed NFs due to increase in cationic disorder, smaller particle size and large interfacial polarization.

The magnetic microstructures and coordination of Fe3+ ions in these NFs were investigated by MFM and Mossbauer spectroscopy, respectively. Zn-NFs have *unique single axis oriented* domains and highly distorted coordination of Fe3+ cations. Multi-domain magnetic microstructure and canted spins in sub-lattice were observed for Mn-NFs and Ni-NFs. Over bandwidth of 8 to 18 GHz, Zn-NF-CB/PVA has the largest shielding effectiveness (SAE = 25dB). It is caused by enhancement in interfacial polarization due to motion of polarons across multiple heterogeneous interfaces. \( \mu'' \) is almost twice in Zn-NF based composites compared to other due to distorted co-ordination of Fe3+ and *unique single axis oriented* domains.

---

**L70.00386: Biosensors Protected by Biomimetic Membrane with Carbon Nanotube Porins**

XI CHEN (Presenter), University of California, Merced; Lawrence Livermore National Laboratory, HUANAN ZHANG, RAMYA H TUNUGUNTLA, Lawrence Livermore National Laboratory, ALEKSANDR NOY, University of California, Merced; Lawrence Livermore National Laboratory — Limited biocompatibility and fouling propensity can restrict real-world applications of a large variety of biosensors. Biological systems are adept at protecting and separating vital components of biological machinery with semipermeable membranes that often contain defined pores and gates to restrict transmembrane transport only to specific species. Here we use a fouling-resistant membrane, which mimic the architecture of cellular membranes in nature to protect biosensors. We integrate silicon nanoribbon transistor sensors with an antifouling lipid bilayer coating that contains carbon nanotube porin (CNTP) channels and demonstrate robust detection of proton and cations in a variety of complex biological fluids. Preliminary results of CNTP as a conduit bridging through cell membranes are also discussed.
Iron Oxide Nanoparticles with Controlled Size and Shape

SHIRIN POURMIRI (Presenter), University of Delaware, VASILEIOS TZITZIOS, chemical engineering, Khalifa University of Science and Technology, GEORGE C HADJIPANAYIS, University of Delaware — Controlling the shape of Fe₃O₄ particles is still a big challenge. It has been shown that the SAR value for hyperthermia measurements, has been related to the magnetic anisotropy of the nanoparticles which depends on their size and shape [1]. Therefore, it’s very important to control the shape and the size of Fe₃O₄ nanoparticles precisely.

Here, a simple approach for synthesizing Fe₃O₄ nanoparticles is studied. The synthesis takes place in an oleylamine/dodecylamine solution, using Fe(acac)₃ as the Iron precursor. The XRD measurements, show a pure Fe₃O₄ phase. It is observed that the nanoparticles made with Oleylamine-Oleic acid mixture, are completely spherical; however, the shape of nanoparticles synthesized with Dodecylamine-Octadecene mixture, could be easily changed from spherical to facet. It is shown that by decreasing the amount of dodecylamine from 10 to 2.5 mmol, the nanoparticles start having a more facet shape than spherical shape. Also, the size of particles in both cases was controlled by changing the temperature and time. Our data show that by changing the reaction temperature from 220 to 250 °C, the average diameter of nanoparticles can be increased from 1-3 nm to 8-10 nm.

Resonance Energy Transfer in Arbitrary Media: Two Entangled Photons*

KOBRA NASIRI AVANAKI (Presenter), Northwestern University — We report the resonance energy transfer between two uncoupled two-level atoms jointly excited by temporally entangled field. The virtual photons arising from three-level cascade decay are inherently ordered in time of emission. Since the induced joint resonance in two-atom excitation probability comes from the field correlation and the suppression of one of the time-ordered excitation pathways, we see the rate in two-photon energy transfer increases with the time-frequency entanglement. This is justifying the enhancement of energy transfer through the entangled two-photon by a large factor as compared to uncorrelated photons. Based on the new formulation derived here and due to the permanent entangled field interacting with the system over the time scale of energy transfer, the rate depends on the emitter’s properties dominantly. The situation would be more complicated if the process mediated by inhomogeneous, dispersive media.

Electrochemical Hydrogen Evolution Reaction of Supported Pt Nanoclusters on MoS₂: Cluster Expansion Investigation

TIMOTHY YANG, University of Pittsburgh, TECK TAN, Institute of High Performance Computing Singapore, WISSAM SAIDI (Presenter), University of Pittsburgh — Supported metal nanoclusters on MoS₂ have shown catalytic activity towards hydrogen evolution reaction (HER) that is comparable or better than bulk Pt. We use density functional theory calculations in conjunction with cluster expansion and ab initio thermodynamics to investigate the activity of supported Ptnanoclusters on MoS₂. We determine the hydrogen adsorption configurations under HER conditions by including multiple adsorption sites. Our results show that both Volmer-Heyrovsky and Volmer-Tafel reactions are facile on the cluster while as only the Volmer-Tafel reaction is observed for Pt (111) surfaces. This results in enhanced catalytic activity of the nano cluster. The underpinning of this behavior is discussed.

Ab-initio investigation of water adsorption and hydrogen evolution on Co₉S₈ and Co₃S₄ low index surfaces*

MARCO FRONZI (Presenter), International Research Centre for Renewable Energy, Xi'an Jiaotong University, HUSSEIN ASSADI, Center for Computational Sciences, University of Tsukuba, MICHAEL J. FORD, School of Mathematical and Physical Sciences, University of Technology, Sydney — We used density functional theory approach, with the inclusion of a semi-empirical dispersion potential to take into account van der Waals interactions, to investigate the water adsorption and dissociation on cobalt sulphides Co₉S₈ and Co₃S₄ (100) surfaces. We first determined the nanocrystal shape and selected representative surfaces to analyse. We then calculated water adsorption and dissociation energies, as well as hydrogen and oxygen adsorption energies, and we found that sulphur vacancies on Co₉S₈ (100) surface enhance the catalytic activity toward water dissociation by raising the energy level of un-hybridized Co3d states closer to the Fermi level. Sulphur vacancies, however, do not have a significant impact on the energetics of Co₃S₄ (100) surface.

L70.00391: Modifying H2 adsorption and desorption on palladium using polymers – a first-principles study  LUCY CUSINATO, ANDERS HELLMAN (Presenter), Chalmers University of Technology — In a future hydrogen-based energy system it will be crucial to have sensors that are able to detect hydrogen leaks immediately. DOE has proposed very demanding performance targets, and in an effort to meet these, optical nanoplasmonic hydrogen sensors based on hydride-forming palladium nanoparticles have been introduced. Experimentally, the presence of metal-organic frameworks or polymers has been shown to lower the apparent activation energy of hydrogen adsorption/desorption. Here, we study this phenomenon from a theoretical (using DFT) point of view. The behavior of palladium and palladium hydride nanoparticles towards H2 adsorption and desorption, with and without polymer (PTFE, PVDF and PMMA) coating, is studied. A particular focus is set on how to model this kind of nanoparticle/polymers systems for the case of bare and hydride palladium. Stability of palladium hydride nanoparticles is studied, as well as different types of interaction at the Pd-polymer interface. These results are then used to shed light on how the presence of polymers, and the existence of a palladium/polymer interface, can affect the kinetics and thermodynamics of the system in order to facilitate H2 adsorption and desorption processes.

L70.00392: The role of potassium on CO oxidation  BIN DI (Presenter), College of Chemistry and Molecular Engineering, Peking University — Alkali metals are regarded as promoters in many catalysts which can promote the reaction rate of various chemical processes including ammonia synthesis, CO oxidation, the water-gas shift reaction and so on. However, an unambiguous picture of how alkali metals impact catalytic activity have not been drawn. In order to uncover alkali-metals promotion effect, we focus on the chemical and physical properties of atomically dispersed alkali metal, such as atomic potassium, supported on ultrathin metal oxide film and the interaction of alkali metals with noble metals which possess promotion effect, we focus on the chemical and physical properties of atomically dispersed alkali metal, such as atomic potassium, supported on ultrathin metal oxide film and the interaction of alkali metals with noble metals which possess promotion effect. Au/CuO can catalyze CO oxidation in a relative low temperature. Using K/CuO/Cu(110) model system, we investigate the potassium atoms in low coverage on one monolayer CuO and K-Au interaction.

L70.00393: Alkali Metals on Ultrathin Oxide Surface: A Low-Temperatruce STM research  ZHANTAO PENG (Presenter), CCME, Peking University — Alkali metal plays an important role in heterogeneous catalysis, semiconductor physics, superconducting physics and has received extensive attention in its adsorption behavior and electronic properties on both single crystal surface and oxide surface. In this report, a low-temperature scanning tunneling microscopy (LT-STM) is employed to investigate the behavior of alkali metal on ultrathin CuO surfaces. While the electronic properties of some transitional metals atoms on such an oxide surface can be dramatically affected by the co-adsorption alkali metals.

L70.00394: Structure, magnetic properties, and thermal stability of chemically prepared nickel carbide nanoparticles*  GRANT LU, Charter High School, JEROME R TROY, GERALD R POIRIER, RODDEL REMY, KARL UNRUH (Presenter), University of Delaware — Single phase nickel carbide nanoparticles and phase separated nickel carbide/elemental nickel nanocomposites have been prepared by the reduction of nickel acetate in triethylene glycol at reduction temperatures between 250 and 290 °C. The structure, magnetic properties, and thermal stability of these samples have been studied by x-ray diffraction (XRD), vibrating sample magnetometry (VSM), and differential scanning calorimetry (DSC) measurements. The XRD measurements indicate that the nickel carbide phase is hexagonal (S.G. 167) with lattice parameters of a=0.45908(1) and c=1.30080(3) nm; somewhat larger values than previously reported. The hexagonal phase has a room temperature magnetization of about 0.2 emu/g and a Curie temperature of about 330 °C. At a heating rate of 10 °C/min the hexagonal phase irreversible transforms to face-center-cubic elemental nickel starting at a temperature of about 380 °C.

L70.00395: Collective cell migration induced by the interplay of contractile force and adhesion with delay under ERK signal propagation.  TATSUYA FUKUYAMA (Presenter), HIROYUKI EBATA, Kyushu University, YOHEI KONDO, National Institute for Basic Biology, SATORU KIDOAKI, Kyushu University, KAZUHIRO AOKI, National Institute for Basic Biology, YUSUKE T. MAEDA, Kyushu University — Collective migration is ubiquitously observed in epithelial cell sheets during wound healing and morphogenesis. For epithelial MDCK cells, ERK MAP kinase forms solitary wave and propagate across migrating cells. Cells orient their directions of migration oppose to the ERK wave, however, their guidance is distinct from tactic behavior. To understand the underlying mechanism of ERK directed collective migration, we propose simple theoretical model where interplay of focal adhesion and contractile force is regulated by ERK signal. Given that ERK signal locally increases both contractile force and focal adhesion onto substrate, we construct the equation of force-balance between viscous cellular fluid and dissipative friction. When ERK signal moves in two-dimensional space, local gradients of enhanced contractile force and reduced friction make viscous cell body easily streamed. Then, the net motion of fluids occurs and its velocity is given by an analytical solution. We test theoretical result by using optogenetic control of cell migration and find that cells are steered opposite to synthetic ERK signal. Our finding, including optimal velocity of cell migration against ERK wave, suggests the guidance of collective migration is driven by dissipative mechanics of cells.
The Heusler System And How You Can Use It As A Lego Box To Build The States You Are Interested In

CLAUDIA FELSER (Presenter), Max Planck Institute for Chemical Physics of Solids — The periodic table becomes one hundred years old just this year. The family of Heusler compounds uses nearly all the elements in the Periodic Table to allow for the design of materials with all sorts of properties. These include: hard and soft magnets, shape memory and magnetocaloric metals, thermoelectric semiconductors, topological insulators, and Weyl semimetals. These are just a few examples of more than 1000 known members of this remarkable class of materials that can display such a wide range of extraordinary multifunctional and tunable properties. Many more remain to be discovered! Just like a box of Lego bricks we can put together certain atoms (valence electrons), arranged in a particular symmetry, to achieve a desired electronic energy band structure. A necessary precondition for such a straightforward approach is a single particle picture: this allows for the prediction of many properties in this versatile class of materials, and equally enables “inverse design”. In my talk I will discuss the simple rules that we have learned to date and what the future might portend for further additions to the large and ever-growing Heusler family.

Stacking atomic layers one by one: quest for new materials and physics

PHILIP KIM (Presenter), Harvard University — Modern electronics has been heavily relied on the technology to confine electrons in the interface layers of semiconductors. In recent years, scientists discovered that various atomically thin materials including graphene, a single atomic carbon layer, can be isolated. In these atomically thin materials, quantum physics allows electrons to move only in an effective 2-dimensional (2D) space. By stacking these 2D quantum materials, one can also create atomic-scale heterostructures with a wide variety of electronic and optical properties. I will discuss the creation of new heterostructures based on atomically thin materials and emerging new physics with technological implications therein.

The Design And Growth Of Ultra-Stable Glasses

MARK EDIGER (Presenter), University of Wisconsin - Madison — Glasses are generally regarded as highly disordered and the idea of “controlling” molecular packing in glasses is reasonably met with skepticism. However, as glasses are non-equilibrium materials, a vast array of amorphous structures are possible in principle. Physical vapor deposition (PVD) allows a surprising amount of control over molecular packing in glasses and can be used to test the limits of amorphous packing in two ways. PVD can prepare glasses that approach the limits of the most dense and lowest energy amorphous packings that are possible. The activation barriers for rearrangements in these materials are very high, giving rise to high thermal and chemical stability. In addition, PVD allows control over anisotropic packing in glasses. For rod-shaped molecules, for example, glasses can be prepared in which the molecules have a substantial tendency to stand-up or lie-down relative to the substrate. As these materials have applications in organic electronics, an important question is: How much anisotropic order can be added to a glass without destroying key technological advantages such as macroscopic homogeneity? The high density and anisotropic packing of PVD glasses can be explained by a mechanism that is “anti-epitaxial” as structure is templated by the top surface rather than by the underlying substrate.

*Support from DOE (DE-SC0002161) and the UW-Madison MRSEC (NSF DMR-1720415) is gratefully acknowledged.
Colloidal Crystals, Quasicrystals and the Entropic Bond [Invited] SHARON GLOTZER (Presenter), University of Michigan — Entropy, information, and order are important concepts in many fields, relevant for materials to machines, for biology to economics. Entropy is typically associated with disorder; yet, the counterintuitive notion that particles with no interactions other than excluded volume might self-assemble from a fluid phase into an ordered crystal has been known since the mid-20th century. First predicted for rods, and then spheres, the ordering of hard shapes by nothing more than crowding is now well established. In recent years, surprising discoveries of entropically ordered colloidal crystals of extraordinary structural complexity have been predicted by computer simulation and observed in the laboratory. Colloidal quasicrystals, clathrate structures, and structures with large and complex unit cells typically associated with metal alloys, can all self-assemble from a disordered phase of identical particles due solely to entropy maximization. These findings demonstrate that entropy alone can produce order and complexity beyond that previously imagined. They also suggest that, in situations where other interactions are present, the role of entropy in producing order may be underestimated. We present the latest discoveries for entropic systems of identical particles, including a Bergman-like phase with a 432-particle unit cell, and fluid-fluid transitions preceding crystallization that are reminiscent of liquid-liquid phase separation in water, proteins, and even within cells. To understand these phenomena, and in loose analogy with traditional chemical bonds that produce order in atomic and molecular substances, we introduce the notion of the entropic bond.

Intracellular Liquid Condensates: New approaches to understand and control biomolecular phase transitions in living cells [Invited] CLIFF BRANGWYNNE (Presenter), Princeton University — In this talk I will discuss our work to understand and engineer intracellular phase transitions, which play an important role in organizing the contents of living cells. Membrane-less RNA and protein rich condensates are found throughout the cell, and regulate the flow of genetic information. We’ve shown that liquid-liquid phase separation (LLPS) underlies the assembly of these structures. LLPS driven by intrinsically disordered protein regions (IDRs) explains many condensate features, for example the internal subcompartments of the nucleolus, which has important consequences for sequential ribosomal RNA processing. Our lab has developed a suite of new approaches, which use light to enable spatiotemporal control of intracellular phase transitions, allowing us to engineer the assembly and disassembly of these structures within defined subregions of the cytoplasm and nucleus. We are now using these tools to quantitatively map intracellular phase diagrams for the first time, providing unprecedented access to the biophysical principles underlying RNP condensate self-assembly. This approach has also begun to yield rich insights into the link between intracellular liquids, gels, and the onset of pathological protein aggregation, and still largely unexplored mechanical interactions between these structures and the genome.

Wednesday, March 6, 2019 2:30 PM - 5:30 PM

Session P01 DCMP: Fractional Quantum Hall Effect: New Systems BCEC 106 - Robert Willett, Bell Labs

Single photon Chern insulator in superconducting microwave lattices* CLAI OWENS (Presenter), BRENDAN SAXBERG, RUICHAO MA, JONATHAN SIMON, DAVID SCHUSTER, Physics, University of Chicago — We present the latest progress in developing a novel architecture for exploration of topological quantum matter. We construct microwave photonic lattices from tunnel-coupled, time-reversal-broken microwave cavities that are both low loss and compatible with Josephson junction-mediated photon-photon interactions, allowing us access to topological phenomena such as the fractional quantum Hall effect. We employ seamless 3D microwave cavities all machined from a single block of niobium, so our meta-material is scalable and directly compatible with the cQED toolbox, as it is composed only of niobium for the cavities, plus Yttrium-Iron-Garnet (YIG) spheres and Neodymium magnets to produce the synthetic magnetic field. After observing topologically protected chiral edge states with microsecond lifetimes circling the superconducting lattice, we now push to couple tunable qubits to the lattice in order to make lattice sites nonlinear and create particle interactions.

*Support was provided by the Chicago MRSEC, which is funded by NSF through grant DMR-1420709. This work was also supported by ARO Grant No. W911NF-15-1-0397. This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. DGE-1746045.
**2:42PM P01.00002: Cu[Li$_{1/3}$Sn$_{2/3}$]O$_2$ and Cu[Na$_{1/3}$Sn$_{2/3}$]O$_2$: Crystal Structure and Phonon Dispersion in Quaternary Honeycomb Delafossites**

FARANAK BAHRAMI (Presenter), MYKOLA ABRAMCHUK, Physics, Boston College, OLEG I. LEBEDEV, Laboratorie CRISMAT, ENSICAEN-CNRS, OLLE HELLMAN, Division of Engineering and Applied Science, California Institute of Technology, NATALIA E. MORDVINova, Laboratorie CRISMAT, ENSICAEN-CNRS, JASON W. KRIZAN, Physics, Boston College, KENNETH METZ, Chemistry, Boston College, DAVID A BROIDO, FAZEL FALLAH TAFTI, Physics, Boston College — Magnetic materials with spin-1/2 ions on a two dimensional honeycomb lattice are candidates for a Kitaev spin liquid phase. The study of non-magnetic honeycomb delafossites provides a basis to model the physical properties of magnetic honeycomb materials. Here, we report two new quaternary non-magnetic delafossites, Cu[Li$_{1/3}$Sn$_{2/3}$]O$_2$ and Cu[Na$_{1/3}$Sn$_{2/3}$]O$_2$, with honeycomb ordering synthesized via a topotactic cation-exchange reaction. The monoclinic C2/c space group and twinned stacking faults are determined from the Rietveld refinement and TEM analysis. Additionally, the phonon heat capacity for these non-magnetic layered oxides is captured accurately by first principles calculations. These results are an important step toward having a reliable model to calculate phonon contribution to the heat capacity in magnetic delafossites\(^1\).

**2:54PM P01.00003: Observation of Chiral Surface Excitons in a Topological Insulator Bi$_2$Se$_3$*  

HSIANG-HSI KUNG (Presenter), Quantum Matter Institute, University of British Columbia, ADAMYA P GOYAL, DMITRII MASLOV, Department of Physics, University of Florida, XUEYUEN WANG, ALEXANDER LEE, Department of Physics, Rutgers University, ALEXANDER KEMPER, Department of Physics, North Carolina State University, SANG-WOOK CHEONG, GIRSH E BLUMBERG, Department of Physics, Rutgers University — Photoluminescence (PL) emission arising due to recombination of excitons in conventional semiconductors is usually unpolarized because of scattering by collective modes during exciton thermalization. Here on the contrary, we observe almost perfectly polarization-preserving PL peak centered at 2.3 eV from the surface of an archetypical three-dimensional topological insulator (TI), Bi$_2$Se$_3$. Based on the dependences of the PL spectra on the energy and polarization of incident photons, we propose that the observed PL can be semi-quantitatively explained by composite particles – chiral excitons – formed by the Coulomb attraction between massless (Dirac) electrons and massive holes, both subject to strong spin-orbit coupling which locks their spins and momenta into chiral textures. We experimentally demonstrate that the chiral excitons can be optically oriented with circularly polarized light in a broad range of excitation energies between 2.5 to 2.8 eV, and that the orientation remains preserved even at room temperature.

**3:06PM P01.00004: Spin wave transport through electron solids and fractional quantum Hall liquids in graphene**

HAOXIN ZHOU (Presenter), HRYHORIY POLSHYN, Department of Physics, University of California, Santa Barbara, CA 93106, USA, TAKASHI TANIGUCHI, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, Tsukuba, Ibaraki 305-0044, Japan, ANDREA YOUNG, Department of Physics, University of California, Santa Barbara, CA 93106, USA — In monolayer graphene, the interplay of electronic correlations with the internal spin- and valley- degrees of freedom leads to a complex phase diagram of isospin symmetry breaking at high magnetic fields. Recently, Wei et al. (Science (2018)) demonstrated that spin waves can be electrically generated and detected in graphene heterojunctions, allowing direct experiment access to the spin degree of freedom. Here, we apply this technique to high quality graphite-gated graphene devices showing robust fractional quantum Hall phases and isospin phase transitions. We use an edgeless Corbino geometry to eliminate the contributions of edge states to the spin-wave mediated nonlocal voltage, allowing unambiguous identification of spin wave transport signatures. Our data reveal two phases within the $v = 1$ plateau. For exactly $v=1$, charge is localized but spin waves propagate freely while small carrier doping completely quenches the low-energy spin-wave transport, even as those charges remain localized. We identify this new phase as a spin textured electron solid. We also find that spin-wave transport is modulated by phase transitions in the valley order that preserve spin polarization, suggesting that this technique is sensitive to both spin and valley order.
separating kernel and non-kernel states becomes more interesting because certain of these models (e.g., the "Gaffnian") are related to a non-unitary cft which is now believed to mean that they have gapless bulk excitations in the thermodynamic limit, and perhaps represent critical states at continuous transitions between topologically-distinct FQH states. I will discuss these fundamental questions, and review strategies and progress towards answering them.

conformal field theories (cft). These model Hamiltonians have a non-trivial kernel spanned by a basis of quasi-hole states (quasiparticle) eigenstates of these models, and the persistence of the energy gap in the thermodynamic limit. They have analogies to the AKLT spin-chain model, for which such questions have been answered. The question of proving (or disproving) a lower bound to the spectral gap separating kernel and non-kernel states becomes more interesting because certain of these models (e.g., the "Gaffnian") are related to a non-unitary cft which is now believed to mean that they have gapless bulk excitations in the thermodynamic limit, and perhaps represent critical states at continuous transitions between topologically-distinct FQH states. I will discuss these fundamental questions, and review strategies and progress towards answering them.

realization of high-order non-Abelian excitations* TAILUNG WU, ZHONG WAN, ALEKSANDR KAZAKOV, YING WANG (Presenter), LEONID ROKHINSON, Department of Physics and Astronomy, Purdue University, West Lafayette, Indiana 47907, USA, purdue university — It has been proposed that parafermion excitations can emerge in the fractional quantum Hall effect (FQHE) regime if two counter-propagating chiral edge states with fractionally charged excitations and opposite polarization are brought into close proximity in the presence of superconducting coupling. In this work we present formation of conducting channels at boundaries between incompressible polarized and unpolarized states in FQHE regime. We demonstrate that in a triangular quantum well polarizations of a 2DEG can be locally controlled by electrostatic gating at a filling factor ; Conductance of channels formed at a boundary of polarized and unpolarized phases does not depend significantly on the magnetic field direction, indicating formation of helical domain walls. Such local control of polarization allows formation of a reconfigurable network of domain walls and can provide a platform for parafermion manipulation and braiding when superconductivity is proximity-induced into these domain walls.

Particle-Hole Symmetric Pfaffian* KIRYL PAKROUSKI (Presenter), FREDERICK D HALDANE, Princeton University, EDWARD H REZAYI, Physics, California State University, Los Angeles, JIE WANG, Princeton University, KUN YANG, National High Magnetic Field Laboratory and Department of Physics, Florida State University — A recent experiment of Banerjee et al. [Nature 559, 205 (2018)] measured the thermal Hall conductance to be 5/2 for the ν=5/2 fractional quantum Hall effect. This observation is compatible with the particle-hole symmetric Pfaffian topological order where the chirality of the Majorana edge mode is reversed with respect to that of the Pfaffian. The particle-hole symmetric Pfaffian has not appeared as a viable candidate for the stable gapped phase at ν=5/2 in any numerical calculations for a disorder free system. We construct the particle-hole symmetric Pfaffian wavefunction in sphere and torus geometries for a number of system sizes and study its properties and further investigate the prospect of a particle-hole symmetric Pfaffian topological phase in clean systems.

Study of the inelastic length under microwave photo-excitation in the GaAs/AlGaAs 2D electron system

RASANGA SAMARAWEERA (Presenter), BINUKA GUNAWARDANA, THARANGA NANAYAKKARA, C. RASADI MUNASINGHE, U. KUSHAN WIJEWARDENA, SAIJITH WITHANAGE, ANNIKA KRIISA, Department of Physics and Astronomy, Georgia State University, CHRISTIAN REICHL, WERNER WEGSCHEIDER, Laboratorium für Festkörperphysik, ETH-Zürich, RAMESH MANI, Department of Physics and Astronomy, Georgia State University — Magnetotransport measurements in ultra-high mobility GaAs/AlGaAs 2D electron systems (2DES) exhibit a narrow negative magnetoresistance (MR) effect around the null magnetic field, which is similar in appearance to the well-known weak localization (WL) effect in metals, semiconductors, etc. However, the origin of WL-like effect in high mobility GaAs/AlGaAs 2DES specimens is still under debate. In this experimental work, the results exhibit that the incident microwave (MW) significantly modifies the observed narrow negative-MR feature, such that the WL-like peaks disappear at high power regime. This study aims to examine the influence of MW power on the WL-like effect. Thus, the observed negative-MR data were fit using 2D WL model by Hikami et al., to extract the characteristic inelastic length ($l_i$) as a function of MW power [1]. Results suggest that the fit extracted $l_i$ is reduced by 50% upon increasing the MW power up to 2 mW. Further analysis of the data suggest that MW induced electron heating is partly responsible for the observed reduction in the $l_i$ under photo-excitation.

Interacting topological phases in Fibonacci quasicrystals

POUYAN GHAEMI MOHAMMADI (Presenter), MOSHE FINK, City College of New York, AREG GHAZARYAN, Physics, Austrian IST — Recently it was realized that quasicrystals could exhibit non-trivial topological properties and topological equivalence between different types of quasicrystals (such as the Harper model and the Fibonacci quasicrystal). Exciton-polaritons have been recently employed to experimentally verify both band structure and the topological character of the Fibonacci quasicrystal. Given these recent advancements, it is essential to understand the effects of interactions, such as exciton-exciton interactions, on the topological nature of the states corresponding to topological quasicrystals. In this work, we have studied the interacting topological phases in Fibonacci quasicrystals and examined the possible experimental signatures for the effect of interactions in exciton-polariton systems formed in quasicrystal structures.

Evolution of the line shape of radiation-induced magnetoresistance oscillations under bi-chromatic microwave excitation

BINUKA GUNAWARDANA (Presenter), C.RASADI MUNASINGHE, RASANGA SAMARWEERA, THARANGA NANAYAKKARA, ANNIKA KRIISA, U. KUSHAN WIJEWARDENA, SAIJITH WITHANAGE, Physics and Astronomy, Georgia State University, CHRISTIAN REICHL, WERNER WEGSCHEIDER, Laboratorium für Festkörperphysik, ETH Zürich, RAMESH MANI, Physics and Astronomy, Georgia State University — We examine the evolution of the line shape of radiation-induced magnetoresistance oscillations under bi-chromatic microwave excitation as the microwave power level at one frequency is held fixed and the power level at the other frequency is varied. In order to overcome signal to noise issues in the limit of small oscillations at very low magnetic fields, we applied a double modulation, double lock-in technique where the magnetic field was modulated sinusoidally while applying a small ac-current to the sample. With this approach, it became possible to measure the magnetic field derivative, $dR_{xx}/dB$, of the diagonal resistance, and realize more oscillations, especially in the low $B$-field limit. Thus, while using this double lock in measurement technique, the sample was bi-chromatically excited at various bi-chromatic microwave frequency combinations. Half cycle plots of $dR_{xx}/dB$ reveal that the bi-chromatic response magneto-transport response follows mostly low frequency response at low magnetic field region and starts following the high frequency response at high magnetic field regions. Here we present the results to address the question of whether or not superposition is followed in the bi-chromatic microwave magnetoresistance response.
4:42PM P01.00012: Interferometer parameters that allow observation of non-Abelian e/4 properties.*

ROBERT WILLETT (Presenter), physical sciences, Nokia Bell Labs, KIRILL SHTENGEL, Dept. of Physics, U.C. Riverside, MICHAEL MANFRA, Dept. of Physics, Purdue University, LOREN PFEIFFER, PRISM, Princeton University, SAeed FALLahi, GEOFFREY GARDNER, Dept. of Physics, Purdue University, KENNETH WEST, KIRK BALDWIN, PRISM, Princeton University — Fabry-Perot interferometers have been used to examine 5/2 filling factor, and have shown interference consistent with Abelian e/2 charges and non-Abelian e/4 charges. Simple magnetic field sweeps and independently side gate sweeps can each expose even-odd effects indicating non-Abelian e/4. These results have been compiled using a series of different heterostructure types, different illumination procedures, and different interferometer geometries, sizes, and gate charging procedures. In this talk summary results will be presented, but the focus will be these device parameters and procedures employed to reveal the non-Abelian properties. Central to this effort is the use of heterostructures that require illumination to produce high mobilities. The illumination and charging protocols exercised on different fundamental heterostructure types will be described, including the consequences, both good and bad, on 5/2 interference. Given these advantages and constraints on the 2D electron material systems, means to mitigate problems in the measurements by adjusting the interference devices themselves will be discussed.

4:54PM P01.00013: A Particle-Hole-Symmetric Model for Paired Fractional Quantum Hall States In a Half-filled Landau Level*

MICHAEL PETERSON (Presenter), WILLIAM HUTZEL, JOHN MCCORD, California State University, Long Beach, PETER RAUM, BEN STERN, Virginia Tech, HAO WANG, Southern University of Science and Technology, VITO SCAROLA, Virginia Tech — The fractional quantum Hall effect (FQHE) observed at half filling of the second Landau level is believed to be caused by a BCS-type pairing of composite fermions captured by the Moore-Read Pfaffian wave function. The generating Hamiltonian for the Moore-Read Pfaffian is a purely three-body model that breaks particle-hole symmetry and lacks properties expected from a physical model. We use exact diagonalization to study the low energy states of a more physical two-body generator model derived from the three-body model. We find that the two-body model exhibits the essential features expected from the Moore-Read Pfaffian: pairing, non-Abelian anyon excitations, and a neutral fermion mode. The model also satisfies constraints expected for a physical model of the FQHE at half-filling because it is: short range, spatially decaying, particle-hole symmetric, and has a roton mode with a robust spectral gap in the thermodynamic limit. Hence, this two-body model offers a bridge between exact generator models of paired states and the physical Coulomb interaction and can be used to further explore properties of non-Abelian physics in the FQHE.

5:06PM P01.00014: Spin-resolved tunneling in the fractional quantum Hall effect regime*

HEUN MO YOO (Presenter), Massachusetts Institute of Technology, LOREN PFEIFFER, KIRK BALDWIN, KENNETH WEST, Electrical Engineering, Princeton University, RAYMOND ASHOORI, Massachusetts Institute of Technology — Strong Coulomb interactions and internal spin degrees of freedom lead to a plethora of correlated electronic phases in quantum Hall (QH) systems. Despite the successes of nuclear magnetic resonance and optical techniques, spin-sensitive measurements have remained challenging, particularly at low carrier density or in higher Landau levels (LLs). Here we introduce a new method, spin-resolved tunneling, that can probe the spin texture of both the ground and excited states of QH systems. We establish a complete phase diagram of the ground-state spin in a wide range of filling factors $\nu$ and magnetic fields. Our phase diagrams show the detailed structure of the composite fermion (CF) phases in the lowest LL, in which the changes in the Zeeman energy and $\nu$ drive phase transitions between the spin-unpolarized, the spin-polarized, and the topological spin skymion states. On the other hand, the non-Laughlin correlated behavior, such as the absence of spin transitions at $\nu = 2 + 1/2$ and $2 + 2/3$ states, is observed in the first excited LL, where the conventional CF picture is no longer valid due to the softened pair interactions.

5:18PM P01.00015: Symmetry protected Luttinger liquids in Quantum Hall Ferromagnets on the surface of Bi(111).*

KARTIEK AGARWAL (Presenter), McGill University, MALLIKA RANDERIA, SHIVAJI SONDHI, ALI YAZDANI, Princeton University, SIDDHARTH PARAMESWARAN, University of Oxford — Quantum Hall Ferromagnets are a unique platform to study the confluence of symmetry-broken order parameter and topology. Recent experiments by Feldman et al.[1] observe clear signatures of valley-polarized Quantum Hall Ferromagnets on the surface of Bi(111) in the presence of strong magnetic fields. The tunneling conductance shows a discrete spectrum indicating the formation of Landau levels while individual nematic Landau level orbits pinned to impurities indicate selective occupation of certain valleys. Further recent experiments[2] observe domain wall states between such nematic domains. Most curiously, domain walls between these domains appear to host low energy excitations that appear to be gapped/gapless depending upon the filling fraction of the nematic quantum Hall states. We explain[3] these observations both qualitatively and quantitatively by highlighting the role of interactions and symmetries in engendering such exotic Luttinger liquids.

Session P02 DMP: Topological Materials -- New Theoretical Approaches BCEC 107A - Ying Ran, Boston
Coll - Tag(s): Focus

2:30PM P02.00001: Topological band structures in electric circuits* TOBIAS HELBIG (Presenter), TOBIAS HOFMANN, Institute for Theoretical Physics and Astrophysics, University Wuerzburg, CHING HUA LEE, Department of Physics, National University of Singapore, MARTIN GREITER, RONNY THOMALE, Institute for Theoretical Physics and Astrophysics, University Wuerzburg — Topolectrical circuits [C.H. Lee at al., Comm. Phys. 1,39] present themselves as a platform to investigate fundamental topological states of matter realized in classical synthetic crystals. The manifold degrees of freedom unfolding as lattice connectivity and parameter choice in electric networks enable the implementation of arbitrary tight-binding models. We report on the design, measurement and engineering of admittance band structures in periodic circuits [T. Helbig, T. Hofmann et al., arXiv:1807.09555v1] providing an extensive symmetry classification. Furthermore, we review the effect of individual constituents on the presence of global symmetries. We employ our approach on explicating several examples reaching from the Su-Schrieffer-Heeger and the graphene model over the implementation of a Chern state [T. Hofmann, T. Helbig et al., arXiv:1809.08687v2] up to the realization of non-Hermitian physics in this classical environment.

2:42PM P02.00002: Topological Superconductivity in Honeycomb Dirac Systems* TAMAGHNA HAZRA (Presenter), KYUNGMIN LEE, MOHIT RANDERIA, NANDINI TRIVEDI, Ohio State University — There has been a surge of recent interest in superconductivity (SC) in 2D Dirac materials ranging from transition metal dichalcogenides to twisted bilayer graphene. It is important to understand the precise conditions under which one obtains a topological SC state in such systems. We address this question in the simplest honeycomb lattice models that hosts both topological and trivial insulating states in 2D: the Kane-Mele (KM) model for spin-1/2 fermions and the Haldane model for spinless fermions. We describe the results of our extensive self-consistent Bogoliubov-deGennes calculations [1] for these models with a variety of pairing interactions, and show that topological SC states arise only for nearest-neighbor attraction. In the KM model, we find four distinct SC phases, all with finite center-of-mass momentum pairing. Two of these are topological SCs: one a helical spin-triplet SC which is time-reversal invariant and another a chiral spin-triplet SC with Chern number ±1 with equal-spin pairing in one valley and opposite-spin triplet pairing in the other valley. We also discuss possible experimental signatures of these phases.

*Work supported by NSF DMR-1410364 (TH and MR) and NSF DMR-1629382 (KL and NT).
2:54PM P02.00003: Haldane Circuit*  TOBIAS HOFMANN (Presenter), TOBIAS HELBIG, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg, CHING HUA LEE, Department of Physics, National University of Singapure, MARTIN GREITER, RONNY THOMALE, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg — We propose an implementation of the Chern state in a topological circuit network, featuring topologically protected, unidirectional propagation of voltage packages at its boundary [T. Hofmann, T. Helbig, et al., arxiv:1809.08687]. Recently, electric circuit arrays have been established as an easily accessible and tunable environment to host synthetic topological states of matter [C. H. Lee, et al., Comm. Phys. 1, 39; T. Helbig, T. Hofmann, et al., arxiv:1807.09555]. The breaking of reciprocity and time-reversal symmetry as well as minimizing dissipation effects constitute the central challenges arising in a circuit realization of the Chern state. In this talk, we present operational amplifiers in a negative-impedance converter configuration as the key component to master these challenges. We report on our results of a dissipation-corrected circuit implementation of the Haldane model.

*This work is supported by ERC-StG-TOPOLECTRICS-336012 and DFG-SFB 1170 (Project B04).

3:06PM P02.00004: Theory of Topological Phases and Topological Band Engineering of Graphene Nanoribbons* TING CAO (Presenter), Physics Department, UC Berkeley and Geballe Laboratory for Advanced Materials, Stanford University, FANGZHOU ZHAO, STEVEN G. LOUIE, Physics Department, UC Berkeley and Lawrence Berkeley National Lab — Using first-principles and model Hamiltonian calculations, we show that 1D symmetry-protected topological phases exist in graphene nanoribbons (GNRs). Semiconducting GNRs of different width, edge shape, and terminating unit cells can belong to electronic topological classes characterized by different values of a $Z_2$ invariant. Interfaces between topologically distinct GNRs characterized by different $Z_2$ are predicted to support robust in-gap topological interface states which can be utilized as a tool for material engineering. The experimental realizations of these predictions and rational design of topologically-engineered GNR superlattices synthesized from molecular precursors have been achieved. We present here the theoretical basis and calculations for these states, showing novel robust electronic bands with desirable properties. We discuss how this manifestation of 1D topological phases may be used in future studies of 1D quantum spin physics.

Computational resources have been provided by DOE at NERSC and the NSF through XSEDE resources at NICS.

3:18PM P02.00005: Spin-orbit torques in topological superconducting hybrid structures  CECILIA HOLMQVIST (Presenter), ADAM SZEWCZYK, CARLO CANALI, Linnaeus University — Dirac materials with strong spin-orbit interaction have been shown to generate large surface spin accumulations in response to applied currents. Such materials have, in addition, been demonstrated to exert spin-orbit torques on adjacent ferromagnetic structures. This magnetoelectric effect in these materials is strong due to the efficient spin-momentum locking. In heterostructures consisting of superconductors and three-dimensional superconductors, this spin-momentum locking leads to an induced unconventional superconductivity that may be useful for superconducting spintronics. Here, we investigate theoretically the quantum transport properties of a ballistic junction consisting of two topological superconductors coupled over a quantum dot that is coupled to a ferromagnet. The spin-orbit torques acting on the ferromagnet are examined and are shown to depend strongly on the magnetization direction relative to the current direction.

3:30PM P02.00006: Topological Mechanics from Supersymmetry* MICHAEL LAWLER (Presenter), Department of Physics, Cornell University, USA, JAN ATTIG, Institute for Theoretical Physics, University of Cologne, Germany, KRISHANU ROYCHOWDHURY, Department of Physics, Cornell University, USA, SIMON TREBST, Institute for Theoretical Physics, University of Cologne, Germany — In topological mechanics, the identification of a mechanical system's rigidity matrix with an electronic tight-binding model allows inferring topological properties of the mechanical system, such as the occurrence of 'floppy' boundary modes, from the associated electronic band structure. Here we introduce an approach to systematically construct topological mechanical systems by an exact supersymmetry (SUSY) that relates the bosonic (mechanical) and fermionic (e.g. electronic) degrees of freedom. As examples, we discuss mechanical analogs of the Kitaev honeycomb model and of a second-order topological insulator with floppy corner modes. Our SUSY construction naturally defines hitherto unexplored topological invariants for bosonic (mechanical) systems, such as bosonic Wilson loop operators that are formulated in terms of a SUSY-related fermionic Berry curvature.

*We gratefully acknowledge the hospitality of the Kavli Institute for Theoretical Physics, supported by NSF PHY-1125915, where this work was initiated during the “Intertwined orders” program. The Cologne group acknowledges partial funding from the DFG within CRC 1238 (project C02) and CRC/TR 183 (project B01).
3:42PM P02.00007: Effects of electric field on topological phases in graphene nanoribbons

FANGZHOU ZHAO (Presenter), TING CAO, STEVEN G. LOUIE, University of California, Berkeley — We have recently shown that graphene nanoribbons (GNRs) host distinct topological phases. By first-principles calculations and tight-binding methods, we demonstrated that GNRs of different width, edge shape and end terminations can belong to different topological classes characterized by a $Z_2$ invariant. Electric field, on the other hand, is also an essential external element that can be used to tune the electronic properties of nanomaterials such as their band gaps. We thus carry out studies on the effects of electric field on the topological phases in various graphene nanoribbons by first-principles calculations.

*This work is supported by the National Science Foundation (NSF), the NSF Center for Energy Efficient Electronics Science, the Department of Energy, and the Office of Naval Research under the MURI Program. Computational resources have been provided by DOE at Lawrence Berkeley National Laboratory's NERSC facility.

3:54PM P02.00008: Engineering of Chern insulators through defects

EMMA MINARELLI, School of Physics, University College Dublin, KIM PÖYHÖNEN, Department of Applied Physics, Aalto University, GERWIN VAN DALUM (Presenter), Institute for Theoretical Physics, Utrecht University, TEEMU OJANEN, Department of Applied Physics, Aalto University, LARS FRITZ, Institute for Theoretical Physics, Utrecht University — Impurities embedded in electronic systems induce bound states which can hybridize and lead to impurity bands. Recently, doping of insulators with impurities has been identified as a promising route towards engineering electronic topological states of matter. We illustrate how to engineer Chern insulators starting from a three-dimensional topological insulator with a gapped surface that is intentionally doped with magnetic impurities. The main advantage of the protocol is that it is robust and independent of details, always leading to a Chern insulator supporting a topological phase with Chern number one.

4:06PM P02.00009: Symmetry Indicators of Band Topology

[Invited] HOI CHUN PO (Presenter), Massachusetts Institute of Technology — Topological invariants of band structures are generally defined using the Bloch wave functions, which make them challenging to compute in realistic first-principles calculations. Spatial symmetries, however, can provide very powerful shortcuts for diagnosing certain classes of topological materials, as is epitomized by the Fu-Kane criterion for inversion-symmetric topological insulators. I will describe our theory of symmetry indicators\(^1\), which utilizes symmetry data in a maximal manner to diagnose band topology in any symmetry setting, including magnetic materials\(^2\). Aside from serving as an anchor for a more unified theoretical treatment of topological crystalline insulators\(^3\), the simplicity of the theory allows us to perform a comprehensive database search and uncovers thousands of topological materials\(^4\).

4:42PM P02.00010: Anomalous Hall Effect in Symmetry Protected Topological Metals

XUZHE YING (Presenter), ALEX KAMENEV, University of Minnesota — Anomalous Hall effect is known to have several major contributions, including the intrinsic contribution from the Berry phase of Bloch electrons and skew scattering from impurities. Previously we showed that there exists a class of materials dubbed as symmetry protected topological (SPT) metals. In SPT metals, the intrinsic part of the Hall conductivity shows a discontinuity over the topological phase transition. Such a discontinuity is protected by a certain symmetry, like the particle-hole symmetry.

In this work, we studied the skew scattering contribution to the thermal Hall conductivity in such a system. Our model is based on a two dimensional $p+ip$ superconductor with a supercurrent applied in a particular direction. This system breaks time reversal symmetry which is necessary for skew scattering processes. The disorder potential is modeled by a delta potential. The scattering matrix is calculated self-consistently with the Lippman-Schwinger equation. With the help of the Boltzmann transport equation, we were able to show that skew scattering does not smear out the sharp feature from the intrinsic contribution of the thermal Hall conductivity at the topological phase transition.
4:54PM P02.00011: Classification of flat bands from irremovable discontinuities of Bloch wave functions*
JUN-WON RHIM (Presenter), BOHM-JUNG YANG, Seoul National University — We show that flat bands can be categorized into two distinct classes, that is, singular and nonsingular flat bands. In the case of a singular flat band, its Bloch wave function possesses irremovable discontinuities generated by the band crossing with other bands. This singularity precludes the compact localized states from forming a complete set spanning the flat band. Once the degeneracy at the band crossing point is lifted, the singular flat band becomes dispersive and can acquire a finite Chern number in general, suggesting a new route for obtaining a nearly flat Chern band. On the other hand, the Bloch wave function of a non-singular flat band has no singularity, and thus it can be completely isolated from other bands while preserving the perfect flatness. We show that a singular flat band displays a novel bulk-boundary correspondence such that the presence of the robust boundary mode is guaranteed by the singularity of the Bloch wave function. Moreover, we develop a general scheme to construct a flat band model Hamiltonian in which one can freely design its singular or non-singular nature. Finally, we propose a general formula for the compact localized state spanning the flat band.

*J.-W. Rhim acknowledges the support from Institute for Basic Science (IBS-R009-D1)

5:06PM P02.00012: A membrane-network model for (3+1)D topological phases
AKIN MORRISON (Presenter), MENG HUA, ALEXANDER K SIROTA, CHI YAN JEFFREY TEO, University of Virginia — Non-chiral topological phases in 2D can be understood using the Levin-Wen string-net model. Here, we construct a membrane-network model in 3D. The model has as input a generalized tensor category, which consists of a collection of modular tensor categories and equipped with a non-associative product structure, such as anyon pair condensation, that respects locality. The construction outputs an exactly soluble Hamiltonian in 3D. We speculate this model describes topological phases in 3D that dynamically generate (1+1)D stringy excitations that host low-energy conformal field theories.

5:18PM P02.00013: Hierarchical Majoranas in a Programmable Nanowire Network*
ZHICHENG YANG (Presenter), Boston University, THOMAS IADECOLA, Joint Quantum Institute, CLAUDIO CHAMON, Boston University, CHRISTOPHER M MUDRY, Paul Scherrer Institute — We propose a hierarchical architecture for building “logical” Majorana zero modes using “physical” Majorana zero modes at the Y-junctions of a hexagonal network of semiconductor nanowires. Each Y-junction contains three “physical” Majoranas, which hybridize when placed in close proximity, yielding a single effective Majorana mode near zero energy. The hybridization of effective Majorana modes on neighboring Y-junctions is controlled by applied gate voltages on the links of the honeycomb network. This gives rise to a tunable tight-binding model of effective Majorana modes. We show that selecting the gate voltages that generate a Kekule vortex pattern in the set of hybridization amplitudes yields an emergent “logical” Majorana zero mode bound to the vortex core. The position of a logical Majorana can be tuned adiabatically, without moving any of the “physical” Majoranas or closing any energy gaps, by programming the values of the gate voltages to change as functions of time. A nanowire network supporting multiple such “logical” Majorana zero modes provides a physical platform for performing adiabatic non-Abelian braiding operations in a fully controllable manner.

Wednesday, March 6, 2019 2:30 PM - 5:30 PM
Session P03 DCMP: Surfaces of Topological Systems BCEC 107B
Interaction of the Topological Surface States with Spin Excitons in SmB$_6$ - Dependency on the Crystallinity

Preparation of High-Quality Junctions on SmB$_6$ for Planar Tunneling Spectroscopy

JENNIFER SITTLER (Presenter), LAURA H GREENE, Physics, Florida State University, DAE-JEONG KIM, ZACHARY FISK, Department of Physics and Astronomy, University of California- Irvine, WESLEY T FUHRMAN, JUAN CHAMORRO, SEYED KOOPHAYEH, WILLIAM PHELAN, TYREL MCQUEEN, Institute for Quantum Matter, Johns Hopkins University — Previous works have utilized planar tunneling spectroscopy to investigate the possible topological surface states in SmB$_6$ [1,2]. When superconducting Pb is used as a counter-electrode, the tunneling conductance spectra revealed, coherence peaks with an asymmetrical temperature evolution as well as an additional peak at ~ 5 mV. These features were attributed to inelastic tunneling processes involving the emission and absorption of spin excitons [3,4]. The tunnel barrier in these reproducible junctions was formed by oxidizing the top layer of the SmB$_6$ [1,2]. Improving the junction quality even further, would allow for measurements of the second harmonic, which may reveal additional details about the spin excitons. The preparation of high-quality junctions on SmB$_6$ single crystals and thin films will be discussed. [1] W. K. Park et al., PNAS, 113, 6599 (2016). [2] L. Sun et al., Phys. Rev. B. 95, 195129 (2017). [3] W. T. Fuhrman et al., PRL 114, 036401 (2015). [4] G. A. Kapilevich et al., PRB 92, 085113 (2015).

Magnetize Topological Surface States of Bi$_2$Se$_3$ with a CrI$_3$ Monolayer

YUSHENG HOU, University of California, Irvine, JEONGWOO KIM, Department of Physics, Ulsan National Institute of Science and Technology, RUQIAN WU (Presenter), University of California, Irvine — To magnetize surfaces of topological insulators without damaging their topological feature is a crucial step for the realization of the quantum anomalous Hall effect (QAHE), and still remains as a challenging task. Through density functional calculations, we found that adsorption of a semiconducting two-dimensional van der Waals (2D-vdW) ferromagnetic CrI$_3$ monolayer can create a sizable spin splitting at the Dirac point of the topological surface states of Bi$_2$Se$_3$ films. Furthermore, general rules that connect different quantum and topological parameters are established through model analyses. This work provides a useful guideline for the realization of QAHE at high temperature in heterostructures of 2D-vdW magnetic monolayers and topological insulators.

Topological invariant of S4 protected high-order topological insulator

ZHIDA SONG (Presenter), Department of Physics, Princeton University — The point group symmetry S4 protects a high-order topological state that is gapped on all its 2D surfaces but gapless on a 1D hinge. In this talk, I present a bulk topological invariant of this S4 topology in terms of Wilson loop of Wilson loop. The nonlocal Wilson loop operator provides an effective Hamiltonian on the surface, the Wilson loop of which provides an intuitive understanding of the hinge state. Based on this picture, the breaking of Kirchhoff's law on surfaces are discussed.
3:18PM P03.00005: Bound State Signatures in a Mesoscopic TI Josephson Junction* KONSTANTIN YAVILBERG (Presenter), Physics, Ben-Gurion University of the Negev, ERAN GINOSSAR, Advanced Technology Institute and Department of Physics, University of Surrey, EYTAN GROSFELD, Physics, Ben-Gurion University of the Negev — The engineering of hybrid Josephson junctions has increasingly become a key source in the experimental access to topological superconductivity, as these allow a high degree of robustness and control of their characteristic excitations. Here we consider a device where a topological insulator nanowire of type Bi2Se3 is proximitized to an isolated mesoscopic Josephson junction. Threaded with magnetic flux, the nanowire nucleates two pairs of topologically protected Majorana fermions as well as Andreev bound states in the weak-link. We investigate processes of coherent charge transfer mediated by these low-energy bound states in a mesoscopic setting, and show that they have a notable effect on the fermionic parity of the superconductors, as is evident in the response of the system to electromagnetic radiation.

*This project has received funding from the European Unions Horizon 2020 research and innovation programme under grant agreement No. 766714

3:30PM P03.00006: Topological States in Restrictive Geometries* LIAM O’BRIEN (Presenter), Department of Physics, University of Massachusetts Amherst, KARUNYA SHIRALI, DANIEL E SHEEHY, ILYA VEKHTER, Department of Physics & Astronomy, Louisiana State University — Topological Insulators (TIs) are a novel class of materials possessing symmetry-protected surface states that have promising applications in spintronics and quantum computing. The properties and robustness of TI surface states are well understood for macroscopic samples with flat boundaries, but it is not clearly established what features are retained for curved boundaries - especially when the radius of curvature and/or the sample size are decreased and become comparable to the decay length of the surface states. Consequently, here we investigate the nature of the topological surface states for finite samples with curved interfaces. In particular, we study a model of a 2-dimensional TI with circular boundary of radius R, described by a 4 × 4 Dirac-like Hamiltonian. We present exact solutions for the surface states of this system, derive the effective surface Hamiltonian, and discuss the deviations of the dispersion and spin texture from the flat surface case.

*We thank the National Science Foundation for supporting this work through the REU Site in Physics & Astronomy (NSF grant #1560212) at Louisiana State University; we also acknowledge support though NSF grants DMR-1410741 and DMR-1151717.

3:42PM P03.00007: Observation of quadrupole topological insulators MARC SERRA GARCIA (Presenter), VALERIO PERI, SEBASTIAN D HUBER, ETH Zurich — Many topological phenomena can be understood as a symmetry-induced quantization of the Berry phase, which describes the charge polarization inside the unit cell. This theory relating topology and polarization has been recently extended to higher-order multipolar moments. In this talk, we will discuss experimental observations of a multipolar (quadrupole) topological insulator and quadrupole transitions in phononic and LC-circuit platforms. Our measurements confirm the theoretical predictions and provide a route towards protected wave guides in three dimensional materials.

3:54PM P03.00008: Characterization of Electron Beam Damage to (BixSb1-x)2Te3-Based Topological Insulators* LINSEY RODENBACH (Presenter), ILAN ROSEN, ELI J FOX, Stanford University, LEI PAN, PENG ZHANG, KANG L. WANG, University of California Los Angeles, DAVID GOLDHABER-GORDON, Stanford University — Models for topological superconductivity based on proximitized superconductivity in quantum Hall systems have proven difficult to realize, in part, because high magnetic fields destroy Cooper pairing. The discovery of the quantum anomalous Hall (QAH) effect in Cr- and V-doped (BixSb1-x)2Te3 has attracted attention because it provides a platform to demonstrate the same models of topological superconductivity without high magnetic fields. A remaining barrier is fabrication of the desired structures. Photolithographic patterning has been employed with QAH materials to great effect but lacks the spatial resolution needed to define, for example, Josephson junctions and quantum point contacts. Electron beam lithography has largely been avoided for fear of damaging or doping the QAH material, whose Fermi level must be very precisely positioned to observe the QAH effect. We discuss our efforts to characterize electron beam damage to (BixSb1-x)2Te3-based topological insulators. We also propose possible approaches for submicron patterning involving no electrons hitting the substrate.

Quantum-Hall to insulator transition in ultraclean topological insulator films

MARYAM SALEHI (Presenter), Materials Sci. & Eng., Rutgers University, HASSAN SHAPOURIAN, Physics, University of Chicago, ILAN ROSEN, Applied Physics, Stanford University, MYUNG-GEUN HAN, Condensed Matter Physics and Materials Science, Brookhaven National Lab, JISOO MOON, Materials Sci. & Eng., Rutgers University, PAVELE SHIBAYEV, DEEPTI JAIN, Physics, Rutgers University, DAVID GOLDHABER-GORDON, Physics, Stanford University, SEONGSHIK OH, Physics, Rutgers University — Under a magnetic field, many two-dimensional electronic systems including semiconductor 2DEGs, graphene, and topological insulators (TIs) exhibit quantum Hall effect (QHE), where $R_{xy}$ is quantized at $h/(\nu e^2)$ while $R_{xx} \to 0$. In the high field limit, the QH state gives way to an insulating state in semiconductor 2DEGs as the Fermi level falls into localized states at the tail of the lowest Landau level. However, for a Dirac system such as TIs, the presence of the zeroth Landau level makes it questionable whether such a QH-to-insulator-transition (QIT) should occur at all. Here, in newly-developed ultraclean TI films, we report the first observation of QIT in TIs, with a well-defined scaling behavior. Surprisingly, the scaling analysis revealed the first example of an unconventional QIT behavior distinct from those in 2DEGs. This observation raises new questions on the origin of the insulating phase near the center of the zeroth Landau level in TIs and other Dirac materials as well.

Electronic Properties of Bismuth Iodide (Bi$_4$I$_4$)

YULU LIU (Presenter), RUOYU CHEN, Ohio State University, SHENG LI, XIAOYUAN LIU, University of Texas at Dallas, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, BING LV, FAN ZHANG, University of Texas at Dallas, CHUN NING LAU, Ohio State University — In recent years, topological insulator materials have been attractive to many scientists because of their gapless conductive surface states that are protected against perturbations. Bi$_4$I$_4$ is a quasi-one-dimensional van der Waals material, and its $\beta$-phase is predicted to be a topological insulator, thus offering a new platform for exploring the physics of topological phases. Here we report fabrication and measurement of Bi$_4$I$_4$ devices. Its electrical transport properties are investigated as a function of channel length, electrode materials, mobility and magnetic field.

Local tuning of edge states in a 2D-Topological Insulator quantum well

M. REYES CALVO (Presenter), CIC nanoGUNE, TINEKE VAN DEN BERG, Materials Physics Center (CFM), San Sebastian, Spain, DARIO BERCIOUX, Donostia International Physics Center, San Sebastian, Spain, CHRISTOPH BRÜNE, LAURENS MOLENKAMP, University of Wurzburg, DAVID GOLDHABER-GORDON, Stanford University — We study the conductance of a 2D-Topological Insulator HgTe quantum well device as a function of both the overall density of carriers and the local electric field created by a movable metallic tip. Conductance maps as a function of tip position confirm on the one hand the existence of scattering at the edges due to charge puddles and, on the other hand, show remarkably different behavior for different values of overall carrier density when the tip is positioned above the bulk or the edge areas of the sample respectively. When the bulk is fully depleted, changes in conductance occur only in the case the tip is positioned above the edge - accounting for about a 10% of the unperturbed conductance of the device. The edge areas where the tip has a clear effect in conductance shift towards inner positions of the device bulk with increasing the overall electron doping. These results suggest a scenario where current at the edge is mostly carried by topologically protected Quantum Spin Hall states, in addition to tunable, diffusive extra channels.

Commuting-projector Hamiltonians for 2D time-reversal-invariant fermionic topological phases and many-body topological invariants

JUN HO SON (Presenter), Stanford University, JASON ALICEA, Caltech — Inspired by a recently constructed commuting-projector Hamiltonian for a 2D time-reversal-invariant topological superconductor [Wang et al., Phys. Rev. B 98, 094502 (2018)], we introduce a commuting-projector model that describes an interacting yet exactly solvable 2D time-reversal-invariant topological insulator. We explicitly show that the edge properties of our model, both gapped and gapless, are consistent with those of band-theoretic or weakly interacting quantum spin Hall systems. Additionally, the models for both topological insulators and superconductors can be defined on non-orientable spatial manifolds while retaining the commuting-projector Hamiltonian structure. Ground-state wavefunctions of these models on non-orientable manifolds provide intuitive pictures of many-body topological invariants of time-reversal-invariant fermionic topological phases.
**4:54PM P03.00013: Ferromagnetism in Cr-doped Bi₂Se₃ thin films via surface-state engineering and carrier-selective anomalous Hall effect**  
JISOO MOON (Presenter), NIKESH KOIRALA, Physics and Astronomy, Rutgers, The State University of New Jersey, MARYAM SALEHI, Materials Science and Engineering, Rutgers, The State University of New Jersey, SEONGSHIK OH, Physics and Astronomy, Rutgers, The State University of New Jersey — Anomalous Hall effect (AHE) is a non-linear Hall effect appearing on magnetic conductors, boosted by internal magnetism beyond what is expected from ordinary Hall effect. With the recent discovery of quantized version of the AHE, the quantum anomalous Hall effect (QAHE), in Cr- or V-doped topological insulator (TI) (Sb,Bi)₂Te₃ thin films, AHE in magnetic TIs has been attracting significant interest. However, one of the puzzles in this system has been that while Cr- or V-doped (Sb,Bi)₂Te₃ and V-doped Bi₂Se₃ exhibit ferromagnetic (hysteric) AHE, Cr-doped Bi₂Se₃ has failed to exhibit even ferromagnetic AHE, the necessary predecessor to QAHE, though it is the first material predicted to exhibit QAHE. Here, we have successfully implemented ferromagnetic AHE in Cr-doped Bi₂Se₃ thin films by utilizing a surface state engineering scheme. Surprisingly, all the observed ferromagnetic AHE, as in other Cr- or V-doped TIs, are always p-type even if the majority carrier type remains n-type. This can be well explained by a carrier-selective anomalous-Hall-effect model in which the local magnetic moments interact only through p-type carriers.

**5:06PM P03.00014: Topological States at Interfaces and in Heterostructures**  
KARUNYA SHAILESH SHIRALI (Presenter), WILLIAM A. SHELTON, ILYA VEKHTER, Louisiana State University — Engineering topological insulator (TI) devices involves making heterostructures which combine these materials with other compounds. For a model Hamiltonian, it was shown [1] that properties of the topological interface states may differ from those of the surface states. Motivated by this observation we use a combination of ab initio and model calculations to investigate the consequences of interface potentials breaking spatial symmetries (with and without time reversal symmetry breaking) on the spectral and spin properties of the interface states. We use first principles density functional theory calculations to investigate the topological states at the boundaries between Bi₂Se₃ and binary semiconductors and magnetic insulators, obtain the form of the spin-momentum locking and anisotropy of energy dispersion, and compare these features with the outcomes of model analytical calculations. We also make connections with recent experiments on topological heterostructures, and discuss the importance of our results for tuning topological materials for potential device applications.

**5:18PM P03.00015: Dice Lattice in Ribbons and their Topological Properties**  
RAHUL SONI (Presenter), NITIN KAUSHAL, Physics, University of Tennessee-Knoxville, SATOSHI OKAMOTO, Oak Ridge National Laboratory, ELBIO R DAGOTTO, Physics, University of Tennessee-Knoxville — The existence of nearly flat bands with non-zero Chern numbers in a two-dimensional dice lattice has been studied [1] in the presence of Rashba spin-orbit coupling and a magnetic field. In this work, we studied the topological properties of the dice lattice defined using ribbons both with open and periodic boundary conditions. We found that the Chern numbers [2] are finite even for narrow systems such as Nx3 [3]. We also observed spin currents moving along the edges at half filling, when ribbons are in a cylindrical geometry with open conditions in the long direction. Understanding these topological properties in ribbon-like geometry is important because of computationally exact techniques like DMRG can be used to investigate the effect of Hubbard interactions on dice lattices.

Optical Control of Chiral Charge Pumping in a Topological Weyl Semimetal

MEHDI JADIDI (Presenter), Columbia University, MEHDI KARGARIAN, Sharif University of Technology, MARTIN MITTENDORFF, YIGIT AYTAC, University of Maryland College Park, BING SHEN, University of California, Los Angeles, JACOB KÖNIG-OTTO, STEPHAN WINNERL, Helmholtz-Zentrum Dresden-Rossendorf (HZDR), NI NI, University of California, Los Angeles, THOMAS E. MURPHY, H. DENNIS DREW, University of Maryland College Park — Solids with topologically robust electronic states exhibit unusual electronic and optical transport properties not seen in other materials. A peculiar example is chiral charge pumping (also called chiral anomaly) in recently discovered topological Weyl semimetals, where simultaneous application of parallel static electric and magnetic fields causes an imbalance in the number of topological chiral carriers. Here, using time-resolved terahertz measurements on the Weyl semimetal tantalum arsenide (TaAs) in a magnetic field, we uncover the optical control of chiral anomaly by dynamically pumping the chiral charges and monitor their relaxation. Rigorous theory based on Boltzmann transport shows that the observed optically-induced control of chiral anomaly is governed by the optical nonlinearity in the chiral charge pumping process. Our measurements reveal that the chiral pumping relaxation is much longer than 1 ns. The optically-controlled long-lived chiral carriers observed here in a Weyl semimetal exhibit similar behavior to the valley-polarized carriers in 2D semiconductors, but with the extra feature of topological protection, suggesting possible valleytronic applications of Weyl semimetals.

Circular photogalvanic effect of layered type-II Weyl semimetal MoTe2 in mid-infrared band

JUNCHAO MA (Presenter), QIANGQIANG GU, YINAN LIU, Peking University, PENG YU, Nanyang Technological University, JIAWEI LAI, XIAO ZHUO, Peking University, ZHENG LIU, Nanyang Technological University, JIANHAO CHEN, JI FENG, DONG SUN, Peking University — Td-Phase Molybdenum ditelluride (MoTe2) has attracted enormous research interests as a Type-II Weyl semimetallic state and the fascinating properties it exhibits. By applying circularly polarized 4.0-μm and 10.6-μm excitation at normal incidence, circular photogalvanic effect (CPGE) has been observed in topological Td-phase MoTe2. The CPGE signal is not allowed by the C2v symmetry by second order nonlinear effect under our experimental geometry. This work is one of the first experimental realizations of this effect in type-II Weyl semimetals with the MIR spectral regime, which is suitable to unveil the physics related to Weyl cones. The occurrence of CPGE in MoTe2 is attributed to a built-in electric field, which can remove full C2v symmetry, resulting in nonzero injection current via an third order nonlinear optical effect. The field is produced by the work function difference between samples and electrodes or photothermoelectric effect after photo-excitation. Additionally, the existence of CPGE in our experiments is an unique signature of the Td phase, which is in consistence with the recently-reported Barkhausen effect during phase transition of MoTe2.

Anisotropic Broadband Photo Response of Layered Type-II Weyl Semimetals

JIAWEI LAI (Presenter), XIN LIU, JUNCHAO MA, QINSHENG WANG, Peking University, KENAN ZHANG, Tsinghua University, XIAO REN, YINAN LIU, QIANGQIANG GU, XIAO ZHUO, WEI LU, Peking University, YU PENG, ZHENG LIU, NTU, YUAN LI, JI FENG, Peking University, SHUYUN ZHOU, Tsinghua University, JIANHAO CHEN, DONG SUN, Peking University — Td-MoTe2 and TaIrTe4, two-dimensional layered Type-II Weyl semimetal, are expected to share several unique advantages with Dirac semimetals for photodetection. The extremely high mobility and the chiral Fermions near the Weyl node lead to several advantages over traditional semiconductor-based photodetectors. Here, we report the realization of broadband self-powered photodetectors based on Td-MoTe2 and TaIrTe4, two-dimensional layered Type-II Weyl semimetal, are expected to share several unique advantages with Dirac semimetals for photodetection. The extremely high mobility and the chiral Fermions near the Weyl node lead to several advantages over traditional semiconductor-based photodetectors. Here, we report the realization of broadband self-powered photodetectors based on Td-MoTe2 and TaIrTe4. Broadband responses from visible to mid-infrared are experimentally tested. The PC generation mechanisms are investigated and it is found that PTE effect plays critical role in PC generation. Furthermore, we found that the anisotropy is wavelength dependent, and the degree of anisotropy increases as the excitation wavelength gets closer to the Weyl nodes which can be used for polarization-sensitive photo detection. Thus Td-MoTe2 and TaIrTe4 provide a new class of material platform for high performance photodetection applications.

This project was supported by the National Natural Science Foundation of China (NSFC Grant Nos. 91750109, 11674013).
Contributions from the bulk and surface states of the studied materials are also distinguished. The relation of the different components of the optical conductivity tensor are determined and studied as a function of frequency. Based on a Wannier interpolation scheme, which takes into account the realistic electronic structure of these materials.

Nöthnitzer Straße-40, 01187 Dresden, Germany, DARIUS TORCHINSKY, Department of Physics, Temple University, JOSEPH ORENSTEIN, University of California, Berkeley — Topological materials, and in particular Weyl semimetals, offer a playground for diverse optical properties. When inversion symmetry is broken, such materials additionally allow second-order bulk nonlinear effects. We present a spectroscopic second harmonic generation study of a Weyl semimetal, and discuss data taken as a function of incident and emitted polarization angle over a range of incident frequencies from the visible to the infrared.

3:18PM P04.00005: Optical Response Characteristics of the Weyl Semimetals WTe₂ and MoTe₂* 

ADRIAN POPESCU (Presenter), LILIA M WOODS, Department of Physics, University of South Florida — Weyl semimetals are 3D systems exhibiting linear dispersion band crossings which act as Berry curvature monopoles in the reciprocal space. A key signature for Weyl semimetals is the appearance of surface Fermi arcs as a result of the projection of the bulk Weyl points on the surface of the material. Here we report first-principles calculations for the dynamical conductivity tensor, a basic quantity for the light-matter interactions, of the Weyl semimetals MoTe₂ and WTe₂. The calculations rely on the Kubo formula, computed based on a Wannier interpolation scheme, which takes into account the realistic electronic structure of these materials. The different components of the optical conductivity tensor are determined and studied as a function of frequency. Contributions from the bulk and surface states of the studied materials are also distinguished. The relation of the calculated results with the experimental ones, as well as the temperature effects, are also discussed.

3:30PM P04.00006: Optical evidence of chiral Landau level in Weyl semimetal 

XIANG YUAN (Presenter), FAXIAN XIU, Fudan University — Weyl semimetal has been extensively studied with exotic phenomena such as chiral anomaly. Despite the numerous experimental efforts to explore the chiral anomaly in different materials, electrical transport is the main approach where negative magneto-resistivity works as a criterion. More evidence of chiral anomaly, such as the existence of chiral Landau level, is desired for further study. Here we report a magneto-optical study in Weyl semimetal. Allowed optical transition under magnetic field can reveal the Landau level structure. The Chiral Landau levels are experimentally found in typical Weyl semimetals NbAs while the system is driven close to the quantum limit. The related optical transition exhibits distinct difference from other normal Landau levels. The z momentum can be finite with unique magnetic field evolution. Meanwhile, multiple carriers with different topological origins are found, indicate complex band structure of the crystal. Our results demonstrate an effective tool for studying complex topological systems. Further evidence of chiral magnetic effect will also be discussed.

3:42PM P04.00007: Second harmonic generation studies on the Weyl semimetal WTe₂ 

EDBERT JARVIS SIE (Presenter), CLARA M NYBY, AARON LINDENBERG, Stanford University — Tungsten ditelluride (WTe₂) is a layered material that is both a ferroelectric and a Weyl semimetal. The coexistence of these two properties stems from inversion symmetry breaking, a condition that is sensitive to the atomic-scale lattice distortions in this material. Here, we performed second harmonic generation (SHG) studies on tungsten ditelluride. We will report on unusual and large-amplitude temperature dependent responses of the SHG as a probe of the inversion-breaking phase in WTe₂.

3:54PM P04.00008: Terahertz Generation Measurements in Inversion-Symmetry Breaking Weyl Semimetals with Spectrally Resolved Excitation Fields* 

DYLAN REES (Presenter), University of California, Berkeley, BAOZHU LU, MANITA RAI, Department of Physics, Temple University, KAUSTUV MANNA, CLAUDIA FELSER, Max-Planck-Institute for Chemical Physics of Solids, Joseph TORCHINSKY, Department of Physics, University of California, Berkeley — Topological materials, and in particular Weyl semimetals, offer a playground for diverse optical properties. When inversion symmetry is broken, such materials additionally allow second-order bulk nonlinear effects. We present terahertz generation data with excitation fields ranging across the near infrared spectrum. Measurements were taken with both linear- and circular-polarized light in a variety of geometries.

Quantum Materials program supported by the Director, Office of Science, Office of Basic Energy Sciences, Materials Sciences and Engineering Division, of the U.S. Department of Energy under Contract No. DE-AC02- 05CH11231.

*Gordon and Betty Moore Foundation's EPIQs Initiative, Grant No. GBMF4537.
Recently, Weyl semimetals have been experimentally discovered in both inversion-symmetry-breaking and time-reversal-symmetry-breaking crystals. The non-trivial topology in Weyl semimetals can manifest itself with exotic phenomena which have been extensively investigated by photoemission and transport measurements. Despite the numerous experimental efforts on Fermi arcs and chiral anomaly, the existence of unconventional zeroth Landau levels, as a unique hallmark of Weyl fermions which is highly related to chiral anomaly, remains elusive owing to the stringent experimental requirements. Here, we report the magneto-optical study of Landau quantization in Weyl semimetal NbAs. High magnetic fields drive the system towards the quantum limit which leads to the observation of zeroth chiral Landau levels in two inequivalent Weyl nodes. As compared to other Landau levels, the zeroth chiral Landau level exhibits a distinct linear dispersion in z momentum direction and allows the optical transitions without the limitation of zero z momentum or $\sqrt{B}$ magnetic field evolution. The magnetic field dependence of the zeroth Landau levels further verifies the predicted particle-hole asymmetry of the Weyl cones. Meanwhile, the optical transitions from the normal Landau levels exhibit the coexistence of multiple carriers including an unexpected massive Dirac fermion, pointing to a more complex topological nature in inversion-symmetry-breaking Weyl semimetals. Our results provide insights into the Landau quantization of Weyl fermions and demonstrate an effective tool for studying complex topological systems.

This work was supported by the National Natural Science Foundation of China (Grant No. 11474058, 61674040, 11674189) and the National Key Research and Development Program of China (Grant No. 2017YFA0303302, 2016YFA0203900, 2017YFA0303504).

The chiral anomaly is a phenomenon characteristic of Weyl fermions, which has condensed matter realizations in Weyl semimetals. Efforts to observe a smoking gun signatures of the chiral anomaly in electronic transport has proven non-trivial. Recent works have proposed an alternative approach of probing phonon dynamics for signatures of the chiral anomaly in non-mirror-symmetric crystals. Here, we show that such phononic signatures can be extended to mirror symmetric crystals, broadening the pool of candidate materials. We show that the background magnetic field can break mirror symmetry strongly enough to yield observable signatures of chiral anomaly even in mirror-symmetric materials. Specifically for mirror-symmetric Weyl semimetals such as TaAs and NbAs, including the Zeeman interaction at $B\sim10T$, we predict an IR reflectance peak will develop with an $E_{\text{IR}}B$ dependence.

Weyl semimetals (WSM) are a recently realized class of topological materials with low energy electronic excitations characterized by a three-dimensional, linear dispersion. While much focus has been directed at characterizing and understanding the electronic properties of various WSMs, little attention has been paid to the vibrational properties. In the WSMs NbAs and TaAs such considerations are crucial for understanding the anomalously high mobility and thermal response. We present temperature and polarization dependent Raman spectra which reveal anomalous lineshapes, as well as deviations from standard anharmonic behavior.

Optical Evidence of Chiral Magnetic Anomaly in Weyl Semimetal TaAs

ANTONIO LEVY (Presenter), ANDREI B SUSHKOV, Department of Physics, Center for Nanophysics and Advanced Materials, University of Maryland, FENGGUANG LIU, Anhui Agricultural University, BING SHEN, NI NI, Department of Physics and Astronomy, University of California, Los Angeles, HOWARD DREW, Department of Physics, Center for Nanophysics and Advanced Materials, University of Maryland, GREGORY S JENKINS, Laboratory for Physical Sciences — Chiral pumping from optical electric fields oscillating at THz frequencies is observed in the Weyl material TaAs with electric and magnetic fields aligned along both the a- and c-axes. Free carrier spectral weight enhancement is measured directly for the first time, confirming theoretical expectations of chiral pumping. A departure from linear field-dependence of the Drude weight is observed at the highest fields in the quantum limit, providing direct evidence of field-dependent Fermi velocity of the chiral Landau level. Implications for the chiral magnetic effect in Weyl semimetals from the optical f-sum rule are discussed.

2:30PM P05.00001: The Electronic Transport Properties of Silicon Meta-lattice Made by High Pressure CVD
ZHAOHUI HUANG (Presenter), VINCENT H. CRESPI, Pennsylvania State University — A nanoscale 3D superlattice, called meta-lattice, can be synthesized by infiltrating a template of close-packed nanometer-scale silica spheres with Si by high pressure chemical vapor deposition. Their structures can be controlled by using different size spheres; accordingly, their electronic transport properties are geometry-dependent, and both localized and extended electronic states in three dimensions may exist, hence both band conduction and variable range hoping (VRH) may occur simultaneously. Metalattices offer a platform to continuously change properties of electronic transport by changing their geometries. We employ a tight-binding method to quantitatively look into the impact of geometry. The resultant electronic band structure is also used in the case of VRH conductance.

2:42PM P05.00002: Observation of Exposed and Hidden Au Quantum Well States in Au/Ag Heterostructures
QIANGSHENG LU (Presenter), GUANG BIAN, University of Missouri — In this work, atomically uniform Au films are grown on a Ag(111) thin film. The Au quantum well states (QWS) are clearly observed by using Angle-resolved photoemission spectroscopy (ARPES). The Au QWSs hybridize with the Ag states and thus, show an energy dependence on the thickness of the supporting Ag film. Furthermore, a sandwich structure of Ag/Au/Ag is fabricated with various thicknesses of each constituent layer. The Au QWSs, though buried under the Ag overlayer, are still observable through hybridization with the Ag states. Interestingly, the hybrid quantum well states with Au d orbitals states possess a large effective mass as a result of hybridization with partially localized d states. Detailed first-principles simulations are performed to illustrate the orbital components of hybrid QWSs and provide an insight into the band dispersion of hybrid states.

2:54PM P05.00003: On the formation of suspended double-stranded atomic chains
CARLOS SABATER (Presenter), Departamento de Física Aplicada, Universidad de Alicante, Campus de San Vicente del Raspeig, E-03690 Alicante, Spain, University of Alicante, JUAN JOSE PALACIOS, Departamento de Física de la Materia Condensada, Cantoblanco, 28049 Madrid, Spain, Universidad Autónoma de Madrid., MARÍA JOSÉ CATURLA, CARLOS UNTIEDT, Departamento de Física Aplicada, Universidad de Alicante, Campus de San Vicente del Raspeig, E-03690 Alicante, Spain, University of Alicante — The smallest structures with higher stability connecting two metallic electrodes can be identified by the evolution of the conductance in the process of the controlled breakage of the contact between two metals. Here we report on the identification of double-stranded atomic chains formed on Au using a Scanning Tunneling Microscope. Molecular dynamics simulations and density functional theory electron transport calculations help to unveil the richness of geometric structures possible with double-stranded chains, their stability and how these can evolve to form monoatomic chains.
Universal Conductance Fluctuation in Sierpinski Carpet

Yulei Han (Presenter), University of Science and Technology of China, Fumng Xu, Shenzhen University, Zhenhua Qiao, University of Science and Technology of China

We report a theoretical investigation on conductance fluctuation of disordered two-terminal device in Sierpinski carpet. We find that the conductance fluctuation does not display a universal feature in circular orthogonal ensemble. But in the presence of magnetic field or spin-orbit coupling, a universal conductance fluctuation (UCF) appears. More specify, in the presence of magnetic field, the UCF value is about 0.74 ± 0.01 (e²/h), while when applied spin-orbit coupling the UCF value exists also around 0.74 ± 0.01 (e²/h). By further investigating the conductance distribution in the critical disorder strength, we find that both of the symmetries share the same distribution function. Our work provide a better understanding of the transport properties of regular fractal structure and shed light on more transport studies of fractals.

3:18PM P05.00005: Experimental demonstration of nanoelectronics below 1 mK electron temperature

Nikolai Yurttagül (Presenter), Matthew Sarsby, Attila Geresdi, Delft University of Technology

Extending the experimental temperature domain of nanoelectronic devices into the microkelvin regime would make novel quantum states of matter accessible with great potential for quantum technologies. Cooling bulk metals to microkelvin temperatures by adiabatic demagnetization of nuclear spins has been an established technique for decades, however reaching electron temperatures below 1 mK in nanofabricated devices remained an unsolved challenge up until now. This is due to the thermal decoupling of electrons in micro- and nanostructures from the cold substrate in combination with high frequency electronic noise directly heating the electron system. We demonstrate the first successful nuclear magnetic cooling of electrons in a nanofabricated device to microkelvin temperatures, achieved by integrating indium as nuclear refrigerant onto the metallic islands of a Coulomb blockade thermometer with the device leads attached to bulk indium nuclear cooling stages. By performing the nuclear demagnetization process, we demonstrate electron temperatures below 500 μK by primary electron thermometry, and show that the device stays below 1 mK for several days.

Trapped Ion Heating from Correlated Motion of Electrode Adsorbates

Vincenzo Lordi (Presenter), Keith Ray, Changueun Kim, Lawrence Livermore Nat Lab, Benjamin Foulon, Brenda Rubenstein, Brown University

Trapped ion qubits are plagued by a phenomenon called “anomalous heating,” where motional modes of the ion are excited by the environment causing decoherence of the encoded quantum information. Evidence suggests the origin of this heating is associated with the surface of the trapping electrodes. In this work, we combine first-principles electronic structure calculations, molecular dynamics simulations, and master equations to explore the role of high densities of adsorbed molecules on the electrode surface as a potential source of trapped ion heating. Weakly adsorbed molecules interact with the metallic surface and acquire an induced dipole, which can couple to the ion, causing electric field noise. When a large density of adsorbates are present, on the order of a monolayer, their collective vibrational motion can create non-trivial frequency-dependent electric field noise and thus ion heating. We analyze the coverage dependence of this effect for different possible electrode adsorbates.

2D Fermi-Hubbard Quantum Simulation with and Oxide Nanoelectronic Platform

Shan Hao (Presenter), Jianan Li, Yuhe Tang, Aditi Nethwewala, Yang Hu, Department of Physics & Astronomy, University of Pittsburgh, Hyungwoo Lee, Jungwoo Lee, Chang-beom Eom, Department of Materials Science and Engineering, University of Wisconsin—Madison, Patrick Irvin, Jeremy Levy, Department of Physics & Astronomy, University of Pittsburgh

The interface of LaAlO₃/SrTiO₃ supports a 2D electron gas [1] that can be further reconfigured into nanostructures, using conductive AFM lithography [2]. The density of nanostructures (~2 nm) is comparable to the mean electron separation, giving rise to the idea that this platform could be used for quantum simulation of 2D Fermi-Hubbard problems. Here we describe efforts to create various 2D lattice structures, and investigate their properties at low temperatures and high magnetic fields.

*Prepared by LLNL under Contract DE-AC52-07NA27344.
4:06PM P05.00009: Doping dependence of phonon anomalies in (Bi,Pb)2(Sr,La)2CuO6 revealed by inelastic X-ray scattering* 

YINGYING PENG (Presenter), ALI HUSAIN, SANGJUN LEE, University of Illinois at Urbana-Champaign, AHMET ALATAS, Argonne National Laboratory, KITTIHAT KRONGCHON, XIAOLAN SUN, University of Illinois at Urbana-Champaign, AYMAN SAID, Argonne National Laboratory, YING DING, XINGJIANG ZHOU, Institute of Physics, Chinese Academy of Sciences, LUCAS WAGNER, PETER ABBAMONTE, University of Illinois at Urbana-Champaign — While charge modulations are ubiquitous in high-temperature superconducting cuprates, understanding their coupling to phonons can provide crucial insight into the role of electron-phonon interactions in high-temperature superconductivity. Here, we have used high-resolution inelastic X-ray scattering to study the doping dependence of the low-energy phonons in the monolayer cuprate (Bi,Pb)2(Sr,La)2CuO6+d, from heavily underdoped (p=0.03) to overdoped (p=0.21) samples. We observe that the longitudinal acoustic phonon along the Cu-O bond direction exhibits a line-shape broadening near the wave vector ~ 0.25 rlu in underdoped samples even when charge order is suppressed, while no broadening occurs in the overdoped samples. Surprisingly, an additional low energy mode around 4 meV is observed in the underdoped samples and is absent in overdoped materials. The origin of the longitudinal phonon broadening and the new low energy mode will be discussed especially in relation to charge order.

*This work was supported by DOE grant DE-FG02-06ER46285.

4:18PM P05.00010: High Tc Superconductor-Half metallic ferromagnet planar devices* 

SOPHIE D’AMBROSIO (Presenter), SALVATORE MESORACA, XAVIER PALERMO, ADRIAN BALAN, Unité Mixte de Physique, CNRS/Thales, Université Paris Sud, Université Paris-Saclay, Palaiseau, France, DAVID SÁNCHEZ-MANZANO, FABIAN CUELLAR, GFMC, Dpto. Física de Materiales, Universidad Complutense de Madrid, Spain, CHRISTIAN ULYSSE, Centre de Nanosciences et de Nanotechnologies, CNRS, Université Paris-Saclay, Palaiseau, France, LAURENT VILA, SPINTEC, CEA-INAC/CNRS/Univ. Grenoble Alpes, Grenoble, France, NICOLAS BERGEAL, JÉRÔME LESUEUR, Laboratoire de Physique et d’Etude des Matériaux, ESPCI Paris, PSL Research University, CNRS, Paris, France, ANKE SANDER, Unité Mixte de Physique, CNRS/Thales, Université Paris Sud, Université Paris-Saclay, Palaiseau, France, JACOBO SANTAMARIA, GFMC, Dpto. Física de Materiales, Universidad Complutense de Madrid, Spain, JAVIER VILLEGAS, Unité Mixte de Physique, CNRS/Thales, Université Paris Sud, Université Paris-Saclay, Palaiseau, France — Superconducting spintronics is an emergent field where the interfacial interactions between superconductors (S) and ferromagnets (F) are crucial. These interactions can give rise to equal-spin triplet Cooper pairs, thereby opening the door to coherent, dissipationless spin transport. In this scenario, the case of high-temperature d-wave superconductors (e.g. YBa2Cu3O7) combined with half-metal ferromagnets (e.g. La0.7Sr0.3MnO3) is especially interesting. One of the challenges specific to those materials is the fabrication of nanoscale planar devices in which multiple S/F interfaces can be concatenated and electrically sensed individually. The difficulty comes from the fact that complex-oxides are often incompatible with many of the bottom-up nanofabrication approaches that are standard with metals. We will describe here various top-bottom approaches we have developed ad hoc to fabricate oxide planar S/F nanodevices, which are a combination of Pulsed Laser Deposition, Electron Beam Lithography and Ion Beam Etching. We will also present temperature-dependent magnetotransport measurements performed to characterize their superconducting and magnetic properties.

4:30PM P05.00011: The Formation of Wannier Mott-Frenkel Hybrid Excitonic Polariton In Different Heterostructures  DAVID FACEMYER (Presenter), QUE HUONG NGUYEN, Marshall University — It has been suggested theoretically and realized experimentally that combining organic material and inorganic semiconductors in one heterostructure would result in resonant interactions between the Frenkel excitons in the organic material and the Wannier-Mott excitons in the semiconductors, leading to the formation of an exciton hybridization state. The new materials, possessing the complimentary characteristics of both exciton types, such as large exciton radius, enormous oscillator strength and room-temperature operation properties, would enhance optical nonlinearities and promise to have useful applications in both the field of Bose-Einstein condensation of polaritons and polariton lasers. In this work, we consider a strong coupling of the hybrid excitons and photons near excitonic resonance analytically with the purpose of determining the electronic structure, energy, and dispersion relation of the hybrid exciton-polariton. We study different confinement parameters for various nano-scale heterostructures, and in doing so, we discuss the conditions necessary for their formation. Our ab initio approach moves us a step closer to realizing new, novel optoelectrical materials that exhibit the strengths of each constituent.

4:42PM P05.00012: X-ray Optics Fabrication Using Unorthodox Approaches  Umut Tunca Sanli, Margarita Baluktsian, Modern Magnetic Systems, MPI for Intelligent Systems, Hakkan Ceylan, Metin Sitti, Physical Intelligence, MPI for Intelligent Systems, Markus Weigand, Gisela Schuetz, Kahraman Keskinbora (Presenter), Modern Magnetic Systems, MPI for Intelligent Systems — X-ray microscopes are unique tools for studying buried features of biological and magnetic systems with high spatiotemporal resolution. The limitations of the standard e-beam lithography method for fabricating these delicate nano-photonic devices can be overcome by using unconventional lithography methods such as direct-write and gray-scale ion beam lithography, ion beam implantation lithography, a combination of atomic layer deposition and focused ion beam micromachining and last but not least by using two-photon photopolymerization (2PP). For instance, bottom-up growth of atomic layer deposition allows atomic scale control over the zone width while top-down micromachining using focused ion beams allow freely selectable aspect ratios and tilt angles. In another approach, we took advantage of 2PP and fabricated high aspect ratio diffractive/refractive kinoforms out of low-loss polymeric materials for the first time. We will discuss the benefits of these methods over the conventional fabrication routes based on theoretical coupled wave theory calculations, direct imaging experiments as well as ptychographic coherent diffractive imaging.

4:54PM P05.00013: Observation of Bulk Polarization Transitions and Second-Order Acoustic Corner States Protected by Generalized Chiral Symmetry  Xiang NI (Presenter), Matthew Weiner, The City College of New York, Andrea Alu, Graduate Center of the City University of New York, Alexander Khanikaev, The City College of New York — A new class of topological lattice characterized by bulk polarization has been introduced recently, such system has been shown to host Wannier-type higher order states. Here, we introduce and measure topological bulk polarization in 3D printed two-dimensional acoustic meta-structures, and observe topological transitions as the design parameters are tuned. We also demonstrate that our topological meta-structure hosts both 1D edge and Wannier-type second-order corner states with unique acoustic properties. The edge states have the angular momentum that reverses for opposite propagation direction, thus supporting directional excitation. We observe the second order topological states protected by the generalized chiral symmetry of the meta-structure, which are localized at the corners and are pinned to ‘zero energy’. Interestingly, unlike the corner states protected by the conventional chiral symmetry, the generalized chiral symmetry of our three-atom sublattice enables their spectral overlap with the continuum of bulk states without leakage. The confinement and inherent robustness of the corner states is theoretically analyzed and experimentally confirmed by deliberately introducing disorder. Our findings open new directions for advanced sound propagation and manipulation.

Session P06 DCMP: Strongly Correlated Ce- and Yb-based Materials  BCEC 109A - Sheng Ran - Tag(s): Focus
Magnetic Ordering Competition Leading to Disorder Between CeIn₃ and NdIn₃

JACKSON BADGER (Presenter), Department of Chemistry, University of California, Davis, RUMIKA MIYAWAKI, Department of Physics, Tokyo Metropolitan University, PETER KLAVINS, ZACHARY BRUBAKER, RENA ZIEVE, Department of Physics, University of California, Davis, TATSUMA D. MATSUDA, Department of Physics, Tokyo Metropolitan University, VALENTIN TAUFOUR, Department of Physics, University of California, Davis — Both CeIn₃ and NdIn₃ crystallize in the same cubic structure (Pm-3m) and show antiferromagnetic ordering below 10.1 K and 5.9 K, respectively. We investigate the magnetic ordering of single crystals of Ce₁₋ₓNdₓIn₃ and discover a region of frustrated magnetism near x ~ 0.45 where the magnetic order is suppressed to below 1.8 K. In this region, the two antiferromagnetic orderings appear to be in competition with one another despite the fact that antiferromagnetic interactions are still observed. We present the sample synthesis and characterizations, as well as a discussion of the observed magnetic properties in the context of heavy-fermion behavior, Kondo interactions, and magnetic anisotropy.

Electronic structure study of the heavy-fermion superconductor CeIrIn₅ by ARPES

QIUYUN CHEN (Presenter), China Academy of Engineering Physics, KEVIN HUANG, LEI SHU, Fudan University, STEFAN KIRCHNER, Zhejiang University, DONGLAI FENG, Fudan University — Crystal electric field states in rare earth intermetallics show an intricate entanglement with the many-body physics that occurs in these systems and that is known to lead to a plethora of electronic phases. Here we attempt to trace different contributions to the crystal electric field (CEF) splittings in CeIrIn₅, a heavy-fermion compound and member of the CeMIn₅ (M = Co, Rh, Ir) family. To this end, we utilize high-resolution resonant angle-resolved photoemission spectroscopy (ARPES) and present a spectroscopic study of the electronic structure of this unconventional superconductor over a wide temperature range. As a result, we show how ARPES can be used in combination with thermodynamic measurements or neutron scattering to disentangle different contributions to the CEF splitting in rare earth intermetallics. We also find that the hybridization is stronger in CeIrIn₅ than CeCoIn₅ and the effects of the hybridization on the Fermi volume increase is much smaller than predicted.

Weak hybridization effects revealed by ARPES in heavy-fermion Ce₂IrIn₈

HAJJANG LIU (Presenter), HONG DING, YUANJI XU, Institute of physics, Chinese academy of sciences — We utilize high resolution on-resonant (hv~120eV) angle-resolved photoemission spectroscopy (ARPES) to study the band structure and hybridization effect of heavy-fermion compound Ce₂IrIn₈. Hybridization between 4f electron and conduction electron plays a significant role on the behavior of heavy-fermion compounds. Band structure experiments fit well with the results of DFT calculation. We observe obvious flat band below coherent temperature Tcoh~40 K which characterize electrical resistance maxima indicate the onset temperature of hybridization. But the Fermi surface (FS) volume and Fermi vector k_F don't change largely, which challenge the widely believed evolution from high temperature small FS to low temperature big FS.

Critical charge fluctuations and ω/T scaling at the Kondo breakdown of Heavy-fermion systems

YASHAR KOMIJANI (Presenter), PIERS COLEMAN, Rutgers University, New Brunswick — A number of recent experiments on quantum critical materials CeRuIn₄, YbRh₂Si₂, CeCu₂Si₂, and YbAlB₄ have observed critical charge fluctuations coinciding with magnetic transition, a phenomena that goes beyond the Landau-Ginzburg paradigm. We will argue that such soft charge fluctuations are natural consequences of an abrupt change in the Fermi surface volume that accompanies Kondo breakdown (KBD) in heavy-fermion systems.

Using a model 1D Kondo lattice in which each moment is connected to a separate conduction bath, we show that a KBD transition develops between a heavy Fermi liquid and a gapped spin liquid via a QCP with \omega/T scaling, which features residual entropy and a critical charge mode directly associated with the break-up of Kondo singlets.

Furthermore, We contrast the cases of ferromagnetic (FM) and antiferromagnetic (AFM) couplings. While with a purely Ising magnetic coupling, both models map to the dissipative transverse-field Ising model, the Heisenberg limit is quite different: The charge mode is incoherently broadened in the FM system, while it remains sharp, protected by the spin liquid gap, in frustrated AFM system. We discuss the implications of these effects on the experiments.

The suppression of ferromagnetism in metallic systems may result in the appearance of modulated magnetic phases. Recent studies have shown that the application of pressure in the CeTiGe$_3$ system is a possible example of such phenomenon. By combining magnetic field and pressure, a wing-structure phase diagram with a quantum tricritical point is observed. Here we show that substituting vanadium in place of titanium will suppress ferromagnetism, and an antiferromagnetic state is observed near the V-rich end. We discuss the evolution of the ordering temperature and of the magnetic anisotropy as Ti is progressively substituted by V in single crystals of the CeTi$_{1-x}$V$_x$Ge$_3$ series.

3:30PM P06.00006: Evolution of Charge Density Wave Order in CeTe$_2$  
BISHNU SHARMA (Presenter), MANOJ SINGH, BURHAN AHMED, BONING YU, Clark University, PHILIP WALMSLEY, IAN R FISHER, Stanford University, MICHAEL C BOYER, Clark University — The rare-earth tellurides are a family of low-dimensional compounds which host charge density wave (CDW) states. While CDW states in the rare-earth tri-tellurides (RTe$_3$) are relatively well-studied, less is known about CDW states in the rare-earth di-tellurides (RTe$_2$). The RTe$_2$ compounds are quasi two dimensional materials with a crystal structure which consists of alternating insulating rare-earth block layers and single-layer conducting Te sheets. Here we present our scanning tunneling microscopy measurements on CeTe$_2$. Our measurements detect two unidirectional, perpendicular, spatially separated CDW states which smoothly evolve from one to the other. Our measurements shed light on the connection between CDW states and local strain.

3:42PM P06.00007: Thermal expansion measurements of heavy-fermion CeAuSb$_2$*  
SOONBOM SEO (Presenter), SEAN THOMAS, FILIP RONNING, ERIC BAUER, JOE D THOMPSON, PRISCILA ROSA, Los Alamos National Laboratory — CeAuSb$_2$ is a heavy-fermion antiferromagnet hosting two field-induced transitions at $H_{c1} \sim 2.8$ T and $H_{c2} \sim 5.6$ T when field is applied along the c-axis. At $H_{c1}$, the magnetic structure changes from a single-\textit{q} to a multi-\textit{q} spin density wave [3]. Here we report the temperature dependence of the resistivity ($\rho$) and thermal expansion ($\Delta L/L$) of CeAuSb$_2$ when $H \parallel c$-axis. Our results show that $\rho$ and $\Delta L/L$ display signatures of the different magnetic structures, and are susceptible to the critical end point. We will discuss both pressure and field effects on the multiple phase transitions in the three-dimensional phase diagram of CeAuSb$_2$.

*Work at Los Alamos was performed under the auspices of the US DOE, Division of Materials Sciences and Engineering. S. S. acknowledges support of the LANL LDRD program through a Director’s Postdoctoral Fellowship.

3:54PM P06.00008: Competing incommensurate orders in a heavy fermion antiferromagnet CeNiGe$_2$  
LEKH POUDDEL (Presenter), YANG ZHAO, ZHIJUN XU, WILLIAM RATCLIFF, NIST Center for neutron research, National Institute of Standard and Technology, Gaithersburg, MD, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advance Materials, University of Maryland, College Park, MD, JEFFREY W LYNN, NIST Center for neutron research, National Institute of Standard and Technology, Gaithersburg, MD — We have determined the magnetic structure and phase diagram of a heavy fermion compound CeNiGe$_2$ as a function of magnetic field and temperature using single crystal neutron diffraction. At zero field and the base temperature of 0.4 K, CeNiGe$_2$ shows a complex magnetic structure comprising two propagation vectors $k_1 = (0.23, 0, 0)$ and $k_2 = (0.18, 0, 0)$. The intensities observed at several magnetic satellites indicate that the moments are predominantly along the c-axis. At higher temperatures the order parameter corresponding to $k_1$ (OP1) decreases until it is suppressed at $T_{N1} = 3$ K. The order parameter for $k_2$ (OP2) initially increases with increasing temperature and only begins to decrease above $T_{N1}$ until it vanishes at $T_{N2} = 4.2$ K. A similar but opposite trend in order parameters is observed when a magnetic field is applied along the c-axis. OP2 is suppressed at a lower critical field of $B_{c2} = 0.75$ T, whereas OP1 first increases until it reaches maximum at $B_{c2}$ and begins to decrease and vanishes at the critical field of $B_{c1} = 2.75$ T. Taken together, CeNiGe$_2$ provides an interesting platform where competition between two nearby incommensurate orders can be systematically tuned by temperature and magnetic field.
**4:06 PM P06.00009: Thermodynamic and transport properties of R Cd₃P₃ (R = La and Ce) single crystals**  
ANJA RABUS, JEONGHUN LEE, EUDEOK MUN (Presenter), Department of Physics, Simon Fraser University — R Cd₃P₃ (R = La and Ce) compounds crystallize into a hexagonal ScAl₃C₃-type structure. The magnetic Ce atoms form the triangular lattice of the two dimensional layer. Thermodynamic and transport properties of R Cd₃P₃ were investigated by measuring the magnetization, electrical resistivity, and specific heat. The magnetic susceptibility of CeCd₃P₃ follows the Curie-Weiss law at high temperatures with very large negative Weiss temperature. The specific heat measurement of CeCd₃P₃ clearly indicates a magnetic ordering below 0.41 K with large electronic specific heat coefficient. In this talk, anomalous physical properties due to the geometrical frustration of Ce atoms will be discussed.

**4:18 PM P06.00010: Field-induced Pseudogap in the Heavy-fermion Superconductor CeCoIn₅**  
KESHAV SHRESTHA (Presenter), LAURA H GREENE, Florida State University, ERIC BAUER, JOE D THOMPSON, Los Alamos National Laboratory, YOU LAI, RYAN BAUMBACH, Florida State University, KALYAN SASMAL, M BRIAN MAPLE, Department of Physics, University of California, San Diego, WAN KYU PARK, Florida State University — The heavy-fermion superconductor CeCoIn₅, whose order parameter is known to have dx²-y² symmetry [1], manifests an interesting spin density wave-like Q-phase [2]. Despite several recent scanning tunneling spectroscopic measurements [3], there are no phase-sensitive measurements in the Q-phase. Our planer tunneling spectroscopy data at 20 mK show sharp coherence peaks and the estimated gap size is 0.65 meV. Quite intriguingly, the superconducting gap-like features evolve into a pseudogap as superconductivity is destroyed with temperature and magnetic fields. The field-induced pseudogap is enhanced further with increasing fields up to the highest measurements field of 18 T. The possible origin of the pseudogap and implications of our results will be discussed.

**4:30 PM P06.00011: Thermal expansion near the bicritical point in YbAgGe**  
GEORGE SCHMIEDESHOFF (Presenter), Physics, Occidental College, J.-H. PARK, D. GRAF, National High Magnetic Field Laboratory, S.L. BUD’KO, P.C. CANFIELD, Physics and Astronomy, Ames Laboratory and Iowa State University — A flexible-plate capacitive dilatometer, designed to operate while immersed in the liquid helium "mash" of a top-loading dilution refrigerator, was used to measure the thermal expansion of the heavy-fermion antiferromagnet YbAgGe near the bicritical point reported near 0.3 K in a magnetic field of 4.5 T applied parallel to the ab-axis [1]. We will discuss the phase diagram and quantum bicriticality of YbAgGe and the new dilatometer.

*Work at Occidental College was supported by the National Science Foundation under DMR-1408598. A portion of this work was performed at the National High Magnetic Field Laboratory, which is supported by the National Science Foundation Cooperative Agreement No. DMR-1157490 and the State of Florida. Work at Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.
4:42PM P06.00012: Pressure-temperature phase diagram of YbNi2B2C* LI XIANG (Presenter), YUJI FURUKAWA, Department of Physics, Iowa State University, Ames Laboratory, Ames, Iowa 50011, USA, VIKTOR V. STRUZHKIN, Carnegie Institution of Washington, Geophysical Laboratory, Washington, DC 20015, USA, ALEXANDER GAVRILIUK, FSRC Crystallography and Photonics of Russian Academy of Sciences, Moscow 119333, Russia, SERGEY BUDKO, PAUL CANFIELD, Department of Physics, Iowa State University, Ames Laboratory, Ames, Iowa 50011, USA — The RNi2B2C (R = Gd - Lu, Y) series have attracted much attention due to the interplay between superconductivity and local-magnetism. For the Lu, Tm - Dy, superconducting transition temperature $T_c$ decrease and the AFM transition temperature $T_N$ increases and scales with de Gennes scaling at ambient pressure. However, YbNi2B2C displays neither superconductivity nor magnetism down to low temperature at ambient pressure but rather is a heavy fermion compound with $\gamma \sim 530$ mJ/mol K$^2$. Studies suggest YbNi2B2C might be close to a quantum critical point (QCP) on the nonmagnetic side in the Doniach phase diagram. Resistance of single-crystalline YbNi2B2C is measured under pressure up to 16 GPa down to 50 mK as an attempt to reach QCP. Temperature-pressure phase diagram will be presented and discussed.

Keck Foundation V.S. acknowledges support by DOE/BES under contract No. DE-FG02-99ER45775. A. G. acknowledges support of RSF 16-12-10464 grant.

4:54PM P06.00013: THz Spectroscopy of the Heavy Fermion Metal YbAl3 DAVID BARBALAS (Presenter), Johns Hopkins University, SHOUVIK CHATTERJEE, UCSB, KYLE M SHEN, DARRELL G. SCHLOM, Cornell University, NORMAN ARMITAGE, Johns Hopkins University — Due to the interaction of local moment physics and mixed-valence behavior in Yb compounds, Yb heavy fermion compounds have not demonstrated the same range of phenomena seen in other f-orbital materials. Up to this point it has been difficult to measure the low energy electrodynamic response of these materials. However, high quality films of YbAl3 have been successfully grown and demonstrate significant changes in the electronic structure of the material mediated by the valence change in Yb. We have investigated the THz range electrodynamic response of these materials and discuss the results from the optical conductivity in the context of prevailing theories.

Wednesday, March 6, 2019 2:30 PM - 5:30 PM

Session P07 DCMP: Topological Electronic States in Kondo insulators and other f-electron materials

2:30PM P07.00001: Neutral Fermi surfaces in Mixed Valent Kondo Insulators: Majorana Hubbard Operators* PIERS COLEMAN (Presenter), Rutgers University, New Brunswick — The development of slave particle approaches provides a way to explore different patterns of operator fractionalization in strongly correlated systems. The recent observation of quantum oscillations in mixed valent SmB$_2$ has raised the possibility of neutral Fermi surfaces in this material[1-4]. This motivates a search for a representation of the Hubbard operator in terms of Majorana, rather than Dirac fermions. In this talk I will describe how this can be achieved and using the method, discuss the prospects for a two-phase description of SmB$_6$, in terms of a competition between a fully gapped strong topological insulator and a strange dielectric.

*Work supported by Department of Energy Basic Energy Sciences grant DE-FG02-99ER45790.
The role of $f-p$ hybridization in the bulk $f$-electronic structure of SmB$_6$

Jonathan Denlinger (Presenter), Lawrence Berkeley National Laboratory, Dae-Jeong Kim, Seoul National University, Zachary Fisk, UC Irvine — The topological origin of in-gap surface states of mixed-valent SmB$_6$, a candidate topological Kondo insulator, is currently being debated. In addition, there exist distinct discrepancies in the bulk electronic structure between DFT-based theory, ARPES, recent NIXS determination of the unoccupied $f$-hole symmetry [1], and the existence of low temperature dHvA oscillations [2,3]. Here we explore the role of $f-p$ hybridization in assisting $f-d$ hybridization in the formation of an insulating gap in its $f$-electronic structure. In a five-band model, the relative phase of $f-d$ and $f-p$ hybridizations allows tuning of the $f$-band structure between DFT-like and ARPES-like solutions, and hybridization amplitude tuning allows selection of the unoccupied X-point $f$-hole character. Also theoretically enabled is prediction of a distinct ARPES-measured 3D bulk $f$-hole-like dispersion at the "H"-point between adjacent X-point $d$-electron pockets. The $H$-point $f$-dispersion then naturally leads to exploration of the Landau level sharp DOS-discontinuity model [4] to quantitatively explain the size and shape of the dominant dHvA orbits.

Effect of reduced sample dimensions on the insulating state of SmB$_6$ *

Joonbum Park (Presenter), Mun Chan, Priscila Rosa, Neil Harrison, Los Alamos National Laboratory — The putative topological Kondo insulator SmB$_6$ has shown compelling evidence of robust conductive surface states, however less attention has been paid to the insulating bulk states which lies beneath. Here, we present the electrical transport measurements of the insulating state of SmB$_6$ down to $T \sim 250$ mK. We observed that the temperature dependence of resistivity shows additional power law-like dependence with temperature. These features develop below $T < 1.5$ K with reduction of sample dimensions, typically below 150 μm. We discuss whether the origin of these features are from dominant surface conduction over bulk conduction or due to impurities.

Search for charge neutral majorana fermions in SmB$_6$ under uniaxial strain

Brian Casas (Presenter), Laisi Chen, Zachary Fisk, Jing Xia, University of California, Irvine — The existence of a charge neutral fermi surface as evidenced from measurements of a large three dimensional fermi surface has motivated renewed interest in the bulk of samarium hexaboride. Thermal transport measurements have been performed using both flux and floating zone crystals, each resulting in different conclusions regarding a fermionic contribution suggestive of these charge neutral majorana fermions. Uniaxial strain has been shown to tune the mixed valence physics in the bulk and as such may be critical in understanding the underlying behavior of SmB$_6$. Here we report our progress on thermal transport on SmB$_6$ under uniaxial strain.

Ionic liquid gating on Al-flux grown SmB$_6$ using Hall bar geometry*

Alexa Rakoski (Presenter), Dmitri Mihaliov, Cagliyan Kurda, Department of Physics, University of Michigan, Priscila Rosa, Los Alamos National Laboratory, Zachary Fisk, Department of Physics and Astronomy, University of California Irvine — Samarium hexaboride (SmB$_6$) is a correlated material in which strong f-d interactions lead to the opening of a small hybridization gap below 100 K at the Fermi energy. Below 4 K, the plateau in resistivity which was a long standing mystery in SmB$_6$ has been proposed to arise from a crossover to surface conduction due to topological effects. We investigate how this plateau, as well as the corresponding plateau in the Hall coefficient, can be tuned by gating with the ionic liquid DEME-TFSI. Results are obtained on an Al-flux grown sample in Hall bar geometry prepared by finely polishing on all sides. The sample is suspended in the ionic liquid to ensure that all surfaces contributing to transport are gated. We find that resistivity can be changed by over 15% in the range of accessible voltages in the liquid, and that the Hall coefficient demonstrates a much larger effect of up to 33% change over the same range. We also present a model based on measured parameters of the 2D Fermi surface in SmB$_6$ to explore these changes.

3:30PM P07.00006: Itinerate states in rare-earth hexaborides observed via resonant inelastic x-ray scattering
DONAL SHEETS (Presenter), University of Connecticut, JIAN-XIN ZHU, Los Alamos National Laboratory, MAXIM DZERO, Kent State, DIEGO M CASA, JUNGHOO KIM, Argonne National Lab, PRISCILA ROSA, Los Alamos National Laboratory, ZACHARY FISK, University of California - Irvine, IGNACE JARRIGE, Brookhaven National Lab, JASON HANCOCK, University of Connecticut — We present X-ray resonant inelastic x-ray scattering (RIXS) data collected at the L edges of divalent hexaborides YbB₆ and EuB₆. At an incident energy corresponding to the divalent resonance, we observe strong RIXS signal which appears to be well-described by the unoccupied 5d density of states calculated from density functional theory. In addition, we observe a second set of RIXS excitations at higher incident energy which does not correspond to any observable feature in absorption. This anomalous scattering persists to low incident energy and therefore induces excited states which are relevant to material behavior. The two classes of excitation show distinct polarizationdependence and we propose a process which describes the origin of this RIXS intensity. Our results suggest far-reaching utility of L-edge RIXS in characterizing itinerate states of f-filling materials at a microscopic level.

3:42PM P07.00007: Charge neutral fermions and quantum oscillations in a topological Kondo insulator YbB₁₂
YUKI SATO (Presenter), Physics, Kyoto University, ZHI XU, Physics, University of Michigan, YUICHI KASAHARA, TOMOYA TANIGUCHI, SHIGERU KASAHARA, Physics, Kyoto University, LU CHEN, TOMOYA ASABA, COLIN TINSMAN, Physics, University of Michigan, HINAKO MURAYAMA, Physics, Kyoto University, OHEI TANAKA, YUTA MIZUKAMI, TAKASADA SHIBAUCHI, Advanced Materials Science, University of Tokyo, FUMITOSHI IGA, Science, Ibaraki University, JOHN SINGLETON, Los Alamos National Laboratory, LU LI, Physics, University of Michigan, YUJI MATSUDA, Physics, Kyoto University — Recent observations of quantum oscillations (QOs) in transport and thermodynamic parameters at high magnetic fields in a Kondo insulator YbB₁₂ have been a big surprise since it seems to host a Fermi surface, which is a defining character of a metal. In this talk, I will present low-temperature heat-transport measurements to discuss low energy excitations in the ground state of YbB₁₂. At zero field, despite the conductivity in the zero-temperature limit, κ₀xx/℃ is clearly resolved, leading to a spectacular violation of the Wiedemann-Franz law: the Lorenz ratio L = κ₀xx/ρxx/℃ T is 10⁴-10⁵ times larger than that expected in conventional metals. These data indicate that YbB₁₂ is a charge insulator but a thermal metal, suggesting the presence of itinerant neutral fermions. Remarkably, more insulating crystals with larger activation energies exhibit larger amplitudes of the resistive QOs as well as a larger κ₀xx/℃, in stark contrast to conventional metals. Moreover, we find that these fermions couple to magnetic field, despite their charge neutrality. Our findings expose novel gapless and highly itinerant, charge-neutral quasi-particles in this unconventional quantum state.

3:54PM P07.00008: Enhanced quantum oscillations in Kondo Insulators*
YEN-WEN LU (Presenter), Deparmeny of Physics, National Tsing Hua University, Hsinchu, Taiwan, CHUNG-HOU CHUNG, Electrophysics Department, National Chiao-Tung University, Hsinchu, Taiwan, CHUNG-YU MOU, Deparmeny of Physics, National Tsing Hua University, Hsinchu, Taiwan — We investigate quantum oscillations resulting from the Kondo screening due to Landau levels in Kondo insulators. It is shown that even for large Kondo insulating gap, appreciable amplitudes of oscillations for Kondo insulators in moderate magnetic fields are present in magnetization even at zero temperature. Specifically, based on the Anderson Lattice Hamiltonian, we analyze the magnetization of Kondo insulators by resorting to the slave-boson method. By including Landau levels, mean-field solutions are determined self-consistently. We find that mean-field parameters oscillate in response to the change of the magnetic field. As an outcome, instead of being rigid electronic structure, the energy band of Kondo insulators is non-rigid and oscillate with respect to the change of the magnetic field. Our results indicate that the nonrigidity of the electronic structure in Kondo insulators results in enhanced and observable quantum oscillations in magnetization.

4:06PM P07.00009: Anomalous symmetry-breaking response in proposed type-II Weyl semimetal
HALYNA HODOVANETS (Presenter), CHRIS ECKBERG, DANIEL CAMPBELL, DANIEL J KRAFT, SEAN A WINTERS, HYUNSOO KIM, JOHNPIERRE PAGLIONE, University of Michigan, College Park — We present details of flux growth and physical properties of noncentrosymmetric magnetic RAiGe (where R = Rare Earth) single crystals. The RAiGe family has been proposed, based on systematic first-principles band structure calculations, to host key elements of Weyl semimetals and as such offers a playground for new and exciting physics. We will discuss the effects of different rare earth species on the ground state magnetic order, magnetic anisotropy and correlation of the magnetotransport and crystal symmetry in the ordered state.
4:18PM P07.00010: Many-body dynamics and Kondo coherence collapse in an ultrafast driven Kondo insulator

WEI ZHU (Presenter), ALEXIS CHACON, JIAN-XIN ZHU, Los Alamos National Laboratory — Intense ultrafast pulse-driven electronics have provided systematic insights into the dynamics of electrons in condensed matter systems, which opens up prospects for quantum control of solids and all-optical band structure reconstruction. So far the studies have been carried out in solids where ‘bare’ electronic excitations dominate quantum dynamics. However, the underlying many-body dynamics due to correlations and couplings with other degrees of freedom such as lattice, spin or orbitals, has remained out of reach. Here, we introduce an ultrafast laser to optically pump and probe a Kondo lattice, in which conducting electrons strongly couple with magnetically local moments. The laser field excites collective doublon-hole pairs and drives a transient Kondo insulator melting, which are documented through the time-, frequency-, and momentum-dependent influence on the electronic structure. After photo-excitation, doublon-hole re-collision results in high-frequency photon emission. The information that we demonstrate as being accessible with time- and angle-resolved photo-electron spectroscopy and high-harmonic generation spectra, will stimulates the investigation of non-equilibrium dynamics and non-linear phenomenon in heavy-fermion systems.

4:30PM P07.00011: Exploring the valence transition in CeOs4Sb12 in high magnetic fields*

KATHRIN GOETZE (Presenter), MATTHEW J. PEARCE, PAUL GODDARD, Department of Physics, University of Warwick, Coventry CV4 7AL, United Kingdom, ALIX MCCOLLAM, THOMAS KHOURI, High Field Magnet Laboratory (HFML-EMFL), Radboud University, Toernooiveld 7, 6525 ED, Nijmegen, The Netherlands, MARCELO JAIME, National High Magnetic Field Laboratory, Los Alamos National Laboratory, Los Alamos, NM 87545, M BRIAN MAPLE, KALYAN SASMAL, Department of Physics, University of California, San Diego, La Jolla, CA 92093, TATSUYA YANAGISAWA, Department of Physics, Hokkaido University, Sapporo 060-0810, Japan, JOHN SINGLETON, National High Magnetic Field Laboratory, Los Alamos National Laboratory, Los Alamos, NM 87545, PEI-CHUN HO, Department of Physics, California State University, Fresno, Fresno, CA 93740 — We present measurements of resistivity, magnetostriction, and PDO conductivity on the skutterudite CeOs4Sb12 in static and pulsed magnetic fields up to 30/60 T, respectively. The temperature and field dependencies allow us to map out the boundaries of the low temperature phase (L phase) in the H-T-phase diagram which - contrary to previous results - shows an unusual dome-like appearance extending to 45 T. The L phase is characterized by semiconducting behaviour with a small Fermi surface whereas the metallic high-temperature, high-field H phase exhibits a large Fermi surface. Magnetostriction results suggest that the L to H transition is accompanied by a valence transition. Additional features in transport and PDO within the L phase point towards further alteration of the band structure with applied field. We discuss the phase diagram of CeOs4Sb12 in the context of hybridization of 4f electrons and compare it to other skutterudites.

4:54PM P07.00013: Bulk topological Fermi arcs in heavy fermion systems*  

YUKI NAGAI (Presenter), Japan Atomic Energy Agency, YANG QI, Fudan University, HIROKI ISOBE, VLADYSLAV KOZII, LIANG FU, Massachusetts Institute of Technology — We find that heavy fermion systems can have bulk Fermi arcs. In an interacting electron system, we can define the effective Hamiltonian \( H_{\text{eff}} = H + \Sigma \), where the many-body Hamiltonian is Hermitian, but the one-body quasiparticle Hamiltonian is non-Hermitian due to the finite quasiparticle lifetime. By introducing a topological theory of finite-lifetime quasiparticles, we can find that the low-energy dispersion of the Dirac material is reshaped and a topologically protected bulk Fermi arc appears[1,2]. Finite quasiparticle lifetime is a generic property of quantum many-body systems, resulting from scatterings. The exceptional points of the non-Hermitian quasiparticle Hamiltonian matrix play a crucial role. With the use of the dynamical mean field theory (DMFT) calculation, we confirm our statement in Kondo insulators with a momentum-dependent hybridization in two-dimensions. We show that the concept of the exceptional points in the non-Hermitian quasiparticle Hamiltonian is one of powerful tools to predict new phenomena in strongly correlated electron systems.

5:06PM P07.00014: Exploration of large anomalous Hall effect and topological Berry curvature in strongly correlated d- and f-electron magnets  

ERIC BAUER (Presenter), T. ASABA, NAKHEON SUNG, M. M. PIVA, M. CURTIS, SEAN THOMAS, PRISCILA ROSA, JOE D THOMPSON, FILIP RONNING, Los Alamos National Laboratory — The discovery of new topological states of matter and the effects of topology on the bulk properties of materials has attracted widespread attention [1], as these states are promising candidates for future technological applications such as quantum computing, memory storage, and sensors. While much of the research has focused on the exploration of topological states in materials without strong electronic correlations, these correlations open up new routes to generating novel topological states. For example, competing interactions among the magnetic moments of d- or f-electrons lead to magnetic frustration and often give rise to non-collinear or non-coplanar spin structures. Mobile conduction electrons feel the effects of a large (fictitious) magnetic field when they move in the topological spin texture of these non-collinear and non-coplanar magnets, which gives rise to a large anomalous Hall effect in compounds such as Mn3Sn [2,3]. In this talk, I discuss our recent work on the exploration of the anomalous Hall effect and topological Berry curvature in a variety of strongly correlated d- and f-electron magnets.

5:18PM P07.00015: Possible observation of topological surface states in a d-electron Kondo Insulator with angle-resolved photoemission spectroscopy*  

KEJUN XU (Presenter), YU HE, SUDI CHEN, Stanford University, MAKOTO HASHIMOTO, DONGHUI LU, SLAC national accelerator laboratory, SUNG-KWAN MO, Lawrence Berkeley National Laboratory, ZHIXUN SHEN, Stanford University — We use angle-resolved photoemission to probe the low energy bands of a d-electron Kondo Insulator exhibiting many similar properties as the prototypical f-electron topological kondo insulator candidate SmB6. We find a set of fermi surface features that disperse across \( E_F \), despite the bulk being insulating. Photon energy dependence shows the 2D nature of these bands. We discuss similarity and differences to SmB6 and open questions that challenges the current understanding of strongly correlated insulators.

*We acknowledge support from DOE/BES, Moore foundation, and NSF

Fermi-surface morphology and signatures of quantum critical points in the high-Tc cuprate HgBa2CuO4+δ revealed by high-magnetic fields* MUN CHAN (Presenter), NEIL HARRISON, ROSS MCDONALD, ERIC BAUER, Los Alamos National Laboratory — A paradigm of unconventional superconductivity invoked for the cuprates is that the unusually high superconducting temperatures is caused by strong electronic interactions near a zero temperature phase transition termed a quantum critical point (QCP). We report measurements of the low temperature electronic structure of the single-layer cuprate featuring the highest superconducting temperatures, HgBa2CuO4+δ (Hg1201). Quantum oscillations indicate that the Fermi surface is comprised of only a single quasi-two dimensional pocket that likely results from Fermi-surface reconstruction by a charge density wave order. High magnetic field measurements up to 90 T allow us to determine the boundaries of this order and identify two putative quantum critical points. Measurements of the doping dependent effective mass and upper critical fields provide additional support for strong-correlations around these QCPs.

Probing the Fermi surface of Nd-LSCO with angle-dependent magnetoresistance measurements YAWEN FANG (Presenter), Physics, Cornell University, ANAELLE LEGROS, GAELE GRISONNANCHE, FRANCIS LALIBERTE, Physics, Université de Sherbrooke, PAUL GODDARD, Physics, University of Warwick, LOUIS TAILLEFER, Physics, Université de Sherbrooke, BRAD RAMSHAW, Physics, Cornell University — Characterizing the Fermi surface of high-temperature superconductors in the pseudogap phase is one of the major challenges in understanding the origin of this mysterious partial gap in the electronic density of states. The Fermi surface between p=0.08 and p=0.15, the same doping range where charge order is observed, has been determined via quantum oscillations to be a small electron pocket. Above the critical doping p*, in the Fermi-liquid phase, a single large hole surface has been reported. However, in the pseudogap phase, the topology of the Fermi surface at low temperature in the absence of superconductivity or charge-density-wave order is still unknown. To study the topology of this Fermi surface, we performed an angle-dependent magneto-resistance (ADMR) study of Nd-LSCO. We measured the ADMR of single crystal La1.6-xNd0.4SrxCuO4 (Nd-LSCO) with x=p=0.2,0.21,0.22,0.23,0.25, up to 45 tesla and down to 6 kelvin. At p=0.25, above p*, we find a large Fermi surface whose geometry is consistent with that observed by ARPES, but with a strongly anisotropic quasiparticle lifetime. Below p*, in the pseudogap state, we observe a dramatic change in the ADMR, and preliminary analysis suggests that strong anti-nodal scattering is responsible.

Superconducting Higgs mode in cuprate thin films HAO CHU (Presenter), MIN-JAE KIM, Max Planck Institute for Solid State Research, KOTA KATSUMI, Department of Physics, University of Tokyo, SERGEY KOVALEV, Helmholtz Centre Dresden-Rossendorf, ROBERT DAWSON, LUKAS SCHWARZ, Max Planck Institute for Solid State Research, NAOHAKA YOSHIKAWA, Department of Physics, University of Tokyo, GIDEON KIM, Max Planck Institute for Solid State Research, SEMYON GERMANSKIY, JAN-CHRISTOPH DEINERT, NILESH AWARI, BERTRAM W GREEN, MIN CHEN, MOHAMMED BAWATNA, Helmholtz Centre Dresden-Rossendorf, GEORG CRISTIANI, GENNADY LOGVENOV, Max Planck Institute for Solid State Research, YANN GALLAIS, Laboratoire Matériaux et Phénomènes Quantiques, Université Paris Diderot, ALEXANDER BORIS, BERNHARD KEIMER, ANDREAS P SCHNYDER, DIRK MANSKE, Max Planck Institute for Solid State Research, MICHAEL GENSH, ZHE WANG, Helmholtz Centre Dresden-Rossendorf, RYO SHIMANO, Department of Physics, University of Tokyo, STEFAN KAISER, Max Planck Institute for Solid State Research — Cuprate high-Tc superconductor hosts multiple competing orders such as the pseudogap, incommensurate magnetism, charge order, etc. These diverse phases were discovered via spectroscopy tools that probe the charge-/spin-excitations of an ordered state. Yet, despite the immense knowledge about cuprates learnt from these experiments, a coherent understanding of the microscopic mechanism behind high-Tc superconductivity is still lacking. A potential answer to this question may come from investigating the collective excitation of the superconducting order parameter itself, which is charge- and spin-neutral and difficult to access by conventional techniques. We accomplish this goal by using an undulator-based high-field THz pulse, which nonlinearly couples to the superconducting condensate and leads to characteristic third harmonic generation. Using this technique, we unveil the collective amplitude oscillation of the superconducting order parameter, the superconducting Higgs mode, in three archetypal families of cuprates for the first time. In addition, we show evidence for a hitherto unreported collective mode universally exhibited by optimally doped samples. A finite Higgs-like response above Tc is also observed in our experiment, suggesting a finite pairing amplitude above Tc.
3:06PM P08.00004: Breaking the universal Tc-P relation to higher Tc of cuprate HTS* CHING-WU CHU (Presenter), LIANGZI DENG, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204, YONGPING ZHENG, Materials Science & Engineering, University of Texas at Dallas, Richardson, TX 75080, ZHENG WU, SHUYUAN HU, CHUN YUAN, HUNG-CHENG WU, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204, KYEONGJAE CHO, Materials Science & Engineering, University of Texas at Dallas, Richardson, TX 75080 — By investigating the bulk superconducting state via dc magnetization measurements, we have discovered the resurgence of the superconductive transition temperature Tcs of the monolayer Bi2Sr2CuO6+δ and bilayer Bi2Sr2CaCu2O8+δ to beyond the maximum Tc-maxs predicted by the universal Tc-P relation at higher pressures. We have attributed the resurgence to a possible pressure-induced electronic transition in the compounds, associated with a charge transfer between the Cu 3dx2-y2 and the O 2p bands, leading to an increase of the density of states at the Fermi level, in agreement with our density functional theory calculations. Similar Tc-P behavior has also been reported in the trilayer Br2Sr2Ca2Cu3O10+δ. The observations suggest that higher Tcs in the layered cuprate high temperature superconductors than those previously reported can be achieved by breaking away from the universal Tc-P by the application of higher pressures.

3:18PM P08.00005: Thermoelectric evidence of anomalous quantum criticality in the electron-doped cuprates* PAMPA MANDAL SARKAR (Presenter), TARAPADA SARKAR, RICHARD L. GREENE, University of Maryland, College Park — In electron-doped cuprates, the low upper critical field allows one to study the putative quantum critical phenomena at low temperature and to understand its connection to the long standing problem of the origin of high-Tc superconductivity. We have measured the low temperature normal state thermopower (S) of the electron-doped cuprate superconductor La2-xCexCuO4 (LCCO) from x=0.11 to 0.19. We observe quantum critical S/T versus ln(1/T) behavior over an unexpectedly wide doping range x = 0.15 - 0.17 above the putative QCP (x=0.14) with a slope that scales monotonically with the superconducting transition temperature. We find similar behaviour in another n-type cuprate, PCCO, strongly indicating that this is a universal behaviour in electron-doped cuprates. The presence of quantum criticality over a wide doping range provides a new window on the criticality. The thermopower behavior also suggests that the critical fluctuations are linked with Tc. For x = 0.11 and 0.13, S/T has a completely different behavior, an indication of a Fermi surface reconstruction. Above the superconductivity dome, at x=0.19, a conventional Fermi-liquid S-T behavior is found for Ts≤40 K.

3:30PM P08.00006: Josephson interferometry measurements of the superconducting pairing symmetry in the overdoped cuprate La1.75Sr0.25CuO4 --- search for disorder-induced deviations from d-wave symmetry* DAVID HAMILTON (Presenter), University of Illinois at Urbana-Champaign, MASAKI FUJITA, Tohoku University, DALE J VAN HARLINGEN, University of Illinois at Urbana-Champaign — Extensive measurements have shown that cuprate superconductors exhibit a robust d x2-y2 global superconductor pairing symmetry. It has been proposed that in a disordered d-wave superconductor near criticality, the superconductivity will nucleate in spatially-separated puddles with orthogonal phase alignment of the d-wave order parameter. When these puddles are dilute, such as in highly overdoped samples, Josephson coupling between puddles can favor global s-wave superconductivity. To explore this regime, we perfromed Josephson interferometry measurements of LSCO-Au-Nb Josephson junctions formed on edges and corners of an overdoped single crystal of La1.75Sr0.25CuO4 with a Tc of ~18K. In preliminary measurements of l.c vs. magnetic field, we observe deviations from Fraunhofer patterns expected for uniform edge junctions and from the characteristic corner junction pattern expected for dx2-y2 symmetry. We see rapid modulations in the critical current indicating the presence of discrete order parameter domains with opposite sign. At temperatures near where the junction supercurrent vanishes, we observe diffraction patterns with a maximum centered on zero field in the corner junctions, as we would expect to see in an s-wave superconductor.

3:42PM P08.00007: The New NMR Shift and Relaxation Scenario of the Cuprates  JUERGEN HAASE (Presenter), Leipzig University — Based on experiments and a comprehensive literature analysis of cuprate NMR shift and relaxation data we present the new scenario for the cuprates. It has almost ubiquitous fermionic excitations that govern the nuclear relaxation above Tc and begin to disappear below Tc, i.e., for all materials from slightly underdoped to heavily overdoped. For the highest doping levels, this nuclear relaxation is related to the sample’s spin shift via the Korringa relation for a simple Fermi liquid to which the nuclei couple isotropically. Therefore, it is argued that the spin shifts of the cuprates are typically suppressed, already in the overdoped region, and that there is no enhanced nuclear relaxation compared to that of a Fermi liquid. This means, no spin fluctuations have to be invoked to explain the difference between shift and relaxation. This suppression of the shift above Tc must be related to the pseudogap, which enters nuclear relaxation only through a temperature independent change in the anisotropy of the coupling of the nuclei to the electronic bath. It is argued that two antiferromagnetically coupled spin components that have different orbital origin can explain all the data, even the NMR orbital shift conundrum.

3:54PM P08.00008: Apical charge flux-modulated in-plane transport properties of cuprate superconductors*  XIN LI (Presenter), SOORAN KIM, XI CHEN, WILLIAM FITZHUGH, Harvard University — For copper-based superconductors, the maximum superconducting transition temperature, $T_{c,max}$, of different families measured from experiments can vary by an order of magnitude from 38 K in La$_2$CuO$_4$ to 135 K in HgBa$_2$Ca$_2$Cu$_3$O$_8$ at optimal hole doping concentration. We demonstrate herein, using ab initio computations, a new trend suggesting that the cuprates with stronger out-of-CuO$_2$-plane chemical bonding between the apical anion (O, Cl) and apical cation (e.g. La, Hg, Bi, Tl) are generally correlated with higher $T_{c,max}$ in experiments. We then show the underlying fundamental phenomena of coupled apical charge flux and lattice dynamics when the apical oxygen oscillates vertically. This triggers the charge flux among the apical cation, apical anion and the in-plane CuO$_4$ unit. The effect not only dynamically modulates the site energy of the hole at a given Cu site to control the in-plane charge transfer energy, but also can modulate the in-plane hole hopping integral in a dynamic way by the cooperative apical charge fluxes.

*This work is supported by the computational resources from XSEDE and the Odyssey cluster at Harvard University.

4:06PM P08.00009: Non-equilibrium study of the phase diagram of cuprates  FABIO BOSCHINI (Presenter), ELIA RAZZOLI, MARTA ZONNO, RYAN P DAY, MATTEO MICHIARDI, QMI, University of British Columbia, EDUARDO H DA SILVA NETO, Physics, Univ of California - Davis, GENDA GU, Cond. Matt. Physics and Material Science, Brookhaven Natl Lab, SERGEY ZHDANOVICH, ARTHUR K MILLS, GIORGIO LEVY, DAVID J JONES, QMI, University of British Columbia, CLAUDIO GIANNELLI, Mathematics and Physics, Univ. Cattolica Brescia, ANDREA DAMASCELLI, QMI, University of British Columbia — The phase diagram of cuprates hosts numerous intertwined phases, such as high-temperature superconductivity, charge order and the pseudogap phenomenon. This makes the precise description of each separate phase challenging. In particular, thermal excitations govern the appearance of different phases and thermodynamic phase transitions. We recently demonstrated the capability to study the superconductor-to-normal state transition in Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ cuprate superconductor in an ultrafast fashion. In particular, we demonstrated that time-resolved photoemission spectroscopy can disentangle the dynamics of phase fluctuations and charge excitation, establishing the dominant role of phase coherence in the emergence of high-temperature superconductivity [1]. In the same line of thought, we applied this non-equilibrium approach to (i) reveal the transient competition between charge-order and superconducting phases and (ii) explain the enhanced electron-boson band renormalization (kink) in terms of the opening of the superconducting gap and pseudogap.

4:18PM P08.00010: Fluctuating superconductivity and absence of charge order in heavily overdoped cuprate Bi-2212*  YU HE (Presenter), SUDI CHEN, Stanford University, MAKOTO HASHIMOTO, SLAC, ALEX FRANCO, Physics, University of California, San Diego, MING YI, Physics, Rice University, YU SONG, SHAN WU, Physics, University of California, Berkeley, DONGJOON SONG, Physics, Yonsei University, HIROSHI EISAKI, AIST, ROBERT J BIRGENCEAU, Physics, University of California, Berkeley, ZHIXUN SHEN, Stanford University — We identify significant superconducting fluctuations on a single coherent, hole-like Fermi surface in heavily overdoped cuprate superconductor Bi-2212. No evidence of pseudogap or valence electron charge order are found in the meantime. Both amplitude and phase fluctuations are quantitatively estimated via measurements of resistivity anisotropy, specific heat jump, and superconducting coherent length. The important role of the quasi-two-dimensional flat band and the van Hove singularity are discussed in the end.

*US Department of Energy, Basic Energy Sciences
4:30PM P08.00011: Phase fluctuation in overdoped cuprates? Superconducting dome due to Mott-ness of the tightly bound preformed pairs  
ZIJIAN LANG (Presenter), School of Physics and Astronomy, Shanghai jiaoTong University, FAN YANG, School of Physics, Beijing Institute of Technology, WEI KU, School of Physics and Astronomy, Shanghai jiaoTong University — In contrast to the current lore, we demonstrate that even the overdoped cuprates suffer from superconducting phase fluctuation in the strong binding limit. Specifically, the Mott-ness of the underlying doped holes dictates naturally a generic optimal doping around 15% and nearly complete loss of phase coherence around 25%, giving rise to a dome shape of superconducting transition temperature in excellent agreement with experimental observations of the cuprates. We verify this effect with a simple estimation using Gutzwiller approximation of the preformed pairs, obtained through variational Monte Carlo calculation. This mechanism also provides a natural explanation for the observed relation between superconducting temperature and superfluid density near the overdoped end of the dome. This realization suggests strongly the interesting possibility that the high-temperature superconductivity in the cuprates might be mostly described by Bose-Einstein condensation, without crossing over to amplitude fluctuating Cooper pairs.

4:42PM P08.00012: Angular Magnetoresistance Measurements as a Probe of the Fermi Surface in Hg1201*  
KATHERINE SCHREIBER (Presenter), MUN CHAN, NEIL HARRISON, ERIC BAUER, Los Alamos National Laboratory — The Fermi surface of underdoped cuprates is reconstructed by charge density wave order. An elucidation of the exact morphology of the reconstructed Fermi-surface is expected to provide insight into the relationship between charge order and superconductivity. We present measurements of the Fermi surface of underdoped HgBa2CuO4+d (Hg1201), obtained through angular magnetoresistance. Transport along the c-axis was measured in pulsed magnetic fields of up to 65 T, applied along many polar and azimuthal angles in order to map out the Fermi surface. We discuss the implication of our measurements for the shape of the Fermi surface, including the interlayer warping, and comment on its dependence on temperature and doping.

*This work is funded by the US DOE-BES "Science at 100T" LANL F100 grant. Work was done at the National High Magnetic Field Laboratory which is supported by the National Science Foundation through NSF/DMR-1644779 and the State of Florida.

4:54PM P08.00013: Universal $T$-linear resistivity and Planckian dissipation in cuprates  
LOUIS TAILLEFER (Presenter), ANAELLE LEGROS, Université de Sherbrooke, Canada, SIHAM BENHABIB, WOJCIECH TABIS, LNCMI Toulouse, France, FRANCIS LALIBERTE, MAXIME DION, MAUDE LIZAIRE, Université de Sherbrooke, Canada, BAPTISTE VIGNOLLE, DAVID VIGNOLLES, LNCMI Toulouse, France, HÉLÈNE RAFFY, ZZ LI, PASCALE AUBAN-SENZIER, Université Paris-Sud, France, NICOLAS DOIRON-LEYRAUD, PATRICK FOURNIER, Université de Sherbrooke, Canada, DOROTHÉE COLSON, CEA Saclay, France, CYRIL PROUST, LNCMI Toulouse, France — The perfectly linear temperature dependence of the electrical resistivity observed as $T\to 0$ in a variety of metals close to a quantum critical point is a major puzzle of condensed matter physics. Here we show that $T$-linear resistivity as $T\to 0$ is a generic property of cuprates, associated with a universal scattering rate [1]. We measured the low-temperature resistivity of the bi-layer cuprate Bi2212 and found that it exhibits a $T$-linear dependence with the same slope as in the single-layer cuprates Bi2201, Nd-LSCO and LSCO, despite their very different Fermi surfaces and structural, superconducting and magnetic properties. We then show that the $T$-linear coefficient (per CuO$_2$ plane), $A$, is given by the universal relation $A T_F = \hbar / 2 e^2$, where $e$ is the electron charge, $\hbar$ is the Planck constant and $T_F$ is the Fermi temperature. This relation, obtained by assuming that the scattering rate $1 / \tau$ of charge carriers reaches the Planckian limit [2], whereby $h / \tau = 2 \pi k_B T_F$ works not only for hole-doped cuprates but also for electron-doped cuprates, despite the different nature of their quantum critical point and strength of their electron correlations.

Here, we use the d-form factor density wave (DW), imaged via scanning tunneling microscopy, to probe the ground state evolution in superconducting (Pb,Bi)$_2$(Sr,La)$_2$CuO$_{6+\delta}$ (Bi-2201). We employ the disorder caused by local dopant inhomogeneity to gain continuous access to the doping axis of the phase diagram, both via standard Fourier techniques and machine learning. We find a transition in the DW from commensurate to incommensurate, which occurs simultaneously with the Fermi surface transition, where open arcs are replaced by a conventional large Fermi surface. The coincidence of these transitions indicates an intimate link between the commensurate instability and the mechanism underlying the Fermi arcs.

**5:18PM P08.00015: Nodeless high-Tc superconductivity in highly-overdoped monolayer CuO$_2$**

KUN JIANG (Presenter), Boston College, XIANXIN WU, Physics, University of Wurzburg, JIANGPING HU, Chinese Academy of Sciences, ZIQIANG WANG, Boston College — We study the electronic structure and superconductivity in CuO$_2$ monolayer grown recently on d-wave cuprate superconductor Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$. Density functional theory calculations indicate significant charge transfer across the interface such that the CuO$_2$ monolayer is heavily overdoped into the hole-rich regime. We show that both the Cu d$_{x^2-y^2}$ and d$_{3z^2-r^2}$ orbitals become important and the Fermi surface contains one electron and one hole pocket associated with the two orbitals respectively. The liberated low-energy d$_{3z^2-r^2}$ band and the hole FS pocket around M enable an analogy to the multiorbital Fe-pnictides superconductors. Constructing a minimal strongly correlated two-orbital model for the e$_g$ complex, we show that the spin-orbital exchange interactions produce an intrinsic nodeless superconductor with extended s-wave pairing symmetry and a pairing energy gap comparable to the bulk d-wave gap, in agreement with recent experiments. The findings point to a direction of realizing new high-Tc superconductors over-extended doping regimes with liberated orbitals in ozone grown transition-metal-oxide heterostructures.

**Session P09 DCMP: Superconductivity in Dichalcogenides and Similar Materials**

Patrick Vora, George Mason Univ
Superconductors of monolayered transition metal dichalcogenides such as MoS$_2$ and NbSe$_2$ give rise to TSC. However, as of date, few-layer NbSe$_2$ is produced mainly through mechanical exfoliation. There is a demand to construct large scale NbSe$_2$ thin films to further enable fabrication of scalable heterostructures. In contrast, in this talk, we report our progress on few-layer NbSe$_2$ grown on insulating substrates by MBE. The layers are characterized by in-situ reflection high energy electron diffraction (RHEED) and ex-situ Raman spectroscopy. A clear superconducting transition has been observed with the transition temperature (Tc) above 2K. We will discuss correlations between layer quality and the Tc. We will also present our studies regarding the critical field in thin film NbSe$_2$.

The ability to fit this transition using activated scaling shows that this transition is well described by an infinite-randomness critical point and quantum Griffiths singularities.

Superconductivity in few-layer NbSe$_2$ grown by molecular beam epitaxy

PENG WEI, University of California, Riverside — Superconductors with strong spin-orbit coupling (SOC) are attractive for generating triplet Cooper pairs and topological superconductivity (TSC). In few-layer NbSe$_2$, strong SOC is reported to give rise to TSC. However, as of date, few-layer NbSe$_2$ is produced mainly through mechanical exfoliation. There is a demand to construct large scale NbSe$_2$ thin films to further enable fabrication of scalable heterostructures that can exhibit the unique properties of TSC. Recent reports show that NbSe$_2$ can be grown on graphene by molecular beam epitaxy (MBE). In contrast, in this talk, we report our progress on few-layer NbSe$_2$ grown on insulating substrates by MBE. The layers are characterized by in-situ reflection high energy electron diffraction (RHEED) and ex-situ Raman spectroscopy. A clear superconducting transition has been observed with the transition temperature (Tc) above 2K. We will discuss correlations between layer quality and the Tc. We will also present our studies regarding the critical field in thin film NbSe$_2$.

Ising superconductivity in NbSe$_2$-Te$_x$ with tunable spin-orbit coupling

ZHENYU ZHANG (Presenter), LEIQIANG LI, WEI QIN, PING CUI, CHANGGAN ZENG, University of Science and Technology of China — The Ising superconductors of monolayered transition metal dichalcogenides such as MoS$_2$ and NbSe$_2$ have been shown to possess strongly enhanced upper critical fields. In these systems, the spin-orbit coupling (SOC) pins the electron spins to the out-of-plane direction because of in-plane mirror symmetry breaking, thereby becoming insensitive to the lateral external magnetic fields. Here, using first-principles density functional theory calculations, we demonstrate that the Te substitution of Se in NbSe$_2$ will enhance the strength of the SOC, as characterized by the increased spin splitting in the electronic structures of NbSe$_2$-Te$_x$. As a consequence, the upper critical fields of these systems will be further enhanced. Moreover, as x approaches to 2, the enhanced SOC leads to a band inversion around the high symmetry M point in the Brillouin zone, indicating a quantum phase transition towards a topological superconducting state.

The enhancement of in-plane Hc$_2$ in monolayer centrosymmetric superconductor 1T'-WTe$_2$ via strong spin-orbital coupling

YINGMING XIE (Presenter), WENYU HE, KAM TUEN LAW, Hong Kong University of Science and Technology — Recently, it was reported that the two-dimensional quantum spin Hall insulator 1T'-WTe$_2$ can be gated into the superconducting phase. The in-plane Hc$_2$ in this centrosymmetric superconductor is enhanced up to 2-4 times Pauli limit. However, unlike the typical enhancement of Hc$_2$ in a non-centrosymmetric superconductor, the mechanism here is not clear. In this work, we find due to the strong spin-orbital coupling (SOC), the spin susceptibility is reduced in the low gating region. In other words, the magnetic field felt by electrons near the Fermi energy is renormalized, which in turn enhances the Hc$_2$. The amplitude of enhancement is comparable to the experiments. Moreover, in this mechanism, the anisotropic SOC will lead to obvious anisotropy in Hc$_2$, which can be tested in experiments by rotating the magnetic field.
3:30PM P09.00006: Superconductivity in Br-doped misfit compounds \((\text{PbSe})_{1.12}(\text{TaSe}_2)\)^* ZHUAN XU (Presenter), Physics Department, Zhejiang University — We report the discovery of superconductivity with a maximum \(T_c\) of 1.28 K in Br-doped \((\text{PbSe})_{1.12}(\text{TaSe}_2)\), which is a new misfit compound consisting of alternating layers of distorted rocksalt PbSe and dichalcogenide TaSe_2. The Br-doping is required for the formation of this misfit compound and superconductivity can be tuned by changing Br content. The large anisotropic parameters in both resistivity and upper critical field \(H_{c2}\) are found. The estimated c-axis coherence length of 6.3 nm is larger than the c-axis lattice constant, which implies that this compound is an anisotropic three-dimensional superconductor. The Hall coefficient measurements suggest that the charge transport is dominated by the hole-type charge carrier and there is a charge transfer from the PbSe layer to the conducting TaSe_2 layer. The small normalized specific heat jump and electron-phonon coupling constant of 0.61 indicate that Br-doped \((\text{PbSe})_{1.12}(\text{TaSe}_2)\) should be a weak-coupling BCS superconductor. The point-contact Andreev reflection spectroscopy is also studied.

3:42PM P09.00007: Superconductivity and Charge Density Wave in SnSe\textsubscript{2}-based Heterostructures* YIMIN ZHANG (Presenter), JIA-QI FAN, CANLI SONG, XUCUN MA, QIKUN XUE, Department of Physics, Tsinghua University — We report the direct observation of interface superconductivity and interface-induced charge density wave on monolayer SnSe\textsubscript{2}-based heterostructures. Tunneling spectrums on epitaxial monolayer SnSe\textsubscript{2} grown on graphited SiC(0001) substrate showed a fully-gapped superconducting state with rather conventional character. Occurrence of vortices under external magnetic field further confirmed the superconductivity. We attribute the superconductivity to the two-dimensional gas formed at the interface of SnSe\textsubscript{2} and graphene. Besides, charge density waves (CDW) with \(2 \times 2\) periodicity were observed in SnSe\textsubscript{2} thin films grown on SrTiO\textsubscript{3}(001) and Si(111), which disappear as the film thickness increases. Our finding opens new perspectives to understand not only interface superconductivity but also possible relationship between superconductivity and CDW.

3:54PM P09.00008: Superconductivity in electron-doped layered 1T-SnSe\textsubscript{2} HANLIN WU (Presenter), SHENG LI, Physics, University of Texas at Dallas, TIMOTHY HAUGAN, MICHAEL SUSNER, Air Force Research Laboratory, Wright-Patterson Air Force Base, BING LV, Physics, University of Texas at Dallas — Layered metal chalcogenide 2D materials have attracted great attention in the recent years due to their emergent new physics phenomena such as surface states, magnetism, giant magnetoresistance, quantum spin Hall effects, and superconductivity. Chemical intercalation, or physical electron-gating, has been found out to be very effective to tune the electronic structures and the associated physical properties. In this presentation, we will focus on our experimental intercalation studies of the CdI\textsubscript{2}-type 1T-SnSe\textsubscript{2} phase. Both electron doping by alkaline metal intercalation and polar organic solvent cointercaltion have been carried out through soft chemical methods. The associated structural characteristics, magnetic, electrical resistivity changes upon doping, and the unconventional superconductivity will be presented. The possible competing orders of charge density wave and superconductivity upon intercalation will be discussed as well.

4:06PM P09.00009: Theory of unconventional superconductivity in gated monolayer WTe\textsubscript{2} YI-TING HSU (Presenter), WILLIAM COLE, RUI-XING ZHANG, JAY SAU, Physics, University of Maryland, College Park — Recent observation of superconductivity in monolayer WTe\textsubscript{2} upon gating has attracted much interest since the undoped WTe\textsubscript{2} has been experimentally established as a quantum spin Hall insulator. Although the nature of the superconductivity remains elusive, the prevailing expectation is that inducing superconductivity in already topological materials is a promising route to identifying new exotic superconductors. Here we investigate the dominant pairing instabilities under different microscopic interactions by solving the linearized gap equation. We find equal-spin paired state that is consistent with the experimentally found high critical field, and we discuss the possibility of topological paired state. Finally, we consider the effects of a single impurity, as the first step towards determining how disorder impacts the phase diagram.
4:18PM P09.00010: Nodeless superconductivity in the type-II Dirac semimetal PdTe2: London penetration depth and pairing-symmetry analysis*  

PETER ORTH (Presenter), SERAFIM TEKNOWJOYO, NA HYUN JO, Iowa State University, MATHIAS SCHEURER, Harvard University, MAKARIV A TANATAR, Iowa State University, KYUIL CHO, Ames Laboratory, SERGEY BUDKO, P.C. CANFIELD, RUSLAN PROZOROV, Iowa State University — London penetration depth and normal-state resistivity were measured in single crystals of type-II Dirac semimetal PdTe2. Superfluid density is exponential at low temperatures and follows single-gap BCS model with weak-coupling \( \Delta(0)/T_c = 1.76 \) in the whole temperature range. Electrical resistivity is compatible with a classical metal with dominant electron-phonon scattering obtained from the fit to Bloch-Grüneisen formula with a Debye temperature of 207 K from specific heat data. We compare these experimental results with expectations from a detailed theoretical symmetry analysis and reduce the number of possible superconducting pairing states in PdTe2 to only three nodeless candidates: a regular, topologically trivial s-wave pairing, and two distinct odd-parity triplet states that both can be topologically nontrivial depending on the microscopic interactions driving the superconducting instability. Finally, we theoretically discuss the effect of disorder on the different pairing states.

*Work done at Ames Laboratory was supported by the U.S. DOE Office of Basic Energy Sciences, DMSE. Ames Laboratory is operated for the U.S. DOE by Iowa State University under Contract No. DE-AC02-07CH11358. NHJ by the Gordon and Betty Moore Foundation's EPiQS Initiative through Grant GBMF4411.

4:30PM P09.00011: Robust parity-mixed superconductivity in disordered 2D transition metal dichalcogenides*  

DAVID MÖCKLI, MAXIM KHODAS (Presenter), Hebrew University of Jerusalem — Monolayer NbSe2 is a nodal topological Ising superconductor at magnetic in-plane fields exceeding the Pauli limit, with nodal points strictly on high symmetry lines in the Brillouin zone. Here, we use a combined numerical and group-theoretical approach in real-space to characterize the unconventional superconducting state in monolayer transition metal dichalcogenides. Even with a conventional pairing interaction, the superconducting state is intrinsically parity-mixed and robust against on-site disorder. The interplay between the Zeeman magnetic field, strong spin-orbit interaction, and electronic orbital content confer the unique superconducting and topological properties. The discussion also extends to strongly hole-doped MoS2 and its relatives.

*Israel Science Foundation, Grant No. 1287/15

4:42PM P09.00012: Ising superconductors in in-plane magnetic fields  

STEFAN ILIC (Presenter), JULIA MEYER, MANUEL HOUZET, Univ. Grenoble Alpes, CEA, INAC-Pheliqs, Grenoble, France — Transition metal dichalcogenide monolayers are a new class of two-dimensional superconductors. They host a strong intrinsic spin-orbit coupling (SOC), that acts as an effective Zeeman field with opposite, out-of-plane, orientations in the +K and –K corners of the Brillouin zone (valleys). This SOC causes unconventional “Ising pairing” of the Cooper pairs, formed of electrons from opposite valleys with strongly pinned out-of-plane spins. In-plane fields are thus not efficient in breaking the Cooper pairs by the paramagnetic effect, which results in a large enhancement of the in-plane upper critical field – the main signature of Ising superconductivity.

Using a quasiclassical formalism for disordered Ising superconductors, we calculate the in-plane upper critical field, as well as the density of states in the superconducting phase. We show that these quantities are not affected by intravalley scattering, and are determined by the interplay of the SOC and intervalley scattering. The smearing of the density of states with the applied field cannot be captured with the standard Abrikosov-Gor’kov theory. We compare our results with recent experiments.

4:54PM P09.00013: Superconductivity in Re6Se8Cl2, a Superatomic Two Dimensional Semiconductor  

EVAN TELFORD (Presenter), JAKE RUSSELL, JOSH SWANN, KIHONG LEE, XIAOYANG ZHU, XAVIER ROY, CORY R DEAN, Columbia University — We report on low temperature transport measurements of Re6Se8Cl2 - a synthesized van der Waal cluster solid with a hierarchical structure composed of covalently linked Re6Se8 clusters. Samples are prepared by mechanical exfoliation onto a PDMS stamp, then transferred to metallic leads pre-patterned on a SiO2 substrate. As grown, this material is a weakly-doped semiconductor, with strongly insulating behavior observed at cryogenic temperatures. Using a current annealing technique we demonstrate the ability to induce an insulator to superconductor transition, in situ. This transition is accompanied by an increase in the carrier density by 3-4 orders of magnitude. The chemical (EDX) and structural (Raman) analysis after current annealing show no change in chemical composition or lattice structure. We conjecture that the transition results from a small loss of interplanar chlorine atoms through the application of large currents. Details of the superconducting state and its possible nature will be discussed.
YUN-YI PAI (Presenter), MEGAN BRIGGEMAN, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, JUNG-WOO LEE, Department of Materials Science and Engineering, University of Wisconsin-Madison, MENGCHEN HUANG, JIANAN LI, Department of Physics and Astronomy, University of Pittsburgh, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — We investigate the effects of the geometrical shapes of the 1D nanowires created at LaAlO3/SrTiO3 in order to study the origin of superconductivity of SrTiO3, which has puzzled researchers for more than 50 years. It was recently suggested that electron pairing in SrTiO3 may be related to ferroelastic domain walls [1]. By using conductive-AFM lithography [2] to create 1D superconducting nanowires at the LaAlO3/SrTiO3 interface, we can investigate the influence of nanowire shape, and in particular the effect of sharp turns in the nanowire, on superconducting behavior in the nanowires. We find a significant stabilization of the superconducting state in “zigzag” wires compared with straight control wires, both created at the same time and located only a few micrometers apart. We discuss possible origins for this behavior within the context of ferroelastic domain structure that surrounds the nanowires.

MATTHIAS HECKER (Presenter), TKM, Karlsruhe Institute of Technology (KIT), EREZ BERG, Weizmann Institute of Science, JOERG SCHMALIAN, TKM, Karlsruhe Institute of Technology (KIT) — Under Cu or Nb doping, the topological insulator Bi2Se3 becomes superconducting with a maximal Tc~3-4 K. The pairing symmetry has been intensely studied and in recent years, experiments have consistently pointed towards an unconventional, odd-parity triplet pairing in the two-dimensional irreducible representation Eu of the crystal point group D3d. Due to a low carrier density and a small ratio of the superconducting coherence length and the Fermi wavelength, fluctuations are increasingly important, even to the extent that they allow for a preformed nematic state with T_n> T_c. Inside this performed phase, we study resistivity, elastic constants, and fluctuating diamagnetism. Furthermore, we investigate how the superconducting ground state in a constant magnetic field is affected by the preformed phase.
3:06 PM P11.00002: Design of Two-Level Quantum state in 2D Materials for Single Photon Emission  SUNNY GUPTA (Presenter), JI-HUI YANG, BORIS YAKOBSON, Rice University — Due to reduced dimensionality, defect levels in two-dimensional (2D) semiconductors are often far away from band edges, making 2D semiconductors ideal systems for single photon emission (SPE), if they can host defects forming a two-level quantum state. Recently, SPE was experimentally observed in different 2D materials. However, the defect centers serving as sources for SPE are yet to be identified and the possible mechanism for the formation of the ideal two-level quantum state is yet to be uncovered. Here, using first-principles calculations and group theory analysis we highlight the advantages of 2D materials as host systems and also identify and design defects in various 2D materials for SPE. A generalized strategy is proposed to design defect complex by adding a paramagnetic impurity next to a vacancy defect, which forms an ideal two-level quantum system. The electronic states of the designed defect complex are well isolated from the host band edges, belong to a majority spin eigenstate, and can be controllably excited by $x$-polarized light, thereby satisfying all the criteria required for an ideal SPE. The defect complex is thermodynamically stable, and appears feasible for experimental realization, to serve as an SPE-source, essential for quantum computing.

3:18 PM P11.00003: The Effects of Disorder on 2D Material Properties*  BLAKE DUSCHATKO (Presenter), CHRISTOPHER CICCARINO, PRINEHA NARANG, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Two dimensional materials, such as hexagonal boron nitride and transition metal dichalcogenides, are emerging platforms for quantum information science, where the controlled introduction of atom-like defects can be utilized for numerous applications. While the excitement surrounding these systems has grown, a great deal of work remains to be done in order to realize the full integration of 2D materials into quantum devices. In this talk, I present how recent advances in high precision atomic imaging can be leveraged with ab initio calculations to advance our ability to characterize material properties. Working with atomic coordinates of monolayer MoS$_2$, we find that it possesses out of plane ripples on the order of 50 picometers, effectively hindering equilibration. The general disorder present in such nonzero temperature samples has substantial effects on the dynamics of the material and optical properties of engineered defects. I will show calculations that capture the effects of disorder and discuss how this presents a significant step forward in 2D material theory.

3:30 PM P11.00004: Theoretical Investigation of Color Centers in Diamond for Quantum Information Science*  CHRISTOPHER CICCARINO (Presenter), JOHANNES FLICK, Harvard University, MATTHEW TRUSHEIM, Massachusetts Institute of Technology, PRINEHA NARANG, Harvard University — Color centers in diamond have emerged as leading solid-state “artificial atoms” for a range of promising technologies from quantum sensing to quantum networks. While properties and limitations of canonical color centers NV$^-$ and SiV$^+$ have been well documented, exploration and a fundamental understanding of novel color centers presents an exciting opportunity to improve upon the current state of the art. We leverage our unique first-principles methods to detail crucial defect properties in the SnV$^-$, PbV$^+$[1] and SiV$^0$, in addition to novel diamond color centers. We capture the zero phonon line energies and phonon sideband profile and in particular investigate the potential for Jahn-Teller distortion effects in each of these systems, where electron-spin-phonon coupling phenomena are capable of drastically altering predicted spin-orbit splitting and ZPL energies. We detail our unique theoretical approach to the study of these defects, and through our results offer a comprehensive perspective of diamond defects for applications in quantum devices.

*All authors acknowledge support from the Army Research Office MURI (Ab-Initio Solid-State Quantum Materials) grant number W911NF-18-1-0431.
Color centers in hexagonal boron nitride have shown enormous promise as single-photon sources, but a clear understanding of electron-phonon interaction dynamics is critical to their development for quantum communications or quantum simulations. We demonstrate photon antibunching in the zero phonon line. We will discuss the feasibility of quantum phononics via further exploration of the density of states for single photon purity of 80% in a phonon replica and cross-spectral correlations of 82% between a phonon replica and the zero phonon line. We will discuss the feasibility of quantum phononics via further exploration of the density of states for phononic cavities coupled to single quantum emitters in 2D materials.

Microwave dielectric loss of hexagonal Boron Nitride in the low-temperature, single-photon regime* MEGAN YAMOAH (Presenter), Physics, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, JOEL WANG, Research Laboratory of Electronics, Massachusetts Institute of Technology, CHARLOTTE BOETTCHER, Physics, Harvard University, BHARATH KANNAN, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, DAVID K KIM, Massachusetts Institute of Technology Lincoln Laboratory, PHILIP KRANTZ, Research Laboratory of Electronics, Massachusetts Institute of Technology, DANIEL RODAN LEGRAIN, ORIOL RUBIES-BIGORDA, Physics, Massachusetts Institute of Technology, JONILYN L YODER, Massachusetts Institute of Technology Lincoln Laboratory, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, Japan, TERRY PHILIP ORLANDO, Research Laboratory of Electronics, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, PABLO JARILLO-HERRERO, Physics, Massachusetts Institute of Technology, WILLIAM D OLIVER, Research Laboratory of Electronics, Physics, Lincoln Laboratory, Massachusetts Institute of Technology — The use of 2D van der Waals (vdW) heterostructures in quantum computing devices, due in part to the potential of combining different materials with epitaxial precision, has begun to merge the superconducting and 2D material platforms. Hexagonal boron nitride (hBN), a vdW material widely used as an ultra-clean substrate, gate dielectric, and protection layer in vdW heterostructures, may be used in building high-quality Josephson elements and qubit capacitors. VdW materials have been extensively studied in the DC and optical regimes, but understanding their response to microwave excitations is vital to introducing them into superconducting circuits. We study hBN in the microwave regime by integrating the material in a superconducting LC resonator to extract its loss tangent. Our scheme can be used for characterizing not only the electromagnetic properties of hBN, but also other 2D materials.

Towards coherent control of single nuclear spins of $^{171}\text{Yb}$ in YVO* JONATHAN KINDEM (Presenter), ANDREI RUSKUC, JOHN BARTHOLOMEW, JAKE ROCHMAN, ANDREI FARAON, California Institute of Technology — Optically addressable solid-state spins are a promising platform for the development of scalable quantum technologies. Rare-earth ions in crystals are an attractive candidate for such systems due to their long optical and spin coherence lifetimes. By interfacing these ions with nanophotonic cavities, we can significantly enhance the photon-ion interaction to overcome their intrinsically weak optical transition strengths and enable detection and manipulation of single ions.

Here we describe work towards coherent control of long-lived nuclear spins of individual $^{171}\text{Yb}$ ions coupled to a nanoscale photonic crystal cavity fabricated in the YVO host crystal. We first present results on detection and coherent optical manipulation of single ions in such a cavity. We then show that the cavity enhanced emission rate enables efficient optical pumping and spin initialization. Finally, we present initial results towards coherent microwave control of the electron and nuclear spin of single ions.

*The authors gratefully acknowledge funding from the National Science Foundation and the Institute for Quantum Information and Matter.
**4:18PM P11.00008: Characterization of epitaxially grown Er doped Y2O3 for quantum optics applications**

KUMAR SINGH (Presenter), University of Chicago, KHAN ALAM, TJANA RAJH, Argonne National Laboratory, TIAN ZHONG, University of Chicago, SUPRATIK GUHA, Argonne National Laboratory — Rare earth ions (REI) are strong candidates for optical quantum memory applications. Erbium, with optical transition in the 1.5 μm band is of particular interest. Recent studies have shown coherence times exceeding 1 sec in 167Er. The coherence properties of REI are critically dependent on the host crystals, and methods of incorporating REI into the host structures play an important role as structural defects and impurities determine the local environment of the ions, which is an important factor contributing to line-broadening mechanisms.

Rare-earth oxides with low or no nuclear spin, such as CeO2 and Y2O3 are preferred host material for REI defects. The ability to tailor the properties of these systems on demand will be a powerful tool for quantum information applications. Molecular beam epitaxy (MBE) allows us to grow single crystal thin epitaxial films of certain RE oxides, and also enables precise control over the doping concentrations. We have investigated Er-doped Y2O3 thin films, grown epitaxially on Si(111) MBE. A range of concentration is explored. Characterization results using EPR, XRD and photoluminescence are reported. The influence of oxygen vacancies on EPR lines is also discussed.

*The authors acknowledge funding support form the CNM at Argonne and EFRC.

**4:30PM P11.00009: Precisely Located Si Vacancies in 4H-SiC Generated via Focused Li-ion Beam for Quantum Information Science Applications**

SHOJAN PAVUNNY (Presenter), ASEE Research Fellow at U.S. Naval Research Laboratory, 4555 Overlook Ave SW, Washington DC 20375, USA, EDWARD S BIELEJEC, Sandia National Laboratories, Albuquerque, New Mexico 87185, USA, SAMUEl CARTER, Electronics Science & Technology Division, U.S. Naval Research Laboratory, 4555 Overlook Ave SW, Washington DC 20375, USA, HUNTER BANKS, NRC Research Fellow at U.S. Naval Research Laboratory, 4555 Overlook Ave SW, Washington DC 20375, USA, RACHAEL MYERS-WARD, Electronics Science & Technology Division, U.S. Naval Research Laboratory, 4555 Overlook Ave SW, Washington DC 20375, USA, PAUL BARRY KLEIN, KeyW Corp., Arlington, VA 22203, MATTHEW T DEJARLD, ASEE Research Fellow at U.S. Naval Research Laboratory, 4555 Overlook Ave SW, Washington DC 20375, USA, ALLAN S BRACKER, EVAN RICHARD GLASER, DAVID KURT GASKILL, Electronics Science & Technology Division, U.S. Naval Research Laboratory, 4555 Overlook Ave SW, Washington DC 20375, USA — Photo-stable and spin (S = 3/2) coherent silicon vacancies (VSi) in the CMOS compatible semiconductor SiC are of interest for future applications in scalable quantum information and sensing. The ability to precisely create the desired density at the optimal location in a three-dimensional solid-state matrix with nanometer accuracy and excellent optical properties is indispensable for the above applications. Here we demonstrate the precise generation of single and ensemble emitter arrays in defect-free epitaxial 4H-SiC layer through Li-ions, implanted with an energy of 100 keV and doses ranging from $10^{12}-10^{15}$ Li/cm$^2$ using a maskless focused ion beam technique (~25 nm diameter spot positioned with ~25 nm accuracy and having anion travel depth of ~400 nm). High-resolution photoluminescence (E.LC) studies revealed the scalable and reproducible defect generation with a mean efficiency of ~17% and intensity (~8 kC/s), yield (~28%), statistical distribution, average number of single VSi/spot, fluorescence saturation, and photostability of single emitters. Given the encouraging results, we will discuss utilizing this approach to implant single VSi into the mode maximum of SiC photonic crystal cavities with Purcell enhancement of zero-phonon line and increased photon indistinguishability.

**4:42PM P11.00010: Radiationless Creation and Patterning of Color Centers in Diamond**

PATRICK J MCQUADE (Presenter), ANDREW ELIAS-GONZALEZ, MATTHEW A GEBBIE, NICHOLAS A MELOSH, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory — Spatially patterned and scalable creation of optical color centers remains a key bottleneck in fabrication for quantum computing and quantum sensing applications. Host lattice vacancies are necessary to form electronic defect states with transition energies in the visible light range. Current fabrication methods use high-energy ion irradiation to create these vacancies, leading to significant lattice damage and limited spatial control. I will present a new approach for creation and patterning of color centers in diamond without the use of irradiation. We demonstrate vacancy doping into diamond through the use of “vacancy injection” films. We also show the ability to pattern color centers on the nanoscale by using conventional photolithography to pattern film deposition. These methods enable a higher level of control for color center creation and decreased host lattice damage, as compared to methods that rely on high-energy irradiation. Additionally, this method provides a general strategy for controllably doping vacancies into a wide range of materials using conventional CMOS processing techniques, with potential applications in microelectronics and 2-D magnetic materials.

Strongly Extended Superradiance in Optical Dirac Cone Metamaterials

OLIVIA MELLO (Presenter), Harvard University, YANG LI, Tsingua University, PHILIP CAMAYD-MUNOZ, Physics, California Institute of Technology, LINBO SHAO, CLEAVEN CHIA, ERIC MAZUR, MARKO LONCAR, Harvard University — Zero index metamaterials (ZIM) experience near-perfect spatial coherence and infinite spatial wavelength.[1] We design and simulate a diamond metamaterial with zero refractive index at 737 nm. This occurs due to a Dirac cone within the dispersion of our metamaterial. With this property we analytically and numerically demonstrate the hallmarks of superradiance: an N^2 scaling of enhancement of power within our structure over a spatial extent much greater than a wavelength, where N is the number of emitters, as well as cooperative decay rate enhancement relative to the single emitter decay rate. Additionally, we demonstrate preliminary fabrication results with the intention to experimentally implement this concept using silicon vacancy centers (SiV) in diamond.

Electron-electron interactions in highly degenerately doped embedded Si:P delta layers in silicon produced by variable PH3 dosing

JOSEPH HAGMANN (Presenter), XIQIAO WANG, RANJIT KASHID, PRADEEP NAMBOODIRI, JONATHAN WYRICK, SCOTT W SCHMUCKER, NEIL ZIMMERMAN, M. D. STEWART, RICHARD M. SILVER, CURT A RICHTER, National Institute of Standards and Technology — Key to producing quantum computing devices based on the atomistic placement of dopants in Si by STM lithography is the formation of embedded highly doped Si:P delta layers (δ-layers). This study investigates the transport behavior and the electron-electron interaction (EEI) physics in the highly doped regions of embedded Si:P-based devices by means of self-consistent magnetotransport (MT) measurements. In earlier work, we demonstrated that a careful MT study at low T, along with analysis of the weak localization (WL) signal, allows us to extract parameters associated with the electronic transport that offer a meaningful quantitative characterization of δ-layer quality and dopant diffusion. We build on this work by examining EEI behaviors in a set of samples with embedded Si:P delta layers produced with different PH3 exposure procedures prior to Si encapsulation. We show that the charge carriers behave as 2DEGs in embedded Si:P δ-layers in samples grown with a locking layer (LL) to bolster confinement of the dopants, while samples grown without a LL demonstrate several signatures of transport and EEI in a 3D system. The impact between δ-layer confinement and EEI on screening lengths affects both electrostatic gating of and tunneling transport through Si:P single atom transistors.

Atomic Scale Patterned Arsenic in Silicon

TAYLOR STOCK (Presenter), MARCEL VAN LOON, University College London, OLIVER WARSCHKOW, The University of Sydney, EMILY HOFMANN, ELEANOR CRANE, STEVEN SCHOFIELD, NEIL J CURSON, University College London — Over the past two decades, scanning tunnelling microscopy - hydrogen desorption lithography (STM-HDL) has been developed and utilized to great effect. Atomic scale devices can now be fabricated by positioning phosphorus (P) atoms in a silicon (Si) surface with near atomic precision. Expanding STM-HDL fabrication to include multiple species of dopant impurity atoms could provide new possibilities for device structure and function. Working towards expanding the materials palette of STM lithography, we have examined the compatibility of arsenic (As) with STM-HDL. We have studied AsH3 adsorption on Si(001) and Si(001)-H, and compared this to the well-studied Si(001)-PH3 system (used in 2D patterning of P in Si). We observe a number of subtle, but important differences between these two systems and discuss possible implications for advanced device fabrication strategies. In addition to the adsorption behaviour of the AsH3 molecules on the Si surface, we also discuss the incorporation and encapsulation of patterned 2D As within the Si lattice, and the optimization of electrical transport properties of As delta-layers in Si. Finally, we demonstrate nanoscale device structure patterning in Si using the two unique donor species (P and As) within a single 2D plane.

2:30PM P12.00001: Scanning Probe Microscopy of Inhomogeneous States in 2D Materials† LAVISH PABBI (Presenter), RIJU BANERJEE, TOMOTAROH GRANZIER-NAKAJIMA, ANNA BINION, MAURICIO TERRONES, ERIC HUDSON, Pennsylvania State University — The ability of the Scanning Tunneling Microscope (STM) to study material surfaces with atomic resolution makes it a perfect tool for measuring local structural and electronic properties and their relationships. This ability is especially beneficial in the investigation of 2D materials, whereby their very nature there are frequently large variations in local structure, for example due to strain or changing substrate interactions, leading to concomitant variations in local electronic properties. As one example, I will here present results of recent STM measurements of single-layer graphene on copper, and on the graphene nano-ribbons that form when draped over copper step edges. In particular, I will focus on the interesting measurement challenge presented by the topological nature of the states that arise at the edges of these and other systems.

*This material is based upon work supported by the National Science Foundation under Grant No. 1229138

2:42PM P12.00002: Isotropic charge screening of the anisotropic black phosphorus revealed by potassium adatoms ZHEN TIAN (Presenter), JIAMIN XUE, ShanghaiTech University — Recent angle-resolved photoemission spectroscopy and transport experiments have shown that at the macroscopic level the electronic structure of black phosphorus can be greatly modified by potassium adatoms. Understanding the effects of individual potassium adatoms at the microscopic level is of great importance. To this end, we use scanning tunneling microscopy to study black phosphorus with potassium adatoms. We find that the potassium atoms are almost fully ionized even at 4.5 K. The Fermi level of black phosphorus is shifted due to electron doping while the band gap shows no significant change. Due to the puckered anisotropic lattice structure, we find that potassium ions can easily migrate along the zigzag direction but not along the armchair direction. Using tip as a moving gate, we can control the ionization of potassium ions. With this technique, we probe the screening effect of charged impurities in black phosphorus at the atomic scale. Remarkably, we find that it shows in-plane isotropic screening behavior even though the underlying electronic dispersion and lattice structure has distinct anisotropy. We also construct two potassium-adatom clusters as a coupled system to study the interaction of them. These results reveal the rich anisotropic physics in black phosphorus.

2:54PM P12.00003: Substrate screening effects on the quasiparticle band gap and defect charge transition levels in MoS2. MIT NAIK (Presenter), MANISH JAIN, Department of Physics, Indian Institute of Science, Bangalore — Monolayer MoS2 has emerged as an interesting material for nanoelectronic and optoelectronic devices. The effect of substrate screening and defects on the electronic structure of MoS2 are important considerations in the design of such devices. We find a giant renormalization to the free-standing quasiparticle band gap in the presence of metallic substrates, in agreement with recent scanning tunneling spectroscopy and photoluminescence experiments. Our sulfur vacancy defect calculations using the DFT+GW formalism, reveal two CTLs in the pristine band gap of MoS2. The (0/-1) CTL is significantly renormalized with the choice of substrate, with respect to the pristine valence band maximum. The (+1/0) level, on the other hand, is pinned 100 meV above the pristine VBM for the different substrates. This opens up a pathway to effectively engineer defect charge transition levels in 2D materials through choice of substrate.

3:06PM P12.00004: Scanning Tunneling Microscopy Study of Epitaxial Growth of Wafer Scale, Single Atomic Sheet Honeycomb BeO Two-dimensional Insulator† MADISEN HOLBROOK (Presenter), University of Texas at Austin, HUI ZHANG, Physics, University of Science and Technology of China, FEI CHENG, HYOUNGDO NAM, MENGKE LIU, University of Texas at Austin, CHI-RUEI PAN, Physics, Georgia Institute of Technology, DAMIEN WEST, SHENGBAI ZHANG, Physics, Rensselaer Polytechnic Institute, MEI-YIN CHOU, Physics, Georgia Institute of Technology, CHIH-KANG SHIH, University of Texas at Austin — We report the discovery of a novel 2D insulator comprised of a single atomic sheet honeycomb structure BeO, though its bulk counterpart has a wurtzite structure. Such a single sheet of BeO is grown epitaxially on Ag(111) thin films, also epitaxially grown on Si(111) wafers. Using scanning tunneling microscopy and spectroscopy (STM/S) we observe this novel BeO atomic sheet has a lattice constant of 2.65 Å and a band gap of 6 eV. We also found the BeO has a weak van der Waals (vdW) interaction with the Ag(111) substrate, which agrees well with predictions of our density functional theory calculations. Moiré pattern analysis shows the BeO honeycomb structure maintains long range phase coherence in atomic registry even across Ag steps. This novel material provides a scalable platform for 2D electronics, as an attractive 2D insulator due to its potentially much higher thermal conductivity than that of hBN. More significantly, the ability to create a single crystalline atomic sheet with no bulk counterpart of similar structure opens a new avenue toward tailoring novel 2D electronic materials.

*Our research was funded by grants from the Welch Foundation (F-1672), the US National Science Foundation (MRSEC DMR-1720595, EFMA-1542747, DMR-1808751) and the US Airforce (FA2386-18-1-4097).
3:18PM P12.00005: The Band Structure and Contact Issues of Quasi One Dimensional TiS₃  SIMEON GILBERT
(Presenter), Physics, University of Nebraska - Lincoln, HEMIAN YI, Synchrotron SOLEIL, TAKASHI KOMESU, Physics, University of Nebraska - Lincoln, ALEXEY LIPATOV, Chemistry, University of Nebraska - Lincoln, GUANHUA HAO, ANDREW J YOST, Physics, University of Nebraska - Lincoln, ALEXANDER SINITSKII, Chemistry, University of Nebraska - Lincoln, JOSE AVILA, CHAOYU CHEN, MARIA ASENSIO, Synchrotron SOLEIL, PETER A DOWBEN, Physics, University of Nebraska - Lincoln — Titanium trisulfide (TiS₃) is a transition metal trichalcogenide whose atoms form chains of trigonal prisms creating a quasi-one-dimensional structure. This 1D structure results in an anisotropic band structure and edge perfection that can reduce the edge scattering effects experienced in sub 10 nm field-effect transistors. Furthermore, a recent theoretical study indicates that monolayer TiS₃ is a direct-gap semiconductor with a bandgap of ~1 eV and an electron mobility near 10,000 cm²V⁻¹s⁻¹ making TiS₃ an ideal candidate for high mobility transistors. Our recent work directly measured the in-plane anisotropy of few layer TiS₃ flakes using nanospot angle resolved photoemission spectroscopy. The effective hole mass at the top of the valence band was found to be -0.95 ± 0.09 mₑ along the chain direction and -0.37 ± 0.1 mₑ perpendicular to the chain direction. The measured mobility for TiS₃ transistors has remained well below the predicted value, but it is common for contact issues to lower the measured mobility. The interactions between TiS₃ and Au or Pt contacts have been investigated using x-ray photoemission spectroscopy which shows that strong bonding with sulfur is the key to prevent Schottky barrier formation.

3:30PM P12.00006: Bulk compressibility measurements of WSe₂ heterostructures  QIANHUI SHI (Presenter), EN-MIN SHIH, Physics, Columbia University, DANIEL A RHODES, BUMHO KIM, Mechanical Engineering, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, JAMES HONE, Mechanical Engineering, Columbia University, CORY R DEAN, Physics, Columbia University — 2D semiconductors have attracted a great deal of attention due to their unique properties including strong spin-orbit coupling, large effective mass and high tunability. However, quantum transport studies have been complicated by the difficulties in making Ohmic contacts. Non-ideal contacts also limit studies in more complex structures such as twisted bilayers and double-layers which may host interesting correlated phases. Here we report on magneto-capacitance measurements on WSe₂ heterostructures which probe the bulk electronic compressibility. This approach has a much lower requirement on the contact quality and allows improved resolution of both zero-field and finite field features, and over a wider range of density than previously accessible.

3:42PM P12.00007: Flavor Symmetry and Ferroelectric Nematics in Transition Metal Dichalcogenides*  PATRICK CHEUNG (Presenter), ZHI-QIAN BAO, FAN ZHANG, University of Texas at Dallas — Recent magneto-transport experiments have provided compelling evidence for the presence of an energetically isolated threefold Q-valley degeneracy in few-layer transition metal dichalcogenides. We study the flavor SU(3) symmetry breaking when each Landau level triplet is one-third filled or empty and predict that a pure flavor nematic phase and a flavorless charge-density-wave phase will occur respectively below and above a critical magnetic field. Surprisingly, electrons carry flavor-dependent electric dipole moments even at zero magnetic field, rendering the nematics ferroelectric, allowing electric-field manipulation of the flavors, and leading to the concept of flavortronics.

*Research was sponsored by the Army Research Office and was accomplished under Grant Number W911NF-18-1-0416.

3:54PM P12.00008: ARPES microscopy of hBN flakes*  ROLAND KOCH (Presenter), Advanced Light Source, Lawrence Berkeley National Laboratory, JYOTI KATOC, Department of Physics, Carnegie Mellon University, SIMON K MOSER, DANIEL SCHWARZ, Advanced Light Source, Lawrence Berkeley National Laboratory, ROLAND KAWAKAMI, Department of Physics, The Ohio State University, AARON BOSTWICK, ELI ROTENBERG, CHRIOS JOZWIAK, Advanced Light Source, Lawrence Berkeley National Laboratory, SOREN ULSTRUP, Department of Physics and Astronomy, Aarhus University — Hexagonal boron nitride (hBN) is an essential component in van der Waals heterostructures. It provides high-quality and weakly interacting interfaces that preserve the electronic properties of adjacent materials. We will present the full valence-band (VB) electronic structure of micrometer-sized exfoliated flakes of hBN using angle-resolved photoemission spectroscopy with micrometer and nanometer spatial resolution. We identify the π - and σ -band dispersions, the hBN stacking order, and determine a total VB bandwidth of 19.4 eV. We compare these results with electronic structure data for epitaxial hBN on graphene on silicon carbide grown in situ using a borazine precursor. The epitaxial growth and electronic properties are investigated using photoemission electron microscopy. Our measurements show that the fundamental electronic properties of hBN are highly dependent on the fabrication strategy.

4:06PM P12.00009: Large-Area Epitaxial Growth of Curvature-Stabilized ABC Trilayer Graphene with Tunable Band Gap* ZHAOLI GAO (Presenter), University of Pennsylvania, SHENG WANG, University of California at Berkeley, JOEL M BERRY, QICHENG ZHANG, JULIAN GEBHARDT, WILLIAM PARKIN, University of Pennsylvania, JOSE AVILA, HEMIAN YI, CHAOYU CHEN, Synchrotron-SOLEIL, SEBASTIAN HURTADO PARRA, MARIJA DRNDIĆ, ANDREW RAPPE, DAVID SROLOVITZ, J. M. KIKKAWA, University of Pennsylvania, ZHENGTANG LUO, Hong Kong University of Science and Technology, MARIA C. ASENSIO, Synchrotron-SOLEIL, FENG WANG, University of California at Berkeley, ALAN T JOHNSON, University of Pennsylvania — The physical properties of epitaxially-grown layered van der Waals (vdW) materials can be engineered to an extraordinary degree by manipulating the number of atomic layers, their compositions, and their relative stacking configurations and twist angles. vdW trilayer graphene (TLG) can stack in either a semi-metallic ABA configuration or a semi-conducting ABC configuration with a gate-tunable band gap but to this point has only been produced via exfoliation, which greatly limits its scientific and technological development. Here we present a scalable approach to epitaxial TLG growth via chemical vapor deposition that reliably enhances the fraction and size of ABC stacked TLG domains compared to other methods. The key insight is that nanoscale substrate curvature can locally stabilize ABC domains, typically leading to alternating regions of ABC and ABA on topographically corrugated growth substrates. Unambiguous electronic signatures of ABC-TLG were revealed by nano angle-resolved photoemission spectroscopy and infrared scanning near-field microscopy. The ABC fraction remains high after transfer onto a device substrate, as confirmed by transport measurements showing a sizable and tunable ABC-TLG band gap.

4:18PM P12.00010: Spin and valley degree of freedom in a bulk massless-Dirac electron system, α-(BEDT-TTF)$_2$I$_3$ under magnetic fields KAZUYA MIYAGAWA (Presenter), MATSUNO MANABU, Applied Physics, University of Tokyo, MICHIHIRO HIRATA, IMR, Tohoku University, TAMURA MASAFUMI, Physics, Tokyo University of Science, KAZUSHI KANODA, Applied Physics, University of Tokyo — Since the discovery of massless-Dirac Fermions (MDF) in graphene, MDF states have found in a range of materials. A quasi-2D organic conductor, α-(BEDT-TTF)$_2$I$_3$, in which a MDF phase appears under pressure. The bulk nature of α-(BEDT-TTF)$_2$I$_3$ enables one to investigate the properties by experimental probes that require sample volume, such as NMR. When the magnetic field is applied normal to the 2D planes of MDFs, the orbital-quantized Landau levels (LLs) contains the n=0 state (zero mode LL). The MDF system has two degrees of freedom, spin and valley. In case of non-zero fields, there are two possible states, depending on which of spin- or valley-splitting dominates over the other in energy, that is, spin polarized (QHF) and a non-magnetic state (QHI).

We measured $^{13}$C NMR with a magnetic field applied perpendicular to the 2D layers. With decreasing temperature, the shift of spectra decreases, since the thermal-averaged density of state characteristic of Dirac cones decreased. At low T, the NMR shift increases because of the formation of the zero-mode LL. Upon further cooling, a large NMR shift is observed, which indicates the generation of local fields. The value of the shift agrees with the value estimated from the Zeeman spin splitting of the zero-mode LL, indicating the QHF state.

4:30PM P12.00011: Strain-dependent ab-initio tight binding Hamiltonians for T-type transition metal dichalcogenides* DANIEL LARSON (Presenter), SHIANG FANG, WEI CHEN, JENNIFER COULTER, STEVEN TORRISI, STEPHEN CARR, EFTHIMIOS KAXIRAS, Harvard University — Many transition metal dichalcogenides (TMDs) adopt a T-structure in which the metal atom is octahedrally coordinated by the chalcogens. In particular, MX$_2$ with M=(Nb, Ta, Ti) and X=(S, Se) all exhibit fascinating electronic properties including various charge density wave phases. Using Density Functional Theory followed by a Wannier transformation we extract the strain-dependent tight binding parameters for single-layer TMDs. The resulting tight binding Hamiltonian respects the crystal symmetry and gives a very accurate yet simple description of the electronic band structure which is easily augmented to include spin-orbit effects and interlayer couplings. The knowledge of the strain dependence of the electronic properties is critical in order to correct for the effects of relaxation in realistic simulations of twisted nanostructures.

Interplay between p- and d- orbitals yields multiple Dirac states in two-dimensional ZrB2 and CrB4

ALEJANDRO LOPEZ BEZANILLA (Presenter), Los Alamos National Laboratory — Theoretical evidence of the existence of 12 Dirac cones in the low-spectrum diagram of transition metal-rich monolayered hexagonal networks is provided. Both Zr and Cr are efficient in creating six additional cones with respect to graphene when combined with boron honeycomb lattices. The four d-electrons of Cr, and similarly the two d-electrons of Zr, are yielded to the B sublattices creating an isoelectronic structure to graphene where the interplay between p- and d-orbitals leads to the appearance of Dirac states on both one- and two-dimensional geometries. Ab initio calculations show that, although spin–orbit interaction splits the cone-shaped valence and conduction bands, monolayered ZrB2 and CrB4 are semimetals with compensated electron–hole pockets.

The effect of the adsorption of the toxic hydrazine on the electronic structure of the WS2 monolayer: the first principle calculations

MD RAJIB KHAN MUSA (Presenter), CONGYAN ZHANG, ADEL ALRUQI, GAMINI SUMANASEKERA, MING YU, Physics and Astronomy, University of Louisville — Two-dimensional layered WS2 possesses novel electronic properties and has various promised applications. Its sensitivity to various molecules [1] makes it possible as sensor. Our recent experiment results show that its resistance changes dramatically with the response to the toxic hydrazine vapor. Our first-principle calculations also found the effect of the adsorption of the hydrazine on the electronic structure of WS2 monolayer. In particular, the impurity state associated with the toxic hydrazine just pin at the middle of the band gap, resulting to an n-type like behavior. A detail discussion will be presented. Symmetry controlled adsorption of di-iodobenzene on MoS2

ZAHRA HOOSHMAND

GHAREHBAGH (Presenter), Physics, University of Central Florida, PRESCOTT E EVANS, Physics and Astronomy, University of Nebraska-Lincoln, DUY LE, Physics, University of Central Florida, PETER A DOWBEN, Physics and Astronomy, University of Nebraska-Lincoln, TALAT S. RAHMAN, Physics, University of Central Florida — In a joint experimental and theoretical study, we have uncovered evidence of the importance of symmetry in the adsorption of the isomers of di-iodobenzene on MoS2(0001). The intensity ratio of iodine to molybdenum measured, as a function of exposure for different isomers of the diiodobenzene, show that while for ortho (1,2-) and para (1,4-) di-iodobenzene the rate of adsorption at 100 K is very low, that for meta (1,3-)di-iodobenzene is considerably more facile. We have applied van der Waals corrected density functional theory based calculations to understand the subtleties in the electronic structure and geometry of adsorption of these three di-iodobenzene isomers on MoS2(0001). All three are found to weakly chemisorb onto MoS2(0001) with the same binding strength as well as adopt similar configurations. The calculated electron affinity of the three molecules also do not show a specific trend that would verify experimental data. However analysis of the frontier orbitals indicate that those of 1,3-di-iodobenzene is strongly affected by interactions with MoS2, while that of the other two isomers remain unchanged. Our results show that symmetry is the identifying factor in the adsorption characteristics of di-iodobenzene on MoS2.

Portable Surface-Enhanced Raman Spectroscopy of Pyridine and Diazines on MoS2

ROBERT HART (Presenter), SHARAD AMBARDAR, PRASANA SAHOO, DMITRI VORONINE, University of South Florida — Raman spectroscopy is a widely used analytical technique for biosensing applications. It has been commonly applied to bulk samples. However, the applications to small amounts of chemical substances is challenging due to weak signals. Surface-enhanced Raman scattering (SERS) can be used to improve sensitivity by the electromagnetic enhancement mechanism using plasmonic nanoparticles or by the chemical mechanism using atomically-thin semiconducting 2D materials. Also, portable Raman spectroscopy instrumentation is needed for medical and industrial point-of-care applications. We investigate the effects of the addition of few-layer molybdenum disulfide (MoS2) nanocrystals on the enhancement of Raman signals of pyridine and its diazine derivatives. The introduction of MoS2 leads to the shifts of the Raman peak positions and changes in the relative peak intensities and overall signal strength of respective ν1 mode for each of the diazines and pyridine, as well as affecting a range of other modes for each compound, observed using a handheld Raman spectrometer, an effect most apparent in the pyrimidine ν1 mode. This information can be valuable to a number of potential fields including studies in biophotonics, which could have numerous industrial, medical and public safety applications.

Wednesday, March 6, 2019 2:30 PM - 5:30 PM
2:30PM P13.00001: Effect of MoS₂ thickness on properties of adsorbed Au nanoparticles*  
DUY LE (Presenter), TALAT S. RAHMAN, Department of Physics, University of Central Florida — Transition metal nanoparticles supported by MoS₂ is a system of interest in catalytic applications. The question whether the thickness of MoS₂ plays any critical role in determining the chemical activity of the supported nanoparticle is still debated. In this work, using density functional theory based calculations, we study the electronic density of states of Au nanoparticles of varying size supported by single layer, bilayer, and trilayer MoS₂. We find that thickness of MoS₂ support has only a minor effect on the d states (frontier orbitals) of Au nanoparticles. This effect is most notable on Au atoms located at the perimeter of the nanoparticles, which are in contact with the MoS₂ basal plane. Using CO oxidation as a prototype, we comment on the implication of these findings on catalytic properties of MoS₂-supported Au nanoparticles and compare with available experimental data.

*This work is supported in part by DOE grant DEFG02-07ER15842

2:42PM P13.00002: A complete picture for the band topology in twisted bilayer graphene  
JIANPENG LIU (Presenter), JUNWEI LIU, XI DAI, Department of Physics, Hong Kong University of Science and Technology — We provide a complete picture for the band topology of twisted bilayer graphene. We propose that the electronic structure of twisted bilayer graphene can be understood as Dirac fermions under pseudo magnetic fields generated by the moiré pattern. The two low-energy flat bands from each valley originate from the two zeroth Landau levels of Dirac fermions under such opposite effective magnetic fields. They possess opposite sublattice polarizations and are decoupled from each other as a result of an emergent chiral symmetry in the low-energy subspace. They carry opposite Chern numbers ±1 and give rise to the odd windings of the Wilson loops.

Besides, we show that all the high-energy bands below or above the flat bands are also topologically nontrivial in the sense that the sum of their Berry phases is quantized as ±π. Such quantized Berry phases give rise to two nearly flat edge states, which are robust regardless of the orientation of the edge but depend on truncations on the moiré scale. In addition, we also find the atomic corrugations would significantly enlarge the topological gaps, and may drive transitions between topological insulating and semimetallic phases.

2:54PM P13.00003: Functionalization of hexagonal boron nitride – effect on chemical, morphological, electrical and thermal properties*  
EVGENIYA LOCK (Presenter), Materials Science and Technology Division, Naval Research Laboratory, KARTHIK SRIDHARA, Electronics Science and Technology Division, Naval Research Laboratory, ZARIANA MOBLEY, Materials Science and Technology Division, Naval Research Laboratory, LUKE NYAKITI, Materials Science and Engineering, Texas A&M, BORIS FEIGELSON, Electronics Science and Technology Division, Naval Research Laboratory, DAVID OLSON, JOHN GASKINS, PATRICK HOPKINS, Mechanical and Aerospace Engineering, University of Virginia — Hexagonal boron nitride (h-BN) has gained significant importance in plasmonics and quantum electronics applications. In addition, there is a plethora of theoretical, yet relatively few experimental studies, showing modification of h-BN properties via functionalization, namely through induction of magnetism and band gap engineering. In this effort we show h-BN films functionalization with three different compounds. Chemical, morphological and structural characterization is performed using X-ray photoelectron spectroscopy, Fourier transform infrared reflection absorption spectroscopy, as well as scanning and transmission electron microscopies. This characterization quantifies the elemental composition changes and shows preferential molecular binding towards the edges of the grains after functionalization. In addition, we perform conductive atomic force microscopy studies and thermal boundary conductance mapping to assess the changes in interfacial thermal properties. All of these characterization methods contribute toward the overarching goal of evaluating the potential of functionalized h-BN for practical applications.

*This work was partially supported by the Office of Naval Research through Naval Research Laboratory Base Program.
3:06PM P13.00004: Density of States of Graphene Doped with Transition Metals*  SHOHAM SEN (Presenter), KAUSHIK DAYAL, Civil and Environmental Engineering, Carnegie Mellon University, YANG WANG, Pittsburgh Super Computing, Carnegie Mellon University — We perform electronic structure calculations for Graphene using density functional theory based ab initio method with linear scaling Greens function approach, known as Locally Self Consistent Multiple Scattering Method (LSMS). The Greens function for the Kohn-Sham (KS) equation is solved in the framework of Multiple Scattering Theory (MST), in which the Greens function of the KS equations are calculated in terms of multiple scattering path matrices and single site solutions. The multiple scattering path matrix represents the electron scattering off the atoms in a crystal. By making an assumption of "near-sightedness" or "local interaction zone" of the electronic multiple scattering processes around each atom, the computational cost for calculating the Green function is reduced from O(N^3) to O(N), where N is the number of atoms in the unit cell. We apply the LSMS method to the study of density of states and magnetic structure of Graphene doped with Cobalt.

*We would like to thank the DOD MURI program for financial support.

3:18PM P13.00005: Electronic transport in graphene decorated with adatoms or nanoparticles*  JAMIE ELIAS (Presenter), JOSHUA COHEN, Physics, Washington University, St. Louis, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Material Science, FUDONG WANG, WILLIAM BUHRO, Chemistry, Washington University in St. Louis, ARASHDEEP S THIND, ROHAN MISHRA, Mechanical Engineering and Material Science, Washington University in St. Louis, ERIK HENRIKSEN, Physics, Washington University, St. Louis — There is much interest in inducing a spin-orbit coupling into monolayer graphene in order to engineer the Kane-Mele Hamiltonian and thereby enable observation of the quantum spin Hall effect in graphene. Numerous adatoms have been studied toward this end. Here, we present measurements of monolayer graphene Hall bars with dilute coatings of either osmium adatoms or Bi₂Te₃ nanoparticles (NPs). With osmium adatoms, we find an unusual hole doping to occur, whereas most metals show electron doping. Nanoparticles of Bi₂Te₃ have recently been reported to yield possibly quantized transport [1]. We use high quality NPs, monodispersed with diameters of ~15 nm. Transport is studied after depositing the nanoparticles, and again after an argon anneal to remove the polyvinylidene fluoride coating on the NPs. In this case a small electron doping response is observed. Further measurements on higher density coatings of both osmium adatoms and Bi₂Te₃ nanoparticles will be discussed.

Sandia National Labs

3:30PM P13.00006: Nearly Flat Unoccupied State in Intercalated Graphene: Observation and Interpretation*  YI LIN (Presenter), GE CHEN, Columbia University, JERZY T. SADOWSKI, Brookhaven National Lab, YUNZHE LI, Columbia University, SAMUEL TENNEY, Brookhaven National Lab, JERRY DADAP, Columbia University, MARK HYBERTSEN, Brookhaven National Lab, RICHARD M OSGOOD, Columbia University — By using two-photon-photoemission, we observe a near-zero-dispersion empty state in oxygen-intercalated graphene-Ir interface, approximately 2.6 eV above the Fermi energy and near the Brillouin zone center. DFT method and band-unfolding technique are used to calculate the spectral weights for the graphene-Ir supercells with and without the intercalants. The calculations reproduce the measurements. Our analysis reveals the nature of the observed nearly flat band to be the replicates states from near the Dirac cone that have little dispersion due to trigonal warping. This interpretation is further supported by the results from angle-resolved photoemission. Our work explicitly demonstrates the persisting perturbation on the graphene even for the intercalated quasi-freestanding graphene. Our work demonstrates a pathway for tailoring the graphene electronic structure and generating nearly flat bands by using intercalation.

*We acknowledge support from the US DOE, Office of Basic Energy Sciences, under Contract Number DE-FG02-90ER14104. Our research used resources of the CFN and the NSLS-II, which are U.S. DOE Office of Science Facilities, and the Scientific Data and Computing Center, a component of the Computational Science Initiative, at BNL, under Contract No. DE-SC0012704.
3:42PM P13.00008: Photo-oxidation: Finding the Ambient Air Oxidation Mechanism of WS$_2$*  
JIMMY KOTSAKIDIS (Presenter), Physics and Astronomy, Monash Univ, QUANHUI ZHANG, Civil Engineering, Monash University, AMADEO LOPEZ VAZQUEZ DE PARGA, Condensed Matter Physics, Autonoma de Madrid, SHAUN JOHNSTONE, CHANGXI ZHENG, Physics and Astronomy, Monash Univ, MARC CURRIE, U.S. Naval Research Laboratory, KRISTIAN HELMERSON, Physics and Astronomy, Monash Univ, DAVID KURT GASKILL, U.S. Naval Research Laboratory, MICHAEL FUHRER, Physics and Astronomy, Monash Univ — Monolayer WS$_2$ exhibits exceptional optical and electronic properties, however, it also oxidizes in ambient conditions leading to the degradation of its optical and electrical performance over time.

In this work, we reveal that the oxidation of WS$_2$ in ambient conditions is driven by bandgap photo-excitation (i.e. a photo-oxidation effect) and we describe a possible oxidation chemical reaction pathway. Through a series of controlled experiments, WS$_2$ monolayers grown via chemical vapor deposition were exposed to low power light ($10^3$ to $10^4$ mW/m$^2$) with wavelengths of 532nm, 650nm and 760nm for 7 days. Our findings suggest that WS$_2$ is only oxidised in ambient conditions when exposed to light with enough energy to excite an optical bandgap transition.

Furthermore, we find that even limited exposure to above-bandgap illumination in ambient – at levels routine for photoluminescence or Raman spectroscopy characterization – causes significant oxidation. We predict that this photo-oxidation effect may be universal across all monolayer semiconducting transition metal dichalcogenides, and thus, these results could have far reaching consequences to past, present and future studies.

*We acknowledge support from the Australian Research Council grant DP150103837 and the U. S. Office of Naval Research
ZHIMING WANG, Institute of Fundamental and Frontier Sciences, University of Electro-dissociated oxygen from the SiO2 substrate. Oxygen is released from underneath the substrate and etches the graphene

JIMING BAO, Department of Electrical and Computer Engineering, University of Houston, USA — Planar alignment of disc-like multilayer on 300nm thick SiO2/Si substrates. A recent mechanism was proposed in which the etching was due to transitions as the system goes through a series of local free-energy minima.

First-order transition. In particular, our results show that the transition can be viewed as a sequence of 2D structural transitions as the system goes through a series of local free-energy minima. We performed large-scale MD simulations based on reactive force field potentials to investigate the kinetics of this intriguing first-order transition. In particular, our results show that the transition can be viewed as a sequence of 2D structural transitions as the system goes through a series of local free-energy minima.

4:30PM P13.00011: Planar alignment of graphene sheets by a rotating magnetic field for full exploitation of graphene as a two dimension material* FENG LIN (Presenter), Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, China, GUANG YANG, Department of Materials Science and Engineering, University of Houston, USA, CHAO NIU, Department of Electrical and Computer Engineering, Baylor University, USA, YANAN WANG, ZHUAN ZHU, Department of Electrical and Computer Engineering, University of Houston, USA, HAOKUN LUO, School of Optical and Electronic Information, Huazhong University of Science and Technology, China, CHONG DAI, YANDI HU, Department of Civil and Environmental Engineering, University of Houston, USA, JONATHAN HU, Department of Electrical and Computer Engineering, Baylor University, USA, XUFENG ZHOU, ZHAOPING LIU, Ningbo Institute of Materials Technology & Engineering, Chinese Academy of Sciences, China, ZHIMING WANG, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, China, JIMING BAO, Department of Electrical and Computer Engineering, University of Houston, USA — Planar alignment of disc-like nanomaterials is required to transfer their superior anisotropic properties from microscopic individual structures to macroscopic collective assemblies. However, such alignment by electrical or magnetic field is challenging due to their additional degrees of orientational freedom compared to that of rod-like nanostructures. Here, the realization of planar alignment of suspended graphene sheets using a rotating magnetic field produced by a pair of small NdFeB magnets and subsequent demonstration of high optical anisotropy and potential novel device applications is reported. Compared to partially aligned sheets with a static magnetic field, planar aligned graphene suspensions exhibit a near-perfect order parameter, much higher birefringence and anisotropic absorption/transmission. By immobilizing and patterning aligned graphene in a UV-curable polymer resin, we further demonstrated an all-graphene permanent display, which exhibits wide-angle, high dark-bright contrast in either transmission or reflection mode without any polarizing optics. The ability to control and pattern graphene orientation in all three dimensions opens up new exploration and broad device applications of graphene.

4:42PM P13.00012: Chemical enhancement of Raman scattering on graphene oxide in the quantum plasmonic regime SHARAD AMBARDAR (Presenter), DMITRI VORONINE, University of South Florida — Optoelectronic and mechanical properties of graphene oxide have been widely investigated. We observed two chemical enhancement mechanisms, one from the gold plasmonic tip via the tip-enhanced Raman spectroscopy (TERS) and the other from graphene oxide via the surface-enhanced Raman spectroscopy (SERS). We observed strong chemical enhancement from the gold plasmonic tip in the quantum plasmonic regime when the tip-sample distance is less than 1 nm. We improve the efficiency of the chemical enhancement by varying the tip-sample distance which allows us to clearly observe the effect of graphene oxide using nanoscale TERS imaging. Strong chemical enhancement can be used to improve the quality of sensors and nanophotonic devices on non-metallic substrates.

4:54PM P13.00013: Large-scale reactive molecular dynamics simulations of structural transitions in transition metal dichalcogenides COLE MILES (Presenter), CHUNRUO DUAN, DESPINNA LOUCA, GIA-WEI CHERN, University of Virginia — We present extensive molecular dynamics (MD) simulations of structural phase transitions in transition metal dichalcogenides (TMD). These quasi-two-dimensional materials are described by the general formula MX2 with M a transition metal atom (Mo, W, etc) and X a chalcogen atom (S, Se, Te). The crystal structure of a TMD consists of Van der Waals bonded layers, resembling that of graphene. TMDs are hosts of exotic quantum states with potential technological applications. Our work is motivated by recent experiments on MoTe2, showing diffuse scattering in the vicinity of the 1T'-Td structural transition which is indicative of stacking disorders resulting from layer misalignments along the c-axis. We performed large-scale MD simulations based on reactive force field potentials to investigate the kinetics of this intriguing first-order transition. In particular, our results show that the transition can be viewed as a sequence of 2D structural transitions as the system goes through a series of local free-energy minima.
5:06PM P13.00014: Angle-resolved photoemission spectroscopy on wet-transferred highly oriented MoS2 monolayers on HOPG substrates*  
WOOJOO LEE (Presenter), Physics, University of Texas at Austin, LI-SHUAN LU, WEI-CHEN CHUEH, WEN-HAO Chang, Electrophysics, National Chiao Tung University, CHIH-KANG SHIH, Physics, University of Texas at Austin — The ability to create a large area of monolayer 2D electronic materials with the same orientation on different substrates will play a very critical role for scalable flatland electronics. It has been shown that highly-oriented monolayer (ML) MoS2 can be grown on a carefully prepared sapphire substrate with nearly full coverage and transferred to different substrates [1]. However, it is still unclear whether such a transfer process will introduce unwanted defects that will affect the electronic structure. Here, we report successful preparation of high quality ML MoS2 transferred to HOPG substrates by using a wet transfer method. With a proper treatment, we reveal detailed electronic band structure using high resolution angle-resolved photoemission spectroscopy. Due to the fact that these MoS2 monolayers are highly oriented and interaction with a substrate is very weak [2], we are able to resolve the electronic band structure clearly including K point band splitting.

*Supported by Welch foundation F-1672, NSF MRSEC DMR-1720595, NSF EFMA-1542747, NSF DMR-1808751 and US AIRFORCE FA2386-18-1-4097

5:18PM P13.00015: Multifunctional nanoporous graphene  
ARAN GARCIA-LEKUE (Presenter), Donostia International Physics Center (DIPC), San Sebastian, Spain, CESAR MORENO, Catalan Institute of Nanoscience and Nanotechnology (ICN2), Barcelona, Spain, MANUEL VILAS-VARELA, Centro de Investigación en Química Biológica e Materiales Moleculares (CIQUS), Santiago de Compostela, Spain, BERNHARD KRETZ, Donostia International Physics Center (DIPC), San Sebastian, Spain, MARIUS V. COSTACHE, MARCOS PARADINAS, MIRKO PANIGHEL, GUSTAVO CEBALLOS, SERGIO O. VALENZUELA, Catalan Institute of Nanoscience and Nanotechnology (ICN2), Barcelona, Spain, DIEGO PEÑA, Centro de Investigación en Química Biológica e Materiales Moleculares (CIQUS), Santiago de Compostela, Spain, AITOR MUGARZA, Catalan Institute of Nanoscience and Nanotechnology (ICN2), Barcelona, Spain — Nanoporous graphene shows a great potential as an active component of field effect transistors and as an atom-thick selective molecular nanosieve. Recently, we have reported the bottom-up formation and electronic characterization of atomically precise nanoporous graphene comprising an ordered array of pores separated by ribbons, which can be tuned down to the one nanometer range [1]. Our combined Density Functional Theory (DFT) and Scanning Tunneling Spectroscopy (STS) study reveals a highly anisotropic electronic structure, where orthogonal one-dimensional electronic bands with an energy gap of ~1 eV coexist with a novel family of confined pore states. These properties can be tuned by changing, e.g. the size and morphology of the pore, making this 2D mesh a highly versatile semiconductor for simultaneous sieving and electrical sensing of molecular species. Session P14 DCMP: 2D Materials: Stack and Twist Theory  
BCEC 153C - Liujun Zou, Harvard University

2:30PM P14.00001: First-Principles Electronic Structure Investigation of 2D Twisted Bilayers  
ISHAAN KUMAR (Presenter), XUAN LUO, National Graphene Research and Development Center — Since the recent experimental observation of unconventional superconductivity in Twisted Bilayer Graphene (TBG) has brought 2D twisted materials to the front lines of research, there is a need to cover the underlying physics accurately and efficiently. We utilize the first-principles method to calculate both band structures and density of states (DOS) for various sized 2D twisted bilayers of Graphene, BN and MoS2. Our results reveal that introducing a twist opens a band gap, and Van Hove Singularities are seen symmetric to the dirac point in the DOS. The introduction of a twist angle in graphene also creates a parabolic band dispersion of the dirac cones, normally seen only in Bernal stacked graphene on account of strong stability and interlayer correlation. We evaluate the contribution of cell size to band structure by enlarging the unit cell from 2x2 to 12x12. The electronic properties of the smaller cell remains constant as the cell size increases. Furthermore, we treat a non-periodic 2D twisted bilayer by introducing a vacuum, from which we can draw parallels between the electronic structures and reveal the deep underlying physics.
2:42PM P14.00002: A multi-scale numerical approach to model two-dimensional layered materials* SHIANG FANG (Presenter), STEPHEN CARR, ZIYAN ZHU, EFTHIMIOS KAXIRAS, Harvard University — Since the discovery of single-layer graphene crystal, more different types of two-dimensional layered materials are exfoliated or synthesized. The theoretical modeling would guide the further design and understanding with these materials. We develop a multi-scale numerical approach to model these layers and their heterostructures. The microscopic modeling is based on the density functional theory (DFT) calculations followed by Wannier transformation to derive localized orbitals. These allow us to capture the effects from coupling with adjacent layers and the deformation within each layer from crystal relaxations. The faithful representation of the wavefunction characters also enables the computation of Berry curvatures and responses to external electric and magnetic fields.

2:54PM P14.00003: Gate-Tunable Topological Flat Bands in Trilayer Graphene-Boron Nitride Moiré Superlattices* BHEEMA LINGAM CHITTARI (Presenter), Department of Physics, University of Seoul, Seoul 02504, Korea, GUORUI CHEN, Department of Physics, University of California at Berkeley, Berkeley, CA 94709, USA, YUANBO ZHANG, Institute for Nanoelectronic Devices and Quantum Computing, Fudan University, Shanghai 200433, China, FENG WANG, Department of Physics, University of California at Berkeley, Berkeley, CA 94709, USA, JEIL JUNG, Department of Physics, University of Seoul, Seoul 02504, Korea — We investigate the electronic structure of the flat bands induced by moiré superlattices and electric fields in nearly aligned ABC trilayer graphene-boron nitride interfaces where Coulomb effects can lead to correlated gapped phases. Our calculations indicate that valley-spin resolved isolated superlattice flat bands that carry a finite Chern number \( C = 3 \) proportional to layer number can appear near charge neutrality for appropriate perpendicular electric fields and twist angles. When the degeneracy of the bands is lifted by Coulomb interactions these topological bands can lead to anomalous quantum Hall phases that embody orbital and spin magnetism. Narrow bandwidths of \( \sim 10 \) meV achievable for a continuous range of twist angles \( \theta \leq 0.6^\circ \) with moderate interlayer potential differences of \( \sim 50 \) meV make the TLG/BN systems a promising platform for the study of electric-field tunable Coulomb interaction driven spontaneous Hall phases.

3:06PM P14.00004: Composition and Stacking Dependent Topology in Bilayers from the Graphene Family* LILIA M WOODS (Presenter), ADRIAN POPESCU, Department of Physics, University of South Florida, PABLO RODRIGUEZ LOPEZ, Consejo Superior de Investigaciones Cienticas (CSIC), Instituto de Ciencia de Materiales de Madrid (ICMM) — We investigate from first-principles the electronic and structural properties of silicene, germanene, and stanene bilayers. Due to the staggering of the individual layers, several stacking patterns are possible, most of which are not available to the bilayer graphene. Our results reveal the appearance of distinct band features, including orbital hybridization and band inversion, and they are attributed to the combined effects of the composition, stacking, and to the presence of the spin-orbit coupling. It is found that particular arrangements give rise to topological features in the Hall response, offering new directions for exploring Dirac features in 2D systems.

*Financial support from the US Department of Energy under Grant No. DE-FG02-06ER46297 is acknowledged. 3:18PM P14.00005: Ultraflat bands and shear solitons in Moiré patterns of twisted bilayer transition metal dichalcogenides MIT NAIK, MANISH JAIN (Presenter), Department of Physics, Indian Institute of Science — Ultraflat bands in twisted bilayers of two-dimensional materials have potential to host strong correlations, including the Mott-insulating phase at half-filling of the band. Using first-principles density functional theory calculations, we show the emergence of ultraflat bands at the valence band edge in twisted bilayer MoS2, a prototypical transition metal dichalcogenide. The computed band widths are comparable to that of twisted bilayer graphene near ‘magic’ angles. Large structural transformations in the Moiré patterns lead to the formation of shear solitons at stacking boundaries and strongly influence the electronic structure. We extend our analysis for twisted bilayer MoS2 to show that flat bands can occur at the valence band edge of twisted bilayer WS2, MoSe2 and WSe2 as well.
3:30PM P14.00006: Topological phases and twisting of graphene on a dichalcogenide monolayer  
ABDULRHMAN ALSHARARI (Presenter), Physics Department, Tabuk University, MAHMOUD ASMAR, Department of Physics and Astronomy, Louisiana State University, SERGIO E ULLOA, Ohio University — Graphene placed in proximity to a transition metal dichalcogenide semiconductor monolayer has been shown to exhibit interesting modifications of its electronic properties. The role of incommensurability and a possible relative twist between layers require implementing a continuum model approach to fully investigate this multilayered system. Results of this model are in agreement with simplified approaches, such as the tight-binding model, that assumes commensurate supercells. We show that the misaligned system can also exhibit multiple different topological phases depending on the relative twist angle and applied gate voltages between the layers[1]. An interesting topological phase exhibits inverted bands which is robust to incommensurate structure effects. Using an effective Hamiltonian to fully describe the continuum model of graphene-TMD heterostructure reveals that a staggered potential and effective SOC are induced onto the graphene, which controls the appearance of the non-trivial topological phase. Our estimates suggest that the intrinsic SOC induced onto graphene deposited on typical TMDs is somewhat weak and must be enhanced by additional means, such as heavy metal intercalation, to achieve a tunable quantum spin Hall phase.

3:42PM P14.00007: Band nesting and valley exciton in monolayer MoS₂  
MACIEJ BIENIEK (Presenter), Department of Theoretical Physics, Wroclaw University of Science and Technology, LUDMILA SZULAKOWSKA, PAWEL HAWRYLAK, Department of Physics, University of Ottawa — We report the effect of band nesting on single valley excitons in monolayer MoS₂. We start with ab-initio based electronic structure obtained within tight binding model of MoS₂ [1]. We next turn on electron-electron interactions, form a Hartree-Fock ground state and construct electron-hole excitations. We compute e.-e. interactions, self-energy in the screened exchange and Coulomb hole approximation and direct and exchange electron-hole interaction. We solve Bethe-Salpeter equation to obtain exciton states and absorption spectrum. We disentangle effects of electron-hole dispersion, details of band structure on Coulomb intra/inter-valley interactions, topology, screening and dielectric environment. In particular, we discuss the effect of Q-points and band nesting on ground and excited states of excitons in MoS₂.

3:54PM P14.00008: A metal-insulator transition by hole doping in boron triangular Kagome lattice  
WOO HYUN HAN (Presenter), Department of Physics, KAIST, SUNGHYUN KIM, Department of Materials, Imperial College London, IN-HO LEE, Korea Research Institute of Standards and Science, KEE JOO CHANG, Department of Physics, KAIST — A flat band is the hallmark of a variety of exotic phases because electrons are confined in a narrow energy window with a very high density of states. Recently, much attention has been paid to magic-angle twisted bilayer graphene which possesses a flat band feature and exhibits strongly correlated and unconventional superconducting phases. This experiment indicates that partially-filled flat bands are the birthplace of many interesting phenomena and motivate further studies for the hidden physics of partially-filled flat bands in other systems. In this work, through first-principles calculations, we investigate the electronic structure and structural stability of a partially-filled flat band in boron triangular Kagome lattice which has been recently predicted. We find that a large Fermi surface nesting in the partially-filled flat band enhances electron-phonon interactions and induces dynamical instability. For hole doping levels above a 2/3-filling of the spin-polarized flat band, a metal-insulator transition occurs. Our results suggest that the boron triangular Kagome lattice is a suitable material to study the effect of partially-filled flat bands on exotic phases.

4:06PM P14.00009: Landau levels in bilayer transition metal dichalcogenides*  
PENG PENG ZHENG (Presenter), FAN ZHANG, University of Texas at Dallas — The quantum binary system at low temperature is not limited to only spin, but that of valley and layer degrees of freedom as well. A prime example is bilayer transition metal dichalcogenide (TMD). Here we examine the Landau level structure of bilayer TMD. We show how the interlayer electric field and the magnetic Zeeman field couple and control the layer and valley pseudospins, respectively, thereby tuning the Landau levels. To understand the underlying mechanics, we develop an effective model accurate within the experimental range to model and analyze the results. Our work sheds a new light on the quantum Hall effects of atomically thin TMD’s.

*Research was sponsored by the Army Research Office and was accomplished under Grant Number W911NF-18-1-0416.
4:18PM P14.00010: Tunable spin-polarized edge currents in proximitized transition metal dichalcogenides*  
NATALIA CORTES, Departamento de Fisica, Universidad Tecnica Federico Santa Maria, OSCAR AVALOS OVANDO (Presenter), Department of Physics and Astronomy, Ohio University, LUIS ROSALES, PEDRO ORELLANA, Departamento de Fisica, Universidad Tecnica Federico Santa Maria, SERGIO E ULLOA, Department of Physics and Astronomy, Ohio University — We explore proximity-induced ferromagnetism on transition metal dichalcogenide (TMD), focusing on molybdenum ditelluride (MoTe2) ribbons with zigzag edges, deposited on ferromagnetic europium oxide (EuO). A three-orbital tight-binding model allows modeling MoTe2 monolayer structures in real space, incorporating the exchange and Rashba fields induced by proximity to the EuO substrate. For in-gap Fermi levels, electronic modes in the nanoribbon are strongly spin-polarized and localized along the edges, acting as 1D conducting channels with tunable spin-polarized currents. We also study the effect of atomic defects on the 1D conducting channels and on the spin-polarized currents, finding a nonvanishing spin-polarized current even in the presence of either Te and/or Mo vacancies. Hybrid structures such as the MoTe2/EuO configuration can serve as building blocks for spintronic devices and provide versatile platforms to further understand proximity effects in diverse materials systems.

4:30PM P14.00011: Tight-binding modeling of bilayer TMDCs with lithium intercalation  
ZHEYU LU (Presenter), STEPHEN CARR, DANIEL LARSON, EFTHIMIOS KAXIRAS, Harvard University — We present an ab-initio tight-binding modeling of bilayer TMDCs with lithium intercalation based on the wannier transformation of first-principles calculations. Specifically, we take MoS2 as an example. As a starting point, we investigate the energetics of different intercalation sites for Li between layers of MoS2. We find that the intercalation energetics is related to the local coordination type and the number of vertically aligned molybdenum atoms. In addition, we verify that Li intercalation tunes the Fermi level to the conduction bands and make the system metallic. Further, we use three variables to characterize the relative configuration between the sulfur pair and the Li and describe the interlayer sulfur-sulfur interactions. As expected, Li brings extra influence and dramatically tunes the interlayer interactions. Our results pave the way for further modeling of twisted bilayer TMDCs with Li intercalation.

4:42PM P14.00012: Properties of doubly-aligned graphene/boron nitride heterostructures*  
NATHAN FINNEY (Presenter), MATTHEW YANKOWITZ, LITHURSHANAA MURALEETHARAN, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, CORY DEAN, JAMES HONE, Columbia University — A long-wavelength superlattice moiré potential emerges in heterostructures of graphene and boron nitride (BN) with small interlayer twist. The bandstructure of graphene is substantially modified by this superlattice potential, with secondary Dirac cones emerging at finite energy and band gaps opening at both the original and secondary Dirac points. We investigate the behavior of BN-encapsulated graphene in which the bottom BN is aligned to the graphene and the top BN can be rotated freely. We observe a significant enhancement of the band gap at the Dirac point in the case where both the top and bottom BN layers are perfectly aligned to the graphene. Additionally, while rotations of 60° are equivalent in typical graphene on BN heterostructures, we observe symmetry under 120° rotations of the top BN in our doubly-aligned devices, owing to the inequivalence of the boron and nitrogen potentials in the BN unit cell. In particular, we find the resistance of the Dirac point at room temperature is enhanced with the top BN at 0° but suppressed at 60°.

*N.F. acknowledges the Stewardship Science Graduate Fellowship program's support, provided under cooperative agreement number DE-NA0002135.
4:54PM P14.00013: Modifying the Band Structure of Hexagonal Boron Nitride with Metal Electrodes* MEHMET DOGAN (Presenter), MARVIN L COHEN, Physics, UC Berkeley — Tuning the large band gap of BN to make it functional in a given device configuration has been challenging. Theoretical attempts via an external electric field, strain, and changing the interlayer distance have produced promising results, however, at unrealistically high electric field and strain values. In this DFT-based study, we propose an alternate scheme for tuning the electronic states in BN. We investigate systems in which a few layers of BN are sandwiched between two metals with different work functions, such as Cu/BN/K, creating a large electric field through the BN slab. We find that the energy gap among the BN states can be significantly decreased in such configurations. We also report on the dependence of this effect on the different metals used and the number of BN layers, as well as the BN stacking order, as the controlled growth of an alternative (Bernal) stacking order was recently reported (S. M. Gilbert et al., arXiv:1810.04814) and thus became available for such applications.

*This work was supported by the Department of Energy under Contract No. DE-AC02-05-CH11231, and the National Science Foundation under Grant #DMR 1508412.

5:06PM P14.00014: Exchange driven dimerization, band gap, and magnetism of diamond(111) surface from first principles* BETUL PAMUK (Presenter), Cornell University, MATTEO CALANDRA, Sorbonne Université — Strong electron-electron interaction in ultraflat edge states can be responsible for correlated phases of matter, such as magnetism, charge density wave or superconductivity. The diamond(111) surface, after Pandey reconstruction, presents zig-zag carbon chains, generating a very flat surface band. More than 100 years after Bragg determined the structure of bulk diamond, the structure of the (111) surface of diamond is still controversial. Full structural optimization using hybrid density functionals with exact exchange shows that a substantial dimerization occurs on the Pandey π-chains — that is the primary mechanism for the opening of an insulating gap. This effect is absent in standard functionals. The exchange interaction further stabilizes a ferrimagnetic order along the Pandey π-chains with magnetic moments of 0.27 μB, opening a direct band gap of ~1.4 eV, in agreement with experiments. Our work is relevant for systems with flat bands in general and wherever the interplay between structural and electronic degrees of freedom is crucial, as in twisted bilayer graphene, IVB atoms on IVB(111) surfaces such as Pb/Si(111) or molecular crystals.

*We thank the Graphene Flagship, RhomboG grant (ANR-17-CE24-0030) from ANR, PRACE, and NSF (PARADIM) Cooperative Agreement No. DMR-1539918.

5:18PM P14.00015: Nano-Makis: Two-Dimensional Carbon derived from One-Dimensional Carbon LEI ZHAO (Presenter), California State University Northridge, WEI LIU, TAO HU, Beijing Computational Science Research Center, DALAR KHODAGHOLIAN, California State University Northridge, FENGLONG GU, South China Normal University, HAI-QING LIN, Beijing Computational Science Research Center, YONGHAO ZHENG, University of Electronic Science and Technology of China, MAOSHENG MIAO, California State University Northridge — The synthesis of carbon nanotubes and the rediscovery of graphene has sparked experimental and theoretical studies on new allotropes of carbon. Herein, we report first-principles calculations on novel two-dimensional carbon allotropes that are formed from embedding single-walled carbon nanotubes (SWNTs) within graphene sheets. The SWNTs are joined to the sheet via hexagonal or tetragon-octagon rings. We call this predicted allotrope of carbon nano-makisu. Results of phonon and molecular dynamics calculations demonstrate that these new carbon allotropes are dynamically and thermally stable, and they are energetically more favorable than pure SWNTs. Electronic structure calculations indicate that these two-dimensional carbon allotropes are metallic. Moreover, anisotropic Dirac-cone like features are found in nano-makisu. Because of its intriguing electronic transport properties nano-makisu are potential materials for nanoelectronics.
DHAVALA SURI (Presenter), Francis Bitter Magnet Laboratory and Plasma Science and Fusion Center, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, GREGORY STEPHEN, Department of Physics, Northeastern University, WEI KONG, Department of Material Science and Engineering, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, MIRKO ROCCI, Francis Bitter Magnet Laboratory and Plasma Science and Fusion Center, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, NARENDRA KUMAR, YIPING WANG, KENNETH BURCH, Department of Physics, Boston College, JEEHWAN KIM, Department of Material Science and Engineering, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, DON HEIMAN, Department of Physics, Northeastern University, JAGADEESH MOODERA, Francis Bitter Magnet Laboratory and Plasma Science and Fusion Center, MASSACHUSETTS INSTITUTE OF TECHNOLOGY — Ferromagnet (FM)/2D material interface with broken symmetry is a potential avenue for new physics and to realize exchange field controllable future spintronics devices. Proximity-induced effects of a FM on TI and graphene (G) have been explored previously with EuS as the ferromagnet, inducing magnetic correlations in the adjacent layer [1]. Magnetic semiconductor GdN would enable higher temperature operation. We report successful sputter growth of ultrathin excellent GdN films on high-quality G synthesized on SiC substrate to form G/FM heterostructures. The properties of G are unperturbed with 15 nm thick GdN film grown over it, having a magnetic moment ≈ 7 μB and Curie temperature ≈ 33 K. Temperature-dependent Raman spectrum of electric field tunable GdN/G system shows a clear signature of graphene G peak near 1580 cm⁻¹ and G' peak near 2700 cm⁻¹ confirming its quality. The induced magnetic correlations in G creating exchange gap in the Dirac surface states by GdN is investigated. Furthermore, patterning a superconductor over this bilayer for Josephson pair tunnelling studies in G will be presented.

*Funding Acknowledgement: NSF (DMR 1700137) and CIQM (DMR-1231319).

AHMET AVSAR (Presenter), ALBERTO CIARROCCHI, MICHELE PIZZOCHERO, DMITRII UNUCHEK, OLEG YAZYEV, ANDRAS KIS, Ecole polytechnique federale de Lausanne — While intrinsic magnets rarely occur in nature, long range magnetism in nonmagnetic materials can be introduced in a variety of forms, e.g., adatom intercalation, proximity coupling and defect engineering. The latter has been predicted for several two-dimensional (2D) materials including transition metal dichalcogenides (TMDCs), but such magnetic ordering of spins in the atomically thin limit has not been experimentally realized yet. Here, we will present defect-induced magnetism for an environmentally stable 2D TMDC crystal. By utilizing magneto-transport and polar refractive magnetic circular dichroism techniques, we demonstrate ferromagnetic or anti-ferromagnetic ground state orderings depending on the number of layers, similarly to recently discovered CrI₃. Attempts on further manipulation of magnetism within a layer by precise defect engineering will be also shown. Our findings broaden the horizon of 2D magnets to include normally nonmagnetic stable materials by introducing defects.

CHING-HAO CHANG (Presenter), SHENG-CHIN HO, TSE-MING CHEN, National Cheng Kung University, Taiwan, CARMINE ORTIX, Utrecht University — Local deformation in graphene are gathering great interest because it introduces huge pseudo-magnetic field to modify the electronic states nearby to host novel transport properties [1]. The graphene nanobubble, for instance, is predicted to strongly polarize the valley of an injecting current [2]. In this respect, the nontrivial valley-dependent band structure can be introduced when a local deformation turns into periodic. In this talk, we will show that the Rashba-like valley bands form in corrugated graphene systems. Moreover, the low-energy bands refer to magnetic snake states moving along the corrugations and thus can provide one-dimensional-like ballistic valley transport.

**3:06PM P15.00004: Triangular antiferromagnetism on the honeycomb lattice of twisted bilayer graphene***

ALEXANDRA THOMSON (Presenter), Caltech, SUBIR SACHDEV, Harvard University, SHUBHAYU CHATTERJEE, UC Berkeley, MATHIAS SCHEURER, Harvard University — We present the electronic band structures of states with the same symmetry as the three-sublattice planar antiferromagnetic order of the triangular lattice. Such states can also be defined on the honeycomb lattice provided the spin density waves lie on the bonds. We identify cases which are consistent with observations on twisted bilayer graphene: a correlated insulator with an energy gap, yielding a single doubly-degenerate Fermi surface upon hole doping. We also discuss extensions to metallic states which preserve spin rotation invariance, with fluctuating spin density waves and bulk $\mathbb{Z}_2$ topological order.

*This research was supported by the NSF under Grant DMR-1664842. Research at Perimeter Institute is supported by the Government of Canada through Industry Canada and by the Province of Ontario through the Ministry of Research and Innovation. SS also acknowledges support from Cenovus Energy at Perimeter Institute. MS acknowledges support from the German National Academy of Sciences Leopoldina through grant LPDS 2016-12.

**3:18PM P15.00005: Interplay Between Ferromagnetism and Superconductivity in van der Waals Devices***

ROBERT POLSKI (Presenter), HARPREET SINGH ARORA, JEANNETTE KEMMER, Watson Laboratory of Applied Physics, California Institute of Technology, YOUNGJOON CHOI, Department of Physics, California Institute of Technology, HECHEN REN, Watson Laboratory of Applied Physics, California Institute of Technology, YIRAN ZHANG, Department of Physics, California Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, STEVAN NADJ-PERGE, Watson Laboratory of Applied Physics, California Institute of Technology — Two-dimensional van der Waals materials have unlocked the ability to stack electronically dissimilar materials into heterostructures that are highly tunable using proximity effects, gate modulation, and varying layer numbers. Interest in superconducting proximity effects, such as Andreev reflection in superconductor-normal (S-N) junctions and Josephson junctions, have thus provoked numerous studies in these systems, but the combination of spin-singlet superconductors (S) and spin-polarized ferromagnets (F) into S-F interfaces has been largely unexplored in van der Waals materials. Proper understanding and control of these interfaces could lead to advances in spintronics and novel realizations of unconventional superconductivity. We used superconducting and ferromagnetic van der Waals materials to study the electrical properties of S-F interfaces through transport measurements as we vary both the temperature and the magnetic field.

*This work was supported by NSF (Partly through grant DMR 1753306) and by Gist-Caltech collaboration program memorandum of understanding.

**3:30PM P15.00006: Voltage Control of a van der Waals Spin-Filter Magnetic Tunnel Junction***

TIANCHENG SONG (Presenter), University of Washington, MATISSE WEI-YUAN TU, University of Hong Kong, CAITLIN CARNAHAN, Carnegie Mellon University, XINGHAN CAI, University of Washington, TAKASHI TANIGUCHI, KENJI WATANABE, NATIONAL INSTITUTE FOR MATERIALS SCIENCE, STEPHEN MCGUIRE, Oak Ridge National Laboratory, DI XIAO, Carnegie Mellon University, WANG YAO, University of Hong Kong, XIAODONG XU, University of Washington — Atomically thin chromium triiodide ($\text{CrI}_3$) has recently been identified as a layered antiferromagnetic insulator, in which adjacent ferromagnetic monolayers are antiferromagnetically coupled. This unusual magnetic structure naturally comprises a series of anti-aligned spin filters which can be utilized to make spin-filter magnetic tunnel junctions with very large tunneling magnetoresistance (TMR). Here we report voltage control of TMR formed by four-layer $\text{CrI}_3$ sandwiched by monolayer graphene contacts in a dual-gated structure. By varying the gate voltages at fixed magnetic field, the device can be switched reversibly between bistable magnetic states with the same net magnetization but drastically different resistance (by a factor of ten or more). Our work demonstrates new kinds of magnetically moderated transistor action and opens up possibilities for voltage-controlled van der Waals spintronic devices.

**3:42PM P15.00007: Controlling magnetism in layered metal halides by doping***

ZHONG LIN (Presenter), QIANNI JIANG, ZAIYAO FEI, BEVIN HUANG, Physics, University of Washington, Seattle, YUE SHI, Materials Science and Engineering, University of Washington, Seattle, JUN-HAW CHU, XIAODONG XU, Physics, University of Washington, Seattle — van der Waals magnets such as chromium triiodide show thickness dependent magnetic properties which can be further controlled by electrostatic gating. Engineering their intrinsic magnetism via compositional and structural modification remains largely unexplored. I will present our recent efforts on doping layered metal halides, including the characterization of bulk crystals and exfoliated flakes down to their 2D limit.

*This work is supported by DOE BES Pro-QM EFRC (DE-SC0019443).
Spin and charge conversion in two dimensional magnets*  
ABHISHEK SOLANKI (Presenter), AVINASH RUSTAGI, PRAMEY UPADHYAYA, Purdue University — Interconversion between spin and charge degrees of freedom is one of the central goals of spintronics. In recent years, a host of quantum materials—Rashba interfaces, topological insulators, superconductors and non-collinear antiferromagnets—have emerged as promising candidate material systems, where various novel spin-dependent phenomena allow for efficient spin and charge interconversion [npj Quantum Materials **3**, 27 (2018)]. More recently, van der Waal magnets (such as CrI3) [**Nature** **546**, 270 (2017)] have emerged as a unique two-dimensional platform, where electron-electron interactions can be significantly altered—from being ferromagnetic to antiferromagnetic—by charge doping [**Nature Mat.** **17**, 406 (2018)]. In this work, we develop a phenomenological theory of spin-charge interconversion enabled by electrically controlled spin-spin interactions in these two-dimensional magnets, predicting new efficient schemes for converting between spin and charge. In combination with the unique toolkit of heterostructure engineering offered by the van der Waal materials [**Science** **353**, aac9439 (2016)], the predicted spin charge interconversion could give rise to a new set of nonvolatile spintronics devices.

*We acknowledge NSF grant DMR-1838513.

Current-induced torques in heterostructures of 2D van der Waals magnets  
VISHAKHA GUPTA (Presenter), GREGORY STIEHL, ARNAB BOSE, KAIFEI KANG, SHENGWEI JIANG, KIN FAI MAK, JIE SHAN, ROBERT BUHRMAN, DANIEL RALPH, Cornell University — The recent discovery of magnetic order in layered 2D van der Waals materials has opened a new platform for spintronic devices, allowing studies of current-induced torques in high-quality heterostructures of single-crystal 2D magnets and large spin-orbit coupling (SOC) materials. Here, we integrate mechanically exfoliated thin flakes of the insulating 2D ferromagnet Cr2Ge2Te6 into a heterostructure with heavy metal Tantalum as the large SOC material. We report initial results of current induced deflections of the out-of-plane magnetic moment of Cr2Ge2Te6 and characterize the spin-orbit torque generated. This work represents a first step towards improved strategies for magnetic memory and logic using heterostructures of van der Waals 2D magnets.

Ion Implantation Leading to Magnetism in Many-Layer Graphene*  
ALESSANDRO MAZZA (Presenter), Physics, University of Missouri, ANNA L MIETTINEN, Physics, Georgia Institute of Technology, TIMOTHY CHARLTON, Spallation Neutron Source, Oak Ridge National Lab, THOMAS WARD, Materials Science and Technology, Oak Ridge National Lab, XIAOQING HE, Department of Mechanical and Aerospace Engineering and Electron Microscopy Core, University of Missouri, ALEX A DAYKIN, SUCHISMITA GUHA, GUANG BIAN, Physics, University of Missouri, EDWARD H. CONRAD, Physics, Georgia Institute of Technology, PAUL F MICELI, Physics, University of Missouri — P-orbital magnetism observed in graphene is of interest both to fundamental physics and for its potential application in new classes of spintronic devices. In this talk, we will demonstrate how low energy ion bombardment of graphene with hydrogen can be used to manipulate defect type and concentration to induce room temperature ferromagnetism in layered graphene. SQUID magnetometry measurements show that it is possible to control the magnetic properties by varying the H energy and dose. In-situ x-ray diffraction shows that ion distribution leads to layer expansion and an increase in RMS height variations of the graphene layers. Neutron reflectivity reveals that implanted H ions remain in the sample after dosing via chemisorption. The relationship between these results and magnetometry measurements, which show that ion implantation leads to a ferromagnetic moment at room temperature, will be discussed.

4:30PM P15.00011: Kondo Effect in Graphene Nanoribbons with Magnetic Impurities* GINETOM DINIZ (Presenter), Unidade Acadêmica Especial de Ciências Exatas, Universidade Federal de Goiás, Jataí, Goiás 75801-615, Brazil, GISELE IORIO LUIZ, Instituto de Física, Universidade Federal de Uberlândia, Uberlândia, Minas Gerais 38400-902, Brazil, ANDREA LATGE, Instituto de Física, Universidade Federal Fluminense, Niterói, Rio de Janeiro 24210-340, Brazil, EDSON VERNEK, Instituto de Física, Universidade Federal de Uberlândia, Uberlândia, Minas Gerais 38400-902, Brazil — In this work we have performed a detailed analysis of the Kondo effect of a magnetic impurity in graphene nanoribbons with zigzag edge termination [1]. We have considered an adatom coupled to the graphene nanoribbon via a hybridization amplitude in two different configurations: hollow or top site. In addition, the adatom is also weakly coupled to a metallic STM tip by a hybridization function that provides a Kondo screening of its magnetic moment. We have described the entire system by the well-known Anderson-like Hamiltonian [2] whose low-temperature physics is accessed by employing the numerical renormalization group approach [3], which allows us to obtain the thermodynamic properties used to compute the Kondo temperature of the system. In our numerical calculation, two screening regimes were observed: local singlet and Kondo singlet, which strongly depends on the impurity adatom location and on the coupling strength of the carbon sites of the graphene nanoribbon with the adatom impurity.

4:42PM P15.00012: Analysis of Magnetoresistance in CrI3-graphene Heterostructures via First-principles Calculations JONATHAN HEATH (Presenter), MARCELO KURODA, Auburn University — Recently, spin transport was demonstrated in heterostructures based on two-dimensional (2D) materials. Here we characterize electronic transport through multilayer CrI3 systems (bilayer, trilayer, and tetralayer) using the density functional theory (DFT) and the Landauer formalism for ballistic transport. Electronic structure of these tunneling junctions reveal that the interplay of quantum confinement and metamagnetic configurations defines the different tunneling rates. Hence, atomistic calculations capturing coupling between layers are key to these descriptions. Our ballistic transport calculations are in agreement with recent experimental measurements of magnetoresistance in graphene/CrI3/graphene [Klein et al., Science 360, 1218 (2018)]. We apply our transport studies for this type of tunneling junction to other metallic leads with Fermi level density of states larger than that of graphene and compare to other Cr halides junctions. While tunneling resistivity is significantly reduced, magnetoresistance ratios do not necessarily increase due to the intricate complex band structure of these systems. The atomistic details provided by this work may prove valuable towards the use of these 2D material-based spintronic devices.

4:54PM P15.00013: Assembly, X-ray diffraction and electronic transport measurement of atomically thin Bi2Sr2CaCu2O8+y high temperature superconducting van der Waals cuprate heterostructures. NICOLA POCCIA (Presenter), SHU YANG FRANK ZHAO, YUVAL RONEN, HYOBIN YOO, Department of Physics, Harvard University, Cambridge, MA 02138, USA., RUIDAN ZHONG, GENDA GU, XIAOJING HUANG, HANFEI YAN, YONG S. CHU, Department of Condensed Matter Physics and Materials Science, Brookhaven, Brookhaven National Laboratory, Upton, New York 11973-5000, USA., KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Namiki 1-1, Tsukuba, Ibaraki 305-0044, Japan., SVETLANA POSTOLOVA, Rzhanov Institute of Semiconductor Physics, Siberian Branch, Russian Academy of Sciences, Novosibirsk 630090, Russia., GAETANO CAMPI, Institute of Crystallography, CNR, via Salaria Km 29.300, Monterotondo Stazione, Roma 00016, Italy., VALERII VINOKUR, Materials Science Division, Argonne National Laboratory, 9700 S. Cass Ave, Argonne, IL 60439, USA., PHILIP KIM, Department of Physics, Harvard University, Cambridge, MA 02138, USA. — Unique physical properties of low-dimensional electronic systems arise from the fine balance and interplay of often competing phenomena in the reduced dimensionality. We fabricated van der Waals heterostructure based on atomically thin Bi2Sr2CaCu2O8+y (BSCCO) high temperature superconductor. Unlike conventional superconductors, atomically thin BSCCO film exhibits an intrinsic multi-scale heterogeneity and a complete new set of imaging and nanofabrication tools are required to tame this complexity. In this talk, we will show the structural nanoscale heterogeneity using advanced X-ray nanoprobes of an assembled few-unit cells van der Waals cuprate high temperature superconducting heterostructure. Towards the end, I will demonstrate our recent realization of Josephson junctions made of assembled van der Waals cuprate heterostructures.
Ultrafast photoemission momentum microscopy* CHRISTOPHER CORDER (Presenter), PENG ZHAO, JIN BAKALIS, MICHAEL G WHITE, THOMAS ALLISON, Stony Brook University, Stony Brook, NY 11794 — Understanding the electronic properties in material systems is key to unlocking new technologies. To probe the carrier dynamics on their natural timescale, ultrafast spectroscopies are employed, typically with femtosecond optical lasers. However, the observed features in these measurements are often ambiguous when attempting to identify the carriers involved and their location in the material band structure. Recent advances in ultrafast extreme-ultraviolet sources [1,2] now allow direct observation of carrier energy and momentum using angle-resolved photoelectron spectroscopy with the high data rates and low space-charge required for observing band structures. We demonstrate the capabilities when one of these XUV sources is paired with a time-of-flight momentum microscope [3] enabling time-resolved multidimensional measurements simultaneously spanning energy and two dimensions of momentum space.

Session P16 DCOMP DCP: Aqueous Solutions, Solvated Interfaces, and Ionic Polarization

II BICE 155 - Marivi Fernandez Serra, Stony Brook University - Tag(s): Focus

The Role of Interfaces for Chemical Transformations and Transport under Confinement* [Invited] TERESA HEAD-GORDON (Presenter), University of California, Berkeley — Chemical transformations, selectivity, and transport rarely occur in a single homogeneous aqueous phase, but instead occur in niches, crevices, and impurity sites at confining interfaces between two or more phases of gases, liquids or solids. The effects of confinement are ubiquitously present across diverse fields spanning nanochemistry and chemical catalysis, environmental and energy sciences, geosciences, and functional materials. Fundamentally, confinement at interfaces alters water and solution compositions and phases to reformulate the thermodynamics of selectivity, transition states and pathways of chemical reactions, nucleation events, and kinetic barriers for transport. I will provide three different examples of theoretical studies of confinement around anhydrous clays, synthetic enzymes, and a general non-equilibrium phenomena of confinement which we refer to as dynamical inversion of the energy landscape.

*The catalysis application supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Chemical Sciences, Geosciences, and Biosciences Division under Contract No. DE-AC02-05CH11231. The material on theory and methods is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research, Scientific Discovery through Advanced Computing (SciDAC) program. This research received a 2017 ASCR Leadership Computing Challenge (ALCC) allocation at the National Energy Research Scientific Computing Center, a DOE Office of Science User Facility supported by the Office of Science of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.
3:06PM P16.00002: Water/mineral interfaces: Structure and Dynamics from Nonlinear Vibrational Spectroscopy and Ab Initio Molecular Dynamics* [Invited] LUANA PEDROZA (Presenter), Universidade Federal do ABC, Brazil, FABIO R. NEGREIROS, Departamento de Quimica Teorica y Computacional, Facultad de Ciencias Quimicas, Universidad Nacional de Cordoba, Argentina, GUSTAVO DALPIAN, Universidade Federal do ABC, Brazil, JACIARA DE CARVALHO SANTOS, PAULO B MIRANDA, Instituto de Fisica de Sao Carlos, USP, Brazil — Water–mineral interfaces are important for several environmental, industrial, biological, and geological processes. In particular, gypsum is a widespread mineral of high technological, medical, and environmental relevance, but little is known about its surface structure and its interaction with water. A molecular-level understanding of gypsum/water interface is given here by a combined experimental/theoretical study. We investigate the structure and dynamics of water adsorbed from vapor on the gypsum (010) single-crystal surface at room temperature, combining sum-frequency generation (SFG) vibrational spectroscopy experiments and ab initio molecular dynamics (AIMD) simulations. The theoretical results corroborate the experimental ones and provide an accurate atomic characterization of the surface structure.

*We thank the Brazilian agencies FAPESP (grants 11/19924-2, 14/01595-0, 14/14271-9, 18/13753-0, 17/10292-0) and CNPq for financial support. Computer simulations were performed at CENAPAD-SP and on the Santos Dumont supercomputer at LNCC.

3:42PM P16.00003: Efficient calculation of level alignment at weakly coupled molecule-metal interfaces using substrate screening within the GW approach ZHENFEI LIU (Presenter), Department of Chemistry, Wayne State University, FELIPE DA JORNADA, STEVEN G. LOUIE, Department of Physics, University of California, Berkeley, JEFFREY B NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory — The physics of level alignment at molecule-metal interfaces can often be accurately captured by the ab initio GW approach. However, the computational cost for such GW calculations for typical interfaces is significant, given their large system size and chemical complexity. In the past, approximate self-energy corrections constructed from image-charge models have been used to compute level alignment with good accuracy. However, this approach neglects dynamical effects of the polarizability and requires the definition of an image plane. In this work, we propose a new approximation for GW calculations of molecule-metal interfaces, where we greatly simplify the evaluation of the polarizability of the combined system. This is done by first computing the polarizability of each individual system in smaller cells, followed by unfolding and interpolation techniques to efficiently combine these quantities. Overall, this approach greatly reduces the computational cost for GW calculations of level alignment without sacrificing the accuracy. Moreover, this approach captures both dynamical and nonlocal polarization effects without the need to invoke a classical image charge expression. We benchmark our approximation for the case of a benzene molecule physisorbed on Al(111) surface.

3:54PM P16.00004: Dielectric dependent hybrid functionals for surfaces and interfaces* HUIHUO ZHENG (Presenter), Leadership Computing Facility, Argonne National Laboratory, MARCO GOVONI, Materials Science Division, Argonne National Laboratory, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — We present a dielectric dependent hybrid density functional which accurately describes the electronic properties of heterogeneous interfaces, as well as those of three- and two-dimensional bulk solids. The functional is constructed by generalizing the dielectric hybrid functional for solids proposed in Ref. [1] to include a spatially varying, local dielectric function. The latter is determined self-consistently using a finite field approach. We present results for the band gap and dielectric constants of bulk materials (2D and 3D), and band offsets for interfaces (Si/Si3N4, Si/H2O) and surfaces (H-Si), as obtained with the Qbox code [2].

*This work was supported by MICCoM, as part of Comp. Mats. Sci. Program funded by the U.S. DOE, Office of Sci., BES, MSE Division. This research used resources of the ALCF, which is a DOE Office of Sci. User Facility under Contract DE-AC02-06CH11357.
**4:06PM P16.00005: Direct Z-Scheme Water Splitting Photocatalyst Based on Two-Dimensional Van Der Waals Heterostructures**

**RUIQI ZHANG** (Presenter), Tulane University, LILI ZHANG, QIJING ZHENG, PENGFEI GAO, JIN ZHAO, JINLONG YANG, University of Science & Technology of China — Mimicking the natural photosynthesis in plants, Z-scheme water splitting is a promising strategy to improve photocatalytic activity. Searching for the direct Z-scheme photocatalysts is urgent and the crucial factor for the photocatalytic efficiency is the photogenerated electron–hole (e–h) recombination rate at the interface of two photosystems. In this report, based on time-dependent ab initio nonadiabatic molecular dynamics (NAMD) investigation, we first report a two-dimensional (2D) metal-free van der Waals (vdW) heterostructure consisting of monolayer BCN and C2N as a promising candidate for direct Z-scheme photocatalysts for water splitting. It is shown that the time scale of e–h recombination of BCN/C2N is within 2 ps. NAMD simulations based on frozen phonon method prove that such an ultrafast interlayer e–h recombination is assisted by intralayer optical phonon modes and the interlayer shear phonon mode induced by vdW interaction. In these crucial phonon modes, the interlayer relative movements which are lacking in traditional heterostructures with strong interactions, yet exist generally in various 2D vdW heterostructures, are significant. Our results prove that the 2D vdW heterostructure family is convincing for a new type of direct Z-scheme photocatalysts searching.

**4:18PM P16.00006: Volume-Dependent Atomic Polarizabilities for Vibrational Spectroscopy**

**MARK DELLOSTRITTO** (Presenter), RUIYU WANG, MICHAEL L KLEIN, ERIC U BORGUET, Temple University — Vibrational spectroscopy methods, such as Raman and SFG, are valuable tools for characterizing the structure and dynamics of a wide range of systems. Computing spectra from MD simulations remains a significant challenge, as accurate polarizabilities (α) are required for a large range of molecular configurations, and ab-initio α can be prohibitively expensive to compute for even small molecules. We extend the Thole model by making the initial atomic α functions of the interatomic distances, scaling them by the radius of the atom as defined by the volume the atom occupies in the molecule. This allows us to compute accurate α for molecules far from their equilibrium configuration. We then compute accurate Raman spectra of water and urea, and SFG spectra at the alumina-water interface.

*This work was supported by the Center for Complex Materials, an Energy Frontier Research Center funded by the U.S. Dept. of Energy, Office of Science, Basic Energy Sciences, (Grant DE-SC0012575), and includes calculations carried out on Temple University's HPC resources and thus was supported in part by the National Science Foundation through major research instrumentation grant number 1625061 and by the US Army Research Lab. under contract W911NF-16-2-0189.

**4:30PM P16.00007: Transferability of local density assisted implicit solvation models for homogeneous fluid mixtures**

**DAVID ROSENBERGER** (Presenter), Technische Universität Darmstadt, TANMOY SANYAL, M. SCOTT SHELL, Chemical Engineering, University of California Santa Barbara, NICO VAN DER VEGT, Technische Universität Darmstadt — Dependency on density or concentration of the state chosen during parametrization leads to low transferability in density/concentration space in bottom-up coarse graining. For fluid phase equilibria the application of local density potentials appears a promising approach to overcome this shortcoming, as shown in previous work by Sanyal and Shell (J. Phys. Chem. B, 2018, 122, 5678). Here, we want to further explore this method and test its ability to model solutions of methanol and water. We find that a water-water LD potential improves the transferability of an implicit-methanol CG model towards high water concentration. Conversely, a methanol-methanol LD potential does not significantly improve the transferability of an implicit-water CG model towards high methanol concentration. These differences appear due to the presence of cooperative interactions in water at high concentrations that the LD potentials can capture. In addition, we formally demonstrate the analytical and numerical assumptions under these relative entropy optimization and the Inverse Monte Carlo method yield equivalent results.

*Funding by the German Research Foundation (DFG) within the SFB-TRR 146 grant and from the National Science Foundation through grant no. CHEM-1300770*
The reconstruction of molecular force fields for small molecules using the recently developed symmetric gradient-domain machine learning (sGDML) approach. The sGDML approach faithfully reproduces complex high-dimensional potential-energy surfaces from just a few 100s of molecular conformations generated by ab-initio MD simulations. The data efficiency of the model allows employing high-level wavefunction-based atomic forces and energies for training, such as the "gold standard" CCSD(T) method. We demonstrate that the flexible nature of this fully data-driven model recovers any local and non-local quantum interaction coming from \(-F=\phi^* \frac{\partial H}{\partial \phi} \phi\) (e.g. H-bonding, proton transfer, lone pairs, changes in hybridization states, steric repulsion and n->pi* transitions) without relying on prior knowledge of the phenomena. The analysis of MD@sGDML trajectories yields new qualitative insights into dynamics, chemistry, and spectroscopy of small molecules close to spectroscopic accuracy.

Nanosecond-scale ab initio molecular dynamics of fully solvated biomolecules with periodic boundary conditions using the Oak Ridge Leadership Computing Facility (OLCF) supercomputers

We present nanosecond-scale molecular dynamics simulations of small ribonucleic acids with full solvation shells of explicit water and ions at the density functional theory (DFT) level, using high performance ab initio molecular dynamics programs and the Oak Ridge Leadership Computing Facility (OLCF) supercomputers. Comparison of the trajectories to classical molecular dynamics is performed, including effects of polarization, changes in molecular conformations, and dynamics of the system in metastable states and with respect to barrier crossing. We find important differences in the conformational dynamics and analyze the effects of dynamic changes in charge density and polarization that are available from the first-principles description and which may be essential to correct simulation of conformational ensembles of these difficult-to-model molecules.

*This research used resources of the Oak Ridge Leadership Computing Facility, which is a DOE Office of Science User Facility supported under Contract DE-AC05-00OR22725

Advances in machine learned potentials for molecular dynamics simulation

Recent machine learning techniques allow emulation of quantum chemistry with stunning fidelity. For example, deep neural networks can now predict molecular properties with accuracy approaching that of coupled cluster theory, at a tiny fraction of the computational cost. We present methods for building machine learned potentials based on the following key ideas: (1) encoding physical symmetries, (2) active learning to dynamically grow the training dataset, and (3) transfer learning to incorporate data from varying sources. The aim is to enable large-scale and highly accurate molecular dynamics simulations, e.g., for chemistry, materials science, and biophysics applications.

*LDRD and ASC/PEM programs at Los Alamos National Laboratory.
2:30PM P17.00001: Equation of State Calculations With First-Principles Computer Simulations of Matter at Extreme Conditions* [Invited] BURKHARD MILITZER (Presenter), FELIPE J GONZALEZ, University of California, Berkeley, SHUAI ZHANG, Lawrence Livermore National Laboratory, HENRY PETERSON, University of California, Berkeley, KEVIN P DRIVER, Lawrence Livermore National Laboratory, FRANCOIS SOUBIRAN, University of California, Berkeley — The properties of materials at extreme pressure and temperature conditions are important in astrophysics and fusion science. When models for the interiors of Saturn and Jupiter are constructed to match gravity data from the NASA missions Cassini and Juno, an accurate knowledge of the equation of state of hydrogen-helium mixtures is essential. Modern dynamic compression experiments typically probe megabar and gigabar pressures. In order to provide a comprehensive theoretical description of materials at such extreme conditions, we combine results from path integral Monte Carlo (PIMC) and density functional molecular dynamics simulations. We present equation of state results for first-row elements and compounds such as boron, CH plastic, and oxygen. The shock Hugoniot curves are derived and compared with experimental data. Then we discuss how bound states can be incorporated efficiently into the nodal structure in the PIMC simulations, which enables us to simulate second row elements. We present results from equation of state computations for sodium, aluminum, silicon, and magnesiosilicates.

*This research was supported by the U.S. Department of Energy under Grants No. DE-SC0016248.

3:06PM P17.00002: The Challenge of Assessing Uncertainty in Equation of State (EOS) Generation* CHRISTINE J WU (Presenter), CARRIE PRISBREY, MIGUEL MORALES, Lawrence Livermore Natl Lab — We have recently developed multiphase EOSs for a number of materials including Beryllium and Gallium, based not only on experiments, but also on theoretical calculations for regions where experiments are not available or in conflict. Building EOSs unavoidably involves multiple sources of uncertainties, including experimental error bars, and uncertainties due to theoretical approximations and different choices of the free energy model. We will discuss our baseline EOS models and preliminary attempt to address and bound EOS uncertainties.

*This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344

3:18PM P17.00003: Determining temperature-pressure-density relations of shock-compressed post-transition metals using optimal functionals SHUAI ZHANG (Presenter), MIGUEL MORALES, RICHARD BRIGGS, MARTIN G GORMAN, DAYNE FRATANDUONO, Lawrence Livermore National Laboratory — Dynamic compression techniques offer very useful ways of measuring the equation of state (EOS) of materials at extreme conditions. Many properties, in particular the pressure-density relation along the shock Hugoniot curve, can usually be determined with high accuracy. However, there lacks a generic way to measure temperature. This is problematic when studying phase transformation boundaries of non-transparent materials, which can have large uncertainties depending on the EOS model being used. We propose a method for determining the temperature-pressure-density relation of materials under shock compression using quantum simulations based on optimal functionals. The choice of the functional is constrained by well-established experimental data, such as pressure-density Hugoniot and static compression results. These constraints are from multiple regions of the phase space, therefore making our predictions widely reliable. We apply this method to studying post-transition metals, of which the phase and structural property changes are of great interest to the high-pressure and materials physics communities.

Work prepared under the auspices of LLNL under contract DE-AC52-07NA27344.

3:30PM P17.00004: First-principles calculation of third-order elastic constants via numerical differentiation of the second Piola-Kirchhoff stress tensor DAVID CUFFARI (Presenter), ANGELO BONGIORNO, College of Staten Island — Third-order elastic constants (TOECs) of materials are difficult to measure experimentally and produce large errors. Computational methods are needed for overcoming these difficulties. Previous methods to calculate TOECs are based on fitting energy-strain and/or stress-strain curves calculated from density functional theory (DFT). These methods rely on symmetry relationships, and for this reason, so far they have been applied mainly to cubic and hexagonal crystals. In this paper, we present a novel method to calculate TOECs that is applicable to any system, regardless of its symmetry and dimensionality. This method relies on second-order numerical differentiation of the second Piola-Kirchhoff stress tensor. In this work, we combine this method to a plane-wave DFT approach to calculate the TOECs of aluminum, diamond, silicon, magnesium, graphene, and graphane. A comparison to experimental results shows that our new method is valid and accurate.
3:42PM P17.00005: Analysis of heating curves and optical properties for the liquid-liquid transition to metallic hydrogen

JACQUES TEMPERE (Presenter), MATTHEW HOUTTURE, Theory of Quantum and Complex Systems, Universiteit Antwerpen, ISAAC SILVERA, Lyman Laboratory of Physics, Harvard University — Hydrogen at high temperatures and pressures undergoes a phase transition from liquid molecular to liquid atomic metallic hydrogen. This transition takes place on the planet Jupiter and has been studied in the laboratory. Experiments in a diamond anvil cell for temperatures up to 2000 K and pressures of 100-170 GPa determine heating curves and optical properties. Heating curves (the temperature of the sample as a function of heating power) have a positive slope with increasing power with a plateau in temperature, most likely associated with the latent heat of transformation. Plateaus are associated with an abrupt rise in reflectance and absorption of visible light as expected for a metal. We carry out a realistic finite element analysis of heating curves and optical properties. The simulation shows that the plateaus and onset of absorption are related to the phase transition. However much larger values of latent heat are required than have been predicted by theory. The transition may be more complex than considered in current models.

3:54PM P17.00006: Free energies of reaction for aqueous glycine condensation chemistry at extreme temperatures

NIR GOLDMAN (Presenter), MATTHEW KROONBLAWD, Lawrence Livermore Natl Lab — We have performed high throughput quantum molecular dynamics simulations to determine the free energy surface for aqueous glycine condensation reactions from moderate to extreme temperatures similar to oceanic hydrothermal vents (1g/cm³ and temperatures ranging from 300 K to 1000 K). Our simulations identify significant changes in the free energy surface topology and subsequent chemical reactivity with increasing temperature. We predict that temperatures at 400 K and below glycine favor dipeptide formation whereas higher temperatures facilitate the reverse hydrolysis reaction, with solvated glycine molecules showing greater stability. This change in favorability is correlated with a shift in the location and characteristics of specific reaction bottlenecks or barriers. Simultaneously, we observe that relative free energy barriers (total energy plus entropic contributions) for both condensation and hydrolysis reactions generally decrease with increasing temperature. Our results indicate that relatively modest temperatures near 400 K may best facilitate formation of oligoglycine molecules in oceanic systems related to the synthesis of life-building compounds. Prepared by LLNL under Contract DE-AC52-07NA27344.

4:06PM P17.00007: First principles simulation of the non-linear Peltier effect

XAVIER ANDRADE (Presenter), ALICIA R. WELDEN, ALFREDO A. CORREA, Lawrence Livermore Natl Lab — When matter is subject to large electric fields or temperature gradients, the usual linear approximations for the transportation of charge and heat, Ohm’s and Fourier’s law, break down. This gives rise to non-linear transport phenomena like negative-differential conduction.

We have developed a method based on real-time electron dynamics to simulate non-linear conduction from first principles. Our approach was first implemented for electrical conduction. We now extend the method to account for non-linear thermal conduction, using a quantum theory of heat based on real-time time dependent density functional theory (TDDFT).

In this talk we present our initial results for the simulation of the non-linear heat transport effects for hydrogen at a high-pressure metallic phase. By applying a strong electric field to the material and following in real time the induced heat current, we can predict the non-linear Peltier coefficient for the material.

The results of these simulations will help us understand when non-linear conduction effects appear and when they are important to understand the behavior of matter under extreme conditions.

*This work was performed under DOE Contract No. DE-AC52-07NA27344. Computing support for this work came from the LLNL Institutional Computing Grand Challenge.
4:18PM P17.00008: Optical absorption properties of laser-dressed matter* BING GU (Presenter), IGNACIO FRANCO, University of Rochester — We develop a theory for the optical absorption of electronic materials driven far from equilibrium by resonant and non-resonant lasers. In it, the interaction between matter and the driving light is treated exactly through a Floquet analysis, while the effects of the probing light are captured to first order in perturbation theory. The formalism is employed to characterize the optical properties of a nanoscale semiconductor dressed by non-resonant light of intermediate intensity (non-perturbative, but non-ionizing). As shown, non-resonant light can reversibly turn this transparent semiconductor into a broadband absorber and open strong absorption/stimulated emission bands at very low frequencies (~meV). These developments offers a platform to understand and predict the emergent optical properties of materials dressed by the electric field of light, and catalyze the design of laser-dressed materials with desired optical properties.

*This material is based upon work supported by the National Science Foundation under CHE-1553939.

4:30PM P17.00009: Radiation Induced Dissociation Pathways and Charge Redistribution in X-ray Free-Electron Laser Imaging* OSCAR GRÅNÄS (Presenter), Department of Physics and Astronomy, Uppsala University — Historically, structure determination of nano-crystals, proteins and macromolecules required the growth of high-quality crystals sufficiently large to diffract x-rays efficiently while withstanding radiation damage. The development of the x-ray free-electron laser (XFEL) has opened the door for high resolution single particle imaging using x-rays, as the extreme intensity ensures that enough diffraction statistics is collected before the sample is destroyed by radiation damage. Still, recovery of the structure is a challenge, in part due to the partial fragmentation of the sample during the diffraction event.

In this study, we use first-principles based methods to study the effect of radiation induced ionization of seven amino-acids. We benchmark a hierarchy of methods, considering theory on the level of Born-Oppenheimer molecular dynamics as well as non-adiabatic molecular dynamics. In addition, we study the impact on our results of how the ionization process is approximated. In order to estimate the effects of radiation damage on structural recovery, we study dissociation pathways, fragmentation statistics and charge redistribution.

The Swedish Science Council (VR), grant 637-2013-7303

4:42PM P17.00010: Matter in Extreme Environments: Theoretical Studies of Light Elements Under Pressure* [Invited] MIGUEL MORALES (Presenter), Lawrence Livermore Natl Lab — Despite their apparent simplicity, light elements at extreme conditions of pressure and temperature display remarkable properties that have fascinated theoreticians and experimentalists for over a century. Recent advances in first-principles simulation methods have allowed us to elucidate ever more properties of these materials giving us predictive capabilities which, when combined with continuously improving experimental platforms, allow us to obtain new insight into the behavior of matter at extreme conditions. In this talk I will present an overview of the current state of the art in first-principles simulation capabilities for light elements at extreme environments. I will pay particular attention to simulation methods that operate directly in the physical picture of electrons and ions, including density functional theory and quantum Monte Carlo. As a demonstrative example of the predictive capabilities of these methods, I will present recent predictions in the phase diagram of hydrogen during metallization and molecular dissociation in connection with recent experimental observations of metallization. I will present the most recent predictions for the location of the metal-insulator transition in the compressed liquid along with predictions of the optical properties near the dissociation regime. We show how state-of-the-art simulations are able to provide a comprehensive picture of molecular dissociation and metallization in the liquid which explains the conflicting experimental results obtained for several different platforms.

*This work was performed in part under the auspices of the US DOE by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

Session P18 DCOMP: Materials Theory and Computation BCEC 156B - Silvina Gatica, Howard University

2:30PM P18.00001: Are most jammed packings of dry, frictionless grains similar? PAPPU ACHARYA (Presenter), Physics, TIFR, Hyderabad — We study disordered jammed packings of frictionless disks interacting by either (one-sided) harmonic or Hertzian contact forces. We show that ensembles of such packings, in mechanical equilibrium, exhibit a very simple structure. In each case, we find that non-trivial fluctuations of the contact force network may be parameterised by a single dimensionless quantity for a large range of densities and disorder strengths. Surprisingly, a harmonic theory for displacement fluctuations in a crystal at thermal equilibrium is able to account for the statistics of these fluctuations.
2:42PM P18.00002: Percolation Around Structurally Disordered Sand Grains: A Dynamical Infiltration Study
DONALD PRIOR (Presenter), Youngstown State University — Percolation transitions, marking the boundary between configurations which admit the fluid or charge flow and those which are impermeable on large scales are salient phenomena for transport through porous materials where flow is through irregular spaces around impenetrable grains instead of well-defined linear channels. Using dynamical infiltration simulations involving virtual tracers moving in void regions, we calculate critical grain densities per unit volume where the inclusions are positionally and orientationally disordered. In addition, as a novel element, we also consider varying degrees of structural disorder, in which the shapes of grains are subject to random variation. In the case of ellipsoids, tetrahedrons, and rectangular solids we find that if expressed in units of the mean grain volume, the critical concentration is remarkably robust, with little variation for light to moderate disorder in the inclusion shapes. We also discuss scenarios in which in random variations in facet plane distances for solids such as dodecahedrons eventually yield non-dodecahedral fragments; with large scale dynamical infiltration simulations we seek to determine if percolation thresholds remain robust with increasing diversity in types of grain shapes or instead undergo a shift.

2:54PM P18.00003: From Birefringent Electrons to a Marginal or Non-Fermi Liquid of Relativistic Spin-1/2 Fermions: An Emergent Superuniversality*
BITAN ROY (Presenter), Max-Planck-Institut für Physik komplexer Systeme, Dresden, Germany, MALCOLM KENNETT, Department of Physics, Simon Fraser University, Canada, KUN YANG, Florida State University, Tallahassee, Florida, USA, VLADIMIR JURICIC, NORDITA, the Nordic Institute for Theoretical Physics, Stockholm University and KTH, Stockholm, Sweden — In this talk, we present the quantum critical theory of an interacting nodal Fermi liquid of quasirelativistic pseudospin-3/2 fermions that have a noninteracting birefringent spectrum with two distinct Fermi velocities [1]. As we show, when such quasiparticles interact with gapless bosonic degrees of freedom that mediate either the long-range Coulomb interaction or its short range component (responsible for spontaneous symmetry breaking), in the deep infrared or quantum critical regime in two dimensions, the system is, respectively, described by a marginal- or a non-Fermi liquid of relativistic spin-1/2 fermions (possessing a unique velocity), and is always a marginal Fermi liquid in three dimensions. We consider a possible generalization of these scenarios to fermions with an arbitrary half-odd-integer spin, and conjecture that critical spin-1/2 excitations represent a superuniversal description of the entire family of interacting quasirelativistic fermions.

3:06PM P18.00004: Spatially-correlated Site Occupancy in the Nonstoichiometric Meta-stable ε-Al60Sm11 Phase during Devitrification of Al-10.2 at.% Sm Glasses*
LIN YANG, Iowa State University, FENG ZHANG, FAN-QIANG MENG, LIN ZHOU, YANG SUN, XIN ZHAO, ZHUO YE, MATTHEW J. KRAMER, CAI-ZHUANG WANG, Ames Laboratory, KAI-MING HO (Presenter), Iowa State University — We examine a metastable ε-Al60Sm11 phase that appears during the initial devitrification of as-quenched Al-10.2 at.% Sm glasses. The phase is nonstoichiometric in nature since Al occupation is observed on the 16f Sm lattice sites. STEM images reveal profound spatial correlation of Sm content on these sites, which cannot be explained by the “average crystal” description from Rietveld analysis. Monte Carlo simulations based on a cluster-expansion model also give qualitatively different correlation functions from experiments. On the other hand, molecular dynamics simulations of the growth of ε-Al60Sm11 show that when the diffusion range of Sm is limited to ~ 4 Å, the correlation function of the as-grown structure agrees well with that of the STEM images. Our results show that kinetic effects, especially the limited diffusivity of Sm atoms plays the fundamental role in determining the nonstoichiometric site occupancies of the ε phase during the crystallization process.

The interaction of carbon and boron nitride nanotubes as well as graphene with metals*  
CHRISTOPH ROHMANN (Presenter), University of Maryland, College Park, MICHAEL P ZWOLAK, PML, National Institute of Standards and Technology — The interaction of carbon nanotubes with metals is significant for a wide variety of applications. For example, the binding of tubes to transition metal nanoparticles plays a role in their catalytic growth, as well as in their nucleation observed by ETEM, HRTEM, STM or Raman measurement. We performed quantum chemical calculations to investigate (i) the binding strength and geometry of a variety of metals with carbon nanotubes and graphene (ii) the curvature dependence of the binding energy and lastly (iii) we offer an explanation as to why the reported metal-CNT/graphene binding strength varies widely in the literature.

WITHDRAWN ABSTRACT —

Ab Initio Calculations of Partial Basal Dislocations in Bilayer Graphene*  
PAVLOS MOURATIDIS (Presenter), KENNY JOLLEY, JAMES MCHUGH, MALCOLM HEGGIE, Chemistry, Loughborough University, PATRICK BRIDDON, School of Engineering, Newcastle University — Graphite has been the material of choice in construction of nuclear reactors for many years due to its low neutron absorption cross-section and high scattering cross-section. The physical properties of a graphite moderator can greatly influence the cost, safety and lifespan of a reactor. Neutron collision damage in graphite results in the formation of basal dislocations. The subsequent interaction of basal dislocations with each other and the surrounding lattice causes severe dimensional changes along the basal direction. There has been a lot of interest recently in AB and AC stacking grain boundaries in bilayer graphene. Transition from AB to AC stacking can be described by the glide of basal dislocations resulting in expansion of dislocation cores and buckling of the bilayer. Herein we present a new model for the dimensional change of nuclear graphite which considers buckling and folding of graphene sheets due to the basal dislocations glide. Full ab initio and molecular dynamics calculations of oppositely sign on basal dislocations in bilayer graphene have been carried out. Analysis of dislocation cores and buckled sinusoidal harmonics has revealed absorbing results compared to previous theoretical works.

Plasmonic capacitance and profiling the energy distribution of plasmonic hot electrons in planar metal-dielectric structures  
ABBAS GOUDARZI (Presenter), SAHAR BEHPOUR, YURI ROSTOVTSEV, OSCAR GARCIA, University of North Texas — Propagation of plasmonic excitations in metal-dielectric structures is always accompanied by the loss which includes the generation of hot electrons in the vicinity of the metal surface. This results in the formation of a 2-D hot electron gas in the metal slab. Here, we theoretically show that in a metal-insulator-metal (MIM) capacitor, which is under an applied AC bias, the plasmonic-hot electrons are trapped by the interface states existing in the interfacial region of the dielectric slab leading to the creation of “plasmonic-capacitance”; an increase in the capacitance of the MIM configuration due to the charge of interface that reveals dependence on the frequency of the AC bias. This dependency is used to profile the energy distribution of the plasmonic-hot electrons. Importantly, the obtained energy distribution can be employed as the signature of the plasmonic excitation. The approach we introduce in this work suggests a new way to study all types of plasmonic phenomena occurring in planar hyperbolic metamaterials including high-k hyperbolic plasmons and epsilon near zero modes.

The effect of Ni impurities on the nucleation rates of undercooled Sn droplets  
SITARAM PANTA (Presenter), ERIC J COTTS, Binghamton University — Although high purity Sn can undercool more than forty percent of its melting temperature, small amount of Ni in Sn decrease undercooling to 10 K. We report on measurements of the nucleation rate of undercooled Sn droplets as a function of temperature and Ni content, within the context of classical nucleation theory. The undercooling of these Sn-Ni alloys was found to decrease linearly up to 0.5at% of Ni. Analysis of the dependence of nucleation rates of Sn-Ni alloy on temperature revealed that the barrier height to nucleation systematically decreased with Ni concentration, by more than three orders of magnitude upon the addition of Ni. Such a huge increase in nucleation rate is difficult to explain with a simple picture of heterogeneous nucleation of Sn on Ni3Sn4 which eventually forms during solidification process. Previous work has revealed that Ni3Sn4 is a poor inoculant for Sn nucleation. In contrast, the huge increase in nucleation rate observed in this work would require very low wetting angles to explain with such a heterogeneous nucleation picture. The increase in nucleation rate and hence the decrease in energy barrier can be explained by a decrease in surface energy between liquid and nucleating solid.
4:18PM P18.00010: Generating amorphous structures by combining Reverse Monte Carlo and molecular dynamics and analyzing with graph theory algorithm* ALEC MISHKIN (Presenter), JUN JIANG, MAHER YAZBACK, Department of Physics and Quantum Theory Project, University of Florida, KIRAN PRASAI, RICCARDO BASSIRI, MARTIN FEJER, Ginztom Laboratory, Stanford University, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida — We present results from atomistic modeling of amorphous zirconia-doped tantala with an aim to understand the sources of mechanical loss in its structure. This material is a candidate for future LIGO gravitational wave detector mirror coatings, where lower mechanical loss coatings are essential to reduce thermal noise. We use Reverse Monte Carlo (RMC) modeling, which is a common technique used to generate atomic models based on experimental data. Here we use pair distribution functions (PDFs) as the reference experimental data set for the RMC. However, the structural solutions from RMC based on PDFs are not unique, and other constraints are needed to rule out unphysical solutions. In this work, we use molecular dynamics as the additional constraint, and show that allowing the structure to perform ionic and volume relaxation in between RMC runs can generate models that are in good agreement with the PDF data and energetically favorable. We also present an analysis of the intermediate range order from these models. This analysis is achieved by converting amorphous structures into graphs, where atoms are vertices and bonds are edges, and analyzing the structures that are responsible for short and intermediate range segments of the PDF.

4:30PM P18.00011: Scaling of emergent symmetry at a first-order transition in the simplest classical model* JUN TAKAHASHI (Presenter), Institute of Physics, Chinese Academy of Sciences, Beijing, China, ANDERS W SANDVIK, Boston University / IOP-CAS, Beijing — Emergent symmetry has attracted attention due to its possible connections with deconfined quantum criticality, where the phase boundary between a dimerized and a Neel phase is generically continuous, contrary to the standard Ginzburg-Landau picture where a first-order phase transition is predicted.

While emergent symmetries of multicritical points have been studied in various ways [1], less is known about how the emergent symmetry remains at the first-order transition line starting from such multicritical points [2].

In this study, we analyze a simple model with two competing orders, by extensive Monte Carlo simulation. The model has three phases (one paramagnetic and two Z2 symmetry-breaking phases) when varying the temperature and a parameter in the Hamiltonian. We observe that the bicritical point where the three phases meet has emergent O(2) symmetry, as predicted by field-theory [1]. Furthermore, we find that the first-order transition line separating two ordered phases has a remainder of the emergent symmetry up to a certain length scale. We quantitatively discuss how this length scale diverges.

4:42PM P18.00012: Magnetic Cooling for Nanoelectronics below 1 mK* YEMLIHA BILAL KALYONCU, CHRISTIAN SCHELLER, MARIO PALMA, DARIO MARADAN, University of Basel, Department of Physics, ANNA V FESHCHENKO, MATTHIAS MESCHKE, Aalto University, Low Temperature Laboratory, DOMINIK ZUMBUHL (Presenter), University of Basel, Department of Physics — Temperatures below 1 mK in quantum transport experiments could open the door for new physics such as novel nuclear spin phases, fragile fractional QH states, topological phases and unprecedented coherence. However, this is a formidable challenge since the thermal coupling becomes weak, making devices susceptible to heat leaks, microwaves and electronic noise. Our approach is to provide a separate nuclear refrigerator in each sample wire, cooling the device through the electronic degree of freedom.

Combining on-and-off chip demagnetization provides cooling of the islands of a Coulomb blockade thermometer as well as the electrical leads connecting to the sample, thus reducing external heat leaks [1]. The device comprises a linear array of Al/AlOx/Al tunnel junctions with huge copper islands in between, serving as spin reservoirs for demagnetization, thus enabling on-chip cooling. This scheme results in a lowest electronic temperature of 1.8 ± 0.1 mK. We also present a model which gives a good match and suggests how to overcome the main limitations to cool below 1 mK, thus opening the door for future microkelvin nanoelectronics.

**4:54PM P18.00013: Compressive photoacoustic imaging in scattering media**  
YUNING GUO (Presenter), XIAOBO YIN, BAO Wen LI, Department of Mechanical Engineering, University of Colorado Boulder — Nowadays optical imaging in highly scattering media is still challenging to meet the requirement for wide-field visualization with a high resolution across the physical and biomedical science. Photoacoustic imaging, which relies on the ultrasonic waves emitted by absorbing structures under pulsed light illumination via thermoelastic stress generation, provides an efficient way to overcome the optical diffusion limitation. Compressive sensing, an efficient signal processing technique by finding solutions to underdetermined linear systems, is adapted to reduce the burden posed by traditional imaging requirements. It can be used to improve the trade-off between spatial resolution and acquisition time of sequential measurements, which can overcome the limiting of real-time applications to relative low resolutions. Based on compressive sensing, we design a photoacoustic imaging system that can achieve effective 3D imaging in scattering media with just a few sensors. It has the capability to image structured objects hidden in diffused media with a high resolution at a faster pace and works in the fields where the signal reduction is beneficial such as invasive bioimaging.

**5:06PM P18.00014: Manipulating thin film properties by search for substrates over databases**  
PEDRAM TAVADZE (Presenter), LIAN LI, CHENG CEN, ALDO H ROMERO, Physics Department, West Virginia University — Substrates can have major effects on the growth direction, orientation, nucleation, morphology, field emission in carbon nanotubes, superconductivity, and etc. The influence of substrate on the thin film can be mechanical, electronic, or both. Specific applications require different substrates. In order to tune the characteristics of the thin film to ones needs, one has to explore a large set of possible substrates. As experimentally this work is almost impossible, one has to use computational methods to evaluate possible substrates. In this work we report a flowchart on how to search for optimal substrates and complement the selection by specific electronic structure characterization. We apply our methodology to FeSe, where the superconductor properties are very sensitive to the substrate. We employ the available algebraic algorithm provided by MPInterfaces package to search for geometrical matches in the OQMD database and calculate the work-function of the matched substrates as the criteria to select a good substrate. The results from the geometrical matches are input to a machine learning algorithm to increase the search speed in the databases.

**5:18PM P18.00015: A novel semi-metallic allotrope of carbon**  
JOEL THERRIEN, MICHAEL MASAKI (Presenter), ECE, University of Massachusetts Lowell, PURUSOTTAM JENA, Physics, Virginia Commonwealth University — A previously unknown allotrope of 3-dimensional crystalline carbon has been synthesized via CVD. Formation occurs when specific hydrocarbons react with certain metal or metal-oxide catalysts such as copper or aluminum oxide at temperatures above 800°C. The material has been characterized by XRD, Raman, FTIR and XPS. Raman spectra indicate the material consists of a mixture of sp² and sp³ bonded carbon. X-ray diffraction shows distinct peaks which do not correlate with graphite or diamond. Upon annealing at 1,100°C the diffraction peaks show considerable sharpening indicating the formation of larger domains. This is also reflected in the Raman spectrum which also shows a sharpening of the D and G carbon peaks. XPS analysis did not indicate the presence of any element beside carbon. The material has a high reflectivity from far UV to mid IR and visually appears mirror-like when deposited on smooth substrates. The temperature dependent conductivity has a negative temperature coefficient suggesting the material is most likely a semi-metal as opposed to a true metal; something not unexpected with carbon.

Session P20 DCOMP DMP GMAG: First-principles Modeling of Excited-state Phenomena in Materials IX: Applications of First Principles Methods to Magnetic and Catalytic Materials BCEC 157A - David Strubbe, University of California, Merced - Tag(s): Focus
Charge separation and band alignment at photo-electrochemical interfaces* [Invited] ISMAILA DABO (Presenter), Pennsylvania State University — Solar energy is the most abundant energy source available to humankind, but this energy cannot be harnessed on demand due to the variability of sunlight. Artificial photosynthesis overcomes that variability through the direct photocatalytic storage of solar power into chemical fuels. Nevertheless, most of the stable photocatalysts in use today rely on metal oxide semiconductors whose bandgap does not match the solar spectrum. This presentation will discuss the development and experimental validation of computational protocols to understand, predict, and optimize visible-light-active materials that can split water into hydrogen and oxygen with a focus on answering the critical questions that surround (1) solar compatibility using electronic-structure methods beyond density-functional theory, (2) electrochemical stability by exploiting quantum-continuum embedding methods, and (3) band-edge alignment by means of machine-learning statistical techniques.

*This work is supported by the National Science Foundation under grant number DMR-1729338.

Ground and excited states of iron-phthalocyanine: a DFT+DMFT analysis* VOLODYMYR TURKOWSKI (Presenter), SHREE RAM ACHARYA, Physics, University of Central Florida, Orlando, 32816 FL, CARLOS GARCIA-FERNANDEZ, NICOLAS LORENTE, Donostia International Physics Center, 20018 San Sebastian, Spain, TALAT S. RAHMAN, Physics, University of Central Florida, Orlando, 32816 FL — Although the iron-phthalocyanine (FePc) molecule has been the subject of numerous experimental and theoretical studies, questions still remain about its ground and excited states. We have performed a Density Functional Theory+Dynamical Mean-Field Theory (DFT+DMFT) analysis of the spin resolved density of states of this interesting molecule to show that local dynamical effects (time-resolved on-site electron-electron interactions), which are inherently taken into account within DMFT, modify the DFT and DFT+U electronic spectrum of the molecule in the following way: they shift energy of a number of levels (most notably in the HOMO-LUMO energy range) and lead to new peaks. Such a modification may help resolve the issue of the ground state of FePc (complicated by the competing close-in-energy configurations) and can dramatically affect the transport, electronic and other properties of the molecule. Though further experimental test of the results are needed to quantify the accuracy of the DMFT approach for nanoscale systems, our results suggest that similar to extended systems time-resolved on-site electron-electron interactions play an important role in molecules that contain transition-metal atoms.

Electron-phonon coupling in photoexcited Bi$_2$Te$_3$* JOSE QUERALES-FLORES (Presenter), IVANA SAVIC, Tyndall National Institute, ÉAMONN MURRAY, Department of Physics and Department of Materials, Imperial College London, STEPHEN B FAHY, Department of Physics, University College Cork, JONATHAN SOBOTA, Department of Applied Physics, Stanford University, SAMUEL W TEITELBAUM, SLAC National Accelerator Laboratory, Stanford Institute for Materials and Energy Sciences, TAKAHIRO SATO, MATTHIEU CHOLLET, Stanford PULSE Institute, SLAC National Accelerator Laboratory, JAMES M GLOWNIA, SLAC National Accelerator Laboratory, MARIANO TRIGO, SLAC National Accelerator Laboratory, Stanford Institute for Materials and Energy Sciences, TREVOR P BAILEY, CTIRAD UHER, Department of Physics, University of Michigan, PATRICK S KIRCHMANN, SLAC National Accelerator Laboratory, Stanford Institute for Materials and Energy Sciences, ZHI-XUN SHEN, Stanford University, COSTEL R. ROTUNDU, Department of Applied Physics, Stanford University, THOMAS HENIGHAN, DAVID A REIS, Stanford University — Bi$_2$Te$_3$ is a topological insulator and thermoelectric material with a high figure-of-merit at room temperature. Strong spin-orbit coupling leads to the inversion of its bulk valence and conduction bands, which results in the formation of topologically-protected surface states [1]. Despite this protection, the surface states may be scattered by lattice vibrations [2]. Here we study the electron-phonon interaction of the surface states in Bi$_2$Te$_3$ using density functional theory and density functional perturbation theory. We calculate the deformation potentials of the surface states due to coupling to the coherent A$_{1g}$ modes driven by photoexcitation. Our computed deformation potential values agree well with those obtained from time-resolved ARPES measurements and time-resolved Bragg diffraction. Our calculations also quantitatively reproduce the experimentally observed magnitude of the surface phonon softening. These findings open opportunities for reliable first principles predictions of the topological transport properties of Bi$_2$Te$_3$ and related V$_2$-VI$_3$ materials.

*This work was supported by Science Foundation Ireland under Investigators Programme No. 15/IA/3160.
3:30PM P20.00004: Calculation of excitation energies using locally-projected real-space geminal screened electron-hole interaction kernel* PETER MCLAUGHLIN, ARINDAM CHAKRABORTY (Presenter), Syracuse University — The geminal-screened electron-hole interaction kernel (GSIK) is a real-space representation for describing electron-hole correlation in charge-neutral excitations. Unlike MBPT and EOM methods, the GSIK method avoids using virtual or unoccupied orbitals for constructing electron-hole interaction kernel. This feature allows GSIK method to be used for chemical systems where inclusion of a large number of unoccupied orbitals will be computationally prohibitive. This talk will present the locally-projected formulation of the GSIK method where the electron-hole interaction kernel is calculated using an atom-in-cluster approach. It will be demonstrated that the local-projection allows the evaluation of the kernel to be performed at a linear-scaling cost. The locally-projected GISK method was applied to large metallic (Au300) and semiconductor (Pb150S150) nanocluster for calculation of optical gap and electron-hole binding energies. The results from these calculations demonstrate the efficacy of the GSIK method for capturing electron-hole correlation in large clusters and nanoparticles.

*This research was supported by the National Science Foundation under Grant No. CHE-1349892.

3:42PM P20.00005: Structural parameters governing excited-state properties of self-assembling π-conjugated peptides: a classical and quantum study* BRYCE THURSTON (Presenter), Center for Integrated Nanotechnologies, Sandia National Laboratories, ETHAN SHAPERA, Physics, University of Illinois at Urbana-Champaign, ANDRE SCHLEIFE, Materials Science and Engineering, University of Illinois at Urbana-Champaign, ANDREW L FERGUSON, Institute for Molecular Engineering, University of Chicago — Peptides that self-assemble are of significant interest for use in the fabrication of biocompatible nano-aggregates. Non-natural π-conjugated subunits may be embedded into the peptide backbone, leading resulting β-sheet-like ribbons formed from self-assembly to have electronic and photophysical properties. Alteration of the amino acid composition of the peptides can have a significant impact on the measured absorption spectra of aggregates, but the exact geometric origin of these changes is unknown. In order to probe these composition-induced alterations, we utilize time-dependent density functional theory calculations to study the excited state properties of peptide configurations extracted from molecular dynamics simulations. We identify geometric variables describing π-conjugated core geometries that appear to be determinative of the wavelength at which the absorption spectrum reaches its peak. When applied to MD simulations, the resulting regression model is shown to be in qualitative agreement with experiment, laying the foundation for in silico prediction of absorption properties of peptide aggregates.

*National Science Foundation Grant No. DMR-1729011

3:54PM P20.00006: Understanding battery and catalytic reactions via core-level spectroscopies [invited] LIANG LI, Argonne National Laboratory, JOHN VINSON, ERIC SHIRLEY, National Institute of Standards and Technology, MARIA CHAN (Presenter), Argonne National Laboratory — Materials often undergo local changes in structure and electronic properties during operations. For example, transition metal oxide battery materials and catalysts often undergo coordination and oxidation state changes. In order to probe these changes, core-level spectroscopy including x-ray absorption, emission, non-resonant and resonant inelastic x-ray scattering, as well as electron energy loss spectroscopy, is often informative. Because of the integrated nature of these signals, the interpretation of these experiments can be at times ambiguous, but can be significantly aided by the use of first principles modeling of core-level spectra. In this talk, we discuss the use of OCEAN [1], a code based on the Bethe-Salpeter Equation, for accurate prediction of core-level spectra, and how the results have helped informed oxygen redox accompanying battery reactions [2,3,4] and detection of CO adsorption during catalytic CO2 reduction reaction [5] in transition metal oxides.

4:30PM P20.00007: Quantum Nonlinear Ferroic Optical Hall Effect*  HUA WANG (Presenter), XIAOFENG QIAN, Department of Materials Science and Engineering, Texas A&M University — Nonlinear optical responses provide basis for ultrafast probing of material's intrinsic symmetry [1]. Here we present first-principles theory of quantum nonlinear ferroic optical Hall effect (QNFOHE)[2], a Hall-like photocurrent originated from the second order current response in (multi)ferroics. The interplay of crystalline, permutation, gauge, time reversal symmetries and inherent causality governs the symmetry of QNFOHE. We elucidate QNFOHE in a class of 2D multiferroics [3] using first-principles calculations and group theoretical analysis. Our results suggest QNFOHE-based optical technique as a route for ultrafast characterization of multiferroic orders and domain evolution in multiferroic materials. These microscopic understandings of QNFOHE from first-principles theory, together with very recent discoveries of 2D ferroics/multiferroics, will open up a variety of new avenues for nonlinear optoelectronics.

*This research was supported by NSF under award number DMR-1753054 and Texas A&M High Performance Research Computing.

4:42PM P20.00008: Polar magneto-optical Kerr effect from antiferromagnetic M2As (M=Cr, Mn, and Fe) under external magnetic field*  KISUNG KANG (Presenter), KRITHIK PUTHALATH, DAVID G CAHILL, ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — Polar magneto-optical Kerr effect (PMOKE) is a great tool to detect ferromagnetic domains and their magnetization but is of no use for antiferromagnets without external magnetic field. To understand PMOKE from antiferromagnets under external magnetic field, we use first-principles density functional theory. Due to the lack of net magnetization in the ground state, spin tilting is only induced by an external field, leading symmetry breaking and thus PMOKE signal arises. Based on band structure analysis, exchange splitting and spin-orbit coupling effects are confirmed, similar to ferromagnetic materials. While the spin-orbit coupling is affected little by the external field, exchange splitting arises due to spin tilting. Majority and minority spin states are increasingly separated as external magnetic field increases. Furthermore, in antiferromagnets magnetic susceptibility is related to spin tilting. We compute the magnetic susceptibility of Cr2As, Mn2As, and Fe2As and find that Fe2As presents largest PMOKE signal at a given external magnetic field as well as the largest susceptibility. Large susceptibility leads to larger spin tilting and, hence, more exchange splitting and stronger PMOKE signal.

*Illinois MRSEC NSF DMR-1720633

4:54PM P20.00009: Study of LaScO3 by electronic structure quantum Monte Carlo methods  CODY MELTON (Presenter), LUBOS MITAS, North Carolina State University — Transition Metal Oxide perovskites (ABO3) are a set of materials that have been widely studied due to the coupling of their charge, spin, orbital, and lattice degrees of freedom, leading to a variety of interesting properties. These materials are typically studied with DFT+U, hybrids, or GW methods to correct for the self-interaction errors within DFT, typically due to the localized nature of the occupied d-orbitals and are often further complicated by various magnetic states. However, even in cases where there is no d-occupancy and the material is a non-magnetic insulator, such as LaScO3, there can be significant errors from these methods due to inaccuracies in the description of electron correlation. For example, the GW methods underestimate the bandgap by roughly 1.5 eV, and hybrid DFT must be tuned in order to reproduce the bandgap. Here, we present a study of LaScO3 using the highly accurate Fixed-Node Diffusion Monte Carlo (FNDMC) method. We show that by carrying out the standard FNDMC methodology, we are able to accurately reproduce the experimental bandgap of LaScO3 without any parameter tuning as is required by DFT and related methods. Additionally, we present calculations of the cohesive energy, equation of state, and other properties using FNDMC.
Photoactive metal-organic frameworks for gas separation

ROBERTA POLONI (Presenter), Univ. Grenoble Alpes, CNRS, Grenoble, CLAUDIO ATTACCALITE, CINAM, CNRS, Marseille, JING LI, Institut Neel, CNRS, Grenoble, ASEEM RAJAN KSHIRAGAR, Univ. Grenoble Alpes, CNRS, Grenoble — Metal-organic frameworks (MOFs) are attracting much attention in recent years for their potential use in CO2 capture technologies. Recently, it has been shown that an efficient capture-and-release process can be obtained upon light treatment in photoactive MOFs [1,2]. We demonstrated that in these MOFs the notable change in gas uptake, upon light irradiation, is due to the blocking of the strongly adsorbing metal sites upon isomerization of the azo groups from trans to cis [3]. Interestingly, our study suggests a large fraction of cis at the photostationary state. A large S1/S2 absorption band separation between trans and cis within the MOF could support this hypothesis. In order to address this, we have computed the optical absorption spectra of these MOFs and their ligands using embedded GW/BSE calculations as implemented in FIESTA. Embedding is considered first at the DFT level (COSMO solvation model and ESP charges) and then, in the calculation of the modified screened Coulomb potential. CASSCF/CASPT2 and periodic GW/BSE are performed to benchmark, respectively, the DFT starting point and the choice of the fragment. Work supported by ANR-15-CE06-0003-01. Electronic and Magnetic Properties of KTa\textsubscript{1-x}Mn\textsubscript{x}O\textsubscript{3}; (x = 0, 0.50, 0.67)

GOPI CHANDRA KAPHLE (Presenter), NIRMALA ADHIKARI, Central Department of Physics, Tribhuvan University — KTa\textsubscript{1-x}Mn\textsubscript{x}O\textsubscript{3} (x = 0, 0.50, 0.67) are perovskites used for fuel cells, memories devices, and spintronic applications. In the present work, we performed the first-principles calculations to study the structural, electronic and magnetic properties of pristine KTaO\textsubscript{3} perovskite and Manganese doped perovskites KTa\textsubscript{1-x}Mn\textsubscript{x}O\textsubscript{3} system along Ta site of super-cell. Our study based on super-cell calculations. Our finding shows that the pure perovskite KTaO\textsubscript{3} is indirect type band gap semiconductor having band gap 2.13 eV which is close agreement with experimental reported value 2.15 eV within 1% deviation. In the study of Mn doped system, we observed that there is indirect band gap decrease from 2.13 eV to 0.84 eV at 50% Mn doped on perovskite KTa\textsubscript{0.5}Mn\textsubscript{0.5}O\textsubscript{3} along Ta site and 0.81eV at 67% Mn doped on perovskite KTa\textsubscript{0.33}Mn\textsubscript{0.67}O\textsubscript{3} along Ta site. Further investigations shows antisymmetric distribution of DOS for spin-up and spin-down electronic states for Mn doped states. The contribution to total DOS is due to 2p-orbital of oxygen and 3d-orbital of manganese around the Fermi level. Whole doped system behaves as half metallic.

G.C.K. thanks Dr. M. P. Ghimire, CDP, TU for fruitful discussions.

*G.C.K acknowledges the computational support from CMPRC-Butwal and Prof. Regmi, CDP, TU.
AIDAN THOMPSON (Presenter), Sandia National Laboratories — Molecular dynamics (MD) is a powerful materials simulation method whose accuracy is limited by the interatomic potential (IAP). In many materials science applications suitably accurate potentials simply do not exist. SNAP is an automated methodology for generating application-specific IAPs using large and diverse datasets of quantum electronic structure calculations. The SNAP IAP is formulated in terms of a set of general four-body geometric invariants that characterize the local neighborhood of each atom. This approach has been used to develop potentials for diverse applications, including metal plasticity (Ta), defects in III-V semiconductors (InP), and fusion energy materials (W/Be/He/H). In each case, the SNAP IAP is fit to density functional theory calculations of energy, force, and stress for many small configurations of atoms. Cross-validation analysis and evaluation on test problems are used to further improve IAP fidelity and robustness. Varying the number of geometric descriptors allows a continuous tradeoff between computational cost and accuracy. The resultant potentials enable high-fidelity MD simulations of these materials, providing insight into their behavior on lengthscales and timescales unreachable by other methods. The relatively large per-atom computational cost of SNAP is offset by combining LAMMPS' spatial parallel algorithms with Kokkos-based hierarchical multithreading, enabling the efficient use of large CPU and GPU clusters, allocating only a few atoms to each node. Recent extensions of the SNAP approach include multi-element geometric descriptors and the use of higher-order terms.

ARAVIND KRISHNAMOORTHY (Presenter), University of Southern California, PANKAJ RAJAK, Argonne Leadership Computing Facility, Argonne National Laboratory, AIJIRO NAKANO, RAJIV KALIA, PRIYA VASHISHTA, University of Southern California — Scalable synthesis of two-dimensional (2D) materials is a major bottleneck to more widespread adoption of layered material-based devices. Chemical vapor deposition (CVD) has emerged as a viable method for large-scale synthesis of 2D materials. However, neither experiment nor theory has been able to decipher mechanisms and selection rules, or make predictions of optimized growth parameters. Experimental challenges stem from the use of probes like TEM to characterize CVD growth reactions in situ under elevated temperatures and pressures. Computational synthesis, which simulates CVD processes using reactive molecular dynamics methods provides the atomistic resolution necessary for the deduction of reaction mechanisms. Here we use neural networks trained on trajectories from several hundred simulations of computational synthesis of MoS2 monolayers to uncover the dependence of product stoichiometry, crystallinity and phase distribution on reaction parameters like temperature, sulfur and hydrogen partial pressures, thus paving the way for rational design of CVD synthesis techniques.

This work was supported as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award Number DE-SC0014607.

TALAT S. RAHMAN (Presenter), DUY LE, Department of Physics, University of Central Florida — Recently, defects in hexagonal boron nitride (h-BN) have been shown to play an important role in determining its novel chemical and optical properties, which may have a variety of possible technological applications. Characterization of the structure and dynamics of these defects would be most facilitated by the availability of accurate interatomic potentials that enable large length and time scale simulations. In this work, we will summarize our development of an artificial neural network (ANN) potential for h-BN with and without defects. The ANN potential was trained by using about 70000 data points obtained from ab initio molecular dynamic simulations of point defect on a (6x6) h-BN layer. The trained ANN potential is capable of producing system energetics in agreement with that obtained from density functional theory (within few meV per atom for both training and validation). The structure and dynamics of defects and grain boundaries in h-BN using the ANN potential will be presented and results compared with available experimental data.

**Active-learning strategy for the development of application-specific machine-learning force fields**

HUAN TRAN (Presenter), ROHIT BATRA, JAMES CHAPMAN, CHIHO KIM, ANAND CHANDRASHEKARAN, RAMAMURTHY RAMPRASAD, Georgia Institute of Technology — Emerging data-driven approaches in materials science have triggered the development of a plethora of machine-learning (ML) force fields (FFs). In practice, they are constructed by training a statistical model on a reference database to predict potential energy or atomic forces. While most of the FFs can accurately recover the reference data, some of them are becoming useful for actual molecular dynamics simulations. In this work, we develop a simple active-learning strategy for the development of ML FFs targeted at specific simulations (applications). The strategy involves (1) preparing and fingerprinting a diverse reference database of atomic configurations and forces, (2) generating a pool of ML FFs by learning the reference data, (3) validating the FFs against a series of targeted applications, and (4) selectively and recursively improving the FFs that remain unsuitable for a given application while keeping their performance on other applications uncompromised. We demonstrate this strategy by developing a series Al and Cu ML FFs that can simultaneously be used for various applications, including (elastic) stress/strain analysis, stacking-fault energy calculations, and melting simulations. This strategy is generalizable, i.e., it may be used for other materials as well.

**Deep Generative Model of Interfacial Structures in Phase Transformation of an MoWSe2 Monolayer**

PANKAJ RAJAK (Presenter), Argonne national laboratory, ARAVIND KRISHNAMOORTHY, AIICHIRO NAKANO, RAJIV KALIA, PRIYA VASHISHTA, University of Southern California — Optical and electrical properties of two-dimensional layered materials can be tuned by mechanical straining, which induces transformations from semiconducting to metallic phases. We use deep generative variational autoencoder (VAE) model, trained by molecular dynamics simulation data of dynamic fracture in an MoWSe2 monolayer, to predict transition pathways consisting of novel intermediate structures (a and b) between the semiconducting (2H) and metallic (1T) phases. In addition, a conditional variational autoencoder (CVAE) is used to generate intermediate structures such as a or b, and defects. Structures synthesized from VAE and CVAE are validated by quantum simulations based on density functional theory. Quantum simulations show that structures generated by VAE and CVAE are stable and can be used for nanoelectronics applications.

*The work was supported by the grant DE-SC0018195 funded by the U.S. Department of Energy, Office of Science. Simulations were performed at the Argonne Leadership Computing Facility under the DOE INCITE program and at the Center for High Performance Computing of the University of Southern California.

**Magnetism and superconductivity in amorphous carbon**

YUKI SAKAI (Presenter), Institute for Computational Engineering and Sciences, University of Texas at Austin, JAMES CHELIKOWSKY, Department of Physics, University of Texas at Austin, MARVIN L COHEN, Department of Physics, University of California at Berkeley — We study magnetic and superconducting properties of amorphous carbon based on molecular dynamics simulations. First we use spin constrained first-principles simulations to obtain amorphous carbon structures with a desired magnetization. We show that the existence of sp2-like threefold coordinated carbon atoms plays an important role in causing magnetism in amorphous carbon. We predict detailed geometries of threefold carbon atoms that induce the magnetic order in amorphous carbon. We also consider the effect of boron doping on superconducting properties of amorphous carbon. By considering amorphous structures with various sp2:sp3 ratios, we find that sp3-hybridized atoms are necessary for high superconducting transition temperature in contrast to the magnetism.

Magnetostriction and Long-Range Interactions in Coupled Spin and Lattice Dynamics*

JULIEN TRANCHIDA (Presenter), MITCHELL A WOOD, ATTILA CANGI, STAN G. MOORE, Sandia National Laboratories, PASCAL THIBAudeau, Le Ripault, CEA-DAM, STEVEN JAMES PLIMPTON, AIDAN THOMPSON, Sandia National Laboratories — A scalable and symplectic algorithm for coupled spin dynamics and molecular dynamics was recently released in the molecular dynamics code LAMMPS. Our presentation will focus on two of its recent improvements: (1) incorporating magnetostrictive effects in and (2) implementing scalable techniques to compute long-range magnetic interactions.

A methodology accounting for magnetostriction in hexagonal crystals based on Néel's work on pair anisotropy models was developed and applied to HCP-cobalt. We parametrized our model using ab-initio calculations within the Spin-Dependent Density Functional Theory framework including the Spin-Orbit coupling. We will show how typical magnetostrictive results were recovered. Although negligible for most small magnetic simulations, the magnetic dipolar energy becomes fundamental for larger configurations, where magnetic domains can nucleate and be stabilized. In order to account for it (and for the associated magneto-mechanical interactions), two methodologies, Ewald sums and Particle-Particle Particle-Mesh, were coupled to the spin-lattice symplectic algorithms developed in LAMMPS. Scaling and energy preservation results will be presented.

*JT acknowledges financial support through a joint CEA-NNSA grant.

Employing autoencoders for configuration space sampling: Application to small molecules.

IGOR POLTAVSKYI (Presenter), ALEXANDRE TKATCHENKO, FSTC, University of Luxembourg — The behavior of molecular systems in different equilibrium physical processes or chemical reactions is governed by the free energy (FE). Calculations of FE require a thorough sampling of configuration space for given external conditions. State-of-the-art sampling techniques, based on molecular dynamics, are formally applicable to systems of arbitrary size. However, in practice, they suffer from the curse of dimensionality and the limitation of the time step by the fastest process present in the system. These make FE calculations for complex molecules, where the entropy effects are of utmost importance, extremely challenging and computationally demanding. Here we propose to use a machine-learning approach based on autoencoders to generate new sampling configurations. By transition to the feature space, we effectively decrease the dimensionality of the problem and resolve the time step limitation. Training autoencoders cost only a small fraction of statistically converged molecular dynamics simulations, paving the way to efficient calculations of thermodynamic properties for complex molecular systems.

Atomistic mechanisms of phase transitions from Machine Learning*

RODRIGO FREITAS (Presenter), EVAN REED, Department of Materials Science and Engineering, Stanford University — Identifying and characterizing atomic mechanisms of phase changes is of fundamental importance in the study of the kinetics of the nucleation and growth process. This talk will describe a new approach in extracting information from atomistic simulations of phase transitions using Machine Learning (ML) methods. In this approach the local neighborhood of atoms is characterized in terms of symmetry functions that are used as input to a ML algorithm trained to identify atomic rearrangements leading to structural transformations. The application of the method is illustrated using Molecular Dynamics simulations of crystallization from the liquid or amorphous phase. We also discuss how meaningful physical properties can be extracted from the output of the ML algorithm.

*This material is based upon work supported by the Department of Energy National Nuclear Security Administration under Award Number DE-NA0002007.

Efficient Training of Neural-Network Interatomic Potentials with Atomic Forces*

SIMON BATZNER (Presenter), BORIS KOZINSKY, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Neural-Network Interatomic Potentials have emerged as a promising method to accelerate time and length scales in Molecular Dynamics simulations of condensed systems. In the learning process, models are usually trained to a set of reference energies from electronic-structure calculations. In addition to total energies, local atomic forces are often also available by the Hellmann–Feynman theorem. Including atomic forces of quantum-mechanical accuracy in the training process can greatly enhance fidelity of the learned potential energy surface as it provides a wealth of additional information about its shape. However, this training scheme often comes at a much greater computational expense. In this talk, we address the speed and fidelity of integrating forces into the training process and examine strategies for rapid training of neural-network potentials for complex systems involving large training sets.

2:30PM P22.00001: Electrons modified by phonons: Adiabatic versus non-adiabatic, and the persistence of electron quasiparticles* [invited] PHILIP B. ALLEN (Presenter), Stony Brook University — This talk will briefly review various types of renormalization of electron quasiparticles by phonons, including the question of when quasiparticle properties persist. Several new concerns will be discussed. In summary, band structure energies of order eV's are affected by phonons of energy 100 times smaller. Semiconductor band gaps are altered by shifts of order 0.1 eV, and are temperature (T)-dependent. The component from thermal expansion is typically smaller than the renormalization from phonons. In metallic bands, an additional low T "mass renormalization", m*/m > 1 is observed. The ratio can range between 1.1 and 3.0. This is a non-adiabatic effect. At low T, metallic electrons notice the time-dependence of the vibrational displacements. The Eliashberg reformulation of conventional BCS superconductivity is closely related. The spectral functions of metallic electrons are often so broad that no recognizable quasiparticle peak is seen. Yet the quasiparticle picture functions nicely for understanding resistivity. Developments in computation have enabled good calculations of semiconductor band renormalization by phonons, which is mostly an adiabatic effect. Recently it has been realized that Froehlich polaron effects (and also piezo-polaron effects) need special treatment when computing energies of electrons close to the band gap. The (non-adiabatic) Froehlich polaron has a clear quasiparticle peak, plus phonon "satellites" in its spectral function. Surprisingly, the peak and satellites are badly misplaced in a conventional perturbative treatment. A "cumulant" version of the spectral function appears to solve the problem nicely. There are still aspects of phonon interactions with electrons that need reformulation, and remain challenges for theory and computation.

3:06PM P22.00002: The electron-phonon problem reconsidered ILYA ESTERLIS (Presenter), STEVEN KIVELSON, Stanford University, DOUGLAS J SCALAPINO, Physics, University of California Santa Barbara — The phase diagram of the electron-phonon (e-p) problem, as a function of e-p coupling and temperature, is presented. We work with the Holstein model and present determinant quantum Monte Carlo results for both large and infinite ion mass. In weak-coupling the system is a Fermi-liquid (and ultimately a "low temperature" superconductor), while beyond a critical coupling strength there is a transition to a (π,π) charge-density wave state. At elevated temperatures we find a cross-over to a pseudo-gap regime, corresponding to the formation of bound pairs of electrons with large effective mass (bipolarons). We compare MC results both with predictions from Migdal theory and strong-coupling expansions. For sufficiently weak coupling the Migdal approximation works extremely well but breaks down catastrophically upon entering the pseudo-gap regime, where the physics is accurately described by an Ising lattice gas model, as expected from the strong-coupling expansion.

3:18PM P22.00003: Temperature effects on the electronic band structure of PbTe from first principles* STEPHEN B FAHY (Presenter), University College Cork, JOSE QUERALES-FLORES, JIANG CAO, IVANA SAVIC, Tyndall National Institute — We present a fully ab-initio calculation of the temperature dependence of the electronic band structure of PbTe [1]. We address two main features relevant for its thermoelectric figure of merit: the temperature variations of the direct gap and the difference in energies of the two topmost valence band maxima located at L and Σ [2]. We account for the energy shift of the electronic states due to thermal expansion, as well as electron-phonon interaction computed using the Allen-Heine-Cardona formalism within density functional perturbation theory [3]. We capture the increase of the direct gap with temperature in very good agreement with experiment. We also predict that the valence band maxima at L and Σ become aligned at ~ 620 K. We find that both thermal expansion and electron-phonon interaction have a considerable effect on these temperature variations. The electron-phonon induced renormalization of the direct gap and the two topmost valence band maxima is produced mostly by high-frequency optical phonons.

3:30PM P22.00004: First-principles electronic lifetimes and phonon-limited mobility in Si, Diamond, GaP, GaN and SnO$_2$*  
GUILLAUME BRUNIN (Presenter), HENRIQUE MIRANDA, MATTEO GIantomassi, GIAN-MARCO RignaneSE, GEOFFROY HAUTIER, Universite catholique de Louvain — Correctly understanding and computing the electronic transport quantities is crucial for the discovery and developments of new functional materials. Within the Boltzmann transport formalism, the computation of the electrical conductivity of a material is usually performed using the constant relaxation time approximation. In this framework, the electronic lifetime is a parameter extracted either from experimental data or from various semi-empirical models. Only recently, \textit{ab initio} computations of the electronic lifetimes due to electron-phonon interactions have been reported for various semiconductors and metals, making the full \textit{ab initio} computation of the phonon-limited (intrinsic) conductivity of materials possible [1-2].

In this work, we compute the electronic lifetimes for Si, Diamond, GaP, GaN and SnO$_2$, and explain how they are used to compute the intrinsic conductivity within the semi-classical Boltzmann transport equation. We compare the lifetimes obtained with EPW [3] and ABINIT [4] and explore ways to reduce the computational load while keeping a similar accuracy for the electronic lifetimes.

3:42PM P22.00005: Anharmonic suppression of charge-density-wave instability in bulk and monolayer NbS$_2$  
RAFFAELLO BIANCO (Presenter), Caltech, ION ERREA, University of the Basque Country, LORENZO MONACELLI, Università di Roma, La Sapienza, MATTEO CALANDRA, CNRS, FRANCESCO MAURI, Università di Roma, La Sapienza — The superconducting transition-metal dichalcogenide 2H-NbS$_2$, in sharp contrast to the isoelectronic compound 2H-NbSe$_2$, at low temperature does not show any charge-density-wave (CDW) ordering co-existing with the superconductive phase. That is in strong disagreement with \textit{ab initio} harmonic phonon calculations, which predict that 2H-NbS$_2$ is dynamically unstable. In this talk we will show that anharmonicty is the key factor to reconcile numerical results with experiments. With the stochastic-self-consistent-harmonic technique [1], we go beyond the harmonic approximation including quantum anharmonic effects in the \textit{ab initio} calculations and we obtain temperature-dependent phonon frequencies in quantitative agreement with experiment. In particular, the instability observed at harmonic level is removed. Furthermore, we analyze the effect of anharmonicity at low dimensions. Despite in the trigonal single layer form the CDW instability is even more incipient than in the bulk, the system still remains stable at low temperatures. Finally, we verify that the striking difference between 2H-NbS$_2$ and 2H-NbSe$_2$ is not simply ascribable to a mass effect, but it is dominated by the different electron screening felt by the ions in the two cases.

3:54PM P22.00006: Ab Initio Approach for Exciton-Phonon Interactions  
HSIAO-YI CHEN (Presenter), Department of Physics, Caltech, DAVIDE SANGALLI, CNR-ISM, Division of Ultrafast Processes in Materials (FLASHit), ANDREA MARINI, Istituto di Struttura della Materia of the National Research Council, MARCO BERNARDI, Department of Applied Physics and Materials Science, Caltech — We derive a formalism to compute exciton-phonon (ex-ph) interactions in crystals within the \textit{ab initio} GW-Bethe Salpeter equation (BSE) approach. Using first order perturbation theory and the Tamm-Dancoff approximation, we express the ex-ph coupling constant as a superposition of electron- and hole-phonon coupling processes. We discuss numerical calculations of such ex-ph coupling and the related scattering rates, which are challenging as they combine electron-phonon and finite-momentum BSE calculations; we carry them out by using the YAMBO code to obtain exciton dispersions and the PERTURBO code to compute electron-phonon coupling and the ex-ph scattering rates. We apply this framework to investigate ex-ph interactions in bulk hexagonal boron nitride (h-BN), for which we compute the exciton relaxation time due to ex-ph interactions and map it onto the exciton dispersions. We also employ an exciton Boltzmann transport equation to simulate the out-of-equilibrium dynamics of excitons and their equilibration with phonons in h-BN. Our work is a first step toward understanding electron-phonon interactions in composite electronic quasiparticles. It sheds light on correlated electron-phonon processes and provides new computational tools to investigate excited state dynamics.

4:06PM P22.00007: WITHDRAWN ABSTRACT
are solved, a computation of e-ph interactions reliably by using a pseudopotential method remains as an open question for further research. Before the problems are solved, a full-potential method for the calculation of e-ph interactions can be used to circumvent the problems.

*The work was funded in part by NSF (Award # HRD 1736136) and ARO (Award # W911NF-15-1-0483).

FENG GAO (Presenter), GUANG-LIN ZHAO, Southern University — The calculations of electron-phonon (e-ph) interactions in solid materials from first-principles remain as an important fundamental and applied problem in condensed matter physics. The pseudopotential method has been successfully used to study the valence electronic structure and related physical properties of solid materials. However, when atoms move, they will carry their true electronic potentials with them, not pseudopotentials. The derivatives of true electronic potentials with respect to atomic shifts in a solid will be quite different from the derivatives of pseudopotentials with respect to the same atomic shifts because of the smooth and non-local nature of the pseudopotentials. The essential part of the calculations of e-ph interactions is a reliable computation of the derivatives of electronic potential with respect to atomic position shifts. Consequently, determining how to calculate e-ph interactions reliably by using a pseudopotential method remains as an open question for further research. Before the problems are solved, a full-potential method for the calculation of e-ph interactions can be used to circumvent the problems.

Work at the University of Missouri is supported by the Department of Energy, Basic Energy Sciences, Award DESC0019114.

**4:42PM P22.00010: Plasmonic hot carriers in transition metal nitrides**

ADELA HABIB (Presenter), FRED FLORIO, RAVISHANKAR SUNDARARAMAN, Rensselaer Polytechnic Institute — Transition metal nitrides (TMNs) are well established as hard protective coatings on account of their excellent mechanical properties and chemical stability. With recent advances in synthesis, they are becoming increasingly competitive for their opto-electronic properties as refractory plasmonic materials. However, their potential for plasmonic hot carrier harvesting remains largely unknown. In this talk, we show that certain TMNs have a unique wide-band plasmonic behavior that extends deep into the ultraviolet regime. From first-principles calculations, we predict plasmonic response, hot carrier generation and subsequent thermalization of all group IV, V and VI transition metal nitrides, fully accounting for direct and phonon-assisted transitions as well as electron-electron and electron-phonon scattering mechanisms. We find hot carrier lifetimes and mean free paths in these TMNs comparable to those of gold and silver. Finally, we explore mechanisms responsible for the negative real permittivity extending to high frequencies in TMNs, an exciting prospect for stable ultraviolet plasmonics.

**4:54PM P22.00011: Electron-phonon coupling within Quasiparticle Self-consistent GW**

SAVIO LARICCHIA (Presenter), NICOLA BONINI, MARK VAN SCHILFGAARDE, Department of Physics, King’s College London — There is clear evidence that standard Density Functional Theory (DFT) underestimates electron-phonon coupling interaction in many materials, including even simple sp-bonded compounds. Hybrid functionals and quasiparticle GW corrections suggest that nonlocal exchange-correlation enhances the electron-phonon interaction as a consequence of an improved description of the electronic screening. This has highlighted the need to move beyond local exchange-correlation functionals within DFT, but complete field-theoretic investigations are still missing. In this talk I will introduce the development of a field-theoretic methodology which is able to predict on an equal footing electronic quasiparticles and phonons as well as their interaction. Such an approach has been implemented within the Quasiparticle Self-consistent GW (QSGW) formalism which describes well the electronic properties for a wide range of materials, including many where standard DFT fails.
5:06PM P22.00012: Ab Initio Next-to-Leading Order Electron-Phonon Interactions: Two-Phonon Electron Scattering Processes and their Temperature and Energy Dependence  NIEN-EN LEE (Presenter), JIN-JIAN ZHOU, HSIAO-YI CHEN, MARCO BERNARDI, Caltech — Electron-phonon (e-ph) interactions are a current focus of first-principles calculations. The lowest-order e-ph self-energy is computed in most works, and only recently there were attempts to include higher-order e-ph interactions using the cumulant method. However, diagrammatic approaches beyond the lowest order have not been attempted for computing e-ph interactions ab initio.

Here, we compute the scattering rates of e-ph processes involving two external phonons. Their expression is derived using many-body perturbation theory and the Matsubara technique on the two skeletonically nontrivial second-order diagrams. The numerical calculations are challenging since they involve Brillouin zone integrals over two crystal momenta and the intermediate state lifetime plays a critical role. Using random grids and Monte Carlo integration, we are able to compute and systematically converge such next-to-leading order e-ph scattering rates. Results are discussed for GaAs and SrTiO3, in which we analyze the two-phonon contributions to e-ph scattering as a function of temperature and carrier energy, and compare them with the lowest-order results. We discuss how our formalism can be extended to detect strong e-ph coupling and polaron formation.

5:18PM P22.00013: Simulation of time-resolved electron-phonon scattering on a Dirac cone  BENJAMIN NOSARZEWSKI (Presenter), Stanford University, ARTHUR K MILLS, MENGXING NA, FABIO BOSCHINI, MATTEO MICHIARDI, RYAN P DAY, ELIA RAZZOLI, ALEXANDER SHEYERMAN, MICHAEL SCHNEIDER, GIORGIO LEVY, SERGEY ZHDANOVICH, University of British Colombia, ALEXANDER KEMPER, North Carolina State University, THOMAS DEVHEREUX, Stanford University — Ultrafast spectroscopy is a powerful tool for studying the dynamical properties of quantum materials driven out of equilibrium. The relaxation dynamics of the non-equilibrium state can provide insights into the properties of the elementary scattering process and many-body interactions present in equilibrium. Using the Keldysh formalism we simulate time- and angle-resolved photoemission spectroscopy on a Dirac cone to capture the quantized relaxation processes of electrons coupled to optical phonons. Including retarded electron-phonon interactions, the simulation naturally captures the appearance of a direct excitation peak at an energy set by the frequency of the pump pulse and the delayed appearance of a secondary non-thermal peak above the Fermi level due to electron-phonon scattering as observed in an experiment performed on graphite.

Wednesday, March 6, 2019 2:30 PM - 4:54 PM

Session P23 GMED: Physics in Medicine: Computational Modeling  BCEC 158 - Robert Austin, Princeton University

2:30PM P23.00001: Synergistic Effect of Immunotherapy and Radiotherapy: a Computational Model  DAMIJAN VALENTINUZZI (Presenter), Jozef Stefan Institute, KATJA URSIC, Department of Experimental Oncology, Institute of Oncology Ljubljana, URBAN SIMONČIČ, Faculty of Mathematics and Physics, University of Ljubljana, MATEA MARUNA, Department of Experimental Oncology, Institute of Oncology Ljubljana, SIMON BUCEK, Department of Cytopathology, Institute of Oncology Ljubljana, MARUŠA TURK, Faculty of Mathematics and Physics, University of Ljubljana, MARTINA VRANKAR, Division of Radiotherapy, Institute of Oncology Ljubljana, MAJA CEMAZAR, GREGOR SERSA, Department of Experimental Oncology, Institute of Oncology Ljubljana, ROBERT JERAJ, Department of Medical Physics, University of Wisconsin – Madison — The Nobel Prize in Medicine 2018 was awarded for discovery of cancer immunotherapy (IT). Treatment effects are impressive, however, only a minority of patients respond. Because of favourable effects of radiotherapy (RT) on the immune system, combinations of IT and RT have been widely studied to improve the response rates. To identify possible biomarkers of response, we built a physical model capable of simulating tumour response to IT + RT. Interplay between a tumour, the immune system and the therapeutic effects is described with an experimentally verifiable population model, because the underlying biology is described with a minimum number of parameters. The model was able to reproduce experimental results from literature. To analyse possible biomarkers of response, sensitivity study of key parameters was performed. The most sensitive parameter was major histocompatibility complex class I expression, i.e. a receptor responsible for presentation of foreign proteins. Model predictions will be benchmarked against experiments on 3 different murine tumours, which will receive a single dose of RT with different IT schedules. Such models show promise to support, guide and accelerate immunotherapy research.
2:42PM P23.00002: Computational model of treatment resistance heterogeneity  MARUŠA TURK (Presenter), URBAN SIMONČIČ, Faculty of Mathematics and Physics, University of Ljubljana, ALISON ROTH, Department of Medical Physics, University of Wisconsin, Madison, DAMIJAN VALENTINUZZI, F8, Jozef Stefan Institute, ROBERT JERAJ, Department of Medical Physics, University of Wisconsin, Madison — In metastatic cancer patients, diverse levels of resistance, which are the result of genetic heterogeneity, lead to treatment response (TR) heterogeneity. To evaluate the role of resistance on TR, we constructed a population model, simulating cellular dynamics in individual metastasis. The model was benchmarked with imaging metrics extracted from the 18F-NaF PET/CT scans of 39 metastatic prostate cancer patients, received at baseline and after 3 cycles of therapy. Patients were treated with chemotherapy or hormonal therapy. Two model settings were evaluated: one considering only inter-patient and one considering both inter- and intra-patient heterogeneity in the proportion of intrinsically resistant cells (IR). Model performance, considering both settings, was evaluated using the Akaike information criterion (AIC). TR after 6, 9, and 12 months was predicted and compared using the Wilcoxon rank sum test. Considering both inter- and intra-patient heterogeneity in IR resulted in significantly better model performance (AIC=-250) than considering only inter-patient heterogeneity (AIC=6). Differences in predicted TR were not significant between treatment groups (p>0.15). The model has identified IR as an important factor influencing on inter- and intra-patient TR heterogeneity.

2:54PM P23.00003: Dynamics of Tumor Subpopulations in Response to Targeted Therapies*  DAVID MCCLATCHY (Presenter), CHANGRAN GENG, SOPHIA KAMRAN, HENNING WILLERS, HARALD PAGANETTI, AARON HATA, CLEMENS GRASSBERGER, Massachusetts General Hospital — Drugs targeting the specific genetic expression of a patient’s tumor have revolutionized the treatment of metastatic cancer. However, these tumors commonly recur due to the somatic evolution of drug persistent and resistant subpopulations during treatment. To better understand and combat acquired drug resistance, we developed a coupled, non-linear, differential system to model the dynamics of resistant and persistent tumor subpopulations. A Gompertz growth model is used to simulate bounded cell growth, while a general stochastic evolutionary pathway leading to drug resistance is implemented, based on in-vitro observations. Work will be presented on model development, and its parameterization based on measured tumor responses in lung cancer patients treated with targeted therapy. We further performed a comprehensive sensitivity analysis of model behavior in response to varying degrees of genomic instability, and derive estimates of initial pre-existing/persisting drug resistance that hold independent of parameter choice.

3:06PM P23.00004: Understand the role of chemotherapeutic gradient in the emergence of polyploid giant cancer cells using mean field model*  KE-CHIH LIN (Presenter), Princeton University, GONZALO TORGA, Johns Hopkins University, YUSHA SUN, Princeton University, ROBERT AXELROD, University of Michigan, KENNETH J. PIENTA, Johns Hopkins University, JAMES STURM, ROBERT AUSTIN, Princeton University — Polyploid giant cancer cells (PGCCs) have been shown to correlate with poor response to chemotherapy and contribute to tumor heterogeneity regulation through asymmetric cell division [1][2]. However, most in vitro cancer studies do not replicate the complexity of in vivo tumors, while animal models are difficult to study in a comprehensive manner. The dynamics of PGCC emergence remain unclear in the context of the complex heterogeneity of the tumor ecosystem. In a recent paper, we presented the Evolution Accelerator (EA) [3], which allowed the quantitative study of the interactions of multiple cell types on a chemotherapy gradient. Utilizing the EA technology, we discovered that a docetaxel gradient greatly elevated the emergence of PGCCs and increased survival of the cancer population. With population analysis and careful experimental control, we demonstrated with a simple mean field model that the coexistence of the emerging drug-resistance PGCCs and proliferative diploid cells may serve as a survival strategy for the cancer population.

TOPAS-nBio: Modeling effects of radiation with nanometer-scale Monte Carlo simulations

JAN SCHUEMANN (Presenter), AIMEE L MCNAMARA, Radiation Oncology, Massachusetts General Hospital & Harvard Medical School, Boston, MA, JOSE RAMOS-MENDEZ, Radiation Oncology, University of California San Francisco, San Francisco, CA, JOSEPH PERL, SLAC National Accelerator Laboratory, Menlo Park, CA, KATHRYN D HELD, HARALD PAGANETTI, Radiation Oncology, Massachusetts General Hospital & Harvard Medical School, Boston, MA, SEBASTIEN INCERTI, CNRS, IN2P3, CENBG, UMR 5797, F-33170 Gradignan, France, BRUCE FADDEGON, Radiation Oncology, University of California San Francisco, San Francisco, CA — The Monte Carlo (MC) method has been successfully employed to simulate radiotherapy down to the cellular scale. In order to understand how energy deposition within irradiated cells (physics) connects via molecular reactions (chemistry) to cell kill/repair (biology), one has to understand how damage and repair of cellular components is linked to frequencies of energy depositions in sub-cellular targets such as DNA.

MC simulation offers a unique tool to explore these effects. To make this method more accessible we developed TOPAS-nBio, a nanometer scale extension for radiobiology to the TOPAS MC system layered on top of the Geant4/Geant4-DNA MC toolkit. TOPAS-nBio includes detailed cell geometries, such as various DNA models, mitochondria and cells (e.g. fibroblasts or neurons). Two implementations of chemistry can be used with up to 72 reactions classified into 6 types between neutral and charged species. We reproduced time-dependent G-values within 7% for $^\cdot$OH and $e^-_{aq}$ and 50% for $H_2O_2$ as well as DNA damage in plasmids within 50%. The physical and chemical simulations depict direct and indirect damages to cells which are propagated using mechanistic models of DNA repair kinetics.

Computational Assessment of Radiation Dose Enhancement and Secondary Electron Production for Variable Sizes and Concentrations of Gold Nanospheres in a Tumor using MCNP6.2

TARA GRAY (Presenter), KATHRYN MAYER, Physics, University of Texas at San Antonio, NEIL KIRBY, Medical Physics, UT Health San Antonio MD Anderson Cancer Center — The purpose of this study is to computationally quantify dose enhancement effects of using different concentrations and sizes of gold nanospheres in high dose rate (HDR) brachytherapy and external beam radiotherapy. A MicroSelectron HDR Ir-192 brachytherapy source and a Varian 600C gantry head with a 6MV photon energy were modeled using Monte Carlo N-Particle radiation transport software (MCNP 6.2, Los Alamos National Laboratory). The repeating structures capability of MCNP6.2 was utilized to simulate nanospheres of sizes 4.5 nm, 30 nm and 60 nm at varying nanosphere concentrations of 5 nM, 10 nM and 20 nM, inside a tumor, with a diameter of 1 x 1 x 1 cm$^3$. Dose enhancement factors (DEFs) were computed as the ratio of dose to the tumor containing gold nanospheres relative to that without. The highest DEF of 1.7 was observed with the Ir-192 source for a total nanosphere concentration of 20 nM and diameters of 4.5 nm. It was observed that increasing concentration and decreasing the size of the nanospheres produced the greatest dose enhancement for both HDR brachytherapy and external beam radiotherapy cases. This work indicates the potential for significant dose enhancement and more effective tumor cell killing in radiation oncology practice.

*Funded by San Antonio Medical Foundation

Physical dose enhancement of gold nanoparticles and their impact on water radiolysis in radiotherapy

BENEDIKT RUDEK (Presenter), Radiation Oncology, Massachusetts General Hospital and Physikalisch-Technische Bundesanstalt, AIMEE L MCNAMARA, Radiation Oncology, Massachusetts General Hospital, HILARY BYRNE, ZDENKA KUNCIC, University of Sydney, JAN SCHUEMANN, Radiation Oncology, Massachusetts General Hospital and Harvard Medical School — Gold nanoparticle (GNP) radio-sensitization is a promising technique to increase the dose deposition in the tumor while sparing neighboring healthy tissue. The sensitization is most pronounced for keV x-rays, where the mass energy-absorption coefficient of gold is up to 150 times larger than that of soft tissue. Measurements in vitro and in vivo also showed an effect on cell survival and tumor control for other modalities such as MV photons and proton beams, where the physical dose enhancement by GNPs is expected to be negligible.

Most simulation studies have, thus, focused on photon irradiation of isolated GNPs in water neglecting experimental evidence of GNP clustering within cells. In a systematic study, we use the Monte Carlo simulation tool TOPAS-nBio to model the GNP radio-sensitization within a cell as a function of GNP concentration, size and clustering for a wide range of energies for photons, protons and carbon ions. Moreover, we include water radiolysis and subsequent chemistry as implemented in Geant4-DNA.

While the physical dose enhancement for 10MeV protons at 1% GNP concentration was only 0.07% compared to 62% for 50keV photons, we find the yield of reactive oxygen species change by up to 15% which could partly explain the experimental dose enhancement for protons.
3:54PM P23.00008: Compensatory enlargement of atherosclerotic vessels — An analysis through morphoelasticity*

PAK-WING FOK (Presenter), University of Delaware — In 1987 Seymour Glagov published a key result on how atherosclerotic arteries remodel. His post-mortem data on human coronary arteries suggested that over the course of atherosclerotic disease, the vessel wall expands, keeping the lumen area approximately constant before before luminal encroachment occurs. This “compensatory” enlargement has been confirmed in-vivo and in other organisms. However, this behavior has never been explained physically.

We propose a three-layer morphoelastic model to describe arterial remodeling. Each layer is described as a collagen-fiber reinforced anisotropic composite. Growth occurs in the intima only. This simple biomechanics model is able to reproduce the main features of the data. We discuss a methodology using finite elements and provide a physically appealing explanation of Glagovian remodeling.

4:06PM P23.00009: Computational Modeling Helps Tissue Engineered Heart Repair*

MORITZ KALHÖFER-KÖCHLING (Presenter), Fluid Physics, Pattern Formation, and Biocomplexity, Max-Planck-Institute for Dynamics and Self-Organization, MARTIN UECKER, WOLFRAM ZIMMERMANN, Universitätsmedizin Göttingen, EBERHARD BODENSCHATZ, YONG WANG, Fluid Physics, Pattern Formation, and Biocomplexity, Max-Planck-Institute for Dynamics and Self-Organization — Understanding the mechanical influence of scarred tissue is key to understand how ischemia affects the efficacy of the heart and consequently how supportive devices can help restoring the same. With medical images and nonlinear mechanics, we are developing a patient-specific heart model for tissue engineering. Employing the Holzapfel-Ogden rule we analyse how different types of infarcts impair the contractile function of the left ventricle using end diastolic and end systolic pressure volume relations as key markers. The patient specific tissue properties and hence model parameters play a crucial role on how much heart function will be compromised after an infarct, demanding an in-depth study of said parameter space, in order to develop patient-specific solutions. As such, we also investigate how engineered heart muscle tissue can restore healthy capacity targeting at clinical applications.

4:18PM P23.00010: Improving influenza vaccine development with the pEpitope model: application to the 2018-19 season*

MELIA BONOMO (Presenter), Department of Physics & Astronomy, Rice University, RACHEL KIM, Weiss School of Natural Sciences, Rice University, MICHAEL DEEM, Department of Bioengineering, Department of Physics & Astronomy, Rice University — The annual influenza vaccine has been shown to reduce flu-related hospitalizations and severe illness outcomes. Minimizing the antigenic differences between the vaccine strain and circulating strains ensures the vaccine will adequately prime the immune system against infection. We developed a theory of antibody response to infection following vaccination that produced a novel measure of antigenic distance. The model, called pEpitope, considers the modularity and hierarchy of antibody binding to the epitope regions of the viral hemagglutinin protein. The pEpitope model is able to explain over 90% of the variance in human vaccine epidemiological data from recent studies conducted by the US Centers for Disease Control and Prevention. Analysis of A(H3N2) strains circulating during the 2017-18 season identified the emergence of a new quasispecies cluster that is sufficiently distant from the 2018-19 vaccine and is therefore predicted to dominate. The pEpitope model is a valuable tool that predicts vaccine effectiveness to enhance vaccine strain selection and development.

4:30PM P23.00011: Network physiology reveals relations between network topology and physiological function*

XIYUN ZHANG (Presenter), FABRIZIO LOMBARDI, Physics Department, Boston University, RONNY BARTSCH, Department of Physics, Bar-Ilan University, PLAMEN CH IVANOV, Physics Department, Boston University — The human organism is an integrated network where complex physiological systems, each with its own regulatory mechanisms, continuously interact, and where failure of one system can trigger a breakdown of the entire network. Identifying and quantifying dynamical networks of diverse systems with different types of interactions is a challenge. Here we develop a framework to probe interactions among diverse systems, and we identify organ interaction networks. We find that each physiological state is characterized by a specific network structure, demonstrating a robust interplay between network topology and function. Across physiological states, the organ interaction network undergoes specific reorganization process that is preserved across subject with different ages, indicating the existence of a robust relation between organ interaction networks and physiological states.

*We acknowledge support from the W M Keck Foundation.
CHRISTINA POSPISIL (Presenter), Mathematics and Physics Department, University of Massachusetts Boston, TONG SHU, Physics Department, Yale University — In this first part we present a theoretical mathematical model for the information flow from teeth to organs, which is a part of a study modelling illness (e.g. catching a cold, etc.) and health conditions from the physics point of view and leads to the question of interaction/ reciprocal action of information as a phenomenon (as we understood it, physics is the science of phenomena) in general (getting ill is a certain kind of interaction with the environment). Moreover, we will give an overview about how this model can be tested experimentally.

BCEC 159 - Michael Buchhold, Caltech

2:30PM P24.00001: Observation of the Higgs mode in the superfluid BEC-BCS crossover in Fermi gases* JOHANNES KOMBE (Presenter), ALEXANDRA BEHRLE, TIMOTHY HARRISON, KUIYI GAO, MARTIN LINK, JEAN-SEBASTIEN BERNIER, CORINNA KOLLATH, MICHAEL KOEHL, University of Bonn — Thanks to recent advances, investigating the non-equilibrium dynamics of interacting systems is now possible. Using time-dependent perturbations, one can probe from a different angle the mechanisms responsible for the collective phenomena present in correlated systems. Taking advantage of this progress, we investigate both theoretically and experimentally the evolution of a three-dimensional Fermi gas while the interaction strength is effectively modified. Our study, carried out on the BCS side, reveals various collective excitations. Interestingly, this approach highlights the presence of the Higgs mode.

2:42PM P24.00002: Constrained Hilbert Spaces and Many-body Scars in a Landau Level SANJAY MOUDGALYA (Presenter), Physics, Princeton University, NICOLAS REGNAULT, Laboratoire Pierre Aigrain, B ANDREI BERNEVIG, Physics, Princeton University — We study a "pair-hopping" model that arises within a Landau level in the thin-torus limit of the quantum Hall effect. At filling \( \nu = 1/3 \), we show that the model maps on to the "PXP model", a constrained model for the Rydberg atom chain known to exhibit quantum many-body scars (ETH-violating states in the middle of the spectrum). Further, for general fillings factors \( \nu = p/(2p+1) \), we show the mapping onto spin-chains with constrained Hilbert spaces that share several features with the PXP model, including the presence of many-body scars and slow thermalization of particular product states. Finally, we investigate the stability of scars in the presence of electrostatic and long-range hopping terms that are always present in the quantum Hall setup.

2:54PM P24.00003: Computing thermalization times and hydrodynamic modes from microscopic quantum dynamics* EHUD ALTMAN (Presenter), XIANGYU CAO, DANIEL PARKER, University of California, Berkeley, DAVID HUSE, Physics, Princeton University — Computing quantum dynamics of an interacting system presents a fundamental challenge. The Heisenberg time evolution of a local operator generates superpositions with an exponentially growing number of terms, each representing increasingly non local operators. To address this problem, we construct the graph of basis operators (Pauli string in spin-half systems) spanned by applying the Liouvillian \( n \) times; \( n \) serves as a truncation cutoff. Integrating out the outward flow of operators across the truncation boundary toward "large operators" gives rise to an imaginary self energy term that acts as an absorbing boundary condition. The resulting non-unitary dynamics respects all conservation laws related to local operators, e.g. energy, charge and spin. The approximation scheme depends on a single free rate parameter, which we determine numerically by requiring the results to become cutoff independent asymptotically. For a broad class of ergodic models this scheme allows to identify slowly decaying operators, and compute the diffusion constant of hydrodynamic modes. Furthermore this scheme captures the non diffusive dynamics in certain integrable models.

*EA and XC acknowledge support from ERC synergy grant UQUAM
TIBOR RAKOVSZKY (Presenter), FRANK POLLMANN, Physics Department, Technical University of Munich, CURT W VON KEYSERLINGK, School of Physics and Astronomy, University of Birmingham — We investigate how the incoherent (diffusive) transport of conserved quantities affects the growth of entanglement in generic non-integrable systems. We develop a general picture by considering random unitary circuit dynamics with a U(1) symmetry which allows for an efficient numerical treatment and, in a certain coarse-grained limit, leads to a simple equation of motion for the entanglement entropy, which takes the form of a random, space-time dependent surface growth model. Based on this we argue that an initial state with large-scale inhomogeneities in the conserved densities gives rise to an uneven entanglement profile across the system, with features whose "height" and "width" both grow as $t^{1/2}$. We confirm this prediction by numerically investigating a variety of different initial states, both in the random circuit model away from the coarse-grained limit, and in a deterministic spin chain. Moreover, we investigate the effects of charge-fluctuation and find that these can lead to a slow-down in entanglement growth even for spatially homogenous states.

*RT and FP are supported by Research Unit FOR 1807 through grants no. PO 1370/2-1 and the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (grant agreement no. 771537).

JOHANNES FELDMEIER (Presenter), MICHAEL KNAP, FRANK POLLMANN, Technical University of Munich — The study of dynamical properties in systems with local constraints has attracted a lot of interest, spurred by experiments with Rydberg blockaded atoms, that naturally implement constrained many-body models. We study the quench dynamics in a 2D quantum dimer model to identify dynamical phase transitions in constrained models by means of exact diagonalization on systems of sizes up to 8x8 sites. We find that the quenched quantum system thermalizes efficiently by determining the relaxation dynamics of both the order parameter (OP) and local correlation functions. The observed fast relaxation to thermal expectation values allows us to study the underlying thermal BKT-transition between a columnar ordered valence bond solid (VBS) and a symmetric liquid (VBL) phase in the form of a dynamical phase transition. The existence of this finite-temperature transition in the dynamics is confirmed by the long-time averaged values of the OP. Moreover, upon quenching across the VBS-VBL phase boundary, the dynamical transition can be shown to be manifest in the Loschmidt-echo, whose rate-function displays kinks at the zero-crossings of the columnar OP.

*We acknowledge support from the DFG grant No. KN 1254/1-1 and DFG TRR80 (Project F8).

KRISTOF HARMS (Presenter), LORENZO CEVOLANI, STEFAN KEHREIN, SALVATORE MANMANA, Institute for Theoretical Physics, University of Göttingen — We investigate the dynamics of a one-dimensional system of spinless fermions, which is initially prepared in a highly correlated groundstate of an interacting Hamiltonian. In particular, for a global quench that turns off the interaction, we evolve the initial state obtained via density matrix renormalisation group (DMRG) using analytical solutions of the equations of motion. This allows us to reach arbitrary times. We examine features of the dynamics of density-density correlations and susceptibilities on several time scales. Shortly after the quench, we identify, in addition to the typical lightcone-behavior, periodic recurrences of the initial correlations outside the lightcone. At very long times, we use our approach to investigate the Fluctuation-Dissipation theorem in this strong nonequilibrium situation.

*Funding by the SFB/CRC 1073 (project B03) of the Deutsche Forschungsgemeinschaft (DFG) is gratefully acknowledged.

VALENTIN KASPER (Presenter), JAMIR MARINO, Department of Physics, Harvard University, SI CONG, JOERG SCHMIEDMAYER, Institute of Atomic and Subatomic Physics, TU Vienna, EUGENE DEMLER, Department of Physics, Harvard University — The high flexibility of ultracold atoms allows for the design, control and investigation of quantum matter. In this work we consider two one-dimensional Ramsey tunnel-coupled Bose gases and show that the low-energy effective theory of this system is described by the quantum Prokrovsky-Talapov model. We study the ground state with variational wave-functions and elaborate on the modification of the quantum phase transition due to a finite system size. Finally, we consider the non-equilibrium evolution determined by quench from an uncoupled Bose gases to the Ramsey tunnel coupled case and predict the experimental relevant evolution of phase correlations.
Dynamics of fractional Chern insulators under global quantum quenches  

JOHANNES MOTRUK (Presenter), JOEL MOORE, University of California, Berkeley and Lawrence Berkeley National Laboratory — Recent progress in the control of synthetic gauge fields in optical lattices has brought the realization of strongly correlated topological phases in cold atom experiments within reach. Due to longer time scales compared to solid state systems, the quantum dynamics in such setups are experimentally more amenable and may encode information about the topological properties of the state.

In this work, we investigate quantum quenches between Hamiltonians with a fractional Chern insulator (FCI) ground state and topologically trivial Hamiltonians. Focusing on the experimentally realized Hofstadter model, we study the post-quench behavior of various quantities such as edge currents, Hall response and Loschmidt echo and determine how they display signatures of the topologically ordered initial state. Furthermore, we comment on implications for dynamically detecting FCI states in cold atom experiments.

Loschmidt Amplitude and Work Distribution in Quenches of the Sine-Gordon Model*  

COLIN RYLANDS (Presenter), University of Maryland, College Park, NATAN ANDREI, Physics, Rutgers University — The Sine-Gordon model is ubiquitous in low-dimensional physics, with applications that range from cold atom and strongly correlated systems to quantum impurities. In this talk we present a study of its non-equilibrium dynamics using the quantum quench protocol. By means of the Bethe Ansatz we calculate exactly the Loschmidt amplitude, the fidelity and work distribution characterizing the quench for different values of the interaction strength. Some universal features are noted as well as an interesting duality relating quenches in different parameter regimes of the model.

*Supported by NSF grant DMR 1410583

Quench dynamics across topological quantum phase transitions*  

SHIUAN-FAN LIOU (Presenter), KUN YANG, Physics, National High Magnetic Field Laboratory and Florida State University — We study the dynamics of systems quenched through topological quantum phase transitions and investigate the behavior of the bulk and edge excitations with various quench rates. Specifically, we consider the Haldane model and checkerboard model in slow quench processes with distinct band-touching structures leading to topology changes. The generation of bulk excitations is found to obey the power-law relation Kibble-Zurek and Landau-Zener theories predict. However, an anti-Kibble-Zurek behavior is observed in the edge excitations. The mechanism of excitation generation on edge states is revealed, which explains the anti-Kibble-Zurek behavior.

Phonon Coupling’s Role in the Non-Equilibrium Dynamics of a Quasicondensate*  

RYAN PLESTID (Presenter), DUNCAN O’DELL, McMaster University — Cold atoms loaded into cigar shaped traps can realize the Lieb Liniger model where the effective 1-D coupling constant depends both on the three-dimensional scattering length of the atomic species, and on the trap’s transverse frequency. By performing a quantum quench of the transverse trapping frequency, non-equilibrium density and phase dynamics can be induced. In the low temperature regime, these dynamics are well characterized by Bogoliubov theory, however at higher temperatures intermode (i.e. phonon-phonon) coupling can become important. In this work we report on classical field simulations of a quasi condensate undergoing the quench protocol outlined above, and comment on the consequences of intermode coupling both for damping, and energy transfer.

*This research is supported by the Natural Sciences and Engineering Research Council (NSERC) of Canada.

2:42PM P25.00002: Quantum Zeno effect and the many-body entanglement transition* YAODONG LI (Presenter), University of California, Santa Barbara, XIAO CHEN, Kavli Institute for Theoretical Physics, MATTHEW P A FISHER, University of California, Santa Barbara — We introduce and explore a one-dimensional "hybrid" quantum circuit model consisting of both unitary gates and projective measurements. While the unitary gates are drawn from a random distribution and act uniformly in the circuit, the measurements are made at random positions and times throughout the system. By varying the measurement rate we can tune between the volume law entangled phase for the random unitary circuit model (no measurements) and a "quantum Zeno phase" where strong measurements suppress the entanglement growth to saturate in an area-law. Extensive numerical simulations of the quantum trajectories of the many-particle wavefunctions (exploiting Clifford circuitry to access systems up to 512 qubits) provide evidence for a stable "weak measurement phase" that exhibits volume-law entanglement entropy, with a coefficient decreasing with increasing measurement rate. We also present evidence for a novel continuous quantum dynamical phase transition between the "weak measurement phase" and the "quantum Zeno phase", driven by a competition between the entangling tendencies of unitary evolution and the disentangling tendencies of projective measurements.

2:54PM P25.00003: Tomography of the temporal-spectral state of subnatural-linewidth single photons from atomic ensembles* CE YANG (Presenter), ZHENJIE GU, PENG CHEN, Department of Physics, East China Normal University, Shanghai 200241, China, Quantum Institute for Light and Atoms, ZHONGZHONG QIN, Shandong University, Taiyuan, Shanxi 030006, China, Collaborative Innovation Center of Extreme Optics, JIEFEI CHEN, Department of Physics, East China Normal University, Shanghai 200241, China, Quantum Institute for Light and Atoms, WEIPING ZHANG, Department of Physics and Astronomy, Shanghai Jiao Tong University, Shanghai 200240, China, Tsung-Dao Lee Institute — The temporal mode of a single photon is considered more and more important in quantum information processing. On one hand, qubits or multi-dimension qudits can be constructed in photonic temporal mode, which are advantageous in long-distance transportation compared to other degrees of freedom, and thus have important applications in photonic quantum processing. On the other hand, to achieve a maximum efficiency in quantum memory, the temporal mode of a single photon is important in the matter-light coupling. Here we utilize cavity-free homodyne detection scheme for reconstructing the temporal density matrix of the subnatural-linewidth single photons generated from a cold atomic cloud. The characterization of the pure temporal-spectral state of narrowband single photons paves the way for exploiting the temporal-spectral degree of freedom to develop photonic quantum information processing.

3:06PM P25.00004: Floquet-engineered quantum state preparation in a noisy qubit MOHIT PANDEY (Presenter), ERIC BOYERS, DRIES SELS, DAVID K CAMPBELL, ANATOLI POLKOVNIKOV, ALEX SUSHKOV, Boston University — Noise and decoherence caused by the environment are two major challenges in applying adiabatic protocols to quantum technologies. Counter-diabatic (CD) and fast-forward (FF) driving protocols, which are also known as "shortcuts-to-adiabaticity," provide powerful alternatives by allowing one to change Hamiltonian parameters rapidly while still mimicking adiabatic dynamics. However, implementing exact CD or FF driving in complex systems is hard in general. In this work, we propose a new efficient and generic method of Floquet engineered FF protocols, which effectively realize CD driving. We report on its experimental realization in a single nitrogen-vacancy center in diamond. Our protocol achieves near unit fidelity with our target state for fast protocols when our system is driven periodically at high frequency. Moreover, we find experimentally that our Floquet-engineered protocols are less susceptible to decoherence than standard fast forward protocols and allow us to reach near perfect fidelity even in the presence of a strong external noise.
3:18PM P25.00005: Amplification without Population Inversion from a Strongly Driven Superconducting Qubit
PING YI WEN, Department of Physics, National Tsing Hua University, Taiwan, ANTON FRISK KOCKUM, Department of Microtechnology and Nanoscience, Chalmers University of Technology, Sweden, HOU IAN, Institute of Applied Physics and Materials Engineering, University of Macau, Macau, JENG-CHUNG CHEN, Department of Physics, National Tsing Hua University, Taiwan, FRANCO NORI, Center for Emergent Matter Science, RIKEN, Japan, IO CHUN HOI (Presenter), Department of Physics, National Tsing Hua University, Taiwan — Amplification of EM fields is often achieved by strongly driving a medium to induce population inversion such that a weak probe can be amplified through stimulated emission. Here we strongly couple a superconducting qubit to the field in a semi-infinite waveguide. When driving the qubit strongly on resonance such that a Mollow profile appears, we observe a few percent amplitude gain for a weak probe at frequencies in between the Mollow profile. This amplification is not due to population inversion, but instead results from a four-photon process that converts energy from the strong drive to the weak probe. We find excellent agreement between the experimental results and numerical simulations without any free fitting parameters.

3:30PM P25.00006: Multiphoton pumping between two microwaves mediated by transmon qubit
HOSSEIN JOOYA (Presenter), ITAMP, Harvard-Smithsonian Center for Astrophysics, GUOZHU SUN, JIAZHENG PAN, PEIHENG WU, Research Institute of Superconductor Electronics, Nanjing University, SIYUAN HAN, Department of Physics and Astronomy, University of Kansas, HOSSEIN R. SADEGHPOUR, ITAMP, Harvard-Smithsonian Center for Astrophysics — In this work, we analyze the interference patterns, observed in the multiphoton absorption spectrum of a transmon qubit, when it is driven by a pair of microwaves, tuned near and far off the qubit resonance. The appearance of such structures in the spectrum is explained as various photon contributions from the two microwave drives. We show that each of these manifolds demonstrates single or multiphoton pumping from one microwave to another. A many-mode Floquet formalism, with longitudinal coupling, is used to simulate the observed quantum interference. An intuitive graph theoretic approach is introduced to derive the effective Hamiltonian that elucidate main features of the Floquet results. The analytical solutions also illustrate how controllability is achievable for desired single- or multiphoton pumping processes in a wide frequency range. The proposed experimental design and the theoretical approach can be extended to tunable qubit circuits or solid state semiconductors, in general, which offer full controllability of the energy gaps.

3:42PM P25.00007: Periodically Pulsed Quantum Light from a Superconducting Qubit Ensemble
ELENA REDCHENKO (Presenter), FARID HASSANI, MATILDA PERUZZO, Institute of Science and Technology Austria, 3400 Klosterneuburg, Austria, MATTHIAS ZENS, HIMADRI SHEKHAR DHAR, DMITRY O. KRIMER, STEFAN ROTTER, Institute for Theoretical Physics, Vienna University of Technology (TU Wien), Wiedner Hauptstraße 8-10/136, 1040, Vienna, Austria, European Union, JOHANNES FINK, Institute of Science and Technology Austria, 3400 Klosterneuburg, Austria — Nonclassical light sources are extremely important in the fields of quantum information, quantum communication, and photonic quantum technologies. We study a driven inhomogeneous ensemble of superconducting qubits coupled to a microwave resonator. The constructive rephasing of spins in the frequency comb is predicted to result in a periodic pulse train of quantum light ($g_2(t,0)<1$) which corresponds to the collective transfer of excitations from the qubit ensemble to the resonator [1]. Such periodic nonclassical pulses are interesting for a temporal synchronization in quantum memory protocols. We will present results of our ongoing experiments on periodic quantum light generation in the system of five transmon qubits capacitively coupled to a coplanar waveguide resonator.

*This work was supported by the European Research Council under the grant agreement No 758053 (ERC StG QUNNECT).
In nano-electromechanics, quantum mechanical phenomena can be studied in the literal sense. For example, the coupling of a nanomechanical element to a superconducting resonator allows to cool the mechanical mode to its ground state and to squeeze its motion. Replacing the linear microwave resonator with a nonlinear one enables the preparation of more complex non-classical mechanical states.

In this presentation, we discuss various opto-mechanical coupling schemes in nano-electromechanical circuits employing nonlinear elements. In this context, Josephson junctions in superconducting circuit environments are the obvious choice. In particular, we envisage the scenario of a mechanically compliant tensile string embedded in a resonator including Josephson junctions, e.g. a transmon qubit or a flux-tunable resonator. We discuss realistically achievable opto-mechanical coupling strengths for these circuit layouts. In addition, we set this in context with the limitations imposed by such circuits, in particular in view of the photon numbers. Such hybrid systems open new perspectives in the field of optomechanics ranging from sensing applications to the preparation of quantum states.

*We acknowledge funding via the Nanosystems Initiative Munich and EU project MaqSens (Proj. No:736943)

**Engineered Reservoirs for Thermalization of Many-Body Quantum Systems**

**MEKENA METCALF** (Presenter), **MOHAN SAROVAR**, Sandia National Laboratories California, **JONATHAN MOUSSA**, Molecular Sciences Software Institute — Engineering genuine thermal states in quantum analog simulation platforms are addressed by a technique based on a many-body spin Hamiltonians coupled to driven, dissipative ancilla spins. A Born-Markov master equation describing the dynamics of a many-body system coupled to fast-relaxing, driven ancilla qubits is developed, and if the ancilla energies are periodically modulated and swept across the system energy spectrum, with a carefully chosen hierarchy of timescales, one can effectively thermalize a many-body system. Analytical proofs and numerical investigations are used to validate the requirements of thermalization and demonstrate the true thermal state is an approximate dynamical fixed point.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA-0003525. **A phononic network of spin qubits for quantum computing**

**MARK KUZYK** (Presenter), **HAILIN WANG**, University of Oregon — We describe a general architecture for networking solid-state qubits through vibrational motion. The architecture makes use of alternating phononic crystal waveguides to facilitate communication between distant qubits in a scalable manner. We discuss a specific realization of the architecture using Nitrogen vacancy centers in diamond, and show that state-of-the-art devices operating at 500 mK can implement two-qubit universal quantum gates with a fidelity exceeding 0.99.

4:30PM P25.00011: Quantum phase investigation of a single nuclear spin in a magnetic molecule  
CLÉMENT GODFRIN (Presenter), Physique, Université de Sherbrooke, RAFIK BALLOU, EDGAR BONET, Institut Néel, Université Grenoble Alpes, MARIO RUBEN, SVETLANA KLYATSKAYA, WOLFGANG WERNSDORFER, Karlsruhe institute of technology, FRANCK BALESTRO, Institut Néel, Université Grenoble Alpes — More than a hundred years ago, physicists used thought experiments to debate the controversial point of quantum theory while undoing the experimental constraints. Since then, advances in experimental techniques offer physicists the opportunity to study systems worthy of those imagined by the founders of the quantum theory. During the presentation, we will investigate the quantum dynamic of one of these toy model systems, namely a single 3/2 nuclear spin.

We will first see how to measure a single electronic [1] and nuclear spin using a molecular magnet transistor. Then we will couple the nuclear spin to a microwave electric field [2] and measure the coherent manipulation of the 3 nuclear spin transitions, thus demonstrating a full controlled of a 4-level quantum system, a qudit [3]. With their state space of dimension d>2, Qudits open fascinating experimental prospects. In this presentation I will show implementation of protocols based on a generalization of the Ramsey interferometry to a multi-level system to measure the accumulation of geometric phases and of quantum gate phase [4].

4:42PM P25.00012: Practical Implementations of Photonic Quantum Walks on Graphs*  
SHUTO OSAWA (Presenter), DAVID SIMON, ALEXANDER SERGIENKO, Boston University — Discrete-time quantum walks have become a subject of great interest because of their potential applications for quantum information processing tasks. Quantum walk-based algorithms provide significant speedup over classical algorithms in a range of tasks including search algorithms, solving the element distinctness problem, and evaluating NAND trees. Up to this point, work on quantum walk-based algorithms has been largely theoretical, as discrete-time quantum walk systems are difficult to implement beyond a few time steps. Here we demonstrate a step forward in producing practical experimental realization of optical quantum walks by means of directionally-unbiased linear optical multiports, which have recently been experimentally demonstrated in the form of tabletop setups. These multiports or other related devices, such as reversible optical tritters, can be considered as additional fundamental blocks for quantum walk applications, and can serve as scattering vertices for practical implementations of optical graph systems.

4:54PM P25.00013: Double-slit Interference as a Lossy Beam-splitter  
SIMANRAJ SADANA (Presenter), Raman Research Institute, BARRY SANDERS, University of Calgary, URBASI SINHA, Raman Research Institute — A post-selected unitary description of optical interferometers makes them a good machine for quantum information processing and computation. However, slit diffraction/interference lacks a unitary description. We present a classical post-selected unitary description of slit diffraction, bringing it at par with other interferometers.

The solution of Helmholtz equation in three dimensions with N sources are projected on two-dimensional surfaces called slices, all parallel to each other. A post-selected unitary description of slit diffraction is achieved by representing diffraction as a map between slices as they pass through slits and projecting the slices on N detectors to obtain an N × N transfer matrix.

Using such a formalism, we show that a double-slit with post-selection taking into account the losses in the diffraction process, is a beam-splitter. With the use of FDTD simulations, the application of this formalism is demonstrated for near-field and far-field cases. We also show that such a framework can be used to get a post-selected unitary description of a diffraction grating.

The classical treatment sets the stage for future research on diffraction-based quantum interferometry which involves quantizing the fields and the construction of sophisticated interferometers.
Nearly optimal quantum control: an analytical approach*  
CHEN SUN (Presenter), Brown University, AVADH SAXENA, NIKOLAI SINITSYN, Los Alamos National Laboratory — We propose nearly optimal control strategies for changing the states of a quantum system. We argue that quantum control optimization can be studied analytically within some protocol families that depend on a small set of parameters for optimization. This optimization strategy can be preferred in practice because it is physically transparent and does not lead to combinatorial complexity in multistate problems. As a demonstration, we design optimized control protocols that achieve switching between orthogonal states of a naturally biased quantum two-level system.

*The work was carried out under the auspices of the National Nuclear Security Administration of the U.S. Department of Energy at Los Alamos National Laboratory under Contract No. DE-AC52-06NA25396. Authors also thank the support from the LDRD program at LANL.

Limitations on the Use of the Heisenberg Picture in Quantum Optics  
JAMES FRANSON (Presenter), RICHARD A BREWSTER, University of Maryland, Baltimore County — The Heisenberg picture is often used to analyze the performance of optical components, such as a beam splitter or an optical parametric amplifier. We consider a sequence of two or more unitary transformations and show that the Heisenberg operator produced by the first transformation cannot be used as the input to the second transformation [1]. As a result, an inappropriate use of the Heisenberg picture can give misleading or incorrect conclusions. The experimental consequences of this will be illustrated using several examples from quantum optics.

Session P26 DQI: Superconducting Circuits: New Qubit Components and Packaging BCEC
160B - Sami Rosenblatt, IBM Thomas J. Watson Research Center

Scaling up package I/O for superconducting qubits*  
STEVEN WEBER (Presenter), DANNA ROSENBERG, JOVI MILOSHI, JOHN CUMMINGS, JAMES KRIEGER, SAM ALTERMAN, DAVID CONWAY, RABINDRA DAS, CYRUS F. HIRJIBEHEDIN, DAVID K KIM, ELIZABETH KOWALSKI, MIT Lincoln Laboratory, BENJAMIN LIENHARD, Massachusetts Institute of Technology, ALEXANDER MELVILLE, BETHANY M. NIEDZIELSKI, JOHN ROKOSZ, WAYNE WOODS, JONILYN L YODER, ANDREW JAMES KERMAN, WILLIAM D OLIVER, MIT Lincoln Laboratory — Device packages, which house qubit chips and make connections to control and readout wiring, are an essential component of any superconducting qubit architecture. In this presentation, we discuss our efforts to design packages with an increasing number of signal connections, for applications in quantum annealing and gate-based quantum computing. We present strategies for achieving high-density wiring while avoiding package modes and reducing crosstalk. We characterize package performance using electromagnetic simulations, room-temperature measurements, and cryogenic qubit measurements.

2:42PM P26.00002: Simulation and Analysis of Packaging of Superconducting Qubits*

Benjamin Lienshard (Presenter), Electrical Engineering and Computer Science, Massachusetts Institute of Technology, Wayne Woods, Danana Rozenberg, MIT Lincoln Laboratory, Kevin P O'Brien, Electrical Engineering and Computer Science, Research Laboratory of Electronics, Massachusetts Institute of Technology, Greg Calusine, Steven J. Weber, MIT Lincoln Laboratory, Terry Philip Orlando, Electrical Engineering and Computer Science, Research Laboratory of Electronics, Massachusetts Institute of Technology, Simon Gustavsson, Research Laboratory of Electronics, Massachusetts Institute of Technology, William D Oliver, Department of Physics, Research Laboratory of Electronics, Lincoln Laboratory, Massachusetts Institute of Technology — Precise and accurate coherent control of qubits is critical to the success of superconducting quantum computing. Microwave crosstalk is a ubiquitous problem for large scale superconducting quantum processors and poses a challenge to scaling up few-qubit coherent control results. Although crosstalk is classical, deterministic, and can be mitigated to some degree with electromagnetic nulling, the frequency dependence of crosstalk and significant calibration overhead for compensation schemes motivate hardware solutions. 3D integration techniques such as through silicon vias and bump bonds offer a solution at the cost of fabrication complexity. We propose and present initial experiments on a crosstalk mitigation scheme using commercial multilayer printed circuit boards (PCBs) to enable rapid turnaround and widespread adoption.

2:54PM P26.00003: Engineering the environment of superconducting quantum processors with multilayer PCBs

Kaidong Peng, Kevin O'Brien (Presenter), Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology — Arrays of superconducting lumped circuit elements can be used to make metamaterial resonant structures, which can exhibit novel spectra with a high density of modes in the same frequency range where superconducting qubits are typically operated. We study the dynamics of a flux-tunable transmon qubit when coupled to such a metamaterial. We measure the coupling strength of the qubit to several modes by tuning the flux bias and compare the resulting vacuum Rabi splittings with numerical and analytical models. Using a separate conventional resonator to read out the qubit state, we are able to track the qubit as we tune it through many of the metamaterial resonances. With this capability, we are able to measure the qubit T1 time as a function of frequency. We observe that T1 correlates with the metamaterial spectrum and is consistent with Purcell loss into the various modes, as described by a circuit model. In addition, we present measurements of Stark shifts of the qubit transition while driving a separate microwave tone in the vicinity of the various metamaterial modes.

3:06PM P26.00004: Qubit Dynamics in a Multi-mode Environment with a Superconducting Metamaterial Resonator

Sagar Indraneet (Presenter), Haozhi Wang, Matthew D Hutchings, Matthew Lahaye, Syracuse University, Bruno G. Taketani, Frank K Wilhelm, Saarland University, Britton L Plourde, Syracuse University — Precise and accurate coherent control of qubits is critical to the success of superconducting quantum computing. Microwave crosstalk is a ubiquitous problem for large scale superconducting quantum processors and poses a challenge to scaling up few-qubit coherent control results. Although crosstalk is classical, deterministic, and can be mitigated to some degree with electromagnetic nulling, the frequency dependence of crosstalk and significant calibration overhead for compensation schemes motivate hardware solutions. 3D integration techniques such as through silicon vias and bump bonds offer a solution at the cost of fabrication complexity. We propose and present initial experiments on a crosstalk mitigation scheme using commercial multilayer printed circuit boards (PCBs) to enable rapid turnaround and widespread adoption.

3:18PM P26.00005: Kerr- and cross-Kerr-free Josephson four-wave mixing device*

Shantanu O. Mundhada (Presenter), Nicholas E. Frattini, Shruti Puri, Akshay Koottandavid, Shyam Shankar, Steven Girvin, Michel H. Devoret, Department of Applied Physics, Yale University — Parametrically pumped four-wave mixing is a key building block for many developments in the field of superconducting quantum information processing. However, undesired frequency shifts such as Kerr, cross-Kerr and Stark shifts, inherent with four-wave mixing, lead to difficulties in tuning up the desired parametric processes and, for certain applications, severely limit the fidelities of the resulting operations. In this talk, we explore a Josephson four-wave mixing device consisting of a SQUID transmon coupled to a half-flux biased SNAIL transmon, a.k.a. capacitively shunted flux qubit. When the two transmons have matching frequencies, an interference effect cancels the negative Kerr of the SQUID transmon with the positive Kerr of the SNAIL transmon while preserving parametric four-wave mixing capabilities. We present the design and experimental characterization of such a device.

3:30PM P26.00006: Quickly tunable refrigerator for superconducting qubits* JAN GOETZ (Presenter), ANDRAS GUNYHO, QCD Labs, Aalto University, MATTI SILVERI, Research Unit of Nano and Molecular Systems, University of Oulu, HAO HSU, GIANLUIGI CATELANI, JARA Institute for Quantum Information (PGI-11), Forschungszentrum Jülich, MIKKO MÖTTÖNEN, QCD Labs, Aalto University — The emerging quantum technological devices call for fast and accurate initialization of functional quantum degrees of freedom to a low-entropy state. Here, we theoretically study a recently demonstrated quantum-circuit refrigerator \[1\] in the case of superconducting qubits. We find that for typical parameters, the refrigerator is suitable for quickly cooling both transmon and flux qubits close to their ground states. The maximum refrigeration rate of transmon qubits is roughly an order of magnitude stronger than that of resonators \[2\], providing additional flexibility in the design criteria. The on/off ratio of the refrigerator assumes values above \(10^4\) with typical experimental parameters. Thus the refrigerator is a promising tool for quantum technology and for studies of open quantum systems. Finally, we present an experimental realization based on transmon qubits and coupled qubit-resonator systems, which are the workhorses of quantum processors based on superconducting circuits.

3:42PM P26.00007: Quickly Tunable Electromagnetic Environment for Superconducting Quantum Circuits* VASILI SEVRIUK (Presenter), KUAN YEN TAN, MATTI SILVERI, SHUMPEI MASUDA, JAN GOETZ, MATTI PARTANEN, DIBYENDU HAZRA, QCD Labs, Aalto University, JOONAS GOVENIUS, Aalto University, RUSSELL LAKE, Boulder, NIST, VISA I VESTERINEN, LEIF GRÖNBERG, JUHA HASSEL, SLAWOMIR SIMBIEROWICZ, Technical Research Centre of Finland Ltd, VTT, MARTON GUNYHO, AARNE KERÄNEN, JANI TUORILA, Aalto University, TAPIO ALA-NISSILA, Departments of Mathematical Sciences and Physics, Loughborough University, HERMANN GRABERT, Department of Physics, University of Freiburg, MIKKO MÖTTÖNEN, QCD Labs, Aalto University — In the qubits operation it is of utmost importance to be able to quickly remove any unwanted excitations on demand for fast and accurate initialization. We recently introduced a device referred to as a quantum-circuit refrigerator (QCR) \[1\]. It is a stand-alone component that can readily be integrated into superconducting quantum electric devices, with negligible perturbation to the device operation. In our experiments, we demonstrate the ability to tune the dissipation of a superconducting resonator by orders of magnitude by the convenient application of a bias voltage on the QCR. The switching time of the tunable dissipation can be as low as a few nanoseconds. We also observe a tunable Lamb shift owing to the dissipation induced by the QCR. 1 K. Y. 3:54PM P26.00008: Optimal Impedance Taper in the Presence of Nonlinear Voltage Reflections* ROBERT ERICKSON (Presenter), MUSTAFA BAL, DAVID PAPPAS, Quantum Devices, NIST-Boulder — A signal introduced into a load-bearing transmission line will partially reflect back along the input line if an impedance mismatch exists at the injection interface. Placement of a tapered impedance transformer at the interface can reduce these reflections. \[1\] In earlier work we showed how to determine the optimal shape of a continuous lossless taper of wide frequency bandpass. \[2\] Our theory assumed impedance mismatch sufficiently small that large voltage reflections within the taper could be considered negligible. Here we extend our earlier theory, allowing for arbitrarily sized impedance mismatches and large voltage reflections, reporting results for a lossless taper. Our extended theory has important application to the design of tapered transformers for electronic devices with unavoidably large impedance mismatches, and can be leveraged to construct on-chip Purcell filters used in the fast readout of superconducting transmon and Xmon qubits.

4:18PM P26.00010: Fast flux control of 3D transmon qubits using a magnetic hose  STEFAN OLENSCHKO (Presenter),

OSCAR GARGIULO, University of Innsbruck, JORDI PRAT-CAMPS, University of Sussex, MAXIMILIAN ZANNER, GERHARD

KIRCHMAIR, University of Innsbruck — An important feature in analog quantum simulation experiments with

superconducting qubits [1] is the possibility to change the frequency of SQUID-based transmon qubits by applying

magnetic flux. Implementing fast flux control on a transmon remains challenging in the 3D cavity architectures due to the

presence of a massive metallic cavity. Here we introduce a new approach for fast flux control on 3D transmon qubits. We

use a magnetic hose similar to the one proposed by C. Navau et al. [2] to guide a fast flux pulse from the outside to the inside of a microwave cavity. This hose enables us to locally circumvent any magnetic shielding effects such as the appearance of eddy currents in cavities made out of copper or the Meissner effect in superconducting cavities made out of aluminum. First experiments show that the transition frequency of a transmon can be tuned in less than 100 nanoseconds. Besides the high speed, the frequency shift is precise, without showing any ringing or hysteresis. Using a magnetic hose with an aluminum cavity preserves the benefits of a superconducting cavity, like providing magnetic field shielding and a high internal quality factor, along with the possibility to fast-tune individual qubits.

4:30PM P26.00011: Kinetic Inductance Microwave Resonators for Quantum Simulation of Nonequilibrium Bose-Hubbard Models*  MATTIAS FITZPATRICK (Presenter), ALICIA KOLLAR, ANDREW HOUCK, Princeton University — The field of circuit-QED (cQED) provides a rich toolbox for doing both quantum computation and quantum simulation with superconducting circuits. Here we will discuss the use of kinetic inductance nonlinearities in microwave resonators as a new tool for quantum and classical-nonlinear simulation of Bose-Hubbard models. We explore the interplay between nonlinearities, dissipation, and disorder in large-scale circuits consisting of cavity arrays or multimode cavities. In contrast to other quantum simulation platforms, the particles in cQED (photons) are inherently dissipative, allowing the study of Bose-Hubbard models from a driven-dissipative and open system context.

*We acknowledge funding from the NSF MURI W911NF-15-1-0397.

4:42PM P26.00012: Josephson Junctions with Two-Dimensional van der Waals Tunnel Barrier  KAN-HENG LEE (Presenter), SRIVATSAN CHAKRAM, FAUZIA MUJID, CHIBEOM PARK, HUI GAO, DAVID SCHUSTER, JIWOONG PARK, The University of Chicago — Better device structure and materials control have contributed to the performance improvement of the Al/AIO_{x}/Al-based superconducting qubits, allowing the technology to initiate practical applications in quantum computing. However, one current limitation of such qubits is the use of amorphous alumina as the tunnel barrier, which is known to have defects that may compromise the qubit coherent time and performance stability. Here, we report novel Josephson Junctions with 2D van der Waals tunnel barriers made with stacked N-layer MoS_{2} that has minimal number of defects. We first generate a MoS_{2} membrane with controlled layer number N by vacuum stacking monolayer MoS_{2} as the tunneling barrier, and then depositing Al superconductor on either side to form the Josephson junctions. We show that we can reliably fabricate large numbers of Josephson junction devices on a single chip, and they show critical supercurrent that can be directly tuned by changing the N. We also characterize the microwave properties of Al/MoS_{2}/Al junctions in a bulk superconducting cavity. Our work offers a new, powerful platform for generating and studying novel qubits with diverse 2D materials, and thus may provide an additional route to further improve the qubit performance for advancing the quantum technology.
4:54PM P26.00013: Observation of a broadband Lamb shift in a superconducting resonator* MATTI SILVERI, Department of Physics, University of Oulu, SHUMPEI MASUDA, BASILII SEVRIUK, KUAN YEN TAN, ERIC HYYPÄ, MATTI PARTANEN, JAN GOETZ, QCD Labs, Aalto University, RUSSELL LAKE, Boulder, NIST, LEIF GRÖNBERG, QTF Centre of Excellence, VTT Technical Research Centre of Finland, MIKKO MÖTTÖNEN (Presenter), QCD Labs, Aalto University — The shift of energy levels owing to broadband electromagnetic vacuum fluctuations—the Lamb shift—has been pivotal in the development of quantum electrodynamics and in understanding atomic spectra. Currently, small energy shifts in engineered quantum systems are of paramount importance owing to the extreme precision requirements in applications such as quantum computing. However, without a tunable environment it is challenging to resolve the Lamb shift in its original broadband case. Consequently, the observations in other than atomic systems are limited to environments comprised of narrowband modes. Here, we experimentally observe in high-quality superconducting resonators a Lamb shift of several megahertz, by externally tuning the coupling strength of an engineered broadband environment based on hybrid normal-metal–superconductor tunnel junctions. Our results may lead to improved control of dissipation in high-quality engineered quantum systems such as superconducting qubits.

*We acknowledge European Research Council Grant No. 681311 (QUESS); Academy of Finland grants Nos. 312300, 312059, 265675, 305237, 305306, 308161, 312300, 314302, 316551; the Jane and Aatos Erkko Foundation, and the Technology Industries of Finland Centennial Foundation.

5:06PM P26.00014: Quantum Dynamics of a few-photon Microwave Parametric Oscillator ZHAOYOU WANG (Presenter), MAREK PECHAL, AMIR SAFAVI-NAEINI, Stanford University — We experimentally investigate quantum dynamics of a non-linear superconducting RF resonator in the intermediate (n ~ 5) photon number regime. In particular, we study parametric processes induced by modulation of the resonator’s inductance to prepare non-classical photon states, which may be useful in future continuous-variable quantum error correction schemes. The system can be described as a Kerr parametric oscillator (KPO) with linewidth significantly smaller than the single photon Kerr shift. We observe narrowing of the linewidth when approaching the parametric stability threshold as well as non-classical signatures in the resonator state’s free evolution caused by the Kerr non-linearity. To read out the quantum state of the resonator, we developed a tomography method which utilizes its nonlinear character to estimate the system’s density matrix from the power spectrum of the field emitted by it.

5:18PM P26.00015: Packaging Large-scale Superconducting Quantum Computer with Airbridge* HIROTO MUKAI (Presenter), KEICHI SAKATA, Physics, Tokyo University of Science, DEVITT J SIMON, Faculty of Engineering and Information Technology, University of Technology Sydney, RUI WANG, YUKITO NAKAJIMA, JAW-SHEN TSAI, Physics, Tokyo University of Science — For superconducting circuits with quantum error correction, a two-dimensional array of qubits is required. Recently it is challenged to build a practical large-scale superconducting circuit with the array on a chip by using this three-dimensional wiring technique to control the qubits, while maintaining high fidelity operations. In this talk, we present the novel arrangement of the array of qubits without non-monolithic special technology of three-dimensional wiring. In this architecture, standard two-dimensional external lines are adopted and local crossovers of interqubit connections are required. The crossovers are realized by airbridge technology. We show this novel architecture and the result of quality factor of resonator with airbridge at center line.

Session P27 DQI: General Quantum Information and Quantum Computation BCEC 160C - Todd Brun, University of Southern California
2:30PM P27.00001: Fundamental limits to quantum channel discrimination* STEFANO PIRANDOLA (Presenter), RICCARDO LAURENZI, COSMO LUPO, University of York — What is the ultimate performance for discriminating two arbitrary quantum channels acting on a finite-dimensional Hilbert space? Here we address this basic question by deriving a general and fundamental lower bound. More precisely, we investigate the symmetric discrimination of two arbitrary qudit channels by means of the most general protocols based on adaptive (feedback-assisted) quantum operations. In this general scenario, we first show how port-based teleportation can be used to completely simplify these adaptive protocols into a much simpler non-adaptive form, designing a new form of teleportation stretching. Then, we prove that the minimum error probability affecting the channel discrimination cannot beat a bound determined by the Choi matrices of the channels, establishing an ultimate and elegant formula for quantum hypothesis testing. As a consequence of this bound, we derive the ultimate limits for adaptive quantum illumination and single-photon quantum optical resolution. Finally, we show how the methodology can also be applied to other tasks, such as quantum metrology, quantum communication and secret key generation.

*This work is supported by the EPSRC via the `UK Quantum Communications Hub' (EP/M013472/1) and by the Innovation Fund Denmark (Qubiz project).

2:42PM P27.00002: Quantum Dimension Witness and Assisted Quantum State Discrimination* UMAN KHALID (Presenter), YOUNGMIN JEONG, HYUNDONG SHIN, Department of Electronic Engineering, KyungHee University, Korea — The relevance between quantum information processing tasks such as witnessing the dimension of an unknown quantum system and quantum state discrimination is indebted to the statistics obtained from the quantum measurement. A quantum dimension witness (QDW) provides a lower bound on the minimum dimensions that are necessary to describe the quantum correlation originated from the measurements on an unknown quantum system. Such measurement-based quantum correlations (MbQCs) are not only observer dependent but also depend on how strongly an observer perturbs the unobserved system. Based on the aforementioned measurement scenario, we present a quantitative measure that is both the QDW and MbQC measure for arbitrary dimensional bipartite quantum systems. The quantitative measure serves well for bipartite mixed quantum systems and vanishes only for a non-quantum system. We also show that MbQCs are more general than traditional quantum correlations in an optimal assisted quantum state discrimination task.

2:54PM P27.00003: Fidelity estimation via local measurements in the presence of arbitrarily correlated noise LIANGZHONG RUAN (Presenter), STEPHANIE WEHNER, QuTech, Delft University of Technology — Fidelity estimation for entangled states shared by remote nodes is an essential building block for the quality control in quantum networks. In the literature, the issue of minimizing the efficiency loss in fidelity estimation due to the limitation of local operations and the issue of characterizing the accuracy of fidelity estimation protocols in the presence of arbitrary noise remain interesting challenges. This work addresses these two challenges, designs a protocol for estimating the average fidelity of qubit pairs shared by remote agents, whose efficiency reaches the fundamental upper bound achievable with local operations, and characterizes the performance of the proposed protocol in the presence of arbitrary noise. Analysis has been performed to characterize which factors affect the estimation accuracy and how. Numerical tests have been performed to check the preciseness and robustness of the proposed protocol, as well as to characterize the proper parameter setting. The analysis and numerical tests have identified the distinctive factors that affect the estimation accuracy in the presence of arbitrary noise, and have given clear instructions on how to properly address these factors.

3:06PM P27.00004: Effective Hamiltonian theory of the geometric evolution of quantum systems* VLADYSLAV SHKOLNYKOV (Presenter), GUIDO BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — We present an effective Hamiltonian description of the quantum dynamics of a generalized Lambda system undergoing adiabatic evolution [1]. We assume the system to be initialized in the dark subspace and show that its holonomic evolution can be viewed as a conventional Hamiltonian dynamics in an appropriately chosen extended Hilbert space. In contrast to the existing approaches, our method does not require the calculation of the non-Abelian Berry connection and can be applied without any parametrization of the dark subspace, which becomes a challenging problem with increasing system size.

*We acknowledge funding from DFG through SFB767.
3:18PM P27.00005: Dense Measurements for Gate-Model Quantum Computers* LASZLO GYONGYOSI (Presenter), University of Southampton, SANDOR IMRE, Budapest Univ. of Tech — The measurement procedure is a fundamental cornerstone of gate-model quantum computers. The main issues in current quantum measurement strategies are the high number of measurement rounds to determine a global optimal measurement output and the low success probability of finding a global optimal measurement output. Each measurement round requires preparing the quantum system and applying quantum operations and measurements with high-precision control in the physical layer. These issues result in high-cost measurements with a low probability of success. Here, we define a novel measurement for gate-model quantum computers called dense quantum measurement. The dense measurement strategy aims at fixing the main drawbacks of standard quantum measurements by achieving a significant reduction in the number of necessary measurement rounds and by radically improving the success probabilities of finding global optimal outputs. We provide application scenarios for quantum circuits with arbitrary unitary sequences. The dense measurement also provides an experimentally implementable solution for practical quantum computations.

3:30PM P27.00006: Why the Quantum WILLIAM STUCKEY (Presenter), Physics, Elizabethtown College — To answer Wheeler’s question `Why the quantum?` via quantum information theory per Bub, one must explain why the world is quantum rather than classical and why the world is quantum rather than superquantum, i.e., `Why the Tsirelson bound?` We show that the quantum correlations resulting from two Bell basis states, which uniquely produce the Tsirelson bound for the Clauser-Horne-Shimony-Holt quantity, can be derived from the conservation of angular momentum (on average) for the quantum exchange of momentum. This explanation of the Tsirelson bound does not require hidden variables or `causal influences`. Since superquantum correlations exceed quantum correlations, we know that they would violate conservation of angular momentum and we show how this happens using the Popescu-Rohrlich correlations. Thus, quantum correlations responsible for the Tsirelson bound satisfy conservation of angular momentum for the quantum exchange of momentum while both classical and superquantum correlations can fail to satisfy this constraint. We generalize the result to conservation per any measurement associated with a Bell basis state. While this constraint is not surprising per se, the details on how it obtains evidence a deeper principle at work in Nature, i.e., no preferred reference frame.

3:42PM P27.00007: Wavefunction; The Guided Energy of Wave DESMOND AGBOLADE ADEMOLA (Presenter), Physics, Olabisi Onabanjo University — This paper expound the true nature of wavefunction and answered questions that arise from quantum foundation such as what is nature of wavefunction? Is mathematical formalism of wavefunction correct? Does wavefunction collapse during measurement? Do quantum physical entanglement and many world interpretations really exist? In addition, is there uncertainty in the physical reality of our nature as being concluded in the quantum foundation? The fundamental analysis presented in this work show that mathematical formalism of wavefunction was wrongly formulated. Because, we discovered that, wavefunction is the guided energy of wave by the reason that the universe and everything in it from large particle to the smallest tiny particle, physical and imaginary, visible and invisible, existing and non-existing has guided energy which is wavefunction. We further show that wavefunction is not collapse, only disengaged and engaged gradually. The gradual process of wavefunction disengagement display how the particle-like behavior return to wave-like behavior and the gradual process of wavefunction engagement also display how wave-like behavior return to the particle-like behavior. Convergence and divergence of wavefunction exhibit precise position of a particle and wave amplitude respectively.

3:54PM P27.00008: Quaternion Series Spin DOUGLAS SWEETSER (Presenter), Quaternions.com of Acton, MA — Abstract

Quantum mechanics today uses a complex-valued Hilbert vector space for its mathematical substructure. Quaternion series quantum mechanics is an effort to replace every complex number with a quaternion. Each quaternion can represent physical quantitat such as events in space-time, 4-potentials, energy-momentum, 4-currents, etc.. A series of quaternions is a vector. One can multiply quaternion series together because the quaternion series are a semigroup with inverses. This may of limited utility given the key role of unitarity to quantum mechanics.

The intrinsic spin of a particle can be described by a quaternion series with two state dimensions. The spin operator is often characterized as one quaternion. With quaternion series quantum mechanics, spin operators are 2x2 matrices of quaternions, so four simple quaternions in all (zero, plus one, and negative one, normalized is one possible representation). Much effort is devoted to understanding the operators. If one instead examines what a spin operator does to a spin state, there is a simple message: spin operators can mix information found in a spin state in every possible way.
4:18PM P27.00010: Entropic Energy-Time Uncertainty Relation† PATRICK J COLES, Theoretical Division, Los Alamos National Laboratory, VISHAL KATARIYA (Presenter), Department of Physics and Astronomy and Center for Computation and Technology, Louisiana State University, SETH LLOYD, Dept. of Mechanical Engineering and Research Laboratory of Electronics, Massachusetts Institute of Technology, IMAN MARVIAN, Departments of Physics & Electrical and Computer Engineering, Duke University, MARK M WILDE, Department of Physics and Astronomy and Center for Computation and Technology, Louisiana State University — Energy-time uncertainty plays an important role in quantum foundations and technologies, and it was even discussed by the founders of quantum mechanics. However, standard approaches (e.g., Robertson’s uncertainty relation) do not apply to energy-time uncertainty because, in general, there is no Hermitian operator associated with time. Following previous approaches, we quantify time uncertainty by how well one can read off the time from a quantum clock. We then use entropy to quantify the information-theoretic distinguishability of the various time states of the clock. Our main result is an entropic energy-time uncertainty relation for general time-independent Hamiltonians, stated for both the discrete-time and continuous-time cases. Our uncertainty relation is strong, in the sense that it allows for a quantum memory to help reduce the uncertainty, and this formulation leads us to reinterpret it as a bound on the relative entropy of asymmetry. Due to the operational relevance of entropy, we anticipate that our uncertainty relation will have information-processing applications.

*The authors would like to thank the following funding agencies: LANL ASC Beyond Moore's Law Project, Dept. of P&A, LSU, IARPA QEO Program, NSF, ARO Blue Sky Initiative, and NSF grant no. 1714215 respectively.

4:30PM P27.00011: Duality and free energy analyticity bounds for few-body Ising models with extensive homology rank† YI JIANG (Presenter), Department of Physics & Astronomy, University of California, Riverside, ILYA DUMER, Department of Electrical Engineering, University of California, Riverside, ALEXEY KOVALEV, Department of Physics & Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, LEONID PRYADKO, Department of Physics & Astronomy, University of California, Riverside — We consider pairs of few-body Ising models such that each model can be obtained from the dual of the other after freezing \( k \) spins on large-degree sites. Such a pair of Ising models can be interpreted as a two-chain complex with \( k \) being the rank of the first homology group. Our focus is on the case where \( k \) is extensive. In the presence of bond disorder, we prove the existence of a low-\( T \) weak-disorder region where additional summation over the defects has no effect on the free energy density \( f(T) \) in the thermodynamical limit, and of a high-\( T \) region where in the ferromagnetic case an extensive homological defect does not affect \( f(T) \). We also discuss the convergence of the high- and low-temperature series for the free energy density, prove the analyticity of \( f(T) \) at high and low temperatures, and construct inequalities for the critical point(s) where analyticity is lost. As an application, we prove multiplicity of the conventionally defined critical points for Ising models on all \( \{ f, d \} \) tilings of the infinite hyperbolic plane. For these infinite graphs, we show that critical temperatures with free and wired boundary conditions differ, \( T_c^{(f)} < T_c^{(w)} \).

4:42PM P27.00012: Complexity phase transition in interacting and long-range bosonic Hamiltonians NISHAD MASKARA, Department of Physics, Caltech, ABHINAV DESHPANDE (Presenter), CONG MINH TRAN, BILL FEFFERMAN, Joint Center for Quantum Information and Computer Science, MICHAEL FOSS-FEIG, Army Research Laboratory, ALEXEY V GORSHKOV, Joint Center for Quantum Information and Computer Science — We investigate the complexity of sampling from time-evolved states due to bosonic Hamiltonians. We obtain timescales for which approximate sampling is easy and hard, generalising the results in Ref. [1] to systems with interacting bosons and to systems with long-range couplings. The easiness results rely on recent developments in the simulation of spatially local Hamiltonians [2,3]. For free bosons with long-range hops, where the strength of the hopping term decays with distance as a power law, we observe the hardness setting in earlier than the nearest-neighbor case. We also obtain hardness results for interacting bosons. Along the way, we develop methods and tools that are of independent interest. Our work maps out the timescale between easiness and hardness of sampling on a “complexity phase diagram”, giving a testbed for exploring physical manifestations of the computational complexity of simulating interacting quantum systems.

4:54PM P27.00013: Unitary designs for continuous variable systems* THOMAS SCHUSTER (Presenter), QUNTAO ZHUANG, University of California, Berkeley, BENI YOSHIDA, Perimeter Institute for Theoretical Physics, NORMAN YAO, University of California, Berkeley — The study of information scrambling in many-body systems has sharpened our understanding of quantum chaos. In discrete variable (DV) systems (finite-dimensional, e.g. spins), the scrambling ‘strength’ of a unitary is often measured by its closeness to a Haar random unitary. This leads to a hierarchy of increasingly fine-grained measures of scrambling known as ‘unitary k-designs’. Here, we extend the notion of unitary designs to continuous variable (CV) systems (infinite-dimensional, e.g. photons). Although there is no generalization of Haar randomness to CV systems, we show that averages of physical quantities over Haar random unitaries remain well-defined in the CV limit, and use this to define CV unitary designs. Surprisingly, Gaussian unitaries, despite being non-interacting, form a CV 2-design and can therefore `quasi-scramble' information. Extending further, we show that unitary 4-designs maximize the phase space volume of generic time-evolved operators.

*DOE, NSF, Government of Canada.

5:06PM P27.00014: Scrambling and complexity in phase space* QUNTAO ZHUANG (Presenter), THOMAS SCHUSTER, Department of Physics, University of California, Berkeley, California 94720, USA, BENI YOSHIDA, Perimeter Institute for Theoretical Physics, Waterloo, Ontario N2L 2Y5, Canada, NORMAN YAO, Department of Physics, University of California, Berkeley, California 94720, USA — In this talk, we will describe extensions of the study of scrambling and complexity to infinite-dimensional continuous variable (CV) systems. Unlike their discrete variable (DV) cousins, continuous variable systems exhibit two complementary domains of information scrambling: 1) scrambling in the phase space of a single mode and 2) scrambling across multiple modes. Moreover, for each of these domains, we identify two distinct "types" of scrambling: strict scrambling, where an initial operator localized in phase space spreads out and quasi-scrambling, where a local ensemble of operators distorts but the overall phase space volume remains fixed. To characterize these behaviors, we introduce a CV out-of-time-order correlator (OTOC) based upon displacement operators, which can be experimentally measured. By studying operator spreading and entanglement formation in a random local Gaussian circuit ensemble, we infer the dynamics of generic, chaotic, locally-interacting systems. Our work opens the door to experimentally probing phase space scrambling in CV systems, including cavity QED and quantum optics architectures.

*DOE, NSF, and Govt. of Canada.

5:18PM P27.00015: Characterizing the performance of continuous-variable Gaussian quantum gates KUNAL SHARMA (Presenter), MARK M WILDE, Louisiana State University — The required set of operations for universal continuous-variable quantum computation can be primarily be divided into two categories: Gaussian and non-Gaussian operations. Furthermore, any Gaussian operation can be decomposed as a sequence of phase-space displacements and symplectic transformations. Although Gaussian operations are ubiquitous in quantum optics, their experimental realizations are generally approximations of the ideal Gaussian unitaries. In this work, we study different performance metrics to analyze how well these experimental approximations simulate the ideal Gaussian operations. In particular, we find that none of these experimental approximations converge uniformly to the ideal Gaussian processes. However, convergence occurs in the strong sense, or if the discrimination strategy is energy bounded, then the convergence is uniform. We indicate how these energy-constrained bounds could be used for experimental implementations of these Gaussian operations in order to achieve any desired accuracy.

Session P28 DQI: Quantum Measurement and Sensing II BCEC 161 - Bradley Moores, University of Colorado, Boulder
2:30PM P28.00001: Imaging Vortex Dynamics in High-Tc Superconductors using Ensemble Nitrogen Vacancy (NV) Centers in Diamond* ADITYA MALUSARE (Presenter), SUMIRAN PUJARI, Department of Physics, Indian Institute of Technology Bombay, SHAMASHIS SENGUPTA, Centre de Sciences Nucléaires et de Sciences de la Matière (CSNSM), KASTURI SAHA, Department of Electrical Engineering, Indian Institute of Technology Bombay — Nitrogen-Vacancy (NV) centers are excellent quantum sensors due to their long spin-coherence time and ultrahigh magnetic field sensitivity. An ensemble of NVs can be used for vector magnetometry of high-Tc superconductors to investigate several processes of interest with nanometer resolution over a wide field. We study the feasibility of measuring vortex dynamics, which plays a pivotal role in understanding the mechanisms underlying superconductivity. In this work, we make a fully functional simulation of a thin-film type-II superconductor with properties similar to materials like BSCCO or YBCO and theoretically demonstrate a scheme for mapping vortices in real time. Utilizing the capabilities of the NV center as a high-speed imaging sensor, we can probe the dynamics of vortex pinning and nucleation. Effects of impurities, thermal fluctuations, varying thickness and other defects can be examined through NVs with nanometer resolution as shown in our simulations as well.

2:42PM P28.00002: Zappe Photon Upconverters for Quantum Measurements of Low-Frequency Electrical Resonators, Part I: Theory* SAPTARSHI CHAUDHURI (Presenter), Stanford University, HSIAO-MEI CHO, SLAC National Accelerator Laboratory, CARL DAWSON, Stanford University, PETER W. GRAHAM, Stanford Institute for Theoretical Physics, RACHEL GRUENKE, STEPHEN KUENSTNER, Stanford University, DALE LI, SLAC National Accelerator Laboratory, ARRAN TJ PHIPPS, CHARLES TITUS, Stanford University, BETTY YOUNG, Santa Clara University, CYNDIA YU, KENT DAVID IRWIN, Stanford University — We present the Zappe Photon Upconverter (ZPU), a Josephson-junction-based readout amplifier for performing quantum measurements on lumped-element LC resonators (100 Hz-300 MHz). The ZPU exploits the symmetries of a three-junction Zappe interferometer embedded inside a microwave resonator. The Zappe element acts as a flux-variable inductor, cleanly implementing a three-wave-mixing interaction between the low-frequency resonator at the flux input and the high-frequency (~6 GHz) microwave resonator. The interaction is analogous to the interaction between resonators in electromechanical and optomechanical systems. We establish protocols for flux sensing at the Standard Quantum Limit (SQL), as well as backaction evasion techniques that permit measurements below the SQL. We discuss applications of ZPUs, in particular axion dark matter searches, where these devices can enable scan rate enhancements of orders of magnitude.

*The authors would like to acknowledge the support of the Department of Energy's Quantum Information Science Enabled Discovery (QuantISED) program.

2:54PM P28.00003: Zappe Photon Upconverters for Quantum Measurements of Low-Frequency Electrical Resonators, Part II: Implementation of the Prototype* STEPHEN KUENSTNER (Presenter), SAPTARSHI CHAUDHURI, Stanford University, HSIAO-MEI CHO, SLAC National Accelerator Laboratory, CARL DAWSON, Stanford University, PETER W. GRAHAM, Stanford Institute for Theoretical Physics, RACHEL GRUENKE, Stanford University, DALE LI, SLAC National Accelerator Laboratory, ARRAN TJ PHIPPS, CHARLES TITUS, Stanford University, BETTY YOUNG, Santa Clara University, CYNDIA YU, KENT DAVID IRWIN, Stanford University — We describe progress towards the first Zappe Photon Upconverter (ZPU), a Josephson-junction-based device capable of performing quantum mechanical readout protocols on low-frequency, lumped-element electromagnetic resonators. The prototype ZPU is being constructed using techniques similar to those used in superconducting transmon qubits, where the Josephson device is connected to a lithographed antenna immersed in the electromagnetic field of a three-dimensional microwave cavity. We describe the constraints on the circuit design and propose targets for the component values. We also present measurements of the quality factor of the superconducting microwave cavity designed for use with the first-generation ZPU, numerical modeling of the circuit parameters, and projections of the sensitivity enhancement available from backaction evading measurements using a prototype ZPU.

*The authors would like to acknowledge the support of the Department of Energy's Quantum Information Science Enabled Discovery (QuantISED) program.
3:06PM P28.00004: Optical sensing of biological processes with nitrogen-vacancy centers in nanodiamonds

CHANGHAO LI (Presenter), Research Laboratory of Electronics and Department of Nuclear Science and Engineering, Massachusetts Institute of Technology, DOMINIKA LYZWA, Research Laboratory of Electronics, Massachusetts Institute of Technology, MOHAMMAD KOHANDEL, Department of Applied Mathematics, University of Waterloo, PAOLA CAPPELLARO, Research Laboratory of Electronics and Department of Nuclear Science and Engineering, Massachusetts Institute of Technology — Nitrogen-vacancy (NV) centers in nanodiamonds are very attractive probes for sensing chemical reactions and biological processes. Their relaxation times are especially sensitive to the surrounding environment and can be probed with an all-optical protocol. To induce strong variations in the relaxation, the nanodiamonds can be brought in proximity to Gadolinium (Gd) ions which are strongly paramagnetic and can effectively quench the NV relaxation time. By optically monitoring the relaxation, it is possible to observe chemical and biological processes that affect the distance between Gd and nanodiamond. Here we first directly cover the nanodiamonds with chelated Gd and characterize the quenching effect for different Gd concentrations on an ensemble of nanodiamonds with an average diameter of around 20 nm. We will further show how the nanodiamonds can be connected with Gd via a cleavable peptide sequence. Specific enzymes, released during apoptosis, can cut the connection thus separating NVs from Gd and decreasing the relaxation rate. The nanodiamond sensors have the potential to be used simultaneously as drug delivery probes in addition to optical sensing, hence they might allow for monitoring chemotherapy.

RAJESH PATEL (Presenter), ANGELO FRANGESKOU, GUY STIMPSON, ELEANOR NICHOLS, WILLIAM THORNLEY, BEN G BREEZE, BEN GREEN, Department of Physics, University of Warwick, Coventry, CV4 7AL, UK, SHINOBU ONODA, Takasaki Advanced Radiation Research Institute, National Institutes for Quantum and Radiological Science and Technology, Takasaki, Gunma 370-1292, Japan, JUNICHI ISOYA, Research Center for Knowledge Communities, University of Tsukuba, 1-2 Kasuga, Tsukuba, Ibaraki 305-8550, Japan., GAVIN MORLEY, Department of Physics, University of Warwick, Coventry, CV4 7AL, UK — The negatively charged nitrogen-vacancy (NV) centre in diamond is one of the most studied solid-state defects because it has spin states that can be initialised and detected optically at room temperature [1]. A key technological development is the use of an ensemble of these defects for applications in high sensitivity magnetometry [2] which may lead to the development of medical devices for techniques such as magnetocardiography [3]. We present a fiber-coupled system which aims to detect the magnetic fields produced by electrical currents in the heart.

*We gratefully acknowledge the funding provided by the Engineering and Physical Sciences Research Council and the Royal Society of the United Kingdom.

3:30PM P28.00006: Dopant-Free Single Electron Pumps for Quantum Metrology

FRANCOIS SFIGAKIS (Presenter), BRANDON BUONACORSI, ARJUN SHETTY, Institute for Quantum Computing, University of Waterloo, Waterloo, Canada, CHRIS DEIMERT, ALAN TAM, HOSUNG KIM, ZBIG WASILEWSKI, Department of Electrical and Computer Engineering, University of Waterloo, Waterloo, Canada, NIELS UBBELOHDE, FRANK HOHLS, Physikalisch-Technische Bundesanstalt (PTB), Braunschweig, Germany, JONATHAN D BAUGH, Institute for Quantum Computing, University of Waterloo, Waterloo, Canada — At low temperature, we have observed low-disorder quantized conductance in quantum wires fabricated in dopant-free GaAs/AlGaAs two-dimensional electron gases (2DEG) with mobilities up to $7 \times 10^5$ cm$^2$/Vs (at $2.9 \times 10^{11}$ /cm$^2$), with a 1D subband energy level spacing that can be tuned from 1 meV to more than 5 meV on individual devices. The absence of (intentional) dopants produces an environment with ultra low disorder [1] and very little charge noise [2]. Single electron pumps [3,4] were fabricated and measured at 1 MHz, with up to 3 quantized current plateaus observed. Thus, dopant-free quantum wires provide a unique platform to investigate electron-electron interactions, and could offer a path towards single electron pumps suitable for a quantum current standard [5].

*This research was undertaken thanks in part to funding from NSERC, Defence Research and Development Canada (DRDC), the Canada First Research Excellence Fund, and the University of Waterloo's Quantum NanoFab facility.
MARK KU (Presenter), Harvard - Smithsonian Center for Astrophysics & Department of Physics, Harvard University, TONY ZHOU, Department of Physics, Harvard University & School of Engineering and Applied Sciences, Harvard University, QING LI, YOUNG JAE SHIN, JING SHI, CLAIRE BURCH, Department of Physics, Harvard University, HUILIANG ZHANG, FRANCESCO CASOLA, Harvard - Smithsonian Center for Astrophysics & Department of Physics, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, PHILIP KIM, AMIR YACOBY, Department of Physics, Harvard University & School of Engineering and Applied Sciences, Harvard University, RONALD L WALSWORTH, Harvard-Smithsonian Center for Astrophysics & Department of Physics, Harvard University & Center for Brain Science, Harvard University — Collective behavior due to strong electron-electron interactions can lead to transport resembling that of a hydrodynamic fluid. Novel flow patterns, for example parabolic velocity profile known as the Poiseuille flow, arise due to viscosity in such electron fluids. In this work, we directly observe viscous Poiseuille flow in hBN-encapsulated graphene channels via imaging the associated stray magnetic field with nitrogen-vacancy (NV) centers in diamond. With wide-field magnetic imaging, we obtain diffraction-limited 2D image of the stray field generated by current flow in a graphene device on a diamond surface. The measured current density across the channel strongly deviates from the profile of a uniform flow and instead matches that of a viscous fluid. We then employ scanning NV microscopy to image the stray field with ~50 nm resolution. As a benchmark, we demonstrate the ability to image the uniform Ohmic flow in a thin metallic wire. In the case of a graphene channel, we observe a parabolic current profile corresponding to viscous Poiseuille flow. Our measurement establishes the viscous flow of a hydrodynamic electron fluid in graphene at room temperature.

3:54PM P28.00008: Imaging the local charge environment of nitrogen-vacancy centers in diamond*  
THOMAS MITTIGA (Presenter), SATCHER HSIEH, CHONG ZU, BRYCE H KOBRIN, FRANCISCO MACHADO, PRABUDHYA BHATTACHARYYA, NICHOLAS Z RUI, ANDREY JARMOLA, SOONWON CHOI, DMITRY BUDKER, NORMAN YAO, University of California, Berkeley — Characterizing the local internal environment surrounding solid-state spin defects is crucial to harnessing them as nanoscale sensors of external fields. This is especially germane to the case of defect ensembles which can exhibit a complex interplay between interactions, internal fields and lattice strain. In this talk, we demonstrate that local electric fields dominate the magnetic resonance behavior of ensembles of nitrogen-vacancy (NV) centers in diamond at low magnetic field. We introduce a microscopic model that quantitatively captures the observed spectra for samples with NV concentrations spanning over two orders of magnitude. Motivated by this understanding, we present the implementation of a novel method for the nanoscale localization of individual charges within the diamond lattice.

*This work was supported as part of the Center for Novel Pathways to Quantum Coherence in Materials, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award #DE-AC02-05CH11231. 4:06PM P28.00009: Spatial noise filtering through new error-correcting codes for quantum sensing  
DAVID LAYDEN (Presenter), Research Laboratory of Electronics, Massachusetts Institute of Technology, SISI ZHOU, LIANG JIANG, Department of Physics, Yale University, PAOLA CAPPELLARO, Research Laboratory of Electronics, Massachusetts Institute of Technology — Quantum systems can be used to measure various quantities in their environment with high precision. Often, however, their sensitivity is limited by the decohering effects of this same environment. Dynamical decoupling schemes are widely used to filter environmental noise from signals, but their performance is limited by the spectral properties of the signal and noise at hand. Quantum error correction schemes have therefore emerged as a complementary technique without the same limitations. To date, however, they have failed to correct the dominant noise type in many quantum sensors, which couples to each qubit in a sensor in the same way as the signal. We show how quantum error correction can correct for such noise, which dynamical decoupling can only partially address. Whereas dynamical decoupling exploits temporal noise correlations in signal and noise, our scheme exploits spatial correlations. To this end, we introduce a new family of quantum error-correcting codes for sensing, which are both application- and hardware- adapted.

4:18PM P28.00010: Continuous error correction for quantum metrology  
SHENGLI PANG (Presenter), Fermilab, YI-CONG ZHENG, Tencent Quantum Lab, Tencent, TODD BRUN, University of Southern California, ANDREW N JORDAN, University of Rochester — Protecting the information in quantum metrology by quantum error correction has been studied intensively in recent years. The usual assumption in quantum error correction is that the syndrome measurements and correction operations are done frequently enough so that errors generated by the noise are correctable with high probability. Here, we analyze how the rate of continuous-time quantum error correction affects quantum metrology. We show that if the rate of error correction is finite, the Heisenberg limit in quantum metrology can only be sustained for a finite period. Moreover, in contrast to quantum metrology without noise (or with sufficiently fast quantum error correction), a longer evolution time does not always produce more information. There exists an optimal time at which the Fisher information reaches the maximum. We use the simple three-qubit bit-flip code to illustrate this result.
4:30PM P28.00011: Optical hyperpolarization in nanodiamonds: towards quantum-enhanced NMR/MRI

ASHOK AJJOY (Presenter), RAFFI NAZARYAN, XUDONG LV, KRISTINA LIU, EMANUEL DRUGA, JEFFREY A REIMER, University of California, Berkeley, CARLOS A. MERILES, Physics, CUNY, ALEXANDER PINES, University of California, Berkeley — Atom-like defect center spins in wide bandgap materials, such as Nitrogen Vacancy (NV) center spins in diamond, are compelling platforms for the optical dynamic nuclear polarization (DNP) of nuclear spins. NV electronic spins can be optically polarized at room temperature, and this polarization potentially transferred to external nuclei to hyperpolarize them to levels far in excess of Boltzmann levels. Nanodiamond powder is particularly attractive in this quest: they have large surface areas (>7m²/g for 100nm particles), and one could arrange for a close physical contact between the polarized NVs and external nuclear spins.

In this work, we produce "optically hyperpolarized nanodiamonds", obtaining high bulk $^{13}$C polarization (~1%) [1]. We develop a remarkably simple, low-field optical DNP technique that proves to be fully orientation independent [2]. Our technique also allows simple control of the hyperpolarization direction, that only depends on the direction of microwave sweeps across the electron spectrum. This paves for quantum-assisted classical NMR and MRI, allowing for vastly accelerated spectroscopy and imaging with chemical specificity.

4:42PM P28.00012: Optically hyperpolarized Nano-Diamond MRI at Room Temperature

XUDONG LV (Presenter), EMANUEL DRUGA, RAFFI NAZARYAN, TOMMY MCKNELLY, ALEXANDER PINES, ASHOK AJJOY, University of California, Berkeley, JEFFREY WALTON, University of California, Davis — Diamond nano-particles with surface functionalization nanoparticles for biomedical applications such as targeting, sub-cellular tracking, and non-toxic therapy [1]. The versatility of nano-diamond has motivated the development of new diamond-based imaging agents that will 'light up' under MRI to produce a bright field contrast image. Conventional Dynamic Nuclear Polarization mechanism which has been successfully demonstrated in diamond to hyperpolarize $^{13}$C nuclei, has to rely on high fields and cryogenic temperatures. Here we demonstrate a room temperature hyperpolarized nano-diamond $^{13}$C imaging with an enhancement of ~600 against 7T thermal polarization[2]. We were also able to achieve back ground suppression in magnetic resonance imaging with the ability of on demand controlling the sign of the hyperpolarization signal. Furthermore, combing both MRI and optical imaging of powder diamond, we present a new dual-modality nano-diamond imaging approach with orders of magnitude SNR enhancement.

4:54PM P28.00013: Environment-assisted quantum sensing with entangled electronic spins in diamond

WON KYU CALVIN SUN (Presenter), Massachusetts Institute of Technology, ALEXANDRE COOPER, California Institute of Technology, JEAN-CHRISTOPHE JASKULA, PAOLA CAPPELLARO, Massachusetts Institute of Technology — Intuitively, enlarging a quantum system by the addition of controllable qubits should only enhance—not decrease—its performance: in other words, any extra qubit should prove a resource. For quantum metrology, the transition from N=1 to N=2 qubits seems especially good for both promised improvement in sensitivity—via N-fold faster phase accumulation—and in readout—via quantum non-demolition measurements. This transition is further motivated in solid-state spin systems that inevitably host a decohering spin bath: its partial conversion into resources simultaneously reduces its size. Thus, utilizing a single nitrogen-vacancy (NV) center and a nearby electron spin (X) in diamond, we explore this question by comparing the performance of N=1 (NV) and N=2 (NV + X) register in ac magnetometry. We find experimentally the ostensible benefits of the resource can be overshadowed by its very cost: namely the increased complexity to perform the same task—resulting in decreased control fidelity and duty cycle—and sensitivity to noise—resulting in decreased dynamic range. We analytically confirm these results and find a parameter space in which the bath qubit will prove a resource. Extending this work for few-qubit algorithms should aid designs of small-scale registers with a quantum advantage.
5:06PM P28.00014: Nanoscale mechanical sensing at ambient conditions*  CHUFENG LIU (Presenter), KANGWEI XIA, WENG HANG LEONG, ZHIYUAN YANG, QUAN LI, REN-BAO LIU, Physics, The Chinese University of Hong Kong — Negative charge nitrogen vacancy center in diamond (NV center) has attracted huge interest due to its unique spin properties even at room temperature. Its spin state could be optically addressed, manipulated and readout with excellent photo stability. Meanwhile, NV center is sensitive to many parameters, such as magnetic field, strain, and temperature, which opens up many applications ranging from magnetometry, temperature sensing to nanoscale NMR spectroscopy. In this talk we will discuss the application of diamond NV centers in nanoscale mechanical sensing at ambient conditions.

*This work was supported by RGC/CRF C4006-17G and CUHK group research scheme

5:18PM P28.00015: Nanoscale mechanical sensing in aqueous solutions* KANGWEI XIA (Presenter), CHUFENG LIU, WENG HANG LEONG, MAN-HIN KWOK, REN-BAO LIU, QUAN LI, Department of Physics, The Chinese University of Hong Kong — Negatively charged NV- center is optically active, and photo-stable. It shows unique properties that the electron and nuclear spins of NV centers can be optically initialized, coherently manipulated and optically readout in ambient conditions. Meanwhile NV centers are also sensitivity to the surrounding environments. The varying of the local magnetic field, electric field, temperature and strain will affect the performance of the NV centers. Thus, they can be explored as magnetic, electric, temperature and strain sensor in extreme precision with nanometer spatial resolution, with many applications ranging from magnetometry, temperature sensing to nanoscale NMR spectroscopy. In this talk we will discuss the application of diamond NV centers in nanoscale mechanical sensing in aqueous solutions.

*This work was supported by RGC/CRF C4006-17G and CUHK group research scheme.

Wednesday, March 6, 2019 2:30 PM - 5:30 PM

Session P29 DQI: Semiconducting QC Architectures and Quantum Photonics BCEC 162A - Samuel Carter, United States Naval Research Laboratory - Tag(s): Focus

2:30PM P29.00001: Full 300mm fin based QD device characterization HUBERT C GEORGE (Presenter), NICOLE THOMAS, RAVI PILLARISETTY, LESTER LAMPERT, THOMAS WATSON, JEANETTE MARIE ROBERTS, STEPHANIE BOJARSKI, PAYAM AMIN, JESSICA TORRES, MATTHEW METZ, Components Research, Intel Corporation, GUOJI ZHENG, ANNE-MARIJE ZWERVER, JELMER BOTER, JUAN PABLO DEHOLLAIN, GERTJAN EENINK, LEONARDO MASSA, DIEGO SABBAGH, NODAR SAMKHARADZE, CHRISTIAN VOLK, BRIAN PAQUELET WÜTZ, MENNO VELDHORST, GIORDANO SCAPPUCI, LIEVEN VANDERSYPEN, QuTech and Kavli Institute of Nanoscience, TU Delft, JIM CLARKE, Components Research, Intel Corporation — Intel's efforts towards the fabrication of spin qubit devices have required a comprehensive device characterization, from transistors and quantum dots, to qubits, which have been co-fabricated in the same die/wafer. In this talk, we will present an in-depth device characterization, and the results from quantum dot devices manufactured in a full 300mm line. We will give details of the fin based process flow which yields high charging energy devices. The extraction of QD related figures of merit from room and low temperature testing (1.6K) are part of the method to rapidly screen 300mm wafers with thousands of devices which are used to determine the spin qubit devices that will be taken to the milli-kelvin measurements; keeping up with the pace of the 300mm fab output.

2110 of 3305
2:42PM P29.00002: Simulating Nagaoka Ferromagnetism in a 2×2 Quantum Dot Array
UDITENDU MUKHOPADHYAY (Presenter), JUAN PABLO DEHOLLAIN, VINCENT P. MICHAL, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, CHRISTIAN REICHL, WERNER WEGSCHEIDER, Solid State Physics Laboratory, ETH Zurich, BERNHARD WUNSCH, Department of Physics, Harvard University, MARK RUDNER, Niels Bohr International Academy, University of Copenhagen, EUGENE DEMLER, Department of Physics, Harvard University, LIEVEN VANDERSYPEN, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — The Fermi-Hubbard model provides a description of interacting electrons in a lattice. The interaction between electrons in arrays of electrostatically defined quantum dots is naturally described by a Fermi-Hubbard Hamiltonian; moreover, the high-degree of tunability in these systems make them a perfect platform to explore different regimes of the Hubbard model through analogue quantum simulations1.

Last year we established a 2x2 gate-defined quantum dot array as a promising solid-state analogue quantum simulator2. Here we present results on simulation of Nagaoka Ferromagnetism in this system. We experimentally observe a ferromagnetic ground state in an almost-half-filled lattice, as predicted3. We use the high-levels of control in our system to manipulate the Hamiltonian parameters and perform measurements that test the validity of our observations. For example, breaking the periodic boundary condition gets rid of the ferromagnetic ground state altogether. To our knowledge, this is the first experimental verification of Nagaoka's prediction as well as the first simulation of magnetism using quantum dot arrays.

2:54PM P29.00003: Coherent control of individual electron spins in a two-dimensional array of tunnel coupled quantum dots* 
[Invited] TRISTAN MEUNIER (Presenter), CNRS Institut Néel — Controlling nanocircuits at the single electron spin level in quantum dot arrays is at the heart of any scalable spin-based quantum information platform. The cumulated efforts to finely control individual electron spins in linear arrays of tunnel coupled quantum dots have permitted the recent coherent control of multi-electron spins and the realization of quantum simulators. However, the two-dimensional scaling of such control is a crucial requirement for simulating complex quantum matter and for efficient quantum information processing, and remains up to now a challenge.

Here we demonstrate such two-dimensional coherent control using individual electron spins in arrays up to 9 tunnel-coupled lateral quantum dots. Two-electron spin initialization, spin readout and spin transfer enable exploration of the spin dynamics in the QDs array. We demonstrate a procedure that permits local enhancement of the tunnel coupling between two dots of the array up to a range where coherent exchange oscillations, the basis of the two-qubit gates for electron spin qubits, are observed. Taking advantage of the tunability of the structure, we finally realize complex and multi-directional displacements of one and two electrons through quantum dot arrays. This work demonstrates key quantum functionalities, crucial for using two-dimensional quantum dot arrays for quantum simulation and computation.

3:30PM P29.00004: A large-scale single-photon source and spin qubit arrays in a photonic integrated chip* NOEL WAN (Presenter), TSUNG-JU LU, KEVIN CHEN, MATTHEW TRUSHEIM, LORENZO DE SANTIS, MICHAEL WALSH, ERIC BERSIN, SARA MOURADIAN, Massachusetts Institute of Technology, EDWARD S BIELEJEC, Sandia National Laboratories, DIRK R. ENGLUND, Massachusetts Institute of Technology — Single-photon sources are essential components in a variety of optical quantum technologies. We demonstrate a large array of single-photon sources and spin qubits on a single photonic chip. Our single-photon source array is composed of color centers in a monolithic diamond nanophotonic structure that is efficiently coupled to a photonic integrated circuit. Additionally, the long-lived spin states of color centers in diamond may serve as quantum memories in a repeater network.

*We acknowledge funding support from the National Science Foundation and the Army Research Laboratory Center for Distributed Quantum Information.
3:42PM P29.00005: On-chip Integrable Spectrally Uniform Ordered Quantum Dot Single Photon Source Array with High Emission Purity (>98.99%) for Scalable Quantum Optical Networks* JIEFEI ZHANG (Presenter), SWARNABHA CHATTARAJ, University of Southern California, SIYUAN LU, IBM Thomas J. Watson Research Center, ANUPAM MADHUKAR, University of Southern California — Towards the goal of building scalable on-chip optical networks we have proposed a new paradigm that integrates an array of mesa top single quantum dot (MTSQD) single photon sources (SPSs) with dielectric light manipulating units (LMUs) [1]. We demonstrated InGaAs/GaAs MTSQDs in 5x8 array [1] showing remarkably improved spectral uniformity than the typically studied self-assembled island QDs but, more importantly, several pairs of MTSQDs exhibit emission wavelengths within 300μeV, the instrument resolution [2]. The measured single photon emission purity was thus limited to 90% at 9K. In this talk we report studies with improved high resolution of ~10μeV demonstrating single photon emission purity > 98.99% (g(2)(0)<0.02) in these MTSQDs at 9.4K. The MTSQD neutral exciton's intrinsic linewidth and fine structure splitting are found to be ~10µeV and <10µeV, respectively. The results highlight the potential of the spatially-ordered MTSQDs-LMU integrated system for realizing quantum optical circuits[3]. Work on examining photon indistinguishability and coherence is underway.

3:54PM P29.00006: Tuning Photonic Crystal Cavity Resonances with Phase Change Material GeTe* JEROME THOMAS MLACK (Presenter), NRC Research Associate at the Naval Research Laboratory, ALLAN S BRACKER, JOEL Q GRIM, SAMUEL CARTER, U. S. Naval Research Laboratory, MIJIN KIM, KeyW Corporation, CHUL SOO KIM, MICHAEL K YAKES, U. S. Naval Research Laboratory, BUMSU LEE, NRC Research Associate at the Naval Research Laboratory, DANIEL G GAMMON, U. S. Naval Research Laboratory — Photonic crystal slabs are a promising architecture for a variety of computational and sensor architectures including quantum computers and neuromorphic networks. Such devices consist of a 2-D membrane of cavities and waveguides with embedded quantum dots (QDs). While many advances such as demonstrations of indistinguishable single photon sources and quantum entanglement have been shown, such devices are still difficult to scale as a network. The primary limitations are from natural variations during material growth and device fabrication, which cause resonances of the QDs and cavities to span energies much larger than their linewidths. One solution is to use capping layers which can tune the underlying device, changing properties such as strain and effective index of refraction, and whose structural phase can be locally altered using laser annealing, potentially allowing for local tuning of QDs or cavities. We show results of using thin films of such a phase change material, GeTe, to tune cavity resonances independent of local QDs in such devices. This tuning is dependent on the original resonance energy of the cavity and the amount of material deposited.

*JTM and BL are funded via the NRC Research Associate program. This project was funded via the Office of Naval Research.

4:06PM P29.00007: Integrated Quantum Networks of Mie-resonance based All-Dielectric Optical Circuits with Single Photon Sources for Quantum Entanglement* SWARNABHA CHATTARAJ (Presenter), Ming Hsieh Department of Electrical Engineering, University of Southern California, JIEFEI ZHANG, Mork Family Department of Chemical Engineering and Materials Science, University of Southern California, SIYUAN LU, IBM Thomas J. Watson Research Center, Yorktown Heights, ANUPAM MADHUKAR, Mork Family Department of Chemical Engineering and Materials Science, University of Southern California — Recently we introduced [1] a new approach to on-chip optical circuits based on subwavelength scale dielectric building blocks (DBBs) metastructures integrated with single photon sources (SPSs) such as the mesa-top single quantum dot (MTSQD) ordered array [1] in which a single collective Mie resonance of the DBB metastructure provides all needed five light manipulating functions [2]: (1) SPS emission rate enhancement, (2) emission directionality, (3) wave-guiding (4) beam-splitting and (4) beam-combining. The simulations reported were for spherical DBBs as it enables analytical calculations [1]. The lithographic fabrication of such structures will have rectangular DBBs and thus in this talk we present the design and simulation of networks of rectangular DBBs, co-designed for monolithic integration with GaAs/InGaAs MTSQD SPS arrays such that every MTSQD is coupled to the same single collective mode of the network. Finite element based simulation results for such networks with coupled SPSs will be presented that suggest quantum effects such as path-entanglement and super-radiance- constituting a step towards quantum information processing.

*This work is funded by ARO, Grant#W911NF-15-1-0298.
4:18PM P29.00008: Optical locking of a quantum dot electron spin qubit  JONATHAN BODEY (Presenter), CLAIRE LE GALL, ROBERT STOCKILL, DORIAN GANLOFF, GABRIEL ETHERI-MAJCHER, METE ATATURE, University of Cambridge — InGaAs quantum dots (QDs) can function as solid state quantum network nodes, offering a field-leading interface between a single spin and an optical mode [1]. Exploiting this interface requires complete control of a QD spin, to tailor spin-photon entanglement in such a network. Whilst the rotations offered by the current state of the art are highly coherent [2], full SU(2) control relies on varying delays between sequential pulses, limiting the scheme to simple few-gate sequences. Spectral splitting of a laser into two sidebands through modulation allows us to resonantly address a Raman transition between the two ground states of a spin in our QD. This all-optical scheme gives direct access to the phase and frequency of the field linking our states, releasing us from the need for well-defined sequence delays. We use Rabi oscillations and Ramsey interferometry to demonstrate complete control of our Rabi vector. This enables us to perform spin-locking, protecting our qubit state for longer than the homogeneous dephasing time and allowing high-fidelity gates on this timescale. Our work represents versatile spin control and provides a way towards on-chip all-optical spin manipulation.

4:30PM P29.00009: 4H-SiC-on-Insulator Platform for Quantum Photonics with Color Centers*  DANIIL LUKIN (Presenter), CONSTANTIN DORY, MARINA RADULASKI, SHUO SUN, DRIES VERCRUYSSE, JELENA VUCKOVIC, Stanford University — Defects in Silicon Carbide (SiC) are considered for quantum photonics applications because of their favorable spin coherence properties and optical emission wavelengths. To aid integration of these defects into nanophotonic structures, we develop a 4H-SiC-on-insulator platform based on bonding and thinning techniques. The process results in 4H-SiC films of pristine crystal quality with no radiative defects in the 800 - 1000 nm wavelength range. Color centers are readily introduced via irradiation. We demonstrate 4H-SiC ring resonators and photonic crystal cavities with Q ~ 10^4

4:42PM P29.00010: Scalable frequency locking of single photon sources for quantum photonic technologies*  JACQUES CAROLAN (Presenter), UTTARA CHAKRABORTY, Research Laboratory of Electronics, Massachusetts Institute of Technology, NICHOLAS C HARRIS, Lightmatter, MIHIR PANT, Research Laboratory of Electronics, Massachusetts Institute of Technology, TOM BAEHR-JONES, MICHAEL HOCHBERG, Elenion Technologies, DIRK R. ENGLUND, Research Laboratory of Electronics, Massachusetts Institute of Technology — Large-scale quantum technologies require exquisite control over many individual quantum systems. Typically, such systems are very sensitive to environmental fluctuations, and diagnosing errors via measurements causes unavoidable perturbations. Here we present an in situ frequency locking technique that monitors and corrects frequency variations in single photon sources based on microring resonators. By using the same classical laser fields required for photon generation as a probe to diagnose variations in the resonator frequency, our protocol applies feedback control to correct photon frequency errors in parallel to the optical quantum computation without disturbing the physical qubit. We implement our technique on a silicon photonic device and demonstrate feedback controlled quantum state engineering. Our approach enables frequency locking of many single photon sources for large-scale photonic quantum technologies.

Event-ready entangled photons from a solid-state single-photon source. MARCELO DE ALMEIDA (Presenter), NOR AZWA ZAKARIA, ARC Centre of Excellence for Engineered Quantum Systems, The University of Queensland, Brisbane, Australia., JUAN CARLOS LOREDO, Centre de Nanosciences et de Nanotechnologies, CNRS, Univ. Paris-Sud, Univ. Paris-Saclay, Marcoussis, France., LEONARDO ASSIS, JIHUN CHA, ARC Centre of Excellence for Engineered Quantum Systems, The University of Queensland, Brisbane, Australia. — Solid-state emitters, such as semiconductor quantum dots, are a promising platform to develop single-photon sources. Recent breakthroughs in material syntheses and fabrication processes led to a new generation of devices, combining high emission brightness with near unity indistinguishable pure single-photon output [1]. These new generation single-photos sources are staring to enable experiments with multiple indistinguishable photons [2], a key step towards large-scale optical quantum technologies.

Here we employ a quantum dot source to demonstrate a 4-qubit Type-II Fusion Entangling Gate [4]. The Type-II Fusion Gate relies on the conditional detection of two ancillary qubits to generate entanglement between the two remaining qubits. We study the performance of this entangling gate as a function of the single-photon indistinguishability. We also discuss potential applications for the Type-II fusion gate as an event-ready source entangled photons.

Lithium Niobate as a Wide Bandgap Quantum Photonics Platform* IAN CHRISTEN (Presenter), Electrical Engineering and Computer Science, Massachusetts Institute of Technology, MICHAEL MILLER, KENNETH DOUGLAS, MATT EICHENFIELD, Sandia National Laboratories, DIRK R. ENGLUND, Electrical Engineering and Computer Science, Massachusetts Institute of Technology — A robust and active photonics platform is essential for scalably-engineered photon-mediated quantum interactions. Such a platform must have sufficiently wide bandgap, as atom-like quantum systems emit dominantly into the visible spectrum. Lithium niobate is a compelling material platform satisfying these requirements: being transparent down to the UV and having a strong electrooptic nonlinearity. We examine the performance—in particular, the achievable propagation loss and the effect of photo refractive damage—of x-cut and magnesium-doped lithium niobate nanophotonic waveguides across and beyond the visible spectrum. We explore the modulation of light at wavelengths of relevance for a wide range of leading quantum memories including, in particular, diamond color centers, cold atoms, and quantum dots.

*Work funded by NSF awards EFMA-1641064, DMR-1231319, and DMR-1747426.

Optimized Quantum Photonics in Diamond* CONSTANTIN DORY (Presenter), DRIES VERCRUYSSE, KYOUL YANG, NEIL V. SAPRA, ALISON RUGAR, SHUO SUN, DANIIL LUKIN, ALEXANDER Y. PIGGOTT, JINGYUAN LINDA ZHANG, MARINA RADULASKI, KONSTANTINOS LAGOUTHAKIS, JELENA VUCKOVIC, Stanford University — Diamond hosts a variety of quantum emitters and is thus a promising material platform for applications in quantum information processing and quantum sensing. Such quantum technologies will likely operate at the level of single or few photons. Therefore, they require highly efficient integrated photonic circuits to harness the full potential of the excellent optical properties of color centers in diamond. However, state-of-the-art design and fabrication techniques for diamond devices in quantum optics strongly limit the geometry and variety of the device components. We utilize inverse design optimization and fabrication methods based on quasi-isotropic etching to significantly improve on efficiency, scalability, and functionality of diamond photonics. To showcase the significance of these advances, we solve outstanding design challenges, such as optical free space interfaces and improve on efficiency and scalability of diamond photonics.

Session P30 DPOLY: Polymer Networks, Gels, and Elastomers III: Architecture BCEC 162B - Ross Behling, 3M Corp. - Tag(s): Focus
2:30PM P30.00001: Relationship between optical properties and network topology in gels crosslinked using controlled radical polymerization*  MAHATI CHINTAPALLI (Presenter), STEPHEN MECKLER, GABRIEL IFTIME, JESSY B. RIVEST, PARC — Controlled radical polymerization can be used to prepare crosslinked polymer gels and aerogels with a variety of unique features: tunable optical transparency, high specific surface area, controlled pore size, and narrow pore size distribution. Such materials enable a range of applications in size- and interaction-selective separations, catalysis and photocatalysis, and thermally insulating materials. We demonstrate that controlled radical polymerization can be used to control network topology, which directly impacts the optical properties and pore structure of crosslinked polymer gels. Two novel methods to control the degree of “livingness” in the gelation reaction are reported. The degree of livingness in the gelation was used to tune the visible light transmittance of a 3 mm gel from 0 % to >70 %. Porous aerogels can be produced from the solvated gels by solvent evaporation at ambient pressure and temperature. Controlled radical gelation led to aerogels with porosities over 60 % and Brunauer Emmett Teller surface areas over 1000 m²/g.

2:42PM P30.00002: Mechanical and Thermal Performance of Interpenetrating versus Single Networks of Dynamically Crosslinked Polymers*  MEHDI ZANJANI (Presenter), BALLAL AHAMMED, Mechanical and Manufacturing Engineering, Miami University, BORUI ZHANG, DOMINIK KONKOLEWICZ, Chemistry and Biochemistry, Miami University, ZHIJIANG YE, Mechanical and Manufacturing Engineering, Miami University — Dynamically crosslinked polymer composites have received great attention in the past decade due to their unique properties such as self-healing, malleability, and shape memory. Dynamic crosslinkers of two main types, i.e. non-covalently bound crosslinkers and dynamic covalently bound crosslinkers, provide a versatile platform to engineer various types of crosslinked networks with desired properties.

Here, we report a combined computational and experimental study of two main categories of self-healing polymer composites: Interpenetrating Networks (IPNs) and Single Networks (SNs). We establish detailed models of the polymer networks by implementing a coarse-grained scheme: IPNs are modeled based on allowing one type of crosslinker per polymer chain, while SNs are modeled through random positioning of both types of crosslinkers along polymer chains. We then perform Non-equilibrium Molecular Dynamics simulations to evaluate mechanical and thermal properties of various IPN and SN systems. Our predictive models and experiments show that, in general, IPNs outperform SNs in terms of their mechanical and thermal properties provided that the overall crosslinker densities are the same within the two network types.

*We acknowledge support from NSF (DMR 1749730) and the OSC (Award PMIU0139).

2:54PM P30.00003: Influence of weak ionic associations on the mechanical properties of hydrogels crosslinked by hydrophobic associations*  BRYAN VOGT (Presenter), CHAO WANG, ROBERT A WEISS, KATHERINE DEITRICK, The University of Akron — Since the initial reports of double network hydrogels, a variety of routes to provide energy dissipation in hydrogels have been reported such as the inclusion of physical crosslinks to provide reversible crosslinks. These hydrogels based on physical crosslinks tend to creep due to the reversibility. Inclusion of a second stronger network generally has been used to reduce creep and improve the elastic recovery. Here we take the opposite approach and include weak ionic associations (zinc diacrylate) to manipulate the mechanical behavior of hydrogels formed by hydration of copolymers of hydroxyethyl acrylate (HEA) and 2-(N-ethylperfluorooctane-sulfonamido)ethyl methacrylate (FOSM). The terpolymer-based hydrogel contained >85% of the water of a HEA-FOSM copolymer hydrogel with the same FOSM content, but the storage modulus was nearly an order of magnitude larger for the terpolymer hydrogel. To obtain the same storage modulus, the FOSM content would need to be more than doubled, but this HEA-FOSM copolymer-based hydrogel has almost 40 % less water than the terpolymer hydrogel. These results illustrate the ability to tune the mechanical response of hydrogels through weak ionic associations.

*This work was supported by NSF-DMR 1659531 and NSF-CBET 1606685
This talk will highlight two distinct reversible covalent crosslinking mechanisms, namely the reversible addition and reversible exchange mechanisms, leading to distinctly different mechanical responses. The incorporation of reversible addition crosslinks into the network, such as a Diels–Alder (DA) reaction, enables one to explore the properties related to conversion, such percolation near the gel point. Furthermore, external triggering of reversible gelation in a DA–ferromagnetic nanoparticle polymer composite is demonstrated using an AC field. The incorporation of reversible exchange moieties, such as an allyl sulfide, enables light-triggered network connectivity shuffling. Additional functionality within the network provides a mechanism for photo-directed materials strengthening, exhibiting a local increase in the modulus and also enabling simultaneous healing in fractured materials. Finally, the shape of the elastomer can be manipulated and locked into place via irradiation, providing a route to engineer wrinkled topography for lens and sensors to surface functionalization for coatings.

This gel consists of collapsed PS endblock aggregates acting as crosslinks, while PI midblocks bridge those aggregates. The gel architecture, as captured by the small angle x-ray scattering, is tuned by varying the polymer volume fraction and midblock length. Tensile experiments reveal a rate dependent mechanical properties, particularly for the samples with entangled midblocks. Energy release rate (G) for fracture scales linearly with the crack-tip velocity (v) indicating a velocity toughening effect in these gels. The G-v relationship strongly depends on the polymer concentration and chain length. These gels fail as a result of endblocks pullout from aggregates. The pullout process involves an entropic penalty associated with the midblock stretching, friction with other endblocks in aggregates, and an enthalpic penalty associated with pulling the endblocks in the non-favorable solvent. We attempt to incorporate all these factors in estimating G and compare that with the experimental values.

### 3:54PM P30.00006: Modelling of chemo-mechanical coupling in polymer gels via nonlinear finite element method

PRIYANKA NEMANI (Presenter), Department of Chemical Engineering, Indian Institute of Technology Gandhinagar, RAVI SASTRI AYYAGARI, Department of Mechanical Engineering, Indian Institute of Technology Gandhinagar, PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology Gandhinagar — Design of multifunctional biomimetic materials that exhibit large amplitude actuation through chemical triggers has been a challenge in the field of smart materials. Polymer gels that utilize self-oscillating Belousov Zhabotinsky (BZ) reactions are pioneers among smart materials due to their biomimetic characteristic of chemo-mechanical transductions. Here, we present a computational framework to simulate the dynamics of self-oscillating polymer gels that undergo large deformations under isothermal conditions. Unlike earlier approaches, we harness a complete nonlinear finite element framework that combines the reaction-diffusion phenomena occurring in BZ reaction, with elastic deformations of the polymer gel. Specifically, we use three variable Oregonator model to incorporate reaction kinetics, non-Gaussian mechanical theory for elastic deformations and Flory-Huggins theory to couple the chemical kinetics with the deformation. We demonstrate that actuation capacity of self-oscillating polymer gels can be amplified and controlled by manipulating the reaction kinetics under specific conditions. We believe that our approach brings in a new perspective to design complex bio-inspired systems and provides the necessary framework to control their behaviour.

4:06PM P30.00007: Expanding Gelation Conditions in Dynamically Crosslinked Networks* SETH CAZZELL (Presenter), NIELS HOLten-ANDerSEN, Massachusetts Institute of Technology — Polymer networks with dynamic physical crosslinks have generate widespread interest as tunable and responsive viscoelastic materials. A subclass of these materials containing multi-component, or complimentary, crosslinks, such as host-guest interactions and metal-coordination, are limited by their ability to percolate under stoichiometric imbalances of their crosslink components. Here we present a method to relax this stoichiometric requirement through the use of a third component, a dynamic, free competitor. This approach to expand the conditions that result in gelation is demonstrated experimentally with metal-coordinated hydrogels, and simulations are used to show the thermodynamic criteria that are necessary to expand the previously understood tight stoichiometric tolerance for gelation. This work can then be generally applied to advance engineering of the broadening class of polymer materials with dynamic crosslinks.

*This work was supported primarily by the MRSEC Program of the National Science Foundation under award number DMR 14-19807.

4:18PM P30.00008: Melt Blown Cross-linked Fibers from Thermally Reversible Diels-Alder Polymer Networks* KAILONG JIN (Presenter), SUNG-SOO KIM, JUN XU, FRANK BATES, CHRISTOPHER ELLISON, Chemical Engineering and Materials Science, University of Minnesota — Melt blowing is a process in which liquid polymer is extruded through orifices and then drawn by hot air jets to produce nonwoven fibers. Melt blown nonwovens constitute more than 10% of the $50 billion global nonwovens market. Thermoplastic feedstock, such as polyethylene, polypropylene, and poly(butylene terephthalate), have dominated melt blown nonwovens because of their combined cost, good chemical resistance and high-temperature performance. Cross-linked nonwovens from other commodity polymers (e.g., (meth)acrylates, styrenics, silicones, etc.) could be attractive alternatives; however, no commercial cross-linked nonwovens currently exist. Here, cross-linked fibers were produced via one-step melt blowing of thermoreversible Diels-Alder polymer networks comprised of furan- and maleimide-functional methacrylate-based polymer backbones. These dynamic networks decross-link and flow like viscous liquids under melt blowing conditions, then revert to a network via cooling-induced cross-linking during/after melt blowing. Finally, the resulting cross-linked fibers can be recycled because of their reversible dynamic nature, which may help address the microfiber pollution problem.

4:30PM P30.00009: Carefully Controlled Photo-catalyzed Thiol-ene Networks of Poly(lactic acid)* NICHOLAS BAKSH (Presenter), Mechanical Engineering, University of South Florida, RYAN TOOMEY, Chemical Engineering, University of South Florida, NATHAN GALLANT, Mechanical Engineering, University of South Florida — PLA is researched for TE scaffolds, drug delivery, implants, and environmentally safe plastics. Bulk PLA has a tensile and flexural modulus of 3.5 and 6 GPa respectively and a Rockwell hardness of 88; thus despite bioabsorbable advantages, it is weak compared to metal implants. Additionally, a uniform degradation rate, which needs to be tuned to match tissue growth and regulate drug delivery, requires minimal molecular variability. Crosslinkable PLA would not only improve mechanical properties, but offer tunability via crosslink density. Further, catalysis by cell safe light and orthogonality of crosslinkable groups allow in-vivo crosslinking, minimizing implant procedures. Bis alpha, omega –ene functionalized PLA oligomers for use with thiolene chemistry were synthesized with polydispersities around 1.3 using organic catalysts. Ordered networks were photo-catalyzed with a multi-arm thiol. End functionalities allow crosslink density to be controlled by oligomer length, and the ordered network minimizes molecular variability. Crosslinked samples prepared with the same oligomer consistently show identical characterizations as analyzed by DSC, NMR, FTIR, and nano-indentation. Lastly, stress-strain curves exhibited a singular linear elastic regime.

*NSF CMMI - 1538727

4:42PM P30.00010: Characterizing Network Structure and Protein Separation in Lignin-Based Hydrogel Composites NICHOLAS GREGORICH (Presenter), JUNHUAN DING, MARK C THIES, ERIC DAVIS, Clemson University — Lignin-based hydrogels have recently garnered attention for use in a variety of biological applications involving proteins such as protein separation and delivery as lignin is a sustainable, naturally abundant biopolymer. However, to date, the use of these materials in protein related applications has been hindered by our limited understanding of how the addition of lignin, both as a crosslinker and ‘passive’ filler, affects the network (pore) structure of the crosslinked hydrogel. In this study, lignin-poly(vinyl alcohol) composites were synthesized using lignin of controlled, narrow molecular weights (MWs), allowing for the fabrication of membranes with more homogeneous network structures. The permeability of different proteins through the hydrated composites was measured via ultraviolet-visible spectroscopy, where protein permeability was found to depend on the MW and end group functionality of the lignin. In addition, poroelastic relaxation indentation was used to characterize both the mechanical (elastic modulus) and transport properties (diffusivity, effective pore size) of the composites. Results from this study illustrate how the incorporation of well-defined lignin into hydrogel composites can be used to directly tune the properties of the resultant membrane.
Modeling reconstituted silk fibroin gels during deformation

PETER OLMSTED, PEIRAN JIN (Presenter), Georgetown University — Silk from silkworms has been used in the textile industry for thousands of years. It consists of β-sheet structures formed from hydrophobic domains in the protein fibroin. Recently, a physical electrogel (e-gel) was made by reconstituting Bombyx mori silk into stable aqueous solutions and then applying small DC electric field [Tabatabai et al, Soft Matter 11 (2015) 756]. The e-gels exhibit distinctive strain hardening and are partially recoverable from strain.

We build a coarse-grained model of fibroin protein polymers, which comprise crystallizable domains and amorphous domains. To study the structural changes and nonlinear behavior of the gel during deformation, gels are tested by shearing, oscillating and stretching. We find that the kinetics of unfolding and refolding of crystallizable domains changes the number and functionality of crosslinks in the physical network, and thus causes the strain hardening of the gel and the non-recoverable strain. This model can also be useful in other associating polymer systems.

Overcoming the Achilles' Heel of Dynamic Vitrimer Networks: Modification and Application of Flory-Stockmayer Theory to Minimize Creep

LINGQIAO LI (Presenter), JOHN TORKELSON, Northwestern University — Vitrimers are a promising class of dynamic polymer networks, but they have an Achilles' heel: above Tg, vitrimers exhibit significant creep under conditions where permanently cross-linked networks exhibit little or no creep. Vitrimers can be designed with strongly suppressed creep and excellent reprocessability by incorporating a subcritical fraction of permanent cross-links. This fraction of permanent cross-links, which has little or no effect on reprocessability, is defined by the gelation point of only permanent cross-links leading to a percolated permanent network. Modifying Flory–Stockmayer theory, we developed a simple theory that predicts an approximate limiting fraction. To test our theory, we designed vitrimers with controlled fractions of permanent cross-links. Our experiments support our theoretical prediction: when the fraction of permanent cross-links is subcritical, the vitrimer can be reprocessed with full recovery of cross-link density. In particular, with a predicted limiting fraction of 50 mol %, a vitrimer system designed with 40 mol % permanent cross-links achieved full property recovery associated with cross-link density after reprocessing and ~70% creep reduction relative to a similar vitrimer without permanent cross-links.

Defects as a Highway to Stress Relaxation of Vitrimers

SIMONE CIARELLA (Presenter), Eindhoven University of Technology, FRANCESCO SCIORTINO, Sapienza Universita’ di Roma, WOUTER ELLENBROEK, Eindhoven University of Technology — Vitrimers are a promising class of plastics made by disordered networks of polymers. They are an ideal recyclable material being both strong and malleable, because unlike common plastics, vitrimers can swap their bonds without breaking. The swap mechanism also grants them exceptionally versatile properties ranging from self-healing to responsiveness to chemical and physical stimuli. Understanding how the mechanics of vitrimers follow from such bond-swap dynamics is a key physical question that we address using a new coarse-grained MD model which captures the essence of the bond dynamics while being insensitive to other chemical details. Our results reveal a dramatic dependence of their malleability on the number of polymer chains that loop back onto themselves. This highlights the importance of choosing the right building blocks for these new materials, as choices concerning polymer architecture have immediate implications for the number of such loops. Our work thus provides new guidelines for designing and developing these remarkable plastics. [1] Ciarella et al., PRL 2018.

Session P31 DCP: Advances in Hierarchical Systems: Theory and Experiments II BCEC 203 -
Neeraj Rai, Mississippi State University; Dongxia Liu, University of Maryland - Tag(s): Invited
2:30PM P31.00001: Nanosized zeolites: targets and challenges* [Invited] SVETLANA MINTOVA (Presenter), CNRS, ENSICAEN, Normandy University, Laboratory of Catalysis and Spectrochemistry — This presentation will highlight recent developments in the synthesis and unconventional applications of nanosized zeolites. The factors controlling the formation of nanosized zeolites underlining the most promising approaches from the viewpoint of large-scale production will be discussed. The strategies available for the preparation of nanosized zeolites including organic-template assisted, organic-template free, and seed approach will be presented. A special attention will be paid to zeolite formation in conventional organic-template-free zeolite yielding systems. Additionally the preparation of defect free zeolites using a “soft” chemistry approach will be discussed.

Finally, the advantages and limitations of the synthesis methods for nanosized zeolites and their utilization in existing and advanced applications will be addressed. The newest developments in the preparation of nanosized zeolites (either free of organic template or free of defects), supported zeolite films/layers, and self-assembled structures for optical and medical applications will be revealed.

*The Region of Normandy, France and the Thousand-talent program, CUP-Qingdao, China for the financial support are gratefully acknowledged.

3:06PM P31.00002: Characterization of silanol defect sites on amorphous versus crystalline 2-D silicate surfaces* [Invited] NICOLAS GROSSO GROSSO-GIORDANO, Chem and Biomol Eng, UC Berkeley, CHRISTIAN SCHROEDER, Institut für Physikalische Chemie, Universität Münster, ALEXANDER OKRUT, Chem and Biomol Eng, UC Berkeley, HUBERT KOLLER, Institut für Physikalische Chemie, Universität Münster, STACEY I. ZONES, Chevron Energy Technology Company, ALEXANDER KATZ (Presenter), Chem and Biomol Eng, UC Berkeley — We compare and contrast the nature of silanols on open, two-dimensional surfaces comprising amorphous and crystalline siliceous materials. We compare the thermal treatment of silanols in both sets of materials, using several forms of spectroscopy for characterization. The ramifications of the observed differences on applications will be highlighted.

3:42PM P31.00003: Synthesis and Catalytic Performance of Hierarchical Materials Derived from Metal-Organic Frameworks* [Invited] JASON HICKS (Presenter), Chemical & Biomolecular Engineering, University of Notre Dame — Hierarchical materials have many benefits in catalytic applications. We have been specifically interested in the synthesis of hierarchical materials for a variety of energy-related applications including biomass fast pyrolysis, coupling of aldehydes and/or ketones from biomass feed streams, and sulfur removal from petroleum feed sources.1-4 This presentation will provide our current progress in the following areas: 1) synthesis and characterization of hierarchical metal-organic framework (MOF) materials, and 2) metal nanoparticles supported on hierarchical carbon supports derived from MOFs. I will discuss a vapor-assisted crystallization method developed in our lab using zeolite synthesis literature as inspiration, where a dry gel is initially formed that promotes MOF crystallization and the formation of hierarchical materials. The detailed characterization of these novel materials will be discussed, as well as their catalytic performance.

*Acknowledgement is made to the donors of the American Chemical Society Petroleum Research Fund for support of this research (PRF# 53874-DNI10). We also thank the ND Energy Materials Characterization Facility and the Notre Dame Integrated Imaging Facility.
Hierarchical zeolites are advanced materials possessing the catalytic and adsorption properties of conventional zeolites while potentially eliminating their transport limitations through the introduction of mesopores. Recent experiments comparing the adsorption and transport in hierarchical self-pillared pentasil (SPP) zeolites (SPP) to microporous silicalite-1 (MFI) revealed an interesting crossover in sorbate loading and significantly slower than expected diffusion for alkanes, but explanation for these observations are not readily available through experimental probes due to the complications arising from the presence of multiple adsorption sites and blocked pore entrances. In this talk, we will present results from Gibbs ensemble Monte Carlo and canonical ensemble molecular dynamics simulations to unravel the peculiar properties of SPP zeolites. Computed isotherms for argon, hydrogen, alkanes, ethanol, and water demonstrate striking differences in the adsorption behavior for these adsorbates. Depending on the loading, diffusion can proceed via the micropores, on the mesopore walls, or through the mesopore interior.

*This work was primarily supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Chemical Sciences, Geosciences and Biosciences through the Nanoporous Materials Genome Center under award numbers DE-FG02-12ER16362 and DE-FG02-17ER16362. The work used computational resources of the Argonne Leadership Computing Facility, which is a DOE Office of Science User Facility supported under Contract DE-AC02-06CH11357. Additional computer resources were provided by the Minnesota Supercomputing Institute.

Hierarchical zeolites and zeolite nanocrystals with micropore lengths on the order of nanometers have been synthesized with the aim of reducing mass transfer limitation. However, due to the large external surface to volume ratios, the mass transport in these materials can be hindered by a secondary rate limitation step imposed on the external surface of the zeolites. In this talk, I will present our recent study on the mass transport in hierarchical zeolites and zeolite nanoparticles. We show that surface barrier is related to the presence of pore re-entry caused by strong sorbate/sorbent interaction at the zeolite surface. In order to understand the nature of the surface barrier, a set of silica nanoparticle (SNP)/Silicalite-1 composites with different external surface to micropore surface ratios was synthesized. It was found that the strong sorbate/sorbent interaction at the external surface of Silicalite-1 nanoparticles can cause diffusing molecules to re-enter into micropores and repeat the micropore diffusion process. This pore re-entry step can lead to an unusually long micropore diffusion length. We also demonstrate that this repeated micropore diffusion process can be effectively reduced by mixing the zeolite nanoparticles with secondary, nonporous nanoparticles. It was concluded that the surface barrier in hierarchical zeolites and zeolite nanoparticles is likely due to a combination of pore re-entry of adsorbates and pore blockage.

Session P32 DCP: Gas Phase Clusters - Experiment and Theory in Concert (C): Other Clusters (GPC3) BCEC 204A - Knut Asmis, Leipzig University - Tag(s): Focus
2:30PM P32.00001: Finite temperature anharmonic gas phase vibrational spectroscopy with DFT-based MD simulations* [Invited] MARIE-PIERRE GAIGEOT (Presenter), Physics, LAMBE UMR8587, Universite d'Evry val d'Essonne, Universite Paris-Saclay — We will review our works on gas phase vibrational spectroscopy of gas phase molecules and clusters by finite temperature DFT-based molecular dynamics simulations. The anharmonic dynamical spectra have been used in order to make systematic links to the most advanced action spectroscopy experiments.

Our combined theoretical-experimental works on the IR-MPD (Infra Red Multi Photon Dissociation) and IR-PD (Infra Red Pre-Dissociation) action spectroscopies of gas phase molecular ions will be shown, where the importance of conformational dynamics, proton transfers, temperature, potential energy surface and dipolar anharmonicities, entropic effects, high energy conformers, will be emphasized. Our more recent works on the far-IR/THz spectroscopy of gas phase peptides will also be presented in relation with the most advanced IR-UV ion dip experiments probing the 100-800 cm\(^{-1}\) spectral domain. In this spectral range, DFT-MD anharmonic spectroscopy has proved essential into assigning spectral features to 3D structures, with a robustness not reached by other anharmonic theoretical methods. We will emphasize the importance of large amplitude motions and highly flexible H-Bonds into the 100-800 cm\(^{-1}\) signatures, and will show which modes are intrinsically anharmonic vs harmonic. This calls for the development of mixed harmonic/anharmonic methods. Our recent innovative theoretical developments into the calculation of gas phase anharmonic spectra from DFT-MD simulations, going beyond the time-correlation function of dipole moments, will also be presented.

3:06PM P32.00002: Deconstructing the curious behavior of carboxylate at the air-water interface with cluster ion spectroscopy* [Invited] MARK JOHNSON (Presenter), Yale Univ — The transport of divalent metal ions (e.g., Mg\(^{2+}\) and Ca\(^{2+}\)) into the troposphere is thought to arise from preferential complexation with the anionic head groups of fatty acids at the surfaces of sea-spray aerosols. Attempts to quantify the formation of these ionic complexes by monitoring the vibrational frequencies of the CO stretching vibrations has proven to be difficult, however, because the ion-driven spectral response is surprisingly similar to that of the hydrated anion. We trace the origin of this effect by studying the stepwise hydration behavior of the isolated carboxylate and contact ion pair in the gas-phase. The results reveal the critical importance of solvent coordination in the structural interpretation of surface-sensitive spectral signatures of ion complexation at the interface. Surprisingly, not only does stepwise hydration of the RCO\(^{-}\) anion and the [Ca\(^{2+}\)-RCO\(^{-}\)]\(^+\) contact ion pair yield solvatochromic responses in opposite directions, but in both cases, the responses of the two (symmetric and asymmetric stretching) CO bands to hydration are opposite to each other. The result is that the two CO bands evolve toward their interfacial asymptotes from opposite directions. Theoretical simulations of the [Ca\(^{2+}\)-RCO\(^{-}\)]\(^+\)\(-(H_{2}O)_{n}\) clusters indicate that the metal ion remains directly bound to the head group in a contact ion pair motif as the asymmetric CO stretch converges at the interfacial value by \(n = 12\). This establishes that direct metal complexation can account for the interfacial behavior.

We discuss these effects in the context of a model that invokes the water network-dependent local electric field along the C-C bond that connects the head group to the tail as the key parameter driving the observed trends.

*NSF CCI CAICE
3:42PM P32.00003: Accurate spectroscopic characterization of molecular complexes as a first step toward the understanding of intermolecular interactions [Invited] CRISTINA PUZARINI (Presenter), Dpt. Chemistry “Giacomo Ciamician”, University of Bologna — Noncovalent interactions play a key role in several biological and technological processes, yet their characterization and interpretation are still far from being satisfactory. Integrated experimental and computational investigations of molecular complexes can play an invaluable role to understand the properties of intermolecular interactions.

In the past decade, many gas-phase spectroscopic investigations have focused on the understanding of the nature of weak interactions in model systems, and a great effort has been devoted – for example – to studies dealing with complexes formed by small biomolecules with either water or other solvents. In this connection, molecular complexes involving hydrogen bonding between nitrogen-containing systems can be considered as prototypes for studying the (N-H...N) interaction in biological systems [1].

Along with the well-established hydrogen bonds, emerging classes of noncovalent interactions are attracting increasing attention, such as those involving a pnictogen or chalcogen atom [2,3] because of the fundamental role they play in different fields such as catalysis, drug design, self-assembly processes, and crystal packing. Understanding the mechanisms at the basis of these technological processes requires the characterization of the directionality, strength, and nature of such interactions as well as a comprehensive analysis of their competition with other noncovalent bonds, also taking into account the tuning of these properties by different environments.

4:18PM P32.00004: A cluster approach to solvation effects in flexible peptides* [Invited] ETIENNE GARAND (Presenter), University of Wisconsin - Madison — Utilizing a method based upon a unique combination of mass spectrometry and laser spectroscopy, our research focuses on capturing and characterizing complexes of interest to provide a molecular-level detailed examination of their structures and interactions. To access microsolvated charged complexes, we have developed new capabilities to perform controlled gas-phase clustering in cryogenic ion trap. This versatile approach enables us to form clusters with >30 solvent molecules surrounding any bare ion obtained by electrospray ionization. The structures of these carefully isolated and prepared complexes are then directly probed in the mass spectrometer using infrared predissociation spectroscopy, yielding well-resolved spectra that contain a wealth of information. Recent studies on the solvation-dependent structures of flexible model peptidic systems, (Gly)nH+ and (Ala)nH+ will be presented. In addition, this talk will highlight two methodologies necessary for deconvoluting the complex vibrational spectra of these species: IR-IR conformer-specific spectroscopy and solvent-specific isotope labeling. This combination of spectroscopic characterizations yields unambiguous spectral assignments and clearly reveals the structural evolution of the flexible peptides in response to increasing solvation. The results also provide insights on the isomerization pathways and energetics involved in these structural changes.

*This research is funded by the Department of Energy under grant DE-SC0018902

4:54PM P32.00005: Observation of H2O and D2O water dimers in CCl4 at room temperature via Matrix Isolation Spectroscopy DOSEOK KIM (Presenter), ADAM H TURNER, SUNG HYUN HUH, SOO RYEON RYU, Sogang University — The vibrational spectrum of a single molecule is typically investigated in the gas phase, however, the spectrum is crowded by combination bands with rotational transitions and not all molecules can be prepared in the gas phase. Room-temperature matrix isolation spectroscopy (MIS) is a tool that utilizes a low solubility of the solute molecule as well as weak interactions between solute and solvent molecules to obtain a spectrum of isolated solute molecules. Water (H2O and D2O) was loaded on top of the nonpolar solvent CCl4, and the in situ inclusion process was monitored in the CCl4 phase by infrared absorption spectroscopy. These in situ spectra showed non-linear deviations from the monomer spectrum over time attributed to formation of water dimers. The water dimer spectrum was extracted from the time-series of the spectra using 2D correlation spectroscopy and principal component analysis (PCA). These dimer peaks from the 2D correlation and PCA analysis compared to those obtained from DFT calculations using the CC-VSCF approximation showed good agreement and allowed the assignment of the dimer modes. Changes from the monomer to the dimer spectra as well as the difference between H2O and D2O dimer spectra were discussed in terms of hydrogen bonding.
5:06PM P32.00006: Exploring molecular formation and growth upon ionization of van der Waals clusters using ab-initio molecular dynamics  TAMAR STEIN (Presenter), Chemistry, Hebrew University of Jerusalem Israel, PARTHA BERA, TIMOTHY J LEE, NASA, MARTIN HEAD-GORDON, University of California, Berkeley — Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous in the interstellar medium (ISM)\(^1\). The mechanism for their formation in the low temperature environment of the ISM is, as of yet, nonetheless a mystery. Understanding the mechanism of formation of complex molecules such as PAHs and nitrogen-based PAHs (PAHN) is a long-standing challenge which has been drawing much attention for the past several decades.

Formation of the building blocks of PAHs and PAHNs upon ionization of van der Waals clusters will be presented. Results on small (up to 6 acetylene/HCN units) van der Waals clusters, indicate that, due to the fact that the clusters possess a large amount of extra energy after ionization, a rich chemistry can occur\(^2\). For example, after ionization, structures on the \(\text{C}_6\text{H}_6^+\) potential energy surface (PES) are accessible without barriers. Moreover, the formation of the basic building block of PAHs, namely the benzene cation, has been demonstrated by means of ab-initio molecular dynamic. The presence of spectator molecules has been proven to change the PES as well as to partake a catalytic role in the formation of the benzene cation\(^2\).

5:18PM P32.00007: Investigation of effect of temperature and size on the ionization potential of semiconductor clusters using effective stochastic potential method*  SHAFI ALI (Presenter), JEREMY SCHER, ARINDAM CHAKRABORTY, Syracuse University —

Knowledge of the ionization potential (IP) give important chemical insights into electron-attachment and electron-detachment processes. For semiconductor cluster and nanoparticles, the effect of structure on IP is extremely important because of the quantum confinement effect. However, traditional methods for calculating IPs become computationally expensive for the determination of non-zero temperature ensemble-averaged properties which require the calculation of a large number of structures. This presentation will present the ESP-GF method which combines the effective-stochastic potential (ESP) method with 1-particle Green's function theory for efficient calculation of the ionization potential to obtain ensemble-averaged properties at non-zero temperatures. The ESP method uses random-matrix theory to describe the distribution of structures present in the NVT ensemble which allows an efficient calculation of IPs. The ESP-GF method has been applied to a series of colloidal ZnSe clusters at \(T=300\text{K}\) and the distributions of IPs will be presented. The results from this project highlight the importance of performing ensemble-averaged calculations for predicting quasiparticle properties in semiconductor clusters.

Session P33 FIAP: Spectroscopy and Oxides  BCEC 204B - Harishankar Jayakumar, City College of New York
2:30PM P33.00001: Time-Domain Spectroscopy of Mesoscopic Conductors Using Voltage Pulses* PABLO BURSET (Presenter), JANNE KOTILAHTI, Department of Applied Physics, Aalto University, MICHAEL MOSKALETS, Department of Metal and Semiconductor Physics, NTU Kharkiv Polytechnic Institute, CHRISTIAN FLINDT, Department of Applied Physics, Aalto University — The development of single-electron sources are paving the way for a novel type of experiments in which individual electrons are emitted into a quantum-coherent circuit. However, to facilitate further progress towards fully coherent on-chip experiments with electrons, a detailed understanding of the quantum circuits is needed. We propose to perform time-domain spectroscopy of mesoscopic conductors by applying Lorentzian-shaped voltage pulses to an input contact. We show how characteristic timescales of a quantum-coherent conductor can be extracted from the distribution of waiting times between charge pulses propagating through the circuit. To illustrate our idea, we employ Floquet scattering theory to evaluate the electron waiting times for an electronic Fabry-Pérot cavity and a Mach-Zehnder interferometer. Our spectroscopic method benefits from the particle-like behavior of the charge pulses, while still being sensitive to their quantum statistics. This unique combination makes our scheme promising for the characterization of quantum-coherent circuits.

2:42PM P33.00002: Dynamics of strongly coupled singlet fission molecules in optical microcavity BIN LIU (Presenter), City College of New York, CUNY, MATTHEW Y SFEIR, Brookhaven National Laboratory, VINOD M MENON, City College of New York, CUNY — We have experimentally studied the dynamics of a singlet-fission molecule-metal microcavity system under strong coupling by using pump-probe transient absorption technique. Under one-photon pump, where the system is selectively pumped by wavelengths which are resonant with exciton, upper, and lower polariton, the dynamics of polariton states is found to be determined by that of the exciton, which has long-time character. Moreover, comparing to the neat film without cavity, the kinetics of the molecular triplet state is not significantly modified by strong singlet molecular exciton-photon coupling within the cavity. Under two-photon pump, short-time (sub-picosecond) dynamics is observed from both the polariton cavity system and solid-state neat film, indicating this results from the ultrafast optical response of the nonlinear organic molecules.

2:54PM P33.00003: Measurement of Quadratic Terahertz Optical Nonlinearities Using Second-Harmonic Lock-in Detection* SHUAI LIN (Presenter), SHUKAI YU, DIYAR TALBAYEV, Department of Physics and Engineering Physics, Tulane University, New Orleans, LA, United States. — We present a method to measure quadratic terahertz optical nonlinearities in terahertz time-domain spectroscopy. We use a rotating linear polarizer (a polarizing chopper) to modulate the amplitude of the incident terahertz pulse train. We use phase-sensitive lock-in detection at the fundamental and the second harmonic of the modulation frequency to separate the materials' responses that are linear and quadratic in a terahertz electric field. We demonstrate this method by measuring the quadratic terahertz Kerr effect in the presence of the much stronger linear electro-optic effect in the (110) GaP crystal. We propose that the method can be used to detect terahertz second-harmonic generation in noncentrosymmetric media in time-domain spectroscopy, with broad potential applications in nonlinear terahertz photonics and related technology.

3:06PM P33.00004: Optical spectroscopy of emission from GeSn waveguides on Si

JAY MATHEWS (Presenter), Department of Physics, University of Dayton, ZAIRUI LI, ELAHEH GHANATI, Department of Electro-Optics and Photonics, University of Dayton, JOHN KOUVETAKIS, School of Molecular Sciences, Arizona State University, JOSE MENENDEZ, Department of Physics, Arizona State University, IMAD AGHA, Department of Physics, University of Dayton — GeSn alloys are attractive for infrared emission due to the tunable band gap in the infrared and the quasi-direct or direct nature of the gap. Epitaxial growth of GeSn on Si has been demonstrated using multiple growth techniques and is now being incorporated into commercial device fabrication. Recently, laser emission from GeSn waveguides on Si has been demonstrated at temperatures up to 240 K, but the search for room temperature Si-based laser continues. In this work, we investigate the optical emission from optically-pumped GeSn waveguides at room temperature using optical spectroscopy. The results show that there is a highly nonlinear dependence on the total emission output power with respect to the input pump power. However, measurements of the emission spectrum do not show any narrowing of the emission peak, and Fabry-Perot measurements do not show any observable modes. Modeling of spontaneous emission from these materials indicates that the experimental power dependence can only be the result of optical gain in the GeSn. This result shows that optical gain at room temperature is possible.

*Funding for this project was provided by an Air Force Office of Scientific Research Young Investigator Award, Grant No. FA95501710146.

3:18PM P33.00005: The Physics of Optical Dispersion Equations

WILLIAM KARSTENS (Presenter), Saint Michael’s College, DAVID SMITH, University of Vermont and Argonne National Laboratory — We explore the disparate optical dispersion equations used to interpolate the refractive index from measurements at a limited number of spectral lines. Initial 19th-century formulations were based on elastic and electromagnetic theories. Subsequent developments were primarily empirical fits to optical-glass data and are misleading when applied to non-polar semiconductors. We show that the theoretical results of Cauchy, Sellmeier, etc., either classical or quantum-mechanical, follow from linear-response theory via the Kramers-Kronig relations regardless of the mechanism assumed. Their use is limited by the number of parameters required. In contrast, most empirical relations were chosen for simplicity and compatibility with classical ray-tracing. Their reliance on measurements in the visible blurs the roles of electronic and ionic polarization. Moreover, most empirical equations predict indices of odd parity in photon energy, in conflict with time-reversal invariance. A reformulation of the empirical dispersion equations consistent with linear-response theory corrects the parity error and clarifies their application to polar and non-polar materials.

*Supported in part by the US Department of Energy, Office of Science, Office of Nuclear Physics under contract DE-AC02-06CH11357.

3:30PM P33.00006: Calculating form-dependent optical scattering at vacuum- and extreme-ultraviolet wavelengths off nanoelectronic structures

BRYAN BARNES (Presenter), MARK-ALEXANDER HENN, HUI ZHOU, MARTIN SOHN, RICK SILVER, Nanoscale Device Characterization Division, National Institute of Standards and Technology — Form birefringence, where the orientation of periodic structures yields effective refractive index differences between orthogonal polarizations, is the basis for several applications including the successful detection of aperiodic imperfections (e.g., defects in nanoelectronics) at visible and ultraviolet wavelengths. As shorter wavelengths are employed by industry, the key assumption behind form birefringence - that the wavelength is larger than the periodicity - is challenged even with decreasing device dimensions. Here, the form dependence of high spatial-frequency scattering off periodic structures is numerically assessed among deep-, vacuum-, and extreme-ultraviolet illumination wavelengths (DUV, VUV, EUV). Form-dependent scattering intensity ratios of the scattering off ideal periodic arrays decrease with wavelength into the VUV, but dramatically increase for the 47 nm EUV wavelength due primarily to the wavelength-dependent optical properties of the dielectrics involved. After adding a bridging defect to this array, the 47 nm wavelength remains most sensitive to these patterning faults. These results should be extensible, not only to structures in nanoelectronics, but also to emerging engineered optical materials for DUV and shorter wavelengths.
Exceptional points (EPs) are generic degeneracies of non-hermitian systems, where two eigenvalues and eigenvectors of a linear operator coalesce, e.g. degenerate resonances of an open system. We identify a new kind of physically realizable exceptional point (EP) corresponding to degenerate coherent perfect absorption, in which two purely incoming solutions of the wave operator for electromagnetic or acoustic waves coalesce to a single state. Such non-hermitian degeneracies can occur at a real-valued frequency without any associated noise or non-linearity, in contrast to EPs in lasers. The absorption lineshape for the eigenchannel near the EP is quartically flat in frequency around its maximum in any dimension. In general, for the parameters at which an operator EP occurs, the associated scattering matrix does not have an EP. However, in one dimension, when the S-matrix does have a perfectly absorbing EP, it takes on a universal one-parameter form with degenerate values for all scattering coefficients. For absorbing disk resonators, these EPs give rise to chiral absorption: perfect absorption for only one sense of rotation of the input wave.

Hydrothermal Growth of zinc oxide nano-rods doped with manganese*

RAJNI BAGGA (Presenter), VO-VAN TRUONG, PABLO BIANUCCI, Concordia University — We synthesised ZnO Nanorods arrays doped with and without Mn doping (at a 1% concentration of the precursor salts) by a hydrothermal method at low temperature. They were characterised by scanning electron microscopy (SEM), Photoluminescence (PL) and electron paramagnetic (EPR) spectroscopy. All samples produced broad band Photoluminescence (PL) emissions in the yellow-orange-red range, typically attributed to defects in the crystalline structure. The PL spectra does not seem to show significant changes in the ratio of the near band edge emission and the defect emission with the Mn doping. From this, we infer that the crystal quality of the ZnO nanorods does not change with Mn doping. The EPR spectrum from the ZnO nanoparticles formed in the growth solution confirms the presence of Mn in them. We use Micro-Raman spectroscopy to investigate the local crystal structure of the nanomaterials. Room temperature micro-Raman spectra confirms the wurtzite structure.

4:30PM P33.00011: Hysteresis response of 2D electron nematics in the presence of material disorder* SAYAN BASAK (Presenter), ERICA CARLSON, Purdue University, KARIN ANDREA DAHMEN, University of Illinois at Urbana-Champaign — Electron nematic phases, which break the rotational symmetry of the host crystal while retaining liquidity, have been observed in a variety of systems, including strontium ruthenates, iron superconductors, cuprate superconductors, the (111) surface of bismuth, and high fractional Landau levels. Depending upon interactions with the lattice, the nematic may either be in the XY or the Ising universality class.

Previously, we proposed new experimental tests [1] that can reveal the universality class, based on hysteresis: Upon cycling an applied orienting field, a clean 2D XY electron nematic will show no hysteresis, whereas a clean Ising nematic will show robust hysteresis.

However, no material system is defect-free, and no spontaneous symmetry breaking can occur in the 2D Ising model in the presence of random fields. In this talk, we discuss the hysteresis characteristics of XY and Ising nematics in the presence of material disorder.

4:42PM P33.00012: Supersonic propagation of atomic motion by phasons in fresnoite* MICHAEL MANLEY (Presenter), Oak Ridge National Laboratory, PAUL J STONAHA, Physics, Idaho State University, DOUGLAS L ABERNATHY, SONGXUE CHI, Oak Ridge National Laboratory, RAFFI SAHUL, Meggitt Sensors, RAPHAEL HERMANN, JOHN D BUDAI, Oak Ridge National Laboratory — Our recent inelastic neutron scattering measurements reveal that waves of atomic motion propagate at surprisingly high speeds of up to 4.3 times the speed of sound in the form of phasons in the piezoelectric mineral fresnoite (Ba$_2$TiSi$_2$O$_8$). Phasons are quasiparticles that exist because of an incommensurate modulation (or ‘wrinkles’) in the flexible framework structure of fresnoite. They are associated with atomic rearrangements that change the phase of waves describing the incommensurate modulation. Phasons are usually overdamped and move diffusively, and are thus much slower than phonons (vibrations involving the translation of atoms, rather than rearrangements). However, the phasons in fresnoite are found not to be overdamped owing to a characteristic rotation of the phasons away from the driving soft phonon, yielding the supersonic propagation. These supersonic phasons enhance thermal conductivity and channel lattice energy at speeds well beyond the limits of phonons.

4:54PM P33.00013: Effects of substitutional defects on the thermal-physical properties of Gd$_2$Zr$_2$O$_7$ pyrochlores* FENGAI ZHAO (Presenter), XIAN-MING BAI, Department of Materials Science and Engineering, Virginia Tech, HAIYAN XIAO, XIAOTAO ZU, University of Electronic Science and Technology of China — Rare-earth pyrochlores, particularly Gd$_2$Zr$_2$O$_7$, have been proposed as promising candidates for the next-generation thermal barrier coatings (TBCs) due to their good structural stability, low thermal conductivities at high temperatures. In this work, systematic studies of the incorporation of Yb$^{3+}$, Nd$^{3+}$, La$^{3+}$, Ti$^{4+}$, Hf$^{4+}$, Ce$^{4+}$ into cation sites in Gd$_2$Zr$_2$O$_7$ has been investigated by density functional theory (DFT) calculations to explore the underlying mechanisms for modifying its thermal-physical properties. Among these doped cations, incorporation of oversized Ce$^{4+}$ at the Zr-site leads to significantly smaller Young’s modulus, better ductility, smaller Debye temperature, and lower thermal conductivity. In particular, the thermal conductivity of Ce-doped Gd$_2$Zr$_2$O$_7$ decreases as large as 21 % with the complete Ce substitution based on the Clarke’s model. The incorporation of oversized Ce cations weakens the interatomic bonds, which is the main factor for the improved thermal-physical properties of Gd$_2$Zr$_2$yCe$_y$O$_7$ pyrochlores. The results provide theoretical predictions of the behavior and performance of pyrochlores at high temperatures and may promote experimental investigation in the future.

**5:06PM P33.00014: Investigations on the Electronic and Optical Properties of Double Perovskites Ba$_2$BiSbO$_6$**

BISHNU PRASAD BELBASE (Presenter), SHALIKA RAM BHANDARI, GOPI CHANDRA KAPHLE, MADHAV PRASAD GHIMIRE, Central Department of Physics, Tribhuvan University, DINESH KUMAR YADAV, Advanced Materials Laboratory, Condensed Matter Physics Research Center — Recent research on double perovskites with large spin-orbit coupling (SOC) assisted materials are of great interest due to their novel properties. Materials with band gap in the visible range are found suitable for optoelectronic devices. Depending on the types of gaps (indirect or direct), materials can be used for photo detectors or optoelectronic emitters. Using first principle density functional (DF) approach, we study the electronic and optical properties of newly synthesized Ba$_2$BiSbO$_6$. Within generalized gradient approximation without SOC, an indirect band gap of 1.85 eV was observed which reduces to 1.72 eV when SOC is taken into account. Significant changes due to SOC has been found at Gamma point in the band structure where band splitting of ~1.3 eV has been observed just above the fermi level with possible indication from indirect to direct band gap semiconductor. Strong hybridization between Bi-6p, Sb-5p and O-2p states observed on the electronic density of states. Optical study shows interband electron transition with energy larger than the bandgap of the material. This suggests Ba$_2$BiSbO$_6$ as a candidate material for photodetectors (absorbers).

**Session P34 FIAP: Recent Advances on Spintronics-based Computing: from Deterministic to Probabilistic**

**2:30PM P34.00001: Recent progress in reducing the current and time for magnetization switching in magnetic tunnel devices for memory applications**

JONATHAN SUN (Presenter), IBM Thomas J. Watson Research Center — In spin-transfer-torque switched magnetic random access memory (STT-MRAM) using magnetic tunnel junctions (MTJ), the STT switching current directly affects selection transistor size and circuit density. This is a critical attribute for cost competitiveness in commercial applications. Recent developments in STT-MRAM have been focusing on reducing switching current well below 100 uA, increasing speed beyond 50 ns, and improving switching reliability to better than $10^{-9}$, while simultaneously aiming for data retention of 10 years at operating temperatures ranging between -40 and + 85°C or beyond. In this talk, I will review the fundamental device and materials physics that govern the STT-switching dynamics. While the switching threshold current is more directly related to data-retention, the actual operating switching current for ensuring a certain speed and reliability (switching error) for fast, below 10ns switching can also exceed macrospin expectations. Experiments show the switching current required to achieve deep error floor can be less than estimated from macrospin. For further improvements it is important to understand the dynamics involving a nanomagnet's internal degrees of magnetic freedoms during STT switching, a potentially complex subject rich in nonlinear dynamics. These complex nonlinear mechanisms can speed-up the intended switching of the MTJ, but can also affect the reference-layer stability, requiring special care. Longer term, for even faster manipulation of nanomagnets approaching or below 1 ns, new sources of spin-current with better charge-to-spin current conversion needs to be considered, such as thermal magnonic or spin-orbit-derived spin-currents. I will briefly discuss recent advances with these new sources of spin currents, and the likely common challenges they will give rise to, in terms of materials and device design and development.

3:06 PM P34.00002: Spintronic Devices for Neural Networks* [Invited] SHUNSUKE FUKAMI (Presenter), Research Institute of Electrical Communication, Tohoku University — Representing the human brain in computers, so-called neuromorphic computing, is one of the focuses of interest in recent electronics as the brain is a model system that can readily accomplish complex tasks at small power consumption level, in contrast to conventional von Neumann computers. An artificial neural network offers a promising approach for low-power and intelligent neuromorphic computing. A key ingredient for the network is an artificial synapse that has analog and nonvolatile memory functionalities and frequent learning capability as in the real synapse in the brain. Here we show an artificial neural network with spintronic artificial synapses, which meet these requirements [1]. We will first describe an analog spin-orbit torque (SOT) switching device consisting of an antiferromagnet/ferromagnet bilayer structure [2], which can serve as the artificial synapse. The mechanism of analog and nonvolatile property [3] will be described. Secondly, a proof-of-concept demonstration of an artificial neural network with 36 SOT devices will be shown. An associative memory operation is performed based on the Hopfield model and learning ability of the spintronic artificial synapse is confirmed [4].

This work is jointly carried out with H. Ohno, W. A. Borders, A. Kurenkov, S. Sato, Y. Horio, and H. Akima of Tohoku University and P. Gambardella of ETH Zurich.

*A portion of this work was supported by the R&D Project for ICT Key Technology of MEXT, ImPACT Program of CSTI, JST-OPERA, JSPS KAKENHI 17H06093 and 18KK0143, and Cooperative Research Projects of RIEC.

3:42 PM P34.00003: Supervised learning of an artificial opto-magnetic neural network with picosecond laser pulses [Invited] THEO RASING (Presenter), Radboud University, Nijmegen, Netherlands — The explosive growth of data and its related energy consumption is pushing the need to develop novel, brain inspired and energy efficient schemes and materials for data processing and storage. The prospect of continuous magnetization state manipulation of a Co/Pt thin film via picosecond optical laser pulses offers the possibility of exploiting this material for neuromorphic computing. Here, we demonstrate that such material can be used as an artificial adaptive synapse by controlling its internal magnetization state using circularly polarized picosecond laser pulses. We also show experimentally an efficient implementation of perceptron learning on a supervised opto-magnetic neural network, consisting out of such magnetic synapses. Importantly, we show that optimization of synaptic weights is achieved by a global feedback mechanism, such that learning does not rely on external storage or additional optimization schemes.

4:18 PM P34.00004: p-Bits for Probabilistic Spin Logic* [Invited] SUPRIYO DATTA (Presenter), Purdue University — The growing field of quantum computing is based on the concept of a q-bit which is a delicate superposition of 0 and 1, along with coherent coupling techniques for entangling them. By contrast a probabilistic bit or a p-bit is a robust classical entity that fluctuates between 0 and 1, and can be correlated using techniques borrowed from the field of neural networks. Correlated p-bits are of course no substitute for entangled q-bits, but we will argue that they can be used as a poor man’s q-bits that address a broad class of important problems including inference, “invertible” logic and optimization, using the same quantum algorithms but with added versatility. Further we will show that existing embedded MRAM technology with minor modifications can be used to implement room temperature p-bits and build large scale p-circuits [1].

*This work was supported in part by ASCENT, one of six centers in JUMP, a Semiconductor Research Corporation (SRC) program sponsored by DARPA and in part by the Center for Probabilistic Spin Logic for Low-Energy Boolean and Non-Boolean Computing (CAPSL), one of the Nanoelectronic Computing Research (nCORE) Centers, a Semiconductor Research Corporation (SRC) program sponsored by the NSF.
Brains display many features typical of non-linear dynamical networks, such as synchronization or chaotic behavior. These observations have inspired a whole class of models that harness the power of complex non-linear dynamical networks for computing. In this framework, neurons are modeled as non-linear oscillators, and synapses as the coupling between oscillators. However, there are few hardware implementations of these systems, because large numbers of interacting non-linear oscillators are necessary. In this talk, we will see why coupled magnetic nano-oscillators are very promising for realizing cognitive computing at the nanometer scale. Then, we will present our experimental and theoretical results. We will show how speech recognition can be performed using the transient dynamics and the synchronization of a few harmonic spin torque oscillators [1]. These results highlight key opportunities and requirements for harnessing spintronics for bioinspired computing. We will also show how superparamagnetic oscillators can code and transform information in a robust population-type scheme [2]. These results highlight that some apparently undesirable phenomena like superparamagnetism can become compelling for bioinspired schemes. We will finally discuss how this line of research can take inspiration from both neuroscience and machine learning, and finish by open questions raised by our research.

Session P35 DQI: Theory and Scaling of Benchmarking and Tomography 8CEC 205B - Matthew Ware, BBN Technologies - Tag(s): Focus

2:30PM P35.00001: A new class of randomized benchmarking protocols: theory and experiment* [invited] JONAS HELSEN (Presenter), XIAO XUE, LIEVEN VANDERSYPEN, STEPHANIE WEHNER, Delft University of Technology — In this talk I will discuss a new class of randomized benchmarking protocols called character randomized benchmarking. Character randomized benchmarking allows one to extend standard randomized benchmarking in a principled manner to groups beyond the Clifford group. I will discuss the theory of character randomized benchmarking, some example protocols such as benchmarking a T gate and performing two qubit interleaved randomized benchmarking using only single qubit gates as reference, and I will also present some recent experimental implementations of character randomized benchmarking.

*JH and SW are funded by STW Netherlands, NWO VIDI, an ERC Starting Grant and by the NWO Zwaartekracht QSC grant. XX and LMKV are funded by the Army Research Office (ARO) under Grant Number W911NF-17-1-0274.

3:06PM P35.00002: Randomized Benchmarking as Convolution SETH MERKEL (Presenter), HRL Laboratories — We show that the standard randomized benchmarking protocol can be described as a convolution, and is thus amenable to Fourier analysis. We utilize a form of Fourier transform that maps matrix-valued functions on group elements to matrix-valued functions of the group’s irreducible representations in order to map the average over sequences of Clifford operations to the power of a single matrix. We can then demonstrate that as long as our faulty gate-set is close to some representation of the Clifford group, an RB sequence is described by the exponential decay of a process that has exactly two eigenvalues close to one and the rest close to zero, even though the bounds with respect to any particular representation of the Clifford group may not tightly describe the rate of decay.
3:18PM P35.00003: Randomized Benchmarking under Different Gatesets  KRISTINE BOONE (Presenter), ARNAUD CARIGNAN-DUGAS, JOEL WALLMAN, JOSEPH EMERSON, University of Waterloo — We provide a comprehensive analysis of the differences between two important standards for randomized benchmarking (RB): the Clifford-group RB protocol proposed originally in [1] and [2], and a variant of that RB protocol proposed later by the NIST group in [3]. While these two protocols are frequently conflated or presumed equivalent, we prove that they produce distinct exponential fidelity decays leading to differences of up to a factor of 3 in the estimated error rates under experimentally realistic conditions. These differences arise because the NIST RB protocol does not satisfy the unitary two-design condition for the twirl in the Clifford-group protocol and thus the decay rate depends on non-invariant features of the error model. Our analysis provides an important first step towards developing definitive standards for benchmarking quantum gates and a more rigorous theoretical underpinning for the NIST protocol and other RB protocols lacking a group-structure. We conclude by discussing the potential impact of these differences for estimating fault-tolerant overheads.

3:30PM P35.00004: On the freedom in representing quantum operations*  JUNAN LIN (Presenter), BRANDON BUONACORSI, RAYMOND LAFLAMME, JOEL WALLMAN, University of Waterloo — We discuss the effects of a gauge freedom in representing quantum information processing devices, and its implications for characterizing these devices. We demonstrate with experimentally relevant examples that there exists equally valid descriptions of the same experiment which distribute errors differently among objects in a gate-set, leading to different error rates. Consequently, it can be misleading to attach a concrete operational meaning to figures of merit for individual gate-set elements. We propose an alternative operational figure of merit for a gate-set, the mean variation error, and a protocol for measuring this figure.

3:42PM P35.00005: Using Fourier Analysis and Maximum Likelihood Estimation to Identify and Model Non-Markovian Noise in Quantum Operations  GARRETT SIMON (Presenter), Massachusetts Institute of Technology, COLIN BRUZEWICZ, KEVIN OBENLAND, Lincoln Laboratory, ISAAC CHUANG, RICHARD RINES, JULES STUART, Massachusetts Institute of Technology, ROBERT NIFFENEGGER, JOHN CHIAVERINI, JEREMY SAGE, Lincoln Laboratory — The most well-studied error models for quantum operations or gates are Markovian, which assume that the error is “memoryless.” Generically, most error sources can lead to gate errors which violate this assumption. One such source includes periodic noise, which causes the amplitude of gate errors to fluctuate at a characteristic frequency, requiring a non-Markovian error model. Characterizing periodic errors, rather than just identifying them, requires data processing and error modeling beyond the standard procedures used to identify Markovian errors. Using an open-source Fourier transform implementation for qubit measurement data (pyGSTi), we were able to identify the presence of periodic error in quantum operations on trapped-ion qubits. This information allowed us to hypothesize the sources of periodic noise, and create a time-dependent error model, or waveform, whose parameters we optimized to fit the measured data via maximum likelihood estimation. This procedure allows us to quantitatively characterize and predict error sources in an experimental set up, as well as provide a basis for building more generalized non-Markovian error models.

3:54PM P35.00006: Idle tomography: Efficient gate characterization for N-qubit processors*  ROBIN BLUME-KOHOUT (Presenter), ERIK NIELSEN, KENNETH RUDINGER, KEVIN YOUNG, MOHAN SAROVAR, TIMOTHY PROCTOR, Sandia National Laboratories — Quantum process tomography is famously unscalable to many qubits. But the problem is actually the size of the model — arbitrary $N$-qubit process matrices — rather than the number of qubits. The vast majority of possible $N$-qubit errors will not occur in real processors. Here, we introduce a concrete reduced model of low-weight (few-qubit) errors on $N$ qubits. It has $O(N^2)$ parameters, and captures all the commonly conceived failure modes. Then, we introduce a simple and transparent tomography protocol for measuring the error rates, whose complexity scales very efficiently with $N$. We demonstrate it with simulations and experimental results.

Randomized benchmarking of many-qubit devices

TIMOTHY PROCTOR (Presenter), KENNETH RUDINGER, ROBIN BLUME-KOHOUT, Sandia National Laboratories, ARNAUD CARIGNAN-DUGAS, Institute for Quantum Computing and the Department of Applied Mathematics, University of Waterloo, ERIK NIELSEN, KEVIN YOUNG, Sandia National Laboratories — Quantum information processors incorporating 5 - 10s of qubits are now commonplace, but the standard method for benchmarking quantum gates - Clifford randomized benchmarking - is infeasible to implement on more than a few qubits in any near-term devices. In this talk, we present a series of modifications to Clifford randomized benchmarking that enable truly holistic benchmarking of entire devices. Importantly, these new techniques are adaptable based on experimental goals. They can be made highly robust or more scalable as needed, and they can be used to estimate, e.g., two-qubit gate error rates or the magnitude of crosstalk errors. Moreover, our methods allow for the benchmarking of universal gates, and continuously parameterized gates. We demonstrate our techniques on current systems, with experimental results on up to 16 qubits.

Perturbative density matrix propagation in Gate Set Tomography

ERIK NIELSEN (Presenter), Sandia National Laboratories, ROBIN BLUME-KOHOUT, Center for Computing Research, Sandia National Laboratories, TIMOTHY PROCTOR, Sandia National Laboratories, KENNETH RUDINGER, Center for Computing Research, Sandia National Laboratories, MOHAN SAROVAR, KEVIN YOUNG, Sandia National Laboratories — Model-based quantum tomography protocols like Gate Set Tomography optimize a noise model with some number of parameters in order to fit experimental data. As the number of qubits increases, two issues emerge: 1) the number of model parameters grows, and 2) the cost of propagating quantum states (density matrices) increases exponentially. The first issue can be addressed by considering reduced models that limit errors to being low-weight and geometrically local. In this talk, we focus on the second issue and present a method for performing approximate density matrix propagation based on perturbative expansions of error generators. The method is tailored to the likelihood optimization problem faced by model-based tomography protocols. We will discuss the advantages and drawbacks of using this method when characterizing the errors in up to 8-qubit systems.

Benchmarking the quantum processing power of large-scale quantum processors to execute specific programs

JOSEPH EMERSON (Presenter), JOEL WALLMAN, Institute for Quantum Computing, University of Waterloo — We propose an experimentally measurable quantity, the circuit quality Q of any hardware implementation of a quantum circuit, which can be efficiently estimated via clock cycle benchmarking, and discuss how this quantity can be applied to two key applications of circuit benchmarking: (i) determining the size of a quantum program that can be run on specific quantum hardware to within a specified tolerance; and (ii) establishing a family of cross-platform benchmarks for overall hardware performance. The first application provides an efficient means of assessing the overall error probability with which hardware can implement a quantum program beyond the horizon of classical computability, which will be tremendously important once quantum processors can outperform their classical counterparts. The second application is to define a practical, even-handed, and robust cross-platform benchmark of hardware performance for standardized quantum circuits. Our proposal for circuit benchmarking overcomes several problematic limitations of the `quantum volume' figure of merit and the implicit recipe for measuring it. These circuit quality benchmarks will be essential to assessing and improving hardware performance on the road to practical quantum computation that can solve real-world problems.

4:42PM P35.00010: Efficient learning of Pauli channels: learning tensor network models. STEVEN FLAMMIA (Presenter), University of Sydney; Yale University; Quantum Benchmark Inc.; JOEL WALLMAN, University of Waterloo; Quantum Benchmark Inc. — Noise is the central obstacle to building large-scale quantum computers. Of crucial importance is the ability to reliably and efficiently characterize quantum noise afflicting a large scale quantum device with high precision. Here we show that where we have a Pauli channel whose errors are have only k-local correlations we can learn the entire n-qubit Pauli channel to relative precision ε with only O(ε^{-2} n^2 log(n)) measurements. This is efficient in the number of qubits and represents a major breakthrough in the characterization of multi-qubit devices. These results have proven recovery guarantees for quantum channels to relative precision, representing a qualitative shift in the ability to characterize quantum devices. These results are practical, relevant and immediately applicable to characterizing error rates in current intermediate scale and future large-scale quantum devices on hundreds to thousands of qubits.

4:54PM P35.00011: Efficient learning of Pauli channels: learning sparse models JOEL WALLMAN (Presenter), University of Waterloo, STEVEN FLAMMIA, School of Physics, University of Sydney — The recent development of randomized compiling ensures that the general noise channel afflicting a universal quantum device can be reduced to stochastic Pauli noise. To characterize and optimize the remaining errors, methods are needed to characterize Pauli noise channels in intermediate and large-scale quantum devices. Here we introduce estimation protocols with relative error guarantees that enable efficient reconstructions of both complete and sparse Pauli channels. The protocol developed and analyzed is a variant of randomized benchmarking and the recently introduced cycle benchmarking. Like those protocols, the estimate is robust to state preparation and measurement error (SPAM). This robustness to SPAM together with the relative precision guarantees make the protocol appropriate for applications involving the characterization of high-accuracy gates. These results enable a host of applications beyond just characterizing noise in large-scale quantum systems: they pave the way to tailoring quantum codes, optimizing decoders, and customizing fault tolerance protocols to suit a particular device.

5:06PM P35.00012: Experimental reconstruction of all correlated error rates on a 16 qubit device. ROBIN HARPER (Presenter), University of Sydney, Quantum Benchmark, STEVEN FLAMMIA, University of Sydney, Yale University, Quantum Benchmark, JOEL WALLMAN, JOSEPH EMERSON, University of Waterloo, Quantum Benchmark — Recent results by Flammia and Wallman have shown how to reliably and efficiently characterize Pauli channels on intermediate and large-scale quantum devices. Here we leverage those results to give a complete, efficient, and high-precision, characterization of IBM's online 16 qubit device. Using experimental results from the device we obtain and present complete information about the correlated error rates across the device, comparing device characteristics when qubits are operated in single qubit mode and with qubit-to-qubit interactions enabled. The protocol we use obtains multiplicative precision and robustness to SPAM errors by using techniques originating from randomized benchmarking, and it can be executed on all current NISQ devices. The protocol is easy to implement, involving just computational basis state preparation and measurement together with only one-qubit Clifford gates. We show how this protocol can be scaled up to even larger devices of 100 or even 1000 qubits.

5:18PM P35.00013: Efficient Unitarity Randomized Benchmarking of Few-qubit Clifford Gates BAS DIRKSE (Presenter), JONAS HElsen, STEPHANIE WEHNER, QuTech, Delft University of Technology — Unitarity randomized benchmarking (URB) is an experimental procedure for estimating the unitarity of implemented quantum gates independently of state preparation and measurement (SPAM) errors. The unitarity is a measure of coherence of a quantum gate that provides information independent of average fidelity. A central problem in the URB experiment is relating the number of data points to rigorous confidence intervals around the unitarity. In this work we analyze the statistics of Clifford URB. We provide a bound on the required number of data points as a function of confidence and experimental parameters. The main ingredient for this result is a sharp bound on the variance of the data points due to the random sampling. Our result shows that estimating the unitarity of gates requires fewer data points as the gates become closer to being unitary, up to constant contribution due to SPAM errors. The bound is sufficiently sharp to benchmark small-dimensional systems in realistic parameter regimes using a modest number of data points. For example, we show that the unitarity of single-qubit Clifford gates can be rigorously estimated using few hundred data points under the assumption of gate-independent noise. This is a reduction of orders of magnitude compared to previously known bounds.

Session P37 GMAG DCMP DMP: Honeycomb Lattice and Other Low-D Models BCEC 206A -
Matthias Gohlke, Max-Planck-Institut fur Physik komplexer System - Tag(s): Focus
ZHENG-XIN LIU (Presenter), Department of Physics, Renmin University of China, BRUCE NORMAND, Neutrons and Muons Research Division, Paul Scherrer Institute — Kitaev materials have attracted great attention thanks to their potential for realizing the Kitaev model, an exactly solvable spin model that hosts topological quantum spin liquids. However, most Kitaev materials undergo phase transition into a magnetically ordered phase at low temperatures, indicating that non-Kitaev interactions are non-negligible. Recent experiments on the Kitaev material α-RuCl3 showed that, under very low temperature an intermediate in-plane magnetic field can suppress the static zigzag magnetic order and induce a liquid-like disordered phase. The nature of the field-induced disordered phase was not fully understood. Motivated by this issue, we studied the K-Γ model (K = 6.8 meV and Γ = 9.5 meV) which was the minimal model proposed to describe the low-energy physics of α-RuCl3. From variational Monte Carlo calculations, we found that in-plane magnetic field can indeed cause a phase transition from a zigzag ordered phase into a gapless U(1) Dirac spin liquid phase [1]. Our results semi-quantitatively explain the observed temperature dependence of spin-lattice relaxation rate $1/T_1 \sim T^3$ in a recent nuclear magnetic resonance experiment [2]. It was also shown that an out-of-plane magnetic field can induce a Kalmeyer-Laughlin-type abelian chiral spin liquid phase, which would show an integer-quantized thermal Hall effect. Our theory hopefully captures the low energy physics of α-RuCl3 and provides a clue to understand the experiments in related materials.

*This work was supported by the National Natural Science Foundation of China (Grant No. 11574392), the Ministry of Science and Technology of China (Grant No. 2016YFA0300504), and the Fundamental Research Funds for the Central Universities and the Research Funds of Renmin University of China (No. 15XNLF19).

DAVID RONQUILLO (Presenter), ADU VENGAL, NANDINI TRIVEDI, Ohio State University — The main question we address is how to probe the fractionalized excitations of a quantum spin-liquid (QSL), for example, in the Kitaev honeycomb model. From analyzing the energy spectrum and entanglement entropy, for antiferromagnetic couplings and a field along either [111], or [-110], we find a new gapless QSL phase, sandwiched between the non-Abelian Kitaev QSL and polarized phases. Rotating the field towards [001] destroys this intermediate QSL phase and results in a considerable reduction in the number of frequency modes. In certain parameter regimes, we observe a beating pattern in the local dynamical correlations, possibly observable in pump-probe experiments. Finally, we explore the field strength and orientation dependence of the longitudinal and transverse thermal conductivities of this model as a function of temperature.

*We acknowledge the support of DOE-BES grant DE-FG0207ER46423

JACOB GORDON (Presenter), ANDREI CATUNEANU, University of Toronto, ERIK SORENSEN, McMaster University, HAE-YOUNG KEE, University of Toronto — The Kitaev model is a rare example of an exactly solvable model which exhibits a spin liquid ground state, and hosts non-Abelian anyon excitations. Recent research has focused on material realization of Kitaev physics, with α-RuCl3 emerging as a leading candidate. Compelling evidence for a chiral spin liquid (CSL) is a half-quantized thermal Hall conductivity in α-RuCl3, a signature of Majorana edge currents. However, it remains a non-trivial task to explain the existence of a CSL in α-RuCl3 from a microscopic model, due to dominant ferromagnetic (FM) Kitaev interactions. This is because the FM Kitaev phase almost immediately transitions to the polarized phase in an applied field, with no intervening phase. Here we present a microscopic theory describing the existence of a CSL near the FM Kitaev regime under a magnetic field. Further implications related to the quantized thermal Hall conductivity are also discussed.

3:30PM P37.00004: Classical Kitaev model in a magnetic field  JEFFREY G. RAU (Presenter), PAUL A. MCCLARTY, Max Planck Institute for the Physics of Complex Systems, KARLO PENC, Hungarian Academy of Sciences, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems — We study the classical version of Kitaev's honeycomb model in the presence of a magnetic field. For an anti-ferromagnetic Kitaev coupling a classical spin liquid phase persists over a large window of field strength, independent of field direction. We characterize this phase using analytic arguments, a coarse-grained theory and via Monte Carlo simulations, finding the Coulomb correlations present at zero-field are immediately destroyed when the field is applied. We further probe the nature of this phase via the introduction of vacancies. Over a wide field range we find removing a site leaves the magnetization unchanged, the liquid exactly compensating the missing spin. Finally, we speculate on implications for the quantum model in the semi-classical limit.

3:42PM P37.00005: Plaquette order in classical spin liquid stabilized by strong off-diagonal exchange  ZHIJIE FAN (Presenter), PREETHA SAHA, DEPEI ZHANG, GIA-WEI CHERN, University of Virginia — We report a new classical spin liquid in which the collective flux degrees of freedom break the translation symmetry of the honeycomb lattice. This exotic phase exists in frustrated spin-orbit magnets where a dominant off-diagonal exchange, the so-called $\Gamma$ term, results in a macroscopic ground-state degeneracy at the classical level [1]. We demonstrate that the system undergoes a phase transition driven by thermal order-by-disorder at a critical temperature $T_c \approx 0.04 |\Gamma|$. Interestingly, while the cubic symmetry is broken at $T < T_c$, spins in the low temperature phase remain disordered. We show that this phase transition actually corresponds to plaquette ordering of hexagonal fluxes. By introducing a proper order parameter to describe this translational symmetry breaking, we performed extensive Monte Carlo simulations and finite-size analysis to investigate the nature of the plaquette-ordering transition. We also study the dynamical behavior of fluxes and the influence of other types of interactions on the phase transition.[1] I. Rousochatzakis and N. B. Perkins Phys. Rev. Lett. 118, 147204 (2017).

3:54PM P37.00006: Designing $S = 1$ Kitaev materials*  ANDREI CATUNEANU (Presenter), PANAGIOTIS PETER STAVROPOULOS, DARREN PEREIRA, HAE-YOUNG KEE, University of Toronto — As the spin $S = 1/2$ Kitaev model is gaining increasing attention, there have been theoretical efforts to understand if $S = 1/2$ Kitaev features appear in generalized Kitaev models with higher spins. In particular, numerical studies on the $S = 1$ Kitaev model show interesting results, but there is no microscopic understanding on how to generate such a bond-dependent $S = 1$ interaction in solid state materials. Here we present a microscopic mechanism and necessary ingredients to design the $S = 1$ Kitaev interaction. Candidate materials are also discussed.

*Supported by the NSERC of Canada, CIFAR and Compute Canada.

4:06PM P37.00007: Dynamical and finite temperature properties of Kitaev magnet beta-Li2IrO3 in magnetic field*  MENGQUN LI (Presenter), University of Minnesota, IOANNIS ROUSOCHATZAKIS, Department of Physics, Loughborough University, NATALIA PERKINS, University of Minnesota — We present theoretical study of the field-induced magnetic phases in the three-dimensional, hyperhoneycomb Kitaev compound beta-Li2IrO3. We show that a relatively weak magnetic field along the crystallographic b-axis drives the system from its incommensurate counter-rotating order to a correlated paramagnet, with a significant uniform ‘zigzag’ component superimposing the magnetization along the field. We compute the magnon excitation spectra, the dynamical spin structure factors and their polarization dependence and argue that our results provide additional distinctive fingerprint that can be checked experimentally. Finally, using extensive Monte Carlo simulations, we study the evolution of the magnetic orders with temperature and provide the finite temperature phase diagram of field-induced magnetic phases.

*NSF DMR-1511768

4:18PM P37.00008: Using light to tune magnetism on the honeycomb lattice  VICTOR QUITO (Presenter), REBECCA FLINT, Department of Physics and Astronomy, Iowa State University — The search for spin liquid phases in condensed matter systems has generated a lot of interest in recent years. In practice, however, such phases are usually restricted to small regions of phase diagrams, which makes them challenging to access in experiments. Concerning this issue, circularly polarized Floquet potentials have been shown to generate chiral fields on the kagome lattice, making it possible to tune between Z2 and chiral spin liquids [1]. Given the potential deconfined criticality and chiral spin liquid phases on honeycomb lattices, here we address the effects of different Floquet potentials in these lattices. We discuss, in particular, how periodic optical drives can be used to manipulate different spin exchange couplings. We also comment on how our results can be relevant to experiments.

Classification of spin liquids on the stuffed honeycomb lattice

JYOTISMAN SAHOO (Presenter), Iowa State University, DMITRII KOCHKOV, BRYAN CLARK, Physics, University of Illinois at Urbana Champaign, REBECCA FLINT, Iowa State University — We introduce the stuffed honeycomb lattice (a honeycomb lattice coupled to its dual - a triangular lattice) that interpolates between the triangular and the honeycomb lattices. We consider $S = 1/2$ Heisenberg spins. Our classical phase diagram reveals a multi-critical point on the triangular lattice axis, with two new neighboring noncollinear phases appearing only off axis. Our quantum phase diagram found via exact diagonalization hosts a large spin liquid (SL) region that eats up most of the phase space of the new classical phases around the multi-critical point. We present a projective symmetry group analysis of all possible symmetric SLs on the stuffed honeycomb lattice and attempt to probe the possible nature (gapless, nematic, etc) to compare to the SL region found in exact diagonalization. Among these SLs, we focus on characterizing the competitive ones found in a variational Monte Carlo analysis.

Field-induced Spin Liquid-like State in a Magnetic Honeycomb Lattice

RUIDAN ZHONG (Presenter), ROBERT CAVA, Department of Chemistry, Princeton University — Quantum fluctuations in magnetic lattices can yield a quantum spin liquid (QSL) state, where no long-range order appears even at zero temperature. The variety of mechanisms that can generate the spin liquid state and the more exotic QSL state remain unclear, however. Here, we report a new magnetic honeycomb system, BaCo$_2$(P$_{1-x}$V$_x$)$_2$O$_8$, in which the spin correlations can be tuned by the disorder, leading to different magnetic behaviors. At low $x$, the material has a spin glass ground state that appears to be due to coexisting and competing correlations. We have found that an external magnetic field can introduce spin liquid-like behavior for some members of the solid solution, testified by the magnetic and thermodynamic experiments. Our results suggest that structural geometry, chemical disorder and external field may help enhance quantum fluctuations in magnetic honeycomb materials.

Ripple state in the frustrated honeycomb-lattice antiferromagnet

TOKURO SHIMOKAWA (Presenter), Okinawa Institute of Science and Technology Graduate University, HIKARU KAWAMURA, Osaka University — Rich nontrivial magnetic structures in multiple-$q$ states have attracted much attention these days. One of the most celebrated example might be a skyrmion-lattice state known as a triple-$q$ state with forming periodic vortex-crystal structure. We have found a new type of multiple-$q$ state, a "ripple state" in the $J_1$-$J_2$ classical honeycomb-lattice Heisenberg antiferromagnet by means of extensive Monte Carlo simulations. This honeycomb model has been known to have an infinite ring-like degeneracy in the ground state. In the ripple state, surprisingly, order-by-disorder mechnism does not work and all wavevectors on the degenerate ring equally contribute to its order. The real-space spin texture of the ripple state does not form a crystal in spite of the breaking of the translational symmetry and seems to be like a "water ripple" observed when we throw a stone on the surface of water. We will talk about the detail of the intriguing properties of the ripple state and discuss the possible realization in the honeycomb-lattice spin-liquid material, Bi$_3$Mn$_4$O$_{12}$(NO$_3$).

AKLT-like valence bond solid state in the frustrated ferromagnetic $J_1$-$J_2$ chain

CIÒ EFTHIMIA AGRAPIDIS (Presenter), STEFAN-LÜDWIG DRECHSLER, JEROEN VAN DEN BRINK, S. NISHIMOTO, Institute for Theoretical Solid State Physics, IFW Dresden — Frustrated one-dimensional (1D) magnets are known as ideal playgrounds for new exotic quantum phenomena. We consider an elementary frustrated 1D system: the spin-1/2 ferromagnetic ($J_1$) Heisenberg chain with next-nearest-neighbor antiferromagnetic (AFM) ($J_2$) interactions. On the basis of density-matrix renormalization group calculations we show the existence of a finite spin gap at $J_2/|J_1| > 1/4$ and we find the ground state in this region to be a valence bond solid (VBS) with spin-singlet dimerization between third-neighbor sites. The VBS is the consequence of spontaneous symmetry breaking through order by disorder. Quite interestingly, this VBS state has an Affleck-Kennedy-Lieb-Tasaki-type topological order. We also investigate the possibility of multipolar physics induced by AFM interchain coupling.

5:18PM P37.00013: Critical properties of six-state clock model on randomly frustrated 2D lattices* TASRIEF
SURUNGAN (Presenter), Physics, Hasanuddin University, INDONESIA — We study the antiferromagnetic six-state clock model on bond-diluted triangular lattice, which is randomly frustrated. The corresponding pure system of the model experiences two separated phase transitions, i.e., the Kosterlitz-Thouless (KT) transition of magnetic ordering and the chiral ordering transition which occurs at slightly higher temperature. Due to discrete symmetry of spins there exists an additional KT transition at lower temperature, separating the true (magnetic) and the quasi-long range order (QLRO). As randomness is important for phase transition, it is desirable to probe the role played by dilution in affecting the existing KT transitions as well as the chiral ordering transition. With the presence of bond dilution in the triangular lattice the system is transformed from the fully frustrated into a randomly frustrated case. As the energy of the model is represented by the multiple of $J/2$, where $J$ is the coupling constant, we use Wang-Landau algorithm of Monte Carlo method. Various concentrations of depleted bonds were simulated. We observed a systematic decrease of critical temperatures, both for the KT transition and chiral transition, as the concentration of dilution increases. We obtained the phase diagram of the system.

Session P38 GMAG DMP: 2D Magnetism III BCEC 206B - Roopali Kukreja, University of California, Davis - Tag(s): Focus

2:30PM P38.00001: Properties of Monolayer Vanadium Dichalcogenides grown by molecular beam epitaxy* [Invited]
MATTIHAS BATZILL (Presenter), University of South Florida — Ferromagnetic ordering in monolayer vanadium dichalcogenides was predicted by DFT, despite the lack of ferromagnetic ordering in its bulk form. Ferromagnetic 2D materials with high Curie temperatures are highly sought to enable spintronic devices based on van der Waals heterostructures. In this talk we present a discussion of VSe$_2$ and VTe$_2$ monolayers grown by molecular beam epitaxy and study the difference of their monolayer properties compared to the bulk. In addition, to charge order states and structural variations of the monolayer and the bulk, we critically assess the origin of the measured ferromagnetic properties [1] in (sub)monolayer VSe$_2$.

3:06PM P38.00002: Rashba-type Dzyaloshinskii-Moriya interaction in h-BN/Co and graphene/Co heterostructures
JINGHUA LIANG (Presenter), Key Laboratory of Magnetic Materials and Devices, Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences, Ningbo, China, ALI HALLAL, FATIMA IBRAHIM, Univ. Grenoble Alpes, INAC-SPINTEC, F-38000 Grenoble, France, HONGXIN YANG, Key Laboratory of Magnetic Materials and Devices, Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences, Ningbo, China, MAIRBEK CHSHIEV, Univ. Grenoble Alpes, INAC-SPINTEC, F-38000 Grenoble, France — With the recently observed chiral domain wall structures at the graphene/ferromagnet interfaces [1,2], the Dzyaloshinskii-Moriya interaction (DMI) in light element/ferromagnet heterostructures has become of great interest for spintronics. Here, we present a comparative study of the Rashba-type DMI in the h-BN/Co and graphene/Co heterostructures using first-principles calculations. Unexpectedly, they show opposite trend as a function of Co thickness. With the increase of Co thickness, the DMI coefficient of h-BN/Co first increases gradually and then saturates at around 1.1 meV for thick Co layers, whereas the DMI at graphene/Co interfaces first decreases and then stabilizes at about 0.1 meV for large Co thickness. For thick Co layers, the DMI strength of h-BN/Co is one order of magnitude larger than that of graphene/Co. The origin of this discrepancy is attributed to the different contribution from the hybridization between dz$^2$ and d$xz$ orbitals of the interfacial Co layer to the DMI energy source. These results give deeper insight into microscopic formation of DMI and should help to optimize the material selection for future spin-orbitronic devices.

**3:18PM P38.00003: Strong and Tunable Spin Lifetime Anisotropy in Dual-Gated Bilayer Graphene**
JINSONG XU (Presenter), TIANCONG ZHU, YUNQIU (KELLY) LUO, YUAN-MING LU, ROLAND KAWAKAMI, Ohio State University — We report the discovery of a strong and tunable spin lifetime anisotropy with excellent out-of-plane spin lifetimes up to 7.8 ns at 100 K in dual-gated bilayer graphene. Remarkably, this realizes the manipulation of spins in graphene by electrically-controlled spin-orbit fields, which is unexpected due to graphene's weak intrinsic spin-orbit coupling (~12 μeV). We utilize both the in-plane magnetic field Hanle precession and oblique Hanle precession measurements to directly compare the lifetimes of out-of-plane vs. in-plane spins. We find that near the charge neutrality point, the application of a perpendicular electric field opens a band gap and generates an out-of-plane spin-orbit field that stabilizes out-of-plane spins against spin relaxation, leading to a large spin lifetime anisotropy (defined as the ratio between out-of-plane and in-plane spin lifetime) up to ~12 at 100 K. This intriguing behavior occurs because of the unique spin-valley coupled band structure of bilayer graphene. Our results demonstrate the potential for highly tunable spintronic devices based on dual-gated 2D materials.

**3:30PM P38.00004: Ultrafast Spin and Charge Dynamics in Monolayer WSe₂-Graphene Heterostructures**
MICHAEL NEWBURGER (Presenter), YUNQIU (KELLY) LUO, Ohio State University, KATHLEEN MCCREARY, Naval Research Lab, Iwan MARTIN, ELIZABETH MCCORMICK, Ohio State University, BEREND JONKER, Naval Research Lab, ROLAND KAWAKAMI, Ohio State University — Monolayer transition metal dichalcogenides (TMDs) have garnered much attention due to their long spin/valley lifetimes and ability to optically excite spin/valley polarization. Additionally, one of the great strengths of TMDs is their ability to compliment other materials, such as graphene, by acting as a means of optical spin injection or proximity coupling. Recently proximity mediated charge transfer and optical spin injection has been demonstrated in TMD/graphene heterostructures. However, the spin transfer dynamics across a TMD/graphene interface remain largely unexplored.

Here we use time-resolved Kerr rotation (TRKR) microscopy to image the spatial dependence of spin/valley dynamics in monolayer WSe₂/graphene heterostructures. While the bare WSe₂ demonstrates long-lived spin valley lifetimes, spatial maps reveal a quenching of spin-valley signal at the WSe₂/graphene interfaces. Time delay scans show this quenched lifetime to be up to 3 orders of magnitude lower than in bare WSe₂. These interfaces also exhibit quenched photoluminescence and enhanced photoconductivity, demonstrating efficient charge transfer from WSe₂ to graphene. Consequently, we attribute the ultrafast spin/valley quenching to spin transfer by conducted charge carriers.

**3:42PM P38.00005: Organization and magnetic properties of mass-selected FePt nanoparticles deposited on epitaxially grown graphene on Ir(111)**
FLORENT TOURNUS (Presenter), PIERRE CAPIOD, LAURENT BARDOTTI, ALEXANDRE TAMION, VERONIQUE DUPUIS, Institut Lumière Matière, Université Lyon 1-CNRS, GILLES RENAUD, INAC, Univ. Grenoble Alpes - CEA, PHILIPPE OHRESSER, Synchrotron SOLEIL — The FePt alloy, when chemically ordered in the L1₀ phase, is among the magnetic materials displaying the highest magnetic anisotropy constant. Therefore it is a perfect candidate for ultra-high density magnetic storage applications, provided nanoparticles can be prepared in such a high anisotropy phase and organized in a 2D array. One path of bottom-up elaboration following a physical route consists in using template surfaces with specific sites regularly distributed. Such a 2D lattice can be obtained with the moiré (hexagonal lattice of 2.5 nm cell parameter) displayed by a graphene layer epitaxially grown on a Ir(111) surface [2]. For the first time, we have characterized the organization and the magnetic properties of FePt nanoparticles on such a moiré pattern. FePt/graphene/Ir(111) samples have been prepared using Low Energy Cluster Beam Deposition [3] of preformed size-selected FePt nanoparticles (around 2 nm diameter). We will discuss the organization of such particles on specific sites of the moiré lattice, as determined by grazing incidence x-ray scattering measurements [4]. The deposited nanoparticles are sensitive to the moiré pattern and we find that the resulting organization can be preserved up to temperatures around 700°C. Using X-ray Magnetic Circular Dichroism measurements, we will report a clear evolution of the magnetic properties of the FePt nanoparticles induced by annealing (anisotropy modification, interface effects between FePt and the graphene...), while the particles keep their individuality (no layer formation is observed).

which could be useful to manipulate spins for a long time at room temperature. Our work provides an insight into the physical origin of long-lived spin polarization in Weyl semimetals addition, we find the spin polarization is firmly pinned along the strong internal out-of-plane magnetic field induced by recombination rate and suppression of backscattering required by time-reversal and lattice symmetry operation. In this work, we show a room-temperature spin relaxation time of 1.2 ns (0.4 ns) in CVD-grown WTe2 (MoTe2) thin films using measurements allow us to calculate the momentum relaxation time as a function of carrier concentration and compare it to the spin lifetime [1]. We demonstrate the operation of WS2/graphene/fluorographene non-local spin valves and extract the spin lifetimes for a range of carrier concentrations by Hanle effect measurements. Four-terminal charge transport measurements allow us to calculate the momentum relaxation time as a function of carrier concentration and compare it to the spin lifetime. These data show that the Dyakonov-Perel' mechanism is the dominant spin relaxation mechanism for WS2/graphene/fluorographene devices. Without WS2, linear scaling between the spin and momentum lifetimes points to spin-flip scattering during strong elastic scattering events strongly coupled to the electron spin. We attribute the change in spin relaxation type in part with the inclusion of WS2 as a substrate to proximity induced spin-orbit coupling due to the adjacent WS2 layer, and we compare our data to the literature. [1] A.L. Friedman, et al. Carbon 131, 18-25 (2018).

**4:42PM P38.00008: Oscillated Dzyaloshinskii-Moriya interaction at hydrogenated Graphene/Co interfaces**

BAISHUN YANG (Presenter), QIRUI CUI, JINGHUA LIANG, HONGXIN YANG, Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences — Magnetic topological structures such as chiral domain walls and Skyrmions are becoming a hot topic due to its potential application for future information storage. One of the key ingredient for the formation of these spintextures is the Dzyaloshinskii-Moriya interaction (DMI) in symmetry broken systems. Recently, it was reported that DMI can be induced in Co/Gr heterostructure due to the Rashba effect.[1] Considered that hydrogenated graphene (H-graphene) can enhance the spin orbit coupling of carbon atoms. Therefore, here, we propose to use interfaces between Co and H-graphene to tune DMI. Using first principles calculations, we find that the strength of DMI can be largely modulated by the concentration of H coverage on graphene, e.g., the anti-clockwise chiral of Co/Gr could be tuned to clockwise chiral in a Co(2ML)/1/2H-graphene with amplitude up to 1.0 meV/bond. Moreover, there is an obvious oscillation of DMI as a function of Co thickness ranging from 1ML to 7ML. The strength of DMI and this oscillation may origin from the change of SOC energy and electron filling in Co/Gr with different hydrogen concentration.

**4:30PM P38.00007: Examination of the magnetic interactions between divacant Fe dimers in graphene**

RONALD E PUTNAM (Presenter), Department of Physics, University of North Florida, ALEXANDER BALATSKY, Institute for Materials Science, Los Alamos National Laboratory, JASON HARALDSEN, Department of Physics, University of North Florida — In this study, we investigate the isolated magnetic interactions between two identical Fe atoms substituted into graphene. Using density functional theory, we simulated the electronic and magnetic properties for a supercell of graphene with variably-spaced iron atoms in the divacant configuration. Overall, we find that the exchange interaction between the two Fe atoms fluctuates from ferromagnetic to antiferromagnetic as a function of the spatial distance in the armchair direction. Given the induced magnetic moment and increased density of states at the Fermi level by the surrounding carbon atoms, we conclude that the exchange interactions between the Fe atoms can be characterized by an RKKY-like interaction. Furthermore, we examined the same interactions for Fe atoms along the zig-zag direction in graphene and find no evidence for an RKKY interaction as this system shows standard superexchange between the transition-metal impurities. Therefore, we determine that Fe-substituted graphene produces a directional-dependent spin interaction, which may provide stability to spintronic and multifunctional devices and applications for graphene.

*Institute for Materials Science at Los Alamos

**4:42PM P38.00008: Spin relaxation and proximity effect in WS2/graphene/fluorographene non-local spin valves**

ADAM FRIEDMAN (Presenter), Laboratory for Physical Sciences, KATHLEEN MCCREARY, JEREMY T ROBINSON, OLAF M VAN TERVE, BEREND JONKER, US Naval Research Laboratory — Control of the spin relaxation in graphene-based structures is necessary to achieve the envisioned utility of graphene in future spintronic devices beyond Moore's law. Proximity induced spin relaxation caused by contact to a high spin-orbit material, such as WS2, offers a promising avenue to manipulate the spin lifetime [1]. We demonstrate the operation of WS2/graphene/fluorographene non-local spin valves and extract the spin lifetimes for a range of carrier concentrations by Hanle effect measurements. Four-terminal charge transport measurements allow us to calculate the momentum relaxation time as a function of carrier concentration and compare it to the spin lifetime. These data show that the Dyakonov-Perel' mechanism is the dominant spin relaxation mechanism for WS2/graphene/fluorographene devices. Without WS2, linear scaling between the spin and momentum lifetimes points to spin-flip scattering during strong elastic scattering events strongly coupled to the electron spin. We attribute the change in spin relaxation type in part with the inclusion of WS2 as a substrate to proximity induced spin-orbit coupling due to the adjacent WS2 layer, and we compare our data to the literature. [1] A.L. Friedman, et al. Carbon 131, 18-25 (2018).

**4:54PM P38.00009: Room-temperature long-lived spin polarization in Weyl semimetal thin film**

QISHENG WANG (Presenter), HYUNSOO YANG, Department of Electrical and Computer Engineering, and NUSNNI-NanoCore, National University of Singapore — The Weyl semimetals WTe2 and MoTe2 show a great potential in generating large spin currents since they possess topologically-protected spin-polarized states and can carry a very large current density. In addition, the intrinsic noncentrosymmetry of WTe2 and MoTe2 endows with a unique property of crystal symmetry-controlled spin-orbit torques. An important question to be answered for developing spintronic devices is how spins relax in WTe2 and MoTe2. In this work, we show a room-temperature spin relaxation time of 1.2 ns (0.4 ns) in CVD-grown WTe2 (MoTe2) thin films using the time-resolved Kerr rotation (TRKR). Based on ab initio calculation, we identify a mechanism of long-lived spin polarization resulting from a large spin splitting (~40 meV) around the bottom of the conduction band, low electron-hole recombination rate and suppression of backscattering required by time-reversal and lattice symmetry operation. In addition, we find the spin polarization is firmly pinned along the strong internal out-of-plane magnetic field induced by large spin splitting. Our work provides an insight into the physical origin of long-lived spin polarization in Weyl semimetals which could be useful to manipulate spins for a long time at room temperature.
5:06PM P38.00010: Gate-tunable magnetism of C adatoms on graphene* JOHANNES NOKELAINEN (Presenter), Lappeenranta University of Technology, IGOR ROZHANSKY, Ioffe Institute, BERNARDO BARBIELLINI, ERKKI LAHDERANTA, KATARIINA PUSSI, Lappeenranta University of Technology — We have performed density functional theory calculations of graphene decorated with carbon adatoms, which bind at the bridge site of a C–C bond. Earlier studies have shown that the C adatoms have magnetic moments and have suggested the possibility of ferromagnetism with high Curie temperature. Here we propose to use a gate voltage to fine tune the magnetic moments from zero to 1\(\mu_B\) while changing the magnetic coupling from antiferromagnetism to ferromagnetism and again to antiferromagnetism. These results are rationalized within the Stoner and RKKY models. When the SCAN meta-GGA correction is used, the magnetic moments for zero gate voltage are reduced and the Stoner band ferromagnetism is slightly weakened in the ferromagnetic region.

*This work was supported by the Academy of Finland Grants No. 277829, 318500 and benefited from the generously allocated computer time at CSC — Finnish IT Center for Science.

5:18PM P38.00011: Quench dynamics of localized zero energy states in graphene* DEEPAK IYER (Presenter), Physics and Astronomy, Bucknell University, MATTHEW FOSTER, Physics and Astronomy, Rice University — In an external magnetic field, graphene forms Landau levels with an 'anomalous' level spacing due to the low energy linear dispersion. This creates a significant difference between the Landau level splitting and Zeeman splitting, allowing for nontrivial spin dynamics within a Landau level. It is expected that the ground state of the half-filled zeroth Landau level supports Skyrmions as low energy charged excitations, which can in principle exhibit collective dynamics under an external time dependent electromagnetic field via direct coupling to the Skyrmion (topological) charge density. In order to understand the dynamics, we study the related problem of massive Dirac fermions in two dimensions after a quench from an initial state containing localized zero-modes (vortices, in particular) into a homogeneous system with a Haldane mass. The Haldane term gives the leading order effect of a high-frequency drive. The one dimensional version of the problem with mass defects also leads to localized zero modes, and fractional charge. We follow the time evolution of various order parameters in these models and look for dynamical signatures of these zero modes.

Session P39 GMAG DCMP DMP: Magnetism and Spins in Semiconductors BCEC 207 - Yu-Sheng Ou, University of Delaware - Tag(s): Focus

2:30PM P39.00001: First-principles investigation of the magnetic transition in Fe-doped GaSb and InSb HIKARI SHINYA (Presenter), Yokohama National University, TETSUYA FUKUSHIMA, AKIRA MASAGO, KAZUNORI SATO, Osaka University, HIROSHI KATAYAMA-YOSHIDA, The University of Tokyo — Recently, Fe-doped semiconductors have been attracting much attention as ferromagnetic semiconductors due to the possibility of high Curie, fascinating functions such as low power consumption and high-speed operation, and fabrication of both n- and p-type. In this study, we have focused on GaSb and InSb as host semiconductors, and performed density functional theory calculations using the Korringa-Kohn-Rostoker Green's function method with the coherent potential approximation (KKR-CPA). Our calculations reveal that, (Ga,Fe)Sb and (In,Fe)Sb show complex magnetic properties, which are determined by the correlation between magnetic exchange coupling constants and chemical pair interactions. Isoelectronic Fe-doped GaSb and InSb show strong antiferromagnetic interactions that originate from the super-exchange mechanism works between the Fe atoms. By modulating the chemical potentials—i.e., by n- or p-type doping—, the magnetic property can be changed drastically from antiferromagnetism to ferromagnetism, because the ferromagnetic double exchange mechanism becomes dominant. This transition can be well understood in terms of the Alexander-Anderson-Moriya mechanism. Our calculations indicate the possibility of manipulating (Ga,Fe)Sb and (In,Fe)Sb to achieve high Curie temperatures.
2:42PM P39.00002: A multi-bands Hubbard model of intrinsic long range magnetic order in diluted magnetic semiconductors* WEIYI GONG (Presenter), CHING-HIM LEUNG, CHUEN-KEUNG SIN, JINGZHAO ZHANG, XIAODONG ZHANG, BIN XI, JUNYI ZHU, Physics, The Chinese University of Hong Kong — Recently, new long range ferromagnetic order has been discovered both experimentally and theoretically in carrier free semiconductor. However, there lacks quantitative model to explain the coupling mechanism that may extend to 7th nearest neighbors. In this work, we derived a multi-bands Hubbard model to explain the long range mechanism mediated by localized d states. Based on this model and combining with DFT calculations, we discovered a long range AFM order in DMS systems. Our model provides fundamental understandings of the new type of magnetic order in DMS.

*We are grateful for the financial support of Chinese University of Hong Kong (CUHK) (Grant No.4053084), University Grants Committee of Hong Kong (ECS Grant No. 24300814, GRF Grant No. 14319716, GRF Grant No. 14307018), and start-up funding of CUHK.

2:54PM P39.00003: Theoretical prediction of maximum Curie temperatures of Fe-based dilute magnetic semiconductors by first-principles calculations HIKARI SHINYA, Yokohama National University, TETSUYA FUKUSHIMA (Presenter), AKIRA MASAGO, KAZUNORI SATO, Osaka University, HIROSHI KATAYAMA-YOSHIDA, The University of Tokyo — Recently, Fe-based dilute magnetic semiconductors (DMSs), such as (In,Fe)As, (In,Fe)Sb and (Ga,Fe)Sb, have strongly attracted scientific and industrial attention, because of their high Curie temperatures and n-type carrier induced ferromagnetism. Several experiments showed that the ferromagnetic properties in Fe-based DMSs are strongly related to the inhomogeneous distribution of the Fe atoms, i.e., the Curie temperatures are modulated by the spinodal nano-decomposition, depending on crystal growth conditions. In this work, we predict the maximum Curie temperatures of the Fe-based DMSs with the spinodal nano-decomposition, on the basis of the Korringa-Kohn-Rostoker (KKR) Green's function method within the density functional theory. The magnetic exchange coupling constants between the Fe atoms are calculated by the Liechtenstein's formula, and then the Curie temperatures are estimated by the mean field approximation. It is found, from our calculations, that one can expect very high Curie temperatures beyond the room temperature in Fe-based DMSs, if the many Fe atoms gather together in the host semiconductor with keeping the zinc-blende structure and additional n- or p-type carriers are introduced.

3:06PM P39.00004: Element- and momentum-resolved electronic structure of the dilute magnetic semiconductor manganese doped gallium arsenide [Invited] SLAVOMIR NEMSAK (Presenter), Advanced Light Source, Lawrence Berkeley National Laboratory, JAN MINÁR, University of West Bohemia, CHARLES S FADLEY, Department of Physics, University of California, Davis — The dilute magnetic semiconductors have shown great promise in spin-based electronics applications due to their potential for ferromagnetic order at room temperature, and various unique switching and spin-dependent conductivity properties. However, the precise mechanism by which the transition-metal doping produces ferromagnetism has been controversial. We have studied a dilute magnetic semiconductor (5% manganese-doped gallium arsenide) with Bragg-reflection standing-wave hard X-ray angle-resolved photoemission spectroscopy (SW-HARPES), and resolved its electronic structure into element- and momentum- resolved components. The measured valence band intensities have been projected into element-resolved components using analogous photon energy scans of Ga 3d, Mn 2p, and As 3d core levels, with results in excellent agreement with element-projected Bloch spectral functions, further clarifying the electronic structure of this prototypical material. We will further discuss the capabilities of the SW-HARPES technique, which should be broadly applicable to other multi-element materials.

3:42PM P39.00005: Ferromagnetic Stabilization of Eu-doped GaN Enhanced by Ga-vacancies AKIRA MASAGO (Presenter), CSRN, Osaka University, HIKARI SHINYA, Graduate School of Engineering, Yokohama National University, TETSUYA FUKUSHIMA, INSD, Osaka University, KAZUNORI SATO, Graduate School of Engineering, Osaka University, HIROSHI KATAYAMA-YOSHIDA, CSRN, The University of Tokyo — We report that the ferromagnetic states are stabilized by the double exchange interaction which enhanced by partially occupied N-2p hole band caused by Ga-vacancies in Eu-doped GaN, based on self-interaction-corrected (SIC) local density approximation. Eu-doped GaN is renowned for red light emitting diodes (LEDs), whereas it is interesting as a circular-polarized emission in the magnetic materials. In this study, we used a constant volume assumption and the coherent potential approximation (CPA) in the Korringa-Kohn-Rostoker (KKR) method with SIC. As a result, it indicates that electron-hole doping enhances the ferromagnetic states, because the dominant magnetic interaction is changed from Zener's p-f exchange interaction to Zener's double exchange interaction caused by the partially occupied N-2p band. In the enhancement, a major contribution to the magnetism is derived from the Ga-vacancies more than magnetic impurities Eu, which coupled with N anti-ferromagnetically.
4:06PM P39.00007: Biaxial-stress driven tetragonal symmetry breaking in and high-temperature ferromagnetic semiconductor from half-metallic CrO$_2$ * XIANG-BO XIAO (Presenter), BANG-GUI LIU, Institute of Physics — Here, we find through first-principles investigation that when a biaxial compressive stress is applied on rutile CrO$_2$, the density of states at the Fermi level decreases with the in-plane compressive strain, there is a structural phase transition to an orthorhombic phase at the strain of -5.6%, and then appears an electronic phase transition to a semiconductor phase at -6.1%. Further analysis shows that this structural transition, accompanied by the tetragonal symmetry breaking, is induced by the stress-driven distortion and rotation of the oxygen octahedron of Cr, and the half-metal-semiconductor transition originates from the enhancement of the crystal field splitting due to the structural change. Importantly, our systematic total-energy comparison indicates that the ferromagnetic Curie temperature remains almost independent of the strain, near 400 K. This biaxial stress can be realized by applying biaxial pressure or growing the CrO$_2$ epitaxially on appropriate substrates.

4:18PM P39.00008: Design of Super-High-T$_C$ high-entropy ferromagnetic semiconductors in Fe-doped III-V compound semiconductors by spinodal nano-decomposition and volume compensated codoping HIKARI SHINYA, Yokohama National University, TETSUYA FUKUSHIMA, AKIRA MASAGO, KAZUNORI SATO, Osaka University, HIROSHI KATAYAMA-YOSHIDA (Presenter), The University of Tokyo — Based on the three general design rules of (1) the volume compensations [VC] by codoping, (2) spinodal nano-decomposition [SND], and (3) high-entropy ferromagnetic semiconductors [HEFS], we design the super-high-T$_C$ (T$_C$ > 1000K) HEFS in Fe-doped III-V compound semiconductors by computational nano-materials design. The substitutional(S) Fe impurity [Fe(S)] reduces the volume, while the interstitial (I = tetrahedral or octahedral site) Fe impurity [Fe(I)] expands the volume in III-V compound semiconductors, which is called volume compensation. The solubilities of the Fe(S) and Fe(I) are low due to the positive formation energy, so that the SND occurs due to the positive mixing energy. Based on the codoping of isoelectric Fe(S) and triple donors of Fe(I) more than 15~20%, we design the HEFS with super-high-T$_C$ based on the strong ferromagnetic double exchange interactions in SND.

4:30PM P39.00009: Interlayer Exchange Coupling Mediated by a Bulk Rashba Semiconductor * MAHMOUD ASMAR (Presenter), WANG KONG TSE, Physics and Astronomy and The Center for Materials for Information Technology, The University of Alabama, Tuscaloosa. — Spin orbit coupling (SOC) in solids is a crucial ingredient in spintronic and magnetoelectronic phenomena. An example of SOC in solids is the 3D Rashba effect that arises in materials with broken inversion symmetry such as BiTeX (X=I,Cl and Br). These bismuth tellurohalides exhibit a giant Rashba coupling and are known as bulk Rashba semiconductors. In this talk, we present a RKKY theory for the interlayer exchange coupling in ferromagnet-BiTeX-ferromagnet trilayers. Due to the helical in-plane spin textures and associated Berry phase of the low-energy electrons, the interlayer exchange coupling as a function of layer thickness is found to exhibit unconventional dependence on the Rashba SOC.

4:42PM P39.00010: Bias dependence of spin accumulation voltage in a non-degenerate Si spin valve  
SOOBEOM LEE (Presenter), FABIEN RORTAIS, RYO OHSHIMA, YUICHIRO ANDO, Department of Electronic Science and Engineering, Kyoto University, SHINJI MIWA, YOSHISHIGE SUZUKI, Graduate School of Engineering Science, Osaka University, HAYATO KOIKE, Advanced Products Development Center, TDK Corporation, MASASHI SHIRAISHI, Department of Electronic Science and Engineering, Kyoto University — Si spintronics attracts great attention, and recent achievements in the field, such as the room temperature (RT) operation of spin MOSFET and the output spin voltage of more than 1 mV at RT due to the spin drift effect [1, 2], have been done by using non-degenerate (ND) Si. In the previous research [2], the spin voltages exhibited saturation under a high electric current ($I_{inj}$) injection regime, suggesting a possibility of modification of spin transport properties in the ND Si. Hence, we clarified the origin of the $I_{inj}$ dependence of the spin signals in the ND Si in this study.

The non-local 4-terminal measurement and the Hall measurement revealed that spin lifetime of the ND Si channel were independent of the $I_{inj}$ at RT. Meanwhile, interface resistance of Fe/MgO/Si contact was reduced to the same order of spin resistance of the Si channel. A model calculation considering these results nicely reproduced the experimental $I_{inj}$ dependence [3]. The detail will be discussed in the presentation.

4:54PM P39.00011: Magnetotransport in InSb nanowires with ferromagnetic contacts  
ZEDONG YANG (Presenter), University of Minnesota, YIFAN JIANG, University of Pittsburgh, DIANA CAR, SASA GAZIBEGOVIC, Eindhoven University of Technology, PAUL CROWELL, University of Minnesota, SERGEY M FROLOV, University of Pittsburgh, ERIK P. A. M. BAKkers, Eindhoven University of Technology, VLAD S Pribiag, University of Minnesota — InSb semiconductor nanowires are a promising and intensely-studied platform for investigating Majorana bound states [1]. Their strong spin-orbit coupling also makes them interesting for all-electrical control of single spins [2]. Moreover, owing to their relatively long mean free paths and quasi-one-dimensionality, InSb nanowires also have great potential for novel devices which could allow electrical control of spin currents. Motivated by these intriguing possibilities, we fabricated InSb nanowire devices with ferromagnetic contacts, which show evidence of ballistic transport. We report hysteretic features in the magneto-conductance measured at different back-gate voltages, and discuss the possible physical mechanisms responsible for these observations.

Session P40 GMAG DMP DCOMP: Emergent Magnetism in Oxide Films and Heterostructures  
BCEC 208 - Jian Liu, University of Tennessee - Tag(s): Focus

2:30PM P40.00001: Decoupling the Strain and Doping Effects on Magnetic Anisotropy in La$_x$Sr$_{1-x}$MnO$_3$ via ferroelectric Polarization Control*  
YIFEI HAO (Presenter), ANIL K RAJAPITAMAHUNI, LINGLING TAO, XIAOSHAN XU, EVGENY Y TSYMBAL, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln — In this study, we use epitaxial Pb(Zr,Ti)O$_3$ (PZT)/ La$_{0.8}$Sr$_{0.2}$MnO$_3$ (LSMO) heterostructures as a model system to decouple the effects of epitaxial strain and charge doping on the magnetocrystalline anisotropy (MCA) in LSMO. By switching the polarization of PZT, we have achieved nonvolatile modulation of the biaxial in-plane magnetic anisotropy in LSMO, as revealed by planar Hall effect studies. The magnetic anisotropy energy (MAE) in the hole accumulation state is enhanced by about 22% compared to the depletion state, in quantitative agreement with the DFT calculations. In contrast, the MAE extracted in chemically doped LSMO films is significantly lower than the theoretical prediction, clearly illustrating the difference between the electric field effect doping and chemical substitution. The discrepancy has been attributed to the different lattice parameters for bulk LSMO at these compositions, where the higher doping sample is subjected to a larger tensile strain on SrTiO$_3$ substrates, concomitantly lowering the MCA. Our result provides the first combined experimental and theoretical study that unambiguously identifies the role of charge doping in determining the MCA in LSMO.

Ultra-low-power magnetization rotation by orbital selection at a La$_{0.67}$Sr$_{0.33}$MnO$_3$/SrTiO$_3$ interface*

LE DUC ANH (Presenter), TAKASHI YAMASHITA, HIROKI YAMASAKI, DAISEI ARAKI, MUNETOSHI SEKI, HITOSHI TABATA, MASAAKI TANAKA, SHINOBU OHYA, University of Tokyo — Reducing the power consumption for magnetization switching is essential for the realization of energy-saving spin devices. Here, using a magnetic tunnel junction consisting of La$_{0.67}$Sr$_{0.33}$MnO$_3$ (LSMO) / SrTiO$_3$ (STO) / LSMO grown on STO (001), we demonstrate a deterministic and magnetic-field-free 90°-magnetization switching solely by applying an extremely small electric field of 0.05 V/nm on the tunnel barrier and an infinitesimal current density of ~ 10$^{-2}$ A/cm$^2$, which is ~8 orders of magnitude smaller than that in the present magnetic random access memory. We reveal that this magnetization rotation is induced by a sharp change in the magnetic anisotropy (MA), which occurs at the bias voltage $V$ of ~ ±0.1 V. By measuring the angular dependence of the density of states on the magnetization direction for the same device, we show that the change of MA occurs when the quasi-Fermi level ($E_F$) moves from $e_g$ to $t_{2g}$ bands at the LSMO/STO interface with increasing $|V|$ [1]. These findings suggest that highly efficient magnetization control can be realized by designing materials so that the $E_F$ lies close to the band edges of different-symmetry orbitals.

Oxygen Vacancies Control Interface Magnetism in La$_{0.7}$Sr$_{0.3}$MnO$_3$/SrTiO$_3$ Heterostructures*

JUAN I. BELTRAN, JAVIER GRANDAL, JAVIER TORNOS, CARLOS LEON, JACOBO SANTAMARÍA, MARIA VARELA (Presenter), Complutense University, M. CARMEN MUÑOZ, ICMM-CSIC, Spain — O vacancies strongly influence the properties of complex oxides and give rise to novel and unexpected phenomena. Here we combine first-principles density-functional theory with high spatial resolution electron energy-loss spectroscopy and energy-loss magnetic chiral dichroism (EMCD) to show that O vacancies control interface magnetism in La$_{0.7}$Sr$_{0.3}$MnO$_3$/SrTiO$_3$ heterostructures grown by high-pressure O$_2$ sputtering. EMCD measurements obtained at low temperature (<100K) are sensitive to the local magnetization with atomic resolution, revealing the formation of Ti and the increase of Mn magnetic moments near the interface. Comparison to the calculated electronic properties unambiguously demonstrates the O vacancy origin of the enhanced interface magnetism. The ideal interface - cleavage of bulk components - shows no charge transfer to the STO, while O vacancies induce finite occupancy of the Ti d-orbitals and hole depletion at the Mn interface planes, enhancing interface magnetism. Our results indicate that the control of O vacancies is a promising approach to improve the magnetic properties of LSMO/STO interfaces.

Local Control of Magneto-crystalline Anisotropy of La$_{0.7}$Sr$_{0.3}$MnO$_3$ Thin Films through Ion Implantation*

MICHAEL STEVEN LEE, Materials Science and Engineering, University of California, Davis, RAJESH V CHOPDEKAR, ELKE ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, YAYOI TAKAMURA (Presenter), Materials Science and Engineering, University of California, Davis — Control of the functional properties of thin films, including the magneto-crystalline anisotropy, is critical for the development of future memory and spintronic devices. Perovskite oxides offer stimulus-sensitive properties due to the strong coupling between their spin, orbital, lattice, and charge degrees of freedom. In this work, we found that ion implantation of La$_{0.7}$Sr$_{0.3}$MnO$_3$ films induces changes in the magnetic anisotropy by causing an out-of-plane lattice expansion while the film remains coherently strained to the substrate. However, the ion implantation also leads to a reduction in Curie temperature and saturation magnetization. X-ray absorption spectroscopy shows this degradation in magnetic properties is in part due to the reduced Mn oxidation state, in addition to crystalline damage. With the proper substrate selection and optimization of ion implantation conditions, the easy axis of the film can be tuned from in-plane to out-of-plane while minimizing the reduction in magnetization. These results may enable the design of unique magnetic spin textures such as magnetic skyrmions in a single layer of material containing adjacent regions of in-plane and out-of-plane magnetization.

Precipitating the unique transition from paramagnet to ferromagnet found in LaCoO₃ films. In essence, spin state order is frozen by epitaxial strain, concurrent order of Co charge and spin states arises, as shown by a combination of resonant x-ray scattering and as observed in the x-ray absorption near edge structure (XANES) and stabilize an ordered arrangement of Co sites. In turn, symmetry from rhombohedral in bulk to monoclinic. These structural distortions reduce the Co-O orbital hybridization strain lengthens the in-plane Co-O bonds, thereby distorting the cobalt containing oxygen octahedra, and lowers the observed magnetic phase transition, from antiferromagnetic at 5 unit cells (uc) of LMO or below to ferromagnetic at 6 ucs or above. Here, we offer an atomic resolution picture of electronic reconstruction by quantifying the charge distribution across this abrupt magnetic transition using STEM-EELS. We find that the electronic reconstruction is confined within the first 2 ucs of LMO from the interface, and more importantly, it is robust against oxygen non-stoichiometry. When restoring stoichiometry, we achieve a ferromagnetic insulating state in LMO films with a thickness as thin as 2 nm, making LMO readily applicable as barriers in spin filters.

Size restricted magnetotransport in the non-magnetic delafossite metals PdCoO₂ and PtCoO₂

NABHANILA NANDI (Presenter), Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, THOMAS SCAFFIDI, Department of Physics, University of California, Berkeley, California 94720, USA, SEUNGHYUN KHAM, PALLAVI KUSHWAHA, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, JOEL MOORE, Department of Physics, University of California, Berkeley, California 94720, USA, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — Ultra-pure delafossite metals can present bulk mean free paths as long as tens of microns, long enough such that the momentum conservation of the electron fluid might play a role in electrical transport [1]. As the signatures of this are most prominent in the mesoscopic limit, we use focussed ion beam (FIB) techniques to thin bulk samples down to widths as small as submicron, much smaller than the bulk mean free path. In this talk I will present magnetotransport measurements in these highly-conducting delafossites, specifically PdCoO₂ and PdCoO₂, at the mesoscopic limit. Magnetic field introduces a variable length-scale, the cyclotron radius, to the system which can be used to tune through different transport regimes. I will discuss the ballistic and hydrodynamic signatures in the transport that in principle become accessible through magnetic field tuning in such mesoscopic samples.

Emergent Ferromagnetism in (111)-oriented CaRuO3/CaMnO3 superlattices* MARGARET KANE (Presenter), CHARLES FLINT, Material Science and Engineering, Stanford University, ARTURAS VAILIONIS, Geballe Laboratory for Advanced Materials, Stanford University, ALEXANDER GRUTTER, National Institute of Standards and Technology, YURI SUZUKI, Applied Physics, Stanford University — Emergent ferromagnetism has been observed at the interface of CaRuO3 (CRO), a paramagnetic metal, and CaMnO3 (CMO), an antiferromagnetic insulator. The leakage of itinerant CRO electrons into the CMO results in a double exchange interaction among interfacial Mn. Since CMO is a G-type antiferromagnet, films grown in (111) direction should have fully uncompensated surfaces and higher interfacial moments than compensated (001) surfaces. We demonstrate the synthesis and characterization of (111) CRO/CMO superlattices with 3 layers of CRO and 3-19 layers of CMO. To grow smooth (111) superlattices, we developed an interval pulsed laser deposition process. SQUID magnetometry measurements indicate larger interfacial Mn moments in our (111) superlattices compared to (001) superlattices. Coercive fields of the superlattice are similar, regardless of CMO thickness, and with increasing CMO thickness, the exchange bias field in the magnetization loops increases. Since CMO and CRO are isovalent, CRO/CMO systems do not exhibit a polarity mismatch across the interface, providing a model system to explore emergent ferromagnetism.

Strain induced topological Hall effect of SrRuO3 single-layered thin films LUDI MIAO (Presenter), HARI NAIR, NATHANIEL SCHREIBER, JACOB P RUF, YINGFEI LI, CYRUS ZELEDON, SHENGWEI JIANG, BERIT GOODGE, ISMAIL EL BAGGARI, KIN FAI MAK, JIE SHAN, LENA KOURKOUTIS, DARRELL G. SCHLOM, KYLE M SHEN, Cornell University — Topology in condensed matter physics has led to fruitful areas such as topological insulators, Majorana fermions and valleytronics. Among them, the topological Hall effect (THE) of magnetic materials has attracted much attention due to the discovery of magnetic skyrmions, a topologically protected spin texture that is promising for future magnetic/electronic devices. Recently, a THE has been observed at the interface between a ferromagnetic SrRuO3 (SRO) and a heavy metal SrIrO3 (SIO), although the spin texture of both bulk SRO and bulk SIO are topologically trivial. Here, we will demonstrate the discovery of an unexpected THE on perovskite SRO single-layered films stabilized by molecular beam epitaxy. We will show that the epitaxial strain in SRO films stabilizes a non-coplanar spin texture and leads to the topologically non-trivial phenomenon. SRO is a widely-used material in complex oxide heterostructures. Our results can potentially lead to major progresses in novel phenomena in SRO-based heterostructures as well as the applications of next generation all-oxide electronic and magnetic devices.

Anisotropic magnetoresistance in Nb: SrTiO3 thin films under epitaxial strain LUCÍA IGLESIAS (Presenter), FRANCISCO RIVADULLA, CIQUIS, University of Santiago de Compostela — We report the effect of epitaxial strain and cationic vacancies on the anisotropic magnetoresistance (AMR) of SrTiO3 (STO) thin films. Cationic vacancies affect the structural properties of the STO thin films, determining the rotation pattern of the TiO6 octahedra [1], and produce a characteristic minimum at T* in the temperature dependence of the electrical resistivity of this material. Our results show a change of sign of the AMR, from negative above T*, to positive below this temperature. Seebeck coefficient measurements do not support an interpretation based on the Kondo effect. We will discuss the possible existence and the nature of a magnetic phase below T*. As the effect is only observed in thin films <20 nm, and it is lost in thicker films (>35 nm), this suggests a contribution from accumulated defects close to the interface with the substrate.

4:54 PM P40.00011: Magnetic and Electrical Transport Properties of YbFe$_2$O$_4$*  
RAM RAI (Presenter), J HINZ, MICHELLE K PASCOLINI, JAMES PAWLAK, M DEMARCO, Buffalo State College —

We present magnetic properties, Mössbauer, resistivity, magnetoresistance, and dielectric properties of a polycrystalline YbFe$_2$O$_4$ prepared by an electron-beam assisted solid state reaction. The ferrimagnetic transition temperature of YbFe$_2$O$_4$ was measured at 242 K, followed by the two low-temperature transitions at ~200 K and 70 K, respectively. The M-H hysteresis loops exhibit a strong temperature dependence with the strongest coercive field and residual magnetization at ~100 K. The temperature dependence of the magnetic properties suggests that YbFe$_2$O$_4$ has a complex magnetic phase below 100 K. Room temperature Mössbauer measurement indicates the presence of Fe$^{2+}$ and Fe$^{3+}$ ions in the sample. Resistivity of YbFe$_2$O$_4$ has been analyzed based on Mott's variable-range hopping model. The magnetoresistance effects in the ferrimagnetic state were observed and the effects could be attributed to the field-induced changes in the electron hopping processes. We also discuss the temperature and frequency dependence of the dielectric constant of YbFe$_2$O$_4$, which were found to be strongly influenced by the contact effects, indicating no evidence of the intrinsic ferroelectricity.

Session P41 GMAG DMP: Thermal Spintronics BCEC 209 - Joseph P Heremans, Ohio State Univ - Columbus - Tag(s): Focus 2:30PM P41.00001: Controlling heat by spin caloritronics*  
[Invited] KEN-ICHI UCHIDA (Presenter), National Institute for Materials Science — Interaction between spin and heat is actively studied in the field of spin caloritronics from the viewpoints of both fundamental physics and applications. Early studies on spin caloritronics mainly focused on phenomena that generate a spin current from a heat current, such as the spin Seebeck effect, toward the development of versatile thermoelectric generators. In contrast, there are many heat-generation phenomena that use spin and charge currents as input, e.g., the spin Peltier effect, which is the reciprocal of the spin Seebeck effect; the anisotropic magneto-Peltier effect, in which the charge-to-heat current conversion efficiency depends on the angle between the charge current and magnetization in a ferromagnet; and the anomalous Ettingshausen effect, in which a heat current is generated in the direction perpendicular to both the applied charge current and magnetization. Recently, we successfully observed the thermal response from these phenomena by means of an active infrared emission microscopy called the lock-in thermography, and demonstrated thermal control functions that cannot be actualized without using spins [1-4]. In this talk, we review our recent experimental results by focusing particularly on the thermal imaging measurements of the spin-caloritronic phenomena.

3:06PM P41.00002: Spin-Seebeck Effects in Pyrochlore Iridates  
BOWEN MA (Presenter), University of Texas at Austin, BENEDETTA FLEBUS, UCLA Foundation, GREGORY FIETE, University of Texas at Austin — The spin-Seebeck effect (SSE) refers to voltage signals induced by the Inverse Spin Hall Effect (ISHE), with thermally driven spin currents through adjacent magnetic systems. It has been studied before mostly in collinear magnetic systems. Here, we present a general theory of the SSE in the case of a non-collinear antiferromagnetic insulator (AFI)/non-magnetic metal heterostructure. In our model, we apply a periodic boundary condition in the transverse plane and an open boundary condition at the interface. If there is a non-equilibrium temperature difference within the two materials, the exchange coupling between the electrons in the metal and magnons of interfacial spins in the AFI can give rise to a longitudinal spin current across the system. We also numerically compute the spin current using a pyrochlore iridate as the AFI where the spin configuration is the all-in-all-out (AIAO) ground state. We compare the results of different crystal interfaces arising from different crystalline orientations to make a connection with experiments and practical devices.
Spin Seebeck effect induced by antiferromagnetic magnons and spin fluctuations in epitaxial FeF₂ films

JUNXUE LI (Presenter), Department of Physics and Astronomy, University of California, Riverside, CA 92521, USA, ZHONG SHI, School of Physics Science and Engineering, Tongji University, Shanghai 200092, China, VICTOR ORTIZ, MOHAMMED ALDOSARY, CLIFF CHEN, PENG WEI, JING SHI, Department of Physics and Astronomy, University of California, Riverside, CA 92521, USA — Recently, the spin Seebeck effect (SSE) in antiferromagnetic (AFM) Cr₂O₃ and MnF₂ has been reported and the signals were found to rise significantly above the spin-flop (SF) field. However, it is still unclear whether the SSE requires an induced magnetic moment or just the presence of AFM magnons. Here we report a study of the SSE of FeF₂/Pt heterostructures in which FeF₂ is an insulating AFM epitaxial film. The high SF field (42 T) of FeF₂ makes it a perfect candidate for studying the SSE below the SF field. The AFM properties of FeF₂ film are characterized by exchange bias. The SSE signal of FeF₂/Pt under different magnetic fields shows very similar temperature-dependent behaviors. First, there is a peak at around 11.6 K due to AFM-magnons’ contribution. Second, we observe a “bump” at the AFM ordering temperature (70 K), beyond which the SSE signal decays and persists up to 250 K under high magnetic fields, indicating that short-range spin fluctuations also contribute to the SSE signal.

Spin Seebeck imaging of spin-torque switching in antiferromagnetic Pt/NiO/Pt heterostructures

ISAIAH GRAY (Presenter), Applied and Engineering Physics, Cornell University, TAKAHIRO MORIYAMA, Institute for Chemical Research, Kyoto University, NIKHIL SIVADAS, Applied and Engineering Physics, Cornell University, RYAN NEED, BRIAN KIRBY, NIST Center for Neutron Research, National Institute for Standards and Technology, DAVID LOW, Applied and Engineering Physics, Cornell University, GREGORY STIEHL, Department of Physics, Cornell University, JOHN HERON, Department of Materials Science and Engineering, University of Michigan, Ann Arbor, DANIEL RALPH, KATJA NOWACK, Department of Physics, Cornell University, TERUO ONO, Institute for Chemical Research, Kyoto University, GREGORY FUCHS, Applied and Engineering Physics, Cornell University — We demonstrate spin Seebeck microscopy as a sensitive table-top method for imaging in-plane antiferromagnetic order in thin films. In Pt/NiO(111)/Pt samples, we resolve antiferromagnetic spin domains within crystalline twin domains and image the effects of DC current-induced spin-orbit torque switching. We find a linear correlation between spin-torque-induced changes in the integrated spin Seebeck signal and the spin Hall magnetoresistance, confirming that we image the Néel order. The measurements show that changes driven by spin-orbit torque can occur both by antiferromagnetic domain wall motion and domain flopping, and only a small fraction of the NiO sample is altered.

This research was supported by the Cornell Center for Materials Research with funding from the NSF MRSEC program (DMR-1719875) and by JSPS KAKENHI Grant Numbers JP15H05702, JP17H04924, and JP17H05181. Characterization of topological band structures by the anomalous Nernst effect

YAN SUN (Presenter), JONATHAN NOKY, JOHANNES GOOTH, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids — Resolving the structure of energy bands in transport experiments is a major challenge in condensed matter physics and material science. Sometimes, traditional electrical conductance or resistance measurements only provide very small signals, and thus limit the ability to obtain direct band structure information. In this case, it has been proven beneficial to employ thermoelectric measurements which are sensitive to the first derivative of the electrical characteristics with respect to energy, rather than to its value itself. The common way to access the Berry curvature in topological materials directly via measurements is the anomalous Hall effect, but the corresponding signal can be too small to be detected when the topological band structures lie far off the Fermi level. In this work we propose to investigate topological band structure features utilizing the anomalous Nernst effect, that are elusive in anomalous hall measurements. This work demonstrates that anomalous Nernst measurements can be an effective tool for characterization of topological band structures away from Fermi level.

A comparative study of spin Seebeck effect and anomalous Nernst effect in a ferromagnetic metal/normal-metal bilayer system.

AVIRUP DE (Presenter), Physics, Indian Institute of Science Education and Research, Pune, ARUP GHOSH, Physics, National University of Singapore (NUS), Singapore, RAJESH MANDAL, SUNIL NAIR, Physics, Indian Institute of Science Education and Research, Pune — In the emerging field of Spin Caloritronics, the central interest is the study of the interactions of spins with heat current. Thus a pure spin current got an enormous importance for such kind of studies. On the other hand, spin seebeck effect (SSE) pertains to the generation of pure spin current under application of a thermal gradient across a magnetic material. Although for magnetic-metals, the SSE signal is contaminated by the anomalous Nernst signals (ANE). In this work, we identify and investigate longitudinal spin seebeck effect (LSSE) phenomenon in La0.7Ca0.3MnO3 /Pt bilayer system over a wide temperature range 20K ≤ T ≤ 295K. We separate out LSSE from the ANE. Further a detailed-analysis on LSSE shows a very good agreement with the current theoretical models.

Avirup De is thankful to UGC, Govt. of India for providing financial support through a Senior Research Fellowship.

Enhancement of Thermal Spin Injection Effects in Nonlocal Spin Valves on Silicon Nitride Membranes

RACHEL K BENNET (Presenter), University of Denver, ALEX HOJEM, University of California - San Diego, DEVIN J WESENBERG, BARRY L ZINK, University of Denver — Nonlocal spin valves (NLSVs) have the unique capability to separate charge and spin currents, and thus are an important tool for both applied and fundamental research in nanomagnetism. [1,2] Previous research shows that changes to the composition of the NLSV substrate can have a marked effect on the background nonlocal resistance by changing the substrate thermal conductance.[3] Our research demonstrates enhancement of non-local spin resistance by the anomalous Nernst effect (ANE) and dramatically lowered thermal conductance in NLSVs fabricated on SiN membranes.[4,5]

We present refined values as low as 0.27 for the Nernst coefficient of permalloy as determined by 2D finite-element analysis of Py/Al NLSVs, where the thermal gradient is confined to two dimensions by the membrane-supported construction. We also present new insight into thermal spin injection effects other than ANE, including thermally-assisted electrical spin injection.

NSF grant ECCS-1610904

Spin-orbit torque and Nernst effects in Bi-Sb/ferromagnet heterostructures

NIKLAS ROSCHEWSKY (Presenter), Physics, University of California, Berkeley, EMILY S WALKER, ECE, University of Texas, Austin, PRAVEEN GOWTHAM, EECs, University of California, Berkeley, SARAH MUSCHINSKE, ECE, University of Texas, Austin, FRANCES HELLMAN, Physics, University of California, Berkeley, SETH R BANK, ECE, University of Texas, Austin, SAYE EL SALAHUDDIN, EECs, University of California, Berkeley — Topological insulators have gained considerable interest recently due to their potential as spin current generators for room temperature memory applications. In this work we show harmonic Hall measurements of spin-orbit torque (SOT) in MBE grown Bi-Sb/Co bilayers [1]. We find that signals in our samples are dominated by the ordinary Nernst effect (ONE). This thermal effect can be a spurious signal in harmonic Hall measurements and has not been taken into account in previous experiments.

We are proposing two control experiments to separate the ONE in Bi-Sb from SOT. First, we compare harmonic measurements in Bi-Sb/Co and Bi-Sb/Al. While SOT is absent in the sample without magnet, we still see large signals in the second harmonic Hall voltage due to the ONE. Second, we investigate the scaling of V2ω with external magnetic field Bext. While it is expected that SOT effects are suppressed at large magnetic fields, we find that the second harmonic voltage in Bi-Sb/Co scales linearly with the external field, as expected from the ONE. These results provide an important contribution to the understanding of the ultra-large SHA that was recently reported in TI/ferromagnets.

The spin-Seebeck effect (SSE) is an advective transport process in a bilayer composed of a ferromagnet (FM) and a nonmagnetic (NM) material with strong spin-orbit coupling. In a temperature gradient, the flux of magnons in the FM transfer spin angular momentum to the electrons in the NM, which, by the ISHE contributes an SSE voltage. In contrast, the intrinsic anomalous Nernst (ANE) conductivity in homogeneous FMs is understood as a non-advective process due to the effect of the temperature gradient on electrons: in MnBi, one can calculate the ANE conductivity from the Berry curvatures using a 32 band tight-binding Hamiltonian with the spin-orbit interaction and magnetization. We show that there can be an additional advective magnonic contribution to the ANE similar to the SSE effect but in uniform metallic FMs. Further, as was done in Ni/Pt, we synthesized composites of aligned MnBi needles in a Bi matrix. In this geometry, we expect an additional SSE contribution from the magnons in MnBi to the Nernst effect in the Bi. In composites with Mn concentration far below the percolation threshold, we observe a large boost in the thermopower and Nernst over the Bi host, which we attribute to advective spin transport.

**5:06PM P41.00001: Pure Spin Current Driven by a Thermally Induced Magnon Chemical Potential**

KEVIN OLSSON (Presenter), University of Texas at Austin, KYONGMO AN, École Polytechnique Fédérale de Lausanne, JIANSHI ZHOU, LI SHI, XIAOQIN (ELAINE) LI, University of Texas at Austin — A major goal of spintronics is to develop devices that rely on spin current, rather than charge current. Of the few methods for generating pure spin current in magnetic insulators (MI), the spin Seebeck effect (SSE) is an attractive method, due to its simplicity. The SSE relies on a thermal gradient to generate a nonequilibrium distribution of magnons, collective spin quasiparticles, which carry spin current. Describing these magnons requires a thermally driven magnon chemical potential, never before measured in such a nonequilibrium system. Here we report the use of Brillouin light scattering for measuring a magnon chemical potential generated by a thermal gradient in the MI yttrium iron garnet (YIG): Y3Fe5O12. Boltzmann transport analysis allows for the quantification of spin currents due to the magnon temperature and chemical potential gradients. Finally, the range of energies and wavevectors of the magnons that contribute to the spin current are identified. Experimental determination of these items will facilitate advancing the theories describing coupled heat and spin transport. Furthermore, this technique allows for the determination intrinsic spin current generating ability of an MI, not possible using previous techniques.

**5:18PM P41.00003: Effects of thermal spin disorder on the half-metallicity of Co2MnSi with antisite defects and Fe substitution**

GIOVANNI BAEZ FLORES (Presenter), KIRILL BELASHCHENKO, University of Nebraska - Lincoln — Heusler alloys based on Co2MnSi have a high Curie temperature and high spin polarization at the Fermi level, which is promising for applications in spintronics. Band structure calculations show Co2MnSi to be half-metallic at zero temperature. Alloying with Fe on the Mn sublattice is believed to shift the Fermi level closer to the middle of the half-metallic gap. Here, we study the effects of thermal spin fluctuations on the electronic spectrum near the Fermi level, both in pure Co2MnSi and in the presence of crystallographic defects or Fe substitution for Mn. We find that all magnetic antisite defects are strongly exchange-coupled to the host magnetization, and thermal spin fluctuations do not easily destroy the half-metallic gap. In this respect, Co2MnSi differs from NiMnSb, where Mn antisites on the Sb sublattice strongly reduce the spin polarization already at rather low temperatures [1]. We also find that partial substitution of Mn by Fe results in considerable changes in the Bloch spectral function near the Fermi level, which are very different from the rigid-band picture that is usually assumed.

**Session P42 DQI: Quantum Annealing: Architectures** BCEC 210A - Richard Harris

**2:30PM P42.00001: A proposed superconducting circuit quantum annealer with fully programmable all-to-all coupling**

PETER MCMAHON (Presenter), TATSUHIRO ONODERA, EDWIN NG, Stanford University — A grand challenge for quantum annealing is the development of annealing hardware that allows fully programmable all-to-all connectivity between logical qubits, with the lowest possible overhead in physical resources. The LHZ [1] scheme achieves fully programmable all-to-all connectivity with a planar architecture that is amenable to implementation with superconducting circuits [2], but does so at a cost of $O(N^2)$ physical qubits to realize $N$ logical qubits. We propose a novel architecture for a superconducting circuit quantum annealer that requires only $N$ physical qubits to realize $N$ logical qubits, and present analytical and numerical evidence that fully connected and programmable quantum annealers with $N=1000$ logical qubits can be constructed with technology that requires only modest improvements over what currently exists.

2:42PM P42.00002: Coherent oscillations in the annealing of a flux qubit* MOSTAFA KHEZRI (Presenter), HUO CHEN, HUMBERTO MUNOZ BAUZA, DANIEL A LIDAR, University of Southern California — Annealing of a single qubit under certain schedules can reveal characteristics related to the coherence of a 2-level system in the form of oscillations in the success probability vs anneal time. We study how these characteristics appear in a multi-level superconducting flux qubit by mapping the Ising coefficients to qubit control fluxes. We investigate the effects of higher energy levels on the problem, and analyze the possibility of an experimental implementation using state-of-the-art flux qubits.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050.

2:54PM P42.00003: Modeling Coherent Oscillations in the Ground State Probability of Annealed Qubits* HUMBERTO MUNOZ-BAUZA (Presenter), HUO CHEN, MOSTAFA KHEZRI, DANIEL A LIDAR, University of Southern California — The ground state amplitude of an annealed qubit oscillates as a function of the anneal time away from the adiabatic limit. We propose and characterize classes of anneal schedules that exhibit experimentally accessible oscillations as signatures of quantum coherence of a qubit, presenting both time-dependent perturbation theoretic analysis and open system results.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050.

3:06PM P42.00004: Coupling annealing-capable high-coherence flux qubits* STEVEN DISSELER (Presenter), JAMES I. BASHAM, JEFFREY GROVER, SERGEY NOVIKOV, DAVID FERGUSON, ZACHARY A STEGEN, ALEXANDER MARAKOV, Northrop Grumman, DAVID K KIM, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, JONILYN L YODER, MIT Lincoln Laboratory, ROBERT HINKEY, Northrop Grumman, DANIEL A LIDAR, University of Southern California, KENNETH M. ZICK, Northrop Grumman — Despite progress in quantum annealing algorithms and hardware development, key questions remain regarding the role of quantum coherence, entanglement, etc., on key figures of merit needed for real world applications. In this talk we will discuss results of small scale annealing experiments with high-coherence superconducting flux qubits as a part of the Quantum Enhanced Optimization program, which seeks to understand and address these issues. Using systems of two and three fully-connected qubits, we demonstrate controllable, scalable couplings between the Z-like fields of individual qubits. We will discuss the impact of coupling on the coherence of the system as it relates to both multi-qubit measurement fidelity as well as the potential importance as a source of error during computation.

3:18PM P42.00005: Development of a Scalable Annealing Machine Dedicated to Integer Factoring* HANPEI KOIKE (Presenter), KENTARO IMAFUKU, SHIRO KAWABATA, National Institute of Advanced Industrial Science and Technology — Commercial annealing machines such as D-Wave and Fujitsu necessarily features general-purpose programmability to cover as wide area of combinatorial optimization problems and thus to obtain as much markets as possible. On the contrary, research annealing machines can enjoy freedom to specialize in a specific problem and to investigate the optimal calculation method to maximum extent. We call this approach Application Specific Annealing Circuit (ASAC). We chose integer factoring as the first target application in our ASAC research. Integer factoring is accomplished by reverse-directional calculation of a digital multiplier circuit by expressing the logic circuit as an energy function and by finding the minimum energy state using annealing method. We have developed a scalable classical ASAC machine using commercial electronic components as a proof of concept. We call our experimental machine AIST Analog Annealer (AAA). We are going to introduce this machine in our presentation.

*This presentation is partly based on results obtained from a project commissioned by the New Energy and Industrial Technology Development Organization (NEDO), Japan.
Fluxonium Qubit Systems for Coherent Quantum Annealing

MAXIM VAVILOV (Presenter), ZHENYI QI, Department of Physics, University of Wisconsin - Madison, Madison, WI 53706, MARK DYKMAN, Department of Physics and Astronomy, Michigan State University, East Lansing, MI 48824, VLADIMIR MANUCHARYAN, Department of Physics, University of Maryland, College Park, MD 20742 — Fluxonium systems are perfect candidates for coherent quantum annealing. Individual fluxonium qubits have: (i) substantially long coherence time in excess 5 μs away from sweet spot and 100 μs at the half-flux sweet spot[1], (ii) strong X-X qubit coupling, which can be made to exceed the qubit transition energy[2], and (iii) two low-energy states, well separated from higher-energy states. These characteristics are expected enable long-coherence annealing protocols, while keeping the system in the computational subspace. A potential resource for quantum speed up is multiqubit tunneling in hard optimization problems [3]. In this talk, we describe the multiqubit tunneling in the system of strongly coupled fluxonium qubits during annealing. We discuss the effect of flux noise and dielectric losses on the multiqubit tunneling events.

Flux qubit readout at the degeneracy point*

MARIUS SCHÖNDORF (Presenter), Saarland University, ADRIAN LUPASCU, University of Waterloo, FRANK K WILHELM, Saarland University — The role of measurement is crucial for the realization of a real world quantum computer. A promising candidate to deliver a platform to perform quantum algorithms are superconducting qubits, one of which is the flux qubit. Due to their natural coupling properties, flux qubits are especially interesting for the implementation of quantum annealer. The most robust point of flux qubits against environmental effects that decohere the qubit (e.g. 1/f noise) is the so called degeneracy point. Because of this property one wants to operate at this specific point. However, performing a readout that conserves the measured observable (QND) is difficult here.

In this work we present an indirect measurement scheme for flux qubits which works at arbitrary bias points, most interesting also at the degeneracy point. We show that our protocol is able to reach high fidelities while acting QND on the measured qubit.

*This research is funded by the Intelligence Advanced Research Activity (IARPA). High coherence annealing, Part 1: fast, high-fidelity readout*

JAMES BASHAM (Presenter), JEFFREY GROVER, STEVEN DISSELER, SERGEY NOVIKOV, DAVID FERGUSON, ZACHARY A STEGEN, ALEXANDER MARAKOV, ROBERT HINKEY, MOE S KHALIL, Northrop Grumman, DAVID KIM, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, JONILYN L YODER, MIT Lincoln Laboratory, ANTHONY J PRZYBYSZ, Northrop Grumman, DANIEL A LIDAR, University of Southern California, KENNETH M. ZICK, Northrop Grumman — Recently developed capacitively-shunted flux qubits offer a promising path toward building a high-coherence quantum annealer. These qubits take advantage of lower persistent currents to achieve lower noise sensitivity. As such, readout of their state at the end of the anneal operation presents unique challenges. We report experimental results of a persistent current readout scheme that provides fast readout while isolating the qubit from the resonator during the anneal.

High coherence annealing, Part 2: fast annealing experiments

JEFFREY GROVER (Presenter), JAMES I. BASHAM, STEVEN DISSELER, SERGEY NOVIKOV, DAVID FERGUSON, ZACHARY A STEGEN, ALEXANDER MARAKOV, Northrop Grumman, DAVID K KIM, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, JONILYN L YODER, MIT Lincoln Lab, ROBERT HINKEY, MOE S KHALIL, Northrop Grumman, DANIEL A LIDAR, Univ of Southern California, KENNETH M. ZICK, Northrop Grumman — Recently developed capacitively-shunted flux qubits offer a promising path toward building a high-coherence quantum annealer. These qubits take advantage of lower persistent currents to achieve lower noise sensitivity. Using the fast readout scheme and device discussed in Part 1, Part 2 presents single-qubit annealing experiments performed using RF bias lines. We study the behavior of the qubit transition width by changing the annealing time, and we use excited state readout to determine other parameters of the system. This setup also allows for programming highly nonlinear annealing schedules to probe quantum coherence.

High-order and long-range connectivity for embedding problems in quantum annealing with superconducting flux qubits

DENIS MELANSON (Presenter), ANTONIO MARTINEZ, Physics and Astronomy, Institute for Quantum Computing, Waterloo Institute for Nanotechnology, University of Waterloo, MUHAMMET ALI YURTALAN, Electrical and Computer Engineering, Institute for Quantum Computing, Waterloo Institute for Nanotechnology, University of Waterloo, YONGCHAO TANG, Physics and Astronomy, Institute for Quantum Computing, Waterloo Institute for Nanotechnology, University of Waterloo, DAVID K KIM, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, JONILYN L YODER, MIT Lincoln Laboratory, SERGEY NOVIKOV, Northrop Grumman Corporation - Mission Systems, EVGENY MOZGUNOV, DANIEL A LIDAR, University of Southern California, ADRIAN LUPASCU, Physics and Astronomy, Institute for Quantum Computing, Waterloo Institute for Nanotechnology, University of Waterloo — A high degree of connectivity between qubits is believed to be important in quantum annealing. An approach for implementing high connectivity in superconducting flux qubit annealers was proposed in which the qubits are connected via chains of rf-SQUID couplers. We report an application of this concept in building problem-specific annealing architectures with high-order connectivity. We analyzed the coupling strength between qubits and the coupler network induced qubit decoherence for application-oriented architectures, using both simplified spin models and full quantum circuit models. We designed devices with capacitively shunted flux qubits coupled by coupler trees. We discuss experimental prospects and the relevance for large scale annealing.

Multi-body flux-qubit couplers for quantum annealing

GIOELE CONSANI (Presenter), PAUL A. WARBURTON, NEDEEN AL SHARIF, University College London — Despite the enormous progress achieved in the field of quantum annealing over the last decade, the demonstration of a computational advantage over classical methods remains elusive. One possible solution is to provide quantum annealers with qualitatively new features, such as higher-order terms in the driver and/or problem Hamiltonians and error-suppression. These capabilities both rely on the physical implementation of multi-body interactions. While interactions between pairs of flux qubits can be achieved rather easily, multi-body interactions require more sophisticated constructions. Some of these use ancillary qubits, while others are based on coupling loops with carefully-engineered flux non-linearities. Here we present a comparative analysis of a few such proposed implementations and propose a quantitative way to compare their performances, with specific focus on their possibility to generate the correct quantum energy spectrum during the annealing process.

*This research was supported in part by Intelligence Advanced Research Projects Activity (IARPA), via the U.S. Army Research Office Contract No. W911NF-17-C-0050
SERGEY NOVIKOV, STEVEN DISSELER, JAMES BASHAM, JEFFREY GROVER, ALEXANDER MARAKOV, ZACHARY A STEGEN, and spin-boson Hamiltonian are employed respectively. This comparison is done numerically for a small frustrated between qubits. We compare the efficiency of ground state preparation for direct and mediated couplings, for which Ising by the standard Nb superconducting multilayer integration technology.

network. Where qubits can be fabricated by the standard Al angled evaporation, the resonator network can be fabricated actual fabrication of the system, we can conveniently separate the fabrication processes of qubit itself and resonator exceedingly gigantic compound qubit, we can realize a unique network of fully coupled large number of spins. For the arrangement of deep strongly coupled circuit QED system is resulted with an extremely long novel quantum system. With quantum annealers based on flux qubits. This device consists of two RF-SQUIDs coupled to the measured qubits. We simulate the quantum measurement process, including realistic implementation effects. We consider generalizations of this approach to higher-order parity measurements. We also present a different approach based on symmetrical coupling of a flux readout device, designed to measure parity information. Prospects for experimental demonstration are discussed.

Quantum annealing with mediated interactions: from a perturbative to a ultrastrong mediated coupling.* MANUEL PINO GARCIA (Presenter), JUAN JOSE GARCIA-RIPOLL, Instituto de Física Fundamental, Consejo Superior de Investigaciones Científicas — We present a study of a quantum annealer where bosons mediate the Ising-type interactions between qubits. We compare the efficiency of ground state preparation for direct and mediated couplings, for which Ising and spin-boson Hamiltonian are employed respectively. This comparison is done numerically for a small frustrated antiferromagnet, with a careful choice of the optimal adiabatic passage that reveals the features of the boson-mediated interactions. Those features can be explained by taking into account what we called excited solutions: states with the same spin correlations as the ground-state but with a larger bosonic occupancy. For similar frequencies of the bosons and qubits, the performance of quantum annealing depends on how excited solutions interchange population with local spin errors. We report an enhancement of quantum annealing thanks to this interchange under certain circumstances.

Schrieffer-Wolff Methods for Interacting Superconducting Qubits RUDOLPH J MAGYAR (Presenter), DAVID FERGUSON, Northrop Grumman — There are many possible methods for implementing a low-energy Pauli decomposition of a quantum circuit Hamiltonian as a continuous function of qubit and coupler control fields. Effective low energy models are helpful designs tools to optimize performance in device applications where quantum effects are important. In this talk, we report a method based on the Bravyi et al Schrieffer-Wolff transformation [1] that provides a Pauli decomposition with the following desirable properties: (i) the effective Hamiltonian remains block diagonal so that the computational subspace is completely decoupled from the non-computational states, (ii) the adiabatic connection terms generated by the time dependence of the computational subspace are block off-diagonal and thus do not generate any terms within the computational subspace, and (iii) the computational subspace has a non-trivial holonomy over the control parameter manifold. We report application of these methods to tunable flux qubits comparing results to more explicit models and experimental measurements.

Superconducting Quantum Annealing Architecture with LC Resonators* AKIYOSHI TOMONAGA (Presenter), HIROTU MUKAI, Physics, Tokyo University of Science Kagurazaka Campus, JAW-SHEN TSAI, CEMS, Riken,Wako Saitama Japan — We report on the architecture and experimental results of superconducting quantum annealer with LC resonator. In the architecture, qubit and a LC resonator are connected via a Josephson junction to realize deep strong-coupling. Such arrangement of deep strongly coupled circuit QED system is resulted with an extremely long novel quantum system. With the exceedingly gigantic compound qubit, we can realize a unique network of fully coupled large number of spins. For the actual fabrication of the system, we can conveniently separate the fabrication processes of qubit itself and resonator network. Where qubits can be fabricated by the standard Al angled evaporation, the resonator network can be fabricated by the standard Nb superconducting multilayer integration technology.

*This research is supported by NEDO IoT project, JST CREST project and ImPACT project.
2:30PM P45.00001: *Operando* bi-modal studies of complex oxides growth with RHEED and surface x-ray diffraction*

HAWOONG HONG (Presenter), Argonne National Laboratory, XINYUE FANG, MENG-KAI LIN, TAI-CHANG CHIANG, Department of Physics, University of Illinois Urbana-Champaign, FRIEDERIKE WROBEL, ANAND BHATTACHARYA, Argonne National Laboratory — An oxide MBE chamber was developed for simultaneous use of RHEED and surface x-ray diffraction at the same time. It is mounted and coupled to a 6-circle diffractometer. X-ray reflection intensity measurement at one point in reciprocal space is similar to RHEED intensity oscillation measurement. The relationship between two methods has been reported for homo-epitaxial complex oxide growth [1]. With large photon flux at the Advanced Photon Source, the x-ray intensity measurement could be extended to a real-time collection of data on a large swath of a line scan utilizing multi-angle fly scans [2]. Rapid acquisition in the volume around x-ray diffraction rods and RHEED measurements were obtained simultaneously during the growth. This bimodal study was made during La$_2$CuO$_4$ (001) film growth on SrLaAlO$_4$ (001) substrates with MBE techniques. Discussed will be the relation between two different observations and future impacts from utilizing this bimodal method.

2:42PM P45.00002: Suppression of Bi disproportionation in minimally electron doped BaBiO$_3$ epitaxial thin films*

HUI CAO (Presenter), Department of Chemical Physics, University of Science and Technology of China — BaBiO$_3$ is a semiconductor due to three dimension charge density wave (CDW), and it can become a superconductor, with a maximum $T_C$ of 30K via holes doping. We have studied the three-dimensional charge-density-wave in high quality BaBiO$_3$ and electron doped BaBiO$_3$ single crystal thin films by X-ray photoelectron spectroscopy, X-ray absorption spectroscopy, Raman shift and ellipsometry technique. The electron doping is achieved by very small amount of oxygen vacancies purposely induced by vacuum annealing. Our results have found that the electron doping can remove bismuth disproportionation ($2\text{Bi}^{4+} \rightarrow \text{Bi}^{3+} + \text{Bi}^{5+}$) but has less effect to the insulating gap. Different from the hole-doping side, the amount of electron needed to suppress the bismuth disproportionation is extremely small. Our study provides new insights to the intricate correlation between CDW and the hybridization between oxygen 2p and Bi 6s orbitals.

*National Natural Science Foundation of China (Grants No. 11574287)

2:54PM P45.00003: Polarization switch on h-LuFeO$_3$ multiferroic*

PETRUCIO BARROZO DA SILVA (Presenter), BHAGWATI PRASAD, VISHAL THAKARE, SUJIT DAS, RAMAMOORTHY RAMESH, Physics Department, University of California, Berkeley — The properties of improper ferroelectrics are known to be very different from properties present in the proper ferroelectrics. However, the switching behavior of the electric polarization and the dynamics of the ferroelectric domain walls in the multiferroics with improper ferroelectricity don't have been yet reported. In this work, we study the ferroelectric properties of hexagonal LuFeO$_3$ (h-LFO). This structure was firstly obtained in 2004 [1], but its properties are yet not all understood. The epitaxial thin films of h-LFO on YSZ(111) was produced by pulsed laser deposition. The switch of polarization was studied in the screen of Ishibashi-Orihara model [2]. We have observed that the electrical coercive field in improper ferroelectric (h-LFO) grow very fast with the frequency if compared with proper ferroelectric (e.g. PbTiO$_3$ or BiFeO$_3$). In this presentation, we also will discuss mechanisms to reduce the electrical coercive field as well as how to reduce the dependence of the electrical coercive field with the frequency.

*Thanks to Brazilian fund agencies CNPq and CAPES.
3:06PM P45.00004: Superconductivity in doped SrTiO₃  LUCA GALLETTI (Presenter), KAVEH AHADI, YUNTIAN LI, SUSANNE STEMMER, University of California, Santa Barbara — We report on the transport properties of a series of doped 250-nm-thick SrTiO₃ films, grown by molecular beam epitaxy on undoped (001) SrTiO₃ substrates. In particular, we demonstrate anomalies in the superconducting properties. A systematic study of the critical temperatures and fields as a function of the carrier density and type of doping atom reveal deviations from BCS behavior and points towards the role of the specific doping atom. Moreover, the transport properties of the normal state show peaks in the transverse resistance, which indicates an electron nematic phase above the superconducting transition. We discuss the mechanisms of superconductivity of SrTiO₃ thin films.

3:18PM P45.00005: Comparative Study of Surface Structural and Physical Properties of Sr₃T₂O₇ (T = Mn, Ru)  YIFAN YANG (Presenter), LINGYI XING, MOHAMMAD SAGHAYEZHIAN, RONGYING JIN, E WARD PLUMMER, Louisiana State University — Double-layered Ruddlesden-Popper oxides are known to exhibit a strong correlation between octahedral distortion and physical properties. Using low-energy electron diffraction (LEED) and high-resolution electron energy loss spectroscopy (HREELS), we have investigated the surface structural and physical properties of Sr₃T₂O₇ (T = Mn, Ru). While surface RuO₆ octahedron in Sr₃Ru₂O₇ has both rotation (~ 12°) and tilt (~ 3°), our LEED – IV analysis reveals that MnO₆ octahedron in Sr₃Mn₂O₇ has a similar rotation (~ 11°) but no tilt. HREELS data suggest that both the surface of Sr₃Mn₂O₇ and Sr₃Ru₂O₇ are semiconducting but for different reasons. The implication of these findings will be discussed.

3:30PM P45.00006: Electronic and magnetic properties of double perovskite thin film Sr₂CrReO₆*  JOSE FLORES (Presenter), KENG-YUAN MENG, ADAM AHMED, FENGYUAN YANG, Ohio State University — Chiral magnetic spin textures, such as skyrmions, have been found in systems that have the Dzyaloshinskii-Moriya interaction and ferromagnetic exchange, e.g., heavy metal/ferromagnet bilayers. However, to make skyrmions relevant for modern applications, skyrmions need to operate at room temperature and be sufficiently small for high information densities. Oxides offer an excellent platform to accomplish this owing to their pristine epitaxy and highly tunable properties. We explore this possibility in high magnetic ordering temperature Sr₂CrReO₆ thin films. Sr₂CrReO₆ films were grown by off-axis dc magnetron sputtering on SrTiO₃(001) and Sr₂CrNbO₆/LSAT(001) substrates. Films were characterized by X-ray diffraction and atomic force microscopy showing both a high degree of crystalline quality and smooth surface topography, respectively. We will also discuss how choice of substrate for growth of Sr₂CrReO₆ is crucial as strain can significantly change the magnetic anisotropy—a crucial tuning parameter for skyrmion stability. Lastly, we will show magnetic and electrical characterization of these films and the potential for future skyrmion heterostructures.

*This research was supported by the Defense Advanced Research Projects Agency Grant No. D18AP00008

3:42PM P45.00007: High-k perovskite dielectric BaHf₁₋ₓTiₓO₃  HAHOON LEE (Presenter), DOWON SONG, KOOKRIN CHAR, Seoul National University — Interest in high-k materials continues as the semiconductor devices shrink in size and in its operating voltage. BaTiO₃ is a well-known perovskite ferroelectric material and BaHFO₃ is a perovskite high-k dielectric material with a dielectric value of 38. In this study, we fabricated capacitors with an atomically-mixed BaHf₁₋ₓTiₓO₃ (BHT, with x varying from 0 to 0.8) layer as the dielectric insulator with a perovskite semiconductor La-doped BaSnO₃ (BLSO) layer as the electrode. All the layers were epitaxially grown on SrTiO₃ substrates by pulsed laser deposition. X-Ray diffraction was used to investigate the structural properties, from which we confirmed the epitaxial growth of all the layers and obtained their respective lattice constants. The electrical properties of the capacitors, such as the capacitance and breakdown field, were measured. As the x value increased, the relative permittivity value increased and the dielectric breakdown field decreased. When the x value of BHT was 0.4, the relative permittivity and breakdown field values were 61.7 and 5.85 MV/cm, respectively, yielding the maximum 2D charge density 2x10¹⁴ cm⁻². We will report on the field effect transistor performances with BHT as the gate dielectric and BLSO as the channel layer.
Defect-controlled transport phenomena at complex oxide interfaces

JACQUELINE BOERGERS, MARC ROSE, RWTH Aachen University, REGINA DITTMANN, Forschungszentrum Julich, FELIX GUNKEL (Presenter), RWTH Aachen University — Electric-field control of 2-dimensional electron systems (2DES) in oxide heterostructures is a key tool for tuning properties such as carrier density, magnetism, and superconductivity. There remain open questions however if in all cases gate-tunable properties can be ascribed to electronic phenomena deriving directly from varying the charge accumulated in the interfacial potential well. Here, we discuss that various gate-tunable properties observed in 2DES can also be mimicked by controlling the ionic defect structure and lattice disorder in the vicinity of the interface. As we will show accumulation of scatter centers at the interface can result in diminished charge transfer, while the magnetic response of the electron system is enhanced and quantum interference phenomena (weak-anti-localization) arise. Additionally, we discuss how a controlled and homogenous defect background in thin film SrTiO3 intrinsically yields a transition from positive to negative magnetoresistance, at comparable carrier concentration. Our results yield an ionic-electronic perspective on electrical gating experiments frequently conducted in the oxide electronics community. We provide a comprehensive discussion of the coupling of electronic gating and gradual defect profiles.

Superoxygenation study of cuprate and iridate thin films

HAO ZHANG (Presenter), CHAO ZHANG, Department of Physics, University of Toronto, NICOLAS GAUQUELIN, SHAOBO CHENG, GIANLUIGI BOTTON, Canadian Centre for Electron Microscopy and Brockhouse Institute for Materials Research, McMaster University, CHRISTOPHER MCMAHON, DAVID G HAWTHORN, Department of Physics and Astronomy, University of Waterloo, PATRICK CLANCY, SAE HWAN CHUN, Department of Physics, University of Toronto, AMBROSE SEO, Department of Physics and Astronomy, University of Kentucky, JOHN Y.T. WEI, Department of Physics, University of Toronto — High-pressure O2 has been used to hole-dope and to stabilize high-oxidation phases of cuprates. We extend this superoxygenation technique to YBa2Cu3O7-δ thin films, which are more reactive due to their large surface-to-volume ratio, and to the layered iridate Sr2IrO4, which is difficult to hole-dope by cation substitution. First, YBa2Cu3O7-δ thin films grown by PLD are annealed in up to 700 atm O2 and then characterized by TEM, XRD and XAS. The annealed films show phaseconversion to Y2Ba4Cu7O15-δ and Y2Ba4Cu8O16, as well as regions of YBa2Cu5O9-δ and YBa2Cu6O10-δ. Second, epitaxial thin films of Sr2IrO4 are subjected to extended high-pressure annealing and similarly characterized. The post-annealed films show up to 3 order-of-magnitude drop in room temperature resistivity and an evolution towards semi-metallic behaviour. Furthermore, as film thickness is reduced, the annealed films show a structural transformation towards a quasi-cubic phase. Our results demonstrate the potential of using superoxygenation to stabilize exotic phases of transition metal oxides not achievable in bulk form. [1]

Temperature-induced metal-to-insulator transition in epitaxially grown NbO2 films

TOYANATH JOSHI (Presenter), ELI CIRINO, DAVID LEDERMAN, University of California, Santa Cruz — Transition metal oxides demonstrating metal-to-insulator transitions (MIT), such as VO2 and NbO2, are widely studied materials for use as selector elements in resistive random-access memory (RRAM). The MIT transition temperature (TMIT) of VO2 is close to room temperature (~340 K). NbO2, on the other hand, has a much higher transition temperature (TMIT = 1081 K), which complicates the direct observation of the MIT in thin films and has not been reported in an epitaxial film, so far. In this presentation, we will demonstrate temperature dependent electrical resistivity of epitaxially grown NbO2 thin films revealing the actual mechanism of MIT in NbO2. High-quality epitaxial films were grown using pulsed laser deposition and structural characterization was performed using x-ray diffraction and atomic force microscopy. The resistivity of the as-grown films was measured from room temperature to 1100 K under a controlled environment using the four-probe resistivity measurement technique. Also, we will examine the effect of epitaxial strain to MIT of NbO2 was demonstrated by varying thickness of the films from 12 to 45 nm.
4:30PM P45.00011: Interfacial Mott state in iridate-nickelate superlattices*  XIAORAN LIU (Presenter), MICHELE KOTIUGA, HEUNG SIK KIM, Rutgers University, New Brunswick, ALPHA N’DIAYE, Advanced Light Source, YONGSEONG CHOI, Advanced Photon Source, YANWEI CAO, Chinese Academy of Science, BANABIR PAL, FANGDI WEN, MIKHAIL KAREEV, Rutgers University, New Brunswick, JOHN WILLIAM FREELAND, DANIEL HASKEL, Advanced Photon Source, PADRAIC SHAFER, ELKE ARENHOHLZ, Advanced Light Source, KRISTJAN HAULE, DAVID VANDERBILT, KARIN RABE, JAK CHAKHALIAN, Rutgers University, New Brunswick — In new SrIrO3/LaNiO3 superlattices up to a full electron transfer at the interface from Ir to Ni is experimentally observed, triggering a massive structural and electronic reconstruction. The large crystal eld splitting from the distorted interfacial IrO6 octahedra surprisingly dominates over the spin-orbit coupling, and together with the Hund’s coupling results in the high-spin (S = 1) configurations on both Ir and Ni sites. First-principles calculations agree well with the experimental results, supporting the formation of an intricate Mott state in the superlattices.

4:42PM P45.00012: Doping study of ultra-wide bandgap spinel semiconductor ZnGa2O4 films  SUNGYUN HONG (Presenter), YEAJU JANG, JIHOON SEO, Seoul National University — ZnGa2O4 is a cubic spinel oxide with a bandgap of about 4.6 eV, almost same as that of monoclinic b-Ga2O3 in which the interest keeps increasing for its potential in high power devices. We will report the effect of various dopants on ZnGa2O4. For this study, we grew ZnGa2O4 films on c-Al2O3 substrates via pulsed laser deposition. XRD analysis conirmed the epitaxial growth of the films. Three elements, Sn, Si, and H were chosen as dopant candidates. The Sn-doped film remained highly insulating, showing no significant decrease in resistivity compared to the undoped film. The resistivity of the Si-doped film decreased to the order of 10^3 Ω*cm, confirming that some carriers were generated by Si dopants. The H-doped films showed a large decrease in resistivity down to the order of 10^1 Ω*cm. Further annealing of the H-doped films under an O2 environment increased the resistivity up to the order of 10^0 Ω*cm while the Hall measurements on the post-annealed H-doped films yielded mobility values of up to ~50 cm^2*V-1*s-1 with a carrier density of ~10^17 cm^-3.

4:54PM P45.00013: AFM Study of Temperature Driven Phase Transitions in Vanadates*  ANNA BINION (Presenter), RIJU BANERJEE, LAVISH PABBI, JASON M LAPANO, ROMAN ENGEL-HERBERT, ERIC HUDSON, Pennsylvania State University — Vanadates have many interesting properties with possible applications ranging from solar energy to transparent electronics. As many applications depend on the variation of structural and electronic properties thru phase transitions, to develop new applications it is important to have a good understanding of these transitions. Here we present results from atomic force microscopy studies of vanadates undergoing temperature driven phase transitions. In particular, we observe changes in a stripe order parameter as the materials pass through their structural transition temperatures. These observations give us insight into the nature of these transitions and how they can be controlled.

**This material is based upon work supported by the National Science Foundation under Grant No. 1229138

5:06PM P45.00014: Inversion symmetry breaking at the heterointerface of SrRuO3 thin films  CHANG JAE ROH (Presenter), Department of Physics and Photon science, Gwangju Institute of Science and Technology, JEONG RAE KIM, Department of physics, Seoul National University, YONG RYUN JO, Department of Materials Science and Engineering, Gwangju Institute of Science and Technology, JEONG GI CHOI, Department of Physics and Photon science, Gwangju Institute of Science and Technology, JIN KWON KIM, YEONGJAE SHIN, BONGJU KIM, Department of physics, Seoul National University, BONG JOONG KIM, Department of Materials Science and Engineering, Gwangju Institute of Science and Technology, TAE WON NOH, Department of physics, Seoul National University, JONGSEOK LEE, Department of Physics and Photon science, Gwangju institute of Science and Technology — We investigate the structural symmetry of SrRuO3 thin films grown on the SrTiO3 substrate by exploiting optical second harmonic generation (SHG) technique. We observe that SHG responses are strongly dependent on the film thickness and temperature; the azimuth-dependence becomes more anisotropic as the film becomes thicker, and the SHG response diminishes as temperature increases above 400 K. We analyze the azimuth dependences by considering the electric dipole and electric quadrupole contributions, and find that the tetragonal and orthorhombic phases are stabilized in fully strained and strain-relaxed regions, respectively. In particular, we demonstrate that the inversion-symmetry-broken state emerges as a stable phase at the interface between centrosymmetric tetragonal and orthorhombic phases.
5:18PM P45.00015: Effect of perovskite dielectric $Ba_xSr_{1-x}HfO_3$ on $BaSnO_3$  

HYEONGMIN CHO (Presenter), YOUNG MO KIM, KOOKRIN CHAR, Seoul National University — La-doped BaSnO$_3$ (BLSO) is a wide bandgap semiconducting perovskite oxide with high electron mobility and excellent oxygen stability at room temperature [1]. In recent reports on the excellent carrier modulation of BLSO channel by field effect on perovskite SrTiO$_3$ (STO) [2] and non-perovskite MgO substrates [3], we found an optimized thickness for undoped BaSnO$_3$ (BSO) buffer layer to be around 150 nm. However, BSO shows persistent and large photoconductivity under the light with wavelength smaller than 400 nm.

To prevent the change of channel conductance by such photoconductivity of the BSO buffer layer, we fabricated an atomically-mixed $Ba_xSr_{1-x}HfO_3$ (BSHO) buffer layer. Both BaHfO$_3$ (BHO) and SrHfO$_3$ (SHO) have wider bandgaps than BSO (5.8 eV and 6.1 eV respectively) and show no measurable photoconductivity. Also, BHO is a high-k dielectric material with a dielectric constant of 38. We reduced BSHO lattice mismatch with BLSO by finding a suitable ratio of BHO to SHO. We will report on the field effect transistor performances with BSHO as a buffer layer on BLSO channel layer as well as a gate dielectric.

Session P46 DMP GMAG: Complex Oxide Interfaces & Heterostructures -- Skyrmions & Novel Magnetism

2:30PM P46.00001: Observation of Nanoscale Skyrmions in SrIrO$_3$/SrRuO$_3$ Bilayers and SrRuO$_3$ Single Layers in Two Distinct Regimes*  

[Invited] ADAM AHMED (Presenter), KENG-YUAN MENG, Ohio State University, ANDRADA-OANA MANDRU, MIRKO BACANI, XUE ZHAO, Empa, Swiss Federal Laboratories for Materials Science and Technology, BRYAN D. ESSER, JOSE FLORES, DAVID W. MCCOMB, Ohio State University, HANS-JOSEF HUG, Empa, Swiss Federal Laboratories for Materials Science and Technology, FENGYUAN YANG, Ohio State University — The advent of skyrmion imaging and electrical detection is an exciting avenue of research as skyrmions hold promise for next-generation magnetic storage. Oxide materials are a great platform to study in this regard owing to their highly tunable properties, pristine epitaxy, and stability. In this talk, I will show Hall detection and real-space imaging of nanoscale skyrmions in perovskite oxide heterostructures of SrIrO$_3$/SrRuO$_3$ (SIO/SRO) epitaxial films grown on SrTiO$_3$(100) substrates. We show regions of large topological Hall resistivity at low temperatures which coincide with the field where the magnetization reverses. Additionally, we present a new high-temperature topological Hall effect not seen before in both bilayer SrIrO$_3$/SrRuO$_3$ and single layer SrRuO$_3$ films. This high temperature phase manifests as a “coercive field switching” in the electrical data and, consequently, as a large topological Hall effect signal. To corroborate our topological Hall signals with skyrmions, we have collected real-space images of isolated skyrmions with low-temperature magnetic force microscopy and show nanoscale skyrmions with diameters as small as 10 nm. Remarkably, the region where skyrmion bubbles are present precisely coincides with the topological Hall peaks. Our results open a platform for tunable nanoscale skyrmions in functional oxide materials.

SCHLOM, A. B. MEI, Cornell University, Ithaca, New York 14853, USA, JORGE INIGUEZ, Luxembourg Institute of Science and Technology (LIST), 5 avenue des Hauts-Fourneaux, L-4362 Esch/Alzette, Luxembourg., PABLO GARCIA-FERNANDEZ, Universidad de Cantabria, Cantabria Campus Internacional, Avenida de los Castros s/n, E-39005 Santander, Spain., LONG Q. CHEN, The Pennsylvania State University, University Park, Pennsylvania 16802, USA, JAVIER JUNQUERA, Universidad de Cantabria, Cantabria Campus Internacional, Avenida de los Castros s/n, E-39005 Santander, Spain., LANE MARTIN, R RAMESH, Department of Materials Science and Engineering, University of California, Berkeley, California 94720, USA. — Recent discovery of polarization flux closures, vortices and skyrmions in polar oxide superlattices suggests the presence of a complex, multi-dimensional system capable of exotic physical responses.[i]-[ii],[iii] where the exploration of novel emergent phenomena and exotic phases in condensed-matter physics is greatly facilitated. Here, we have observed a room-temperature polar skyrmions in a PbTiO3/SrTiO3 superlattices grown on SrTiO3 (001) substrate. X-Ray diffraction and large scale scanning transmission electron microscopy imaging confirmed the present of the polar skyrmions phase. In addition, phase-field modeling and second-principles calculations reveal that the polar skyrmions have a skyrmion number of +1. Moreover, special uniform chirality was revealed by resonant soft X-ray diffraction experiments showing obvious circular dichroism. Such nanometer-scale polar skyrmions are the electric analogs of magnetic skyrmions, and could advance ferroelectrics towards new levels of functionality.

3:18PM P46.00003: Electric field Controllable “Negative Capacitance” in Polar Skyrmions: Topological transition?* SUJIT DAS (Presenter), University of California, Berkeley, ZIJJAN HONG, The Pennsylvania State University, University Park, Pennsylvania 16802, USA, SAHAR SAREMI, BHAGWATI PRASAD, University of California, Berkeley, PABLO G. FERNANDEZ, Departamento de Ciencias de la Tierra y Física de la Materia Condensada, Universidad de Cantabria, Cantabria Campus Internacional, Avenida de los Castros s/n, E-39005 Santan, MARGARET MCCARTER, YUN-LONG TANG, University of California, Berkeley, JAVIER JUNQUERA, Departamento de Ciencias de la Tierra y Física de la Materia Condensada, Universidad de Cantabria, Cantabria Campus Internacional, Avenida de los Castros s/n, E-39005 Santan, LONG Q. CHEN, The Pennsylvania State University, University Park, Pennsylvania 16802, USA, LANE MARTIN, SAYEEF SALAHUDDIN, RAMAMOORTHY RAMESH, University of California, Berkeley — Complex topological configurations are a fertile arena to explore novel emergent phenomena and exotic phases in condensed-matter physics. For example, the recent discovery of polar skyrmions, vortices and skyrmions in polar superlattices suggests the presence of a complex, multi-dimensional system capable of exotic physical responses. Here, we demonstrate electric field controlled room-temperature negative capacitance and topological phase transition in polar skyrmions. In epitaxially grown heterostructures of PbTiO3 and SrTiO3 capacitance was found to be larger compared to its individual constituent’s capacitance SrTiO3, PbTiO3. This indicates the indicates the ferroelectric was stabilized in a state of negative capacitance at room temperature. This phenomenon could be controlled by electric field and temperature. The STEM measurement, Phase field and Second principle calculation confirms the stable negative capacitance is due to boundary of polar skyrmions. Such phenomena could advance ferroelectrics towards new levels of functionality.

3:30PM P46.00004: Resonant X-ray diffraction study of chiral polar skyrmions in PbTiO3/SrTiO3 superlattices*
MARGARET MCCARTER (Presenter), Department of Physics, University of California, Berkeley, SUJIT DAS, Department of Materials Science & Engineering, University of California, Berkeley, YUN-LONG TANG, Materials Science Division, Lawrence Berkeley National Laboratory, CHRISTOPH KLEWE, PADRAIC SHAFER, ELKE ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, JAVIER JUNQUERA, Departamento de Ciencias de la Tierra y Física de la Materia Condensada, Universidad de Cantabria, LANE MARTIN, RAMAMOORTHY RAMESH, Department of Materials Science & Engineering, University of California, Berkeley —
Emergent topologies in ferroelectric heterostructures—the polar analogs of magnetic vortices and skyrmions—have become a recent topic of interest for their potential to host exotic functionalities (e.g., emergent chirality and negative capacitance). These topologies can be stabilized in low-dimensional ferroelectrics; namely, superlattices of PbTiO3/SrTiO3. Polar skyrmion structures have been observed in PbTiO3/SrTiO3 superlattices grown on SrTiO3 substrates with a combination of scanning transmission electron microscopy, X-ray diffraction, and second-principles calculations. Using resonant soft X-ray diffraction, we study the chirality of these polar skyrmions and show that the skyrmions have a preferred handedness. The origin of the circular dichroism is shown to be a chiral configuration of the titanium orbitals in the skyrmions.

3:42PM P46.00005: Living on the edge: multiple phase competition and topological order in pyrochlore oxides*
[Invited] NICHOLAS SHANNON (Presenter), HAN YAN, Okinawa Institute of Science and Technology, OWEN BENTON, Condensed Matter Theory, RIKEN, LUDOVIC JAUBERT, CNRS Bordeaux — Pyrochlore oxides, A2B2O7, are one of nature's best tricks - ubiquitous minerals, capable of incorporating an extremely wide range of metal cations. Over the past decade these materials have risen to prominence in the community studying frustrated magnetism, for their ability to instantiate so many different novel, and topological phases of matter. Best known among these is spin ice, celebrated for its magnetic monopole excitations, but small changes in chemistry can lead to a wide range of other exotic phenomena, including both classical and quantum spin liquids.

In this talk, we explore one particular avenue in this lively field, namely the multiple-phase competition which occurs in magnetic oxides with strong spin-orbit coupling. Considering Yb2Ti2O7, Er2Ti2O7 and Er2Sn2O7 as examples, we show how the seemingly diverse physics of these systems can be understood through a single unifying principle, namely the interplay between different competing forms of order [1]. We also explore how this conceptual framework can be used to "design" new forms of spin liquid, including phases which realise fracton topological order.

Finally, we pose the question, could different modes of growth give us access to pyrochlore oxides with even more exotic, or controlable, properties?

4:18PM P46.00006: Anisotropic magnetoresistance in multiorbital systems*
ILIA KHAIT (Presenter), NAZIM BOUDJADA, ARUN PARAMEKANTI, Department of Physics, University of Toronto — Magnetotransport is a useful probe for studying magnetism, electron-electron interactions, as well as the underlying symmetries of a crystal. We study the impact of an in-plane magnetic field on 2D multiorbital electron gases as a function of electron density, scattering length, temperature, and spin-orbit interactions. These parameters affect the shape of the different spin-split Fermi surfaces, which in turn is shown to set the amplitude of the anisotropic magnetoresistance and its dominant symmetry components. We comment on the validity of the relaxation-time approximation and the necessity to resort to the full Boltzmann equation.

**4:30PM P46.00007: Imaging, controlling and harnessing non-collinear magnetism in perovskite oxides** [Invited]

MANUEL BIBES (Presenter), CNRS/Thales — In magnetic perovskites, first-neighbour antiferromagnetic super-exchange interactions usually dominate, but may coexist with other terms such as ferromagnetic double-exchange or Dzyaloshinskii-Moriya interactions. This often produces non-collinear spin configurations leading to weak ferromagnetism or to spatially modulated spin structures. A prototypical non-collinear magnetic oxide is multiferroic BiFeO₃ that shows a cycloidal order with a 64 nm period in the bulk. In this talk, I will present real-space images of the cycloidal structure and its manipulation by electric field [1]. In a second part, I will report the observation of a very large topological Hall effect (THE) in thin films of a lightly electron-doped manganite. Magnetic force microscopy reveals the presence of small magnetic bubbles, whose density vs. magnetic field peaks near the THE maximum, as is expected to occur in skyrmion systems. The THE critically depends on carrier concentration and diverges at low doping, near the metal-insulator transition, suggesting its amplification by strong correlations, in the vicinity of the Mott transition [2].

*Supported by the ERC CoG MINT (#615759)

**5:06PM P46.00008: High-throughput Design of Interfacial Perpendicular Magnetic Anisotropy at Heusler/MgO Heterostructures**

KESONG YANG (Presenter), SAFDAR NAZIR, University of California, San Diego — Thin magnetic tunnel junctions (MTJs) with a large interfacial perpendicular magnetic anisotropy ($K_I$) have great applications in spin transfer torque magnetoresistance random access memories. A large $K_I$ is required for achieving a high thermal stability of the MTJ, and thus to design an interfacial perpendicular magnetic anisotropy at the interface between ferromagnetic electrodes and oxide barriers is of great interests. Here we show that, by modelling Heusler/MgO heterostructures using high-throughput first-principles electronic structure calculations, we are able to rapidly identify a series of Heusler/MgO heterostructures with a large $K_I$ value. This work shows an effective way to design novel magnetic materials via high-throughput electronic structure calculations.

**Session P47 GERA: Recent Advances in Energy Conversion Devices** BCEC 213 - Jeffrey Owrutsky, United States Naval Research Laboratory

**2:30PM P47.00001: Battery alternative: Harvesting energy from vibrations** MILLICENT GIKUNDA (Presenter), PAUL THIBADO, University of Arkansas — Development of energy harvesting systems is becoming increasingly important. This is due to an increased need to produce self-charging, portable, implantable and wireless electronics with extended lifespans. Operation of these devices require low power which is normally supplied by batteries that require regular replacement. Emphasis has been placed on scavenging vibrational energy as an alternative to batteries. A notable breakthrough is the discovery that mechanical buckling (change of curvature from concave to convex and vice versa) in freestanding graphene occurs spontaneously at room temperature. This spontaneous mechanical buckling is a source of renewable energy that is to be harvested. Here, I will discuss the relationship between the energy barrier which separates the two lowest energy configurations to strain and height of the ripple and model the ripple curvature inversion dynamic due to thermal energy using Langevin’s equation for freestanding graphene. Mechanical power calculations estimates that a naturally occurring ripple can yield up to and a ripple can yield Thus a quartz wristwatch whose approximate consumption is can be powered by a ripple.
By adjusting the structural properties, we find a minimum thermal conductivity to be reached at ~ 35 mWm\(^{-1}\)K\(^{-1}\) in air, whereas 7 mWm\(^{-1}\)K\(^{-1}\) can be achieved in vacuum. Thus, tailor-made particle ensembles based on hollow silica nanoparticles represent a dispersion processable, breathable, and non-flammable alternative to common polymer foams.

3:30PM P47.00006: Reversing Thermal Equilibration by Differential Magneto-Thermal Force  WEILI LUO (Presenter), JUN HUANG, DARIAN SMALLEY, Physics,, University of Central Florida, T. S. LIU, Western Michigan University — A special magnetic body force was proposed to reverse thermal equilibration in a fluid [1]. In this work, we discuss the fulfilment of the requirements for this force and the experiment to verify it. We present experimental [2-3] and analytical [4] results that clearly demonstrate: 1) approaching thermal equilibrium in our magnetic fluid sample was indeed “reversed” as the magnetic body force introduces the localized flows that stop the conventional convective heat transfer; 2) The differential magneto-thermal force density calculated with experimental parameters agrees with the design principle. These results prove the feasibility of the proposed mechanism for a new generation of heat transfer apparatus that has high efficiency and no exhaust, a clean energy source that will improve our environmental protection.

3:42PM P47.00007: Development of Thermoacoustic Arrays for Power.  OREST SYMKO (Presenter), SEO YOUNG AHN, University of Utah — Thermoacoustic heat engines with piezoelectric devices provide a simple approach to converting heat to electricity. Heat generates sound in an acoustic resonator, which is converted to electricity. For high power, arrays of engines are used. The development of such approach deals with the coupling of engines for synchronization, frequency tuning of resonant components, stability, and performance. Standing wave thermoacoustic engines (2 to 6) at ~2.5 kHz were mounted on a cavity housing piezoelectric devices for converting sound to electricity, and the cavity provided coupling. Above a threshold temperature difference, oscillations were initiated, and they appeared synchronized. The engines were tuned to the piezos. Temperature changes led to detuning. This was compensated by using two piezos of different resonant frequencies, and each piezo was coupled to a Helmholtz resonator, making broadband response and maintaining sensitivity. The increase in power density in the above-coupled engines can be eventually applied to large systems, i.e. arrays.

3:54PM P47.00008: Electronic, Magnetic and Magnetocaloric Properties of Hole-Doped La$_2$MnFeO$_6$ and their Potential for Magnetic Refrigeration*  C. GAUVIN-NDIAYE (Presenter), ANDRE-MARIE TREMBLAY, REZA NOURAFKAN, Institut quantique, RQMP, Université de Sherbrooke — Magnetic refrigeration at room-temperature is a technology that could potentially be more environmentally-friendly, efficient and affordable than traditional refrigeration. Known ferromagnets that satisfy the requirements of near room temperature Curie temperature and large refrigerant capacity are expensive. Double Perovskites La$_2$MnXO$_6$ with X=Ni,Co have refrigerant capacity comparable to the more expensive materials but their Curie temperature $T_C$ is low [1]. Previous theoretical studies have reproduced the trend in $T_C$ of these materials and shown that strong electronic interactions in Fe-d orbitals [2] make the X=Fe compound a ferrimagnet. Based on this insight, we use ab initio, mean-field and Monte-Carlo calculations to propose two materials with promising magnetocaloric properties. They are obtained by hole doping the X=Fe compounds by substituting half of the lanthanum with Sr or Ba, LaBaMnFeO$_6$ and LaSrMnFeO$_6$ [3].

4:06PM P47.00009: Photoelectrochemical water splitting systems for the sustainable growth of hydrogenotroph biomass* CAMILLA TOSSI (Presenter), LASSI HÄLLSTRÖM, ERICH SEE, Electronics and Nanoengineering, Aalto University, MICHAEL LIENEMANN, JUHA-PEKKA PITKÄNEN, MARJA NAPPA, PETER BLOMBERG, JUSSI JÄNTTI, MERJA PENTTILÄ, VTT Technical Research Centre of Finland, Ltd., ILKKA TITTONEN, Electronics and Nanoengineering, Aalto University — An important and presently not yet deeply investigated application of photoelectrochemical (PEC) water splitting is the use of the generated hydrogen to feed a population of hydrogenotroph bacteria. Such bacteria exist in a sufficient variety to satisfy different demands, from fuel components to edible and highly proteic biomass. The need for sustainable food production techniques is an urgent matter, as our planet is expected to produce enough nourishment to sustain 9 billion people by 2050, while at the same time reducing the carbon footprint of the population. We developed a PEC cell equipped with a bioreactor, demonstrating the growth of a Rhodococcus Opacus population with forced electrolysis over the span of several days: the present focus is on the engineering progress of the working electrode, a stack of semiconductor thin films with noble metal co-catalyst nanoparticles, to match both the durability and the solar-to-hydrogen efficiency necessary to the self-sustainability of the system.

4:18PM P47.00010: Density functional theory study of water splitting on ZnO catalyst adsorbed on Graphene Oxide* DUWAGE PERERA (Presenter), JAYENDRAN C RASAIAH, University of Maine — We discuss results from density functional theory (DFT) calculations of water splitting on ZnO surfaces using the hybrid B3LYP exchange functional and the 6-311G basis sets. The production of H2 and O2 occurs through the formation of a Zn-H bond generated from the hydrolyzed product of ZnO. We discuss the Transition state of the reaction using the Synchronous Transit-Guided Quasi-Newton (STQN) method following calculations of the Intrinsic Reaction Coordinate (IRC) using the same level of theory. We discuss an extension of our work using RB3LYP/DGDZVP method for water splitting on ZnO adsorbed on graphene oxide (GO) surface (GO-ZnO) which forms a p-n hetero junction enhancing the rate of H2 evolution as it does for a GO-TiO2. GO sheet can facilitate exciton formation and acts as an electron sink to store the separated electrons. Hydrogen production was observed on the GO-ZnO surface using five different GO models.

*We thank Stephen Cousins of the University of Maine High Performance Computing Group for his technical assistance and significant allotment of computer time.

4:30PM P47.00011: Synthesis of Zn-doped MoS2-graphene heterostructure for efficient water splitting MD DELOWAR HOSSAIN (Presenter), ZHENGTANG LUO, Chemical and Biological Engineering, The Hong Kong University of Science and Technology — The demand of renewable energy increases day by day as we progress towards near future. Here we report new type of 2D heterostructures which show superior electrochemical performance towards both hydrogen and oxygen evolution reaction. We demonstrate the synthesis of heterostructure by mixing graphene oxide, Mo-salt, and thiourea via hydrothermal method at 180 oC for 12 hrs. The heterostructure has lots of defected area which enhanced the active sites for both reactions, was revealed by SEM, TEM characterization. Later on, we have performed density functional theory calculation, which demonstrate that the activity mainly comes from sulfur and zinc sites of this heterostructure represented by Gibbs free energy diagram. The density of states calculation shows that the presence of zinc in MoS2-graphene heterostructure increases the electron density throughout the whole structure. Finally, the band structure calculation reveals that zinc reduces the band gap for heterostructure and increases the water splitting capacity into hydrogen and oxygen.

4:42PM P47.00012: Engineered Photo-electrochemical Properties of Nano-Structured SnO2 ZINEB KERRAMI (Presenter), Physics, Mohammed V University — In the present study, photo-electrochemical properties of SnO2 Thin-film have been examined using first principles calculation. Increasing SnO2 film thickness from 0.3 nm to 2.5 nm results in band gap decrease, which revealed a strong quantum confinement effect. Our results indicate that visible-light absorption and charge carrier's mobility of a chosen SnO2 film (2.5 nm) could be improved by applying tensile strain. Although, large pH value (pH ≥ 10) is needed to enhance band edges positions relative to the water redox (H2O/H2) levels. All these improvements make tensile strained-SnO2 a potential candidate for hydrogen production through water splitting.
4:54PM P47.00013: Close Space Sublimation Synthesis and Photoelectrochemical Efficiency of Vertical Tin Disulfide (SnS$_2$) Nanoflake Photoanodes  BINOD GIRI (Presenter), PRATAP RAO, Worcester Polytechnic Institute — Tin disulfide (SnS$_2$) is a 2-dimensional material similar to MoS$_2$ and WS$_2$, with layers held together by weak Van der Waals forces. It has excellent optical and electronic properties that are suitable for a number of applications. Because of its high optical absorption coefficient, moderate band gap, and conduction and valence band edges that straddle the reduction and oxidation potentials of water, SnS$_2$ is a promising material for photoelectrochemical (PEC) water splitting. Several reports describing fundamental properties and synthesis methods have been published, however very few have successfully realized SnS$_2$-based photoanodes.

In this work, vertically aligned 2D SnS$_2$ nanoflakes were grown directly on FTO-glass substrates using a scalable close space sublimation (CSS) method. Scanning electron microscopy revealed that our nanoflakes contain vertical tapered structures with high aspect ratios and high density of exposed edges. They exhibit an indirect bandgap of 2.28eV and are excellent photoabsorbers. Photoanodes consisting of these nanoflakes were synthesized and measured in aqueous pH7 buffer containing Na$_2$SO$_3$ as hole-scavenger. Photocurrents up to 4.5mAcm$^{-2}$ were obtained at 1.23 V vs. RHE under simulated sunlight.

5:06PM P47.00014: 2D Photocatalysts on GaN Nanowires*  XIANGHUA KONG (Presenter), DAWEI KANG, BAOWEN ZHOU, McGill University, ZETIAN MI, University of Michigan, HONG GUO, McGill University — Hydrogen generation via PEC water splitting is an appealing approach for conversion of solar energy into chemical fuel. PEC requires photocatalysts to function and 2D photocatalysts have received tremendous attention. We report an investigation of solar fuel generation using defect-free GaN nanowires as linker between planar Si wafer and 2D photocatalyst MoS$_2$, focusing on the modeling side [1]. The electronic interaction as well as excellent geometric-matching structure between GaN and MoS$_2$ enable excellent electron-migration channels for high charge extraction efficiency, leading to outstanding photocatalytic performance. Our approach[1] of constructing super-heterostructures offers clear benefits for solar water splitting, including the use of low-cost, large-area Si wafer for light harvesting, earth-abundant MoS$_2$ catalyst for proton reduction, and defect-free GaN nanowires for highly efficient charge carrier extraction and for exposing a high-density of active sites. We further report a general numerical procedure for quantitative estimation of band edge positions and band edge shifts and microscopic origins of these shifts for solid/liquid system[2].

Session P48 DFD GSOFT GSNP: Thin Films, Surface Flows, Interfaces and Microfluidics II
BCEC 251 - Anand Oza, New Jersey Institute of Technology

2:30PM P48.00001: Characteristic interfacial structure behind a rapidly moving contact line*  MENGFEI HE (Presenter), SIDNEY ROBERT NAGEL, University of Chicago — A solid rapidly pushed into a liquid, of viscosity $\eta$, at velocity $U$ entrains surrounding air along with its moving surface. Using high-speed interferometry we find a robust characteristic structure of the entrained air layer: there is a thin-thick alternation of gap thickness in the transverse direction and this feature occurs both in wetting and de-wetting. In the thin regions we find that the gap thickness scales approximately as $(\eta U)^{0.5}$. We present a model using the assumption that the velocity profile is robust to thickness fluctuations that gives a good quantitative estimate of this gap thickness. This is in contrast to the Landau-Levich analysis which had previously been assumed applicable to this problem.

Levitation of fizzy fluids

PHILIPPE BOURRIANNE (Presenter), DIVYA PANCHANATHAN, PHILIPPE NICOLLIER, KRIIPA K VARANASI, GARETH MCKINLEY, Massachusetts Institute of Technology — Liquids generally spread on solids they encounter. However, under particular circumstances, such a wetting can be reduced or even avoided, a situation of obvious practical interest in terms of anti-adhesion or even thermal and mechanical insulations. By using superhydrophobic coating, a water drop can thus limit its contact with the substrate at a low fraction. Liquid levitation can even be achieved using the volatility of the liquid and creating a thin insulating vapor layer as early described by Leidenfrost in 1756. More recently, other strategies have been developed involving external fields such as air flows, Faraday waves or magnetic fields. We here describe a novel approach using active liquids able to sustain levitation in the absence of external forces. We will first discuss the levitation of carbonated water. In this regime, the drop self-generates the gas cushion which provides levitation. We will model the lubrication theory behind this insulation. Finally, we will generalize this new regime to different kinds of substrates and non-volatile liquids.

Dewetting Front Instabilities for Micro-patterning

SAMANTHA MCBRIDE (Presenter), Massachusetts Institute of Technology, SEVERINE ATIS, Harvard University, KRIIPA K VARANASI, Massachusetts Institute of Technology — It has long been known that fluid instabilities can be harnessed for low-effort self-assembly of ordered structures on the nano- and micro- scales. Here, we demonstrate how a known thin film instability resulting from Van der Waals forces in an evaporating film can generate a number of extraordinarily ordered nano- and micro-structures. The patterns that can arise include hexagonal lattices, lines, branches, and triangular sawtooth structures. We find that the patterning mechanism is driven by fluid dynamics and Ostwald ripening of crystallizing salts at the fluid dewetting front. Controllability of these patterns can be further enhanced by application of flow-control strategies. We present a phase diagram of substrate properties that result in patterning, and perform stability analysis to predict the wavelength of the instability. Such patterns may have potential applications in sensor arrays, photonics, dielectric materials, and materials of controlled porosity.

Nanosecond Pulsed Imaging for Ethanole Electrospraying Breakup in a Modified Nozzle

ELAHE JAVADI (Presenter), Mechanical Engineering, Northeastern University, MOHAMMAD REZA MORAD, Department of Aerospace Engineering, Sharif University of Technology — An electrified liquid jet breakup behavior and modes of disintegration indifferent ow rates and applied voltages are investigated. The present phenomenology belongs to a new injector introduced recently by Morad et al. (2016). This injector is shown to highly extend the stability and ow rate of electrospray particularly in the Taylor cone-jet mode. The experimental investigation is performed using a high-power light-emitting diode (LED) illumination as the light source. The light source is developed to operate in the pulsing condition when synchronized with a digital camera, and is particularly designed to function properly in presence of high electromagnetic interference (EMI). Details of the light source development is presented with the captured images from the jet breakup at different modes. The operational map of the new injector is obtained, and the physical mechanisms of different behaviors are explained and discussed.

From droplets to waves: interfacial instabilities of viscosity-stratified flows in microchannels

XIAOYI HU (Presenter), THOMAS CUBAUD, Stony Brook University — Rapid layering of viscous materials in microsystems encompasses a range of hydrodynamic instabilities that facilitate mixing and emulsification processes of fluids having large differences in viscosity. We experimentally study dispersed droplet and separated viscous wave flow regimes arising from viscosity-stratified microflows made of fluid pairs with large viscosity ratios and systematically investigate the effects of control parameters such as flow rate, viscosity ratio, and interfacial tension between model fluid pairs. We demonstrate that key features of periodic droplets and interfacial viscous waves, including emission frequency, propagating celerity, and wavelength, can be readily described by functional relationships, which delineate effects of inertial, capillary and viscous forces. We also shed light on wave crest breaking process, which produces viscous ligaments that continuously transport thick material into the fast co-flowing low-viscosity stream. Finally, we examine the transition from droplet to wave regime to provide a comprehensive scenario of interfacial instabilities in microfluidic viscosity-stratified flows.

3:54PM P48.00008: High precision characterization of a binary fluid interface using surface light scattering spectroscopy* NABIN K. THAPA (Presenter), Physics, Kent State University, ANTHONY E. SMART, Scattering Solutions, Inc., Costa Mesa, CA, WILLIAM V. MEYER, ALEXANDER BELGOVSKIY, Scattering Solutions, Inc., Cleveland, OH, J. ADIN MANN, Chemical Engineering, Case Western Reserve University, ELIZABETH MANN, Physics, Kent State University — Thermally excited capillary waves (ripplons) with an rms height of ~1 nm perturb any fluid interface. The Doppler spectrum of these ripplons, which can be characterized by Surface Light Scattering Spectroscopy (SLSS), depend upon interfacial properties such as surface tension and surface viscoelasticity, via the capillary wave surface response function, a refinement of the classical dispersion equation. Innovative optical design has increased signal and signal-to-noise ratio. This enhances measurement accuracy over the entire range of wave numbers, while enabling measurements at higher wave numbers above 1500/cm. We demonstrate the validity of the technique with high precision and high accuracy measurements of standard fluids. Subsequent measurements of pentane/2-methyl pentane mixtures anticipate an upcoming NASA microgravity experiment intended to optimize the effectiveness of wickless heat pipes for space flight applications.

4:06PM P48.00009: NEMD Simulations Quantifying the Influence of Surfaces Roughness on Conductive Heat Transfer at Liquid/Solid Interfaces HIROKI KAIFU (Presenter), SANDRA TROIAN, MC128-95, CALTECH, Pasadena, CA 91125 — Rapid developments in extreme ultraviolet lithography are soon expected to produce integrated circuit components with feature sizes of about 10 nm. At these small scales, the interfacial or so-called Kapitza resistance, which tends to increase with diminishing system size, progressively hinders the transfer and evacuation of heat, ultimately compromising performance. Although numerous experiments and simulations over the past few decades have elicited trends in the Kapitza resistance which correlate with system size and surface roughness, good quantitative understanding for atomistically rough interfaces is still lacking. In this talk, we discuss some of the effects on Kapitza resistance induced by surface roughness at liquid/solid interfaces as investigated by non-equilibrium molecular dynamics (NEMD) simulations using realistic solid walls modeled by an interacting 12-6 Lennard-Jones potential. Comparison between atomistically smooth and rough interfaces, contrasting such behavior as the vibrational density of states, helps interrelate the phonon spectrum and phonon modes transmitted across the interface with various quantitative measures characterizing interfacial roughness.

4:18PM P48.00010: Oblique water entry of micron particles* BINGQIANG JI (Presenter), QIANG SONG, QIANG YAO, Tsinghua University — Water entry problem has attracted much interest in the past century, but few research focused on the oblique water entry of micron particles, which is very common in nature and industrial processes. The oblique water entry of micron PMMA particles with different impact angles is realized by a self-made impactor and observed with a high speed camera. It was found that the distortion of the liquid surface after impact is non-axisymmetric due to the lateral velocity of the particle, and the wetted part of the particle surface is not axisymmetric along the impact direction, which produces a force perpendicular to the impact direction and makes the particle's motion direction changes during the water entry process. The critical velocity for the particle to sink increases with the decrease in impact angle. A simple model is established to analyze the energy balance during the critical sinking process and the expression of the critical sinking velocity is given, which agrees well with our experimental results.

*This work is supported by the National Natural Science Foundation of China (51576109).

4:30PM P48.00011: Rebound dynamics of a superhydrophobic sphere* ISABELLE BAUMAN (Presenter), DANIEL M HARRIS, School of Engineering, Brown University — Small solid particles impacting a water surface can become trapped, rebound, or pass through the interface [Lee & Kim, Langmuir, 24 (2008)]. In the present work, we focus on the bouncing dynamics of millimetric superhydrophobic spheres impacting the surface of a quiescent water bath. Through experiments, we characterize the dependence of the normal coefficient of restitution and contact time on the impact velocity, radius, and relative density of the sphere. We also highlight a qualitatively new regime identified that occurs near the sinking threshold for many spheres. Ongoing work and future directions will be discussed.

*We would like to acknowledge the financial support of the Brown Seed Award and the Brown Undergraduate Teaching and Research Award (UTRA).
Characterization of Liquid Transport in MicroCapillaries via X-Ray Photon Correlation Spectroscopy

DHIRAJ NANDYALA (Presenter), Stony Brook University, ANDREI FLEURASU, YUGANG ZHANG, Photon Sciences, Brookhaven National Laboratory, CARLOS E COLOSQUI, Stony Brook University — X-ray photon correlation spectroscopy (XPCS), a novel x-ray scattering technique analogous to dynamic light scattering, enables probing the hydrodynamics of liquids on length scales ranging from microns to nanometers and time scales ranging from seconds to microseconds. The National Synchrotron Light Source II (NSLS-II) of Brookhaven National Laboratory (BNL), which started operating in 2015 as one of the world's most advanced synchrotrons can enable XPCS studies with unprecedented spatio-temporal resolution. This presentation will discuss ongoing work at the Coherent Hard X-ray Scattering (CHX) beamline of NSLS-II where XPCS techniques are employed to characterize flow velocity profiles and mass diffusivity in microcapillaries. A genetic algorithm is developed to determine local flow velocities and diffusion coefficients from the intensity autocorrelation function obtained from XPCS experiments. The developed XPCS techniques and analytical methods can provide new insights into the hydrodynamic and rheological behavior of liquids in micro/nanoscale confinement.

Suppression of the viscous fingering instability by shear

THOMAS ERIK VIDEBÆK (Presenter), SIDNEY ROBERT NAGEL, Physics, University of Chicago — During the viscous fingering instability, the interface between two fluids confined to a thin gap is unstable to finger formation when the less viscous fluid invades the higher viscosity one. Here, we study the instability between pairs of miscible fluids. When experiments are conducted in a radial geometry there is a period of stable growth which persists up to a critical radius that depends on the viscosity ratio of the fluids and the injection rate. The presence of fingers appears to be tied to specific interfacial structure across the small dimension of the gap. In this work we see how actively interfering with this structure formation affects the instability. By applying an oscillatory translational shear to the top plate of our Hele-Shaw cell we observe a dramatic delay in the onset of the instability. We suggest that this delay is tied to changing the curvature of the interface at the leading edge of the pattern. This phenomenon could lead to novel control techniques to suppress this instability.

Experimental Pressure Analysis Techniques in the Viscous Fingering Instability

SAVANNAH GOWEN (Presenter), THOMAS ERIK VIDEBÆK, SIDNEY ROBERT NAGEL, Physics, University of Chicago — When a lower viscosity fluid displaces a higher viscosity one in a confined geometry, the interface between the two fluids is unstable to the formation of fingers. The fluid flow is governed by Darcy's law so that the local velocity is proportional to the pressure gradient. Using thin rings of dyed fluid we visualize the local flow field within a radial Hele-Shaw cell and are able to map pressure gradients throughout the pattern-formation process. In particular, we measure the pressure gradients as a function of distance from the unstable fluid interface. Using various image processing techniques, we examine the role of the fluids' viscosity ratio as a parameter governing pattern formation.

Equilibrium shapes and their stability for liquid films in fast flows

ANAND OZA (Presenter), Department of Mathematical Sciences, New Jersey Institute of Technology, LIKHIT GANEDI, Department of Mathematical Sciences, Carnegie Mellon University, MICHAEL JOHN SHELLEY, Courant Institute / Flatiron Institute, LEIF RISTROPH, Courant Institute — We present the results of a combined experimental and theoretical investigation of a suspended liquid film deformed by an external flow en route to forming a bubble. We identify a family of nonminimal but stable equilibrium shapes for flow speeds up to a critical value, beyond which the film inflates unstably. A model based on free-streamline theory accounts for the observed nonlinear deformations and forces. Our theoretical predictions suggest that bubble formation at low speeds results from the instability of overly-inflated shapes, and at high speeds from the loss of equilibrium solutions.

Session P49 DPOLY GSOFT DFD GSNP: Tribology of Polymers and Soft Materials II: Friction and Slip

BCEC 252A - Catheryn Jackson - Tag(s): Focus
ASHLIE MARTINI (Presenter), ARASH KHAJEH, JEJOON YEON, Mechanical Engineering, University of California Merced, XIN HE, SEONG KIM, Chemical Engineering, Penn State University — Shear force is used to drive chemical reactions in many natural and engineering processes. However, despite the important role of these so-called tribochemical reactions, their fundamental mechanisms are still poorly understood due to challenges associated with directly measuring processes that occur inside a moving contact. To address this, we investigate shear-driven polymerization of molecules adsorbed on silica surfaces, a model system that enables identification of shear-driven reaction pathways. This system is studied using reactive molecular dynamics simulations complemented by pre- and post-sliding surface characterization. The results show that interfacial shear not only accelerates polymerization reactions but opens reaction pathways that are not accessible thermally. Specifically, the simulations reveal that chemisorption and shear-induced deformation of the reactants are critical steps in tribochemical processes. In general, these findings may form the basis for design of systems where shear force can be leveraged to tune or lower the energy cost of chemical reactions.

*National Science Foundation Grant No. CMMI-1727356 and 1727571

MARION GRZELKA (Presenter), MARCEAU HÉNOT, Univ of Paris - Sud 11 CNRS, ALEXIS CHENNEVIÈRE, Laboratoire Léon Brillouin CEA Saclay, CNRS, LILIANE LÉGER, FREDERIC RESTAGNO, Univ of Paris - Sud 11 CNRS — The slippage of polymer melts is now well understood. In particular, Hénot et al. have investigated the dependence of the slip length on the viscosity of the sheared polymer melt [1]. They proved that the friction of polymer melt is due to the friction of monomers on the surface.

More recently, we studied the effect of temperature on slippage of polymer melts far above glass transition temperature [2]. We showed that friction is a thermodynamically activated process.

With solutions, the concentration can change the interdigitation between the chains anchored to a surface and the solution. Furthermore, depletion layer may appear. The disentanglement and depletion are competing.

We will present the results of experiments of friction of polystyrene in diethyl phthalate on different substrates. We investigate the dependence of the slip length on concentration of the solutions in the Newtonian and the shear-thinning regimes.

*This work was supported by ANR-ENCORE program (ANR-15-CE06-005).

DAISUKE KAWAGUCHI (Presenter), NOZOMI ITAGAKI, YUKARI ODA, Kyushu University, NORIFUMI L. YAMADA, KEK, KEIJI TANAKA, Kyushu University — Frictional Properties, which are closely related to aggregation states at the outermost surface, of hydrogels are pivotal importance for many applications. Recently, we synthesized poly(2-methoxyethyl vinyl ether) (PMOVE) containing photo-cross-linkable 2-(vinylloxy)ethyl methacrylate (VEM) units by living cationic polymerization. Here, interfacial density profiles and frictional properties of cross-linked PMOVE (c-MrV) thin films in water were examined by neutron reflectivity (NR) and lateral force microscopic (LFM) measurements, respectively. The density profile of the c-MrV films in close proximity to the water interface was well described by a parabolic function, which was generally used for polymer brushes in a liquid. The lateral force ($F_L$) for the hydrogel films swollen in water was a function of normal force ($F_N$) applied on to a probe tip. For all films, $F_L$ first increased with $F_N$ and then remained constant at an $F_N$. The critical depth, in which $F_L$ reached a constant, well corresponded to the thickness of the interfacial swollen layer determined by the NR measurement.
3:30PM P49.00004: Microgel systems containing phospholipid: Role of component interactions on rheology and tribology  
BARBARA FARIAS, SAAD KHAN (Presenter), North Carolina State University — Microgel systems containing phospholipids are often used in personal care products due to their gelling and emulsifying properties. Herein, we investigate how the type of microgel (hydrophobically modified versus hydrophilic) and its interaction with phospholipid manifest itself on the tribology and rheological behavior of the system. We examine two different polymers one forming a microgel with hydrophobic moieties on the surface (Pemulen) and the other being a hydrophilic microgel (Carbopol). While both polymers exhibit gel-like features rheologically, their mode of interaction with phospholipid is different. Phospholipid addition to the Pemulen leads to an increase in elastic modulus because of the interaction of the hydrophobic moieties with the phospholipid tails. Such active participation is verified using heat of interaction measured through isothermal calorimetry. Tribological behavior, measured with a soft model polydimethylsiloxane (PDMS) contact, reveals lower friction coefficients in the boundary regime for the hydrophobic Pemulen with and without phospholipid. Adsorption of phospholipids and Pemulen on the PDMS substrate are attributed to the decreased friction coefficient, which we verify through optical microscopy and with Quartz Crystal Microbalance measurements.

3:42PM P49.00005: Orientation of nanodomains of star-shaped (PMMA-b-PS)$_6$ in thin films with different molecular weights*  
SOYEONG PARK (Presenter), CHUNGRYONG CHOI, KYUSEONG LEE, SEUNGKYOOP KARK, EUNSEOK KIM, JIN KIM, Pohang University of Science and Technology — To apply block copolymer (BCP) to nanolithography, vertically oriented nanodomains in thin film are needed. When the chain architecture of BCPs was changed from linear to star shape, vertically oriented cylinders and lamellae were obtained by using only thermal annealing without any special treatment. This is because the vertical orientation is entropically favored over parallel oriented one. Here, we study the effect of the molecular weight of (PMMA-b-PS)$_6$ star shaped block copolymer on the orientation of nanostructures on a silicon oxide changed. When the molecular weight is small, but still larger than the critical molecular weight corresponding to the order-disorder transition (ODT), parallel orientation is observed. This is because the entropic loss arising from the formation of vertical oriented nanostructures is not large; thus the orientation of nanostructures is greatly affected by surface treatment of a substrate. On the other hand, at large molecular weights, the entropic penalty for parallel orientation becomes huge, resulting in vertical orientation.

3:54PM P49.00006: Concentration-Dependent Long-Range Repulsive Interactions of Adsorbed Associative Polymers  
TIMOTHY MURDOCH (Presenter), Chemical and Biomolecular Engineering, University of Philadelphia, EUGENE PASHKOVSKI, Lubrizol, ROBERT W CARPICK, Mechanical Engineering and Applied Mechanics, University of Philadelphia, DAEYON LEE, Chemical and Biomolecular Engineering, University of Philadelphia — Colloidal atomic force microscopy is used to study the quasi-static and velocity-dependent normal force-separation response of adsorbed layers of associative and non-associative olefin copolymers (OCP). OCP containing a small fraction of a polar group forms transient bonds, leading to a stronger concentration-dependent viscosity than native OCP. This functional group also imparts a strong surface affinity to OCP, leading to strong adsorption. Quasi-static measurements show that the surfaces with native OCP have minimal interaction on approach, and strong adhesion on retraction due to bridging. In contrast, surfaces with associative OCPs exhibit repulsive interactions on approach with the magnitude and onset increasing with the polymer concentration. The interaction distances are long range, approaching 10x the unperturbed polymer dimension. Adhesion on retraction is greatly reduced and occurs over a range close to the contour length of the polymer. Increasing the approach velocity leads to long range repulsion for both polymers due to hindered solvent drainage. The magnitude of repulsion is highest for the associating OCP, but the onset of interaction is comparable for both. These results correlate well with impact of these polymers on friction in the boundary regime.

4:06PM P49.00007: Beyond the lubrication approximation: capillary levelling of holes in freestanding polymer films  
JOHN NIVEN (Presenter), McMaster University, VINCENT BERTIN, ESPCI, THOMAS SALEZ, University of Bordeaux, ELIE RAPHAEL, ESPCI, KARI DALNOKI-VERESS, McMaster University — Capillary levelling experiments have been used previously to study nano-scale flow in thin viscous films with a variety of hydrodynamic boundary conditions. Theoretical models developed to understand these experiments have primarily used the lubrication approximation, which omits flow normal to the film. In this work, thin bilayer polystyrene films were prepared freestanding in air, with one of the two films containing micrometer scale cylindrical holes. The viscoelastic relaxation of the holes was studied using atomic force microscopy. In order to equilibrate internal Laplace pressure, a hole will undergo a viscous symmetrization process, resulting in identical holes at the two interfaces. A novel 3D axisymmetric hydrodynamic model, which includes vertical flow, was developed to understand the dynamics of this symmetrization process, and is shown to be in excellent agreement with experiments.
4:18PM P49.00008: Understanding Polymerization-Induced Nanostructural Transitions Using in situ Characterization Methods  
ROBERT HICKEY (Presenter), JACOB A LANASA, EVERETT ZOFCHAK, Pennsylvania State University  
Polymerization-induced structural transitions have been used to create nanostructured in a host of applications ranging from energy to separation technologies. Recently, our group has achieved order-order and disorder-order structural transitions by polymer grafting from linear block polymers mixed with monomer. In our approach, we are able to induce either a lamellar-to-hexagonally-packed cylinder (LAM-HEX) or a disordered-to-HEX transition via the polymerization of styrene, which initially acts as a neutral solvent for the lamellar-forming diblock copolymer, poly(styrene)-block-poly(butadiene) (PS-PBD). In situ small-angle X-ray scattering (SAXS) and rheological experiments during the polymerization process reveal a complex phase path in which we initially disorder the lamellar morphology at elevated temperatures. During the progression of the polymerization, the disordered phase transitions first to an ordered state, and then converts into the double gyroid phase. We are able to recover the HEX phase after polymerization when the sample is cooled to room temperature. The work presented here highlights how the chemical process of converting standard linear diblock copolymers to grafted-block polymers drives interesting and controllable morphology transitions.

4:30PM P49.00009: Lubricated friction on microtextured soft substrates*  
YUNHU PENG (Presenter), CHRISTOPHER SERFASS, LILIAN HSIAO, North Carolina State University  
Natural cartilage is durable and elastic, providing a low friction coefficient to moving joints under frequent applications of heavy loads. However, the physical mechanisms contributing to this low friction coefficient is not well understood. We hypothesize that the non-ideal surface geometry of cartilage gives rise to its low friction coefficient in certain directions of motion. We design soft poly(dimethyl siloxane) (PDMS) substrates with controlled dimensions and spacings to study the influence of surface geometry on their frictional and lubrication properties. Tribological tests performed with a thin layer of aqueous glycerol solution between the PDMS substrates show that the frictional behavior does not follow the type of Stribeck curve that is typically observed with flat surfaces. This major difference can be explained by a scaling theory we developed, in which the friction force and the normal force are expressed with a combination of lubricant properties, experimental conditions and surface geometries. Our study establishes a design framework for the friction of elastomers based on their surface microtextures, and paves the way for engineering soft materials in technological applications such as wearable electronics, antifouling coatings, and synthetic implants.

* CBE@NCSU

4:42PM P49.00010: Effective Orientation Control of Block Copolymer Nanostructures in Thin Films by Surface Modification using Self-assembled Copolymer Adsorption Layer  
DONG HYUP KIM (Presenter), SO YOUN Y KIM, Ulsan National Institute of Science and Technology  
Block copolymers (BCPs) have been extensively studied due to their ability to self-assemble into well-defined nanostructures. In particular, self-assembly of BCPs in a two-dimensionally confined state of thin films has been widely exploited for a bottom-up nanofabrication in the use of many applications. In order to achieve meaningful nanopatterns in BCP thin films, a perpendicular orientation of BCP morphology is required. Here, we demonstrate that self-assembled copolymer adsorption layers (SCALs) can effectively control the morphology orientation of BCPs in thin films as modifying a surface energy of substrates. SCALs were derived from an interfacial self-assembly (ISA) of BCPs based on our finding that the self-assembled BCPs at the air/water interface can be transferred and irreversibly adsorbed onto a solid substrate. Precise modification of the surface energy was possible by controlling nanostructures of SCALs as a function of a surface pressure for ISA of BCPs. Moreover, we found irreversible adsorption for ISA of BCPs is universal for any substrates. Therefore, SCALs can be readily prepared on wherever ISA of BCPs is transferred to, thus enabling much more effective surface modification of various substrates, such as metals, ceramics, flexible or curved substrates.
Contact and slip mechanics between crosslinked hydrogel surfaces using in situ microscopy

ALISON DUNN (Presenter), CHRISTOPHER L JOHNSON, JIHO KIM, SHABNAM Z BONYADI, University of Illinois at Urbana-Champaign — The contact mechanics of soft-soft interfaces provide a backdrop for the slip mechanics due to the conformal contact at the interface, in which any surface asperities are fully compressed, and the apparent area of contact is the real area of contact. However, assumptions regarding the nature of the soft material as a thermal, semi-dilute mesh network, poroelastic solid, or other, will control the contact mechanics, especially over time. In this work we show detailed measurements of contact areas with polyacrylamide hydrogels during microindentation and slip which are revealed through particle inclusion and/or exclusion microscopy. The particles are green fluorescent polystyrene spheres of 0.5 or 1 µm in diameter. We identify time-dependent contact mechanics in migrating, stationary, and self-mated “Gemini” contact. Our data suggest that for long times, Gemini contact approaches a constant-pressure contact model, which depends upon the equilibrium osmotic pressure of the sample. Finally, we present for the first time asymmetric contact areas as visualized by in situ particle exclusion which manifests as a flow field around the probe. The results of this work begin to connect hydrogel material properties with surface mechanics.

Wall slip of complex fluids: Interfacial friction versus slip length

BENJAMIN CROSS, CHLOÉ BARRAUD, LiPhy, Université Grenoble Alpes, CYRIL PICARD, LILIANE LÉGER, FREDERIC RESTAGNO (Presenter), Université Paris-Sud, ELISABETH CHARLAIX, LiPhy, Université Grenoble Alpes — If the slip length is an useful notion to describe the friction of simple fluids, we will show that the slip length is not appropriate for viscoelastic liquids. Rather, the appropriate description lies in the original Navier’s partial slip boundary condition, formulated in terms of an interfacial friction coefficient. We establish an exact analytical expression to extract the interfacial friction coefficient from oscillatory drainage forces between a sphere and a plane, suitable for dynamic SFA or atomic force microscopy noncontact measurements. We use this model to investigate the boundary friction of viscoelastic polymer solutions over 5 decades of film thicknesses and 1 decade in frequency. The proper use of the original Navier’s condition describes accurately the complex hydrodynamic force up to scales of tens of micrometers, with a simple Newtonian-like friction coefficient that is not frequency dependent and does reflect closely the dynamics of an interfacial depletion layer at the solution-solid interface.

Mechanical and thermodynamic properties of Aβ42, Aβ40 and α-synuclein fibrils from molecular-scale simulation

ADOLFO POMA (Presenter), Biosystems and Soft Matter, Polish Academy of Sciences, HORACIO VARGAS, Polymer Theory, Max Planck Institute for Polymer Research, MAI SUAN LI, PANAGIOTIS THEODORAKIS, Theoretical Physics, Polish Academy of Sciences — Atomic force microscopy (AFM) is a versatile tool to characterise the mechanical properties of biological systems. However, AFM deformations are tiny, which makes impossible the analysis of the mechanical response by experiment. Here, we have employed a simulation protocol to determine the elastic properties of several biopolymers (i.e. biological fibrils). For these systems, the simulation approach is sufficient to provide reliable values for three different types of elastic deformation, i.e. tensile ($Y_t$), shear ($S$), and indentation ($Y_I$). Our results enable the comparison of the mechanical properties of these fibrils. In particular, we find a significant elastic anisotropy between axial and transverse directions for all systems. In addition, our methodology is sensitive to molecular packing of the fibrils. Interestingly, our results suggest a significant correlation between mechanical stability and aggregation propensity (rate) in amyloid systems, that is, the higher the mechanical stability the faster the fibril formation takes place.

Session P50 DPOLY DMP: Organic Electronics II: Structure and Morphology

DeLongchamp, National Institute of Standards and Technology - Tag(s): Focus
3:06PM P50.00004: Exploring the impact of atomistic substitution on thin-film structure in a germanyl-ethynyl functionalized pentacene  JANIS SORLI (Presenter), Department of Chemical and Biological Engineering, Princeton University, QIANXIAI AI, DEVIN GRANGER, CHAD RISKO, JOHN ANTHONY, Department of Chemistry, University of Kentucky, LYNN LOO, Department of Chemical and Biological Engineering, Princeton University — Functionalization of organic semiconductors through the attachment of bulky side groups to the conjugated core has imparted solution processability to this class of otherwise insoluble materials. A consequence of this functionalization is that the bulky side groups impact the solid-state packing of these materials. To examine the importance of side group electronic character on accessing the structural phase space of functionalized materials, germanium was substituted for silicon in trisopropylsilyl-ethynyl-pentacene (TIPS-Pn) to produce trisopropylgermanyl-ethynyl-pentacene (TIPGe-Pn), with the TIPGe side group comparable in size to TIPS, but higher in electron density. We find TIPGe-Pn single crystals to exhibit slip-stack, herringbone and brickwork packing depending on growth conditions, a stark contrast to TIPS-Pn, which only accesses the brickwork packing motif in both single crystals and thin films. Polycrystalline thin films of TIPGe-Pn exhibit two new, unidentified polymorphs from spin-coating and post-deposition annealing. Our experiments suggest that access to the structural phase space is not solely guided by the size of the side group. Its electronic character appears to play a significant role in dictating the accessible solid structures.
3:18PM P50.00005: Investigation on charge transport properties of Cyclopentadithiophene-based D-A type semiconducting copolymers* JIYOU LEE (Presenter), JISANG HONG, Pukyong National University — We have studied the charge transporting properties in Cyclopentadithiophene (CDT)-based donor (D) – acceptor (A) type semiconducting copolymer, which is known to have high performance, as an active layer of a field-effect transistor. In order to investigate the relationship between the charge-carrier mobility and the structural property of each polymer, the CDT-based polymer thin-films were analyzed by ultraviolet-visible spectroscopy, Raman spectroscopy, and density function theory (DFT) simulation. From our experimental results, it was found that the charge transports in the CDT-based polymeric thin-film is more dependent on the efficient intramolecular transport than the intermolecular charge transports. These results suggest that improving the planarity and rigidity of the polymer backbone is essential for efficient intramolecular charge transfer in order to design a high performance D-A type semiconducting copolymer.

3:30PM P50.00006: Printing Conjugated Polymers to Order via Non-Equilibrium Assembly* [Invited] YING DIAO (Presenter), Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign — Controlled morphology evolution via directed assembly has played a central role in the development of modern electronic, optical and clean energy materials. In comparison to conventional ‘hard’ materials, polymer-based functional materials can be easily processed into diverse form factors by low-cost, high-throughput methods such as roll-to-roll printing and 3D printing. The printing conditions intimately couple with the assembly process and sensitively modulate the solid-state properties in the fabricated devices. We are particularly interested in semiconducting polymers which have demonstrated potential uses in a diverse range of applications from transistors, thermoelectrics, sensors, light-emitting diodes to solar cells etc. However, major challenges remain, in controlling the nucleation, growth and aggregation of conjugated polymers during solution printing and coating, which critically impact the printed device performance by orders of magnitude. The rapid printing process creates a complex environment with coupled physics that drive the polymer assembly far from equilibrium.

In our work, we combine printing experiments, morphology and device characterizations with governing-equation-based modeling and simulations to present new insights and strategies for controlling multi-scale assembly of semiconducting polymers. We observe unexpected flow-induced morphology and electronic transition that accompanies change in printing regimes. We elucidate that printing flow in a moving, drying meniscus can drastically alter the polymer assembly pathways by flow-induced conformation change. We further establish tools for investigating design rules for flow-induced conjugated polymer crystallization. High degree of morphology control from molecular to device scale further enables new insights into charge transport properties of semiconducting polymers and realizes advanced electronic device applications.

4:06PM P50.00007: Molecular Orientation in Thin Films of Poly(3-hexylthiophene) And Poly(3-(6-bromohexyl)-thiophene) Crystallized on Graphene OLEKSANDR DOLYNCHUK (Presenter), Experimental Polymer Physics, Institute of Physics, Martin Luther University Halle-Wittenberg, PHILIP SCHMODE, PAUL M. REICHSTEIN, Applied Functional Polymers, Macromolecular Chemistry I, University of Bayreuth, MATTHIAS FISCHER, Experimental Polymer Physics, Institute of Physics, Martin Luther University Halle-Wittenberg, MUKUNDAN THELAKKAT, Applied Functional Polymers, Macromolecular Chemistry I, University of Bayreuth, THOMAS THURN-ALBRECHT, Experimental Polymer Physics, Institute of Physics, Martin Luther University Halle-Wittenberg — Recent findings have shown that crystallization of polymers on a substrate is advantageous for inducing molecular orientation, especially for semicrystalline conjugated polymers due to their anisotropic charge transport properties. Although graphite induces face-one crystal orientation in monolayers of poly(3-hexylthiophene) (P3HT), a full face-one orientation in thicker P3HT films was not realized so far. The latter is assumed to be a result of two competing interfacial orientations due to different interactions of P3HT side chains with vacuum and the graphite substrate. Here we show that modification of the chemical structure of P3HT side chains can alter the interfacial interactions and result in completely face-on oriented crystals. Specifically, we present a comparative study of the substrate induced molecular orientation of poly(3-(6-bromohexyl)-thiophene) (P3BrHT) and P3HT. The crystal orientation in ultrathin films of both polymers crystallized on a single layer graphene was explored by grazing incidence XRD. The results indicated that P3BrHT on graphene had solely face-on oriented crystals, whereas P3HT on graphene showed mixed crystal orientation with edge-on crystals formed at the top surface.
A Study on Intrinsic Mechanical Properties of n-type Conjugated Polymer via Controlling the Molecular Weight: The Importance of Critical Molecular Weight for Stretchable Organic Electronics

JONNYEONG CHOI, Department of Chemical and Biomolecular Engineering, KAIST, WANSUN KIM, TAEK-SOO KIM, Department of Mechanical Engineering, KAIST, BUMJOON KIM (Presenter), Department of Chemical and Biomolecular Engineering, KAIST — The understanding on the mechanical properties of semicrystalline n-type conjugated polymers is very important for developing the stretchable electronics. In this work, we investigated the intrinsic mechanical properties of naphthalene diimide (NDI) based n-type conjugated polymer, P(NDI2OD-T2) via controlling the number-average molecular weight (Mn), ranging from low to very high Mn = 15, 20, 48, 103 and 163 kg mol⁻¹. While we observed the general increasing trend of tensile properties as a function of Mn, a sharp transition in the strain at fracture and toughness values was observed between 48 and 103 kg mol⁻¹ with an increase by a factor of 26 and 160, indicating the presence of the critical molecular weight. This distinct transition from brittle to ductile is mainly attributed to large fraction of amorphous regions including tie molecules and interchain entanglements, which can effectively dissipate a substantial strain energy. The molecular weight dependence of mechanical behavior coincide well with thermal, viscoelastic and microstructural and thin film morphological properties. Therefore, our work suggests design rule for n-type conjugated polymer having good compromise between mechanical reliability and electrical performance for producing stretchable electronics.

Critical Role of Electron-donating Thiophene Group on the Thermomechanical Property of Donor-Acceptor Semiconducting Polymers

SONG ZHANG (Presenter), XIAODAN GU, University of Southern Mississippi — Organic semiconducting polymers are promising candidates for stretchable electronics for their mechanical compliance. Donor-Acceptor type conjugated polymers have been the key drive for recent boost in device performance. Up to date, the effect of the backbone structure on the thermomechanical property of conjugated polymers has not been carefully studied. This paper investigated the structure and thin film mechanical property relationship for donor-acceptor polymers with systematically varied backbone structures. The pseudo-free standing tensile test was used to obtain the full stress-strain curve, the glass transition temperature was measured for both thin and bulk films. In the meantime, detailed morphology was detected using AFM, UV-vis, and GIWAXS for further understanding. A general trend was observed and applied to the design of new stretchable conjugated polymers.

Polymer light-emitting diodes with an emitting layer based on a nano-confined semiconducting polymer blend

ANIELEN RIBEIRO, PAUL BLOM, JASPER MICHELS (Presenter), Max Planck Institute for Polymer Research — Blending a visible light-emitting organic semiconductor with an insulator alleviates the trap-limited nature of the electron current. Organic light emitting diodes (OLEDs) comprising such a blend as emissive layer exhibit a two-fold increase in luminous efficiency with only 10% semiconductor. Due to this low content of semiconductor, polymer-LEDs are more attractive than small molecule-based devices. However, polymers impose the difficulty of an inherently low miscibility. In a plain blend macro-phase separation can be avoided if the molecular weight is kept low, which, in case of the semiconductor, is a disadvantage as it suppresses charge carrier mobility. An alternative strategy is to impose a nano-confinement. We prepare aqueous nanodispersions of red (PPV) and blue (polyfluorene) emitting polymers, blended with polystyrene as insulator. We seem to fully suppress macro-phase separation in both cases. For the latter, the combination of nano-confinement and blending influences the phase morphology of the semiconductor in an unprecedented way. Fabricating OLEDs with an emitting layer consisting of nanoparticles poses a considerable challenge due to high operational current densities. We now succeed in fabricating such devices in a reproducible way at very decent efficiencies.
Complexation of a Conjugated Polyelectrolyte and Impact on Optoelectronic Properties*

SCOTT DANIELSEN (Presenter), THUC-QUYEN NGUYEN, GLENN FREDRICKSON, RACHEL SEGALMAN, University of California, Santa Barbara — Electrostatic assembly of conjugated polyelectrolytes (CPEs), which combine a π-conjugated polymer backbone with pendant ionic groups, offer an opportunity for overcoming the limited solubility of most semiconducting polymers to make concentrated inks with tunable materials properties and device performance. Complex coacervation, a liquid–liquid phase separation upon complexation of oppositely charged polyelectrolytes in solution, is used to form dense suspensions of π-conjugated material. A model system was used to investigate this complexation behavior of conjugated polyelectrolytes in terms of electrostatic strength, solvent quality, and polymer concentration. The balance of electrostatic interaction between the oppositely charged polyelectrolytes together with their charge compensating counter-ions and solvent quality for the hydrophobic π-conjugated backbone leads to a rich phase diagram of soluble complexes, precipitates, and complex coacervates. The CPE in the polyelectrolyte complexes has an increased π-conjugation length and enhanced emissivity, with ideal chain configurations due to the reduction of kink sites and torsional disorder.

Atomistic modeling of conjugated PEDOT:PSS complexes*

WESLEY MICHAELS (Presenter), JIAN QIN, Chemical Engineering, Stanford University — The performance of poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) complexes as conductive or thermoelectric coatings is sensitive to film microstructure and molecular packing details inaccessible to experiment. We combine ab initio calculation, DFT, and atomistic simulation to investigate the effects of ion doping, molecular polarizability, and cosolvent addition on PEDOT-PSS complexation. The results suggest that ionic liquids which bind more strongly to PEDOT are more likely to induce morphological rearrangements. Conformational properties of PEDOT:PSS under varying salinity and processing conditions are characterized, providing the basis for multi-scale morphological modeling of this conjugated polyelectrolyte complex.

Chemical and Dynamic Heterogeneities in Interfaces for Adaptive Polymer Nanocomposites*

PINAR AKCORA (Presenter), Stevens Institute of Technology — It is well-known that particle-polymer interactions strongly control the binding and conformations of adsorbed chains on particles. Interfacial layers around nanoparticles consisting of adsorbed and free matrix chains have been extensively studied to reveal their contribution to the overall thermal and mechanical behavior of nanocomposites. Using miscible polymers of different chemistries as adsorbed and matrix layers in composites, the interfacial layer dynamics, hence the mechanical properties can be modulated unusually. We recently showed that when glass transition temperature difference between adsorbed and matrix polymers were large and polymer-polymer interactions were neutral, they reversibly stiffened with temperature. In this talk, I will present the extent of chemical heterogeneity of interfacial layers in adsorbed and polymer-grafted nanoparticles and discuss the role of interfacial layer mixing and chain conformation on the mechanical properties. Low glass-transition temperature composites with different matrix polymers (poly(vinyl acetate), poly(methyl acrylate) and poly(ethylene oxide)) will be discussed with particles of different surface chemistry; and polymers with different architectures. Interfacial layer design strategies in polymer nanocomposites will be outlined. These dynamic and chemical heterogeneities in interfacial layers can be used to design mechanically adaptive polymer nanocomposites.

3:06 PM P52.00002: Coexistence Curve and Theta Temperature of Polymer Grafted Nanoparticle (PGN) Solutions
SARAH IZOR, TONY Dagher, CHRIS GRABOWSKI, ALI JAWAID, KYOUNGWON PARK, RICHARD VAIA (Presenter), Materials and Manufacturing, Air Force Research Laboratory — PGNs are emerging as an enabling technology, not only for nanocomposite formulation, but also for separations, energy storage, devices and coatings. Their tunability arises from the modularity of the hard-soft architecture, and understanding its impact on phase behavior in small molecules is crucial to fabrication and processing. Unfortunately, minimal data or theoretical insight is available; or how PGNs relate to the role of macromolecular architecture on solution phase behavior. Herein, we discuss the upper critical solution coexistence curve and theta temperature (Θ) of polystyrene (PS)-grafted Au-nanoparticles in cyclohexane. As molecular weight of the PS graft increases (20—50kDa), the coexistence curve shifts to higher temperatures (e.g. $T_c \sim 12$—20°C @ 10nM ($\Phi \sim 3 \times 10^{-5}$)), as determined by spectroscopy, dynamic light scattering, and x-ray scattering. Θ, estimated from extrapolating the low concentration region of the co-existence curve, also increased with graft size (Θ~25–27°C). Overall, these values are less than prior reports of PS stars (Θ~30°C) and linear chains (Θ~33°C). Understanding the macroscopic and mesoscopic solution behavior of these soft colloids in context to structured macromolecules and curved brushes is essential to their future development.

3:18 PM P52.00003: Simulating Nanoparticle Dynamics in Semidilute Polymer Solutions
RENJIE CHEN (Presenter), RYAN POLING-SKUTVIK, Department of Chemical and Biomolecular Engineering, University of Houston, Houston, ARASH NIKOUBASHMAN, Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg, MICHAEL P HOWARD, McKetta Department of Chemical Engineering, University of Texas at Austin, Austin, SERGEI EGOROV, Department of Chemistry, University of Virginia, Charlottesville, JACINTA CONRAD, JEREMY C PALMER, Department of Chemical and Biomolecular Engineering, University of Houston, Houston — The dynamics of polymers and particles in nanocomposites are of great interest in materials processing. Particle mobility is well described by the generalized Stokes-Einstein relation when the particles are much larger than the polymers, but less understood when it comes to smaller or comparable sized particles. We investigate this smaller sized regime using advanced particle-based simulation techniques, with the multi-particle collision dynamics (MPCD) scheme modeling solvent-mediated hydrodynamic interactions. We demonstrate that the translational center-of-mass motions of both particles and polymers are sub-diffusive on short times before transitioning into the diffusive regime, and the highly correlated sub-diffusive exponents suggest that not only local polymer relaxations but also polymer center-of-mass motions play a role in the coupling between the dynamics of polymers and nanoparticles. Finally, we perform simulations tuning flexibility of the polymers, and as the persistence length increases, the particle dynamics become more sub-diffusive and decouple from the dynamics of the polymer chain center-of-mass.

3:30 PM P52.00004: Interphase structures and dynamics near nanofiller surfaces in polymer solutions*
TADANORI KOGA (Presenter), DEBORAH BARKLEY, MAYA ENDOH, Stony Brook University, MICHIHIRO NAGAO, NIST, TAKASHI TANIGUCHI, Kyoto University, JAN-MICHAEL CARRILLO, BOBBY G SUMPTER, ORNL, MAHO KOGA, Cornell University, TOMOMI MASUI, HIROYUKI KISHIMOTO, SRI — We report the structures and dynamics of hydrogenated polybutadiene (PB) chains bound to carbon black nanoparticle surfaces in polymer solutions composed of deuterated PB and deuterated toluene using small-angle neutron scattering and neutron spin echo techniques together with molecular dynamics (MD) simulations. The experimental results showed that the swollen bound chains exhibit the so-called breathing dynamics at polymer concentrations $c$ below and above the overlap polymer concentrations. Interestingly, the collective dynamics slowed down by a factor of 2 compared to that in pure $d$-toluene when the chain lengths of the bound and matrix polymer are equal. However, when the free polymer chains were longer than the bound chains, the decrease in collective dynamics was not as significant. MD simulations showed that the matrix chains, whose length is equal to that of the bound chains, can be accommodated in the bound layer effectively and are “strangulated” by the bound chains, while the longer matrix chains only partly penetrate into the bound chains and the diffusion behavior was hardly affected compared to that in bulk.

3:42PM P52.00005: Dynamics of polymer-grafted nanoparticles controlled by soft confinement  ALI SLIM (Presenter), RYAN POLING-SKUTVIK, JACINTA CONRAD, RAMANAN KRISHNAMOORTI, Chemical and Biomolecular Engineering, University of Houston — The efficacy of polymer-grafted nanoparticles (PGNPs) in applications depends on their transport within complex soft matrices featuring heterogeneities similarly sized to the PGNPs. Further, the deformability of the grafted polymers leads to soft interactions that may alter the dynamics, depending on the relative size of the grafted polymer and particle core. When the radius of gyration $R_g$ of grafted polymer is much smaller than NP radius $R_{NP}$, dynamics of PGNPs are expected to be similar to a hard sphere. Conversely, when $R_g$ is much larger than $R_{NP}$, PGNPs behave like a dendritic polymer or a star. In the intermediate regime where $R_g$ and $R_{NP}$ are comparable, the structure and dynamics become complex soft matrices featuring heterogeneities similarly sized to the PGNPs. Further, the deformability of the grafted polymers could be tracked to the resolution of a few nanometers.

4:06PM P52.00007: Solvent-Induced Self-Assembly of Triblock Copolymers for Creating Polymer Nanocomposite Gels  CHAO LANG (Presenter), YIFAN XU, JACOB A LANASA, MANISH KUMAR, ROBERT HICKEY, Pennsylvania State University — The self-assembly of ABA triblock copolymers has been a focus of many studies over the years because of their possible applications in thermoplastic elastomers, solid electrolytes, and drug delivery systems. Triblock copolymers exhibiting ABA-type polymer architectures will self-assemble into either flower-like micelles or physically-crosslinked gel networks when added to B-block selective solvent. Although the two final states, micelles and gels, are well-established, controlling the self-assembly process to design specific nanostructures, while incorporating inorganic nanoparticles has yet to be fully established. Here, we present a recently developed method for creating nanostructured nanocomposite hydrogels by quickly injecting a solution containing ABA amphiphilic triblock copolymers and hydrophobic nanoparticles into water. During the ABA polymer/nanoparticle solution injection process, the nanoparticles aggregate within the physically-crosslinked hydrophobic A-block domains. By adding hydrophobic gold nanoparticles to the initial polymer solution, we are able to incorporate plasmonic properties into the nanostructured gels. The research presented here highlights the great potential in kinetic manipulation of self-assembled structures for making polymer nanocomposite gels.

YIGE GAO (Presenter), PAUL KIM, SATYAM SRIVASTAVA, ALEXANDER RIBBE, THOMAS RUSSELL, DAVID HOAGLAND, University of Massachusetts Amherst — Functionalized with polymer ligands, nanoparticles can segregate to liquid interfaces, where their two-dimensional organization and dynamics depend on nanoparticle areal fraction. Here, these organization and dynamics were imaged for PEGylated silica nanospheres on ionic liquids, the latter's nonvolatility facilitating high resolution scanning electron microscopy at vacuum. An in situ liquid cell varied surface area and thereby areal fraction, and particle interactions were well approximated as those of hard spheres. A focus was high areal fraction nanoparticle mixtures approaching and/or exceeding the threshold for jamming; such mixtures were prepared for nanospheres of different diameter and nanospheres mixed with nanorods, and in both cases, composition was varied. By image analysis, quality of mixing and nanoparticle organization were assessed through orientational and translational order parameters. For uniform nanospheres, when compressed beyond jamming, surface wrinkling and buckling were observed, and when held jammed for large times before decompression, cracking was noted; throughout the imaging, individual nanospheres could be tracked to the resolution of a few nanometers.

*NSF/DMR-1807255
4:30PM P52.00009: Self-assembly of Janus rods in binary blends of polymers. Part I: phase behavior under equilibrium*  
SHAGHAYEGH KHANI (Presenter), FELIPE LEIS PAIVA, Macromolecular Science and Engineering, Case Western Reserve University, ARMAN BOROMAND, Mechanical Engineering and Material Science, Yale University, VERONICA CALADO, School of Chemistry, Universidade Federal do Rio de Janeiro, ARGIMIRO SECCHI, COPPE Chemical Engineering Graduate Program, Universidade Federal do Rio de Janeiro, JOAO MAIA, Macromolecular Science and Engineering, Case Western Reserve University — Janus rods due to their shape anisotropy and amphiphilic nature result in superior properties when incorporated into multi-phase polymer systems. Self-assembly of these particles at the interface of binary polymer blends can provide a means for fabrication of advanced functional materials. In this presentation we will discuss the interplay between the entropic and enthalpic factors that determine the self-assembled structure of Janus rods at the interface of two immiscible liquids. We have performed molecular simulations to investigate the role of individual parameters. Janus rods orientation is controlled by the entropic factors such as aspect ratio and concentration as well as the interfacial energy which also has consequences on the dynamics. Their interfacial assembly is also shown to be highly influential in altering the phase separation process in binary polymer blends. Janus rods exhibiting hexagonally-packed, liquid crystalline-like structures favor faster phase separation kinetics, while Janus rods of higher aspect ratio that are tilted at the interface aggregate side-by-side; are able to hinder phase separation kinetics.

*The authors thank Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for financial support.

4:42PM P52.00010: Self-assembly of Janus rods in binary blends of polymers. Part II: phase behavior under shear flow and relaxation*  
FELIPE LEIS PAIVA (Presenter), SHAGHAYEGH KHANI, Macromolecular Science and Engineering, Case Western Reserve University, ARMAN BOROMAND, Mechanical Engineering and Materials Science, Yale University, VERONICA CALADO, School of Chemistry, Universidade Federal do Rio de Janeiro, ARGIMIRO SECCHI, COPPE Chemical Engineering Graduate Program, Universidade Federal do Rio de Janeiro, JOAO MAIA, Macromolecular Science and Engineering, Case Western Reserve University — Janus particles are highly active at the interface of immiscible fluids and thus they can self-assemble into different structures when incorporated into multiphase systems. In Part I, we performed mesoscale Dissipative Particle Dynamics simulations to investigate the influence of individual parameters on the structures formed by Janus rods at the interface of two immiscible liquids. In particular, we showed how interfacial orientation and self-assembly of Janus rods are highly influential in controlling the phase separation process when added to a polymer blend. Moreover, we also monitor herein the microstructures formed by these systems under flow conditions and upon relaxation after flow cessation. We verified in our simulations various stabilizing effects provided by Janus rods of higher aspect ratio that present a tilted configuration at the interface. We also studied the Janus aggregate-breakup process during shear and how these interfacial aggregates rebuild upon flow cessation. The results of this study can be used for designing new approaches for directing nano-particles into desired morphologies by applying shear flow.

*The authors thank Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for financial support.

4:54PM P52.00011: Fabrication and Optical Properties of Polymer-Grafted Gold Nanorod Assemblies  
JASON STREIT (Presenter), KYOUNGWEON PARK, Air Force Research Lab, JOON-JAE YI, Wright State University, RICHARD VAIA, Air Force Research Lab — Precise, large-scale assembly of polymer-grafted nanoparticles (PGNs) has shown great promise for the scalable manufacturing of sensors, energy storage devices, and photonic elements. Different than traditional ligand-coated nanoparticles, PGNs are stabilized by high molecular weight polymers at relatively low grafting densities. In this regard, PGNs behave as soft colloids, possessing favorable processing properties typical of polymer systems while still retaining the ability to pack into ordered structures. Herein, we demonstrate that large scale, highly uniform monolayer films of gold-polystyrene nanorods can be fabricated from PGN inks within a few seconds using a simple flow-coating technique. Using a combination of AFM, SEM, and GISAXS, we observe nanorod positional and orientational order dependent on coupling between processing conditions, polymer canopy, and surface energy. Additionally, optical extinction measurements reveal strong plasmonic coupling between the gold nanorods which can systematically be tuned by varying film morphology. With fundamental understanding of structure-processing relationships, we demonstrate optical notch filters using laser-induced reshaping of resonant nanoparticle subpoulations.
Constructing conductive composites by spinodal decomposition of miscible polymer blends with graphene nanoplatelets

YANGMING KOU (Presenter), XUANG CHENG, CHRIS W MACOSKO, Department of Chemical Engineering and Materials Science, University of Minnesota — Conductive polymer composites (CPCs) enjoy broad industrial applications such as electrostatic discharge (ESD) protection. Herein, we construct CPCs by solution-blending graphene nanoplatelets (GNPs) in a miscible blend of poly(methyl methacrylate) (PMMA) and poly(styrene-co-acrylonitrile) (SAN). By inducing PMMA/SAN spinodal decomposition via annealing above the lower critical solution temperature (LCST), we obtain spatially regular, cocontinuous polymer domains where high aspect ratio GNPs preferentially localize within the SAN phase to form a conductive network. Compared to the traditional CPC manufacture approach of blending carbon black into a homopolymer, our approach lowers the percolation threshold required to enhance electrical conductivity. At 1 wt% GNP loading, our blend shows a bulk electrical conductivity of up to ~10^{-8} S/cm upon phase separation, suitable for ESD protection. To understand the structure-property relations of our CPCs, we develop TEM image analysis methods to quantitatively characterize the final PMMA/SAN/GNP blend morphology and GNP localization, allowing us to address important questions such as how the state of GNP dispersion within the blend affects the coarsening length scale and domain size distribution throughout the composite.

Molecular dynamics simulation of spherical PEO brush: Curvature and Grafting Density Effect

ELENA DORMIDONTOVA, UDAYA R DAHAL (Presenter), Polymer Program, Institute of Materials Science and Physics Department, University of Connecticut, Storrs, CT 06269 — Nanoparticle modification by polyethylene oxide (PEO) is commonly used to ensure nanoparticle solubility, dispersion and protection from undesirable interactions. Using atomistic molecular dynamics simulations, we studied spherical PEO brushes grafted to gold nanoparticles of different radii and with varying grafting densities. We analyzed the scaling behavior of the radial polymer volume fraction, which is found to follow the Daoud-Cotton model, except for low grafting density when PEO adsorption onto gold surface is observed. We also investigated PEO hydration in the spherical brush and determined the existence in the surface vicinity of a dehydrated or low hydration zone, which substantially expands with an increase of grafting density and/or decrease of nanoparticle radius of curvature. The implications for water exchange within the polymer brush and with the surrounding solution will be discussed.

Session P54 DPOLY DBIO: Tuning Polymer Sequence and Architecture

Polymer chain sequence effects on the glass transition

WILLIAM DRAYER (Presenter), DAVID SIMMONS, Department of Chemical and Biomedical Engineering, University of South Florida — Progress in synthetic chemistry over the last 20 years has opened the door to synthesis of polymers with an increasing spectrum of monomer sequence control, ranging from gradient copolymers to peptoids. In many of these polymers as in sequence non-controlled polymers, the glass transition plays a central role in dynamic, mechanical, and transport properties. However, the effect of sequence on the glass transition remains poorly understood. Here we employ molecular dynamics simulations of sequence controlled glass-forming liquids to quantify the effect of sequence on glass transition behavior. Results indicate that sequence can have a profound impact on Tg. Ultimately, we explore the transition from sequence effects to interface effects on Tg as monomer block size increases to the phase-separating limit.

Identical levels of block saturation, indicating a strong enhancement in compatibility. Further work delineating the effect of measured $X$ of 0.30 MPa, which is lower than the measured $X$ (uncorrected) of a PI-hPB diblock copolymer (0.52 MPa) with selectively saturated block-random copolymer with ~10 wt% styrene in the random block (PI-hSBR10) exhibited a $X$ of 0.81 MPa, after correcting the measured value of $X$ for the imperfect selectivity of the hydrogenation catalyst. A selective saturation of the butadiene units. Diblock copolymers with no S (PI-hPBs) exhibited an interaction energy density generally show limited compatibility (high interaction energy density, $X$). We investigate the thermodynamic interactions in symmetric amorphous polydiene-polyolefin block copolymers composed of polyisoprene (PI) and hydrogenated medium-vinyl polybutadiene (hPB). The regular solution model suggests that styrene units (S), given the higher solubility parameter of polystyrene, can boost inter-block miscibility when incorporated in small amounts into the hPB block via random copolymerization (hSBR). Block and “block-random” copolymers were prepared by anionic polymerization, followed by activated bond breakage and local cage reorganization processes, and the correlation between structure and dynamics, are studied as a function of experimentally controllable variables such as polymer volume fraction, fraction of stickers, strength and spatial range of the attractive interaction, and chain length.

**2:54PM P54.00003: Coherent States Field Theory Simulations for Supramolecular Multiblock Copolymers**  DANIEL VIGIL (Presenter), Chemical Engineering, University of California, Santa Barbara, KRIS T DELANEY, Material Research Laboratory, University of California, Santa Barbara, GLENN FREDRICKSON, Chemical Engineering, University of California, Santa Barbara — We present simulation results for a binary mixture of telechelic polymers that can reversibly bond to the opposite species to form multi-block copolymers. Traditional auxiliary-field (AF) polymer field theory can neither accurately nor efficiently simulate the telechelic system because of the challenges of counting an infinite number of possible reaction products. Instead, we extend a “coherent states” framework (CS), originally due to Edwards and Freed, to a form that automatically accounts for all reaction products. A previously reported algorithm for simulating CS theories did not converge in ordered block copolymer microphases, so new algorithms were developed for this work. We verify our methods against the classic diblock copolymer system and present new results for the phase behavior of binary telechelic polymer mixtures.

*The authors acknowledge support from the NSF Graduate Research Fellowship Program under Grant No. 1650114 and the NSF CMMT Program under Grant No. DMR-1822215. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the NSF.

**3:06PM P54.00004: Miscibility Enhancement in Polyisoprene-Polyolefin Block Copolymers**  SRAVYA JANGAREDDY (Presenter), RICHARD ALAN REGISTER, Chemical and Biological Engineering, Princeton University — Polydienes and polyolefins generally show limited compatibility (high interaction energy density, $X$). We investigate the thermodynamic interactions in symmetric amorphous polydiene-polyolefin block copolymers composed of polyisoprene (PI) and hydrogenated medium-vinyl polybutadiene (hPB). The regular solution model suggests that styrene units (S), given the higher solubility parameter of polystyrene, can boost inter-block miscibility when incorporated in small amounts into the hPB block via random copolymerization (hSBR). Block and “block-random” copolymers were prepared by anionic polymerization, followed by selective saturation of the butadiene units. Diblock copolymers with no S (PI-hPBs) exhibited an interaction energy density of 0.81 MPa, after correcting the measured value of $X$ for the imperfect selectivity of the hydrogenation catalyst. A selectively saturated block-random copolymer with ~10 wt% styrene in the random block (PI-hSBR10) exhibited a measured $X$ of 0.30 MPa, which is lower than the measured $X$ (uncorrected) of a PI-hPB diblock copolymer (0.52 MPa) with identical levels of block saturation, indicating a strong enhancement in compatibility. Further work delineating the effect of S content on inter-block miscibility is underway.

**3:18PM P54.00005: Theory of interchain packing and dynamics in associating copolymer liquids**  ASHESH GHOSH (Presenter), KENNETH S. SCHWEIZER, University of Illinois at Urbana-Champaign — We employ liquid state theory to explore the role of attractive groups regularly co-polymerized in a chain backbone on the structure and dynamics of unentangled polymer liquids that can form thermoreversible bonds. Significant progress has been made by others using coarse-grained polymer physics models based on phenomenological input parameters that quantify the sticker association energy and bond dissociation lifetime. However, these approaches are not force-based, and do not include molecular-scale information about packing correlations and its consequences on sticker clustering, dynamic bond formation and dissociation events. Based on the microscopic forces and single chain structure as input, we combine equilibrium integral equation theory and generalized Rouse models that capture local caging and physical bond formation to study the latter aspects and related issues such as emergent elasticity. The timescale for stickers and non-stickers that define the coupled activated bond breakage and local cage reorganization processes, and the correlation between structure and dynamics, are studied as a function of experimentally controllable variables such as polymer volume fraction, fraction of stickers, strength and spatial range of the attractive interaction, and chain length.
WEIHUA LI, Fudan University, JIN KIM, Pohang University of Science and Technology — Block copolymers have been extensively investigated because of their various nanostructures. For a simple diblock copolymer, hexagonally packed cylindrical microdomains have been found with volume fractions of one block (fA) having 0.2~0.35, while gyroid microdomains were observed at fA having ~0.35. So, gyroid and cylindrical microdomain could not prepare pore volume larger than this value (~0.35) in diblock copolymers, because lamellar microdomains are expected. Here, we investigated morphology transitions of linear tetrablock copolymers of polystyrene-block-polyisoprene-block-polystyrene-block-polyisoprene (S1I1S2I2) by varying volume fraction of PI1 block (fPI1), while maintaining the symmetric volume fraction of total PS blocks and PI blocks (fPS1+fPS2 : fPI1+fPI2 = 1:1). An interesting sequence of morphology transitions was observed as fPI1 was increased: lamellae→asymmetric lamellae→hexagonally packed PI-cylinders→double gyroid with PI-network domains→short-period lamellae. It is particularly interesting that cylindrical and gyroid morphologies were observed in linear block copolymers with symmetric overall volume fraction.

3:42PM P54.00007: Genetically encoded biomaterials that self-assemble across multiple length scales [Invited] ASHUTOSH CHILKOTI (Presenter), Duke University — Elastin like polypeptides (ELPs), composed of repeats of VPGXG pentapeptides that recur in all tropoelastin sequences, are the best studied class of peptide polymers that exhibit lower critical solution temperature (LCST) phase behavior in water, and these polymers have enabled innovative approaches to nanoparticle self-assembly, cancer therapy, regenerative medicine and protein purification. I will discuss how this class of intrinsically disordered polypeptides is an enormously mutable model system that has allowed us to probe the sequence origins of aqueous phase behavior in polypeptides, leading to the identification of sequence heuristics for the de novo design of peptide polymers that exhibit aqueous phase behavior. I will also discuss how we have used ELPs as a template to encode higher order, hierarchical self-assembly into macroscopic biomaterials by modulating the degree of order in these intrinsically disordered polymers, and by genetically encoding a post-translational modification into an ELP.

4:18PM P54.00008: Multicompartment Copolymer Micelles: effects of chain architecture, composition and interaction strength BOYUAN YU (Presenter), Institute for Molecular Engineering, University of Chicago, ABELARDO RAMIREZ-HERNANDEZ, COE BIOMEDICAL ENGINEERING, The University of Texas at San Antonio, JUAN DE PABLO, Institute for Molecular Engineering, University of Chicago — Controlling the self-assembly of block copolymers in solution will enable engineering of multicompartment micelles (MCMs), with target structures for applications including drug delivery, or stimuli-responsive carriers. While extensive research has been carried out on amphiphilic di-block copolymers, little is known about the phase behavior of multiblock polymers in solution. In this work, a mesoscopic approach is used to explore the self-assembly behavior of tetrablock copolymers with varying architectures, block sequences, compositions, and interaction strengths. Our results are summarized in phase diagrams that reveal the influence of different parameters on the morphologies of MCMs. The results presented in this work could provide a useful guide for the synthesis of new MCMs.

4:30PM P54.00009: Interpreting the hierarchical morphology of ABC miktoarm terpolymers using self-consistent field theory* JYOTI MAHALIK (Presenter), Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, HYEYOUNG KIM, Polymer Science and engineering, University of Massachusetts Amherst, MATTHIAS ML ARRAS, Large Scale Structures Group, Neutron Scattering Division, Oak Ridge National Laboratory, WEIYU WANG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, SERGEY CHERNYY, Micro- and Nanotechnology, Technical University of Denmark, Productionstorvet, 2800 Lyngby, Denmark, KUNLUN HONG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, GREGORY S SMITH, Large Scale Structures Group, Neutron Scattering Division, Oak Ridge National Laboratory, BOBBY G SUMPTER, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, THOMAS RUSSELL, Polymer Science and engineering, University of Massachusetts Amherst, RAJEEV KUMAR, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — Miktoarm stars based on poly(cis 1,4-isoprene), poly(styrene) and poly(2-vinylpyridine) (ISV) were studied using small-angle X-ray scattering (SAXS), small-angle neutron scattering (SANS), transmission electron microscopy (TEM) and self-consistent field theory (SCFT). Array of morphologies are observed for different composition of ISV-x (where x is the volume ratio of V:I and I:S are kept fixed at 1:1). Typically, TEM and SANS are sufficient to characterize the bulk morphology of diblock copolymers. But for ABC miktoarms additional characterization tools are necessary. Picking one system from the array of samples, we have demonstrated how self-consistent field theory (SCFT) can guide the interpretation of hierarchical morphology. The SCFT studies also provides guidelines for deuterating the correct arm prior to SANS investigation.

**4:42PM P54.00010: Miktoarm Stars via Grafting-Through Copolymerization: Self-Assembly and the Star-to-Bottlebrush Transition**

JOSHAU LEQUIEU (Presenter), ADAM E LEVI, CHRISTOPHER M BATES, GLENN FREDRICKSON, University of California, Santa Barbara — The grafting-through copolymerization of two distinct macromonomers via ring-opening metathesis polymerization is typically used to form random or diblock bottlebrush polymers with large total backbone degrees of polymerization ($N_{BB}$) relative to that of the side-chains ($N_{SC}$). Here, we demonstrate that Grubbs-type chemistry in the opposite limit, namely $N_{BB} \ll N_{SC}$, produces well-defined materials with excellent control over ensemble-averaged properties, including molar mass, dispersity, composition, and number of branch points. The dependence of self-assembly on these molecular design parameters was systematically probed using small angle X-ray scattering and self-consistent field theoretic simulations. Our analysis reveals that two-component bottlebrush copolymers with small $N_{BB}$ behave like miktoarm star polymers. The star-to-bottlebrush transition is quantifiable for both random and diblock sequences by unique signatures in the experimental scaling of domain spacing and simulated distribution of backbone/side-chain density within lamellar unit cells. These findings represent a conceptual framework that simplifies the synthesis of miktoarm star polymers when dispersity in molar mass and composition can be tolerated.

**4:54PM P54.00011: Exploring the Phase Behavior of Poly(styrene)-block-Poly(dimethylsiloxane) Brush Block Copolymers**

HUAIFENG FEI (Presenter), BENJAMIN M YAVITT, XIYU HU, GAYATHRI KOPANATI, ALEXANDER RIBBE, JAMES J WATKINS, University of Massachusetts Amherst — We report the experimental phase behavior of a family of poly(styrene)-block-poly(dimethylsiloxane) (PS-b-PDMS) bottlebrush block copolymers (BBCPs). The BBCPs rapidly self-assemble into microphase separated morphologies after mild thermal annealing. By systematically tuning architectural parameters such as volume fraction ($f_{PS}$), side chain length ($N_{SC}$), and overall backbone length ($N_{bb}$), a diverse array of morphologies were resolved and a phase map was constructed. We identify ordered lamellar, cylindrical, and deformed spherical morphologies. The lamellar window spans a wide range of $f_{PS}$ from 0.40 to 0.75 when $N_{bb}$ is short and $N_{SC}$ of PS and PDMS are equal. However, order-order transitions to cylindrical and spherical morphology are observed as $N_{bb}$ increases and $N_{SC}$ becomes asymmetric. The self-assembly and phase transitions are described by a contrast between both the backbone and side chain flexibility of the PDMS and PS blocks. These findings provide an insight into the rich phase behavior of this architecturally complex class of macromolecules and provide direction towards the future fabrication and design of BBCP templated functional materials.

**5:06PM P54.00012: Molecular Architecture Driven Self-Assembly of Block Copolymers**

SHIFENG NIAN (Presenter), ZIHAO GONG, Materials Science and Engineering, University of Virginia, LIHENG CAI, Materials Science and Engineering and Chemical Engineering, University of Virginia — Block copolymers composed of immiscible polymeric blocks self-assemble to a rich variety of ordered nanostructures that find applications in many technologically important realms. Among different types of block copolymers, linear-bottlebrush-linear (LBBL) triblock copolymers present an emerging platform for creating multifunctional nanostructures. However, little is known about the fundamental mechanism of their self-assembly. We synthesize a series of LBBL polymers with precisely controlled anisotropy of bottlebrush block and weight fraction of the linear block. Characterizing morphology and microphase separation of the self-assembled nanostructures, we find that the molecular anisotropy of bottlebrush is sufficient to drive LBBL polymers self-assemble to long range ordered nanostructures with exceptionally large domain sizes inaccessible by existing copolymer systems. Our results suggest that the self-assembly of LBBL polymers is driven by their molecular architecture rather than detailed chemistry. Such understanding may enable discovery of polymeric nanostructures with unprecedented properties and multifunction.

**5:18PM P54.00013: Strong Induced Chiroptical Effects in Light Emitting Polymer Blends**

JESSICA WADE (Presenter), LIWAN, Imperial College London — Current OLED displays rely on a circularly polarised (CP) filter to enhance contrast by trapping ambient light inside the display. This means that 50% of the randomly polarised light emitted from each OLED pixel never leaves the screen, halving display efficiency and decreasing operational lifetime. To overcome this, we pair a chiral small molecule with a non-chiral device optimised polymer, which allows for CP-dependent applications while retaining the performance properties of the original polymer. Previously circularly polarised polymer emission has been achieved by the propagation of linearly polarised light through cholesteric stacks, where light becomes circularly polarised as it moves through an entire pitch. For the first time, we demonstrate a system where CP electroluminescence arises due to both intrinsic emission from chiral dipoles and extrinsic propagation through a cholesteric stack. Remarkably, this competition results in an inversion of the handedness of the CP EL emission as a function of film thickness. We compare how the chemical structure of the polymer and post-deposition processing impacts the chiroptical response of the resulting device in an effort to provide a set of design rules for future high performance CP-OLEDs.

2:30PM P55.00001: Microscopic Observation of Interface-Induced Crystallization via Prefreezing from Polymers Melts* [Invited]  ANN-KRISTIN FLIEGER, OLEKSANDR DOLYNCHUK, MUHAMMAD TARIQ, THOMAS THURN-ALBRECHT (Presenter), Institute of Physics, Martin-Luther University Halle-Wittenberg —
The microscopic ordering process that a liquid undergoes during crystallization is often initiated at an interface to a solid. Different processes have been suggested by theory to occur at this interface. Of special interest is prefreezing - the formation of a thin crystalline layer at the interface already at temperatures above the melting temperature. Because of the difficult accessibility of the buried interface, experimental proof of crystallization by prefreezing has been elusive in molecular systems. We here present in situ AFM-observations of such a process in two polymeric model systems and show that prefreezing is a first-order prewetting transition. A quantitative description of the phenomena is possible with a phenomenological theory. The results not only contribute to our fundamental understanding of crystallization but might also be useful for the preparation of well-ordered oriented thin films of crystalline organic materials.

3:06PM P55.00002: Supramolecular Crystals and Crystallization  STEPHEN Z D CHENG (Presenter), Polymer Science, University of Akron — Supramolecular crystal and crystallization is a field that is an extension of polymer crystals and crystallization. This topic associates with non-equilibrium thermodynamic features via analyzing and understanding structures and morphologies of supramolecular crystals. These crystals possess semi-ordered structures which are caused by crystallization and phase transformation kinetics controlled by nucleation processes and growth. We will focus on a few examples of the formation of Frank-Kasper phase and quasicrystal kinetics in the melt and transition between these phases. Specific mechanisms of phase stricture changes will be revealed in these supramolecular crystals.

3:18PM P55.00003: Crystallization of conjugated polymers* LUCIA FERNANDEZ-BALLESTER (Presenter), RAMIN HOSSEINABAD, University of Nebraska — The final semicrystalline morphology of a polymer strongly depends on the processing conditions under which crystallization occurs. Even small variations in the degree of crystallinity, size/orientation of crystallites, and connectivity between crystalline aggregates can lead to significant changes in final properties. For conjugated polymers, the basic interplay between molecular structure, processing parameters and structure development remains particularly elusive because, typically, the crystallization process occurs under ill-defined flow and thermal conditions while a solvent evaporates relatively quickly. Here, we explore the crystallization behavior of poly-3-hexylthiophene of various molecular weights under well-defined conditions. The results suggest that memory and self-nucleation can play an important role in the way crystallization proceeds.

3:30PM P55.00004: Tuning the Phase Behavior of Hydrogenated Polynorbornene via Epimerization  
JARED PHILLIP KLEIN (Presenter), RICHARD ALAN REGISTER, Princeton University — Hydrogenated polynorbornene (hPN) synthesized by ring-opening metathesis polymerization exhibits a thermotropic polymorphic transition at a temperature \( T_{cc} \) below the melting point \( T_m \). Though atactic, hPN is able to crystallize, and the ability of hPN to accommodate defects within the crystal allows the influence of a variety of defects on \( T_{cc} \) to be studied. Polynorbornene (PN) can be saturated via multiple pathways, and the choice of hydrogenation route influences both the crystal structure and \( T_{cc} \). Three hydrogenation routes for complete PN saturation are compared: a homogeneous route that generates a diimide molecule \textit{in situ}, a Ni/Al catalyst complex, and a supported Pd catalyst. The resulting polymer chains show zero, minor (\(< 4 \%\)), and major (\( > 8 \%\)) amounts of epimerization of the cyclopentylene ring (from \textit{cis} to \textit{trans}) for the diimide, Ni/Al, and Pd-hydrogenated hPNs respectively, but all show similar degrees of crystallinity. The window of stability of the rotationally-disordered polymorph (\( T_m - T_{cc} \)) increases with increasing epimerization. The crystal structure of the rotationally-ordered polymorph – observed below \( T_{cc} \) – changes sharply with low levels of epimerized units along the chain, but is weakly influenced by further epimerization.

3:42PM P55.00005: Gap Dependent Percolation of Spherulites during Crystallization: Rheology, Microscopy and Simulation  
DEBJANI ROY, DEBRA AUDUS, KALMAN MIGLER (Presenter), National Institute of Standards and Technology — We employ simultaneous mechanical rheology and optical microscopy, with augmentation by deterministic reconstruction and simple simulations to develop a geometrical model of spherulitic percolation during polymer crystallization. We observe nucleation of surface and bulk spherulites of isotactic polypropylene which are initially isolated and then impinge on each other to form clusters that eventually span the gap, and correlate this with rheology. There is a strong gap dependence to our observations, which is explained by two distinct mechanisms that both work to enhance kinetics at lower gaps. First, the time required for a cluster to span the gap decreases with decreasing gap width, attributable to finite size effects in percolation theory. Second surface nucleation enhances the overall crystallization rate in a fashion which increases in relative importance as the gap width decreases. The modulus-crystallinity relationship can be described through general effective medium theory which indicates a transformation from percolating behavior at large gap towards a linear behavior at small. We describe our results in terms of dimensionless parameters that indicate when gap dependent effects can be anticipated.

3:54PM P55.00006: Miniemulsions as Dynamic Confinement Environments for Polymer Crystallization  
MARK STAUB (Presenter), CHRISTOPHER LI, Drexel University — Introducing interfaces and/or confinement to the polymer crystallization process is unique as the resulting kinetics, structure, and morphology can be vastly different compared to the bulk. Manipulating the confinement size and interfacial energy can provide control over the crystallization process resulting in tunable morphologies and properties. Miniemulsions where polymer/poor solvent is used as the dispersed phase present an intriguing case where the confinement is introduced by the liquid/liquid (L/L) interface and the confinement length scale, droplet size, can be readily tuned. A unique aspect of this system is the (L/L) interface that is dynamic when compared to solid/liquid, solid/solid, or vapor/liquid and that has a tunable interfacial energy by choice of emulsifier, solvent, and polymer. The nanoscale curvature of the interface is also interesting in regard to polymer crystallization where the curvature is incommensurate with the crystal’s translational symmetry. Our group has recently utilized a miniemulsion system to study polymer crystallization at curved (L/L) interface for a variety of polymers and hybrid materials. This talk will focus on our findings of the unique nanoscale morphologies obtained along with the unique thermal and mechanical properties observed.

4:06PM P55.00007: Solvent Vapor Annealing to Control Polymer Crystal Morphology  
SAMUEL E BLIESNER, JULIE ALBERT (Presenter), Chemical and Biomolecular Engineering, Tulane University — Poly(\( \varepsilon \)-caprolactone) (PCL) is a semi-crystalline, hydrophobic, biodegradable polymer that has found uses in the packaging industry and in biomedical engineering as an anti-adhesion biomaterial film and drug delivery medium among other applications. Degree of crystallinity, crystal morphology, and crystal size are known to affect the biodegradation profile of PCL fibers and films by enzymes, so morphological control is important to designing PCL coatings and films for these applications. Inspired by the literature related to solvent vapor annealing (SVA) in block copolymer films and solvent-induced crystallization in semi-crystalline polymers, we are studying how SVA treatments impact crystal morphology. We use in-situ grazing incidence wide-angle X-ray scattering to determine when/if polymer crystals dissolve during solvent uptake and at what solvent concentrations recrystallization occurs during solvent removal. Additionally, we examine polymer morphology across multiple length scales using a combination of optical microscopy, profilometry, and atomic force microscopy.

*1. NSF 1554555 (J. N. L. Albert, NSF CBET CAREER)  
4:18PM P55.00008: Crystallite Dissolution in Poly(ethylene oxide) Polymers Caused by Water  DANIEL HALLINAN (Presenter), ONYEKACHI D OPARAJI, OLUWAGBENGA IYIOLA, Chemical and Biomedical Engineering, FAMU-FSU College of Engineering, MATTEO MINELLI, ANDREA SARDANO, Department of Civil, Chemical, Environmental and Materials Engineering (DICAM), Alma Mater Studiorum; University of Bologna — Poly(styrene)-block-poly(ethylene oxide) (PS-b-PEO) is a semicrystalline block copolymer (BCP) with interesting properties. It is mechanically tough and amphiphilic. The mechanical toughness is due to the crystallinity of PEO and the glassiness of PS, as well as the morphological structure of the BCP. These polymers have high CO₂, water, and salt solubility that derive from the polar PEO component. Potential applications include CO₂ separation, water purification, and lithium air batteries. In all of the aforementioned applications, water transport is an important parameter. The presence of water can also affect thermal and mechanical properties. Water transport and thermal and mechanical properties of a lamellar PS-b-PEO copolymer, as well as PS and PEO homopolymers have been measured as a function of water activity. Water was found to dissolve PEO crystallites and plasticize PS, which in turn affects the transport. Fourier transform infrared-attenuated total reflectance (FTIR-ATR) spectroscopy was employed to examine crystallite dissolution and water diffusion. A model accounting for both processes captured the experimental observations.

4:30PM P55.00009: Epitaxial growth of polyethylene oxide atop muscovite mica  JASON LIU (Presenter), CRAIG ARNOLD, Department of Mechanical and Aerospace Engineering, Princeton University, RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — Semi-crystalline polymers confined to nanoscale dimensions often crystallize in unexpected ways vastly different from that of bulk crystallization. The crystallization of ultrathin (< 100 nm) films atop solid surfaces is one example, in which the interaction of polymer chains with the underlying substrate is vital in determining the crystallization kinetics and film morphology. Additionally, geometric matching at the molecular scale between the polymer and substrate may induce epitaxial growth. In this work, we deposit ultrathin films of polyethylene oxide atop muscovite mica by matrix-assisted pulsed laser evaporation. We demonstrate an epitaxial relationship between needle-like polymer crystals and the substrate. Mechanisms of nucleation and growth of the epitaxial crystals are discussed.

4:42PM P55.00010: Effect of zone annealing on anisotropic nanoparticle reordering in polymer nanocomposites*  ALEJANDRO KRAUSKOPF (Presenter), ANDREW JIMENEZ, SANAT KUMAR, Columbia University, ELIZABETH LEWIS, BRYAN VOHT, The University of Akron, JULIA PRIBYL, BRIAN C BENICEWICZ, University of South Carolina — Improving mechanical properties of polymeric systems is a primary research focus within the soft matter community. Isothermal crystallization studies have been performed on systems composed of polymer-grafted nanoparticles dispersed within a polymeric matrix, where the crystallized samples exhibit an increase in the tensile modulus by almost an order of magnitude as compared with the well-dispersed samples. Recently, a technique called zone annealing has been developed in which samples are rotated or translated across a fixed temperature gradient. This technique reduces processing times from days to hours. Initial X-ray scattering experiments have demonstrated that the nanoparticles seem to order in an anisotropic fashion along the crystallizing polymer lamellae after zone annealing.

4:54PM P55.00011: Utilizing Mixed Nanofillers to Control Crystallization Induced Ordering*  ANDREW JIMENEZ (Presenter), SANAT KUMAR, Columbia University, JACQUES JESTIN, CEA/CNRS, Laboratoire Léon Brillouin — The technique of controllably tuning nanoparticle ordering in semicrystalline polymers by crystallizing at very slow growth velocities (i.e. high temperatures) represents a very interesting physical situation. While organized PMMA-g-silica fillers have been shown to further enhance the mechanical properties, the particles' inherent effect on the crystallization process leads to significantly longer processing times and lower degrees of crystallinity than is desirable. To combat this, a mixture of fillers of different sizes (specifically a bimodal distribution) is used to simultaneously increase the rate of crystallization, through nucleation, while allowing smaller fillers to continue to organize. This provides the simultaneous benefit of adding another level to the hierarchically ordered system. By tuning the relative size of either particle or aggregate one can optimize this nucleation effect while benefiting from the structural reinforcement of the secondary filler.

Crystallization behavior in spin-coating film-forming processes has been investigated for Poly(ε-caprolactone) (PCL) having the weight-average molecular weight ($M_w$) of $129 \times 10^3$, $39 \times 10^3$ and $16.8 \times 10^3$ by time-resolved measurements of grazing-incidence small-angle and wide-angle X-ray scattering (GISWAXS) using synchrotron radiation in SPring-8 (RIKEN, Japan). Effect on the rotational speed, the PCL concentration in solutions and the molecular weight of PCL on crystallization kinetics and lamellar orientation during spin-coating will be explained in my presentation.

This research was partly supported by JSPS KAKENHI Grant Number 26410135 and CREST, JST. The synchrotron radiation experiments were performed at BL45XU in SPring-8 with the approval of RIKEN (Proposal No. 20140061, 20150076, 20160041, 20170094).

Regenerated cellulose fibers: Relating mechanical response to semicrystalline microstructure

We compare regenerated cellulose fibers manufactured using Viscose and Lyocell processes. These fibers show qualitatively similar mechanical response in different experiments e.g. stretching, stress relaxation and stress recovery. We show that the linear viscoelastic response of these fibers is accurately captured using a phenomenological model. The model parameters correlate well to the structural features and thus provide a robust structure-property relation for the linear region response. When stretched beyond the linear region, regenerated cellulose fibers show a transition in the slope of stress strain curve at a critical strain. This transition has been attributed in the literature to yielding of fibers. We demonstrate that this is incorrect and that the critical strain corresponds to an apparent yield. When subjected to strains higher than this apparent yield point, the fibers retain a memory of the mechanical deformation, that decays logarithmically with time and is lost over about a day as the fiber structure transitions back to the original as spun fiber.

Exploring the mechanics of curved creased origami with a discrete bar and hinge model

Simulation approaches from computer graphics were some of the first to study the complex geometries and resultant elastic behaviors of curved crease origami. In this work, we present an extension of these approaches by adapting a simplified, discrete, and physics-based bar and hinge approach to simulate the mechanics of these intriguing origami structures. This model can capture stretching and shearing of the thin sheet, bending of the sheet along principle curvature directions, and bending along the prescribed curved creases. With insight from differential geometry, we use the model to explore the elastic folding sequence, the stiffness, and the global large deformation mechanics of curved crease origami.

The authors acknowledge funding from the Office of Naval Research Grant N00014-18-1-2015. S.R.W acknowledges support from the National Science Foundation Graduate Research Fellowship.
2:42PM P56.00002: Mapping of Fold Path Bifurcations in Origami Structures  ANDREW GILLMAN (Presenter), UES Inc. / Air Force Research Laboratory (WPAFB), PHILIP BUSKOH, Air Force Research Laboratory (WPAFB) — Origami has proven value in numerous technological applications including lightweight composites, soft robotics, metamaterial design, and deployable space structures, where discrete and modular folding motifs are leveraged to form novel tessellations. The material (stiffness mismatch among deformation modes) and geometric (slender elements) contrasts in origami structures can lead to highly nonlinear mechanical behavior with unique macroscopic properties, such as multi-stability. To efficiently navigate this complex nonlinear space, we have recently developed an efficient nonlinear truss finite element model with linear eigenanalysis heuristics for branch switching off the flat state. However, more efficient and robust methods have proven essential when performing topology optimization in this non-convex design space involving energy landscapes with many bifurcations and stable equilibrium points. Our work focuses on the incorporation of robust continuation methods for bifurcation point detection and branch switching to map these multistable energy landscapes and characterize the role of discrete fold stiffness distributions.

2:54PM P56.00003: Pairing global symmetries with folding mechanics to transform all periodically triangulated origami  D. ZEB ROCKLIN (Presenter), JAMES MCINERNEY, Georgia Institute of Technology, BRYAN G CHEN, Physics, University of Pennsylvania, LOUIS THERAN, Math, University of St. Andrews, CHRISTIAN SANTANGELO, Physics, U. Mass. Amherst — Thin sheets restricted to folding at designated creases, as in the traditional Japanese art of origami, have been engineered to deploy devices from the atomic to the macroscopic scale. However, the relation between the crease pattern and the paths to accessible structures is highly nontrivial. We investigate the entire class of periodically triangulated origami, revealing a hidden symmetry between global motions and linear folding mechanisms. Such periodic patterns always admit a two-dimensional manifold of cylindrical configurations as previously shown by Tomohiro Tachi. Adding a single quadrilateral face to the unit cell restricts the system to a single degree of freedom without fine-tuning the geometry. By transforming along these paths, we can change the mechanical response at the boundary. Our analysis can be extended to similar systems with balanced constraints and degrees of freedom such as kirigami, continuum sheets, and magnetic systems.

3:06PM P56.00004: Mechanics-Based Design for Computational Fabrication  [Invited]  EMILY WHITING (Presenter), Boston University — Advancements in rapid prototyping technology are closing the gap between what we can simulate with computers and what we can build, as it is now possible to create shapes of astounding complexity. Despite innovations in hardware, however, costly bottlenecks still exist in the design phase. Today's computational tools for design are largely unaware of the fundamental laws that govern how geometric models will behave in the real world. In this talk I will present recent work combining digital geometry processing, engineering mechanics, and rapid prototyping. The aim is to infuse principles of mechanics into design processes for fabrication. I will highlight specific applications including balance, buoyancy, acoustics, and architectural construction.

3:42PM P56.00005: Geodesy: Self-rising 2.5D Tiles by Printing along 2D Geodesic Closed Path  JIANZHE GU (Presenter), Human-Computer Interaction Institute, Carnegie Mellon University, DAVID E. BREEN, Computer Science, Drexel University, JENNY HU, School of Design, Carnegie Mellon University, LIFENG ZHU, Department of Mechanical Engineering, Carnegie Mellon University, YE TAO, Human-Computer Interaction Institute, Carnegie Mellon University, TY ZANDE, School of Design, Carnegie Mellon University, GUANYUN WANG, Human-Computer Interaction Institute, Carnegie Mellon University, JESSICA YONGJIE ZHANG, Department of Mechanical Engineering, Carnegie Mellon University, LINING YAO, Human-Computer Interaction Institute, Carnegie Mellon University — Thermoplastic and Fused Deposition Modeling (FDM) based 4D printing is rapidly expanding to allow for space- and material-saving 2D printed sheets morphing into 3D shapes when heated. However, to our knowledge, all the known examples are either origami-based models with obvious folding hinges, or beam-based models with holes on the morphing surfaces. Morphing a flat thermoplastic sheet into continuous double-curvature surfaces remains a challenge, both in terms of a tailored toolpath-planning strategy and a computational model that simulates it. In Geodesy, we focus on the morphing of continuous double-curvature surfaces or surface textures. We suggest a unique tool path - printing thermoplastics along 2D closed geodesic paths to form a surface with one raised continuous double-curvature tiles when exposed to heat. The shape space is further extended to more complex geometries composed of a network of rising tiles (i.e., surface textures). Both design components and a mass-spring-model-based computational pipeline are explained in the paper, followed by several printed geometric examples.
3:54PM P56.00006: Estimating friction in cloth, using simulation and machine learning*  ABDULLAH RASHEED (Presenter), VICTOR ROMERO, FLORENCER BERTAILS-DESCOUBES, Univ. Grenoble Alpes, Inria, CNRS, Grenoble INP, LJK, Grenoble, France, ARNAUD LAZARUS, Sorbonne Université, Institut Jean Le Rond d’Alembert, Paris, France, STEFANIE WUHRER, JEAN-SEBASTIEN FRANCO, Univ. Grenoble Alpes, Inria, CNRS, Grenoble INP, LJK, Grenoble, France — We explore the utility of deep neural networks to estimate parameters in cloth motion, specifically the friction coefficient. Our idea is to use realistic cloth motion sequences as video training data for our model and use both spatial and temporal features for parameter estimation. Following recent works, we aim to avoid complex experimental setup for the generation of training data by leveraging cloth simulation as a ground truth model for cloth dynamics. However, this is only meaningful if the simulation is accurate and predictable enough in the range of scenarios envisioned. To ensure realistic simulations, we validate the physical accuracy of Argus, a recent cloth simulator developed in computer graphics which relies on an implicit contact friction solver for capturing exact Coulomb friction. We successfully verify the physical realism of this simulator by conducting physical experiments analogous with simulations, following a protocol previously suggested in literature for measuring Coulomb’s friction coefficient in a Hookean elastic material contacting a rigid surface. We further investigate utilizing a similar protocol for cloth with varying material properties, which is modelled as an orthotropic material in the simulator.

4:06PM P56.00007: Discrete Kirchhoff Rod Networks for Optimization-Driven Design  BERNHARD THOMASZEWSKI (Presenter), JONAS ZEHNDER, Computer Science and Operations Research, Université de Montréal — Many examples from architecture, mechanical engineering, and material science can be described as networks of elastic rods. Designing rod networks that exhibit desired characteristics is made difficult by the fact that the mapping between design parameters and performance at equilibrium is highly nonlinear. We propose a computational approach to this problem that leverages simulation and optimization algorithms for rapid design exploration. The technical core of our approach is formed by an efficient computational model for networks of discrete elastic Kirchhoff rods, paired with an inverse problem solver based on sensitivity analysis. We validate our model against standard solid finite element simulations and present applications to compliant mechanisms, deployable pretensioned membranes, structural curve networks, and mechanical metamaterials.

4:18PM P56.00008: Inverse design of a suspended Kirchhoff rod: From theory to practice*  VICTOR ROMERO (Presenter), FLORENCER BERTAILS-DESCOUBES, Université Grenoble Alpes, Inria, CNRS, Grenoble INP, LJK, ALEXANDRE DEROUET-JOURDAN, OLM Digital Inc., ARNAUD LAZARUS, University of Paris VI: Pierre-and-Marie-Curie University — Our study focuses on finding the natural shape of a given hanging deformed isotropic rod, made of a known material, the input shape is described as a mere geometric curve that we subsequently frame to compute a material curvature field and feed our inverse problem.

We prove that the natural shape of the rod satisfying equilibrium exists and is unique, regardless of the infinity compatible frames for the input curve. The natural shape is computed efficiently by solving in sequence three linear initial value problems. We illustrate our theoretical results through numerical examples of well known curves to which we apply our inverse procedure. By direct simulation we show that indeed those natural shapes fall, under the effect of gravity, onto the expected equilibrium. We stress on the fact that the obtained rest shapes are complex and far from intuitive.

We complement this study with experimental corroborations. By means of a standard array of cameras, we spatially reconstruct real elastic hanging rods with well-defined geometrical features. We find some good agreements with model prediction despite the experimental limitations on the estimation of the curvature fields of the rod’s center line.

**4:30PM P56.00009: Jamming limiting the percolation of square tiles on square lattices**  
**EUGENIO VOGEL (Presenter), JULIO F. VALDES, University of La Frontera, Chile, PAULO M. CENTRES, ANTONIO J. RAMIREZ-PASTOR, Univ. Nac. San Luis, Argentina — Square tiles of $k \times k$ sites ($k^2$-mers) are deposited irreversibly on $L \times L$ square lattices of exactly the same inter-site distance; no overlapping is allowed. Coverage is defined as $q = Nk^2/L^2$, where $N$ represents the number of deposited tiles. Percolation thresholds $q_p(k)$ are reported with high precision for $k=1, 2,$ and $3$. For $k \geq 4$ jamming suppresses percolation. The coverages at which jamming appears $q_j(k)$ are also reported accurately [1]. It is observed that $q_p(2) < q_j(2)$ and $q_p(3) < q_j(3)$ while this inequality is reversed for $k \geq 4$, namely, $q_p(k) > q_j(k)$, which explains the suppression of percolation for $k \geq 4$. Monte Carlo techniques are used to simulate these depositions for $k^2$-mers from $k=2$ to $k=100$, and lattice sizes with sides much larger than $k$. Calculations based on exact enumeration were done for $k \leq 6$ and several $L$ values to show that this property is inherent to these systems. Finite size scaling is used to estimate the thresholds in the thermodynamic limit. The universality class of this deposition corresponds to random percolation; the corresponding critical exponents $\nu$, $\gamma$, and $\beta$ are reported with good accuracy.

**4:42PM P56.00010: Rotating Matter: The Bearing State**  
**HANS HERRMANN (Presenter), PMMH, ESPCI Paris — Granular materials are characterized by an additional degree of freedom, rotations, which become particularly relevant for spherical particles. A packing of spheres is called bi-chromatic if every loop formed by contacts is even. In three dimensions, bi-chromatic bearings have many different sliding-free configurations, so called bearing states. Packings with bearing states can even be made space-filling. Their bearing states can be viewed as a realization of solid turbulence exhibiting Kolmogorov scaling and anomalous heat conduction. In three dimensions a continuum of such configurations can be obtained as cuts through four-dimensional space-filling bearing states. Bearings states can be perceived as physical realizations of networks of oscillators with asymmetrically weighted couplings. These networks can exhibit optimal synchronization properties through tuning of the local interaction strength as a function of node degree or the inertia of their constituting rotor disks through a power-law mass-radius relation. Under this condition, the average participation per disk is maximized and the energy dissipation rate is homogeneously distributed among elementary rotors. The synchronization of rotations occurs in avalanches following a broad size distribution.

**4:54PM P56.00011: Non-equilibrium dynamics of isostatic spring networks**  
**FEDERICO GNESOTTO (Presenter), BENEDIKT REMLEIN, CHASE BROEDERSZ, Arnold-Sommerfeld-Center for Theoretical Physics and Center for NanoScience, Ludwig-Maximilians-Universität München — Mechanical systems exhibit rich critical behavior in the vicinity of the isostatic point. Inspired by living matter such as cytoskeletal networks and tissue, we here consider marginal assemblies driven out of equilibrium by internal activity. To date it remains unclear how the critical nature of such systems affects their non-equilibrium dynamics. We elucidate the role of the isostatic threshold in active diluted spring networks: heterogeneously distributed active noise sources drive the system into a non-equilibrium steady state. The non-equilibrium dynamics between pairs of network nodes are quantified by the characteristic cycling frequency $\omega$—a measure of the circulation of the associated phase space currents. We reveal critical scaling of the cycling frequencies and intuitively understand their local behavior employing a mean-field approach. Overall, our work serves as a bridge connecting the well-established theory of mechanical stability to the novel field of non-equilibrium statistical mechanics.
Contact networks in jammed granular systems, derived from contact forces between dry grains in mechanical equilibrium, can be represented in a dual force space as a network of edges that form a space-filling tiling. This force tiling paradigm has been found to be particularly useful in the characterization of stress-induced transitions in granular materials. As a generic network itself, the force network can be studied with techniques used in the investigation of more conventional networks.

Using jammed granular packings obtained from simulations, we explore the duality between the resultant real-space contact networks and force tilings. We analyze the relationship between zero modes and states of self-stress in these dual networks, and connect it to physical properties of jammed packings and to unjamming. In particular, this can provide improved understanding of the stability of granular systems against the effect of external perturbations.

Session P57 GSNP DBIO: Noise-driven Dynamics in Far-from-equilibrium Systems I

2:30PM P57.00001: Noise-induced dynamics in far-from-equilibrium electronic transport systems [invited] STEPHEN TEITSWORTH (Presenter), JUAN PABLO GONZALEZ, YURIY BOMZE, Duke University, JOHN NEU, Mathematics, University of California, Berkeley — Bistable systems occur throughout the natural sciences and when such systems are subjected to noise, one observes probabilistic transitions between co-existing metastable states. Such behavior is found in chemical reaction kinetics, driven nonlinear mechanical systems, nonlinear electronic transport systems, climate dynamical models, and pulse propagation dynamics in neurons, to name but a few. In the case of electronic transport systems, experimental studies focus on probabilistic switching transitions between distinct states of electrical current flow in tunneling structures such as semiconductor superlattices and tunnel diodes. In particular, tunnel diode circuits provide an excellent experimental platform for the precision measurement of switching time statistics over a wide dynamic range. Furthermore, the measurement of mean switching times versus system parameters such as applied voltage near bifurcation points allows the determination of scaling behavior with remarkable precision. In related work, we have experimentally and theoretically studied linear electrical networks that are driven by non-thermal noise sources with a focus on the development of novel methods to characterize violations of detailed balance. Three methods of particular interest for experiments are: 1) construction of probability current from data, 2) stochastic area measurement, and 3) construction of statistical fluctuation loops. In this talk, we highlight the advantages and limitations of each of these approaches.

3:06PM P57.00002: Learning force fields from stochastic trajectories PIERRE RONCERAY (Presenter), ANNA FRISHMAN, Princeton University — When monitoring the dynamics of microscopic systems, disentangling deterministic forces from thermal noise is challenging. Indeed, we show that there is an information-theoretic bound on the rate at which information about the force field can be extracted from a trajectory. We propose a practical method, Stochastic Force Inference, that optimally uses this information to approximate force fields. This technique readily permits the evaluation of out-of-equilibrium currents and entropy production with a limited amount of data.

3:18PM P57.00003: Noise-driven ionic currents in a viscosity gradient* DEREK STEIN (Presenter), BENJAMIN WIENER, Physics, Brown University — Gradients of voltage, pressure, temperature, or salinity can transport objects in micro- and nanofluidic systems by well-known mechanisms. I will describe the discovery of an electrokinetic transport effect driven by a viscosity gradient: An imposed liquid viscosity gradient causes an ionic current to flow inside a glass nanofluidic channel. Measurements of the current and numerical simulations reveal that the counterions in the electric double layers near the nanochannel surfaces drift in the direction of decreasing viscosity. The measurements are well described by a simple model in which the counterion drift speed equals the gradient of an ion's local diffusivity. Drift in a viscosity gradient, or viscophoresis, is a consequence of multiplicative (state-dependent) noise, where the magnitude of the thermal fluctuations experienced by a particle depends on its position.

*We acknowledge support from NSF under award 1409577 and from Oxford Nanopore Technologies.
SHAYAN LAME (Presenter), DEREK STEIN, physics, Brown University — We report an experimental technique to increase and control the diffusivity of individual DNA polymers in a nanofluidic environment. We applied white electrical noise with a Gaussian distribution of voltage fluctuations across nanofluidic slits containing fluorescently labeled DNA molecules. The effective diffusivity of the molecules in the direction parallel to the applied fields increased linearly with the noise power, reaching 19 times the thermal diffusivity with an applied noise amplitude of 36 V. This technique, which can subject DNA molecules to noise levels equivalent to 5300 K, enables us to experimentally investigate noise-driven dynamical phenomena in a previously inaccessible regime.

*We acknowledge support from NSF under award 1409577

SAHIL AGARWAL (Presenter), Yale Univ, WOOSOK MOON, Stockholm University and Nordita, JOHN WETTLAUFER, Yale University and Nordita — Understanding multidecadal variability is an essential goal of climate dynamics. For example, the recent phenomenon referred to as the "global warming hiatus" may reflect a coupling to an intrinsic, preindustrial, multidecadal variability process. Here, using a multifractal time-series method, we demonstrate that 42 data sets of 79 proxies with global coverage exhibit pink-noise characteristics on multidecadal timescales [1]. To quantify the persistence of this behavior, we examine high-resolution ice core and speleothem data to find pink noise in both pre- and postindustrial periods. We examine the spatial structure with an empirical orthogonal function analysis of the monthly averaged surface temperature from 1901 to 2012. The first mode clearly shows the distribution of ocean heat flux sinks located in the eastern Pacific and the Southern Ocean and has pink-noise characteristics on a multidecadal timescale. We hypothesize that this pink-noise multidecadal spatial mode may resonate with externally driven greenhouse gas forcing, driving large-scale climate processes.

CHLOE GAO (Presenter), DAVID LIMMER, University of California, Berkeley — Nonlinear response occurs naturally when a strong external perturbation takes a system far from equilibrium. While linear response can be directly related to equilibrium fluctuations, nonlinear response is difficult to predict in a general and efficient way. In this talk, we illustrate a method to compute arbitrarily high order transport coefficients of stochastic systems from derivatives of a large deviation function. We explore a selection of examples ranging from a single Brownian ratchet to thermal rectification in a mass-graded Fermi-Pasta-Ulam chain. Our method not only derives transport coefficients with relatively small statistical error, but also can be useful in studying mechanism by which nonlinear behavior arises.

ALEXANDRU BACANU (Presenter), JAMES PELLETIER, JUNANG LI, JORDAN HOROWITZ, TODD GINGRICH, NIKTA FAKHRI, Massachusetts Institute of Technology — Many biological systems act as ATP chemostats, maintaining a constant ATP chemical potential across numerous and variable free energy sources and sinks. It remains unclear how much free energy cells allocate to active mechanical fluctuations of the cytoplasm among other processes. To characterize nonequilibrium cytoskeletal mechanics, we imaged shape fluctuations of single-walled carbon nanotubes (SWNTs) embedded in an actin-intact Xenopus cytoplasmic extract. Normal mode decomposition of SWNT shape fluctuations resolved the spatial structure of myosin-driven forces, which were not only stochastic, but also nonstationary due to dynamic remodeling of the actomyosin network. Based on the normal mode correlation functions, we defined metrics for nonequilibrium mechanical activity. To measure how active cytoskeletal mechanics depended on the ATP chemical potential and flux, we increased the ATP chemical potential via a phosphoenolpyruvate energy mix and decreased it via apyrase-catalyzed ATP hydrolysis. These passive measurements reveal how local nonequilibrium fluctuations of the cytoplasm respond to global thermodynamics and the ATP chemical potential.
4:18PM P57.00008: Mutual information driven colloidal heat engine* GOVIND PANERU, SANDIPAN DUTTA, TSVI TLUSTY, Center for Soft and Living Matter, Institute for basic science, HYUK KYU PAK (Presenter), Ulsan National Institute of Science and Technology — We report on the direct measurement of the mutual information as a function of error size for a Brownian information engine operating in non-equilibrium steady state. Each engine cycle consists of the measurement of the particle position, feedback control, resetting of the particle position and relaxation. The measurement involves a Gaussian noise of controlled width. The performance of the information engine depends on the cycle period τ and the width of the noise N. The mutual information decreases with decrease in τ and increase in N, thereby reducing the amount of work extraction. Our system operates as a cooling or a heating device depending on the noise width. The efficiency of information-to-work conversion increases as the system is allowed to relax more at the end of each cycle. The maximum efficiency is obtained at the finite value of N. The generalized Jarzynski equality was found to be valid either when the initial state of the system is in thermal equilibrium, or when noise and signal width are equal.

4:30PM P57.00009: Realization of an artificial active bath with controlled activity* JINTAE PARK (Presenter), Ulsan National Institute of Science and Technology, GOVIND PANERU, Center for Soft and Living Matter, Institute for Basic Science, HYUK KYU PAK, Ulsan National Institute of Science and Technology — We study the motion of a Brownian particle in artificially generated active bath. The particle is confined in a time dependent optical harmonic potential generated by optical tweezers. Therefore, the particle feels an external active noise in the background of a thermal white noise. This system is assumed to mimic the motion of a Brownian particle in active bath such as a bath of swimming bacteria. In comparison to the real bacterial bath experiments in which the activity parameters cannot be controlled easily, in this experiments the activity of the artificially generated active bath can be modulated in more controlled manner. Consequently, it allows us to study the thermodynamics of the Brownian particle in the active bath of various conditions.

4:42PM P57.00010: Deformation of nonequilibrium limit cycle oscillators due to stochasticity JANAKI SHETH (Presenter), Physics, University of California at Los Angeles — Non-equilibrium dynamics are exhibited by numerous biological systems, often modeled as non-linear oscillations driven by an internal energy-consuming process. Thermal processes lead to stochasticity in the measurements of their variables. Thus, experiments can only access the mean limit cycle, which may be different from the underlying zero-temperature one. This can lead to discrepancies between measurements and deterministic numerical models.

One example of an active oscillator is the inner ear hair cell. Its dynamics are here modeled with a set of equations that incorporates the physiological variables and their noise amplitudes. We observe a gradual rounding of the mean limit cycle with increasing noise strength and explore causes for such rounding that makes sharper features of the noiseless oscillator experimentally inaccessible.

To simplify the system, we simulate a generalized Hopf oscillator, with added features in the scalar potential. The oscillation, powered by an internal active mechanism, requires a nonzero vector potential. By varying noise strengths under such general conditions, we observe distortion of the zero-temperature limit cycle. We suggest that this temperature effect imposes inherent limitations on complex models seeking to reproduce experimental dynamics.

4:54PM P57.00011: Numerical study for controlling surface roughening in KPZ growth process* PRIYANKA. (Presenter), UWE CLAUS TAUBER, MICHEL PLEIMLING, Virginia Tech — The Kardar-Parisi-Zhang (KPZ) equation has been used to describe growth processes in a variety of systems, and the corresponding exponents have been shown to prevail in both numerical models and experiments. Our objective in this work is to control the surface roughening for the KPZ growth process in (1+1) dimensions. We aim to saturate the surface roughness to the desired value using feedback control and try to understand the effect of the feedback control on the underlying dynamics. To this end, we apply a numerical integration scheme of the KPZ equation (with and without control) using the pseudo-spectral method. The numerical results show that controlling only a few small wave numbers leaves the system in the KPZ universality class. However, perturbing the wave numbers beyond a certain threshold changes the underlying kinetics, depending on the specific type of implemented (linear or nonlinear) control.

5:06PM P57.00012: Self-organization in robot swarms and beyond*  PAVEL CHVYKOV (Presenter), Massachusetts Institute of Technology, WILLIAM C SAVOIE, ZACHARY JACKSON, AKASH VARDHAN, KURT A WIESENFELD, Physics, Georgia Tech, JEREMY L ENGLAND, Massachusetts Institute of Technology, DANIEL GOLDMAN, Physics, Georgia Tech — Swarms of interacting simple robots are interesting because of their potential for adapting rapidly to the demands of different group tasks. They also provide a playground for studying the physics of emergent self-organization. We studied a closely packed ensemble of periodically deforming simple robots, and observed the group to spontaneously organize into orderly patterns of collective motion. Viewing the collective as an emergent whole, we characterized its dynamics using an analysis originally developed for understanding fruit-fly behaviors. Our findings point to design principles for the controlled stabilization of ordered behaviors in interacting systems.

5:18PM P57.00013: Negative differential response of chemical reaction currents  GIANMARIA FALASCO, TOMMASO COSSETTO (Presenter), EMANUELE PENOCCHIO, MASSIMILIANO ESPOSITO, University of Luxembourg — Reaction currents in chemical networks can decrease when increasing their driving affinities. Such negative differential response (NDR), a hallmark of nonequilibrium physics, is found in reaction schemes of major biological relevance, namely, substrate inhibition and autocatalysis. We display it by deriving the full counting statistics of two minimal representative models by large deviation methods. We explore the consequences of NDR for biochemical networks in terms of precision-dissipation tradeoff and stability against external perturbations. Furthermore, we go beyond the realm of biochemistry and examine the relevance of NDR in artificial applications, showing how it limits the performance of dissipative self-assembly.

Session P58 GSOFT: Disordered and Glassy Systems II BCEC 257A - Elijah Flenner, Colorado State Univ

2:30PM P58.00001: Measurement and modification of two-level tunneling states in amorphous aluminum oxide*  THOMAS METCALF (Presenter), XIAO LIU, MATTHEW ABERNATHY, United States Naval Research Laboratory, BATTOGTOKH JUGDERSUREN, KeyW Corporations — Low energy excitations modeled as two-level tunneling systems (TLSs)—a significant source of decoherence in qubits built around superconducting Josephson junctions—are found nearly universally in amorphous dielectrics. Although TLS-free amorphous dielectric materials would be a technological boon, to date there is only one such material system: amorphous silicon thin films vapor deposited onto substrates held at elevated temperatures. The question arises whether TLSs can be eliminated in other, technologically pertinent amorphous dielectrics. To this end we have measured the internal friction of 100–300nm sputter-deposited aluminum oxide films, at substrate temperatures up to 500°C. This measurement directly yields the tunneling strength parameter from the TLS model, and we find a factor of five reduction in tunneling strength for films deposited at high temperatures.

*Work supported by the Office of Naval Research

2:42PM P58.00002: Entropy-dominated squeezout force and incipient glass formation in confined ionic liquids*  ROSARIO CAPOZZA (Presenter), Environmental Engineering, Edinburgh University, UK, ERIO TOSATTI, SISSA and ICTP, Trieste, Italy — The squeezout force for an ionic liquid (IL) confined in a nanoscale channel between two approaching plates generally shows just short-range layering steps. Close to freezing temperature and at large squeezout speeds, recent data in a simple IL showed instead that short-range layering is replaced by a smooth intermediate range repulsive force tail. Along with the expected viscosity rise as in experiment, our squeezout simulations in a simple IL model additionally show that the confinement-induced strong and smooth repulsive squeezout force is of entropic origin, whereas the short-range layering steps are only controlled by internal energy. Our interpretation is guided by bulk glass-forming liquids, where the viscosity rise upon cooling is indeed associated with an entropy drop through the Adam-Gibbs mechanism, involving the formation of cooperatively rearranging regions (CRRs). We find that the confined IL the entropy drop and viscosity rise which accompany squeezout are also connected with remnants of a confinement-induced glassy CRRs forming at constant temperature, a mechanism that should be more general than this specific case.

*Supported by ERC MODPHYSFRICIT Contract no. 320796
Topological phases, fragility- and reversibility-widows in GePxSe100-2x ternary

AARON WELTON (Presenter), RALPH CHBEIR, SOUMENDU CHAKRAVARTY, PUNIT BOOLCHAND, University of Cincinnati — The fragility index, \( m \), in homogenized chalcogenide melts, are found to display values of \( m < 20 \) for compositions that reside in the Intermediate Phase (IP) in the Ge-Se, Ge-S binary systems yielding a fragility window. The enthalpy of relaxation of corresponding glasses, \( \Delta H_{nr}(x) \), becomes minuscule in IP displaying a reversibility window[1]. That correlation between \( \Delta H_{nr}(x) \) and \( m(x) \) illustrates a basic principle that melt dynamics encode glass topological phases. Here we examine the titled glasses to investigate if the principle extends to the present ternary. We have synthesized titled glasses over a wide range of compositions, \( 2\% < x < 26\% \) by alloying the pure elements in evacuated quartz tubes. Melts were alloyed till the variance in Ge stoichiometry \( x \) across the 2 gram batch composition nearly vanished using Raman profiling. In such homogenized glasses we are now examining the variation in \( \Delta H_{nr}(x) \) and \( m(x) \) using Modulated DSC, and will present the results of these observations. In a previous study[2] variation of \( \Delta H_{nr}(x) \) was examined but no attempt to measure the fragility index was made.

The Energy Distribution of Two-Level Systems in Various Amorphous Thin Films Measured Using Internal Friction

MATTHEW ABERNATHY (Presenter), XIAO LIU, THOMAS METCALF, Code 7130, Naval Research Laboratory, Washington, DC, BATTOGTOKH JUGDERSUREN, KeyW Corporations, Hanover, MD — Amorphous materials are known to universally possess various low-energy excitations generally modeled as two-level systems (TLS) capable of tunneling between states at low temperatures (~1K) and thermal excitation at higher temperatures (>5 K). The measurement and modeling of these states in bulk materials is well represented in the literature, however, relatively few measurements of amorphous thin films have been similarly analyzed. In this presentation, we fit the model of Rau et al. (Phys. Rev. B, 52, 7179, 1995) to the mechanical loss features attributed to TLS in thin films of a-Se, a-Al2O3, and others.

*This work is supported by the Office of Naval Research

Can you hear the shape of a crumpled sheet?

YOAV LAHINI, Tel Aviv University, SHMUEL RUBINSTEIN, ARIEL AMIR (Presenter), Harvard University — Thin, crumpled sheets show surprisingly intricate dynamics: when subject to a constant load, they exhibit an extremely slow volume relaxation that spans many decades in time – from fractions of a second to weeks. After an abrupt change in the load, they show slow, non-monotonic aging and memory effects reminiscent of glassy systems. We have recently shown that these dynamics and scaling relations can be captured accurately using a phenomenological model in which the relaxation process is assumed to be governed by a linear superposition of many relaxation modes, that have a broad distribution of relaxation times. Here, we study, theoretically and experimentally, the statistics of discrete micro-mechanical relaxation events occurring within the system as it relaxes or exhibits memory. We find that during logarithmic relaxations the waiting time between these micro-mechanical ‘quakes’ displays approximate Poisson-statistics at any point in time, but with an average that grows linearly with the age of the system from preparation. The model is also used to predict the pattern of micro-relaxation events during the non-monotonic aging regime. The model predictions and experimental data of acoustic emission show good agreement.
3:30PM P58.00006: Critical size for dynamic crossover in amorphous nanoparticles*  
SHAN ZHANG (Presenter), PENGFEI GUAN, LIJIN WANG, Beijing Computational Science Research Center — The fragility, defined according to the non-Arrhenius degree of the viscosity-temperature dependence of a system in a supercooled state, is the essential, crucial, and universal dynamic attribute of the glass-forming liquid. It is related to the material-specific properties in liquid and glass state. We found that with the metallic glass nanoparticle's size reduced to critical size $R_c$, a fragile-to-strong transition appeared. This transition is the result of particle size reduction and the fast surface dynamic behavior. The analysis of morphology in PEL suggests that the strong liquids have the large fraction of low-energy excitations, reflecting the systems have a lower density of minima, fewer paths to translate into structural collapse. Meanwhile, this phenomenon is related to the atomic inherent structure energy and the two-body excess entropy in the surface. This fragile-to-strong transition is conducive to understand the micro-mechanism of the metallic glass at nano-scale further.
