4:30PM H14.00011: Influence of a Gaussian nanobubble on quantum Hall conductance across a p-n junction in graphene* NOJOON MYOUNG, physics education, chosun university, HEE CHUL PARK (Presenter), Institute for Basic Science — Structural deformations in graphene can emerge during the fabrication processes. Although the nanobubbles in graphene has a capability to be applied in valleytronics and nano electromechanics, they also act as disorders causing inelastic scatterings in Dirac fermion transport. It is important to locate where the nanobubbles are formed in graphene surface not only for exploiting them to applications but also for avoiding them to acheive ballistic transport. Here, we report a theoretical investigation of influence of a Gaussian nanobubble on quantum Hall conductance with a p-n junction in graphene, showing strain-induced conductance oscillations as the position and strain strength of the Gaussian nanobubble vary. We reveal that the reported conductance oscillations stem from the rotation of valley isospin along the p-n junction interface. Due to the pseudo-magnetic field produced by the Gaussian nanobubble, there are localized states for given strain strengths, and Fano resonances can appear in the quantum Hall conductance as a consequence of coupleline between the localized and extended states.

*National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT and MOE) (2017R1C1B5076824, Project IBS-R024-D1,NRF2016-R1D1A1B04-935798) and Chosun University (2017).
4:42PM H14.00012: Splitting of conductance resonance through a magnetic quantum dot in graphene*  NOJOON MYOUNG, Physics education, Chosun University, JUNG-WAN RYU, HEE CHUL PARK, PCS, Institute for Basic Sciences, SEUNG JOO LEE, Dongguk University, SUNGJONG WOO (Presenter), PCS, Institute for Basic Sciences — We report a dual resonance feature in ballistic conductance through a quantum Hall graphene nanoribbon with a magnetic quantum dot. Such a magnetic quantum dot localizes Dirac fermions exhibiting anisotropic eigenenergy spectra with broken time-reversal symmetry. Interplay between the localized states and quantum Hall edge states is found to be two-fold, showing Breit-Wigner and Fano resonances, which is reminiscent of a double quantum dot system. By fitting the numerical results with the Fano-Breit-Wigner lineshape from the double quantum dot model, we demonstrate that the two-fold resonance is due to the valley mixing that comes from the coupling of the magnetic quantum dot with quantum Hall edge channels; an effective double quantum dot system emerges from a single magnetic quantum dot in virtue of the valley degree of freedom. It is further confirmed that the coupling is weaker for the Fano resonance and stronger for the Breit-Wigner resonance.

4:54PM H14.00013: Giant pseudo-magnetic fields, valley polarization and topological channels by nanoscale strain engineering of monolayer graphene*  CHEN-CHIH HSU (Presenter), JIAQING WANG, MARCUS TEAGUE, NAI-CHANG YEH, Physics, Caltech — We report the use of nearly strain-free PECVD-grown graphene [1] to induce controllable strain and pseudo-magnetic fields (Bs) by placing graphene on periodic nanostructure arrays [2]. We fabricated these arrays using focused ion beam and electron-beam lithography. These nanostructures were covered by a monolayer h-BN followed by a monolayer graphene, we found that graphene appeared to wrinkle up along the nanostructures. Each wrinkle results in four parallel channels of alternating positive and negative pseudo-magnetic fields, which are natural topological channels for valley-polarized propagation. Properly designed arrays of nanostructures could induce the desirable Bs values and spatial distributions, which can function as a valley splitter to separate valley-unpolarized currents, or a valley propagator to guide valley-polarized currents. To enable valleytronic applications, we pattern strained graphene with these topological channels into Hall bar geometry to study the valley Hall effect.

*This work was supported by the Army Research Office, National Science Foundation and Kavli Foundation.

5:06PM H14.00014: Scaling and quantum phase transitions of disordered graphene in the quantum Hall regime.*  TATIANE DOS SANTOS (Presenter), LEANDRO LIMA, CAIO LEWENKOPF, Instituto de Física, Universidade Federal Fluminense — We investigate the magneto-transport properties of disordered graphene samples in the quantum Hall (QH) regime. Despite the huge attention that the QH effect in graphene has received in the past decade, there are still open questions about the effects of the disorder on the transition states between Hall plateaus, especially regarding scaling properties. Such transition states have been intensively studied in the context of two-dimensional electron gases and found to exhibit universal scaling behavior. The situation is less clear in graphene, which displays an anomalous quantum Hall effect as a consequence of the valley degeneracy. For a sufficiently strong disorder that causes valley mixing, theoretical works have predicted Landau level splittings and even a transition to the conventional quantum Hall regime. The latter behavior has not been experimentally reported. To elucidate this issue, we address the problem by calculating the longitudinal and Hall resistances of graphene systems up to 10^5 atoms in a Hall bar geometry via the Landauer-Büttiker formalism. We consider both scalar and chiral disorder with different disorder correlation lengths. Finally, we discuss how intervalley/intravalley scatterings affect the QH transition states in graphene.

5:18PM H14.00015: Spin-relaxation in superconducting graphene*  DENIS KOCHAN (Presenter), JAROSLAV FABIAN, University of Regensburg — 2D materials in the proximity to a superconductor are expected to host a wide spectrum of different phenomena. In my talk I will focus on spin-relaxation in graphene proximitized by an s-wave superconductor. Adatom impurities can affect spin-relaxation via locally enhanced spin-orbit coupling (SOC) and local magnetic moments. I will discuss their impact on quasiparticle spin-relaxation with an attempt to disentangle contributions from the local SOC and local magnetic moments. Moreover, I will analyze the stability of the induced local magnetic moments and the emergence of Yu-Shiba-Rusinov (YSR) bound states in such proximity induced superconducting systems.

Session H15 DMP: 2D Materials (Semiconductors) -- Optical Properties II BCEC 154 - Hiroshi Idzuchi

*This research was supported by NSF under award number DMR-1753054 and Texas A&M High Performance Research Computing.

2:42PM H15.00002: Exciton-dynamics of molybdenum disulfide on gallium nitride  YUBA RAJ POUDEL (Presenter), SEETHARAAN SAIRAMAN, Physics Department, University of North Texas, ZACHARIAH HENNIGHAUSEN, SWASTIK KAR, Physics Department, Northeastern University, FRANCIS D’SOUZA, ARUP NEOGI, Physics Department, University of North Texas — Layered transition metal dichalcogenides (TMD) have generated significant research interest because of interesting optical properties that are strongly dependent on the substrate. The integration of two dimensional (2D) materials with the bulk semiconductors provides an attractive platform to enhance the device functionality. Of all the 2D/3D heterostructures, MoS$_2$/GaN structures are at the top because of strong lattice matching and direct gap structures of both semiconductors. The properties of the heterostructures are governed by the excitons, which are weakly bound in nitrides but are strongly localized in MoS$_2$. Here we present the exciton dynamics of single layer MoS$_2$ on GaN. We studied the non-equilibrium exciton-dynamics with pump-probe spectroscopy using a tunable laser as a pump and a supercontinuum white light probe. The transient absorption spectrum shows different excitonic states. We will discuss the evolution of these states at different delay times starting as early as 200 fs and the corresponding decay kinetics. Our study will be useful to understand the energy transfer as well as the charge transport across the junction in the heterostructure which is crucial to enhance the performance of the device.
2:54PM H15.00003: Influence of the electric field on the optical properties of bilayer graphene nanoribbons*

TRUONG VAN TRAN, SRMP, CEA Saclay, SRMP, CEA Saclay, Université Paris-Saclay, F-91191, Gif-sur-Yvette, France — Increasing attention has been paid to multilayer graphene, especially to bilayer graphene nanoribbons (BLGNRs)[1]. The interlayer interactions in BLGNRs result in a deformation of the electronic band structure with a change in the slope of the subbands. Recent studies show that the bandgap of BLG is widely tunable by external electric fields (EF) [2,3]. Here, the optical properties of BLGNRs under effects of EF are investigated by using a tight-binding model and the gradient approximation. The EF can induce the subband (anti)crossing, change the subband spacing, cause the oscillating bands, and distort the band-edge states as well. Our results demonstrate that the optical absorption spectra exhibit rich prominent peaks that mainly stem from the subbands. In addition, the number, spectral intensity, and energy of the absorption peaks are strongly dependent on the interlayer atomic interactions and the ribbon width. The dependence of the optical excitations on both the magnitude and direction of the EF is studied as well. This study could be validated by optical spectroscopy measurements. These results provide a view of the possibilities for applying future optoelectronic applications base on BLGNRs.

3:06PM H15.00004: Excitation Density-Dependent Exciton Transport in a h-BN Encapsulated WSe2 Monolayer*

ZIDONG LI ( Presenter), Department of Electrical and Computer Engineering, University of Michigan, DARWIN FERNANDO CORDOVILLA LEON, Applied Physics Program, University of Michigan, SUNG WOON JANG, PARAG BHASKAR DEOTARE, Department of Electrical and Computer Engineering, University of Michigan — We report an excitation density-dependent visualization of excitonic energy diffusion in a h-BN encapsulated WSe2monolayer. At low excitation densities, we observe a linear evolution of the mean-squared displacement of the exciton density with a diffusivity of 0.5 cm²/s and a mono-exponential decay (300ps) of time-resolved photoluminescence (TRPL). At high excitation densities, however, the TRPL splits into two regimes: an excitation density-dependent, short-lived regime (150ps to 80ps), and an excitation-independent, long-lived regime (300ps). This observation and the fact that the exciton density preserves its initially Gaussian profile suggest that the results are not due to exciton-exciton annihilation but due to the remaining density of unfilled trap states. We also observe an excitation density-dependent increase in exciton diffusivity in the short-lived regime that saturates at 3 cm²/s and eventually transitions into the long-lived regime with a diffusivity of 0.5 cm²/s. At the transition point, the exciton density corresponds to the trap density in the WSe2monolayer which was measured to be 5*10¹¹/cm².

*3:18PM H15.00005: Ultrafast carrier and structural dynamics of supported monolayer MoS2*

XING HE (Presenter), MAZHAR CHEBL, DING-SHYUE YANG, Chemistry, University of Houston — Two-dimensional materials, such as graphene and transition metal dichalcogenides, have been considered promising for novel (opto)electronic and energy applications due to their unique properties at the mono- to few-layer limit. A thorough understanding of their carrier dynamics and energy transport behavior is therefore needed. Here, we present ultrafast carrier and energy-transport dynamics observed in sapphire-supported monolayer MoS2 following photoexcitation, using femtosecond transient reflectivity and ultrafast electron diffraction (UED). In particular, both monolayer MoS2 and the sapphire substrate were probed by reflection UED, which allows direct monitoring of structural motions at the interface. It is determined that dissipation of the photoexcitation energy undergoes a few steps with their characteristic time constants: ultrafast carrier relaxation and recombination as well as carrier-phonon coupling in MoS2, energy transport from the monolayer to the substrate on a 10-ps time scale, and slower thermal diffusion in bulk sapphire. Temperature-dependent observations will also be discussed.

*We acknowledge the support from the R. A. Welch Foundation and Samsung Global Research Outreach Program and the partial support from a National Science Foundation CAREER Award.
3:30PM H15.00006: Optical absorption in 2D MoS2 monolayers conformally grown on 3D Si and SiO2 nanocone arrays
EUNAH KIM (Presenter), Physics, Ewha Womans University, JIN-WOO CHO, Applied Physics, Kyung Hee University, TRI NGUYEN, Physics and Energy Harvest Storage Research Center, University of Ulsan, TRANG THI THU NGUYEN, SEOKHYUN YOON, Physics, Ewha Womans University, SUN-KYUNG KIM, Applied Physics, Kyung Hee University, YONG SOO KIM, Physics and Energy Harvest Storage Research Center, University of Ulsan, DONGWOOK KIM, Physics, Ewha Womans University — We prepared 2D MoS2 monolayers conformally coated on Si and SiO2 nanocone (NC) arrays using metal organic chemical vapor deposition technique, and investigated the influences of the refractive indices of 3D NCs on the optical properties of 2D MoS2 monolayers. The height, bottom diameter, and the period of the hexagonal Si NC array were 460, 250, and 300 nm, respectively. The SiO2 NC array was prepared by thermal oxidation of the Si NC array. The photoluminescence and Raman intensities of the MoS2 monolayer on the SiO2 NC were higher than those on the Si NC, although the Si NC exhibited much lower optical reflectivity in the visible wavelength range compared with the SiO2 NC. Numerical calculations showed that the strongly confined light in the high refractive index Si NC prevented a large electric field formation at the NC surface. In contrast, the weak light confinement in the low refractive index SiO2 NC resulted in a large electric field intensity and enhanced absorption in the MoS2 monolayer on the SiO2 NC. This work demonstrates that the 2D MoS2 and 3D Si hybrid nanostructures can provide a useful means to realize high-performance optoelectronic devices.

3:42PM H15.00007: Photocurrent Measurement of Monolayer Transition Metal Dichalcogenides*
TIANMENG WANG (Presenter), ZHIPENG LI, Rensselaer Polytechnic Institute, ZHENGGUANG LU, National High Magnetic Field Laboratory, YUZE MENG, YANWEN CHEN, Rensselaer Polytechnic Institute, DMITRY SMIRNOV, National High Magnetic Field Laboratory, SUFEI SHI, Rensselaer Polytechnic Institute — Monolayer transition metal dichalcogenides (TMDs) exhibit unique excitonic physics due to the reduced screening and enhanced Coulomb interactions. The strong light matter interaction in monolayer TMDCs gives rise to large response of photocurrent which involves carrier extraction after the excitation of the exciton. Photocurrent measurement thus provides a unique tool to investigate the combined effects of optical absorption and gain mechanism, revealing the spatial electric field distribution and photocurrent generation mechanism. The monolayer TMDs based photodetector exhibits large signal to noise ratio and can be exploited for sensitive photon sensor. The photocurrent measurement can also read out the valley degree of freedom of monolayer TMDs, excited by light of certain helicity.

3:54PM H15.00008: Exciton Up-conversion in Transition Metal Dichalcogenide Monolayers
XAVIER MARIE (Presenter), BO HAN, CEDRIC ROBERT, INSA/CNRS, MICKAEL GLAZOV, LEONID GOLUB, Ioffe Institute, MARCO MANCA, SHIVANGI SHREE, EMMANUEL COURTADE, PIERRE RENUCCI, BERNHARD URBASZEK, THIERRY AMAND, INSA/CNRS, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS/Tsukuba — The optical properties of Transition Metal Dichalcogenide (TMD) monolayers are governed by robust excitons. We have systematically investigated the excited exciton states by photoluminescence up-conversion spectroscopy in high quality MoS2, MoSe2, MoTe2 and WSe2 monolayers (MLs) encapsulated in hBN [1]. The excitation laser is tuned into resonance with the A:1s exciton ground state transition, and we observe for all the investigated MLs clear emission of excited exciton states (A:2s, A:3s...) up to 450 meV above the laser energy. The optical transitions are further investigated by reflectivity, photoluminescence excitation, and resonant Raman scattering, confirming their origin as excited excitonic states. We interpret the efficient up-conversion process as the consequence of exciton-exciton interactions where one of the excitons is annihilated while the second exciton acquires large extra energy. This mechanism is expected to be quite weak because it should satisfy both energy and momentum conservation laws. However our model calculations suggest an efficient exciton-exciton (Auger) scattering mechanism specific to TMD monolayers involving an excited conduction band, thus generating high-energy excitons with small wave vectors.

4:06PM H15.00009: Valley Polarized Excitonic Complexes in Monolayer TMD alloy* YUZE MENG (Presenter), Nanjing University, TIANMENG WANG, ZHIPENG LI, Rensselaer Polytechnic Institute, YING QIN, Arizona State University, ZHEN LIAN, YANWEN CHEN, MICHAEL C LUCKING, KORY BEACH, Rensselaer Polytechnic Institute, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, SEFAATTIN TONGAY, Arizona State University, FENGQI SONG, Nanjing University, HUMBERTO TERRONES, SUFEI SHI, Rensselaer Polytechnic Institute — Monolayer transition metal dichalcogenides (TMDs) have superior optical properties. Particularly, Tungsten based TMDs are known for their excellent valley polarization due to the strong spin-orbit coupling. However, the optical bandgap is limited by these two materials, which hinders the valleytronics applications that rely on the resonant excitation. We explore the possibility to overcome this limitation through the monolayer alloy, WS2xSe2(1-x), which promises an atomically thin semiconductor with tunable bandgap. We find that the high-quality BN encapsulated monolayer alloy WS0.6Se1.4 inherits the superior optical properties of tungsten-based TMDs, including a trion splitting of ~ 6 meV and valley polarization as high as ~60%. In particular, we demonstrate the emerging interlayer electron-phonon coupling in the BN/WS0.6Se1.4/BN van der Waals heterostructure. This coupling can be sensitively tuned by electrostatic gating and renders the otherwise optically silent Raman modes visible.

4:18PM H15.00010: Ultrafast charge dynamics and photoluminescence in bilayer MoS2* NASEEM UD DIN (Presenter), VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Physics, University of Central Florida — In a recent experiment it was shown that despite having an indirect band gap, the dominating peak in the emission spectrum of bilayer MoS2 corresponds to direct transitions. [1] To understand this phenomenon, we have applied density-matrix based time-dependent density-functional theory to examine ultrafast charge dynamics and emissive properties of bilayer MoS2. In particular, we demonstrate that despite initial accumulation of excited charge at the valleys between the K and Γ points of the two-dimensional Brillouin zone, photoemission takes place through direct charge recombination at the K and K' points. Analysis of the phonon spectrum suggests that the main reason for the direct emission is phonon-assisted transfer of the excited electrons to the K and K' valleys. We also analyze the role of the spatial structure of the electron and hole excitations in the ultrafast charge dynamics and hence photoemission to find that d(Mo)-p(S) hybridized character of the holes facilitates inter-layer charge transfer. Our results thus reveal the importance of ultrafast charge dynamics in photoemissive properties of a few-layer transition-metal dichalcogenides.

4:30PM H15.00011: Polarisation switching and electrical control of interlayer excitons in two-dimensional van der Waals heterostructures ALBERTO CIARROCCHI (Presenter), DMITRII UNUCHEK, AHMET AVSAR, Ecole polytechnique federale de Lausanne, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, ANDRAS KIS, Ecole polytechnique federale de Lausanne — Interlayer excitons in van der Waals heterostructures of transition metal dichalcogenides are of great interest due to their fascinating spin-valley and moiré physics. These aspects could be implemented to realize next-generation photonic and valleytronic devices, as well as exploring new physical phenomena. However, the efficient manipulation of the exciton valley-state, a necessary requirement for valley information encoding, is still lacking. In this talk, we will demonstrate electrical control of interlayer excitons in a MoSe2/WSe2 heterostructure. Encapsulation of aligned monolayers with boron nitride allows to resolve two separate interlayer transitions with opposite helicities under circularly polarized excitation, either preserving or reversing the polarization of incoming light. By electrically modulating these resonances, we realize a polarization switch with tuneable emission intensity and wavelength in the near-infrared. By applying magnetic fields, we assign the origin of the effect to the moiré-induced brightening of forbidden optical transitions, as also predicted by recent theoretical works. The ability to control the polarization of interlayer excitons is a step forward towards the practical manipulation of the valley degree-of-freedom in device applications.
4:42PM H15.00012: Intrinsic multi-particle bound-state luminescence emission from high-quality monolayer tungsten diselenide*  JUN YAN (Presenter), SHAO-YU CHEN, THOMAS A GOLDSTEIN, Physics, University of Massachusetts - Amherst, ZHENGGUANG LU, DMITRY SMIRNOV, National High Magnetic Field Lab, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan — Monolayer WSe$_2$ is an interesting semiconductor that hosts versatile light emitting manybody states. While the bright exciton photoluminescence (PL) is ubiquitous, PL at higher energies are challenging to observe due to Kasha's rule, and PL at lower energies are often plagued by extrinsic peaks from trapped excitons. In this talk, I'll show that with our high-quality samples, excited Rydberg exciton PL up to the 4s exciton become visible, and in the lower energy window PL due to four-particle biexcitons and five-particle exciton-trions are resolved. In magnetic fields up to 31 Tesla, the Rydberg exciton energy displays increasing curvature against magnetic field strength from 1s to 4s, reflecting their increasingly larger diameter. The biexciton and the exciton-trion are found to be intervalley complexes composed of a dark exciton in one valley and a bright exciton / trion in the other valley. This spin-valley configuration gives rise to counter-intuitive inverted PL valley polarization as compared to the two-particle bright and dark excitons.

4:54PM H15.00013: Room-Temperature Valley Coherence in a Polaritonic System*  LIANGYU QIU (Presenter), CHITRALEEMA CHAKRABORTY, SAJAL DHARA, NICK VAMIVAKAS, University of Rochester — In the flourishing field of valleytronics, demand for coherently manipulating valley information at elevated temperature continues to escalate. Monolayer transition metal dichalcogenide, due to its strongly bonded excitons and degenerated valleys, nominates itself as a promising candidate for room temperature operation of valley degree of freedom (DOF). Through the hybridization of valley-resolved exciton and helicity-resolved photon mode, the valley DOF will be inherited by half-light, half-matter polaritons. Here, we demonstrate non-vanishing valley coherence of exciton-polaritons at room temperature in a cavity-embedded monolayer Tungsten Diselenide. The extra decay path through the exciton-cavity coupling, which is free of decoherence, is the key for intervalley phase correlation. These observations pave the way for room temperature valleytronic devices.

5:06PM H15.00014: Exciton behaviors at the metal-semiconductor interface*  JAYDEEP JOSHI (Presenter), George Mason University, SERGIY KRYLYUK, ALBERT DAVYDOV, Functional Nanostructured Materials Group, NIST, PATRICK VORA, George Mason University — The application of transition metal dichalcogenides in optoelectronics technology requires an understanding of how metal-semiconductor contacts impact exciton photophysics. In this study we explore changes in excitons at the interface of monolayer tungsten diselenide (1L-WSe$_2$) and a series of conventional metals. Low-temperature hyperspectral PL measurements reveal intriguing changes in exciton linewidth and energy on approach to the junction that persist over multiple microns. In particular, the neutral exciton experiences a blueshift as the interface between the metal and WSe$_2$ is approached, a phenomenon that persists at higher temperatures. These results are difficult to rectify as a charge doping effect since electrostatic gating of WSe$_2$ leads to insignificant shifts of the exciton. Lattice strain from the contact is also not responsible since a redshift would be expected. The precise mechanisms governing this effect therefore remain an open question but a critical one for the 2D community.

Valley-selective exciton bistability in a suspended monolayer semiconductor

HONGCHAO XIE (Presenter), Penn State & Cornell University, SHENGWEI JIANG, JIE SHAN, KIN FAI MAK, Cornell University — Monolayer transition metal dichalcogenide (TMD) semiconductors such as WSe$_2$, are direct band gap materials, which exhibit over 80% reflectance contrast at the fundamental exciton resonance. This extremely strong light-matter interaction can lead to optical nonlinearity or even bistability at high optical pump intensity. Furthermore, the valley degree of freedom (DOF) carries valley contrasting orbital magnetic moments, which enables K and K' valleys of the Brillouin zone exclusively coupled to the incident light with opposite helicity. Valley-selective exciton bistability can be achieved, in principle, by combining the above two properties of monolayer TMD semiconductors. In this work, we demonstrate robust bistable exciton resonance by continuous-wave (cw) optical excitation in a suspended WSe$_2$ sample. The detailed excitation wavelength and power dependence studies of the sample reflectance, as well as numerical simulation, quantitatively support a photothermal mechanism with internal feedback contributing to the observed excitonic bistability. The presence of external magnetic field further allows control of the sample reflectivity purely by varying the polarization of incident light.

Session H16 DMP: Computational Materials Design and Discovery -- Structure Prediction and Optimization

BCEC 155 - Ramamurthy Ramprasad, University of Connecticut

Solving Unknown Crystal Structures in a High-Throughput Manner*

SEAN GRIESEM (Presenter), LOGAN WARD, CHRISTOPHER WOLVERTON, Northwestern University — Databases of density functional theory (DFT) calculations, such as the Open Quantum Materials Database (OQMD), have paved the way for accelerated materials discovery. DFT requires a crystal structure as input; however, due to inherent challenges in solving a compound's structure from powder diffraction data alone, there are thousands of known compounds whose structures remain unsolved. Although structure solution methods involving DFT-based algorithmic optimization have been demonstrated, their computational cost limits their applicability. We present a more rapid DFT-based structure solution method in which we search the OQMD for structure types that match the cell geometry and stoichiometry of the compound, and evaluate them as possible solutions using DFT and match to diffraction pattern. As this approach is straightforward and inexpensive, we employed it in a high-throughput manner to solve hundreds of previously-undetermined structures from the Powder Diffraction File, including many new elpasolites, transition metal oxides, and mixed anion structures, as well as wide range of scarcely explored structure types.

*We acknowledge funding by the Center for Hierarchical Materials Design (CHiMaD), which is supported by U.S. Department of Commerce, NIST under Award No. 70NANB14H012.

Determining nanoparticle structures using FANTASTX

ISAAC MALSKY (Presenter), SPENCER T HILLS, FATIH SEN, MICHAEL STERNBERG, GRACE LU, ALPER KINACI, KENDRA LETCHWORTH-WEAVER, MARIA CHAN, Argonne National Laboratory — Determining the atomistic structures of nanoparticles is a fundamental problem. Their structures determine their functionality, and therefore their effectiveness in applications. Although there are both experimental and computational methods to determine these nanoscale structures, they both possess limitations. We develop FANTASTX (Fully Automated Nanoscale To Atomistic Structure from Theory and eXperiment) to overcome the limitations of either by combining both experimental and computational data. We demonstrate the effectiveness of FANTASTX by determining the structures of Au and IrO$_2$ nanoparticles from x-ray pair distribution function (PDF) data and density functional theory (DFT) calculations, using multi-objective optimization and a variety of canonical and grand canonical sampling algorithms.
2:54 PM H16.00003: Evolutionary Niching in the GAtor Genetic Algorithm for Molecular Crystal Structure Prediction
TIM C ROSE (Presenter), FARREN CURTIS, NOA MAROM, Carnegie Mellon University — The goal of molecular crystal structure prediction is to find all plausible polymorphs for a given molecule. This requires performing global optimization over a high dimensional search space. Genetic algorithms (GAs) perform global optimization by mimicking evolution. New structures are generated by breeding the fittest structures in the population. Typically, the fitness function is based on relative lattice energies, such that structures with lower energies have a higher probability of being selected for mating. GAs may be adapted to perform multi-modal optimization by using evolutionary niching methods that support the formation of several stable subpopulations and suppress the over-sampling of densely populated regions. Evolutionary niching is implemented in the GAtor molecular crystal structure prediction code by using machine learning to dynamically cluster the population by structural similarity. A cluster-based fitness function is constructed such that structures in less populated clusters have a higher probability of being selected for breeding. Using evolutionary niching increases the success rate of generating the experimental structure of 1,3-dibromo-2-chloro-5-fluorobenzene and additional low-energy structures with similar packing motifs.

3:06PM H16.00004: First-principles study on electrode – solid electrolyte interfaces in solid-state battery via efficient structure prediction method
BO GAO (Presenter), Center for Materials research by Information Integration (CMI2), Research and Services Division of Materials Data and Integrated System, National Institute for Materials Scie, RANDY JALEM, Center for Green Research on Energy and Environmental Materials & Global Research Center for Environment and Energy based on Nanomaterials Science (GREEN), National Institute, YANMING MA, State Key Laboratory of Superhard Materials, Jilin University, YOSHITAKA TATEYAMA, Center for Green Research on Energy and Environmental Materials & Global Research Center for Environment and Energy based on Nanomaterials Science (GREEN), National Institute — Understanding the origin of high interfacial resistances between electrodes and solid-electrolytes is crucial for commercial application of solid-state batteries (SSBs). [Chem. Mater. 26, 4248-4255] [ACS Appl. Mater. Interfaces 9, 286-292]. Here we utilized the CALYPSO structure prediction method [Physical Review B 82, 094116] to investigate the interface structures between LiCoO2 cathode and β-Li3PS4 sulfide electrolyte. About 20000 configurations are sampled to search the stable interface structures. The results show that the interfacial reaction layer is formed accompanied by the cation mixing and anion mixing. It is confirmed that the preferential Li depletion can occur at interface upon charging, even in very distorted region. Furthermore, CALYPSO interface structure prediction method can be applied to the solid-solid interface systems beyond the SSBs.

*This research has been supported by National Institute for Materials Science (NIMS) - “Materials research by Information Integration” Initiative (MI2I).

3:18PM H16.00005: An efficient algorithm for novel two-dimensional crystal structure prediction
KISUNG CHAE (Presenter), YOUNG-WOO SON, Korea Institute for Advanced Study — Two-dimensional (2D) materials are promising for their intriguing standalone properties and a number of combinatorial heterostructures. In this regard, crystal structure prediction (CSP) can enhance both material and property spaces significantly, accelerating innovative materials discovery. However, conventional approaches based on global optimization may be inefficient for 2D CSP due to enormously enhanced search space. Here, we will discuss an efficient algorithm for predicting novel 2D materials based on spatial symmetry of the atomic arrangements. We show the method was used to predict a number of novel 2D silicon crystals [1] and group IV and group VI compounds (namely, TXene) [2]. In addition, we will show that the method is efficient and transferable, and can be further applied to propose novel 2D materials.

3:30PM H16.00006: From Pentagonal Geometries to Two-Dimensional Materials
LEI LIU (Presenter), IMMANUELLA KANKAM, HOULONG ZHUANG, Arizona State University — Most of the most popular two-dimensional (2D) materials, such as semiconducting MoS2 and magnetic CrI3, adopt hexagonal structures. Inspired by the geometries of the existing 15 types of convex pentagons that can tessellate a plane without creating a gap or overlap, we combined these pentagonal geometries and density functional theory (DFT) calculations to predict novel 2D materials. We showed that this combination leads to a new direction in the field of 2D materials. In particular, we discovered a hidden pattern of pentagons called the Cairo tessellation in a group of bulk materials with the pyrite structure. We predicted single-layer PtP2 to exhibit a completely planar, pentagonal structure and a direct band gap. Our work shows that encoding quantum mechanics into pentagonal geometries and with the help of DFT calculations open up a novel route for accelerating discovery of new 2D materials.

**3:42PM H16.00007: Dominant in-plane cleavage direction of CrPS₄**

MINWOONG JOE (Presenter), JINHWAN LEE, CHANGGU LEE, School of Mechanical Engineering, Sungkyunkwan University — In-plane cleavage directions of two dimensional (2D) crystals are displayed and often well-defined in their flakes exfoliated by the mechanical exfoliation method. Here, we investigate the correlation between dominant in-plane cleavage direction and elastic properties in different directions. CrPS₄ flakes show a preferential in-plane cleavage direction of 67.5°, corresponding to <110> direction. To explain it, we calculated the directional dependence of Young's modulus and fracture energy using first-principles density functional theory calculations. We found that fracture energy is directly relevant to the in-plane cleavage direction of CrPS₄. Our study can provide a facile approach to figure out the direction of 2D crystals without complex characterization process, which is valuable for material processing of 2D materials.

**3:54PM H16.00008: Conformations, electronic, and mechanical properties of monolayer diamene**

TENGFEI CAO (Presenter), ANGELO BONGIORNO, chemistry, college of staten island — Experiments show that diamond-like (diamene) films can be obtained from multilayer graphene, either by compression or surface passivation. Based on DFT calculations, we predict that diamene assumes various conformations, requiring either one or both surfaces being passivated. Conformations with surfaces fully passivated exhibit insulating properties, whereas diamene films presenting a clean surface show variable electronic properties, from insulating to semiconducting and metallic. Interestingly, regardless being monolayers or having a clean surface, all conformers of diamene exhibit elastic moduli comparable to those of the corresponding sp³ bulk phase, retaining Young's moduli along their transverse direction that are between 50% and 80% of bulk phases. Moreover we suggest that diamene film can be obtained from multilayer graphene by means of compression and/or wear without the need of chemical passivants, and the energies and pressures involved in the transformation depend critically on the structure and chemistry of the interface with the substrate.

*We acknowledge the support of the NSF grant CMMI-1436375. We also acknowledge support from the CUNY High Performance Computing Center and the Extreme Science and Engineering Discovery Environment (XSEDE).

**4:06PM H16.00009: Inverse Design for Self-assembly of Materials with Targeted Mechanical Properties**

PENGJI ZHOU (Presenter), Department of Chemical Engineering, University of Michigan, Ann Arbor, MI, USA, JAMES C PROCTOR, Department of Materials Science & Engineering, University of Michigan, Ann Arbor, MI, USA, JULIA DSHEMUCHADSE, Department of Chemical Engineering, University of Michigan, Ann Arbor, MI, USA, GREG VAN ANDERS, Department of Physics, Engineering Physics, and Astronomy, Queen's University, Kingston, ON, Canada, SHARON GLOTZER, Department of Chemical Engineering, University of Michigan, Ann Arbor, MI, USA — Inverse design is a promising yet challenging approach to develop new materials. To create materials with new properties, several inverse approaches have been proposed to design building blocks for target structures. However, the relationship between a material's structure and its properties is often unknown for novel materials. This calls for the development of inverse approaches that can directly target materials properties without having to target structures as the intermediary. Here, we present an inverse-design approach for particles with interacting potentials to self-assemble crystal structures with targeted mechanical properties. We do so through a novel molecular dynamics implementation of the 'digital alchemy' inverse-design approach. We give examples in which model particles interact via isotropic pair potentials that are designed to yield structures with a desired bulk modulus. Our results demonstrate that we can directly target mechanical properties via inverse materials design, and that our algorithm can be generalized to other properties.
Effect of alloying concentration on the mechanical properties of $B_2Cr_{1-x}Mo_x$* VIVIANA DOVALE-FARELO (Presenter), PEDRAM TAVADZE, ALDO H ROMERO, West Virginia University —

Transition metal borides as $Mo_2FeB_2$, $Mo_2NiB_2$, and $WCoB$ have recently caught attention because they exhibit excellent mechanical properties for wear resistant applications. On the other hand, it is widely known that the addition of Cr and/or Mo as alloying elements improves the mechanical properties and corrosion resistance of some alloys. In this investigation, first principles calculations were performed to study the structural properties of the ternary $B_2Cr_{1-x}Mo_x$ within DFT formalism. The $B_2Cr_{1-x}Mo_x$ compounds were studied for a concentration $x$ of 25%, 50%, and 75%. The Minima Hopping method was used to search over the stable and metastable structures for each concentration. $B_2Cr_{1-x}Mo_x$ structures were optimized to obtain the lattice parameters, total energies and formation enthalpies in each case. The elastic constants were calculated to verify the mechanical stability of the compounds, as well as the bulk modulus, shear modulus, Young's modulus, and Poisson's Ratio. The mechanical strength of the ternary was maximized as a function of the alloying concentration. Free energies were also calculated to study the thermal stability of the found crystal phases.

Amorphous materials modeling and classification for low mechanical loss mirror coatings using machine learning methods* JUN JIANG (Presenter), MAHER YAZBACK, ALEC MISHKIN, Department of Physics and Quantum Theory Project, University of Florida, KIRAN PRASAI, RICCARDO BASSIRI, MARTIN FEJER, E. L. Ginzton Laboratory, Stanford, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida — Instead of the well-defined atomic structures of crystals, amorphous materials are more complicated due to intrinsic randomness. Modeling and predicting the properties of amorphous materials (amorphous $Ta_2O_5$, doped $Ta_2O_5$) are important to understand experimental results and to find lower mechanical loss mirror coatings to reduce thermal noise in the next generation of LIGO laser interferometer gravitational wave detectors. In our work, thousands of atomic models of amorphous materials are generated using reverse Monte Carlo (RMC) and molecular dynamics (MD) simulations based on experimental data. Classifying them into different groups according to their properties and features with the help of machine learning, enables us to understand the differences between these models and use the information from these structures to find the best materials for low mechanical loss mirror coating.

*NSF/PHY 1707870 and NSF/PHY 1404110. Thanks Ximing Wang for the discussion and the help with the machine learning method.

Discovery of Novel Layered Heteroanionic Materials from Pauling's Rules* JAYE HARADA (Presenter), KENNETH POEPPELMIEIER, JAMES M RONDINELLI, Northwestern University — Heteroanionic materials, such as oxyfluorides and oxynitrides, display a myriad of functional properties derived from the presence of two anions of difference size, charge, and electronegativity. To aid synthetic efforts focused on compound discovery, we propose a workflow that can be used to predict new and stable $n = 1$ Ruddlesden-Popper type heteroanionic materials using principles from inorganic chemistry and supported with density functional theory calculations. We show that a simple structural optimization scheme based on Pauling's rules is an effective method to evaluate the stability of novel heteroanionic materials and predict new stable oxyfluorides. Last, we describe some of the properties exhibited by the newly identified compounds.

*This work is supported by the National Science Foundation Grant No. DMR 1454688.
Pressure-induced dimerization of the hyperkagome framework in Na$_3$Ir$_3$O$_8$

ERNESTO SANDOVAL (Presenter), ALEKSEY KOLMOGOROV, Department of Physics, Applied Physics and Astronomy, Binghamton University, FEI SUN, Center for High Pressure Science and Technology Advanced Research (HPSTAR), JOHN MITCHELL, Materials Science Division, Argonne National Laboratory, DANIEL HASKEL, Advanced Photon Source, Argonne National Laboratory — The ambient-pressure cubic Na$_3$Ir$_3$O$_8$ phase has been observed to undergo a symmetry-breaking transformation around 10 GPa [1]. Structure determination proved to be a challenge due to the large system size and the low symmetry of the new ground state. We performed extensive ab initio evolutionary searches [2] without any input from the high-pressure experiment and identified a complex monoclinic phase with 56 atoms per unit cell that agreed well with the collected XRD patterns. According to our ab initio calculations, the monoclinic phase features a dimerized Ir hyperkagome framework and a lower bulk modulus compared to that of the starting cubic phase. Study of the compound's electronic structure revealed significant convergence problems in the DFT+U approach.

Numerical Studies of Thermal Conductivity in Functionalized Carbon Nanotubes

ALEXANDER KERR (Presenter), KIERAN MULLEN, DANIEL T. GLATZHOFER, LIANGLIANG HUANG, University of Oklahoma — Although carbon nanotubes (CNTs) possess a large thermal conductivity, when they are incorporated in a polymer matrix their severe boundary resistance makes them ineffective at improving the thermal conductivity of the resulting composite. This resistance at CNT interfaces can be altered via chemical functionalization using mixed molecular chains to match the thermal impedance between CNTs and their environment. We explore the vast chemical space of possible configurations through meta-heuristics such as genetic algorithms and present candidate structures with optimal thermal conductance. We make comparisons of these CNT systems to certain harmonic lattices and look for important correlations among molecule parameters that contribute to the thermal conductivity, as is done in machine learning. We will summarize these results in general design rules for improving the thermal conductivity across molecular interfaces.

*This work was supported by NSF grant DMR-1310407.

On the Superconductivity in Ag-Au Alloys

DASARI PRASAD (Presenter), SURENDER SINGH, Department of Chemistry, Indian Institute of Technology Kanpur — In light of the recent reports on the evidence [1] and absence [2] of room temperature superconductivity at 1 atm pressure in Ag-Au nanostructured materials synthesized using colloidal and pulsed-laser deposition techniques, respectively, we have extensively investigated and predicted Ag-Au bulk and two-dimensional alloys for superconductivity. The structures are predicted by means of data-mining and evolutionary algorithms. The energies and forces are calculated at DFT-PBE and electron-phonon matrix elements are solved at DFPT. Superconducting transition temperatures are estimated within the BCS-like formalism. In our calculations, it is found that among all the stable and metastable structures resulted, only a few are found to be superconductors with Tc not more than one mK. No significant improvements noted in Tc when electrons and holes are externally injected to the bands near Fermi energy [3].

*D.L.V.K.P. acknowledges financial support through Initiation Grant No. IITK/CHM/20130116. S.S. thanks the CSIR, India for a SRF fellowship. We acknowledge CC/CHM-IITK, and RNJH HPC facilities.

Session H17 DCOMP: Matter in Extreme Environments: Iron in Planetary Interiors

BCEC 156A

- Xiaoyu Wang - Tag(s): Focus
2:30PM H17.00001: Chemical equilibrium in the Earth’s core* [Invited] DARIO ALFE (Presenter), MONICA POZZO, University College London, CHRIS DAVIES, DAVID GUBBINS, University of Leeds — The core of the Earth is a source of thermal energy for the mantle, helping to drive convection, plate tectonics and volcanism. It is mainly formed by iron, but is also contains light impurities. The exact chemical inventory of the core is unknown, but it is believed that oxygen may be present in relatively large quantities, as it is a major element in the mantle. Freezing of the inner core causes oxygen to be released in the liquid, which is thought to be the main form of energy driving core convection at the present day, responsible for the generation of the magnetic field. One of the fundamental questions is therefore how oxygen entered the core in the first place.

Using first principles calculations of chemical potentials we put contraints on the equilibrium concentrations of oxygen between liquid iron and a liquid silicate mixture, representative of long lived magma ocean (MO) at the base of the mantle. We show that the presence of a large fraction of oxygen in the core can be explained by a relatively large thermodynamic advantage of partitioning from the MO into the liquid core.

We also computed chemical potentials in solid ferropericlase, thought to be one of the main constituents of the Earth’s mantle, and found that the current oxygen concentration in the core is lower than its equilibrium concentration, suggesting that the mantle may be continually pumping oxygen into the core, even at the present day. This has important consequences for our understanding of convection in the core, supporting the idea of the presence of a stratified, oxygen rich, layer at the top of the core, which may have been observed in the seismological record.

3:06PM H17.00002: Transport properties of iron under Earth’s core conditions* RONALD COHEN (Presenter), Geophysical Laboratory, Carnegie Institution for Science, RONALD COHEN, Earth and Environmental Sciences, LMU Munich — Transport properties of iron in Earth’s core control the dynamo that generates Earth’s magnetic field. If the thermal conductivity is high, heat transport is through conduction, and if low by convection. Conventional dynamo theory considered thermal convection primarily to drive the dynamo, but it is also possible to sustain a dynamo through chemical segregation, such as growth of Earth’s inner core. We computed the electrical resistivity and thermal conductivity of solid and liquid iron under core conditions, including both electron-ion (electron-phonon) and electron-electron scattering (Xu et al., PRL 121 096601, 2018). We have included saturation effects in different approximations. We find somewhat higher resistivity than recent resistivity measurements and somewhat higher thermal conductivity than recent thermal conductivity measurements. Thermal conductivities are lower than would be obtained using an ideal Wiedemann-Franz Lorenz factor. Electron-electron scattering also decreases the thermal conductivity. Our results are consistent with a convection driven dynamo.

3:18PM H17.00003: Ab initio study of iron isotope fractionation during Earth’s core-mantle segregation* TIAN QIN (Presenter), Department of Earth Sciences, University of Minnesota, RENATA WENTZCOVITCH, Department of Applied Physics and Applied Mathematics, Columbia University, MICHEL MARCONDES, Lamont-Doherty Earth Observatory, Columbia University, GAURAV SHUKLA, Physics, Bennett University — Recent studies have revealed that the iron isotope composition of mid-ocean ridge basalts (MORBs) is +0.1‰ richer in heavy Fe isotope (56Fe) relative to primitive chondritic meteorites, while basalts from Mars and Vesta have similar Fe isotopic composition as these meteorites. Here we investigate the hypothesis that iron isotope fractionation may have occurred during core formation on Earth. In particular, we compute Fe isotope fractionation factors among the lower mantle phases, bridgmanite (Bdg) and ferropericlase (Fp), and the metal phase at relevant pressure-temperature conditions. We pay particular attention to the effect of the spin crossover in Fe in Bdg and Fp on these fractionation factors. In addition, Fe in Bdg can occupy more than one crystalline site and can be in more than one valence state. In the metal phase, we consider variable amounts of Ni, the other metallic element expected to alloy with Fe in the core. Considering all these possible states of Fe in the silicate, oxide, and metallic phase, we show that the spin crossover in Fe, which does not occur in Mars or Vesta, may have played an important role in the Fe isotope fractionation during core-mantle segregation in the Earth.

*NSF grant EAR-1503084
4:18PM H17.00008: Viscosity of the Inner Core*  ANATOLY BELONOSHKO (Presenter), Royal Institute of Technology, Sweden, JIE FU, Department of Physics, Ningbo University, China, TARAS BRYK, Institute of Condensed Matter Physics, Ukraine, SERGUEI I SIMAK, Department of Physics, Linköping University, Sweden, MAURIZIO MATTESINI, Department of Earth’s Physics and Astrophysics, Complutense University of Madrid — The Earth solid inner core (IC), composed mostly by iron, is a highly attenuating medium. This property of the core is at odds with the widely accepted paradigm of the hexagonal close-packed (hcp) phase stability under the inner core conditions, because sound waves propagate through the hcp iron without energy dissipation. We show by first-principles molecular dynamics that the body-centered cubic (bcc) phase of iron, recently demonstrated to be thermodynamically stable under the IC conditions, is considerably less elastic than the hcp phase. Being a crystalline phase, the bcc iron possesses the viscosity close to that of a liquid iron. The attenuation of the inner core is due to the unique diffusion characteristic of the bcc phase. The liquid-like nature of the bcc phase at extreme pressures and temperatures allow to resolve a number of controversies and explain enigmatic features of the Core.

4:30PM H17.00009: Exploring Thermal Conductivity of h.c.p. Iron (ε-Fe) at the Earth’s Core Conditions from Direct ab initio Molecular Dynamics Simulations  SHENG-YING YUE, Department of Mechanical Engineering, University of California Santa Barbara, MING HU (Presenter), Department of Mechanical Engineering, University of South Carolina — The exact value of electronic thermal conductivity ($\kappa_{\text{el}}$) of ε-Fe under the extreme pressure and temperature conditions still remains poorly known both experimentally and theoretically. Previous experiments reported quite scattered results of $\kappa_{\text{el}}$ of ε-Fe, which could differ by several folders. By utilizing our newly developed methodology based on direct non-equilibrium ab initio molecular dynamics (NEAIMD) simulation coupled with the concept of electrostatic potential oscillation (EPO), we evaluate the electronic thermal conductivity of iron in h.c.p phase without any artificial manipulation of computational parameters. Unlike the previous theoretical studies, our methodology inherently includes all possible interactions and scattering of electrons under extreme conditions. The results of electronic thermal conductivity of iron in the Earth’s core are consistent with some previous theoretical and experimental results. More importantly, our study provides a totally new physical picture of heat transfer process in iron at Earth’s core conditions from the electrostatic potential oscillation point of view. This simulation methodology offers a new approach to study thermal transport property of pure metals in planet’s cores with different temperature and pressures.

4:42PM H17.00010: Electrical conductivity of silicate liquids at extreme conditions and planetary dynamos*  LARS STIXRUDE (Presenter), Earth, Planetary, and Space Sciences, University of California, Los Angeles, ROBERTO SCIPIONI, Earth Sciences, University College London, MICHAEL PAUL DESJARLAIS, Pulsed Power Sciences Center, Sandia National Laboratory, EERO HOLMSTRÖM, Earth Sciences, University College London, A. S. FOSTER, Applied Physics, Aalto University — We find that Earth’s earliest magnetic field may have been produced in a deep magma ocean, and that silicate dynamos may exist in super-Earth exoplanets as well. Our conclusions are based on ab initio molecular dynamics simulations and Kubo-Greenwood computations of the electrical conductivity. These show that silicate liquids are semi-metallic at the extreme pressure and temperature conditions characteristic of planetary interiors with conductivity exceeding 10,000 S/m. In silica, the electrical conductivity shows a remarkable non-monotonic dependence on pressure that reveals connections to the underlying atomic structure, and highlights broken charge ordering as a novel compression mechanism. We compare the behavior of silica liquid with that of (Mg,Fe)O liquid and a multi-component composition (MgO-FeO-CaO-Al2O3-Na2O-SiO2) representative of the bulk silicate Earth.

Structure Evolutions of Iron Compounds under Pressure Show an Unusual Chemistry in Deep Earth

MAOSHENG MIAO (Presenter), California State University, Northridge, XIAOLI WANG, Institute of Condensed Matter Physics, Linyi University, XIAOLEI FENG, Center for High Pressure Science and Technology Advanced Research (HPSTAR), JIANFU LI, Institute of Condensed Matter Physics, Linyi University, MATTHEW JACKSON, FRANK SPERA, Department of Earth Science, University of California Santa Barbara, SIMON REDFERN, Department of Earth Sciences, University of Cambridge — The terrestrial abundance of many elements, including heavy halogens Cl, Br, and I is approximately one order of magnitude lower than that predicted from their volatilities. One possible explanation is that these heavy elements are sequestered into the Earth’s core. This suggestion is supported by recent computational studies showing that heavy p elements may combine with iron at high pressure. Using first-principles electronic structure calculations and the automatic crystal structure search method based on particle swarm optimization algorithm, we also studied the stability and structures of Fe-halogen compounds under high pressure up to 350 GPa. Our calculations show that the compounds with higher Fe composition become more stable with increasing pressure and the reaction propensity of Fe might become opposite to ambient pressure. Our detailed electronic structure analysis reveals that the charge capture by Fe 3d orbitals and the reduction of the lone pair electrons in halogens are the major factors that govern the structure evolution under increasing pressure. Our results suggest that the distribution of many p-block elements in the Earth core might be much higher than we usually believe.

Thermal equation of state of ε-Fe at exoplanetary interior conditions

JINGYI ZHUANG (Presenter), HONGJIN WANG, QI ZHANG, KANCHAN SARKAR, RENATA WENTZCOVITCH, Department of Applied Physics and Applied Mathematics, Columbia University in the City of New York, 500 W. 120th St., Mudd 200, MC 4701 New York, NY 10027, USA — The equation of state (EoS) of hcp-iron (ε-Fe) is essential for investigating physical properties of planetary cores. Despite its importance to geophysics and planetary astronomy, experimental investigations of ε-Fe at relevant conditions are still challenging. Therefore, ab initio calculations can contribute decisively to elucidating the equation of state (EoS) and other properties of this system. In this study, we present ab initio results of the properties of ε-Fe covering a wide range of pressures (0 - 1,400 GPa) and temperatures (300 - 8,000 K). Two new techniques are employed: i) a PAW dataset for iron specially designed for very high-pressure calculations [1], and ii) a free energy calculation approach based on the phonon gas model compatible with temperature dependent phonon frequencies, here produced by thermal electronic excitations. These new features of the calculation produce an isentropic EoS in good agreement with data from recent ramp compression experiments up to 1,400 GPa conducted at the National Ignition Facility (NIF)[2].

Vibrational spectrum throughout the iron spin crossover in ferropericlase (Mg_{1-x}Fe_xO)

MICHEL MARCONDES (Presenter), Department of Earth and Environmental Sciences, Columbia University, FAWEI ZHENG, Institute of Applied Physics and Computational Mathematics, RENATA WENTZCOVITCH, Department of Applied Physics and Applied Mathematics, Columbia University — Ferropericlase (Fp), (Mg_{1-x}Fe_x)O, is the second most abundant phase in the Earth’s lower mantle. At relevant pressure-temperature conditions, iron in Fp undergoes a high spin (HS), S=2, to low spin (LS), S=0, state change. The nature of this phenomenon is quite well understood now, but there are still basic questions regarding the structural stability and the existence of soft phonon modes during this iron state change. General theories exist to explain the volume reduction, the large elastic anomalies, and the broad nature of this HS-LS crossover. These theories make extensive use of the quasi-harmonic approximation (QHA), therefore, dynamical and structural stability are essential to the validity of these theories. Here, we investigate the vibrational spectrum of Fp throughout this spin crossover using ab initio DFT+Usc calculations. We address vibrational modes associated with isolated and (2nd) nearest neighbor Fe atoms undergoing the HS-LS state change. As expected, acoustic modes of this solid solution reproduce the well-known elastic anomalies, but optical modes display unusual features. We show that there are no soft phonon modes across this HS-LS crossover and Fp is dynamically stable at all mantle pressures and relevant iron concentrations.

Session H18 DCOMP DCMP DAMOP: Machine Learning Quantum States III

BCEC 156B - Juan Carrasquilla, Vector Institute - Tag(s): Focus
2:30PM H18.00001: Hybrid neural network - quantum simulator [Invited ] GIACOMO TORLAI (Presenter), Center for Computational Quantum Physics, Flatiron Institute — The recent advances in qubit manufacturing and coherent control of synthetic quantum matter are leading to a new generation of intermediate-scale quantum hardware, with promising progress towards scalable quantum simulation of strongly-correlated systems. In order to enhance the capabilities of this class of quantum devices, some of the more arduous experimental tasks can be off-loaded to classical algorithms running on conventional computers. In particular, generative neural networks trained on measurement data can be implemented to obtain an approximate reconstruction of the experimental wavefunction, allowing specialized measurements which are either costly or not accessible in the experimental setup. I will present this classical-quantum hybridization for quantum hardware based on trapped ultra-cold atoms and superconducting qubits.

3:06PM H18.00002: Reinforcement Learning Decoders for Fault-Tolerant Quantum Computation* RYAN SWEKE, MARKUS KESSELRING, Dahlem Center for Complex Quantum Systems, Freie Universitaet Berlin, EVERT VAN NIEUWENBURG (Presenter), Caltech, JENS EISERT, Dahlem Center for Complex Quantum Systems, Freie Universitaet Berlin — Topological error correcting codes, and particularly the surface code, provide a promising and feasible roadmap towards large-scale fault-tolerant quantum computation. Obtaining fast and flexible decoding algorithms for these codes, within the experimentally relevant context of faulty syndrome measurements, is therefore an important milestone. The problem of decoding such codes, in the full fault-tolerant setting, can be naturally reformulated as a process of repeated interactions between a decoding agent and a code environment. Reinforcement learning can then be used to obtain such a decoding agent, and can successfully learn to decode in the fault-tolerant setting.

*This research was supported by the Swiss National Science Foundation through grant P2EZP2-172185, the DFG (CRC 183, EI 519/14-1, and EI 519/7-1), the ERC (TAQ), the Templeton Foundation, and the BMBF (Q.com). This work has also received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 817482 (PASQUANS).

3:18PM H18.00003: The recoverable quantum information: A smart reward for reinforcement learning of quantum error correction THOMAS FOESEL (Presenter), PETRU TIGHINEANU, Max Planck Institute for the Science of Light, TALITHA WEISS, IQOQI, University of Innsbruck, FLORIAN MARQUARDT, Max Planck Institute for the Science of Light — Quantum information can be encoded in a complex manner in entangled multi-qubit states. But how well is this information preserved, given the dissipative time evolution of a system? In order to address this question, we have developed a new quantity, which we call the recoverable quantum information.

Beyond the possibility to judge how well existing techniques perform, it is particularly useful for the autonomous discovery of new quantum error correction strategies, by using it as an immediate reward scheme for a reinforcement learning approach as demonstrated in [1]. The recoverable quantum information is applicable generically, i.e. independent of the concrete hardware platform, noise model, etc. In this talk, this quantity will be introduced and motivated, an intuitive interpretation is given, it is shown how it evolves in some exemplary systems, and I will sketch how it can be computed numerically.

3:30PM H18.00004: Quantum error correction for the Toric code using Deep reinforcement learning PHILIP ANDREASSON, SIMON LILJESTRAND, JOEL JOHANSSON, MATS GRANATH (Presenter), University of Gothenburg — We implement a quantum error correction algorithm for the Toric code using Deep reinforcement learning. An action-value Q-function encodes the discounted value of moving a defect to a neighboring site on the square grid (the action) depending on the full set of defects on the torus (the syndrome or state). The Q-function is represented by a deep convolutional neural network. Using the translational invariance on the torus allows for viewing each defect from a central perspective which crucially simplifies the Q-function representation independently of the number of defect pairs.

The training is done using experience replay, where data from the algorithm being played out is stored and used for batch upgrade of the Q-network.

Performance is close to that achieved by the Minimum Weight Perfect Matching algorithm for moderate system sizes and for the uncorrelated noise model.
3:42PM H18.00005: Restricted Boltzmann Machines and Matrix Product States of 1D Translational Invariant Stabilizer Codes*  
YUNQIN ZHENG (Presenter), HUAN HE, Princeton University, NICOLAS REGNAULT, Laboratoire Pierre Aigrain, Ecole normale superieure, ANDREI B BERNEVIG, Princeton University — We discuss the relations between the restricted Boltzmann machine (RBM) states and the matrix product states (MPS) for the ground states of 1D translational invariant stabilizer codes. A generic translational invariant and finitely connected RBM state can be expressed as an MPS, and the matrices of the resulting MPS are of rank 1. We dub such an MPS as an RBM-MPS. This provides a necessary condition for exactly realizing a quantum state as an RBM state, if the quantum state can be written as an MPS. We mostly focus on generic 1D stabilizer codes having a non-degenerate ground state with periodic boundary condition. We obtain an expression for the lower bound of their MPS bond dimension, and also an upper bound for the rank of their MPS matrices. In terms of RBM, we provide an algorithm to derive the RBM for the cocycle Hamiltonians whose MPS matrices are proved to be of rank 1. Moreover, the RBM-MPS produced by our algorithm has the minimal bond dimension. A family of examples is provided to explain the algorithm.

3:54PM H18.00006: Neural loop algorithm for square ice model*  
YING-JER KAO (Presenter), KAI-WEN ZHAO, WEN-HAN KAO, National Taiwan University — We discuss how to apply a reinforcement learning framework on the square spin ice model. Spin ice is a frustrated magnetic system with a strong topological constraint on the low-energy configurations called the ice rule. The conventional single spin-flip Monte Carlo update breaks this constraint. We exploit a reinforcement learning method that parameterizes the transition operator with neural networks. By extending the Markov chain to a Markov decision process, the algorithm can adaptively search for a global update policy through its interactions with the physical model. We find that the global loop update emerges without the explicit knowledge of the ice rule. This method might serve a general framework to search for efficient update policies in other constrained systems.

4:06PM H18.00007: Variational optimization in the AI era: supervised wave-function optimization and computational graph states.*  
DMITRII KOCHKOV (Presenter), BRYAN CLARK, Physics, University of Illinois at Urbana-Champaign — An important approach to the quantum many-body problem is to write down a compact variational ansatz which represents the target quantum state. The success of a particular model depends on its ability to capture the structure of the state and optimize all variational parameters. We introduce a machine learning inspired computational framework that works with wave-functions represented as differentiable computational graphs and develop a novel optimization algorithm Supervised Wave-function Optimization, that allows for effective optimization of such models. We present results on several architectures showing the efficiency of our approach.

4:18PM H18.00008: Generalized Transfer Matrix States from Artificial Neural Networks  
LORENZO PASTORI (Presenter), Institute of Theoretical Physics, TU Dresden, RAPHAEL KAUBRUEGGER, Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences, JAN CARL BUDICH, Institute of Theoretical Physics, TU Dresden — We propose and investigate a new family of quantum states, coined generalized transfer matrix states (GTMS), which bridges between tensor network states and states derived from artificial neural networks (ANNs). In particular, we show by means of a constructive embedding that the class of GTMS contains generic matrix product states while at the same time being capable of capturing more long-ranged quantum correlations that go beyond the area-law entanglement properties of tensor networks. While generic deep ANNs are hard to contract, meaning that the corresponding state amplitude can not be exactly evaluated, the GTMS network is shown to be analytically contractible using transfer matrix methods. With numerical simulations, we demonstrate how the GTMS network learns random matrix product states in a supervised learning scheme, and how augmenting the network by long-ranged couplings leads to the onset of volume-law entanglement scaling. We argue that this capability of capturing long-range quantum correlations makes GTMS a promising candidate for the study of critical and dynamical quantum many-body systems.
4:30PM H18.00009: Construction of Hamiltonians by supervised learning of energy spectra* HIROYUKI FUJITA, YUYA NAKAGAWA, Institute for Solid State Physics, University of Tokyo, SHO SUGIURA (Presenter), Physics, Harvard University, MASAKI OSHIKAWA, Institute for Solid State Physics, University of Tokyo — Handling the large number of degrees of freedom with proper approximations, namely the construction of the effective Hamiltonian is at the heart of the (condensed matter) physics. Here we propose a simple scheme of constructing Hamiltonians from a given energy spectrum [1]. The sparse nature of the physical Hamiltonians allows us to formulate this as a solvable supervised learning problem. Taking a simple model of correlated electron systems, we demonstrate the data-driven construction of its low-energy effective model. We present potential applications for the construction of entanglement Hamiltonians and materials discovery through the construction of parent Hamiltonians from effective models of topological matters. O. is supported in part by JSPS KAKENHI Grant No. 16K05469.

4:42PM H18.00010: Backflow Transformations via Neural Networks for Quantum Many-Body Wave-Functions* DI LUO (Presenter), BRYAN CLARK, University of Illinois at Urbana-Champaign — Obtaining an accurate ground state wave function is one of the great challenges in the quantum many-body problem. In this paper, we propose a new class of wave functions, neural network backflow (NNB). The backflow approach, pioneered originally by Feynman, adds correlation to a mean-field ground state by transforming the single-particle orbitals in a configuration-dependent way. NNB uses a feed-forward neural network to learn the optimal transformation via variational Monte Carlo. NNB directly dresses a mean-field state, can be systematically improved and directly alters the sign structure of the wave-function. It generalizes the standard backflow[1] which we show how to explicitly represent as a NNB. We benchmark the NNB on a Hubbard model at intermediate doping finding that it significantly decreases the relative error, restores the symmetry of both observables and single-particle orbitals, and decreases the double-occupancy density.

4:54PM H18.00011: Contrasting the Building Blocks of Grain Boundaries using Local vs. Multi-Scale Universal Descriptors* DEREK HENSLEY (Presenter), CONRAD W ROSEN BROCK, ANDREW H NGUYEN, GUS HART, ERIC HOMER, Brigham Young University — The behavior and properties of Grain Boundary (GB) Systems arise from a myriad of atomistic interactions. Is it possible to describe the properties of any GB in the system using knowledge of only a few? If so, which GBs have these essential, atomistic “building blocks” from which all other GB properties can be predicted? Previously, a universal similarity metric for GBs based on the Smooth Overlap of Atomic Positions (SOAP) descriptor was shown to effectively discover the underlying physics of GBs and find these atomistic building blocks. We present another universal GB representation using a multi-scale, scattering transform that also discovers GB building blocks. We contrast the building blocks discovered by SOAP with those of scattering transform to show the merits of local vs. multi-scale universal descriptors in describing the physics of GB.

Session H19 DCOMP DCMP: Precision Many Body Physics VI BCEC 156C - Shiwei Zhang - Tag(s): Focus
2:30PM H19.00001: Precision spectral densities in correlated systems* [Invited] KAREN HALLBERG (Presenter), YURIEL NÚÑEZ FERNÁNDEZ, Condensed Matter Theory, Centro Atómico Bariloche and Instituto Balseiro, CNEA, CONICET — We develop an efficient numerical method to calculate spectral densities of complex impurities based on the Density Matrix Renormalization Group (DMRG) and use it as the impurity solver of the Dynamical Mean Field Theory (DMFT). By using a self-consistent bath configuration with very low entanglement, we take full advantage of the DMRG to calculate dynamical response functions paving the way to treat large effective impurities such as those corresponding to multi-orbital interacting models and multi-site or multi-momenta clusters. It also solves for complex impurities using ab-initio input which opens its realm of applications to real materials. This method leads to reliable calculations of non-local self energies on the real frequency axis directly, at zero temperature, arbitrary dopings and interactions and at all energy scales. We will show results for multi-site and multi-orbital models in which interesting features arise such as emergent low-energy bound states.

3:06PM H19.00002: Approximation to an exchange-correlation functional on the basis of renormalization-group theory* [Invited] LUIZ OLIVEIRA (Presenter), KRISZIA ZAWADZKI, Sao Carlos Institute of Physics at the University of Sao Paulo — Approximations to the exchange-correlation functional are central to Density Functional Theory. Generalizations of the Local-Density Approximation typically describe electronic systems very well. Nonetheless, many exceptions are known. The molecular junction offers an outstanding example, one in which nonlocal correlations stem from the Kondo effect. The junction comprises two metallic leads bridged by a molecule. At low temperatures, the molecular-orbital spin and the low-energy conduction-electron spins lock into a singlet, an entangled state that renders local approximations inadequate, so large is its diameter. To take a nonlocal approach, we resort to renormalization-group concepts. As the temperature $T$ is reduced, the junction crosses over from the vicinity of a high-$T$ fixed point, in which the molecular spin and lead electrons are decoupled, to a low-$T$ fixed point, in which they are strongly coupled. The high-$T$ fixed point is devoid of entanglement, hence well described by local approximations. We can therefore set up and solve the Kohn-Sham equations for that fixed point. We then combine the resulting Kohn-Sham eigenstates with the molecular spin to define a single-impurity Anderson Hamiltonian. Numerical renormalization-group diagonalization of the latter depicts the crossover to the low-$T$ fixed point and yields the ground-state and temperature-dependent zero-bias transport properties of the junction. As an illustration, results for an inhomogeneous Hubbard model will be presented and compared with experimental data.

3:42PM H19.00003: Sign-blessed Diagrammatic Monte Carlo Method for Electrons Interacting with the Long-range Coulomb Repulsion KUN CHEN (Presenter), KRISTJAN HAULE, Department of Physics, Rutgers University — We show that combining a variational approach with a new diagrammatic quantum Monte Carlo method results in a powerful and accurate solver to the generic solid state problem, in which a macroscopic number of electrons interact by the long range Coulomb repulsion. We apply the solver to the quintessential problem of solid state, the uniform electron gas (UEG), which is at the heart of the density functional theory (DFT) success in describing real materials, yet it has not been adequately solved for over 90 years. While some wave-function properties, like the ground state energy, have been very accurately calculated by the diffusion Monte Carlo method (DMC), the static and dynamic response functions, which are directly accessed by the experiment, remain poorly understood. Our method allows us to calculate the momentum-frequency resolved spin response functions for the first time, and to improve on the precision of the charge response function. The accuracy of both response functions is sufficiently high, so as to uncover previously missed fine structure in these responses. This method can be straightforwardly applied to a large number of moderately interacting electron systems in the thermodynamic limit, including realistic models of metallic and semiconducting solids.
3:54PM H19.00004: First principles study of correlation effects in solids* SERGEI ISKAKOV (Presenter), ALEXANDER RUSAKOV, EMANUEL C GULL, DOMINIKA ZGID, University of Michigan — Designing reliable, predictive, and computationally affordable methods to address electronic correlations in realistic solids is an ongoing challenge for quantum chemistry, condensed matter physics, and material science. Recent advances have made computations with density functional theory (DFT) routine and Green’s function based approaches such as GW feasible. In this talk we present the finite-temperature statistical mechanics formulation of perturbation theory self-consistently to second order, and obtain a solution for periodic three-dimensional solids in a fully self-consistent conserving approximation.

*This project was supported by the Simons Foundation via the Simons Collaboration on the Many-Electron Problem.

4:06PM H19.00005: Theory of Time-Resolved Raman Scattering in Correlated Systems: Ultrafast Engineering of Spin Dynamics and Detection of Thermalization* CHENG-CHIEN CHEN (Presenter), University of Alabama at Birmingham, YAO WANG, Harvard University, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory — Ultrafast characterization and control of elementary excitations are critical to understanding and manipulating emergent phenomena in correlated systems. In particular, spin interaction plays an important role in unconventional superconductivity, but efficient tools for probing spin dynamics especially out of equilibrium is still lacking. Here we develop the theory of time-resolved Raman scattering, which can be a powerful tool for nonequilibrium studies. We also simulate a pumped single-band Hubbard model using exact diagonalization. Different ultrafast processes are shown to exist in the time-resolved Raman spectra and dominate under different pump conditions. For high-frequency and off-resonance pumps, the Floquet theory is shown to work well in capturing the bimagnon softening. We also show that effective heating dominates at small pump fluences, while many-body effect takes over at larger pump amplitudes and frequencies resonant to the Mott gap. Time-resolved Raman scattering thereby provides the platform to explore ultrafast processes and design material properties out of equilibrium.

4:18PM H19.00006: Charge self-consistent DFT + DMFT study on magnetism of transition metals* MANCHEON HAN (Presenter), HYOUNG JOON CHOI, Department of Physics, and Center for Computational Studies of Advanced Electronic Material Properties, Yonsei University — Density functional theory (DFT) is a static approximation, so it describes system with static magnetic moment quite well. However, if spin fluctuation is much larger than static moment, DFT is not appropriate tool for investigate such material. For example, the high-temperature paramagnetic state of a magnetic material can not be adequately described by DFT alone. Dynamical Mean Field Theory (DMFT), which accounts the local dynamic correlation effects exactly, can be used to account such fluctuation effects. We studied the magnetic properties of period 4 transition metals using our charge self-consistent density function theory + dynamical mean field theory (DFT + DMFT) program. Our calculation shows temperature dependence of magnetism, which is not observed in ordinary DFT calculation. Moreover, paramagnetic phase was investigated by calculating total spin angular momentum and magnetic susceptibility for several temperatures.

4:30PM H19.00007: Almost exact energies for the G1/G2 set with the semistochastic heat-bath configuration interaction method* YUAN YAO (Presenter), JUNHAO LI, CYRUS JEHANGIR UMRIGAR, Cornell University — The recently developed semistochastic heat-bath configuration interaction (SHCI) method is a systematically improvable selected configuration interaction plus perturbation theory method capable of giving essentially exact energies for larger systems than is possible with other such methods. We compute SHCI atomization energies for the 55 molecules in the G1/G2 set, for which accurate experimental data are available. Basis sets from cc-pVDZ to cc-pV5Z are used, totaling up to 500 orbitals and a Hilbert space of $10^3$ determinants for the largest molecules. To speed up convergence, we first optimize orbitals using 1-body and 2-body reduced density matrices constructed from SHCI wavefunctions with a large convergence threshold. For each of the basis sets, the extrapolated energy is within chemical accuracy (1 kcal/mol) of the exact energy for that basis using only a tiny fraction of the entire Hilbert space. The energies are extrapolated to the basis set limit and compared to the experimental atomization energies. We also use our almost exact energies to benchmark coupled cluster theory (CCSD(T)) energies.

4:42PM H19.00008: One-electron spectral properties of self-assembled structures and defects on semiconductors*
JOSE CARMELO (Presenter), Department of Physics, Boston University, TILEN CADEZ, CSRC, Beijing, YOSHIYUKI OHTSUBO, SHIN-ICHI KIMURA, DAVID K CAMPBELL, Department of Physics, Osaka University — Twin grain boundaries in monolayers of transition metal dichalcogenides such as molybdenum diselenide [MoSe(2)] and self-assembled atomic structures on the surface of semiconductors such as a bismuth-induced anisotropic structure on indium antimonide [Bi/InSb(001)] are exceptional candidates for truly one-dimensional metals. The microscopic mechanisms behind their exotic spectral properties involve long-range interactions of electrons confined to one-dimensional channels. We extend the universal theory for the finite-energy spectral properties of a wide class of one-dimensional correlated lattice systems whose microscopic mechanisms involve phase shifts imposed by a mobile quantum impurity to electronic lattice systems with long-range interactions. In contrast to theoretical schemes that do not account for the effects of long-range interactions, our theoretical predictions agree quantitatively with the observed one-electron spectral properties of one-dimensional metallic states in MoSe(2) line defects and in Bi/InSb(001).

4:54PM H19.00009: On the limitations of cRPA downfolding CARSTEN HONERKAMP (Presenter), RWTH Aachen University, HIROSHI SHINAOKA, Department of Physics, Saitama University, FAKHER F. ASSAAD, Theoretical Physics, University of Würzburg, PHILIPP WERNER, Department of Physics, University of Fribourg — We check the accuracy of the constrained random phase approximation (cRPA) downfolding scheme by considering one-dimensional two- and three-orbital Hubbard models with a target band at the Fermi level and one or two screening bands away from the Fermi level. Using numerically exact quantum Monte Carlo simulations of the full and downfolded model we demonstrate that depending on filling the effective interaction in the low-energy theory is either barely screened, or antiscreened, in contrast to the cRPA prediction. This observation is explained by a functional renormalization group analysis which shows that the cRPA contribution to the screening is to a large extent cancelled by other diagrams in the direct particle-hole channel. We comment on the implications of this finding for the ab-initio estimation of interaction parameters in low-energy descriptions of solids.

5:06PM H19.00010: Maximum quantum entropy method: the analytic continuation of matrix-valued Green's functions* JAE-HOON SIM (Presenter), MYUNG JOON HAN, Department of Physics, KAIST — Analytic continuation of the quantum Monte Carlo data written in the imaginary-frequency to the real-frequency axis is one of the difficult numeric problems, due to the ill-conditioned nature of the kernel matrix. While the maximum entropy method (MEM) is one of the most suitable choices to gain information from the noisy input data, its applications are limited by the non-negative condition of the output spectral function. Here we have extended the MEM to the matrix-valued function, introducing quantum relative entropy as a regularization function [1]. As a true matrix-valued method, our maximum quantum entropy method (MQEM) is invariant under the arbitrary unitary transformation of the input matrix. Without introducing further ambiguity, Bayesian probabilistic interpretation can be applied to the MQEM. Using our DFT+DMFT package, DMFTpack, the MQEM is applied for real materials, namely Sr₂IrO₄. The application shows that the generalized method provides a reasonable band structure without introducing a material specific base set.

*This work was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (2018R1A2B2005204).

5:18PM H19.00011: Diagrammatic Quantum Monte Carlo for Molecular Systems JIA LI (Presenter), MARKUS WALLERBERGER, EMANUEL C GULL, University of Michigan — Electron correlations in chemical systems give rise to a wide range of interesting physical properties. Although traditional mean-field quantum chemical algorithms can reliably calculate ground state observables, finite temperature and spectral properties are only accessible with explicit inclusion of electron correlations. Diagrammatic Monte Carlo (DiagMC), which expands the physical observable in terms of connected Feynman diagrams and samples the resulting series stochastically, is a powerful technique for studying electron correlations and does not suffer from numerical sign problem which worsens with increasing system size. Recent developments in DiagMC algorithms have greatly improved their numerical efficiency. In this talk, we aim to introduce our DiagMC implementation for multi-orbital systems, and discuss the difficulties and potentials when it is applied to realistic molecular systems.
2:30PM H20.00001: Non-orthogonal configuration interaction for molecular excited states: Valence and core excitations and strong correlations* [Invited] MARTIN HEAD-GORDON (Presenter), University of California, Berkeley — Most electronic structure methods are designed using a single set of orthogonal orbitals. Using multiple sets of orbitals, that are orthogonal within a given configuration, but non-orthogonal from one configuration to another, is an interesting alternative that is the basis of the non-orthogonal configuration interaction (NOCI) approach to electronic structure. NOCI provides great flexibility to compactly incorporate the different physics of different configurations. A very simple example is a molecule in which an ionic configuration (e.g. Li⁺F⁻) competes with a covalent configuration (e.g. LiF). Orbital relaxation is very different in the two configurations, and accounts for a large part of what would conventionally be termed dynamic correlation. Far more complicated examples natural arise in mixed valent systems, and systems with low-lying charge-transfer excited states. Core excitations are another natural class of examples. I shall discuss the NOCI method, ways in which it can be made nearly black-box for interesting classes of valence and core excitations, and how to describe remaining dynamic correlation effects using a generalized second order perturbation theory. A variety of molecular examples will be shown for each of these types of NOCI. I hope to convey the message that the NOCI framework can be very useful for both computing and interpreting electronic structure, with bright prospects for further developments in the future.

* This work was supported by the Director, Office of Science, Office of Basic Energy Sciences of the US Department of Energy under Contract No. DE-AC02-05CH11231, with additional support for part of the work from the SciDAC program of DOE.

3:06PM H20.00002: Quantum embedding for excited states in molecular and periodic systems XUELAN WEN (Presenter), DHABIH CHULHAI, JASON GOODPASTER, Department of Chemistry, University of Minnesota, Twin Cities — Projection-based quantum embedding methodologies provide a framework for performing DFT-in-DFT and wavefunction-in-density functional theory (WF-in-DFT) calculations. The previous application of using absolute localization on the ground states of molecular systems\(^1\) and periodic systems\(^2\) showed high accuracy and improved computational efficiency.

In this work, we extend the absolute localization method to study localized excited states in molecular and periodic systems. We show the accurate embedding results on small organic molecules and green fluorescent protein (GFP). We are further extending our methods to periodic systems. Ray et al.\(^3\) found that different density functionals have to be used for CsM\(_3\) (M = Ge, Sn, Pb, Mg, Ca, Sr and Ba) to reproduce the experimental band gaps. Not a single exchange-correlation functional can give consistently good results among these inorganic perovskites.\(^3\) We discuss our progress of making periodic WF-in-DFT embedding methods applicable to such systems.

3:18PM H20.00003: Coupled cluster theory for coupled electron-photon systems  ULIANA MORDOVINA (Presenter), HEIKO APPEL, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany, FREDERIK R. MANBY, Centre for Computational Chemistry, School of Chemistry, University of Bristol, Bristol, UK — Recent experiments show that properties of materials and energy landscapes of chemical reactions can change drastically when put inside a high-Q optical cavity. Understanding these phenomena require novel theoretical approaches, where both parts of the problem, light and matter, are treated on an equal quantum mechanical footing. Extension of existing electronic structure methods to include photons provides one route in this direction.

One prominent tool in electronic structure theory is coupled cluster (CC) theory which is often called the gold-standard in quantum chemistry, as it is a robust polynomial-scaling approach for handling weak correlations.

In the present work we develop methodology to extend CC theory to coupled electron-photon systems. We show benchmark results for model molecular hamiltonians coupled to cavity photons. By comparing to full configuration interaction results, we study the accuracy of the proposed method. We show that our method includes effects like multiphoton processes, which ab-initio methods so far fail to describe. Therefore, not only does our method go beyond standard quantum optical approaches, since it includes an accurate treatment of electronic structure, it also goes beyond existing methods such as QEDFT in terms of its description of light.

3:30PM H20.00004: A quantum embedding theory in the screened Coulomb interaction: Combining configuration interaction with GW/BSE†  MARC DVORAK (Presenter), PATRICK RINKE, Aalto University — We present a new quantum embedding theory called dynamical configuration interaction (DCI) that combines wave function and Green’s function theories. DCI captures static correlation in a correlated subspace with configuration interaction and couples to high-energy, dynamic correlation outside the subspace with many-body perturbation theory based on Green’s functions. DCI takes the strengths of both theories to balance static and dynamic correlation in a single, fully ab-initio embedding concept. We show that treating high-energy correlation up to the GW and Bethe-Salpeter equation level is sufficient even for challenging multi-reference problems. Our theory treats ground and excited states on equal footing, and we compute the dissociation curve of N$_2$, vertical excitation energies of N$_2$ and C$_2$, and the ionization spectrum of benzene in excellent agreement with high level quantum chemistry methods and experiment.

*The research is supported by Academy of Finland grant no. 316347.

3:42PM H20.00005: Locality and Computational Reliability of Linear Response Calculations for Molecular Systems  LUIGI GENOVESE (Presenter), INAC, CEA Grenoble, MARCO D’ ALESSANDRO, ISM, CNR — We explore the interplay between locality of the response density operator and numerical convergence of Linear Response quantities. We show that for frequencies below the first ionization potential (IP) of the system, it is possible to express the response density by employing localized states only. Above this threshold energy, such a locality property cannot be achieved. Such considerations may be transposed in terms of the molecule’s excited states. We show that not all the system's excitations can be considered on equal footing. There is a discrete sector of excitations - which may extend above IP - that can be parametrized by observable, localized states, which can be computationally expressed with high precision, provided an adequate level of completeness. The remaining excitation modes belong to a continuum spectrum that, on the contrary, is not directly associated to observable properties and can only be effectively represented in a given computational setup. Such considerations are important not only for reproducibility of the results among different computer codes employing diverse formalisms, but also in view of providing a deeper understanding on the impact of models' approximations on the scientific outcomes of the simulation.
ARKAJIT MANDAL

CS-RPMD also holds a very promising method to apply in non-equilibrium dynamics. With a two-state model system show very good agreement with the exact quantum results. Besides the equilibrium regime, multiple beads for nuclei, CS-RPMD preserves detailed balance and an approximate QBD. Numerical tests of this method sampled distribution with an additional phase factor. In a special limit that there is one bead for mapping variables and oscillations. At the time equivalent to zero, the quantum Boltzmann distribution (QBD) is recovered by reweighting the not contain any inter-bead coupling term in the state-dependent potential and correctly describes electronic Rabi quantum effects. This new approach is derived by using coherent-state mapping representation for the electronic degrees of freedom. Direct simulations of the exact quantum dynamics remains to be computationally challenging. Here we propose to develop an efficient simulating quantum dynamics effects is one of the central challenges in modern theoretical chemistry. Direct approach, a diabatic quantum dynamics method, with Density Functional Tight Binding, an electronic structure approach diabatization or to formulate them back to the adiabatic representation. We combine Partial Linearized Density Matrix interface diabatic quantum dynamics approaches with adiabatic electronic structure calculation. This scheme uses the crude adiabatic basis as a diabatic basis for a short-time nuclear dynamics propagation and updates it in each consecutive nuclear step. This scheme extends the scope and applicability of the diabatic quantum dynamics approaches and allows us to propagate on-the-fly quantum dynamics with them, avoiding any additional non-trivial efforts to perform diabatization or to formulate them back to the adiabatic representation. We combine Partial Linearized Density Matrix approach, a diabatic quantum dynamics method, with Density Functional Tight Binding, an electronic structure approach to demonstrate the applicability of our proposed scheme.

4:06PM H20.00007: Coherent State Mapping Ring Polymer Molecular Dynamics for Nonadiabatic Quantum Propagations SUTIRTHA CHOWDHURY (Presenter), PENGFEI HUO, Chemistry, University of Rochester — Accurately and efficiently simulating quantum dynamics effects is one of the central challenges in modern theoretical chemistry. Direct simulations of the exact quantum dynamics remains to be computationally challenging. Here we propose to develop a classical trajectory based method to accurately describe electronic non-adiabatic dynamics as well as capture nuclear quantum effects. This new approach is derived by using coherent-state mapping representation for the electronic degrees of freedom (DOF) and the ring-polymer path-integral representation for the nuclear DOF. The CS-RPMD Hamiltonian does not contain any inter-bead coupling term in the state-dependent potential and correctly describes electronic Rabi oscillations. At the time equivalent to zero, the quantum Boltzmann distribution (QBD) is recovered by reweighting the sampled distribution with an additional phase factor. In a special limit that there is one bead for mapping variables and multiple beads for nuclei, CS-RPMD preserves detailed balance and an approximate QBD. Numerical tests of this method with a two-state model system show very good agreement with the exact quantum results. Besides the equilibrium regime, CS-RPMD also holds a very promising method to apply in non-equilibrium dynamics.

4:18PM H20.00008: Quasi-Diabatic scheme for on-the-fly quantum dynamics propagation ARKAJIT MANDAL (Presenter), PENGFEI HUO, Chemistry, University of Rochester — We develop a nonadiabatic quantum dynamics scheme to interface diabatic quantum dynamics approaches with adiabatic electronic structure calculation. This scheme uses the crude adiabatic basis as a diabatic basis for a short-time nuclear dynamics propagation and updates it in each consecutive nuclear step. This scheme extends the scope and applicability of the diabatic quantum dynamics approaches and allows us to propagate on-the-fly quantum dynamics with them, avoiding any additional non-trivial efforts to perform diabatization or to formulate them back to the adiabatic representation. We combine Partial Linearized Density Matrix approach, a diabatic quantum dynamics method, with Density Functional Tight Binding, an electronic structure approach to demonstrate the applicability of our proposed scheme.

4:30PM H20.00009: Electronic Non-Adiabatic Dynamics: memory-dependence and electron-nuclear correlation ALI ABEDI KHALEDI (Presenter), Max Planck Institute for Microstructure Physics — Time-Dependent Density Functional Theory (TDDFT) is one of the most promising theoretical tools in describing the electronic dynamics. In spite of its great success calculating spectra in the linear response regime, it performs poorly in the case of the strong-field dynamics of atoms and molecules. Two main obstacles concerning the application of TDDFT to atoms and molecules in ultrashort intense laser pulses are:

i) Lack of memory dependence in the usual exchange-correlation approximations. The exact functional depends on the history of the density that is neglected in almost all of the existing approximations.

i) Lack of a proper description of the electron-ion correlation.

Towards tackling these problems, we have developed a memory-dependent functional for two-site Hubbard model that fulfills the recently proposed exact condition (Fuks et al. PRL 114, 183002 (2015)). Furthermore, by utilising the Exact-Factorization framework, we have studied the exact potential acting on the electron in charge-resonance enhanced ionization in H2+ molecule and showed that there can be significant differences between the exact potential and that used in the traditional quasistatic analyses, arising from non-adiabatic coupling to the nuclear system (Khosravi, Abedi, Maitra, PRL 115, 263002 (2015)).
4:42PM H20.00010: Optical conductivity and charge fluctuation spectroscopy in the time domain*  
ALEXANDER KEMPER (Presenter), ANKIT KUMAR, North Carolina State University — Using ultrashort laser pulses it is possible to study the dynamics of many-body systems in the time domain. The response functions are often two-particle correlation functions, including optical or terahertz transmission spectroscopy (current) and charge fluctuation spectroscopy momentum resolved EELS (charge). We have studied two-particle response functions using functional derivatives within a non-equilibrium Keldysh Green's function method. This has several advantages over common approaches, most notably the natural inclusion of vertex corrections. We present the equilibrium and non-equilibrium response of a few model systems including electrons interacting with each other and with a bath of phonons, and discuss the implications for experiments.

*This work is supported by NSF DMR-1752713.

4:54PM H20.00011: Ab initio study of photo-induced phase transitions*  
CHAO LIAN (Presenter), BRYAN M WONG, University of California, Riverside — Ultrafast real-time lattice dynamics is a powerful tool to study the fundamental properties and behavior of solids. Ultrafast electronic dynamics in solids lies at the core of modern condensed matter and materials physics. To construct a practical ab initio method for studying solids under photoexcitation, we developed a momentum-resolved real-time time-dependent density functional theory algorithm using a numerical atomic basis, together with the implementation of both length and vector gauges of an electromagnetic field. When applied to the simulation of elementary excitations in both bulk and two-dimensional materials, different excitation modes are only distinguishable in momentum space. We also discuss various examples of photoinduced phase transitions such as amorphizations, charge density wave enhancements, and ultrafast solid-solid transitions.

5:06PM H20.00012: Modeling Excitation Energies of Quantum Dots based on First Principles Data  
EZEKIEL OYENIYI, Dept. of Physics, University of Ibadan, NIGERIA, OMOLOLU AKIN-OJO (Presenter), University of Rwanda, East Africa Institute for Fundamental Research (EAIFR) — Wave function ab initio methods are prohibitively expensive for determination of excited states of large systems such as quantum dots. In this work, we present a method for determination of excitaton energies of large systems having more than 10,000 electrons. The method is based on the use of a semi-empirical hamiltonian appropriately parameterized to reproduce ab initio "EOM-CCSD" excitation energies of small systems. The same set of parameters is then extended to the calculation of excited state properties of large systems. Our results compare well with EOM-CCSD, TDDFT, and CIS(D) results whenever they are available.

Session H21 DCOMP DCMP GSNP: Advances in Computational Methods for Statistical Physics and Their Applications III  

JONATHAN MACHTA (Presenter), CHRIS AMEY, University of Massachusetts Amherst, NATHAN ROSE, 1QBit — Population annealing is an algorithm that is well-suited for sampling equilibrium distributions for systems such as spin glasses and configurational glasses with rough free energy landscapes. Population annealing is massively parallel and easily implemented either on large clusters or GPUs. In addition to being massively parallel, population annealing has several attractive features: (1) it gives direct access to thermodynamic potentials, (2) multiple independent runs can be combined using weighted averaging to improve both statistical and systematic errors and (3) equilibration can be assessed with an intrinsic measure. In this talk population annealing will be introduced and put in the context of other sequential Monte Carlo and annealing algorithms. Applications to spin glasses, configurational glasses and first order transitions will be discussed.

*This work was supported by the National Science Foundation (Grant No. DMR-1507506).
3:06PM H21.00002: Population annealing: A massively parallel algorithm for simulating systems with rough free energy landscapes*  CHRIS AMEY (Presenter), University of Massachusetts Amherst, NATHAN ROSE, 1QB Information Technologies, JONATHAN MACHTA, University of Massachusetts Amherst, Santa Fe Institute — Population annealing is a massively parallel sequential Monte Carlo algorithm that is designed to sample equilibrium states of systems with rough free energy landscapes. Population annealing is closely related to simulated annealing. In population annealing, the relevant equilibrium ensemble is represented by a large population of replicas of the system. The population is initialized in an easy to equilibrate region of parameter space and is then "annealed" in parameter space to a more difficult, target region. Resampling the population of replicas during each annealing step ensures that the population remains near equilibrium. The entropy and thermodynamic potentials together with intrinsic estimates of systematic errors are readily accessible from the simulations. We will describe both canonical and microcanonical versions of the population annealing algorithm, and discuss applications to spin glasses, binary hard sphere fluids in the glassy regime, and large q Potts models.

*This work was supported by the National Science Foundation (Grant No. DMR-1507506).

3:18PM H21.00003: Quantum Free Energy Differences from Non-Equilibrium Path Integral Methods*  LISANDRO HERNANDEZ DE LA PENA (Presenter), Kettering University, RAMSES VAN ZON, University of Toronto, JEREMY SCHOFIELD, Chemistry, University of Toronto, GILLES PESLHERBE, Chemistry and Biochemistry, Concordia University — In this work, we discuss how the imaginary-time path integral representation of the quantum canonical partition function and non-equilibrium work fluctuation relations can be combined to yield methods for computing free energy differences in quantum systems using non-equilibrium processes. The path integral representation is isomorphic to the configurational partition function of a classical field theory to which a natural Hamiltonian dynamics can be associated. It is then shown that both, Jarzynski nonequilibrium work relation and Crooks fluctuation relation, formally hold for this classical field theory. Since the energy diverges in canonical equilibrium, regularization methods need to be introduced in order to limit the number of degrees of freedom M to be finite. The convergence of the work distribution as M tends to infinity is demonstrated analytically for a system composed of a quantum particle trapped in a harmonic well, and numerically for a quartic double-well potential with varying asymmetry. Finally, the method is used to study the relevance of protonic quantum effects in ionic water clusters.

3:30PM H21.00004: Stable Recursion Relation for the Canonical Partition Function of Non-Interacting Fermions*  JIANGYONG YU (Presenter), HATEM BARGHATHI, ADRIAN DEL MAESTRO, University of Vermont — While the thermodynamics of a system of non-interacting fermions can be straightforwardly determined in the grand canonical ensemble, results for a specific number of N particles are more difficult to obtain. In this talk we will present a general recursion scheme for the canonical partition function of free fermions with a quadratic energy level spacing as might be present for ultracold fermionic atoms confined inside a box trap. Exact results for the entropy, specific heat and one and two particle occupation probabilities are numerically obtained to arbitrary precision and compared with their corresponding grand canonical values. The numerical stability of the recursion relation allows us to quantify deviations from Wicks theorem in the canonical ensemble for a variety of temperatures and densities.

3:42PM H21.00005: New Approaches to Tensor Network Simulation of 2D Quantum Systems  KATHARINE HYATT (Presenter), MILES STOUDENMIRE, Center for Computational Quantum Physics, Flatiron Institute — Accessing generic many-body quantum ground states in two full dimensions remains an outstanding problem in numerical condensed matter physics. Quantum Monte Carlo suffers from the sign problem, exact diagonalization cannot access large systems, DMRG struggles to reach beyond quasi-1D ladders, and many existing 2D tensor network approaches still have much room for improvement in terms of computational costs and numerical stability. We develop a PEPS approach, inspired by successful DMRG methods in one spatial dimension, which has much better performance than DMRG while retaining many of its advantages. We discuss the benefits and some drawbacks of the method, and we present some preliminary successes in fully two dimensional simulations with an eye to working towards simulating models on the frontier of numerical and analytical understanding.
3:54PM H21.00006: Accelerating Monte Carlo Simulations of Two-Dimensional Spin Models using GPUs  
BENJAMIN HIMBERG (Presenter), Physics, University of Vermont, SANGHITA SENGUPTA, Physics, Institut quantique de l'Université de Sherbrooke — Utilizing the vast computational power of Graphics Processing Units, we develop novel algorithms in both OpenCL and CUDA to study the statistical mechanical properties of two-dimensional spin models. Our basic technique is the general Markov chain Monte Carlo method which uses a Metropolis-Hastings step. In contrast to the popular method of checkerboard updates, we have devised an unconventional procedure that traverses rows to generate the spin configurations. This special implementation allows us to simulate large system sizes (~ 10^9 spins) and, when tested on our fastest GPU, produces an average time per spin-flip of 0.005 ns with a speed-up factor of 600 compared to an optimized single-core CPU algorithm. We test the performance characteristics of our techniques for simulating 2D spin models such as the Ising, XY, and Potts on hexagonal and square lattices. Finally, as a theoretical proof of our computational concept we present critical temperatures of the models based on finite-size scaling methods.

4:06PM H21.00007: Accelerated simulation of gelation  
ROMAIN DUPUIS (Presenter), CNRS/MIT/AMU Joint Laboratory MultiScale Materials Science for Energy and Environment, UMI 2, LAURENT BELAND, Department of Mechanical & Materials Engineering, Queens university, ROLAND JM PELLENQ, CNRS/MIT/AMU Joint Laboratory MultiScale Materials Science for Energy and Environment, UMI 2 — The formation of gels is a complex issue that has to be resolved to investigate manifold synthetic materials - among them: porous materials such as cement, high-quality glass fiber and geomaterials for radioactive waste sealing.

Being able to simulate the structural, mechanical and dynamical properties of gels would have far-reaching consequences to improve the synthetization of materials and to lengthen their lifetime. This requires rather demanding computational power, which is worsen by the fact that gels have weak long-distance ordering (which requires large simulation cells) and that the gelation is a slow process due to high energy barrier for bond formation.

In order to reproduce the gelation we coupled GCMC and Parallel tempering methods to enhance the formation of silicate chains and reduce the computational costs. Using such cost-efficient method, we were able to study the formation of alkali-silica gels that is key to understand concrete structures failure.

4:18PM H21.00008: Heuristic optimization and sampling with tensor networks for quasi-2D spin glass problems  
MASOUD MOHSENI (Presenter), Google AI Quantum, MAREK RAMS, Institute of Physics, Jagiellonian University, BARTEK GARDAS, Institute of Physics, University of Silesia — We devise a deterministic classical algorithm to reveal the structure of low energy spectrum for certain spin-glass systems that encode classical optimization problems. We employ tensor networks to represent probability distributions of all possible configurations. We then develop efficient techniques for approximately extract the relevant information from the networks for a class of quasi-two-dimensional Ising Hamiltonians. To this end, we apply a branch and bound approach over marginal probability distributions by approximately evaluating tensor contractions. Our approach identifies configurations with the largest Boltzmann weights corresponding to low energy states. We discover spin-glass droplet structures at finite temperatures, by exploiting local nature of the problems. This droplet finding algorithm naturally encompass sampling from high quality solutions within a given approximation ratio. It is, thus, established that tensor networks techniques can provide profound insight into the structure of large low-dimension spin-glass problems, with ramifications both for machine learning and noisy intermediate-scale quantum devices. Moreover, limitations of our approach highlight alternative directions to establish quantum speed-up and possible quantum supremacy experiments.
4:30PM H21.00009: Studying the finite temperature properties of ferroelectrics*
KRISHNA CHAITANYA PITIKE (Presenter), Materials Science and Technology Division, Oak Ridge National Laboratory, YING WAI LI, National Center for Computational Sciences, Oak Ridge National Laboratory, SIMUCK F YUK, Basic and Applied Molecular Foundations, Pacific Northwest National Laboratory, MARKUS EISENBACh, National Center for Computational Sciences, Oak Ridge National Laboratory, SERGE M NAKHMANSOn, Department of Materials Science and Engineering, University of Connecticut, VALENTINO R. COOPER, Materials Science and Technology Division, Oak Ridge National Laboratory — ABO₃ perovskite ferroelectrics, as well as their solid solutions, exhibit rich transitional behavior patterns that can be exploited, e.g., to obtain large piezoelectric and dielectric responses. Due to the complexity of the phase diagrams of these materials, mesoscale-level parameterizations capable of accurately reproducing their finite temperature properties are difficult to develop. Furthermore, obtaining such parameters from first principles calculations is complicated by the large number of available exchange correlation (XC) functionals. We investigate the influence of XC functionals on the prediction accuracy of ferroelectric phase transitions in PbTiO₃. LDA, PBE, PBEsol and vdW-DF-C09 XC functionals are evaluated utilizing constant-temperature molecular dynamics, in comparison with Wang-Landau (WL) Monte Carlo and Replica Exchange WL simulations. We find that LDA, PBEsol and vdW-C09 provide good estimates of physical properties near the phase transition, as compared with experiments, while PBE significantly overestimates the transition temperature.

4:42PM H21.00010: Predicting the surface phase diagram of Ag(111) using ab initio grand canonical Monte Carlo*
ROBERT WEXLER (Presenter), TIAN QIU, ANDREW RAPPE, University of Pennsylvania — The structure of a surface can dramatically affect its properties. For example, surface reconstructions can occur that change band alignments and/or catalytic activity. Currently, ab initio thermodynamics is the method of choice for determining the stable surfaces of a material, however, the selection of surfaces to study is done manually, which induces bias that can prevent one from finding global minima in the surface energy. We present an implementation of ab initio grand canonical Monte Carlo (GCMC) that automatically predicts surface phase diagrams and apply it to the Ag(111) system. We obtain an Ag₇O₁₀ overlayer, which is consistent with the most stable reconstruction found experimentally and computationally. We extracted structure-stability trends from our simulation data using machine learning and find that surface coordination and bond angles are important descriptors for stability. We analyzed the stochastic evolution of the surface and discovered a possible mechanism for the formation of the Ag₇O₁₀ overlayer. Ab initio GCMC therefore offers a rich set of possibilities for studying interfacial systems.

4:54PM H21.00011: A Lattice Boltzmann Method for Simulating Dry and Dense Active Fluids
DAVID NESBITT (Presenter), Bioengineering, Imperial College London, GUNNAR PRUSSNER, Mathematics, Imperial College London, CHIU FAN LEE, Bioengineering, Imperial College London — Symmetry serves a foundational role in all areas of physics today. In classical many-body problems, by first clarifying the underlying symmetries of a system of interest, one can derive the hydrodynamic equations of motion that govern the dynamics of the system. Analysis of a hydrodynamic theory can elucidate the universal behavior exhibited by all generic systems respecting the prescribed set of symmetries; conversely, any particular many-body system defined by microscopic rules that respect the same set of symmetries can also be used to study the associated universal behavior in the hydrodynamic limit. An example of the latter is the use of lattice gas cellular automata to study the Navier-Stokes equations. Superseding the lattice gas cellular automata is the celebrated lattice Boltzmann method, which led to a drastic improvement in computational efficiency. Surprisingly, the development of a lattice Boltzmann method for dry active fluids is still lacking, which is what we accomplish here. We will demonstrate the usefulness of our approach by clarifying the phase behaviour of polar active fluids and motility-induced phase separation. In particular, we show that there are generically three distinct phases in polar active fluids separated by two discontinuous phase transitions.
Spin-flop transition in the 3D anisotropic Heisenberg antiferromagnet: Finite size scaling for a first order transition where a continuous symmetry is broken

JIAHAO XU (Presenter), SHAN-HO TSAI, DAVID P LANDAU, Center for Simulational Physics, University of Georgia, KURT BINDER, Institut für Physik, Johannes Gutenberg Universität Mainz — We use Monte Carlo simulations to explore the 3D anisotropic Heisenberg antiferromagnet in a field in order to study the finite size behavior of the first order "spin-flop" transition between the Ising-like antiferromagnetic state and the canted, XY-like state[1]. Finite size scaling for a first order phase transition where a continuous symmetry is broken is developed using an approximation of Gaussian probability distributions with a phenomenological "degeneracy" factor, q, included. Our theory yields q = π, and it predicts that for large linear dimension L the field dependence of all moments of the order parameters as well as the fourth-order cumulants exhibit universal intersections. The values of these intersections at the spin-flop transition point can be expressed in terms of the factor q. Our theory and simulation imply a heretofore unknown universality can be invoked for first order phase transitions.

Evaluating the Jones polynomial with tensor networks*

KONSTANTINOS MEICHANETZIDIS (Presenter), School of Physics & Astronomy, University of Leeds, STEFANOS KOURTIS, Physics, Boston University — We introduce tensor network contraction algorithms for the evaluation of the Jones polynomial of arbitrary knots. The value of the Jones polynomial of a knot maps to the partition function of a q-state Potts model defined as a planar graph with weighted edges that corresponds to the knot. For any integer q, we cast this partition function into tensor network form and employ fast tensor network contraction protocols to obtain the exact tensor trace, and thus the value of the Jones polynomial. By sampling random knots via a grid-walk procedure and computing the full tensor trace, we demonstrate numerically that the Jones polynomial can be evaluated in time that scales subexponentially with the number of crossings in the typical case. This allows us to evaluate the Jones polynomial of knots that are too complex to be treated with other available methods. Our results establish tensor network methods as a practical tool for the study of knots.

An optimal approach to computing phonons and their interactions via finite displacements*
LYUWEN FU (Presenter), MORDECHAI C KORNBLUTH, ZHENGQIAN CHENG, CHRIS MARIANETTI, Columbia University — Phonons and their interactions are critical to predicting a wide range of materials properties. Therefore, efficiently extracting a high resolution Taylor series expansion of the Born-Oppeheimer surface from an arbitrary first-principles approach is of great importance. Here we present an optimal formalism to compute phonons and their interactions at arbitrary order and crystal dimension on a regular grid using finite displacements; yielding a Taylor series purely in terms of group theoretically irreducible derivatives. Building on a key theorem we derive, our approach ensures that a given derivative can always obtained from the smallest possible supercell dictated by the translation group. Our approach maximally exploits any derivatives the first-principles approach can efficiently deliver perturbatively (e.g. Hellman-Feynman forces, etc) to obtain higher order derivatives. We prove that our approach is superior to any single-supercell finite displacement approach. Applications are presented for graphene, computing and tabulating the irreducible derivatives up to 5th order. A number of critical tests are performed to demonstrate the fidelity of our results.

New Thermal Transport Regime for Partial-Crystalline Partial-Liquid Materials [Invited]  MING HU (Presenter), Department of Mechanical Engineering, University of South Carolina — Materials in partial-crystalline partial-liquid (PCPL) state are now widely used as thermoelectrics and battery electrodes, due to their low thermal conductivity and high ionic conductivity, respectively. However, the well-developed computational methods for pure crystalline materials such as anharmonic lattice dynamics coupled with Boltzmann transport equation cannot be used to study such systems. By performing first-principles and molecular dynamics simulations, we give a robust explanation of the thermal transport mechanism in PCPL material Li₂S. At the temperature range where the system can be regarded as a solid, the large hopping of Li is found to be responsible for phonon thermal conductivity's deviation from the traditional 1/T relationship. At high temperatures, the contribution of convection and liquid-phonon interaction increase significantly due to the fluidization of Li ions. Furthermore, there is an interplay between the enhanced phonon scattering and the increased force hopping between neighboring atoms as temperature arises, which results in a dip in the evolution of the virial term around 1200K. When the temperature is even higher, the virial term increases with temperature due to the contribution of vibrations with extremely short mean free path (diffusons). This point is validated by the evolution of the accumulative thermal conductivity with mean free path. At 1300 K, more than 46% of the heat carried by the S sublattice is contributed by the carriers with mean free path smaller than a few angstroms, which is the typical hopping distance. Our study [1] provides a clear physical map of the heat transport in PCPL materials and describes the key mechanism to guide the design of future thermoelectric materials and battery electrodes.

Observation of second sound in graphite at temperatures up to 100 K* RYAN DUNCAN (Presenter), SAMUEL HUBERMAN, KE CHEN, BAI SONG, VAZRIK CHILOYAN, ZHIWEI DING, ALEXEI MAZNEV, GANG CHEN, KEITH ADAM NELSON, Massachusetts Institute of Technology — Wavelike thermal transport in solids, referred to as second sound, has until now been an exotic phenomenon limited to a handful of materials at low temperatures. This has restricted interest in its occurrence and in its potential applications. Through time-resolved optical measurements of thermal transport on 5-20 μm length scales in graphite, we have made direct observations of second sound at temperatures above 100 K. The results are in qualitative agreement with ab initio calculations that predict wavelike phonon hydrodynamics on ~ 1-μm length scale up to almost room temperature. The results suggest an important role of second sound in microscale transient heat transport in two-dimensional and layered materials in a wide temperature range.

3:54PM H22.00006: First-principles study of lattice thermal conductivity in concentrated solid solution alloys*  
SAI MU (Presenter), LUCAS LINDSAY, RAINA OLSEN, BENNETT C LARSON, GEORGE MALCOLM STOCKS, Oak Ridge National Laboratory — Energy dissipation of concentrated solid solution alloys can be controlled by the number and types of alloying elements and has impacts on the defect formation and recombination after radiation. Here we use an ab-initio supercell method combined with a phonon unfolding technique to access the effects of disorder on the lattice-mediated thermal conductivity in a series of 2-4 component equiatomic alloys (e.g. NiFe, NiCo, NiCoCr, NiFeCo, NiFeCoCr) where the mass disorder is small while the force constant disorder is pronounced. We demonstrate that force constant disorder itself can efficiently reduce the thermal conductivity. We further show that the low-conductivity Cr-containing alloys present the largest force constant fluctuations across the studied alloys and that this is electronically driven. The results provide a new tuning parameter, based on the electronic structure, to manipulate the force constant disorder, thereby facilitating the design of materials with desirable thermal transport properties.

*This work was supported as part of the Energy Dissipation to Defect Evolution (EDDE), an Energy Frontier Research Center funded by the US Department of Energy, Office of Science, Basic Energy Sciences under contract number DE-AC05-00OR227.

4:06PM H22.00007: The influence of interfacial structure and strain energy on phonon transport*  
RILEY HANUS (Presenter), JEFF SNYDER, Northwestern University — Phonon transport across interfaces is an inherently complex topic of great scientific and technological importance. Several experimental and theoretical results which aim to establish a fundamental understanding of heat transfer across interfaces will be presented. First, I will demonstrate how phonon diffraction and dimensionality crossover effects arise when the nanoscale structure and strain field of interfaces and grain boundaries (GBs) are considered. Next, an experimental study is presented where the thermal boundary resistance is measured on individual Si-Si twist GBs at different twist angles. The thermal boundary resistance at GBs, again, seems to be dominated by the interfacial strain field. Finally, it is shown how the thermal boundary resistance can be controlled by modifying the GB with 2D materials. Several layers of graphene were introduced into the GBs of skutterudite materials which dramatically increases the materials thermal boundary resistance, negligibly effecting electronic transport, resulting in a 24% improvement in measured thermoelectric device efficiency.

*GJS and RH acknowledge EFRC Solid-State Solar-Thermal Energy Conversion Center (S3TEC) Grant DE-SC0001299. RH acknowledges support from the Johannes and Julia Randall Weertman Graduate Fellowship.

4:18PM H22.00008: Thermal properties of magnetic materials from first principles*  
MATTHEW HEINE (Presenter), Physics, Boston College, OLLE HELLMAN, Linkoping University, DAVID A BROIDO, Physics, Boston College — In addition to representing an active area of physics research, magnetic materials are used in finite temperature applications such as computer memory technology. In this study we use the Temperature Dependent Effective Potential (TDEP) approach to calculate finite temperature properties of magnetic materials from first principles. In this approach, thermal disorder of the lattice and magnetic moments are incorporated self consistently to yield temperature-dependent properties. Calculations are performed within the framework of Density Functional Theory (DFT) using constrained, fully noncollinear magnetic moments. The effects of such thermal disorder are demonstrated across a range of temperatures spanning the magnetic transition temperature.

*Dissertation Fellowship Award (Boston College)

4:30PM H22.00009: Nonperturbative modeling of high-frequency Holstein-coupled modes using matrix product states  
BENEDIKT KLOSS (Presenter), DAVID REICHMAN, ROEL TEMPELAAR, Columbia University — Many nonequilibrium phenomena of current interest involve coupling of electronic coordinates to vibrational modes whose frequency and reorganization energy are high or comparable to other relevant energies. A proper theoretical account of such modes needs to be non-perturbative and non-classical. The commonly applied direct diagonalization approach rapidly becomes prohibitively expensive with increasing system sizes. We present an alternative approach based on tensor network states, merging concepts from the condensed matter physics and molecular quantum dynamics communities. Focusing on the one-particle (electronic) sector, relevant for exciton and polaron dynamics, we construct the vibronic wavefunction as a set of matrix product states, representing the vibrational degrees of freedom surrounding the particle. This approach allows for an exact treatment of Holstein-driven processes at an unprecedented scale.
4:42PM H22.00010: Accuracy of Lorenz number estimates based on transport data* ADITYA PUTATUNDA (Presenter), DAVID SINGH, University of Missouri — Determination of the thermal conductivity (κ) and its separation into its major constituent lattice and electronic parts is of importance in certain materials. In this work, we study the Wiedemann-Franz law which is used broadly by experimentalists to estimate these parts to investigate κ. For a group of known thermoelectric materials, we investigated the temperature and doping dependence of the Lorenz number (L). In relation to this, we examined the accuracy of an expression proposed by Kim et al. relevant in the literature which is used frequently to estimate L. Solving the Boltzmann transport equations for first-principles band-structure results, we find that this expression, despite being mathematically simple, captures the observed variations of L with satisfactory accuracy for wide band gap materials. It does not work as well for some other materials e.g. PbTe and MgSb2 which primarily have non-parabolic band structures.

* Work at the University of Missouri is supported by the Department of Energy, Basic Energy Sciences, Award DE-SC0019114

4:54PM H22.00011: Automatic ab initio calculations of electronic transport of semiconductors HENRIQUE MIRANDA (Presenter), GUILLAUME BRUNIN, MATTEO GIANTOMASSI, GIAN-MARCO RIGNANESE, GEOFFROY HAUTIER, Universite catholique de Louvain — We address the problem of calculating electronic transport quantities on semiconductors of technological interest (Si,GaAs,MoS2) with minimal user intervention. An important technical challenge is to accurately obtain quantities that depend on integrations on the band-structure. Several methods have been proposed based on Wannier functions or atomic orbitals with the drawback that they often require time-consuming user intervention. For automatic calculations, we use the Shankland-Koelling-Wood interpolation as implemented in the Boltztrap2[1] code. We will discuss some often seen interpolation artifacts, its limitation in reproducing band-crossings and how those affect the final results. We compare these with calculations done using a newly developed driver to obtain electron velocities within the Abinit[2] code on large k-point meshes integrated using the tetrahedron method. We will then show the importance of the accuracy of these quantities when performing calculations including the electronic lifetimes due to electron-phonon scattering.

5:06PM H22.00012: Evidence for the weak coupling scenario of the Peierls transition in the blue bronze K0.3MoO3* BOGDAN GUSTER, MIGUEL PRUNEDA, PABLO ORDEJON (Presenter), Catalan Institute of Nanoscience and Nanotechnology, ENRIC CANADELL, ICMAB-CSIC, JEAN-PAUL POUGET, Laboratoire de Physique des Solides, Université de Paris-Sud — In this work we confirm the interband nesting mechanism for the Charge Density Wave in the blue bronze K0.3MoO3 by a direct calculation of the Lindhard function using the DFT band structure [1]. Furthermore, our calculation of the thermal dependence of the Lindhard function allows to quantitatively account for the standard weak coupling scenario of the Peierls transition. To the best of our knowledge, this type of validation of the weak coupling scenario based on actual data for a real material has never been reported in the literature [2].

A model to incorporate electron-phonon coupling into classical molecular dynamics

ARTUR TAMM (Presenter), Quantum Simulations Group, Lawrence Livermore National Laboratory, MAGDALENA CARO, Department of Mechanical Engineering, Virginia Polytechnic Institute, ALFREDO CARO, Virginia Science and Technology Center, George Washington University, ALFREDO A. CORREA, Quantum Simulations Group, Lawrence Livermore National Laboratory — We have developed a new model to incorporate equilibration of ions and electrons at the corresponding timescales into classical molecular dynamics (MD) simulations. The model is based on Langevin dynamics where the stochastic description does not generate any linear momentum nor torque in the system. This is achieved by introducing spatial correlations into friction and random forces which have a range described by atomic electron density.

All the model parameters can be described fully by using results from first principles realtime time-dependent density functional theory calculations. We use this model to study the phonon lifetimes due to electron-phonon coupling in classical MD simulations in large and complex systems. Particularly, our model is able to capture the wavevector and polarization dependence of phonon lifetimes in qualitatively good agreement with more exact methods.

Finally, we apply the model to study the laser heating of a material similar to pump-probe laser experiments. In conclusion, this model should be used to study the dynamics of any metallic system where the electronic and lattice temperatures diverge due to fast phenomena, like, radiation damage, laser-material interaction, and compressions shocks.

Magnetic Resonance Relaxometry and Macromolecular Mapping: An Inverse Problem Framework, with Applications to Alzheimer's Disease and Osteoarthritis

RICHARD G SPENCER (Presenter), Magnetic Resonance Imaging and Spectroscopy Section, National Institute on Aging, National Institutes of Health — Quantification of changes in the macromolecular constituents of tissue is a major theme in biomedical magnetic resonance (MR). In many cases, constituents can only be distinguished through their differing water transverse relaxation times, instead of by frequency differences as is more familiar in MR spectroscopy. However, this requires implementation of multiexponential transverse relaxation analysis (METRA), a special case of the inverse Laplace transform, a notoriously ill-posed and unstable inverse problem. Our work in this area combines basic science studies with methodologies that carry immediate translational potential. We will discuss METRA as a means to quantify the myelin water fraction (MWF) of total brain water as a marker for myelin, a critical element of signal transmission within the central nervous system, in the mathematical setting of a linear inverse problem. In addition, we have stabilized MWF estimates using a rapid steady-state MR pulse sequence through Bayesian analysis of the corresponding non-linear inverse problem. With this, we provide the first report of myelination deficits using direct MWF measurements in subjects with mild cognitive impairment and Alzheimer's disease. We have implemented similar methods to map cartilage proteoglycan, the macromolecule most vulnerable to loss in osteoarthritis, obtaining results indicating the potential for improved detection of this condition. Finally, we describe extensions of METRA to higher dimensional experiments, with two or more independent time variables. We discuss the stability of parameter estimates from these experiments, as well as correlation experiments providing insight into chemical exchange between macromolecular constituents. All of these studies are directed toward the clinical goal of improving the ability of MR to diagnose pathology and monitor disease progression, and to define therapeutic targets for treatment.

3:06PM H23.00002: Fractional Anisotropy by DTI in Patients with Myotonic Distrophy Type I*  
MARGARITA LOPEZ (Presenter), Instituto de Neuroetología, Universidad Veracruzana, ROSALINDA DÍAZ, CARLOS HERNÁNDEZ, Facultad de Medicina, Universidad Nacional Autónoma de México, JONHATAN MAGAÑA, Instituto Nacional de Rehabilitación, JUAN FERNÁNDEZ, Instituto de Neuroetología, Universidad Veracruzana — Myotonic Distrophy Type I (DM1) is a neurodegenerative and hereditary disorder; its more typical symptoms are muscle weakness and hypotonia, which may lead to several complications like respiratory failure and cardiac arrest. The aim of this study is to find biomarkers that help us to characterize the evolution of this disorder related to white matter. In the present work 74 volunteer participants (37 DM1 patients and 37 healthy control subjects) were matched by age, gender and level education, then underwent an MRI session in a 3T Philips Ingenia scanner with 32 channel head sense coil. Diffusion Tensor Images (DTI) were acquired with 33 diffusion direction (64 axial slices with spatial resolution of 3mmx3mmx3mm). The image post-processing analysis was done with specialized software FSL 5.0.8. The DTIs were reoriented to the standard space, then artifact corrected and the Fractional Anisotropy maps was obtained. For the statistical analysis a t-test for unpaired samples was applied.

3:18PM H23.00003: Stability of Parameter Estimates from Multieponential Decay in MR Relaxometry and Related Experiments in One, Two, and Three Dimensions*  
RICHARD G SPENCER (Presenter), MUSTAPHA M BOUHRARA, National Institute on Aging, National Institutes of Health — Analysis of one-dimensional (1D) multieponential decay has remained a topic of active research for over 200 years. This attests to the ubiquity of such signals as well as the difficulty in deriving parameters of the underlying monoexponential decays. However, we have shown in the context of nuclear magnetic resonance (NMR) relaxometry that parameter estimates derived from two-dimensional (2D) exponential decays, with two distinct time variables, exhibit substantially greater accuracy than those obtained from analysis of 1D data with a single time variable [1]. Here, we present statistical underpinnings of this remarkable fact and indicate applications in 2D NMR relaxometry and related experiments. These may be constructed, for example, as T1-T2 experiments correlating longitudinal (T1) and transverse (T2) relaxation times or as T2-diffusion (T2-D) correlation experiments. These results are readily generalizable to higher dimensions and may provide a means of circumventing conventional limits on multieponential parameter estimation.

3:30PM H23.00004: Mote-carlo simulation to reduce sensor dimension of EEG neurofeedback device*  
PRASANTA PAL (Presenter), Radiology, University of Massachusetts Medical School, DANIEL L. THEISEN, MICHAEL DATKO, Center for Mindfulness, University of Massachusetts Medical School, REMKO V LUTTERVELD, ALEXANDRA ROY, JUDSON BREWER, Center for Mindfulness, Brown University — Neuro-feedback (NF) training using EEG device is finding wide acceptance for treatment of ADHD, epilepsy, anxiety, dyslexia, schizophrenia etc. In realistic clinical practice, high quality delivery of NF signal is possible only with high sensor density devices. Unfortunately, these are often cost-prohibitive, time consuming and unmanageable due to large number of sensors. So, reduction of sensor dimension without compromising the quality of the signal is an important clinical problem.

On the contrary, inexpensive low density devices lacks clinical precision. This can be solved by generating reduced dimension sensor configuration by Monte Carlo (MC) sampling of high-quality data. In our experiment, high quality EEG data was collected from NF sessions with 72 subjects. MC sampling of all possible 32 configurations were used to generate a targeted set of montages to produce NF source signal equivalent to those from the original high-density configuration.

We found a large pool of potential montage configurations with only 32 sensors that can reproduce results from high density sensor system with more than 80%. Thus, MC sampling can be utilized to design low cost clinical grade EEG devices without compromising the quality.

LUKE D’IMPERIO (Presenter), JUAN M. MERLO, CHAOBIN YANG, YITZI M CALM, Physics, Boston College, MEGI MACI, Biology, Boston College, MICHAEL J BURNS, Physics, Boston College, TIMOTHY CONNOLLY, THOMAS C CHILES, Biology, Boston College, MICHAEL J NAUGHTON, Physics, Boston College — Diagnostic tools e.g., those used in the biomedical field, have greatly benefited from taking advantage of the properties of plasmonic phenomena in micro- and nano-scale thin films and structures [1]. Here, we discuss the considerations involved in the design and fabrication of a previously reported plasmonic microstructure towards the goal of sensitive detection of disease biomarkers [2]. We show current fabrication results and motivate relevant processes, parameters and materials therein. We describe our measurement setup and provide comparison to a commercially available system, particularly to motivate how our device can extend existing detection tools to point-of-care applications. We introduce preliminary device responses and our approaches to current obstacles of the project.

[3] The authors thank Dr. Fan Ye and Steve Shepard for beneficial communications.

*M. MILANIC (Presenter), JOST STERGAR, LUKA ROGELJ, ROK DOLENEC, MARTIN HORVAT, University of Ljubljana — Hyperspectral imaging (HIS) is an optical technique providing both spectral and spatial information in one measurement. A big challenge in the medical HIS (diagnostics and surgery) is effective processing of a huge amount of data and extraction of relevant parameters.

An analytical solution of the 2D radiative transfer equation (RTE) was derived for a multi layered biological tissue. The solution represents reflectance from the tissue surface. Each tissue layer was specified by a set of optical properties including refractive index. The solution served as an azimuthal single scattering approximate inverse light transport model for analyzing HSI.

Hyperspectral images of a human forearm were recorded in the 400–1000 nm spectral range. A cuff test was performed to simulate hypo-, hyper- and normoxia of the skin. The inverse RTE was used to determine physiological parameters of the skin (e.g., oxygenation, hemoglobin concentration). A good agreement with the parameters reported in the literature was obtained.

The RTE solutions can be effectively used to analyze medical HIS. The RTE is as accurate but significantly less computationally demanding as the alternative Monte Carlo approach.

*ARRS grants P1-0389 and J2-8171.

LJUBICA PETROVIC (Presenter), University of Massachusetts Boston — This study uses a 3D cell culture approach to study the impact of gold nanoparticles (GNP) uptake and localization on radiation dose enhancement, as well as on combined photodynamic (PDT)/photothermal treatment (PTT). The use of 3D cell cultures reveals that GNP resides in the extracellular matrix (ECM) for surprisingly long durations after initial delivery and prior to localization in tumor nodules, an effect which, as it will be shown here, has a big impact on the treatment outcomes for nanoparticle-aided therapy.

Here we show that heavy metal such as gold in a form of gold nanorods (GNRs) influences PDT outcome. GNRs were used to excite surface plasmon resonance (SPR) and consequently, to induce heat via PTT, which combined with PDT raises treatment response. It turned out that presence of GNRs does enhance PDT outcome, not via thermal effect, but rather because of gold photochemistry and the appearance of the heavy atom effect\(^1\), which efficiency depends on the amount of GNRs present in the 3D cancer nodule itself.

In combined x-ray/GNP treatment, GNPs act as a source of short-range secondary radiation effects\(^2\), where disproportionate accumulation of GNP in ECM significantly reduces radiation response in 3D tumor spheroids.

MRI-guided focal proton radiation therapy for locally advanced prostate cancer  MARYAM MOTEABBED (Presenter), Radiation Oncology, Massachusetts General Hospital, MUKEH HARISINGHANI, Radiology, Massachusetts General Hospital, JASON A EFSTATHIOU, HSIAO-MING LU, Radiation Oncology, Massachusetts General Hospital — We investigate the dosimetric efficacy and clinical implications of proton radiation therapy of prostate cancer with dose microboost to the MRI-defined dominant intraprostatic lesions (DIL).

For 6 patients with high-risk prostate cancer, DILs were delineated using multiparametric MRI based on hypointense appearance on T2-weighted and apparent diffusion coefficient maps. After transferring the contours to CT via image registration, conventional and boosted pencil beam scanning proton treatment plans were created. Dose-volume histograms were analyzed. Tumor control probability (TCP) and normal tissue complication probability (NTCP) were compared between the two scenarios.

In all cases the addition of up to 60% (of prescribed dose) boost to the DILs was achievable without violating the organs at risk (OAR) planning constraints. The increase in OAR mean dose was within 1.5 Gy, and all volume indices remained within clinical tolerance for all cases. TCP of DILs increased by at least 59% depending on the boost amount and model parameters. Bladder and rectum NTCP increase remained negligible.

Proton therapy of high-risk prostate cancer with MRI-guided focal boost to highly malignant DILs is feasible and could yield significant improvement in treatment outcome without increasing toxicities.

Radiation cabinet to study the effect of Low-dose radiation on cells  BISHWAMBHAR SENGUPTA (Presenter), DONALD MEDLIN, XIAORAN ZHENG, ENDRE TAKACS, Clemson University — Exposure to ionizing radiation comes from many sources: medical imaging, radiotherapy, nuclear fallout, and natural or background radiation. However, the biological effects of ionizing radiation can be paradoxical. In fact, the current radiation risk assessment model - the Linear No Threshold model - has been challenged by recent research that shows evidence of radiation hormesis at low-doses. To better understand the biological effects of radiation the primary aim of our research group is to study the effects of low-dose, well-characterized radiation on various cell cultures. The biological effects of irradiations vary with radiation type, energy, total dose delivered and dose rate; however, most research in this field is focused only on the total dose, and thus most irradiators used are not well characterized. The goal of this study was to develop a spectrally and dosimetrically well-characterized X-ray irradiation cabinet to explore the relationships of these variables and their biological effects in a systematic manner. Here we report the overall design, hardware used, calibration methods, and the dose calculation methods used for this study.

A new entropic algorithm to measure of the impact of magnetic field on dose distribution: application to MRI-guided radiotherapy*  JEAN-LUC FEUGEAS (Presenter), CELIA, Université de Bordeaux — Purpose - The integration of magnetic resonance imaging, providing an efficient soft-tissue contrast opens real perspective for a better radiotherapy-based treatment. However, the magnetic fields will modify the localization of radiation dose always induced by charged particles. The fast development of these new facilities is one of the recent challenges for the next generation of treatment planning softwares.

Material and methods - Our theoretical physics group proposes a direct resolution of linear Boltzmann transport equation thanks to an angular momentum closure based on the principle of entropy maximization [1,2,3,4]. This algorithm, originally developed for the energetic particle transport in magnetized plasmas, is perfectly suited for modeling dose deposition for MRI-guided radiotherapy [3,4].

Results - We confirm the ability of our entropic closure to take efficiently into account magnetic effects on dose deposition for complex realistic geometries [3,4].

**4:54PM H23.00011: A Vector-Space Representation of Cytoskeletal Drug Mechanisms for Intracellular Doppler Spectroscopy**  
ZHE LI (Presenter), Department of Physics and Astronomy, Purdue University, JOHN TUREK, Department of Basic Medical Sciences, Purdue University, DAVID NOLTE, Department of Physics and Astronomy, Purdue University — Biodynamic imaging is sensitive to intracellular transport and has been successfully used to profile drug effects in 3-D cell culture. We report the use of biodynamic imaging to provide phenotypic profiles of cytoskeletal drugs that have a wide range of mechanisms of action (MoA). These profiles serve as “fingerprints” of the drug MoA and can be queried by machine learning clustering algorithms. In this study, 7 cytoskeletal drugs are used, including cytochalasins and latrunculin that inhibit the polymerization of actin, jasplakinolide that enhances actin polymerization, colchicine and nocodazole that inhibit microtubule polymerization, and taxanes that stabilize microtubules. In contrast, blebbistatin is a molecular motor inhibitor that inhibits ATPase activity. Biodynamic imaging is sensitive to subtle changes in intracellular motion, and drugs that affect the cytoskeleton are particularly strong inducers of biodynamic fingerprints. Biodynamic imaging uses short-coherence digital holography to profile cytoskeletal drug responses of 3D cultured tumor spheroids. Drug responses and their relations are examined in a high-dimensional space spanned by vectors of biomarkers and related with their mechanism of actions and targeted cytoskeletal components.

**2:30PM H24.00001: Phonon excitations in a one dimensional Bose gas**  
FEDERICA CATALDINI (Presenter), BERNHARD RAUER, THOMAS SCHWEIGLER, SICONG JI, MOHAMMADAMIN TAJIK, JOAO SABINO, JOERG SCHMIEDMAYER, Technical University of Vienna — Cold atomic gases provide a powerful tool to investigate quantum many-body systems [1]. Phonons, which are low-energy collective excitations for one dimensional superfluids, play a major role in the relaxation dynamics of such systems. It has been shown that mechanisms of phonon dephasing and rephasing generate, respectively, losses and recurrences of coherence in a quantum isolated system, and that the long time behavior of the system itself is determined by the spectrum of the phononic modes [2]. In our experiment we are able to excite and detect phonon modes individually and to monitor them over time.

Our system consists in a 1D BEC of $^{87}$Rb atoms confined in a box trap, which provides a dispersion relation where the phonon energies are commensurate. We implement a shaking process that modulates the box walls symmetrically at a fixed frequency. The density profile of the cloud can be obtained via absorption imaging at different times. Doing so, we are able to investigate, within a reasonably broad range of frequencies, the growth of the lower symmetric modes when the system is excited, and their subsequent evolution and damping after the end of the shaking.

**2:42PM H24.00002: Exact strong-ETH violating eigenstates and quasiparticle descriptions of many-body scar states in the Rydberg-blockaded atom chain**  
CHENG-JU LIN (Presenter), OLEXEI I MOTRUNICH, Caltech — A recent experiment in the Rydberg atom chain observed unusual oscillatory quench dynamics with a period-2 charge density wave initial state (Z2 state), and theoretical works identified a set of many-body “scar states” in the Hamiltonian as potentially responsible for the atypical dynamics. In the same nonintegrable Hamiltonian, we discover several eigenstates at infinite temperature that can be represented exactly as matrix product states with finite bond dimension, for both periodic boundary conditions (two exact $E = 0$ states) and open boundary conditions (two $E = 0$ states and one each $E = \pm \sqrt{2}$). This discovery explicitly demonstrates violation of strong eigenstate thermalization hypothesis in this model. These states show signatures of translational symmetry breaking with period-2 bond-centered pattern, despite being in 1d at infinite temperature. We show that the whole tower of Z2 many-body scar states can be excellently approximated as single or multiple “quasiparticle excitations” on top of our exact $E = 0$ states, and propose a quasiparticle explanation of the strong oscillations observed in experiments. We also discuss the possibility of similar construction for Z3 many-body scar states relevant for quench with period-3 CDW initial state.
2:54PM H24.00003: Observation of Non-Gaussian Statistics and Levy Flights in Nitrogen Vacancy Centers*  DAVID LEVONIAN (Presenter), Harvard University, MICHAEL L GOLDMAN, Physics, University of Maryland College Park, KRISTIAAN DE GREVE, SUSANNE F YELIN, MIKHAIL LUKIN, Harvard University — A nitrogen-vacancy center can be used as a probe of the interacting 13C nuclear spins in a diamond crystal. Under the right conditions, its behavior can be described as a random walk with step sizes drawn from a distribution without a well-defined mean or standard deviation. Its behavior is then described by Levy statistics, providing an opportunity to study Levy statistics in a well understood system.

3:06PM H24.00004: Detection of quantum phases via out-of-time-order correlators  CEREN DAG (Presenter), KAI SUN, Physics Department, University of Michigan, LUMING DUAN, Center for Quantum Information, IIIS, Tsinghua University — We elucidate the relation between out-of-time-order correlators (OTOCs) and phase transitions via analytically studying the OTOC dynamics both in non-degenerate and degenerate spectra. Our method indicates that for a wide variety of quantum phase transitions, OTOCs can directly characterize various quantum phases as well as their symmetry breaking patterns. Key ingredients about how to utilize OTOC to detect and characterize a quantum phase transition are presented. We further discuss how our method could be useful to understand the dynamical features of the OTOCs.

3:18PM H24.00005: Beyond Bose Fireworks: Stimulated Emission of Exotic Shaken Condensates  HAN FU (Presenter), JOOHEON YOO, LEI FENG, CHENG CHIN, KATHRYN LEVIN, University of Chicago — Periodic modulation of the two-body interaction in a Bose condensate has led to the interesting observation of “Bose fireworks” [Nature 551, 356–359 (2017)]; these were later shown to be well captured by our time-dependent Gross-Pitaevskii simulations [prXiv:1807.08781]. The promise of these experiments is that this stimulated emission may, through the process of parametric amplification, make it possible to unravel the structure (i.e., wavefunction amplitude and phase) of an unknown condensate. We seek to fulfill this promise by presenting numerical simulations of analogous fireworks patterns in more complex systems. We consider single and multiple imprinted vortices (giving rise to "chiral jets") as well as more exotic states. Using the far-field jets to reveal the character of the initial condensate is reminiscent of established procedures in particle physics and we address how this expertise can be exploited.

3:30PM H24.00006: Dynamical critical behavior of long-range spin models  PARAJ TITUM (Presenter), Joint Quantum Institute/ NIST University of Maryland, College Park, MOHAMMAD MAGHREBI, Michigan State University — Long range interacting spin models exhibit a variety of order-to-disorder phase transitions. We consider prototypical long-range spins models, and investigate dynamical properties of the order parameter as well as entanglement after a sudden quench in the Hamiltonian. The quench dynamics is studied through a combination of exact numerics and analytical calculations. We show that, depending on the nature of quench, different dynamical critical behavior arises. Specifically, we identify regimes when the stationary state at long times exhibits a non-thermal scaling behavior, and describe the signatures in the entanglement. Our results are amenable to realization in experiments with trapped-ion experiments where long-range interactions naturally arise.

3:42PM H24.00007: Floquet resonances from integrability: Spin polarization in a driven central spin model*  PIETER W. CLAEYS (Presenter), Boston University, STIJN DE BAERDEMACKER, Ghent University, JEAN-SEBASTIEN CAUX, University of Amsterdam — Adiabatically varying the driving frequency of a periodically driven many-body quantum system can induce controlled transitions between resonant eigenstates of the time-averaged Hamiltonian, corresponding to adiabatic transitions in the Floquet spectrum and presenting a general tool in quantum many-body control. Using the central spin model as an application, we show how such controlled driving processes can lead to a polarization-based decoupling of the central spin from the decoherence-inducing environment at resonance. While it is generally impossible to obtain the exact Floquet Hamiltonian in driven interacting systems, we exploit the integrability of the central spin model to show how techniques from quantum quenches can be used to explicitly construct the Floquet Hamiltonian in a restricted many-body basis and model Floquet resonances.

3:54PM H24.00008: Floquet-Induced Superfluidity with Periodically Modulated Interactions of Two-Species Hardcore Bosons in a One-dimensional Optical Lattice* SHIJIE HU (Presenter), Physics Department, Univ. Kaiserslautern, TAO WANG, School of Science, Wuhan Institute of Technology, SEBASTIAN EGGERT, AXEL PELSTER, Physics Department, Univ. Kaiserslautern, XUEFENG ZHANG, Department of Physics, Chongqing University — We consider two species of hard-core bosons in a one-dimensional optical lattice with periodically modulated repulsive interactions. Using Floquet theory the periodic can be mapped to an effective Hamiltonian for high frequencies, which is described by a static interaction and hopping parameters that depend on the local densities. In particular, if the density difference of one species is non-zero on neighboring sites, the effective hopping of the other species is reduced and can even take on negative values. Using a combination of analytic calculations and different numerical simulations we establish the full quantum phase diagram for half-integer filling for this system. The density-dependent reduction of hopping drives a quantum phase transition into a superfluid phase. For negative hopping a previously unknown state is found, where one species induces a gauge phase of the other species, which leads to a new superfluid phase. The corresponding experimental signatures in time-of-flight experiments are calculated and show characteristic signatures of the different phases.

4:06PM H24.00009: Analysis of weakly-driven multi-emitter cQED systems* RAHUL TRIVEDI (Presenter), MARINA RADULASKI, KEVIN A FISCHER, JELENA VUCKOVIC, SHANHUI FAN, E. L. Ginzton Laboratory, Stanford University — In this work, we show that a weakly driven multi-emitter cQED system can be analyzed by approximating the driving coherent state with a single- and two-photon Fock state, and using the Scattering matrix formalism to analyze the response of this system to these Fock states. This is a significantly more computationally feasible approach than the master equation formalism, allowing the analysis of multi-emitter systems with ~50 emitters. We use this approach to analyze the transmission and second order correlations induced in the incident coherent state by the multi-emitter system. In particular, we show that for identical emitters, increasing the number of emitters does not improve the polaritonic photon blockade. Moreover, we analyze the impact of inhomogeneous broadening on the second order correlation function of the light emitted by the multi-emitter system with large number of emitters, and analyze the emergence and behaviour of subradiant photon blockade in such multi-emitter systems.

4:18PM H24.00010: The Density Matrix Renormalization Group for Periodically Driven Many-Body Systems SHAON SAHOO (Presenter), IMKE SCHNEIDER, SEBASTIAN EGGERT, University of Kaiserslautern — Driving a quantum system periodically in time can profoundly alter its long-time dynamics and trigger exotic quantum states of matter. We propose a new DMRG method which directly deals with the Fourier components of the eigenstates of a periodically driven system using Floquet theory. With this new method we can go beyond effective Hamiltonians and take into account higher Floquet modes. Numerical results are presented for the isotropic Heisenberg antiferromagnetic spin-1/2 chain under both local (edge) and global driving for energies, spin-spin correlation and temporal fluctuations. As the frequency is lowered, the spin system enters into a Floquet regime with a coherent exciations of a large number of Floquet modes, which shows characteristic quantum correlations that cannot be described by any effective static model.

4:30PM H24.00011: Effective Cross Section Enhancement from Embedded Atomic Lattice Impurities* TAYLOR PATTI (Presenter), DOMINIK S WILD, EPHRAIM SHAHMOON, MIKHAIL LUKIN, SUSANNE F YELIN, Physics, Harvard University — Atoms arranged in a two-dimensional lattice strongly interact with light via collective excitations. Such lattices can be supplemented with impurity atoms which couple to the collective array modes and permit the manipulation of emission properties. In particular, the combination of strong array-light coupling and large impurity atom non-linearity enable highly nonlinear responses to collimated, far-field radiation. We explore the effective enhancement of impurity cross section which results from this coupling in a variety of lattice potentials and parameter regimes. Higher-order photon correlations are calculated and pertinent extensions, such as long-lived photon bound states and multi-impurity systems, are discussed.

*This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. DGE1745303.
**4:42PM H24.00012: Scrambling dynamics across a thermalization-localization quantum phase transition**

SUBHAYAN SAHU (Presenter), SHENGLONG XU, Condensed Matter Theory Center and Department of Physics, University of Maryland, College Park, BRIAN SWINGLE, Condensed Matter Theory Center, Maryland Center for Fundamental Physics, Joint Center for Quantum Information and Computer Science, and Department of Physics, University of Maryland — We study quantum information scrambling, specifically the growth of Heisenberg operators, in large disordered spin chains using matrix product operator dynamics to scan across the thermalization-localization quantum phase transition. We observe ballistic operator growth for weak disorder, and a sharp transition to a phase with sub-ballistic operator spreading. The critical disorder strength for the ballistic to sub-ballistic transition is well below the many body localization phase transition, as determined from finite size scaling of energy eigenstate entanglement entropy in small chains. In contrast, at the eigenstate localization transition, the operator dynamics changes from a power-law behaviour to logarithmic, which is hard to detect from our numerics. These data are discussed in the context of a universal form for the growing operator shape and substantiated with a simple phenomenological model of rare regions.

*This material is based on work supported by the Simons Foundation via the It From Qubit Collaboration, by the Air Force Office of Scientific Research (FA9550-17-1-0180), and by the NSF Physics Frontier Center at the Joint Quantum Institute (PHY-1430094).

**4:54PM H24.00013: Quantum Brownian motion in a quasiperiodic potential**

AARON FRIEDMAN (Presenter), Rudolf Peierls Centre for Theoretical Physics, Oxford University, ROMAIN VASSEUR, University of Massachusetts Amherst, AUSTEN LAMACRAFT, TCM Group, Cambridge University, SIDDHARTH A PARAMESWARAN, Rudolf Peierls Centre for Theoretical Physics, Oxford University — We study the behavior of a quantum particle in one dimension subject to Ohmic dissipation, moving in a bichromatic quasiperiodic potential. The bath is described by the Caldeira-Leggett model; absent the potentials, the particle-bath system resolves the Langevin equation in the classical limit. In a single-period potential, the particle undergoes a zero-temperature localization-delocalization transition as dissipation strength is decreased. We show that the delocalized phase is absent in the quasiperiodic case, even when the deviation from periodicity is infinitesimal. Using the renormalization group, we determine how the crossover time to the localized phase depends on the dissipation strength and incommensurability of the two frequencies, and from this, extract a localization length. Finally, we show that a similar problem can be realized as the strong-coupling limit of a mobile impurity moving in a periodic optical lattice and immersed in a one-dimensional Fermi or Bose gas.

**5:06PM H24.00014: Design and characterization of a quantum gas heat pump**

ARKO ROY (Presenter), DANIEL VORBERG, ANDRE ECKARDT, Quantum Chaos and Quantum Dynamics, Max Planck Institute for the Physics of Complex Systems — We propose a novel scheme for quantum heat pumps powered by weak rapid time-periodic driving that enables extraction of heat from fermionic reservoirs at finite temperatures and chemical potentials. We focus our investigation on a system consisting of two coupled driven quantum dots in contact with the reservoirs. Experimentally, such a configuration can be realized in a quantum-gas microscope. To this end, we theoretically characterize the device by describing the coupling to the reservoirs using the Floquet-Born-Markov approximation. For weak driving, we reveal that an optimal temperature and chemical potential difference between the two reservoirs facilitates the working of the heat-pump with minimal particle loss in the reservoirs. Furthermore we show that for strong driving, the device departs away from working as a heat-pump. The genesis lies in the coupling of the higher energy Floquet states with the reservoir energy states. Finally, we discuss the optimal system parameters in which the proposed heat-pump is most useful for refrigeration. That is, one can attain temperature as low as ~0.05 T_F. With the aid of two such pumps combined in series, the minimum temperature that could be achieved is ~0.01 T_F.
5:18PM H24.00015: Memories of Initial States in the Dynamics of Disordered Systems*  
AHANA CHAKRABORTY (Presenter), Department of Theoretical Physics, Tata Institute of Fundamental Research, India, PRANAY GORANTLA, Department of Physics, Princeton University, New Jersey, USA, RAJDEEP SENSARMA, Department of Theoretical Physics, Tata Institute of Fundamental Research, India — We consider the dynamics of a one dimensional closed disordered system of non-interacting bosons/fermions which is initialized to a Fock state with a pattern of 0 and 1 particles on alternating sites. We show that in the long time limit, the imbalance between the densities in the two sublattices reach a finite value in the localized phase given by, $I(\infty) = \tanh \left( \frac{1}{2} \xi \right)$, where $\xi$ is the localization length. For a chain with random potential disorder, the imbalance is finite for any disorder, whereas for the Aubrey Andre model, it shows a localization-delocalization transition. For a modified Aubrey Andre model, the imbalance as a function of the disorder shows a kink when the mobility edge first appears. We find that in this case, $I(\infty) = \sum_i \tanh \left( \frac{1}{2} \xi_i \right)$, where $\xi_i$ is the localization length corresponding to each of the three bands in the model. Our work relates experimentally measurable non-equilibrium quantities in these systems to the localization length and hence shows a new method for extracting the localization length in these systems.

Session H25 DAMOP: Trapped Ions and Polaritons

2:30PM H25.00001: Electric-field noise from thermally-activated fluctuators in a surface ion trap*  
MAYA BERLIN-UDI (Presenter), CRYSTAL NOEL, CLEMENS MATTHIESEN, University of California, Berkeley, VINCENZO LORDI, Lawrence Livermore National Laboratory, HARTMUT HAEFFNER, University of California, Berkeley — Electric-field noise originating from surfaces is a major source of motional decoherence in ion trap chips. A better understanding of this noise is important for the fabrication of low-noise quantum devices. We probe electric-field noise near the aluminum-copper surface of an ion trap chip in a previously unexplored high-temperature regime. A saturation of the noise amplitude occurs around 500 K, which, together with a small change in the frequency scaling, points to thermally activated two-state fluctuators as the origin of the noise. We find intriguing similarities in the distribution of activation energies extracted from our data and corresponding data from resistance fluctuation measurements for polycrystalline aluminum films. These similarities suggest atomic motion as a relevant microscopic mechanism, likely taking place at the metal trap surface.

* NSF, Lawrence Livermore National Laboratory, ONR

2:42PM H25.00002: An Ion-trap Collider: Entangling Distant Atomic Ions by Direct Collisions  
LINGZHEN GUO (Presenter), Max Planck Institute for the Science of Light (MPL), PENGFEI LIANG, Department of Physics, Beijing Normal University (BNU) — We propose a novel scheme to entangle two atomic ions in linear Paul traps. The two traps are designed capable of merging into one single trap allowing two ions to be accelerated and collide periodically in the trap, which we call the Ion-trap Collider. We show that the direct collisions of two ions induce an effective spin-spin interaction due to the exchange effect, which decreases with the third power of the two ions’ trapping distance instead of the conventional exponential behaviour of static exchange interaction. The collision-induced spin-spin interaction is about 9 orders of magnitude stronger than the direct spin-spin interaction through the magnetic dipole-dipole coupling. It possible to generate entangled pairs of atomic ions with very large distance for quantum information processing, and realize universal two-qubit square root of SWAP gate for quantum computing.

2:54PM H25.00003: Zero-temperature properties of the long-range transverse-field Ising model on the triangular lattice  
JAMES GARRISON (Presenter), KEVIN WANG, ALEXEY V GORSHKOV, Joint Quantum Institute and Joint Center for Quantum Information and Computer Science, NIST/University of Maryland — We investigate the ground state properties of the transverse-field Ising model with long-range, antiferromagnetic interactions on the triangular lattice. Our study is motivated by experiments on trapped beryllium ions, where the ions form a 2D Wigner crystal with tunable $1/r^\alpha$ Ising interactions in the range $0 \leq \alpha \leq 3$, where $r$ is the distance between two spins. Our results are obtained using a projector variant of the stochastic series expansion (SSE) Monte Carlo method, which allows direct access to ground state properties throughout the phase diagram.
1.3 x 10^5 A m^{-2} sr^{-1} eV^{-1} and a maximum continuous current of 1.16 ± 0.06 nA. These values significantly surpass previous present the design and detailed characterization of 7Li magneto-optical trap ion source (MOTIS) with a peak brightness of.

High-field photoionization of Beryllium using a low-cost solid-state laser*

Portables quantum technologies based on trapped ions. Development of an ultranarrow laser compatible with integrated photonic resonators is a key part of the design of future suppress temperature fluctuation of the central frequency of the fiber resonator to enable precise control of ions. The to achieve lasing at a linewidth comparable to that of a ULE cavity-stabilized laser. Additionally, we apply a novel technique scattering (SBS) nonlinearity in a fiber-based cavity with a quality factor similar to those of integrated photonic resonators quality factors as high as those in ULE cavities. In this work, we demonstrate the application of the stimulated Brillouin scattering (SBS) nonlinearity in a fiber-based cavity with a quality factor similar to those of integrated photonic resonators to achieve lasing at a linewidth comparable to that of a ULE cavity-stabilized laser. Additionally, we apply a novel technique to suppress temperature fluctuation of the central frequency of the fiber resonator to enable precise control of ions. The development of an ultranarrow laser compatible with integrated photonic resonators is a key part of the design of future portable quantum technologies based on trapped ions.

Quantum Control of a Trapped Ion using a Stimulated Brillouin Scattering Laser JULES STUART (Presenter), Massachusetts Institute of Technology, WILLIAM LOH, COLIN BRUZEWICZ, ROBERT MCCONNELL, ROBERT NIFFENEGGER, MIT Lincoln Laboratory, GAVIN WEST, GARRETT SIMON, Massachusetts Institute of Technology, JEREMY SAGE, JOHN CHIAVERINI, MIT Lincoln Laboratory — Trapped ions are natural qubit candidates for quantum information processors and sensors, but high-fidelity quantum operations require high quality laser oscillators. In typical trapped-ion experiments, high finesse, free-space optical cavities made of ultralow expansion (ULE) glass are used to reduce the emission linewidth of commercial lasers to the level of the ion's natural linewidth. Integration of these narrow laser systems into compact or scalable platforms presents a challenge, since it is not currently possible to fabricate integrated photonic resonators with quality factors as high as those in ULE cavities. In this work, we demonstrate the application of the stimulated Brillouin scattering (SBS) nonlinearity in a fiber-based cavity with a quality factor similar to those of integrated photonic resonators to achieve lasing at a linewidth comparable to that of a ULE cavity-stabilized laser. Additionally, we apply a novel technique to suppress temperature fluctuation of the central frequency of the fiber resonator to enable precise control of ions. The development of an ultranarrow laser compatible with integrated photonic resonators is a key part of the design of future portable quantum technologies based on trapped ions.

High-field photoionization of Beryllium using a low-cost solid-state laser* ROBERT WOLF (Presenter), CHRISTIAN MARCINIAK, MICHAEL JORDAN BIERCUK, School of Physics, The University of Sydney — The generation of a pure sample of ions is a prerequisite for a variety of experiments in atomic and molecular physics, in particular using ion traps. Resonant laser photoionization has the advantage of being element and isotope selective, therefore permitting precise control of the composition of the generated ionic species. In this talk we describe experiments employing a novel system for the photoionization of Beryllium at a 2T magnetic field in a Penning trap. Our system is based on injection-locking of a low-cost, high-power multimode diode at 470nm which can then be frequency doubled to the relevant wavelength near 235nm. The optical setup and its application will be presented.

*This research was supported by the Australian Research Council Centre of Excellence for Engineered Quantum Systems (project ID CE170100009).

Characterization of a High-Brightness, Laser-Cooled Li+ Ion Source JAMIE GARDNER (Presenter), WILLIAM McGEHEE, JABEZ J MCCLELLAND, National Institute of Standards and Technology — Ion sources based on laser cooling have recently provided new pathways to high-resolution microscopy, ion milling, and ion implantation. Here, we present the design and detailed characterization of 7Li magneto-optical trap ion source (MOTIS) with a peak brightness of. 1.3 x 10^5 A m^2 sr^{-1} eV^{-1} and a maximum continuous current of 1.16 ± 0.06 nA. These values significantly surpass previous Li MOTIS performance benchmarks. Using simple models, we discuss how the performance of this system relates to fundamental operating limits. This source will support a range of projects using lithium ion beams for surface microscopy and nanostructure characterization, including Li+ implantation for studies of ionic transport in energy storage materials.
4:06PM H25.00009: Mitigation of frequency noise due to mechanical vibration in a cryogenic trapped-ion quantum processor  COLIN BRUZEWICZ (Presenter), JULES STUART, GARRETT SIMON, ROBERT NIFFENEGGER, ROBERT MCCONNELL, JEREMY SAGE, JOHN CHIAVERINI, MIT Lincoln Laboratory — Trapped-ion systems equipped with closed-cycle cryocoolers confer several cost-efficient advantages over traditional room-temperature designs. For example, operation of ion traps at cryogenic temperatures has been shown to lower rates of anomalous motional heating, a limit to multi-qubit logic fidelity, by up to two orders of magnitude. This environment also permits the use of superconducting materials to shield the ion qubits from magnetic field fluctuations. Additionally, cryopumping quickly produces ultrahigh vacuum conditions without the need for extended high-temperature chamber bakeouts, greatly reducing the cycle time of ion trap prototyping. However, mechanical vibrations caused by the cryocooler compressor can degrade quantum gate performance. Specifically, we have identified uncompensated Doppler shifts due to the relative motion of the ion with respect to the laser driving our gates as a leading source of decoherence. Here we describe the recent implementation of an interferometric stabilization scheme that actively modulates the qubit laser frequency to compensate for the motion induced by the cryocooler vibration. We observe a significant increase in the laser-ion coherence time and investigate the effect of this frequency stabilization on two-qubit gate performance.

4:18PM H25.00010: Observation of the Polariton Drag Effect*  BURCU OZDEN (Presenter), DAVID MYERS, JONATHAN BEAUMARIAGE, DAVID SNOKE, Physics, University of Pittsburgh, LOREN PFEIFFER, Physics, Princeton University, KENNETH WEST, Physics, University of Pittsburgh — In this work, we report the observation of polariton drag effect in a semiconductor structure that has been designed to maximize the light-matter coupling, the namely strong coupling of exciton-polaritons in a solid-state microcavity. We show that collisions of polaritons with the free electrons results in a change in the angle of emission of the photons from the cavity structure. The effect is asymmetric, significantly slowing down the polaritons when they move oppositely to the electrons, while the polaritons are only slightly accelerated by electrons moving in the same direction. In conclusion, we have demonstrated proof of principle that a DC current can directly alter the momentum of photons moving in the cavity; this has the direct effect of changing the angle of emission. This polariton drag effect is beam steering using a DC current to tune the angle of a light beam since the experiment is a photon-in, photon-out system.

*The work at Pittsburgh was funded by the Army Research Office (W911NF-15-1-0466). The work of sample fabrication at Princeton was funded by the Gordon and Betty Moore Foundation (GBMF-4420) and by the National Science Foundation MRSEC program through the Princeton Center for Complex Materials (DMR-0819860)

4:30PM H25.00011: Exciton-Polariton Condensate in a Ring Microcavity*  SHOUVIK MUKHERJEE (Presenter), DAVID MYERS, Physics and Astronomy, University of Pittsburgh, ROSARIA LENA, Physics and SUPA, University of Strathclyde, BURCU OZDEN, JONATHAN BEAUMARIAGE, Physics and Astronomy, University of Pittsburgh, MARK STEGER, National Renewable Energy Laboratory, ZHENG SUN, Physics and Astronomy, University of Pittsburgh, LOREN PFEIFFER, KENNETH WEST, Electrical Engineering, Princeton University, ANDREW DALEY, Physics and SUPA, University of Strathclyde, DAVID SNOKE, Physics and Astronomy, University of Pittsburgh — Ring microchannels for exciton-polaritons were created using optical photolithography followed by an inductively coupled plasma etch to pattern the top mirror of the microcavity in a ring shape. Due to the variation in the thickness of the microcavity across the ring, there was a gradient of potential energy across each ring. Polariton condensates were created by non-resonantly pumping the ring at the highest energy region using short laser pulses. A polariton condensate was formed at the location of the pump spot which flowed towards the minimum energy region. We observed natural oscillations of the condensate about this energy minimum by time resolving the photoluminescence using a streak camera. The time period of the oscillations was in good agreement with the numerical simulation of the time evolution of a wave packet in a rigid pendulum potential. A time-reversal -symmetry-broken rotational mode was also observed in the ring. The temporal oscillations in energy and density of the polaritons at a given spatial point provide a direct measurement of the exciton-exciton interaction strength (~ 5 μeV-μm²) in a GaAs quantum well.

The development of high-Q microcavity quantum well samples has led to long lifetime polaritons, thus allowing for long distance propagation of polaritons. However, long lifetime polaritons have very narrow line widths, as a result we can no longer resolve the polariton branches in the reflectivity spectrum of these samples. This makes accurately determining the detuning of polariton populations difficult. Accurate detuning information is essential for quantitative work involving absolute density of the polariton population. In this work, we will discuss our modern characterization techniques. We have two methods which we currently use. One method involves fitting large angle dispersion curves of the lower polariton with the theoretical predictions of a two state model. The other method involves measuring accurate dielectric functions for our materials, and then comparing experimental reflectivity data to the predictions of a transfer matrix model to determine the cavity mode. Both of these methods depend on the measurement of the rabbi splitting by photoluminescent emission scans. We found these two methods agree well with each other.

4:54PM H25.00013: Long-Range Exciton Transport in Microcavity Exciton-Polariton Systems*  
DAVID MYERS (Presenter), SHOUVIK MUKHERJEE, JONATHAN BEAUMARIAGE, University of Pittsburgh, MARK STEGER, National Renewable Energy Lab, LOREN PFEIFFER, KENNETH WEST, Princeton University, DAVID SNOKE, University of Pittsburgh — It has previously been assumed that the transport distance of excitons in microcavity exciton-polariton systems is limited by the bare exciton diffusion length (≤ 1 μm). In the case of non-resonant excitation, this implies that excitons created by the pump laser would be mostly confined to the pump location. While this is clearly generally true given the close similarities between the spatial pump and lower polariton potential profiles, we show that there is an important minority population of slightly polaritonic excitons that can move distances similar to those of the much more photonic polaritons (~ 30 μm). This population, which resides in the bottleneck region of the lower polariton branch, is often not detected in a typical photoluminescence experiment due to limited numerical aperture. While small in number compared to the total population of excitons, they can substantially outnumber the polaritons below the bottleneck. This has significant implications for creating potential landscapes using a non-resonant pump, and for measurements of the interaction strength between polaritons.

Session H26 GIMS: Advances in Scanned Probe Microscopy II: High Frequency, and Optical and Low Temperature Measurements  
BCEC 160B - Tag(s): Focus

2:30PM H26.00001: What limits time resolution in AFM?*  
PETER GRUTTER (Presenter), McGill University — Developing a technique that combines nanometer spatial and sub-femtosecond temporal sensitivity is a crucial step towards exposing the inner mechanisms of chemical reactions, single molecule motion, electron dynamics in solids, and the effects of defects or trap states on electron motion and behavior, amongst many other questions relating to the most fundamental processes in molecular systems.

Our most recent advances in mechanically detecting ultrafast events will be presented. In particular, a non-linear optically induced polarization in a solid will directly lead to a force which can be detected by AFM with its intrinsic nanometer spatial resolution. I will show how one can mechanically measure a change in the sample response as a result of a delay time as short as 25 atto seconds between a pump and probe stimulation pulse on LiNbO3 or monolayers of MoSe2.

The realization of ultrafast AFM opens the door to understanding ultrafast electron dynamics on surfaces. As such, we are able to demonstrate that the lower limit of timing precision in mechanical detection in a pump-probe experiment is determined by the smallest detectable signal, and not, as might be expected, by the mechanical resonance frequency of the oscillator.

Work done in collaboration with Z. Schumacher, R. Rejali, R. Pachlatko, A. Spielhofer, Y. Miyahara, and D. Cooke

*Supported by NSERC, FRQNT and CFI
3:06PM H26.00002: Subsurface Second Harmonic Speckle Defect Microscopy* FARBOD SHAFIEI, The University of Texas at Austin, TOMMASO ORZALI, SEMATECH, ALEXEY VERT, P Y HUNG, SEMATECH/Sunny Polytechnic Institute, GENNADI BERSUKER, The Aerospace Corporation, MICHAEL C DOWNER (Presenter), The University of Texas at Austin — Growing crystals epitaxially over substrates is a critically important process for opto-electronic applications. Due to generally occurred atomic-level mismatches between the crystal and substrate, these semiconductor thin films are vulnerable to varieties of defects (like threading dislocation in GaAs-Si), which act as scattering sites for electrons and photons. Multi-scattering from these defects can result in the localization of the light. We demonstrate that a signature of this localization (in the case of III-V films) can be picked by a fiber scanning probe microscope in nonlinear regime. The size of these light localizations, which optically appear like speckles, have strong correlation to the density of the film dislocations. We introduce this noninvasive optical technique capable of identifying the presence of threading dislocations, their density, as well as orientation and structural arrangements of these defects.

*Welch Foundation

3:18PM H26.00003: Optical evolution of dislocation speckle imaging inside and outside of thin films* FARBOD SHAFIEI, The University of Texas at Austin, TOMMASO ORZALI (Presenter), SEMATECH, ALEXEY VERT, SEMATECH/Sunny Polytechnic Institute, MAN HOI WONG, SEMATECH, GENNADI BERSUKER, The Aerospace Corporation, MICHAEL C DOWNER, The University of Texas at Austin — We have employed a fiber scanning probe microscopy to study light localization due to multi-scattering of light by dislocation defects in III-V films (in particular, GaAs-Si). By sputtering the film down to the semiconductor-substrate interface we observe how the nonlinear optical signature of the dislocation defects changes with the increasing density of a dislocation area. The same probe microscopy approach was used to track the evolution of the propagating optical fields from these dislocation speckles, outside the thin film. Such approach can be used as an extremely high resolution monitoring tool of propagating electromagnetic fields.

*Welch Foundation

3:30PM H26.00004: Vibration measurements of a scanning SQUID microscope in a cryogen-free dilution refrigerator* DAVID LOW (Presenter), GEORGE FERGUSON, ALEXANDER B JARJOUR, RACHEL RESNICK, BRIAN SCHAEFER, ERIC N SMITH, KATJA NOWACK, Cornell University — Scanning probe microscopy is more challenging in cryogen-free systems due to vibrations introduced at the sample by the cryocooler. We built a cryogen-free scanning superconducting quantum interference device (SQUID) magnetic probe microscope operating in a cryogen-free dilution refrigerator with a base temperature of 10 mK. We report characterization of both the vibrations at the mixing chamber plate and of probe-to-sample vibrations. For the latter, we follow Schliessl et al. (Appl. Phys. Lett. 109, 232601 (2016)) and measure noise spectra at multiple locations above a sample where strong magnetic field gradients are present. This allows us to disentangle vibrations in different spatial directions. We find that the most pronounced vibrations are below 10 nm/Hz^{1/2} and occur at low harmonics of the pulse tube cycle. We will also discuss future improvements to our microscope and refrigerator that will further reduce the vibrations in our system.

*Work was supported by the Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, under Award DE-SC0015947 (vibration characterization, mK microscope) and by the Cornell Center of Materials Research with funding from the NSF MRSEC program under Award DMR-1719875 (microscope design).

3:42PM H26.00005: Upgrading a low-temperature scanning tunneling microscope for electron spin resonance experiments* FABIAN NATTERER (Presenter), University of Zurich, FRANÇOIS PATTHEY, TOBIAS BILGERI, PATRICK FORRESTER, NICOLAS WEISS, HARALD BRUNE, Ecole polytechnique federale de Lausanne — We describe the upgrade of a helium-3 STM to an electron spin resonance enabled apparatus [1]. We are able to transmit RF power to the tunnel junction at frequencies of up to 30 GHz. Our apparatus is benchmarked via magnetic field sweep ESR on the model system TiH/MgO/Ag(100) [2] for which we find a magnetic moment of (1.00±0.001) μB. We can chose a DC mode for regular STM operation or an ultra-fast mode for pump-probe spectroscopy or the reading of spin-states. In both modes, simultaneous radiofrequency excitation is possible, which we add via a resistive pick-off tee to the bias voltage path. We discuss our transmission, indicate potential pitfalls in the upgrade and demonstrate how to synchronize the arrival times of RF and DC pulses coming from different paths to the STM junction, a prerequisite for future pulsed ESR experiments.

*Support from the Swiss National Science Foundation under project numbers PZ00P2_167965 and 200020_176932 is appreciated.
3:54PM H26.00006: An Ultra-High Vacuum Cryogen-free Low Temperature Proximal Probe System for the Exploration of Low Dimensional Materials and Nano-devices* ANGELA COE (Presenter), GUOHONG LI, EVA ANDREI, Rutgers University, New Brunswick — We introduce a new design concept that combines into one instrument, several scanning probe microscopy modules, ultra-high vacuum, low temperature, magnetic field, and cryogen free operation. The integration of these capabilities is made possible by the realization of an ultra-compact scanning probe microscopy (SPM) head with a modular design for accommodating interchangeable probes including STM, AFM, and MFM. A novel transfer mechanism makes it possible to transfer the SPM head between various chambers of a compact UHV system for loading probes, tips, and samples. The instrument is equipped with stages for sputtering, e-beam film deposition, and exfoliation for in-situ sample preparation and tip conditioning. Following the UHV room-temperature assembly, the entire SPM with the loaded sample is transferred without breaking vacuum to a variable temperature cryogen-free cryostat and magnet. The integration of all these capabilities into one instrument enables in-situ nano-scale characterization of low dimensional systems and devices in an ultra-clean environment, and under controlled temperature and field conditions.

*Work supported by NSF-DGE 1842213 (A.M.C.), DOE-FG02-99ER45742 (E.Y.A.), NSF-MRI 1337871 (G.L.), and NSF-DMR 1708158 (G.L.).

4:06PM H26.00007: Low temperature magnetic force microscope with simple design.* JEFFREY VIT (Presenter), University of Texas at Austin, KWOK-WAI NG, University of Kentucky, ALEJANDRO DE LOZANNE, University of Texas at Austin — We present a new design for a magnetic force microscope that will operate at variable temperatures down to liquid helium in fields up to 8 Tesla. As with our previous designs, the temperature/field design goals are achieved most efficiently by maintaining everything within a one-inch cylinder. [Rev. Sci. Instrum. 78, 053710 (2007)] Unlike other designs, this one has an open architecture that results in simplified machining, assembly, modification/repair, and daily operation. The new microscope has three homemade stick-slip stages that provide several millimeters of relative travel between tip and sample.

*Supported by NSF DMR-1507874

4:18PM H26.00008: Advances in SQUID-detected Magnetic Resonance Force Microscopy MARTIN DE WIT (Presenter), GESA WELKER, FREDERIK HOEKSTRA, TJERK OOSTERKAMP, Leiden University — Magnetic Resonance Force Microscopy (MRFM) is a technique that combines magnetic resonance protocols with an ultrasensitive cantilever to measure the forces exerted by extremely small numbers of spins. The fundamental limit for the sensitivity of MRFM is given by the thermal force noise, so experiments should be performed at the lowest possible temperature. For this reason, we have developed a three stage mechanical low pass filter, which combines good vibration isolation (expected attenuation > 100 dB at 100 Hz) with a high thermal conductance (cooling power 113 μW at 100 mK). The MRFM can be operated at temperatures around 20 mK thanks to a SQUID-based detection scheme and the mechanical generation of the alternating B1 fields required for the magnetic resonance. We use these technical advances to perform MRFM experiments on a thin copper film, where we obtain frequency-shift signals from the Boltzmann polarization of spins in a volume as small as (40 nm)3. We propose an experiment on a sample containing protons where magnetic resonance imaging with a voxel size < (10 nm)3 should be possible.

4:30PM H26.00009: Incommensurate surface superstructure observed on epitaxially grown Al(111) films by scanning tunneling microscopy at mK temperature SUNGMIN KIM (Presenter), JOHANNES SCHWENK, WILLIAM G CULLEN, Physical Measurement Laboratory, National Institute of Standards and Technology, YOUNG KUK, Department of Physics and Astronomy, Seoul National University, JOSEPH A STROSCIO, Physical Measurement Laboratory, National Institute of Standards and Technology — Superconducting aluminum samples are generally used as a standard reference for testing the energy resolution of cryogenic scanning tunneling microscopes operating at ultra-low temperatures by measuring its superconducting tunneling gap spectrum. However, only a few of the atomic structure of the aluminum surface have been reported in those studies because of the difficulties in preparing atomically clean surfaces due to its strong reactivity. In this presentation, we report the observation of an incommensurate superstructure on Al(111) films grown epitaxially on graphene on SiC substrates. The observed superstructure has 3-fold symmetry with a 3.3 periodicity. The superstructure closely resembles a charge density wave structure, for example, similar to that typically observed on NbSe2. We therefore speculate that possibly Al(111) may support a surface CDW at ultra-low temperatures due to same electron-phonon coupling which is responsible its superconductivity. Other possible explanations for a surface or bulk CDW phase include such soft phonons resulting from strain effects [1], which will be discussed.

4:42PM H26.00010: Photonic crystal fiber assisted nano-antenna for tip-enhanced Raman spectroscopy

KHANT MINN, BLAKE BIRMINGHAM, BRYNNA R NEFF, Department of Physics, Baylor University, MARLAN O SCULLY, The Institute for Quantum Science and Engineering, Texas A&M University, HOWARD HO WAI LEE, ZHENRONG ZHANG (Presenter), Department of Physics, Baylor University — Metallic plasmonic nano-probes can efficiently excite and detect the near-field at nanoscale for near-field imaging and sensing applications such as tip-enhanced Raman spectroscopy (TERS). In this paper, we report the design, fabrication and far-field characterization of a photonic-plasmonic probe. In our device, light in a photonic crystal fiber (PCF) couples with the surface plasmons of a nano-antenna. The needle-shaped antenna is grown by electron beam assisted chemical deposition of platinum on the PCF's end facet. Plasmonic resonance conditions can be optimized by controlling the deposition parameters, height, and base diameter of the antenna. Far field emission to the side of the probe, optical spectra and mode profiles transmitted through the probe demonstrate the excitation of surface plasmons on the antennae. The probe can be implemented into TERS setup to obtain spectroscopic information at the nanoscale.

4:54PM H26.00011: Cryogen-free variable temperature scanning SQUID microscope*

LOGAN BISHOP-VAN HORN (Presenter), ZHENG CUI, JOHN KIRTLEY, KATHRYN ANN MOLER, Stanford University — Scanning Superconducting QUantum Interference Device (SQUID) microscopy is a powerful tool for imaging local magnetic properties, but it requires a low-vibration cryogenic environment, traditionally achieved by thermal contact with a bath of liquid helium or the mixing chamber of a "wet" dilution refrigerator. We mount a SQUID microscope on the 3 K plate of a Bluefors pulse tube cryocooler and characterize its vibrational spectrum by measuring SQUID noise in a region of sharp flux gradient. By implementing passive vibration isolation, we reduce relative sensor-sample vibrations to 20 nm in-plane and 15 nm out-of-plane. A variable-temperature sample stage that is thermally isolated from the SQUID sensor enables measurement at sample temperatures from 2.8 K to 110 K. We demonstrate these advances by imaging inhomogeneous susceptibility and vortex pinning in optimally doped YBCO above 90 K. Together with sub-micron spatial resolution and 350×350 μm² scan range, these advances position us for further studies of magnetic and superconducting materials and devices over a temperature range not previously accessible to scanning SQUID microscopy.

Session H27 DQI: Quantum Information in Relativistic and Condensed Matter Systems

BCEC 160C - Shenglong Xu, University of Maryland, College Park - Tag(s): Focus

2:30PM H27.00001: Quantum Interferometry Meets General Relativity

IGOR PIKOVSKI (Presenter), Stevens Institute of Technology — The interplay between Einstein's theory of gravity and quantum mechanics remains one of the open questions in physics. Each of the theories has been confirmed individually, but phenomena described by the two usually take place at very different physical regimes. Nevertheless, gravity can affect quantum systems and some aspects of the interplay can be probed in experiments. In this talk, I will discuss a quantum version of the “twin paradox” in which a clock is brought in superposition of being at two different gravitational potentials. The effect leads to new and measurable consequences at the interplay between quantum theory and general relativity and causes decoherence of composite quantum systems. I will also discuss how these effects can be accessed in quantum interference experiments.
2:42PM H27.00002: Gravitational entanglement with Gaussian states*  
SOFIA QVARFORT (Presenter), SOUGATO BOSE, ALESSIO SERAFINI, University College London — Is gravity a quantum force? This question was recently addressed by two proposals (see [1] and [2]) which explored the possibility of detecting entanglement as generated by gravity. Successful detection of entanglement due to a gravitational interaction would imply that gravity is fundamentally a quantum force, since only quantum systems can mediate entanglement.

In my talk, I will show how the experimental scheme in [1] can be modeled for Gaussian states in the continuous variable framework using massive optomechanical spheres for two different settings: trapped systems and freely-falling systems. We evaluate the entanglement generated by the Newtonian potential for both cases and propose the use of two specific continuous variable entanglement witnesses to simplify the detection. The approach also allows us to include other central-potential interactions, such as the attractive Casimir effect.

*SQ acknowledges funding from EPSRC.

2:54PM H27.00003: General relativistic time dilation and spacetime uncertainty in quantum clocks*  
SHISHIR KHANDELWAL (Presenter), Institute for Theoretical Physics, ETH Zürich, MAXIMILIAN P. E. LOCK, Institute for Quantum Optics and Quantum Information (IQOQI), Vienna, Austria, MISCHA WOODS, Institute for Theoretical Physics, ETH Zürich — The general theory of relativity associates a proper time with each object via its spacetime trajectory. In quantum theory on the other hand, such trajectories are forbidden. Here we demonstrate that, in the weak-field and low-velocity limit, all "good" quantum clocks experience the time dilation dictated by general relativity for the most classical states of motion. For nonclassical states of motion, on the other hand, we find that quantum interference effects give rise to a significant discrepancy between the proper time and the time measured by the clock. Moreover, we show how our ignorance of the clock's state of motion leads to a larger uncertainty in time measurements with the clock, a consequence of entanglement between the clock time and its center-of-mass degrees of freedom.

*Swiss National Science Foundation

3:06PM H27.00004: Ontological models for relativistic quantum information*  
[Invited] IAN DURHAM (Presenter), Saint Anselm College — Epistemic models of nature prove to be problematic in many settings, particularly in those for which measurement procedures are ill-defined. By contrast, in ontic models of nature, measurement results are independent of the procedure used to obtain them. If we assume that all measurement results can be expressed in terms of pointer readings, then any useful ontology would need to unambiguously specify the positions of things. We review a number of proposals for such ontologies in the context of relativistic quantum information and quantum many-body theories, and we propose a new ontology based on the Wheeler-DeWitt equation that overcomes some of the problems inherent in existing models. Our model includes a set of deterministic constraints for the geometry, matter field, and action.

*Funding provided by FQXi and the Silicon Valley Community Fund, Grant No. 2016-165593.

3:42PM H27.00005: Relativistic wave equations from quantum walks  
TODD BRUN (Presenter), LEONARD MLODINOW, University of Southern California — Quantum walks are unitary analogues of classical random walks. We examine the quantum walk on the 3D body-centered lattice, and show that a set of natural symmetry assumptions lead, in the long wavelength limit, to its wave functions becoming solutions to the Dirac equation. These assumptions require at least a four-dimensional internal space. Taking this as a model of a particle propagating in discrete spacetime, we show that the discreteness could be detected in non-parallel matter interferometers. We also look at the problem of generalizing to the many-body case, by replacing the quantum walk with a quantum cellular automaton that gives the same evolution as the quantum walk for the single-particle sector. This automaton approaches a quantum field theory in the long-wavelength limit.
4:06PM H27.00007: Locality and digital quantum simulation of power-law interactions  MINH TRAN (Presenter), ANDREW Y GUO, QuICS/JQI, University of Maryland, College Park, YUAN SU, QuICS, University of Maryland, College Park, JAMES GARRISON, ZACHARY ELDREDGE, QuICS/JQI, University of Maryland, College Park, MICHAEL FOSS-FEIG, United States Army Research Laboratory, ANDREW CHILDS, QuICS, University of Maryland, College Park, ALEXEY V GORSHKOV, QuICS/JQI, University of Maryland, College Park — The propagation of information in non-relativistic quantum systems obeys a speed limit known as a Lieb-Robinson bound. We derive a new Lieb-Robinson bound for systems with interactions that decay with distance $r$ as a power law, $1/r^\alpha$. The bound implies an effective light cone tighter than all previous bounds. Our approach is based on a technique for approximating the time evolution of a system, which was first introduced as part of a quantum simulation algorithm by Haah et al. To bound the error of the approximation, we use a known Lieb-Robinson bound that is weaker than the bound we establish. This result brings the analysis full circle, suggesting a deep connection between Lieb-Robinson bounds and digital quantum simulation. In addition to the new Lieb-Robinson bound, our analysis also gives an error bound for the Haah et al. quantum simulation algorithm when used to simulate power-law decaying interactions. In particular, we show that the gate count of the algorithm scales with the system size better than existing algorithms when $\alpha>3D$ (where $D$ is the number of dimensions).

4:18PM H27.00008: Composite quantum systems at the interface with general relativity* [Invited] MAGDALENA ZYCH (Presenter), The School of Mathematics and Physics, The University of Queensland — A major goal of modern physics is to understand and test the regime where quantum mechanics and general relativity both play a role. However, new effects of this regime are usually thought to be relevant only at high energies or in strong gravitational fields, beyond the reach of present-day experiments. I will discuss a novel framework for achieving this goal, focused on low-energy but composite quantum systems and using the tools of quantum information science. Quantum coherence of composite particles can be measurably affected by general relativity even at low-energies and in weak gravitational fields through time dilation. I will explain the resulting new phenomena and how they can be tested. I will discuss broader relevance of the approach for quantum sensing, communication and quantum information processing.

*ARC Discovery Early Career Researcher Award (DECRA) DE180101443

4:54PM H27.00009: Signature of quantum chaos in operator entanglement in 2d conformal field theories+ LAIMEI NIE (Presenter), MASAHIRO NOZAKI, Kadanoff Center for Theoretical Physics, University of Chicago, SHINSEI RYU, Kadanoff Center for Theoretical Physics and James Franck Institute, University of Chicago, MAO TIAN TAN, Kadanoff Center for Theoretical Physics, University of Chicago — We study operator entanglement measures of the unitary evolution operators of $(1+1)$-dimensional conformal field theories (CFT), aiming to uncover their scrambling and chaotic behaviors. In particular, we compute the bi-partite and tri-partite mutual information for various configurations of input and output subsystems, and as a function of time. We contrast three different CFTs: the free fermion, the compactified free boson at various radii, and CFTs with holographic dual. We found that the bi-partite mutual information exhibits distinct behaviors for these CFTs, reflecting the different information scrambling capabilities of these unitary operators; while a quasi-particle picture can describe well the case the free fermion and free boson CFTs, it completely fails for the case of holographic CFTs. Similarly, the tri-partite mutual information also distinguishes the unitary evolution operators of different CFTs. In particular, its late time behaviors, when the output subsystems are semi-infinite, are quite distinct for these theories. We speculate that for holographic theories the late time value of the tri-partite mutual information saturates the lower bound among quantum field theories.

5:06PM H27.00010: Exact bosonization in two and three spatial dimensions and new classes of lattice gauge theory
YU-AN CHEN (Presenter), ANTON KAPUSTIN, Caltech, DJORDJE RADICEVIC, Physics, Perimeter Institute — We will describe 2d (3d) analogs of the Jordan-Wigner transformation which maps an arbitrary fermionic system on a 2d (3d) lattice to a lattice gauge theory while preserving the locality of the Hamiltonian. The lattice gauge theory can be understood as a stabilizer code. When the space is simply-connected, this bosonization map is an equivalence. On 2d square lattice, our bosonization mapping is equivalent to Bravyi-Kitaev "Superfast simulation of Fermions" and it has possible applications on quantum simulation of fermions. We also describe Euclidean actions for the corresponding lattice gauge theories and find that the (2+1)D theory contains Chern-Simons-like terms, which can be considered as Z/2Z version of particle-vortex duality.

5:18PM H27.00011: Momentum-space entanglement of disordered non-interacting one-dimensional fermions after a quantum quench
REX LUNDGREN (Presenter), FANGLI LIU, Joint Quantum Institute, NIST/UMD, PONTUS LAURELL, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, GREGORY FIETE, Department of Physics, The University of Texas at Austin — We investigate the momentum-space entanglement entropy and spectrum of several disordered one-dimensional free-fermion systems that circumvent Anderson localization, such as the random-dimer model, after a quantum quench. We numerically observe two different types of momentum-space entanglement entropy dynamics, an interesting slow logarithmic-like growth followed by saturation or rapid saturation. The type of dynamics one observes depends on the Fermi level of the intial state and the scattering matrix element structure in momentum-space. We then discuss when the momentum-space entanglement spectrum reveals the presence of delocalized states after a quench in these systems. We find if there are vanishing momentum-scattering states, the momentum-space entanglement spectrum clearly reveals the presence of delocalized states for long times.

2:30PM H28.00001: Nonequilibrium thermodynamics and many-body dynamics in open quantum systems* [Invited]
MASAHITO UEDA (Presenter), University of Tokyo — Quantum gas microscopy has revolutionarized our view on quantum many-body systems where atoms trapped in an optical lattice can be observed in real time at the single-particle level. At such extreme precision, the measurement backaction due to Heisenberg's uncertainty relation can no longer be ignored. One should naturally led to the question of whether or not nonequilibrium thermodynamics and statistical physics should be modified be modified and, if so, in what way and, in particular, how thermalization proceeds under continuous observation. A similar situation has emerged in a system of superconducting qubits under feedback control. I will address these issues and closely related problems of thermalization, heating and many-body localization in isolated and open quantum systems.

3:06PM H28.00002: Multiplexed Readout of Superconducting Qubits in 3D cQED Architecture Using Impedance Engineered Broadband JPA*
SUMAN KUNDU (Presenter), DCMP&MS, Tata Institute of Fundamental Research, Mumbai, NICOLAS GHEERAERT, Neel institute, CNRS and University Grenoble-Alpes, Grenoble, France, SUMERU HAZRA, DCMP&MS, Tata Institute of Fundamental Research, Mumbai, TANAY ROY, Department of Physics, University of Chicago, USA, KISHOR SALUNKHE, MEGHAN P. PATANKAR, RAJAMANI VIJAYARAGHAVAN, DCMP&MS, Tata Institute of Fundamental Research, Mumbai — We propose and demonstrate a frequency-multiplexed readout scheme in 3D cQED architecture. We use four transmon qubits coupled to individual rectangular cavities which are aperture-coupled to a single rectangular waveguide feedline. A coaxial to waveguide transformer at the other end of the feedline allows to launch and collect the multiplexed signal. The reflected readout signal is amplified by an impedance engineered broadband parametric amplifier with 380 MHz of bandwidth. This provides us high fidelity single-shot readout of multiple qubits using compact microwave circuitry, an efficient way for scaling up to more qubits in 3D cQED. We also discuss possible designs for multiplexing larger number of qubits. Finally, we discuss the saturation properties of our broadband JPA and explore a few approaches to improve them to increase the number of qubits that can be measured simultaneously.

Increasing qubit readout fidelity and efficiency with two-mode squeezed light

XI CAO (Presenter), GANGQIANG LIU, TZU-CHIAO CHIEN, PINLEI LU, MICHAEL HATRIDGE, Physics and Astronomy, University of Pittsburgh — Implementing quantum information processing on a large scale with flawed components requires highly efficient, quantum non-demolition (QND) qubit readout. In superconducting circuits, qubit readout using coherent light with fidelity above 99% has been achieved by using a quantum-limited parametric amplifier such as the Josephson Parametric Converter (JPC), as the first stage amplifier. However, further improvement of such measurement is fundamentally limited by the vacuum fluctuations on the ports of the JPC. Alternatively, readout with squeezed input can entangle the vacuum fluctuations in different modes, thus allowing for the reduction of the noise by controlling their interference. In this talk, we demonstrate a dispersive qubit readout scheme which exploits the two-mode squeezed light generated by a first JPC and processed by a second JPC to form an amplified interferometer [1]. We have observed a 22% improvement in the voltage Signal-to-Noise Ratio (SNR) of the measurement compared to coherent light. We can also extend this scheme to generate remote entanglement. We will discuss how the role of losses changes in this system for coherent vs two-mode squeezed light.

cross-resonance-based readout scheme of a superconducting flux qubit

FUMIKI YOSHIHARA (Presenter), National Institute of Information and Communications Technology, SAHEL ASHHAB, Qatar Environment and Energy Research Institute, TOMOKO FUSE, KOUICHI SEMBA, National Institute of Information and Communications Technology — We propose a cross-resonance-based readout scheme of a superconducting flux qubit, in which a flux qubit is coupled to a resonator, and a microwave flux pulse tuned to the resonator is applied to the flux qubit. At the optimal flux bias, the persistent current of the flux qubit is an increasing or decreasing function of the flux bias, depending on the state of the qubit. When a microwave flux drive is applied to the qubit, the phase of the induced microwave signal felt by the resonator depends on the state of the qubit, and the difference between the two values is 180 degrees. Since this qubit-state-dependent phase difference is larger than that of dispersive-interaction schemes [1], the proposed cross-resonance-based readout scheme has the potential to be faster. The proposed scheme takes advantage of the large contrast of the flux-bias dependence of the persistent current, and, hence, faster readout is expected compared to the alternative readout schemes [2, 3], which are mainly for transmon qubits.

Continuous joint measurement of two-qubit fluorescence: quantum dynamics and entanglement

PHILIPPE LEWALLE (Presenter), ANDREW N JORDAN, Physics and Astronomy, University of Rochester — We consider a continuous weak measurement scheme in which two qubit-cavity systems are allowed to fluoresce, and their fluorescence signals are mixed before being routed to a measurement apparatus. We theoretically investigate the stochastic quantum trajectories, qubit state dynamics, and entanglement dynamics between the qubits under such a joint-measurement scheme. Equivalent systems should be experimentally realizable with existing circuit-QED technologies.

*We acknowledge funding from NSF DMR-1809343. PL acknowledges additional partial support as a GAANN fellow (US Dept. of Education GR506598).
Qubit measurements in a computational basis are a necessary component of quantum computation. Examples include measurement at the end of a quantum algorithm and projective measurements during teleported operations. Although qubit readout suffers from errors, they may be repeated if the readout is quantum non-demolition (QND). In this way, individual imperfect readouts can be combined via methods such as majority voting to form a more accurate measurement. The measurement fidelity will be limited, however, by state transitions between qubit basis states. For two-level qubits, a single relaxation event destroys the information in the qubit. An increased distance in the Hilbert space between basis states for qubits encoded in bosonic modes, however, exponentially suppresses this infidelity limit due to transitions. In this talk, we present a measurement scheme in the circuit quantum electrodynamics (cQED) platform that utilizes repeated QND readouts to suppress measurement infidelity due to both individual readout errors and relaxation. [1] We characterize the fidelity of this scheme in terms of experimental parameters for various encodings.

4:30PM H28.00009: Measuring qubit quasi-probability distributions behind out-of-time-ordered correlators*  
RAZIEH MOHSENINIA (Presenter), JOSE RAUL GONZALEZ ALONSO, MORDECAI WAEGELL, Chapman University, NICOLE YUNGER HALPERN, California Institute of Technology, JUSTIN DRESSEL, Chapman University — The non-classicality of the quasi-probability distribution (QPD) behind an out-of-time-ordered correlator (OTOC) is a more nuanced witness for information scrambling than the OTOC itself. We use the method introduced in Phys. Rev. A 98, 012132 (2018) to provide different experimental protocols for obtaining such a QPD in a multi-qubit system. We show that by strategically averaging sequential measurements of any strength, we can reconstruct both OTOCs and QPDs in spite of disturbances caused by intermediate strong measurements.

4:42PM H28.00010: Time-resolved single-shot single-gate RF spin readout in silicon*  
PRASANNA PAKKIAM (Presenter), ANDREY V. TIMOFEEV, MATTHEW HOUSE, MARK HOGG, TAKASHI KOBAYASHI, MATTHIAS KOCH, SVEN ROGGE, MICHELLE Y SIMMONS, Univ of New South Wales — For solid-state spin qubits, single-gate RF readout can minimise the number of gates required for scale-up since the readout sensor can integrate into the existing gates used to manipulate the qubits [1][2]. However, state of the art topological error correction codes benefit from the ability to resolve the qubit state within single-shot, that is, without repeated measurements [3]. Here we show single-gate, single-shot readout of a singlet-triplet spin state in silicon, with an average readout fidelity of 82.9% at 3.3kHz measurement bandwidth. We use this technique to measure a triplet T to singlet S0 relaxation time of 0.62ms in precision P-donor quantum dots. We also show that the use of RF readout does not impact the spin lifetimes (S0 to T decay remained 2ms at zero detuning). This establishes single-gate sensing as a viable readout method for spin qubits.

*Research supported by ARC CoE for Quantum Computation and Communication Technology (Project No. CE110001027) and U.S. ARO under Contract No. W911NF-17-1-0202. The device is fabricated at the NSW node of ANFF. M.Y.S. acknowledges an ARC Laureate Fellowship.

4:54PM H28.00011: Radio-frequency reflectometry of a quantum dot using an ultra-low-noise SQUID amplifier*  
FELIX SCHUPP (Presenter), NATALIA ARES, AQUILA MAVALANKAR, Oxford University-USE 4643, JONATHAN GRIFFITHS, GEB JONES, Physics, Cambridge University, IAN FARRER, Physics, Sheffield University, DAVID A RITCHIE, CHARLES G SMITH, Physics, Cambridge University, GEORGE ANDREW DAVIDSON BRIGGS, Oxford University-USE 4643, EDWARD LAIRD, Physics, Lancaster University — Fault-tolerant spin-based quantum computers will require fast and accurate qubit readout. This can be achieved using radio-frequency reflectometry given sufficient sensitivity to the change in quantum capacitance associated with the qubit states. Here, we demonstrate a 23-fold improvement in capacitance sensitivity by supplementing a cryogenic semiconductor amplifier with a SQUID preamplifier. The SQUID amplifier operates at a frequency near 200 MHz and achieves a noise temperature below 550 mK when integrated into a reflectometry circuit, which is within a factor 115 of the quantum limit. It enables a record sensitivity to capacitance of 0.07 aFHz^-0.5 and a sensitivity to oscillating charge of 5.9 x 10^{-24}Chz^{-0.5}. We use this circuit to measure the stability diagram of a gate-defined quantum dot, and show that the sensitivity should be sufficient for single-shot readout of a singlet-triplet qubit in GaAs without a charge sensor.

Advantages of Independent Heat Sinking of a Two-Stage Cryogenic Amplifier for Quantum Dot Readout

JOELLE CORRIGAN (Presenter), TREVOR KNAPP, JOHN DODSON, NATHAN HOLMAN, BRANDUR THORGRIMSSON, THOMAS MCJUNKIN, SAMUEL NEYENS, E. R. MACQUARRIE, RYAN FOOTE, Department of Physics, University of Wisconsin-Madison, LISA EDGE, HRL Laboratories, LLC, SUSAN COPPERSMITH, MARK ALAN ERIKSSON, Department of Physics, University of Wisconsin-Madison — Reduced device electron temperature while using a cryogenic HEMT amplifier is achieved by moving the amplifier to an adjacent PCB electrically connected to the sample PCB. The amplifier PCB is directly heat sunk to the mixing chamber of a dilution refrigerator, and connects to the sample through a short stainless steel coax. Using straightforward measurements of gain and RMS noise, the two stages are tuned separately to minimize the input-referred noise for a given level of power dissipation. A single shot measurement with 650 ns rise time using 10 µW of power results in a 2.3:1 SNR and 150mK electron temperature. An electron temperature of 115 mK is achieved with lower power, and the effect of these various powers on SNR is examined for bandwidths of 540kHz and 170kHz. The large amplifier bandwidth enables high frequency lock-in measurements, resulting in lower noise data than possible without such an amplifier. The ease of use of cryogenic amplification combined with relatively low electron temperature and large bandwidth provides a useful tool for characterization of semiconductor quantum dot qubits.

Fast high fidelity qubit readout of a transmon molecule using longitudinal coupling

VLADIMIR MILCHAKOV (Presenter), REMY DASSONNEVILLE, OLIVIER BUISSON, LUCA PLANAT, SÉBASTIEN LÉGER, JAVIER PUERTAS, KARTHIK SRIKANTH BHARADWAJ, FARSHAD FOROUGHI, CECILE NAUD, WIEBKE HASCH-GUICHARD, NICOLAS ROCH, Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, 38000 Grenoble, France — The most common technique of qubit readout in cQED relies on the transverse dispersive coupling between a qubit and a microwave cavity. However, despite important progresses, implementing fast high fidelity readout remains a major challenge. Indeed, inferring the qubit state is limited by the trade-off between speed and accuracy due to Purcell effect and unwanted transitions induced by readout photons in the cavity. To overcome this, we introduce a transmon molecule based on two transmons coupled by a large inductance, which is inserted inside a 3D-cavity. The full system presents one transmon –used as qubit– with a large direct cross-Kerr(longitudinal) coupling to a non-linear readout resonator, called polaron mode. This polaron mode results from the hybridization between the microwave cavity and the second mode of the transmon molecule circuit. The direct cross-Kerr coupling is a key point of our readout scheme since it protects the qubit from Purcell effect. We will present qubit readout performance with fidelity as high as 95.7% in 120ns and discuss the quantum non-demolition properties of this novel readout.

2:30PM H30.00001: Assembling and organizing block copolymer nanostructures with the aid of liquid crystals

CHINEDUM OSUJI (Presenter), Chemical and Biomolecular Engineering, University of Pennsylvania, YOUNGWOO CHOO, MANESH GOPINADHAN, Yale Univ, MASAFUMI FUKUTO, RUIPENG LI, Brookhaven National Lab, DENNIS NDAYA, REUBEN BOSIRE, University of Connecticut, YEKATERINA ROKHLENKO, Yale Univ, KEN KAWAMOTO, JEREMIAH JOHNSON, Massachusetts Institute of Technology, RAJESWARI KASI, University of Connecticut — Attaching mesogens to block copolymer backbones (BCP) can result in a rich interplay of self-assembly on multiple lengthscales, and provides new opportunities to control nanostructure development. We examine the self-assembly and directed-self assembly under magnetic fields of LC BCPs and BCP-analogous macromolecules containing mesogens. We observe a rich phase behavior, including the formation of gyroid morphologies and highly asymmetric phase diagrams, and we encounter systems with structural periodicities as small as ~6 nm. We consider the phase behavior and field alignment of a cylinder-forming system in the presence of labile mesogens that swell the LC block. The system transitions from hexagonal cylinders to FCC spheres beyond a critical mesogen concentration. Despite the isometric nature of the cubic lattice, the system aligns with the [100] axis parallel to the applied magnetic field, resulting in a degenerate, fiber-like texture. We speculate that this response may originate from symmetry breaking due to the action of the field that leads to a 2-step ordering process of the spherical microdomains. Alternatively, the response may indicate the presence of an unexpected magnetic easy axis in this cubic system.

2:42PM H30.00002: Bipolar to Radial Drop Transitions in the Presence of Novel Surfactants

JAKE SHECHTER (Presenter), BENJAMIN STRAIN, LINDA OSTER, University of Massachusetts Amherst, JESSICA SLEATOR, Springfield College, FNU MANISHA, UMA SRIDHAR, University of Massachusetts Amherst, JUAN DE PABLO, University of Chicago, SANKARAN THAYUMANAVAN, JENNIFER ROSS, University of Massachusetts Amherst — Liquid crystals (LCs) are a class of molecules that can form a variety of phases that can be influenced by external interactions. We are interested in controlling the phase of a liquid crystal droplet by controlling the interface between the organic liquid crystal (5CB) and the aqueous surfactant medium. This is an interesting physical system because the molecules at the surface can alter the phase of the LC throughout the interior by balancing the elastic energy of splay, twist, and bend against the interfacial tension. Here, we test the effects of novel amphiphiles, in the presence of SDS, on the phase of the LC droplets. We have synthesized molecules with various triggerable stimuli, such as pH, light, and protein binding. To help us understand the dynamics of the phase changes, we compare our experiments to simulations. We find that the phase transition is triggered by the addition of SDS, but not the novel surfactants. The concentration at which the phase transition occurs does not appear to depend on the droplet size, but does depend on the novel surfactant in the solution. Interestingly, we find a hysteresis in the concentration of the phase transition, from bipolar to radial and back again, that depends on the novel surfactant used.

2:54PM H30.00003: Physical insights on the self-assembly of myelin sheaths: what drives healthy lamellar stacks to disrupted inverted hexagonal phase

ROY BECK (Presenter), RONA SHAHARABANI, Tel Aviv University — Myelin sheath is a multimilayer complex of various lipids and proteins that surrounds axons and acts as an insulating layer for proper nerve conduction. In multiple sclerosis (MS), the myelin structure is disrupted impairing its function. Previous studies showed that MS is correlated with a small lipid composition variation and a reduction in the adhesive myelin basic protein (MBP). We show that such alterations result in structural instabilities and phase transition from a lamellar to inverted hexagonal phase, in accordance with pathological in vivo studies. Moreover, alteration in local environmental conditions, such as elevated salinity and temperature, drive the myelin system further into the inverted hexagonal phase [2]. Finally, we will demonstrate that the self-assembly of such complex system presents ion-specific structural modulation that is physiologically relevant. Since the etiology and recovery pathways of MS are currently unclear, these findings delineate novel functional roles to dominant constituents in cytoplasmic myelin sheaths.

Mechanics and Ion Transport in Dynamic Polymer Networks based on Metal-Ligand Coordination in Polymeric Ionic Liquids* [Invited] RACHEL SEGALMAN (Presenter), NICOLE MICHENFELDER-SCHAUSER, SEAMUS JONES, RAM SESHADRI, University of California, Santa Barbara — Polymers that contain ionic liquid constituent retain many of the properties of ionic liquids including ionic conductivity. Further, the polymerized cation (such as imidazolium) forms transient ligand bond interactions with dissolved metal ions allowing them to conduct while also forming a dynamic network. Dynamic polymer networks based on metal-ligand coordination are promising materials to accomplish such decoupling due to the transient nature of the coordination interaction. The general system of interest comprises a metal salt mixed in a polymeric medium with ligands located either along the backbone or on pendant side-chains. The molecular design of these materials allows for precise and independent control over the nature and concentration of ligand and metal, the salt dissolution, and the binding energy between the ligand and metal, all of which shown to be critical for controlling bulk ion conduction and polymer mechanics. Salt dissociation is universally governed by coordination number, equilibrium constant, and initial salt and ligand concentrations. Salt dissociation is enhanced by larger equilibrium constants and higher cation valency. The sensitivity of the ionic conductivity on equilibrium constant, coordination number, and the ratio of cation to anion diffusion coefficients is much higher for monovalent salts compared to divalent or trivalent salts. In a model system composed of poly(ethylene oxide) with tethered imidazole moieties that facilitate salt dissociation of both nickel (II) bis(trifluoromethylsulfonyl)imide (NiTFSI) and lithium bis(trifluoromethylsulfonyl)imide (LiTFSI), the nickel-imidazole interactions physically crosslink the polymer, increase the number of elastically active strands, and dramatically enhance the modulus while allowing Li⁺ to conduct quickly through the matrix.

Orientation of hard semiconducting nanoparticles by soft lyotropic lipid constructs* DYLAN STEER (Presenter), JOSEPH C FLANAGAN, MARILYN PORRAS GOMEZ, MOONSUB SHIM, CECILIA LEAL, University of Illinois at Urbana-Champaign — Quantum nanorods (QnR) are fluorescent nanoparticles with tunable optoelectronic properties depending on size and shape. These properties make them attractive in many biotechnology applications but due to their hydrophobic nature they are often hybridized by a shell of soft amphiphilic molecules. Anisotropic nanocrystals have orientation dependent properties, however controlling QnR alignment when drying from an organic solvent is difficult. We investigate the ability of amphiphilic molecules that are mostly known as stabilizers of QnRs in water to act as a matrix to guide QnR orientational order. Lipids are amphiphilic molecules that rapidly assemble into hierarchic liquid crystalline structures with various levels of positional and orientational order. These structures rapidly experience phase transitions depending on lipid composition, relative humidity, and temperature. Here we use glancing-incidence small angle X-ray diffraction (GI-SAXS) and fluorescence microscopy to study the co-assembly of lipid – QnR composites in highly concentrated regimes. Conditions are found to promote either the separation into lipid and highly ordered QnR domains, or the mixture of these components into a single phase with distinct structural characteristics.

*Office of Naval Research N000141612886

Elementary smectic ordering of “gapped” DNA duplexes* PRABESH GYAWALI (Presenter), RONY SAHA, Department of Physics, Kent State University, Kent, OH USA, MIREK SALAMONCZYK, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA USA, JAMES GLEESON, Department of Physics, Kent State University, Kent, OH USA, ANTAL ISTVAN JAKLI, Chemical Physics Interdisciplinary Program, Liquid Crystal Institute, Kent State University, Kent, OH USA, HAMZA BALCI, SAMUEL SPRUNT, Department of Physics, Kent State University, Kent, OH USA — We used small angle X-ray scattering and optical microscopy to study the liquid crystalline behavior of “gapped” DNA duplexes in aqueous solution. Our previous work revealed the occurrence of a smectic-A phase for DNA concentrations in the range ~230 to ~300 mg/ml and for a single-strand “gap” between duplexes of 20 thymine bases. Here we describe evidence for two coexisting/competing smectic-A-like layer structures, whose relative population varies with temperature and “gap” length. Smectic layering occurs for gap lengths down to 4 bases but disappears when the gap is reduced to 2 bases. Transitions from smectic to cholesteric/nematic state are observed as a function of temperature.

4:06PM H30.00007: Lipid-driven Crystallization of Block Copolymers in Lipid-Polymer Alloys*. YOO KYUNG GO
(Presenter), CECILIA LEAL, Department of Materials Science and Engineering, University of Illinois, Urbana Champaign — Tailoring crystallinity of blocks in crystalline-crystalline diblock copolymers (BCPs) is a route to gain control over the material's optical and mechanical properties. One methodology that has successfully tuned BCPs crystallinity is to include additives to the assembly.[1] In this work, we investigate the crystallization behavior of BCPs as tuned by the addition of a biological lipidic component. We adopted 1,2-dipalmitoyl-sn-glycero-3-phosphocholine (DPPC) as an additive to induce crystallization-driven self-assembly of poly(ε-caprolactone)-b-poly(ethylene oxide) (PCL-b-PEO). Herein, we scrutinize the effects of the lipids on crystallization of each block in PCL-b-PEO at multiple length scales by IR spectroscopy, differential scanning calorimetry, wide-angle X-ray scattering, small-angle X-ray scattering, and polarization optical microscopy. We discovered that DPPC and BCPs assemble in a uniform alloy with a lamellar structure at the mesoscale. Within this structure, the lipid can enhance crystallinity of PCL while suppressing that of PEO. The crystalline domains appear tubular at the nanoscale and the alloy displays large platelet morphologies at the microscale compared to pure neat polymeric systems. 4:18PM H30.00008: Molecular Dynamics Simulations of Elastic Capsomeres Self Assembling into a Virus Capsid*
LAUREN NILSSON (Presenter), JAYANATH CHAMINDU KADUPITIGE, Intelligent Systems Engineering, Indiana University Bloomington, MARTIN JARROLD, Department of Chemistry, Indiana University Bloomington, VIKRAM JADHAO, Intelligent Systems Engineering, Indiana University Bloomington — Viruses are an important class of soft biological materials that are capable of self-assembling into capsids that are often icosahedral-shaped. However, this self-assembly process is not completely understood in part due to the arduousness and simulation cost of correlated investigations between experiments and rigid-body models of constituent capsomere subunits. Experimentally-informed, hybrid OpenMP/MPI parallelized molecular dynamics simulations of a coarse-grained model composed of elastic capsomeres are used to investigate the assembly pathway of heterogeneous icosahedral viruses, focusing on Hepatitis B virus (HBV) as a first application. Simulation results are correlated to data from charge detection mass spectrometry. Based on the time-dependent mass spectrums and steady-state phase diagrams associated with the self-assembly of HBV at 5-100 micromolar protein and 100-500 millimolar salt concentrations, we propose that the formation of both 90- and 120-capsomere (T3, T4) structures in 100-500 micromolar salt concentrations, we propose that the formation of both 90- and 120-capsomere (T3, T4) structures at the nanoscale and the alloy displays large platelet morphologies at the microscale compared to pure neat polymeric systems. [1] ACS Nano 2015, 9, 4, 3627-3640

4:30PM H30.00009: Luminescent Liquid Crystals Based on Platinum(II) Complexes* XINGTIAN HAO, HAIYAN PENG (Presenter), XIAOLIN XIE, Huazhong University of Science and Technology — Luminescent liquid crystals, which hold outstanding optical anisotropy, fluidity and intrinsic photoluminescence characteristic, show a great potential to be widely applied in liquid crystal display, organic light-emitting diode, optical information storage, etc. Yet, it still remains a big challenge to enhance and tune the luminescent properties. Herein, we report a highly luminescent liquid crystals based on platinum(II) complexes. These complexes are able to relax from the excited state back to the ground state through spin-forbidden transitions, giving rise to distinct photochemical and photophysical features in comparison with traditional organic fluorophores. Flexible side chains are found to play a significant role in enabling the liquid crystal phase due to the strong intermolecular interaction between the complex's square-planar structure.

*NSFC (51503045, 51433002 and 51773073)

4:42PM H30.00010: Effect of Lipid Headgroup on Polymer-Lipid Bilayer Association WENJIA ZHANG (Presenter), FRANK BATES, TIMOTHY LODGE, University of Minnesota — Cell membrane composition plays an important role in binding to polymers. We have investigated the effect of lipid headgroup on the interaction between model membranes and amphiphilic and biocompatible diblock and triblock polymers composed of ethylene oxide and propylene oxide. Large unilamellar phospholipid vesicles were used as model membranes to mimic the lipid bilayer structure of cell membranes. The composition of the lipid headgroup was manipulated by altering the amount of phosphatidylcholine and phosphatidylglycerol in the lipid bilayers, thereby varying the molar ratio of choline to glycerol headgroups. Polymer binding to lipid bilayers was quantified by pulsed-field-gradient NMR, which differentiated the polymers bound to lipid bilayers from free polymers based on their distinct diffusivities. It was observed that polymer binding significantly increases as the concentration of glycerol in the lipid bilayer increases, which could be due to the hydrogen bonds formed between poly(ethylene oxide) and the glycerol group of phosphatidylglycerol.
Spontaneous and diverse morphological transitions of nematic liquid crystal oligomer micro-droplets

WEI-SHAO WEI (Presenter), Department of Physics and Astronomy & LRSM, University of Pennsylvania, Philadelphia, PA, USA, YU XIA, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, PA, USA, SOPHIE ETTINGER, Department of Physics and Astronomy & LRSM, University of Pennsylvania, Philadelphia, PA, USA, SHU YANG, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, PA, USA, A. G. YODH, Department of Physics and Astronomy & LRSM, University of Pennsylvania, Philadelphia, PA, USA — Viruses and pollen grains are known for their diverse morphologies and surface patterns, which play important roles to their functions. It begs the questions how the patterns were originated and then evolved. Here, we report the spontaneous morphological transformations from micro-droplets, consisting of polydisperse nematic liquid crystal oligomers (NLCOs) suspended in water, to a strikingly rich set of nematic structures, including roughened spheres, flowers, and filamentous structures. We investigate the interplay of elasticity and interfacial tension within the drop as a function of temperature, surfactant concentrations, and the LCO chain length distribution. We show that heterogeneity of LCO chain length is a feature leading to segregation of LCOs within the micro-droplet. The transformed morphologies are highly uniform in size and can be locked via UV curing. The study of synthetic systems offers a first attempt to understand the origin of complex morphologies in biological world.

Design Diblock Copolymers for More Efficient Encapsulation

BILIN ZHUANG (Presenter), Materials Science and Engineering, Institute of High Performance Computing, MINH TUAN NGUYEN, National Junior College, Singapore, FREDA C.H. LIM, Materials Science and Engineering, Institute of High Performance Computing — The encapsulation of active molecules is often a crucial step in pharmaceutical and consumer care formulation processes. Diblock copolymers, with the right chemical structures, are potentially effective in encapsulating various hydrophobic active molecules. A model that predicts the encapsulation efficiency of diblock copolymers would therefore be helpful to guide the design of the diblock copolymers so that the encapsulation of specific active molecules can be maximized. Here, by combining group contribution method and self-consistent-field theory, we develop a model for computing the encapsulation free energy of drug molecules by diblock copolymers in a solution, based on the chemical structures of the constituents in the system. We systematically explore how the encapsulation free energy and the resulting morphology of the encapsulates depend on the variation in the chemical structures of the diblock copolymers.

Deciphering and Engineering Reentrant Phase Transition of Intrinsically Disordered Proteins

PRIYA BANERJEE (Presenter), Department of Physics, University at Buffalo, The State University of New York — Formation of intracellular RNA- and protein-rich granules (RNP granules) are primarily driven by liquid phase condensation of Intrinsically Disordered Proteins (IDPs). What are the molecular driving forces that control the material properties and morphology of RNP granules? Using mixtures of multivalent charged IDPs and RNA that display reentrant phase behavior, we show that (a) the condensed phase is predominantly droplet-like under equilibrium conditions, and (b) the material properties are primarily tuned by the charge regulated electrostatic interactions. Unexpectedly, hollow condensates are formed under non-equilibrium conditions by RNA influx into RNP droplets. We propose that this spontaneous morphological transformation of RNP droplets is actuated by RNA-mediated mixing phase transition at the droplet center. By controlling the RNA inflow using simple microfluidic designs, complex patterns of hollow condensates can be generated stochastically. Our results suggest that cellular processes that can drive an active RNA influx into RNP droplets, such as transcription, can spatiotemporally control their material properties and morphology.

Improving the prediction of magnetic interactions from DFT methods: Non-collinear magnetization and self-interaction

JUAN PERALTA (Presenter), RAJENDRA JOSHI, KAI TREPTE, KOBLAR JACKSON, Department of Physics, Central Michigan University — Electronic structure methods are routinely used to predict magnetic properties of diverse materials, including molecular nanomagnets, clusters, and crystals. Density functional theory (DFT) has been one of the workhorses of modern electronic structure methods, and as such, it has been used extensively for the prediction of magnetic properties. In this talk I will summarize our efforts to improve the prediction of magnetic exchange couplings J from DFT methods in two fronts. First, I will show a proposed method to extract J based on differential rotations of the local atomic magnetization. This method avoids the explicit evaluation of energy differences, which can become impractical for large complexes and clusters. Our approach is based on the evaluation of the transversal magnetic torque between magnetic centers using constraints of the local magnetization direction via Lagrange multipliers and involves non-collinear spin DFT.[1] This, combined with a local partitioning of $\langle S^2 \rangle$, [2] makes possible the evaluation of J couplings entirely from first principles without ad-hoc nominal spin values. Second, I will show how self-interaction error (SIE) impacts the prediction of J couplings using an efficient implementation for SIE removal based on Fermi-Löwdin orbitals (FLOSIC).[3] Using this method, removing SIE from the simple local spin density approximation improves calculated J couplings,[4] in line with previous observations for small model systems.

Efficient Implementation of RT-TDDFT on Siesta 4.0

FERNANDO VILA (Presenter), MARILENA TZAVALA, JOHN REHR, University of Washington — Real-time time-dependent DFT (RT-TDDFT) provides a versatile method for computing electronic response in both linear and non-linear regimes. Here we introduce RT-Siesta4, an efficient implementation of RT-TDDFT which combines the LCAO approach for electronic structure in Siesta 4.0 with an efficient Crank-Nicolson time-evolution operator to propagate Kohn-Sham states in the presence of an external electric field. This development extends our previous implementation with Siesta 2.0. RT-Siesta4 uses a predictor-corrector scheme to ensure time-reversibility, thus enabling long time steps. Its capabilities include full spectrum linear optical response, single frequency NLO response, and response to shaped pulses. Benchmarks for typical systems are presented showing how the faster evaluation of the TD Hamiltonian in Siesta 4.0 improves the performance of our real-time implementation. Finally, we discuss the need to extend scalability into the peta- and exa-scales.

*Supported as part of the Comput. Chem. Sci. Program funded by the U.S. DOE, Office of Science, BES, CSGB Division in the Center for Scalable and Predictive methods for Excitations and Correlated phenomena (SPEC) at PNNL, and with computer support from DOE-NERSC.

Performance of Generalized Gradient Approximations with Nearly Correct Asymptotic Potentials on Molecular and Solid-State Properties

ALBERTO VELA (Presenter), ANGEL ALBAVERA-MATA, Department of Chemistry, Cinvestav, KARLA BOTELLO MANCILLA, Escuela Superior de Ingeniería Química e Industrias Extractivas, IPN, JAVIER CARMONA-ESPÍNDOLA, Department of Chemistry, UAM-Iztapalapa, SAM B TRICKEY, Quantum Theory Project, Department of Physics and Department of Chemistry, University of Florida, JOSE L GAZQUEZ, Department of Chemistry, UAM-Iztapalapa — The recently developed nearly correct asymptotic potential (NCAP) and its predecessor (CAP) are generalized gradient approximations (GGAs) for exchange and correlation designed to capture the asymptotic behavior of the exchange potential [1,2]. Compared to more common GGAs, they improve the description of frequency-dependent response properties in molecules, yet provide good accuracy of thermodynamic and kinetic properties. NCAP incorporates a potential shift accounting for the derivative discontinuity of the potential and has an overall performance, for molecules, competitive with current meta-GGAs. In this work, we present and discuss the performance of these GGAs on extensive tests involving lattice constants, bulk moduli, and cohesive energies for a set of solids and compare that performance with molecular results.

4:06PM H31.00005: Ionization potentials and static dipole polarizabilities of polyacenes using Fermi-Lowdin self-interaction corrected density functional approximation*  SHARMIN AKTER, YOH YAMAMOTO, LUIS BASURTO, TUNNA BARUAH (Presenter), RAJENDRA ZOPE, University of Texas, El Paso — We study the static electric dipole polarizabilities and the first ionization potentials of polyacenes from benzene to pentacene using the Fermi-Lowdin Orbital based self-interaction corrected (FLOSIC) density functional method. Most common density functional approximations (DFA) that often accurately predict equilibrium properties show deviation from the piecewise exact linear behavior between integer electron numbers. These functionals favor fractional charges and cause excessive electron delocalization resulting in incorrect electron densities. Due to delocalization errors, the ionization potentials obtained using the LDA and PBE functionals rapidly decrease as a function of length. The application of the FLOSIC method shows that it corrects for this many-electron self-interaction error in ionization potentials of polyacenes. Furthermore, it is observed that the FLOSIC corrected electron density when used in simple LDA functionals results in a remarkably accurate prediction of the ionization potentials of polyacenes.

4:18PM H31.00006: Enhancing the efficiency of density functionals with a novel iso-orbital indicator*  JAMES FURNESS (Presenter), JIANWEI SUN, Tulane University — The accuracy and efficiency of a density functional depends on the basic ingredients it uses and how the ingredients are built into the functional as a whole. An iso-orbital indicator based on the electron density, its gradients, and the kinetic energy density, has proven an essential dimensionless variable allowing density functionals to recognise various types of chemical bonding, both strong and weak. Density functionals constructed around the iso-orbital indicator usually require dense real-space grids for numerical implementation that deteriorate computational efficiency, compromising the improved accuracy. A novel iso-orbital indicator is proposed based on the same ingredients that retains the capability to identify the same chemical bonds while relieving the requirement of dense grids. The novel iso-orbital indicator improves recognition of electron density tail regions and is constraint-free for the exchange-correlation potential. The novel iso-orbital indicator is therefore expected to be the prime choice for density functional development and we discuss aspects of its use in cutting edge meta-generalised gradient approximations.

4:30PM H31.00007: Density driven error and many-body dispersion in the calculation of protobranching energies in alkanes*  JORGE NOCHEBUENA (Presenter), ALBERTO VELA, Center for Research and Advanced Studies of the National Polytechnic Institute — It is well known that branched alkanes are more stable than their linear isomers. Protobranching energies are energetic footprints of this isomeric preference. They have been estimated accurately (compared to experimental values) through highly correlated wave function methods. In contrast, calculations based on density functional approximation (DFA) errors can be classified as errors due to the density (density-driven error) and errors due to the functional (functional error). Functional errors can be related to the inability of common DFAs to describe long-range electronic correlations (dispersion forces). Such forces can be efficiently included in DFT calculations through the many-body dispersion method [1]. Density-driven errors can be corrected using the partition DFT scheme [2]. In this work, we evaluate the role played by both corrections in the relative stability of alkanes. We also delineate the role of medium-range correlation through protobranching energy calculations with range-separated DFAs.

*J.N. and A.V. thank Conacyt for grant Fronteras 867.
4:42PM H31.00008: Gapping of MnO, FeO, CoO, and NiO Mott insulators by SCAN without U* YUBO ZHANG, Tulane University, ZHI WANG, ALEX ZUNGER, RASEI, University of Colorado, Boulder, JIANWEI SUN (Presenter), Tulane University — Mott insulation is generally enabled by the physics of symmetry conserving on-site interelectronic repulsion U on single 3d sites via the celebrated Hubbard Model. DFT, exact for the ground state properties in principle, can not consistently open band gaps for MnO, FeO, CoO, and NiO Mott insulators if one uses symmetry conserving structures along with conventional semi local approximations to its exchange correlation functional. It has been recently shown [1] that using energy-lowering symmetry breaking mechanisms, DFT+U which distinguishes occupied and empty orbitals, opens band gaps for the monoxides. Here we show that even without invoking U, the semi local SCAN density functional [2] whose potentials are orbital dependent via the kinetic energy density dependence, opens band gaps for the monoxides in their AFM and PM (modeled with SQS) phases. The mechanism of gapping is analyzed. This success revives DFT for d electron materials and encourages the development of more sophisticated density functionals.

4:54PM H31.00009: The Jahn-Teller effect in density functional theory* MARK PALENIK (Presenter), BRETT IGOR DUNLAP, DANIEL GUNLYCKE, United States Naval Research Laboratory — Using degenerate perturbation theory, Jahn and Teller proved that open-shell molecules with symmetry distort into lower symmetry configurations. Extending this proof to Kohn-Sham (KS) density functional theory (DFT) is not straightforward because of the nonlinear Coulomb and exchange-correlation potentials. These potentials affect the relationship between nuclear symmetry and electronic degeneracy, altering degenerate perturbation theory itself. Using our recently developed degenerate density functional perturbation theory, we define a perturbative approach to Jahn-Teller distortions for KS DFT. We use fractional occupation numbers to symmetrize the initial electron density, artificially stabilizing the nuclei in the highest possible symmetry. Using second-order perturbation theory, we find the changes in geometry that occur when the symmetry of the electron density is broken to form a state with integer occupation numbers. This methodology allows us to retain many of the computational benefits of working in higher symmetry. We demonstrate the resulting equations in a system of ten electrons in a superatom-like harmonic oscillator potential.

*This work has been supported by the Office of Naval Research, directly and through the U.S. Naval Research Laboratory.

5:06PM H31.00010: Self-interaction corrected dipole polarizabilites of free atoms and their ions* KUSHANTHA PRADEEP KUMARA WITHANAGE (Presenter), Central Michigan University, SHARMIN AKTER, Physics, University of Texas, El Paso, CHANDRA SHAHI, Physics, Temple University, TUNNA BARUAH, RAJENDRA R ZOPE, Physics, University of Texas, El Paso, JOHN P PERDEW, Physics, Temple University, JUAN PERALTA, KOBLAR JACKSON, Central Michigan University — Conventional density functional theory (DFT) suffers from electron self-interaction error (SIE) and hence tends to underbind the electrons. As a consequence, within DFT the electrons’ density in free atoms and their ions tends to be too responsive to an external electric field. Self-interaction corrected density functional theory (SIC-DFT) calculations improve the description of electron binding, because the unphysical SIE is removed. We apply Fermi-Löwdin orbital self-interaction correction (FLO-SIC) to calculate static dipole polarizabilites of free neutral atoms, their cations and their anions. We compare FLO-SIC-DFT polarizabilites of these systems against results from parent DFT functionals. We find FLO-SIC-DFT polarizabilites agree better with experimental and accurate quantum chemistry calculation result

5:18PM H31.00011: Performance of the Fermi-Lowdin Self-Interaction Correction Method in Combination with meta-GGA Functionals* YOH YAMAMOTO (Presenter), CARLOS MANUEL DIAZ, RAJENDRA ZOPE, TUNNA BARUAH, Physics, University of Texas at El Paso — Despite the success of DFT in describing the electronic properties of many electrons systems, the most widely used density functional approximations (DFA) suffer from self-interaction errors which limit their predictive power. We have recently implemented the meta-GGA functionals including the recent SCAN functional [1] that satisfies all 17 known exact constraints and is appropriately normed in the Fermi-Lowdin Self-Interaction Correction (FLOSIC) code [2,3]. The FLOSIC is a size-extensive implementation of the self-interaction-free DFA. In this talk, we present the results of FLOSIC calculations using the meta-GGA functionals. We present the performance of FLOSIC in combination with meta-GGA functionals in total energies, ionization potential, and atomization energies of various atoms and molecules.

2:30PM H32.00001: Revisiting Glassy Behavior in Polystyrene with Single Molecule Approaches* [Invited] LAURA KAUFMAN (Presenter), ALYSSA MANZ, KEEWOOK PAENG, NICOLE MANDEL, Columbia University — Polystyrene in the rubbery regime displays phenomenology also seen in small molecule supercooled liquids, and dynamic heterogeneity in this system has been well studied. We have revisited several aspects of glassy behavior and dynamic heterogeneity in polystyrene using single molecule approaches. In particular, we have characterized exchange time (τex, the timescale a particular dynamical environment maintains a given dynamics) at a number of temperatures down to and including the glass transition temperature. These studies reveal that the ratio of τex to the alpha relaxation time (τex/τα) is independent of temperature in the range probed. More recently, we have characterized dynamic heterogeneity in polystyrene as a function of fragility as controlled by molecular weight. Over a broad range of molecular weights, we find a similar degree of dynamic heterogeneity and ratio of τex to the alpha relaxation time in polystyrene. Finally, aiming to resolve long-standing questions regarding the origins of rotational-translational decoupling, we have combined rotational and translational measurements of single molecule probes in polystyrene. Initial results suggest slowly rotating molecules are typically also slowly translating molecules but continue to suggest overall translational diffusion is faster than would be expected given system viscosity.

3:06PM H32.00002: Nucleation of the short-chain n-alkanes from the vapor phase: Experiments and Monte Carlo simulations* [Invited] BARBARA WYSLOUZIL (Presenter), KEHINDE OGUNRONBI, Ohio State University, ALIASGHAR SEPEHRI, BIN CHEN, Chemistry, Louisiana State University — The n-alkanes do not nucleate easily from the vapor phase, and, when rapidly cooled in a supersonic expansion, saturation levels on the order of 10,000 are typical. [1, 2] The nucleation rates measured for n-pentane through n-heptane, at temperatures ranging from ~109 K to 168 K, are on the order of 10^{17} cm^{-3}s^{-1}, increasing slightly with decreasing temperature. Despite the high degree of supercooling, Monte Carlo (MC) simulations suggest that for n-pentane through n-heptane the critical clusters remain liquid like under experimental conditions, whereas n-octane and n-nonane adopt more ordered structures. For all three alkanes, the scaled experimental and simulated nucleation rates are offset by ~3 orders of magnitude. Explicitly accounting for the surface tension difference between the real and model substances, however, increases the offset to ~ 6 orders of magnitude, equivalent to a a formation free energy difference of ~13k_BT . This difference could be reduced by changing the cutoff criterion or by using model potentials that better describe n-alkane behavior.

3:42PM H32.00003: Inferring properties of intrinsically disordered proteins from single-molecule FRET and small-angle X-ray scattering data* [Invited] ROBERT BEST (Presenter), Laboratory of Chemical Physics, NIDDK, National Institutes of Health — Intrinsically disordered proteins are a class of polypeptides in which a significant portion of the chain is not folded into a specific three-dimensional structure. Because of their abundance and importance in many biological contexts, it is important to characterize the extent of structure formation in these proteins. However, as a result of their extensive disorder, conventional structure-determination methods used for folded proteins are not appropriate, and the broad distribution of structures in such a disordered system needs to be considered. I will describe methods for using molecular simulations to account for the diversity of structures in intrinsically disordered proteins while fitting to the experimental data, which help to reconcile differences between different experimental methods. Methods based on molecular simulation are more computationally demanding, but also the most general approach. I will show how in many cases, if the IDP is sufficiently disordered, it is also possible to use simpler approximations which we have developed.

4:18PM H32.00004: Accurate modeling of liquid water and proton transfer in water* [Invited] XIFAN WU (Presenter), Temple University — Water is of the utmost importance for life and proton transfer via hydronium and hydroxide ions in water is also ubiquitous. A genuinely predictive ab initio model of water is the key to understanding the proton transfer effect in water. However, accurate prediction of water requires to climb up the Jacob’s ladder within density functional theory to include the treatment of van der Waals interactions and the mitigation of self-interaction error. We demonstrate that a fully ab initio approach, relying on the strongly constrained and appropriately normed (SCAN) density functional, provides such a description of water. SCAN accurately describes the balance among covalent bonds, hydrogen bonds, and van der Waals interactions that dictates the structure and dynamics of liquid water. At the similar level of theory, we then show that structural diffusion of hydronium preserves the previously recognized concerted behavior. However, by contrast, proton transfer via hydroxide is dominated by stepwise events, arising from a stabilized hyper-coordination solvation structure that discourages proton transfer. Specifically, the latter exhibits non-planar geometry, which agrees with neutron scattering results. Asymmetry in the temporal correlation of proton transfer enables hydronium to diffuse faster than hydroxide and may underlie observed isotope anomalies.

4:54PM H32.00005: Imaging excited states of nanomaterials* [Invited] DUC NGUYEN (Presenter), Northwestern University, JOSHUA J. GOINGS, University of Washington, Seattle, HUY A. NGUYEN, JOSEPH W LYDING, University of Illinois at Urbana-Champaign, XIAOSONG LI, University of Washington, Seattle, MARTIN GRUEBELE, University of Illinois at Urbana-Champaign — Nanomaterials are promising for applications in photocatalysis, photosensitization, photodetection, photovoltaics and optoelectronics. In these applications, nanomaterials are first photoexcited, then the generated energy or charge is either used to break chemical bonds or transferred to nearby electrodes, particles or molecules of interest. Understanding photoexcited nanomaterials at their characteristic length scale is critical for performance optimization, however, is challenging given their small size and fast relaxation. We develop and use single-molecule adsorption scanning tunneling microscopy (SMA-STM), a powerful technique capable of imaging photoexcited nanomaterials with sub-nanometer spatial resolution, to investigate photoexcited quantum dots (QDs), carbon nanotubes (CNTs) and their interactions. Images of individual photoexcited QDs (absorption images) vary significantly from dot-to-dot. For a single QD, different excited states are probed by changing the applied electric field. Using the STM tip to nudge and roll the QDs on the surface, different images of the excited state at different angles are obtained. Energy transfer in arrays of QDs, QD-CNT interactions are also imaged and manipulated at individual nanoparticle level. Finally, I will discuss my recent work on probing molecular-scale catalytic interactions of oxygen with an oxygen reduction molecular catalyst using another optical STM technique, STM tip-enhanced Raman spectroscopy (STM-TERS).

Session H33 FLAP: Functional Oxides BCEC 204B - Turan Birol, University of Minnesota - Tag(s): Focus

2:30PM H33.00001: Enhancement of Thermal Conductivity Across the Metal-Insulator Transition in Vanadium Dioxide* LU CHEN (Presenter), ZIJI XIANG, COLIN TINSMAN, TOMOYA ASABA, Department of Physics, University of Michigan, QING HUANG, HAIDONG ZHOU, Department of Physics and Astronomy, The University of Tennessee, Knoxville, LU LI, Department of Physics, University of Michigan — The metal-to-insulator transition (MIT) in vanadium dioxide (VO2) is investigated by electrical and thermal transport measurements. We report an order-of-magnitude enhancement of thermal conductivity across the MIT region in the VO2 single crystal. Magnetic field dependent measurements reveal that the thermal conductivity peak doesn't show an obvious dependence on the magnetic field, which indicates that the enhancement of thermal conductivity could come from neutral heat carriers such as phonons. Our experiment explores a potential direction for achieving thermal management in phase-change materials.

*This work is mainly supported by the Office of Naval Research through the Young Investigator Prize under Award No. N00014-15-1-2382 (thermal transport and electrical transport measurements). The sample growth in UTK is supported by NSF-DMR-1350002 (sample growth). The measurement instrument benefit from the National Science Foundation Major Research Instrumentation award under No. DMR-1428226 (supports the purchase of the PPMS). Q.H. thanks for the support from the Go students program of ORNL.

2:42PM H33.00002: Structural and Electronic properties of Copper Doped amorphous Alumina* KASHI SUBEDI (Presenter), Ohio University, KIRAN PRASAI, Applied Physics, Stanford University, DAVID A DRABOLD, Ohio University — To understand the atomic properties of Conducting Bridge Random Access Memory(CBRAM) devices based on Alumina with Copper as one of the active electrodes, we offer new models of amorphous Alumina with varying concentrations of Cu having general form (a-Al2O3)1-nCun with n = 0, 0.10, 0.20 and 0.30. We study the structural properties of these models. It turns out that Cu atoms cluster because of its less proclivity to diffuse in the highly ionic host a-Al2O3. The clustering produces a narrow conducting path for electrical current. To elucidate the electric conduction path, we employ the Kubo-Greenwood formula in a novel space-projected form[1]. We show that the conduction-active component of the network is an interconnected Cu cluster.

*Work supported by NSF grants under DMR awards 1507670, 1507166 and 1506836
Phase transitions and optical properties of Sr$_2$SnO$_4$  

NIKOLAOS MEMMOS (Presenter), TURAN BIROL, Department of Chemical Engineering and Materials Science, University of Minnesota — Layered perovskite Ruddlesden Popper (RP) transition metal oxides are interesting because of the effects of their 2 dimensional crystal structure on their lattice response, as well as electronic and optical properties. The Stannate Sr$_2$SnO$_4$ has the K$_2$NiF$_4$ type RP structure at high temperatures, but undergo multiple structural phase transitions as the temperature is lowered. In this talk, we present our first principles Density Functional Theory results that elucidate the mechanism behind these phase transitions. We discuss the details of the octahedral tilting and examine its effects on the electronic and optical properties of Sr$_2$SnO$_4$.

*NSF DMREF Grant No. DMR-1629260

Formulation and characterization of sinterless Barium Strontium Titanate (BST) nanocomposite dielectric inks for flexible RF and Microwave electronics applications  

OSHADHA RANASINGHA (Presenter), MAHDI HAGHZADEH, CRAIG ARMIENTO, ALKIM AKYURTLU, Department of Electrical and Computer Engineering, University of Massachusetts-Lowell — The demand for printable electronics over conventional electronics is rising exponentially due to various reasons. Tunable radio frequency (RF) and microwave (MW) devices make a high impact on the size, cost and the overall performance of flexible electronics. The dielectric constant of BST can be tailored by an applied electric field, which allows BST to be used in varactors for tunable RF and MW applications such as tunable filters and conformal antennas.

The Curie temperature ($T_C$) of (Ba$_x$Sr$_{1-x}$TiO$_3$) can be tailored by adjusting the molar fraction of barium. BST has a paraelectric phase above the Curie temperature and below the Curie temperature, BST has a ferroelectric phase. BST shows highest dielectric properties such as tunability, high dielectric constant and low loss tangent in the paraelectric phase.

These inks can be processed below 150 0C and a high performance can be achieved without sintering the BST nanoparticles. Also, these inks are compatible with different types of printing technologies, such as dispensing and ink jet and aerosol jet. These BST-polymer inks showed 44.29 ± 1.85 as the highest dielectric constant and 0.02 ± 0.01 as the lowest loss tangent at 10 GHz. The maximum tunability achieved was 15% at 10 GHz with an applied electric field of 10 V/µm.

Chromium Pairs in Combustion Synthesized α-Alumina  

JOHN KREBS (Presenter), SARAH ROBITAILLE, NED STEPHEN DIXON, LINDA S FRITZ, Franklin & Marshall College — High surface area alumina has gained much attention as a support structure for a number of possible biological and biomedical applications. Combustion synthesis provides a simple route to produce large quantities of alumina with optically active impurities after liquid phase mixing. In this report, we present results on chromium ion separation in combustion-synthesized highly-doped ruby. Aluminium and chromium nitrates are dissolved in water/urea solutions. The solutions are then heated above 500 degrees, at which point they undergo a self-propagating combustion reaction transforming them into high-surface area solids. X-ray diffraction confirms the single phase a-alumina structure. Optically excited fluorescence (excited at 473 nm) spectra are used to measure the ratio of the fourth nearest neighbour emission peak to that of the single ion peak to quantify impurity pair formation as a function of chromium concentration. The ratio increases linearly over the concentration range up to four atomic percent. Time-resolved decay dynamics of the pairs will be presented.

Producing p-ZnO via rf magnetron sputtering onto a thin evaporated layer of Zn$_3$As$_2$  

JOHN COLTON (Presenter), JAMES ERIKSON, MICAH N SHELLEY, JAMES COLTER STEWART, CARRIE EMMA MCCLURE, SPENCER KING, NATHAN SCHWARTZ, DAVID D ALLRED, GARY RENLUND, Brigham Young University — Zinc oxide (ZnO) is a wide band gap semiconductor with many potential applications, including UV lasers, transparent circuits, and radiation resistant devices. The native defects in ZnO cause it to be n-type, and stable high quality p-type ZnO has proven hard to create. We report on a technique whereby As-doped p-ZnO is created using rf magnetron sputtering onto a thin evaporated layer of Zn$_3$As$_2$. The optical characteristics and thickness of the Zn$_3$As$_2$ layer have been determined by spectroscopic ellipsometry. ZnO quality and doping has been studied with photoluminescence, X-ray diffraction, Hall effect, and other techniques. Annealing in a vacuum leads to better sample quality, although the p-type characteristics have not always been reproducible.
4:06PM H33.00009: Structurally triggered metal-insulator transition in rare-earth nickelates and related $e_g^1$ perovskites PHILIPPE GHOSEZ (Presenter), Theoretical Materials Physics, Q-MAT, CESAM, University of Liege — Rare-earth nickelates (RNiO₃), apart from LaNiO₃, exhibit on cooling a metal-insulator transition (MIT), a concurrent structural phase transition and a magnetic phase transition. Here, I first assess the ability of first-principles calculations within the DFT+U formalism to describe the properties of rare-earth nickelates. Then, using such a formalism, I show that the MIT in nickelates can be seen as a structurally triggered phase transition [1] highlighting so a first concrete example of such a kind of phase transition in simple perovskites. The origin of this unusual mechanism is then traced back in the electronic and magnetic properties, revealing a Peierls-type instability, structurally triggered by oxygen rotation motions and eventually assisted by magnetic ordering. This knowledge helps rationalizing the evolution of the MIT in thin films and heterostructures [2] and is also relevant to other $e_g^1$ perovskites like alkaline-earth ferrites and rare-earth manganites [3].

**4:30PM H33.00011: Enhancement of Young's modulus in freestanding SrTiO$_3$ thin films** VARUN HARBOLA (Presenter), Physics, Stanford University, SAMUEL CROSSLEY, SEUNG SAE HONG, Applied Physics, Stanford University, YORICK BIRKHOLZER, Institute for nanotechnology, University of Twente, DI LU, Physics, Stanford University, YASUYUKI HIKITA, Stanford Institute for Material and Energy Sciences, SLAC National Accelerator Laboratory, HAROLD HWANG, Applied Physics, Stanford University — Recent developments in thin film growth provide a powerful route to free-standing single-crystal films of perovskite oxides by water etching of a sacrificial underlayer (Di Lu et al., Nature Materials 15, 1255 (2016)). We have used atomic force microscopy to systematically probe the elastic properties of suspended SrTiO$_3$ films, in a thickness series from 4-98 nm, which has been previously inaccessible and unexplored. We observe the thickness dependence of elastic modulus of SrTiO$_3$ to be non-monotonic, with a strong enhancement of stiffness for thicknesses below 30 nm. We provide evidence that the nature of this elastic stiffening lies in an effective flexoelectric coupling. This study provides the basis for studying strain manipulation and strain control of oxides at the nanoscale. In particular, oxide membranes can be designed to mimic stiffnesses of 2d materials like graphene and transition metal dichalcogenides.

**4:42PM H33.00012: Examination of the high-temperature optical properties of HfO$_2$ thin films for metamaterial selective-emitter applications** MINSU OH (Presenter), NICOLE PFIESTER, MARGARET STEVENS, KEVIN GROSSKLAUS, THOMAS VAN DER VEEL, Tufts University — Metamaterial selective-emitters can enhance the efficiency of thermophotovoltaic (TPV) energy conversion systems by selecting the wavelengths of light emitted towards the TPV photodiodes. As such, the optical properties of any material used as part of a metamaterial selective-emitter must be known and controlled. As one of the highest melting point dielectric materials, hafnium dioxide (HfO$_2$, melting point of ~2760°C) has attracted researchers’ attention for use in high-temperature applications; such as metamaterial selective-emitters. In this work, HfO$_2$ was deposited on a Si substrate by atomic layer deposition (ALD) and then diced into smaller pieces. The frequency-dependent complex permittivity of the HfO$_2$ films was measured via ellipsometry during annealing at temperatures from room temperature (RT) up to 600°C and then again at RT after annealing. The ellipsometric measurements were conducted over a wavelength range of 200 – 500 nm. The degree of crystallization and film density is correlated with the measured permittivity of HfO$_2$ by X-ray reflectivity (XRR) and X-ray diffraction (XRD).

**4:54PM H33.00013: phonoRam: A workflow tool for predicting Raman activity with DFT** ANDREW MISKOWIEC (Presenter), JENNIFER NIEDZIELA, Oak Ridge National Laboratory — The Raman activity tensor is a fundamental property describing the coupling of light with matter. As polarized Raman spectroscopy becomes more routine, detailed knowledge of the tensor components is necessary to interpret spectra, in addition to the powder-averaged value measured in unpolarized experiments. We present phonoRam, a python-based workflow tool based on the phonopy phonon analysis package, that simplifies and manages the calculation of the Raman activity tensor using DFT. We present an overview of the package, convergence of the macroscopic dielectric tensor values, and a set of test cases. We present an investigation of U$_3$O$_8$, a material with 68 Raman active modes and polarization dependence, using polarized Raman and phonoRam to analyze the crystallite structure.

**5:06PM H33.00014: Optical Bandgap and Electric Transportation of Co- and Al-co-doped ZnO with Low Defect Concentration** HSUHUNG CHOU (Presenter), H. C. LIN, National Sun Yat-sen University, I. EDELMAN, Institute of Physics, Krasnoyarsk, 660036, Russia, SHIH-JYE SUN, Department of Physics National University of Kaohsiung, Kaohsiung City, Taiwan — The defects in Co- and Al-co-doped ZnO, Co$_{0.05}$Al$_{0.02}$Zn$_{0.93}$ (CAZO), films were generated during sputtering growth by mixing low percentage of hydrogen, 0.1–1% denoted as CAZO-H2%, along with argon gas at 450°C. For comparison, an extremely low defect film, except the native oxygen vacancies, was grown under a mixture of oxygen with argon gas, which is denoted as CAZO-O2. The optical band gaps and electric resistivities were measured as a function of the H$_2$%. We found the CAZO-O2 is insulating while the resistance drops to a single digit (less than 10 Ω) with the addition of a very small amount of H$_2$, 0.1%, in the growth atmosphere and reaches the minimum for CAZO-1%. Combining previous data with higher defect concentrations, the lowest resistance was observed for the CAZO-1% sample. The optical bandgap, E$_{opt}$, however, shows the opposite trend that increases smoothly with the defect concentration from E$_{opt}$=3.4eV for CAZO-O2 sample, similar to the bandgap of pure ZnO, to 3.61eV for CAZO-1.1%. The role of defects on the bandgap and resistance will be presented.

In this work, we demonstrate how the electron-counting model (ECM) can be used in understanding the phases, particularly in explaining the stability of the oxygen-vacancy channels (OVCs), and in examining the Co valance problem in SCO2.5 and HSCO2.5. Using density-functional theoretical (DFT) methods, we analyze the crystalline, electronic, and magnetic structures of BM- and H-Sco. We discovered stable phases with large bandgaps (> 1 eV) for both BM-Sco and H-Sco, with reasonable agreement with experiments. Our calculation also indicates limited charge transfer from H to O that may explain the special stability of the H-Sco phase and the reversibility of H incorporation observed in experiments. In contrary to the initial study, our calculation also suggests intrinsic antiferromagnetism (AFM) of H-Sco, showing how the measured ferromagnetism (FM) has possible roots in hole doping.

4:18PM H34.00004: Optimal Sound Absorption Metastructures: Practical Solutions from Fundamental Physics

[invited] PING SHENG (Presenter), The Hong Kong University of Science and Technology — Even in the 21st century, noise still constitutes a major environmental problem, with the low frequency noise being especially pernicious. While resonance-based acoustic metamaterials can display many novel wave manipulation capabilities, they have the Achilles' heel of being narrow-frequency in character. It would be most desirable if a sound absorber can be designed to fit the noise spectrum, with a minimum allowed thickness. Such sound absorbing structures can now be realized through a design recipe that incorporates the causality constraint on the acoustic response\(^1\). We use the causality constraint to delineate what is ultimately possible for sound absorbing structures, and denote those which can attain near-equality for the causality constraint to be "optimal." Anchored by the causality relation, an integration strategy can be formulated for realizing structures with target-set absorption spectra and a sample thickness close to the minimum value as dictated by the causality constraint. By using this approach, we have realized a 10.86 cm-thick structure that exhibits a broadband, near-perfect flat absorption spectrum starting at around 400 Hz, while the minimum sample thickness from the causality constraint is 10.36 cm. To illustrate the versatility of the approach, two additional optimal structures with different target absorption spectra are presented. This "absorption by design" strategy would enable the tailoring of customized solutions to difficult room acoustic and noise remediation problems.

Tuesday, March 5, 2019 2:30 PM - 5:06 PM

Session H35 DQI: Semiconducting Qubits: Characterization of Electron and Hole Spin Qubits BCEC 205B - Andrew Pan, HRL Laboratories, LLC - Tag(s): Focus

2:30PM H35.00001: Four-qubit quantum processor in isotopically enriched silicon\(^*\) ANTHONY SIGILLITO (Presenter), JAMES LOY, DAVID ZAJAC, FELIX BORJANS, MICHAEL GULLANS, JASON R PETTA, Physics, Princeton University — Quantum processors based on spins in semiconductors are rapidly becoming a strong contender in the race to build a quantum computer. When coupled with micromagnets, these devices offer high fidelity single-qubit [1] and two-qubit [2,3] control while maintaining long coherence times. Until now, silicon spin qubit devices incorporating micromagnets have been limited to one and two qubit demonstrations, even though a one-dimensional extended array of silicon quantum dots has been demonstrated [4]. In this presentation, we will present a four-spin-qubit device architecture. This device is fabricated on an isotopically enriched \(^{28}\text{Si}/\text{SiGe}\) quantum well and offers four individually addressable spin qubits. Multi-qubit gates can be implemented by gating nearest-neighbor exchange interactions. Preliminary data demonstrating single- and multi-qubit operation will be presented.

*Research sponsored by ARO grant No. W911NF-15-1-0149 and the Moore Foundation's EPIQS Initiative through grant GBMF4535. We thank Lisa Edge for providing the \(^{28}\text{Si}\) heterostructure. Devices were fabricated in the Princeton University QDNL.
Characterization of gate fidelities in a Si/SiGe two-qubit device

XIAO XUE (Presenter), THOMAS F WATSON, QuTech & Kavli Institute of Nanoscience, Delft University of Technology, JONAS HELSEN, QuTech, Delft University of Technology, DANIEL WARD, DONALD E SAVAGE, MAX G LAGALLY, SUSAN COPPERSMITH, MARK ALAN ERIKSSON, University of Wisconsin-Madison, STEPHANIE WEHNER, QuTech, Delft University of Technology, LIEVEN VANDERSYPEN, QuTech & Kavli Institute of Nanoscience, Delft University of Technology — Various candidate implementations for future quantum computers have been investigated over the past twenty years. Silicon spin qubits show great promise [1] for their long coherence times and integration using semiconductor technology but there have been very few quantitative studies of the fidelities of two-qubit gates. Here we characterize the gate fidelities of a C-Phase gate using randomized benchmarking. For single-qubit gates, we perform randomized benchmarking on each spin by itself and also on both spins simultaneously, to probe cross-talk effects. Furthermore, we developed and experimentally verified a new method called character randomized benchmarking [2,3], which combines the advantages of simultaneous and interleaved randomized benchmarking. With this new method, we characterized the fidelity of a C-Phase gate with tighter bounds than those in the traditional approach.

Benchmarking of two-qubit gates for singlet-triplet qubits

CHENGXIAN ZHANG (Presenter), City University of Hong Kong and South China Normal University, XIN WANG, City University of Hong Kong — We perform benchmarking to evaluate the performance of two-qubit dynamically corrected gates (DCGs) in the singlet-triplet spin qubit system. We execute two types of circuits, i.e. the Deutsch-Jozsa algorithm and Grover algorithm, each of which is carried out with DCGs and gates not immune to noise. The benchmarking process is performed by repeating 100 times of the respective circuit under 1/f noises with different noise exponents (α). The average error per execution of one algorithm is compared between DCGs and non-noise-correcting ones, and whether DCGs offer improvement depends on the noise exponent, α. We have found that when α < 0.8 the DCGs would not offer improvements, but DCGs can outperform the non-correcting ones otherwise. The fact that DCGs can offer improvement for a wide range of α, on one hand, suggests using DCGs on two-qubit gates can reduce the error, but on the other hand also indicates that quantum algorithms involving two-qubit gates suffer more heavily from noises than those only involving single-qubit gates if no correction to noise is performed.

Noise correlations in a two-qubit Si/SiGe quantum dot device

JELMER BOTER (Presenter), XIAO XUE, THOMAS F WATSON, TOBIAS KRAHENMANN, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, VICKRAM PREMAKUMAR, DANIEL WARD, DONALD E SAVAGE, MAX G LAGALLY, MARK G FRIESEN, SUSAN COPPERSMITH, MARK ALAN ERIKSSON, ROBERT JAMES JOYNT, University of Wisconsin-Madison, LIEVEN VANDERSYPEN, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — Qubits are affected by noise in their environment, but conversely can also be used to probe this noise and study properties such as spectral density and correlations. We use a two-qubit device in a Si/SiGe heterostructure [1] to investigate noise correlations by studying the decay of two Bell states. These Bell states are insensitive to either correlated or anti-correlated noise, resembling the concept of decoherence-free subspaces, which allows us to extract the uncorrelated, correlated and anti-correlated contributions to the noise affecting the qubits from the decay times for the different initial states. Knowledge about the noise properties makes it possible to design operations that are less sensitive to this noise, and yields information on the noise source, which potentially makes it possible to reduce the noise. We demonstrate this method by artificially adding (anti-) correlated noise and use it characterize the noise in our system.

Magnetic-Field Effects on Error and Leakage in Randomized Benchmarking of a Si/SiGe Triple-dot Qubit  
CODY JONES (Presenter), HRL Laboratories, LLC — The exchange-only, triple-dot qubit is fully controllable through voltage-based modulation of the exchange interaction between neighboring dot pairs, requiring no magnetic gradients or magnetic resonance. Nevertheless, several magnetic effects play important roles in errors and leakage of the qubit under operation, whether by dephasing for an idle qubit or during a multi-pulse experiment such as randomized benchmarking. This talk discusses the magnetic-field-dependent impacts of three types of magnetic gradients: magnetic screening gradients due to the Meissner effect in superconducting gates, interface-spin-orbit effects, and contact hyperfine interactions including the full vector of nuclear magnetization. While Meissner and spin-orbit gradients are suppressed by operating near zero magnetic field, we find that gradients oriented in directions transverse to the field, in particular the flip-flop terms of the hyperfine component, play a more dominant role. Isolating the effects of magnetic gradients on qubit performance is aided by modifications to the randomized benchmarking protocol that allow reliable extraction of the proportion of total error due to leakage, which is a signature of magnetic gradient effects in exchange-only qubits.

Analyzing the fidelity of a singlet-triplet spin-orbit qubit in silicon using gate set tomography  
CHLOE BUREAU-OXTON (Presenter), Universite de Sherbrooke, KENNETH RUDINGER, NOAH T JACOBSON, DANIEL WARD, JOHN ANDERSON, RONALD P. MANGINELL, JOEL R. WENDT, TAMMY PLUYM, MICHAEL P LILLY, Sandia Natl Labs, MICHEL PIORO-LADRIERE, Universite de Sherbrooke, DWIGHT R LUHMAN, MALCOLM S. CARROLL, Sandia Natl Labs — It has been recently demonstrated that spin-orbit effects observed in silicon quantum dots are much larger than what is expected for bulk silicon [1-3]. These spin-orbit effects can be used to achieve all-electrical universal control of a double quantum dot singlet-triplet qubit without the need for any external components, such as micromagnets or microwave resonators, to produce a magnetic field gradient [4]. In this work, we use gate set tomography to analyze the fidelity of these gates. We also explore the possibility of using AC control, both in the weak and strong driving regimes, to improve the fidelity of qubit operations.

Measurements of capacitive coupling in two double dots in Si/SiGe for application in two qubit gates  
SAMUEL NEYENS (Presenter), EVAN R MACQUARRIE, JOHN DODSON, NATHAN HOLMAN, BRANDUR THORGRIIMSSON, THOMAS McJUNKIN, JOELLE CORRIGAN, MARIO PALMA, Department of Physics, University of Wisconsin-Madison, LISA EDGE, HRL Laboratories, LLC, MARK G FRIESEN, SUSAN COPPERSMITH, MARK ALAN ERIKSSON, Department of Physics, University of Wisconsin-Madison — We present measurements of a Si/SiGe quantum dot device made with overlapping self-oxidized Al gates. The device includes a linear array of four quantum dots and two auxiliary dots for charge sensing. The dots have a lithographic pitch of 130 nm and are separated from the gates by a 30 nm SiGe spacer and 5 nm of aluminum oxide deposited by ALD. We measure the charge noise in all six dots and observe a power spectral density that is approximately 1/f in the 1-200 Hz range with a chemical potential noise amplitude of 1-2 μeV/Hz^{1/2} at 1 Hz. We tune the device to form two tunnel-coupled double dots and observe the capacitive coupling with both double dots at the (0,1)-(1,0) polarization line. We measure a detuning shift of ~8 GHz due to the change in polarization of the adjacent double dot, demonstrating the potential of the system for coherent two-qubit coupling via capacitive interaction.
3:54PM H35.00008: Detuning dependence of capacitive coupling for quantum dot hybrid qubits* ARMAN SETSER

Implementation of robust two-qubit entangling gates is necessary in order to form a universal set of multi-qubit operations. We derive the coupling form between two capacitively coupled qubits, each consisting of three electrons in a double quantum dot (i.e., two hybrid qubits), and show how the effective coupling behaves as a function of detuning. By pulsing the detuning adiabatically, we show how two-qubit entangling operations can be performed on relatively fast 100ns timescales. The entangling operations are then simulated in the presence of experimentally measured quasistatic noise. The fidelities are typically only around 90%, pointing to the need for further improvement via shaped-pulse optimization.

4:06PM H35.00009: Induced quantum dot probe for qubit and material characterization CHARLES TAHAN (Presenter), YUN-PIL SHIM, RUSKO RUSKOV, HILARY HURST, Laboratory for Physical Sciences — We propose a non-destructive means of characterizing quantum dot parameters across a semiconductor wafer by inducing a quantum dot on the material system of interest with a separate probe chip that can also house the measurement circuitry. We show that a single wire can create the dot, determine if an electron is present, and be used to measure critical device parameters. Adding more wires enables more complicated setup and measurements. As one application for this concept we consider silicon metal-oxide-semiconductor and silicon/silicon-germanium quantum dot qubits relevant to quantum computing and show how to measure low-lying excited states (so-called `valley' states) in a novel way. The approach provides a simple and flexible method for characterization applicable to various quantum systems.

4:18PM H35.00010: Device-level modeling of hole quantum dot qubits in germanium* MITCHELL BRICKSON (Presenter), ANDREW BACZEWSKI, WILL HARDY, NOAH T JACOBSON, TZU-MING LU, LEON MAURER, DWIGHT R LUHMAN, Sandia National Laboratories — Holes in Ge quantum wells in Ge/SiGe heterostructures have a number of promising properties that have made them the target of growing interest for qubit applications. These include strong intrinsic spin-orbit coupling, the absence of valley degeneracy, and small effective masses. In this talk, we will describe ongoing work towards developing comprehensive models of these systems to facilitate the design and optimization of devices and the rationalization of experiments. We make use of electrostatic/strain modeling to compute the potential landscape and capacitances of a given device structure. The potential landscape is fed into a multi-band effective mass theory, with other parameters drawn from first principles models, to extract a qubit Hamiltonian. We will report on work describing ongoing quantum dot experiments and make projections pertaining to qubit tunability and performance.

*This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences, user facility. Sandia National Labs is managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a subsidiary of Honeywell International, Inc., for the U.S. Dept. of Energy's National Nuclear Security Administration under contract DE-NA0003525.

4:30PM H35.00011: EDSR of a single heavy hole in a lateral GaAs/AlGaAs quantum dot qubit SERGEI STUDENIKIN (Presenter), MOTOI TAKAHASHI, GUY AUSTING, ALEX BOGAN, LOUIS GAUDREAU, MAREK J KORKUSINSKI, PIOTR ZAWADZKI, ANDREW SACHRAJDA, National Research Council of Canada, LISA A TRACY, JOHN RENO, TERRY HARGETT, Sandia National Laboratories — Single holes are attractive as spin qubits due to their advantageous properties which include a reduced hyperfine interaction, a strong spin-orbit coupling for sub-nanosecond spin rotations, and the absence of valley complications. Here we report single hole electric dipole spin resonance (EDSR) measurements over the 20-50 GHz range taking advantage of the strong spin-orbit coupling. The experiment was performed in a GaAs double quantum dot device described in [1] tuned in such way that only one of the dots contained a single heavy hole with the Fermi level of the adjacent lead positioned in between Zeeman split spin states. In this situation one hole is initialized in the lowest spin level and the current is blocked. A small microwave voltage is applied to a plunger gate to mediate EDSR rotating the hole spin from the lower to the upper spin level allowing the hole to tunnel to the lead. The spin resonance is detected as an increase in current when the resonant condition is fulfilled. The second dot is used as an auxiliary tool to tune the g-factor via a strong spin-dependent tunnel coupling[1]. We show that g-factor can be tuned in the range of 30% by a small change of the voltage applied to the auxiliary dot plunger gate.

Origins and enhancement of hole spin-mixing in InAs quantum dot molecules

ARTHUR LIN (Presenter), Joint Quantum Institute, University of Maryland and NIST, MATTHEW F DOTY, Department of Materials Science and Engineering, University of Delaware, GARNETT BRYANT, National Institute of Standards and Technology — Hole spins in self-assembled InAs quantum dots molecules (QDMs) are a strong candidate for qubit architecture due to their all-optical operation and enhanced tunability via voltage bias across the two dots. In order to capitalize on the all-optical operation and the enhanced tunability, we exploit the spin-mixing provided by the “molecule-like” coupled hole states. Through an atomistic tight-binding model and perturbative field analysis, we discuss the origin of spin-mixing and compare it with previous models using effective Hamiltonians. We then apply our understanding to the case where the GaAs inter-dot region is alloyed with a dilute amount of Bi. Replacing As atoms with the heavier Bi atoms enhances spin-orbit effects and, in turn, increases spin-mixing. However, it complicates the model, as atomistic alloying effects have to be considered, something not explored by prior models. Finally, we briefly discuss the practical operation of InAs/GaBiAs QDM qubits with the enhanced spin-mixing.

Controlling hole spin in quantum dots: Rashba or not Rashba

GARNETT BRYANT (Presenter), National Institute of Standards and Technology, ARTHUR LIN, Physics, University of Maryland — Hole spins in semiconductor quantum dots (QD) are promising qubits. Zeeman-split states form two-level systems with splitting determined by the physical spin of the hole. Due to strong spin-orbit coupling, hole spin orientation is locked to the QD axis for magnetic fields B away from the Voigt configuration. However, in Voigt configuration, the hole spin displays significant texture across the dot but is weakly polarized. Application of an electric field parallel or antiparallel to B in the Voigt configuration restores the hole spin. This spin control can be related to the QD geometry. The question remains whether this can be explained as a Rashba effect originating from interface fields or is inherent to an atomistic description of hole spins in QDs. Tight-binding theory is used to study GaAs/AlAs QDs with a graded alloy describing the QD interface to minimize Rashba effects of sharp interfaces. The results are compared with results for QDs with sharp interfaces. Several examples illustrate how a graded interface influences the spin locking seen for QDs with sharp interfaces and how this changes spin texture and spin polarization in the Voigt configuration. The results are used to assess the contribution of Rashba effects.

Session H36 DCOMP: Real-Space Methods for Large Scale Electronic Structure Problems

BCEC 205C - Leeor Kronik, Weizmann Institute of Science - Tag(s): Invited

Real-space numerical grid methods: The next generation of electronic structure codes

JAMES CHELIKOWSKY (Presenter), University of Texas at Austin — Two physical ingredients, pseudopotentials and density functional theory, are widely used in electronic structure computations for a variety of materials applications. If we wish to address large, complex systems, the implementation of these ingredients on high performance computational platforms is vital. Real space grid methods offer a compelling vehicle for such computations. These methods are mathematically robust, very accurate and well suited for modern, massively parallel computing resources [1]. I will illustrate the utility of these methods as implemented in the PARSEC code [2]. Key algorithms in this code include subspace filtering based on Chebyshev polynomials for an accelerated eigenvalue solution, spectrum slicing for an added level of parallelism, Cholesky QR algorithms to improve the performance of orthogonalization, and a 2D partition of the wave functions for efficient matrix-vector operations. Applications will be illustrated for nanostructures containing tens of thousands of atoms.

*Supported by a subaward from the Center for Computational Study of Excited-State Phenomena in Energy Materials at the Lawrence Berkeley National Laboratory, which is funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DEAC02-05CH11231.
3:06PM H36.00002: Large-scale density-functional calculations in real space and its application to bilayer graphene and semiconductor epitaxial growth [Invited] ATSUSHI OSHIYAMA (Presenter), Institute of Materials and Systems for Sustainability, Nagoya University — Facing current and future massively parallel architecture of supercomputers, we need to make close collaboration between the fields of physical science and computer science. Such collaboration we name COMPUTICS is already in progress (http://computics-material.jp/index-e.html). I here explain an example of such collaboration which allows us to perform total-energy electronic-structure calculations based on the density-functional theory (DFT) in the real-space scheme for tens-of-thousands-atom systems and also the real-space Car-Parrinello Molecular Dynamics simulations for thousands-of-atom systems. I first explain how we are able to perform such large-scale computations efficiently in our code named RSDFT. Recent development of the device simulation combined with the non-equilibrium Green's function (NEGF) method and its application to Si nanowire MOSFETs are also reported. As examples of the application to materials science, I will discuss (1) the localization of Dirac electrons induced by moire pattern in twisted bilayer graphene, (2) ammonia decomposition and N incorporation on epitaxially grown GaN films, (3) intrinsic carrier traps near SiC/SiO2 interfaces, and possibly (4) the formation of amorphous systems with thousands of atoms.

In collaboration with J.-I Iwata (Advance Soft), D. Takahashi (U Tsukuba), G. Milnikov (Osaka U), N. Mori (Osaka U), K. Uchida (Kyoto Inst Tech), Y.-i. Matsushita (Tokyo Inst Tech), K. M. Bui (Nagoya U), M. Boero (Strasbourg U), and K. Shiraishi (Nagoya U).

3:42PM H36.00003: Discontinuous projection method for large, accurate electronic structure calculations in real space* [Invited] JOHN PASK (Presenter), Lawrence Livermore Natl Lab — For decades, the planewave (PW) pseudopotential method has been the method of choice for large, accurate Kohn-Sham calculations of condensed matter systems, in ab initio molecular dynamics simulations in particular. However, due to its reliance on a Fourier basis, the method has proven notoriously difficult to parallelize at scale, thus limiting the length and time scales accessible. In this talk, we discuss new developments aimed at increasing the scales accessible substantially, while retaining the fundamental simplicity, systematic convergence, and generality instrumental to the PW method's success in practice. The key idea is to release the constraint of continuity in the basis set, and with the freedom so obtained, employ a basis of local Kohn-Sham eigenfunctions to solve the global Kohn-Sham problem. In so doing, the basis obtained is highly efficient, requiring just a few tens of basis functions per atom to attain chemical accuracy, while simultaneously strictly local, orthonormal, and systemically improvable. We show how this basis can be employed to accelerate current state-of-the-art real-space methods substantially by reducing the dimension of the real-space Hamiltonian by up to three orders of magnitude. Results for metallic and insulating systems of up to 27,000 atoms using up to 38,000 processors demonstrate the scalability of the methodology in a discontinuous Galerkin formulation. Proceeding via projection of the real-space Hamiltonian instead promises to reach larger scales still.

*This work was performed, in part, under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. Support for this work was provided through the Scientific Discovery through Advanced Computing (SciDAC) program funded by the U.S. Department of Energy, Office of Science, Advanced Scientific Computing Research and Basic Energy Sciences.
AMIR NATAN (Presenter), Physical Electronics, Tel-Aviv University — The use of hybrid and screened hybrid functionals in Density Functional Theory (DFT) became popular as they allow to reduce the error between the calculated and experimentally measured properties. The calculation of the Fock exchange operator, required for those methods, is becoming a computationally prohibitive task with system size. An efficient approach, is to replace the explicit calculation of the Fock operator with its projection on the Hilbert sub-space that is spanned by the previous self-consistent field (SCF) occupied eigenvectors. It is possible to extend the method by projecting also on low lying empty eigenvectors to calculate also the empty eigenvalues. We have implemented this method1 within the PARSEC2,3 real-space code and combined it with efficient Poisson solvers4 and further hardware acceleration by Graphical Processing Units (GPUs) to achieve affordable hybrid calculations of atomistic structures with 1000 atoms on a single workstation5. We demonstrate the efficiency of this method by calculating the electronic properties of silicon quantum dots (QD) and graphene nano-ribbons with hybrid and screened hybrid functionals (e.g. PBE0 and HSE)5. We show how the formalism can be equally applied in real-space to 3D6 and 2D periodic systems.

2:30PM H37.00001: Thermodynamic properties of the Shastry-Sutherland model from quantum Monte Carlo simulations  
ANNA HONECKER (Presenter), Laboratoire de Physique Théorique et Modélisation, Cergy-Pontoise University, IDO NIESEN, Institute for Theoretical Physics, University of Amsterdam, JONAS STAPMANN, Institut für Theoretische Festkörperphysik, RWTH Aachen University, BRUCE NORMAND, Neutrons and Muons Research Division, Paul Scherrer Institute, FREDERIC MILA, Institute of Theoretical Physics, Ecole Polytechnique Fédérale Lausanne (EPFL), PHILIPPE CORBOZ, Institute for Theoretical Physics, University of Amsterdam, STEFAN WESSEL, Institut für Theoretische Festkörperphysik, RWTH Aachen University — We investigate the minus-sign problem that afflicts quantum Monte Carlo (QMC) simulations of frustrated quantum spin systems, focusing on spin S=1/2, two spatial dimensions, and the extended Shastry-Sutherland model. We show that formulating the Hamiltonian in the diagonal dimer basis leads to a sign problem that becomes negligible at low temperatures for small and intermediate values of the ratio of the inter- and intra-dimer couplings. This is a consequence of the fact that the product state of dimer singlets is the exact ground state both of the extended Shastry-Sutherland model and of a corresponding sign-problem-free model. We map the sign problem throughout the extended parameter space from the Shastry-Sutherland to the fully frustrated bilayer model and compare it with the phase diagram computed by tensor-network methods. We use QMC to compute with high accuracy the temperature dependence of the magnetic specific heat and susceptibility of the Shastry-Sutherland model for large systems up to a coupling ratio of 0.526(1) and down to low temperature.

2:42PM H37.00002: Thermal Critical Points and Quantum Critical End Point in the Frustrated Bilayer Heisenberg Antiferromagnet  
JONAS STAPMANN, RWTH Aachen University, PHILIPPE CORBOZ, University of Amsterdam, FREDERIC MILA, EPFL Lausanne, ANDRAES HONECKER, Universite de Cergy-Pontoise, BRUCE NORMAND, Paul Scherer Institute, Villingen, STEFAN WESSEL (Presenter), RWTH Aachen University — We present a quantum Monte Carlo scheme for the simulation of frustrated quantum magnets that allows us to reduce or even eliminate the spin-problem for several dimerized quantum spin systems. We discuss in particular its application to the thermal properties of the spin-1/2 Heisenberg model on a frustrated square lattice bilayer. At zero temperature for the later model, a discontinuous quantum phase transition separates an interlayer singlet phase from an antiferromagnetic ground state formed by interlayer triplets. We show that this discontinuous transition extends up to finite temperatures and terminates in a quantum critical point. We identify this critical point as belonging to the Ising universality class, alert long-range order being absent at finite temperatures. We furthermore trace the discontinuous quantum phase transitions between the fully frustrated and the unfrustrated bilayer model using iPEPS tensor network methods. In particular, we identify a quantum critical end point that terminates the quantum critical line originating from the critical point of the unfrustrated bilayer system on the discontinuous transition line.

2:54PM H37.00003: Dimers on the checkerboard: model, partition sum, and correlations*  
ALEXANDER SEIDEL (Presenter), Department of Physics, Washington University in St. Louis, JULIA WILDEBOER, Department of Physics, Arizona State University — We present analytic results on a special dimer model on the (sem non-bipartite) checkerboard that does not allow for parallel dimers surrounding diagonal links. We report exact results on the enumeration of closed packed dimer coverings on finite checkerboard lattices under periodic boundary conditions. Further, we comment on the behavior of the dimer-dimer correlations and find that the correlations between any two dimers vanishes identically if the distance between them is larger than two unit cells.

*JW thanks NSF DMR 1306897 and NSF DMR 1056536 for partial support.

3:06PM H37.00004: Semiclassical Analysis of Quantum Dimer Models*  
GARRY GOLDSTEIN (Presenter), Physics, Rutgers University, CLAUDIO CASTELNOVO, Physics, Cambridge University, GABRIEL KOTLIAR, Physics, Rutgers University, ALEXEI TSVELIK, Physics, Brook Haven National Laboratory — We use the slave boson approach to develop the semiclassical description of the Rokshar Kivelson square lattice quantum dimer model, which allows a 1/S expansion. The action reproduces a generalized height representation. We extend these results to the dimer model on the cubic lattice, where we obtain emergent quantum electrodynamics description. The estimated speed of light: c = S/2*Sqrt([[J − V ]]/4)). We confirm aspects of the height mapping such as the correlation between the sign of the terms in the height action and the sign of the potential term in the RK Hamiltonian. In dimensions D = 2, 3 the QED emerges at wave vectors (π,π) and (π,π,π) respectively. Our estimate of the RK parameter is 1/16 which is within a 20 to 30 percent of the exact value of 1/4π. We extend our analysis to the hexagonal and diamond lattices, and we find that the speed of light for the diamond lattice is given by c^2 = 8^4*(J − V )/64.

3:18PM H37.00005: Quantum Order-By-Disorder in Frustrated Spin Nanotube Models* PREMALA CHANDRA (Presenter), PIERS COLEMAN, Rutgers University, Piscataway NJ, PETER P. ORTH, Iowa State University, Ames IA, SHIVAJI SONDHI, Princeton University, Princeton NJ — Thermally driven order-by-disorder has been extensively studied in two-dimesional frustrated Heisenberg magnets where it gives rise to long-range discrete order. Here we discuss the quantum analogue in frustrated magnets wrapped around one-dimensional nanotubes that we call "wrapped magnets". We show that as a function of the ratio of the frustrated bond couplings, wrapped magnets develop quantum phase transitions into states with nematic spin orders. For the simplest J1-J2 wrapped magnet, the emergent order parameter has Z2 symmetry and thus can undergo a transition from disordered to ordered at T=0 (D = 1+ 1). The quantum critical point is in the Ising universality class, and has gapless Ising excitations. In more complex models, such as the wrapped windmill model, there is the interesting possibility of an intermediate spin Luttinger liquid phase.

3:30PM H37.00006: Magnetization Process of the Triangular- and Kagome-Lattice Antiferromagnets TORU SAKAI (Presenter), HIROKI NAKANO, Graduate School of Material Science, University of Hyogo — The S = 1/2 kagome- and triangular-lattice Heisenberg antiferromagnets are investigated under a magnetic field using the numerical-diagonalization method[1]. A procedure is proposed to extract data points with very small finite-size deviations using the numerical-diagonalization results for capturing the magnetization curve. For the triangular-lattice antiferromagnet, the plateau edges at one-third the height of the saturation and the saturation field are successfully estimated. This study additionally presents results of magnetization process for a 45-site cluster of the kagome-lattice antiferromagnet; the present analysis suggests that the plateau does not open at one-ninth the height of the saturation.In addition the quantum phase transition of the triangular-lattice antiferromagnet at the 1/3 magnetization with respect to the next-nearest-neighbor interaction[2].

3:42PM H37.00007: Identifying Hidden Spin Nematic Order with Interpretable Machine* KE LIU (Presenter), JONAS GREITEMANN, LODE C POLLET, Ludwig Maximilian University of Munich — Frustrated magnetism is one of the central topics in modern condensed matter physics, as frustration often acts as a firm source of unconventional states of matter. Canonical examples include various spin liquids and spin nematics. However, distinguishing these states and identifying their characterization are usually challenging. In this talk, we present a machine learning protocol to detect and discern general spin-orientation orders. This method may be used as an alternative tool in studying phase transitions in frustrated spin and orbital systems, and may prove useful for identifying hidden spin nematics and ruling out spurious spin liquid candidates.

*This work is supported by FP7/ERC Consolidator grant No. 771891 (Lode Pollet).

3:54PM H37.00008: Uncovering anisotropic magnetic phases via fast dimensionality analysis* MANOHAR KARIGERASI (Presenter), Materials Science and Engineering, University of Illinois Urbana-Champaign, LUCAS WAGNER, Physics, University of Illinois Urbana-Champaign, DANIEL P SHOEMAKER, Materials Science and Engineering, University of Illinois Urbana-Champaign — A quantitative geometric predictor for the dimensionality of magnetic interactions is presented. This predictor is based on networks of superexchange interactions and can be quickly calculated for crystalline compounds of arbitrary chemistry, occupancy, or symmetry. The resulting data are useful for classifying structural families of magnetic compounds. We have examined compounds from a demonstration set of 42 520 materials with 3d transition metal cations. The predictor reveals trends in magnetic interactions that are often not apparent from the space group of the compounds, such as triclinic or monoclinic compounds that are strongly 2D. It can be used to identify quantum spin liquids, cuprate superconductors and other quasi-dimensional systems. We present specific cases where the predictor identifies compounds that should exhibit competition between 1D and 2D interactions, and how the predictor can be used to identify sparsely populated regions of chemical space with as-yet-unexplored topologies of specific 3d magnetic cations.1

We present our \( ^{23}\text{Na} \) and \( ^{75}\text{As} \) NMR study of the over-doped pnictide \( \text{NaFe}_{1-x}\text{Cu}_x\text{As} \), which has been demonstrated to be a possible Mott insulator near \( x \approx 0.5 \) [1,2]. Our NMR spectral-weight and linewidth analysis of the \( ^{23}\text{Na} \) quadrupolar spectrum reveals inequivalent Na sites and indicates a progressive formation of real space Cu and Fe stripe ordering as the Cu concentration approaches 0.5. Our spin-lattice relaxation data shows an antiferromagnetic transition at 190 K for \( x = 0.48 \). At lower Cu concentration there is a spin-glass transition evident from both susceptibility and spin-lattice relaxation data that appears at 80 K for \( x = 0.39 \). We have performed numerical simulation of our \( ^{75}\text{As} \) lineshape by testing a Cu-induced staggered magnetization model and discuss these in the context of the \( ^{23}\text{Na} \) NMR data. **4:18PM H37.00010: Tuning Magnetic Order with Iron Intercalation in Transition Metal Dichalcogenides**

CAOLAN JOHN (Presenter), SPENCER DOYLE, ERAN MANIV, Physics, University of California, Berkeley — The transition metal dichalcogenides are a class of two-dimensional materials currently under intense research due to their attractive electronic properties. Through the process of intercalation, magnetic atoms can be inserted between the layers of these materials to introduce long range magnetic order, enabling the exploration of magnetism in these systems. I will present magnetization and thermodynamic measurements that indicate precise control of this introduced magnetic order in iron intercalated \( \text{NbS}_2 \), with antiferromagnetic order being established at iron intercalation values above \( x = 1/3 \) in \( \text{Fe}_x\text{NbS}_2 \). In addition, I will discuss evidence of a new frustrated magnetic order emerging below critical intercalation values.

*Caolan John is supported by the Haas Scholars Program and by the Gordon and Betty Moore Foundation's EPiQS Initiative through Grant GBMF4374.

**4:30PM H37.00011: Magnetization plateaus in \( \text{Tb}_2\text{SrFe}_2\text{O}_7 \)**

HUIBO CAO (Presenter), YAN WU, WEI TIAN, Neutron Scattering Division, Oak Ridge National Laboratory, JAE-WOOK KIM, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University — Discovery of emergent magnetic states has drawn a lot of interest in studying geometrically frustrated magnets. We recently studied magnetization plateaus in a layered perovskite \( \text{Tb}_2\text{SrFe}_2\text{O}_7 \). \( \text{Tb}_2\text{SrFe}_2\text{O}_7 \) has a bilayer perovskite structure (\( \text{A}_3\text{B}_2\text{O}_7 \)) with Tb and Sr both at A-sites alternately ordered along the c-axis. Different from the multiferroic \( \text{Ca}_2\text{SrFe}_2\text{O}_7 \) that hosts the polar crystal structure and the magnetic ordered state with canted Fe moments, \( \text{Tb}_2\text{SrFe}_2\text{O}_7 \) has the non-polar structure symmetry of \( \text{P}42/mnm \) and the antiferromagnetic structure for the Fe-sublattice below 600 K. The magnetization plateaus were observed below the second transition at 15 K. With the field applied along c-axis, three plateaus were observed. Single crystal neutron diffraction revealed that the magnetic transition at 15 K is from magnetic order of Tb-sublattice accompanied with the spin reorientation of Fe-sublattice. It was also proved that the order of 2-in-2-out spin structure is due to magnetic coupling with the Fe-sublattice. In this presentation, I will show the evolution of the spin structure with temperature and magnetic field and disclose the nature of the magnetization plateaus in \( \text{Tb}_2\text{SrFe}_2\text{O}_7 \).

Tuesday, March 5, 2019 2:30 PM - 5:30 PM

Session H38 GMAG DMP: Monolayer Magnets
2:30PM H38.00001: First-principles approach to novel 2D ferromagnets  
SILVIA PICOZZI (Presenter), HRISHIT BANERJEE, CNR-SPIN Chieti (IT), Consiglio Nazionale delle Ricerche — There is currently an increasing enthusiasm towards long-range magnetic order in two-dimensional materials (such as CrI3 and Cr2Ge2Te6), from the fundamental and from the applicative point of view, from theory and from experiments. In this work, we carry out an extensive investigation based on density functional theory on an extended class of such materials, starting from the database of exfoliable materials reported in N. Mounet et al., Nature Nano. 13, 26 (2018). In the aim of optimizing the properties of 2D-ferromagnets, in particular focusing on an increase of the Curie temperature, our analysis ranges from semiconducting chalcohalides (with formula M-VI-VI, where M is a transition metal, VI and VII are chalcogen and halogen elements) to di-halides (with formula M-(VII)2). In addition to structural and electronic properties, we analyse magnetic properties, in terms of magnetic moments, Heisenberg exchange coupling constants and magnetic anisotropy energy. Some of the considered materials (such as CrSBr or NiBr2) show exchange coupling constants significantly larger than the prototypical CrI3, so they might be promising candidates for larger transition temperatures.

2:42PM H38.00002: Anisotropic magnetic interactions in CrI3  
IGOR MAZIN (Presenter), United States Naval Research Laboratory, SERGEY STRELTSOV, Ural Federal University, Ekaterinburg, Russia, DANIEL KHOMSKII, University of Cologne, Germany — CrI3 is famous among van-der-Waals materials because it displays ferromagnetism in the bulk form, and also in the monolayer form, with an only slightly reduced Curie temperature. Since Heisenberg and XY models do not allow long-range ordering in 2D, it was initially assumed that the magnetic Hamiltonian in CrI3 is of the Ising symmetry. However, it was later shown that it is not the single-site anisotropy, but exchange interaction anisotropy (driven by the spin-orbit coupling on I) that ensures the high Curie temperature. It was assumed, however, without any theoretical justification, that this interaction is of the simplest, pseudo-Ising, form, namely $S^z S^z$, $z$ being the global hexagonal axis. In this talk, we will present first principle calculations showing that not only this pseudo-Ising interaction is present in the system, but all three nearest-neighbor anisotropic terms allowed by symmetry ($S^x S^y S^y$ and $S^y S^z S^z$, plus proper rotations for two other bonds) are of similar order.

2:54PM H38.00003: Interlayer magnetic coupling in bilayer CrI3: A first-principles study  
SANG-HOON LEE (Presenter), CHANUL KIM, YOUNG-WOO SON, School of Computational Sciences, Korea Institute for Advanced Study — Recent discoveries of two-dimensional van der Waals (vdW) magnetic materials, especially CrI3, has accelerated various experimental and theoretical investigations. It has been shown that CrI3 has the intriguing interlayer magnetic orderings: In contrast to the ferromagnetic bulk crystal, a bilayer CrI3 shows an antiferromagnetic coupling between the layers that is hardly computed as magnetic ground states within conventional first-principles computational methods. In this talk, we show that the spin-dependent vdW interactions and the extended on-site correlation are of vital importance in describing the magnetism in a bilayer CrI3 within ab initio computation schemes.

3:06PM H38.00004: Tuning Magnetism in Atomically Thin CrI3 by Hydrostatic Pressure  
TINGXIN LI (Presenter), SHENGWEI JIANG, JIE SHAN, KIN FAI MAK, Cornell University — Atomically thin CrI3 has recently been discovered as a two-dimensional magnetic semiconductor. Remarkably, while monolayer CrI3 is ferromagnetic, antiferromagnetic inter-layer coupling is favored in few-layer CrI3. Because the interlayer exchange coupling is relatively weak, it is expected to be sensitive to external perturbations. Indeed, control of the interlayer magnetic order in atomically thin CrI3 by an electric field and electrostatic doping has recently been demonstrated. Here we report an experimental study of the magnetic order in few-layer CrI3 under hydrostatic pressure. We utilized the giant tunneling magnetoresistance observed in CrI3 spin-filter devices to probe the interlayer magnetic order. We found that the magnetic properties of atomically thin CrI3 can be tuned by applying a moderate pressure.

3:18PM H38.00005: Criticality, anisotropy and dimensionality in the van der Waals ferromagnet CrI3  
EFRÉN NAVARRO-MORATALLA (Presenter), Instituto de Ciencia Molecular, Universitat de Valencia, MATHIAS AUGUSTIN, DINA ABDUL WAHAB, School of Mathematics and Physics, Queen's University Belfast, IVAN JESUS VERA MARUN, KOSTYA NOVOSELOV, School of Physics and Astronomy, University of Manchester, RICHARD F. L. EVANS, Department of Physics, The University of York, ELTON J. G. SANTOS, School of Mathematics and Physics, Queen's University Belfast — Magnetic order is prohibited in the 2D Heisenberg isotropic model at finite temperatures by the long-established theorem put forward by Mermin and Wagner. Indeed, the recent studies on true 2D magnets have nothing but confirmed that magnetic anisotropy is pivotal for eliminating this restriction and allowing, for example, the onset of 2D ferromagnetism in a bilayer of chromium germanium telluride, or in a single layer of chromium triiodide (CrI3). These materials happen to be two identical uniaxial systems from the point of view of their magnetic anisotropy. However, the critical behavior of these 2D magnets is still a matter of debate amidst contradictory reports of the critical exponents. By modelling magnetometry experiments on bulk crystals and magneto-optic data of the monolayer we will shed new light on the universality class of these van der Waals magnets.
Distinct spin-lattice and spin-phonon interactions in monolayer magnetic CrI₃*

LUCAS G. WEBSTER, Department of Physics, Astronomy, and Geosciences, Towson University, 8000 York Road, Towson, MD 21252, USA., Towson University, LIANGBO LIANG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, Oak Ridge National Lab, JIA-AN YAN (Presenter), Department of Physics, Astronomy, and Geosciences, Towson University, 8000 York Road, Towson, MD 21252, USA., Towson University — We apply the density-functional theory to study various phases (including non-magnetic (NM), anti-ferromagnetic (AFM), and ferromagnetic (FM)) in monolayer magnetic chromium triiodide (CrI₃). We found that (1) the introduction of magnetism in monolayer CrI₃ gives rise to metal-to-semiconductor transition; (2) the electronic band topologies as well as the nature of direct and indirect band gaps in either AFM or FM phases exhibit delicate dependence on the magnetic ordering and spin-orbit coupling; and (3) the phonon modes involving Cr atoms are particularly sensitive to the magnetic ordering, highlighting distinct spin-lattice and spin-phonon coupling in this magnet. First-principles simulations of the Raman spectra demonstrate that both frequencies and intensities of the Raman peaks strongly depend on the magnetic ordering. The polarization dependent A₁g modes at 77 cm⁻¹ and 130 cm⁻¹ along with the E₂g mode at about 50 cm⁻¹ in the FM phase may offer a useful fingerprint to characterize this material. Our results not only provide a detailed guiding map for experimental characterization of CrI₃, but also reveal how the evolution of magnetism can be tracked by its lattice dynamics and Raman response.

Nature of the Magnetic Anisotropy in the Two-Dimensional Honeycomb Ferromagnet CrI₃*

FRANZ UTERMOHLEN (Presenter), INHEE LEE, KYUSUNG HWANG, Department of Physics, The Ohio State University, DANIEL WEBER, Department of Chemistry and Biochemistry, The Ohio State University, CHI ZHANG, Department of Physics, The Ohio State University, JOHAN VAN TOL, STEPHEN HILL, National High Magnetic Field Laboratory, JOSHUA E. GOLDBERGER, Department of Chemistry and Biochemistry, The Ohio State University, NANDINI TRIVEDI, P CHRIS HAMMEL, Department of Physics, The Ohio State University — The recent discovery of intrinsic ferromagnetism in two-dimensional (2D) van der Waals crystals, such as CrI₃, has drawn much interest due to its potential for future 2D spintronic applications; however, the nature of the anisotropic magnetic interactions that allow 2D ferromagnetic order in this system remains poorly understood. In this work, we provide a detailed description of the anisotropic spin interactions in monolayer CrI₃ using a microscopic spin Hamiltonian constructed from the symmetries of the system. We present the results of our mean field theory and linear spin-wave theory calculations for this model and explain which interaction is responsible for stabilizing 2D ferromagnetic order in this system. Finally, we provide estimates for the strength of each interaction by comparing these results to our experimental data from angle-dependent ferromagnetic resonance on bulk CrI₃ single crystals.

*NT acknowledges the support of the Center for Emergent Materials: an NSF MRSEC, under award number DMR-1420451. FU acknowledges support from the DOE-BES grant DE-FG02-07ER46423.

Origin of magneto-crystalline anisotropy underlying 2D ferromagnetism in CrI₃ single crystals from ferromagnetic resonance

INHEE LEE (Presenter), KYUSUNG HWANG, UTERMOHLEN G. FRANZ, DANIEL WEBER, CHI ZHANG, Ohio State University, JOHAN VAN TOL, STEPHEN HILL, National High Magnetic Field Laboratory, JOSHUA E. GOLDBERGER, NANDINI TRIVEDI, P CHRIS HAMMEL, Ohio State University — We provide the detailed magnetic anisotropy structure of a CrI₃ single crystal obtained through the measurement of the angle dependence of ferromagnetic resonance. We present a microscopic spin model describing the anisotropic interactions in a monolayer in terms of the experimentally measured Heisenberg, Kitaev, symmetric-anisotropic and quadrupole interactions that incorporate the material’s crystal symmetries. Comparison of Tc calculated using spin wave theory with the experimentally known values reveals that CrI₃ is dominantly a Kitaev ferromagnet rather than Heisenberg. We also find that symmetric-anisotropic interaction stabilizes 2D ferromagnetic order by opening the magnon gap ~ 0.4 meV at the center of the Brillouin zone and we predict a Kitaev-interaction-induced ~ 5 meV magnon gap opening at the Dirac point. This work clarifies the complex anisotropic behaviour of spins in CrI₃, opening a route to develop 2D ferromagnets with higher Tc and explore novel 2D spin orders arising from Kitaev physics in van der Waals materials.
magnetic properties make the ScCl monolayer a promising candidate for spintronic applications. In addition, the ScCl monolayer possesses excellent thermal and dynamical stabilities and great feasibility of experimental exfoliation from its layered bulk. These intriguing electronic and ferromagnetism can also be extended to ScCl bilayers. Moreover, a small amount of hole doping can turn the ScCl monolayer into a half-metal and further improves the magnetic moment and Curie temperature. The novel monolayer (45 K) and the boiling point of liquid nitrogen (77 K). Moreover, a small amount of hole doping can turn the ScCl monolayer into a half-metal and further improves the magnetic moment and Curie temperature. The novel monolayer (45 K) and the boiling point of liquid nitrogen (77 K).

4:06PM H38.00009: Stacking-dependent magnetism in bilayer CrI3+ NIKHIL SIVADAS (Presenter), Cornell University, SATOSHI OKAMOTO, Oak Ridge National Lab, XIAODONG XU, University of Washington, CRAIG J FENNIE, Cornell University, DI XIAO, Carnegie Mellon University — We report the connection between the stacking order and magnetic properties of bilayer CrI3 using first-principles calculations. We show that the stacking order defines the magnetic ground state. By changing the interlayer stacking order one can tune the interlayer magnetism between antiferromagnetism and ferromagnetism. To measure the predicted stacking-dependent magnetism, we propose using a linear magnetoelectric effect. Our results not only gives a possible explanation for the observed antiferromagnetism in bilayer CrI3 but also have direct implications in heterostructures made of two-dimensional magnets.

4:18PM H38.00010: Spectroscopic studies of magnetic ordering in two-dimensional trihalides and chromium-based compounds QIAN SONG (Presenter), Massachusetts Institute of Technology, YUFEI LIU, Physics, Peking University, ZHIHAI ZHU, JIARUI LI, CONNOR A OCCHIALINI, ABRAHAM LEVITAN, MIN GU KANG, JONATHAN PELLICARI, Massachusetts Institute of Technology, LI YUE, Physics, Peking University, RICCARDO COMIN, Massachusetts Institute of Technology — Since the discovery of layer-dependent ferromagnetism in chromium triiodide(CrI3), the two-dimensional(2-D) crystals with intrinsic magnetism persisting even into monolayer attract widespread concern. This kind of 2-D magnets provide us a totally new platform for further development of spintronics, magnetoelectronics etc. Even though the details of the magnetic coupling between layers have not been fully understood, such ferromagnetism in CrI3 give us hint that other 2-D trihalides and chromium-based compounds may also show remarkable magnetic properties down to thin layers. Here we will present our work on looking for new 2-D magnets and the understanding of the magnetic ordering in these materials.

4:30PM H38.00011: High Curie-temperature intrinsic ferromagnetism and hole doping-induced half-metallicity in two-dimensional scandium chlorine monolayers+ BING WANG (Presenter), Southeast University — High Curie-temperature ferromagnetic two-dimensional (2D) materials with large spin polarization have been a long-sought goal due to their potential in spintronics applications. Here we report a promising 2D scandium chloride (ScCl) monolayer with intrinsic ferromagnetism and high Curie temperature up to 185 K, which is much higher than that of the reported CrI3 monolayer (45 K) and the boiling point of liquid nitrogen (77 K). Moreover, a small amount of hole doping can turn the ScCl monolayer into a half-metal and further improves the magnetic moment and Curie temperature. The novel ferromagnetism can also be extended to ScCl bilayers. In addition, the ScCl monolayer possesses excellent thermal and dynamical stabilities and great feasibility of experimental exfoliation from its layered bulk. These intriguing electronic and magnetic properties make the ScCl monolayer a promising candidate for spintronic applications.

4:42PM H38.00012: Probing magnetism of a 2D magnet with Pt through magnetoresistance+ TANG SU (Presenter), International Center for Quantum Materials, Peking University, MARK LOHMANN, JUNXUE LI, MOHAMMED ALGHAMDI, MOHAMMED ALDOSARY, YADONG XU, YAWEN LIU, VICTOR ORTIZ, WEI YUAN, University of California, Riverside, KENJI WATANABE, TAKASHI TANIGUCHI, 1-1 Namiki, Tsukuba, National Institute for Materials Science, JING SHI, University of California, Riverside — 2D magnetic materials have lately attracted tremendous research interest in condensed matter physics. Very interestingly, chromium triiodide (CrI3), an insulating member of the 2D magnet family, has been discovered to possess antiferromagnetic coupling between layers, as demonstrated by magneto-optic Kerr effect and tunneling measurements in ultra-thin samples. In our work, we place a CrI3 flake in direct contact with a pre-patterned Pt Hall bar which serves as a sensing layer. We observe a sharp increase in magnetoresistance (MR) at H(along c-axis) ~ 2T. This feature coincides with a major magnetization switching previously reported in CrI3 flakes with thickness above 3 layers. Temperature and field direction dependent MR measurements have also been conducted and the results reveal further information about the nature of the magnetic interactions. Our approach offers a unique platform to study magnetic ordering in CrI3 and other highly resistive 2D magnetic materials through electrical transport measurements. It also provides an interesting perspective for studying the intriguing physics of exchange proximity coupling and spin current effect at 2D van der Waals interfaces.

*This work was supported by DOE BES Award No. DE-FG02-07ER46351 and NSF-ECCS under Award No. 1610447.
4:54PM H38.00013: Dipolar interaction and exchange anisotropy in two-dimensional ferromagnetic quantum Heisenberg spin lattices.*

JOREN VANHERCK (Presenter), Physics Department, University of Antwerp, BART SORREE, Department of Electrical Engineering (ESAT), KU Leuven, WIM MAGNUS, Physics Department, University of Antwerp — Spin wave majority gates are considered as a viable beyond CMOS technology [1], if sufficiently scaled down. Although quantum effects are important when considering such scaled-down devices with thin ferromagnets, these are not sufficiently taken into account in today’s device simulations. Similarly, the effect of magnetic dipolar interaction on both the direction and magnitude of magnetization is poorly understood.

We present results [2] on the magnetization in two-dimensional ferromagnets with exchange anisotropy in an external magnetic field applied in an arbitrary direction. Using double-time temperature-dependent Green's functions, we take into account quantum and thermal effects and we show the existence of a magnetic reorientation transition in anisotropic Heisenberg ferromagnets. Additionally, the framework can be extended to fully take into account magnetic dipole-dipole interaction, including its effect on the magnetization direction.

*We acknowledge funding from IMEC.

5:06PM H38.00014: Checkerboard Antiferromagnetic Order in FeSe Monolayer

SHUANG QIAO (Presenter), Tsinghua University — Although the paramagnetic state has been confirmed in FeSe bulk via inelastic neutron-scattering (INS), the magnetic states in FeSe monolayer and thin films remain mysterious due to the difficulties in both experimental and theoretical approaches. Experimentally, current magnetic measurement techniques are extremely difficult to be applied to thin film structures. Theoretically, first principle calculation can not deal with paramagnetic system with strong spin fluctuations. Here we report a systematic approach based on surface defects and in-plane strain, and utilizing scanning tunneling measurements (STM) combining with first-principles calculations, to identify the magnetic states in FeSe monolayer and thin films. We provide a strong evidence of the existence of checkerboard antiferromagnetic order in FeSe monolayer by measuring and computing scanning tunneling microscopy images of two typical surface defects. The checkerboard antiferromagnetic order in FeSe monolayer is further verified by estimating the magnetic property of surface defect experimentally and theoretically. Moreover, we confirm the checkerboard antiferromagnetic order exists also in FeSe thin films by studying the electronic band structure evolution with in-plane strain.

5:18PM H38.00015: High Temperature Half-metallicity in Two-Dimensional CoGa2X4 (X=S, Se, Te)*

SHUQING ZHANG (Presenter), XIAOLONG ZOU, Tsinghua-Berkeley Shenzhen Institute — The recent discoveries of intrinsic ferromagnets CrI3 and Gr2Ge2Te6 with critical temperatures lower than 45 K create huge potential for spintronic applications of two-dimensional (2D) van der Waals crystals. Here, we discover a family of 2D half-metallic ferromagnets CoGa2X4 (X=S, Se or Te), which exhibit high critical temperature, fully polarized spin state and strain-dependent magnetization direction simultaneously. The Magnetocrystalline anisotropy energy calculation with spin-orbital coupling indicate that CoGa2X4 favor easy plane magnetizations, which are expected to have BKT transitions. According to the 2D XY model, the critical temperatures \( T_c \) of transitions for CoGa2X4 are much higher than room temperature. Further, under experimentally achievable biaxial tensile strain (2%~6%), the magnetization directions of CoGa2X4 could change from in-plane to out-of-plane, providing a route to control the efficiency of spin injection/detection. The proposed half-metallic CoGa2X4 system belong to the big family of layered AB2X4 compounds, and these materials would enrich the available 2D candidates for various applications.

**History-Dependent Dynamic Nuclear Polarization in Gallium Arsenide in the Resonant Spin Amplification Regime**

JOSEPH IAFRATE (Presenter), MICHAEL MACMAHON, MICHAEL J DOMINGUEZ, HUA-WEI HSU, VANESSA SIH, University of Michigan — Dynamic nuclear polarization (DNP) arises through the interaction of atomic nuclei in a material with spin-polarized electrons. An optically-driven electron system transfers spin polarization to the nuclei. In turn, nuclear spins produce a magnetic field that affects electron spin precession frequency. We use a pulsed laser to excite and measure electron spin polarization in a gallium arsenide epilayer, in the regime of resonant spin amplification. By measuring Kerr rotation as a function of applied magnetic field, we can detect the influence of the nuclear spins. We report an unexpected dependence of DNP on both magnetic field history and transverse electron spin polarization [1]. Variations of the applied field sequence and duration reveal a minutes-long precise memory of the particular field history of the system.

**Spin Dynamics in the Thermoelectric Li:MnTe Antiferromagnetic Semiconductor**

RAPHAEL HERMANN (Presenter), MICHAEL MANLEY, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge TN-37831-6064, USA, VASILE O GARLEA, DOUGLAS L ABERNATHY, Neutron Scattering Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831-6475, USA, HUAIZHOU ZHAO, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, People's Republic of China, JOSEPH P C HEREMANS, Department of Mechanical and Aerospace Engineering, Department of Physics, Department of Materials Science and Engineering, The Ohio State University, Columbus, OH 43210, USA — We report the magnetic structure and excitation spectrum of Li0.03:MnTe, a material related to the MnTe antiferromagnetic semiconductor with a Néel temperature of ~307 K. MnTe was proposed to exhibits a strong contribution of magnon drag to the thermopower[1]. Neutron scattering reveals the magnetic structure and spin-spin correlations in the ordered and disordered phases of Li0.03:MnTe. Above the magnetic ordering temperature, strong quasielastic paramagnon scattering is observed. The characteristic energy width of the scattering is temperature independent and provides evidence for slow, ~30 fs, magnetic fluctuations. These data provide necessary input for modelling of the transport properties.

**Dependence of dynamic nuclear polarization on resonant spin amplification and external field history under periodic optical electron spin pumping**

MICHAEL MACMAHON (Presenter), JOSEPH IAFRATE, MICHAEL J DOMINGUEZ, HUA-WEI HSU, VANESSA SIH, University of Michigan — Greater control of nuclear spin polarization could provide breakthroughs in both classical and quantum information storage and processing. We use optical pump-probe techniques in a gallium arsenide epilayer to manipulate an electron spin polarization that persists over several pulse cycles1. The interference of spins excited from different pulses in a swept external magnetic field results in resonant spin amplification (RSA), and we demonstrate a dynamic nuclear polarization perpendicular to the electron spin polarization that actively responds to the external field sweep direction and magnitude of RSA. We also show that the electron-nuclear spin system retains memory of the external field history, including interruptions and reversals in magnetic field sweeps, and present a model that explains key features of these results.

*This work was supported in part by NSF and by the U.S. Department of Defense NDSEG program*
For spin-based quantum computation in semiconductors, dephasing of electron spins by a fluctuating background of nuclear spins is a main obstacle. It has been shown that in self-assembled InAs quantum dots, this nuclear background can be precisely controlled by periodically exciting single electron spins using optical laser pulses. A feedback mechanism between the electron spin polarization and the nuclear system focuses the electron spin precession frequency into discrete modes that are commensurate with the laser repetition rate. In such a spin-mode-locked system, the electron spin lifetime within individual dots can surpass the limit given by nuclear background fluctuations. Here we show that spin mode-locking is a universal phenomenon that also occurs in ensembles of lithographically-defined many-electron GaAs/AlGaAs dots [1]. This opens the door to achieve long electron spin coherence times also in systems that can be controlled in shape, size and position. We discuss possible mechanisms of spin mode-locking and show experiments that suggest that the optical Stark effect plays an important role in the nuclear focusing of our many-electron dots.

We have studied the dynamics of previously reported spin-dependent charge carrier recombination transitions in Tris(8-hydroxyquinolinato) aluminium (Alq3) thin films with both continuous wave [2] as well as pulsed [3] electrically detected magnetic resonance (EDMR) spectroscopy under bipolar injection conditions. The measurements revealed transverse charge carrier spin relaxation times, $T_2$, shorter, but of the same order of magnitude to those previously observed in other organic semiconductors thin films such as various π-conjugated polymers, spin-orbit induced $g$-strain of the charge carrier magnetic resonances, as well as the local hyperfine field distribution magnitudes of both the electrons and the holes. Our measurements show that, qualitatively, the nature of spin-dependent recombination transitions in Alq3 film is similar to that of the polymer materials and metal-organic complex Zinc phthalocyanine(ZnPc) [4].

This work has been supported by the National Science Foundation, NSF-DMR #1701427.

In this talk, we will show that the spin lifetime in OSECs can be further prolonged by improving the charge delocalization. HFI, originating from the coupling between electron spins and nuclei, has been demonstrated to strongly influence the spin dynamics in OSECs. Nevertheless, the role of charge localization on the HFI strength in organic thin films has not yet been experimentally investigated. In our PRL (120, 086602, 2018), the statistical relation hypothesis that the effective HFI of holes in regioregular poly(3-hexylthiophene) (P3HT) is proportional to $1/N^{0.5}$ has been examined, where $N$ is the number of the random nuclear spins within the envelope of the hole wave function. First, we verify that HFI is the dominant spin interaction in P3HT. Second, assuming that holes delocalize fully over the P3HT polycrystalline domain, the strength of HFI is experimentally demonstrated to be proportional to $1/N^{0.52}$ in excellent agreement with the statistical relation. Finally, the HFI of electrons in P3HT is about 3 times stronger than that of holes due to the stronger localization of the electrons.
4:06PM H39.00007: Two-electron-spin ratchets as a platform for microwave-free dynamic nuclear polarization of arbitrary material targets  PABLO ZANGARA, JACOB HENSHAW (Presenter), DANIELA PAGLIERO, Department of Physics, City College of New York, ASHOK AJAY, Department of Chemistry, University of California Berkeley, JEFFREY A REIMER, Department of Chemical and Biomolecular Engineering, University of California Berkeley, ALEXANDER PINES, Department of Chemistry, University of California Berkeley, CARLOS MERILES, Department of Physics, City College of New York — Recently, several schemes centered around the negatively charged Nitrogen Vacancy(NV) color center in diamond as means to hyperpolarize nuclei have been realized1–2. Here we theoretically consider the case of the NV and the substitutional nitrogen (P1) centers in diamond to show that outside protons spin-polarize efficiently upon a magnetic field sweep across the NV–P1 level anti-crossing. In particular, the nuclear polarization buildup during the low-to-high and high-to-low stages of the sweep cycle adds constructively regardless the relative sweep velocities. The system dynamics can be interpreted in terms of an NV–P1 spin ratchet whose sign depends on the relative timing of an accompanying optical excitation pulse. Our calculations indicate that the polarization transfer process is insensitive to the NV axis orientation, and efficient over a broad range of electron-electron and electron-nuclear spin couplings, even if the proxy spins suffers from short relaxation times.

4:18PM H39.00008: Spin-orbit coupling in antiferromagnetic MnTe*  GEN YIN (Presenter), Electrical and Computer Engineering, University of California, Los Angeles, JIE-XIANG YU, Physics, University of New Hampshire, YIZHOU LIU, ROGER LAKE, Electrical and Computer Engineering, University of California, Riverside, JIADONG ZANG, Physics, University of New Hampshire, KANG WANG, Electrical and Computer Engineering, University of California, Los Angeles — We show that the spin-orbit coupling (SOC) in α-MnTe impacts the transport behavior by generating an anisotropic valence-band splitting, resulting in four spin-polarized pockets near Gamma. A minimal k-dot-p model is constructed to capture this splitting by group theory analysis, a tight-binding model and ab initio calculations. The model is shown to describe the rotation symmetry of the zero-field planer Hall effect (PHE). The PHE percentage is determined by the SOC induced band shape, and is quantitatively estimated to be 25% ~ 31% for an ideal thin film with a single antiferromagnetic domain. The k-dot-p Hamiltonian given by this research is not only effective, but also minimal. The quartic spin-orbit coupling terms in the model is necessary, in the absence of which, the extra C4T symmetry rules out any Hall effect. The predicted value of PHE percentage is an order of magnitude greater than previous experimental observations, suggesting a vast space to optimize the material for device applications.

4:30PM H39.00009: Paramagnon drag yields a high thermoelectric figure of merit in Li-doped MnTe*  YUANHUA ZHENG (Presenter), Ohio State University, TIANQI LU, Institute of Physics, Chinese Academy of Sciences, MD MOBARAK HOSSAIN POLASH, MORTEZA RASOULIANBOROUJENI, North Carolina State University, NING LIU, Institute of Physics, Chinese Academy of Sciences, MICHAEL MANLEY, Oak Ridge National Laboratory, YUAN DENG, Beihang University, PEIJIE SUN, XIAOLONG CHEN, Institute of Physics, Chinese Academy of Sciences, RAPHAEL HERMANN, Oak Ridge National Laboratory, DARYOOSH VASHAEE, North Carolina State University, JOSEPH P C HEREMANS, Ohio State University, HUAIZHOU ZHAO, Institute of Physics, Chinese Academy of Sciences — MnTe is an antiferromagnetic semiconductor with a Neel temperature of 307 K. In the antiferromagnet phase, the magnon-electron interaction gives rise to a magnon-drag contribution to thermopower. Surprisingly this magnon-drag thermopower extends to the paramagnetic phase. Experimental results provide evidence for the effect of locally ordered thermal fluctuations of magnetization with finite lifetime (paramagnons). When the lifetime of the paramagnons is longer than the electron-paramagnon scattering time, the paramagnons can effectively push the electrons and contributes to thermoelectric power. By analyzing the measured thermopower, resistivity, Hall coefficient, specific heat and magnetization, a quantitative explanation is given for thermopower of both the AFM and PM regime based upon the hydrodynamic theory [1]. As a result, the ZT of the best sample exceeds 1 at 950 K.

4:42PM H39.00010: Modification of the Heavy Hole Wave-function in Multiply Occupied Magnetic Quantum Dots

James Piętka (Presenter), St. Bonaventure University, Peiyao Zhang, Tenzin Norden, Arman Najafi, Physics, State Univ of NY - Buffalo, Biplob Barman, Physics, University of Michigan-Flint, Yutsung Tsaí, Physics, Univ of Texas, Bruce Mccomboe, Jong E Han, Igor Zutic, Athos Petrou, Physics, State Univ of NY - Buffalo, Rafal M Oszwalowski, Physics, South Dakota School of Mines and Technology, Wen-Chung Fan, Wu-Ching Chou, National Chiao Tung University — We compare the magnetic field PL peak energy red shift of ZnTe Quantum Dots (QDs) embedded in a ZnMnSe matrix using two types of laser excitation: (a) Excitation at 405 nm (3.06 eV) with photon energy above the ZnMnSe matrix gap. This leads to electron-hole pair generation mainly in the matrix. (b) Excitation at 488 nm (2.54 eV) with photon energy below the ZnMnSe matrix gap but above the bandgap of the ZnTe QDs. In the latter case, carriers are excited directly into the ZnTe QDs.

The PL peak energy magnetic red shift is up to 3 times larger with 488 nm excitation compared to excitation using 405 nm excitation. Under 488 nm excitation an additional PL feature associated with the e_1l_1 shell is observed indicating multiple hole occupancy of the QDs. Using exact diagonalization, we study the doubly occupied quantum dot. We find that in our system, the enhanced exchange interaction between the hole and the Mn ion spins causes the triplet state to be the ground state. Furthermore, the hole-hole repulsion results in the extension of the hole wavefunction further into the ZnMnSe matrix which leads to enhanced magnetic PL red shift.

4:54PM H39.00011: Ferromagnetic Contacts to InSb nanowires

Yifan Jiang (Presenter), Department of Physics and Astronomy, University of Pittsburgh, Zedong Yang, School of Physics and Astronomy, University of Minnesota Twin Cities, Diana Car, Sasa Gazibegovic, Badaowy Ghada, Roy L. M. OP Hét Veld, TU Eindhoven, Sébastien Plissard, LAAS Toulouse, Erik P. A. M. Bakkers, TU Eindhoven, Vlad S Pribiag, School of Physics and Astronomy, University of Minnesota Twin Cities, Sergey M Frolov, Department of Physics and Astronomy, University of Pittsburgh — InSb nanowires are versatile platforms for a variety of quantum transport experiments. Here we develop ferromagnetic contacts onto InSb nanowires. We fabricate four terminal devices (spin-valve geometry) using both Ti/Au and CoFe contacts. At low temperature, both local and non-local experiments demonstrate hysteretic spin-valve like signals. Besides spin injection, we are considering other explanations, for example, the magneto-Coulomb effect. In addition, magnetized ferromagnetic contacts themselves create local magnetic fields, which may affect conductance in high g-factor InSb nanowires.

5:06PM H39.00012: Electrical Spin Injection into Silicon Nanowires with Axial Doping Gradient

Konstantinos Kountouriotis, Jorge L Barreda, Timothy Keiper, Department of Physics, Florida State University, Mei Zhang, Department of Industrial and Manufacturing Engineering, FAMU/FSU College of Engineering, Peng Xiong (Presenter), Department of Physics, Florida State University — For nanoscopic semiconductor spintronic devices, the all-important issue of the ferromagnet/semiconductor (FM/SC) interface becomes even more critical. Here we elucidate the effects of the FM/SC nano interface on electrical spin injection and detection, utilizing a unique type of Si nanowires (NWs) with an inherent axial doping gradient. Two-terminal and nonlocal four-terminal lateral spin-valve measurements were performed using different combinations from a series of FM contacts positioned along the same NW. The data are analyzed with a general model of spin accumulation in a normal channel under electrical spin injection from a FM, which reveals a distinct correlation of decreasing spin-valve signal with increasing injector junction resistance. The observation is attributed to the diminishing contribution of the d-electrons in the FM to the injected current spin polarization with increasing Schottky barrier width. The results demonstrate that there is a window of interface parameters for optimal spin injection efficiency and current spin polarization, which provides important design guidelines for nano-spintronic devices with quasi-1D semiconductor channels.

Session H40 GMAG DMP DCOMP: Complex Oxide Films and Heterostructures II: Iridates and Multiferroics BCEC 208 - Yayoi Takamura, University of California, Davis - Tag(s): Focus
Controllable emergent 2D quantum antiferromagnetism realized in iridate-based heterostructures [Invited] JIAN LIU (Presenter), University of Tennessee — The physics of a square lattice of pseudospin-half electrons in layered iridates has been shown to be particularly rich, giving rise to a novel playground for some of the most outstanding and challenging problems in condensed matter physics, such as metal-insulator transition and quantum magnetism. Significant interests have been focused on the analogy with high-$T_c$ cuprates due to the appealing electronic and magnetic similarities with the CuO$_2$ plane despite the much larger spin-orbit coupling (SOC) of Ir. However, unlike the large material family of cuprates, studies on the layered iridates have been limited to a few Ruddlesden-Popper compounds. This talk will discuss our recent work on overcoming this bottleneck by constructing different artificial variants of the two-dimensional (2D) lattice with heteroepitaxial growth of perovskite iridate. By tuning the layer dimension and the quantum confinement structure, our results show that the magnetic order and exchange interactions of the pseudospin are highly sensitive to the lattice degrees of freedom. By leveraging this structural control, we demonstrate a giant response of the 2D antiferromagnetic order to a sub-Tesla external field. This effect manifests a hidden spin rotational symmetry, which was originally proposed for the CuO$_2$ plane but never observed due to the lack of SOC, illustrating the power of atomic layering in exploring and revealing the intriguing SOC-driven emergent behavior beyond the cuprate phenomenology.

Tuning electronic and magnetic states of pseudospin-$\frac{1}{2}$ square lattice in artificial iridate superlattice JUNYI YANG (Presenter), LIN HAO, Physics and Astronomy, Univ of Tennessee, Knoxville, DEREK MEYERS, Materials Science and Engineering, University of California, Berkeley, HAN ZHANG, Physics and Astronomy, Univ of Tennessee, Knoxville, HAIXUAN XU, Materials Science and Engineering, Univ of Tennessee, Knoxville, MARK DEAN, Brookhaven National Laboratory, JIAN LIU, Physics and Astronomy, Univ of Tennessee, Knoxville — The discovery of $J_{\text{eff}}=1/2$ Mott insulating state in the Sr$_2$IrO$_4$ has drawn a lot of attention since this 2D pseudospin-$1/2$ square lattice is analogous to high-$T_c$ cuprates. On the other hand, the emergent phenomena exhibited by the pseudospin-$1/2$ electrons could be highly susceptible to small changes in the structural degrees of freedom due to the cooperation between electronic correlation and spin-orbit coupling (SOC). Engineering a layered structure of pseudospin-$1/2$ square lattice in artificial superlattices can afford extra tunability of the electronic and magnetic interactions for stabilizing novel collective quantum states. Through controlling dimensionality, spacing layer and epitaxial strain in perovskite iridate-based superlattices, we have investigated the evolution of the spin-orbit-entangled electronic and magnetic ground state under different control parameters. The results from a suite of characterizations, including transport measurements, magnetometry, and synchrotron-based x-ray spectroscopy and scattering, reveal new routes to drive the collective behavior of the interacting pseudospin-$1/2$ electrons, which is not achievable in the bulk.

Metal insulator transition in SrIrO$_3$ Ultra-Thin Films examined by ionic liquid gating* FERNANDO GALLEGO, JAVIER TORNOS, FABIAN CUELLAR, MARIONA CABERO, ALBERTO RIVERA-CALZADA, JUAN I. BELTRAN, Universidad Complutense de Madrid. Spain, M. CARMEN MUÑOZ, F.J. MOMPEÁN, MAR GARCÍA-HERNÁNDEZ, Instituto de Ciencia de Materiales de Madrid ICM-CSIC, CARLOS LEON, JACOBO SANTAMARIA (Presenter), Universidad Complutense de Madrid. Spain — Perovskite SrIrO$_3$ (SIO) is a narrow-band semimetal, which combines strong spin-orbit coupling and electron correlations. This system has attracted much attention because it is at the verge of a Mott transition. Epitaxial SIO ultrathin-layers show a thickness dependent metal-insulator transition (MIT) which is controlled by strain. The insulating state exhibits a strong temperature dependence of the resistance, hysteretic-magnetoresistance and anomalous Hall effect at low temperature, indicating ferromagnetic order. We have explored MIT in SIO ultrathin-layers by using Electric Double Layer (EDL) techniques, that employ ionic liquid as gate dielectric. We have simultaneously measured longitudinal (magneto) resistance and Hall effect across this transition to address whether the MIT is band-width or carrier-density-controlled.

3:30PM H40.00004: Probing Skyrmion Phases in SrIrO3/SrRuO3 thin film by Topological Hall Minor Loops* KENG-YUAN MENG (Presenter), ADAM AHMED, BRYAN D. ESSER, JOSE FLORES, DAVID W. MCCOMB, FENGYUAN YANG, Ohio State University — Skyrmions are topological quasi-particles promising for next generation magnetic storage devices. Fundamental understanding of how field history affects skyrmion formation in host materials is vital in regards to technological application. Topological Hall effect is one of major techniques in probing the skyrmion formation. Magnetization and Hall minor hysteresis loops could reveal critical information in addition to traditional full loops. Here we show Hall minor loops of a SrIrO3/SrRuO3 bilayer, which host nanoscale skyrmions as revealed by pronounced topological Hall effect. At low temperature Hall minor loops track the magnetization reversal process, indicating that the skyrmion formation is closely related to magnetization reversal. However, at high temperatures, the Hall resistivity switches before reaching zero field induced by the dominant topological Hall effect; furthermore, the Hall minor loops reveal truly novel behavior that significantly deviates from the magnetization minor loops. We propose such behaviors could due to stabilization of skyrmions even when applied field is larger than magnetization coercive field.

3:42PM H40.00005: Giant magnetic response of a two-dimensional antiferromagnetic iridate* LIN HAO (Presenter), Department of Physics and Astronomy, University of Tennessee, DEREK MEYERS, Department of Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, HIDE MARO SUWA, JUNJI YANG, Department of Physics and Astronomy, University of Tennessee, TAMENE R. DASA, HAIXUAN XU, Department of Materials Science and Engineering, University of Tennessee, CRISTIAN BATISTA, Department of Physics and Astronomy, University of Tennessee, MARK DEAN, Department of Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, JIAN LIU, Department of Physics and Astronomy, University of Tennessee — Layered iridates are featured of preserving a hidden SU(2) symmetry such that anisotropic exchange interactions have no contribution to spin anisotropy. Achieving this symmetry, however, is highly challenging because it's necessary to incorporate strong spin-orbit coupling, control the 2D lattice structure, and minimize the interlayer coupling. We solved this issue through top-down design and bottom-up synthesis of SrIrO3 and SrTiO3 superlattices [1] to realize a pseudospin-half antiferromagnetic (AFM) square lattice. We observed giant AFM responses to sub-tesla external fields by exploiting the strong 2D critical fluctuations preserved under the symmetry-invariant exchange anisotropy. The observed field-induced logarithmic increase of the ordering demonstrates a new pathway for the highly efficient control of AFM order [2]. Further investigation on the transport properties suggests a novel coupling between AFM fluctuations and charge fluctuations, highlights the application potential in semiconductor devices.

3:54PM H40.00006: Interfacial symmetry control of the chiral magnetism in iridate-manganite superlattices* ELIZABETH SKOROPATA (Presenter), JOHN A NICHOLS, ANKUR RASTOGI, CHANGHEE SOHN, Materials Sciences and Technology Division, Oak Ridge National Laboratory, RYAN DESAUTELS, Large Scale Structures Division, Oak Ridge National Laboratory, XIANG GAO, SATOSHI OKAMOTO, MATTHEW BAHLEK, HO NYUNG LEE, Materials Sciences and Technology Division, Oak Ridge National Laboratory — Correlated oxides have been extensively studied due to the diverse physical properties arising from strong 3d electron correlations combined with lattice and orbital degrees of freedom. Recently, progress toward the creation of exotic quantum and topological properties has been led by the synthesis of 5d oxides with strong spin-orbit coupling. We will present our recent work examining the physical properties of high-quality epitaxially grown LaMnO3/SrIrO3 superlattices. By creating large inversion symmetry breaking with different A- and B-sites in LaMnO3/SrIrO3, we obtain an “topological” Hall effect (THE) that results from interface-induced chiral magnetism resulting from interfacial Dzyaloshinskii-Moriya interactions (DMI). We explore the role of interface symmetry to drive the emergence of the THE at 3d/5d oxides by altering DMI at single interfaces. Furthermore, we compare the effects of (atomic) interfacial DMI and extended superlattice symmetry which together are responsible for the total effective DMI that drive the THE.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.
4:06PM H40.00007: Dynamical multiferroicity*  DOMINIK JURASCHEK (Presenter), Department of Materials, ETH Zurich — In this talk, I present how circularly polarized optical phonons create magnetic moments, reminiscent of atomistic electromagnetic coils. An appealing mechanism for inducing multiferroicity in materials is the generation of electric polarization by a spatially varying magnetization that is coupled to the lattice through the spin-orbit interaction. Here, I describe the reciprocal effect, in which a time-dependent electric polarization induces magnetization even in materials with no existing spin structure. I present a formalism for this dynamical multiferroic effect in the case for which the polarization derives from optical phonons, and estimate the strength of the phonon Zeeman effect, which is the solid-state equivalent of the well-established vibrational Zeeman effect in molecules, using density functional theory. I further show that a recently observed behavior—the resonant excitation of a magnon by optically driven phonons—is described by the formalism.

*This work was supported by the ETH Zürich. Calculations were performed at the Swiss National Supercomputing Centre (CSCS) supported by the project IDs s624 and p504.

4:18PM H40.00008: Coupling of single atom magnetic anisotropy to the neighboring electric polarization  JOSE MARTÍNEZ CASTRO, MARTEN PIANTEK, Instituto de Nanociencia de Aragón, University of Zaragoza, MATS PERSSON, Department of Chemistry, University of Liverpool, CYRUS F. HIRJIBEHEDIN, London Centre for Nanotechnology, University College London, DAVID SERRATE (Presenter), Instituto de Ciencia de Materiales de Aragón, CSIC-University of Zaragoza — Multiferroic coupling arises when two ferroic order parameters influence each other. The most popular case is the coupling of magnetization and electric polarization, arising from the interaction of magnetic moments with the surrounding localized electrical charges. In this work we address such interaction at the atomic scale. More specifically, we have recently reported that it is possible to use the abrupt compositional discontinuity occurring at a surface to induce bistable electric polarization in ultrathin ionic insulators [Nature Nanotech. 13, 19-23 (2018)]. Scanning Probe Methods are capable to manipulate matter at the atomic scale while probing simultaneously its electronic and magnetic properties. In this way, using ultrathin films of binary rock-salts, we have built the specific structural and compositional environment that provides a bistable electric polarization controlled by an external electric field. We have deposited individual Co atoms onto the rock-salt films and measured their magnetocrystalline anisotropy by means of inelastic electron tunneling spectra. We show that the uniaxial anisotropy can reversibly tuned to two stable values following the electric polarization switching as a consequence of the crystal electric field experienced by the Co atom.

4:30PM H40.00009: Strain-Induced Anisotropy in NiCo2O4 Epitaxial Films*  CORBYN MELLINGER (Presenter), University of Nebraska - Lincoln, JACE C WAYBRIGHT, South Dakota State University, XIAOZHE ZHANG, XIAOSHAN XU, University of Nebraska - Lincoln — The room temperature ferrimagnetic spinel structured NiCo2O4 (NCO) has garnered interest due to its potential applications in high-capacity supercapacitors. Additional applications in spintronics necessitate studies on its magnetic behavior, which comes about from the magnetic Co tetrahedral and mixed Ni/Co octahedral sites.

We present SQUID measurements on pulsed laser deposited NCO thin films. Measurements show NCO grown on (001)-oriented MgAl2O4 (MAO) single-crystal substrates display an unconventional out-of-plane magnetic easy axis, overcoming shape anisotropy effects of the thin film. NCO/MAO(110) and NCO/MAO(111) films show in-plane easy axes defined by the crystallographic orientation of the substrate. The anisotropy comes about due to distortion of the local environments around the magnetic cations. Observations are explained using single-ion anisotropy and crystal field theory considerations. Research presented opens possibilities for dynamic control of magnetism based on applied strain.

*This work was supported by the Nebraska Public Power District through the Nebraska Center for Energy Sciences Research at the University of Nebraska-Lincoln.
response upon strain is strongly dependent on the material. For LaTiO₃, the interaction parameters are determined by the degree of localization of the orbitals, and grow with increasing tensile strain. In contrast, LaCrO₃ shows the opposite trend: the interaction parameters shrink upon tensile strain. This is caused by the enhanced screening due to the larger electron filling. LaVO₃ shows an intermediate behavior.

*Research sponsored by the Estonian Ministry of Education and Research (IUT23-3) and Estonian Ministry of Education and Research and the European Regional Development Fund project TK134.

5:06PM H40.00012: Effects of strain on the dynamic magnetic properties of europium iron garnet* VICTOR ORTIZ (Presenter), BASSIM ARKOOK, JUNXUE LI, WEI YUAN, TANG SU, IGOR BARSUKOV, JING SHI, Physics and Astronomy, University of California, Riverside — Ferrimagnetic insulators (FMI) have attracted the interest of the spintronic community as a source of pure spin currents and as a medium for long-range magnon spin transport. Among FMI, rare earth iron garnet (REIG) have a plethora of attributes desirable for practical applications. Epitaxial growth of REIG thin films offers an opportunity to control the magnetic properties; in the case of europium iron garnet (EuIG), the role of Eu for tuning magnetic properties remains elusive. In this work, we present an experimental study on the effect of strain in EuIG thin films on the dynamic magnetic properties. EuIG films of varying thickness (10-100 nm) were grown on various (111) garnet substrates by pulsed laser deposition. The strain was controlled by film thickness and substrate used, as characterized by X-ray diffraction. We performed angular and frequency dependent ferromagnetic resonance measurements on the samples and found a systematic increase in the values of Gilbert damping $\alpha$ and inhomogeneous linewidth $\Delta H_0$ and the appearance of higher order anisotropies when a large strain is exerted in the films.

*This work is supported as part of SHINES, an Energy Frontier Research Center funded by the US Department of Energy, Office of Science, Basic Energy Sciences under Award SC0012670.

Session H41 GMAG DMP: Skyrmion Crystals BCEC 209 - Lisa DeBeer-Schmitt, Oak Ridge National Laboratory - Tag(s): Focus
2:30PM H41.00001: Various topological spin textures and their dynamics in helimagnets* [Invited] XIUZHEN YU (Presenter), CEMS, RIKEN — The ability to manipulate topological spin textures such as skyrmions is a key to the development of electronic devices that are very low in power consumption. Recently, hexagonal skyrmion lattice (hex-SkL) have been discovered in several systems, such as chiral/polar magnets and ferromagnets with uniaxial anisotropy. In addition to the hex-SkL, we have observed the first for a square lattice of merons and antimerons (sq-ML)—topologically distinguish with skyrmions in a thin plate of the helimagnet Co8Zn9Mn3. By finely varying the magnetic field applied perpendicularly to the plate, the transformation between the sq-ML and hex-SkL has been obtained. We found that the skyrmions were very robust, lasting even as we lowered the temperature of the plate, but the merons and antimerons were much more sensitive, and relaxed into spin helices as the temperature fell.

The transition between a hex-SkL and non-topological spin textures, helical or conical structure, have been also demonstrated by the in-situ Lorentz transformation electron microscopy observations with current excitation or field cooling in a helimagnet FeGe. The skyrmion dynamics, such as the collective transformation of sparsely-populated skyrmions to microcrystals of skyrmions, and the current-driven skyrmion motion have been observed. This work has been done in collaboration with Profs. Yoshinori Tokura, Naoto Nagaosa, Taka-hisa Arima, Yusuke Tokunaga and Fumitaka Kagawa, and with Drs. Wataru Koshibae, Yasujiro Taguchi, Daisuke Morikawa, Naoya Kanazawa, Tomoyuki Yokouchi and Kiyou Shibata.

*This work was supported in part by Japan Science and Technology Agency (JST) CREST program (Grant Number JPMJCR1874), Japan.

3:06PM H41.00002: Field-tuned skyrmion crystals: anomalous quantum oscillations induced by Zeeman fields*

SOPHEAK SORN (Presenter), STEFAN DIVIC, ARUN PARAMEKANTI, University of Toronto — Recent experiments on chiral magnets have observed skyrmion crystal phases which are stable in the presence of Dzyaloshinsky-Moriya interactions and Zeeman fields. Skyrmion crystal coupled to itinerant electrons manifests itself in electronic transport as the anomalous “topological Hall effect” caused by a real-space Berry-phase mechanism. This also leads a formation of Chern bands which depend on the properties of the skyrmion crystal unit cell. Our study has shown that incorporating quartic spin interactions into a system which hosts a skyrmion crystal results in a field-tunable skyrmion lattice constant. Itinerant electrons coupled to such skyrmion crystals can then be described by a Hofstadter-type model whose Chern bands depend strongly on the Zeeman field coupled to the local moments. Such metallic magnets serve as candidates for observing Zeeman-field-induced anomalous quantum oscillations.

3:18PM H41.00003: Unpinning the skyrmion lattice in MnSi*

CHETAN DHITAL (Presenter), Physics, Kennesaw State University/Louisiana State University, LISA DEBEER-SCHMITT, Oak Ridge National Laboratory, DAVID P YOUNG, JOHN DITUSA, Louisiana State University — Materials hosting magnetic skyrmion lattices are promising materials for future spintronic applications. Given their potential technological use, it is important to understand the response of these magnetic textures under different physical and chemical environments. We have investigated the behavior of the skyrmion lattice in MnSi1-xGa2 single crystals with variations in the temperature and the magnitude and direction of a magnetic field using small angle neutron scattering and magnetization measurements. Our results indicate that the disorder caused by the inclusion of even of small amount of a heavier element such as Ga can substantially change the pinning of the skyrmion lattice when compared to pure MnSi.

*This material is based upon the work supported by the U.S. Department of Energy under EPSCoR Grant No. DE-SC0012432 with additional support from the Louisiana Board of Regents. C. Dhital also acknowledges Department of Physics Kennesaw State University.
3:00PM H41.00004: Magnetic Hysteresis of the Skyrmion Lattice in MnSi

ALLAN LEISHMAN (Presenter), MORTEN ESKILDSEN, University of Notre Dame, MARC JANOSCHEK, ERIC BAUER, Los Alamos National Laboratory, DIRK HONECKER, Institut Laue-Langevin, LISA DEEBER-SCHMITT, Oak Ridge National Laboratory, JONATHAN S WHITE, Paul Scherrer Institute — Understanding the complex dynamics of skyrmion formation and destruction is key to developing new technologies which make use of them. Here we report the observation of a hysteresis effect associated with forming and destroying the SkL in the chiral magnet MnSi using small angle neutron scattering (SANS). This effect is very small when compared to the applied field of the cryomagnet (~ 1 mT vs 200 mT), but is observable and reproducible by the added precision of a custom built solenoid supplementing the cryomagnet. This hysteresis effect is due to an intrinsic energy barrier associated with forming and destroying the SkL. We have explored the time dependence and magnetic history dependence of the phenomenon to better understand its origin, which we believe to be related to the intrinsic topological energy barrier associated with forming the skyrmions.

*This work is supported by the US DOE, Office of Basic Energy Sciences Award No. DE-SC0005051. Work at Los Alamos Natl. Lab. was performed under the auspices of the US DOE. A portion of this research used resources at the High Flux Isotope Reactor, a US DOE Office of Science User Facility operated by Oak Ridge Natl. Lab., at Institut Laue-Langevin, and at the Swiss spallation neutron source SINQ, Paul Scherrer Institute.

3:42PM H41.00005: Transitions between skyrmion- and hedgehog-lattice states in cubic chiral magnets MnSi$_{1-x}$Ge$_x$

YUKAKO FUJISHIRO (Presenter), NAOYA KANAZAWA, University of Tokyo, TARO NAKAJIMA, XIUZHEN YU, RIKEN Center for Emergent Matter Science, KAZUKI OHISHI, YUKIHIKO KAWAMURA, KAZUHISA KAKURAI, Neutron Science and Technology Center, Comprehensive Research Organization for Science and Society, TAKAHISA ARIMA, HIROYUKI MITAMURA, ATSUSHI MIYAKE, University of Tokyo, KAZUTO AKIBA, Okayama University, MASASHI TUKUNAGA, AKIRA MATSUO, KOICHI KINDO, University of Tokyo, TAKASHI KORETSUNE, Tohoku University, RYOTARO ARITA, YOSHINORI TOKURA, University of Tokyo — Topological spin textures such as magnetic skyrmions and spin hedgehogs show novel emergent phenomena, which can be exploited for spintronic functionalities. Whereas the formation or deletion of them has been intensively studied so far, switching of spin textures among different topologically-nontrivial classes remains largely unexplored.

We report on transitions between skyrmion- and hedgehog-lattice states in cubic chiral magnets MnSi$_{1-x}$Ge$_x$ with variation of lattice constant controlled by Si/Ge substitution. By combining neutron scattering, Lorentz transmission electron microscopy and high-field transport measurements, we observe three different topological spin textures: skyrmion lattice in $x = 0-0.25$ as well as two distinct hedgehog lattices in $x = 0.3-0.7$ and $x = 0.8-1$, as respectively characterized by large topological Hall effects.

The emergence of various topological spin states in the chemical-pressure-controlled materials suggests a new route for direct manipulation of the spin-texture topology by a simple mechanical method such as pressure.

3:54PM H41.00006: First-principles study of oxide skyrmion crystal Chern insulator

FUMIYUKI ISHIH (Presenter), Nanomaterials Research Institute, Kanazawa University, YO PIERRE MIZUTA, HIKAURO SAWAHATA, NAOYA YAMAGUCHI, Graduate School of Natural Science and Technology, Kanazawa University — The magnetic skyrmion crystal (SkX), formed by a topological vortex-like spin in condensed matter, has attracted considerable attention in last decade. We performed density functional calculations for SkX in electron-doped EuO monolayer and found Chern insulating ground state where Chern number $C=2$[1]. Calculated large anomalous Nernst effect [1,2] and electric-field effect will be discussed.

4:06PM H41.00007: Collective antiskyrmion-mediated phase transition and defect-induced melting in chiral magnetic films

LEONARDO PIEROBON, Department of Materials, ETH Zurich, CHRISTOFOROS MOUTAFIS, YU LI, School of Computer Science, University of Manchester, JÖRG F. LÖFFLER, Department of Materials, ETH Zurich, MICHALIS CHARILAOU (Presenter), Department of Physics, University of Louisiana at Lafayette — The topological stability of skyrmions goes beyond the energetics of materials and strongly depends on the dynamics of magnetization textures, and the combined effects of energetics, topology, and magnetization dynamics, lead to wildly rich phenomena. Based on detailed high-resolution micromagnetic simulations, we have found a new first-order field-induced phase transition in which a skyrmion lattice inverts its polarity through a metastable creation and annihilation of an antiskyrmion lattice. Importantly, we have observed that in the presence of even a single defect in the material, the phase transition becomes second-order and progresses through a gradual melting of the skyrmion lattice. Our analysis suggests that in a perfect skyrmion lattice the response to an external magnetic field is an abrupt collective phenomenon due to topological constraints, whereas a single defect disrupts the constraint and facilitates topological charge melting, consequently leading to the gradual response of the material to an external field. This provides a basis for a much wider scope of experiments on skyrmion lattices, with emphasis on the interplay between topological constraints and material defects.
4:18PM H41.00008: Skyrmion Crystals in Decorated Transition Metal Dichalcogenides.*

ALDO RAELIARJAONA (Presenter), KIRILL BELASHCHENKO, ALEXEY KOVALEV, University of Nebraska - Lincoln — We investigate the existence of skyrmion crystal phases in decorated transition metal dichalcogenides (TMDs) such as X/MoS2, for (X=Co,Ni,Fe). We model the system using a frustrated triangular lattice, in the presence of in-plane and out-of-plane Dzyaloshinskii-Moriya interaction. We study the phase diagram by varying the strength of the Heisenberg exchange, Dzyaloshinskii-Moriya interaction, and anisotropy. We also perform Monte Carlo simulations to study the H-T (magnetic field - temperature) phase diagram. We study the appearance of the antiferromagnetic skyrmion crystals residing on the three sublattices of the decorated TMDs. The phase transitions and characteristics of the phases are obtained by computing the specific heat C and the spin structure factor $S_k$.

*U.S. DOE, under Award No. DE-SC0014189

4:30PM H41.00009: Chiral domain topology, Moiré patterns, and magnetism in M1/3Nb(Ta)S(Se)2 (M=transition metals)

SANG-WOOK CHEONG (Presenter), FEI-TING HUANG, KAI DU, SEONG JOON LIM, JAE-WOOK KIM, Rutgers University, New Brunswick, KASUN GAMAGE, JUNJIE YANG, Department of Physics, Central Michigan University, MYUNG-GEUN HAN, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — Transition metal dichalcogenides (TMDs) have been extensively investigated as 2D materials last decade. A large amount of transition metals can be intercalated into the van der Waals gaps of a wider range of TMD materials, but a limited studies have been recently reported in intercalated TMDs. The limited examples include Fe$_x$TaS$_2$ crystals with $x=1/4$ and 1/3, which exhibit intriguing configurations of antiphase and/or chiral domains related to ordering of intercalated M ions with 2a×2a and $\sqrt{3}$a×$\sqrt{3}$a superstructures, respectively. In addition, Cr$_{1/3}$NbS$_2$ undergoes helical spin order below 133 K, and shows an interesting solitonic behavior when in-plane magnetic fields are applied in the helical spin state. We have explored a series of chiral M1/3Ta(Nb)S(Se)$_2$ (M=transition metals) to investigate the correlation among crystallographic and magnetic domain topologies and their physical properties. These results as well as Moiré patterns with self-twisted TMDs induced by intercalation will be discussed.

4:42PM H41.00010: Monte Carlo studies of the phases and phase diagram of quasi 2D Skyrmion systems*

PO-KUAN WU (Presenter), JAMES ROWLAND, Ohio State University, YING-JER KAO, Physics, National Taiwan University, MOHIT RANDERIA, Ohio State University — We present results for large-scale Monte Carlo simulations of the field-temperature phase diagram of thin-film chiral magnets with ferromagnetic exchange and Dzyaloshinskii-Moriya interaction. Using spin structure factors, skyrmion density structure factors, magnetization and specific heat, we show that there are five interesting regions of the phase diagram: (1) a skyrmion solid phase, (2) a skyrmion liquid regime, (3) a helical phase, (4) a fluctuating helical regime, and (5) a field-polarized regime. Using orientational order parameters we identify the phase boundaries for the skyrmion melting transition and the helical melting transition. We also investigate the phase diagram as a function of film thickness $L$, showing how that the interlayer correlations and the maximum transition temperature for the skyrmion solid evolves as a function of $L/L_D$, where $L_D$ is the helical pitch length.

4:54PM H41.00011: Computational-Guided Search for Ultrasmall Skyrmions in Ferrimagnets*

CHUNG MA (Presenter), Department of Physics, University of Virginia, YUNKUN XIE, JIANHUA MA, Department of Electrical and Computer Engineering, University of Virginia, WEI ZHOU, JIE QI, HAMED VAKILITALEGHANI, Department of Physics, University of Virginia, AVIK GHOSH, Department of Electrical and Computer Engineering, University of Virginia, JOSEPH POON, Department of Physics, University of Virginia — Magnetic skyrmions are topologically protected spin textures. They can potentially improve density and energy efficiency in memory and logic devices. With the immense material's space, it could take years to experimentally explore all the possible materials for skyrmions' device application. To guide experiments, we employ computational models to identify several materials for stabilizing ultrasmall skyrmions at room temperature. One of the more promising candidates is amorphous rare-earth-transition-metal ferrimagnet. Our atomistic stochastic Landau-Lifshitz-Gilbert (LLG) model has revealed that Néel skyrmions, with a diameter of 10 nm or less, are stable in 5 nm thick GdFe and GdCo at room temperature. Following this guidance, we have fabricated GdCo samples and controlled the Dzyaloshinskii-Moriya interaction (DMI) through tuning the interfacial layers. Results from these samples are used as feedbacks to refine our computational models. Using this computational-guided approach, the time needed to explore promising materials for skyrmions-based devices will be vastly reduced.

*This work is supported by the DARPA TEE program.
5:06PM H41.00012: Imaging Skyrmion Magnetization Dynamics in Time-Resolved Lorentz Electron Microscopy
GABRIELE BERRUUTO (Presenter), IVAN MADAN, YOSHIE MUROOKA, GIOVANNI MARIA VANACORE, THOMAS LAGRANGE, Institute of Physics, EPFL, DAMIEN MCGROUTHER, YOSHIHIKO TOGAWA, SUPA, University of Glasgow, FABRIZIO CARBONE, Institute of Physics, EPFL — The creation, annihilation, movement, and control of magnetic skyrmions with different tools has been the subject of intensive research in recent years. So far, little attention has been given to the use of light as (yet another) external knob to trigger magnetic changes in skyrmion-hosting materials.

With a combination of camera-rate and ultrafast pump-probe Lorentz Transmission Electron Microscopy we directly resolve the spatio-temporal evolution of the skyrmion magnetization ensuing (fs and ns) optical excitation. The laser-induced creation and annihilation of skyrmions in bulk (Bloch) and interfacial (Néel) systems is reported, and the ultimate speed of such writing and erasing is discussed. In a 60-nm thick slab of the prototypical chiral magnet FeGe, we study how the extreme cooling rates of the crystal ( > 10⁷ K/s) following the photoexcitation can quench the magnetization into a disordered metastable skyrmion lattice.

5:18PM H41.00013: Dynamics in Multiferroic Skyrmion GaV₄S₈
WILLIAM RATCLIFF (Presenter), JEFFREY W LYNN, MARKUS BLEUEL, National Institute of Standards and Technology, LUNYONG ZHANG, Laboratory for Pohang Emergent Materials and Max Plank POSTECH Center for Complex Phase Materials, Pohang University of Science and Technology, SANG-WOOK CHEONG, Physics, Rutgers University — GaV₄S₈ is a rare example of a material hosting a multiferroic Neel-type Skyrmion [1]. We have grown 91 mg single crystals of this material and explored the field/temperature phase diagram using Small Angle Neutron Scattering (SANS) as a probe. We have also investigated the dynamics of the skyrmion phase. In this study, we apply a static field along the [111] crystallographic direction. We also apply a modulated magnetic field along this direction and observe time tagged events on our detector to observe the time dependence. In this talk, we will discuss our results in the context of recent AC susceptibility measurements [2].

*The work at Rutgers University was supported by the NSF under Grant No. DMR-1629059.
The work at Postech was supported by the National Research Foundation of Korea(NRF) funded by the Ministry of Science and ICT(No. 016K1A4A4A01922028).
Access to NG7SANS was provided by the Center for High Resolution Neutron Scattering, a partnership between NIST and the National Science Foundation under Agreement No. DMR-1508249.

Tuesday, March 5, 2019 2:30 PM - 5:30 PM
Session H42 DPOLY: Dillon Medal Symposium BCEC 210A - Mark Ediger, University of Wisconsin - Madison - Tag(s): Focus
2:30PM H42.00001: John H. Dillon Medal Talk: Probing Glass Physics Through Measurements of Polymer Dynamics in Thin films and in Strongly Confined Systems*  
[invited] ZAHRA FAKHRAAI (Presenter), Chemistry, University of Pennsylvania  
— Extensive research in the past two decades has shown that the free surfaces of glasses have dramatically faster dynamics compared to the bulk dynamics with much lower activation energies for rearrangement. In ultrathin films of polymers and molecular glasses, the enhanced surface mobility results in large changes in the value of the glass transition temperature (T_g), enhanced overall dynamics, as well as other property changes such as elasticity, mechanical response, and aging rate.

In this presentation, I will discuss how as the film thickness is reduced below ~30 nm, the dynamics at the two interfaces strongly correlate such that the bulk-like dynamics disappear, and the free surface dynamics are influenced by the substrate dynamics and vice versa. In molecular glasses, supported on weakly interacting substrates these effects can cause a sharp transition from bulk dynamics to liquid-like behavior resulting in dewetting of 30nm films at temperatures well below T_g. These long-range dynamical correlations cannot be simply explained by changes in local interaction potentials. Furthermore, the thickness of this transition remains independent of chemical structure or substrate interactions and appears to be set by the bulk glass properties. As such, the strong perturbation at the free surface can be used as a probe of fundamental aspects of dynamics in bulk super-cooled liquids close or below their T_g.

In contrast, in highly confined systems such as polymers infiltrated into dense nanoparticle packings, while strong changes in T_g and viscosity are still observed, the geometric confinement effect is only significant when the pore sizes are a few nanometers. This is a much shorter length scale than what is observed in systems with free surfaces, suggesting that geometric confinement and free surfaces can have distinctly different effects on the dynamics.

3:06PM H42.00002: The glass transition in polydisperse polymers: contribution of mixing entropy  
VALENTIN RUFFINE, ADAM RAEGEN, JAMES FORREST (Presenter), University of Waterloo — All polymerization processes give rise to polydisperse samples where the molecules exhibit a distribution of polymerization index, N. Due to the strong dependence of glass transition temperature, T_g, on N for small N, such polydispersity can potentially have a strong impact on the measured T_g values. Gibbs and DiMarzio 60 years ago (J. Chem. Phys. 28, 373 1958) suggested that the T_g value of polydisperse samples is determined by the number average N of the sample “except for an ordinarily small correction” due to the excess mixing entropy. By considering mixtures of near oligomeric polystyrene with different compositions but the same number average molecular weight we can separate the entropic contribution due to chain ends from that of the chain mixing. We find that the measured T_g values of these mixtures has a significant composition dependence. We quantify this difference by considering the extra mixing entropy of the small chains. This analysis is also able to explain previously measured anomalies in bimodal mixtures of PS.

3:18PM H42.00003: Investigation of deformation mechanism of impact polypropylene  
YUE ZHANG (Presenter), Product Fundamentals, ExxonMobil Asia Pacific Research and Development Company, Ltd., LI QIAN, YING LU, Changchun Institute of Applied Chemistry, YINGYING SUN, ExxonMobil Chemical Company, YONGFENG MEN, Changchun Institute of Applied Chemistry — Polypropylene (PP) is one of the most important plastics widely used due to its heat resistance, high stiffness and good processability. However, the application of PP is often limited by its poor impact resistance. In industry, in reactor copolymerization of ethylene-propylene (EP) following PP homo polymerization is an economic and efficient way of toughening PP where the product is impact copolymer of polypropylene (ICP). Yet the mechanism of PP toughening is still elusive which may involve several energy adsorbing mechanism upon deformation. Here we investigate the cavitation formation process upon deformation in ICP using ultra-small angle X-ray scattering (USAXS), where cavity size and shape evolution were monitored upon deformation. Different ICP systems with varying EP fraction and compositions were studied, aiming to correlate the micro-structure developed upon deformation with the molecular attributes of different ICP systems.
3:30PM H42.00004: Fragility and the Glass Transition of Geometrically Confined Polynorbornenes  
LAURA GRAY (Presenter), RODNEY PRIESTLEY, Chemical & Biological Engineering, Princeton University — Over the past twenty years many studies have shown a reduction in the glass transition temperature (Tg) of thin polymer films confined on the nanoscale when supported on non-attractive substrates or free-standing. These results have been explained by the propagation of enhanced mobility from the free-surface into the polymer film. Many questions remain as to the varying length scale over which Tg decreases, the magnitude of the Tg perturbation observed for different polymers as well as the role cooperatively rearranging regions play in Tg. In this study we measure the dynamic fragility, cooperative length scale, and confined Tg for a series of chemically similar polynorbornenes. We do not see a clear trend in bulk fragility, cooperative length scale, and the magnitude of the Tg perturbation over a wide range of fragilities. Utilizing the unique capabilities of flash differential scanning calorimetry we are also able to quantify the influence of confinement on the fragility and cooperative motion of polynorbornenes.

3:42PM H42.00005: Polymerization Thermodynamics under Nanoconfinement*  
QIAN TIAN, HAOYU ZHAO, SINDEE SIMON (Presenter), Texas Tech University — The behavior of materials confined at the nanoscale has been of considerable interest over the past several decades, especially changes in the glass transition temperature (Tg) and/or melting point (Tm). Less well studied are the effects of nanoconfinement on polymerization kinetics and thermodynamics. Our recent focus has been on understanding how nanoconfinement influences the polymer/monomer equilibrium in the free radical reaction of poly(alkyl methacrylates). We find that nanoconfinement shifts the monomer/polymer equilibrium back towards monomer, and this effect can be exploited to determine the entropy loss on confining a chain. We find that the entropy loss is as high as 10 J/mol/K, approximately 10 % of the change going from monomer to polymer. The results seem to indicate that as the n-alkyl group increases from methyl to ethyl to butyl, the entropy of confinement decreases. Interestingly, the magnitude of the Tg depression in ultrathin films of poly(n-alkyl methacrylate)s also decreases as the length of the alkyl group increases in work by Vogt et al.; whether the origin is linked to the change in chain confinement entropy is an open question.

*Funding from NSF DMR 1610614 is gratefully acknowledged.

3:54PM H42.00006: Shear modulus and shear-stress relaxation in simulated free-standing polymer films  
JORG BASCHNAGEL (Presenter), GEEVARGHESE GEORGE, Institut Charles Sadron, IVAN KRIUCHEVSKYI, LAMCOS, INSA, Villeurbanne, HENDRIK MEYER, JOACHIM WITTMER, Institut Charles Sadron — Using molecular dynamics simulations of a coarse-grained model for polymer glasses we examine viscoelastic properties of free-standing (nonentangled) polymer films. We focus on the (in-plane) shear relaxation modulus G(t) and the (in-plane) shear modulus μ, which we analyze as a function of film thickness (h) for temperatures (T) above and below the glass transition temperature Tg(h). The shear modulus is determined via the stress-fluctuation formalism and found to depend, in addition to h and T, also on the time window (Δt) employed for data sampling. This dependence on Δt can related quantitatively to the time dependence of G(t), provided time-translational invariance holds. Therefore, G(t) is the important underlying quantity, which obeys, in good approximation, a time-temperature superposition principle. We determine the viscosity of the films. For a given T the viscosity decreases with film thickness. This effect can be mainly traced back to the decrease of Tg with decreasing h. The presence of the free interfaces also weakens the shear rigidity of the polymer glass relative to the bulk, which can be understood via the relation between μ and G(t) mentioned before.

4:06PM H42.00007: Mobility Gradients in Supported Glass-Forming Polymer Films Do Not Imply Gradients in Cooperative Motion  
JACK DOUGLAS (Presenter), WENGANG ZHANG, Materials Science and Engineering Division, NIST, FRANCIS STARR, Department of of Physics, Wesleyan University — We investigate the extent of collective motion in the interfacial regions of a thin supported polymer film and within the film interior by molecular dynamics simulations to understand the role of collective motion in the often large changes in interfacial molecular mobility observed in polymer films. Contrary to commonly stated expectations, we find that the extent of collective motion determining the temperature dependence of the structural relaxation time does not vary significantly within the film, a finding consistent with Adam-Gibbs proposal that the extent of collective motion in glass-forming liquids is related to the configurational entropy, a thermodynamic property that cannot vary with position within the film.
4:18PM H42.00008: Dynamic Phase Transitions in Confined Polymer Glasses  ROBERT RIGGLEMAN (Presenter), ROBERT IVANCIC, University of Pennsylvania — Despite more than two decades of effort, several qualitative features regarding the segmental dynamics of thin films of glass-forming materials remain poorly understood. This challenge is of paramount importance in thin film membranes, organic electronic devices, and critical steps of semiconductor manufacturing. Recent simulations and experiments have provided compelling evidence that the dynamics near surfaces are qualitatively different from those of a bulk supercooled liquid, and in this talk I will describe our efforts at characterizing those dynamics by investigating a non-equilibrium phase transition associated with glass-forming materials. This transition is associated with a supercooled liquid that undergoes a sharp transition from a mobile dynamic phase to a phase with reduced mobility, and it provides a clear signal in the dynamics of the glass-forming polymer under confinement. I will describe our characterization of this transition in free-standing thin films of supercooled liquids, where we find that only the bulk of the film is able to undergo this transition. This suggests that the dynamics at the free surface are not glassy in nature, at least not at the temperatures accessible to our simulations.

4:30PM H42.00009: Coarse-Grained Models for Predicting Structure and Thermodynamics in Polymer Systems with Specific and Directional Intermolecular Interactions  ARTHI JAYARAMAN (Presenter), University of Delaware — Recent work in my research group has been aimed at developing predictive coarse-grained (CG) models for investigating structure and dynamics in soft materials with chemistries that have specific and directional molecular interactions. Although computational studies have been tremendously useful in understanding molecular phenomena and guiding synthesis and engineering of new macromolecular soft materials for a wide variety of applications, the inability to capture small scale specific and directional interactions (e.g., hydrogen bonds) alongside macromolecular length and time scales represents a key limitation of most studies to date. We address this limitation by developing coarse-grained models that capture the anisotropic, directional and specific interactions (e.g., hydrogen bonding interaction) governing the structure and thermodynamics in many polymer systems of interest. We have been using molecular dynamics simulations with these new coarse-grained models for studies of biomaterials and polymer nanocomposites. In this talk, I will discuss one example of how the development of these CG models is enabled by synergistic feedback from concurrent/past experiments which I will highlight alongside the computational results from my group.

4:42PM H42.00010: Heterogeneous polymer degradation due to photothermal heating*  LAURA CLARKE (Presenter), HONGLU HUANG, GABRIEL FIRESTONE, RUSSELL E GORGA, JASON BOCHINSKI, North Carolina State University — We are interested in observing the effects of thermally-driven chemical reactions occurring in small volumes within a solid material, where diffusion of reactants and products is limited. Such experiments can be achieved by photothermally heating metal nanoparticles incorporated within the polymer which results in significant heat generation at the particles and an inhomogeneous steady state temperature distribution within the solid material, where regions far from any particle are cool, whereas those in a particle's immediate vicinity experience temperatures of 100-200 deg. C. Polyethylcyanoacrylate (PECA) degrades by depolymerizing and in confinement, the monomer will repolymerize to form oligomers. In principle, such a process might enable internal conversion of polymer to oligomer without significant loss of mechanical properties, and thus potentially address issues such as microfragmentation of plastics in the environment. We characterize degradation of PECA:starch:nanoparticle composites via GPC, dilute solution viscometry, electron and optical microscopy, and mechanical property measurements, and compare and contrast degradation obtained via photothermal heating with that obtained by conventional means.

4:54PM H42.00011: Charge Density- and Hydrophobicity-Dependent Dynamics of Polyelectrolyte Complex Coacervates  JENNIFER LAASER (Presenter), JUN HUANG, University of Pittsburgh — We use a library of polyacrylamide-based polymers to investigate the roles of charge density and hydrophobicity in determining the phase behavior and viscoelasticity of polyelectrolyte complex coacervates. The polymers, which are made by post-polymerization functionalization of poly(N-acryloxy succinimide), have charged monomer fractions between 60 and 100%, with the balance comprised of either hydrophilic (acrylamide) or hydrophobic (butyl acrylamide) comonomers. We identify the critical salt concentration of the coacervates by optical turbidity, and characterize their degree of swelling and viscoelasticity via thermogravimetric analysis and small amplitude oscillatory shear rheology, respectively. We find that as the charge density of the polymers is decreased, the critical salt concentration and volume fraction of polymer in the coacervates also decrease, and the relaxation dynamics speed up. Interestingly, these properties depend only on the charge density, and not on the hydrophobicity of the comonomer. This suggests that hydrophobic interactions are much weaker than the entropic forces driving coacervate formation, and may provide a new window into understanding the extent to which polymer concentration and electrostatic interactions determine coacervate dynamics.
Rearrangement of 2D aggregates of droplets under compression: signatures of the energy landscape from crystal to glass*

KARI DALNOKI-VERESS (Presenter), JEAN-CHRISTOPHE ONO-DIT-BIOT, McMaster University, PIERRE SOULARD, ESPCI Paris, SOLOMON BARKLEY, McMaster University, ERIC WEEKS, Emory Univ, THOMAS SALEZ, Univ. Bordeaux, ELIE RAPHAEL, ESPCI Paris — We study a signature of the energy landscape through the crystal-to-glass transition by compressing 2D finite aggregates of emulsion droplets. Oil droplets of two distinct sizes are used to compose small aggregates in an aqueous environment. Aggregates range from perfectly ordered monodisperse crystals to disordered bidisperse glasses. The aggregates are compressed between two parallel boundaries; crucially, one of the boundaries acts as a force sensor. The compression forces provide a signature of the aggregate composition and give insight into the energy landscape. In particular, crystals dissipate all the stored energy through single catastrophic fracture events whereas the glassy aggregates break step-by-step. Remarkably, the yielding properties of the 2D aggregates are strongly impacted by even a small amount of disorder.

Photo-Induced Order-Disorder Transitions in Block Copolymer Solutions*

TIMOTHY LODGE (Presenter), CECILIA C HALL, CECELIA RIVERA, CLAIRE SEITZINGER, YUKI HIROSE, University of Minnesota — Photo-stimuli responsive materials are of interest for a broad range of applications, and take advantage of the inherently non-invasive, spatially resolved, and species-selective optical response. We demonstrate here a photo-reversible order-disorder transition in a block copolymer/ionic liquid system. The copolymer is a symmetric poly(methyl methacrylate)-b-poly(benzyl methacrylate-stat-azomethacrylate) diblock, with $M \approx 45 \text{kDa}$, and 5% azomethacrylate in the second block. Poly(benzyl methacrylate) exhibits LCST behavior in the common ionic liquid ethyl methyl imidazolium bistrifluoromethylsulfonimide (EMI TFSI). Under UV irradiation, the trans to cis photoisomerization of azobenzene significantly increases the solubility of the thermoresponsive block, leading to an order-to-disorder transition at appropriate concentrations and temperatures. Under visible light, the cis to trans recovery causes the sample to re-order. The progress of the transition is monitored by in situ photo-rheology, and the morphologies are confirmed by SAXS.

Tuesday, March 5, 2019 2:30 PM - 4:54 PM

Session H43 DCMP: DCMP Prize Session I BCEC 210B - Daniel Arovas, University of California, San Diego - Tag(s): Invited

2:30PM H43.00001: Oliver E. Buckley Condensed Matter Prize talk: Elihu Abrahams: pioneer in the physics of disordered electronic systems [Invited] PATRICK LEE (Presenter), Massachusetts Institute of Technology — Elihu Abrahams (1927-2018) was recognized by the Buckley Prize for his early and key contributions to the theory of transport in doped semiconductors and disordered electronic systems. In a seminal work with his student Miller, he introduced the network model for hopping conductivity. Later he co-authored with Anderson, Licciardello and Ramakrishnan an influential paper (6169 citations) on the scaling theory of localization. I shall review these accomplishments and share memory of a life well lived.

3:06PM H43.00002: Oliver E. Buckley Condensed Matter Prize Talk: Coulomb gap here, there, and everywhere [Invited] BORIS SHKLOVSKI (Presenter), University of Minnesota — In 1975 Alexei Efros and myself discovered that due to electron-electron interactions the density of localized electron states vanishes near the Fermi level as a quadratic function of the energy distance to the Fermi level. We named this phenomenon the Coulomb gap and showed that it leads to the variable range hopping conductivity which depends on the temperature $T$ as $\exp[-(T_E/T)^{1/2}]$. This Efros-Shklovskii law was confirmed in hundreds of experimental papers, where in many cases it describes $10^6$ times dynamic range of conductivity. After going through the history and physics of this discovery I will review many new applications of Efros-Shklovskii law beyond lightly doped semiconductors among which the Quantum Hall Effect is the most prominent. I will also dwell on the McMillan-Shklovskii theory of the Coulomb gap emergence across a Metal-Insulator transition and the related question of screening of the Coulomb gap.
3:42PM H43.00003: APS Medal for Exceptional Achievement in Research: Topology and Other Tools in Condensed Matter Physics* [Invited] BERTRAND I. HALPERIN (Presenter), Harvard University — Notions from topology have played a big role in our current understanding of both classical and quantum systems, and much of my work has been related, in one way or another, to topological ideas. However, topology has only been one tool in my research, sometimes as a starting point and sometimes an afterthought. Other ingredients have included ideas from statistics and quantum mechanics, and analyses of interaction energies and the effects of topological defects on other variables of a system. One portion of my work has focused on phase transitions that could be understood in terms of a proliferation of topological defects, and on dynamic properties that could be understood by the motion of such defects. Other portions of my work have made important use of notions of percolation. My work on quantum Hall systems, at least in retrospect, has always been related to notions of topology in Hilbert space. In my talk, I will present some examples of these applications.

*My research has been supported over the years by Harvard University and Bell Laboratories and by grants from the National Science Foundation and other government agencies, Microsoft Corporation, and Schlumberger Research.

4:18PM H43.00004: Aneesur Rahman Prize for Computational Physics Talk: Digital Alchemy, Machine Learning and Inverse Design for Self Assembly [Invited] SHARON GLOTZER (Presenter), University of Michigan — From the Stone Age to the Silicon Age, the materials available to humankind define the world in which we live. The materials of tomorrow will be designed and engineered on demand, where and when they are needed, with precision and personalization. Computer simulation and machine learning both have critical roles to play in creating this future. Already, they allow — from a nearly infinite number of possibilities — the inverse design of nanoparticle building blocks optimized for self assembly into colloidal crystal structures with targeted properties. In this talk, we present a new thermodynamic computational approach to the inverse design of colloidal matter, and demonstrate its use in obtaining colloidal crystals with arbitrary complexity, engineered phase transitions, and target photonic properties. We show how machine learning can be used to autonomously identify crystal structures in hundreds of thousands of simulations, as well as to identify key alchemical attributes of particles that correlate with colloidal crystal structure.

Session H44 DCMP: Demise of Superconductivity in Overdoped Cuprates BSEC 210C - Tag(s): Invited

2:30PM H44.00001: Starfish-shaped Cooper pairs with ultrashort antinodal length scales across all doping levels in cuprate superconductors.* [Invited] DANIEL DESSAU (Presenter), University of Colorado, Boulder — We access the fully causal electronic self-energy utilizing a brand new 2-dimensional method of ARPES analysis [1], which removes the critical limitations of the previous one-dimensional MDC (Momentum Distribution Curve) and EDC (Energy Distribution Curve) methods. This new method, which utilizes orders-of-magnitude fewer parameters than the MDC and EDC methods, brings in the energy, momentum, and temperature -dependence of the self energies and is fully consistent with the already-successful studies showing the gap filling-in behavior [2,3]. The full set of parameters we access allows us to make the first direct measurements of the shape and size of the pairs [4]. This is all critical information for explaining how coherence between the pairs (the superconducting state) evolves as a function of doping and temperature.

*We acknowledge generous support from the US Department of Energy
The key findings are as follows. (i) The superconducting phase stiffness is extremely low, comparable to $T_c$. (ii) The superfluid density $N_s(T)$ decreases linearly with $T$, up to $T_c$. (iii) $T_c$ scales with $N_{S0}$ linearly but with an offset, except very close to the dome edges where it scales as $\sqrt{N_{S0}}$. (iv) The superconducting state develops from an electronic nematic state that breaks the $C_4$ symmetry of the underlying crystal lattice. (v) The electron fluid behaves as if it were comprised of two components, one Fermi-liquid (FL) like and the other showing resistivity linear in $B$, diminishing with increased doping, and tracking the nematicity, $N_{S0}$, and $T_c$.

The related results of other groups show that the above appears to be typical of high-$T_c$ cuprates and independent on the details of the Fermi surface, the number of CuO$_2$ planes in the unit cell, the presence or absence of CuO chains, the density and the nature of dopants, the superconducting gap size, etc.

We conclude that high-$T_c$ superconductivity in cuprates involves some new physics that entails strong pairing, strong electron correlations, strong thermal phase fluctuations, and strong pair-breaking, intrinsic but $T$- and doping-dependent.

Developing a complete description of the ground state evolution is crucial to decoding the complex phase diagram. Here we use the structure of broken translational symmetry, namely d-form factor charge modulations in (Bi,Pb)$_2$(Sr,La)$_2$CuO$_{6+\delta}$, as a probe of the ground state reorganization which occurs at the transition from truncated Fermi arcs to a large Fermi surface. We use real space imaging of local electronic inhomogeneity as a tool to access a range of dopings within each sample, and we firmly establish the spectral gap $\Delta$ as a proxy for local hole doping. From the $\Delta$-dependence of the charge modulation wavevector, we discover a commensurate to incommensurate transition that is coincident with the Fermi surface transition from arcs to large hole pocket, demonstrating the qualitatively distinct nature of the electronic correlations governing the two sides of this quantum phase transition. Furthermore, the doping dependence of the incommensurate wavevector on the overdoped side is at odds with a simple Fermi surface driven instability.

This is accompanied by an unexpected scaling of the zero-temperature superfluid density with $T_c$, which should be constant within a conventional BCS picture. By considering lifetime effects I show that these observations can be explained by temperature-dependent scattering in the presence of a $d$-wave energy gap, and a decreasing pairing interaction strength with doping.

*The author gratefully acknowledges financial support from Victoria University of Wellington and the MacDiarmid Institute for Advanced Materials and Nanotechnology.
In a superconductor there exist two different types of scattering processes, depending on their action on the Cooper pairs: pair-conserving and pair-breaking. Making use of the microscopic coherent potential approximation, we have developed a phenomenological description of the so-called Dynes superconductors in which both processes are characterized by separate lifetimes [1]. Our theory solves the long-standing puzzle about the origin of the ubiquitous Dynes formula [2] for the tunneling density of states. It also predicts how the electron spectral functions change in presence of both types of scattering, correcting the previously used phenomenological two-lifetime expressions. In this talk, after introducing the concept of the Dynes superconductors, I will discuss its applicability to the d-wave cuprate superconductors, in which the two types of scattering processes correspond to small- and large-angle scattering. I will start by showing that, along fixed tomographic cuts, the Dynes phenomenology provides good fits of the electron spectral functions [3]. Then I will turn to a discussion of the recent electrodynamic experiments on overdoped cuprates [4,5]. I will show that the breakdown of the Homes law at extreme overdoping [4] is a generic property of the Dynes superconductors and I will discuss the relation between the dirty d-wave picture [6] and the Dynes phenomenology. The role of the Fermi liquid corrections and of the inelastic processes will also be discussed.

2:42PM H45.00002: Valley-dependent impurity scattering in α-T₃ ααlattices and specific role of Lorentz forces
Danhong Huang (Presenter), Air Force Research Lab · Kirtland, Andrii Iurov, Center for High Technology Materials, University of New Mexico, Ying-Cheng Lai, Hongya Xu, School of Electrical, Computer and Energy Engineering, Arizona State University, Godfrey Gumbs, Department of Physics and Astronomy, Hunter College of the City University of New York — We have obtained the angular distribution of extrinsic skew-scattering currents related to a set of randomly-distributed impurities in α-T₃ lattices using the Boltzmann moment equations. With the help of the screened second-order Born approximation, we have calculated the inverse momentum-relaxation-time tensor and revealed the anisotropy which appears to be the source of the angle-dependent currents. The static dielectric function was obtained under the random-phase approximation (RPA). The scattering is also modified by Berry-phase variation and local asymmetry in impurity potentials next to the two inequivalent K and K′ valleys. The resulting skew current depends on the electron doping level and is determined by the ratio of energy to momentum relaxation times.

2:54PM H45.00003: Tuning the opto electronic properties of ultrasmooth large area rGO films grown via Pulsed laser deposition (PLD) technique
Muhammad Juvaid (Presenter), IIT Madras and National University of Singapore — We present the growth of large area ultra-smooth reduced graphene oxide (rGO) thin films on a four inch wafer via beam scanning mode of Pulsed laser deposition technique. With the versatility of the PLD technique, the easy tuning of optoelectronic properties is achieved on rGO thin films without employing any buffer layers. The conventional growth mechanism of rGO films involves hazardous chemicals, whereas this physical vapour deposition technique gives high quality rGO films with tunable optoelectronic properties. This wafer-scale growth mechanism of rGO thin films can potentially employ in various optoelectronic applications due to its high transparency and p-type conductivity. We illustrate the optoelectronic tunability of large area rGO films and its use through the evaluation of transparent conducting films, where our rGO films show highest performance as compared to existing p-type transparent conducting films.

3:06PM H45.00004: Intercalation of Cu and Ru beneath the top graphene layer of graphite surfaces
Yong Han (Presenter), Ann Lil-Rosasales, Michael C. Tringides, James William Evans, Patricia A. Thiel, Iowa State University — STM experiments show that Cu forms encapsulated islands under the top graphene layers of graphite, as a result of vapor deposition of Cu on a sputtered graphite surface [JPCC 122, 4454]. Deposition at 800 K is optimal for formation of encapsulated multilayer Cu islands. Deposition below 600 K favors Cu clusters adsorbed on top of graphite, while deposition above 800 K favors single-layer intercalated Cu islands. To form Ru nanoislands below the top graphene layer requires deposition at 1000 K to 1180 K [Nanotechnology 29, 505601]. We present an extensive study of energetics using density functional theory to compare stabilities of a wide variety of configurations of atoms, clusters, and layers of Cu and Ru on/under the graphite surface. For Cu-graphite systems, the only configuration that is significantly more stable under the graphite surface than on top of it, is a single Cu atom. This analysis leads us to conclude that formation of encapsulated Cu islands is kinetically driven, rather than thermodynamically driven. On the contrary, the embedded Ru islands are thermodynamically favored over on-top clusters.

3:18PM H45.00005: Electrical and mechanical properties of h-BN nanoplates on Ir(111) studied by STM and NC-AFM
Mengxi Liu (Presenter), Xiaohui Qiu, National Center for Nanoscience and Technology — Hexagonal boron nitride (h-BN) on metal surfaces is subjected to substrate interactions as well as in-plane strains resulted from the lattice mismatch between h-BN and the underlying substrate. Here, we investigate the electrical and mechanical properties of h-BN nanoplate grown on Ir(111) using a combined approach of scanning tunneling microscopy (STM), noncontact atomic force microscopy (nc-AFM) and density functional theory (DFT) calculations. The in situ synthesized h-BN nanoplates have a characteristic triangular shape with zigzag-type edges. Boron and nitrogen atoms can be identified by distinct chemical interaction with metallic tip. The nc-AFM images show a strong tip-dependent contrast, which transforms from honeycomb lattices to hexagonal spots by switching W-tip to Cl-tip. Based on DFT calculations, we interpret the contrast conversion in terms of a combination of tip dipole and charge transfer from Ir(111) surface to BN nanoplates bound to Ir(111). In addition, the elastic deformation of h-BN nanoplates was measured by nc-AFM force map and lateral stiffness of h-BN nanoplates dramatically depend on their size.

*The work was supported mainly by U. S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.
3:30PM H45.00006: Scanning tunneling spectroscopy study of incorporated Al atoms in Si(100) substrate

HYUNSOO KIM (Presenter), University of Maryland, College Park, ARUNA RAMANAYAKA, Joint quantum institute, KE TANG, University of Maryland, College Park, JOSHUA POMEROY, National Institute of Standards and Technology — We have studied the structures and electrical properties of incorporated Al atoms in Si(100) using scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS) at room temperature in ultra-high vacuum. Our recent work shows that, in Si/Al/Si heterostructures, a hole is a dominant charge carrier and we have achieved a comparable mobilities to previous reports on similar two-dimensional hole gas systems at high charge carrier densities. [1,2] However, the electronic states of Al have not been studied well as dopants in Si. STS can provide the local density of states to understand the electrical properties of incorporated Al atoms in Si(100) similar to the Si/Al/Si heterostructure in our recent work. [1] We will discuss the local density of states measured by STS of incorporated Al atoms in a clean (2x1) reconstructed Si(100) substrate at various densities prepared by thermal Al evaporation and annealing in situ at 550 °C.

3:42PM H45.00007: Discovery of a New Layered Crystal, Hexagonal Beryllium Oxide

LIFEN WANG (Presenter), Institute of Physics, LEI LIU, Department of Materials Science and Engineering, College of Engineering, Peking University, JI CHEN, Electronic structure theory, Max Plank Institute, SHANG-PENG GAO, Department of Materials Science, Fudan University, GONG GU, Department of Electrical Engineering and Computer Science, University of Tennessee — The reported work was prompted by the intriguing question whether sp²-coordinated, layered polymorphs of octet compounds other than BN can exist. While such polymorphs with thicknesses within a thermodynamic limit are predicted, the possibility of their thicker layered crystals has long been dismissed. Here, using high-resolution transmission electron microscopy and electron energy loss spectroscopy, we show that BeO crystallizes in the sp²-coordinated, layered structure in liquid cells formed by sheets of graphene. We further reveal that the layered crystals can be thicker than the thermodynamically determined ultra-thin limit, beyond which the layered phase is energetically unfavored. The discovery counters a long-held dismissal and calls for a reevaluation of the possible existence of sp²-coordinated, layered polymorphs of octet compounds beyond the ultra-thin limit.

3:54PM H45.00008: A Study of Vertical Transport in Silicon-Graphene Junction

SIDONG LEI, XIAODAN ZHU, SHINHUNG TSAI (Presenter), University of California, Los Angeles, XIAODAN ZHU, SHINHUNG TSAI, University of California, Los Angeles, XING ZHANG, Rice University, GEN YIN, CARLOS TORRES, ARYAN NAVABI, University of California, Los Angeles, ZEHUA JIN, Rice University, HUSSAM QASEM, University of California, Los Angeles, ROBERT VAJTAI, Rice University, ROGER LAKE, University of California, Riverside, PULICKEL M AJAYAN, Rice University, KANG WANG, University of California, Los Angeles — In this report, we explore the important roles of single layer graphene in the vertical tunneling process as a tunneling barrier. Although being a semimetal in the lateral lattice plane, the graphene together with the vdW gap acts as a tunneling barrier, that is nearly transparent to vertically tunneling electrons, due to its atomic thickness and the transverse momenta mismatch between the injected electrons and the graphene band structure. This is accentuated using electron tunneling spectroscopy (ETS) showing a lack of features corresponding to the Dirac cone band structure. Meanwhile, the graphene acts as a lateral conductor through which the potential and charge distribution across the tunneling barrier can be tuned. These unique properties make graphene an excellent 2D atomic grid, transparent to charge carriers, and yet offer the control of the carrier flux via the electrical potential.

*We would like to acknowledge the support of National Science Foundation (EFMA-1433541). We would also like to acknowledge the collaboration of this research with King Abdul-Aziz City for Science and Technology (KACST) via The Centre of Excellence for Green Nanotechnologies (CEGN).
4:06PM H45.00009: Construction of graphene/silicene heterostructure by Si intercalation  GENG LI (Presenter),
Institute of Physics, Chinese Academy of Sciences — Geng Li

Institute of Physics & University of Chinese Academy of Sciences, Chinese Academy of Sciences, Beijing 100190, China

Silicene-based van der Waals heterostructures have been theoretically predicted to have interesting physical properties, but their experimental fabrication has remained a challenge because of the easy oxidation of silicene in air. Here we report the fabrication of graphene/silicene van der Waals heterostructures by silicon intercalation. Density-functional-theory calculations show weak interactions between graphene and silicene layers, confirming the formation of van der Waals heterostructures. The heterostructures show no observable damage after air exposure for extended periods, indicating good air stability. The I-V characteristics of the vertical graphene/silicene/Ru heterostructures show rectification behavior.

4:18PM H45.00010: The mechanism for the stabilization and surfactant properties of epitaxial silicene  ALBERTO CURCELLA, ROMAIN BERNARD, YVES BORENSZTEIN, MICHELE LAZZERI (Presenter), GEOFFROY PREVOT, Sorbonne Universite — Using real-time in situ scanning tunneling microscopy and density functional theory simulations, we have studied the growth of Si films on Ag(111) for coverages above the silicene monolayer, evidencing the existence of metastable phases and an original growth mechanism. Above monolayer Si coverage, an initial sqrt(3)Xsqrt(3) structure forms, which is identified as an Ag-free Si bilayer with additional Si adatoms. With further deposition, this structure is replaced by a distinct bilayer structure covered by Si trimers and Ag atoms. The formation of these bilayers follows counterintuitive dynamics: they are partially inserted within the Ag substrate and form by expelling, from the underlying substrate, the atoms that reinsert below the adjacent silicene layer. The growth is therefore characterized by an unexpected “surfactant competition” between Ag and silicene: while silicene is a metastable surfactant for the Ag(111) surface, Ag plays the role of a surfactant for thicker diamond-like Si islands. In spite of being thermodynamically unfavoured, the silicene monolayer is, thus, a remarkably stable structure because of the high kinetic barrier for the growth of thicker layers.

4:30PM H45.00011: Ab initio study of 2D plasmon enhancement in alkali intercalated graphene on metallic substrates  VITO DESPOJA (Presenter), Institute of Physics, Zagreb, LEONARDO MARUSIC, Maritime Department, University of Zadar — Alkali metal (AM) atoms, (e.g. in LiC2 or CsC8) donate electrons to the graphene π band causing the appearance of another Dirac plasmon (DP) in the EEL spectra. At the same time, the AM σ band remains partially filled and supports a strong Dirac plasmon (DP) in the EEL spectra. The same time, the AM σ band remains partially filled and supports another Dirac plasmon, which hybridizes with the Dirac plasmon causing appearance of the weak linearly dispersive plasmon, known as the acoustic plasmon (AP) [1,2]. We present the results of a theoretical simulation of alkali atoms intercalated between the graphene and a metallic substrate (e.g. Ir(111) or Al(111)) and forming a periodic superlattice, which causes a huge enhancement of DP and AP. Moreover the AP intensity and Fermi velocity strongly depend on graphene/substrate separations. This enhancement mechanism, in addition to its very interesting fundamental aspect, suggests many possibilities for plasmonic applications. The theoretical simulation is performed using a state of the art DFT (ground state) + RPA (excited state) technique, adapted for the study of the dielectric properties in large multilayer heterostructures, which completely exclude inter-supercell Coulomb interaction.

4:42PM H45.00012: First-Principles investigation of Epitaxial Pt Layer on Graphene  JI IL CHOI, FAISAL ALAMGIR,
SEUNG SOON JANG (Presenter), School of Materials Science and Engineering, Georgia Institute of Technology — Platinum is a face centered cubic structured crystal that has been widely known as a superior catalyst for various chemical reactions, while low-dimensional structures, such as mono- or bi-layer platinum, have attracted less attention due to experimental difficulties in synthesizing such 2D structures. In this study, we present a computational research on the unique architecture of epitaxial platinum (mono/multi) layers grown on graphene (Pt_ML/GR), in support of remarkable recent progress in the synthesis of these architectures in simple cubic-like (SC-L) and face-centered cubic-like (FCC-L) phases on the graphene. Recently proposed strongly constrained and appropriately normed (SCAN) density function study (DFT) is employed to investigate the structural and electronic properties of the epitaxial SC-L Pt layered graphene. In these architectures, Pt exhibits registry with the C-C bridge sites along the armchair and zigzag directions. Here, the details of the atomistic/electronic structures and binding energies are discussed. Further, the detailed band structure and the partial/total densities of state (DOS) of the Pt_ML/GR architectures, with Pt in an SC-L registry, are presented.
Two dimensional phases of Ag on Ge(111): insights from first-principles calculations

SHREE RAM ACHARYA (Presenter), DUY LE, University of Central Florida, SHIRLEY CHIANG, CHING FONG, Physics, University of California, Davis, TALAT S. RAHMAN, University of Central Florida — Experimental observations using low-energy electron diffraction (LEED) of deposited Ag on the Ge(111) surface have revealed a number of two-dimensional Ag structures which depend on Ag coverage and sample temperature[1]. We have applied density functional theory based calculations to explore the Ag/Ge(111) phase diagram and to obtain insights into the electronic and geometric structures and the vibrational dynamics. In this comparative study of clean Ge(111) with (1x1), reconstructed c(2x8) and (2x1) geometries, and of sub-monolayer Ag covered Ge(111) with (4x4), (v3xv3)R30 and (1x1) overlayers, we find that Ge atoms on the surface prefer three-fold hollow sites and Ag adatoms prefer to form triangular structures. Furthermore, temperature-coverage dependent surface phase diagram constructed by minimizing the surface free energies shows that up to 37% Ag coverage, (4x4) is the stable phase beyond which up to 90% coverage, the phase coexists with (v3xv3)R30 and (1x1) phases at temperature below 600K and higher respectively. Beyond 90% coverage, isolated (v3xv3)R30 and (1x1) phase are the most stable with the same temperature boundary of 600K.

Work supported by NSF DMR-1710306; NSF DMR-1710748.

Study of the surface properties of Tin ultrathin film on superconducting substrate

DANDAN GUAN (Presenter), Shanghai Jiao Tong University — Two dimensional (2D) topological insulators (TIs) are 2D materials that possess a pair of topological edge states connecting the bulk band gap. Later, Kane and Fu predicted that the superconductivity (cooper pairs) of superconductors (SC) would be introduced into TIs to form TI/SC heterostructures, in which majorana fermions could be found [1]. And 2D tin film (stanene) is theoretically predicted as quantum spin Hall (QSH) insulators by Shou-Cheng Zhang’s group [2], many experimental efforts have been devoted to confirming the topological properties of tin film. Here for the Sn/ sSC system, the pure Face-centered cubic (FCC) structure of Sn surface has been obtained for the first time. Superconductivity has also been detected on the FCC-Sn(111) surface, but no topological edge states exist. Furthermore, phase transition occurs from FCC-Sn(111) to β-Sn(001) by keeping the sample at room temperature for a certain time. Due to the strain relaxation on the β-Sn islands, both the in-plane unit cell and out-of-plane structures distort, and the height of surface atoms varies periodically to form a universal ripple structure.

Liquid crystal (5CB) adsorption on two-dimensional materials

PAUL BROWN (Presenter), ASEE Fellow for the United States Naval Research Laboratory, SEAN A FISCHER, United States Naval Research Lab, JAKUB KOLACZ, ASEE Fellow for the United States Naval Research Laboratory, CHRISTOPHER SPILLMANN, DANIEL GUNLYCKE, United States Naval Research Lab — Liquid crystals are widely used in display technologies. Their collective behavior and use ultimately hinges on single molecules interacting with a supporting surface. Since the isolation of graphene in 2004, the potential for combining two-dimensional nanosheets with liquid crystals has become an area of scientific interest. However, little attention has focused on the local interfacial interactions between the mesogen and two-dimensional materials. In this presentation, we discuss the local mesogenic interactions between the well-known nematic liquid crystal 5CB, and a series of monolayer crystals such as graphene, molybdenum disulfide, phosphorene, and h-BN. In particular, we present electronic ground state properties obtained using density functional theory with nonlocal van der Waals corrections that reveal subtle orientational, energetic, and electronic properties for the characterization of local mesogen-substrate interactions, whereby the anchoring of liquid crystal can be understood more generally across atomically flat surfaces.

This work has been supported by the Office of Naval Research, directly and through the U.S. Naval Research Laboratory.

Session H46 DMP GMAG: 4d/5d Transition Metal Systems -- Pyrochlores
Unconventional spin-phonon coupling in 4d and 5d transition metal oxides

The spin-phonon (SP) coupling has long been a central theme in condensed matter physics. To date, most of these phenomena have been understood by considering the Heisenberg interaction between spins. However, recent studies on 4d/5d transition metal oxides (TMOs) have revealed that strong spin-orbit coupling (SOC) plays the crucial role in their magnetism. Since the orbitals are generically coupled to the lattice, the strong SOC present in 4d/5d orbitals creates strong and inevitable interactions between spin and lattice.

Using optical spectroscopy, we carried out comparative studies on the 5d TMOs. From infrared (IR) phonon spectra, we discovered unconventional SP coupling in Cd$_2$Os$_2$O$_7$ and Y$_2$Ir$_2$O$_7$. For Cd$_2$Os$_2$O$_7$, we observed large phonon frequency shifts below $T_N$. This is due to the SP coupling arising from single-ion anisotropy [1,2]. We also identified frequency shifts of Y$_2$Ir$_2$O$_7$ near $T_N$. However, in this case, the Dzyaloshinskii-Moriya interaction plays a crucial role in the phonon renormalization [3]. Using near-IR pump-probe technique, we investigated coherent phonon oscillations of 4d TMO. Recently, Ca$_2$RuO$_4$ has been of particular interest due to its exotic magnetic ground state driven by strong SOC. We observed that a coherent $A_g$ phonon oscillation changes abruptly its amplitude and phase as the spin order develops.

Density functional theory calculations revealed that the structural deformation by the magnetic order can induce such variations in coherent phonons, which we suggest as a unique signature of SP coupling [4]. Our comprehensive studies on unconventional SP coupling may lead to scientific advancement in 4d/5d TMOs, and possibly endow opening new research fields come across.

AC magnetic susceptibility and heat capacity studies of the geometrically frustrated pyrochlores Ce$_2$Zr$_2$O$_7$ and Ce$_2$Hf$_2$O$_7$, as possible quantum spin liquids (QSL’s)

QSL’s are of great interest due to their unusual ground states; they do not exhibit spin freezing even at 0K, have no conventional order parameter associated with a broken symmetry, and can emerge in insulators containing localized spin degrees of freedom. In this work, single crystals of the low-spin geometrically frustrated 2D lattice pyrochlore compounds Ce$_2$Zr$_2$O$_7$ and Ce$_2$Hf$_2$O$_7$ prepared by the floating zone method, were investigated for a possible QSL state. Measurements of AC magnetic susceptibility from 100 Hz to 10 kHz and heat capacity up to 9T were performed down to 100 mK. Despite a well-ordered pyrochlore crystal structure and strong magnetic interactions between Ce$^{3+}$ ions in Ce$_2$Zr$_2$O$_7$ and Ce$_2$Hf$_2$O$_7$, no evidence for a transition to a long-range ordered state was found, possibly due to strong quantum fluctuations that prevent spin freezing and lead to QSL ground state. With increasing magnetic field, the Schottky heat capacity anomaly moves to higher temperatures, indicating the presence of a gap in the excitation spectrum, which increases monotonically with increasing field. The behavior for a two-level system with an excited level at energy $\Delta$ above the ground state is compared with the heat capacity data.

3:18PM H46.00003: Time-resolved optical study of the metal-to-insulator transition in Cd2Os2O7  

CHEN LI (Presenter), XIANG LI, DANIEL SILEVITCH, ALON RON, YISHU WANG, Caltech, Physics, Math & Astronomy, JIAQIANG YAN, DAVID GEORGE MANDRUS, Materials Science and Technology, Materials Science and Technology, THOMAS F ROSENBAUM, DAVID HSIEH, Caltech, Physics, Math & Astronomy — The 5d transition metal oxide Cd2Os2O7 undergoes a continuous metal-to-insulator transition (MIT) with a concomitant magnetic transition into an all-in-all-out (AIAO) antiferromagnetic state below a critical temperature TMIT = 227 K. Here, we investigate the effects of this transition on its photo-carrier dynamics by performing temperature and wavelength dependent ultrafast optical reflectivity measurements. We show that the opening of a charge gap at TMIT causes a divergence like behavior of the photo-carrier relaxation time consistent with a Rothwarf-Taylor model. Our efforts to perform these experiments under high pressure environments will also be discussed, which is motivated by recent resonant x-ray diffraction results on Cd2Os2O7 showing a monotonic suppression of AIAO order with pressure.

3:30PM H46.00004: Tuning the ground state of a candidate Weyl semimetal Eu2Ir2O7 by Bi doping  

PRACHI TELANG (Presenter), KSHITI MISHRA, SURJEET SINGH, Indian Institute of Science Education and Research, Pune — The interplay of spin-orbit coupling (λ) and onsite coulomb interactions (U) in the pyrochlore iridates A2Ir2O7 has been predicted to give rise to a plethora of non-trivial topological phases. Here we investigate the pyrochlore series (Eu1-xBix)2Ir2O7 whose end members are located in two different regions of the λ-U phase space. Eu2Ir2O7 (EIO) shows a metal to insulator (MI) transition at 120 K concomitant with an antiferromagnetic ordering where the Ir moments order in an all-in-all-out(AIAO) structure. EIO is predicted to be a Weyl semimetal; whereas Bi2Ir2O7 (BIO) is a non-Fermi liquid metal with at least two magnetic transitions below 2 K. In this presentation, we show that Bi substitution as high as 3.5% dopes electrons in the system without altering the electronic structure and tunes the Fermi energy with little change in MI/AIAO transitions. However at higher doping levels both these transitions are very strongly suppressed. The sample prepared with 10% Bi doping showed an highly unconventional metallic behaviour and no signs of MI/AIAO ordering down to at least 2 K. For higher doping, the behaviour gradually evolved to that of BIO. Our study exemplifies the appearance of unusual behaviours at the boundary between Weyl semimetal and non-Fermi liquid of the λ-U phase space.

3:42PM H46.00005: Magnetic torque in spin-orbit coupled metal Cd2Re2O7  

SHINYA UJI (Presenter), National Institute for Materials Science, YASUHITO MATSUBAYASHI, KAORI SUGII, DAIGOROU HIRAI, ZENJI HIROI, Institute for Solid State Physics, University of Tokyo, TAKUMI HASEGAWA, Graduate School of Integrated Arts and Sciences, Graduate Hiroshima University, SHIORI SUGIURA, HISHIRO HIROSE, TAICHI TERASHIMA, National Institute for Materials Science — Spin-orbit (SO) interactions lead to peculiar symmetry-broken phases in highly correlated systems. Among various SO coupled metals, a metallic pyrochlore Cd2Re2O7 is known to show unique multipole orders associated with the inversion symmetry breaking below ~200 K, whose order parameter has Eu symmetry. We have measured the magnetic torque of Cd2Re2O7 in a wide temperature and field range. We find that a four-fold symmetry of the magnetic torque signal as well as a two-fold symmetry is significantly enhanced at low temperatures below ~200 K. The symmetry analysis of the torque signal strongly suggests the presence of the primary order parameter (OP) with the even parity Eu symmetry, which induces the four-fold term, whereas the two-fold arises from the odd parity Eu OP. It is very likely that the Eu symmetry OP is purely of electronic origin and the coexistence with the odd-parity Eu OP provides important insights into the origin of the multipole orders induced by the SO coupling.

3:54PM H46.00006: Electronic and magnetic ground states of the Kitaev material candidates A2CeIrO6 (A~ = Ba,Sr)  

ADAM ACZEL (Presenter), Oak Ridge National Laboratory, JAMES P.I. CLANCY, McMaster University, QIANG CHEN, HAI DONG ZHOU, University of Tennessee, DALMAU REIG-I-PLESSIS, GREG MACDOUGALL, University of Illinois at Urbana-Champaign, JACOB RUFF, CHESS, MARY UPTON, Argonne National Laboratory, TRAVIS J WILLIAMS, STUART CALDER, JIAQIANG YAN, Oak Ridge National Laboratory — Quantum magnets with significant bond-directional Ising interactions, so-called Kitaev materials, have attracted tremendous attention recently in the search for exotic spin liquid states. Here we present a comprehensive set of measurements that enables us to elucidate the crystal structures, Ir4+ single ion properties, and magnetic ground states of the double perovskite iridates A2CeIrO6 (A~ = Ba,Sr). The crystal structures of Ba2CeIrO6 and Sr2CeIrO6 are found to be cubic and monoclinic respectively, with a large nearest neighbor distance >~5\AA~between Ir4+ ions. X-ray absorption spectroscopy and resonant inelastic x-ray scattering were used to establish J_{eff}~ = ~1/2~ spin-orbit-assisted Mott insulating states, while bulk characterization and neutron powder diffraction identify A-type antiferromagnetic order. These electronic and magnetic ground states are both consistent with expectations for face-centered-cubic magnets with dominant Kitaev exchange, which indicates that spacing magnetic ions far apart may be a promising design principle for uncovering new Kitaev materials.
**4:06PM H46.00007: Global Metal-Insulator Transition in the Pyrochlore Iridates (Nd_{1-x}Ca_x)_{2}Ir_{2}O_{7}**
ZACH PORTER (Presenter), ELI ZOGHLIN, University of California, Santa Barbara, GENEVA LAURITA, Bates College, JACOB P.C. RUFF, CHESS, YONGSEONG CHOI, DANIEL HASKEL, Argonne National Lab, STEPHEN WILSON, University of California, Santa Barbara — We report on the suppression of the metal-insulator transition (MIT) in polycrystalline samples of Nd_{2}Ir_{2}O_{7} under substitution of Nd for Ca. Each calcium ion effectively dopes one hole on an Ir^{4+} (5d^{4}, j_{eff}=1/2) site, mediating a filling-controlled Mott-like transition. Ca substitution also changes bandwidth by modulating Ir-O bond lengths and angles, without altering site symmetry. Local structure and absorption spectroscopy confirm that Ca substitution does not result in phase separation or large changes to Ir electronic configuration. The MIT has a coincident antiferromagnetic transition on the Ir sublattice (T_N = T_{MIT}) for all measured samples, which both decrease with Ca content. Weak low-temperature upturns in susceptibility and resistivity for samples with high Ca content suggest that Nd sublattice magnetism couples to carriers in the metallic regime.

**4:18PM H46.00008: Enhanced Thermopower in Hole-doped Pyrochlore Iridates: Correlated Metal with Quadratic Band Touching**
RYOMA KANEKO (Presenter), Department of Applied Physics and Quantum-Phase Electronics Center, University of Tokyo, MARIE-THERESE PHILIPP, Center for Emergent Matter Science, RIKEN, JUN FUJIOKA, Graduate School of Pure and Applied Sciences, University of Tsukuba, SHIRO SAKAI, Center for Emergent Matter Science, RIKEN, RYOTARO ARITA, Department of Applied Physics and Quantum-Phase Electronics Center, University of Tokyo, HIROSHI SHINAOKA, Department of Physics, Saitama University, KENTARO UEDA, YOSHINORI TAKURA, Department of Applied Physics and Quantum-Phase Electronics Center, University of Tokyo — Quadratic band touching (QBT) is a band structure in which the parabolic valence and conduction band touch at a point, protected by spatial and time inversion symmetry. The possibility that QBT becomes the source of exotic electronic phases such as Weyl semimetal has been discussed. The existence of QBT has been confirmed in Pr_{2}Ir_{2}O_{7} (PIO), which is a member of pyrochlore-type iridate R_{2}Ir_{2}O_{7} (RIO, R=Rare earth). Since QBT in PIO is stabilized by the crystal symmetry, we can consider the possibility of the universal existence of QBT in the paramagnetic metallic phase of RIO. Therefore, we made hole-doped samples of insulator Eu_{2}Ir_{2}O_{7} to compare its electronic properties with PIO.
Using the charge transport measurement and ab-initio calculation, we have explored the thermopower and electronic structure of correlated metal with QBT in hole-doped pyrochlore iridates. We found that the hole-doped QBT yields a thermopower peak, which can be enhanced exceeding 40 V/K below 50 K by tuning the band-filling and lattice distortion. The thermopower peak is observed even in the doping induced metallic phase created from Mott insulator, indicating that the QBT is robust against the strong electron correlation as well as the lattice distortion while keeping the cubic symmetry.

**4:30PM H46.00009: Stoichiometry Control, Electronic and Transport Studies of Pyrochlore Iridate Thin Films**
WENCAO YANG, Indiana University Bloomington, YUANTAO XIE, Shenzhen University, XING SUN, Purdue University, XIAOHANG ZHANG, University of Maryland, College Park, KYUNGWHA PARK, Virginia Tech, SICHIANG XUE, Purdue University, YANLONG LI, CHENGANG TAO, Virginia Tech, QUANXI JIA, University at Buffalo – The State University of New York, YAROSLAV LOZOVYY, Indiana University Bloomington, HIAYAN WANG, Purdue University, JEAN HEREMANS, Virginia Tech, SHIXIONG ZHANG (Presenter), Indiana University Bloomington — Pyrochlore iridate thin films are predicted to host a variety of exotic magnetic and topological states. Experimental probing of the emergent quantum states strongly relies on the synthesis of high-quality thin film samples. In this work, we demonstrate the epitaxial growth and stoichiometry control of pyrochlore Bi_{2}Ir_{2}O_{7} thin films via pulsed laser deposition followed by a post annealing process. The as-deposited films form a bilayer-like structure consisting of an Ir-deficient top-surface and an Ir metal layer at the bottom. Post annealing in iridium oxide atmosphere significantly improves the stoichiometry and homogeneity throughout the film thickness. Density functional theory calculation shows a fourfold degenerate Dirac node slightly below the Fermi energy at the X point, coexisting with some trivial bands around the Γ point. Transport studies revealed a transition from a weakly-metallic to weakly-insulating behavior at around 150 K, accompanied by positive magnetoresistance at low temperatures.

*Work supported in part by the College of Arts and Sciences in Indiana University, DOE DE-FG02-08ER46532, and NSF DMR-1565822.*
Mapping the magnetic and electronic structure of $(\text{Eu}_{1-x}\text{Ca}_{1-x})_2\text{Ir}_2\text{O}_7$ across a global metal-insulator transition* ELI ZOGHLIN (Presenter), ZACH PORTER, Materials, University of California, Santa Barbara, GENEVA LAURITA, Chemistry and Biochemistry, Bates College, DANIEL HASKEL, YONGSEONG CHOI, Advanced Photon Source, Argonne National Laboratory, STEPHEN WILSON, Materials, University of California, Santa Barbara — Motivated by the prediction of quantum critical behavior with the suppression of the temperature dependent metal-insulator transition in $\text{Ln}_2\text{Ir}_2\text{O}_7$ ($\text{Ln} = \text{Y, lanthanide}$), including the formation of a topological semi-metal phase$^{1,2}$, we present characterization of polycrystalline samples for the series $(\text{Eu}_{1-x}\text{Ca}_{1-x})_2\text{Ir}_2\text{O}_7$. Doping completely suppresses the MIT with only a weak decrease in the magnetic transition, leading to a fully metallic state that retains the bulk magnetism of the $x = 0$ compound. XRD and XAS suggest that the change of $T_{\text{MIT}}$ occurs due to an interplay between bandwidth tuning via a change in the Ir-O-Ir bond angle as well as filling control. X-ray PDF shows no changes in short-range order associated with either the MIT or the magnetic transition, additionally confirming that Ca-doping does not result in significant phase separation. Preliminary XMCD data probing the magnetic state across the MIT will be discussed.*

Session H47 FOEP: From FunSized Physics to Escaping Labs; Adventures in Public Engagement BCEC 213 - James Kakalios, University of Minnesota - Tag(s): Outreach

2:30PM H47.00001: Lessons learned from outreach grant administration JAMES ROCHE (Presenter), American Physical Society — TBD

2:42PM H47.00002: Physics is for Everyone: How to Market Physics for The Masses* PHOEBE SHARP (Presenter), Rhodes College — Marketing science for the general public is challenging. As physics students, we understand the importance and need for science education, so reaching out to those outside of our physics and science communities is a great way to share our curiosity and excitement for how the world works. This summer, I worked on providing accessible and interesting content for patrons of the Physics Central website, a site that works to encourage curiosity in physics through comics, blog posts, and other media outlets. That included writing scientific articles about often overlooked concepts in physics, as well as researching ways to make the website more eye catching and relevant.*

APS Public Outreach Department
APS Education and Diversity Department
Rhodes College

2:54PM H47.00003: The US Physics Team: Training for competition and building community JIAJIA DONG (Presenter), Bucknell University / AAPT — Since the founding of the US Physics Team in the mid-1980s, the team coaches have had the mission of selecting and training the top US high school physics students to compete in the annual International Physics Olympiad. Over the decades, the coaches have worked hard to encourage participation from high schools around the nation, to design challenging training materials, and to build a growing community of students who share their curiosity and passion in physics. The bond built through learning physics together remains strong when the students later find their roles in the society such as physicists, engineers, lawyers, and doctors.

Recently celebrating its 30th anniversary, the Team continues to try to broaden its impact, by reaching more students who are not only interested in learning physics, but enthusiastically embrace the challenges of problem-solving, finding efficient, elegant, and insightful solutions, and discovering new physics. We share the story of the US Physics Team, and invite your contribution to the growth of the program.
3:06PM H47.00004: LabEscape, A Science-Based Escape Room: Where We Are, and How We Got Here*  PAUL KWIAT (Presenter), IAN CALL, ERIC HUDEC, REBECCA WILTFONG, University of Illinois at Urbana-Champaign — Based on APS seed money, we have set up what we believe is the world's first science-based escape room: LabEscape. By interacting with physics components in the room, participants uncover clues that allow them to solve the mystery of missing quantum physicist Professor Alberta Schrodenberg, and escape! Our goal is to show that science can be useful and accessible (no prior background is assumed), as well as beautiful and even fun! The room is operated by undergraduate STEM students, and most of the puzzles were created by them as well, all based on physics phenomena, including polarization, refraction, induction, lasers, etc. Along the way the Agents directly experience some key aspects of scientific research, and are exposed to basic themes in quantum information. To date we've had nearly 4000 participants, and received near perfect reviews. For more information, see LabEscape.org; to sign up at APS, visit LabEscape.org/APS/.

*This project was supported in part by the APS, NSF, and SPIE, as well as the UIUC College of Engineering.

3:18PM H47.00005: LabEscape, A Science-Based Escape Room: Now What*  IAN CALL (Presenter), ERIC HUDEC, PAUL G KWIAT, REBECCA WILTFONG, University of Illinois at Urbana-Champaign —

Our science-based escape room has been operating in our local mall for over two years, and although not it's primary goal, LabEscape has been an excellent laboratory for observing group dynamics (we've had ~800 groups go through), the impact of diversity, and the roles of curiosity, communication, and collaboration. We've developed several different scenarios with varying durations and varying degrees of success. We'll discuss what has and hasn't worked, and our efforts to expand to an even wider audience, e.g., in other cities, science centers, etc. One recent addition is the inclusion of a portable version, which we debuted at the August, 2018 AAPT conference, and have now brought to the APS March meeting.

For more information, see LabEscape.org; to sign up at APS, visit LabEscape.org/APS/.

*This project was supported in part by the APS, NSF, and SPIE, as well as the UIUC College of Engineering.

3:30PM H47.00006: What's been happening at FunSizePhysics?*  SHIREEN ADENWALLA (Presenter), JOCELYN BOSLEY, University of Nebraska - Lincoln, LEIGH SMITH, Physics, University of Cincinnati —

www.funsizephysics.com is a website created with the express purpose of advertizing exciting new developments in condensed matter physics to the tax paying public. In addition, the website was designed to be a convenient place in which to collaborate on and discuss a variety of outreach efforts. The website is unique in that it incorporates research descriptions written by the researchers themselves for a broad audience, unlike numerous science blogs and/or websites. We describe the ongoing efforts to present current and ongoing NSF-funded research to the public in ways that engage a broader audience of non-experts and to make the website a resource for NSF PIs to develop best practices for outreach activities to K-12 students and the general public. We have also embarked on an ambitious program to impact the ability of present and future scientists to communicate with the public, using professional science writers as teachers and modelers for science communication. The ambitious aim is to change how condensed matter physicists communicate with the public.

*Funding from NSF-DMR 1725823 is gratefully acknowledged.

3:42PM H47.00007: Electron Microscopy: Building Nanoscale Knowledge and Community Connections  SARAH GOODMAN (Presenter), Department of Materials Science and Engineering, Massachusetts Institute of Technology —

Electron microscopy (EM) is not only key to solving the greatest challenges we face in the energy sphere, but it can also be a powerful tool for establishing connections between current and aspiring scientists as well as the public. The work of scientists and engineers is often portrayed as complicated and inaccessible, which can alienate the general public and deter students from pursuing the STEM fields, particularly those who don't often see role models like themselves as scientists. Here, I will present the results of three types of community outreach events that used EM to provide both the public and K-12 students an opportunity to engage in the same type of work that researchers do. In two events, the general public was invited to experience EM demos and use the tools themselves, which allowed the process and tools of research become demystified. In another event, a group of middle school students used the transmission electron microscope to image gold nanoparticles at atomic resolution. By including the community in our everyday research activities, we can work towards building trust between scientists and the public to pave the way for stronger science policy in the future.
3:54PM H47.00008: Physics for all ages: Texas A&M Physics Show  TATIANA ERUKHIMOVA (Presenter), Texas A&M University — The Texas A&M Physics Show started in 2007 and has been attended by 22,000 people since then. We offer 40-50 Shows per year. The target audience for the Physics Show is preK-12. The Show lasts 90 min and consists of three parts: 45-60 min Show in the Auditorium, 20 min interactive Hands-on activities in the lobby, and the depth charge outside. Examples of demonstrations that we share with children include clouds, lightning, and magic bubbles, solid air and liquid oxygen, jet propulsion, levitating superconducting trains and flying toilet paper and many more. The presentation is tailored to groups of different ages and "attention spans". We'll discuss pros and cons of starting a similar program and what it takes to run it all year round.

4:06PM H47.00009: How to involve citizen scientists in your research*  JAMES FREERICKS (Presenter), Georgetown University — Citizen science is often viewed as crowd science where citizens are employed in labor intensive data collection or in other tedious activities required for complex research. But the advent of MOOCs makes it easy to identify, recruit, and collaborate with talented citizen scientists on any research problem. The MOOC audience provides a highly educated and motivated space to recruit research partners from. I will describe a number of different citizen science projects I have been involved in in the past year which have lead to three publications and a number of ongoing projects. I will illustrate how one can recruit research partners and examine how one can find appropriate projects to collaborate on. Whether you are in need of research collaborators or just assistance in your research projects, recruiting citizen scientists provides a new resource to advance your research agenda. I recommend it as a best practice to everyone. It is a wonderful way to give back to the community, provide broader impacts of your work, and get more research finished.

*This work was funded by the National Science Foundation under grant number PHY-1620555.

4:18PM H47.00010: Inventing the Future: How to Make Stuff that Can Change the World  RYAN BAUMBACH (Presenter), National High Magnetic Field Laboratory - Florida State University — Condensed matter physics and materials science topics that persistently defy efforts to engage the public imagination. This is despite the fact that modern society thrives due to the development of thousands of new materials that are routine and essential parts of most people's everyday lives. In this talk I will describe progress towards creating video content that is designed to educate and entertain as it tells the story of how a material is conceived, created and embedded into our lives. I will not only present the resulting video, but will also describe the unique collaboration that has led to its production, which involves scientists and science communicators at the National High Magnetic Field Laboratory and filmmakers, actors, and artists at the Florida State University College of Motion Picture Arts. I will present insights gained from this new paradigm for producing science content for public consumption.

Tuesday, March 5, 2019 2:30 PM - 5:18 PM

Session H48 DFD GSNP: Granular, Porous Media, Multiphase Flows & Bubbles  BCEC 251 - Fu-Ling Yang - Tag(s): Focus

2:30PM H48.00001: Dynamical model for nonlocal inertial-number rheology of dense granular flows*  KENG-LIN LEE (Presenter), FU-LING YANG, Mechanical Engineering, National Taiwan University — Dense granular materials present complicated fluid and solid behaviors. The materials flow above a yield stress which is greater than the magnitude when the flow stops, known as hysteresis. Nonlocal flow rheology emerges due to particle cooperative motions, resulting in flow-size dependence in quasistatic regime and long-range collision momentum transport in dense inertial regime. In this talk, we formulate a dynamical Ginzburg-Landau model of phase transition that can describe these features. We choose the inertial number I as a fluidization order parameter and derive the free energy functional using scaling arguments along with a yield-stress weakening mechanism. The model yields a nonmonotonic flow curve in a homogeneous flow environment, accounting for hysteresis and intermittency in the quasistatic regime. The model shows a generalized Bagnold stress revealing two nonlocal mechanisms: collisions among correlated structures within which fluidization spread. The model captures several salient features in inclined flow configuration including hysteretic starting and stopping heights, Pouliquen's inertial flow rule and flow-thickness dependent velocity shapes.

*This project was supported by the Ministry of Science and Technology of Taiwan through Grants No. 106-2628-E-002-012-MY3.
Boundary Condition for Dense Granular Flows on Smooth Boundary* FU-LING YANG, CHENG-CHUAN LIN (Presenter), Mechanical Engineering, National Taiwan University — When granular material moves relative to a smooth boundary, we often assign a Coulomb-type stress boundary condition with a constant effective wall friction coefficient $\mu_w$. Recent experimental and numerical (DEM) investigations on both steady and transient flows reveal a roubst trend that that $\mu_w$ decays monotonically with the distance from a moving boundary such as a free surface, a slip base, or an internal shear band. Individual grain rotation is found to be an internal mechanism to degrade bulk $\mu_w$. We discover that grain anular speed is correlated with granular temperature which has been reported to correlate with bulk slip velocity or shear rate. We integrate the findings to present a boundary condition for dense granular flows with non-zero velocity relative to its boundary.

*The authors acknowledge the financial support from Ministry of Science and Technology, Taiwan from both the grant MOST 106-2628-E-002-012-MY3 and the French-Taiwan Orchid Project 107-2911-I-002-536.

Cooperative and uncooperative motions in gravity-driven flows* KERSTIN NORDSTROM (Presenter), EMMA C THACKRAY, GRACE S CAI, Mount Holyoke College — We present results from experiments and complementary molecular dynamics simulations of 2D gravity driven granular flows. We specifically study silo flow: discharge through an aperture in a rectangular cell. We obtain particle-scale data in our experiments using high-speed, high-resolution video. We find the presence of cooperatively moving regions and characterize them by their sizes, speeds, and lifetimes. We also find the presence of regions of high nonaffine motion and characterize them similarly. In our analysis, we place particular emphasis on the role of initial packing structure on the resulting bulk flow behavior and microscopic deformations. Our results suggest that the transition from clogging behavior to free flow can be modified by changing the packing structure.

*Acknowledgement is made to the donors of the American Chemical Society Petroleum Research Fund (PRF# 56888-UNI9) for support of this research.

New concepts for modeling connectivity effects in capillary pressure hysteresis in porous media ZONGYU GU (Presenter), AMIN AMOOIE, MARTIN BAZANT, Massachusetts Institute of Technology — Continuum models of porous media often characterize microscopic features of the pore space using macroscopic parameters like porosity and tortuosity, and macroscopic state variables like fluid saturations. To account for the effects of pore-scale connectivity between different sized pores, we propose a new parameter, “pore-space accessivity” to contrast serial and parallel arrangements of different sized pores, and a new state variable, “radius-resolved saturation”, to describe the microscopic distribution of fluids. Based on a statistical branching process, we derive a new microscopic constitutive theory of capillary pressure hysteresis for arbitrary drainage-imbibition cycles. Expanding on the classical “capillary bundle” picture by means of providing a useful first approximation for connectivity effects in porous media, these concepts may have much broader utility in continuum modeling of porous media in a variety of applications.

Capillary filling of water in structural defects at fiber-matrix interface of unidirectional composite materials KALPANI GALPAYAGE DONA (Presenter), Department of Physics, Florida Atlantic University, SARAH E DU, LEIF CARLSSON, Ocean and Mechanical Engineering, Florida Atlantic University — Presence of internal structural defects and damages in a polymeric composite can affect its moisture absorption behavior. This study developed a mathematical model to evaluate the behavior of water uptake in the voids at fiber/matrix interface of unidirectional composite materials. The model considers moisture absorption via diffusion by the Fick’s law and water filling driven by capillary action in the voids at the fiber/matrix interface. The water wicking in the voids is modeled using a one-dimensional two-phase fluid flow, where capillary filling is influenced by the initially trapped air bubbles in the voids, permeation of air is enhanced by the pressure from water front of capillary flow. A material parameter, contact angle was introduced to measure the strength of capillary action in the voids. The model was verified experimentally with a carbon fiber reinforced vinyl ester material. The predicted water filling behavior agreed well with the experimentally measured content of absorbed water. Dependences of water absorption behavior on contact angle and void size were discussed.
3:30PM H48.00006: Instabilities of Vertical Time-Dependent Miscible Displacements in Homogeneous Porous Media
YOUSSEF ELGAHAWY (Presenter), JALEL AZAIEZ, Department of Chemical and Petroleum Engineering, University of Calgary — Buoyancy-driven instabilities develop at the interface between fluids in miscible flow displacements. Such instabilities significantly affect the efficiency of displacement processes encountered in many applications such as enhanced oil recovery and CO2 sequestration. Thus, it is imperative to control such instabilities. Most studies on vertical miscible displacements are limited to displacements involving a constant injection rate. However, in some practical processes the injection rate is in fact time-dependent. The objective of this study is to investigate the effects of time-dependent injection rates on the growth of fingering instabilities. The governing equations are solved numerically using the Hartley-Pseudo-spectral method. First, the dynamics of fingering instabilities were examined using nonlinear simulations, under constant injection rates, to determine the criteria for the instability which depends on the mobility ratio, density difference, and the critical injection velocity. Then, utilizing time-dependent injection schemes, it was found that the instability can be attenuated depending on the cycle period and velocity amplitude. Moreover, the flow is always less unstable when the displacement is initiated through an extraction stage rather than an injection one.

3:42PM H48.00007: Continuum-Scale Modeling of Multiphase Flow in Porous Media From a New Microscopic Theory of Hysteresis
AMIN AMOOIE (Presenter), ZONGYU GU, Department of Chemical Engineering, Massachusetts Institute of Technology, MARTIN BAZANT, Department of Chemical Engineering and Department of Mathematics, Massachusetts Institute of Technology — We present continuum modeling of multiphase flow in macroscopic porous media based on a new microscopic hysteresis theory that provides physics-based macroscopic parameters and state variables to capture essential pore-scale features. We propose accessivity to characterize the network connectivity of different-sized pores in a porous medium, and radius-resolved saturations to characterize the distribution of fluid phases within. Developing a statistical theory for quasistatic immiscible drainage-imbibition in arbitrary cycles, we arrive at simple models that naturally arrest hysteresis in capillary pressure and relative permeability. Existing models use empirical case-based modifications to capture hysteretic data and rectify the curvatures of their predictions, which fails to make a physical connection to the medium microstructure. Employing the proposed conceptual framework, here we then develop a novel multiphase flow simulator for macroscopic porous media, where the new constitutive relationships for both capillary pressure and relative permeability consistently link the continuum model to the microscopic state of fluid phases in a porous medium of a given microstructure.

3:54PM H48.00008: Non-orthogonal multiple-relaxation-time lattice Boltzmann method: theory and its application in multiphase flows*
LINLIN FEI (Presenter), Department of Energy and Power Engineering, Tsinghua University, KAI HONG LUO, Department of Mechanical Engineering, University College London — A three-dimensional multiple-relaxation-time lattice Boltzmann method (MRT-LBM) is constructed based on a series of non-orthogonal moments. Compared with the widely used orthogonal-moments-based MRT-LBM, the present formulation simplifies the mapping between the discrete velocity space and the moment space, and exhibits better flexibility across different lattices. The proposed method is then extended to simulate multiphase flows with large density ratio and tunable surface tension, and validated via benchmark cases. Finally, we present simulations of several practical and challenging problems using the non-orthogonal MRT-LBM to highlight its capability for simulating realistic multiphase flows.

*The research has received funding from the MOST National Key Research and Development Programme (Project No. 2016YFB0600805) and the UK Engineering and Physical Sciences Research Council (EPSRC) under the project "UK Consortium on Mesoscale Engineering Sciences (UKCOMES)" (Grant Nos. EP/L00030X/1 and EP/R029598/1).

4:06PM H48.00009: Cavitation in Boxing: A physical approach*
THIBAULT GUILLET (Presenter), JULIETTE AMAUGER, LadHyX, Ecole polytechnique, DAVID QUERE, PMMH, ESPCI, CAROLINE COHEN, CHRISTOPHE CLANET, LadHyX, Ecole polytechnique — When a closed container filled of water (model of the head) is accelerated by a shock, cavitation bubbles can form and eventually, at their collapse, cause the shattering of the container. Predicting the growth and collapse dynamics of a bubble is crucial in limiting its damages. By conducting simultaneous high-speed imaging of the motion and pressure measurements in the fluid, we show that Rayleigh-Plesset equation accurately predicts the time evolution of the bubble radius. Additionally, we both experimentally and theoretically prove that the pressure distribution in the fluid can be directly derived from the acceleration. Finally, the overall bubble dynamics is found to be governed by the maximal acceleration and the timespan of the shock.

*We thank Direction Générale de l'Armement (DGA) for their financial support.
JULIETTE AMAUGER (Presenter), THIBAULT GUILLET, LadHyX - Ecole Polytechnique, DAVID QUERE, PMMH - ESPCI, CHRISTOPHE CLANET, CAROLINE COHEN, LadHyX - Ecole Polytechnique — Traumatic Brain Injury (TBI) is a major healthcare problem, increasingly occurring in sports like rugby, boxing or football. The occurrence of TBI is dependent on the head acceleration and the duration of the shock, as expressed by the empirical Wayne State Tolerance Curve (WSTC). One of the possible causes of TBI is the formation of cavitation bubbles in the cerebro-spinal fluid. To investigate this hypothesis, we experimentally observe the formation of cavitation bubbles due to a shock on a water tank, and we quantify the influence of the acceleration and timespan of the shock on the bubbles dynamics. In the cranial cavity, the cerebro-spinal fluid can flow in and out through the spinal cord. Using a flexible membrane to mimic this phenomenon, we show that this motion is a prerequisite for bubble growth. From the prediction of the bubbles sizes, we build a phase diagram of the damaging capacity of the bubbles on the brain as a function of the acceleration profile, in good agreement with the prediction of the WSTC.

*Project funded by DGA

GARTH EGAN (Presenter), XAVIER LEPRO CHAVEZ, EDMOND LAU, ERIC R SCHWEGLER, Lawrence Livermore Natl Lab — In recent years, it has been suggested that micron and sub-micron scale cavitation can occur in the human brain during explosive pressure wave, blunt trauma, or sports collision type events and that the resulting bubble collapse could be the main cause of damage leading to traumatic brain injuries. However, the behavior of very small bubbles is not yet well understood because of the challenges associated with imaging on the necessary length and time scales. Here, we present the direct imaging of bubble collapse in a liquid cell using the Movie-Mode Dynamic Transmission Electron Microscope (MM-DTEM) at Lawrence Livermore National Laboratory. Bubbles were induced in ~1-3 µm of water using laser heating of 60 nm gold particles and typically found to collapse within 200 ns. Polymer coated on the liquid cell substrates served as witnesses to potential damage. The behavior of the system was further explored with molecular dynamic (MD) simulations.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

CHRISTOPHER BOYCE (Presenter), Department of Chemical Engineering, Columbia University, ALEXANDER PENN, MAXIM LEHNERT, Department of Mechanical and Process Engineering, ETH Zurich, AZIN PADASH, Department of Chemical Engineering, Columbia University, KLAAS P PRUESSMANN, Institute for Biomedical Engineering, ETH Zurich and University of Zurich, CHRISTOPHER MULLER, Department of Mechanical and Process Engineering, ETH Zurich — Rapid magnetic resonance imaging (MRI) is used to measure the dynamics of bubbles and jets of gas injected into 3D gas-fluidized beds of granular particles. When two bubbles initially of equal volume rise side-by-side, one bubble collapses while the other maintains its size. This phenomenon is attributed to channeling of gas flow through one bubble, leaving the collapsing bubble with insufficient gas flow to maintain its roof and rise velocity via drag force. When two jets of gas are injected side-by-side, bubbles pinch off from the two jets at alternating times, creating a zipper-like pattern. This phenomenon is attributed to the growth of one jet pushing particles toward the second jet, causing bubble pinch-off from the second jet. The second jet subsequently grows, pushing particles toward the first jet, causing a cyclical pattern to form. Different bubble and jet interaction patterns are seen depending on the size of the particles in the fluidized bed; these differences are attributed to the variation in gas permeability through assemblies of granular particles with particle size.

*This work was supported by the Swiss National Science Foundation under grant number 200021_153290.

IVO PETERS (Presenter), University of Southampton, YOSHIYUKI TAGAWA, Tokyo University of Agriculture and Technology — The collapse of a vapor bubble near a flat solid boundary results in the formation of a jet that is directed towards the boundary. In more complex geometries such as corners, predictions of the collapse cannot be made in a straightforward manner due to the loss of axial symmetry. We experimentally investigate the bubble collapse and jet formation in corners formed of two flat solid boundaries with different opening angles. Using potential flow analysis, we accurately predict the direction of the jet and bubble displacement. We further show that for a corner with an opening angle $\alpha$, there exist analytic solutions that predict the jet direction for all the cases $\alpha = \pi/n$, where $n$ is a natural number. These solutions cover, in discrete steps, the full range of corners from the limiting case of a bubble near a single wall ($n = 1$) up to a bubble in between parallel walls ($n \to \infty$).
5:06PM H48.00014: Give it a boost -- The shape of a traveling long bubble during the transition between two steady states

YINGXIAN ESTELLA YU (Presenter), LAILAI ZHU, SUIN SHIM, Department of Mechanical and Aerospace Engineering, Princeton University, JENS G EGGERS, School of Mathematics, University of Bristol, HOWARD A STONE, Department of Mechanical and Aerospace Engineering, Princeton University — When a confined long bubble translates steadily in a cylindrical capillary, with negligible gravity effects, a uniform thin film of fluid separates the bubble surface and the tube wall. Although a wide variety of investigations have been carried out analyzing the relationship between the film thickness profile and the bubble velocity, most of the literature considers the case where the translational velocity is a constant, thus the bubble profile is steady. Instead, in this work, we investigate how this steady state is established by considering the transitional motion of the bubble as it adjusts its film thickness profile between two steady states, characterized by two different bubble speeds. Different sections of the time-dependent film profile will be characterized, and we will further discuss how the “travel history” of the bubble is stored in the bubble shape. The theoretical results are further verified both by experiments and numerical simulations. The results can potentially be applied to a tunable in-situ particle separation process.

2:30PM H49.00000: Dillon Prize Talk break —

3:06PM H49.00002: 3D Printing of NdFeB Nylon Polymer Bonded Magnets

MARIAPPAN PARANS PARANTHAMAN (Presenter), Oak Ridge National Laboratory — The main goal of this research is to print near-net shape NdFeB polymer bonded magnets and to minimize the generated waste. One of the ways in which we can achieve this goal is by using extrusion based big area additive manufacturing technique to create complex shapes and geometries of polymer bonded magnets from a computer aided design which requires no tooling but little post-field-annealing reducing the amount of waste generated. We have successfully demonstrated the fabrication of near-net shape magnets with complex geometries and high energy product using over 65vol% of NdFeB in nylon polymer composite magnets. Several configurations of magnetic fields were used for aligning the magnets during printing. A higher energy product of 11.3 MGOe have been obtained for 65 vol% anisotropic composite bonded magnets aligned in 20 kOe with post-annealing. It is also observed at certain conditions; the post-aligned printed magnets didn’t deform and hence the original shape is preserved. We will discuss in detail about the correlation of magnetic alignment with properties.

*This research was supported by the Critical Materials Institute, an Energy Innovation Hub funded by the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Advanced Manufacturing Office.

3:18PM H49.00003: Quantitative mechanical and electrical assessment by local probe methods of inkjet-printed PEDOT:PSS thin films

EDGAR GUTIERREZ-FERNANDEZ, IEM-CSIC, Serrano 121, 28006 Madrid, Spain, I.A. GABALDON-SAUCEDO, Departament d'Enginyeria Electrònica i Biomèdica, IN2UB-Universitat de Barcelona, 08028, Barcelona, Spain., M. C. GARCIA-GUTIERREZ, IEM-CSIC, Serrano 121, 28006 Madrid, Spain, A. VAREA, Departament d'Enginyeria Electrònica i Biomèdica, IN2UB-Universitat de Barcelona, 08028, Barcelona, Spain., A. NOGALES, IEM-CSIC, Serrano 121, 28006 Madrid, Spain, E. REBOLLAR, IQFR-CSIC, Serrano 119, Madrid 28006, Spain, A. VILA, A. CIRERA, Departament d'Enginyeria Electrònica i Biomèdica, IN2UB-Universitat de Barcelona, 08028, Barcelona, Spain., TIBERIO EZQUERRA (Presenter), IEM-CSIC, Serrano 121, 28006 Madrid, Spain — Among the different technologies implied in scalable additive manufacturing inkjet printing is very well-suited for processing polymers. Thin films of PEDOT:PSS on ITO can be prepared by inkjet printing technology. A relatively broad range of thicknesses can be obtained by addition of subsequent polymer layers resembling an additive manufacturing process. The resulting inkjet PEDOT:PSS films are homogeneous as regard both electrical and mechanical properties. In spite of line topography both the Quantitative Nanomechanical Mapping (QNM) and the Conductive-AFM (C-AFM) characterization reveal homogeneous values throughout the polymer surface regardless of the welding zones. The results discussed in this work provide the basis for the application of inkjet printing as deposition method for electrically conducting PEDOT:PSS into large area with mechanical stability.

3:30PM H49.00004: Understanding the Effect of Block Copolymer Micelles on the Nanostructure and Rheological Response of Inks for Direct Ink Writing  RISHABH EKBOTE, DEBORAH LIU, DANIEL KROGSTAD (Presenter), University of Illinois at Urbana-Champaign — Bioinspired, hierarchical materials are of interest due to their ability to create materials with unique combinations of mechanical properties. We are interested in using a combined top-down and bottom-up approach to create synthetic materials with hierarchical structures. Towards this goal, we are using block copolymers to create nanoscale ordering in inks that can be printed using direct ink writing. However, the inclusion of micelle forming block copolymers has significant impact on the rheology of the inks, and thus their printability. Here, we will discuss the progress made towards understanding the effects of the block copolymer structure and concentration on the rheological properties of block copolymer containing epoxy inks.

3:42PM H49.00005: Leveraging Jammed Microgels to Shape Complex Fluids: One Method for 3D Printing with Cells, Gels, Elastomers, and Colloids [Invited]  THOMAS ANGELINI (Presenter), University of Florida — 3D printing is generally a race against instabilities; the challenge is to prevent printed liquid features from flowing of breaking up once deposited. Printing directly into a support material made from jammed granular-scale gel particles mitigates the two nearly ubiquitous sources of instability encountered in 3D printing: surface tension and body forces. The yield stress of these jammed microgels can be tuned over a broad range, making them excellent media in which to create macroscopic structures with microscopic precision. While tracing out spatial paths with an injection tip, the microgels yield at the point of injection and then rapidly re-solidify, trapping injected material in place. In this talk, we demonstrate how this physical approach to creating 3D structures negates the effects of surface tension and gravity, allowing a wide breadth of materials to be structured. With this method we create complex 3D objects made from silicones, hydrogels, colloids, and living cells, including functional living cell constructs and fluidic devices made from silicone. Immediate application areas include tissue engineering, flexible electronics, particle engineering, smart materials, and encapsulation technologies.

4:18PM H49.00006: Utilization of Polymer-Nanoparticle Composite in Micro-Stereolithography 3D Printing  HONGXIA LI (Presenter), AIKIFA RAZA, AFRA ALKETBI, TIEJUN ZHANG, Mechanical Engineering Department, Masdar Institute, Khalifa University — Advances in micro-stereolithography (µ-SL) 3D printing enable the fabrication of complex microstructures for biomedical, energy and other applications. However, the narrow selection of optical-curable printing materials limits its wide deployment. 3D printed micromodels are used to mimic the morphology of natural rock and reveal the microfluidic flow physics for subsurface energy application, but the surface chemistry of the printed polymer micromodel are totally different from natural rock surface. Therefore, polymer-based composites are used to tailor intrinsic properties, such as mechanical strength and surface wettability. In this work, we utilize the composite of polymer and calcite nanoparticle in a high-resolution µ-SL 3D printing system. Light scattering induced by the nanoparticles and its influence on printing resolution are analyzed under various particle sizes and concentrations. The transparency of printed micromodels reduces accordingly, which would affect the microfluidic flow imaging performance. Surface wettability conditions, including the contact angle and its hysteresis, are also characterized. This study provides important guidance in the utilization of polymer/nanoparticle composite in µ-SL 3D printing for broad microfluidic applications.

4:30PM H49.00007: Morphology and Mechanical Properties of Stereolithography-Printed Polymer Networks  ANNA SMALLWOOD-ROONEY (Presenter), RYKELLE ADLEY, ADAM MERKLE, KEITH DENIVO, SUNGMIN PARK, CHANG YEOL RU, Rensselaer Polytechnic Institute — Stereolithography (SLA) is a method of 3D printing in which polymer network objects are formed through the repeated curing of photopolymer resin by a computer-controlled UV laser source. Objects that are 3D printed on a SLA platform show a layered morphology on the microscopic scale, and the resolution of the printed object is determined predominantly by the thickness of each layer, typically on the 100 um scale. Layer formation during printing is dependent on laser intensity and decay during the printing process. Printed layers are generally characterized by a strongly crosslinked region that decays gradually into a more loosely crosslinked domain which is adjacent to a highly crosslinked region of the next layer. This pattern of curing is a function of laser intensity and reflects decay of intensity throughout each curing cycle, or layer. The SLA-printed morphology is characterized on the microscopic scale as a function of laser intensity and decay during printing. High resolution optical microscopy techniques will offer a depiction of crosslinking density change across layered 3D printed structure. The layer curing process will also be investigated by real-time FTIR, DSC, and DMA.
4:42PM H49.00008: Self-Limiting Electrospray Deposition of Polymers and Polymer Composites  
LIN LEI (Presenter), DYLAN A. KOVACEVICH, CHRISTIANNA KUZNETSOVA, JONATHAN SINGER, Mechanical and Aerospace Engineering, Rutgers University — Electrospray deposition is widely used to create polymer microcoatings from dilute spray solutions. In a certain regime of experimental parameters, a limiting thickness emerges where the accumulation of charge repels further spray. This self-limiting electrospray deposition (SLED) can uniformly cover complex multiscale structures efficiently. Here we investigate the application of polymer blends to increasing the durability of the spray films for different mechanical applications. We use the addition of photo- or thermal-crosslinkers that can either maintain the hierarchical spray structure of hollow particles or result in a dense film to obtain stiffer coatings for protective barriers. The results show mechanically-tough coatings with tunable porosity which are resistant to decomposition by chemical reactions and mechanical damage. To make the films that are more flexible for compliant surfaces, polymer blends which consisting of plastic and elastomeric components are sprayed. The net result was a coating that could enhance adhesion and sustain ~17% strain in the underlying structure. Furthermore, we have applied SLED to coat 3D structures produced via additive manufacturing with these mechanically-tuned coatings.

4:54PM H49.00009: 3D Printable Soft Elastomers  
ZIHAO GONG (Presenter), SHIFENG NIAN, Materials Science and Engineering, University of Virginia, LIHENG CAI, Materials Science and Engineering and Chemical Engineering, University of Virginia — Existing feedstock for 3D printing is nearly all plastics. These materials are not only mechanically stiff but also fragile. These severely limit their applications where soft, elastic polymers are required to easily comply with the shapes of objects they contact. Here we develop a soft, 3D printable elastomer through molecular design. We synthesize a triblock copolymer, in which the two end-blocks are poly(styrene) (PS) with a high glass transition temperature, T_g, about 100°C, and the middle block is a poly(dimethylsiloxane) (PDMS) with a low T_g about 100°C. At room temperature, such copolymers self-assemble to a network, in which the effective network strands are the PDMS, and crosslinks are glassy plastic domains formed by PS. This network is extremely soft with Young's modulus below 100kPa, more than three orders of magnitude lower than that of plastics. At high temperature, the glassy domains dissociate, enabling a temperature triggered solid-to-liquid transition. Harnessing this feature, we use extrusion-based 3D printing to create a complex, hierarchical 3D structure with an exceptional combination of softness and deformability. Our studies provide a new strategy for the development of 3D printable soft elastomers.

5:06PM H49.00010: Embedded 3D Printing with Acoustic Focusing  
LEANNE FRIEDRICH (Presenter), MATTHEW BEGLEY, University of California, Santa Barbara — Intra-nozzle particle positioning methods enable the design of composite 3D printed components with structural and functional gradients. One method is acoustic focusing, wherein a piezoelectric actuator establishes a bulk acoustic wave in the nozzle which co-orient and moves particles to the wave nodes. Because acoustic focusing requires low viscosity inks (such as soft materials with functional particles), we use a granular hydrogel as support material. This study investigates how layer-by-layer deposition of support material and printing into a support bath each influence the maintenance of acoustically focused microstructures and the fidelity of printed structures. While layer-by-layer support prevents filaments from breaking into droplets, it can also destabilize filaments near liquid elbows and induce rotational flows that disrupt focused structures. Similarly, though writing into support material enables complex structures, it can also hinder inter-layer and intra-layer fusion and disrupt existing structures. Using digital image analysis and particle image velocimetry, we measure the effects of ink and support composition and printing parameters on maintenance of acoustically focused microstructures, stability of filaments and liquid elbows, and inter-filament fusion.

5:18PM H49.00011: Room Temperature Extrusion 3D Printing of Polyether Ether Ketone Using a Stimuli-Responsive Binder  
CHANG-UK LEE (Presenter), University of Wisconsin - Madison, JOHANNA VANDENBRANDE, ADAM GOETZ, MARK GANTER, DUANE STORTI, University of Washington, ANDREW BOYDSTON, University of Wisconsin - Madison — We report 3D printing of polyether ether ketone (PEEK) at room temperature by direct-ink write technology. The room-temperature extrusion printing method was enabled by a unique formulation comprised of commercial PEEK powder, soluble epoxy-functionalized PEEK (ePEEK), and fenchone. This combination formed a Bingham plastic that could be extruded using a readily available direct-write printer. After printing, thermal processing at 230 °C resulted in crosslinking of the ePEEK components to form a stabilizing network throughout the specimen. A final sintering stage was conducted at 380 °C. The T_g of product specimens was found to be 158 °C, which is 13 °C higher than commercial PEEK as measured by DSC. Moreover, the thermal decomposition temperature was found to be 528 °C, which compares well against commercial molded PEEK samples. Chemical resistance in trifluoroacetic acid and 8 common organic solvents were investigated, and no signs of degradation were observed from parts submerged for 1 week in each solvent. Test specimens also displayed desirable mechanical properties, such as a Young's modulus of 2.5 GPa, which corresponds to 63% of that of commercial PEEK.

Tuesday, March 5, 2019 2:30 PM - 5:30 PM
especially for visualizing polymer dynamics, visualizing nanostructures in life sciences, the application of this technique in polymer science is much more rare, universal, simplified labelling strategy and the ability to visualize polymer assembly and dynamics in situ. A major constraint is from the lack of suitable fluorophore chemistry and simple strategies to label polymer chains. In this talk, we will discuss a functional diarylethene-based photoswitchable fluorophore, which can be directly copolymerized with standard monomers such as styrene and methyl methacrylate with no further post-coupling reactions or purifications needed. The attachment of fluorophores onto polymer chains enables super-resolution imaging of model polymer blend systems (PS/PMMA) with different nanostructures. As each individual fluorophore can switch between its bright and dark state many times, multiple time-lapse images can be acquired to observe the dynamic nanostructural evolution of polymer blends during solvent vapor annealing. With the advantages of a high, localized electric field in the plane of the surface, and subjects that region to UV light. When wet, the electric field forces the polymers to align beneath the tip, and the UV light engenders insoluble PPV, preventing loss of alignment. We align a large rectangular region by scanning a probe using this technique, and use cross-polarization measurements to demonstrate alignment. The ability to fabricate ordered layers removes material variations from studies of conduction and interfacial phenomena, thus represents a significant step towards measuring the intrinsic properties of conducting polymers.
4:18PM H50.00006: Exploring Textures of a Nematic Liquid Crystal for Fourier Phase Contrast Microscopy
CHARLOTTE KYEREMAH (Presenter), JEFFREY LA, DEVULAPALLI RAO, MOHAMED AMINE GHARBI, CHANDRA S
YELLESWARAPU, University of Massachusetts Boston — Phase contrast microscope is used in teaching and research labs to
view transparent specimens such as live cell cultures. It enables to study dynamic biological processes. In the past we have
developed Fourier phase contrast microscopy technique using photoinduced birefringence in liquid crystals that constitute
a fascinating class of matter characterized by the counterintuitive combination of fluidity and long-range order. A low
power laser is passed through a commercial inverted microscope to facilitate the Fourier plane at the output of the video
port. When the liquid crystal cell is placed at the Fourier plane, low spatial frequencies at the center of the Fourier
spectrum are intense to transform the liquid crystal molecules into isotropic phase whereas high spatial frequencies are
not intense enough and remain in the anisotropic phase. This results π/2 phase difference between high and low spatial
frequencies, a basic requirement for phase contrast imaging. Liquid crystal materials are known for their exceptionally
successful applications in displays, smart windows, and biosensing applications. Here we exploit different textures of a
nematic liquid crystal 5CB: planar, perpendicular, hybrid and twisted, and investigate their abilities to improve the contrast
of phase images.

4:30PM H50.00007: Tractor beams for colloidal particles are not self-accelerating modes* ARGHA MONDAL
(Presenter), YISHUAI XU, LEWIS A WRAY, DAVID GRIER, New York University — We previously have demonstrated that
structured laser beam can act as a tractor beam for colloidal particles. In addition to their ability to pull objects upstream,
these modes of light have other remarkable properties. Due to the homology of the paraxial wave equation with
Schrödinger's equation, the wave function for a quantum mechanical particle in a circular box can be prepared in shape-
preserving wave packets that rotate at constant angular speed around the center of the box, similar to a tractor beam.
This apparent violation of Ehrenfest's theorem is resolved by considering the force exerted on the particle's wave packet
by the enclosing wall. Remarkably, the wave packet continues to rotate even after the wall potential is removed. We show
that this force-free finite-energy rotating state actually corresponds to classical motion with constant velocity, again in
agreement with Ehrenfest's theorem. Even so, the classical angular momentum carried by the rotating states poses a
conceptual challenge because it differs from its quantum mechanical angular momentum, and indeed can have the
opposite sign.

by the MRSEC program of the NSF through award number DMR-1420073.

4:42PM H50.00008: High efficiency Fresnel lens design and fabrication in a two-stage photopolymer JOHN E
HERGERT (Presenter), DAVID J GLUGLA, AMY C SULLIVAN, MARVIN D ALIM, ROBERT R MCLEOD, Electrical, Computer, and
Energy Engineering, University of Colorado at Boulder — Diffractive optical elements (DOEs) assimilate optical functionality
within thin (≤100 µm), lightweight films. With the recent advent of high dynamic range two-stage photopolymers, gradient-
index volume DOEs can now achieve diffraction efficiencies competitive with conventional surface-relief DOEs, while also
offering the advantages of contact-free, self-processing optical recording into a flat film that can be laminated between
protective sheets. Here we design and fabricate Fresnel lenses with what we believe to be the highest reported diffraction
efficiencies achieved to date using this gradient-index DOE approach. Our analysis shows that these high diffraction
efficiencies are crucially enabled by the high index modulation of the photopolymer (n1 > 0.01) and the high pixel count of
the single-shot recording exposure (6400 × 6400 pixel chrome mask). The recorded lenses are 50 µm in thickness and up
to 16 mm in diameter, with f-numbers ranging from 16 – 24 and diffraction efficiencies up to 85%. This high performance
represents an important step toward practical applications, ranging through solar energy concentrators, customized vision
optics, integrated photonics, heads-up displays, and hybrid lenses.

4:54PM H50.00009: Quantitative index metrology for 3D voxelated structures in photopolymer DAVID J GLUGLA,
IZABELLA R BERMAN (Presenter), Electrical, Computer and Energy Engineering, University of Colorado at Boulder, MADELINE B
CHOSY, Carleton College, MARVIN D ALIM, Chemical and Biological Engineering, University of Colorado at Boulder, AMY C
SULLIVAN, ROBERT R MCLEOD, Electrical, Computer and Energy Engineering, University of Colorado at Boulder — Thanks to recent
advances in two-stage photopolymers, it is now possible to dictate arbitrary 3D voxelated refractive index structures
within a continuous volume of polymer, with dynamic range Δn in excess of 0.01 and with micron-scale spatial resolution.
However, quantitative metrology for such structures remains an under-explored challenge. Here we demonstrate that TIE-
based phase imaging, in conjunction with scanning confocal reflection microscopy, can achieve unambiguous quantitative
characterization of arbitrary voxelated index structures. This characterization then guides the design, fabrication, and
validation of novel optical components, including flexible gradient-index lenses for in situ medical imaging.
5:06PM H50.00010: Bio-inspired design of Mechanochromisms via surface engineering  
SONGSHAN ZENG, RUI LI, DIANYUN ZHANG, LUYI SUN (Presenter), University of Connecticut — A bilayer structure composed of polyvinyl alcohol composite thin film atop thick polydimethylsiloxane substrate was prepared. The bilayer structure shows dynamic strain-responsive optical properties. The transition between a transparent state to an opaque state can be easily achieved by uniaxially stretching and releasing the device. Also, a series of derivative mechanochromisms with capabilities of switch “on/off” fluorescence, change fluorescent color, reveal/hide information upon mechanical stimuli are prepared. These devices feature virtually no changes in optical/mechanical properties after being repeatedly stretched and released thousands of times, promising for widespread applications.

5:18PM H50.00011: Reversible Self-Focusing in Light-Responsive Spiropyran Functionalized Gels  
DEREK MORIM, Department of Chemistry and Chemical Biology, McMaster University, AMOS MEEKS (Presenter), ANKITA SHASTRI, John A. Paulson School of Engineering and Applied Sciences, Harvard University, ANDY TRAN, Department of Chemistry and Chemical Biology, McMaster University, ANNA SHNEIDMAN, John A. Paulson School of Engineering and Applied Sciences, Harvard University, FARIHA MAHMOOD, Department of Chemistry and Chemical Biology, McMaster University, JOANNA AIZENBERG, John A. Paulson School of Engineering and Applied Sciences, Harvard University, KALAICHELVI SARAVANAMUTTU, Department of Chemistry and Chemical Biology, McMaster University — Self-focusing, where interactions between a light beam and its medium creates a refractive index gradient that acts as a waveguide for the beam, has been observed at low powers (nW-mW) in a variety of soft-matter systems. This intensity dependent refractive index change is often created by the irreversible photopolymerization of monomers in solution. However, a reversible system would enable potential applications in soft all-optical computing based on dynamic interactions between self-focused beams. Here we show a fully reversible soft self-focusing medium based on stimuli-responsive hydrogels (poly(acrylamide-co-acrylic acid) and poly(N-isopropylacrylamide)) doped with photoresponsive spiropyran pendant groups. In this system the intensity-dependent contraction of the gel leads to a local increase in the refractive index, resulting in self-focusing of the incident beam. In addition to being reversible this system shows long-range interactions between beams separated by over 10 beam widths. To explain these experiments we have developed a numerical model coupling the spiropyran isomerization, gel dynamics, and the propagation of light. This model allows us to design more complex beam interactions and thus to create systems where light is dynamically controlled by light.
Sea Urchin Biomineralization – Formation of Intricate Single Calcite Crystals via Amorphous Precursors

[Invited]
YAELE POLITI (Presenter), MARIE ALBÉRIC, ZHAOYONG ZOU, ANDERS WESTERAARD JENSEN, WOUTER HABRAKEN, Max Planck Institute of Colloids and Interfaces, PUPA GILBERT, University of Wisconsin, Madison, EMIL ZLOTOYABKO, Technion-Israel Institute of Technology, PETER FRATZL, LUCA BERTINETTI, Max Planck Institute of Colloids and Interfaces —

Biomineralization of sea urchin skeletal elements results in complex structures with smooth, curved surfaces that diffract as single calcite crystals 1. This is achieved by a crystallization pathway involving amorphous precursor phases 2,3. Similar processes are now recognized in various other organisms. Yet, the dynamics of mineral rearrangement and the energetic landscape of this transformation are still poorly understood. We addressed these questions studying the crystallization of biogenic and synthetic ACCs by state-of-the-art calorimetric, spectroscopic and scattering methods. The skeletal elements of the sea urchin Paracentrotus lividus are composed of ACC, organics, a small amount of water and calcite 4. Insight into the interplay between these components is gained by HR-XRPD of skeletal elements annealed at elevated temperatures. Complementarily, by mapping the distribution of ACC, H2O, ACC and calcite in growing spines by X-PEEM we demonstrated variable transformation kinetics across the spine. In-vitro experiments show that the effect of water, as well as organic and inorganic additives, on the stability of synthetic ACC is primarily kinetic [5]. A key finding with relevant to biomineralization is that although water drastically changes the crystallization enthalpy, the overall ACC thermodynamic stability is independent of the hydration level due to enthalpy-entropy compensation. The rate of the transformation, on the other hand, is critically dependent on the water content; water increases ion mobility, resulting in higher kinetic instability [5].

Multistep Crystallization Pathways for Protein Crystals and Colloidal Assemblies

[Invited]
SHARON GLOTZER (Presenter), SANGMIN LEE, ERIN TEICH, MICHAEL ENGEL, JENS GLASER, University of Michigan — While much is now known about the extraordinary complexity and structural diversity possible for crystals of proteins, nanoparticles and colloids, far less is known about the process by which these crystals form. Simple “classical” models of nucleation and growth may hold for the self-assembly of simple crystal structures, but what of crystals with large unit cells? We present recent results from computer simulation demonstrating that crystallization pathways in protein solutions or entropic colloidal fluids may be as diverse and complex as the resulting crystals, with crystallization following a remarkable variety of multistep pathways that include fluid-fluid transitions. We explore the role of shape, entropy, and, in the case of proteins, both specific and nonspecific interactions in selecting the pathway.

Design of Functional Protein Membranes*

[Invited] MONICA OLVERA DE LA CRUZ (Presenter), BAOFU QIAO, TRUNG NGUYEN, Department of Materials Science and Engineering, Northwestern University — Protein surfaces are composed of sub-nanometer domains, with different degrees of hydrophilicity. These domains play a crucial role in protein assembly, ligand recognition, and drug docking. We explored here the surface domains to disperse enzymes in organic solvents where their activity can be enhanced using random heteropolymers that mimic unstructured proteins in membraneless organelles. The analysis of the correlations between polar domains with the polar components of amphiphilic random heteropolymers mediated by water elucidates the formation of protein-polymer complexes with a core (protein)-shell (polymer) morphology that help stabilize the proteins’ structures and preserve their enzymatic activities in unfavorable solvents as observed in recent experiments (1). At a more coarse-grained resolution, we find that the proteins selectively favor the binding of random copolymers with similar monomer sequences (2). The balance between the energetic and entropy gains in polymer adsorption is determined by the spatial distribution of the polar and non-polar domains and the average composition of the polymers.

The Growth Mechanisms and Biomimetics of Tooth Enamel* [Invited] JANET MORADIAN-OLDAK (Presenter), Biomedical Sciences School of Dentistry, University of Southern California — A very fundamental part of biomineralization is the complex extracellular macromolecular framework in which mineralization occurs, such as the collagen fibrils in bone and dentin, polysaccharides in nacre and amelogenin and non-amelogenin proteins in dental enamel. Unlike other mineralized tissues, such as bone and dentin, mature enamel is acellular and cannot regenerate itself after substantial mineral loss. Biomimetic enamel regrowth is a significant topic in material science and dentistry as an alternative approach for the treatment of defects in dental enamel. We have developed protocols for superficial biomimetic enamel regrowth, based on a novel amelogenin-chitosan hydrogel. Amelogenin is a critical protein for controlling the organized growth of apatite crystals in enamel. We expanded upon the concept of biomineralization to design smaller amelogenin-inspired peptides with conserved functional domains for clinical translation. The synthetic peptides displayed a characteristic nanostructured scaffold reminiscent of ‘nanospheres’ seen in the enamel matrix and effectively controlled apatite nucleation in vitro. Following application of the peptides to sectioned human molar teeth, a robust, oriented, synthetic aprismatic enamel was observed in situ. There was a two-fold increase in the hardness and modulus of the regrown enamel-like apatite layers and an increase in the attachment of the tooth-regrown layer interface compared to control samples. Repeated peptide applications generated multiple enamel-like HAP layers of limited thickness produced by epitaxial growth in which c-axis oriented nanorods evolved on the surface of native enamel. We report that peptide analogues with active domains can effectively regulate the orientation of regenerated HAP layers to influence functional response.

Engineering materials inspired by nature* [Invited] JOANNA MCKITTRICK (Presenter), University of California, San Diego, MICHAEL FRANK, nanoComposix, San Diego, CA — Magnetic field aligned freeze casting is a novel method to fabricate porous, anisotropic ceramic scaffolds with a hierarchy of architectural alignment in multiple directions. This concept was inspired by the structure of trabecular bone and the spiraling nature of the narwhal tusk. A weak rotating magnetic field applied normal to the ice growth direction in a uniaxial freezing apparatus allowed the manipulation of magnetic nanoparticles to create different pore structures and channels with long-range order in directions parallel and perpendicular to the freezing direction. Porous scaffolds consisting of different host ceramics as particles or platelets (hydroxyapatite (HA), ZrO2, Al2O3, or TiO2) mixed with varying concentrations of Fe3O4 nanoparticles were fabricated by freeze casting under no magnetic field, a static or rotating magnetic field. In the magnetic field direction, the compressive strength and stiffness of the scaffolds containing was doubled.

Session H52 GSOFT GSNP: Machine Learning in Nonlinear Physics and Mechanics BCEC 253B - Shmuel Rubinstein, Harvard University - Tag(s): Focus

2:30PM H52.00001: A case study in neural networks for scientific data: generating atomic structures [Invited] TESS SMIDT (Presenter), Computational Research Division, Lawrence Berkeley National Laboratory — Expertise in both the scientific domain of interest and deep learning techniques are essential in order to properly translate scientific problems into tasks amenable to deep learning. Scientific data has a lot of context; for example, the laws of physics obey certain symmetries. Can the network learn this context from the data or should we impose this context as constraints in our network or training procedures? Additionally, scientific data representations, neural network operations and appropriate loss functions desirable for scientific applications can be very different from those most prevalent in the deep learning literature; when is it appropriate to use existing methods and when is it necessary to develop new ones?

We present examples of these challenges when applying deep learning techniques to the generation of atomic systems (new atomic arrangements that may be crystals, molecules, nanoclusters, polymers, proteins, etc.). We present a novel rotation-equivariant convolutional neural network -- or tensor field network -- that has the ability to articulate, recognize and differentiate local and global features in any orientation in complex atomic systems. We discuss strategies for generating hypothetical atomic structures using the concepts of geometric motifs (the recurring patterns of atoms in materials) and neural networks that can manipulate discrete geometry. We present the use of toy models to test the expressiveness and accuracy of tensor field network operations.
3:06PM H52.00002: A computational model for crumpled thin sheets to complement data-driven machine learning* JOVANA ANDREJEVIC (Presenter), JORDAN HOFFMANN, YOHAI BAR-SINAI, LISA LEE, SHRUTI MISHRA, SHMUEL RUBINSTEIN, CHRISTOPHER RYCROFT, Harvard University — Crumpling is ubiquitous across length scales and diverse structures in nature, yet a complete theoretical description of the mechanisms underlying ridge formation remains elusive. To characterize the intricate damage networks of crumpled thin sheets, our recent work has shown that appropriate simulations can assist data-driven machine learning to overcome the scarcity of high-quality experimental data. Inspired by this data augmentation approach, here we detail a computational model for thin, viscoelastic sheets and demonstrate its ability to capture the properties and behavior of crumpled sheets. We validate the model's robustness through statistical comparison with high-quality experimental data, and discuss the prospects for its application in assisting data-driven machine learning.

3:18PM H52.00003: Machine Learning in a data-limited regime: Augmenting experiments with synthetic data uncovers order in crumpled sheets LISA LEE (Presenter), JORDAN HOFFMANN, YOHAI BAR-SINAI, JOVANA ANDREJEVIC, SHRUTI MISHRA, SHMUEL RUBINSTEIN, CHRISTOPHER RYCROFT, Harvard University — Machine learning is a powerful tool for uncovering structure in complex, high-dimensional data. However, a large amount of data is necessary in order to properly train a machine learning network, making it difficult to apply to experimental systems where data is limited. Here we resolve this difficulty by augmenting an experimental dataset with synthetically generated data from a simpler relevant system. Specifically, we study the local order in crease patterns of crumpled sheets, a paradigmatic example of spatial complexity. We supplement sparse crumpled experimental data with abundant simulated sheets of synthetic folds. This technique significantly improves the predictive power in a test problem of pattern completion, demonstrating the usefulness of machine learning in experiments where data may be scarce. Additionally, assessing the accuracy of networks trained with varying types of simulated data reveals the relevance of various physical rules to understanding crease patterns.

3:30PM H52.00004: Search and design of stretchable graphene kirigami using convolutional neural networks PAUL HANAKATA (Presenter), Boston University, EKIN DOGUS CUBUK, Google Brain, DAVID K CAMPBELL, HAROLD PARK, Boston University — Making kirigami-inspired cuts in a sheet has been shown to be an effective way to design stretchable materials with metamorphic properties where the 2D shape can transform into complex 3D shapes. However, a systematic understanding on how cutting patterns alter the mechanical properties of the resulting kirigami remains elusive. Here, we use machine learning (ML) to approximate the objective functions, such as yield stress and yield strain, as functions of the cutting pattern. Our approach enables the rapid discovery of graphene kirigami designs that yield extreme stretchability as verified by molecular dynamics (MD) simulations. We find that convolutional neural networks (CNN) can be applied for regression to achieve an accuracy close to the precision of the MD simulations. This approach can then be used to search for optimal designs that maximize elastic stretchability with only 1000 training samples in a large design space of roughly 4,000,000 candidate designs. This example demonstrates the power and potential of ML in finding optimal kirigami designs at a fraction of iterations that would be required of a purely MD- or experiment-based approach, where no prior knowledge of the governing physics is known or available.

3:42PM H52.00005: Clog prediction in granular hoppers using machine learning methods JESSE HANLAN (Presenter), DOUGLAS DURIAN, Department of Physics and Astronomy, University of Pennsylvania — Grains discharge from a hopper at constant rate, proceeding probabilistically until a stable arch forms. Thomas and Durian (PRL 2015) showed that recasting the characteristic measure of a flow event from the average mass discharged to the fraction of flow microstates that precede (i.e. cause) a clog explains why the former grows as an exponential function of hole diameter, rather than a critical power law. This makes clear that clogs form as the flow brings new microstates into the vicinity of the outlet, which are randomly sampled until a stable arch is found. Characterizing the flow microstates that cause clogs should then better inform a predictive framework. As a first step, Koivisto and Durian (PRE 2017) found that the same statistics governed hoppers in air or submerged in a viscous fluid. This implies that clog formation depends primarily on position degrees of freedom; however, the phase space of grain microstates in a hopper is extremely high-dimensional. Here, we apply deep learning to probe the function space of position microstates in a two-dimensional hopper, to identify and separate out characteristic structures responsible for clogging. Preliminary analysis of a small dataset gives a cross validation success rate of 90%.
MATTHEW PINSON, ARVIND MURUGAN, University of Chicago — Systems with multiple stable states have proven essential in physical knowledge from the high dimensional models implemented. Structure of droplets arising from a Rayleigh-Taylor instability and highlight several techniques to recover significant data-driven framework. We focus on the study of fluid-mediated instabilities. We show that one can predict the spatial accuracy of these models heavily relies on training with extensive dataset and scales accordingly to the number of samples are efficient since their computational complexity scales as a set of matrix-vector multiplications. However, the prediction ability to capture complex relationships and patterns in data. Further, predictions stemming from these trained networks details of the physics of those systems far from equilibrium remains elusive; prompting the need for the development of numerical simulations are computationally expensive and exponentially sensitive to initial conditions. As a result, the forecasting phenomenon arising from nonlinear dynamical systems is a daunting task. Formal models are rarely analytically tractable and numerical simulations are computationally expensive and exponentially sensitive to initial conditions. As a result, the implementation of learned multi-stability. In contrast, our learning framework considers sequential introduction of desired stable states so that material parameters must be incrementally updated to stabilize each additional state. We show that designed states are optimally stable within elastic networks with Hookean springs. However, incremental learning requires springs with strong non-linearity. We interpret such non-linearity as biasing the distribution of strain in these elastic networks to be localized in a sparse subset of springs, much like a Bayesian prior in sparse regression. In this way, we identify principles for practical implementations of learned multi-stability.

TRISTAN A SHARP (Presenter), ANDREA J LIU, University of Pennsylvania — Cellular motion in dense tissues often consists of neighbor-swapping events or rearrangements. The rearrangements underlie the glassy dynamics and much of the collective dynamics of dense disordered cellular packings. Here we present a machine learning (ML) approach that links the local disordered structure surrounding a cell with the propensity of the cell to rearrange in a Voronoi cell vertex model. “Softness,” $S$, an ML-derived quantity originally introduced to quantify the link between local structure and rearrangements in inert glassy liquids, provides an effective proxy for a cell's probability to rearrange, $P_R$. The local structural features that determine the softness of a cell are quantified. Decreasing temperature lowers $P_R$ for a given value of $S$, but the distribution of $S$ also shifts up, opposing the change, leading to previously-observed sub-Arrhenius dynamics. This contrasts with the behavior of Lennard-Jones glassy liquids, where the distribution of $S$ shifts down with decreasing temperature, leading to super-Arrhenius dynamics.

We gratefully acknowledges funding from NSF-DMR-1506625 and No. U54 CA193417

TRISTAN A SHARP (Presenter), ANDREA J LIU, University of Pennsylvania — Cellular motion in dense tissues often consists of neighbor-swapping events or rearrangements. JOEL MARTHELOT, PIERRE-THOMAS BRUN, CBE, Princeton University — Forecasting phenomenon arising from nonlinear dynamical systems is a daunting task. Formal models are rarely analytically tractable and numerical simulations are computationally expensive and exponentially sensitive to initial conditions. As a result, the details of the physics of those systems far from equilibrium remains elusive; prompting the need for the development of new tools. Neural networks have been at the forefront of the machine learning community for their versatility and ability to capture complex relationships and patterns in data. Further, predictions stemming from these trained networks are efficient since their computational complexity scales as a set of matrix-vector multiplications. However, the prediction accuracy of these models heavily relies on training with extensive dataset and scales accordingly to the number of samples in the latter. Here we propose an approach to rethink the traditional experimental setting in applied physics in favour of a data-driven framework. We focus on the study of fluid-mediated instabilities. We show that one can predict the spatial structure of droplets arising from a Rayleigh-Taylor instability and highlight several techniques to recover significant physical knowledge from the high dimensional models implemented.

4:42PM H52.00010: Visualizing probabilistic models and data with Intensive Principal Component Analysis (InPCA)*
KATHERINE QUINN (Presenter), COLIN B CLEMENT, FRANCESCO DE BERNARDIS, MICHAEL D NIEMACK, JAMES PATARASP
SETHNA, Cornell University — Unsupervised learning makes manifest the underlying structure of data without curated
training and specific problem definitions. However, the inference of relationships between data points is frustrated by the
`curse of dimensionality' in high-dimensions. Inspired by replica theory from statistical mechanics, we consider replicas of
the system to tune the dimensionality and take the limit as the number of replicas goes to zero. The result is the intensive
embedding, which is not only isometric (preserving local distances) but allows global structure to be more transparently
visualized. We develop the Intensive Principal Component Analysis (InPCA) and demonstrate clear improvements in
visualizations of the Ising model of magnetic spins, a neural network, and the dark energy cold dark matter
((\Lambda)CDM) model as applied to the Cosmic Microwave Background.

4:54PM H52.00011: Physical Symmetries Embedded in Neural Networks
MARIOS MATTHEAKIS (Presenter), DAVID
SONDAK, PAVLOS PROTOPAPAS, Harvard University — Artificial neural networks (ANNs) have become indispensable tools in
many machine learning applications and in recent years, ANNs have become an active area of research in the physical
sciences. An important consideration for building ANNs for scientific applications is how to incorporate non-negotiable
physical constraints. We propose ANNs with embedded physical symmetries including even-odd symmetry, time-
reversibility, positivity, energy-momentum conservation, and Galilean invariance. We constrain the weights of the NN so
that the physical properties are exactly satisfied by the neural network output. Furthermore, embedding constraints into
the NN can drastically reduce the search space thereby providing an efficient deep learning architecture.

5:06PM H52.00012: Maximizing thermal efficiency of heat engines using neuroevolutionary strategies for
reinforcement learning
CHRISTOPHER BEELER (Presenter), ULADZIMIR YAHORAU, RORY COLES, KYLE MILLS, University of
Ontario, Institute of Technology, ISAAC TAMBLYN, University of Ontario Institute of Technology, University of Ottawa, and National
Research Council of Canada — Classic control problems such as Mountain Car [1] and Acrobat [2] are based on simple
Newtonian physics. Both have been solved previously with reinforcement learning algorithms. Here, we show that
reinforcement learning can also be used to solve classical problems in thermodynamics. Using a reinforcement
learning method based on genetic algorithms, our software agent can learn to reproduce thermodynamic cycles
without prior knowledge of physical laws. We have created a simulated learning environment which models a
simple piston, where an agent can activate thermodynamic processes. With this method, we were able to
optimize an artificial neural network based policy to maximize the thermal efficiency for several different cases.
Depending on the actions available to the agent, different known cycles emerged, including the Carnot, Stirling,
and Otto cycles. Importantly, we show an example of how reinforcement learning can be used to aid scientists in
finding solutions to problems that have yet to be fully explored. In one of the heat engine environments, we
introduced a non-adiabatic process which caused the engine to lose energy. In this case, the agent produced, what
is to the best our knowledge, the best solution for the problem.

Session H53 GSOFT GSNP: Elasto-Active Instabilities
BCEC 253C - Corentin Coulais, University of Amsterdam - Tag(s):
Invited

2:30PM H53.00001: Soft Robots: Functionality via Instabilities [Invited]
KATIA BERTOLDI (Presenter), Harvard University — Soft robots made of compliant materials have drawn significant attention over the past few years because of their ability to produce complex and adaptive motions through nonlinear deformation. The simplicity of their design, ease of fabrication and low cost sparked the emergence of soft robots capable of walking, crawling, camouflaging and assisting humans in grasping. In this talk, I will show that the response of these soft machines can be further enhanced by embracing instabilities. While instabilities have traditionally been avoided as they often represent mechanical failure, here we exploit them to amplify the response of soft actuators, facilitate their motion and trigger instantaneous and significant changes in shape.
Fluttering and dancing elastic rods: the dynamics of the elastica subject to follower and configurational forces* [Invited] DAVIDE BIGONI (Presenter), University of Trento, Italy — Using the elastica theory, configurational or ‘Eshelby-like’ forces will be shown to arise in elastic structures when a change in configuration is possible, with a related release of energy. Configurational forces will be shown to influence the dynamics of a falling body connected through an elastic rod to a sliding sleeve, so that a damped nonlinear oscillator results, which generates a complex motion, nicknamed ‘dancing’. Finally, the dynamics of an elastic rod in a cantilever configuration and subject to a tangential follower load of the ‘Ziegler type’ at its end (the ‘Pfluger problem’) is addressed. This structure is subject to a Hopf bifurcation, corresponding to the initiation of the ‘flutter instability’. A new experimental set-up is presented as designed, produced and tested to realize the follower load. Experiments provide the evidence of flutter and divergence instability and result in the first proof that damping sources have a destabilizing effect on the system (the so-called ‘Ziegler paradox’).

From the onset of creasing as a Kosterlitz-Thouless transition to "buckling without bending" in morphogenesis [Invited] J. M. SCHWARZ (Presenter), Physics, Syracuse University — Cusped inward folds, known as creases, form on a free surface of a soft disordered solid under compression at critical strains below that of buckling. Harnessing a model for composite elastic materials, quasi-particle excitations termed ghost shear lag fibers serve as surface stress localizers to initiate this creasing transition. The mathematics of these stress localizers maps to charges on the free surface of the solid. This mapping, combined with the presence of fluctuations due to the underlying disordered material under compression, point to the creasing transition as a Kosterlitz-Thouless transition. For the sake of contrast, a new shape-changing mechanism, termed “buckling without bending”, involving not only solid material but a proliferating fluid layer under mechanical constraints will also be presented. The implications of creasing, buckling, and “buckling without bending” for the cerebrum, the cerebellum, and brain organoids will be addressed along the way.

Interplay between elasticity and activity: from vibrated elastic particles to penetration of active particles through elastic membranes* [Invited] HARTMUT LOEWEN (Presenter), Institute of Theoretical Physics II, Heinrich-Heine University Düsseldorf —

Here we first discuss the motion of self-propelled vibrated granulates with elastic legs leading to activity [1]. While inertia is usually neglected in standard models, the significance of inertia on macroscopic self-propelled particles is experimentally demonstrated. We observe a distinct inertial delay between orientation and velocity of particles, originating from the finite relaxation times in the system. This effect is fully explained by an underdamped generalisation of the Langevin model of active Brownian motion. In stark contrast to passive systems, the inertial delay profoundly influences the long-time dynamics and enables new fundamental strategies for controlling self-propulsion in active matter.

Second, analytical and simulational results for an active particle navigating against an elastic membrane are proposed [2]. Basically there are three states:

i) penetration of the active particle through the membrane and healing of the membrane,
ii) penetration of the active particle through the membrane and destruction of the membrane,
iii) trapping of the active particle by the membrane.

TBD [Invited] L MAHADEVAN (Presenter), Harvard University — TBD
XUANJI YU (Presenter), Department of Physics, Division of Materials and Science Engineering, Boston University, Boston, MA, United States, FEI CHEN, Department of Physics, Boston University, Boston, MA, United States, CHI-HANG LAM, Department of Applied Physics, Hong Kong Polytechnic University, Hung Hom, Hong Kong, OPHELIA TSUI, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong — The dynamics of interfacial slippage of entangled polystyrene (PS) films on an adsorbed layer of polydimethylsiloxane (PDMS) on silicon was studied from the surface capillary dynamics of the films. By using PS with different molecular weights, we observed slippage of the films in the viscoelastic liquid and rubbery solid state respectively. Remarkably, all our data can be explained by the linear equation, \( J = -M \nabla P \) and a single friction coefficient, \( \xi \), where \( J \) is the unit-width current, \( M \) is mobility and \( P \) is Laplace pressure. For viscous films, \( M \) is accountable by using conventional formulism. For rubbery films, \( M \) takes on different expressions depending on whether the displacements associated with the slip velocity, \( v_s \), dominate or elastic deformations induced by \( \nabla P \) dominate. For viscoelastic liquid films, \( M \) is the sum of the mobility of the films in the viscous and rubbery states.

CATHERYN JACKSON (Presenter), Core R&D, Dow Chemical, DAVID MOSLEY, Electronics and Imaging, DuPont Co. — Chemical mechanical planarization (CMP) uses polyurethane polishing pads and highly engineered slurries to planarize, or polish, silicon wafers for semiconductor manufacturing. Friction is present as a critical aspect of this complex process, and is a function of \( \text{pH} \), isoelectric point of the slurry particles, particle concentration, pad design, and other variables. Despite the connection of friction with CMP outcomes, detailed studies of friction and polishing are lacking due to the expense and difficulty of modifying commercial equipment to make precise tribology measurements. A pin-on-disk tribology attachment for the Anton-Paar MCR-502 rheometer can simulate a commercial polisher, to condition the pad in-situ and then polish the Si wafer. We measure both friction and the z-displacement, or change in gap, at realistic downpressures (1-5 psi) and sliding velocities (up to 1 m/s), which allows careful study of lubrication mechanisms, pad wear and slurry performance. The friction and z-displacement results for water at different pH's are consistent with some mechanistic models used to represent surface and colloidal forces in these systems.

DANIEL GARCIA (Presenter), THOMAS ANGELINI, Mechanical and Aerospace Engineering, University of Florida — The material properties of soft matter systems are measured with rheometers and tensile testing instruments whenever there exist few limitations on sample volume and fixturing where samples can be prepared specifically to work with the hardware of a given instrument. By contrast, indentation methods are advantageous for measuring material properties when sample preparation and geometry are highly constrained, which is often the case with tissue samples, hydrogel coatings, or soft objects with defined shapes like contact lenses. However, many soft matter materials exhibit frequency-dependent moduli, which are challenging to account for using the simple models of Hertz and Winkler. In this talk I will review our recent work to developed a Fourier-analysis method that leverages the Kramers-Kronig relations to extract frequency dependent elastic and viscous moduli from Force-indentation curves, eliminating the challenges associated with physically oscillating contact instruments.
3:42PM H54.00005: Rate and State Dependent Friction Law Showing Convex Velocity Dependence and Vanishing Static Friction Force Derived from Microscopic Point of View.* HIROSHI MATSUKAWA (Presenter), Aoyama Gakuin University — Rate and state dependent friction law, which describe the behavior of the friction force in terms of the sliding velocity and the state variable, is well employed in the study of earthquake and so on. I derive new type of rate and state dependent friction law from microscopic point of view. It turns out that the static friction force vanishes in general. The kinetic friction force grows from zero with increasing sliding velocity. Under some condition the kinetic friction force shows maximum as a function of the sliding velocity in the steady state. The physical mechanism of these behavior of the friction force is explained. The relation with the earthquake is also discussed.

*This work was supported by JSPS KAKENHI Grant Number JP16H06478 in Scientific Research on Innovative Areas “Science of Slow Earthquakes” and JSPS KAKENHI for Scientific Research(C) Grant Number JP17K05586.

3:54PM H54.00006: Structure-Based Design of Anti-Fouling Polymer Nanocoating MAYA ENDOH (Presenter), DANIEL SALATTO, ZHIXING HUANG, MANI K SEN, Stony Brook University, YUMA MORIMITSU, Kyushu University, WEIYI LI, Stony Brook University, DAISUKE KAWAGUCHI, KEJI TANAKA, Kyushu University, YIZHI MENG, DAVID THANASSI, TADANORI KOGA, Stony Brook University — Fouling is the undesirable accumulation of a material on a wide variety of objects, such as medical devices, ship hulls, and membranes, and has now become a widespread global problem from land to ocean with both economic and environmental penalties. Here we report a radically new designed polymeric coating that is a few nanometers thick (“polymer nanocoating”) with an anti-fouling property. It is found that the anti-fouling property of this polymer nanocoating is generalizable to various homopolymer systems regardless of their hydrophilicity/hydrophobicity and their surface energy. This is attributed to the highly packed chain conformations via the self-organization process of the adsorbed polymer chains on the impenetrable solid surfaces. Furthermore, the preparation of the polymer nanocoating is a simple and versatile top-down approach based on good solvent rinsing. We hypothesized that the origin of the anti-fouling property is the highly packed conformation of polymer chains with a large number of segment/solid contacts within a two-dimensional space. This finding facilitates a simple and versatile structure-based design of an anti-fouling coating using common types of synthetic polymers.

4:06PM H54.00007: Mechanisms of Ultra-Low Wear Polymeric Solid Lubricants* [Invited] DAVID BURRIS (Presenter), Mechanical Engineering, University of Delaware — Polymeric solid lubricants can address the many limitations of more traditional lubrication systems including complexity, cost, maintenance requirements, vapor pressure, and sensitivity to environmental contamination, temperature, and composition. At present, commercially available materials have been designed based on the conventional wisdom that wear reductions require increased strength and toughness, and friction reductions require increased availability of soft/lamellar phases. Unfortunately, friction and wear reductions compete in this framework, which fundamentally limits overall tribological performance. The fundamental problem with the conventional wisdom is that it neglects to account for the transfer film, a layer of adhered debris that ultimately protects the solid lubricant from the counterface and vice versa. It is now understood that the friction and wear properties of these systems depend as much (and likely more) on the formation, properties, and stability of the transfer film as they do on the composition, structure, and properties of the solid lubricant itself. Unfortunately, the relevant transfer film properties have proven difficult to measure and the extent to which they contribute to friction and wear reduction remains unclear. In this talk, I will review some of the ultra-low wear polymeric solid lubricants we have developed and studied over the last decade, our efforts to understand the attributes of and specific roles played by the transfer film, and how we have applied these insights to a more useful materials design framework that prioritizes the properties and stability of the transfer film.

*The authors gratefully acknowledges support from the the Air Force Office of Scientific Research (FA9550-10-1–0295) and the National Science Foundation Graduate Research Fellowship (1247394)
Poroeleastic sliding of thin grafted hydrogel layers  JESSICA DELAVOIPiÈRE, YVETTE TRAN, SIMM, ESPCI, BERTRAND HERTEUFEU, Saint Gobain Research Paris, EMILIE VERNEUIL, SIMM, ESPCI, CHUNG YUEN HUI, School of Mechanical and Aerospace Engineering, Cornell University, ANTOINE CHATEAUMINOIS (Presenter), SIMM, ESPCI — We investigate the sliding friction of thin (µm), water swollen, hydrogel layers grafted onto glass substrate with an emphasis on the contribution to friction of stress-induced poroelastic drainage of the hydrogel network. Friction experiments using poly(dimethylacrylamide) hydrogels films are carried out with the contact immersed in water. In addition to friction force measurements, an optical set-up allows imaging the contact. The velocity-dependence of friction force $F_t$ and contact shape is found to be controlled by a Péclet number $Pe$ corresponding to the ratio of advective (sliding) to diffusive components (fluid drainage). When $Pe<1$, the equilibrium circular contact achieved under normal indentation remains unchanged during sliding. Conversely, for $Pe>1$, a decrease in the contact area is observed together with the development of a contact asymmetry when velocity is increased. These findings are discussed in the light of a poroelastic model based on a thin film approximation. This model indicates that changes in contact geometry are due to the development of a pore pressure imbalance when $Pe>1$. An order of magnitude estimate of $F_t$ and its dependence on normal load and velocity is provided under the assumption that most of frictional energy is dissipated by poroelastic flow.

Time-dependent friction and polymer dynamics in hydrogel surface contacts*  NICHOLAS L CUCCIA, SURAJ POTHINENI, JUSTIN BURTON (Presenter), Emory University — Hydrogels are composed of a sparse, crosslinked polymer matrix infused with water. They can be found in a multitude of biological settings, from cell nuclei to cartilage, and are used in many industrial applications. However, their material properties are not well-understood due to their heterogenous nature. Here we investigate the interfacial rheology of both polyacrylamide and agarose hydrogels using a custom, low-force pin-on-disc tribometer under a variety of environmental conditions. Under a constant normal load, these hydrogels exhibit a dynamic frictional transition characterized by a precipitous drop in the friction coefficient at a critical velocity. Within a range of speeds near this dynamic frictional transition, transient behavior can be observed. Upon increasing the speed, the coefficient of friction decreases exponentially, with a characteristic decay time of order 5-10 minutes. Surprisingly, a cessation of sliding results in a much more rapid recovery of the friction coefficient, suggesting that nonlinear processes control these timescales. We will show how this transition can be tuned by varying the liquid salt concentration, liquid viscosity, and sliding geometry.

Granular charging at a distance*  TROY SHINBROT (Presenter), Biomedical Engineering, Rutgers University, New Brunswick, BEHROOZ FERDOWSI, Geosciences, Princeton University, SANKARAN SUNDARESAN, Chemical and Biological Engineering, Princeton University, NUNO ARAUJO, Faculdade de Ciências, Universidade de Lisboa — Contact charging of granular materials can play a dominant role in effects as varied as lightning in sandstorms, the formation of extraterrestrial planetesimals, and segregation of pharmaceutical powders. Yet the physics underlying this charging is exceptionally poorly understood. For example we have no clear theory for how insulating grains recruit enough charge carriers to deposit charge but not enough to discharge. In this talk, we note that charging and discharging kinetics may be distinct, and from this observation we develop a mathematical model. The model surprisingly predicts that charging can decrease as contact frequency increases. We confirm this prediction experimentally in a vibrated bed and propose future steps.

Session H55 GSNP: The Subtle Road to Equilibrium -- or Not?  BCEC 254B - David Campbell, Boston Univ -

Tag(s): Focus
2:30PM H55.00001: The subtle road to equilibrium - or not?* [Invited] CARLO DANIELI (Presenter), MITHUN THUDIYANGAL, YAGMUR KATI, Center for Theoretical Physics for Complex Systems, Institute for Basic Science, DAVID K CAMPBELL, Boston University, SERGEJ FLACH, Center for Theoretical Physics for Complex Systems, Institute for Basic Science — The influence that deviations from equilibrium have on the ergodic equipartitioned dynamics of classical and quantum systems has been widely investigated in the recent years. Classically, systems of many interacting bodies are typically chaotic, and their microcanonical dynamics ensures that time averages and phase space averages are identical, in agreement with the assumption of ergodicity. In proximity to an integrable limit the properties of the network of nonintegrable action space perturbations help decide whether i) ergodization time scales stay on the order of the Lyapunov times, or whether ii) the system fragments into regular regions - formed by coherent localized excitations with anomalously large lifetimes - and chaotic parts. In this latter case, the ergodization time scales overgrows the Lyapunov times, and the system enters a dynamical glass (DG) phase at a finite distance to the integrable limit. We use a set of observables which turn into conserved quantities in the integrable limit to quantify the properties of the DG phase. A sectioning of a typical trajectory by equilibrium Poincare manifolds detects the coherent excitations, whose statistics signals the onset of the DG phase since they control the ergodization time scales of the systems. We forecast that our studies may be successfully extended to quantum models, where the DG phase could consist into a prelude of the MBL phase.

*The author acknowledges financial support from IBS (Project Code No. IBS-R024-D1)

3:06PM H55.00002: Lyapunov exponents, ergodization time and out-of-time-order correlators in chaotic many-particle systems from Loschmidt echoes* ANDREI TARKHOV (Presenter), Center for Photonics and Quantum Materials, Skolkovo Institute of Science and Technology, SANDRO MARCEL WIMBERGER, Dipartimento di Scienze Matematiche, Fisiche e Informatiche, Università di Parma, BORIS V. FINE, Center for Photonics and Quantum Materials, Skolkovo Institute of Science and Technology — We propose an experimentally realizable method to demonstrate Lyapunov instability and to estimate ergodization time in chaotic many-particle systems by monitoring equilibrium noise of virtually any observable quantity before and after time reversal of dynamics (Loschmidt echo). In the quantum regime, the quantity of interest for the method is a counterpart of out-of-time-order correlators (OTOCs). The ergodization time is defined as the characteristic time required to extract the largest Lyapunov exponent from a system's dynamics. The proposal focuses specifically on a lattice of coupled Bose-Einstein condensates in the classical regime describable by the discrete Gross-Pitaevskii equation. We support our theoretical analysis by direct numerical simulations demonstrating that the largest Lyapunov exponent and the ergodization time can indeed be extracted from the Loschmidt echo routine.

3:18PM H55.00003: Quantum versus classical thermalization in many-body isolated systems* FELIX IZRAILEV (Presenter), Benemerita Universidad Autonoma de Puebla — In view of recent studies of the thermalization occurring in many-body isolated systems, we discuss the onset of relaxation towards a steady-state equilibrium, paying main attention to the systems with finite number of interacting particles. We have found that in the models of randomly interacting fermions and bosons, the effective number of components in the wave packets increases exponentially in time, provided the eigenstates are strongly chaotic in the Hilbert space defined by non-interacting particles. Our semi-analytical approach allows one to obtain the estimates for the rate of this increase and for the characteristic time of the saturation which can be considered as the time for a complete thermalization. Special interest has been payed to the correlations between occupation numbers, that increase in time during the scrambling of wave packets in Hilbert space. These correlations are responsible for the onset of the Bose-Einstein and Fermi-Dirac distributions. We discuss the relevance of the exponentially fast quantum dynamics to the Kolmogorov-Sinai entropy characterizing degree of chaos in the corresponding classical systems.

3:30PM H55.00004: Behavior and Breakdown of Higher-Order Fermi-Pasta-Ulam-Tsingou Recurrences*  

SALVATORE PACE (Presenter), DAVID K CAMPBELL, Boston University — We investigate numerically the existence and stability of higher-order recurrences (HoRs), including super-recurrences, super-super-recurrences, etc., in the alpha and beta Fermi-Pasta-Ulam-Tsingou (FPUT) lattices for initial conditions in the fundamental normal mode. Our results represent a considerable extension of the pioneering work of Tuck and Menzel on super-recurrences. For fixed lattice sizes, we observe and study apparent singularities in the periods of these HoRs, speculated to be caused by nonlinear resonances. These singularities depend very sensitively on the initial energy. We compare the mechanisms by which the super-recurrences in the two model's breakdown as the initial energy and respective nonlinear parameters are increased. The breakdown of super-recurrences in the beta-FPUT lattice is associated with the destruction of the so-called metastable state and hence is associated with relaxation towards equilibrium. For the alpha-FPUT lattice, we find this is not the case and show that the super-recurrences break down while the lattice is still metastable. We close with comments on the generality of our results for different lattice sizes.

3:42PM H55.00005: Aperiodically driven integrable systems and their emergent steady states  

DIPTIMAN SEN (Presenter), Indian Institute of Science, SOURAV NANDY, ARNAB SEN, Indian Association for the Cultivation of Science — For periodically driven closed quantum many-body systems, it is known that the local properties of the system eventually synchronize with the drive and can be described by an appropriate periodic Gibbs ensemble. We have studied what happens in a class of integrable systems if they are driven aperiodically. We show that the resulting unitary dynamics leads to new emergent steady states in at least three cases. A random noise causes eventual heating to an infinite temperature ensemble for all local properties. A driving which is self-similar in time leads to an entirely different steady state which we call the ´geometric generalized Gibbs ensemble'. Finally, a quasiperiodic driving which follows the Fibonacci sequence can lead to steady states which are not described by either a periodic Gibbs ensemble or an infinite temperature ensemble. To understand the approach to the steady state, we study the time evolution of certain coarse-grained quantities in momentum space that fully determine the reduced density matrices for subsystems whose sizes are much smaller than the full system. Such quantities provide a concise description for any drive protocol in integrable systems that are reducible to a free-fermion representation.

3:54PM H55.00006: Dynamical Glass Phase and Ergodization Times in Josephson Junction Chains*  

MITHUN THUDIYANGAL (Presenter), CARLO DANIELI, YAGMUR KATI, SERGEJ FLACH, Center for Theoretical Physics of Complex Systems, Institute for Basic Science, Daejeon 34051, Korea — Models of Josephson junction chains turn integrable in the limit of large energy densities or small Josephson energies. Close to these limits the Josephson coupling between the superconducting grains induces a short range nonintegrable network. We compute distributions of finite time averages of grain charges and extract the ergodization time $T_E$ which controls their convergence to ergodic $\delta$-distributions. We relate $T_E$ to the statistics of fluctuation times of the charges, which are dominated by fat tails. $T_E$ is growing anomalously fast upon approaching the integrable limit, as compared to the Lyapunov time $T_\Lambda$ - the inverse of the largest Lyapunov exponent - reaching astonishing ratios $T_E/T_\Lambda \geq 10^8$. The microscopic reason for the observed dynamical glass phase is routed in a growing number of grains evolving over long times in a regular almost integrable fashion due to the low probability of resonant interactions with the nearest neighbors. We conjecture that the observed dynamical glass phase is a generic property of Josephson junction networks irrespective of their space dimensionality.

4:06PM H55.00007: Non-Gibbs states on a Bose-Hubbard Lattice*  ALEXANDER CHERNY, Laboratory of Theoretical Physics, Joint Institute for Nuclear Research, THOMAS ENGL, SERGEI FLACH (Presenter), Center for Theoretical Physics of Complex Systems, Institute for Basic Science — We study the equilibrium properties of the repulsive quantum Bose-Hubbard model at high temperatures in arbitrary dimensions, with and without disorder. In its microcanonical setting the model conserves energy and particle number. The microcanonical dynamics is characterized by a pair of two densities: energy density $\varepsilon$ and particle number density $n$. The macrocanonical Gibbs distribution also depends on two parameters: the inverse nonnegative temperature $\beta$ and the chemical potential $\mu$. We prove the existence of non-Gibbs states, that is, pairs $(\varepsilon, n)$ which can not be mapped onto $(\beta, \mu)$. The separation line in the density control parameter space between Gibbs and non-Gibbs states $\varepsilon \sim n^2$ corresponds to infinite temperature $\beta = 0$. The non-Gibbs phase can not be cured into a Gibbs one within the standard Gibbs formalism using negative temperatures.

4:18PM H55.00008: Probing the mobility edge in an interacting model using MPS* NICHOLAS POMATA (Presenter), Stony Brook University, SRIRAM GANESHAN, Physics, The City College of New York, TZU-CHIEH WEI, Stony Brook University — The quasiperiodic Generalized Aubry-André model is known to exhibit a mobility edge in the noninteracting limit for a certain range of disorder strengths. However, there is not much known about the interacting version of the model. We use the Shift-Invert Matrix Product State method of Yu, Pekker, and Clark to study this system with sizes from 32 to 128 sites, computing excited states for different disorder realizations (produced by varying the phase in the quasiperiodic potentials). Our goal is to determine where many-body localized states are absent or present, starting from the single-particle mobility edge.

4:30PM H55.00009: Effective ergodicity breaking phase transition in a driven-dissipative system* SAKIB MATIN (Presenter), HARVEY GOULD, W. KLEIN, Boston University — The growing interest in non-equilibrium systems has prompted question of what equilibrium methods can be extended to non-equilibrium systems. We discuss a non-equilibrium phase transition in the Olami-Feder-Christensen model that is characterized by critical exponents which obey scaling laws from equilibrium statistical mechanics. Below the critical noise, the sites are trapped in different limit cycles. The probability distributions of different trajectories are distinct and highlight the non-ergodic nature of the phase. Above the critical noise all sites converge to the same time average and the system is effectively ergodic. We use tools from the study of glassy systems and nonlinear dynamics to illuminate various properties of this non-equilibrium phase transition. Our results show a promising start to extending the methods of equilibrium statistical mechanics to a new class of non-equilibrium systems.

4:42PM H55.00010: Investigating many-body mobility edges in isolated quantum systems* XING BO WEI, Department of Physics, Zhejiang Normal University, CHEN CHENG, Beijing Computational Science Research Center, GAO XIANLONG, Department of Physics, Zhejiang Normal University, RUBEM MONDAINI (Presenter), Beijing Computational Science Research Center — The existence of many-body mobility edges in closed quantum systems has been the focus of intense debate after the emergence of the description of the many-body localization phenomenon. Here we propose that this issue can be settled in experiments by investigating the time evolution of local degrees of freedom, tailored for specific energies and intial states. An interacting model of spinless fermions with exponentially long-ranged tunneling amplitudes, whose non-interacting version known to display single-particle mobility edges, is used as the starting point upon which nearest-neighbor interactions are included. We verify the manifestation of many-body mobility edges by using numerous probes, directly comparing it with the predictions of the Eigenstate Thermalization Hypothesis (ETH). Our results indicate the coexistence of regions with finite measure when approaching the thermodynamic limit where thermalization and localization are manifest, suggesting that one cannot explain their appearance as merely being a result of finite-size effects.

Rogue Fluctuations in Fermi-Pasta-Ulam-Tsingou Systems

SURAJIT SEN (Presenter), RAHUL KASHYAP, University at Buffalo, The State University of New York — Rogue waves, also referred to as freak waves, are large, short lived waves in the oceans and have been the subject of intense research due to their destructive nature. We consider discrete strongly nonlinear systems with Fermi-Pasta-Ulam-Tsingou type potentials by means of extensive simulations. We define rogue fluctuations in these systems as large and persistent kinetic energy fluctuations with finite lifetimes in these systems at late enough times. Our simulations suggest that rogue fluctuations are generic to strongly nonlinear systems. We also observe from our simulations that rogue fluctuations show features which are reminiscent of rogue waves in the oceans, providing evidence that they are natural candidates for analogs of rogue waves in discrete systems [1]. Effects arising from the presence of phonons in these systems are also explored.

Quantum coherence in the ergodic and many-body localized phase

SAYANDIP DHARA (Presenter), University of Central Florida, ALIOSCIA HAMMA, Physics, University of Massachusetts - Boston, EDUARDO R MUCCIOLO, University of Central Florida — We use quantum coherence as a tool to study the structure of the eigenstates of disordered and interacting quantum many body systems. In particular, we numerically calculate several different measures of quantum coherence for the excited eigenstates to be able to capture the signatures of the ergodic and the many-body localized phase in these finite systems. It is apparent that the different measures of coherence show different behaviour with the increasing disorder strength. We also investigate how the unitary evolution affects quantum coherence in several disordered spin chains. Starting from a maximal coherent state in the computational basis, we study the dynamics of decoherence in both the ergodic and the many-body localized phase. We show that coherence can capture many important features of quantum dynamical phases and offers important computational advantages.
Laboratory rivers*  [Invited]  OLIVIER DEVAUCHELLE (Presenter), ANAIS ABRAMIAN, Institut de physique du globe de Paris, GREGOIRE SEIZILLES, Nexicap Partners, PAULINE DELORME, Department of Geography and Environment, University of Southampton, ERIC LAJEUNESSE, FRANCOIS METIVIER, LAURIE BARRIER, Institut de physique du globe de Paris — Alluvial rivers transport sediment, and build their own bed out of it. The flow entrains superficial grains of sediment and deposit them downstream, thus deforming the channel that confines it. This fluid-structure coupling generates ripples, dunes, bars and meanders through various instabilities. It also selects a river's size and slope.

To entrain a sediment grain, the flow-induced shear stress must overcome its weight. This threshold, typical of granular materials, sets the characteristic size of alluvial rivers. Beyond this threshold, however, a river needs to balance the cross-stream fluxes of sediment to maintain its bed. Unfortunately, these fluxes are barely accessible to field measurements.

Creating small rivers in laboratory experiments is an old idea, but only now can we track thousands of individual grains, as they travel downstream, to reveal the statistics of sediment transport, and their consequences on a river's shape.

In a laminar flume, we find that the roughness of the bed causes the traveling particles to roam across its surface. This random walk induces a Fickian flux which tends to homogenize the transport of sediment. Meanwhile, the bed assumes a convex shape which brings the traveling grains near its center. As a result, the sediment flux distributes itself in this self-organized potential well according to Maxwell-Boltzman statistics.

The same mechanism allows laboratory rivers to adjust their cross-section and their width to the sediment discharge: they widen and shallow to accommodate a larger input. Beyond a critical sediment discharge, however, a river destabilizes into a braid of intertwined channels. We suggest that a new instability, driven by bedload diffusion, might explain this transition.

Finally, we look for the expression of these dynamics in large sedimentary structures deposited by rivers: alluvial fans.

Fluid-Fluid Displacement Patterns in Microfluidic Analogues of Rough Fractures with Controlled Roughness  YU QIU (Presenter), KE XU, AMIR PAHLAVAN, RUBEN JUANES, Civil and Environmental Engineering, Massachusetts Institute of Technology — We report results of immiscible fluid-fluid displacement experiments on 3D-printed artificial fractures with controlled roughness. Our fracture analogue consists of a microfluidic cell with an irregular post pattern and a "free gap" between the top of the posts and the flat surface. We inject a low-viscosity nonwetting fluid to displace a more viscous wetting fluid and observe a transition from porous media flow to flow between parallel plates as a function of free-gap height. When the free gap is smaller than or comparable to the post height, the drainage pattern is similar to that in a 2D porous micromodel. In contrast, when the free gap is significantly larger than the post height, drainage in the gap dominates, and the displacement pattern is controlled by the capillary number. At high Ca, a film of the defending phase is left on the rough surface behind the front; this film then redistributes and forms discrete wetting clusters. At low Ca, the invading fluid occupies the full height of the free gap, with little wetting phase trapped even under unfavorable viscosity ratio. Our observations point to the mechanistic interplay of roughness and capillarity on trapping of the wetting phase in a rough fracture, a process that significantly affects its multiphase-flow properties.

Erosion of unconsolidated beds by turbidity currents  THOMAS HALSEY (Presenter), ExxonMobil Upstream Research Co — Turbidity currents are gravity flows of fluids with suspended, denser sediment, which remains aloft due to turbulence generated by the current motion itself. To remain active, turbidity currents must have an ability to entrain material from their base to counteract the sedimentation of particles from the current to the base. A number of decades ago, Bagnold, Engelund, and Fredsøe proposed a physical picture for erosion as a function of the overall velocity of the turbidity current (bed stress). Recently, it has been argued that the high-velocity form of this law is critical in determining the overall mechanics of turbidity currents, particularly their predilection to erode or deposit sediment in different locations. I re-examine the Bagnold-Engelund-Fredsøe picture, and determines the corresponding erosion law in a way that is consistent with turbidity current mechanics, and has a high-velocity plateau that determines the qualitative features of turbidity current deposition and erosion. This overall picture implies that the mixing of sediment from the boundary layer near the underlying bed with the overall current-suspended sediment will be the rate-limiting step in erosion.
Characteristic lengths of stream networks in porous terrain

ERIC STANSIFER (Presenter), MIT, OLIVIER DEVAUCHELLE, IPGP, DANIEL ROTHMAN, MIT — The conditions for sediment transport of particles in streams has previously been found to give a relationship between the stream's slope and flux. Using this relationship, we establish a lower bound on the size of features in a stream network. Tributaries that violate this lower bound do not receive groundwater and dry up. This technique also gives bounds on a network's drainage density, which is its total length divided by the area it drains; this is the inverse of a characteristic length. These bounds obey scaling laws with respect to physical constants that describe the hydrological environment of the network, such as grain size, porosity, and water table depth, and we observe the effects of these scaling laws in a real-world network.

Channelling and branching in frangible porous media*

DAVID FRONK, NICHOLAS DERR, Harvard University, AMALA MAHADEVAN, Woods Hole Oceanographic Institution, CHRISTOPHER RYRCROFT, LAKSHMINARAYANAN MAHADEVAN (Presenter), Harvard University — Fluid flowing through a fragile porous medium can cause channels to form due to erosion. We write down an effective theory for the process in terms of a multiphase flow model that couples a Darcy equation with a dynamical permeability to a dynamical equation for the rate of erosion. Solving the problem numerically shows that the appearance of tree-like branches as well as channels depending on the boundary conditions, and the rate of flow change at the boundary. Adding deposition and evaporation to the model leads to patterns similar to vascularization in tissues and suggests ways to engineer soft materials to self organize into biomimetic patterns.

Fingering Instability in Granular Suspension Injected into Thin Fractures*

RAUSAN JEWEL (Presenter), RAM SUDHIR SHARMA, ARSHAD KUDROLLI, Clark University — We discuss observation of a fingering instability when granular beads suspended in a liquid, with the same mass density, are injected into a fracture in the form of a Hele-Shaw cell filled with a similar wetting fluid. When the suspension is injected from a point into the cell, with the same density fluid, we find that the suspension spreads uniformly with a smooth circular front, with an expansion rate proportional to the injection rate. In contrast, when the density of the injected fluid and the interstitial fluid are even slightly different, we find that fingers form when the granular suspension is injected, and as the front spreads above a critical radius. We demonstrate that only the density difference is important, and the patterns form with both higher and lower density interstitial fluid. We will discuss the evolution of the fingers as a function of injection rate and the volume fraction of the beads, and contrast with the Saffman-Taylor instability observed when a less viscous fluid is injected into a more viscous fluid.

Self-organized compaction fronts in cyclically-sheared sinking grains*

JIKAII WANG (Presenter), J. M. SCHWARZ, JOSEPH D PAULSEN, Syracuse University — Suspension that are sheared cyclically at small amplitude can enter an absorbing steady state where the particles return to their initial positions after each cycle. However, much less is known about the transient dynamics leading up to this reversible steady state. We perform simulations of sheared non-Brownian suspensions where the particles are also sinking under gravity at low speed. We observe a rising front between two regions of different particle area fractions that propagates at constant velocity. Although the suspension is relatively dilute, the front has a sigmoidal shape that is similar to the profile of a dynamic jamming front [1]. Surprisingly, the width of the front is independent of the effective diffusion constant for colliding particles, and depends only on the area fractions of the two regions. To understand our findings, we look for front-like solutions in a set of coupled nonlinear PDEs describing our simulations in the continuum limit. This approach should elucidate the potential for compaction front dynamics in related systems.

4:30PM H56.00009: Pattern formation in partially wet granular materials* ANDREAS ZIPPELIUS (Presenter), KAI HUANG, Experimentalphysik V, University of Bayreuth — From sand dunes to Faraday heaping, driven granular matter, i.e., large agglomeration of macroscopic particles, is rich pattern forming system. When a granular material is partially wet (e.g., wet sand on the beach), a different pattern forming scenario arises due to the cohesive particle-particle interactions: Kink-wave fronts were found to be the dominating pattern. Here, we focus on the formation of density-wave fronts in a driven wet granular layer undergoing intermittent gas-liquid-like transition. Fronts, which are curved into a spiral shape, propagate coherently along the circular rim of the container with leading edges. They are stable beyond a critical distance from the container center. Based on the measurement of the critical distance and the rotation frequency, we propose a model for the pattern formation by considering the competition between the time scale for the collapse of cohesive particles and that of the energy injection resisting this process. Possible connections of this pattern to galaxy formation as well as to traffic jam will be discussed.

4:42PM H56.00010: DEM modeling of coupled multiphase flow and granular mechanics: wettability control on fracture patterns YUE MENG (Presenter), BAUYRZHAN PRIMKULOV, Civil and environmental engineering, Massachusetts Institute of Technology, ZHIBING YANG, School of water resources and hydropower engineering, Wuhan University, FIONA KWOK, Civil and environmental engineering, University of Hong Kong, RUBEN JUANES, Civil and environmental engineering, Massachusetts Institute of Technology — As one of the factors that influences multiphase flow in porous media, wettability has been studied for decades, yet many fundamental questions remain. In a recent experimental study, the impact of wettability on the fluid-fluid displacement pattern in a deformable granular pack was investigated. The experiments show the emergence of fracture of the granular pack under certain conditions of injection rate and confining stress. They also show that changes in wettability lead to striking differences in the fracture network morphology. Here we use discrete element modeling (DEM) to provide insight into the mechanisms underpinning these experimental results. We first develop a 2D model with single-phase flow, and validate it against results from fluid-driven deformation of a confined monolayer of hydrogel particles [MacMinn et al., PRX 2015]. To study two-phase flow, we couple a dynamic pore-scale network description of fluid-fluid displacement with a DEM model of the mechanical deformation of the skeleton of solid grains. This modeling approach allows us to capture the effects of varying wettability on the fracture pattern, thereby offering a grain-scale mechanistic understanding of the fracturing process.

Session H58 GSOFT: Emulsions and Foams BCEC 257A - Rodrigo Guerra, New York University

2:30PM H58.00001: Faceted liquid droplets: when colloids are attracted by topological defects* SHIR LIBER (Presenter), ALEXANDER V. BUTENKO, ELI SLOUTSKIN, Physics, Physics Department and Institute of Nanotechnology & Advanced Materials, Bar-Ilan University, Ramat-Gan 5290002, Israel — Particles at disordered droplet interfaces were extensively investigated, aiming both at their fundamental physics and at their applications in particle-stabilized pharmaceuticals and aerosols. Yet, particles residing at the ubiquitous ordered interfaces have never been studied.

We study the dynamics of tracer colloids, incorporated into a curved 2nm-thick crystal, forming at $T=T_s=26$ °C at the interface of liquid oil-in-water emulsion droplets. We demonstrate the particles to be spontaneously dragged to particular surface locations, identified with topological defects within the crystalline structure. At $T=T_d<T_s$ the droplets undergo an unprecedented sphere-to-icosahedron shape transformation, with their bulk remaining liquid. At $T_d$, the attractors self-position onto the vertices of the icosahedra and fix there the colloids’ positions. At an even lower temperature, the particles are spontaneously expelled from the droplets. These phenomena allow functional liquid “atoms” to be designed, with their “valency” fixed by precise temperature-tuned positioning of the interfacial ligands, en route to supra-“atomic” nano-structures. Our observations also impact upon the understanding of protein positioning on cell membranes, controlling essential biological functions.

*ISF #1779/17
2:42PM H58.00002: Adsorption of Anionic Nanoparticles at Oil-water Interfaces Driven by Ion Partitioning*  
ROBERT KEANE (Presenter), WEI HONG, WEI HE, ROBBIE BANCROFT, SAM TEALE, ANTHONY DINSMORE, Physics, University of Massachusetts, Amherst — Adsorption of particles at oil-water interfaces is the basis of Pickering emulsions, which are common in nature and industry. For anionic particles, however, the negative potential at the water-oil interface inhibits spontaneous adsorption, which limits the scope of useful materials. Here we address this problem by adding ions that selectively partition in the two phases, thereby changing the interfacial potential and driving anionic particle adsorption. We add oil-soluble tetrabutyl ammonium perchlorate (TBAP) to the nonpolar phase and Ludox silica nanoparticles to the aqueous phase. We find a threshold TBAP concentration, above which emulsions are stable for months. This threshold increases with particle concentration and with the oil's dielectric constant. Adding salt to the water raises the threshold and causes spontaneous coalescence. The results are consistent with a model based on Poisson-Boltzmann theory, which predicts that TBAP anions (ClO_4^-) migrate into the water phase and leave behind a net positive charge in the oil. Our results clarify the role of interfacial electrostatics and show how a large class of inorganic anionic nanoparticles can be used to stabilize emulsions.

2:54PM H58.00003: Domain, nanoridge and mesa growth kinetics in stratifying foam films*  
VIVEK SHARMA (Presenter), YIRAN ZHANG, SUBINUER YILIXIATI, CHRYSTIAN OCHOA, CHENXIAN XU, University of Illinois at Chicago — Ultrathin films exhibit stratification due to confinement-induced structuring and layering of small molecules in simple fluids, and of supramolecular structures like micelles, lipid layers and nanoparticles in complex fluids. Stratification proceeds by the formation and growth of thinner domains at the expense of surrounding thicker film, and results in formation of nanoscopic terraces and mesas within a film. The detailed mechanisms underlying stratification are still under debate, and are resolved in this contribution by addressing long-standing experimental and theoretical challenges. Thickness variations in stratifying films are visualized and analyzed using interferometry, digital imaging and optical microscopy (IDIOM) protocols, with unprecedented high spatial (thickness < 100 nm, lateral ~500 nm) and temporal resolution (< 1 ms). Using IDIOM protocols we developed recently, we characterize the shape and the growth dynamics of nanoridges and mesas that flank the expanding domains in micellar thin films. We show that topographical changes including nanoridge & mesa growth, and the overall stratification dynamics, can be described quantitatively by nonlinear thin film equation, amended with supramolecular oscillatory surface forces.

*NSF CBET 1806011

3:06PM H58.00004: Iridescent clusters and marginal regeneration in vertical soap films*  
ERICA LI (Presenter), CHENXIAN XU, ELIZABETH JOHN, CHRYSTIAN OCHOA, VIVEK SHARMA, University of Illinois at Chicago — Liquid foams consist of bubbles separated by thin films. Individual films consist of two surfactant-laden surfaces that are ~ 5 nm - 10 micron apart. Sandwiched between these interfacial layers is a fluid that drains primarily under the influence of gravitational, viscous and interfacial forces, including disjoining pressure. Understanding and controlling the drainage kinetics of thin films is an important problem that underlies the stability, lifetime and rheology of foams and emulsions. We experimentally follow the drainage kinetics of foam films using imaging, color science and cluster imaging velocimetry. Interference between light reflected from two surfactant-laden surfaces that are ~ 100 nm - 10 micron apart leads to thickness-dependent iridescent colors in the visible region. Below 50 nm the thin films appear as black. In this study we characterize, track and analyze the motion of thick and thin regions that travel under combined influence of gravity, buoyancy and due to advection by capillary-driven flows. In particular, we study the origin of marginal regeneration, i.e. the complex flow patterns that originate near the borders of foam films.

*NSF CBET 1806011
3:30PM H58.00006: Phase behavior and structure of sodium naphthenate micelles  SHANG GAO (Presenter), Chemical and Biomolecular Engineering, University of California, Los Angeles, SAMANVAYA SRIVASTAVA, Chemical and Biomolecular Engineering, University of California at Los Angeles, VIVEK SHARMA, Chemical Engineering, University of Illinois at Chicago — The formation and stability of petroleum foams and emulsions can sometimes be attributed to sodium naphthenates surfactants. However, relatively little information is available about the sizes and shapes of self-assembled structures formed by sodium naphthenates, limiting our ability to control foam or emulsion stability and the success of sequestration or extraction processes. In this study, we develop a comprehensive understanding of the phase behavior of sodium naphthenate micelles (including size, shape and inter-micellar interactions) through a combination of static and dynamic scattering measurements. Small-angle X-ray scattering (SAXS) measurements revealed intriguing trends – micelle shape and size varied with increasing surfactant concentrations in the dilute (<5 wt%) limit. At higher concentrations (5 wt% – 40 wt%), while the micelle shapes and sizes remained largely invariant, inter-micellar interactions became increasingly significant, leading to stronger structure factor contributions to scattering intensities. These concentration-dependent trends are contrasted against trends in hydrodynamic size and zeta-potential of the micelles from dynamic light scattering measurements, as well as stratification kinetics of foams containing sodium naphthenate micelles.

3:42PM H58.00007: Rheology and structure of macro- and nano-emulsions with adhesive droplets*  NEDA SANATKARAN, REZA FOUDAHI (Presenter), Chemical and Materials Engineering, New Mexico State University — In this work, we investigate the viscoelastic and flow properties of oil-in-water nanoemulsions to verify rheological scaling models of macroemulsion systems. Emulsions were prepared using silicone oil with different average droplet sizes (ranging from 1 μm to below 100 nm) dispersed in sodium dodecyl sulfate solution above the critical micelle concentration. Droplet size distributions were narrow and remained unchanged for all the samples. Viscoelastic responses and yielding of emulsions were examined as a function of dispersed phase volume fractions (35 – 65 %) for each of the droplet sizes. The range of volume fractions for the samples was obtained via an evaporation-dilution technique. We elucidate the experimental result using the theoretical models for interdroplet interactions. The scaling of rheological properties with Laplace pressures becomes invalid in the nanoemulsion regime. The liquid, gel, and glass states are investigated based on the elastic modulus, yield stress and yield strain of studied adhesive emulsions.

*We would like to thank ACS PRF (55725-DNI7) for funding and NSF award #1438584 that made the purchase of the rheometer possible.

3:54PM H58.00008: Formation, growth and coalescence of nanoscopic mesas in stratifying foam films*  CHENXIAN XU (Presenter), SUBINUER YILXIATI, YIRAN ZHANG, VIVEK SHARMA, University of Illinois at Chicago — Ultrathin micellar foam films exhibit stratification due to confinement-induced structuring and layering of micelles. Stratification proceeds by the formation and growth of thinner domains at the expense of surrounding thicker film, and flows and instabilities drive the formation of nanoscopic terraces, ridges and mesas within a film. The detailed mechanisms underlying stratification are still under debate, and are resolved in this contribution by addressing long-standing experimental and theoretical challenges. Thickness variations in stratifying films are visualized and analyzed using interferometry, digital imaging and optical microscopy (IDIOM) protocols, with unprecedented high spatial (thickness < 100 nm, lateral ~500 nm) and temporal resolution (< 1 ms). Using IDIOM protocols we developed recently, we characterize the shape and the growth dynamics of mesas that flank the expanding domains in micellar thin films, and we track their evolution, as well as coalescence dynamics.

*NSF CBET 1806011
4:06PM H58.00009: Foam formation analysis during drainage of a surfactant solution* NICOLLE DE LIMA (Presenter), Mechanical Engineering, Pontificial Catholic University of Rio de Janeiro, SHIMA PARSA, Physics and Applied Physics, Harvard University, MARCIO CARVALHO, Mechanical Engineering, Pontifical Catholic University of Rio de Janeiro — Foam is widely used in oil recovery operations to maximize oil production, and solve problems caused by either a thief zone or gravity override. Foam, that can be pre-formed and injected in the reservoir or produced in-situ through the pore space, fills the high permeability areas known as thief zones and divert the displacing fluid into the direction of trapped oil, reducing the relative permeability of gas and leading to a more stable flood front. The presence of liquid lamellae between gas bubbles in the foam also reduces the gas mobility, by the increase of the gas apparent viscosity. The flow mobility is a function of the pore geometry and foam properties. However, the dynamics of foam in a porous media is not fully understood due to its complexity. The goal of this research is to study foam formation during drainage of a two-dimensional porous media glass model by visualizing the pore scale displacement flow of a surfactant solution by injected gas. A microfluidic setup composed of glass micromodel, syringe pump, pressure transducer, and a microscope is used to study the evolution of the phase distribution and foam characteristics as a function of pore space geometry and flow conditions through image processing.

4:18PM H58.00010: Capillary imbibition of emulsions in thin rectangular channels MASOUD NOROUZI DARABAD (Presenter), SAMIRA ABEDI, SIVA A VANAPALLI, MARK W VAUGHN, Chemical Engineering, Texas Tech University, Lubbock, TX — Emulsions imbibing in a capillary under transient surface-tension driven flow display an unexpected richness in droplet interactions, clustering and ordering. Droplet size and concentration effects on the droplet interactions of monodisperse oil-in-water emulsions are demonstrated by use of a thin channel to form a pseudo 2-dimensional flow. We categorize droplet-droplet and cluster-cluster interactions at the microscale and find markedly different behavior in ordering, relative phase velocity and droplet-induced interface perturbation depending on concentration and the relative size of the droplets compared to the channel height.

4:30PM H58.00011: Spinning and chaining emulsion droplets in ultrasonic standing waves* MOHAMMED ABDELAZIZ (Presenter), JAIRO A DIAZ, DAVID GRIER, Center for Soft Matter Research, New York University, MAURICIO HOYOS, Laboratoire de Physique et Mécanique des Milieux Hétérogènes, ESPCI Paris — We demonstrate experimentally that emulsion droplets of TPM (3-(trimethoxysilyl)propyl methacrylate) in water spin when levitated in ultrasound, and that the spinning droplets organize themselves into long spinning chains. When the same droplets are solidified into spheres by free-radical polymerization, they no longer spin, and they form crystals rather than chains. We explain these acoustokinetic phenomena through a dipole-order expansion of the incident and scattered waves, by analogy to the theory of optical trapping.

*This work was supported by the Materials Research Science and Engineering Center program of the National Science Foundation through award number DMR-1420073.

4:42PM H58.00012: Molecular Dynamics Simulations of Liquid-Liquid Phase Separation in Biology IAN SEIM (Presenter), AMY GLADFELTER, DAPHNE KLOTSA, University of North Carolina at Chapel Hill — A newly appreciated mechanism by which biochemistry is organized in cells without membrane barriers is liquid-liquid phase separation (LLPS). RNA and protein condense into liquid droplets through LLPS and are crucial for normal physiological function, but they are also implicated in the development of several neurological diseases as well as theories about the origins of life and cells themselves. Since the means by which droplets form, maintain shape, and achieve molecular specificity are poorly understood, a major challenge is to understand how nanometer scale molecules coalesce to produce cellular bodies of diverse material properties and distinct identities. Our aim is to model the process and properties of LLPS involving mRNAs and disordered proteins using molecular dynamics (MD). Specifically, by using both low and high-resolution representations of the system, we can map sequence-specific effects onto a low-resolution setting. In the coarse-grained space, the solvent is modeled implicitly using Brownian dynamics and the molecules as bead-spring polymers. These techniques provide access to space and time-scales that are critical to the phase separated state which involves the collective behavior of thousands of molecules.
In situ wrinkling during evaporative drying of a polymer solution drop on a soft swellable substrate is used to facilitate biochemical reactions, provide cellular compartmentalization, and sequester condition-specific factors. Whether biological LLPS events are active processes remains a difficult question to address because experiments that alter cellular ATP levels also affect the liquid properties of LLPS states. Understanding when different biological LLPS phenomena are active will provide insight into how the cell controls and drives their formation. The first instance of biological LLPS defined and one of the best characterized is the P granule of *C. elegans*. P granules exist in the cytosol of *C. elegans* germ-line cells and specify polarity during early embryonic development. To detect active processes in P granules, we measure interfacial tension in the positional trajectories of single-walled carbon nanotube probes targeted to the P granules of *C. elegans* embryos. These extremely bright, photostable, infrared fluorophores provide sufficiently long single-particle trajectories for irreversibility calculations. By measuring irreversibility in the fluctuations of P granules we hope to understand if and when P granules are active liquid states and to directly connect this to a cellular chemical energy input.

Self-swallowing droplets arise when water droplet moves through a partially miscible oil containing large amount of colloidal particles. The rapid mass transfer causes reduction of interfacial area, which leads to particles jamming and phase transition. As a result, an elastic film is generated and soon undergoes a buckling instability in response to the compressive stress due to volume shrinkage of the droplets. Therefore, a re-entrant cavity forms at the rear interface through which a jet of the outer fluid penetrates the droplet. The degree of the swallowing behavior and thus the shape of the droplets could be well adjusted by changing the experimental parameters, and the whole swallowing process could be reversibly regulated. This work not only provides indications for intriguing fundamental questions concerning hydrodynamic and interfacial effects, but also inspires technical innovations including in microfluidics, printing, soft materials processing, etc.

In situ wrinkling during evaporative drying of a polymer solution drop on a soft swellable substrate is used to facilitate biochemical reactions, provide cellular compartmentalization, and sequester condition-specific factors. Whether biological LLPS events are active processes remains a difficult question to address because experiments that alter cellular ATP levels also affect the liquid properties of LLPS states. Understanding when different biological LLPS phenomena are active will provide insight into how the cell controls and drives their formation. The first instance of biological LLPS defined and one of the best characterized is the P granule of *C. elegans*. **Session H59 GSOFT DPOLY DBIO: Rheology of Gels II**

**2:30PM H59.00001: Viscoelasticity of gels with dynamic bonds: molecular kinetics and macroscopic mechanics**

*Invited* RONG LONG (Presenter), University of Colorado, Boulder — Incorporation of dynamic bonds into the polymer network of soft gels has been exploited as a strategy to enhance fracture toughness and to enable self-healing. Gels with dynamic bonds often exhibit macroscopic viscoelasticity which can be traced back to the kinetics of dynamic bonds undergoing dissociation and reformation. I will present our recent efforts to connect the molecular-level chemical kinetics to the continuum-level viscoelasticity. As a model system, I will focus on a hydrogel with two types of crosslinks: dynamic physical crosslinks and permanent chemical crosslinks, and describe two different approaches for modeling the relation between molecular kinetics and viscoelasticity. These two approaches are shown to capture experimental data of tensile tests with various strain histories and oscillatory torsion tests. I will also discuss how our modeling approach can potentially lead to a general theoretical framework of nonlinear viscoelasticity.
Electrolytes containing colloidal gels have been proposed as a possible alternative to overcome the mechanical strength and ionic conductivity trade-off in electrolytes. These results suggest that such open network colloidal gels may provide a means to consider the rheology and conductivity characteristics of open, equilibrium gels designed from an inverse design strategy on the interaction potentials. Using small amplitude oscillatory shear (SAOS) simulations, rheology of these samples also exhibited “dark curing”, the extent of which increased with [LiTf2N]. EPR spectroscopy demonstrates that Li+ can stabilize propagating radicals, leading to enhanced curing following UV exposure. Taken together, these results demonstrate that the rheological behavior of photopolymerized ILs can be tuned by varying the composition and UV dosage.

**3:42PM H59.00005: Selectively enhanced diffusion through polymer gels**

CARL GOODRICH (Presenter), MICHAEL PHILLIP BRENNER, Harvard University, KATHARINA RIBBECK, Massachusetts Institute of Technology — Designing selective hydrogels that passively filter particles based on their interactions is a fundamental goal of nanotechnology. While it is conceptually straightforward for a particle's interactions to facilitate its own retention (specific binding domains on the gel trap particles with complementary recognition sites), it is much more difficult for a particle to facilitate its own diffusion. This requires the binding interaction to locally reorganize the internal structure of the gel. We present a mechanism for this behavior and describe a theoretical model of the diffusion of interacting and non-interaction particles that is backed by numerical results. We also discuss how our results can lead to the design of artificial selective gels inspired by the Nuclear Pore Complex.
3:54PM H59.00006: Rheology of aluminosilicate hydrogels* DONATIEN GOMES-RODRIGUES, NICOLAS COURTOIS, JEAN-BAPTISTE CHAMPENOIS, ARNAUD POULESQUEN (Presenter), CEA Marcoule — Thanks to their environmental acceptability and their adaptability over a wide range of applications, alkali solutions of aluminosilicates are increasingly used in nuclear or building and construction industry. Although such solutions are increasingly used in the industry, there remain outstanding questions regarding the gelation process, that are driven by the composition of the solution, their stabilities and their aging. It is therefore crucial to provide a clear and realistic description of such fluids in order to tune and tailor macroscopic properties.

The aim of this work is to study the linear viscoelasticity properties of the gels throughout a variety of rheological tests, combining with time resolved Small Angle X-ray Scattering (SAXS) from liquid to gelling state. The aluminosilicate gels show a power law behavior that is well described by the Fractional Maxwell Model (FFM). The derived parameters of the FFM are well correlated to the fractal dimension that can be directly extracted from the SAXS measurements. Aging of these gels will also be discussed in relation to the results obtained at mesoscale by SAXS.

*French ANR DYNAMISTE (ANR-15-CE07-0013)

4:06PM H59.00007: Rheology of Gels [Invited] JAMES SWAN (Presenter), MIT — Gels, nonfluid networks of particles or polymers that are pervaded by fluid, appear ubiquitously within soft matter in practical applications as well as in living biological systems. The mechanical properties of gels are intermediate between those of fluids and solids, and depend sensitively on the structure of the gel constituents across multiple length scales. This focus session invites experimental, theoretical, and computational studies of the rheological properties of gels, including chemical and physical gels, hydrogels, colloidal gels, and biological gels, with particular interest and emphasis on connecting structural properties to flow properties. Contributions examining the effect of non-equilibrium activity (driven by molecular motors or by active particles) on gel mechanics are encouraged.

4:42PM H59.00008: Phase behavior of equilibrium linker gels MICHAEL HOWARD (Presenter), RYAN JADRICH, BETH LINDQUIST, THOMAS TRUSKETT, McKetta Department of Chemical Engineering, University of Texas at Austin — Gels made from networks of colloids linked by physical bonds are an important class of soft materials. A standard route to produce a gel is to rapidly cool a suspension of isotropically attractive colloids, with gelation resulting from kinetic arrest during spinodal decomposition. However, such gels are inherently nonequilibrium, and the gel's properties inevitably change as it ages. Alternatively, “equilibrium” gels with open, homogeneous structures that are resilient to aging can be created by restricting the number of bonds that form between particles. Here, we report on equilibrium gelation controlled by the addition of a secondary “linker” macromolecule that mediates bonding between colloids. The phase diagrams of such mixtures were predicted using Wertheim’s thermodynamic perturbation theory (TPT) and compared to molecular dynamics simulations. Good agreement was obtained between the predictions and simulations, with the spinodal region depressed to lower colloid densities by increased linker length at fixed linker-to-colloid number ratio. However, the presence of looping in the colloid–linker networks inhibited percolation compared to TPT predictions at low linker concentrations.

4:54PM H59.00009: Effect of Surface Stiffness on the Interfacial Dynamics of Dense Microgel Liquids KEHUA LIN (Presenter), YINGXI ELAINE ZHU, Wayne State University — Many biological and engineering processes involve highly soft and deformable surfaces, ranging from biolubrication between synovial joints to aquaplaning of rubbery tires. In this talk, I will present our recent study of the effect of surface stiffness on the glassy dynamics of dense microgel liquids. Specifically, we investigate the interfacial dynamics of poly(N-isopropylacrylamide) (PNIPAM) microgels, whose particle stiffness can be tuned by polymer crosslinking degree upon polymerization, at a solid surface coated with PNIPAM microgels of matched or mismatched stiffness. By using confocal laser scanning microscopy, we analyze the mean-squared-displacement (MSD) of PNIPAM particles in the first 1-2 confined layers near the coated surface. The MSD shows strong dependence on surface stiffness and particles tend to approach the Brownian motion at the softest surface even at the microgel volume fraction approaching the one for glass transition. The correlation between dynamic heterogeneity and friction of confined dense PNIPAM suspensions is further examined with varied particle volume fraction and particle-to-surface stiffness ratio.
5:06PM H59.00010: Non-equilibrium deformation and relaxation of giant floppy vesicles in a precisely controlled extensional flow*  DINESH KUMAR (Presenter), CHARLES SCHROEDER, University of Illinois at Urbana-Champaign — In this work, we study the non-equilibrium dynamics of single floppy vesicles under large strain rates (~15 s⁻¹) using a Stokes trap, which is a new technique developed in our lab for controlling the center-of-mass position of multiple particles or single molecules in a free solution. In this way, we directly observe the vesicle shape and conformations as a function of reduced volume, which is a measure of a vesicle's equilibrium shape departure from sphericity. We observe the formation of asymmetric dumbbell shapes, symmetric dumbbell, pearling, and wrinkling and buckling instabilities for vesicles depending upon the nature of flow and amount of membrane floppiness. We report the precise stability boundary of the flow-based phase diagram for vesicles in Capillary number (Ca)-reduced volume space, where Ca is the ratio of the bending time scale to the flow time-scale. We further probe the stability boundary at two different viscosity ratios to understand how the onset of instability in vesicles depends on viscosity ratio. We also present results on the long-time relaxation dynamics of vesicles from high deformation back to their equilibrium shapes after the cessation of flow.

*We thank NSF CBET PMP #1704668 for funding this project.

5:18PM H59.00011: Dependence of Hydrogel-Glass Energy of Adhesion and Kinetics of Delamination on Hydrogel Concentration  RICHARD PARG (Presenter), ERIN SHELTON, JOHN DUTCHER, Department of Physics, University of Guelph — Pseudomonas aeruginosa bacteria move collectively at viscous interfaces via twitching motility¹, which plays an important role in biofilm formation and subsequent infection. This phenomenon is studied by forcing the bacteria to twitch at the interface of a glass microscope slide and a hydrogel such as agar. The expanding bacterial colony needs to break the adhesive bond between the glass and the agar. Although the pulling force generated by the type-IV-pilus² and the stiffness of the agar hydrogel³ have been measured, the adhesive interaction between the glass and the agar is not well characterized. We have used micropipette deflection experiments to measure the increase in the adhesive shear strength with increasing agar concentration: 120 ± 60 N/m² for 1.0% w/v agar, and 260 ± 110 N/m² for 1.5% w/v agar. To more accurately mimic the breaking of the adhesive bond by the bacterial cells, we have developed a confined blister test that measures the energy of adhesion and the kinetics of delamination of agar-glass interfaces. I will describe the results of our measurements performed for different agar concentrations.

Tuesday, March 5, 2019 2:30 PM - 5:30 PM

Session H60 FED DCMP: Jonathan F. Reichert and Barbara Wolff-Reichert Award for Excellence in Advanced Laboratory Instruction: Incorporating State-of-the-Art Research into Advanced Labs  BCEC 258A - Peggy Cebe, Tufts University - Tag(s): Education, Invited, Undergraduate

2:30PM H60.00001: Laboratory courses and the professional preparation of physics majors* [Invited]  BENJAMIN ZWICKL (Presenter), Rochester Institute of Technology — Embracing career preparation as a goal of lab courses is one way to advocate for the maintenance and expansion of labs in the curriculum. If labs are seen as primarily supporting students' conceptual understanding they are in danger of being replaced by virtual simulations optimized for teaching concepts. If labs are viewed as training grounds for the professional preparation of students as they pursue a range of STEM careers, labs become indispensable in the education of physics majors. Drawing from multiple studies of practicing researchers and engineers as well as PER on laboratory courses, labs will be shown to support both the technical competencies (e.g., measurement, data analysis, troubleshooting, design, modeling) and the "soft" competencies (e.g., teamwork, oral communication, documentation, self-directed learning) that are important for professional success. I will suggest ways in which lab courses can best utilize the unique features of the lab environment to explicitly and visibly support students' professional preparation.

3:06PM H60.00002: Open-ended projects in undergraduate lasers and optics courses [Invited]  CHAD HOYT (Presenter), Honeywell — We describe an approach to undergraduate laboratories in two upper-level classes at Bethel University: Optics and Lasers. These courses integrate a standard lecture, lab exercises, and open-ended projects. The projects typically have a novel aspect. Examples include a lithium magnetooptical trap, plasmonics, digital and analog holography, ultrafast fiber laser optics, quantum optics and atomic and molecular spectroscopy.
3:42PM H60.00003: Designing (and re-designing) realistic research practices for undergraduate Advanced Labs

[Invited] SARA CALLORI (Presenter), Department of Physics, California State University, San Bernardino — Our institution is undergoing a quarter-to-semester transition, which has given our department the opportunity to assess and redesign how our instructional laboratories prepare students for futures within physics and other STEM fields. Currently, our one-quarter Advanced Lab course focuses on introducing students to contemporary scientific instrumentation and includes a relatively short independent research project. While both types of activities give students a taste of some facets of scientific research, they do not necessarily touch on other realistic research skills, such as oral and written communication and statistical and error analysis. Here I will discuss the “state of the lab” and reflect on the strengths and weaknesses of our current course and how this assessment is contributing to a course and curricular re-design. This scales from upgrading current Advanced Lab instructions to promote more open-ended analysis, to newly implemented activities designed to build writing and computation skills, to a longer-term overhaul of the entire instructional laboratory curriculum.

4:18PM H60.00004: Advancing the Advanced Lab: Opportunities and Challenges post-BFYIII

[Invited] JOSEPH KOZMINSKI (Presenter), Department of Physics, Lewis University — In the last five years, the American Association of Physics Teachers (AAPT) has approved recommendations for both the undergraduate laboratory curriculum and for computational physics in the undergraduate curriculum. These recommendations along with the Phys 21 report from the APS and AAPT Joint Task Force on Undergraduate Physics Programs emphasize the need for physics programs to help students develop a range of transferrable skills and knowledge that prepares them for diverse job and graduate school opportunities post-graduation. The undergraduate laboratory is a place where many of these experimental, technical, analytical, modeling, and communication skills are addressed. In July 2018, the Third Conference on Laboratory Instruction Beyond the First Year (BFY III) brought together advanced laboratory instructors for a three-day conference with the theme of developing laboratory experiences that integrate experimentation, computation, and theory. Through hands-on workshops, plenary sessions, poster sessions, and small group discussions, participants considered how to transform their upper-level laboratory curricula to include high-impact experiences through which students can build this desired skill-set, develop good laboratory practices, and enrich their understanding of physics and the applications of physics across disciplines. This talk will address the recommended outcomes of the laboratory curriculum, things learned at BFY III, and challenges and opportunities for the advanced lab community in fostering the development of critical skills and competencies through authentic and engaging laboratory experiences.

4:54PM H60.00005: Jonathan F. Reichert and Barbara Wolff-Reichert Award for Excellence in Advanced Laboratory Instruction Talk: Engaging Students in Authentic Scientific Practices in Physics Lab Courses

[Invited] HEATHER LEWANDOWSKI (Presenter), University of Colorado, Boulder — Physics is an empirical science. Therefore, learning physics must include learning how to design and conduct experiments, analyze and interpret data, and revise models and apparatus. Physics lab courses at the introductory and upper-division levels are one of only a few opportunities for students to engage in these authentic physics practices. For many students, instructional labs are the only opportunity. However, these courses do not always have the students reach the desired learning goals. Our work looks to improve lab experiences by improving students’ competency with modeling of physical and measurement systems, troubleshooting skills, documentation practices, and views of the nature of experimental physics.

Tuesday, March 5, 2019 2:30 PM - 5:30 PM

Session H61 GSOFT DBIO GSNP: Active Matter IV BCEC 258B - Daniel Pearce, University of Geneva - Tag(s): Focus
2:30PM H61.00001: Dynamic instabilities of contractile acto-myosin rings* [Invited] KARSTEN KRUSE (Presenter), Biochemistry and Theoretical Physics, University of Geneva — The actin cytoskeleton is a prototypic example of active matter and shows a wealth of dynamic phenomena alien to conventionally studied materials. In living cells, actin filaments and myosin motors often organize into dynamic rings. This is notably the case during the late stages of cell division of animal cells, where such a ring contracts and thereby cleaves the mother cell into two daughters. Similar structures are observed in dividing fission yeast, where their functional role is less clear, though. Furthermore, rings spanning several cells appear upon closure of tissues. It has been found experimentally that myosin forms stationary or moving clusters in acto-myosin rings. The mechanism underlying their formation and their role in ring dynamics remain unclear. Based on the analysis of a phenomenological theory, we show that traveling and stationary clusters are generic features of contractile actin rings. Our numerical results indicate that there is a direct transition from homogenous actin and myosin densities to chaotic dynamics along rings. We then use a mesoscopic approach to study a possible molecular mechanism for the observed generic phenomena. It suggests that the transient formation of bipolar filaments provides a common mechanism underlying the experimentally observed patterns. The theory also shows that stationary myosin clusters are associated with elevated contractile stress, whereas traveling clusters are not. We compare these theoretical results to experimental observations in mammalian and fission yeast cells.

*This work is funded by SNF through grant 205321_175996.

3:06PM H61.00002: Tuning surface aggregation of active particles.* RAGHUNATH CHELAKKOT (Presenter), SUCHISMITA DAS, Physics, IIT Bombay — Collection of disk-like self-propelled particles, interacting via a short-range repulsive force is an effective model to understand the emergent properties in active matter. It is well known that for sufficiently high propulsion speed and density they aggregate to form clusters and at low density, they are in a homogeneous fluid state.

We study the aggregation properties of such particles on a rigid wall at a low density where they do not spontaneously form clusters in the bulk. Our numerical studies show that the cluster formation crucially depends on how the particles interact with the wall and the propulsion speed of the particles. We get two different type of clusters on the surface, as a function of the wall properties. For a range of wall parameters and particle mobility, the particles form a connected cluster all along the wall. For these parameters, we study the surface height fluctuations and compare with studies made on passive particle deposition. For a different range of wall parameters, we observe that the connected cluster becomes unstable and it breaks into smaller clusters. We study the growth dynamics of these clusters and their dependence on wall parameters and particle propulsion speed.

3:18PM H61.00003: Response of a system of passive or active particles to periodic forcing* MICHAEL WANG (Presenter), ALEXANDER GROSBERG, New York University — The presence of active, persistent forces in various biological and artificial systems changes how those systems behave when forced. We present a minimal model of a system of passive or active swimmers driven on the boundaries by a time-dependent forcing. We extract the linear response functions of the system and interpret them in terms of the storage and dissipation of energy through the particles within the system. We find that while a slowly driven active system responds similar to a passive system with a redefined diffusion constant, a rapidly driven active system exhibits a new behavior that may be related to a change in the motoring activity of the active particles due to the forcing.

*This work was supported primarily by the MRSEC Program of the National Science Foundation under Award Number DMR-1420073.

3:30PM H61.00004: Diffusion of active matter with inertia* MARIO SANDOVAL-ESPINOZA (Presenter), Department of Physics, Metropolitan Autonomous University, JOHN F BRADY, Division of Chemistry and Chemical Engineering, Caltech — In this work we study the motion of active Brownian particles (ABPs) while keeping both translational and rotational inertia. Following a Langevin formalism, we theoretically find that whereas translational inertia does not play a role in the ABPs effective diffusion, rotational inertia is able to enhance the ABPs’ diffusion. To elucidate such a new effect, one has to properly take into account the rotational inertia contribution in the orientation correlations. The mean-square speed for this system is also studied and its dependence on translational and rotational inertias is determined theoretically. To validate our analytical results, Brownian dynamics simulations are performed.

*M. Sandoval thanks Consejo Nacional de Ciencia y Tecnologia, CONACYT Grant: CB 2014/237848.
3:42PM H61.00005: Critical motility-induced phase separation belongs to the Ising universality class  
BENJAMIN PARTRIDGE (Presenter), CHIU FAN LEE, Department of Bioengineering, Imperial College London — Active matter is an extreme kind of non-equilibrium system in that detailed balance is broken at the microscopic scale. A typical active system can be a collection of particles that continuously exert mechanical forces on their surrounding environment, and systems of interacting active particles can display novel phenomena, ranging from the emergence of collective motion in two dimensions when the active particles are aligning, to motility-induced phase separation (MIPS) when the particles interact solely via volume exclusion interactions. However, even though active matter breaks detailed balance in a fundamental way, it remains unclear whether the hydrodynamic, universal behavior of active matter necessarily differs from that of equilibrium systems. The investigation of universal behavior, besides being of central interest to physics, allows us to transfer knowledge of a well-known system to a different system of novel interest. Here, we do exactly that by demonstrating that the critical behaviour of MIPS belongs to the Ising universality class with conservative dynamics. We do so using three approaches: hydrodynamic argument, field-theoretic description of a microscopic model, and simulation of a lattice model.

3:54PM H61.00006: Topotaxis of Active Particles  
KOEN SCHAKENRAAD (Presenter), LINDA RAVAZZANO, JOERI WONDERGEM, ROELAND MERKS, LUCA GIOMI, Leiden University — Recent biophysical experiments have shown that the amoeba Dictyostelium Discoideum, while moving persistently in an environment filled with obstacles, can navigate away from more crowded areas towards regions with more space: an effect called topotaxis. We theoretically study active particles in a crowded environment and discuss whether or not persistent motion on itself, in the absence of any more complicated biological interactions, can drive this behavior.

4:06PM H61.00007: The Effect of Confinement on Active Brownian Particles  
CAMILLA M. KJELDBJERG (Presenter), JOHN F BRADY, Division of Chemistry & Chemical Engineering, California Institute of Technology — Active Brownian Particles (ABPs) are subject to confinement effects when their run or persistence length, $l = U_0 \tau_R$, is comparable to the characteristic size of the confining geometry. Here, $U_0$ is the intrinsic swim speed and $\tau_R$ is the reorientation time of the ABPs. Furthermore, ABPs accumulate at no-flux surfaces owing to their persistent swimming. These two effects can produce some unusual and startling effects. For example, it has been seen in simulations (Ray, et al. *PRE* 2014) that two parallel walls attract each other when placed in a dilute bath of ABPs. In this work, we provide a simple model based on the Smoluchowski equation for the ABPs and an overall macroscopic momentum balance to predict analytically this attractive force. We extend this simple modeling to predict the partitioning of ABPs between a confined channel of width $H$ and an infinite reservoir, showing that the concentration within the channel over that in the bulk increases as $l/H$. The theoretical results are compared to Brownian dynamics simulations.

4:18PM H61.00008: The universality class of Motility-Induced Phase Separation  
MATTEO PAOLUZZI (Presenter), Physics, Università Sapienza, CLAUDIO MAGGI, NANOTEC, CNR — Motility-Induced Phase Separation (MIPS) is a dynamical mechanism peculiar of Active Systems that brings to a gas/liquid phase separation even without any attraction force between the active agents. The resulting spinodal decomposition shares many similarities with its equilibrium counterpart. However, the properties of the active system close to the end point of the transition, corresponding to a critical point in equilibrium systems, remain still poorly investigated. In this work, driven by the analogy with gas/liquid phase transition, we investigate numerically the phase diagram of purely repulsive Active Ornstein-Uhlenbeck and Run-and-Tumble particles. We show that in both cases the phase coexistence ends with a critical point.

4:30PM H61.00009: Spatial Variation of Transport Properties of Active Brownian Particles*  
HYEONGJOO ROW (Presenter), JOHN F BRADY, Division of Chemistry and Chemical Engineering, California Institute of Technology — Self-propelling microswimmers such as motile bacteria and Janus particles can be modeled as Active Brownian Particles (ABPs) and characterized by their transport properties: swim speed, translational diffusivity, and rotational diffusivity. We have developed a general theory to describe suspensions of ABPs with spatially varying transport properties. We find that the number density distribution of ABPs is primarily governed by the swim speed and is always lower in the region with the faster swim speed as first shown by Tailleur & Cates (*PRL* 2008). We also show that the translational diffusivities of ABPs smooth out the effect of the variation of swim speed. The theory implies that spontaneous reverse-osmosis is achievable owing to the spatial variation of the swim speed of active matter.

4:42PM H61.00010: Curvature-dependent tension and tangential flows at the interface of motility-induced phases*
ADAM PATCH (Presenter), Physics, Wilkes Honors College, Florida Atlantic University, DAVID YLLANES, BioHub, UC San Francisco, DANIEL SUSSMAN, Physics, Syracuse University, M. CRISTINA MARCHETTI, UC Santa Barbara — Purely repulsive active particles spontaneously undergo motility-induced phase separation (MIPS) into condensed and dilute phases. Remarkably, the mechanical tension measured along the interface between these phases is negative. In equilibrium, this would imply an unstable, expanding interface. However, these out-of-equilibrium systems display long-time stability and intrinsically stiff phase boundaries. In this work, we use active Brownian particle simulations and a novel frame of reference at the phase boundary to carefully study the emergent tangential currents at the interface, finding correlations between local interface curvature and measured values of interfacial tension. The combined observation of tangential currents in the gas and local "self-shearing" of the surface of the dense phase suggest a stiffening interface that redirects particles along itself to heal local fluctuations. In this way, the wildly fluctuating MIPS interface restores itself via an out-of-equilibrium Marangoni effect.

4:54PM H61.00011: Binary mixtures of hard sphere active Brownian particles*
THOMAS KOLB (Presenter), DAPHNE KLOTSA, University of North Carolina at Chapel Hill — We computationally study the phase behavior and dynamics of a binary mixture of active Brownian particles, where each 'species' is distinguished by its persistence of motion (effectively two species: fast, slow active particles). We find that our binary active system demonstrates motility-induced phase separation (analogous to monodisperse active systems) depending on the activity ratio, and concentration of each species. We observe a variety of steady states, which emerge as we vary the ratio of constituent particle activity, ranging from volatile partially segregated steady-state clusters, prone to fission, to a homogenously distributed, relatively stable, single cluster. We extend current theory for passive-active mixtures to account for active-active mixtures as well.

*NSF GRFP

5:06PM H61.00012: Non-equilibrium work and reversibility in active particles in disordered media
JOSHUA STEIMEL (Presenter), University of the Pacific, ALFREDO ALEXANDER-KATZ, MIT — Active particles can in principle extract/do work on the environment. Here we explore experimentally a single active spinning particle in an inclined plane sliding in a disordered array of obstacles. Our results show that there are several interesting features in this system depending on the reversibility of the system during a cycle of the time reversible protocols. In particular we observe the rectification of the activity which allows the spinner to drift faster than the reference drift in the absence of obstacles. Our results should be of interest to understand under what conditions non-equilibrium systems are able to extract work from their environment and connect it to the thermodynamic counterparts.

5:18PM H61.00013: Extreme Active Matter at High Densities*
CHANDAN DASGUPTA (Presenter), Physics, Indian Institute of Science, Bangalore, RITUPARNO MANDAL, Simons Centre for the Study of Living Machines, National Centre for Biological Sciences, Bangalore, PRANAB JYOTI BHUYAN, Physics, Indian Institute of Science, Bangalore, PINAKI CHAUDHURI, The Institute of Mathematical Sciences, Chennai, MADAN RAO, Simons Centre for the Study of Living Machines, National Centre for Biological Sciences, Bangalore — Extreme active matter, consisting of self-propelled particles characterized by large persistence time τp and high Péclet number, exhibits remarkable behavior at high densities. In the limit τp → ∞, the fluid jams as the self-propulsion force f is decreased below a critical value f*(∞). The system is stuck at a force-balanced configuration for f < f*(∞), with stresses concentrated along force chains. For large but finite τp, the approach to dynamical arrest at low f goes through a phase characterized by intermittency in kinetic and potential energy. This intermittency is a consequence of long periods of jamming separated by bursts of plastic yielding associated with Eshelby deformations akin to those found in the response of dense granular materials to an externally imposed shear. In the vicinity of the boundary between the intermittent and "normal" fluid phases, correlated plastic events result in large-scale vorticity and turbulent motion. Thus, dense extreme active matter brings together the physics of glass, jamming, plasticity and turbulence, in a new state of driven classical matter.

2:30PM H62.00001: Beyond the transmon: A new generation of superconducting qubits

[Invited] DAVID SCHUSTER (Presenter), University of Chicago — TBD

3:06PM H62.00002: Entanglement and complexity of interacting transmon qubits subject to asymmetric noise

[Invited] ELIOT KAPIT (Presenter), Physics, Colorado School of Mines — The simulation complexity of predicting the time evolution of delocalized many-body quantum systems has attracted much recent interest, and simulations of such systems in real quantum hardware are promising routes to demonstrating a quantum advantage over classical machines. In these proposals, random noise is an obstacle that must be overcome for a faithful simulation, and a single error event can be enough to drive the system to a classically trivial state. We argue that this need not always be the case, and consider a modification to a leading quantum sampling problem-- time evolution in an interacting Bose-Hubbard chain of transmon qubits [Neill et al, Science 360, 195 (2018)] -- where each site in the chain has a driven coupling to a lossy resonator and particle number is no longer conserved. The resulting quantum dynamics are complex and highly nontrivial. We show that this problem is likely to be harder to simulate than the isolated chain, and that it can achieve volume-law entanglement even in the strong noise limit (likely persisting up to system sizes beyond the scope of classical simulation). Further, we show that the metrics which suggest classical intractability for the isolated chain point to similar conclusions in the noisy case. These results suggest that quantum sampling problems including nontrivial noise could be good candidates for demonstrating a quantum advantage in near-term hardware.

3:42PM H62.00003: Superconducting Gatemon Qubit based on a Proximitized Two-Dimensional Electron Gas

[Invited] LUCAS CASPARIS (Presenter), MALCOLM R CONNOLLY, MORTEN KJÆRGAARD, Niels Bohr Institute, NATALIE PEARSON, Department of Physics, ETH Zurich, ANDERS KRINGHØJ, THORVALD W LARSEN, FERDINAND KUEMMETH, Niels Bohr Institute, TIAN WANG, CANDICE THOMAS, SERGEI GRONIN, GEOFFREY C. GARDNER, MICHAEL MANFRA, Department of Physics and Astronomy, Purdue University, CHARLES M MARCUS, KARL D PETERSSON, Niels Bohr Institute — The coherent tunnelling of Cooper pairs across Josephson junctions (JJs) generates a nonlinear inductance that is used extensively in quantum information processors based on superconducting circuits, from setting qubit transition frequencies and interqubit coupling strengths, to the gain of parametric amplifiers for quantum-limited readout. The inductance is either set by tailoring the metal-oxide dimensions of single JJs, or magnetically tuned by parallelizing multiple JJs in superconducting quantum interference devices (SQUIDs) with local current-biased flux lines. JJs based on superconductor-semiconductor hybrids represent a tantalizing all-electric alternative. The *gatemon* is a recently developed transmon variant which employs locally gated nanowire superconductor-semiconductor JJs for qubit control [1,2]. Here, we go beyond proof-of-concept and demonstrate that semiconducting channels etched from a wafer-scale two-dimensional electron gas (2DEG) are a suitable platform for building a scalable gatemon-based quantum computer [3]. We show 2DEG gatemons meet the requirements by performing voltage-controlled single qubit rotations and two-qubit swap operations. We measure qubit coherence times up to ~2 μs, limited by dielectric loss in the 2DEG host substrate.

4:18PM H62.00004: Quantum computing with driven-dissipative Josephson circuits

[Invited] ZAKI LEGHTAS (Presenter), Mines ParisTech / ENS Paris — Superconducting qubits are one of the most promising platforms to implement quantum technologies. Quantum processors of tens of qubits are now available, and exciting applications with these intermediate size systems are in perspective. However, many algorithms, including all those with a proved quantum speed-up, require extremely low error rates. This will most likely require quantum error correction (QEC). Unfortunately, current QEC architectures require daunting overheads in physical qubits and control electronics. The goal of this research is to reduce this overhead, and our approach is based on two key ideas. First, we use high Q resonators to redundantly encode quantum information. Second, we engineer non-linear dissipation to protect and manipulate this information.
4:54PM H62.00005: A programmable superconducting quantum processor with three all-to-all coupled qubits*

[Invited] TANAY ROY (Presenter), SUMERU HAZRA, SUMAN KUNDU, MADHAVI CHAND, ANIRBAN BHATTACHARJEE, KISHOR SALUNKHE, MEGHAN P. PATANKAR, KEDAR DAMLE, RAJAMANI VIJAYARAGHAVAN, Department of Physics, TATA INSTITUTE OF FUNDAMENTAL RESEARCH — Quantum information processing (QIP) exploits the laws of quantum mechanics to enhance computational capabilities beyond the limits of classical algorithms. Among various platforms for realizing QIP, superconducting qubits are at the forefront as they offer an unparalleled combination of good coherence, fast gates, and design flexibility. A majority of recent experimental demonstrations in the superconducting architecture have utilized transmon-like qubits and transverse inter-qubit coupling for implementing small quantum algorithms. Nevertheless, efficient universal quantum computing has remained a challenge due to the limited connectivity and access to only two-qubit entangling gates. This results in reduced performance due to inefficient implementation of quantum algorithms. In this talk, I will introduce “trimon” [1], a three-qubit device based on a multi-mode superconducting circuit providing strong inter-qubit coupling and access to three-qubit native gates. I will discuss the basic working principles of the device, implementation of generalized controlled-controlled-NOT gates and universal programmability of the processor [2]. Next, I will demonstrate the high-fidelity preparation of various two- and three-qubit entangled states and implementation of a few quantum algorithms [3] like Deutsch-Jozsa, Grover’s search and the quantum Fourier transform. Finally, I will talk about the possibility of scaling to larger systems using the trimon as a building block to achieve improved qubit-qubit connectivity in medium-scale quantum processors.

Session H63 DBIO: Physics of Microbiomes and Microbial Communities II BCEC 259A - Raghuveer Parthasarathy, University of Oregon - Tag(s): Focus

2:30PM H63.00001: Modeling the influence of metabolic trade-offs on microbiota diversity* [Invited] NED WINGREEN (Presenter), Princeton University — Metagenomics has revealed huge diversity in nature, with thousands of microbial species coexisting in microbiota. However, classical resource-competition models predict that the number of species in steady coexistence cannot exceed the number of resources. To investigate the role of environmental conditioning and trade-offs in promoting diversity, we physically modeled the population dynamics of microbes that compete for resources in a chemostat. The model reproduces several notable features of natural ecosystems, including high diversity, keystone species, and characteristics of neutral theory, despite an underlying non-neutral competition for resources. Do metabolic trade-offs still promote diversity if nutrient supplies vary in time or if populations are spatially structured? The answer is yes in both cases. Serial dilutions preserve diversity, but with a surprising non-monotonic dependence on nutrient supply. Spatial structure selects one diverse solution, rather than a degenerate set. Importantly, we find that temporal or spatial variation permit diversity even when trade-offs are only approximate.

3:06PM H63.00002: The motility can drive spatial exclusion and promote coexistence in bacterial populations
ERCAG PINCE (Presenter), Department of Living Matter, AMOLF, SEBASTIAN GÜDE, Quantitative Biology, UC Berkeley, KATJA M. TAUTE, Rowland Institute at Harvard, TOM S SHIMIZU, SANDER J TANS, Department of Living Matter, AMOLF — Bacterial cells encountered in nature rarely live in isolation, they share and compete for space and nutrients with cohabitant microbial communities. They are also known to explore their surroundings and exhibit motility. Despite the ubiquity of motile phenotypes, the fundamental role of bacterial dispersal in the formation of diverse microbial communities and coexistence in spatial habitats have not been elucidated. In this study, we investigated the motility-driven competition for resources between two strains resulting in strong negative frequency-dependent-selection, i.e. each strain becomes fitter than the other when low in frequency. The observed lack of competitive exclusion is a direct consequence of the active segregation: few fast movers can forage and rapidly colonize in virgin territories of the habitat whereas few fast-grower cells can proliferate at the initial contact position. We showed that the coexistence breaks down when the initial contact area is as large as the habitat size or the nutrients become available homogeneously. Our findings demonstrate that motility can foster coexistence between bacterial populations displaying growth-dispersal trade-off in competition for nutrients and space.

3:18PM H63.00003: Single cell segmentation in microbiome imaging* HAO SHI (Presenter), Department of Physics, Cornell University, IWJN DE VLAMINCK, Meining School of Biomedical Engineering, Cornell University — Microbes in nature often live in communities with intricate spatial organization. Recent developments in molecular barcoding strategies and confocal spectral imaging have enabled spatially resolved and highly multiplexed phylogenetic measurements in these communities. However, quantitative analysis of these information-rich imaging dataset remains difficult, primarily due to bottlenecks in accurate single cell segmentation. Here, we present our approach to segment spectral images of environmental microbiome using information contained in the neighborhood of each voxel. We will discuss preliminary segmentation results and quantitative analysis of the spatial organization of microbial communities at the single cell level.

*This work is funded by the Noyce Foundation and a National Institute of Health Director's New Innovator Award.

3:30PM H63.00004: Community coexistence and stability: insights from a mediator-explicit model of microbial interactions* SANDRA DEDRICK, SAMANTHA DYCKMAN, BABAK MOMENI (Presenter), Boston College — Communities of interacting microbes impact our health and environment. For example, microbes in our gut microbiota can collectively (but not as individual species) confer resistance against pathogen colonization. How species form a community is thus an important question for maintaining or manipulating human-associated communities for improved health outcomes.

We formulate and experimentally constrain a model that explicitly incorporates chemical compounds (e.g. metabolites or waste-products) that can mediate microbial interactions. In a continuous-growth setting where resources are supplied (similar to a bioreactor or gut microbiota), our model highlights facilitation and self-restraint as interactions that contribute to coexistence. We show that when interactions are strong, coexistence and stability are determined primarily by the topology of facilitation and inhibition influences and not the strengths of influences. Importantly, we show that consumption of chemical mediators moderates interaction strengths and promotes coexistence. Our results offer insights into how to build or restructure microbial communities of interest.

3:42PM H63.00005: Examining Pairwise and Multi-Species Interactions in Larval Zebrafish* EDOUARD HAY (Presenter), DEEPIKA SUNDARRAMAN, Physics, University of Oregon, DYLAN MARTINS, DREW SHIELDS, KAREN GUILLEMIN, University of Oregon, RAGHUVEER PARTHASARATHY, Physics, University of Oregon — The microbial communities resident in animal intestines are composed of dozens to hundreds of species and play important roles in host health and disease. The determinants of microbial composition, which may include physical characteristics or biochemical interactions, remain largely unknown. Further, it is unclear for many multi-species consortia whether their species-level makeup can be predicted based on an understanding of pairwise species interactions, or whether higher-order interactions are needed to explain community assembly. It is also unclear how spatial organization plays a role in determining the make up of these complex communities.

To address this, we consider commensal intestinal microbes in larval zebrafish, initially raised germ-free to allow introduction of controlled combinations of bacterial species. Using a combination of dissection and plating assays and 3-dimensional live imaging, we demonstrate the construction of communities of 1 to 5 species and test whether outcomes from 2-species competitions contain enough information to predict the abundances in more complex communities. We also quantify changes in species' spatial distributions induced by the presence of other species, which may explain correlations in their abundances.

RACHEL MOK, BOYA SONG, DOMINIC SKINNER, Massachusetts Institute of Technology, JEFFREY OISHI, Bates College, JORN 4:18PM H63.00008: Nonlinear rheological behaviour of bacterial biofilms*

In this study, we focus on the rheological properties of bacterial biofilms at multiple scales in determining the architectures of biofilms in flow. This is achieved by examining the interactions that generate Vibrio cholerae biofilm morphologies. Our results demonstrate the importance of dynamics at the intersections between biofilm architectures and mechanical processes including cell growth, cell-cell interactions within the embedded matrix. Biofilm architectures are sculpted by mechanical processes including cell growth, cell-cell interactions and external forces. Using single-cell live imaging in combination with simulations we characterize the cell-cell and cell-flow interactions that generate Vibrio cholerae biofilm morphologies. Our results demonstrate the importance of dynamics at multiple scales in determining the architectures of biofilms in flow.

4:06PM H63.00007: Emergence of order and structure in biofilms growing in fluid shear PHILIP PEARCE (Presenter), Massachusetts Institute of Technology, RAIMO HARTMANN, PRAVEEN SINGH, Max Planck Institute for Terrestrial Microbiology, RACHEL MOK, BOYA SONG, DOMINIC SKINNER, Massachusetts Institute of Technology, JEFFREY OISHI, Bates College, JORN DUNKEL, Massachusetts Institute of Technology, KNUT DRESCHER, Max Planck Institute for Terrestrial Microbiology — In many situations bacteria aggregate to form biofilms: dense, surface-associated, three-dimensional structures inhabited by cells. Situations bacteria aggregate to form biofilms. We present a physical model to a phenomenon prone to misinterpretation by invoking chemotaxis or quorum sensing.

THOMAS P. CURTIS, JINJU CHEN, School of Engineering, Newcastle University — Mechanical robustness is a hallmark of many bacterial biofilms. Traditionally, these have been characterised in the small strain limit. Rheological studies in the large strain limit are extremely rare and are presumably of interest in various industrial and biomedical scenarios. We perform Large amplitude oscillatory shear (LAOS) on three species of bacterial biofilms: Bacillus subtilis, Comamonas denitrificans and Pseudomonas fluorescens. Our results show a distinct variation in intra-cycle strain stiffening/shear thickening indices and the yield characteristics of the Pipkin space for each of the individual species. Furthermore, mixing two strains of microbes; we study the variation in rheological measures (in Pipkin space) of dual species biofilms and compare them with the single species biofilms. This study builds towards an understanding of the rheological characteristics of multi-species biofilms: starting from a single species perspective, followed by mixtures of microbial species and in the future by using an artificial community which is representative of a microbiome (e.g. wastewater treatment plant).

4:18PM H63.00008: Nonlinear rheological behaviour of bacterial biofilms* SAIKAT JANA (Presenter), SAM CHARLTON, THOMAS P. CURTIS, JINJU CHEN, School of Engineering, Newcastle University — Mechanical robustness is a hallmark of many bacterial biofilms. Traditionally, they have been characterised in the small strain limit. Rheological studies in the large strain limit are extremely rare and are presumably of interest in various industrial and biomedical scenarios. We perform Large amplitude oscillatory shear (LAOS) on three species of bacterial biofilms: Bacillus subtilis, Comamonas denitrificans and Pseudomonas fluorescens. Our results show a distinct variation in intra-cycle strain stiffening/shear thickening indices and the yield characteristics of the Pipkin space for each of the individual species. Furthermore, by mixing two strains of microbes; we study the variation in rheological measures (in Pipkin space) of dual species biofilms and compare them with the single species biofilms. This study builds towards an understanding of the rheological characteristics of multi-species biofilms: starting from a single species perspective, followed by mixtures of microbial species and in the future by using an artificial community which is representative of a microbiome (e.g. wastewater treatment plant).

4:30PM H63.00009: Role of confinement in growing bacterial colonies ZHIHONG YOU (Presenter), Leiden University, DANIEL PEARCE, University of Geneva, LUCA GIOMI, Leiden University — Bacterial colonies are abundant in biological and artificial environments, and they are frequently subject to various types of confinement. Yet, the role of confinement, especially from the mechanical perspective, is still not clear. Here, using molecular dynamics simulations and continuum modelling, we demonstrate that the combination of confinement and growth gives rise to strongly anisotropic stress, resulting in the emergence of global nematic order.

4:42PM H63.00010: Mechanical interactions in growing yeast colonies ANDREA GIOMETTO (Presenter), DAVID R. NELSON, ANDREW MURRAY, Harvard University — Microbial populations often assemble in dense populations in which proliferating individuals exert mechanical forces on the nearby cells. Here, we use yeast strains whose doubling times depend differently on temperature to show that physical interactions among cells affect the competition between different genotypes in growing yeast colonies. Our experiments demonstrate that these physical interactions have two related effects: they cause the prolonged survival of slower-growing strains at the actively-growing frontier of the colony and cause faster-growing strains to increase their frequency more slowly than expected in the absence of physical interactions. These effects also promote the survival of slower-growing strains and the maintenance of genetic diversity in colonies grown in time-varying environments. The three-dimensional structure of these colonies reflects the history of the environments experienced by the colonies, and the survival of strains depends on the geometry of the colony perimeter. A continuum model inspired by overdamped hydrodynamics reproduces the experiments and predicts that the strength of natural selection depends on the width of the actively growing layer at the colony frontier. We verify these predictions experimentally.
**4:54PM H63.00011: Dynamic self-organization of microorganisms far from equilibrium**  
ROUJIN GHAFFARI (Presenter), SEZIN GALIGOLU, UNAM, Bilkent University, EVREN DORUK ENGIN, Institute of Biotechnology, Ankara University, SERIM ILDAY, UNAM, Bilkent University — We report ultrafast laser-induced dynamic self-organization of quasi-2D confined solutions of *e.coli, m.luteus, s.cerevisiae*, and *p.aeruginosa* far from equilibrium. The laser beam has no interaction with the microorganisms; it only creates thermal gradient-induced convective flows in their growth medium. By precisely controlling these flows, we have been able to form aggregates with predetermined sizes and geometries, and manipulate the adaptive behavior of microorganisms under ‘noisy’ environments. We further demonstrate if and how these microorganisms can withstand harsh physical conditions. Last, we showcase separation of gram positive and gram negative bacteria from an initially homogenous mix.

**5:06PM H63.00012: Effect of cellular and environmental conditions on bacterial collective oscillation**  
SONG LIU (Presenter), YILIN WU, The Chinese University of Hong Kong — Collective oscillation in biology is ubiquitous and often arises from coupling between individual oscillators in phase space. Previously, we discovered a novel type of collective oscillatory motion in bacterial suspensions, which arises from weak synchronization and diffusive coupling between random trajectories but does not require individual oscillators. However, it is unclear what determines the intrinsic oscillation frequency in the system. Here we manipulate the cellular and environmental conditions to systematically to identify potential factors controlling the oscillation frequency. Our results will provide necessary information to fully understand the collective oscillatory motion and suggest new directions for active matter engineering.

**Session H64 DBIO GSOFT: Physics of the Cytoskeleton Across Scales III**

**2:30PM H64.00001: Nonlinear microscale mechanics and macromolecular mobility of tunable cytoskeleton composites**  
RAE ROBERTSON-ANDERSON (Presenter), Physics and Biophysics, University of San Diego — Actin and microtubules are two key protein filaments that comprise the cytoskeleton, enabling cells to exhibit multifunctional nonlinear mechanics. However, it remains an open question as to how the structure, interactions, and dynamics of these proteins map to the nonlinear and non-equilibrium mechanics that the cytoskeleton exhibits. We address this open problem by using a robust approach that combines: tunable in vitro cytoskeleton networks, rheology that spans from molecular to mesoscopic scales, and single-molecule transport and mobility measurements. Specifically, we use optical tweezers microrheology to characterize the nonlinear mechanics of cytoskeleton networks while simultaneously using fluorescence microscopy and particle-tracking to determine macromolecular mobility and network stress propagation. To directly map network properties to stress response, we perform measurements using custom-designed in vitro networks of actin and microtubules with structural properties and interactions that can be precisely tuned. I will describe these methods as well as our recent intriguing results that demonstrate the elegant couplings that can emerge between network structure, stress response, and macromolecular mobility in cytoskeleton networks.

3:06PM H64.00002: Reconstitution of basic mitotic spindles in cell-like confinement  [Invited]  MARILEEN DOGTEROM (Presenter), Bionanoscience, TU Delft — Bipolar organization of the mitotic spindle is the result of forces generated by dynamic microtubules and associated proteins in interaction with chromosomes and the cell boundary. Biophysical experiments on isolated spindle components have provided important insights into the force-generating properties of different components, but a quantitative understanding of the force balance that results from their concerted action is lacking. Here we present an experimental platform based on water-in-oil emulsion droplets that allows for the bottom-up reconstitution of basic spindles. We find a typical metaphase organization, where two microtubule asters position symmetrically at moderate distance from the mid-zone, is readily obtained even in the absence of chromosomes. Consistent with simulations, we observe an intrinsic repulsive force between two asters that can be counterbalanced alternatively by cortical pulling forces, anti-parallel microtubule crosslinking, or adjustment of microtubule dynamics, emphasizing the robustness of the system. Adding motor proteins that slide anti-parallel microtubules apart drives the asters to maximum separation, as observed in cells during anaphase. Our platform offers a valuable complementary approach to in vivo experiments where essential mitotic components are typically removed, instead of added, one by one.

3:42PM H64.00003: Revealing Cytoskeletal Dynamics and Avalanches via Active Micropost Arrays*  YU SHI (Presenter), KATHERINE XIAN, SHANKAR SIVARAJAN, Department of Physics and Astronomy, Johns Hopkins University, CHRISTOPHER L PORTER, Department of Chemical and Biomolecular Engineering, University of Pennsylvania, DANIEL H REICH, Department of Physics and Astronomy, Johns Hopkins University, JOHN CROCKER, Department of Chemical and Biomolecular Engineering, University of Pennsylvania — The cytoskeleton is critical for a wide range of cellular behavior, including motility, morphology, and mechanotransduction. However, understanding of the connections between molecular-scale processes and cell-scale dynamics is not complete. Here we present results using poly(dimethylsiloxane) active micropost array detectors (AMPADs) with embedded magnetic actuators to measure the fluctuations and local rheology of cells’ actomyosin stress fiber network and cortex in detail. We find that both structures display consistent power law rheology, along with highly heterogeneous and intermittent fluctuations. Notably, the fluctuating motion is dominated by large step-like displacements, resembling the dynamics observed in avalanches and earthquakes. The effects of substrate stiffness and geometry will also be discussed. Our results imply that actomyosin contractile units act in a highly collective manner and that cellular actomyosin networks self-organize into marginally stable plastic networks whose properties influence the biomechanical behavior of cells.

*Supported in part by NIH grant 1R01HL127087

3:54PM H64.00004: A model of sliding and stalling in microtubule bundles  SHANE FIORENZA (Presenter), MATT GLASER, M. BETTERTON, University of Colorado, Boulder — Microtubules, motor proteins, and crosslinkers self-assemble a variety of cytoskeletal networks within the cell. Minimal systems of two antiparallel microtubules, kinesin-4 motors, and PRC1 crosslinkers reconstitute controlled sliding and stalling, leading to stable antiparallel overlaps like those seen in the mitotic spindle. Experiments show that the final overlap length and initial sliding velocity are both linearly proportional to the two microtubules’ initial overlap length. However, the mechanisms behind this length-sensing are not fully understood. We develop a model to show how crosslinker-motor interactions produce these regulated microtubule overlaps. We observe sliding even when motors exert no direct forces on neighboring microtubules due to purely steric interactions. Direct binding interactions between crosslinkers and motors can significantly increase the lifetime of the final overlap.
How actin dynamics affect membrane nanotube mechanics

ANTOINE ALLARD (Presenter), FLAVIEN BRETTE, ALEXANDRE DESLYS, Curie Institute, GUILLAUME LAMOUR, Université d'Évry Val d'Essonne, FABRICE VALENTINO, Curie Institute, TIMO BETZ, Münster University, CLÉMENT CAMPILLO, Université d'Évry Val d'Essonne, CÉCILE SYKES, Curie Institute — The living cell is an out-of-equilibrium system that constantly remodels its architecture to ensure biological functions such as division or intracellular transport. The latter involves the formation of intermediate cylindrical membrane nanotubes. These nanotubes are then split into membrane compartments transported in other areas of the cell. Whereas mechanics of pure membrane nanotubes are now well understood, the role of the actin cytoskeleton on tube stability remains unclear.

To address this question, we develop a bottom-up approach based on model lipid membranes on which we reconstitute actin assembly with a minimal number of proteins. Two distinct methods allow us to reproduce the in vivo cylindrical membrane geometry. First, nanotubes are pulled from vesicles with optical tweezers. Second, lipid deposits are brushed and characterized by atomic force microscopy. We finally observe the formation of an actin muff that proves successful activation of actin network growth around the tube.

Both methods allow us to derive the viscoelastic properties of the muff. For example, tubes surrounded by the muff retract slowly (3.5 s) compared to pure membranes (< 0.5 s). A striking observation is that tube radius decreases in the presence of actin and may initiate further scission.

Tuning Migratory and Cytoskeletal Response of Cells to Texture with Collagen-IV Coating*

MATT J. HOURWITZ (Presenter), JOHN T FOURKAS, Department of Chemistry and Biochemistry, University of Maryland-College Park, WOLFGANG LOSERT, Department of Physics, University of Maryland-College Park — Cell migration is vital for many physiological processes, both beneficial and detrimental. Actin is a cytoskeletal protein scaffold that assembles and disassembles to accomplish cell motion in a specific region and direction. A stimulus must be provided to influence guided cellular motion. In addition to biochemical signals, physical cues such as the texture of the environment also provide a guiding stimulus. To better understand how cytoskeletal and migratory processes integrate biochemical information with texture information, we studied actin dynamics and migration of MCF10A cells, an immortalized human breast epithelial cell line, on 3D nanotopographical surfaces. We systematically varied the coating with collagen IV, a basement membrane protein representing key biochemistry of the local ECM. Preliminary studies show that the response of actin to surface texture significantly depends on collagen coating concentration.

Microrheology of Microtubule-Actin-Vimentin Composite Cytoskeletal Networks*

YINAN SHEN (Presenter), MARJAN SHAYEGAN, Department of Physics & SEAS, Harvard University, ARTURO MONCHO, Department of Applied Physics & Institute Carlos I for Theoretical and Computational Physics, University of Granada, HUI LI, Institute of Physics, Chinese Academy of Sciences, HUAYIN WU, WEICHAO SHI, Department of Physics & SEAS, Harvard University, SONGLEI LIU, Harvard Medical School, Harvard University, JING XIA, DIANZHUO WANG, LIHENG CAI, MENG ZHANG, RUIHUA DING, Department of Physics & SEAS, Harvard University, FREDERICK MACKINTOSH, Chemistry, Physics and Astronomy & Chemical and Biomolecular Engineering, Rice University, DAVID A WEITZ, Department of Physics & SEAS, Harvard University — Mechanics of the cytoskeleton is known to be responsible for maintaining cell mechanical integrity and determining cellular functions. We develop a method that enables us to reconstruct a three-component in-vitro network composed of intermediate filaments (vimentin filaments), microtubules and F-actin filaments, which are three fundamental cytoskeletal components. This composition is more physiologically relevant compared with any of the previously reconstituted cytoskeletal networks, which are composed of one or two components only. We investigate the structure and mechanical properties of this multicomponent cytoskeletal network using a combination of several microscopies and microrheology. We show that vimentin filaments couple the other cytoskeletal filaments together by introducing steric constraints between cytoskeletal polymers; these inter-network interactions extend the composite network elastic behavior to a longer time scale, prolong the network relaxation time, and facilitate the stress propagation within the network. These findings are helpful to deepen our understanding of the mechanical role vimentin plays in regulating cellular activities.

*NIH grant 2P01GM096971
4:42PM H64.00008: Maximal entropy production rates in non-contractile actomyosin* DANIEL S. SEARA (Presenter), VIKRANT YADAV, IAN LINSMEIER, PASHA TABATABAI, Yale Univ, PATRICK W. OAKES, University of Rochester, ALI TABELI, University of Northern Iowa, SHILADITYA BANERJEE, University College London, MICHAEL MURRELL, Yale Univ — The actin cytoskeleton is an active semi-flexible polymer network whose non-equilibrium properties coordinate both stable and contractile behaviors to maintain or change cell shape. While myosin motors drive the actin cytoskeleton out-of-equilibrium, the role of myosin-driven active stresses in stable states of actomyosin is unclear. To investigate this, we synthesize an actomyosin material in vitro whose active stress content can tune the network from stable to contractile and analyze the resulting filament dynamics using the framework of stochastic thermodynamics. We find that the entropy production rate does not increase monotonically with myosin content, but instead is maximized in a non-contractile, stable state. Our study provides evidence that the origins of system entropy production and activity-dependent dissipation relate to disorder in the molecular interactions between actin and myosin.

4:54PM H64.00009: Actively crosslinked microtubule networks: mechanics, dynamics and filament sliding SEBASTIAN FUERTHAUER (Presenter), CCB, Flatiron Institute, BEZIA LEMMA, UCSB, PETER FOSTER, MIT, STEPHANIE C EMS-MCCLUNG, CLAIRE E WALCZAK, Indiana University, ZVONIMIR DOGIC, UCSB, DANIEL NEEDLEMAN, Harvard University, MICHAEL JOHN SHELLEY, CCB, Flatiron Institute — Cellular components such as cytoskeletal filaments and motors are the essential constituents of a new class of materials: so called active fluids. While much progress has been made in understanding these systems using experiments and phenomenological theories, deriving rigorous theoretical description from microscopic considerations remains a challenge. We present experiments and theory on a system of stabilized microtubules driven by the molecular motor protein XCTK2. Through photobleaching experiments, we demonstrate that in this system microtubules are aligned along the long direction of the system and travel through the gel at a velocity independent of the local average polarity. We show that this result is most naturally understood in the frameworks of an active gel theory that goes beyond pairwise microtubule interactions and treats the gel as highly cross-linked. Our theory bridges the length scales from the microscopic mechanical behavior of motor-filament interactions to the large scale behavior of the active gel and generalizes to describe different kinds of cytoskeletal assemblies.

5:06PM H64.00010: Particle delivery using bead-loading gives insight into heterogeneity of the cellular cytoplasm* WENLONG XU (Presenter), ASHOK PRASAD, Chem & Bio Engr, Colorado State University — Microrheology is an important technique for probing the properties of the cytoplasm, but requires particle delivery inside cells. Here we report a particle delivery method based on a method of protein delivery called bead-loading, requiring no specialized instruments. Bead loading is able to deliver 100nm fluorescent particles that are widely dispersed into the cellular cytoplasm. Particle tracking reveals that the fluorescent particles probe two very different regions of the cytoplasm. One set of beads are significantly confined, and treatment by drugs indicate that the confinement is due to the actin cytoskeleton. The second set of beads seemingly display free diffusion, but ATP depletion experiments show that the motion has an actively driven component. Most strikingly, the main effect of most drug treatments is through changing the relative distribution of these two populations. Our analysis suggests that the specific mode of particle delivery may be strongly affecting the measured properties of cells, underlining the importance of intracellular heterogeneity. The general applicability of our particle delivery technique and the distribution of intracellular movement were confirmed in three different cell lines.

strengths and degrees of shape frustration for which these behaviors are possible. We also show how depolymerization can be prevented or even arrested in-progress (the latter allowing rescue and regrowth) by the presence of even very few GTP-tubulin dimers, and explore the ranges of binding interaction hypothesized as a part of microtubule dynamics, drive depolymerization via the unpeeling "ram's horns" consistent with tubulin, we demonstrate that conformational changes in subunits that frustrate tubulin binding, which have long been understood. Using molecular dynamics simulations of whole microtubules built from a new coarse-grained model of GTP-tubulin dimers (tubulin bound to GTP), but hydrolysis of GTP- to GDP-tubulin within the tubules eventually destabilizes them toward catastrophically-fast depolymerization, if the leading cap of GTP-tubulin is lost. The molecular mechanisms and features of the individual tubulin proteins that drive such apparently contradictory behavior are still not well-understood. Using molecular dynamics simulations of whole microtubules built from a new coarse-grained model of tubulin, we demonstrate that conformational changes in subunits that frustrate tubulin binding, which have long been hypothesized as a part of microtubule dynamics, drive depolymerization via the unpeeling "ram's horns" consistent with experiments. We also show how depolymerization can be prevented or even arrested in-progress (the latter allowing rescue and regrowth) by the presence of even very few GTP-tubulin dimers, and explore the ranges of binding interaction strengths and degrees of shape frustration for which these behaviors are possible.

**2:30PM H65.00001: Controlling the intracellular dynamics of neuronal model systems**

KATE M O’NEILL (Presenter), University of Maryland, College Park — Excitable tissues in the body have unique properties that allow for the transfer of information between individual cells and across larger scales. For example, recent work has investigated the spatiotemporal dynamics of electrical activity propagation in neural and cardiac tissues in both in vivo and in vitro settings. In the present work, we study how the intracellular behavior of in vitro cultures of primary rat cortical neurons can be tuned and controlled with electric fields. However, in addition to the effects on electrical signal propagation that are traditionally studied, we are also interested in the morphological responses of neurons to these electric fields with the goal of understanding the interaction between electrical activity propagation and cytoskeletal dynamics, particularly of actin. To accomplish this goal, we do the following: 1) apply electric field stimulation to the in vitro neuronal culture, 2) image changes in transmembrane potential or intracellular actin, and 3) quantify the intracellular response. We show that the dynamics of actin change significantly over time as the structural components of neurons (axons and dendrites) mature and become more stable. Moreover, we show that neurons can be electrically activated by direct current (DC) electric fields, but the degree and complexity of the response to the field strongly depends on the age of the cells with a more prevalent response observed as the neurons (and therefore, synapses) have matured. In sum, we have found that we can tune neuronal cell behavior with electric fields, and in future work, we hope to apply these same perturbations to other cells and make inferences about the intracellular behavior of other electrically excitable cell types.

*K Kate O’Neill was funded by a MURI grant (#FA9550-16-1-0052) to Dr. Wolfgang Losert.

**3:06PM H65.00002: Precisely regulate ERK signaling pathway with local electric fields**

QUAN QING (Presenter), Arizona State University — Our main research interest is to understand how artificial electronics can interact with biological systems. Live cells rely on a big network of signaling pathways that sense and respond to biochemical, electrical and mechanical (BEM) stimuli. We want to explore if we can modulate this BEM network, particularly with external electric field, and investigate the mechanism at the molecular level.

In this presentation I will talk about our recent discovery of modulation of extracellular-signal-regulated kinase (ERK) pathway using alternative current (AC) electric fields (EFs). The amplitude, duration, and frequency of activation of the ERK pathway code diverse spectrum of information at cell, tissue and organism levels to instruct cells to migrate, proliferate, or differentiate. Synchronized control of ERK activation would provide a powerful approach to regulate cell behaviors. Here we show for the first time that AC EFs in a new frequency range can reproducibly activate ERK activities through patterned local microelectrodes with single-cell resolution. Both the amplitude and frequency of ERK activation can be precisely synchronized and modulated. We pinpointed a new mechanism of AC EF induced highly specific phosphorylation of epidermal growth factor (EGF) receptor (EGFR) to activate the EGFR-ERK pathway, which may serve as a powerful platform for control of cell behaviors with implications in wide range of biomedical applications.

The complete understanding of contact guidance, chemotaxis and electrotaxis may be obtained. By investigating and analyzing the actin cytoskeleton as an excitable system, a more controlled manner, to understand better immune responses. Specifically, we are studying in the cells' intracellular scaffolding, chemical gradients and endogenous electric fields guides cells to the site of inflammation. However, mimicking this system in vitro has not been previously explored. In this work, we combine the above guidance cues artificially, and in a temporally scaled fashion, to understand the emergence of various, driven phenomena, from schooling behavior in fish to electrical network dynamics in neurons and cardiomyocytes. On a tissue scale, these collective dynamics often arise in response to changes in the extracellular and intracellular environment. In this talk, we describe the collective signaling of HEK293T/17 cells modified to express sodium and potassium ion channels that form electrically-active monolayers. We investigate the collective firing dynamics across multiple spatio-temporal scales in these cell sheets in a highly-controlled fashion in order to understand the emergence of various, driven electrical wave morphologies and propagation dynamics. To accomplish this goal, we apply electrical and optical perturbations utilizing a novel optical system—a Multi-Scale Microscope—that allows for simultaneous imaging across two different spatial scales using epifluorescence and rescan confocal imaging techniques.

4:06PM H65.00005: Electric-Field Manipulation of a Cell-Free Gene Expression Reaction

ALEXANDRA TAYAR (Presenter), Physics, University of California Santa Barbara, YUVAL EFRAT, SHIRLEY SHULMAN DAUBE, MICHAEL LEVY, ROY H BAR-ZIV, Weizmann Institute of Science — Biological systems are regulated dynamically to respond to external environmental perturbations, and change their internal state as a result. Introducing controlled dynamical perturbations in minimal systems can provide insight into these processes. Currently, small biomolecular inducers are commonly used, yet applying these inducers locally and dynamically to compartmentalized micron-scaled reactions remains challenging. Here, we report on a DNA compartment fabricated in silicon and connected to thin electrodes, capable of external control of cell-free protein synthesis under steady-state conditions. We demonstrate manipulation of RNA polymerase, ribosomes and GFP in a nonuniform electrical field, using dielectrophoresis (DEP). We show local depletion of nutrients and machinery in an active gene expression reaction at physiologically relevant conditions. The response to the applied field is rapid at the scale of expression dynamics, and spatially confined thereby establishing spatiotemporal resolution of electric field control of gene expression.

*This work was supported by grants from the Israel Science Foundation, The Minerva Foundation, Office of Naval Research. A.M. Tayar thanks the Clore Foundation for a doctoral fellowship.

4:18PM H65.00006: Characterizing electrotaxis for control of cellular migration

TOM ZAJDEL (Presenter), DANIEL COHEN, Princeton University — It is well established that bioelectric fields arise during morphogenetic processes across many cell types, influencing development, metastasis, and wound healing. Many cell types use endogenous electric fields as a cue to guide cell migration in a process known as electrotaxis. While electrotaxis presents a tremendous opportunity for remote electronic control of cell migration, a formal physical approach exploring the limits and plasticity of this guided migration has not been conducted. In this work, we examine the input/output dynamics of electrotaxis in MDCK epithelial cell sheets, using rapid prototyping techniques to produce a versatile, reconfigurable platform capable of applying a programmable electric field to tissues. We modulate stimulation current density and duty cycle to probe the electrotaxis impulse and step responses. We also use live fluorescence imaging in labeled cell lines to characterize the biophysical response of the cytoskeleton during electrotaxis, which generates force during cell migration. Because collective cell migration is crucial to multicellular form and function, tools for reliable control would be invaluable for further studies of the biophysical processes underlying tissue development, wound healing, and other multicellular programs.
4:30PM H65.00007: Design considerations for high-performance dielectrophoretic devices  ZACHARY KOBOS (Presenter), SHARI YOSINSKI, AYASKA FERNANDO, MARK A REED, Yale Univ — Dielectrophoresis (DEP) uses electric field gradients to trap and manipulate the position of particles in solution. The DEP force does not require direct contact with the particle nor the use of any form of labelling mechanism, making it an attractive candidate for manipulation of cells for biological applications. Performing dielectrophoresis in high-conductivity solutions, such as physiological samples, presents significant challenges for the force magnitude, power delivery, and device integrity. We present a coherent set of circuit-level design principles for optimizing electrode geometry for enhanced performance in high-conductivity environments. Investigations of the influence of various design parameters on the DEP force are performed by monitoring changes in the equilibrium velocity, as DEP competes with the Stokes force during fluid flow.

4:42PM H65.00008: Large-scale Actin Wave Patterns Perturbed by Electric and Mechanical Cues in Giant Dictyostelium discoideum* QIXIN YANG (Presenter), Department of Physics, University of Maryland, College Park, MATT J. HOURWITZ, Department of Chemistry, University of Maryland, College Park, LEONARD CAMPANELLO, Department of Physics, University of Maryland, College Park, BEDRI SHARIF, PETER DEVROUTES, Department of Cell Biology, Johns Hopkins, School of Medicine, JOHN T FOURKAS, Department of Chemistry, University of Maryland, College Park, WOLFGANG LOSERT, Department of Physics, University of Maryland, College Park — Dictyostelium discoideum(Dd) provides a good system to study actin dynamics guided by extracellular cues such as electric field, mechanical cues and chemical gradients. However, waves in normal Dd extinguish at the boundary and only show confined sections of wave patterns. Here we apply electrofusion to produce giant Dd, a polykaryotic cell which is up to ten times the size of normal Dd. In those cells F-actin waves travel freely across plasma membrane and show large-scale wave patterns independent of boundary effects. We use this system to explore how nanoridges and DC electric fields perturb actin waves on a scale as large as 50 microns.

*This work is funded by the Air Force Office of Scientific Research grant FA9550-16-1-0052

4:54PM H65.00009: Propagation of electrical activity coupled to actin dynamics in electrically active neuron-like cells* SYLVESTER GATES (Presenter), KATE M O'NEILL, PHILLIP ALVAREZ, SAMIRA AGHAYEE, WOLFGANG LOSERT, Institute of Physical Sciences, University of Maryland, College Park — Coupling between excitable systems is a well-known phenomenon. Recent work focused on the excitability of neural and cardiovascular systems has illuminated the dynamics behind electrical signal propagation in these tissues through the use of recording microelectrodes. Other studies have shown that dendritic spines are enriched with dynamic actin at the synapses of electrically-coupled neurons. Here we investigate both electrical activity propagation and actin dynamics in a simple, excitable system: in vitro cultures of human embryonic kidney (HEK-293) cells. This cell line (NK-HEKs) has been engineered to be electrically excitable through the expression of sodium (Na+) and potassium (K+) channels. We electrically stimulate the cells to induce changes in transmembrane potential monitored noninvasively through new, fast-acting voltage sensitive dyes. We simultaneously image actin sodium (Na+) and potassium (K+) channels. We electrically stimulate the cells to induce changes in transmembrane potential monitored noninvasively through new, fast-acting voltage sensitive dyes. We simultaneously image actin dynamics in the same cells using internal fluorophores with the goal of understanding how changes in actin dynamics may drive or be driven by changes in transmembrane potential. Our results suggest that actin fluctuates in response to stimulation in these electrically active cells.

*This work is funded by an AFOSR MURI grant to WL(PI).

5:06PM H65.00010: Escherichia coli's physiology can turn membrane voltage dyes into actuators LEONARDO MANCINI (Presenter), Centre for Synthetic and Systems Biology, University of Edinburgh, Edinburgh, UK, TIANYAN, Biomedical Pioneering Innovation Center (BIOPIC), Peking University, Beijing 100871, China, GUILLAUME TERRADOT, Centre for Synthetic and Systems Biology, University of Edinburgh, Edinburgh, UK, YINGYING PU, YINGXING LI, Biomedical Pioneering Innovation Center (BIOPIC), Peking University, Beijing 100871, China, CHIEN-JUNG LO, Department of Physics and Graduate Institute of Biophysics, National Central University, Jhongli, Taiwan 32001, ROC, FAN BAI, Biomedical Pioneering Innovation Center (BIOPIC), Peking University, Beijing 100871, China, TEUTA PILIZOTA, Centre for Synthetic and Systems Biology, University of Edinburgh, Edinburgh, UK — Bacteria tend to maintain an energy-costly electric potential across the biological membrane. The voltage thus stored can then be reinvested to fuel essential reactions, such as those required for feeding, movement and anabolism. Assays of Nernstian membrane voltage dyes accumulation are arguably the most widespread techniques to quantify such potential. However, interactions of such molecules with the complex cellular environment and physiology are often poorly understood. Here, we characterize the parametrical landscape in which these molecules behave like sensors and where they actually take the role of actuators. We recommend an experimental framework that can be used to characterize Nernstian dyes and we apply it to the characterization of the dye Thioflavin T in E. coli.
CONNER HERNDON (Presenter), FLAVIO FENTON, Georgia Institute of Technology — Proper contraction of cardiac muscle relies on the coordinated propagation of transmembrane voltage. Disturbances of this propagation can result in deadly cardiac arrhythmias such as fibrillation, the manifestation of chaos in the heart. Even in healthy tissue, high heart rates can drive the system to a dynamical instability known as alternans, a period doubling bifurcation in action potential duration (APD) which is strongly correlated with the onset of fibrillation and sudden cardiac death. Much theoretical effort based on the relationship between the APD and preceding diastolic interval (DI) has aimed to suppress the onset of alternans. Results from simulation and theory claim the suppression of alternans under stimulation at a constant DI; however, few experiments have addressed these predictions. In this talk, I will discuss comparative cardiac dynamics in the hearts of species including rabbit, dog, cat, pig, frog, zebrafish, snake, lizard, and alligator through the use of microelectrode recordings and high spatiotemporal resolution optical mapping of fluorescent voltage and calcium signals across the surfaces of hearts. Furthermore, I will discuss my closed-loop control system for performing constant DI stimulation and the highly unexpected results.

Benjamin Machta

2:30PM H66.00001: Reconstructing biological dictionaries: How does neural code translate into behavior?*

DAMIAN HERNANDEZ, Centro Atómico Bariloche, SAMUEL SOBER, ILYA NEMENMAN (Presenter), Emory University — The problem of deciphering how low-level patterns (action potentials in the brain, amino acids in a protein, etc.) drive high-level biological features (sensorimotor behavior, enzymatic function) represents the central challenge of modern biology. There are no general methods for reconstructing such dictionaries from small data sets, and for building vocabularies of statistically significant, independent words in them. Here we derive a method for solving this class of problems, which we call the unsupervised Bayesian Ising Approximation (uBIA) and demonstrate its utility in deciphering the motor code in the pre-motor neurons of a songbird. From small data sets, we detect codewords that predict behavior. These words contains arbitrary number of precisely timed spikes, confirming that the motor code in this system is build from precisely timed multi-spike patterns. We show that distinct classes of such words are used preferentially in codes responsible for motor exploration versus exploitation, opening a window on how motor behaviors are controlled by the brain.

*This work was supported in part by NIH Grants 1R01-EB022872 and 5R01-NS099375.

2:42PM H66.00002: Learning to Crawl

SHRUTI MISHRA (Presenter), Harvard University, WILLEM VAN REES, Massachusetts Institute of Technology, LAKSHMINARAYANAN MAHADEVAN, Harvard University — We combine a mechanical model for a segmented, soft-bodied crawler (Paoletti and Mahadevan, 2014) with a reinforcement learning algorithm for choosing the neuronal excitations. The crawler chooses the neuronal excitations based on a minimal description of the state of its own body, with the goal of moving forward in 1-D. The gait achieved by learning neuronal excitations in this manner depends on the mechanical properties of the crawler. For a regime of properties, the crawler achieves forward locomotion by means of a peristaltic wave, qualitatively similar to what is observed in D. melanogaster larvae. This provides a mechanism for how organisms may learn to achieve locomotion in the absence of a central pattern generator, or recover from injury. This work also suggests a way to explore actuation patterns for soft-robots in cases where the optimal actuation patterns may not be intuitive and provides a means for online learning while exploring an unfamiliar terrain.
2:54PM H66.00003: Non-Gaussian Bayesian theory of sensorimotor learning with multiple timescales*  
BAOHUA ZHOU (Presenter), DAVID HOFMANN, SAMUEL SOBER, ILYA NEMENMAN, Emory University — Various experimental studies have documented that sensorimotor learning phenomena occur on multiple timescales. Many theoretical models have been proposed to explain these experimental observations. However, while successful in certain aspects, these models only focus on average learning behaviors, and they cannot explain some crucial features of learning. For example, they cannot account for the dynamics of the whole distributions of the motor outputs and cannot explain why learning speed and magnitude negatively correlate with the perturbation size. Here we propose a model that includes multiple hidden dynamical variables, which collectively generate the desired motor command. The model is a multi-dimensional Bayesian filter that deals with the dynamics of non-Gaussian joint distributions of those hidden variables. Our model explains simultaneously the dynamics of distributions of the songbird vocal behaviors in various experiments, including: (i) adaptations after step changes or ramps in the error signal, and (ii) dynamics of relaxation following removal of the perturbation. We expect this model can be applied to data from other species and sensorimotor behaviors.

*This work was supported partially by NIH Grant # 1 R01 EB022872, and NIH Grant # NS084844.

3:06PM H66.00004: Structure from noise: Mental errors yield abstract representations of events*  
CHRISTOPHER LYNN (Presenter), ARI E KAHN, DANIELLE BASSETT, University of Pennsylvania — Humans are adept at uncovering complex associations in the world around them, yet the underlying mechanisms remain poorly understood. Intuitively, learning the higher-order structure of statistical relationships should involve sophisticated mental processes, expending valuable computational resources. Here we propose a competing perspective: that higher-order associations actually arise from natural errors in learning. Combining ideas from information theory and reinforcement learning, we derive a novel maximum entropy model of people’s internal expectations about the transition structures underlying sequences of ordered events. Importantly, our model analytically accounts for previously unexplained network effects on human expectations and quantitatively describes human reaction times in probabilistic sequential motor tasks. Additionally, our model asserts that human expectations should depend critically on the different topological scales in a transition network, a prediction that we subsequently test and validate in a novel experiment. Generally, our results highlight the important role of mental errors in shaping abstract representations, and directly inspire new physically-motivated models of human behavior.

*MacArthur, Sloan, ISI, and Allen Foundations and ARL, ARO, ONR, NSF.

EVE ARMSTRONG (Presenter), CLELIA DE MULATIER, University of Pennsylvania, DAVID WHITE, Wilfred Laurier University, MARC SCHMIDT, VIJAY BALASUBRAMANIAN, University of Pennsylvania — During mating season, most species of songbird engage in a societal evolution wherein monogamous pairs “freeze out”. Presumably, these bonds are a recipe for successful procreation. The means by which all individuals “agree” on this structure is unknown. The role of song is significant\(^1\), but its mechanism of orchestrating bonding is obscure. Moreover, a dynamical systems modeling approach would be premature, as it is not clear how to define the variables.

We tackle this problem with a maximum-entropy Ising model. This approach has been applied to an eclectic set of contexts\(^2,3,4\), but – to our knowledge – not to acoustic signaling. Our inferred model, trained on instances of song, is a stronger predictor of mating pairs than are the statistical correlations: it finds monogamous pairs and also instances of polygamy. Minima on the energy landscape align with particular pairs. The Ising model fails to capture all of the structure in the data, suggesting that triadic interactions matter. Moreover, the language of statistical physics offers a framework for examining the biological motivations for songbird social structure. Refs: 1) Perkes et al., Behavioural processes 2018; 2) Schneidman et al., Nature 2006; 3) Lee, Broedersz, Bialek, J Stat Phys 2015; 4) Louie et al. PNAS 2018.

3:30PM H66.00006: Analytical corrections to entropy for under-sampled discrete distributions.  
DAMIAN HERNANDEZ, AHMED ROMAN (Presenter), ILYA NEMENMAN, Physics, Emory University — Estimating entropy of probability distributions of various data sets is a common question in modern data analysis. A common problem is that the number of independent samples obtained in experiments is limited, so that many states are under-sampled and naive entropy estimators are inaccurate. Previous studies found that the statistics of states that occur in data sets multiple times (coincidences) provide useful corrections to entropy estimates in the extremely under-sampled regime. These corrections are largely numerical in nature and so provide little insight to which features of the dataset cause them. Here, we present analytical approximations to a coincidence-based entropy estimators, which shed some light on this question.
3:42PM H66.00007: Inferring geometric embeddings for single cell data MOR NITZAN (Presenter), Harvard University, NIKOS KARAISKOS, Max Delbruck Center for Molecular Medicine, NIR FRIEDMAN, The Hebrew University of Jerusalem, NIROLAUS RAJEWSKY, Max Delbruck Center for Molecular Medicine — Massively multiplexed sequencing of RNA in individual cells is transforming basic and clinical life sciences. However, in standard experiments sequenced cells do not retain information about their original spatial context although it is crucial for understanding cellular function. Recent attempts to overcome this fundamental problem rely on employing additional imaging data which can guide spatial mapping. Here we present a conceptually different approach that allows to reconstruct spatial positions of cells in a variety of tissues without using reference imaging data. We first show for several complex biological systems that distances of single cells in expression space monotonically increase with their distances across tissues. We therefore seek to map cells to tissue space such that this principle is optimally preserved, while incorporating imaging data when available. We show that this optimization problem can be cast as an optimal transport problem and solved efficiently. We apply our approach successfully to reconstruct the mammalian liver and intestinal epithelium as well as the fly embryo. Our results demonstrate a simple spatial expression organization principle that can be used to infer meaningful spatial position probabilities from the sequencing data alone.

3:54PM H66.00008: Interpreting time series data from dynamic signaling pathways in single cells* WEERAPAT PITTAYAKANCHIT (Presenter), KABIR HUSAIN, ARVIND MURUGAN, University of Chicago — A growing body of evidence suggests that cells encode information in the dynamics of signaling molecules. For instance, both the identity and dose of different external ligands may be encoded in the temporal dynamics of a single transcription factor. Understanding which aspects of experimental time-series are informative, and which can plausibly be decoded by cells given biochemical constraints, remains an open problem. Here, we combine modified versions of interpretable machine learning techniques, such as InfoGAN, with domain knowledge of the NF-kB pathway to obtain insights on how experimental time-series data of NF-kB encodes information about the ligands TNFa and IL-2.

*AM and WP thanks the Simon Foundation for the funding support. KH thanks the James S McDonnell Foundation for the support via a postdoctoral fellowship.

4:06PM H66.00009: Learning image models for optimal information extraction: image registration from first principles* COLIN B CLEMENT (Presenter), MATTHEW BIERBAUM, JAMES PATARASP SETHNA, Cornell University — We demonstrate an unbiased method of image registration which has errors consistent with the Cramer-Rao bound (CRB) by using Super Registration: learning an optimal model for the underlying image and shifting that to match the data. Image registration is the inference of transformations relating noisy and distorted images. Fundamental in computer vision, experimental physics, and medical imaging, even in the simplest case of translation, known methods are biased and none achieve the CRB. Cutting edge experiments operate at extreme limits of signal-to-noise, for example, low-dose TEM imaging of sensitive biological materials. It is in these high-noise scenarios when existing registration techniques fail to correctly infer shifts. Following Bayesian inference, we prove that the standard method of shifting one image to match another cannot reach the CRB. We reach the theoretical lower bound in shift resolution and extract a higher resolution, de-noised model of the latent image. Finally, while sub-pixel errors in shift inference do not dramatically change the reconstructed image for oversampled data, we show that using our new registration method can lead to 10× more precise particle tracking.

*This work was supported by the NSF Center for Bright Beams, award #1549132.
In many biological phenomena, cells migrate through confining environments. To study such confined migration, we place migrating cells in two-state micropatterns, in which the cells stochastically migrate back and forth between two square adhesion sites connected by a thin bridge. We adopt a data-driven approach where we learn an equation of motion directly from the experimentally determined short time-scale dynamics, decomposing the migration into deterministic and stochastic contributions. This equation captures the dynamics of the confined cell and accurately predicts the transition rates between the sites. We thereby derive the emergent non-linear dynamics that governs the migration directly from experimental data. In particular, we find that the deterministic dynamics is poised near a bifurcation between a limit cycle and bistable behaviour. As a result, we find that cells are deterministically driven into the thin constriction; a process that is sped up by noise. Our approach yields a conceptual framework that may be extended to describe cell migration in more complex confining environments.

Single-molecule field-effect transistors (smFET) have been recently exploited to probe molecular dynamic events occurring at the single-molecule scale. Hidden Markov models (HMMs) are commonly used to model single-molecule kinetic trajectories, but they require restrictive assumptions and a priori knowledge of the likely kinetic model, both rarely met in real experiments. In particular, a major challenge in extracting kinetics from smFET data relies on the non-stationarity of the recorded signals due to noise and drifts. Here, we propose a new approach based on machine learning to retrieve the hidden trajectory between molecular states. Our method is a two-step algorithm based on compression of the raw data using a minimum description length cost function, followed by a k-medoid clustering of the compression patterns. A decision-aid tool automatically selects the multi-state model providing the best-fitting trajectory. Based on tests on synthetic and experimental data, we found that this entropy-based method allows to extract a robust idealized trajectory, without requiring any prior or supervision. We also found that using this idealized trajectory as a prior for HMM analysis provides better performances for the detection and modeling of non-stationary molecular dynamics.

Mutations play a critical role in molecular evolution and the development of many diseases, such as cancer and neurodegenerative diseases. A growing body of evidence shows that rates of mutation in DNA are not only highly variable, but also influenced by the specific sites and nearby sequences. We have found that the physics of electron hole localization, most pronounced at or near guanine sites, plays a significant role in influencing sequence-specific mutation rates [M.Y. Suárez-Villagrán, R. B. R. Azevedo, & J. H Miller, Jr., Genome Biology & Evolution, 10, 1039 (2018)]. Most recently we have been applying the predictive capability of Deep Neural Network architectures, among other machine learning approaches, to predict and validate genetic mutation rates in human mitochondrial DNA. Given a segment of a sequence from the neighborhood of a specific base pair, we are able to predict mutation rates with much greater accuracy than that of a random predictor. We are currently testing the limits of automatic predictors for similar tasks, with an aim towards better understanding of both evolution and the emergence of somatic disease states, such as cancer.

The Effects of Non-Specific Binding Kinetics on Fluorescence Activated Cell Sorting (FACS)*

BHAVEN MISTRY (Presenter), Biomathematics, UCLA, THOMAS CHOU, Mathematics, UCLA — Fluorescence activated cell sorting (FACS) is extensively used in biological studies to differentiate cells of interest (mutants) from control cells (wild-types). For mutant cells characterized by expression of a distinct membrane surface structure, fluorescent marker probes can be designed to bind specifically to those structures, resulting in a sufficiently high fluorescence intensity that indicates a mutant cell. However, endogenous membrane structures on wild-type cells may nonspecifically bind to the probes, resulting in false positive results. These same endogenous membrane structures would also be present on mutant cells, allowing both specific and non-specific binding to a single cell. We create a kinetic model of fluorescent probe binding dynamics by tracking populations of mutant and wild-type cells with differing numbers of probes bound specifically and non-specifically. By assuming the suspension is in equilibrium prior to cytometry, we analytically derive a likelihood function of the FACS output in order to infer the total number of mutant cells while accounting for the non-specific binding of probes. We further show how our model can be used to infer unknown binding rates of fluorescent markers if cell counts are a priori known.

Reverse-time inference of targeted biological dynamics

NICOLAS LENNER (Presenter), STEPHAN EULE, FRED WOLF, Max Planck Institute for Dynamics and Self-Organization — Mesoscopic bio-systems typically evolve towards functionally important target-states, such as cell cycle checkpoints or decision boundaries for the release of complex behavior. To infer the underlying directional out-of-equilibrium dynamics from such data, we develop a theory of target-state-aligned ensembles that reveals whether and when the system can be represented by a single, effective stochastic equation of motion. We show how, in this equation, genuine biological forces can be separated from spurious forces, which, invariably arise from target-state-alignment. We apply our inference scheme to canonical biological examples such as cell division and morphogenesis.

Information flow and the accuracy of concentration measurements in a genetic network*

MARIANNE BAUER (Presenter), WILLIAM BIALEK, THOMAS GREGOR, Princeton University, MARIELA D PETKOVA, Biophysics, Harvard University, ERIC WIESCHAUS, Princeton University — Many genes are regulated by transcription factor (TF) proteins which bind to DNA and control the synthesis of messenger RNA (mRNA). The information which output mRNA or protein levels carry about input TF concentrations is a measure of regulatory power. All this information passes through a bottleneck, the occupancy of the relevant binding sites along the DNA, and random arrival of TFs at these sites sets an irreducible noise level, which in turn limits the information capacity. We explore these issues in the gap gene network of the early fly embryo, where recent work shows that the concentrations of these transcription factors carry enough information to specific cellular position to 1% precision along the length of the embryo. But how accurately would the system need to “measure” these concentrations in order to extract this information? We show that these measurements need to be more accurate than is plausible given the physical limits at a single binding site, suggesting that the complex array of multiple binding sites provides a solution to the problem of efficient information transmission.

*Supported in part by the NSF Center for the Physics of Biological Function (PHY-1734030), and grant PHY-1607612; by NIH grants P50GM071508, R01GM077599, and R01GM097275; and by HHMI.

Session H69 DLS: Optical Frequency Comb Spectroscopy

BCEC 052A - Kristan Corwin, Kansas State University -

Tag(s): Invited
2:30PM H69.00001: Tri-comb Spectroscopy* [Invited] STEVEN CUNDIFF (Presenter), BACHANA LOMSADZE, BRAD C SMITH, Department of Physics, University of Michigan — Optical multidimensional coherent spectroscopy (MDCS) has been developed over the last 20 years and proven very powerful at unfolding congested spectra, identifying coupling between resonances, making size-resolved measurements of nanoparticles and revealing many-body interactions [1]. However, MDCS has required a complex apparatus and has suffered from limited spectral resolution.

Inspired by developments in dual-comb spectroscopy, we developed comb-based MDCS, improving the spectral resolution by over an order of magnitude, which we demonstrated by resolving the hyperfine split transitions in a rubidium vapor [2]. With the addition of third frequency comb, which we call "tri-comb spectroscopy," we are able to eliminate all moving parts and further improve the resolution with a data record of less than 0.5 seconds long [3]. These results also demonstrate the separation of the two isotopies of rubidium, showing the promise of MDCS for chemical sensing where the separation of species is a critical challenge.

These results open a path towards an implementation of MDCS that can rapidly produce spectra using a compact and robust apparatus that can be used outside a laboratory.

*The research is based on work supported by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), via contract 18020600001.

3:06PM H69.00002: Widely tunable cavity-enhanced ultrafast spectroscopy and the dynamics of hydrogen bond networks.* [Invited] THOMAS ALLISON (Presenter), MYLES SILFIES, JOSE MIGUEL BAUTISTA, Departments of Chemistry and Physics, Stony Brook University, GRZEGORZ KOWZAN, Institute of Physics, Faculty of Physics, Astronomy and Informatics, Nicolaus Copernicus University in Torun, Poland, YUNING CHEN, Departments of Chemistry and Physics, Stony Brook University — Ultrafast optical spectroscopy methods, such as transient absorption spectroscopy and 2D spectroscopy, are widely used across many disciplines. However, these techniques are typically restricted to optically thick samples, such as solids and liquid solutions. In previous work (Reber et al. Optica 3, 311 (2016)), using frequency comb lasers and resonant optical cavities, we have demonstrated the extension of all-optical ultrafast spectroscopy methods to dilute molecular beams and recorded transient absorption signals with detection limits as low as ΔOD = 2×10^{-10}. In this talk I will discuss our progress in developing widely tunable cavity-enhanced ultrafast spectrometers operating from the ultraviolet to the mid-infrared and their application to the ultrafast dynamics of elementary hydrogen bond networks.

*National Science Foundation award number 1708743

3:42PM H69.00003: Multi-comb coherent control for material studies* [Invited] KAORU MINOSHIMA (Presenter), AKIFUMI ASAHARA, The University of Electro-Communications, JST ERATO-IOS — Dual-comb spectroscopy (DCS), which uses two frequency combs with slightly different repetition frequencies, has become a powerful tool for high-precision spectroscopy because of its capability for rapid, broadband, high-resolution, and high-sensitivity measurement. Recently, the applicability of the DCS has greatly expanded to such as nonlinear spectroscopy and solid-state study. By utilizing the DCS as the tool to retrieve the dynamical response of the electric field of the optical wave in the sub-PHz frequency domain, we can directly obtain the complex optical properties of the materials as the response function, which provides an attractive tool for direct characterization of new materials without model assumption. We have applied the technique for direct characterization of the complex optical properties of solid materials [1] and studying ultrafast phenomena [2]. In this study, we focused on the coherent controllability with multi-comb and realized generation and coherent detection of the raid polarization modulation of ultrashort pulse train. The technique was applied to the dynamical characterization of complex optical tensor of material. Moreover, we realized the spatio-temporal phase control of ultrashort pulse train by combining the optical frequency comb and optical vortex, i.e., optical vortex comb, and applied to the DCS for azimuth sensitive spectroscopy with all the advantages of the standard DCS. Such technique is useful for coherent excitation and control of orbital angular momentum related phenomena, such as topological physics, spintronics, and chiral material.

*This work was supported by Japan Science and Technology Agency (JST) through the Exploratory Research for Advanced Technology (ERATO) MINOSHIMA Intelligent Optical Synthesizer (IOS) Project (JPMJER1304).
Soliton microresonator frequency combs* [Invited] TOBIAS KIPPENBERG (Presenter), Ecole polytechnique federale de Lausanne — Optical frequency combs\(^1\)\(^2\) provide equidistant markers in the IR, visible and UV and have become a pivotal tool for frequency metrology and are the underlying principle of optical atomic clocks, but are also finding use in other areas, such as broadband spectroscopy or low noise microwave generation. Development are underway to create chip-scale frequency comb sources\(^1\) that are low power, compatible with wafer scale processing, exhibit microwave repetition rates, for applications that are airborne or in space. Such "micro-combs" are based on parametric frequency conversion of a continuous wave laser, and make use of dissipative Kerr soliton formation\(^2\)\(^3\) \(^4\) (DKS). Such dissipative Kerr solitons provide access to fully coherent and broadband combs with tailorable bandwidth. In this talk the Physics of dissipative solitons is reviewed, as discovered in crystalline resonators. Microcombs, give rise to a host of nonlinear dynamical phenomena, including Soliton Cherenkov radiation\(^5\), breather solitons\(^6\), soliton switching\(^7\), to soliton crystals\(^8\), and multi-soliton complexes. In addition soliton microcombs have been applied in massively parallel coherent communication\(^9\), dual comb distance measurements\(^10\), with record acquisition rate, and exhibit a bandwidth that can be extended to the biological imaging window. Soliton microcombs have the potential to advance timekeeping, and make frequency metrology ubiquitous.

Dual Comb Spectroscopy for Emissions Measurements+ [Invited] ELEANOR WAXMAN (Presenter), KEVIN COSSEL, FABRIZIO GIORGETTA, WILLIAM SWANN, National Institute of Standards and Technology Boulder, GAR-WING TRUONG, Crystalline Mirror Solutions, MICHAEL CERMACK, National Institute of Standards and Technology Boulder, DANIEL HESSELIUS, IRISS, University of Colorado, IAN CODDINGTON, NATHAN NEWBURY, National Institute of Standards and Technology Boulder — Trace gas measurements are critical for understanding city contributions to greenhouse gas emissions and for identifying and quantifying natural gas leaks from oil and gas wells. Here we present a near-infrared dual comb spectroscopy system that we use for trace gas measurements. Our system is comprised of a dual comb spectroscopy instrument, a telescope and co-located detector, and a retroreflector located at the far end of our measurement path. This enables us to measure over path lengths of several hundred meters to several kilometers. We have compared this system against a near-identical system over the open atmosphere with excellent agreement of retrieved trace gas concentrations. We then deployed this system at NIST to measure the carbon dioxide enhancement over the city of Boulder, Colorado which we primarily attribute to vehicle exhaust. This is coupled with Gaussian plume modeling to estimate the emissions from the city and we have good agreement with the city estimate of vehicle emissions. Finally, we deploy the system in the field in a van to measure emissions from a simulated natural gas leak using a mobile UAS-mounted retroreflector. This work shows the promise of using horizontal column-integrated open-path measurements for emissions quantification.

*We acknowledge funding from DARPA DSO SCOUT program, NRC fellowship program, and the NIST Special Projects office.

Session H29A APS: Planned Giving Session BCEC 162A

4:00PM H29A.00001: Planned Giving Session — tbd

Tuesday, March 5, 2019 4:30 PM - 6:30 PM

Session J72 APS: Meet the Physical Review Journal Editors Reception BCEC East Registration

4:30PM J72.00001: Meet the Physical Review Journal Editors Reception — Learn about the exciting new journal from APS, which begins accepting submissions in 2019. Also take this opportunity to meet the editors and discuss the Physical Review family of journals.

All are welcome. Light refreshments will be served.

Tuesday, March 5, 2019 5:30 PM - 6:30 PM
Session J34 APS: Town Hall: Guide to Effective Practices for Physics Departments: Implications for Program Review and Accreditation BCEC 205A - Tag(s): Education

5:30PM J34.00001: Town Hall: Guide to Effective Practices for Physics Departments: Implications for Program Review and Accreditation — ABET, the accrediting body for nearly every engineering program in the U.S., recently announced that they were actively pursuing accreditation of physics and other undergraduate science programs. APS is concerned that accreditation may stifle educational innovation or lead us into a “check the box” mentality of program review. On the positive side, many chairs have indicated the need for a helpful set of resources that will enable them to run a department more effectively, and address areas of need. As a response to these concerns the APS Council approved the formation of a task force to: “Develop a guide for self-assessment of undergraduate physics programs founded on documented best practices linked to measurable outcomes.” The task force has been working on developing a community-based, living-document that will serve as a guide on how to improve the health of a physics department, tackle common problems, and prepare for external review. We will discuss progress on developing this guide, and solicit input on how to make these materials useful and accessible to the physics community.

Tuesday, March 5, 2019 5:30 PM - 7:00 PM

Session J73 APS/SPS: Student Reception BCEC Ballroom East/West - Tag(s): Undergraduate

5:30PM J73.00001: Student Reception — Graduate and undergraduate students can mingle with working physicists at the special student reception with light fare until 7:00 p.m. Immediately following, all students who presented at the March Meeting in the Undergraduate Research Sessions will be recognized, and students with outstanding presentations will also receive a special prize.

Tuesday, March 5, 2019 5:30 PM - 7:00 PM

Session J81 APS: Reviews of Modern Physics: The First Ninety Years

Session J81.00001: 2D Materials: Science and Technology

7:30PM J81.00001: 2D Materials: Science and Technology [invited] ANTONIO HELIO CASTRO NETO (Presenter), Centre for Advanced 2D Materials, National University of Singapore — The surprising isolation of graphene in 2004 has created a new field of research, namely, 2D Crystals. Nowadays we know that there are thousands of different types of 2D crystals with electronic properties that range from metals and semiconductors to magnets and superconductors. These new materials have had not only an impact in modern science but they are already having a technological impact in the industry. In this seminar I will review the field and its evolution in the last few years.

8:00PM J81.00002: Previews of Modern Physics [invited] NIGEL DAVID GOLDENFELD (Presenter), University of Illinois at Urbana-Champaign — The Reviews of Modern Physics (RMP) is certainly the most well-cited review journal in the world of physics. Its stellar reputation reflects the depth and detail of its reviews of fields that have reached sufficient maturity for a review to be warranted. In this talk, I will argue that there is another factor that has perhaps made an outsize contribution to its impact: some of the most influential articles have been reviews about fields that in some sense do not yet exist, or are still in their formative stages. I will focus on several examples drawn from the world of condensed matter and statistical physics, including: (1) Leo Kadanoff’s RMP on critical phenomena (1967); (2) Ken Wilson’s RMP on the Kondo problem (1975); (3) Jim Langer’s RMP on the field of non-equilibrium pattern formation (1981); (4) Stephen Wolfram’s RMP on cellular automata (1983); (5) Albert and Barabasi’s RMP on the statistical mechanics of networks (2002). I would contend that these review articles owe their success not simply to the traditional metrics of comprehensiveness of scope, timeliness and quality of exposition, but to the fact that they catalyzed the evolution of their respective fields, by inspiring receptive scientists to see possibilities that would not otherwise have been so apparent. I will try to draw some recommendations that could guide future authors who wish to write a “preview” of an emerging field.

8:30PM J81.00003: Interface-induced phenomena in magnetism: writing a review article in an important topical subject with 27 leading scientists as co-authors [invited] FRANCES HELLMAN (Presenter), University of California, Berkeley — This article reviews static and dynamic interfacial effects in magnetism, focusing on interfacially driven magnetic effects and phenomena associated with spin-orbit coupling and intrinsic symmetry breaking at interfaces. It provides a historical background and literature survey, but focuses on recent progress, identifying the most exciting new scientific results and pointing to promising future research directions. It starts with an introduction and overview of how basic magnetic properties are affected by interfaces, then turns to a discussion of charge and spin transport through and near interfaces and how these can be used to control the properties of the magnetic layer. Important concepts include spin accumulation, spin currents, spin-transfer torque, and spin pumping. An overview is provided to the current state of knowledge and existing review literature on interfacial effects such as exchange bias, exchange-spring magnets, the spin Hall effect, oxide heterostructures, and topological insulators. The article highlights recent discoveries of interface-induced magnetism and noncollinear spin textures, nonlinear dynamics including spin-transfer torque and magnetization reversal induced by interfaces, and interfacial effects in ultrafast magnetization processes.

Session K01 DCMP: Floquet Systems

Wednesday, March 6, 2019 8:00 AM - 10:36 AM

Session K01.00003: Interface-induced phenomena in magnetism: writing a review article in an important topical subject with 27 leading scientists as co-authors [invited] FRANCES HELLMAN (Presenter), University of California, Berkeley — This article reviews static and dynamic interfacial effects in magnetism, focusing on interfacially driven magnetic effects and phenomena associated with spin-orbit coupling and intrinsic symmetry breaking at interfaces. It provides a historical background and literature survey, but focuses on recent progress, identifying the most exciting new scientific results and pointing to promising future research directions. It starts with an introduction and overview of how basic magnetic properties are affected by interfaces, then turns to a discussion of charge and spin transport through and near interfaces and how these can be used to control the properties of the magnetic layer. Important concepts include spin accumulation, spin currents, spin-transfer torque, and spin pumping. An overview is provided to the current state of knowledge and existing review literature on interfacial effects such as exchange bias, exchange-spring magnets, the spin Hall effect, oxide heterostructures, and topological insulators. The article highlights recent discoveries of interface-induced magnetism and noncollinear spin textures, nonlinear dynamics including spin-transfer torque and magnetization reversal induced by interfaces, and interfacial effects in ultrafast magnetization processes.
8:00AM K01.00001: Central Charge of Periodically Driven Critical Kitaev Chains* DANIEL YATES (Presenter), YONAH S LEMONIK, ADITI MITRA, New York University — Periodically driven Kitaev chains show a rich phase diagram as the amplitude and frequency of the drive is varied, with topological phase transitions separating regions with different number of Majorana zero and π modes. We explore whether the critical point separating different phases of the periodically driven chain may be characterized by a universal central charge. We affirmatively answer this question by studying the entanglement entropy (EE) numerically, and analytically for the lowest entangled many particle eigenstate at arbitrary non-stroboscopic and stroboscopic times. We find that the EE at the critical point scales logarithmically with a time-independent central charge, and that the Floquet micro-motion gives only sub-leading corrections to the EE. This result also generalizes to multi-critical points where the EE is found to have a central charge which is the sum of the central charges of the intersecting critical lines.

*This work was supported by the US Department of Energy, Office of Science, Basic Energy Sciences, under Award No.–DE-SC0010821.

8:12AM K01.00002: Signatures of Floquet Majorana Fermions in Planar Josephson Junctions* DILLON LIU (Presenter), JAVAD SHABANI, ADITI MITRA, Center for Quantum Phenomena, New York University — We show how Floquet Majorana fermions may be experimentally realized in a periodically driven solid state platform. We consider a planar Josephson junction formed via a superconducting-proximitized 2D electron gas (2DEG) with Rashba spin-orbit coupling and in-plane Zeeman field. Using bulk Floquet topological invariants we analyze the number of zero and π Majorana modes for experimentally realistic parameters. Then we describe several experimental signatures of these exotic modes in finite wires, including differential conductance and local density of states. Notably, features in these quantities exhibit sub-harmonic responses to the drive.

*DTL and AM were supported by the US Department of Energy, Office of Science, Basic Energy Sciences, under Award No. DE-SC0010821. J.S. was supported by the US Army Office of Research, ARO: W911NF-18-1-0067, and US Air Force Office of Scientific Research Young Investigator Award, FA9550-16-1-0348.

8:24AM K01.00003: Time-Crystalline Topological Superconductors* AARON CHEW (Presenter), California Institute of Technology, DAVID MROSS, Weizmann Institute of Science, JASON ALICEA, California Institute of Technology — Time crystals form when arbitrary physical states of a periodically driven system spontaneously break discrete time-translation symmetry. We introduce the notion of 1D time-crystalline topological superconductors, for which time-translation symmetry breaking and Majorana physics nontrivially intertwine. In the simplest realization, such a phase exhibits a bulk magnetization that returns to its original form after two drive periods, together with unconventional Floquet Majorana end modes that recover their initial form only after four drive periods. We also propose experimental implementations and detection schemes for this new phase.

*Grants DMR-1341822 and DMR-1723367 (A. C. and J. A.); the Minerva foundation with funding from the Federal German Ministry for Education and Research (D.F.M.); Grant Award W911NF-17-1-0323 (A. C. and J. A.); BSF Grant No. 2016258; Caltech's IQIM with support of Grant GBMF1250; and the Walter Burke Institute for Theoretical Physics at Caltech.

8:36AM K01.00004: Three-dimensional Chiral Lattice Fermion in Floquet Systems XIAO-QI SUN (Presenter), MENG XIAO, TOMAS BZDUSEK, SHOUCHENG ZHANG, SHANHUI FAN, Stanford University — We show that the Nielsen-Ninomiya no-go theorem still holds on Floquet lattice: there is an equal number of right-handed and left-handed Weyl points in three-dimensional Floquet lattice. However, in the adiabatic limit, where the time evolution of low-energy subspace is decoupled from the high-energy subspace, we show that the bulk dynamics in the low-energy subspace can be described by Floquet bands with extra left/right-handed Weyl points, despite the no-go theorem. Assuming adiabatic evolution of two bands, we show that the difference of the number of right-handed and left-handed Weyl points equals twice the winding number of the adiabatic Floquet operator over the Brillouin zone. Based on these findings, we propose a realization of purely left- or right-handed Weyl particles on a 3D lattice using a Hamiltonian obtained through dimensional reduction of a four-dimensional quantum Hall system. We argue that the breakdown of the adiabatic approximation on the surface facilitates unusual closed orbits of wave packets in applied magnetic field, which traverse alternatively through the low-energy and high-energy sector of the spectrum.
8:48AM K01.00005: Disentangling beyond-cohomology symmetry protected topological phases*  
JEONGWAN HAAH, Microsoft, LUKASZ FIDKOWSKI (Presenter), University of Washington, MATTHEW HASTINGS, Microsoft — We construct a three-dimensional locality preserving unitary operator which disentangles the ground state of the Walker-Wang three fermion model. We show that this locality preserving unitary operator cannot be a quantum circuit, or otherwise one could construct a commuting projector model which realizes a phase with nonzero chiral central charge, which is widely believed to be impossible. We comment on the relation to Many-body localized Floquet topological phases.

*NSF DMR-1519579, Microsoft Research

9:00AM K01.00006: Transport signatures of symmetry protection in one-dimensional topological insulators  
OLEKSANDR BALABANOV (Presenter), HENRIK JOHANNESSON, Department of Physics, University of Gothenburg — The unique feature of any topological insulator is presence of gapless states on its boundaries. In one dimension these states live on the edges and are protected against symmetry-preserving local perturbations. Here we describe a scheme for probing the robustness of the edge states by calculating the transport characteristics of an array of dimers attached to external leads. Numerical results obtained from non-equilibrium Green's function theory will be presented. It will be shown that there is a drop in the differential conductance as the dimer array is perturbed by a local symmetry-breaking perturbation, while the drop is strongly suppressed if the symmetries are maintained. A brief analytic description will be provided in support of the numerics. Both types of 1D topological insulators, conventional time-independent and periodically-driven (Floquet), are considered.

9:12AM K01.00007: Topologically protected braiding in a single wire using Floquet Majorana modes*  
TORSTEN KARZIG (Presenter), BELA BAUER, Station Q, Microsoft, TAMÍ PEREG-BARNEA, Department of Physics, McGill University, MARIA-THERESA RIEDER, Department of Condensed Matter Physics, Weizmann Institute, GIL REFAEL, Department of Physics, Caltech, EREZ BERG, Department of Physics, University of Chicago, YUVAL OREG, Department of Condensed Matter Physics, Weizmann Institute — The non-Abelian nature of Majorana zero modes is most prominently exhibited through braiding. While originally formulated for 2D systems, it has been shown that braiding can also be realized using 1D wires by forming an essentially 2D network. Here, we show that in driven systems far from equilibrium, one can do away with the second spatial dimension altogether by instead using quasienegy as the second dimension. To realize this, we use a Floquet topological superconductor which can exhibit Majorana modes at two special eigenvalues of the evolution operator, 0 and Pi, and thus can realize four Majorana modes in a single, driven quantum wire. We describe and numerically evaluate a protocol that realizes non-local braiding of two Majorana zero modes in a single wire by adiabatically modulating the Floquet drive and using the Pi modes as auxiliary degrees of freedom.

9:24AM K01.00008: Metal to insulator phase transitions in Floquet-Bloch systems*  
ILIYA ESIN (Presenter), Technion - Israel Institute of Technology, MARK RUDNER, Niels Bohr Institute, Copenhagen University, NETANEL LINDNER, Technion - Israel Institute of Technology — Time-periodic drives provide a versatile tool for inducing topological phenomena in quantum many body systems. In this work, we study steady-states of low-dimensional semiconductors subjected to strong resonant periodic drives. Stable steady-states in these systems arise from the balance between phonon-assisted relaxation processes, electron-hole recombination via photo-emission and electron-electron scattering. We show that tuning the parameters of the phonon bath drives the system through a critical point, which separates an electron-hole metal phase from a Floquet insulator phase. Our results may help guide future studies towards inducing novel non-equilibrium phases of matter by periodic driving.

*This work was supported by European Research Council (ERC) under the European Union Horizon 2020 Research and Innovation Programme (Grant Agreement No. 678862 and 639172), the Israeli Science Foundation and the Villum Foundation.
Motivated by recent experimental realizations of topological charge pumping in cold atoms, we theoretically study the Rice-Mele model with spatiotemporal disorder coupled to two leads using the Floquet Keldysh green’s function approach. The temporal disorder characterizes random motion of electrons due to a bath, with diffusive, sub-diffusive, or white noise as special cases. We obtain the pumped charge in the full range of drive frequency away from the adiabatic limit for different strengths of disorder, and for different temporal disorders. We quantify and discuss localization-delocalization transitions in the Floquet spectrum and their effect on the topological pumped charge.

**Floquet Topological Semimetal with Nodal Helix**

KWON PARK (Presenter), KUN WOO KIM, HYUNWOONG KWON, Korea Institute for Advanced Study — Topological semimetal with nodal line is a novel class of topological matter extending the concept of topological matter beyond topological insulators and Weyl/Dirac semimetals. Here, we show that a Floquet topological semimetal with nodal helix can be generated by irradiating graphene or the surface of a topological insulator with circularly polarized light. Nodal helix is a form of nodal line running across the Brillouin zone with helical winding. Specifically, it is shown that the dynamics of irradiated graphene is described by the time Stark Hamiltonian, which can host a Floquet topological insulator and a weakly driven Floquet topological semimetal with nodal helix in the high and low frequency limits, respectively. One of the most striking features of the Floquet topological semimetal at low frequency is that the Berry phase accumulated along the time direction, also known as the Zak phase, has a topological discontinuity of $\pi$ across the projected nodal helix. It is predicted that such a topological discontinuity of the Berry phase manifests itself as the topological discontinuity of the Floquet states. At intermediate frequency, this topological discontinuity can create an interesting change of patterns in the quasienergy dispersion of the Floquet states.

---

**Session K02 DMP: Topological Metamaterials** BCEC 107A - Che-Ting Chan, Hong Kong University of Science and Technology - Tag(s): Focus

**8:00AM K02.00001: Exceptional Nanophotonics** [Invited] LIANG FENG (Presenter), University of Pennsylvania — Integrated nanophotonics promises next-generation computing platforms. In this talk, I will present our work on exceptional nanophotonics, creating “quantum” exceptional points on-a-chip and utilizing their associated topology. Based on the exceptional point-induced unidirectionality, we harness optical losses to enable unique photonics functionalities, in particular, an orbital angular momentum (OAM) microcavity that structures and twists lasing radiations at the micro/nano-scale and a low-power all-optical switch, which may address the growing demand for information capacity. Additionally, I will discuss non-Hermitian topological photonics where optical non-Hermiticity and topological physics are coupled to produce robust photonic integrated circuits and laser sources and novel microscopic thermal sensors.

**8:36AM K02.00002: Definite photon deflections of topological defects in metasurfaces and symmetry-breaking phase transitions with material loss**

HUI LIU (Presenter), CHONG SHENG, Department of Physics, Nanjing University, HUANYANG CHEN, Department of Electronic Science, Xiamen University, SHINING ZHU, Department of Physics, Nanjing University — In this work [1], by using an artificial waveguide bounded with rotational metasurface, the nontrivial effects of a topological defect of spacetime are experimentally emulated. The photon deflection in the topological waveguide has a robust definite angle that does not depend on the location and momentum of incident photons. This is remarkably different from the random optical scattering in trivial space. By including material loss such a topological effect can be well understood from the symmetry breaking of photonic modes. Our technique provides a platform to investigate topological gravity in optical systems. This method can also be extended to obtain many other novel topological photonic devices.

**8:48AM K02.00003: Loss induced high efficient Lorentz nonreciprocal metasurfaces**

WANG TAT YAU (Presenter), WENYAN WANG, KIN HUNG FUNG, Hong Kong Polytechnic University — Lorentz nonreciprocal metasurfaces rely on breaking all symmetries related to energy flow reciprocity. We numerically design a metasurface made of dimer unit cell to achieve nonreciprocity. The dimer consists of a gyromagnetic and lossy dielectric cylinder. Under the biased magnetic field, the TE (nonzero electric field out of plane) polarized plane wave at normal incident in different direction exhibit nonreciprocal transmission. We successfully employ the multiple scattering theory (MST) up to the dominant resonant modes of cylinders to describe the numerical nonreciprocal feature. The nonreciprocal mechanism can be revealed by the eigenresponse theory that different direction incidence comprises of different portion of lossy mode which will favour to excite the lossy dielectric cylinder, leading to nonreciprocal transmission.

9:00AM K02.00004: Topological pumping in a maGneto-mechanical system* INBAR GRINBERG (Presenter), MAO LIN, CAMERON HARRIS, WLADIMIR BENALCAZAR, CHRISTOPHER PETERSON, TAYLOR HUGHES, GAURAV BAHL, University of Illinois at Urbana-Champaign — A topological charge pump conveys quanta of charge across a gapped system while being robust against array disorder, external noise, and disorder in the pumping protocol. The implementation of topological insulators in both optical and acoustic coupled resonator systems has opened exciting paths towards new control over light and sound, however an equivalent temporal topological pump has yet to be demonstrated. In this work, we demonstrate that a 1D classical system that is adiabatically spatio-temporally modulated can produce an equivalent topological pump for bosons. Our experimental demonstration consists of an array of magneto-mechanical resonators, where the inter-resonator coupling rates are controlled by the distance over which the magnetic interaction takes place. We modulate both the coupling rates and the on-site potentials using a mechanical apparatus, and demonstrate that mechanical energy can be pumped from one edge mode of the array to the other edge mode while the system remains gapped. We show that this 1D array is the equivalent of a Chern insulator in one real dimension and one synthetic dimension.

9:12AM K02.00005: Unidirectional excitation of surface plasmon polaritons in a grating system with Parity-Time symmetry YIHAO XU (Presenter), Mechanical Engineering, Northeastern University, LIN LI, YONGMIN LIU, Electrical and Computer Engineering, Northeastern University — Over the past years, there has been rapidly growing interest in non-Hermitian photonic systems. A Hamiltonian with Parity-Time (PT) symmetry can show real spectrum below a certain threshold, known as the exceptional point (EP), accompanied with novel phenomena above the EP. Here we propose a plasmonic grating system with PT symmetry to excite unidirectional surface plasmon polaritons (SPPs). We have designed realistic grating array only consisting of passive rectangular gratings (i.e., without gain materials), which can significantly reduce the challenges in fabrication and optical experiments. In addition, instead of using ideal sinusoidal permittivity modulation in simulation in former paper(2), here we demonstrate in both simulation and experiment that using discrete grating array can also achieve excellent contrast between SPPs in opposite directions. In summary, we have demonstrated a sub-wavelength scale plasmonic grating structure with PT symmetry that can realize high performance for unidirectional excitation of SPPs. These results can be employed as a new approach to designing nanoscale optical devices, such as low-loss plasmonic routers and isolators for optical computation, communication, and information processing.

9:24AM K02.00006: Atomic-scale nanophotonics and quantum optics through 2D phonon polaritons* NICHOLAS RIVERA (Presenter), Applied Physics, Harvard University, THOMAS CHRISTENSEN, Massachusetts Institute of Technology, PRINEHA NARANG, Applied Physics, Harvard University — Recent developments have demonstrated extreme confinement of electromagnetic energy in the mid-infrared via phonon polaritons in polar insulators. Phonon polaritons hold promise for low-loss nanophotonics, as well as realizing extreme interactions with quantum emitters at the single-photon level. To bring these materials to the ultimate limit of optical nano-confinement, it is critical to consider phonon polaritons in low-dimensional polar materials, where the physics of optical phonons is fundamentally different due to the lack of LO-TO splitting. In this talk, we find universal forms for the properties of phonon-polaritons in one- and two-dimensions which result from the unique character of Coulomb interactions in low-dimensional systems. Leveraging first-principles calculations of optical phonons in 2D, we calculate the polaritonic properties of polar insulator monolayers, presenting specific results for hexagonal boron nitride. We find regimes of low-loss and high-confinement of electromagnetic energy, and show how these regimes can be probed with EELS. We then show how nanostructuring can be used to develop ultrafast quantum emitters of phonon polaritons in the mid-IR.

**9:36AM K02.00007: Zak phase of 1-D electrostatically gated graphene grating and optical properties of plasmonic edge state**

ZHIYUAN FAN (Presenter), GENNADY SHVETS, Cornell University — We design periodic metal gates on top of a hBN/Graphene/hBN sandwich heterostructure to modulate local graphene conductivity. We investigated properties of graphene surface plasmon (GSP) of a doubly gated graphene. Stop bands due to GSP modes mixing can be controlled by electrostatic doping. Topology of each plasmon band can be characterized by a Zak phase. When two insulators of a same bandgap but distinct Zak phases are joined together, an edge state in the bandgap has been observed in many physical systems. The edge state observed on our graphene grating platform presents an anisotropic dipole moment. While it radiating into the left or right in the forward direction offers an interrogation approach for band topologies of component graphene gratings, the angle of radiation remains a tunable property that depends on an interplay of the mode's resonant frequency, the bandgap width, its mid-gap frequency and the dimensions of metal gates. Due to its capability of active tuning, this may serve as a stepping stone on the way toward active control of surface plasmon band structures for optical communication, wavefront steering or sensing applications.

**9:48AM K02.00008: Broadside Coupled Resonators for Real-time Tunable Metamaterials**

XIAOGUANG ZHAO (Presenter), Boston University, JINGDI ZHANG, Department of Physics, University of California San Diego, GUANGWU DUAN, Boston University, JACOB SCHALCH, RICHARD DOUGLAS AVERITT, Department of Physics, University of California San Diego, XIN ZHANG, Boston University — Metamaterials based on broadside coupled split ring resonators (BC-SRRs) exhibit large tunability induced by modulating the coupling that arises from mutual capacitance and inductance. We design and fabricate a real-time tunable terahertz metamaterial by integrating BC-SRRs with comb-drive actuators, and characterize the dynamic response using terahertz time domain spectroscopy. The experimental results reveal that we can control the amplitude and phase of the transmission coefficient dynamically by driving the comb-drive actuators. We also observe remarkable modulation in the group delay. A two-port resonator model, derived from coupled mode theory, can analytically explain the experimental results and unveils the critical role of coupling between BC-SRRs. The results demonstrate that the propagation of electromagnetic waves can be dynamically controlled through modulating coupled resonators in metamaterials.

**10:00AM K02.00009: Ultrahigh Numerical Aperture Silicon Metalens at Visible Wavelengths**

JUNTAO LI (Presenter), HAOWEN LIANG, School of Physics, Sun Yat-sen University, China, THOMAS F KRAUSS, Department of Physics, University of York, UK — High Numerical Aperture (NA) Metalens is among the promising optical elements for ultrathin microscope objective [1, 2]. Meanwhile, crystalline silicon (c-Si) has been shown to be used in the high transmission metasurfaces at visible wavelength because of its low loss and low cost [3, 4]. Here, we demonstrate an oil front-immersion metalens with NA = 1.48, a bandwidth of 211 nm and a focusing efficiency of 48% at 532 nm wavelength, base on a 500 nm thick c-Si on sapphire [2] (compared with 50% for back-immersion TiO2 metalenses with NA = 1.1 [1]). Thereby demonstrating the highest NA of any metalens at visible wavelengths reported to the best of our knowledge. We further implement our metalens onto the laser scanning confocal microscopy as the immersion objective to demonstrate the imaging quality. We note that this fabrication process is fully compatible with mature CMOS technologies. We envision this design also to be beneficial for immersion metalens doublets, thereby pushing metasurfaces into practical applications such as confocal microscopy and achromatic lenses.

By using the dyadic Green's matrix spectral method, we demonstrate that aperiodic deterministic Vogel spirals made of electric dipoles support light localization in three dimensions, an effect that does not occur in traditional uniform random media. We discover a transition from an extended to a localized regime by evaluating the Thouless conductance and by performing a finite-size scaling. Vogel spirals are suitable photonic platforms to localize light thanks to their distinctive structural correlation properties that enable collective electromagnetic excitations with strong light-matter coupling. By decomposing the dyadic field propagator in its different components we show that light localization in Vogel arrays originates from collective electromagnetic coupling involving the contributions of multiple length scales. Our results unveil the importance of structural correlations in deterministic aperiodic photonic media for the design of localized states with strongly enhanced light-matter interactions. In addition, our findings may open new vistas for the engineering of mesoscopic transport and localization phenomena and should encourage deeper investigations of photonic devices based on deterministic aperiodic architectures.

**K03.00001: Classification and construction of higher-order symmetry protected topological phases of interacting bosons***

**ALEXANDER RASMUSSEN** (Presenter), **YUANMING LU**, Ohio State University — Motivated by the recent discovery of higher-order topological insulators, we study their counterparts in strongly interacting bosons: `higher-order symmetry protected topological (HOSPT) phases'. While the usual (1st-order) SPT phases in d spatial dimensions support anomalous (d-1)-dimensional surface states, HOSPT phases in d dimensions are characterized by topological boundary states of dimension (d-2) or smaller, protected by certain global symmetries and robust against disorders. Based on a dimensional reduction analysis, we show that HOSPT phases can be built from lower-dimensional SPT phases in a way that preserves the associated crystalline symmetries. When the total symmetry is a direct product of global and crystalline symmetry groups, we are able to classify the HOSPT phases using the Künneth formula of group cohomology. Based on a decorated domain wall picture of the Künneth formula, we show how to systematically construct the HOSPT phases, and demonstrate our construction with many examples in two and three dimensions.

**K03.00002: Intrinsically interacting topological crystalline insulators and superconductor***

**ALEXANDER RASMUSSEN** (Presenter), **YUANMING LU**, Ohio State University — Motivated by recent progress in crystalline symmetry protected topological (SPT) phases of interacting bosons, we study topological crystalline insulators/superconductors (TCIs) of strongly interacting fermions. We construct a class of intrinsically interacting fermionic TCIs, and show that they are beyond both free-fermion TCIs and bosonic crystalline SPT phases. We also show how these phases can be characterized by symmetry protected gapless corner/hinge states.

*NSF under award number DMR-1653769 (AR,YML) and in part by NSF grant PHY-1607611 (YML).
8:24AM K03.00003: Disorder-induced helical phase in magnetic topological insulators*

ARBEL HAIM (Presenter), Caltech, RONI ILAN, Tel Aviv University, JASON ALICEA, Caltech — In magnetically doped thin-film topological insulators, aligning the magnetic moments generates a quantum anomalous Hall phase with a single chiral edge state. We study the de-magnetization process and show that disorder from randomly oriented magnetic moments can produce a quantum-spin-Hall-like phase with counter-propagating helical edge modes protected by a unitary reflection symmetry. This phase is analogous to the quantum spin Hall effect observed in the zeroth Landau level of graphene, which is also protected by a unitary symmetry (spin rotation). We show that introducing superconductivity, combined with selective breaking of reflection symmetry by a gate, allows for creation and manipulation of Majorana zero modes via purely electrical means.

8:36AM K03.00004: Topological states from topological crystals*

ZHIDA SONG, Chinese Academy of Sciences, SHENG-JIE HUANG (Presenter), University of Colorado, Boulder, YANG QI, Fudan University, CHEN FANG, Chinese Academy of Sciences, MICHAEL A HERMELE, University of Colorado, Boulder — We show that crystalline symmetry protected topological states is adiabatically connected to a real-space crystalline pattern of lower-dimensional topological states, which we refer to as a topological crystal. As a demonstration of principle, we explicitly enumerate all inequivalent topological crystals for non-interacting time-reversal symmetric electronic insulators with significant spin-orbit coupling and any one of the 230 space groups in three dimensions. Because every topological crystalline insulator can be deformed into a topological crystal, the enumeration of the latter gives topological crystalline insulators a full classification and for each class an explicit real-space construction.

8:48AM K03.00005: Landau levels of topological surface states probed by quantum capacitance*

SU KONG CHONG (Presenter), RYUICHI TSUCHIKAWA, JARED HARMER, Department of Physics and Astronomy, University of Utah, TAYLOR D. SPARKS, Department of Materials Science and Engineering, University of Utah, VIKRAM V. DESHPANDE, Department of Physics and Astronomy, University of Utah — Three-dimensional topological insulator (3D TI) is known by its unique Dirac dispersion surface states arising from band inversion of its bulk. Development of discrete Landau levels (LLs) in strong perpendicular magnetic field provides strong evidence of quantization from two-dimensional nature of the topological surface states. Density of states of the surface states' LLs can be quantitatively determined through a quantum capacitance measurement. However, quantum capacitance in 3D TI is relatively less explored primarily due to mixing signals from the bulk or narrow bulk bandgap such as strained HgTe. In this work, we study the quantum capacitance of a truly bulk insulating 3D TI via a TI-based van der Waals heterostructures configuration. The quantum capacitance data are compared to the quantum Hall conductance in transport. By controlling the dual-gate voltages, we access the LLs from each surface states. The chemical potentials as function of charge density are extracted to quantify the LL spacings.

9:00AM K03.00006: Band structure and superconductivity in In-doped topological insulator (Pb_{0.5}Sn_{0.5})_{1-x}In_xTe probed by NMR spectroscopy∗ BEN-LI YOUNG (Presenter), PING-CHUN TSAI, Department of Electrophysics, National Chiao Tung University, GENDA GU, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory — The bulk band structure and superconductivity in the In-doped topological crystalline insulators (Pb_{0.5}Sn_{0.5})_{1-x}In_xTe, for x = 0, 0.1, 0.2, and 0.3, have been investigated by nuclear magnetic resonance (NMR) techniques. We found that the NMR frequency shifts of $^{117}$Sn, and $^{207}$Pb are dominated by the spins of free charge carriers, whereas the $^{125}$Te frequency shift is determined by the magnetic orbital moments of the binding electrons. By analyzing these shifts, we conclude that In substitution for 0 ≤ x ≤ 0.3 provides not just hole carriers but also lifts the chemical potential from the valence bands to the conduction bands, in consistent with the results from the electric transport measurements. The superconductivity in the x = 0.3 sample is investigated by the nuclear spin-lattice relaxation rate (1/T_1) as a function of temperature, where a Hebel-Slichter coherence peak is observed near the critical temperature. This suggests that the superconducting gap in the bulk is fully opened and this feature may favor that (Pb_{0.5}Sn_{0.5})_{0.7}In_{0.3}Te is a conventional superconductor rather than a chiral p-wave topological superconductor.

∗This work was supported by Ministry of Science and Technology, Taiwan (Grants No. MOST 104-2112-M-009-013).

9:12AM K03.00007: Disorder-driven phase transitions in chiral-symmetric topological insulators JAHAN CLAES (Presenter), TAYLOR HUGHES, University of Illinois at Urbana-Champaign — Chiral-symmetric topological insulators exhibit properties, such as polarization, that are robust to translation-symmetric perturbations provided the perturbations do not close the energy gap. However, it's unclear to what extent these topologically protected properties are robust to disorder, as disorder breaks the translation symmetry. Here we study a collection of 2D chiral-symmetric models with disorder using a covariant real space formula for the topological invariant. Generically, we find that the topological invariants remain precisely quantized until a critical value of disorder, at which point it smoothly decreases to zero. Furthermore, we find that the critical disorder occurs exactly when states at the Fermi energy become delocalized. We therefore demonstrate that the topological characteristics are robust, and that in the presence of disorder the topology is protected by a mobility gap in place of an energy gap.

9:24AM K03.00008: Low Temperature Terahertz Nano Imaging of WTe2 Thin Film RAN JING (Presenter), YINMING SHAO, Department of Physics, Columbia University, ZAIYAO FEI, XIAODONG XU, Department of Physics, University of Washington, DIMITRI BASOV, Department of Physics, Columbia University — We discuss the development of cryogenic scanning near-field microscope suitable for nano-scale imaging and spectroscopy at terahertz frequency range with the spatial resolution below 130 nm[1]. We report terahertz near-field measurement of WTe2 thin film of 1 to 3 layers[2] above and below the metal-insulator transition. Clear contrast in near-field signal can be observed among regions with different layer numbers and between metallic and insulating state.

9:36AM K03.00009: Detection of higher order topological phase in a disordered breathing Kagome model by using machine learning HIROMU ARAKI (Presenter), TOMONARI MIZOGUCHI, YASUHIRO HATSUGAI, University of Tsukuba — A higher order topological insulator is a new concept of topological states of matter, which is characterized by the emergent boundary states whose dimensionality is lower by more than two compared with that of the bulk, and draws a considerable interest. Yet, its robustness against disorders is still unclear. Here we investigate a phase diagram of higher order topological insulator phases in a breathing Kagome model in the presence of disorders, by using a state-of-the-art machine learning technique. We find that the corner states survive against the finite strength of disorder potential as long as the energy gap is not closed, indicating the stability of the higher order topological phases against the disorders. We also discuss the relation between the higher order topological phase and the Z_3 Berry phase, which is a bulk topological invariant.
9:48AM K03.00010: Double-frequency Aharonov-Bohm effect and non-Abelian braiding property of Jackiw-Rebbi zero-mode * YIJIA WU (Presenter), International Center for Quantum Materials, School of Physics, Peking University, Beijing, China, JIE LIU, Department of Applied Physics, School of Science, Xian Jiaotong University, Xian, China, HAIWEN LIU, Center for Advanced Quantum Studies, Department of Physics, Beijing Normal University, Beijing, China, HUA JIANG, College of Physics, Optoelectronics and Energy, Soochow University, Suzhou, China, XINCHENG XIE, International Center for Quantum Materials, School of Physics, Peking University, Beijing, China — Ever since its first proposal in 1976, Jackiw-Rebbi zero-mode has been drawing extensive attention for its charming properties including charge fractional quantization, topologically protected zero-energy and possible non-Abelian statistics. We numerically investigate the Jackiw-Rebbi zero-mode in a quantum spin Hall insulator heterostructure and show that its zero-energy nature leads to a double-frequency Aharonov-Bohm effect in electronic transport. Such observation suggests that Majorana zero-mode could be viewed as a special case of Jackiw-Rebbi zero-mode. Moreover, similar to the Majorana zero-modes, Jackiw-Rebbi zero-modes also show non-Abelian braiding properties in a cross-shaped junction. However, such non-Abelian property can be destroyed by infinitesimal disorder breaking charge-conjugation symmetry, implying the presence of charge-conjugation symmetry is of equal importance as the topological gap in the topological quantum computation.

10:00AM K03.00011: Quasi-particle Interference on the Step Edges of Epitaxial Stanene on InSb (111) * JIANFENG ZHANG (Presenter), XIAOHU ZHENG, RUI-RUI DU, Peking University — Stanene (single-layer of tin), having an atomic structure similar to graphene, offers a promising platform for achieving room-temperature quantum spin Hall effect with a gap of 0.3 eV [1-3]. We have performed the in-situ scanning tunneling microscopy experiments on stanene which was epitaxially grown on the InSb (111). Several types of step edges have been observed in the atomic-resolution STM topographic image. The quasi-particle interference near the steps has been detected by STS, allowing us to study the electron scattering behavior along the edge in relation to the topological property of the edge state.

10:12AM K03.00012: Experimental demonstration of the robustness of topological surface states on a PbTaSe2 superconductor HAO ZHENG (Presenter), Shanghai Jiao Tong University, SHUANG JIA, Peking University, China, HSIN LIN, Academia Sinica, ZAHID HASAN, Princeton University — Conventional semiconductor electronic surface states are determined by the details of its surface geometry, and the chemical nature of the surface atoms. Conversely, topological surface states arise entirely from the non-trivial bulk band topology. In topological insulators, the bulk electronic structure is always gapped while the surface is metallic everywhere independent of surface details. This bulk-boundary correspondence is the key manifestation of topology in a condensed matter system.

Unfortunately, there has yet to be solid experimental demonstrated in a real material. Here, on superconducting Z2 topological insulator PbTaSe2(001), we uncover two types of surfaces with distinct surface geometry and chemistry, namely 1 × 1-Se and 2 × 2-Pb surfaces. By means of scanning tunneling microscopy, we find metallic surface states on both types of surfaces. Moreover, we discern the superconducting gap to be uniform on both surfaces. Our research serves as the first experimental proof that the topological surface state is robust against surface geometry reconstruction, variation in chemical termination of the surface, and superconducting interactions, possibly opening new pathways for research in topological materials.

10:24AM K03.00013: Study of the topological surface state quantum Hall effect in the bulk-insulating topological insulator devices FENGQI SONG (Presenter), Nanjing University — In the topological insulator BiSbTeSe2 devices, which allowing an optimized surface transport, we observe the well-developed quantum Hall effect. By depositing the Co clusters on the top surface, the quantum Hall plateaus were modulated. We find an anomalous quantization trajectory for the top surface, as well as a quasi-half-integer plateau. This is due to the sizeable Zeeman gap induced by the Co clusters on the top surface through antiferromagnetic exchange coupling, which delays the Landau level hybridization for a moderate magnetic field.

Also, in the high quality Sn-Bi1.1Sb0.9Te2S devices, the quantum Hall plateau show a more precious value, which allows the study of the plateau to plateaua transition. We find the scaling exponent is nearly half of that in the traditional two dimensional electron gas, which may be originate from the electron interactions.
**10:36 AM K03.00014: Chiral Phonon Transport Induced by Topological Magnons**

EVEN THINGSTAD (Presenter), AKASHDEEP KAMRA, ARNE BRATAAS, ASLE SUDBO, Norwegian University of Science and Technology — The plethora of recent discoveries in the field of topological electronic insulators has inspired a search for boson systems with similar properties. There are predictions that ferromagnets on a two-dimensional honeycomb lattice may host chiral edge magnons. In such systems, we theoretically study how magnons and phonons couple. We find topological magneto-polarons around the avoided crossings between phonons and topological magnons. Exploiting this feature along with our finding of Rayleigh edge phonons in armchair ribbons, we demonstrate the existence of chiral edge modes with a phononic character. We predict that these modes mediate a chirality in the coherent phonon response and suggest to measure this effect via elastic transducers. These findings reveal a possible approach towards heat management in future devices.

**10:48 AM K03.00015: First-order topological quantum phase transitions in strongly correlated one-dimensional systems**

SIMONE BARBARINO (Presenter), TU Dresden — Topological quantum phase transitions, such as the transition between a topological insulator and a trivial gapped phase, are hallmarked by the change of a topological invariant [1]. For non-interacting fermions, such transitions between insulating phases are continuous since they are accompanied by the closing of the band gap as long as the symmetries of the system are maintained. For interacting fermions, by contrast, this paradigm is altered and first-order topological quantum transitions can occur [2].

In my talk I discuss the first example of a first-order topological quantum phase transition in a strongly correlated one-dimensional system [3]. Specifically, I consider a four-leg ladder which supports a symmetry protected topological phase in the presence of an on-site repulsive interaction, but is driven towards a trivial phase by a nearest-neighbor interaction. Employing a DMRG approach, I investigate at a numerically exact level the first-order nature of the transition.

Session K04 DMP: Dirac/Weyl Semimetals -- Transport I

**8:00 AM K04.00001: Transport Properties in Dirac semimetal ZrTe5**

QIANG LI (Presenter), Brookhaven National Laboratory — We report transport measurements of Dirac semimetal ZrTe5 single crystals. We found the anomalous peak in the temperature dependence of resistivity is the result of the Lifshitz transition, which also leads to a sign change in thermopower. Large negative longitudinal magneto-resistance is the result of the chiral magnetic effect. Magnetic field effectively transforms Dirac semimetals into Weyl semimetals by breaking time reversal symmetry. Large anomalous Hall effect observed in ZrTe5 is the result of the Berry curvature generated by the Weyl nodes.

*Work at Brookhaven is supported by the Office of Basic Energy Sciences, Materials Sciences and Engineering Division, U.S. Department of Energy (DOE) under Contract No. DE-SC0012704.*
8:12AM K04.00002: Magnetic field induced Weyl points and anomalous transport in Bi$_{89}$Sb$_{11}$* WENJUAN ZHANG (Presenter), Department of Physics, The Ohio State University, DUNG VU, Department of Mechanical and Aerospace Engineering, The Ohio State University, CUNEYT SAHIN, MICHAEL FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, NANDINI TRIVEDI, Department of Physics, The Ohio State University, JOSEPH P C HEREMANS, Department of Mechanical and Aerospace Engineering, The Ohio State University — A significant enhancement of magneto thermal conductivity in semimetal Bi$_{1-x}$Sb$_x$ alloy for a particular Sb concentration x=11% was discovered. As shown in a previous theoretical work on Weyl semimetals [1], Fermi arcs provide efficient ‘conveyor belt’ for magneto thermal transport. In this talk, we argue that Bi$_{1-x}$Sb$_x$ becomes a Weyl semimetal under magnetic field and the enhancement of magneto thermal conductivity is due to the resulting Fermi arcs, based on the tight binding parameterization calculated by a modified virtual crystal approximation. By calculating Chern numbers on two-dimensional slices of the three-dimensional Brillouin zone, we show that a pair of Weyl points appear near L points above a critical field strength, and that the separation between those Weyl points increases with the field strength which explains the anomalous angular dependence of magneto thermal conductivity on magnetic field.

*This research is supported by the Center for Emergent Materials, an NSF MRSEC, under Award Number DMR-1420451.

8:24AM K04.00003: Experimental evidence for the presence of Fermi-arc driven entropy transport in the field-induced Weyl semimetal Bi$_{89}$Sb$_{11}$* DUNG VU (Presenter), Department of Mechanical Engineering, The Ohio State University, CUNEYT SAHIN, Department of Physics and Astronomy, University of Iowa, WENJUAN ZHANG, Department of Physics, Ohio State University, MICHAEL FLATTÉ, Department of Physics and Astronomy, University of Iowa, NANDINI TRIVEDI, Department of Physics, Ohio State University, JOSEPH P C HEREMANS, Department of Mechanical Engineering, The Ohio State University — Topologically protected Fermi arc surface states in Weyl semimetals have been predicted to produce a conveyor-belt entropy transport [1]. Related theory talks [2][3] show that Bi$_{89}$Sb$_{11}$ alloys become Weyl semimetals in a magnetic field applied along the trigonal direction above a critical value $H_C$. Here, we report a strong field-induced increase in electronic thermal conductivity of Bi$_{89}$Sb$_{11}$ single crystals along the trigonal direction in longitudinal magnetic fields $H>H_C$. The Lorenz ratio increases up to 80-fold at $H=9$T. We report the temperature, length, and angular dependence of the effect in 5 different samples of Bi-Sb alloys with mobilities up to 2x10$^6$ cm$^2$V$^{-1}$s$^{-1}$. The effect is absent in fields not oriented along the trigonal direction; when the samples are doped n-type and $E_F$ s not at the Weyl point; and in the ordinary semimetal Bi$_{95}$Sb$_{5}$. We posit that the large positive magnetothermal conductivity is a unique signature of topologically protected surface states.

*Funding: NSF DMR-1420451.

8:36AM K04.00004: Supercurrent oscillations in Weyl Semimetal MoTe$_2$* WUDI WANG (Presenter), STEPHAN KIM, MINHAO LIU, ROBERT CAVA, NAI-PHUAN ONG, Princeton University — MoTe$_2$ is a type-II Weyl semimetal with intrinsic superconductivity and pressure-induced superconductivity. Our interest is in the superconducting state at ambient pressure, with $T_c$ around 100mK. We fabricated microscale MoTe$_2$ flakes with Au contacts by mechanical exfoliation and nanofabrication and measured their transport properties. We observed multiple peaks in the differential resistance (dV/dI) vs. bias current curves, and the positions of these peaks change periodically with magnetic field. Most samples show two kinds of oscillations, one is Fraunhofer Pattern (single slit diffraction) type with oscillation amplitude decreasing at high magnetic field, the other one is Young's Interference Pattern (double-slit interference) type with oscillation amplitude not decreasing. The latter one (Young's type) always has period corresponding to about 60% of the physical area of samples. We conclude that the latter one come from the edge of the crystals and indicating the existence of superconducting edge state in MoTe$_2$

8:48AM K04.00005: General aspects of the anomaly-related magneto-conductance in Weyl semimetals  HIROAKI ISHIZUKA (Presenter), Department of Applied Physics, University of Tokyo, NAOTO NAGAOSA, Center for Emergent Matter Science, RIKEN — Magneto-conductance (MC) in Weyl semimetals is intensively studied as it is presumably related to the chiral magnetic effect. While the theory of anomaly contribution is widely accepted, its relation to the experimentally-observed MC remains controversial, because there are many other mechanisms for MC. For this purpose, the understanding on the general property of the MC is favorable, e.g., the effects of tilting, warping, and other details. However, studies on such effects are still limited, and no general understanding is reached so far. One challenge here is the lack of general and concise formalism, which is convenient for intuitive discussions.

In this work, we discuss the general behavior of anomaly-related MC by introducing a concise formalism. Using this formalism, we explicitly show that the MC in type-II Weyl semimetals is dominated by the electrons around the Weyl nodes [1]. We also show an intuitive explanation of the tilting dependence of the MC [1]. Our formalism also implies that the MC in type-I Weyl semimetals remains robust even when multiple Weyl nodes are enclosed in a Fermi surface [2].

9:00AM K04.00006: Ultra-high surface conductivity in Weyl semimetal NbAs  CHENG ZHANG (Presenter), ZHUOLIANG NI, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai 200433, China, JINGLEI ZHANG, Anhui Province Key Laboratory of Condensed Matter Physics at Extreme Conditions, High Magnetic Field Laboratory of the Chinese Academy of Sciences, Hefei 230031, China, XIANG YUAN, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai 200433, China, XIANGANG WAN, National Laboratory of Solid State Microstructures, School of Physics, Nanjing University, Nanjing 210093, China, SERGEY Y. SAVRASOV, Department of Physics, University of California, Davis, California 95616, USA, FAXIAN XIU, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai 200433, China — In two-dimensional (2D) systems, high mobility is typically achieved in low-carrier-density semiconductors and semimetals. Increasing the carrier density in these systems to be comparable to typical metals usually degrades the mobility value, owing to an enhanced scattering probability from the large Fermi wave vector and possible charged impurities from the doping process. Here, we discover that the surface state of Weyl semimetal NbAs can overcome such a limit and maintain a high mobility even in the presence of a high carrier density. To study its surface transport properties, we first develop a new growth scheme to synthesize high-quality nanostructures of NbAs with tunable Fermi levels. Owing to the large surface-to-bulk ratio, the 2D surface state exhibits dominant quantum oscillations with a high carrier density. Combined with the high mobility value, a record-high surface sheet conductance among non-superconducting 2D systems is achieved up to 5-100 S. Corroborated by theory, we attribute the origin of the ultra-high surface conductance to the disorder-tolerant nature of Fermi arcs. Our results present the first transport evidence for the low-dissipation property of NbAs surface state and establish it as an excellent 2D metal with supreme conductivity.

9:12AM K04.00007: Current at a distance in the Dirac semimetal ZrTe5*  NICHOLAS QUIRK (Presenter), SIHANG LIANG, NAI-PHUAN ONG, Princeton University — Non-local electronic conductivity in Dirac and Weyl semimetals has been predicted to arise from charge pumping in the bulk due to the chiral anomaly, and from cyclotron-like orbits of surface Fermi arcs weaving together with bulk states. We used focused ion beam (FIB) milling to thin samples of the Dirac semimetal ZrTe5 to sub-μm thicknesses, and we created electrical devices with these samples to probe these two non-local conductivity mechanisms. We will discuss difficulties we encountered using FIB and methods we tried in order to overcome them, and we will describe experiments we undertook to detect non-local conduction.

9:24AM K04.00008: Anisotropic Giant Planar Hall Effect in type-II Weyl Semimetals* PENG LI (Presenter), Institute for Quantum Computing, Department of Electrical and Computer Engineering, University of Waterloo, CHENHUI ZHANG, Physical Science and Engineering, King Abdullah University of Science and Technology, GEORGE NICHOLS, LONG CHEN, GUOXING MIAO, Institute for Quantum Computing, Department of Electrical and Computer Engineering, University of Waterloo, XIXIANG ZHANG, Physical Science and Engineering, King Abdullah University of Science and Technology — Recently, giant planar Hall effect originating from chiral anomaly, which is related to the chiral Landau levels, has been predicted and realized in nonmagnetic Dirac/Weyl semimetals. WTe$_2$ is considered to be an intriguing type-II Weyl semimetal with its Weyl cone tilted due to its broken inversion symmetry. Here, we report the observation in WTe$_2$ of the giant planar Hall resistivity that shows a $B^2$ magnetic-field dependences as predicted by theory. Most importantly, we observed a highly anisotropic planar Hall resistivity when the current flows along $a$- and $b$-axis of WTe$_2$. The planar Hall resistivity at low temperatures with current flowing along $b$-axis is almost twice of that along $a$-axis, because the chiral Landau levels and chiral anomaly are well-defined (or absent) when the magnetic field is parallel (or perpendicular) to the tilting direction ($b$-axis) of Weyl cone in WTe$_2$.

9:36AM K04.00009: Fermi surface study of the Weyl type-II semimetal candidate NbIrTe$_4$* RICO SCHOENEMANN (Presenter), National High Magnetic Field Laboratory, SHOUVIK SUR, Northwestern University, VICTOR QUITO, Iowa State University, YU-CHE CHIU, WENKAI ZHENG, National High Magnetic Field Laboratory, GREGORY T. MCCANDLESS, JULIA Y. CHAN, University of Texas at Dallas, LUIS BALICAS, National High Magnetic Field Laboratory — Here we present a study of the Shubnikov-de Haas (SdH) effect in the type-II Weyl semimetal candidate NbIrTe$_4$. Quantum oscillations were obtained at temperatures down to 0.3 K and in high magnetic fields up to 35 T. The angular dependence of the SdH frequencies is in good agreement with results from DFT calculations, although we are not able to detect every orbit. We observe an unusual butterfly shaped magnetoresistance as a function of the sample orientation with respect to the magnetic field, which is likely to originate from the shape and anisotropy of the Fermi surface. Furthermore, we measured a large non-saturating magnetoresistance up to fields 35 T which suggests charge carrier compensation. On the other hand Hall measurements indicate significantly different electron and hole densities, which implies that the non-saturating magnetoresistance is not driven by charge carrier compensation.

9:48AM K04.00010: Weyl fermion-phonon coupling and magnetic-field-induced large thermopower in TaP FEI HAN (Presenter), THANH NGUYEN, Nuclear Science and Engineering, Massachusetts Institute of Technology, NINA ANDREJEVIC, Materials Science and Engineering, Massachusetts Institute of Technology, RICARDO PABLO PEDRO, MINGDA LI, Nuclear Science and Engineering, Massachusetts Institute of Technology — Weyl semimetals (WSM) have massless chiral fermions, the so-called Weyl Fermions. The chiral anomaly in its magneto-transport is one of the signatures for the existence of the plus and minus Weyl nodes which always appear in a pair. Recent theoretical predictions discussed the possibility to detect chiral anomaly based on phonon spectra, where the exotic electronic degrees of freedom in a WSM are playing an increasingly important role to influence the phonon structure. We measured the phonons via inelastic X-ray scattering (IXS) on the TaP crystals near the Weyl points, where an ambipolar behavior is observed when moving away from the Weyl points. This is a reliable indicator of the existence and the strength of Weyl fermion-phonon coupling. We are further using the magnetic field to break the time-reversal-symmetry for observing the central phenomenon of chiral anomaly. We also observed an unexpected magnetic-field-induced large thermopower in TaP. We consider the large thermopower of the Weyl semimetal induced by magnetic field subjected to a quantizing magnetic field. The thermopower of the Weyl semimetal grows linearly with the field without saturation and can reach extremely high values. This sheds lights on the achievement of a record-high thermoelectric figure-of-merit.
10:00AM K04.00011: Observation of Magic Angle Effect in Angular Dependence of Magnetoresistance of ZrTe5 in the Quantum Limit* 

JOSHUA Mutch (Presenter), MINHAO HE, XINGHAN CAI, PAUL MALINOWSKI, XIAODONG XU, JIUN-HAW CHU, University of Washington — We report the discovery of sharp, anomalous dips in the angular dependence of magnetoresistance in ZrTe5 single crystals. These dips occur at fixed "magic angles" once the magnetic field passes the quantum limit. The magic angles correspond to commensurate angles where the field direction connecting neighboring atoms in the lattice, reminiscent of “Lebed's Magic Angles” found in the organic Bechgaard salts (TMTSF)2X. Unlike the Bechgaard salts, a quasi-1D open fermi surface is absent in ZrTe5. In contrast, it has a closed ellipsoidal Fermi surface well contained within a small fraction of the Brillouin zone. We discuss how the effect of commensurability may arise in a 3D Dirac system in high magnetic field.

10:12AM K04.00012: Engineering Spin Hall Conductivity and Topological Character in Group-IV Tellurides and a Family of Weyl Semimetals* 

HAIHANG WANG (Presenter), JAGODA SLAWINSKA, University of North Texas, SILVIA PICOZZI, CNR-SPIN, Chieti, Italy, MARCO BUONGIORNO NARDELLI, University of North Texas — The discovery of topological insulators and topological semimetals has become one of the leading fields of research in condensed matter physics. The origin of these emerging quantum properties can be traced to the topology of the bulk band structure and the interplay with spin-orbit coupling. In particular, the ability to engineer band topologies would open the way to the design of materials with novel functionalities. In this work, we focus on the spin-Hall current as the main physical property emerging from the topology of the bands: through the interplay of strain and ferroelectricity, we demonstrate the emergence of giant spin-Hall effect in Group-IV Tellurides. Finally, we will also discuss the results of a recent investigation on a family of Weyl semimetals that was isolated through a high-throughput screening of materials in the AFLOW database. All the results, including the searching and characterization of topological materials, have been obtained using the PAOFLOW package, which is integrated into the AFLOWπ framework.

10:24AM K04.00013: Quantum limit properties of Weyl semimetals* [Invited] 

BRAD RAMSHAW (Presenter), Cornell University, KIMBERLY MODIC, Max Planck Institute for Chemical Physics of Solids, ROSS MCDONALD, ARKADY SHEKHTER, ERIC BAUER, FILIP RONNING, Los Alamos National Labs, TOBIAS MENG, TU Dresden, YI ZHANG, EUN-AH KIM, Cornell University, MUN CHAN, FEDOR BALAKIREV, ALBERT MIGLIORI, Los Alamos National Labs, PHILIP MOLL, Ecole polytechnique federale de Lausanne, MAJA BACHMANN, Max Planck Institute for Chemical Physics of Solids, NIRMAL GHIMIRE, Argonne National Laboratory —

Electrons confined to their 0th Landau level by extreme magnetic fields—a regime known as the quantum limit—experience strong electron-electron interactions, making them unstable to the formation of new states of matter. The discovery of monopnictide Weyl semimetals has renewed interest in the high-field properties of 3D electrons, with the added twist of linear electronic dispersions. We use magnetic fields up to 95 Tesla to take the Weyl semimetals NbP and TaAs into their quantum limit. In electrical transport and torque magnetometry, we identify signatures of the 0th Landau levels that are unique to Weyl fermions. In NbP, we show that Weyl fermions can be accessed in high fields, even when the zero-field chemical potential lies far from the nodes. In TaAs, we find that the left and right Weyl nodes are mixed by magnetic field, which opens a gap and suppresses the anomalous "ABJ"-induced conductivity. At the very highest fields in TaAs, we observe a thermodynamic phase transition to an as-yet unidentified state, indicating that Weyl semimetals are unstable to the formation of new states of matter.

Session K05 DMP: Topological Superconductivity: Fe-based Materials BCEC 108 - Qimin Yan, Temple Univ - Tag(s): Focus
8:00AM K05.00001: Majorana bound state observed in Fe-based superconductors [Invited] LINGYUAN KONG
(Presenter), Institute of Physics, Chinese Academy of Sciences — Iron-base superconductor (FeSC) is nontrivial on both
topological band structure and exotic quasiparticle excitations. Recently, Majorana bound state (MBS) was observed as
non-split zero-bias conductance peak across a vortex core of Fe(Te, Se). Due to a small Fermi energy, a large energy gap
separates the MBS with other trivial bound states, which makes FeSC a promising high-Tc platform for advance study of
MBS and topological quantum qubit. In this talk, I will focus on the properties of MBS shown in our STM experiments. We
found the observed MBS is most probably contributed by surface “Dirac fermions”. The “unavoidable” bulk of Fe(Se, Te)
plays as quasiparticle bath, which destroys MBS in a lifting temperature. I will also discuss some new Majorana evidences
of FeSC identified in recent tunneling experiments.

8:36AM K05.00002: Probing the Superconducting State of FeTe0.55Se0.55 with Point-Contact Spectroscopy* MASON
GRAY (Presenter), RYAN O’CONNOR, SAMUEL JENKINS, JOSEF FREUDENSTEIN, Boston College, RUIDAN ZHONG, GENDA GU,
Brookhaven National Lab, KENNETH BURCH, Boston College — The material FeTe1-xSex provides an easy platform to study the
Iron-based superconductors due to its simple crystal structure and relatively high superconducting transition temperature.
In addition, some recent ARPES and STM studies suggest that FeTe0.55Se0.45 may be topologically non-trivial. With this in
mind, we use Point-Contact Differential Conductance studies to further investigate this material. We find a “Cusp-like” Zero
Bias Conductance Peak (ZBCP) emerges below Tc. The magnetic field dependence of this ZBCP is investigated as a function
of field angle and temperature in order to determine its physical origin.

8:48AM K05.00003: Fragile zero-energy vortex bound state in the topological superconductor candidate
FeTe0.6Se0.4* TADASHI MACHIDA (Presenter), Center for Emergent Matter Science, RIKEN, YUE SUN, Department of Physics and
Mathematics, Aoyama Gakuin University, SUNSENG PYON, Department of Applied Physics, The University of Tokyo, SHUN TAKEDA,
Materials and Structures Laboratory, Tokyo Institute of Technology, YUHIKO KOHSAKA, TETSUO HANAGURI, Center for Emergent
Matter Science, RIKEN, TAKAO SASAGAWA, Materials and Structures Laboratory, Tokyo Institute of Technology, TSUYOSHI TAMEGAI,
Department of Applied Physics, The University of Tokyo — Majorana fermions are predicted to emerge in vortex cores of
topological superconductors. Although the presence of a zero-energy bound state (ZEBS) is a hallmark of the Majorana
fermions, it is still controversial due to the limited energy resolution and statistics [1-4]. Using a dilution-refrigerator
scanning tunneling microscope [5], we performed high-energy-resolution tunneling spectroscopy on quantum-limit vortex
cores in the topological superconductor candidate FeTe0.6Se0.4. We have found that some vortices host ZEBS and others
do not. The proportion of the vortices with the ZEBS decreases with the field strength, from > 80 % at 1 T to < 10 % at 6 T.
This apparent fragility of the ZEBS sheds light on the relation between the ZEBS and Majorana fermions.

9:00AM K05.00004: Topological Vortex Phase Transitions in Iron-Based Superconductors  
SHENGSHAN QIN, Kavli Institute of Theoretical Sciences, LUNHUI HU (Presenter), University of California, San Diego, XIANXIN WU, Institute for Theoretical Physics and Astrophysics, Julius-Maximilians University of Wurzburg, Am Hubland, D-97074 Wurzburg, Germany, XIA DAI, Key Laboratory of Aperture Array and Space Application, Hefei, 230088, China, CONGCONG LE, Kavli Institute of Theoretical Sciences, CHEN FANG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, FU-CHUN ZHANG, Kavli Institute of Theoretical Sciences, JIANGPING HU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We study topological vortex phases in iron-based superconductors. Besides previously known Majorana zero mode (MZM) phase protected by the existence of a three dimensional (3D) strong topological insulator (TI), we show that there are two additional phases as iron-based superconductors can be doped superconducting 3D weak topological insulators (3DWTI), a series of two dimensional (2D) topological insulators stuck along the third direction weakly. The vortex bound states of a superconducting 3DWTI, unlike in a 3D strong topological insulator, exhibit two different types of quantum states: (1) a robust nodal superconducting phase with pairs of bulk Majorana zero modes; (2) a full-gap topologically nontrivial superconducting phase, which has single vortex end MZM in a certain range of doping level. The recently observed zero bias peak in the vortex of (Li$_{0.8}$Fe$_{0.2}$)OHOFeSe belongs to the second case. We predict that some iron-based superconductors can be 3DWTIs of the first case, namely, their vortex states are quasi one-dimensional topological nodal superconductors.

9:12AM K05.00005: Mixed phase of iron based Dirac superconductors*  
ELIO KOENIG (Presenter), PIERS COLEMAN, Rutgers University, New Brunswick — Recently, bulk 3D Dirac semimetallic touching points were observed via ARPES in Li(Fe$_{1-x}$Co$_x$)As.[1] Separately, zero-bias vortex-core Majorana subgap states were reported using STM on the surface of the topological iron based superconductor FeTe$_{0.55}$Se$_{0.45}$.[2] Crucially, close to the topologically relevant Γ-Z line, this second material has a very similar band structure as Li(Fe$_{1-x}$Co$_x$)As. The Majorana modes are attributed to emergent topological 2D Dirac surface states with proximity induced superconductivity, i.e. via a Fu-Kane like mechanism which is independent from the 3D Dirac bulk states. Yet, we show that, in certain parameter regimes, the 3D Dirac semimetallic touching points also provide Majorana subgap states which disperse along the vortex tube. Here, we investigate experimental signatures of the latter and thereby demonstrate a route to unveil the rich topological structure of iron based superconductors.

9:24AM K05.00006: Quantum anomalous vortex and Majorana zero mode in iron-based superconductor Fe(Fe,S)  
ZIQIANG WANG (Presenter), KUN JIANG, Boston College, XI DAI, Hong Kong University of Science and Technology — In conventional spin-singlet s-wave superconductors, a time-reversal symmetry breaking magnetic impurity creates a vortex-free defect hosting the Yu-Shiba-Rusinov (YSR) states inside the superconducting (SC) gap. We show that this folklore changes in s-wave superconductors with strong spin-orbit coupling (SOC). In this case, topological defect excitations can nucleate through a quantized phase winding of the SC order parameter around the magnetic ion without applying an external magnetic field. The role of the magnetic field is played by the exchange field and SOC as in the anomalous Hall effect. Such vortices, dubbed quantum anomalous vortices (QAVs), support robust Majorana zero-energy modes (MZMs) when superconductivity is induced in the topological surface states. We demonstrate that the zero-energy bound states observed in Fe(Fe,S) superconductors are possible realizations of the MZMs localized at the QAVs produced by the interstitial magnetic Fe. The quantum anomalous vortex matter can provide an advantageous platform for manipulating MZMs in quantum computing.

*This work is supported by the U.S. Department of Energy, Basic Energy Sciences Grant No. DE-FG02-99ER45747.
In this work, we present angle-resolved photoemission spectroscopy study for 122* type TlCo2-xNi_xSe2 (x=0, 0.6, 1.2, 1.6, 1.9, 2.0) samples. The parent TlCo2Se2 (x=0) sample has an incommensurate spiral spin structure. With the increase of Ni doping content, the Néel temperature increase firstly and then decrease above x_c, in conjunction with the variation of lattice parameters. The AFM ordering disappears at x~1.7 eventually after which superconductivity occurs with maximum Tc~4 K for x=2. The superconducting temperature becomes higher with the doping concentration increases. ARPES results show a Dirac cone band along Z-M momentum path. It shifts down rigidly with doping which should be owing to the change of chemical potential. The photoemission circular dichroism suggests the chirality of the orbital angular momentum. Our results thus strongly suggest their possible topological origin. We also shown that the change of effective bandwidth, which is closely related to the iternerant and electron correlation. The study of Fermi surfaces evolution can clarify the carrier-doping-induced phase transition in this system. Our results facilitate to figure out the electronic structure for deep understanding on the complex phase diagram in the system.

**9:48AM K05.00008: Prediction of CoSb as a new layered superconductor**

WENJUN DING (Presenter), M. USMAN MUZAFFAR, WEI QIN, PING CUI, ZHENYU ZHANG, ICQD, University of Science and Technology of China — FeSe-based superconductors have been actively studied in the field of high temperature superconductivity due to their relatively simple structures and exotic superconducting phenomena. Bulk FeSe possesses a superconducting transition temperature (T_c) of ~8 K, while substantially enhanced T_c of ~65 K has been reported in one-unit-cell FeSe films on the SrTiO3(001) substrate. To date, the underlying superconducting and enhancement mechanisms are still under active debate. Here we employ first-principles calculations to predict a new layered superconductor of CoSb, which is isovalent to, and shares the same planar crystal structure with the single-layer FeSe. The electronic structures of the two systems are also very similar. In contrast, the magnetic properties of CoSb are distinctly different from that of FeSe, thereby offering new opportunities for exploiting high-T_c superconductivity and the underlying pairing mechanisms.

**10:00AM K05.00009: Observation of concurrent mass enhancement and superconductivity in a topological state**

NADER ZAKI (Presenter), JONATHAN DAVID RAMEAU, GENDA GU, PETER JOHNSON, Brookhaven National Laboratory — Low energy, laser-based ARPES is used to examine the temperature dependence of a topological state previously reported1,2 for the Fe-based superconductors, FeSe_xTe_1-x. In the present study of the same system at temperatures below the superconducting transition we observe the concurrent onset of mass enhancement at the Dirac point, suggestive of time reversal symmetry breaking, and the appearance of the superconducting gap at the Fermi level crossing. We discuss possible explanations for the coincident presence of these two gaps below T_c. At the same time, focusing on the Dirac state provides some evidence for increased robustness of superconductivity in the surface layer.

**10:12AM K05.00010: Topological Excitations in Three-band Anisotropic Superconductors**

ANDREA BENFENATI (Presenter), EGOR BABAEV, Royal Institute of Technology — In the recent experimental paper [1] it was reported a disordered-driven transition from the s_± to s_++ states in Ba(Fe_{1-x}Rh_x)2 As2. Theoretically this effect was studied in [2] and the field-induced coexistence of superconducting states in dirty multiband superconductors was investigated in [3]. In [4] a structural change in the morphology of vortex cores was found at the impurity-scattering-driven crossover in two-band superconductors.

We report a study of vortex matter in a three-band model near the s_± to s_++ state crossover where the vortex morphology is unusually sensitive to anisotropies, yielding various structural phase transitions in vortex matter. The work was supported by the Swedish Research Council Grant No. 642-2013-7837 and by Göran Gustafsson Foundation for Research in Natural Sciences and Medicine.

10:24 AM K05.00011: Non-local electrostatic gating in Majorana nanowires  
Jouri Bommer (Presenter), Hao Zhang, Michiel de Moor, Di Xu, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Sasja Gazibegovic, Roy L. M. Op Het Veld, Erik P. A. M. Bakkers, Department of Applied Physics, Eindhoven University of Technology, Mihir Pendharkar, Electrical and Computer Engineering, University of California, Santa Barbara, Chris Palmstrom, Materials Engineering, University of California, Santa Barbara, Leo P. Kouwenhoven, Station Q Delft, Microsoft — Ever since the predicted existence of Majorana Zero-Modes (MZMs), the building blocks of topological quantum computation in hybrid semiconductor-superconductor wires, experimental efforts to detect signatures of MZMs have mainly focused on tunneling experiments, culminating in the recent observation of quantized Majorana conductance. However, the local probes used in previous studies cannot unambiguously reveal the non-local separation of MZMs, the hallmark of topological superconductivity. Here we study non-local properties of MZMs in tunneling spectroscopy on InSb nanowires covered with epitaxial aluminium by using two separate gates underneath the superconductor, one to tune part of the wire into the topological phase and an additional remote gate to tune the potential at the far end of the topological section. By tuning the remote gate we observe zero-bias peak splitting in the local tunneling measurement, presumably due to variation in the overlap between MZMs at the two ends. In contrast, trivial Andreev Bounds States, identified by instability with respect to the local gates, are completely insensitive to the remote gate.

10:36 AM K05.00012: Spectroscopic evidence of chiral Majorana modes in a quantum anomalous Hall insulator/superconductor heterostructure  
Jian Lyu (Presenter), Physics, Hong Kong University of Science and Technology — Topological superconductors are considered the key to realize topological quantum computation. With the discovery of quantum anomalous Hall insulator (QAHI), it has been proposed that heterostructure of QAHI with conventional superconductor can be an ideal platform for obtaining Majorana fermion. By introducing superconductivity into dissipationless edge state of QAHI, two chiral Majorana edge modes with different Chern number $N$ of 1 and 2, respectively, can be generated. Recently, He et al. discovered the signature of integer and half-integer quantized conductance plateaus in QAHI/SC heterostructure. However, few arguments have indicated that there may be other mechanism to explain the phenomenon. Here we show spectroscopic evidence to support the existence of superconducting QAHI state at the edge of QAHI/SC heterostructure by using nano-point contact technique. Two different topological non-trivial phases are observed when the QAHI is gradually driven through its magnetization reversal. The $N = \pm 1$ phase with a conductance near $2e^2/h$ occurs in a narrow field regime just before the QAHI enters a trivial insulating state. Our results are consistent with theoretical predictions and will help to confirm the previous result of half-integer quantization due to Majorana fermion.

10:48 AM K05.00013: Topological vortex chain realized in type-II superconductors*  
Wei Qin (Presenter), Zhenyu Zhang, University of Science and Technology of China — In type-II superconductors, the Caroli-de Gennes-Matricon (CdGM) states were predicted as the low-energy quasiparticle excitations around a single Abrikosov vortex. For a periodic vortex lattice, the quantum tunneling effect between intersite CdGM states leads to the formation of Bloch-like bands inside the superconducting gap. In contrast to normal solids, such type of Bloch band describes the behaviors of Bogoliubov quasiparticles with the particle-hole symmetry naturally preserved. Here, we carry out theoretical studies on the potential topological properties harbored by these exotic Bloch bands. First, we investigate the quasiparticle excitations around an isolated magnetic vortex in the presence of Rashba spin-orbit coupling (SOC), which is demonstrated to lift the doubly degenerate CdGM states. Next, we construct a one-dimensional (1D) vortex chain and explore the SOC-induced band gap opening around the Fermi level. Based on symmetry analysis, the opened band gap possesses odd parity, indicating that the vortex chain essentially mimic a Kitaev chain, which is characterized by Majorana end modes. These findings can be naturally extended to 2D vortex lattice, thus providing generic appealing platforms for realizing and manipulating Majorana fermions.

Session K06 DCMP: Hidden Order in URu2Si2 and Other Compounds
BCEC 109A - Ryan Baumbach, National High Magnetic Field Laboratory
8:00AM K06.00001: Field-induced ferrohastatic order in cubic and tetragonal heavy fermion materials*  
REBECCA FLINT (Presenter), JOHN VAN DYKE, MILAN KORNJACA, Physics and Astronomy, Iowa State University — Heavy fermion compounds with non-Kramers doublet ground states can realize a novel heavy Fermi liquid with spinorial hybridization ('hastatic' order) that breaks both single- and double-time reversal. Hastatic order was initially proposed to explain the hidden order in the tetragonal URu2Si2, which is stable in magnetic field up to 35T. Now several cubic Pr-"1-2-20" materials exhibit a suggestive heavy Fermi liquid stabilized in intermediate magnetic fields. In this talk, we develop a simple, yet realistic model of ferrohastatic order in both cubic and tetragonal symmetries, and elaborate its experimental signatures and behavior in field, where it is a good candidate to explain the observed heavy Fermi liquids.

8:12AM K06.00002: Kondo hybridization and enigmatic f-quasiparticles emerging from deep within the antiferromagnetic phase of USb2*  
IOANNIS GIANNAKIS (Presenter), JUSTIN LESHEN, MARIAM KAVAI, Department of Physics, Applied Physics and Astronomy, Binghamton University, Binghamton, SHENG RAN, SHANTA SAHA, NICHOLAS BUTCH, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, PEGOR AYNAJIAN, Department of Physics, Applied Physics and Astronomy, Binghamton University, Binghamton — Novel electronic phenomena frequently form in heavy fermion systems because of the f-electrons' localized and itinerant nature. When magnetically ordered, the f moments are expected to be frozen and localized, decoupled from the Fermi surface. It remains ambiguous whether a Kondo-lattice can emerge from deep inside the magnetic phase or simply breaks down below TN. Using spectroscopic imaging with the scanning tunneling microscope complemented by neutron scattering, we probe the electronic states in the antiferromagnetic USb2 as a function of temperature. We visualize an antiferromagnetic gap at high temperatures (T<TN~200K) in which Kondo hybridization gradually develops below Tcoh~80K near the Fermi energy. At T*=45K we find an electronic transition through the abrupt emergence of non-trivial sharp 5f quasiparticles, whose appearance agrees with the sudden release of entropy seen in specific heat. Our findings demonstrate the emergence of Kondo physics from inside USb2's antiferromagnetic phase, spectroscopically establishing the dual nature of f-electrons, and reveal an enigmatic electronic transition, which may share connection with the ‘hidden order’ phase of URu2Si2.

*We acknowledge support from the U.S. National Science Foundation (NSF) CAREER under award No. DMR-1654482.

8:24AM K06.00003: ARPES/STM study of the surface terminations and 5 f-electron character in URu2Si2*  
WEN ZHANG (Presenter), Science and Technology on Surface Physics and Chemistry Laboratory — Hidden order in URu2Si2 has remained a mystery that is now entering its fourth decade. The importance of resolving the nature of the hidden order has stimulated extensive research. Here we present a detailed characterization of different surface terminations in URu2Si2 by angle-resolved photoemission spectroscopy, in conjunction with scanning tunneling spectroscopy and dynamical mean-field theory calculations that may unveil a piece of this puzzle. The U-terminated surface is characterized by an electronlike band around the X point, while a holelike band characterizes the Si-terminated surface. We also investigate the temperature evolution of the electronic structure around the X point from 11 up to 70 K, and do not observe any abrupt change of the electronic structure around the coherence temperature (55 K). Our results suggest that surface terminations in URu2Si2 are an important issue to be taken into account in future work.

8:36AM K06.00004: Gaussian fluctuation corrections to a mean-field theory of complex hidden order in URu$_2$Si$_2$\textsuperscript{*}

PENGTAO SHEN (Presenter), MAXIM DZERO, Kent State University — Hidden-order phase transition in the heavy-fermion superconductor URu$_2$Si$_2$ exhibits the mean-field-like anomaly in temperature dependence of heat capacity. Motivated by this observation, here we explore the impact of the complex order parameter fluctuations on the thermodynamic properties of the hidden order phase. Specifically, we employ the mean-field theory for the hidden order which describes the hidden order parameter by an average of the hexadecapole operator. We compute the gaussian fluctuation corrections to the mean-field theory equations including both the fluctuations due to “hidden order” as well as antiferromagnetic order parameters. We find that the gaussian fluctuations lead to the smearing of the second-order transition rendering it to become the first-order one. The strength of the first-order transition is weakly dependent on the strength of underlying antiferromagnetic exchange interactions.

8:48AM K06.00005: Pressure-Induced Rotational Symmetry Breaking in URu$_2$Si$_2$

JAEWON CHOI (Presenter), OLEH IVASHKO, NIK DENNLER, Physik-Institut, Universität Zürich, MARKUS HUECKER, Department of Condensed Matter Physics, Weizmann Institute of Science, DAI AOKI, Institute of Material Research, Tohoku University, KARIN VON ARX, Physik-Institut, Universität Zürich, SIMON GEBER, Laboratory for Micro and Nanotechnology, Paul Scherrer Institut, OLOT GUTOWSKI, Deutsches Elektronen-Synchrotron DESY, MARK H FISCHER, Institute for Theoretical Physics, ETH Zürich, JOERG STREMPFER, MARTIN V. ZIMMERMANN, Deutsches Elektronen-Synchrotron DESY, JOHAN CHANG, Physik-Institut, Universität Zürich — The heavy-fermion compound URu$_2$Si$_2$ has provided an excellent arena to study phase transition and related symmetry breaking in correlated electron system. Despite of relentless efforts for several decades, elucidating the nature of hidden order (HO) phase at 17.5 K still remains enigmatic. Even though the experimental evidences for both broken rotational [1] and chiral symmetry [2] were found recently, little is known about crystal structure of the system. Here, we report a hard x-ray diffraction study of the single crystal URu$_2$Si$_2$ under hydrostatic pressure. For pressure above 3.4 kbar, we found a rotational symmetry breaking from tetragonal to orthorhombic crystal structure with onset temperatures near 100 K. Contrast to recent x-ray diffraction study [3], the pressure-induced orthorhomicity is not coincided with the HO transition. Instead, its temperature-dependence suggests possible relevance with the antiferromagnetic (AF) order. This observation has not yet been predicted by theories describing an adiabatic continuity of a complex order parameter. Therefore, our findings provide new perspectives to the long-standing conundrum.

9:00AM K06.00006: Temperature T vs Os concentration x phase diagram for URu$_{2-x}$Os$_x$Si$_2$ single crystals\textsuperscript{*}

ALEXANDER BREINDEL (Presenter), KALYAN SASMAL, NAVEEN POUSE, CHRISTIAN WOLOWIEC, SHENG RAN, M BRIAN MAPLE, University of California, San Diego — The compound URu$_2$Si$_2$ has attracted much interest due to its “hidden order” (HO) phase, whose order parameter has not been definitively determined after more than three decades of research on this compound. The substitution of isoelectronic Fe for Ru in URu2Si2 produces a transition from the HO phase to a large moment antiferromagnetic (LMAFM) phase, similar to what occurs under the application of pressure. This has been attributed to the “chemical pressure” associated with the substitution of the smaller Fe atom for Ru, which increases with Fe concentration. The substitution of isoelectronic Os for Ru also produces a transition from the HO to the LMAFM phase with increasing Os concentration. Since the substitution of Os, which is larger than Ru, generates a negative chemical pressure, this suggests other factors must be involved in the case of Os (e.g., spin-orbit coupling, increased hybridization due to increased spatial extent from Os d-orbitals). In this talk, we present the T vs x phase diagram, based on electrical resistivity, specific heat, magnetization, and thermal expansion measurements as a function of temperature and pressure, for Czochralski grown URu$_{2-x}$Os$_x$Si$_2$ single crystals.

**9:12AM K06.00007: Pressure tuning in URu$_2$Si$_{2-x}$P$_x$**  
GRETA CHAPPELL (Presenter), DAVID E GRAF, KEVIN HUANG, ANDREW GALLAGHER, RYAN BAUMBACH, Florida State University — In an effort to elucidate the unknown hidden ordered state at $T_0 \sim 17.5$ K in the heavy fermion compound URu$_2$Si$_2$, temperature dependent electrical resistivity measurements were performed on the electron doping chemical substitution series Si $\rightarrow$ P under quasi-hydrostatic pressures up to 21 kbar. Previous studies show that electron doping causes the HO to be rapidly suppressed towards zero temperature over a small $x$-range, after which there is a broad paramagnetic (PM) region that is eventually replaced by antiferromagnetic (AFM1) order at large $x$\cite{1,2}. Our results indicate that, like $x = 0$, HO transforms to AFM2 at critical pressures that decrease with increasing $x$, while the PM and AFM1 states are robust against pressure. We will present the resulting $T - x - P$ phase diagram and discuss the ordered states in the electronic phase space surrounding URu$_2$Si$_2$.

*This work was performed at the National High Magnetic Field Laboratory, which is supported by the National Science Foundation Cooperative Agreements Nos. DMR-1644779 and 1157490 and the State of Florida.

**9:24AM K06.00008: Observation of the hybridization gap in different ground states of URu$_2$Fe$_x$Si$_2$ and URu$_2$Si$_2$-xP$_x$**  
SHENZHI ZHANG (Presenter), GRETA CHAPPELL, RYAN BAUMBACH, Florida State University, NADEVEN POUSE, M BRIAN MAPLE, Physics, University of California, San Diego, LAURA H GREENE, WAN KYU PARK, Florida State University — Quasiparticle scattering spectroscopy (QPS) applied to heavy fermions utilizes a ballistic junction to probe how electrons scatter off strongly energy-dependent density of states in the bulk\cite{1}. Our previous QPS study on URu$_2$Si$_{2-x}$P$_x$\cite{2} found that a hybridization gap opens regardless of the ground state ordering as it was also observed in the no-order region, consistent with earlier reports where a hybridization gap was observed to open well above the hidden order transition temperature in URu$_2$Si$_2$\cite{1}. Fe substitution acts like the application of chemical pressure\cite{3} and the resulting phase diagram closely resembles the case of hydrostatic pressure, providing a new opportunity to probe the coexistent/competing region. We will present conductance spectra as a function of temperature and chemical substitution and discuss the correlation between hybridization process and emergent ground states.

**9:36AM K06.00009: Optical conductivity of URu$_2$Si$_{2-x}$P$_x$ from the hidden-order to the antiferromagnetic phase**  
ALEXANDRE ZIMMERS (Presenter), RICARDO LOBO, LPEM, ESPCI, PSL University, CNRS, Sorbonne University, Paris-France, RYAN BAUMBACH, National High Magnetic Field Laboratory, Florida State University — We report the optical spectroscopy of the URu$_2$Si$_{2-x}$P$_x$ heavy fermion chemical substitution series. For $x=0$, this material is the now well-studied URu$_2$Si$_2$ compound with a Kondo temperature of 370K. In this material, the hybridization between heavy f electrons with conduction electrons creates a crossover to a Kondo liquid state having coherent transport properties below 70K. At 17.5K, a second-order mean-field transition creates an electronically ordered state whose origin remains unknown, commonly called the hidden order (HO) phase. Finally below 1.5K an unconventional superconducting phase emerges. The HO phase disappears for $x>0.035$ and, at much higher doping $x>0.25$, an antiferromagnetic phase (AFM) emerges at low temperature ($T_N\sim40K$ for $x=0.28$).

Here we investigated the passing between the HO and AFM phase by measuring the optical conductivity from 300K to 5K for $x=0.02, 0.23$ and 0.28 samples. Distinct optical signatures are observed. For $x=0.02$ (HO), a 6.5meV gap opens at low temperature in accordance with values observed in undoped samples. For the $x=0.28$ (AFM) a distinct higher energy gap is seen for $T<T_N$. At intermediate doping $x=0.23$, no particular spectral feature has been found. The spectral weight transfer of these various gap openings will be presented and discussed.
For strongly correlated f-electron metals it is commonplace for exotic ordered states to occur at temperatures well below the Kondo coherence temperature. More unusual is for phase transitions to emerge from the incoherent f-electron lattice at elevated temperatures, where single ion Kondo physics and strong thermal fluctuations would naively be presumed to be dominant terms. This is despite the prevalence of structural/electronic instabilities in the isolated f-electron elements, where a leading example is plutonium which undergoes six structure changes and features novel behavior including negative thermal expansion in the delta phase. In this talk we will discuss results for two examples: UPt$_2$Si$_2$ and UCr$_2$Si$_2$. Both systems exhibit phase transitions near room temperature that may involve modulation of the lattice or charge density wave order. In addition, UCr$_2$Si$_2$ undergoes a structural phase transition near 210 K. We will focus on efforts to identify the order parameters for these phases.

*This work was performed at the NHMFL, which is supported by the NSF Cooperative Agreement Nos. DMR-1644779 and 1157490 and the State of FL. Research of R.E.B., Y.L., D.G. was supported in part by the US DOE, BES, under Award No. DE-SC0016568 (EFRC-CAST).

UCh$_2-x$Ru$_x$Si$_2$ is an unusual Kondo lattice metal that shows antiferromagnetism at $T_N = 27$ K, a structural phase transition from tetragonal (I4/mmm) to triclinic (P) near $T_s = 210$ K, and a so-far unidentified phase transition near $T_M = 275$ K. Cr $\rightarrow$ Ru substitution results both in expansion of the unit cell volume and filling of the d-shell, causes $T_N$ and $T_S$ to be suppressed to zero temperature near $x_{cr} \approx 0.075$ and 0.13, respectively. In contrast, $T_M$ disappears immediately with small amount of Ru. In the critical region, there is evidence for non-Fermi liquid behavior, (i) a weak logarithmic divergence in the electronic component of the heat capacity divided by temperature and (ii) a sub-quadratic temperature dependence of the electrical resistivity. Thus, we suggest that this may be a model system for studying a lattice instability at zero temperature, its relationship to a nearby antiferromagnetic quantum phase transition, and the resulting impact on electronic properties and lattice modes in a strongly correlated electron metal.

Symmetry broken phases involving higher order multipolar degrees of freedom are historically referred to as so-called "hidden orders", due to the formidable task of detecting them with conventional probes. In this talk, we theoretically propose a novel and powerful means to directly probe higher-order symmetry breaking: magnetostriction. To that end, we focus on the family of Pr-based cage compounds with strongly correlated f-electrons, Pr(Ti,V,Ir)$_2$(Al,Zn)$_{20}$, whose low energy degrees of freedom are composed of purely higher-order multipoles. Employing a symmetry-constructed Landau theory of multipolar moments, we provide key scaling behaviours of the magnetostriction in a range of temperature regimes. These findings provide a way to have clear access to higher order multipolar moments.
10:24AM K06.00013: Sequential Localization and Strange-metal Behavior in a Multipolar Kondo System* SILKE PASCHEN (Presenter), Vienna University of Technology, ANG CAI, Rice University, EMILIAN NICA, Arizona State University, CHIA-CHUAN LIU, Rice University, RONG YU, Renmin University of China, KEVIN INGERSENT, University of Florida, QIMIAO SI, Rice University — Quantum criticality and beyond-Landau physics of Kondo destruction [1,2] in heavy fermion systems with multipolar degrees of freedom is attracting considerable interest. Recent experiments on the heavy fermion compound Ce₃Pd₂₀Si₆ show evidence of two consecutive Fermi surface collapsing quantum critical points (QCP) as it is tuned from a paramagnetic to an antiferroquadrupolar (AFQ) and then to an antiferromagnetic (AFM) state [3]. We are able to understand this behavior by advancing a theory of sequential destruction of an SU(4) spin-orbital-coupled Kondo entanglement in an SU(4) Bose-Fermi Kondo model, which represents an effective model for a multipolar Kondo lattice system with Kugel–Khomskii interaction. As a function of coupling strength to the bosonic bath, we find that a generic trajectory in the parameter space contains two QCPs associated with the Kondo destruction of the orbital and spin degrees of freedom, respectively. For a Kondo lattice, this corresponds to two stages of Fermi surface jump, thus providing a natural understanding of the experimental findings.

10:36AM K06.00014: Switching the propagation vector of hidden-order phases in Ce₃Pd₂₀Si₆ with a magnetic field DMYTRO INOSOV (Presenter), PAVLO PORTNICHENKO, STANISLAV NIKITIN, TU Dresden, ANDREY PROKOFIEV, SILKE BUEHLER-PASCHEN, Vienna University of Technology — Hidden-order phases that occur in a number of correlated f-electron systems are among the most elusive states of electronic matter. Their investigations are hindered by the insensitivity of standard physical probes, such as neutron diffraction, to the order parameter that is usually associated with higher-order multipoles of the f-orbitals. The heavy-fermion compound Ce₃Pd₂₀Si₆ exhibits magnetically hidden order at subkelvin temperatures, known as phase II. Additionally, for magnetic field applied along the [001] cubic axis, another phase II' was detected, but the nature of the II-II' phase transition remained unclear. Here we use inelastic neutron scattering to demonstrate that this transition is associated with a switching in the propagation vector of the antiferroquadrupolar order from (111) to (100). Despite the absence of magnetic Bragg scattering in phase II', its ordering vector is revealed by the location of an intense magnetic soft mode at the (100) wave vector, orthogonal to the applied field. At the II-II' transition, this mode softens and transforms into quasielastic and nearly Q-independent incoherent scattering. Our experiment also reveals sharp collective excitations in the field-polarized paramagnetic phase, after phase II' is suppressed in fields above 4 T.

10:48AM K06.00015: Theoretical X-ray spectroscopic study of 5f-electron signatures in actinide materials* WEI-TING CHIU (Presenter), Physics Department, University of California, Davis, JIAN-XIN ZHU, CINT, Los Alamos National Laboratory — Actinide materials are not only important for power generation nowadays, but also exhibit interesting physical properties from the condensed matter physics perspective. The valence 5f electrons in early actinides are considered to be delocalized, while in the late actinides the 5f electrons show localized behavior. Studying the local moment and 5f-electron occupations will shed insight into the electronic behavior in these materials. X-ray absorption spectroscopy (XAS) and X-ray photoemission spectroscopy (XPS) have been powerful tools to reveal the valence electronic structure with the assistance from theoretical calculations. In this work, we build a single-impurity Anderson model for the materials, and use exact diagonalization method to calculate its eigenenergies and eigenstates. The X-ray spectra are obtained by employing Fermi's golden rule. Comparing the theoretical spectra with the experimental results provides a way to determine the 5f electronic signatures of the actinide materials, helping us understand the 5f electronic correlation effects.

Session K07 DCMP GMAG: Spin Liquids and Ices BCEC 109B - Randy Fishman, Oak Ridge National Laboratory
8:00AM K07.00001: Discovery of chiral-spin order in purported Kitaev spin-liquids
CHANDRA VARMA (Presenter), University of California, Riverside, KIMBERLY MODIC, Max Planck Institute for Chemical Physics, BRAD RAMSHAW, Physics, Cornell University, ARKADY SHEKHTER, National High Field magnet Lab — We examine recent magnetic torque measurements in two compounds, γ-LiIrO$_3$ and RuCl$_3$, which have been discussed as possible realizations of the Kitaev model. The analysis of the reported discontinuity in torque, as an external magnetic field is rotated across the c-axis in both crystals, suggests that they have a translationally-invariant chiral spin-order of the form $< S_j \times S_k > \neq 0$ in the ground state and persisting over a very wide range of magnetic field and temperature. An extra-ordinary $|B|B^2$ dependence of the torque for small fields, beside the usual $B^2$ part, is predicted due to the chiral spin-order. Data for small fields is available for γ-LiIrO$_3$ and is found to be consistent with the prediction upon further analysis. Other experiments such as inelastic scattering and thermal Hall effect and several questions raised by the discovery of chiral spin-order, including its topological consequences are discussed.

8:12AM K07.00002: Characteristics of the intermediate-field ordered phase of alpha-RuCl$_3$ revealed by magnetic diffraction
ARNAB BANERJEE (Presenter), CHRISTIAN BALZ, Oak Ridge National Laboratory, PAIGE LAMPEN-KELLEY, Material Science and Engineering, University of Tennessee, JIAQIANG YAN, Oak Ridge National Laboratory, DAVID GEORGE MANDRUS, Material Science and Engineering, University of Tennessee, YAOHUA LIU, STEPHEN NAGLER, Oak Ridge National Laboratory — There has been great interest in alpha-RuCl$_3$ as a material that manifests Kitaev terms in the spin Hamiltonian and a possible field-induced quantum spin liquid (QSL) phase by 8 T [1]. Bulk Measurements show that in the in-plane magnetic field causes a transition to an intermediate ordered phase around 6 Tesla [1, 2], preceding the total suppression of magnetic order around 7.3 T. Here we use time-of-flight neutron diffraction to elucidate the nature of intermediate phase and its magnetic order. Our results provide new insights into the dimensionality of the magnetic order and the effective spin-Hamiltonian of the material.

*The work performed at ORNL used the Spallation Neutron Source, is sponsored in part by the DOE Office of Science, Basic Energy Sciences, Division of Scientific User Facilities.

8:24AM K07.00003: Magnon thermal Hall effect in the candidate Kitaev spin-liquid α-RuCl$_3$
JONATHAN COOKMEYER (Presenter), JOEL MOORE, Physics, University of California, Berkeley — Motivated by recent experiments measuring the thermal Hall conductivity of α-RuCl$_3$ and using spin-wave theory and model effective Hamiltonians from the literature, the magnon Thermal Hall coefficient in the magnetically ordered phase is computed. Comparing directly with the experiment, no previously proposed model well matches the data. A model is determined which can explain the data demonstrating that the magnon Berry curvature could be responsible. The discrepancy could also be explained by phonons but not by Kitaev-like excitations.

*We acknowledge support from the Quantum Materials Program at LBNL, funded by the US Department of Energy under Contract No. DE-AC02-05CH11231.

8:36AM K07.00004: Effective dimension, level statistics, and integrability of Sachdev-Ye-Kitaev-like models
EIKI IYODA (Presenter), HOSHO KATSURA, TAKAHIRO SAGAWA, University of Tokyo — Recently, quantum many-body systems exhibiting fast scrambling (delocalization of quantum information) have attracted much attention. A well-known example is the Sachdev-Ye-Kitaev (SYK) model, describing random all-to-all four-body interactions among fermions. Here, we introduce a variant of the SYK model, which we refer to as the Wishart SYK model [1]. The model includes the original SYK model without quenched disorder as a special case.
We investigate the Wishart SYK model for complex fermions and that for hard-core bosons. In both cases, the ground state of the model is massively degenerate. We numerically study the out-of-time-ordered correlators (OTOC) and level statistics. Then we find that the OTOC in the fermionic case exhibits large temporal fluctuations at late times, which is attributed to a small effective dimension of the initial state. We also show that the level statistics of the fermionic (bosonic) Wishart SYK model obeys the Poisson (GOE or GUE) distribution. This is consistent with the integrability of the fermionic model, which can be proved by mapping it to a known integrable model.

8:48AM K07.00005: A candidate Theory for the "Strange Metal" phase based on the Sachdev-Ye-Kitaev physics
XIAOCHUAN WU (Presenter), Department of Physics, UC Santa Barbara, XIAO CHEN, Kavli Institute of Theoretical Physics, CHAO-MING JIAN, Station Q, Microsoft Research, YIZHUANG YOU, Department of Physics, Harvard University, CENKE XU, Department of Physics, UC Santa Barbara — We propose a lattice model for strongly interacting electrons with the potential to explain the main phenomenology of the strange metal phase in the cuprate high-temperature superconductors. Our model is motivated by the recently developed "tetrahedron" rank-3 tensor model that mimics much of the physics of the better-known Sachdev-Ye-Kitaev (SYK) model. Our electron model has the following advantageous properties: (1) it needs only one orbital per site on the square lattice. (2) It does not require any quenched random interaction. (3) It has local interactions and respects all the symmetries of the system. (4) The soluble limit of this model has a longitudinal dc resistivity that scales linearly with temperature within a finite temperature window. (5) Again, the soluble limit of this model has a fermion pairing instability in the infrared, which can lead to either superconductivity or a "pseudogap" phase. The linear-T longitudinal resistivity and the pairing instability originate from the generic scaling feature of the SYK model and the tetrahedron tensor model.

9:00AM K07.00006: Charge transport in graphene-based mesoscopic realizations of Sachdev-Ye-Kitaev models*
OGUZHVAN CAN (Presenter), EMILIAN NICA, MARCEL FRANZ, Department of Physics and Astronomy, University of British Columbia — We address transport properties of a mesoscopic realization of the Sachdev-Ye-Kitaev (SYK) model which is an exactly soluble system of interacting spinless fermions connected to the black hole physics through the holographic principle. Starting with a recent proposal for simulating the SYK model in a graphene flake in an external magnetic field and extending it by considering leads attached to it, we model a realistic transport experiment and calculate directly measurable quantities featuring non-Fermi liquid signatures of the SYK physics. We show that the graphene flake realization is robust in the presence of leads and that measuring the tunneling current across the leads one can experimentally observe a non-Fermi liquid - Fermi liquid transition by tuning the external magnetic field threading the flake. After establishing the transport signatures of the SYK model near equilibrium using linear response framework, we then derive a formula to extend our results for tunneling current using Keldysh formalism to explore the effects of finite bias voltage across the leads, going beyond equilibrium.

9:12AM K07.00007: Characterization of quantum many-body chaos with quantum Lyapunov exponents and by two-point correlations: application to a generalized Sachdev-Ye-Kitaev model
HRANT GHARIBYAN, Stanford Institute for Theoretical Physics, Stanford University, MASANORI HANADA, School of Physics and Astronomy, and STAG Research Centre, University of Southampton, BRIAN SWINGLE, Condensed Matter Theory Center, Maryland Center for Fundamental Physics, Joint Center for Quantum Information and Computer Science, and Department of Physics, University of M, MASAKI TEZUKA (Presenter), Department of Physics, Kyoto University — We propose two quantities for characterization of quantum many-body chaos. Firstly, we define a simple quantum generalization of the spectrum of finite-time classical Lyapunov exponents. [1] We study its statistical features for the SYK model and find random matrix behavior, which is lost when the model is deformed away from chaos towards integrability [2] by a random two-fermion term. Secondly, we propose that two-point correlation functions can also characterize quantum many-body chaos, with numerical evidences for the SYK model as well as for the XXZ spin chain with random field, and discuss the plausibility of laboratory experiments.

9:24AM K07.00008: Chiral spin liquid phase of the triangular lattice Hubbard model*
AARON SZASZ (Presenter), JOHANNES MOTRUK, MICHAEL ZALETEL, JOEL MOORE, Physics, University of California, Berkeley — Motivated by experimental studies that have found signatures of a quantum spin liquid phase in organic crystals whose structure is well described by the two-dimensional triangular lattice, we study the Hubbard model on this lattice at half filling using the infinite-system density matrix renormalization group (iDMRG) method. On infinite cylinders with finite circumference, we identify an intermediate phase between observed metallic behavior at low interaction strength and Mott insulating spin-ordered behavior at strong interactions. Chiral ordering from spontaneous breaking of time-reversal symmetry, a fractionally quantized spin Hall response, and characteristic level statistics in the entanglement spectrum in the intermediate phase provide strong evidence for the existence of a chiral spin liquid in the full two-dimensional limit of the model. [arXiv: 1808.00463]

Monopoles in Dirac spin liquids I: from spinon band topology to monopole quantum numbers

XUEYANG SONG (Presenter), Harvard University, CHONG WANG, YIN-CHEN HE, Perimeter Institute, ASHVIN VISHWANATH, Harvard University — We explore a low-energy theory for 2D quantum magnets, the Dirac spin liquid (DSL), a version of Quantum Electrodynamics (QED$_2$) with four flavors of Dirac fermions coupled to photons. We study the spatial/time-reversal symmetry properties of the magnetic monopoles, an important class of excitations that drive confinement. We show that the underlying band topology of spinon insulators, e.g., quantum spin hall phase/wannier insulator protected by rotation provides crucial information on the tricky Berry phase of monopole (under time-reversal / rotations, respectively). We also prove the existence of a trivial monopole on bipartite lattices by invoking its ascension to a QCD with SU(2) gauge structure.

Monopoles in Dirac spin liquids II: towards a unifying description of 2D quantum magnetism

CHONG WANG (Presenter), Perimeter Institute for Theoretical Physics, XUEYANG SONG, Harvard University, YIN-CHEN HE, Perimeter Institute for Theoretical Physics, ASHVIN VISHWANATH, Harvard University — The understanding of monopole quantum numbers in Dirac spin liquids provides a unified description of 2D quantum magnetism. In particular, it allows us to naturally account for various orders on both bipartite lattices such as the square and honeycomb lattice as well as the non-bipartite triangular and Kagome lattices. A dichotomy in behavior between the bipartite and non bipartite lattices is traced to the difference in monopole symmetry properties on these two lattices. We characterize universal signatures of the Dirac spin liquid state, including those that result from monopole excitations, which serve as a guide to numerics and to experiments on existing materials. Even when unstable, the Dirac spin liquid unifies multiple seemingly unrelated ordered states, which could help organize the plethora of phases observed in strongly correlated two dimensional materials.

Interplay of uniform U (1) quantum spin liquid and magnetic phases in rare earth pyrochlore magnets: a fermionic parton approach*

SAMBUDDHA SANYAL (Presenter), Chemistry, Columbia University, KUSUM DHOCHAK, Physics, Indian Institute of Science Education and Research, Bhopal, SUBHRO BHATTACHARJEE, International Centre for Theoretical Science (ICTS), Bengaluru — We study the uniform time reversal invariant quantum spin liquid (QSL) with low energy fermionic quasi-particles for rare earth pyrochlore magnets and explore its magnetic instability employing an augmented fermionic parton mean field theory approach. Self consistent calculations stabilise an uniform QSL with both gapped and gapless parton excitations as well as fractionalised magnetically ordered phases in an experimentally relevant part of the phase diagram near the classical phase boundaries of the magnetically ordered phases. The gapped QSL has a band-structure with a non-zero topological invariant. The fractionalised magnetic ordered phases bears signature of both QSL through fermionic excitations as well as magnetic order. Thus this provides a possible way to understand the unconventional diffuse neutron scattering in rare-earth pyrochlores such as Yb Ti O , Er Sn O and Er Pt O at low/zero external magnetic fields. We calculate the dynamic spin structure factor to understand the nature of the diffuse two-particle continuum.

Microscopic model for Tb-based pyrochlore magnets

WEN JIN (Presenter), DANIEL WONG, MICHEL J P GINGRAS, Department of Physics and Astronomy, University of Waterloo, University of Waterloo — There have been extensive experimental investigations of the magnetic structures and excitations of Tb-based pyrochlores, Tb2B2O7 (B=Ti, Sn, Ge). Tb2Ti2O7 is a candidate for quantum spin ice, while Tb2Sn2O7 and Tb2Ge2O7 have long-range ordered spin ice state coexistent with strong spin fluctuations. However, a microscopic model of these materials is still lacking. In this talk, I will discuss our efforts to derive a pseudo spin-1/2 model of Tb-based pyrochlores via a projection operator approach. We find the virtual crystal field excitations between the two lower doublets result in significant renormalization of the classical Ising interactions and generate symmetry-allowed three-body interactions that play a crucial role in the selection of ground state. We find the electric quadrupole-quadrupole interactions also give rise significant quantum fluctuations.
Magnetic critical dynamics and monopole clustering of pyrochlore spin ice  

PUHAN ZHANG (Presenter), JING LUO, GIA-WEI CHERN, University of Virginia — Spin-ice materials such as Ho2Ti2O7 and Dy2Ti2O7 are a class of geometrically frustrated ferromagnets that retain an extensive residual entropy even at very low temperatures. Importantly, the elementary dipole excitations fractionalize into magnetic monopoles in these compounds. Indeed, the field-induced first-order transition in spin-ice compounds can be understood as a monopole liquid-gas transition. Despite extensive studies on magnetic monopole dynamics at low magnetic field, the kinetics of the liquid-gas transition and the particular role played by monopoles have not been thoroughly investigated. Here we present extensive numerical simulations to investigate the structural as well as dynamical properties of monopoles in the vicinity of the field-induced first-order transition. Our results relate the critical magnetic dynamics to the percolation of magnetic monopoles in the monopole gas phase. Interestingly, we show that similar percolating clusters consisting of bound monopole hole pairs also appear in the dense monopole liquid phase.

Quantum Anomalous Hall Phase Stabilized via Realistic Interactions on a Kagome Lattice*  

YAFEI REN (Presenter), Department of Physics, University of Science and Technology of China, TIANSHENG ZENG, Department of Physics, The University of Texas at Dallas, WEI ZHU, Los Alamos National Laboratory, DONNA SHENG, California State University, Northridge — Spontaneous topological phases driven by interactions have been proposed in various lattice models, which, however, have not been observed in experiments. In this work, we report an experimentally feasible scheme of realizing spontaneous quantum anomalous Hall effect (QAHE) driven by spatially decaying interactions between spinless Fermions on a topologically trivial kagome lattice with a quadratic band touching Fermi point. In the presence of weak first and second nearest-neighbor repulsive interactions (V1 and V2), the presence of QAHE is demonstrated by employing exact diagonalization and density-matrix renormalization group methods. The time-reversal symmetry is broken spontaneously by forming loop currents with long-range correlation. Quantized Hall conductance is obtained by measuring the pumped charge through inserting flux in a cylinder geometry. We find that the topologically nontrivial energy gap can be enhanced remarkably by a moderate V2 < V1 via calculating the spectrum and charge excitation gaps.

Probing The Spin-Spin Correlator Of Kagome Lattice Heisenberg Antiferromagnets Through Non-linear Optical Harmonic Generation  

NICHOLAS LAURITA (Presenter), ALON RON, Caltech, JEONG WOO HAN, JONGSEOK LEE, Department of Physics and Photon Science, Gwangju Institute of Science and Technology, JOHN P SHECKELTON, REBECCA W. SMAHA, WEI HE, JIAJIA WEN, YOUNG SANG LEE, Department of Applied Physics, Stanford University, MICHAEL NORMAN, Argonne National Laboratory, DAVID HSIEH, Caltech — Antiferromagnetically coupled quantum spins on the Kagome lattice are proposed to realize a spin-liquid ground state where short-range spin correlations exist but symmetry breaking is avoided through frustration and quantum fluctuations. The temperature dependence of the short-range spin-spin correlator is important for understanding the underlying spin Hamiltonian of candidate materials but is typically difficult to measure. Here we show that the non-linear optical response embeds the spin-spin correlator in spin-liquid candidates by performing high harmonic generation experiments on Herbertsmithite and Zn-Barlowite. We find the temperature evolution of the spin correlations of these materials to be in very good agreement with the theoretical prediction for the S = 1/2 Heisenberg Kagome antiferromagnet. These results provide a new route to probing the governing spin Hamiltonian of spin-liquid candidates.

Session K08 DCMP DMP: Non-equilibrium Superconductivity  

BCEC 150 - Dirk Van Der Marel, University of Geneva
superconductivity has attracted much attention in the past decade, due to the possibility of dramatically enhancing the transition temperature and finally creating a room-temperature superconductor. One promising realization of nonequilibrium superconducting states is achieved via pumping mid-infrared phonons. In this work, we perform a numerical study of an electron-phonon system after dynamically squeezing the phonons, which mimics the leading impact of the infrared pump. Using a variational non-Gaussian wavefunction, we are able to evaluate not only the superconducting order parameter, but also the time-resolved optical and ARPES spectroscopies. By comparing with optical probes, we identify the physical order parameter as a pair of dressed quasiparticles. Driving the system at different frequencies we observe that superconductivity can be either persistently enhanced or suppressed, depending on the resonant characteristic excitations. Revealing the dynamics of the parametric phonon pump, this work enables the design of conventional non-equilibrium superconductors.

The authors acknowledge the Max Planck/Harvard Research Center for Quantum Optics, AFOSR-MURI Quantum Phases of Matter (Grant FA9550-14-1-0035), and Harvard-MIT CUA, NSF Grant No. DMR-1308435.

8:12AM K08.00002: Allowing for real coherent phonon bursts to defend and actuate the superconducting state in YBCO

JOHN JAMES (Presenter), Saint Louis University — Assuming that BCS superconductivity is unstable for high transition temperatures, what would be required if real coherent phonon bursts formed to prevent (defend against) the complete collapse of this state when the superconducting gap fell to resonance with the low energy optical soft phonon mode? Could the resonant phonon bursts also establish (actuate) the high energy of the gap by requiring the gap formation energy at very low superconducting state density to be the soft optical phonon energy? For this treatment of the BCS gap as a population inversion to produce coherent phonons, the formation times would usually be enormous compared to the electron-defect scattering times. All defect interactions would need to be eliminated because they would be resonant with the phonon energy but differing in momentum. A model is presented in which chain site, out of CuO2 plane, oxygen atoms tend to mutually repel for nearest neighbor sites while attracting at second nearest neighbor, causes the depletion of chain oxygen in the vicinity of all defects. This forces the fermi level into the band gap near all defects and surfaces and allows the slow coherent phonon emission and superconducting ground state formation to occur.

8:24AM K08.00003: Light-induced d-wave superconductivity through Floquet-engineered Fermi surfaces in cuprates

DANTE KENNES (Presenter), Physics, Freie Universität Berlin, MARTIN CLAASSEN, Center for Computational Quantum Physics, The Flatiron Institute, MICHAEL SENTE, Center for Free Electron Laser Science, Max Planck Institute for the Structure and Dynamics of Matter, CHRISTOPH KARRASCH, Physics, Freie Universität Berlin — We introduce a mechanism for light-induced Floquet engineering of the Fermi surface to dynamically tip the balance between competing instabilities in correlated condensed matter systems in the vicinity of a van-Hove singularity. We first calculate how the Fermi surface is deformed by an off-resonant, high-frequency light field and then determine the impact of this deformation on the ordering tendencies using an unbiased functional renormalization group approach. As a testbed, we investigate Floquet engineering in cuprates driven by light. We find that the d-wave superconducting ordering tendency in this system can be strongly enhanced over the Mott insulating one. This gives rise to extended regions of induced d-wave superconductivity in the effective phase diagram in the presence of a light field.

8:36AM K08.00004: Wavelength Dependence of Pumping a Superconductor

TA TANG (Presenter), Applied Physics, Stanford, THOMAS DEVEREAUX, BRIAN MORITZ, Institute for Materials and Energy Science, Stanford — Experiment [E. Casandruc et al] has shown transient enhanced superconductivity in LBCO when pumped by ultrafast pulses. This provides a new way to control the properties of high Tc superconductors and explore non-equilibrium phenomenon. Here we explore the effects of pumping the cuprates at different wavelengths. The model is a multi-band Hubbard model (including apical oxygen sites), which we pump with an ultrafast gaussian-pulse to study its time evolution using exact diagonalization (ED). The results show that holes are pumped from the CuO2 plane into the apical oxygens at characteristic optical wavelengths.
**8:48AM K08.00005: Transient superconductivity without superconductivity**  
GIULIANO CHIRIACO (Presenter), ANDREW MILLIS, IGOR L ALEINER, Columbia University — Recent experiments on K$_3$C$_60$ and layered copper-oxide materials have reported substantial changes in the optical response following application of an intense THz pulse. These data have been interpreted as the stimulation of a transient superconducting state even at temperatures well above the equilibrium transition temperature. We propose an alternative phenomenology based on the assumption that the pulse creates a non-superconducting, though non-equilibrium situation in which the linear response conductivity is negative. The negative conductivity implies that the spatially uniform pre-pulse state is unstable and evolves to a new state with a spontaneous electric polarization. This state exhibits coupled oscillations of entropy and electric charge whose coupling to incident probe radiation modifies the reflectivity, leading to an apparently superconducting-like response that resembles the data. Dependencies of the reflectivity on polarization and angle of incidence of the probe are predicted and other experimental consequences are discussed.

**9:00AM K08.00006: Time-dependent McMillan-Ginzburg-Landau models for light-induced ultrafast phase transitions in cuprates and other complex materials**  
ROLAND ALLEN (Presenter), JIAN WENG, ROSS TAGARAS, Texas A&M University — Earlier we found that a very simple time-dependent Ginzburg-Landau model [1] described several features of the light-induced superconductivity in La$_{1.675}$Eu$_{0.2}$Sr$_{0.125}$CuO$_4$ (LESCO1/8) discovered by Cavalleri and coworkers [2]. But for a more detailed description of complex materials -- cuprate and other high-temperature superconductors, layered transition-metal dichalcogenides, colossal magnetoresistive manganites, ... -- more detailed models are needed, which should properly be called McMillan-Ginzburg-Landau models [3]. The description of both static phase diagrams and ultrafast dynamics with such models will be discussed, with a few examples.

**9:12AM K08.00007: Impact of damping on superconducting gap dynamics induced by intense terahertz pulses**  
TIANBAI CUI (Presenter), School of Physics and Astronomy, University of Minnesota, XU YANG, CHIRAG VASWANI, JIGANG WANG, Department of Physics and Astronomy, Iowa State University, RAFAEL M FERNANDES, School of Physics and Astronomy, University of Minnesota, PETER P. ORTH, Department of Physics and Astronomy, Iowa State University — Recent advances in terahertz pump-probe spectroscopy opened a new route to investigate non-equilibrium superconductivity and gap dynamics. The time-dependent BCS theory predicts 2Δ gap oscillations after an ultrafast non-adiabatic perturbation is turned off, a consequence of the excitation of the Anderson-Higgs mode. Because gap relaxation due to the coupling to the phonons happens usually at longer time scales, the average gap is expected to be constant after the pump is off. This is at odds with recent experiments using intense THz pulses with subgap frequencies in NbN, where the gap is seen to be suppressed already at the tens of ps time scale, after the pump is turned off. We show that this behavior arises from damping within the electronic subsystem due to effects beyond BCS theory, such as interactions between Bogoliubov quasiparticles and decay of the Higgs mode. We develop a semi-phenomenological model where these relaxation processes are conveniently expressed as T$_1$ and T$_2$ relaxation times in the pseudospin formalism. We discuss the impact of each relaxation process to the gap dynamics and show the quantitative agreement with the experiments.
Control of Non-equilibrium Quantum Phases and Collective Modes in Superconductors by Terahertz Light-Driven Supercurrents*  

MARTIN MOOTZ (Presenter), ILIAS PERAKIS, Physics, University of Alabama at Birmingham, JIGANG WANG, Physics and Astronomy, Ames Laboratory, Iowa State University — In superconductors several non-equilibrium phases exist ranging from quenched states to gapless superconducting phases with gapless excitation spectrum but unchanged macroscopic coherence and infinite conductivity. The dynamics of such non-equilibrium phases is associated with observation of collective modes which provide details about the underlying nature of superconductivity. Although recent advances in THz laser spectroscopy make the excitation of collective modes and gapless superconducting phases possible, their observations in ultrafast spectroscopy remain challenging. Here we demonstrate control of the non-equilibrium dynamics in superconductors by THz light-driven supercurrents. By applying a microscopic gauge-invariant theory we show that selective non-equilibrium phases can be excited and amplitude Higgs mode can be detected in the nonlinear response by inducing supercurrents via THz pulse shaping. THz light-control of supercurrents also allows for generation of a comb of odd or odd and even harmonics in emission.

*The work at the University of Alabama, Birmingham acknowledges support by the U.S. Department of Energy, Office of Science, Basic Energy Sciences DoE under award DE-SC0019137. JW acknowledges support from the Army Research Office under award W911NF15-1-0135.

Collective modes in superconductors and their coupling to near field THz probes*  

ZHIYUAN SUN (Presenter), Physics, Columbia University, MICHAEL FOGLER, Physics, University of California, San Diego, ANDREW MILLIS, Physics, Columbia University — We theoretically investigate methods to observe the phase (Anderson-Bogoliubov-Goldstone), amplitude (Higgs) and Carlson-Goldman modes using THz near field techniques. In a quasi-two-dimensional superconductor, we show that the Carlson-Goldman mode appears in the near field reflection coefficient as a weak feature in the sub-Terahertz frequency range. In a system of two superconductor layers separated by nanometer scale, the gapless phase mode reappears due to the mutual screening between the layers, as the antisymmetric plasmon mode of the system. This mode leads to a well defined resonance peak in the near-field THz response. Close to zero temperature, its speed contains the information of the original Goldstone mode. The amplitude mode could appear in the near field third harmonic generation for particle-hole asymmetric superconductors and we also discuss its observability in the linear response.

*This work is supported by the DOE under Grant DE-SC0018218.

The Higgs Amplifier  

DANIEL PODOLSKY (Presenter), Technion - Israel Institute of Technology, YAO WANG, EUGENE DEMLER, Physics, Harvard University — A sudden quench into a superconducting state results in strong Higgs oscillations in the amplitude of the superconducting order parameter. We study theoretically the optical response of a quenched superconductor and find that Higgs modulations lead to a marked enhancement of the reflectance. For strong enough modulations, the reflectance can even exceed unity, corresponding to signal amplification. We discuss possible implications to experiments on light-induced superconductivity in K₃C₆₀.

Collective modes in non-equilibrium in unconventional superconductors with competing ground states  

MARVIN ALEXANDER MÜLLER (Presenter), Institute for Theoretical Physics III, Ruhr-University Bochum, PAVEL VOLKOV, Ruhr-University Bochum and Rutgers University, ILYA EREMIN, Institute for Theoretical Physics III, Ruhr-University Bochum —

Motivated by the recent development of terahertz pump-probe spectroscopy, we investigate the short-time dynamics and collective modes in superconductors with multiple attractive pairing channels. We consider a single-band square lattice model with nearest neighbor attraction. This interaction decouples into s-, d- and p-wave channels leading to strong competition between them for various band fillings. Driving the system out of equilibrium, we find signatures of collective modes of symmetries different from the ground state (so-called Bardasis-Schrieffer modes) for the s-wave ground state. We show that polarization can be used to excite Bradsis-Schrieffer modes of a particular symmetry in a controlled way and discuss implications for the future pump probe experiments.
10:12AM K08.00012: Control of Competing Superconductivity and Charge Order By Non-equilibrium Currents* 
ANNE MATTHIES (Presenter), JIAJUN LI, MARTIN ECKSTEIN, Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg — Strongly correlated materials often have rich phase diagrams. However, in many cases potentially interesting states are suppressed by competing phases which are thermodynamically in close proximity, e.g. superconductivity (SC) and charge-density-wave (CDW) order. How to control and distinguish competing phases arises as a very interesting and relevant question which is currently under intense research. In this work we study the competing CDW and SC order in the attractive Hubbard model under a voltage bias, using non-equilibrium steady-state (NESS) dynamical mean-field theory. We show that the CDW is suppressed in a current-carrying NESS by an effect beyond a simple Joule-heating mechanism. A “supercooled” metallic state is stabilized at a NE temperature lower than the equilibrium SC Tc. Since a current-carrying SC state is dissipation-less and thus not subject to the same non-thermal suppression, it can nucleate out of the supercooled metal. Hence, an electric current can change the relative stability of different phases compared to thermal equilibrium, even when a system appears locally thermal due to electron-electron scattering. This provides a general perspective to control intertwined orders out of equilibrium.

10:24AM K08.00013: Efficient Prediction of Time-and Angle-Resolved Photoemission Spectroscopy Measurements on a Non-Equilibrium BCS Superconductor*  
TIANRUI XU (Presenter), TAKAHIRO MORIMOTO, ALESSANDRA LANZARA, JOEL MOORE, Physics, University of California, Berkeley — We study how time-and angle-resolved photoemission (tr-ARPES) reveals the dynamics of BCS-type, s-wave superconducting systems with time-varying order parameters. Approximate methods are discussed, based on previous approaches to either optical conductivity or quantum dot transport, in order to enable computationally efficient prediction of photoemission spectra. One use of such predictions is to enable extraction of the underlying order parameter dynamics from experimental data, which is topical given the rapidly growing use of tr-ARPES in studying unconventional superconductivity. The methods considered model the two-time lesser Green's functions with an approximated lesser self-energy that describes relaxation by coupling of the system to two types of baths. The approach primarily used here also takes into consideration the relaxation of the excited states into equilibrium by explicitly including the level-broadening of the retarded and advanced Green's functions. We present equilibrium and non-equilibrium calculations of tr-ARPES spectrum from our model and discuss the signatures of different types of superconducting dynamics.

10:36AM K08.00014: Probing Out-of-Equilibrium Spin Modes in a Mesoscopic Superconductor  
MARKO KUZMANOVIĆ (Presenter), Laboratoire de Physique des Solides (CNRS UMR 8502), Bâtiment 510, Université Paris-Sud, Université Paris-Saclay, F-91405 Orsay, France, BIYI WU, National Taiwan University, MAXIMILIAN WEIDENEDER, CHARIS H.L. QUAY, MARCO APRILI, Laboratoire de Physique des Solides (CNRS UMR 8502), Bâtiment 510, Université Paris-Sud, Université Paris-Saclay, F-91405 Orsay, France — While energy and charge-mode excitations in a superconductor (associated to out-of-equilibrium Bogoliubov quasiparticles) are well known, spin modes have been addressed only recently. If spins are injected into a spin-split superconducting Al nanowire, a long-range out-of-equilibrium magnetization can be observed [1], and both the spin accumulation [2] and spin relaxation [3] times have been measured, being ~10-20 ns and ~50 ps respectively. However a key question still remains: can the system be described by a truly spin dependent distribution function? In this work we studied the diffusion of quasiparticles injected into a spin-split superconducting Al nanowire, and performed a spectroscopic study of the quasiparticle population using spin sensitive detectors located at different distances from the injection point. We will present evidence for a spin-mode non-equilibrium distribution at time / length scales shorter that the spin-flip one (about 250 nm) as well as an energy-mode spin accumulation above it.

Maxwell's Demon. can be used as a resource for optimal work extraction even in the absence of feedback, as opposed to a traditional cycle. Our results are explained in the framework of nonequilibrium fluctuation relations. We thus show that irreversibility thermal/charging energy or with probabilities substantially greater than 1/2, despite zero free energy difference over the cycles featuring kicks of the control parameter, we demonstrate work extraction up to large fractions of the electron transistor at the single thermodynamic trajectory level. With two carefully designed out-of-equilibrium driving cycles featuring kicks of the control parameter, we demonstrate work extraction up to large fractions of the

**8:00AM K09.00001: Correlations in the strong pinning theory for vortices in type-II superconductors**

MARTIN BUCHACEK (Presenter), GIANNI BLATTER, VADIM B GESHKENBEIN, ETH Zurich — Vortex pinning in type-II superconductors is usually described within two frameworks, weak and strong pinning theory. Within weak pinning, vortices are pinned due to the collective action of defects while the latter framework assumes strong defects of low density, each of them capable of pinning the vortex lattice independently. By investigating the pairwise action of strong defects, we estimate corrections to the strong pinning theory due to correlations. In the limit of very strong defects, pinning force is determined through jumps in the elastic energy during the vortex depinning. We show that by taking into account the presence of other strong defects, the average size of the jump is reduced, leading to the reduction of the pinning force density. In the opposite limit with only moderately strong defects and on approaching the crossover to weak pinning, the strong pinning contribution would vanish but the pairwise action of defects enhances the pinning. In this case, we recover the result from the weak pinning theory with pinning force density being proportional to the squared density of defects.

**8:12AM K09.00002: Tuning vortex fluctuations and the resistive transition in superconducting films with a thin overlayer**

ALEXANDER GUREVICH (Presenter), Department of Physics, Old Dominion University — It is shown that the temperature of the resistive transition $T_r$ of a superconducting film can be increased by a thin superconducting or normal overlayer due to an “anti-proximity effect” which manifests itself in an initial increase of $T_r(d_2)$ with the overlayer thickness $d_2$ followed by a decrease of $T_r(d_2)$ at larger $d_2$. The nonmonotonic dependence of $T_r(d_2)$ resulting from the interplay of vortex fluctuations and the conventional proximity effect, was obtained by solving the Usadel equations to calculate the BKT transition temperature and the temperature of the resistive transition due to thermally-activated hopping of vortices. The model may explain the nonmonotonic dependence of $T_r(d_2)$ observed on (Ag, Au, Mg, Zn)-coated Bi films, Ag-coated Ga and Pb films or NbN and NbTiN films on AlN buffer layers. The transition temperature can be optimized by tuning the overlayer parameters, which can significantly weaken vortex fluctuations and nearly restore the mean-field $T_c$. These results suggest that bilayers can be used as model systems for systematic investigations of optimization of fluctuations in superconductors.

**8:24AM K09.00003: Superconductivity in a disordered vortex lattice**

AMIT GHOSAL (Presenter), ANUSHREE DATTA, ANURAG BANERJEE, Indian Institute of Science Education and Research, Kolkata, NANDINI TRIVEDI, Ohio State University — Orbital magnetic field, as well as disorder, weaken superconductivity of a type-II superconducting film when acting individually. The Abrikosov vortex lattice, resulting from magnetic field, melts with the increasing field strength turning the superconductor into a metal. On the other hand, disorder causes a two-dimensional superconducting film to undergo a transition to an insulating state beyond a critical strength of disorder. Here we show that the simultaneous presence of these perturbations leads to an interesting evolution of superconductivity. We demonstrate that the local superconductivity strengthen due to a self-consistent spatial reorganization of order parameters. At weak disorder strengths, the same critical field that collapses the superconducting energy gap which is also responsible for the vanishing of the superfluid density. However, these two critical fields diverge from one another at large disorder strengths. In addition, disorder is found to distort the Caroli-de Gennes-Matricon bound state, which in the clean system features a strong zero-bias peak in the local density of states (LDOS) at the vortex-core. This peak disappears featuring a dip in LDOS at core, even for weak disorders. We comprehend such behavior and discuss possible experimental signatures.
9:00AM K09.00006: Imaging individual superconducting vortices in amorphous Mo$_{0.8}$Si$_{0.2}$ by scanning SQUID-on-tip* LORENZO CECCARELLI (Presenter), DENIS VASYUKOV, MARCUS WYSS, GIULIO ROMAGNOLI, MARTINO POGGIO, University of Basel — Understanding vortex pinning and dynamics in superconductors is crucial for the design of devices carrying non-dissipative currents. Here, we use a scanning nanometer-scale superconducting quantum interference device (nanoSQUID) [1,2] to image individual vortices in a Mo$_{0.8}$Si$_{0.2}$ amorphous thin film. MoSi$_{1-x}$ has recently gained prominence in sensitive superconducting single-photon detectors due to its ease of growth, homogeneity, and high critical temperature (~7 K) [3]. The high flux sensitivity and spatial resolution of our scanning nanoSQUID-on-tip allow us to study the behaviour of individual vortices in the presence of applied field and current. In particular, we investigate flux pinning by driving vortices through Lorentz forces exerted by applied currents [4,5], hopping between pinning sites, and the expulsion of magnetic flux upon lowering the applied magnetic field.

9:36AM K09.00009: Time analysis of the voltage response created by a critical current pulse of superconducting NbTi nanowires*  
KHALIL HARRABI (Presenter), ABDELKARIM MEKKI, King Fahd University of Petroleum and Minerals, JEAN PAUL MANEVAL, Physics Department, ENS Paris France, LPA — We have investigated in time domain the voltage response of superconducting NbTi filaments with different thickness to a supercritical (>Ic) step-pulse of electrical current. The resistive state is created in the filament for exceeding the critical current, where a hot spot is found far below to the critical temperature and a permanent phase-slip center close to Tc. In both cases, the resistive response appears after a certain delay time t delay depending upon the temperature and the ratio I/Ic(T) which can been analyzed through a Time-Dependent Ginzburg-Landau equation. We found that the experimental data can be fitted by using a gap relaxation time, independently of the sample widths. However, it depends strongly on the filament thickness. Assuming proportionality to sample thickness, this indicates a phonon escape time of about 80 ps/nm for a NbTi film sputtered on polished crystalline Al2O3.

*KFUPM DSR_161052

9:48AM K09.00010: Critical current and persistent supercurrent in asymmetric superconducting rings  
JACOB HUDIS (Presenter), IRINEL CHIORESCU, PENG XIONG, Florida State University — Magnetic flux quantization through superconducting rings dictate that they contain a persistent supercurrent which switches direction at half-integer external flux quanta. The oscillatory persistent supercurrent manifests in critical current and resistance (Little–Parks) oscillations. Recently, it was shown theoretically and experimentally [1] that in an asymmetrically connected superconducting ring, the critical current may exhibit anomalous periodic behavior with external magnetic flux, including discontinuous jumps. Significant inconsistencies exist between experimental and simulation results [1]. We have performed modeling of the critical current in a superconducting ring as a function of geometrical asymmetries. Our simulations indicate that persistent current might not switch direction at the most energetically favorable locations; and the geometric asymmetry could be used to control the switching. Experimentally, asymmetric superconducting rings have been fabricated by electron-beam lithography, and the critical current will be measured and compared with the simulations. The results may find implications in novel superconducting electronics relying on flux quantization such as superconducting qubits and nano SQUIDs.

10:00AM K09.00011: Rotational transition, dislocations and domain formation in vortex systems with combined six- and 12-fold anisotropic interactions*  
MACIEJ OLSZEWSKI (Presenter), MORTEN ESKILDSEN, University of Notre Dame, CHARLES REICHHARDT, CYNTHIA REICHHARDT, Los Alamos National Laboratory — We introduce a model of vortices in type-II superconductors with a combined 6- and 12-fold anisotropy in the interaction potential, motivated by the vortex lattice (VL) phase diagram in MgB2 and UPt3. Using numerical simulations we show that the VL undergoes a continuous rotational transition as the ratio of the 6- and 12-fold anisotropy is changed, causing the VL to fracture into domains. We explore the structure of domain boundaries, and isolated dislocations present with single VL domains. Furthermore, we calculate the stress field associated with both dislocations and domain boundaries. The simulations provide a real space complement to results obtained from small-angle neutron scattering studies. We discuss how our simulations may be extended to model metastable VL phases observed experimentally, and the kinetics of the metastable-to-equilibrium transition. Finally we compare our numerical results to similar work on graphene lattices, skyrmions and colloids.

*This research was supported in part by the Notre Dame Center for Research Computing. MWO and MRE was supported by the US DOE, Office of Basic Energy Sciences, under Award No. DE-SC0005051. 10:12AM K09.00012: Structural transition kinetics and activated behavior in the superconducting vortex lattice*

MORTEN ESKILDSEN (Presenter), ELIZABETH R LOUDEN, CATHERINE RASTOVSKI, STEPHEN J KUHN, ALLAN LEISHMAN, University of Notre Dame, LISA DEBEER-SCHMITT, Oak Ridge National Laboratory, CHARLES D DEWHURST, Institut Laue-Langevin, NIKOLAI D ZHIGADLO, University of Bern — Structural phase transformations are ubiquitous in solids, exhibiting common features independent of the microscopic properties of a particular material. We show that this commonality extends to phase transition kinetics associated with the superconducting vortex lattice. Using small-angle neutron scattering, we investigated the behavior of a metastable vortex lattice (VL) state in MgB2 as it is driven towards equilibrium by an AC magnetic field. This shows an activated behavior, where the AC field amplitude and cycle count are equivalent to, respectively, an effective “temperature” and “time”. The activation barrier increases as the metastable state is suppressed, corresponding to an aging of the VL. Furthermore, we find a cross-over from a partial to a complete suppression of metastable domains depending on the AC field amplitude, which may empirically be described by a single free parameter. This represents a novel kind of collective vortex behavior, most likely governed by the nucleation and growth of equilibrium VL domains.

10:24AM K09.00013: Numerical approach for vortex dynamics in the presence of mesoscopic pining centers

IVAN SADOVSKYY (Presenter), ROMAN LUTCHYN, Station Q, Microsoft — The efficient and accurate description of superconducting vortex dynamics is required for a number of technological applications extending from microelectronics to dissipationless power transmission lines and powerful magnets.

In the limit of low magnetic fields, it is reasonable to use the Langevin approach for the vortex dynamics, which does not take into account vortex-vortex interaction and therefore is extremely effective from numerical point of view.

In the limit of high fields, the dynamics of vortices is largely determined by their interaction, and a model that correctly describes this interaction is required. In the vicinity of the critical temperature, Ginzburg-Landau (GL) approach is suitable to acquire the statistics of vortex dynamics. However, since the data for the statistical analysis is roughly proportional the number of vortices, the GL approach becomes numerically inefficient in low field limit.

In the present work we propose the efficient and accurate method for vortex dynamics description in low field limit. We combine (i) GL solver to extract effective energy potential for single vortex and (ii) Langevin approach to acquire statistical data for vortex dynamics. We check the applicability of the combined method by comparison results with time-dependent GL solver.

10:36AM K09.00014: Superconducting Nanostructures Grown by Ga+- and He+- Focused Ion Beam Induced Deposition (FIBID)

ROSA CÓRDOBA, PABLO ORÚS, Instituto de Ciencia de Materiales de Aragón (ICMA), Universidad de Zaragoza-CSIC, ALFONSO IBARRA, Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza, DOMINIQUE MAILLY, Centre de Nanosciences et de Nanotechnologies, CNRS, JOSE MARIA DE TERESA NOGUERAS (Presenter), Instituto de Ciencia de Materiales de Aragón (ICMA), Universidad de Zaragoza-CSIC — Since the discovery of superconductivity in W-C deposits grown by Ga+ - Focused Ion Beam Induced Deposition (FIBID) [1], this material has been used as a model system to investigate the interplay of the vortex lattice with geometrical restrictions [2] or with periodic thickness modulations [3, 4]. We have recently carried out experiments for the investigation of non-local transport of vortices in Ga+ - FIBID nanowires [5]. These experiments indicate that long-distance (at least ten microns) propagation of vortices is sustained in such nanowires, with application in information technologies.

On the other hand, the limitations in resolution observed in Ga+ - FIBID nanostructures are overcome by the use of He+ - FIBID [6]. Results will be shown that highlight the potential of He+ - FIBID for the growth of superconducting nanowires and nanotubes with superb resolution. Applications of such nanostructures will be discussed.

10:48AM K09.00015: Suppression of dissipation in superconducting nanostraps by parallel magnetic field*
ANDREAS GLATZ (Presenter), YONG-LEI WANG, Materials Science Division, Argonne National Laboratory, IGOR S ARONSON, Department of Chemistry, Penn State University, ZHILI XIAO, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory — Common wisdom dictates that an increase in the magnetic field escalates the loss of energy since the number of vortices increases. Here we show that this is no longer true if the magnetic field and the current are applied parallel to each other. Experimental studies on superconducting MoGe nanostraps reveal that the initial dissipative state with increasing magnetic field is followed by a pronounced resistance drop, signifying a reentrance of the superconducting state. Large-scale simulations of the 3D time-dependent Ginzburg–Landau model indicate that the intermediate resistive state is due to an unwinding of twisted vortices. When the magnetic field increases, this instability is suppressed due to a better accommodation of the vortex lattice to the pinning configuration. Our findings show that magnetic field and geometrical confinement can suppress the dissipation induced by vortex motion. [PNAS 114, E10274 (2017)]

Session K10 DMP DCOMP: Fe-based Superconductors -- FeSe Intercalates and Interfaces
BCEC 151B - Timur Kim - Tag(s): Focus

8:00AM K10.00001: Light induced non-volatile switching of superconductivity in single layer FeSe/SrTiO₃ heterostructures*  MING YANG, CHENHUI YAN, YANJUN MA, LIAN LI, CHENG CEN (Presenter), West Virginia University — The capability of using light to control the superconducting state is highly desirable for active quantum device applications. Since superconducting materials rarely exhibit strong photoresponses, and vice versa, optically sensitive materials are often not superconducting, the efficient coupling of these two characters in a single material can be a challenging task. Here we show that, in FeSe/SrTiO₃ heterostructures, the superconducting transition temperature in FeSe monolayer can be effectively raised by the interband photoexcitations in the SrTiO₃ substrate, attributed to a light induced metastable polar distortion uniquely enabled by the FeSe/SrTiO₃ interface, this effect only requires a less than 50 µW/cm² continuous-wave light field. The fast optical generation of superconducting zero resistance state is non-volatile but can be rapidly reversed by applying voltage pulses to the back of SrTiO₃ substrate. The capability of switching FeSe repeatedly and reliably between normal and superconducting states demonstrate the great potential of making energy-efficient quantum optoelectronics at designed correlated interfaces.

8:12AM K10.00002: Collective excitations and the superconductivity enhancement of FeSe/SrTiO₃* [Invited]  XUETAO ZHU (Presenter), Institute of Physics, Chinese Academy of Sciences — The observation of substantially enhanced superconducting transition temperatures of single layer FeSe films on SrTiO₃ (STO) substrates has stimulated intensive research to identify the underlying microscopic mechanism. At present, the significant role of interfacial coupling has been widely recognized, but the precise nature of the superconductivity enhancement remains open. By employing high resolution electron energy loss spectroscopy, collective excitations in FeSe/STO system, including the Fuchs-Kliewer (F-K) phonons of STO and the polaronic plasmon originating from collective oscillation of polarons, were measured and studied. With FeSe growth, two dramatic contrasts were observed comparing with bare STO. First, the F-K phonons show indispensable correlation with the polaronic plasmon, indicating F-K phonons participate into the collective oscillation of polarons. Second, the linewidth broadening of the F-K phonons after FeSe growth indicates significant coupling between F-K phonons of STO and electrons in FeSe. It is evidenced that the electrons in FeSe/STO systems are dressed by the strongly polarized local lattice distortions associated with the F-K phonons across the interface. Furthermore, such an interfacial electron-phonon interaction is non-adiabatic in nature, leading to the formation of dynamic interfacial polarons that form the observed polaronic plasmon. The corresponding theoretical model shows that the interfacial polaron-polaron interaction can induce additional attraction between electrons in the systems, resulting in enhanced electron pairing strength and, accordingly, superconductivity.

8:48AM K10.00003: Low-Temperature Gated Raman Spectroscopy and Quantitative EELS of FeSe/STO* NINA ANDREJEVIC (Presenter), Department of Materials Science and Engineering, Massachusetts Institute of Technology, SHENGXI HUANG, Department of Electrical Engineering, Pennsylvania State University, QINGPING MENG, Department of Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, ALEXANDER PURETZKY, DAVID GEOHEGAN, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, CUI-ZU CHANG, WEIWEI ZHAO, Department of Physics, Pennsylvania State University, YIMEI ZHU, LIJUN WU, Department of Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, FEI HAN, MINGDA LI, Department of Nuclear Science and Engineering, Massachusetts Institute of Technology — We characterize the phonon dynamics and interfacial charge transfer in FeTe-capped monolayer (ML) and few-layer FeSe films on SrTiO3 using low-temperature gated Raman spectroscopy and electron energy loss spectroscopy (EELS). In FeTe/ML FeSe/STO, we observe emergence of a silent STO mode at 264 cm⁻¹ and slight hardening of STO phonons with an applied back-gate potential, consistent with the bare STO Raman response under electric field. Interestingly, we observe attenuation of the FeSe B₃g peak accompanied by mild softening of both FeSe and FeTe modes, in sharp contrast to the STO dynamics. Notably, this behavior is absent in our measurement of the few-layer sample, suggesting an interplay between the STO and FeTe layer when the FeSe film is sufficiently thin. This is further corroborated by slight hardening of FeTe phonons as the FeSe film thickness is reduced, which we attribute to a non-local effect by the STO. Finally, the intrinsic charge transfer at the FeSe/STO interface is quantified through comparison of experimental and calculated EELS spectra and contrasted between the ML and few-layer samples.

9:00AM K10.00004: Observation of discrete CdGM states in the vortex core of single layer FeSe/SrTiO₃ CHEN CHEN (Presenter), Department of Physics, Fudan University — For conventional type-II superconductors, confined quasi-particles in the vortex cores will give rise to Caroli-de Gennes-Matricon (CdGM) bound states with energies of \( E = \mu \Delta^2 / E_F \) (where \( \mu \) is a half integer, ±1/2, ±3/2...). However, discrete CdGM states were seldom identified due to the small value of \( \Delta^2 / E_F \), which is usually in the micro-eV range. Here we report a clear observation of multiple discrete CdGM states in single layer FeSe film on SrTiO₃, through high energy resolved tunneling spectrum. We found that the energy of these CdGM states can be well described by \( E = \mu \Delta^2 / E_F \) with \( \mu \) equal to half integers (no zero-bias conductance peak observed). Therefore our results support a simple s-wave pairing scenario for this high Tc system. Besides, we studied magnetic impurity (Fe) induced in-gap state with high energy resolution (\( T = 0.4K \)). We found that all the in-gap state are off zero bias and split at high field, despite their intensity and location may vary for different impurities. Our results would help to further unveil the mechanism underlying the high Tc single layer FeSe/SrTiO₃ superconductor.

9:12AM K10.00005: Cavity-enhanced electron-phonon coupling in monolayer FeSe/SrTiO₃* MICHAEL SENTEF (Presenter), MICHAEL RUGENTHALER, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter — We propose a quantum-electrodynamic setting to address the coupling of a low-dimensional quantum material to quantized electromagnetic fields in quantum cavities. Using a prototypical model system describing FeSe/SrTiO with electron-phonon long-range forward scattering, we study how the formation of phonon polaritons at the 2D interface of the material modifies effective couplings and superconducting properties in a Migdal-Eliashberg simulation. We find that through highly polarizable dipolar phonons, large cavity-enhanced electron-phonon couplings are possible but superconductivity is not enhanced for the forward-scattering pairing mechanism due to the interplay between coupling enhancement and mode softening. Our results demonstrate that quantum cavities enable the engineering of fundamental couplings in solids paving the way to unprecedented control of material properties.

9:24AM K10.00006: On the Tc enhancement mechanism at the FeSe/SrTiO3 interface* TIANLUN YU (Presenter), QI SONG, XIA LOU, Physics, Fudan University, BINPING XIE, Laboratory of Advanced Materials, Fudan University, HAI CHAO XU, CHENHAOPING WEN, QI YAO, Physics, Fudan University, SHUYUAN ZHANG, XUETAO ZHU, LIANDONG GUO, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, RUI PENG, DONGLAI FENG, Physics, Fudan University — At the interface between monolayer FeSe films and STO substrate the superconducting transition temperature (Tc) is unexpectedly high. The mechanism for the Tc enhancement has been the central question, as it may present a new strategy for seeking out higher Tc materials.

To reveal the mechanism, by combining advances in high quality interface growth, 16O-18O isotope substitution, and extensive data from angle resolved photoemission spectroscopy, we provide striking evidence that the high Tc in FeSe/STO is the cooperative effect of the intrinsic pairing mechanism in the FeSe and interactions between the FeSe electrons and STO phonons.

Furthermore, our results point to the promising prospect that similar cooperation between different Cooper pairing channels may be a general framework to understand and design HTSCs.

9:36AM K10.00007: Effect of Mn substitution on superconductivity in iron selenide (Li, Fe)OHFeSe single crystals* HUAXUE ZHOU (Presenter), YIYUAN MAO, ZIAN LI, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, CHAI KE, School of Physics, Beijing Institute of Technology, Beijing 100081, China, SHUNLI NI, MINGWEI MA, SHAOBO LIU, JINPENG TIAN, YU LONG HUANG, JIE YUAN, FANG ZHOU, JIANQI LI, KUI JIN, XIAOLI DONG, ZHONGXIAN ZHAO, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We synthesize a series of Mn substituted (Li, Fe)OHFeSe superconductor single crystals via a modified ion-exchange method, with the Mn dopant concentration z (the atomic ratio of Mn:Se) ranging from zero to 0.07. Interestingly, we find that the superconducting transition temperature Tc and unit cell parameter c of the Mn-doped (Li, Fe)OHFeSe samples display similar V-shaped evolutions with the dopant concentration z. The Mn dopant may be accommodated in the tetrahedral sites of both the (Li, Fe)OH- and FeSe-layers depending on the doping level, leading to a reduced or enhanced interlayer separation of (Li, Fe)OHFeSe. The observed positive correlation between the Tc and lattice parameter c, regardless of the Mn doping level z, indicates that a larger interlayer separation, or a weaker interlayer coupling, is essential for the high-Tc superconductivity in (Li, Fe)OHFeSe.

**10:00AM K10.00009:** ARPES and MBE studies on the role of the interface in Monolayer FeSe on SrTiO3

*SLAVKO REBEC (Presenter), TAO JIA, ZHUOYU CHEN, Stanford University, ROBERT G MOORE, Stanford Synchrotron Radiation Lightsource, SLAC National Accelerator Laboratory, ZHI-XUN SHEN, Stanford University — Monolayer FeSe on SrTiO3 (STO) has been heavily studied in recent years due to the discovery of a large enhancement in its superconducting Tc compared to bulk FeSe, which is attributed to interfacial coupling between the film and substrate. To better understand this interface and how it leads to such a Tc enhancement, we reexamine this system by using MBE grown FeSe and STO coupled with in-situ synchrotron based angle-resolved photoemission spectroscopy (ARPES). Here we present the influence of different STO surface terminations and photon energy dependent ARPES results which help to clarify the role of the substrate in the monolayer FeSe system.

**10:12AM K10.00010:** Ultrafast quasiparticle dynamics and electron-phonon coupling in (Li0.84Fe0.16)OHFe0.98Se

QIONG WU, HUAXUE ZHOU, YANLING WU, LILI HU, SHUNLI NI, YICHAO TIAN, FEI SUN, FANG ZHOU, XIAOLI DONG, ZHONGXIAN ZHAO, JIMIN ZHAO (Presenter), Chinese Academy of Sciences — Distinctive superconducting behaviors between bulk and monolayer FeSe make it challenging to obtain a unified picture of all FeSe-based superconductors. Here, we investigate the ultrafast quasiparticle (QP) dynamics of an intercalated superconductor (Li1-xFex)OHFe1-ySe, which is a bulk crystal but shares a similar electronic structure with single-layer FeSe on SrTiO3. We obtain the electron-phonon coupling (EPC) constant $\lambda_{A1g} (0.23 \pm 0.04)$, which well bridges that of bulk FeSe crystal and single-layer FeSe on SrTiO3. Moreover, we find that such a positive correlation between $\lambda_{A1g}$ and superconducting $T_c$ holds among all known FeSe-based superconductors, even in line with reported FeAs-based superconductors. Our observation indicates possible universal role of EPC in the superconductivity of all known categories of iron-based superconductors, which is a critical step towards achieving a unified superconducting mechanism for all iron-based superconductors.

**10:24AM K10.00011:** Electronic structure of high-Tc topological superconductor monolayer FeTe1-xSex/SrTiO3(001)

XILIANG PENG (Presenter), Institute of Physics, Chinese Academy of Sciences — Topological superconductors are promising platforms for finding Majorana bound states, which are expected to be used in robust quantum computation. However, transition temperature of conventional superconductors is relatively low and single materials combined with high-temperature superconductivity ($T_c$) and topological nontrivial states are scarce in reality. Here, we performed angle-resolved photoemission spectroscopy studies on a series of FeTe1-xSex monolayer films grown on SrTiO3(STO). The superconductivity of the films is robust and rather insensitive to the variations of the band position. However, the band gap between the electron- and hole-like bands at the Brillouin zone center decreases towards band inversion and parity exchange, which drive the system to a nontrivial topological state predicted by theoretical calculations. Our results provide a clear experimental indication that the FeTe1-xSex monolayer materials are high-temperature conrate topological superconductors in which band topology and superconductivity are integrated intrinsically.

**10:36AM K10.00012:** BCS-BEC Crossover of the FeSe/SrTiO3 Interface

SHUYUAN ZHANG (Presenter), XUETAO ZHU, JIANDONG GUO, Institute of Physics, Chinese Academy of Sciences — Superconductivity can be described either in the Bardeen-Cooper-Schrieffer (BCS) limit or in the Bose-Einstein condensation (BEC) limit. Unlike the superconductivity in the BCS limit where the involved electron-boson interaction (EBI) is adiabatic, in the BEC limit, the low superfluid density and short coherence length are expected in the non-adiabatic EBI picture. Our previous studies have shown that the EBI in FeSe/SrTiO3 systems exhibits an indispensable non-adiabatic nature, which leads to the superconductivity beyond the BCS limit. Here, through the analysis of BCS-BEC phase diagram, we find the superconductivity of single-layer FeSe on SrTiO3 substrate locates close to the BCS-BEC crossover unitary. Moreover, the superconductivity can be tuned toward to the BEC limit by surface hole doping. Indeed the potential pseudogap was observed in our scanning tunneling spectroscopy study. These findings provide a rare platform to explore the many-body interactions in superconductors.
The discovery of greatly increased superconducting Tc in FeSe/STO monolayer films (>60 K vs 8 K in bulk) has drawn enormous interest to the prospect of interfacial high-Tc materials. The presence of the STO substrate has been shown to induce heavy electron doping and lattice strain on the adjacent FeSe layer, and is widely proposed to contribute additional enhancement via interfacial phonon coupling. In order to effectively decouple the contributions of these effects to the resultant high-Tc state, we systematically explore the evolution of superconductivity as measured unambiguously by \textit{in situ} electrical resistivity under varied conditions of strain, surface doping concentration, and substrate interface condition. We show that the potassium surface dosing produces a heavily electron doped superconducting layer constrained to the film-vacuum interface, analogous to the monolayer FeSe/STO interface but lacking any STO phonon contribution. In contrast to observations from spectroscopic probes, we observe only modest discrepancies in the zero-resistance Tc for surface doped layers in comparison to monolayer films. We discuss possible explanations for this discrepancy and the implications of these results on the broader understanding of the FeSe/STO enhancement phenomenology.

Session K11 DMP DCOMP FIAP: Defects in Semiconductors -- Wide Band Gap

8:00AM K11.00001: Vibrational spectroscopy of O-H centers in Ga₂O₃*  

MICHAEL STAVOLA (Presenter), W FOWLER, YING QIN, Lehigh University — Hydrogen has a strong influence on the electrical properties of transparent conducting oxides where it can give rise to shallow donors and can passivate deep compensating defects. The ultra-wide bandgap semiconducting oxide Ga₂O₃ is no exception [1,2]. Vibrational spectroscopy shows that the introduction of H into Ga₂O₃ produces several O-H centers with strongly polarized vibrational lines and different thermal stabilities. Some of these defects appear to be shallow donors and others to be V_{Ga}^{nH} centers. Measurements made for samples that contain both H and D provide clues about the number of H atoms each of these defects contains. Our results suggest different O-H centers that contain a single H atom, two equivalent H atoms, and three or more H atoms. The polarization properties and mode coupling effects for these O-H centers provide structure-sensitive information for complementary theory that suggests specific defect structures [3].

*Supported by NSF grant DMR-1160756.

8:12AM K11.00002: Multiple O-H centers in β-Ga₂O₃*  

W FOWLER (Presenter), MICHAEL STAVOLA, YING QIN, Lehigh University — Hydrogen impurities play a crucial role in the electrical conductivity of β-Ga₂O₃ by acting as shallow donors and by passivating deep acceptors [1,2]. Polarized IR spectroscopy in conjunction with heat treatments of β-Ga₂O₃ single crystals treated in an H₂ (D₂) ambient reveals a number of vibrational lines originating from defects containing one or more O-H(D) species [3,4]. Theoretical calculations using the CRYSTAL06 code [5] with hybridized DFT Hamiltonian and the polarization properties of these vibrational lines are used to suggest structures involving one, two, or three O-H(D) species for these defects. We find strong evidence for one or more O-H(D) associated with Ga(1) vacancies and no evidence for any O-H(D) associated with Ga(2) vacancies in the crystals studied.

*Supported by NSF grant DMR 1160756.
LEONARD BRILLSON (Presenter), Ohio State University — Nanoscale optical and electrostatic techniques can now directly measure the movement of native point defects inside oxide semiconductors and how they control space charge regions, tunneling, and contact rectification. Depth-resolved cathodoluminescence spectroscopy (DRCLS) with hyperspectral imaging measures 3-dimensional defect redistribution on a nanoscale for ZnO, Ga2O3, SrTiO3, and BaSrTiO3, revealing how intrinsic and applied electric fields drive defect movement. Defects at metal-ZnO diodes change carrier densities, tunneling, and trap-assisted hopping, altering Zn- vs. O-polar Schottky barriers. Native point defects are present inside, not only on the surfaces of ZnO nano- and microwires as commonly thought.1,2 Nanoscale 3D measurement and imaging reveal electrically-active defects that extend deep inside wires, introducing new donors or acceptors that alter depletion widths, conducting channel volumes, and metal-ZnO nano-contact rectification. Using electron and ion beams, we altered defect distributions to create rectifying, ohmic, or blocking contacts with the same metal on the same nanowire, demonstrating the interplay between the nature of native point defects, the intrinsic doping, and the physical dimensions of the nanostructure itself in determining the electronic properties of the oxide interface.3 DRCLS also enabled us to correlate the dominant luminescence features of Ga2O3 with the most thermodynamically stable O vacancy, Ga vacancy, and Ga vacancy-hydrogen defect states in the band gap predicted theoretically.4 As with ZnO, the combined depth-resolved detection and processing of Ga2O3 suggests new avenues for identifying and controlling native point defects in semiconductors.

*Supported by NSF Grant DMR-1800130 and AFOSR Grant FA9550-18-1-0066.

**Deep acceptors in Ga2O3**

HARTWIN PEELAERS (Presenter), University of Kansas, JOHN LYONS, Center for Computational Materials Science, JOEL BASILE VARLEY, Lawrence Livermore National Laboratory, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara — β-Ga2O3 is a wide-band-gap semiconductor with promising applications in high-power electronics. While n-type doping is straightforward, p-type doping is elusive, with only deep acceptors available. We use hybrid density functional theory to explore the properties of possible acceptors, and discuss the viability of obtaining semi-insulating material. All dopants we considered lead to deep acceptor levels that are more than 1.3 eV above the valence-band maximum. N and Mg were identified as the most promising deep acceptors. We evaluated incorporation in different configurations, and also considered the effect of native defects as well as complexes. We find that both dopants will lead to Fermi-level positions that are at least 1.3 eV away from the band edges. We also predict diffusion activation energies, finding that Mg is significantly more mobile. The information obtained in this study can be used to analyze and explain ion implantation experiments, and to guide design of semi-insulating Ga2O3 layers.

*Work supported by AFOSR, ONR, and DOE.

**A study of deep level defects in β-Ga2O3 using thermal admittance spectroscopy**

J HENDRICKS, Air Force Institute of Technology, Wright-Patterson AFB, MO AHOUJJA (Presenter), Physics, The University of Dayton, SHIN MOU, ADAM T NEAL, Air Force Research Laboratory, Materials and Manufacturing Directorate, Wright-Patterson AFB, OH — The β-Ga2O3 semiconductor is receiving great interest due to its potential applications for high power and deep-ultraviolet devices. However, in spite of a promising future of β-Ga2O3 device technology, its electronic properties, in particular deep level defects, are still not well understood. In this paper we investigated deep level defects in unintentionally doped β-Ga2O3 Schottky diodes, edge-defined film fed grown, using thermal admittance spectroscopy (TAS). An Arrhenius analysis of the TAS measurements shows two deep levels with energies of E1=0.428 eV and E2=1.07 eV and cross sections of σ1=1.83x10^-13 cm^2 and σ2=4.64x10^-13 cm^2, respectively.
9:24AM K11.00006: QSGW calculation of the band structure of Ga2O3-Al2O3 alloys* AMOL RATNAPARKHE (Presenter), WALTER R L LAMBRECHT, Case Western Reserve University — β-Ga2O3 has recently drawn attention as an ultra-wide bandgap semiconductor. The alloys between Ga2O3 and Al2O3 are of interest to obtain even higher band gap materials. The two materials have different ground state structures, monoclinic β-Ga2O3, and corundum α-Al2O3 respectively. We study the Ga2O3-Al2O3 alloys in both the structures using the linearized muffin-tin orbital approach and ABINIT pseudopotential approach for the relaxation of the structural parameters. We consider all possible mixed structures within the common 10 atom primitive unit cells, with compositions $x = 0, 0.25, 0.5, 0.75, 1.0$ in $(\text{Ga2O3})_{1-x} \text{(Al2O3)}_x$. We find the relative ordering of the two structures in the end compounds in agreement with experiment and energy differences in good agreement with previous computational work. We find the Al atoms tend to preferentially occupy the octahedral site when substituting for Ga. The band structure of the alloy models in the two structures is evaluated using the QSGW method.

*This work is supported by NSF under Grant No. DMR-1755479.

9:36AM K11.00007: Enabling p-type doping in In2O3 by a band engineering through alloying† FERNANDO SABINO (Presenter), ANDERSON JANOTTI, Materials Science and Engineering, University of Delaware, SUHUAI WEI, Beijing Computational Science Research Center, — In2O3 is a wide-band gap semiconductor of great importance to the optoelectronic industry. It is often used as transparent contact for solar cells, LEDs, and liquid crystal displays. It has a highly dispersive conduction band, composed of the In s orbitals, that lie relatively low with respect to the vacuum level, making it easy to dope n-type, while the low-energy valence band, composed mostly of O p orbitals, making it difficult to achieve p-type doping because acceptor impurities introduce deep levels in the gap. One way to overcome this limitation is to raise its valence band. Using first-principles calculations we explore different approaches to lift the valence band in In2O3 by alloying. We discuss different alloying elements, both on oxygen and metal sites. We compute the formation enthalpy of these alloys, and their stability with respect to phase separation. We calculate band gaps, and analyze the effects of alloying on the position of the valence and conduction bands, determining the band alignment between the alloys and the parent compounds. Finally, we address their optical properties by calculating absorption coefficients as a function of alloy composition.

9:48AM K11.00008: Non-exponential decay of persistent photocarriers in an AlGaN/AlN/GaN heterostructure DAVID DAUGHTON (Presenter), BOKUAI LAI, JEFFREY LINDEMUTH, Lake Shore Cryotronics (United States) — We report on the kinetics of persistent photoconductivity (PPC) in AlGaN/AlN/GaN heterostructures grown on silicon substrates. Under sub-bandgap illumination (1.91, 2.10, and 2.73 eV), photocarriers from ionized, deep-level defects increase the 2DEG conductivity which persists for hours to days after the illumination has been removed. Using a novel Hall Effect characterization protocol, a logarithmic decay of the persistent carrier concentration, independent of carrier scattering, was observed. The measured logarithmic decay is consistent with a physical separation of defects from the conducting channel and is thought to result from a recombination front propagating through the heterostructure. Persistent photocarrier concentration kinetics were studied as a function of photon dose, wavelength, and temperature. At the shortest wavelength, temperature-dependent studies show the coexistence of two logarithmic decay channels and could indicate PPC in this heterostructure arises from multiple defect species or, perhaps, the defects have different spatial proximity to the conducting channel.

10:00AM K11.00009: Incorporation of Boron in Gallium Nitride† MARK E. TURIANSKY (Presenter), JIMMY SHEN, Department of Physics, University of California, Santa Barbara, DARSHANA WICKRAMARATNE, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara — Ternary alloys of the group-III nitrides are integral in the design of electronic and optoelectronic devices. To extend the capabilities of these alloys, boron-containing nitride alloys, such as B$_x$Ga$_{1-x}$N (BGN), are being considered. Boron nitride, however, is most stable in the hexagonal phase, unlike GaN which is stable in the wurtzite phase. As such, there is a lack of experimental information on the properties of wurtzite-phase boron-containing alloys. Using first-principles calculations with a hybrid functional, we explore the nature of boron incorporation in GaN. In the dilute limit, we consider substitutional and interstitial incorporation of boron. We also study the change in the electronic structure of GaN with increasing boron concentration. Wurtzite BN has an indirect band gap, while GaN has a direct band gap. We investigate the direct and indirect nature of the alloy band gap using a projection scheme and by calculating dipole matrix elements. We find that the fundamental band gap of BGN is direct for boron concentrations below 50%. The large band-gap bowing results in a fundamental band gap that is effectively unchanged from the GaN band gap for a wide range of B concentrations.

Identifying Defects and their Electronic Signatures in Regrown GaN Heterostructures

JIAHENG HE (Presenter), GUANJIE CHENG, DAVIDE DEL GAUDIO, JORDAN M OCCENA, Department of Materials Science and Engineering, University of Michigan, FABIAN NAAB, Michigan Ion Beam Laboratory, University of Michigan, RACHEL GOLDMAN, Department of Materials Science and Engineering, University of Michigan, MOHSEN NAMI, BINGJUN LI, JUNG HAN, Department of Electrical Engineering, Yale University — Although silicon-based electronics are used to power light-emitting diodes and electric vehicles, their utility in high power applications is limited by a low breakdown voltage. The most promising alternative power devices consist of vertical GaN devices, which often require regrown active regions. Thus, advances in high power device performance require a detailed understanding of the influence of regrowth processing steps on interfacial defects and their electronic signatures. In this work, we examine a series of GaN p-i-n structures prepared with and without ex-situ ambient exposure and/or chemical etching. To quantify the concentration of various native and extrinsic point defects, we utilize a combination of ion beam analyses in conjunction with x-ray diffraction. For all samples, channeling Rutherford backscattering spectroscopy data reveals minimum yield values < 2%, with displaced atom densities ranging from 1 to 3 x 10^{20}/cm^3. For all samples, cathodoluminescence spectroscopy reveals the GaN near-bandedge and donor-acceptor pair luminescence. We discuss the influence of interface regrowth on variations in the intensity of yellow and infrared luminescence.

Spectrally resolved dynamics of energy transfer in GaN:Eu

RUOQIAO WEI (Presenter), Lehigh University, BRANDON MITCHELL, West Chester University, DOLF TIMMERMAN, Osaka University, TOM GREGORKIEWICZ, University of Amsterdam, WAXINZHU, YASUFUMI FUJIIWARA, Osaka University, VOLKMAR R G DIEROLF, Lehigh University — Europium(Eu) doped Gallium Nitride has demonstrated great potential as the red-emitting active layer in nitride-based light emitting diodes(LEDs). External quantum efficiency of up to 9.2% have been achieved. In such optimized layers, we performed a systematic series of temperature dependent, spectrally and time resolved photoluminescence measurements with goal to understand the energy transfer processes between the host material and the various energy levels of the Eu ions. Eu ions are affected by their local environment resulting in at least eight different centers that can be spectrally distinguished. For the most dominant centers, we find that the energy transfer to the Eu ion takes place on a time scale faster than 5 ns. Depending on incorporation site, the energy transfer leads to the population of the {5}D_{0} and/or the {5}D_{2} state. Direct energy transfer to the {5}D_{1} states is negligible. We further show that Eu ions in their long-lived {5}D_{0} state can be excited further leading the creation of electron hole pairs which subsequently relax and transfer their energy back to the Eu ions. This leads to a change in the color of the total emitted light and enables color tunability of the LEDs.

Photoluminescence quantum efficiency of Nd optical centers in GaN epilayers

YIFEI WANG (Presenter), HO VINH, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — We report the photoluminescence quantum efficiency of Nd optical centers as well as the thermal quenching mechanism in GaN epilayers prepared by plasma-assisted molecular beam epitaxy. High resolution infrared spectroscopy, quantum yield and temperature dependence measurements of photoluminescence intensity from Er ions in GaN under resonant and non-resonant excitations were performed. The data provide a picture of the thermal quenching processes and activation energy levels of Nd optical centers in GaN epilayers. The results provide an important step in the realization of GaN:Nd epilayers as an optical gain medium at the infrared region.

Interface chemistry and electrical characteristics of 4H-SiC/SiO_{2} after nitridation in varying atmospheres

ANNA REGOUTZ (Presenter), Imperial College London — SiC/SiO_{2} is a prototypical wide-bandgap semiconductor/dielectric interface, which represents the challenges faced by many such material systems. A multitude of different defects leads to unacceptably large defect densities near the SiC conduction band and management of interfacial defects still remains a topic of lively discussion and current interest. Advanced X-ray spectroscopy methods can probe chemical states at interfaces, and X-ray Photoelectron Spectroscopy (XPS) in particular can deliver great insight into interfaces as it combines both qualitative and quantitative information on elemental distributions, chemical environments, and valence states. Here, we present a systematic study of the 4H-SiC/SiO_{2} interface in industrially manufactured samples with a particular focus on the effects of nitridation in a variety of atmospheres, to reduce interface defect states. Clear differences are found in both spectroscopy and electrical behaviour after high temperature treatments in N_{2}, NO, NH_{3} and NO+NH_{3} atmospheres. Core level spectra give a complete picture of chemical environments present in the oxide and carbide layers as well as at the interface providing insight into defect states and how they are compensated by nitridation.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM
Atomically thin, single crystalline 2D electronic materials have recently emerged, offering a remarkably wide range of building blocks of nanostructures, ranging from metals (e.g. graphene), large gap insulators (BN), to semiconductors (transition metal dichalcogenides and black phosphorous). One key advantage of these van der Waals materials lies in the flexibility of stacking different types of materials to form heterostructures, providing a design platform for achieving novel device functionality. In vdW hetero-bilayers, the interface encompasses the whole heterostructure and interlalyer interactions become the controlling parameter for the electronic structure.

In this talk I will first discuss directly probing the inter-layer interactions through the “lens” of moiré patterns using scanning tunneling microscopy and spectroscopy (STM/S). I will show that the interlayer coupling is strongly dependent on the inter-atomic alignment of the constituent layers. Moreover, as a consequence of moiré pattern formation, the energy band structure of the hetero-bilayer also shows lateral modulation, forming a 2D electronic superlattice. The moiré pattern “lens” also provides us with a means to measure the 2D strain tensor with high precision and high spatial resolution. In addition, the strain profile shows a direct correlation with the band gap modification. As the periodic potential modulation also provides lateral confinement for excitons, an intriguing scenario occurs – the 2D lateral superlattices also form 2D exciton quantum dot arrays. Recent reports of ultra-sharp atomic like spectra provide a direct confirmation of such a scenario. Finally, I will add another control knob and show evidence for valley spin mediated interlayer couplings, and their effect on excitonic states of the hetero-bilayer.

8:36AM K12.00002: Insulating Bulk State in Monolayer WTe2*

**BOSONG SUN (Presenter), TAUNO PALOMAKI, PAUL MALINOWSKI, JIUN-HAW CHU, DAVID HENRY COBDEN, University of Washington** — The layered semimetal WTe2 displays a diverse set of properties in the two-dimensional limit. For example, using an electrostatic gate, one can control the carrier density and change the state of monolayer WTe2 from a 2D topological insulator a 2D superconductor. We will discuss our recent work to better understand the properties of the insulating bulk state seen in monolayer WTe2 near charge neutrality. Using graphene as a probe of the transverse penetrating electric field, we determine the chemical potential as a function of charge density, finding a thermodynamic gap of $45\pm5$ meV at low temperatures. We relate the measurements to transport and angle-resolved photoemission measurements.

8:48AM K12.00003: Evidence of Metal-Insulator Transition in 2D Van der Waals layers of Copper Indium Selenide (Culn$_7$Se$_{11}$)*

**PRASANNA DNYANESHWAR PATIL, SUJOY GHOSH, MILINDA WASALA, Department of Physics, Southern Illinois University Carbondale, IL-62901, USA., SIDONG LEI, ROBERT VAJTAI, PULICKEL M AJAYAN, Department of Materials Science and Nano Engineering, Rice University, Houston, TX-77005, USA., SAIKAT TALAPATRA (Presenter), Department of Physics, Southern Illinois University Carbondale, IL-62901, USA.** — Several recent reports have indicated the possibility of metal-insulator transition (MIT) in two-dimensional electron systems (2DES), which also includes atomically thick van der Waals layers of two-dimensional (2D) materials such as MoS$_2$, MoSe$_2$, ReS$_2$ etc. In general it appears that alteration of external control parameters such as pressure, charge carrier density etc. can give rise to such phenomenon in these materials. In this regard, this study will demonstrate the possibility of MIT in 2D van der Waals layers of Copper Indium Selenide (Culn$_7$Se$_{11}$). A study of conductivity ($\sigma$) of 2D Culn$_7$Se$_{11}$ FET devices (fabricated using flakes exfoliated from crystals grown using chemical vapor transport technique) as a function of temperature (T) and charge carrier density ($n_{2D}$) (modulated via electrostatic doping through SiO$_2$ gate) show strong features of MIT. The observed phenomenon will be discussed in light of existing theoretical models.

dichalcogenides MX2 have recently attracted significant attention for their novel electronic properties in monolayer form. Crystals of MX2 materials have a quasi-two-dimensional character reflected in their electronic structure, the coupling between the layers dilutes the many exotic effects appearing in monolayer systems. Here, we report the synthesis of bulk single crystal superlattice materials that physically separate the MX2 layers in the 2H-MX2 structure resulting in enhancements of the 2D nature of their electronic properties observable in their transport behavior.

9:12AM K12.00005: Synthesis and characterization of transition metal chalcogenide superlattice compounds
ARAVIND DEVARAKONDA (Presenter), Department of Physics, Massachusetts Institute of Technology, CIGDEM OZSOY-KESKINBORA, Harvard John A. Paulson School of Engineering and Applied Sciences, Harvard University, TAKEHITO SUZUKI, Department of Physics, Massachusetts Institute of Technology, MANABU KAMITANI, MARKUS KRIENER, YOSHINORI TOKURA, RIKEN Center for Emergent Matter Science (CEMS), DAVID BELL, Harvard John A. Paulson School of Engineering and Applied Sciences, Harvard University, JOSEPH CHECKELSKY, Department of Physics, Massachusetts Institute of Technology — The transition metal dichalcogenides MX2 have recently attracted significant attention for their novel electronic properties in monolayer form. These include optical control of valley polarization, the valley Hall effect, and novel forms of superconductivity. While bulk crystals of MX2 materials have a quasi-two-dimensional character reflected in their electronic structure, the coupling between the layers dilutes the many exotic effects appearing in monolayer systems. Here, we report the synthesis of bulk single crystal superlattice materials that physically separate the MX2 layers in the 2H-MX2 structure resulting in enhancements of the 2D nature of their electronic properties observable in their transport behavior.

9:24AM K12.00006: Transport study of quasi-one dimensional transition metal trichalcogenides down to single-chain limit
KYUNGHOON LEE (Presenter), THANG PHAM, ALEX K ZETTL, Physics, University of California, Berkeley — With the successful isolation of few-to-single layer of graphene and transition metal dichalcogenides (TMDs), two-dimensional van der Waals (vdW) materials have been a central focus in condensed matter physics and materials science. In addition to 2D vdWs, a different class of 1D vdW materials, transition metal trichalcogenides (TMTs) such as NbSe3, is emerging with recent advances in isolation and structural characterization of their few-to-single chain encapsulated within carbon and boron nitride nanotubes. The single chain limit of TMTs may exhibit novel physical phenomena, including unusual ground state and collective-mode electronic transport, for instance sliding charge density wave and superconductivity, as found in their bulk counterparts. However, the experimental investigation of these potential properties has been hindered by the challenge of nanodevice fabricating on such small samples. Here, we propose a new approach, correlating the structure-property of the few-to-single chain vdW materials by transmission electron microscopy and device fabrication on the same individual chain-tube sample on a thin SiN membrane. Our work will open up new opportunities for study and application of 1D TMTs based electronics.

*U.S. Department of Energy, sp2-Bonded Materials Program

9:36AM K12.00007: Pump-probe spectroscopy of ultrathin 1T'-MoTe2
TINA DEKKER (Presenter), Electrical and Computer Engineering, University of Waterloo, NICOLAS RIVAS, ARIEL PETRUK, Chemistry, University of Waterloo, SHAZHOU ZHONG, Physics, University of Waterloo, FANGCHU CHEN, XUAN LU, YUPING SUN, Institute of Solid State Physics, Chinese Academy of Sciences, ADAM TSEN, ALBERTO GERMAN SCIAINI, Chemistry, University of Waterloo — Type II Weyl semimetal candidate MoTe2 in bulk form undergoes a transition at ~250 K from the monoclinic phase (1T'-MoTe2) to the inversion-symmetry breaking, orthorhombic phase (Td-MoTe2). Previous transport and Raman measurements on thin MoTe2 flakes have shown a dimensionally driven transition to the orthorhombic phase at room temperature for flakes less than ~12 nm. Using femtosecond broadband pump-probe spectroscopy, we impulsively excited MoTe2 flakes of varying thickness that are protected from oxidation. The temporal evolution of the vibrational wave packet causes spectral modulations of electronic transitions. A probe pulse following the pump reveals any pump-induced time dependence of these signals, including oscillations of the initially excited coherent nuclear motion. Using some novel data analysis tools, and after background subtraction, we were able to follow characteristic phonon modes of each phase resolved in time and frequency domains.
Local Probe Studies of the Orbital Texture of a Single-Layer Mott Insulator

YI CHEN (Presenter), WEI RUAN, MENG WU, University of California, Berkeley, SHUJIE TANG, Stanford University, HYEJIN RYU, Lawrence Berkeley Nat. Lab, HSIN-ZON TSAI, RYAN LEE, SALMAN ABDUL GAFFAR KAHN, FRANKLIN LIOU, CAIHONG JIA, University of California, Berkeley, OLIVER R ALBERTINI, Georgetown University, HONGYU XIONG, TAO JIA, Stanford University, ZHI LIIU, Shanghai Institute of Microsystem and Information Technology, JONATHAN SOBOTA, Stanford University, AMY LIU, Georgetown University, JOEL MOORE, University of California, Berkeley, ZHI-XUN SHEN, Stanford University, STEVEN G. LOUIE, University of California, Berkeley — Mott insulators are insulating phases induced by strong electron correlation that can lead to exotic states such as high-temperature superconductivity and quantum spin liquids. Recent advances in van der Waals material synthesis enable the exploration of novel Mott systems in the two-dimensional limit. Here we present the characterization of the single-layer Mott insulator 1T-TaSe2 via energy-, spatial-, and momentum-resolved measurement of its electronic structure by scanning tunneling microscopy/spectroscopy and angle-resolved photoemission spectroscopy. Our study establishes single-layer 1T-TaSe2 as a novel Mott insulator, thus providing an ideal experimental platform for investigating strong correlation physics in two-dimensional materials.

Electronic structure of 3d transition-metal dichalcogenide thin films grown by molecular-beam epitaxy

SATOSHI YOSHIDA (Presenter), MASAKI NAKANO, HIDEKI MATSUOKA, YUKI MAJIMA, YUE WANG, YUTA OHIGASHI, MASATO SAKANO, YOSHIHIRO IWASA, KYOKO ISHIZAKA, Department of Applied Physics, The University of Tokyo — There has been increasing interest in atomically-thin transition-metal dichalcogenides (TMDs) hosting intriguing properties absent in their bulk form. For example, in 4d and 5d transition-metal TMDs such as MoS2, WSe2, and NbSe2, valley degree of freedom plays an important role on novel two-dimensional properties. 3d TMDs, on the other hand, are expected to exhibit more varieties of phenomena involving excitonic physics, charge density wave, and magnetism, due to stronger electron-electron, electron-lattice and exchange interactions. Recently, emergent ferromagnetism in monolayer VSe2 was reported, although the situation is still controversial. To unambiguously characterize physical properties of atomically thin TMDs and further understand the origin of the emergent two-dimensional phenomena, the direct observation of electronic structures is crucial. We have fabricated atomically thin films of 3d TMDs by molecular-beam epitaxy with our growth recipe [1] and clarified electronic structures by angle-resolved photoemission spectroscopy (ARPES). In this presentation, we will discuss the physical properties appearing in two-dimensional 3d TMDs by comparison with the ARPES results and band calculations. [1] M. Nakano, et al., Nano Lett. 17, 5595 (2017).

Scanning tunnelling microscopy of ultrathin 1T-TaS2*

SEAN WALKER (Presenter), TARUN M PATEL, DELER LANGENBERG, University of Waterloo, YUPING SUN, Chinese Academy of Sciences, ADAM TSEN, JONATHAN D BAUGH, University of Waterloo — 1T-TaS2 is a two-dimensional transition metal dichalcogenide that shows multiple charge density wave (CDW) transitions. Scanning tunnelling microscopy (STM) has been used to extensively study these transitions in bulk 1T-TaS2. We utilize a device geometry that allows for in-plane transport measurements of ultrathin 1T-TaS2 samples (less than 30 nm thick) prepared via mechanical exfoliation in an inert environment, in conjunction with imaging the CDW at the atomic scale. We also investigate the effects of current-driven transitions on the CDW.

*This research was undertaken in part thanks to funding from the Canada First Research Excellence Fund. The authors would like to acknowledge funding from NSERC.

Exciton Condensation in Electron-hole Doped Hubbard Bilayers -- A Sign-problem-free Quantum Monte Carlo Study

XUXIN HUANG (Presenter), Stanford University, MARTIN CLAASSEN, Simons Foundation Flatiron Institute, EDWIN HUANG, Stanford University, BRIAN MORITZ, THOMAS DEVEREAUX, SLAC and Stanford University — A long-sought state of matter, exciton condensation, recently has been realized experimentally in several systems. We develop a sign-problem-free Determinant Quantum Monte Carlo (DQMC) algorithm for bilayer Hubbard model with electron-hole doping, which is an ideal platform to study exciton condensation due to the suppression of electron-hole recombination. In square lattice systems, we demonstrate a tendency for exciton condensation at momentum (∏, ∏), and this excitonic order appears to compete with a charge ordered state in the parameter regime we study. Exciton condensation on hexagonal lattices, presumably more pertinent to systems used in previous experimental realizations, has also been investigated and the results will be shown in comparison with square lattice results.
A monolayer transition metal dichalcogenide as a topological excitonic insulator

DANIELE VARSANO, Istituto Nanoscienze, Modena, Italy, CNR, MAURIZIA PALUMMO, Dept of Physics, University of Rome Tor Vergata, ELISA MOLINARI, FIM, Modena, Italy, University of Modena, MASSIMO RONTANI (Presenter), Istituto Nanoscienze, Modena, Italy, CNR —

Monolayer transition metal dichalcogenides in the $T'$ phase might realize the quantum spin Hall effect at room temperature, since they have a large bulk hybridization gap between the inverted valence bands that provides topological order with robustness. Here we demonstrate that $T'$-MoS$_2$ is unstable against the spontaneous generation of excitons by using first-principles many-body perturbation theory, as the computed exciton binding energy is larger than the quasiparticle gap. We predict that the true ground state of $T'$-MoS$_2$ is a novel correlated insulator in which both excitonic and topological orders coexist by reducing the spatial point group symmetry, whereas typically interactions tend to disrupt the topological order. A self-consistent calculation provides us with clear-cut signatures of this excitonic topological insulator, such as an enhanced bulk quasiparticle gap (and hence increased topological robustness), spontaneous inversion symmetry breaking, spin-splitting of quasiparticle bands. The phase diagram, in the space whose axes are temperature and strain, includes a second—topologically trivial—excitonic phase that spontaneously breaks mirror symmetry while changing discontinuously the quasiparticle gap, which surprisingly never closes.

Suppression of Exciton Condensation in Copper-Doped TiSe$_2$ Measured with M-EELS

MELINDA RAK (Presenter), SAMANTHA RUBECK, MATTEO MITRANO, ALI HUSAIN, University of Illinois at Urbana-Champaign, ANSHUL KOGAR, Massachusetts Institute of Technology, SEAN VIG, University of Illinois at Urbana-Champaign, JASPER VAN WEZEL, University of Amsterdam, GORAN KARAPETROV, Drexel University, EMILIA MOROSAN, Rice University, PETER ABBAMONTE, University of Illinois at Urbana-Champaign — Excitons were predicted to form a Bose condensate, but for many years there was no direct experimental verification of this condensation in a solid. Using momentum-resolved electron energy-loss spectroscopy (M-EELS), we demonstrated the presence of an exciton condensate in $1T$-TiSe$_2$ by observing a soft electronic collective mode at the charge density wave (CDW) transition temperature, $T_C = 190$ K. As TiSe$_2$ is doped with copper to form Cu$_x$TiSe$_2$, the CDW transition temperature is suppressed and a superconducting dome emerges around $x = 0.04$. Using M-EELS, we found that the electronic collective mode softens partially near $T_C$ for very low dopings ($x < 0.004$), but does not soften above $x \sim 0.01$. Our results indicate that the exciton condensate is rapidly destroyed in Cu$_x$TiSe$_2$ by screening from the Cu atoms and that a conventional Peierls CDW persists above $x \sim 0.01$. We conclude that the excitonic state is not directly related to the superconductivity in Cu$_x$TiSe$_2$.

Session K13 DMP: 2D Materials (General) -- Topology and Exotic Phenomena

Growth and Transport Characterization of Epitaxial Graphene on Non-polar SiC Facets

YIRAN HU (Presenter), School of Physics, Georgia Institute of Technology, VLADIMIR PRUDKOVSKII, Institut Neel/CNRS-Univ. Grenoble Alpes, ANTONIO TEJEDA, Univ. Paris-Sud, ÂMINA TALEB IBRAHIMI, SOLEIL Synchrotron, YUE HU, School of Physics, Georgia Institute of Technology, CLEMENS B. WINKELMANN, Institut Neel/CNRS-Univ. Grenoble Alpes, LEI MA, TICNN, Tianjin University, CLAIRE BERGER, Institut Neel/CNRS-Univ. Grenoble Alpes, WALT A. DE HEER, School of Physics, Georgia Institute of Technology —

The ballistic transport and quantized conductance of $e^2/h$ observed in epitaxial graphene side wall nanoribbons at room temperature still lacks full explanation [1]. In an effort to solve this question, we produced graphene samples on specific SiC facets that host the side wall nanoribbons and fabricated standard transport measurement devices. Pre-growth patterning has been demonstrated to direct the graphene growth and improve growth uniformity. We did a variety of measurements, including AFM, Raman spectroscopy, ARPES, STS and transport measurements. These results indicate a charge-neutral graphene material, showing properties consistent with the observation of ballistic transport in side wall nanoribbons.

8:12AM K13.00002: Strain fields in graphene induced by nanopillars* SLAVISA MILOVANOVIC (Presenter), LUCIAN COVACI, FRANCOIS M PEETERS, University of Antwerp — The mechanical and electronic properties of a graphene membrane placed on top of a superlattice of nanopillars are investigated. We use molecular dynamics simulations to access the deformation fields and the tight-binding approaches to calculate the electronic properties. The system of interest consists of a triangular lattice of nanopillars with a period of $a=750$ nm over which the graphene layer is deposited. Ripples form in the graphene layer that span across the unit cell, connecting neighboring pillars, in agreement with recent experiments. We investigate the dependence of the pseudo-magnetic field (PMF) on unit cell parameters and the van der Waals interaction between graphene and the substrate. We find direct correspondence with typical experiments on pillars, showing intrinsic “slack” in the graphene membrane. PMF values are confirmed by the LDOS calculations at different positions of the unit cell showing pseudo-Landau levels at varying spacings. Our findings can be applied to other 2D materials (hBN, TMDs). Such systems are of interest as single-photon emitters where charge carriers are confined by the strain potential. Our study can be used as a guide to optimize parameters of the system for the improvement of the efficiency of the emitter.

8:24AM K13.00003: Charged topological solitons in zigzag graphene nanoribbons. LUIS BREY (Presenter), M.P. LOPEZ-SANCHO, ICMM-CSIC — Zigzag graphene nanoribbons (ZZGN) have a magnetic ground state (GS) characterized by edge ferromagnetism with antiferromagnetic coupling between opposite edges. This GS appears because of a broken symmetry in the spin sector. Therefore, by inverting the spin polarization of the full system there is another energy degenerate GS. The band structures of the degenerate GS’s are inverted. When connecting two domains with opposite mass i.e. spin orientation, a symmetry protected zero energy topological state appears at the interface between the degenerate GS's. These topological states are soliton-like excitations that carry charge $\pm e$ with half electron localized at each edge of the nanoribbon. The connection between topological defects and electric charge suggests that solitons can be the relevant charge excitation in ZZGN's. Then whenever adding charge to the system an array of solitons can be formed, creating a solitonic phase. By performing numerical calculations, we find that at low doping, charge added to the system creates magnetic domains and becomes localized at the domain walls separating opposite degenerate ground states. Our results show that the topological properties of ZZGNR's are generated by electron-electron interactions rather than by spin orbit coupling.

8:36AM K13.00004: Topological Effects in 1D and 2D Materials: Topological Band Engineering, Optical Selection Rules, and Excitonic Shift Currents* [Invited] STEVEN G. LOUIE (Presenter), University of California at Berkeley and Lawrence Berkeley National Lab — In this talk, I present several fascinating manifestations of topological effects in the electronic and optical properties of atomically thin one-dimensional (1D) and two-dimensional (2D) materials. First, we find that symmetry-protected topological phases exist in graphene nanoribbons (GNRs) [1]. Semiconducting GNRs of different width, edge shape, and terminating unit cells can belong to different electronic topological classes, characterized by a $Z_2$ invariant. Junctions between segments of topologically distinct GNRs are predicted to support robust in-gap topological junction states which can be used for band engineering. Experimental realizations of these predictions have been achieved [2]. Second, we show that the conventional optical selection rules for excitons must be replaced in 2D by a novel, simpler formula, owing to a topological characteristic inherent to the photoexcitation of excitons in 2D [3]. The new selection rule is dictated by a winding number of the interband optical transition matrix elements (a heretofore unrecognized topological invariant). This appealingly simple and general new rule is applied to elucidate the optical spectra of gapped graphene systems. Third, I present some recent work on the effects of electron-hole interactions on shift currents in non-centrosymmetric 2D crystals (so-called bulk photovoltaic effect), in which we show excitonic effects lead to an enormous enhancement and, more interestingly, gives rise to DC conduction with sub-bandgap-frequency excitations.[4]

9:12AM K13.00005: Topological Vortices vs. discommensuration dislocations in charge-density-wave 2H-TaSe$_2$

SEONG JOON LIM (Presenter), Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, CHOOJAE WON, Laboratory for Pohang Emergent Materials, Pohang Accelerator Laboratory and Max Planck POSTECH Center for Complex Phase Materials, Pohang University of Science and Technology., SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, NJ — Charge density wave (CDW) discommensuration (DC) refers to a boundary between two different CDW phases and is a key to understand the phase transition from commensurate to incommensurate CDW. The phase transition can be rendered as a process of creating or eliminating DCs that results in change of incommensurability, and the place of such process, where DCs merge to each other, has been known as CDW dislocation. The idea of CDW DC dislocation has been primarily studied in 2H-TaSe$_2$, which shows a clear phase transition from incommensurate to commensurate CDW. Although there have been several experimental and theoretical results supporting the idea, it has nevertheless not been verified at the atomic scale using, for example, scanning tunneling microscopy (STM). We present an observation of such entangled points of multiple DCs in 2H-TaSe$_2$ by STM. The observation showed no phase slip which is against the idea of CDW dislocation, but the result instead unveiled the formation of topological vortices. In this talk an atomic scale comparison among the CDW DC dislocation model, the experimental results as well as a complicated vortex-like domain topology of 2H-TaSe$_2$ will be presented.

9:24AM K13.00006: Quantum paraelastic two-dimensional materials

TYLER BISHOP (Presenter), ERIN FARMER, AFSANA SHARMIN, University of Arkansas, ALEJANDRO PACHECO-SANJUAN, Mechanical Engineering, Universidad Tecnica Federico Santa Maria, PIERRE DARANCET, Center for Nanoscale Materials, Argonne National Laboratory, SALVADOR BARRAZA-LOPEZ, University of Arkansas — We study the elastic energy landscape of two-dimensional tin oxide (SnO) monolayers and discover a transition temperature using ab-initio molecular dynamics (MD), that is close to the value of the elastic energy barrier $J$ derived from $T = 0$ K density functional theory calculations. The power spectra of the MD evolution permits identifying soft phonon modes likely responsible for the observed structural transformation. The mean atomic displacements obtained from a Bose-Einstein occupation of the phonon modes suggest the existence of a quantum paraelastic phase, that could be tuned charge doping, implying that SnO monolayers could be two-dimensional quantum paraelastic material with a charge-tunable quantum phase transition.

Calculations were performed at Cori (NERSC), Carbon (ANL), and Trestles (Arkansas).

9:36AM K13.00007: Dependence of the hBN Layer Thickness on the Band Structure and Exciton Properties of Encapsulated WSe$_2$ Monolayers

IANN GERBER (Presenter), XAVIER MARIE, LPCNO, Institut National des Sciences Appliquées de Toulouse — The optical properties of two-dimensional transition metal dichalcogenide monolayers such as MoS$_2$ or WSe$_2$ are dominated by excitons, Coulomb bound electron-hole pairs. Screening effects due the presence of hexagonal-BN surrounding layers have been investigated by solving the Bethe Salpeter Equation on top of $GW$ wave functions in density functional theory calculations. We have calculated the dependence of both the quasi-particle gap and the binding energy of the neutral exciton ground state $E_b$ as a function of the hBN layer thickness. This study demonstrates that the effects of screening at this level of theory are more short-ranged that it is widely believed. The encapsulation of a WSe$_2$ monolayer by three sheets of hBN (~1 nm) already yields a 20 % decrease of $E_b$ whereas the maximal reduction is 27% for thick hBN. We have performed similar calculations in the case of a WSe$_2$ monolayer deposited on stacked hBN layers. These results are compared to the recently proposed Quantum Electrostatic Heterostructure approach.

*I. C. Gerber thanks the CALMIP initiative for the generous allocation of computational times, through the project p0812, as well as the GENCI-CINES and GENCI-IDRIS for the grant A004096649. X. Marie acknowledges the Institut Universitaire de France.
9:48AM K13.00008: Revealing of Dark Exciton States by Twisted Light in Two Dimensional Transition Metal Dichalcogenides  KRISTAN BRYAN C SIMBULAN, TENG-DE HUANG, Department of Physics, National Taiwan Normal University, FENG LI, JUNJIE QI, School of Materials Science and Engineering, University of Science and Technology Beijing, TING-HUA LU, YANNWEN LAN (Presenter), Department of Physics, National Taiwan Normal University — Brightening spin- and momentum-forbidden dark exciton in two-dimensional (2D) transition metal dichalcogenides (TMDs) is nontrivial to further advances in optoelectronics applications. In this study, we demonstrate the effects of the interaction between twisted light (light possessing orbital angular momentum) and atomically thin TMD material in the optical measurements. Our results show a reproducible blue shift in the photoluminescence (PL) spectra of both monolayer and bilayer TMD material as the topological charge of the illuminating twisted light is incremented along positive and negative values. This phenomenon is attributed to the transfer of orbital angular momentum from twisted light onto the center-of-mass momentum of excitons which consequently brightens momentum-forbidden dark exciton states. Further, based on the observation on power-dependence of PL spectra, we found a red shift with increasing laser power across different topological charge values of the incident light. It reveals that there is another factor such as heat or strain induced by twisted light, which can replace the dominant mechanism. This study uncovers a new selection rule in 2D TMD materials that can potentially be a useful control mechanism for future optoelectronic device applications.

10:00AM K13.00009: The influence of disorder in the external environment of 2D semiconductors on their electronic and optical properties  ARCHANA RAJA ( Presenter ), University of California, Berkeley, LUTZ WALDECKER, Stanford University and SLAC National Laboratory, JONAS ZIPFEL, University of Regensburg, YEONGSU CHO, University of Chicago, SAMUEL BREM, Chalmers University of Technology, JONAS ZIEGLER, University of Regensburg, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Tsukuba, ERMIN MALIC, Chalmers University of Technology, TIMOTHY BERKELBACH, University of Chicago, TONY F HEINZ, Stanford University and SLAC National Laboratory, ALEXEY CHERNIKOV, University of Regensburg — Disorder in solids typically stems from local fluctuations of material structure itself like composition, strain, and size. Here, we highlight a new source of disorder in atomically thin, two-dimensional (2D) materials: The variation in the effective strength of Coulomb interactions in the 2D material resulting from fluctuations in the dielectric screening of the adjoining environment. We experimentally monitor the influence of dielectric disorder for monolayer WS₂ and WSe₂ on SiO₂, PDMS and h-BN by probing correlations between ground and excited state exciton resonances, which exhibit different sensitivities to the external dielectric environment. Our observations are described in a theoretical framework that considers variation in external dielectric screening and intrinsic phonon scattering channels as contributing to the ground and excited-state exciton linewidths. Even moderate fluctuations in the external dielectric permittivity are shown to induce inhomogeneous variations of the bandgap and exciton binding energies on the order of 100’s of meV, constituting the major source of disorder in the studied samples. We identify elimination of dielectric disorder as key to achieving high material quality through encapsulation of 2D semiconductors in other van der Waals materials.

10:12AM K13.00010: Theory-assisted detection of nano-rippling and impurities in STEM images of angle-mismatched bilayer graphene*  ANDREW O’HARA (Presenter), OLEG S OVCHINNIKOV, JORDAN A. HACHTEL, Department of Physics and Astronomy, Vanderbilt University, STEPHEN JESSE, Center for Nanophase Materials Science, Oak Ridge National Laboratory, SERGEI KALININ, Institute for Functional Imaging of Materials, Oak Ridge National Laboratory, ALBINA Y BORISEVICH, Materials Science and Technology Division, Oak Ridge National Laboratory, SOKRATES T PANTELIDES, Department of Physics and Astronomy, Vanderbilt University — Two-dimensional (2D) materials commonly contain ripples and impurity atoms that limit carrier mobilities, create pseudo-magnetic fields, and affect other electronic and magnetic properties. While scanning transmission electron microscopy (STEM) provides high-accuracy determination of the atomic positions and columns in the image plane, it is difficult to obtain precise atomic positions in the perpendicular direction. Detection of impurities with similar atomic numbers can also be difficult in Z-contrast imaging. In the case of multilayer 2D materials such as bilayer graphene, misalignment of the layers results in a moiré pattern that further compounds the problem of atomic identification. In this work, we introduce a combined approach utilizing STEM imaging and density-functional-theory calculations to recover this information from the experimentally accessible xy-coordinates in twisted bilayer graphene. We find that the strain-induced rippling obeys the continuum model of elasticity and that the moiré-pattern-induced undulations are approximately an order of magnitude smaller. Additionally, using the presented methodology, we are able to establish the presence of a substitutional nitrogen impurity.

*Supported by DOE Grant DE-FG-02-09ER46554 and NSF Grant DMR-1508433.
Strain enhancement of the Kondo effect in graphene

KEVIN INGERSENT (Presenter), Department of Physics, University of Florida, DWAEI ZHAI, SERGIO E ULLOA, NANCY PATRICIA SANDLER, Department of Physics and Astronomy, Ohio University — The Kondo physics of screening of an impurity's magnetic moment by electrons in doped graphene has been predicted to exhibit peculiar features. However, conclusive experimental observation of the phenomenon remains elusive. One possible obstacle to its identification is a very small Kondo temperature $T_K$ in situations where the chemical potential lies near the Dirac point. Here, we propose to use mechanical deformations in graphene to recognize the unique fingerprints that the Kondo regime exhibits [1]. Inhomogeneous deformations are known to produce specific alternating changes in the local density of states that indicate sublattice symmetry breaking effects. These patterns can be magnified to produce significant enhancement or depression of $T_K$ for magnetic impurities positioned at different lattice sites. The deformation-induced changes, particularly the strong increase of $T_K$ expected at certain impurity locations, may lift the Kondo scale into the experimentally relevant range and are suitable for detection using local probes such as scanning tunneling microscopy.

*We acknowledge support from NSF Grant Nos. DMR-1508325 (Ohio) and DMR-1508122 (Florida).

Nano-optical imaging of 2D TMD alloys

DMITRI VORONINE (Presenter), University of South Florida — Two-dimensional transition metal dichalcogenides (2D TMDs) are the materials of recent interest due to many promising applications. Novel materials and devices are based on the heterostructures formed by 2D TMDs. Alloys formed at TMD heterojunctions may enhance or limit the applications. It is important to characterize their optoelectronic properties with nanoscale spatial resolution. Tip-enhanced photoluminescence (TEPL) and tip-enhanced Raman scattering (TERS) techniques were used to image various TMD (MoS$_2$, WS$_2$, MoSe$_2$, WSe$_2$) alloys and heterostructures revealing detailed nanoscale features. Conventional far-field photoluminescence (PL) and Raman imaging provides highly averaged information with spectral congestion. In contrast, the TEPL and TERS methods, not limited by diffraction, provide substantial information related to nanoscale optical properties of 2D materials with resolution down to a few nanometers. The variations in the nanoscale optical properties correlating with the structural variation can provide a better understanding of the 2D TMD materials for the future development of highly efficient, flexible, lightweight optoelectronic devices.

Stacking-dependent interlayer phonons in 3R and 2H MoS$_2$

JEREMIAH VAN BAREN (Presenter), Department of Physics and Astronomy, University of California, Riverside, GAIHUA YE, ZHIPENG YE, POUYAN REZAIE, Department of Electrical and Computer Engineering, Texas Tech University, JIA-AN YAN, Department of Physics, Astronomy, and Geosciences, Towson University, YU PENG, ZHENG LIU, Centre for Programmed Materials, School of Materials Science and Engineering, Nanyang Technological University, RUI HE, Department of Electrical and Computer Engineering, Texas Tech University, CHUN HUNG LUI, Department of Physics and Astronomy, University of California, Riverside — Atomically thin MoS$_2$, a prototype two-dimensional semiconductor, commonly exhibits the 2H stacking order. In even layer numbers, 2H MoS$_2$ restores the inversion symmetry and hence loses many attractive properties, such as second harmonic generation, piezoelectricity and spin-valley coupling. But researchers have recently grown MoS$_2$ crystals with 3R stacking order, which in all layer numbers breaks the inversion symmetry and retains the valleytronic, piezoelectric and nonlinear optical properties as in the monolayer. We have directly probed the stacking-dependent interlayer coupling in the pure 2H and 3R structure of MoS$_2$ by ultralow-frequency Raman spectroscopy. We observe up to three shear branches and four breathing branches in MoS$_2$ samples with thickness from 2 to 13 layers. Our results show distinct behavior of the shear modes between 2H and 3R MoS$_2$, and also suggest a slightly enhanced interlayer coupling in 2H MoS$_2$ compared to 3R MoS$_2$. Through a combination first-principles calculations, group theory, and an effective bond-polarizability model, we account for all the major observations in our experiment.

Session K14 DCMP: Graphene: Electronic Transport and Characterization

BCEC 153C - Ivan Borzenets
Atomic-Resolution Visualization of Complex Structures in Intercalated Bilayer Graphene*

JASON BONACUM (Presenter), ANDREW O’HARA, Department of Physics and Astronomy, Vanderbilt University, OLEG SOVCHEK, Institute for Functional Imaging of Materials, Oak Ridge National Laboratory, GEORGE GORDEEV, SONAKSHI ARORA, STEPHANIE REICH, Fachbereich Physik, Institut für Experimentalphysik, Freie Universität Berlin, JUAN CARLOS IDROBO, Institute for Functional Imaging of Materials, Oak Ridge National Laboratory, RICHARD F HAGLUND, SOKRATES T PANTELIDES, Department of Physics and Astronomy, Vanderbilt University, KIRILL BOLOTIN, Fachbereich Physik, Institut für Experimentalphysik, Freie Universität Berlin — Intercalation in two-dimensional materials has been widely investigated using spectroscopic, diffraction, and electrical measurements. However, these techniques generate spatially averaged data and provide information about the local atomic structure only inferentially. In this work, we deploy aberration-corrected scanning transmission electron microscopy to directly visualize the local atomic structure of FeCl3-intercalated bilayer (BLG) and few-layer graphene (FLG). The data exhibit a crystalline monolayer of FeCl3 inside BLG, atomically sharp intercalation boundaries, a variety of orientations for FeCl3 monolayers in FLG, and regions where the iron is reduced to form monolayer FeCl2. Our density-functional-theory calculations predict a low energy barrier of 0.04 meV/nm2 between different orientations of FeCl3, supporting the observation of multiple orientations. Furthermore, resonant-Raman spectroscopy yields evidence of two distinct graphene doping levels of $E_F=0.98\text{eV}$ and $E_F=1.06\text{eV}$ in intercalated bilayer graphene, which may be attributed to the coexistence of FeCl3 and FeCl2. These results highlight the critical need for atomic-resolution studies of FeCl3 and similar intercalants to understand the dynamics of doping in multilayer graphene and graphene superlattices.

Chiral symmetry breaking in rhombohedral multilayer graphene

NARJES KHEIRABADI, ANDREW HALLWOOD, JONATHAN F P ROGERS, EDWARD MCCANN (Presenter), Physics Department, Lancaster University, Lancaster, UK, MIKITO KOSHINO, Department of Physics, Osaka University, Japan — We model the single-particle electronic properties of rhombohedral multilayer graphene focusing on the topological surface states that yield two flat degenerate bands in the vicinity of the Fermi level. We show that chiral-symmetry breaking tight-binding parameters produce a finite dispersion of the two low-energy bands, but do not lift their degeneracy owing to the conservation of PT symmetry. We model PT symmetry breaking due to external fields, including interlayer asymmetry due to an external gate or substrate (broken space inversion) or an external magnetic field (broken time reversal symmetry).

Direct chemical potential measurements of fractional quantum Hall states in bilayer graphene

ALEXANDER ZIBROV (Presenter), FANGYUAN YANG, University of California, Santa Barbara, TAKASHI TANIGUCHI, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, Tsukuba, Ibaraki, Japan, ANDREA YOUNG, University of California, Santa Barbara — We report measurements of the chemical potential in high quality bilayer graphene (BLG) in the quantum Hall regime as a function of magnetic field, interlayer bias, and charge carrier density. To maintain sample quality while also enabling quantitative determination of the chemical potential of the BLG flake, we use a four plate capacitor heterostructure consisting of graphite top and bottom gates, BLG, and an integrated charge sensing graphene monolayer. The resulting devices show fractional quantum Hall states at odd-denominator filling fractions as large as 11 as well as even-denominator states at fillings $\nu=-5/2$, -1/2, 3/2 and 7/2. Changes in the chemical potential of the BLG flake generate modulations of the charge density in the monolayer graphene sensor layer, which we detect capacitively. These modulations form the error signal for a feedback loop whose control voltage is the BLG chemical potential. We demonstrate chemical potential sensitivity better than 10uV/√Hz, allowing determination of fractional quantum Hall energy gaps in this system. We then use the measured temperature dependence of the chemical potential to estimate the entropy of the electron system, and compare our results to predictions for abelian and nonabelian quasiparticles near fractional filling factors.
Large tunable intrinsic gap in rhombohedral-stacked tetralayer graphene at half filling

SHI CHE (Presenter), Department of Physics, The Ohio State University, KEVIN S MYHRO, YANMENG SHI, YONGJIN LEE, KEVIN THILAHAR, KEVIN BLEICH, Department of Physics and Astronomy, University of California, Riverside, DMITRY SMIRNOV, National High Magnetic Field Laboratory, CHUN NING LAU, Department of Physics, The Ohio State University — Rhombohedral-stacked tetralayer (r-4LG) has a highly unusual energy dispersion, which can be approximated as $E \sim k^4$, where $k$ is the wave vector. At half filling, the very flat energy bands in r-4LG are unstable to electronic interactions, giving rise to electronic states with spontaneous broken symmetries. Using transport measurements on suspended dual-gated devices, we observe an insulating ground state with a large interaction-induced transport gap up to 80 meV at the charge neutrality point. The energy gap is enhanced further with a perpendicular magnetic field, but closed or suppressed upon the application of an out-of-plane electric field of either polarity, increasing charge density or a critical temperature of ~40 K. This insulating gapped state is consistent to that observed in bilayer graphene (BLG) and rhombohedral-stacked trilayer graphene (r-TLG), and therefore proposed to be a layer antiferromagnet with broken time reversal symmetry. The large magnitude of the gap also suggests that, at least in r-4LG, the band flattening effect prevails over the increasing screening and charge de-confinement in thicker graphene, in agreement with a first principle calculation.

Energetics of complex phase diagram in a tunable bilayer graphene probed by quantum capacitance

MANABENDRA KUIRI (Presenter), ANINDYA DAS, Indian Institute of Science — Bilayer graphene provides a unique platform to explore the rich physics in quantum Hall effect. The unusual combination of spin, valley and orbital degeneracy leads to interesting symmetry broken states with electric and magnetic field. Conventional transport measurements like resistance measurements have been performed to probe the different ordered states in bilayer graphene. However, not much work has been done to directly map the energetics of those states in bilayer graphene. Here, we have carried out the magneto capacitance measurements with electric and magnetic field in a hexagonal boron nitride encapsulated dual gated bilayer graphene device. In presence of perpendicular magnetic field, we observe Landau level crossing in our magneto-capacitance measurements with electric field. The gap closing and reopening of the lowest Landau level with electric and magnetic field shows the transition from one ordered state to another one. Further more we observe the collapsing of the Landau levels near the band edge at higher electric field ($D > 0.5 \, V/nm$), which was predicted theoretically. The complete energetics of the Landau levels of bilayer graphene with electric and magnetic field in our experiment paves the way to unravel the nature of ground states of the system.

Quantitative Measurement of Valley Polarization in a Multicomponent Fractional Quantum Hall System

FANGYUAN YANG (Presenter), ALEXANDER ZIBROV, University of California, Santa Barbara, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, MICHAEL ZALETEL, University of California, Berkeley, ANDREA YOUNG, University of California, Santa Barbara — In bilayer graphene, the electronic structure at high magnetic fields are enhanced by spin, valley and orbital degrees of freedom. In particular, the valley quantum number can be directly mapped onto layer polarization, allowing for direct capacitive probes. In this talk, I will present quantitative measurements of valley polarization in high quality bilayer graphene quantum Hall system. The valley polarization is obtained by measuring antisymmetric combinations of top- and bottom- gate capacitances to the graphene bilayer. We improve on past approaches by using a multilayer heterostructure in which the bilayer is encapsulated in successive layers of hexagonal boron nitride (hBN), monolayer graphene, hBN, and graphite, allowing full control of density and layer polarization in both the bilayer and in the monolayer graphene gates. Our layer resolved measurements provide new quantitative insight into the ground states and excitations of both integer and fractional quantum Hall phases in bilayer graphene.
Time-resolved spectroscopies have significantly contributed to the study of the dynamical properties of conventional and quantum materials. By following the dynamics of excited electrons, one can follow the dominant scattering processes and discern the flow of energy from the electronic system to other degrees of freedom. Time and angle-resolved photoemission spectroscopy (TR-ARPES) allow one to access electron dynamics in a momentum resolved way. In this work, a balance of energy and time resolution revealed a peak associated with optical excitation. In addition, we observe quantized energy-loss scattering processes, which comes from the emission of an optical phonon from electrons in the direct-transition peak (DTP). The characteristic time scale associated with the transfer of spectral weight from the DTP to the phonon-scattering-peak can then be directly related to the mode-projected electron-phonon matrix element.

*This research is funded by the Max Planck-UBC-UTokyo Centre for Quantum Materials and the Canada First Research Excellence Fund, Gordon and Betty Moore Foundation’s EPiQS Initiative, NSERC, Canada Foundation for Innovation, and the CIFAR Quantum Materials Program.

Magnetic field shifts the channel away from our electric interface in a way that is inconsistent with the semiclassical expectation from the Lorentz force. Moreover, the magnetic field causes an imbalanced layer occupation preference to the chiral channels. These behaviors can be understood in the limits that either the electric or the magnetic field dominates. We numerically show in the general case that the system can be well-approximated as a weighted sum of the two limits.

There has recently been a wave of interest in the hydrodynamical behavior of quantum many-body systems. Using ‘Coulomb drag’ physics as a guide, we discuss analogues of shear viscosity in quantum systems on discrete lattices. We argue that, although particle-hole symmetric materials have zero Coulomb drag, they nevertheless show a thermal equivalent in the form of drag between energy currents. Using a combination of perturbation theory and techniques from integrability, we give analytical predictions for this effect in coupled one-dimensional wires and compare them to DMRG studies on the Hubbard model. We comment on the generalization of these results to higher dimensional systems.

The study of electric current, dominated by electron-electron interactions, has recently gained interest owing to a new generation of ultra clean materials. In this regime, the flow behaves as viscous hydrodynamics fluid, in contrast to non-interacting flow types such as diffusive and ballistic. In this work, we use a scanning single electron transistor (SET) to image the local potential landscape produced by flowing electrons in an expanding channel of graphene. This geometry is ideal to reveal the spatial manifestation of the quantum contact resistance as well as non-local aspects of ballistic and hydrodynamic flows. In this talk we will present our recent scanning measurements that shed new light on all the above aspects of electron flow.
10:00AM K14.00011: Probing exciton condensates in double layer graphene using the corbino geometry  
YIHANG ZENG (Presenter), J.I.A. LI, OLIVIA GHOSH, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, CORY DEAN, JAMES HONE, Columbia University — Double layer graphene system with a thin tunnel barrier was recently reported to host exciton condensates and novel interlayer fractional quantum hall (FQH) states in the presence of a high magnetic field. The corbino geometry, consisting normally of two concentric rings, provides a direct transport probe of the bulk response, without the contribution of sample edges. In such geometry, combing the parallel flow and counter flow experimental setup, we observe the perfect drag phenomenon, namely the current in each of the two layers has exactly the same intensity but opposite direction. It demonstrates that all the current in the system is carried by excitons and provides an important evidence of the existence of exciton condensate. For the first time, we demonstrate with perfect drag that the exciton coupling remains robust at high landau level where the enhanced screening effect between electrons reduces the interlayer coupling. We study the exciton coupling as a function of interlayer bias, temperature, magnetic field and dc bias. Evidence of a fractional exciton condensate, occurring at total filling fraction of 1/3, is discussed.

10:12AM K14.00012: Direct visualization of electrostatic gating on the band structure of two-dimensional materials via Angled Resolved Photo Emission Spectroscopy (ARPES)  
FREDERIC JOUCKEN (Presenter), Physics, University of California, Santa Cruz, JOSE AVILA, Antares beamline, Synchrotron Soleil, Paris, France, ZHEHAO GE, EBERTHER QUEZADA, Physics, University of California, Santa Cruz, HEMIAN YI, Antares beamline, Synchrotron Soleil, Paris, France, JOHN L DAVENPORT, Physics, University of California, Santa Cruz, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, Tsukuba, Japan, MARIA C. ASENSIO, Antares beamline, Synchrotron Soleil, Paris, France, JAIRO VELASCO JR., Physics, University of California, Santa Cruz — The ability to manipulate the band structure of two-dimensional (2D) materials via electrostatic gating is crucial for the realization of technological applications and study of fundamental physics with these materials. ARPES is the standard experimental technique for band structure visualization, however, to this date, the direct visualization of electrostatic gating on the band structure of 2D materials is lacking. Several obstacles have precluded the incorporation of electrostatic gating with ARPES measurements such as sample size, surface uniformity, and a working gate electrode. To address these obstacles, we performed ARPES experiments with submicron spatial resolution on a heterostructure of bilayer graphene (BLG) and hexagonal boron nitride (hBN) that is back gated with an underlying graphite flake. We found that such a device geometry enabled direct visualization of the BLG bands in conjunction with their shift via electrostatic gating. We will discuss the latest experimental progress towards the direct visualization of electrostatic gate modulation of BLG bands.

10:24AM K14.00013: RKKY Interaction in Graphene Landau Levels*  
JINLYU CAO (Presenter), HERBERT FERTIG, SHIXIONG ZHANG, Indiana University Bloomington — We consider the problem of RKKY coupling of classical magnetic moments on graphene when the conduction electrons are in Landau level states. This can be due to a real applied field, or to non-uniform strain. The problem cannot be fully handled in the usual perturbative approach due to the large degeneracy of the Landau levels. For zero chemical potential and two impurities, we demonstrate that four bound states break away from zero energy, with energies dependent of the relative orientations of the spins, two of which are below the Fermi energy. In strained graphene, these two filled states create an effective spin-spin interaction (\( -J_{SD} \)) in addition to the standard RKKY (\( J_{2sd} \)). Moreover, this contribution is active on only one of the graphene sublattices. At the mean-field level, this sublattice has stronger ferromagnetic coupling than the other, while the two sublattices are anti-ferromagnetically coupled. This can potentially give rise to a ferrimagnetic phase with a broken O(3) symmetry. By comparison, the RKKY interaction of dilute impurities in unstrained graphene in a real magnetic field (perpendicular to sample) allows for a canted antiferromagnetic state with broken U(1) symmetry, and an accompanying Kosterlitz-Thouless transition.

*Supported by NSF and BSF.

10:36AM K14.00014: Texture Transitions of Quantum Hall Skryme Crystals Near Charge Neutrality in Graphene*  
BRADEN FESHAMI (Presenter), HERBERT FERTIG, Indiana University Bloomington — How does the quantum Hall canted antiferromagnetic (CAF) groundstate of graphene transition into the ferromagnet when the system is doped away from zero filling factor? We study this question within a self-consistent Hartree-Fock theory, in which regular Skryme crystals are stabilized by long range Coulomb interactions. In addition to this we include a Hubbard on-site term in the Hamiltonian which breaks the symmetry in the valley degree of freedom, and stabilizes a CAF state when the Zeeman energy is not too large. The full set of possible symmetry-breaking terms in the interactions are realized by incorporating an active window of non-zero Landau levels in our Hartree-Fock state. We explore how textures in the various discrete degrees of freedom evolve with the system parameters, and discuss the consequences of this for the phase diagram within the space of the on-site Hubbard parameter, Zeeman strength, and filling factor.

*Supported by the NSF and the BSF.
Equilibrium-state currents in Quantum Hall graphene quantum dots and pn junctions

CYPRIAN LEWANDOWSKI (Presenter), Department of Physics, Massachusetts Institute of Technology, AVIRAM URI, ELI ZELDOV, Department of Condensed Matter Physics, Weizmann Institute of Science — Charge carriers in a quantum Hall state, when subjected to a spatially dependent electrostatic confining potential, arrange themselves in a characteristic pattern of alternating compressible and incompressible regions. By delineating the individual contribution of each Landau level (LL) to electric currents in these regions, we elucidate the microscopic origin of the currents flowing in thermodynamic equilibrium. We focus on the case of a graphene quantum dot and a pn junction geometry. We find, both theoretically and experimentally, non-zero currents flowing in both compressible and incompressible regions, which alternate in sign between neighboring regions. Whilst all occupied Landau levels contribute to the incompressible currents equally, as expected, the compressible currents receive a contribution only from the last occupied LL with the contribution proportional to its energy. This peculiar dependence of compressible currents on the LL energy is best exemplified by the 0th LL, which due to graphene’s band structure, is expected to carry no current in the compressible region. This behavior is in agreement with experimental observations.

Session K15 DMP: 2D Materials (Semiconductors) -- Transport and Optical Phenomena in Bilayers and Heterostructures

Transport and optical measurement on twisted homo-bilayer WSe2/WSe2 structure

ZHIREN ZHENG (Presenter), THAO DINH, QIONG MA, SUYANG XU, EFREN A NAVARRO-MORATALLA, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, NUH GEDIK, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — The freedom of stacking different layers of 2D van der Waals (vdW) materials with an arbitrary twist angle opens up tremendous opportunities in studying emergent properties that are not accessible in the natural crystal form. In particular, recent measurements on magic-angle twisted bilayer graphene device show strongly correlated electronic properties, including correlated insulating behavior and unconventional superconductivity due to the formation of flat bands. Flat bands are expected in other small twist angle systems, including twisted bilayer transition-metal dichalcogenide (TMD), which could lead to new transport and optical properties. In this work, we fabricated encapsulated and dual-gated twisted homo-bilayer WSe2/WSe2 devices with precise angle control. We studied their electronic and optical properties as a function of charge density, electric/magnetic field, and temperature with an aim to understand how the twist angle can modify the electron behavior in this homo-bilayer TMD systems.

Magneto-reflectance study of Zeeman effect in MoS2 bilayer

TENZIN NORDEN (Presenter), PEIYAO ZHANG, ARMAN NAJAFI, ARINJOY BHATTACHARYA, University at Buffalo, The State University of New York, MAREK J KORKUSINSKI, National Research Council - Canada, ATHOS PETROU, University at Buffalo, The State University of New York — We studied Zeeman splitting $\Delta E$ of different recombination channels in Bilayer MoS2 using magneto-reflectance spectroscopy. The Zeeman splitting of both A and B excitons of bilayer MoS2 is linear in magnetic field with a slope of approximately -0.2 meV/T similar to that of single layer MoS2. In addition, we observed a new feature labeled N at 2.01 eV between A (1.93 eV) and B (2.13 eV) excitons. We note that feature N is not observed in MoS2 monolayers. This new feature shows a positive Zeeman slope of 0.37 meV/T as compared to A and B excitons. Theoretical and experimental studies show that bilayer MoS2 exhibits optical properties resulting from an interplay of the direct-bandgap of monolayer system, and the indirect bandgap of the bulk. A crucial property of the bilayer system appears to be its inversion symmetry and tuning of that symmetry translates into the interplay of contributions of different valleys in the photoluminescence spectra and possible appearance of additional emission. We hypothesize that feature 'N' results from these valley-mixing effects.

Gate controlled emission from hetero-bilayer of transition metal dichalcogenides

By changing the charge carrier density in the WSe2 monolayer, we observe a shift from charge to neutral density in the transition metal dichalcogenide monolayers which modifies the emission of the interlayer exciton at the electrons and holes results in interlayer excitons with large lifetime. In our FET geometry, we control the charge carrier density in the transition metal dichalcogenide monolayers which modifies the emission of the interlayer exciton at the hetero-bilayer. By changing the charge carrier density in the WSe2 monolayer, we observe a shift from charge to neutral exciton in MoSe2 monolayer and simultaneous enhancement of interlayer exciton photoluminescence. We also report observation of localized emission from the hetero-bilayer at a low temperature of 4 K.

Twist, Slip, and Circular Dichroism in Van der Waals Bilayers

Stacking atomically thin 2D materials with a rotational misalignment between its layers produces a van der Waals bilayer in which all mirror symmetries can be broken. A fundamental experimental signature of a twisted multilayer is circular dichroism (CD): the conversion of a linearly polarized incident optical field to an elliptically polarized field in transmission. This work investigates the relation between CD, the twist angle and interlayer slip. In experiments where bilayers are formed by contacting one layer with another one has control of the relative rotation angle between the symmetry axes of each sheet, but not of lateral shifts between the layers. Accounting for the lateral shift the configuration space of the system introduces a phase degree of freedom which manifests in the CD and its frequency dependence. We demonstrate how the symmetry constraints in this expanded configuration space is manifest in CD in twisted bilayers as a function of rotation angle. We apply this approach to discuss twisted graphene bilayers and on bilayer transition metal dichalcogenides where the twist coherently couples the intralayer excitons of the two layers.

Valley Polarization and Coherence in WSe2-WTe2 Alloys

We study the valleytronic properties of monolayer WSe2(1-x)Te2x (x=0...1), an alloy system where the endpoints WSe2 and WTe2 occupy different structural phases (H and 1T', respectively). As the Te composition x is increased, the alloy undergoes a semiconductor-semimetal phase transition, which we explore with temperature-dependent Raman and photoluminescence (PL) measurements. We find that Te incorporation activates new Raman modes, while also leading to non-monotonic shifts in the neutral exciton and trion energies and linewidths. Temperature-dependent PL measurements show valley polarization and valley coherence survive when Te doping is less than ~23%, above which valley polarization disappears while valley coherence gradually decreases. These findings demonstrate that valleytronic properties can be robust against disorder and illustrate the potential of two-dimensional alloys for valleytronic technologies.

O₂-induced *in-situ* manipulation of exciton recombination pathways in 2D heterostructures: Submicron, intensity-programmable pixels with rapid write-read-erase capability, as well as 2D O₂-sensor applications

ZACHARIAH HENNIGHAUSEN (Presenter), ISMAIL BILGIN, COLIN CASEY, KEVIN MENDEZ, MONIKA L EGGENBERGER, SWASTIK KAR, Northeastern University — We present a novel oxygen-induced switching between “non-radiative” and “radiative” exciton recombination in a family of 2D heterostructures: monolayer Bi₂Se₃ grown on arbitrary monolayer transition metal dichalcogenides (TMDs), to include TMD alloys. It is believed to be the result of O₂ diffusing/intercalating between the layers and disrupting the interlayer interaction. The signature photoluminescence (PL) peaks of TMDs are quenched in all as-grown heterostructures, but can be controllably recovered by heating in the presence of oxygen, and then re-quenched by heating in the presence of N₂ or Ar. The intensity PL switching can also be accomplished using a low-power focused laser, while changing the environment from pure nitrogen to air, enabling high control with submicron resolution. This allows for site-programmable, color-selectable, atomically-thin, micron-scale 2D optical "Write-Read-Erase" light-emitting pixels (PLPs) with effective volumes of ~10⁻²¹ m³. The emission intensity can be precisely varied by a factor exceeding 200×, with a wide range of emission energy values in the visible (1.5eV<Eₚh<2eV).

Electrostatic Traps of Interlayer Excitons in MoSe₂/WSe₂ Heterostructures

ANDREW JOE (Presenter), LUIS JAUREGUI, KATERINA PISTUNOVA, YOU ZHOU, KRISTIAAN DE GREVE, ANDREY SUSHKO, GIOVANNI SCURI, MIKHAIL LUKIN, HONGKUN PARK, PHILIP KIM, Harvard University — The two-dimensional (2D) nature and large excitonic binding energy of transition metal dichalcogenides (TMDs) allow for the exploration of novel quantum optical effects. Using type-II heterostructures formed by stacking MoSe₂ and WSe₂ monolayers, optical excitation generates interlayer excitons, bound electrons and holes residing in spatially separated layers. The out-of-plane, permanent dipole moment of interlayer excitons allows for the control of the emission energy by tuning the vertical electric field using dual-gated devices. By spatially varying the vertical electric field with patterned gates, we can generate potential profiles that can spatially control the interlayer exciton energy. We observe changes in the exciton cloud shape and emission brightness depending on a flat, trapping, or anti-trapping electric field profile. Finally, we estimate an upper-bound interlayer exciton density that can be tuned with the trap depth. With the ability to generate high densities of interlayer excitons, trapped interlayer excitons can serve as a platform for generating and exploring Bose-Einstein condensates at high temperatures.

Fowler-Nordheim tunneling through WSe₂ vertical junctions

DONG HOON SHIN (Presenter), Ewha Womans University, TAE YOUNG JUNG, Chungnam National University, HAKSEO NG KIM, Korea Research Institute of Standards and Science (KRISS), SANG WOOK LEE, Ewha Womans University, SUYONG JUNG, Korea Research Institute of Standards and Science (KRISS) — Van der Waals (vdW) materials consisting of 2D atomic layers have attracted lots of interest in the future electronic applications thanks to their superior electrical, optical and mechanical properties. Due to their weak interlayer coupling across physical vdW gaps, vertical charge transport through these vdW layered materials is fundamentally different from in-plane transport behaviors. In this study, we investigate detailed vertical charge transport mechanisms, especially in the regime of Fowler-Nordheim (FN) tunneling, through vertical WSe₂ junctions while controlling WSe₂-layer thickness from a monolayer to multilayers with a single atomic-thick resolution. We implement a simple but reliable device structure, graphite/WSe₂/graphite vertical heterojunctions, fabricated on a h-BN/SiO₂/Si substrate by mechanical transfer technique. We observe vertical charge transport through WSe₂ layers is governed by the FN tunneling even for a monolayer WSe₂ when the vertical junctions are applied by sufficiently high electric fields. Moreover, we find out that FN tunneling characteristics can be used for identifying not only the layer number but also characterizing key material properties of layered vdW materials such as effective mass and quasiparticle energy gap.
Creating and tuning of interlayer exciton gases in transition metal dichalcogenides heterostructures

ZEFANG WANG (Presenter), Penn State University & Cornell University, KIN FAI MAK, JIE SHAN, Cornell University — Stacking two-dimensional materials into van der Waals heterostructure offers a powerful approach toward creating artificial lattices with desired band structures and functionalities. In transition metal dichalcogenides heterostructures, interlayer exciton emerges due to band alignment of constituent layers and has been demonstrated to have long exciton lifetime [1] and valley lifetime [2], providing a platform to study degenerate Boson gases, rich valley physics, and possible optoelectronics applications. Here we report highly tunable interlayer excitons by an out-of-plane electric field in homobilayer WSe\textsubscript{2}. Electric field can tune the interlayer exciton dipole orientation from negative to positive and induce a Stark shift of up to 100meV in the exciton resonance energy. Moreover, with applied electric field, the exciton lifetime is greatly enhanced by more than two orders of magnitude (from ~200ps to >20ns), allowing the creation of interlayer exciton gas with density as high as 1.2x10\textsuperscript{11}cm\textsuperscript{-2} by moderate continuous-wave optical pumping. Furthermore, we can achieve high interlayer exciton density (~10\textsuperscript{12}cm\textsuperscript{-2}) with a trilayer heterostructure by both optical pumping and electrical injection.

A fresh look at interlayer emission from WSe\textsubscript{2}/MoS\textsubscript{2} heterostructures

ELYSE BARRÉ, TONY F HEINZ, Applied Physics, Stanford University — The recent two years have seen a rising interest in the study of interlayer excitons (ILX) in Van der Waals layered materials, where electron-hole pairs are bound together across the interlayer gap. Special attention was drawn to such ILX in heterostructures of semiconductor transition metal dichalcogenides with staggered band alignment such as MoSe\textsubscript{2} and WSe\textsubscript{2}. That includes the exploration of their optical properties, lifetime, optical selection rules, spin/valley properties, the influence of crystal alignment (a.k.a the moire pattern), the role of momentum-indirect transition, etc.. The latter subject was also studied for the ILX observed in WSe\textsubscript{2} and MoS\textsubscript{2} heterostructure (Kunstmann et al. Nature Physics, DOI: 10.1038/s41567-018-0123-y, 2018), where the reported ~1.6 eV emission is assigned to such indirect transition. In this talk, I will report on the observation of a different interlayer emission from the same system. Probing its response to different experimental conditions, I will discuss its properties and its origin.

Observation of Moiré Excitons in van der Waals Heterostructure

CHENHAO JIN (Presenter), EMMA C. REGAN, AIMING YAN, IQBAL B UTAMA, DANQING WANG, University of California at Berkeley, YING QIN, SIJIE YANG, Arizona State University, ZHIREN ZHENG, University of California at Berkeley, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, SEFAATTIN TONGAY, Arizona State University, ALEX K ZETTL, FENG WANG, University of California at Berkeley — Moiré superlattice in van der Waals systems provide a powerful tool to engineer the properties of two-dimensional materials through introducing a new energy and length scale. For example, correlated insulating states and superconductivity have been reported in graphene systems, where the moiré superlattice qualitatively change the behavior of electrons. The effects of moiré superlattice on excitons, on the other hand, is less studies experimentally. Here we report the observation of moiré excitons in heterostructure of two-dimensional semiconductors, and show that the properties of excitons can also be strongly modified by a moiré superlattice.

Spin-charge coupled transport in topological-insulator-based heterostructures

ENRICO ROSSI (Presenter), Department of Physics, William & Mary., MARTIN RODRIGUEZ-VEGA, Department of Physics, Indiana University.; GEORG SCHWIETE, Department of Physics and Astronomy, Center for Materials for Information Technology (MINT), The University of Alabama. — Experimental advances have made possible the creation of heterostructures composed of two or more layers of two-dimensional systems that combine their individual properties to reach desired functionalities. In this talk, we present the spin-charge coupled diffusion equations for heterostructures with random interlayer tunneling and in which one of the layers has strong spin-orbit coupling. We consider two distinct regimes: the weak coupling regime, for which the disorder-induced scattering time is shorter than the tunneling-induced scattering time, and the strong coupling regime, for which random tunneling events are dominant. We then apply our formalism to the case in which a two-dimensional electron gas is placed in proximity to the surface of a three-dimensional topological insulator and discuss the relevance of our results for experiments.

*This work is supported by NSF, ONR, BSF, the College of Arts and Sciences at Indiana University, and the College of Arts and Sciences at the University of Alabama.

Quantum spin-wave dynamics and magneto-transport behaviour in 2D van der Waals heterostructure

SUSHANT KUMAR BEHERA (Presenter), PRITAM DEB, Tezpur University — Spin-wave ensembles in qunatum regime coupled together to offer an exciting prospect of observing complex behaviour interlinking the microscopic spin features with macroscopic spin ensembles [Phys. Rev. Lett. 121, 126401 (2018)]. This feature is quite evidence in two dimensional van der waals heterostructure systems [Phys. Rev. Lett. 121, 067701, 2018]. In those systems, spin-transfer torque plays a major role to explain the induced magneto-transport phenomenon. Here, we demonstrate the collective interactions in an ensemble of spin-waves to unravel the full quantum dynamics and transport studies. We model a time-adaptive variational renormalization group method that accurately captures the underlying spin-wave dynamics and magneto-transport equations with potential device applications [arXiv:1808.04418].

Session K16 DCOMP DCP: Aqueous Solutions, Solvated Interfaces, and Ionic Polarization

Non-equilibrium effects at solvated interfaces under an applied external bias

ALEXANDRE ROCHA (Presenter), Instituto de Física Teórica, State University of Sao Paulo, Brazil, LUANA PEDROZA, Centro de Ciencias Naturais e Humanas, Universidade Federal do ABC, Brazil, PEDRO B. MENDONÇA, Centro de Física de Materiales, Donostia, Spain, MARIVI FERNANDEZ SERRA, Department of Physics and Astronomy, Stony Brook University, U.S.A. — Understanding the local structure of water at the interfaces of metallic electrodes is a key issue in aqueous-based electrochemistry. Nevertheless a realistic simulation of such a setup is challenging, particularly when the electrodes are maintained at different potentials. To correctly compute the effect of an external bias potential applied to truly semi-infinite surfaces, we combine Density Functional Theory and Non-Equilibrium Green's Function methods. This framework allows for the out-of-equilibrium calculation of forces and dynamics, and directly correlates to the chemical potential of the electrodes, which is introduced experimentally. In this work, I will discuss this frame work and some applications to water molecules at the interface with metallic surfaces.

*Funded by DOE Early Career Awards No. DE-SC0003871 and DE-FG02-09ER16052, ICTP-SAIFR (FAPESP project No. 2011/11973-4) and the ICTP-Simons Associate Scheme, FP7 FET-ICT “Planar Atomic and Molecular Scale devices” (PAMS) project (funded by the European Commission under contract No. 610446), the Spanish Agencia Estatal de Investigación (Grant No. MAT2016-78293-C6-4-R) and the Dep. de Educación of the Basque Government and UPV/EHU (Grant No. IT-756-13).
8:36 AM K16.00002: Toward first-principles modelling of charged solid-electrolyte interfaces  CHAO ZHANG (Presenter), Department of Chemistry - Ångström Laboratory, Uppsala University, MICHIEL SPRIK, Department of Chemistry, Cambridge University — Oxide-electrolyte interfaces are universally present in energy storage device, nanofluidic chemical processor, drug delivery nanoparticles and containments treatment in ground water. The surface charge of all these interfaces is controlled by the pH of the electrolyte solution and this leads to the formation of the electric double layer (EDL) by deprotonation of adsorbed water molecules or protonation of the oxide surfaces. Despite of the rapid development of experimental techniques, the missing of microscopic understanding imposes a knowledge gap. In this regard, modelling and simulation of EDL can provide complementary information of the structure, dynamics and energetics of charged interfaces. Here, I will report our current methodological progress on the atomistic modelling of dielectric properties of charged oxide-electrolyte interfaces.

8:48 AM K16.00003: First-principles modeling of electrochemical reactions at the metal-water interface under applied voltages  SUDARSAN SURENDRALAL (Presenter), MIRA TODOROVA, Computational Materials Design, Max-Planck-Institut für Eisenforschung GmbH, MICHAEL W FINNIS, Thomas Young Center, Imperial College London, JÖRG NEUGEBAUER, Computational Materials Design, Max-Planck-Institut für Eisenforschung GmbH — Ab initio modelling using density functional theory (DFT) is a powerful technique to study reactivity at electrochemical interfaces. We have recently developed an approach that allows to describe electrochemical systems under applied voltages and that can be easily implemented in existing DFT codes [1]. We apply this method to study Mg aqueous corrosion at anodic conditions, for which unusually high H2 evolution rates are observed. The DFT based molecular dynamics simulations we perform for the Mg(0001)/H2O system under increasing anodic polarization show dissociation events, proton transfer as well as H2 evolution at the Mg-water interface. A detailed analysis of our calculations reveals a novel and hitherto unconsidered reaction mechanism for the H2 evolution reaction, caused by an unusual adsorption phenomenon triggering a reaction resembling the cathodic Heyrovsky reaction.

9:00 AM K16.00004: DFT Characterization of Solvated NaCl Potentials of Mean Force and Energetics*  ALEC WILLS (Presenter), SEBASTIAN DICK, MARIVI FERNANDEZ SERRA, Stony Brook University — Potentials of mean force have long been a standard of measurement to characterize the energetics of the ion solvation process. In particular, classical molecular dynamics simulations frequently predict deeper minima than DFT simulations for the different solvated states. Moreover, different exchange-correlation functionals often don’t yield consistent potentials within DFT, some even predicting more stable second minima (solvent-separated ion pairs) than the usual deepest first minimum (contact ion pair). In this work, we investigate the electronic structure of solvated NaCl and the effects the charge localization has on nearby water molecules. We further investigate the errors in the system arising from the functional approximations and from the self-consistent ground-state Kohn-Sham electron density, and how the errors contribute to different stability characteristics.

*This material is based upon work supported by the Department of Energy under award number DE-FG02-09ER16052.
9:12AM K16.00005: Energetics of the adsorption of iodide ion at the air-water interface  YANBIN WANG (Presenter), PARTH RAKESH DESAI, SIDDHARTHA DAS, University of Maryland, College Park — Ion adsorption at air-water (a/w) interfaces has been extensively probed due to its significance in a large number of phenomena in environmental science, chemical physics, biophysics, etc. Recently, our group has investigated the ion-capillary wave interaction and its impact on the energetics of ion adsorption at an a/w interface considering generic ion. However, the specific ion adsorption behavior is more important, especially for those ions having a favorable energy of adsorption at the air/water interface. Therefore, we employed molecular dynamics method to study the iodine ion-capillary wave interaction. We reconstruct the potential of mean force using the distance between ion and the Gibbs dividing surface as the reaction coordinate. Furthermore, by analyzing the response of the system to the presence of iodine at the interface, e.g., the energetic change, the change in the overall fluctuations of surface and interfacial water, etc. we shed light to the understanding of the iodine ion adsorption at air/water interface.

9:24AM K16.00006: First-principles based quantification of charged species redistribution at electrochemical interfaces: Model system of zirconium oxide  JING YANG (Presenter), MOSTAFA YOUSSEF, BILGE YILDIZ, Massachusetts Institute of Technology — Modeling local distribution of charged ions and ionic defects at electrochemical interfaces is key to understanding related electrochemical processes. Based on the grand canonical approach which defines the electrochemical potential of individual charged species, a unified treatment of defects in solid oxide and ions on water side can be established. In this work, we apply this framework to the system of ZrO2/water interface. Density functional theory calculations are performed to obtain defect formation energy in the oxide materials and *ab initio* molecular dynamics is used to assess the formation free energy of H+ and OH- ions in water at different distances from the ZrO2 surface. The results are fed into a continuum model which produces the equilibrated distribution of these charged species. The continuum model considers explicitly both ion adsorption and defect segregation in the vicinity of the interface, and the diffuse layer and space charge layer in the extended area. Such a unified description reveals the influence of interfacial chemistry on oxide defect chemistry, and vice versa. This framework based on the grand canonical approach allows easy inclusion of additional charged species into the system and offer a general tool for studying electrochemical interfaces.

9:36AM K16.00007: Polarization induced ion adsorption on aqueous interfaces: Solvent effect on image charge interactions  CHANG YUN SON (Presenter), ZHEN-GANG WANG, Caltech — Understanding electrostatic interactions near interfaces is of critical importance in broad fields of science. Continuum electrostatics expects ions to be attracted to metal electrodes but repelled from low dielectric surfaces, while recent studies found certain ‘chaotropic’ ions are adsorbed on both air/water and graphene/water interfaces. Here we systematically study the effect of polarization of electrode, solvent and solute molecules on the adsorption of ions near interfaces with molecular dynamics simulation. An efficient method is developed to treat an electrolyte system between two surfaces, exploiting the mirror-expanded symmetry of the exact image charge solution. With neutral surfaces, the image interaction induced by the solvent dipoles and ions largely cancel each other, resulting in no significant net differences in the ion adsorption profile regardless of the interface. Under external electric field, the adsorption of ions are enhanced by the polarizing electrode. Explicit polarization of the electrolyte is necessary to capture the increased propensity of big halide ions near the electrode seen in experiments. Our analysis shows inclusion of both electrode and electrolyte polarization is of critical importance to model the electrolyte behavior with interfaces.

9:48AM K16.00008: Intercalation behavior of MXenes from ab initio molecular dynamics*  PAUL KENT (Presenter), WEIWEI SUN, Oak Ridge National Laboratory — MXenes are a large family of two-dimensional materials, primarily transition metal carbides and highly conductive, displaying exceptional performance for supercapacitors, batteries, and water purification. MXenes can host a wide range of species between their layers. Predictions and understanding are complicated by the presence of surface functional groups, such as O, OH, and F. Intercalation with aqueous ions such as Li, K, or Mg results in distinct structural and electrochemical responses. Here we present density functional ab initio molecular dynamics calculations for the behavior of ions confined in wetted MXene Ti3C2 layers. In this confined aqueous environment, ions display distinct behavior relating to their size, preferred solvation shell, and interaction with the surface groups, consistent with recent scanning probe microscopy data. This suggests that, besides the choice of electrolyte, careful selection of the surface groups and choice of MXene surface metal atoms are routes to optimize supercapacitor and sensing performance.

*This work was supported as part of the Fluid Interface Reactions, Structures and Transport (FIRST) Center, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences.
10:00AM K16.00009: Detection of Amino Acids and Other Biochemical Molecules with GaAs Schottky Diodes* T. ALKHIDIR (Presenter), ECE, KUST, C. ALPHA, CNF, Cornell, D. L. GATER, M. ABI-JAOUDE, Chemistry, KUST, A. F. ISAKOVIC, Physics, KUST, Cornell Univ. — The sensitivity of the GaAs surface makes it a good candidate for sensing various molecular species of interest in biochemistry. Simultaneously, the growth in nanofluidics applications calls for detailed understanding of liquid-solid interfaces for a variety of interfaces’ combinations. The 1V operation range for GaAs Schottky sensor is shown to be sufficient to detect H2O, D2O, -OH, as well as PBS solutions of various concentrations at 300K. We show how interfacial density of states changes with each compound probed, and how this density changes with the applied electric field. Inorganic bonds, such as Ga-H, Ga-O (and related As-based ones), are differentiated through correlation of transport and FTIR data of liquid-solid interfaced. The same GaAs Schottky diode can be used to distinguish between different types of amino acids (non-polar, polar, and basic) through the specific examples of Gly, His, and Cys, respectively. Finally, the built-in potential and the interfacial density of states are determined as a function of the pH factor of solutions tested (4 < pH < 9). These results offer perspective on developing GaAs based system for micro- and nanofluidics based detection and differentiation of peptides.

*We acknowledge the support from A2RE-ADEC, SRC, and Cornell CNF.

10:12AM K16.00010: Polarizability, Infrared and Raman Spectra of Water from First-Principles Simulations Using Recent Exchange-Correlation Functionals* MICHAEL D LACOUNT (Presenter), FRANCOIS GYGI, University of California, Davis — We present the results of a series of uncorrelated first-principles molecular dynamics simulations of liquid water obtained with the recently proposed SCAN density functional[1]. Results are compared with those obtained using the PBE density functional, and known experimental results. Estimates of the polarizability, infrared spectra, and Raman spectra are calculated. These results, in addition to previous structural analysis performed by us and others, are used to further evaluate the accuracy of the SCAN functional when applied to simulations of water.

*Supported by the Midwest Integrated Center for Computational Materials (MICCoM), as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences.

10:24AM K16.00011: Polarizable Classical Force Field to Describe the Water/Metal Interfaces in QM/MM Simulations of Electrochemical Interfaces ALINE OLIMPIO PEREIRA (Presenter), LUANA PEDROZA, Centro de Ciências Naturais e Humanas, Universidade Federal do ABC (UFABC), GUSTAVO TROIANO FELICIANO, Instituto de Quimica, câmpus de Araraquara, Universidade Estadual Paulista (UNESP), MAURICIO COUTINHO-NETO, Centro de Ciências Naturais e Humanas, Universidade Federal do ABC (UFABC) — The microscopic understanding and control of the kinetic behavior and reactions that occur in water/metal interfaces play a key role to the development of several technological applications. Atomistic simulations have shown to be a versatile tool to provide a detailed comprehension of such interfaces at the atomistic level. Concerning the quantum aspects and size of such systems, multiscale QM/MM simulations seems to be an efficient approach to describe the electrode interface. One of the key elements in QM/MM approaches is the classical force field. Particularly for metals, the accuracy of the simulation strongly relies in the ability of the force field to reproduce surface polarization effects. Based on this, we develop suitable polarizable force fields to describe the water/metal interface. Charged virtual sites are added to the molecular topology of a simple LJ model in order to create dipoles that reproduce the surface polarization. Two methods are considered: (i) the metallic system is composed of permanent dipoles created by rods and (ii) the metal-virtual site pair is a flexible dipole described by a harmonic oscillator, such as in a Drude model. Both models are tested and adjusted in order to reproduce the polarization and adsorption properties of the metallic surfaces.
8:00AM K17.00001: Physics of Ultra-light Materials Under Pressure: Quantum and isotope effects in lithium metal

[Invited] SHANTI DEEMYAD (Presenter), University of Utah — In this talk I will discuss the physics of ultra-light materials and evolution of quantum effects under extreme pressures. In periodic table lithium is the first element immediately after helium and the lightest metal. While fascinating quantum nature of condensed helium is suppressed at high densities, because of the presence of long range interactions in metallic systems, lithium is expected to adapt more quantum solid behavior under compression. Physics of dense lithium offers a rich playground to look for new quantum phenomena in condensed matter. I will discuss the presence of quantum contributions to the structural phase transitions of lithium at low temperature and will present our results on resolving the long lasting mystery of lithium ground state1,2.

*This research is supported by NSF Division of Materials Research award 1351986

8:36AM K17.00002: Electronic and Optical Properties of SnO2 at High Pressure

NATHAN DASEN BROCK-GAMMON (Presenter), Department of Physics and Astronomy, University of Rochester, RANGA P DIAS, Department of Mechanical Engineering, Department of Physics and Astronomy, University of Rochester, ELLIOT SNIDER, Department of Mechanical Engineering, University of Rochester — Tin oxide (SnO2) is one of the most widely used n-type transparent conducting oxide materials, which has attracted increasing interest due to its outstanding electrical and optical properties for potential applications. We present a detailed investigation on pressure-induced structural, electronic, and optical transitions of SnO2 to 60 GPa, using a diamond anvil cell, micro-confocal Raman spectroscopy, infrared absorption, reflectivity, and electrical resistance measurements. The results indicate that a wide band gap (Eg=3.6 eV) n-type semiconductor undergoes a semiconductor to insulator transition at ~18 GPa. Furthermore, we will present the temperature dependent resistance changes and photoconductivity with different power density at high pressures.

*The NSF grant DMR-1809649 supported this research.

8:48AM K17.00003: Pressure-induced metallization in MoS2

AZKAR SAEED AHMAD (Presenter), South University of Science and Technology of China — Molybdenum disulphide is a material of considerable interest due to its unique semiconducting and opto-electronic properties. There have been several theoretical studies suggesting an electronic phase transition in molybdenum disulphide but solid experimental evidence is still lacking. However, here we perform comprehensive studies on the pressure-dependent electronic, vibrational and structural properties of multilayered molybdenum disulphide up to 67 GPa. Our experimental results reveal that the press-induced metallization is associated with variation in local structure. The metallization happens from the overlap of the valance and conduction bands owing to sulphur-sulphur interactions upon the reduction in interlayer spacing under compression.

*The funding from Shenzhen City Government and Startup funding is greatly acknowledged. We also acknowledge the DESY, ALS, and BSRF, for allowing us to perform synchrotron experiments.
9:00AM K17.00004: Normal state electrical resistivity of thorium metal above a base temperature of 1.1 K and under applied pressure up to \(-100\) GPa* CHRISTIAN WOLOWIEC (Presenter), ZACKARY R REHFUSS, KALYAN SASMAL, Physics Department, University of California, San Diego, JASON R JEFFRIES, Physics Division, Lawrence Livermore National Laboratory, YOGESH KUMAR VOHRA, Physics Department, University of Alabama, Birmingham, SAMUEL T WEIR, Physics Division, Lawrence Livermore National Laboratory, M BRIAN MAPLE, Physics Department, University of California, San Diego — Measurements of electrical resistance were performed on thorium metal in a diamond anvil cell (DAC) under pressure from \(-5\) to \(100\) GPa and down to a temperature of \(-1.1\) K. Previous reports indicate that the ambient pressure superconducting transition temperature \(T_c = 1.4\) K is suppressed to \(-0.7\) K at a pressure of approximately \(15\) GPa. We did not observe any superconducting transition above a base temperature of \(1.1\) K over the pressure range from \(-5\) to \(100\) GPa. There is a sign change near \(15\) GPa in the pressure dependence of the normal state resistivity (from \(dR/dP < 0\) to \(dR/dP > 0\)). Above \(30\) GPa, there is little or no pressure dependence in the electrical resistance suggesting there is no change in carrier number as pressure is increased up to \(100\) GPa. Thorium remains metallic (\(dR/dT > 0\)) from \(300\) K down to \(-20\) K over the entire pressure range up to \(100\) GPa. However, at higher pressures above \(-50\) GPa, there is a reduction in the slope (\(dR/dT > 0\)), which remains constant up to \(100\) GPa, also suggesting there is little or no change in the carrier concentration. Below \(20\) K, \(dR/dT\) is zero.

*High pressure research at the University of California, San Diego was supported by the National Nuclear Security Administration through the U.S. Department of Energy (DOE) under Grant No. DE-NA0002909.

9:12AM K17.00005: Pressure-induced superconductivity in weak topological insulator Bi\(_2\)Te\(_I\) and topological metal Bi\(_3\)Tel* DERRICK VANGENNENP, Department of Physics, University of Florida, YOU LAI, National High Magnetic Field Laboratory, Florida State University, YOGESH KUMAR VOHRA, Department of Physics, University of Alabama at Birmingham, SAMUEL T WEIR, Physics Division, Lawrence Livermore National Laboratory, RYAN BAUMBACH, National High Magnetic Field Laboratory, Florida State University, JAMES J. HAMLIN (Presenter), Department of Physics, University of Florida — Using a newly developed system designed to rapidly screen materials for pressure-induced superconductivity we have performed a series of high pressure electrical transport and ac magnetic susceptibility measurements on single crystals of the weak topological insulator Bi\(_2\)Te\(_I\) and the topological metal Bi\(_3\)Tel. Upon compression at low temperature, we find that Bi\(_2\)Te\(_I\) becomes superconducting at \(-13\) GPa and Bi\(_3\)Tel begins to superconduct at pressures above \(-11.5\) GPa. The superconducting critical temperature \(T_c\) reaches maximum values of \(7\) K and \(7.5\) K for Bi\(_2\)Te\(_I\) and Bi\(_3\)Tel, respectively. We observe distinct anomalies in the resistivity of both samples as a function of pressure, which may arise due to structural transitions.

*Supported by National Science Foundation (NSF) CAREER award DMR-1453752. Equipment development was partially supported by the NSF NHMFL UCGP. A portion of this work was performed at the National High Magnetic Field Laboratory (NHMFL), which is supported by NSF Cooperative Agreements No. DMR-1157490 and No. DMR-1644779 and the state of Florida. Designer diamond anvils were supported by DOE-NNSA Grant No. DE-NA0002928 and under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344.

9:24AM K17.00006: High pressure, high magnetic fields fermiology studies of YBCO.* AUDREY GROCKOWIAK (Presenter), WILLIAM A CONIGLIO, STANLEY W TOZER, Florida State University — The pnictide, cuprate and molecular conductor families exhibit similar phase diagrams, leading to a great deal of interest in a common mechanism for a “universal phase diagram”. The typical ingredients for such phase diagrams include an antiferromagnetic phase, a superconducting dome, and possibly one, or several quantum critical points (QCP). Chemical doping is one traditional way to look at such materials, however thermodynamic variables such as magnetic field or hydrostatic pressure have proven to be powerful tools to explore this phase diagram, with very strong magnetic fields being used to suppress the superconducting dome, allowing one to investigate the QCP.

We report on our high pressure (up to \(25GPa\)) and high fields (up to \(85T\)) Quantum Oscillation measurements of the Fermi surface of YBCO6.5.

*The National High Magnetic Field Laboratory is supported by National Science Foundation through NSF/DMR-1157490 and DMR-1644779 and the State of Florida.
Pressure-Induced Structural Phase Transition and Magnetic Fluctuations in CeNi

ANDREI PODLESNYAK (Presenter), ALEXANDER I KOLESNIKOV, GEORG EHLERS, ANTONIO M. DOS SANTOS, ATHENA S. SEFAT, Oak Ridge National Laboratory, GREGORY J. HALDER, Argonne National Laboratory, ALEX MIRMELSTEIN, Russian Federal Nuclear Center

The pressure-induced structural phase transition and magnetic fluctuations in the intermediate-valence compound CeNi has been investigated by x-ray and neutron scattering techniques. The observed \( Cmcm \rightarrow Pnma \) structural transition is analyzed using density functional theory calculations, which successfully reproduce the ground state volume, the phase transition pressure, and the volume collapse associated with the phase transition. Equations of state for CeNi on both sides of the phase transition are derived and an approximate \( P-T \) phase diagram is suggested for \( P < 8 \) GPa and \( T < 300 \) K.

The inelastic neutron scattering study of the dynamic magnetic response of CeNi reveals that the structural transition increases the characteristic energy of magnetic fluctuations due to enhanced Ce 4f - Ni 3d hybridization. At the same time, the inelastic 4f magnetic form factor remains unchanged.

High Pressure Behavior of Ternary H-C-S Compounds: Structural and Electronic Properties

ELLIOT SNIDER (Presenter), Mechanical Engineering, University of Rochester, NATHAN DASENBROCK-GAMMON, Physics and Astronomy, University of Rochester, RANGA P DIAS, Physics and Astronomy, Mechanical Engineering, University of Rochester

Efforts to identify and develop room temperature superconducting materials are an intensive area of research, motivated by both fundamental science and the prospect for applications. We present pressure-induced structural and electronic properties of ternary H-C-S compounds to 150 GPa, using a diamond anvil cell, micro-confocal Raman spectroscopy, infrared absorption, and electrical resistance measurements. The results indicate that the H-C-S compound undergoes two structural phase transitions and an insulator-metal transition above 55 GPa. The temperature dependent resistance changes further show a gradual electronic transition from an insulator to a metal, which is driven by the pressure induced band gap closing. Also, we will discuss further investigation of these compounds as potential superconductors with high transition temperatures.

*The NSF grant DMR-1809649 supported this research.

High pressure study on a giant magnetoelectric effect hexaferrite via neutron techniques

YAN WU (Presenter), Neutron Scattering Division, Oak Ridge National Laboratory, KUN ZHAI, Institute of Physics, Chinese Academy of Sciences, JAMIE MOLAISON, BIANCA HABERL, Neutron Scattering Division, Oak Ridge National Laboratory, YOUNG SUN, Institute of Physics, Chinese Academy of Sciences, HUIBO CAO, Neutron Scattering Division, Oak Ridge National Laboratory

Multiferroics have attracted tremendous research interests because of their potential in constructing next-generation multifunctional devices. Y-type hexaferrite \( Ba_2Mg_2Fe_{12}O_{22} \) has promising magnetoelectric (ME) properties as a multiferroics which is sensitive to small magnetic field. When doped with Sr, the material keeps its sensitivity to field while the ME coefficients are greatly enhanced with Sr level increasing. Our previous work has reported new records of ME coefficients in single phase materials shown on \( Ba_2Mg_2Fe_{12}O_{22} \) with Sr doping that changes its ground state spin cone symmetry. Temperature dependent neutron diffraction investigation shows pinning effect emerging at heavy Sr doped sample that also change to be an alternating longitudinal conical ground state. Applying hydrostatic pressure has different effects on these simultaneously occurred phenomena, indicating their relatively independent mechanisms. With recent progress of diamond anvil cell (DAC) at the HB-3A beamline, we are able to identify interesting pressure effect picture up 7.3 Gpa on the system magnetic states.

*This research used resources at High Flux Isotope Reactor, a DOE Office of Science User Facility operated by the Oak Ridge National Laboratory.

ABSTRACT WITHDRAWN

10:12AM K17.00010: ABSTRACT WITHDRAWN
10:24AM K17.00011: High Pressure Behaviors of Dense Planetary Mixtures* [Invited] CHOONG-SHIK YOO (Presenter), Washington State University — Hydrogen (H₂) and helium (He) are two most fundamental solids abundant in the Universe. Compression behaviors of H₂ and He are critical to understand many body effects of these quantum solids; develop new condensed matter theories; and get insights into the internal structure of the Giant planets. In contrast to a rapid progress in understanding the phase diagram of H₂ at high pressures, a little is known about the phase behavior of planetary mixtures including the most fundamental quantum solids, H₂ and He. In this talk, we will describe our recent studies on high pressure behaviors of several systems of planetary mixtures including H₂-He, H₂-N₂, He-N₂, and H₂-H₂O. The results underscore a significant level of mixing in these planetary mixtures and thereby strong chemical interactions of the interstitial-filled guest H₂ with the host lattices of He, N₂ and H₂O. Based on these results we will point out several fundamental principles governing the pressure-induced phase and chemical transformations in the planetary mixtures, which include strong repulsive interaction, entropically driven phase mixing, proton exchange and ordering, and kinetic-controlled metastable phases.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K18 DCOMP: Machine Learning Material and Experimental Data BCEC 156B - Noam Bernstein, United States Naval Research Laboratory - Tag(s): Focus

8:00AM K18.00001: Machine learning interatomic potentials with and without (much) human labor [Invited] NOAM BERNSTEIN (Presenter), Naval Research Laboratory — In this talk I will show the state of the art in generating an interatomic potential using machine learning techniques (specifically, the Gaussian Approximation Potential (GAP) framework, with the Smooth Overlap of Atomic Positions (SOAP) representation of atomic geometry) that is capable of representing the Born-Oppenheimer potential energy surface of a material based on data (energies and forces) computed using density functional theory. First I will show that a careful and very human labor-intensive process of assembling a training database results in a potential with exquisite accuracy, far surpassing any empirical potential in the literature in predicting material properties. Then I will demonstrate, using several different elemental compounds with quite different bonding chemistry, that the database building process can be largely automated. A combination of iterative training and ab initio random search (AIRSS) can be used to simultaneously “discover and fit” a material without the need for any prior knowledge of what structures are relevant for a given material.

8:36AM K18.00002: Machine Learning for Ultrafast Electron Diffraction* [Invited] ARAVIND KRISHNAMOORTHY (Presenter), University of Southern California — Ultrafast electron diffraction (UED) experiments provide high-quality data about atomic structure and dynamics of functional materials down to fs-ps timescales. Imminent improvements in repetition rate of electron sources and experimental facilities will dramatically increase the size of this available data and will provide new capabilities for ultrafast science. These advances will require analysis techniques that can efficiently extract atomistic insights from raw diffraction images. In this talk, I will describe a deep generative model, trained on existing ultrafast electron diffraction data on photoexcited two-dimensional and layered materials obtained at SLAC, as well as trajectories from classical molecular dynamics and non-adiabatic quantum molecular dynamics simulations. The model is used to analyze lattice distortions, phonon modes and changes in local crystal structure due to photoexcitation and identify potential precursors to structural phase transformations in these materials. Extensions to the model to utilize streaming data for real-time analysis and the utility of the model in experimental design will also be discussed.

*This work was supported as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award Number DE-SC0014607.
9:12AM K18.00003: Prediction of Molecular Properties Using Graph Kernel and Active Learning* YU-HANG TANG (Presenter), WIBE A DE JONG, Lawrence Berkeley National Laboratory — In this talk, we present a new machine learning method for training predictive models of extensive molecular properties through the application of a similarity kernel on graphical representations of molecules, which is intuitive and can adapt to molecules of arbitrary size and topology. The pairwise similarity matrices between molecules as computed by the graph kernel can be used to construct Gaussian process regression models that can predict extensive properties with provable size scaling. Using an active learning procedure, we demonstrate that models created by our method can achieve a state-of-the-art accuracy of less than 1 kcal/mol on predicting atomization energies for molecules in the QM7 dataset without using any explicit energy decomposition/localization scheme. The method also uses a much smaller number of training samples as compared to other methods to achieve the same level of accuracy.

*This work was supported by the Luis W. Alvarez Postdoctoral Fellowship at Lawrence Berkeley National Laboratory.

9:24AM K18.00004: Tree Tensor Networks for Generative Modeling* SONG CHENG (Presenter), TAO XIANG, LEI WANG, Institute of Physics, PAN ZHANG, Institute of theoretical physics — Tensor Network States are widely used representations for many-body quantum states. They have close connections to the Graphical Models for high-dimensional data. In both research domains employing patterns such as locality or low information complexity are crucial for designing the model architecture. We employ Tree Tensor Network (TTN) for generative model. The TTN exhibits balanced performance in expressibility and efficient training and sampling. We apply TTN generative model on random binary patterns and the binary MNIST datasets and compare its performance with the matrix product states and other the popular generative models such as the Variational AutoEncoder and PixelCNN. Finally, we discuss about the future development of Tensor Network States in machine learning problems.

9:36AM K18.00005: Learning from the Density to Correct Total Energy and Forces in First Principle Simulations* SEBASTIAN DICK (Presenter), MARIVI FERNANDEZ SERRA, Stony Brook University — We propose a new molecular simulation framework that combines the transferability, robustness and chemical flexibility of an ab initio method with the accuracy and efficiency of a machine learned force field. The key to achieve this mix is to use a standard density functional theory (DFT) simulation as a pre-processor for the atomic and molecular information, obtaining a good quality electronic density. General, symmetry preserving, atom-centered electronic descriptors are then built from this density to train a neural network to correct the baseline DFT energies and forces. These electronic descriptors encode much more information than local atomic environments, allowing a simple neural network to reach the accuracy required for the problem of study at a negligible cost. The balance between accuracy and efficiency is determined by the baseline simulation. This is shown in results where high level quantum chemical accuracy is obtained for simulations of liquid water at standard DFT cost, or where high level DFT-accuracy is achieved in simulations with a low-level baseline DFT calculation, at about one order of magnitude reduced cost.

*DOE grant DE-FG02-09ER16052

9:48AM K18.00006: Microscopic Particle Localization Under Low-Light Conditions SHAO RAN HUANG (Presenter), RASHID ZIA, Brown University — Microscopic localization of particles under low-light conditions is a challenging task in microscopy, e.g. in biological physics and quantum photonics. While there has been considerable research on developing novel computational techniques, relatively less attention has been paid to integrated computational-experimental approaches leveraging hardware binning. Hardware binning allows one to judiciously sacrifice resolution, which is often excessive in locating objects of several pixels wide, to enhance the signal-to-noise ratio. Our research questions the default choice of single pixel measurements and investigates potential gains by combining multiple frames with differently hardware-binned images. Given the recent success in deep learning microscopy, we also investigate the use of deep residual learning in computing the convolution of the image with a suitable kernel for localization.
10:00AM K18.00007: Computational screening of experimental structural repositories for novel Li-ion conductors
LEONID KAHLÉ (Presenter), Theory and Simulation of Materials, École Polytechnique Fédérale de Lausanne, Switzerland, ARIS MARCOLONGO, Cognitive Computing and Computational Sciences Department, IBM Research 8803 Zürich, Switzerland, NICOLA MARZARI, Theory and Simulation of Materials, École Polytechnique Fédérale de Lausanne, Switzerland — A comprehensive screening of structural databases for ionic conductors by means of atomistic simulations could identify novel candidates for next-generation solid-state lithium-ion batteries, and deepen our understanding of the microscopic processes and structural motifs governing ionic diffusion in the solid state. This task is challenging because no classical simulation potential is predictive for wide varieties of materials classes, and first-principles simulations struggle to reach the necessary timescales. To model ionic diffusion efficiently and accurately, we derive a novel hybrid quantum/empirical model that can be used for molecular dynamics simulations of solid-state diffusion [1], by applying simple and intuitive approximations to fully self-consistent density-functional theory. This models underpins our high-throughput screening efforts for Li-ion conductors, powered by the AiiDA materials informatics [2] platform. I will present the different screening stages, show how high-level workflows can be used to automate and optimize the calculation of transport coefficients, and provide early results on promising candidates.

10:12AM K18.00008: Insights on materials space*  
CHANDRAMOULI NYSHADHAM (Presenter), KENNEDY LINCOLN, GUS HART, Brigham Young University — Using a kernel-based machine learning surrogate model, we present insights on generating and choosing the training and testing data for optimal modeling of materials space. We introduce a tool that helps us build an “ideal” kernel, which predicts with high accuracy on small training sets. We also present a methodology for quantifying the accuracy of any kernel based surrogate model for interpolating materials space. Our insights (based on analyzing data from over 73,000 unrelaxed DFT calculations comprising 45 different materials) helped improve our model’s predictions by as much as 50% for some systems.

10:24AM K18.00009: Quantum Criticality and Possible Superconductivity in Z_n Anisotropic Quantum Rotor Model Coupled with Free Fermion  
JIANQIAO LIU (Presenter), RYUICHI SHINDOU, School of Physics, Peking University — Quantum rotor model with Zn clock term (Zn anisotropic quantum rotor model) is known to exhibit a U(1) symmetric quantum critical point between Z_n symmetry breaking phase and quantum disorder phase for n ≥ 4. Around such quantum critical point, gapped bosonic excitations in the two phases become massless. Thereby, a coupling between a local boson degree of freedom and a free fermion could lead a superconductivity near the critical point. Motivated by this anticipation, we mapped the model into an electric flux model with electric charge, and carried out a quantum Monte-Carlo simulation study with a global update. Based on a finite-size scaling analysis of a superfluid stiffness parameter and comparison with the critical exponent of the 3D XY universality class, we discuss the critical nature of the quantum critical point. If the time allows, we discuss the possible superconducting pairing instability in the fermion system.

10:36AM K18.00010: OMDB-GAP1: A new dataset for band gap predictions for large organic crystal structures*  
BART OLSTHOORN (Presenter), RICHARD GEILHUFE, NORDITA, STANISLAV BORYSOV, Technical University of Denmark, DTU, ALEXANDER BALATSKY, NORDITA — Large datasets of ab initio calculations have enabled many pioneering studies of machine learning applied to quantum-chemical systems. For example, the machine learning models achieved chemical accuracy on the popular QM9 dataset which contains small organic molecules. Here, we present a new, more challenging dataset of 12,500 large organic crystal structures and their corresponding DFT band gap, freely available at https://omdb.diracmaterials.org/dataset. The dataset is based on the Organic Materials Database (OMDB) which hosts electronic properties of previously synthesized organic crystal structures. With an average of 85 atoms per unit cell, this dataset provides a new challenge for machine learning applications. We also evaluate the performance of two recent machine learning models on this new dataset: Kernel Ridge Regression with the Smooth Overlap of Atomic Positions (SOAP) and the deep learning model SchNet.

10:48AM K18.00011: Theory of band gaps in nano-porous SiC*  
BLAIR TUTTLE (Presenter), COLTON BARGER, Penn State Erie, ANDREW O’HARA, SOKRATES T PANTELIDES, Physics, Vanderbilt University — Nano-porous SiC is an insulator used as a back-end-of-the-line dielectric in scaled integrated circuits. In the present study, nano-porous SiC atomic models are created from cubic SiC supercells. First, pores of varying sizes are created and hydrogen passivated. Then, bond switching techniques are applied to create models with variable bond densities and bond types. Density functional theory calculations are used to determine the model's physical and electronic properties including band gaps. We apply linear regression and random forest techniques to explore the role of bonding on the bandgaps of nano-porous SiC alloys.

Session K19 DAMOP DCMP: Precision Many Body Physics VII  
BCEC 156C - Ehsan Khatami, San Jose State University - Tag(s): Focus

8:00AM K19.00001: Monte Carlo Studies of Quantum Critical Metals [Invited]  
EREZ BERG (Presenter), Condensed Matter Physics, Weizmann Institute — Metallic quantum critical phenomena are believed to play a key role in many strongly correlated materials, including high temperature superconductors. Theoretically, the problem of quantum criticality in the presence of a Fermi surface has proven to be highly challenging. However, it has recently been realized that many models used to describe such systems are amenable to numerically exact solution by quantum Monte Carlo (QMC) techniques, without suffering from the fermion sign problem. I will review the status of the understanding of metallic quantum criticality, and the recent progress made by QMC simulations, focusing on the cases of spin density wave and Ising nematic criticality. The results obtained so far will be described, as well as their implications for superconductivity, non-Fermi liquid behavior, and transport in the vicinity of metallic quantum critical points. Some of the outstanding puzzles and future directions are highlighted.

8:36AM K19.00002: Real time Quantum Monte Carlo for out of equilibrium strongly correlated systems.  
CORENTIN BERTRAND, INAC, CEA, ANTOINE MAILLARD, Ecole Normale Supérieure, SERGE FLORENS, CNRS, OLIVIER PARCOLLET (Presenter), Flatiron Institute, Simons Foundation, XAVIER WAINTAL, INAC, CEA —  
We discuss a real time diagrammatic Quantum Monte Carlo for strongly correlated systems, which allows to reach long time steady states. The method yields the expansion of physical quantities in power in the interaction, with a scaling $2^n$ at order $n$, uniformly in time. We present a systematic method to sum this expansion using conformal transformations and some recent benchmarks on Green functions in quantum impurity models in equilibrium and out of equilibrium.

8:48AM K19.00003: Infinite boundary conditions as a current source for impurity conductance in a quantum wire*  
ADAM IAIZZI (Presenter), National Taiwan University, CHUNG-YU LO, POCHUNG CHEN, Physics, National Tsing Hua University, YING-JER KAO, National Taiwan University — Developing nanoelectronic devices requires a detailed understanding of conduction in quantum wires. Numerical methods based on the density matrix renormalization group (DMRG) are excellent tools for studying one-dimensional quantum systems, but studying finite biases and currents requires time-dependent simulations, which remain challenging. Here we consider the problem of conductance across an impurity (or quantum dot) connected to metallic leads. Previous studies$^1,2$ have used a finite wire with open boundary conditions, which suffers from strong finite-size effects. We use a powerful numerical method incorporating infinite boundary conditions$^3$ (obtained from infinite DMRG$^4$) to simulate semi-infinite leads. We extract linear conductance from static correlation functions within a finite-size window that contains the impurity. Building on that, we use a time-dependent method to extract conductance in the presence of finite bias.

*MOST of Taiwan Grants No. 105-2112-M-002-023-MY3, 104-2628-M-007-005-MY3, 104-2112-M-002-022-MY3
9:00AM K19.00004: Resonant Tunneling with Dissipation in a Spin-full Quantum Dot.† TREVYN LARSON (Presenter), GU ZHANG, CHUNG-TING KE, MING-TSO WEI, HAROLD U BARANGER, GLEB FINKELSTEIN, Department of Physics, Duke University — We study resonant tunneling through a nanotube quantum dot subject to a dissipative environment. It has been previously shown that in the spin-less case, a quantum critical point is realized when the system is tuned on-resonance with symmetric coupling to the leads. At that point, conductance at low temperatures reaches \( e^2/h \) and several scaling laws are observed. Here, we demonstrate a qualitatively different behavior in the case of a spin-full resonance. In particular, the positions of resonant peaks change in a non-trivial fashion as a function of temperature, which is attributed to the lack of the particle-hole symmetry; and the peak height is not quantized and varies with dissipation strength. We argue that these signatures indicate the presence of the intermediate fixed point.

9:12AM K19.00005: Quench dynamics of superconducting fluctuations and optical conductivity in a disordered system* ADITI MITRA (Presenter), YOAH S LEMONIK, New York University — There has been significant interest in the generation of very short-lived superconducting states in solid-state films. Here we consider the role of non-equilibrium superconducting fluctuations in such systems, generated by an interaction quench, considering the limit of large static disorder. In particular, we argue that because of critical slowing down, the regime of the fluctuation dominated (normal state) is more important than might be na"ively thought. We show how such a state might appear in the optical conductivity, and give the appropriate non-equilibrium generalization of the Azlamazov-Larkin and Maki-Thompson fluctuation corrections to the optical conductivity.

*This work was supported by the US National Science Foundation Grant nsf-dmr 1607059.

9:24AM K19.00006: Many-body Dynamic Structure Factors with Phase Space methods† JONATHAN WURTZ (Presenter), ANATOLI S POLKOVNIKOV, Boston University — Recently there has been much interest in describing the behavior of strongly-interacting quantum systems, especially equilibrium relaxation and hydrodynamic response. Intuitively, such behavior is classical, and should have an effective description with polynomial complexity as opposed to the exponential complexity of full quantum dynamics. This talk will detail work on one such semi-classical description, the Cluster Truncated Wigner Approximation, which approximates dynamics in a high-dimensional classical phase space. Via sampling in this phase space, the method precisely reproduces both short-time far-from-equilibrium quantum dynamics and long-time thermal dynamics. In particular, we will show how using this method one can accurately compute the spin diffusion constant with the dynamic structure factor.

9:36AM K19.00007: Berry's ansatz in Fock space: beyond random matrix theory for many-body quantum chaos REMY DUBERTRAND (Presenter), JUAN-DIEGO URBINA, KLAUS RICHTER, Institute für Theoretische Physik, University of Regensburg — Berry's ansatz of random superposition of vector basis to mimic the statistical properties of quantum states in classically chaotic systems, has been highly successful for one-body systems. It is at the heart of the original justification for the eigenstate thermalisation hypothesis (ETH) for many-body quantum systems. We detail its use in many-body Fock space using recent developments in many-body semiclassical techniques for Bose Hubbard models. Quantitative predictions for 2-point correlations in Fock space are given, which agree very well with numerics. This study highlights how semiclassical techniques can be efficient for many-body chaos beyond the universal regime of random matrix theory.
Floquet behavior of correlated systems with light-matter coupling* MONA KALTHOFF (Presenter), Max Planck Institute for the Structure and Dynamics of Matter, JAMES FREERICKS, Georgetown University, GOETZ S UHRIG, TU Dortmund, DANTE KENNES, Freie Universität Berlin, ANGEL RUBIO, MICHAEL SENTEF, Max Planck Institute for the Structure and Dynamics of Matter — Periodically driven nonequilibrium many-body systems have a quasi-energy spectrum which can be tailored by external driving fields, known as Floquet engineering of desired system properties [Sentef et al., Nat. Comm. 6, 7047 (2015); Uhrig et al, arXiv:1808.10199 (2018)]. However, continuous periodic driving is not realizable in pump-probe experiments in solids. For instance it is not clear which criteria a pulse has to meet for a system exposed to a pulsed drive to approach the Floquet limit of a periodically driven system. However, there are analytical results for noninteracting band electrons in infinite dimensions [Kalthoff et al., Phys. Rev. B 98, 035138 (2018)]. Moreover we discuss t-DMRG results for interacting 1D chains in the charge density wave phase to study the emergence of Floquet behavior for realistic pulse shapes. This builds on the recently proposed Floquet engineering in quantum chains [Kennes et al., Phys. Rev. Lett. 120, 127601(2018)].

Ultrafast many-body correlations in an excitonic insulator out of equilibrium RIKU TUOVINEN (Presenter), Max Planck Institute for the Structure and Dynamics of Matter, DENIS GOLEZ, MICHAEL SCHÜLER, PHILIPP WERNER, Department of Physics, University of Fribourg, MARTIN ECKSTEIN, Department of Physics, Friedrich-Alexander University Erlangen-Nürnberg, MICHAEL SENTEF, Max Planck Institute for the Structure and Dynamics of Matter — A fast time propagation method for nonequilibrium Green’s functions [1] based on the generalized Kadanoff-Baym Ansatz (GKBA) [2] is applied to a lattice system with a symmetry-broken equilibrium phase, namely an excitonic insulator [3]. The adiabatic preparation of a correlated symmetry-broken initial state from a Hartree-Fock wave function within GKBA is assessed by comparing with a solution of the imaginary-time Dyson equation [4]. We find that it is possible to reach a symmetry-broken correlated initial state with nonzero excitonic order parameter by the adiabatic switching procedure. We discuss under which circumstances this is possible in practice within reasonably short switching times. We further investigate the out-of-equilibrium dynamics of competing orders and how the balance between them could be controlled by laser driving [5].

Real-time quantum Monte Carlo for the spin-boson model* OLGA GOULKO (Presenter), Boise State University, GUY COHEN, MOSHE GOLDSTEIN, Tel Aviv University — The spin–boson model consists of a two-state system coupled to a bath of non-interacting harmonic modes. This fundamental, yet non-trivial model describes dissipation in a quantum system and can be mapped to an impurity coupled to interacting electron leads. Using the inchworm Monte Carlo algorithm we are able to precisely compute various nonequilibrium properties of the spin-boson model, such as the real-time evolution of the population difference between the two states at different temperatures, different forms of the bosonic bath spectrum, and different values of the spin-bath coupling, including the strong coupling regime. We also discuss how to calculate the heat current through the system coupled to two baths at different temperatures using full counting statistics.

10:24AM K19.00011: Heating Dynamics in a Periodically Driven SYK-Model* CLEMENS KUHLENKAMP (Presenter), SIMON WEIDINGER, MICHAEL KNAP, Technical University of Munich — Periodically driven quantum matter can realize exotic dynamical phases that do not even exist in equilibrium. In order to understand how ubiquitous and robust these phases are, it is important to understand the heating dynamics of generic interacting quantum systems. We study the thermalization and heating dynamics in a generalized SYK-model subjected to a periodic drive, which realize a Fermi-Liquid (FL) to Non-FL crossover at a certain energy scale. Using an exact field theoretic approach we determine two regimes in the heating dynamics. At energies above the crossover scale the system is efficiently thermalizing and heats up exponentially. This crossover in the heating dynamics may be experimentally studied by measuring the absorption of THz laser light that impinges an irregularly shaped graphene flake in a strong magnetic field, which has been proposed to realize exotic SYK physics.

*We acknowledge support from the DFG grant No. KN 1254/1-1 and DFG TRR80 (Project F8).

10:36AM K19.00012: Entropy of the (1+1)-dimensional directed percolation* KENJI HARADA (Presenter), Graduate School of Informatics, Kyoto University — We investigate the informational aspect of a (1+1)-dimensional directed percolation which can be regarded as a reaction-diffusion process in a one-dimensional system and is a canonical model of a non-equilibrium continuous phase transition into an absorbing state. Using a tensor network scheme based on a mapping between a state probability distribution and a wave function, we can numerically calculate a time evolution of a state probability distribution. Although the density of active sites has no singular behavior, there is a new singular point in the conventional active phase at which the dynamical behavior of the entanglement entropy changes. The Rényi entropy has a cusp at the same point. The Rényi entropy also shows a universal relaxation at the critical point of the conventional absorbing phase transition.

*This work was supported by JSPS KAKENHI Grants No. 17K05576, and by MEXT as Exploratory Challenge on Post-K computer (Frontiers of Basic Science: Challenging the Limits) and Priority Issue on the Post-K computer (Creation of New Functional Devices and High-Performance Materials to Support Next-Generation Industries).

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K20 DCOMP DMP: First-principles Modeling of Excited-state Phenomena in Materials VII: 2D Materials and Surfaces BCEC 157A - Ismaila Dabo, Pennsylvania State University - Tag(s): Focus

8:00AM K20.00001: Ab initio time-dependent optical spectroscopy applied to spin and valley dynamics in monolayer transition metal dichalcogenides [Invited] ALEJANDRO MOLINA-SANCHEZ (Presenter), Institute of Materials Science, University of Valencia — Monolayer transition metal dichalcogenides (TMDs) like MoS₂ or WSe₂ are promising semiconducting 2D materials. Not only they have a bandgap in the optical range and suitable transport properties, but also provide a stimulating arena to study fundamental physics. For instance, the valence and conduction bands are spin-split because of the strong spin-orbit interaction. Moreover, due to the lack of inversion symmetry, with circularly polarized light, one can create excitons at selected K valley. The resulting imbalance in the population of the K valleys is the basics of valleytronics.

Ultrafast pump-probe spectroscopy measures accurately the valley dynamics, starting at the photogeneration of excitons at one valley and following the subsequent valley depolarization via intervalley and intravalley scattering. For instance, exploiting the valley selective optical selection rules and using two-colour helicity resolved pump-probe lasers, one can directly measure spin and valley dynamics and to estimate the ratio between intravalley and intervalley scattering rates. In spite of the numerous experimental data, the mechanisms of photo-generation and relaxation of the spin-valley polarization in TMDs are still heavily debated. It is in this context where time-dependent ab initio calculations are helpful to understand and predict the dynamical properties of 2D materials and to reproduce ultrafast spectroscopy experiments.

In this talk I will present our predictive and parameter-free approach to calculating ultrafast carrier dynamics in 2D materials, combining density functional theory with non-equilibrium many-body perturbation theory and including spin-orbit interaction. We calculate the photo-generation of carriers by a laser pulse, taking into account relaxation mechanisms such as electron-phonon scattering or radiative recombination, and simulate time-dependent spectroscopies like Kerr rotation, transient absorption or photoluminescence.
8:36AM K20.00002: The origin of single photon emission in 2D WSe$_2$*  YU JIE ZHENG, Department of Physics, National University of Singapore, YIFENG CHEN (Presenter), Centre for Advanced 2D Materials, National University of Singapore, YU LI HUANG, Institute of Materials Research & Engineering (IMRE), A*STAR (Agency for Science, Technology and Research), PRANJAL KUMAR GOGOI, Department of Physics, National University of Singapore, MING-YANG LI, LAIN-JONG LI, Physical Sciences and Engineering, King Abdullah University of Science and Technology, PAOLO E TREVISANUTTO, Centre for Advanced 2D Materials, National University of Singapore, QIXING WANG, Department of Physics, National University of Singapore, STEPHEN J PENNYCOOK, Department of Materials Science & Engineering, National University of Singapore, ANDREW THYE SHEN WEE, Department of Physics, National University of Singapore, SU YING QUEK, Centre for Advanced 2D Materials, National University of Singapore — Several experimental groups have shown that defect structures in 2D WSe$_2$ result in single photon emission (SPE). However, the origin of SPE is still unknown. We present a first principles study of the nature and optical properties of point defects in 2D WSe$_2$, together with scanning tunneling microscopy (STM) and scanning transmission electron microscopy images. We predict that O$_2$ can dissociate easily at Se vacancies, resulting in O-passivated Se vacancies (O$_{\text{Se}}$) and O interstitials (O$_{\text{ins}}$), which give STM images in good agreement with experiment. Our GW-Bethe-Salpeter-equation calculations show that O$_{\text{ins}}$ defects give exciton peaks ~50-100 meV below the free exciton peak, in good agreement with the localized excitons observed in independent SPE experiments. No other point defect (O$_{\text{Se}}$, Se vacancies, W vacancies, and SeW antisite defects) gives excitons in the same energy range. We conclude that the O$_{\text{ins}}$ defect is a source for the SPE previously observed in 2D WSe$_2$.

8:48AM K20.00003: Moiré Patterns of Excitons in Twisted Bilayer Transition-Metal Dichalcogenides Heterostructure*  XIAOBO LU (Presenter), SHIYUAN GAO, Physics, Washington University, St. Louis, XIAOQIN (ELAINE) LI, Department of Physics and Center for Complex Quantum Systems, Univ of Texas, Austin, LI YANG, Physics, Washington University, St. Louis — Twisted van der Waals heterostructures and the corresponding superlattices, moiré patterns, have been regarded as remarkable platforms to modulate many-electron interactions and optical excitations of two-dimensional structures. We employ first-principles many-body perturbation theory to study excitons and their moiré patterns in twisted bilayer MoSe$_2$/WSe$_2$ heterostructures. Because of significant type-II band offsets of heterostructures, direct interlayer excitons are always the lowest-energy excitons. We find that the energy variation of interlayer excitons is more significant in the R-type twisting structures than that in the H-type ones. Moreover, although the electron-hole binding energy is nearly spatially homogenous, the optical oscillator strength and radiative lifetime of interlayer excitons are very sensitive to the local stacking style, and they can vary in a few orders of magnitude in different regions of twisted bilayer structures. As a result, optical moiré patterns of interlayer excitons with high contrasts of brightness and radiative lifetime are expected.

9:00AM K20.00004: Dimensionality Dependence of Radiative Recombination in Black Phosphorus from First-principles*  FENG WU (Presenter), University of California, Santa Cruz, DARIO ROCCA, University of Lorraine and CNRS, Nancy (France), YUAN PING, University of California, Santa Cruz — Monolayer black phosphorus is a unique anisotropic 2D material with a sizable direct band gap and high mobility that has promising optoelectronic applications. However, the origin of how excitonic effects and excited state lifetime change with dimensionality has not been well understood. In this work we studied the electronic excitations and the radiative recombination in black phosphorus monolayer, nanoribbons and quantum dots by employing GW approximation (GW) and solving Bethe-Salpeter Equation (BSE). We demonstrate that 1) the exciton wavefunctions in 0D, 1D and 2D nanostructures are similar, which extend more along the armchair direction than zigzag, and reducing the size of nanostructures along the armchair direction significantly affects the exciton energy while that along the zigzag direction does not. 2) The radiative lifetime increases dramatically when the dimension shrinks from 2D to 1D to 0D, because the constraint of energy and momentum conversation makes that the radiative lifetime increases approximately $10^3$ times for each dimension reduction. This study provides important insights on engineering excited state properties of nanostructure materials.

*We acknowledge financial support from the National Science Foundation under grant No. DMR-1760260 and Hellman Fellowship
Exciton funnels in BPNRs. The excitons are able to be accumulated in unstrained, tensile or compressed regions, which enriches the means of controlling excitons for photo-detecting or photo-emitting. We find the type of funnels (spatial distribution and motion of excitons) can be tuned by changing the intensity and sign of the strain field, thickness and periodicity (zigzag or armchair) of BPNRs. By forming different funnels, the excitons are able to be accumulated in unstrained, tensile or compressed regions. This work implies that 2D materials are effective atomically thin dielectrics, and uncovers new insights into the unusual physics of screening in reduced dimensions.

Impact of defects on the opto-electronic properties of monolayer GeSe; a many-body perturbation theory perspective

KIRK LEWIS (Presenter), SAHAR SHARIFZADEH, Department of Electrical and Computer Engineering, Boston University — An accurate and detailed knowledge of the influence of defects will be central to the design of promising new 2D materials. Due to their reduced dimensionality and screening, these materials are even more likely to be impacted by defects than their 3D counterparts. We employ first-principles many-body perturbation theory within the GW/BSE approximation to investigate the influence of point defects on the opto-electronic properties of a monolayer semiconductor composed of GeSe. We systematically study a series of charged vacancies, their trap state energies, and their impact on optical absorption. We determine that the excitonic properties of the material are significantly affected by the presence of defects, with implications for devices fabricated using this material system.

Impact of defects on the opto-electronic properties of monolayer GeSe; a many-body perturbation theory perspective

10:00AM K20.00009: Realizing an excitonic insulator by decoupling exciton binding energy from the minimum band gap  JIANG ZEYU (Presenter), Physics, Tsinghua University, YUANCHANG LI, Advanced Research Institute of Multidisciplinary Science, Beijing Institute of Technology, DUAN WENHUI, Physics, Tsinghua University, SHENGBAI ZHANG, Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute — Realizing excitonic insulator state in real materials has long been an attractive subject of condensed matter physics, as motivated by both fundamental interest in many-body physics and the potential application in transport devices due to its bosonic nature. Direct-gap materials serve as promising candidates for excitonic insulators, where the difficulty to distinguish from a Peierls charge density wave is avoided. However, direct-gap materials still suffer from a divergence of polarizability when the band gap approaches zero, leading to a diminishing exciton binding energy. We propose that one can decouple the exciton binding energy from the band gap in materials where band-edge states have the same parity. As a concrete example, we show by first-principles calculations that two-dimensional GaAs and experimentally mechanically exfoliated single-layer TiS$_3$ support prefectly to this principle, thus hold the possibility for experimental realization of excitonic insulators.

10:12AM K20.00010: Linear response and nonlocal dielectric function of freestanding and substrate-supported borophene from first-principles*  ANUBHAB HALDAR (Presenter), SAHAR SHARIFZADEH, Department of Electrical and Computer Engineering, Boston University — Two dimensional boron, or borophene, is a metallic monolayer material that has been recently synthesized on metallic substrates. First principles studies on the mechanical, optical, and electronic properties of borophene have predicted novel applications of borophene in flexible and power electronics. Additionally, borophene is a flexible, transparent, metallic material with highly nonlocal and anisotropic permittivity, and is a candidate as a plasmonic material. Here, we utilized first-principles density functional theory to conduct a systematic investigation of the linear response in isolated and metal-supported borophene, in order to quantitatively describe plasmon resonances in the visible region in the presence of the substrate. We determine that the dielectric properties of borophene are significantly affected by a silver substrate. This has implications for monolayer and thin film plasmonic and optoelectronic devices based on this platform.

*The authors acknowledge funding support from the Department of Energy (Award #DE-SC0018080) and computational resources from MGHPCC and NSF-XSEDE.

10:24AM K20.00011: Charge dynamics in proton-irradiated aluminum sheets*  ALINA KONONOV (Presenter), ANEESH JONELAGADDA, ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — Materials capable of withstanding continual ion radiation are highly desirable in space and nuclear applications. A detailed understanding of the mechanisms leading to degradation of materials under ion bombardment would enable targeted development of radiation resistant materials. As an energetic charged particle penetrates a material's surface, it deposits energy and excites electrons, leading to secondary electron (SE) emission and localized charge within the material. Even when direct collisions with nuclei are rare, fs scale surface charge dynamics may cause Coulomb explosion, which would damage and erode the material surface. We use time-dependent density functional theory to characterize SE emission, surface charge dynamics, and atomic forces in few-layer aluminum sheets under proton irradiation. From first-principles, we compute exit-side and entrance-side SE yields, SE energy spectra, and time scales of charge equilibration within the material as the projectile velocity and material thickness are varied. We also estimate the momentum acquired by aluminum atoms near the impact point. These simulations provide unprecedented insight into the dynamical response of materials' surfaces to ion bombardment.

10:36AM K20.00012: Level Alignment in Large-Scale Hybrid Organic-Inorganic Systems from Hybrid Density Functional Theory

SVENJA JANKE (Presenter), Mechanical Engineering and Materials Science, Duke University, MARIANA ROSSI, Theory Department, Fritz Haber Institute of the Max Planck Society, SERGEY V. LEVCHENKO, Skolkovo Institute of Science and Technology, MATTTHIAS SCHEFFLER, Theory Department, Fritz Haber Institute of the Max Planck Society, MANOJ KUMAR JANA, CHI LIU, DAVID B MITZI, VOLKER BLUM, Mechanical Engineering and Materials Science, Duke University — Hybrid organic-inorganic systems allow to combine the properties of organic and inorganic substances at the nanoscale and hence open up a wide area for design of new materials with tunable properties. The positions of carrier levels and their alignment determine electronic properties of hybrid materials. A key challenge is that the systems in question tend to be large, due to alignment of components with inherently different lattice parameters or due to complex crystal structure packing. We here use hybrid density functional theory (FHI-aims all-electron code) for systems comprising over 1,000 atoms to reliably predict level alignments in two types of systems. For the paradigmatic interface system tetracene and pentacene at H/Si(111), we demonstrate the necessity of choosing large cells of up to 1,200 atoms that reflect the coincidence pattern and find type II heterojunction behavior with potential separation of charge between organic and inorganic component. For a layered double perovskite we demonstrate how level alignment between organic and inorganic compound is affected when the metal ion is exchanged, and rationalize experimentally observed photoluminescence in these systems.

10:48AM K20.00013: Ehrenfest molecular dynamics approach to a light-induced softening of aluminum slab based on time-dependent density functional theory

HIROKI KATOW (Presenter), YOSHIIUKI MIYAMOTO, National Institute of Advanced Industrial Science and Technology — Modulation in lattice kinetics of simple metals under the irradiation of an ultra-short laser pulse is of great interest to both industrial applications and fundamental physics. In our study we performed Ehrenfest molecular dynamics (Ehrenfest MD) simulation of a nine-atomic-layer-thick aluminum slab based on time-dependent density functional approach. In our simulation the slab has (111) surface of aluminum fcc structure. The slab is put in vacuum, and is exposed to a femtosecond laser pulse. To analyze the Ehrenfest MD results, we employed a quasi one-dimensional model that bounds neighboring layers by a quadratic potential. Model parameters are fitted so that they reproduce Ehrenfest MD trajectory. We found a significant and non-uniform reduction of the force constants with the increase of laser intensity suggesting lattice softening by electronic excitation. In this presentation, we compare the results with the case of Born-Oppenheimer MD under finite electron temperature and discuss the correspondence between these two distinct types of theoretical methods.

*This presentation is based on results obtained from a NEDO project “Development of advanced laser processing with intelligence based on high-brightness and high-efficiency laser technologies (TACMI project).

Session K21 DCOMP: Emerging Trends in Molecular Dynamics Simulations and Data Analytics I

8:00AM K21.00001: Reactive molecular dynamics simulations and machine learning* [Invited] PRIYA VASISHHTA (Presenter), Collaboratory for Advanced Computing and Simulations, University of Southern California — Machine learning (ML) is revolutionizing scientific and engineering disciplines owing to its ability to capture hidden patterns in large amounts of data. The recent success of ML can be attributed to increasing amount of data, simulation resources, and improving understanding of statistical inference. For these reasons computational materials science is undergoing a paradigm shift. The main reason is that trial-and-error approach to materials design is inefficient: laboratory trials require a lot of time, and the results of previous trials are not utilized in a systematic fashion. A data-driven approach, which draws upon all relevant data from experiments, and reactive and quantum molecular dynamics simulations, can address these issues. The MAGICS (Materials Genome Innovation for Computational Software) Center develops to aid the synthesis of stacked layered materials by chemical vapor deposition, exfoliation, and intercalation. The identification of different phases can be formulated as a classification problem and can be solved using ML techniques. We have used feed-forward neural network with three hidden layers to identify the different phases present during computational synthesis of MoSe2. Work reported here was carried out in collaboration with Rajiv K. Kalia, Aiichiro Nakano, Lindsay Bassman, Sungwook Hong, Aravind Krishnamoorthy, Kuang Liu, Ankit Mishra, Ken-ichi Nomura, and Pankaj Rajak,

*This work was supported as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award Number DE-SC0014607.
In recent years, machine learning potentials have become a promising new approach for the representation of high-dimensional reactive potential-energy surfaces [1]. After training to a set of reference energies and forces obtained from electronic structure calculations they allow to perform large-scale simulations with first-principles accuracy at a fraction of the computational costs. As they do not contain any system-specific terms, they are applicable to a wide range of problems in chemistry, physics and materials science.

In this talk the methodology of high-dimensional neural network potentials (HDNNPs) [2,3] will be briefly reviewed, and its current scope and limitations will be discussed. The applicability of HDNNPs will be illustrated by recent studies of solid-liquid interfaces using copper [4] and zinc oxide [5,6] as prototypical examples. Since HDNNPs allow to describe the making and breaking of bonds, they enable the detailed investigation of the dissociation and recombination of water molecules as well as proton transport processes at interfaces. While water molecules do not spontaneously dissociate at ideal low-index copper surfaces, the water - zinc oxide system is very dynamic with properties strongly depending on the specific surface termination.

*JB thanks the DFG for a Heisenberg professorship (Be3264/11-2).
9:36AM K21.00005: Machine Learning Polarizable Force Field Parameters* YING LI (Presenter), Argonne National Laboratory, HUI LI, University of Chicago, FRANK PICKARD, National Institutes of Health, BADRI NARAYANAN, SUBRAMANIAN SANKARANARAYANAN, MARIA CHAN, Argonne National Laboratory, BENARD BROOKS, National Institutes of Health, BENOIT ROUX, University of Chicago — Machine learning (ML) techniques with the genetic algorithm (GA) have been applied to determine a polarizable force field parameters using quantum mechanics (QM) data of molecular clusters at the MP2/6-31G(d,p), DFMP2(fc)/cc-pVDZ, and DFMP2(fc)/cc-pVTZ levels to predict experimental condensed phase properties (i.e., density and heat of vaporization). The performance of this ML/GA approach is demonstrated on 4943 electrostatic potentials and 1250 cluster interaction energies for methanol. Excellent agreement between the training data set from QM calculations and the optimized force field model was achieved. The present effort shows the possibility of using machine learning techniques to develop descriptive polarizable force field using only QM data. The ML/GA strategy to optimize force fields parameters described here could easily be extended to other molecular systems.

9:48AM K21.00006: Hot spot formation and shock initiation of RDX* ANKIT MISHRA (Presenter), KEN-ICHI NOMURA, AIICHIRO NAKANO, RAJIV KALIA, PRIYA VASHISHTA, University of Southern California — Hot spot formation mechanism in energetic materials (EM) is crucial to handling and design of safer explosives. Presence of defects such as cracks, voids and grain boundaries are mainly responsible for creation of extreme conditions leading to hot spots. Recent experimental studies have shown that the presence of filled and empty void in EMs are responsible for creation of these regions. Here, we present a million-atom reactive molecular dynamics study to investigate the nature of hot spots during shock compression of RDX in gas filled and empty voids. We observe higher and sustained temperature rise in gas filled voids as compared to empty voids at particle velocities ranging from 2-4 km/sec. Furthermore, we observe that the higher amount of heat release on account of high potential energy drop in gas-filled voids correlate positively to more stable fragment formation, hence validating its role in high impact shock initiation of RDX.

* This work was supported by the Air Force Office of Scientific Research Grant No. FA9550-16-1-0042.

10:00AM K21.00007: Towards Exact Molecular Dynamics Simulations with Machine-Learned Force Fields STEFAN CHMIELA (Presenter), Machine Learning/Intelligent Data Analysis, Technische Universität Berlin, HUZIEL SAUCEDA, Theory Department, Fritz-Haber-Institut der Max-Planck-Gesellschaft, KLAUS-ROBERT MÜLLER, Machine Learning/Intelligent Data Analysis, Technische Universität Berlin, ALEXANDRE TKATCHENKO, Physics and Materials Science Research Unit, Université du Luxembourg — The predictive power of molecular dynamics (MD) simulations hinges on the accuracy of the underlying interatomic potential, however ubiquitous classical force fields are typically challenged by quantum effects. We demonstrate how to leverage symmetric gradient domain machine learning (sGDML) to reconstruct global molecular force fields from high-level ab initio calculations that faithfully represent the accuracy of the reference data. A key feature of our approach is its ability to exploit spatial and temporal physical symmetries in a fully data-driven way, which enables a detailed reconstruction even when the sampling is well below the Nyquist rate. By doing so, the sGDML model can be parametrized from only a few hundred reference calculations and then allows converged MD simulations that provide insights into the dynamical behavior of molecules. We demonstrate how to reconstruct force fields for small molecules at the quantum-chemical CCSD(T) level of accuracy and outline how this process can be scaled to molecular solids using a hierarchical approach where intramolecular cohesive forces within the solid are reconstructed successively.

10:12AM K21.00008: Atomic Scale Response of Electrochemical Systems Under Potential Bias JAMES GOFF (Presenter), Materials Science and Engineering, Pennsylvania State University — In the past decade, there has been considerable progress in the simulation of solid-solution interfaces. This presentation will highlight ongoing developments in the modeling of electrochemical systems at the classical molecular level using the charge-optimized many-body potentials (COMB), and at the electronic-structure level using the self-consistent continuum solvation method (SCCS). The COMB force field in the is a variable-charge potential that enables the description of solvated electrodes, under applied voltage with the eCOMB formalism, with parameterization already available for a range of transition metals. Employing eCOMB, it is possible to simulate an electrochemical cell consisting of a cathode and anode in contact with an aqueous electrolyte. SCCS is an implicit solvation method to model quantum systems embedded in continuum electrolytes. We present a critical assessment of predictions from both models in determining the size-dependent surface distribution and electrochemical stability of transition-metal nanoparticles under electrical bias.
Constructing Accurate Machine Learning Force Fields for Flexible Molecules

VALENTIN VASSILEV GALINDO (Presenter), IGOR POLTAVSKYI, ALEXANDRE TKATCHENKO, Physics and Materials Science Research Unit, University of Luxembourg — Machine learning (ML) models can reproduce potential energy surfaces (PES) for molecules containing up to a few tens of atoms with an accuracy comparable to the most exact \textit{ab initio} methods. This provides a tool for computing thermodynamic properties that would require millions of CPU years otherwise. For instance, a recently developed sGDML\textsuperscript{1} model predicts forces and energy with CCSD(T) accuracy using just a few hundreds of configurations for training. However, up to now ML has been mainly applied to rather rigid molecules. In this regard, our objective is to test ML models for flexible molecules and out-of-equilibrium configurations along transition paths. For this, we select molecules (e.g. azobenzene, stilbene) with relatively complex transition paths, which result from an interplay between long- and short-range interactions. Then, different paths connecting PES minima are tested using sGDML. This allows us to define optimal descriptors and the appropriate strategies for choosing the training sets, which is crucial for ML models relying on a limited number of training points. Our results open an avenue for calculating transport paths, transition rates and other “out-of-equilibrium” properties with previously unattained accuracy.

Machine Learning for Auto-tuning of Simulation Parameters in Car-Parrinello Molecular Dynamics\textsuperscript{*}

JAYANATH CHAMINDU KADUPITIGE (Presenter), GEOFFREY C FOX, VIKRAM JADHAO, Intelligent Systems Engineering, Indiana University Bloomington — Simulating the dynamics of ions near polarizable nanoparticles (NPs) is challenging due to the need to solve the Poisson equation at every simulation timestep. Car-Parrinello Molecular dynamics (CPMD) simulations based on a dynamical optimization framework can bypass this obstacle by representing the polarization charge density as virtual dynamic variables, and evolving them in parallel with the physical dynamics of ions. Using these CPMD simulations of ions near polarizable NPs, we demonstrate the computational gains accessible by integrating machine learning (ML) for parameter prediction in CPMD simulations. An artificial neural network based regression model was integrated with CPMD and it predicted the optimal simulation timestep and critical parameters characterizing the virtual system on-the-fly with 94.3\% accuracy. The ML-enhanced, hybrid OpenMP/MPI parallelized, CPMD simulations generated stable and accurate dynamics of thousands of ions in the presence of polarizable NPs for over 10 million steps (over 30 ns) with walltime reducing from thousands of hours to tens of hours yielding a maximum speedup of ~600.

\textsuperscript{*}This work is supported by the National Science Foundation through Award 1720625.

Parallel Trajectory Splicing and the Value of Information\textsuperscript{*}

ANDREW GARMON (Presenter), Physics, Clemson University, DANNY PEREZ, Los Alamos National Lab — A range of specialized Molecular Dynamics (MD) methods have been developed in order to overcome the challenge of reaching longer timescales in systems that evolve through sequences of rare events. In this talk, we consider Parallel Trajectory Splicing (ParSplice) which works by generating large number of trajectory segments in parallel in such a way that they can later be assembled into a single statistically correct state-to-state trajectory, enabling parallel speedups up to the number of parallel workers. In practice, the ability for ParSplice to scale significantly improves when it is possible to predict where the trajectory will be found in the future. With this insight in mind, we develop a maximum likelihood transition model that is updated on the fly and show how the value of the information gained from generating a segment can rigorously be taken into consideration in order to improve performance.

\textsuperscript{*}This work was supported by the U.S. Department of Energy Office of Science Graduate Student Research (SCGSR) program, administered by the Oak Ridge Institute for Science and Education under DE SC0014664 and by the Exascale Computing Project (17-SC-20-SC).

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K22 DCOMP DMP: Electrons, Phonons, Electron-Phonon Scattering and Phononics II BCEC 157C - Boris Kozinsky, Harvard University - Tag(s): Focus
measurements, we find that a commensurate $\sqrt{3} \times \sqrt{3} \times 1$ superlattice forms in both SnS$_2$ and SnSe$_2$ at elevated pressures.

We implement first-principles calculations based on density functional and many-body perturbation theory. I will discuss the computational methodology and results for phonon-assisted optical absorption in metals and in indirect-gap semiconductors such as silicon (Si), boron arsenide (BAs), and boron nitride (BN). I will also discuss calculations for phonon-assisted Auger recombination in wide-band-gap semiconductors, an important nonradiative mechanism that dominates carrier recombination at high free-carrier concentrations. The results shed light into the interaction of light with materials and the efficiency of light emitters. This work was performed in collaboration with Kyle Bushick, Kelsey Mengle, Guangsha Shi, Andrew McAllister, Dylan Bayerl, and Chris Van de Walle.

*This work was supported by NSF awards 1254314 (DMR/CMMT CAREER program) and 1534221 (DMREF program). Computational resources were provided by the DOE NERSC facility.

8:36AM K22.00002: Time-Resolved Second Harmonic Generation Polarimetry Study of Elemental Tellurium
HONGLIE NING (Presenter), OMAR MEHIO, Institute for Quantum Information and Matter, California Institute of Technology, ELI ZOGHLIN, Materials Department, University of California, Santa Barbara, NICHOLAS LAURITA, Institute for Quantum Information and Matter, California Institute of Technology, STEPHEN WILSON, Materials Department, University of California, Santa Barbara, DAVID HSIEH, Institute for Quantum Information and Matter, California Institute of Technology — Elemental tellurium (Te) is a chiral semiconductor that breaks inversion symmetry, which allows for strong optical second harmonic generation (SHG). We performed time-resolved SHG polarimetry measurements on Te single crystals to understand the effects of inter-band carrier excitations on its lattice structure. I will describe the contrasting temporal evolution of the structure and charge excitations as a function of both temperature and pump fluence.

8:48AM K22.00003: First-principles resonant Raman spectroscopy for 2D materials
YUE YU (Presenter), JUN JIANG, Department of Physics and the Quantum Theory Project, University of Florida, LIANGBO LIANG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, GEORGIOS D BARMARIS, Crete Center for Quantum Complexity and Nanotechnology, Department of Physics, University of Crete, SOKRATES T PANTELIDES, Department of Physics and Astronomy, Vanderbilt University, XIAOGUANG ZHANG, Department of Physics and the Quantum Theory Project, University of Florida — We implement first-principles method for resonant Raman spectroscopy of solids based on a second-order Feynman diagram and the Franck-Condon principle. The Raman Intensity is calculated using an expression in the form of the Kramers-Heisenberg-Dirac (KHD) formula. Sum over all phonon configurations is performed using the Fourier transform into the time domain and evaluated with the help of Feynman path integrals. The triple integration method offers a simple and fast numerical approach that accounts for all multiple phonon processes. The ground state and excited state phonon modes are calculated to provide frequencies and equilibrium atomic positions. The computed Raman intensities for MoS$_2$/WS$_2$ heterostructure is in agreement with experimental data. We also explore the resonance properties of the Raman spectrum, in particular its strong dependence on the energy of incident laser and on temperature.

9:00AM K22.00004: Pressure-induced destabilization and periodic lattice distortion in SnX$_2$ (X = S, Se)
GYANU PRASAD KAFLE (Presenter), Department of Physics, Applied Physics, and Astronomy, Binghamton University-SUNY, CHRISTOPH HEIL, Institute of Theoretical and Computational Physics, Graz University of Technology, HARI PAUDYAL, Department of Physics, Applied Physics, and Astronomy, Binghamton University-SUNY, JIANJUN YING, Geophysical Laboratory, Carnegie Institution of Washington, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research, VIKTOR V. STRUZHKIN, Geophysical Laboratory, Carnegie Institution of Washington, ELENA R MARGINE, Department of Physics, Applied Physics, and Astronomy, Binghamton University-SUNY — Using first-principles calculations we investigate the behavior of tin disulfide (SnS$_2$) and tin diselenide (SnSe$_2$) under compression. In agreement with single-crystal X-ray diffraction, Raman, and transport measurements, we find that a commensurate $\sqrt{3} \times \sqrt{3} \times 1$ superlattice forms in both SnS$_2$ and SnSe$_2$ at elevated pressures. We show that the pressure-induced transition to the commensurate periodic lattice distortion (PLD) phase is due to the combined effect of strong Fermi surface nesting and electron-phonon coupling at a certain wave vector $q = (1/3, 1/3, 0)$. We further compare our findings to similar PLD transitions associated with charge density wave orderings in transition metal dichalcogenides.

*G. P. K. and E. R. M. acknowledge the financial support by the National Science Foundation (Award No. OAC-1740263). C. H. acknowledges support by the Austrian Science Fund (FWF) Project No. J3806-N36 and the Vienna Science Cluster.
9:12AM K22.00005: Microscopic dynamics in the Holstein model at high-temperature: Absence of diffusion*
STUART TRUGMAN (Presenter), CHEN-YEN LAI, Los Alamos National Laboratory — A single itinerant electron in the Holstein model is known to have a large conductivity at low temperatures as the electron is scattered by dilute thermally-excited phonons. At high temperatures, some theories suggest the dynamics are described by simple Boltzmann diffusion since there are many thermally excited phonons. Here, we investigate the dynamics of an itinerant particle of the Holstein model at high temperature. Our results suggest that the microscopic dynamics is not diffusion in some parameter regimes. In one dimension, the particle travels in a constant direction over time, which suggests an infinite conductivity. In higher dimensions, the particle follows a closed trajectory, a type of localization, and the trajectories are fractal.

*We acknowledge support from the US DOE through the Center for Integrated Nanotechnologies.

VÉRONIQUE BROUSSEAU-COUTURE (Presenter), Université de Montréal and RQMP, Montréal, Québec, Canada, ANNA MIGLIO, MATTEO GIANTOMASSI, Université Catholique de Louvain, IMCN/NAPS, Louvain-la-Neuve, Belgium, GABRIEL ANTONIUS, Department of Physics, University of California at Berkeley, California 94720, USA, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, California 9, YANG-HAO CHAN, Department of Physics, University of California at Berkeley, California 94720, USA and Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, California, MICHEL COTE, Université de Montréal and RQMP, Montréal, Québec, Canada, XAVIER GONZE, Université Catholique de Louvain, IMCN/NAPS, Louvain-la-Neuve, Belgium — Computing the zero-point renormalization (ZPR) of the electronic bandgap due to electron-phonon coupling from first principles (FP) is a computationally challenging task, especially for polar materials, for which a very fine phonon wavevector sampling is required [1]. By contrast, the well-known Fröhlich Hamiltonian gives in the perturbative regime a simple analytical formula for the polaron binding energy, based on a few parameters that can be obtained from experiments or from FP calculations.

We compute the ZPR from FP for more than 20 polar binary semiconductors and insulators, and compare these results to those from a generalized Fröhlich model, in which the needed parameters are computed from FP. Despite the lack of Debye-Waller (DW) and interband contributions, we find that the simple Fröhlich approach agrees with FP results within a factor of two for most materials. We analyze the cancellation between the DW and Fan contributions from acoustic modes, and discuss the size of interband contributions in terms of Eliashberg functions. We finally develop a method to estimate the converged ZPR from coarser phonon samplings.

9:36AM K22.00007: First-principles study of self-trapped polarons*
WENG HONG SIO (Presenter), Department of Chemistry, University of Oxford, CARLA VERDI, SAMUEL PONCE, FELICIANO GIUSTINO, Department of Materials, University of Oxford — The polaron is a quasiparticles consisting of an electron or hole dressed by a cloud of phonons. Self-trapped polarons are found when the electron-phonon interaction is so strong that the electron is bound by the potential of the lattice distortion that it induces. Here we investigate the mechanisms of polaron formation in wide-gap insulators, using Li2O2 as a prototypical example. We study self-trapping both via direct density-functional theory (DFT) calculations and using a perturbation theory approach. We analyze the binding energy in terms of the underlying band structure and phonon dispersions, and we compare our findings with previous calculations and with classic models of self-trapped polarons. We discuss open questions in the ab initio study of polarons and possible solutions.

9:48AM K22.00008: Phonon Behaviors of Charged Nanocrystals: Effects of Free Charge Carriers*  SHUN WANG (Presenter), BUTIAN ZHANG, School of Physics, Huazhong University of Science and Technology — The precise knowledge of phonons is important to understand the electronic and photonic properties of nanocrystals (NCs) and NC-based devices. It is common to introduce free charge carriers into NCs for device applications, highlighting the significance of studying the free carrier effects on phonon behaviors. In this study, we introduced the free carriers into a series of NCs (ZnO, CdSe, PbSe) and investigated the carrier-dependent phonon behaviors by using Raman spectroscopy. For charged NCs, the change of phonon frequencies and the overtone to fundamental intensity ratios were explained by the screening and band-filling effects caused by the accumulated free carriers. By using a time-dependent model, the overtone to fundamental intensity ratios were further correlated with the electron-phonon coupling strength of the involved excited states. The effects of free carriers on phonon behaviors, usually neglected in previous studies, should be carefully considered when analyzing the properties of charged NCs. Moreover, the relationship between the free carrier densities and Raman frequencies/relative intensities are potentially useful for nondestructive characterization of free carriers in NCs.

10:00AM K22.00009: Experimental demonstration of generalized Fourier’s Law for heat conduction at the nanoscale  CHENGYUN HUA (Presenter), LUCAS LINDSEY, Oak Ridge National Laboratory, AUSTIN MINNICH, California Institute of Technology — Heat conduction under large temperature gradients that occur over scales of mean free paths of the energy carriers in solids is a topic of intense interest. Although the failure of Fourier’s law is well understood, the appropriate replacement has been the topic of debate. A concise relation that links temperature gradient to heat flux based on a rigorous mathematical interpretation is not only necessary but crucial to advance our knowledge of nanoscale heat transport. Here, we derived a generalized Fourier’s law based on Peierls-Boltzmann transport equation. This generalized Fourier’s law contains two parts, nonlocality of thermal conductivity, which has been previously hypothesized, and nonlocality of external effects, i.e. volumetric heat generation, which has long been ignored in literatures. We demonstrated the validity of this generalized Fourier’s law through comparisons with a series of time-domain thermoreflectance (TDTR) measurements. Furthermore, we showed that misinterpreting the generalized Fourier’s law in the experimental observation of nanoscale heat conduction would lead to erroneous microscopic information of phonons. To map the macroscopic observations to intrinsic phonon properties, it is crucial to appropriately take account into the microscopic heat input.

10:12AM K22.00010: Computing Raman Spectra With Wavelets Using The BigDFT Code*  MAXIME MORINIÈRE (Presenter), MICHEL COTE, Université de Montréal and RQMP, THIERRY DEUTSCH, LUIGI GENOVESE, CEA Grenoble — We report the calculations of Raman spectra using the BigDFT code.

The normal modes of vibration (or phonons) and their associated energies were found by slightly displacing each atom of the system around their ground position (this was already part of the BigDFT suite). We then added the possibility of computing the Raman intensity of each normal mode via electronic polarizability tensor calculations (in practice, this only amounts to applying small electric fields to the system of interest). The Raman spectra thus obtained are compared to the literature. A further check of the quality of the normal modes thus found is done by computing vibrational polarizability tensors.

The main perspective of this work is to use the order N version of the BigDFT code (instead of the usual cubic scaling version used in this work) to perform similar computations on larger systems.

*This project is supported by CEA (France) and Canada NSERC grants RGPIN2016-06666. The computational aspect of this research was enabled in part by support provided by Calcul Québec (www.calculquebec.ca) and Compute Canada (www.computecanada.ca)
GIORGIA FUGALLO (Presenter), BENOIT ROUSSEAU, Heat Transfer and Energy Laboratory of Nantes, CNRS, MICHELE LAZZERI, IMPMC-Sorbonne Université, CRNS — Density functional theory (DFT) is considered a predictive approach to determine anharmonic phonon-phonon interactions in crystals. Such a computational tool is a necessary ingredient, for example, of the first principles computational methods recently developed to determine phonon thermal transport in real systems. In this context, finding measurable quantities that can provide an independent benchmark for theoretical approaches is of paramount importance. Surprisingly, DFT has been rarely used to interpret the anharmonic features observable in infrared (IR) reflectance, transmittance and emittance spectra even though they provide a relatively direct probe to anharmonic properties in heteropolar materials and can be used to directly determine the anharmonic phonon self-energy of the optically active mode. I will show the influence of anharmonic effects on IR spectra of MgO, which is chosen as a test material because of the availability of different kinds of radiative properties measured experimentally and I will explain the limit of validity of a perturbative (multi-phonon) approach.

JIN-JIAN ZHOU (Presenter), MARCO BERNARDI, Caltech — Strong electron-phonon (e-ph) interactions lead to the formation of polarons, quasiparticles consisting of an electron carrying a phonon cloud. Polaron formation lowers the mobility and greatly affects charge transport in transition metal oxides and other polar compounds. Here, we develop a many-body ab initio approach to compute charge transport including polaron effects. We apply our approach to the two perovskite oxides BaSnO₃ and SrTiO₃, and analyze in detail how and why polaron formation affects charge transport in these materials. The calculations are connected with our recent work on SrTiO₃, where, using the Boltzmann Transport equation with lowest-order e-ph scattering, we accurately predicted the temperature dependence of the mobility in SrTiO₃ [1], whose absolute value was however higher than experiment. We show how including polaron effects can correct the lowest-order result, improving agreement with experiment.

SUDEEP ADHIKARI (Presenter), KEVIN BEACH, University of Mississippi — We present a theoretical framework for determining the mass deposited on a mechanical resonator subject to a flux of incoming particles of a single species. We consider the specific example of a vibrating nanostring and infer the history of mass deposition events from the frequency shifts in real time using a numerical optimization algorithm that correctly compensates for the configurational entropy. Our approach is tested against simulated data and is shown to perform well. We comment on its applicability to common inverse problems in physics, such as the extraction of spectral functions from imaginary-time Green's functions, that also suffer from configurational entropy effects.

8:36AM K23.00002: Quantifying Tip-Sample Interactions in Vacuum Using Cantilever-based Sensors: An Analysis
OMUR DAGDEVIREN, CHAO ZHOU, ERIC ALTMAN, UDO DIETMAR SCHWARZ (Presenter), Yale University — We theoretically and experimentally show that the force law obtained from data acquired under vacuum conditions with dynamic force microscopy may deviate more than previously assumed from the actual interaction when the oscillation amplitude of the probe is of the order of the decay length of the force near the surface, which may result in a non-negligible error if correct absolute values are of importance [1]. However, the related inaccuracies can be effectively suppressed by using oscillation amplitudes sufficiently larger than the decay length of the tip-sample interaction. We also propose a novel technique that includes modulating the drive amplitude at a constant height from the surface while monitoring the oscillation amplitude and phase. Ultimately, such amplitude sweep-based force spectroscopy enables shorter data acquisition times and increased accuracy for quantitative chemical characterization compared to standard approaches that vary the tip-sample distance [1, 2]. In addition, since no feedback loop is active while executing the amplitude sweep, the force can be consistently recovered deep into the repulsive regime.

8:48AM K23.00003: Single ion hydrates under the SPM tip* JINBO PENG (Presenter), DUANYUN CAO, ZHILI HE, JING GUO, Peking University, PROKOP HAPALA, Czech Academy of Sciences, RUNZE MA, BOWEI CHENG, Peking University, JI CHEN, University College London, WEN JUN XIE, XIN-ZHENG LI, Peking University, PAVEL JELINEK, Czech Academy of Sciences, LIMEI XU, YI QIN GAO, EN-GE WANG, YING JIANG, Peking University — Ion hydration and transport at interfaces are relevant to a wide range of applied fields and natural processes. To correlate atomic structure with the transport properties of hydrated ions, both the interfacial inhomogeneity and the complex competing interactions among ions, water and surfaces require detailed molecular-level characterization. Here we constructed individual sodium ion (Na+) hydrates on a NaCl(001) surface by progressively attaching single water molecules to the Na+ using a combined scanning tunnelling microscopy(STM) and atomic force microscopy(AFM) system. We found that the Na+ hydrated with three water molecules diffuses orders of magnitude more quickly than other ion hydrates. Ab initio calculations revealed that such high ion mobility arises from the existence of a metastable state, in which the three water molecules around the Na+ can rotate collectively with a rather small energy barrier. Our work suggests that anomalously high diffusion rates for specific hydration numbers of ions are generally determined by the degree of symmetry match between the hydrates and the surface lattice.

*We thank the supports of the National Key R&D Program under Grant No. 2016YFA0300901,etc.

9:00AM K23.00004: Visualizing mineral-solution interfaces using 3D atomic force microscopy* ELIAS NAKOUZI (Presenter), BENJAMIN A. LEGG, SHUAI ZHANG, GREGORY K SCHENTER, JAEHUN CHUN, CHRISTOPHER J MUNDY, MARCEL D. BAER, SEBASTIEN KERISIT, JAMES J DE YOREO, Physical Sciences Division, Pacific Northwest National Laboratory — Understanding processes at solid-liquid interfaces is a key challenge for multiple research fields ranging from surface chemistry and catalysis to bio-membranes and living cells. Recent advances in atomic force microscopy—specifically 3D fast force mapping in amplitude modulated mode—have allowed the direct observation of interfacial solution structure with sub-nanometer resolution. We use this capability to probe multiple mineral-solution systems, including layered silicates (phlogopite and muscovite mica) and aluminum (oxy)hydroxides (boehmite and gibbsite) exposed to salt solutions of different pH and ionic strength. Depending on the system, our data show 3-5 structured layers spaced 0.2–0.5 nm apart and extending ~1.5 nm from the surface, with lateral features templated by the underlying crystal lattice. We compare the results to molecular dynamics simulations and discuss the promises and limitations of this exciting technique.

*A portion of this research was conducted under the Laboratory Directed Research and Development Program at Pacific Northwest National Laboratory, a multiprogram national laboratory operated by Battelle for the U.S. Department of Energy. Elias Nakouzi is grateful for the support of the Linus Pauling Distinguished Postdoctoral Fellowship program.
Fast multifrequency measurement of nonlinear conductance*  

RICCARDO BORGANI (Presenter), DAVID HAVILAND, Nanostructure Physics, KTH Royal Institute of Technology — We demonstrate fast acquisition of nonlinear current-voltage characteristics (IVC) at every pixel of a high-resolution conductive AFM image [1]. The technique exploits phase-coherent multifrequency lock-in measurement to acquire IVCs on a 512x512 grid in under 9 minutes (trace and retrace), and the inverse Fourier transform to perform the analysis in real time. Our approach overcomes the high resistance of the nanometer-scale tip-surface junction and the stray capacitance of the measurement leads which impose speed limitations (tens of seconds) on the traditional methods of measuring IVCs, making maps of variation over a surface impractical. The measurement technique allows for easy cancellation of parasitic displacement current due to the measurement leads and for separation of the galvanic and displacement currents in the junction. This ultrafast (milliseconds) acquisition of IVCs enables the AFM to reveal nanometer-scale variations in the electrical transport properties of organic photovoltaic and semiconducting thin films.

Sub resonance AFM imaging coupled with machine-learning to identify cancer*  

IGOR SOKOLOV (Presenter), MAXIM E DOKUKIN, VEVEKANAND KALAPARTHI, MILOS MILJKOVIC, Tufts University, ANDREW WANG, Phillips Academy, JOHN SEIGNE, Dartmouth-Hitchcock Medical Center, PETROS GRIVAS, University of Washington, EUGENE DEMIDENKO, Geisel School of Medicine — We report on a new approach in diagnostic imaging based on nanoscale-resolution scanning of surfaces of cells collected from body fluids using, sub-resonance AFM tapping, Ringing mode, and machine learning analysis. The surface parameters, which are typically used in engineering to describe surfaces, are used to classify cells. The method is applied to the detection of bladder cancer, which is one of the most common human malignancies and the most expensive cancer to treat. The method, which utilizes cells collected from urine, shows 94% diagnostic accuracy when examining five cells per patient's urine sample. It is a statistically significant improvement (p<0.05) in diagnostic accuracy compared to the currently used clinical standard, cystoscopy, as verified on 43 control and 25 bladder cancer patients. Furthermore, the described approach can be extended to detect cell abnormalities beyond cancer as well as to monitor cell reaction to various drugs (nanopharmacology). Thus, this approach may suggest a whole new direction of diagnostic imaging.

Visualizing the Electrostatic Barrier of a Material Interface to Nanoscale Dimensions: Defects, Silicides, and Dielectrics  

WESTLY NOLTING, JACK ROGERS, STEVEN GASSNER, HYEOSEON CHOI, VINCENT LABELLA (Presenter), Colleges of Nanoscale Science and Engineering, SUNY Polytechnic Institute — Electrostatic barriers at material interfaces are the foundation of current and futuristic electronic and optoelectronic devices. Direct visualizing of the electrostatic barrier of an interface with nanoscale resolution can be accomplished utilizing ballistic electron emission microscopy (BEEM), an STM-based technique [1]. Tens of thousands of BEEM spectra are acquired on a regularly spaced grid and then fit to extract the Schottky barrier height. Physical and chemical insight is provided by computational modeling, which simulates the distributions of barrier heights and includes effects from the interface and transport of the hot electrons in the metal. This presentation will give an overview of the technique and its ultimate spatial and energetic resolution. Measurements of defects, incomplete silicide formation, the presence of multiple metal species at the interface, monolayer thick dielectric layers, and the influence of ionized impurity scattering in the semiconductor will also be presented.

Mapped AFM force spectroscopy on gels: methodological and interpretive developments

GREG HAUGSTAD, Characterization Facility, University of Minnesota, GUICHUAN YU, Informatics Institute, University of Minnesota, YING CHEN, GUFA LIN, Stem Cell Institute, University of Minnesota, ALON MCCORMICK, Chemical Engineering and Materials Science, University of Minnesota, MAGGIE ZENG (Presenter), Boston Scientific Corporation — We present aqueous-immersion force-distance analysis on fibrin gels and polyvinyl pyrrolidone (PVP) gel-phase coatings. Initial applications were mechanical matching (fibrin to tissue) and lubricity/durability assessment (PVP). In both cases we discovered (a) a need for extensive mapping (tens or hundreds of microns) to survey spatial heterogeneities in both mechanics and topography as well as their correlations; and (b) widely ranging modulus values both among gel samples (~0.1-100 kPa) and across individual gels (one order of magnitude). On the softest PVP gel coatings colloid microprobes were used instead of sharp AFM tips to allow a shear contact (friction characterization).

In developing data analytics, we find that vendor algorithms for modulus mapping require modification (here in matlab) in order to: (1) demarcate solid body mechanics (Hertzian) from steric forces within each force curve as a function of distance, and/or treat Poissons ratio as variable with gel compression; (2) account for local surface curvature and thereby system radius of curvature (for colloid probe); (3) invoke criteria for rejecting anomalous force-distance measurements (e.g., sites of fibril adhesion) prior to compiling distribution functions of spatially surveyed modulus measurements.

Conductance spectroscopy of confined water in Montmorillonite clay nanoparticles

KELSEY YEE (Presenter), AYDIN WELLS, N. E. ISRAELOFF, Northeastern University — Montmorillonite (MNT) clay confines water and ions to few-monolayer sheets. We use an SPM-based nano-dielectric-spectroscopy (NDS) technique to study frequency-dependent (10Hz-10 kHz) electrical properties of individual MNT nanoparticles (NP) with variable water content. We study ionic conductivity in this 2D nano-confined geometry, and compare with bulk material with inter-particle contributions. We focus on the high-frequency (HF) power-law regime of the conductivity peak in the electric modulus, M(f) ~ f^1-α, related to a hopping-conductivity, σ = σdc + σacf^α. We apply a sinusoidal voltage to the conducting tip during non-contact portion of a double pass scan, using high-harmonic for feedback, and the fundamental mode to measure the phase and amplitude of the force-derivative (FD). For a range of relative humidity (RH), the FD phase, ϕ(f) exhibits a peak, similar to the peak in bulk M(f), but shifted to lower frequencies. We use finite-element-modelling to extract NP conductivity spectra from data (poster by A. Wells). Simulated ϕ(f) for anisotropically conducting NP have HF power-laws matching M(f). In bulk, for various RH we find exponents, α = 0.3 ±0.05. NP exhibited exponents of α = 0.6 ±0.1. This suggests a different conductivity mechanism in bulk and NP.

How Much Information is in an STM Image?

MITCHELL YOTHERS, SOUMYA BHATTACHARYA, LLOYD BUMM (Presenter), Homer L. Dodge Department of Physics & Astronomy, University of Oklahoma — Scanning tunneling microscope (STM) images contain a wealth of information. We are developing real-space post-processing image analysis tools to extract information that would otherwise be hidden. We use decanethiol self-assembled monolayers (SAMs) on Au(111) as our model system. We demonstrate measurements of the “molecule” locations that are in principle accurate to less than 1 pm in any direction. By creating an averaged unit cell image from many imaged unit cells, we also demonstrate that the unit cell image has no additional symmetry beyond its lattice symmetry. Average unit cell images from different structural domains of the same image demonstrate which image features are due to the surface and which are due to the tip. Time-lapse image series of SAMs allow for time averaging techniques to be used to track and study individual molecules.

*Financial support from the National Science Foundation (CHE-1710102), the Homer L. Dodge Department of Physics, and the OU College of Arts and Sciences, and NVIDIA Corporation (donation of a Tesla K-40 GPU) is gratefully acknowledged.
10:24AM K23.00011: Revealing tip-surface interaction with dynamic force curves
DANIEL FORCHHEIMER (Presenter), RICCARDO BORGANI, DAVID HAVILAND, Royal Institute of Technology — The force between the AFM tip and the surface is conventionally studied using quasi-static deflection-approach curves. These must be converted into force-position curves by a transformation of coordinates, to be compared with models of the interaction, such as the Derjaguin-Muller-Toporov (DMT) model. For the transformation to be valid the motion has to be slow, as to not excite the resonance of the cantilever.

We instead excite the cantilever a two frequencies near its resonance, creating a beat that effectively approaches and retracts from the surface in what is called Intermodulation AFM. By measuring amplitude and phase during this beat, and using a transformation similar to that done for quasi-static curves (but now taking the full dynamics of the cantilever into account) we obtain two dynamic force curves. One conservative, Fi and one disipative, Fq.

Comparing theoretical Fi and Fq curves for standard models, such as the DMT, to experimental result reveal severe limitations of these models. They are typically not sufficient to explain the observed interaction between the tip and the surface. We show how a proposed new tip-surface model, which allow a dynamic surface, can overcome some of these limitations.

10:36AM K23.00012: Scanning Tunneling Microscopy and Spectroscopy of Novel Silver-Containing DNA Molecules
NATALIE FARDIAN-MELAMED (Presenter), Physical Chemistry Department and Center for Nanoscience and Nanotechnology, Hebrew University of Jerusalem, GENNADY EIDELSHTEIN, Biochemistry Department and Center for Nanoscience and Nanotechnology, Tel Aviv University, DVIR ROTEM, Physical Chemistry Department and Center for Nanoscience and Nanotechnology, Hebrew University of Jerusalem, ALEXANDER KOTLYAR, Biochemistry Department and Center for Nanoscience and Nanotechnology, Tel Aviv University, DANNY PORATH, Physical Chemistry Department and Center for Nanoscience and Nanotechnology, Hebrew University of Jerusalem — The quest for a suitable molecule to pave the way to molecular nano-electronics¹ has been met with obstacles for over a decade², ³. Candidate molecules such as carbon nanotubes lack the appealing trait of self-assembly, while DNA seems to lack the desirable feature of conductivity⁴. Silver-containing poly(dG)-poly(dC) DNA (E-DNA) molecules were recently reported as promising candidates for molecular electronics⁵, owing to the selectivity of their metallization, their uniform structure, their resistance to deformation, and their most possible conductivity⁵, ⁶. Here we present an elaborate temperature dependent high-resolution morphology characterization of these unique molecules, alongside a detailed depiction of their electronic level structure. Our findings⁷ were acquired by use of an ultra-high vacuum (UHV) scanning tunneling microscope (STM). The temperature dependence of E-DNA's topographic features and density of states spurs intriguing insights. Moreover, the energy levels found for E-DNA indicate a novel, truly hybrid metal-molecule structure, potentially more conductive than its DNA-based peers.

Session K24 DAMOP DQI: Hybrid/Macroscopic Quantum Systems, Optomechanics, and Interfacing AMO with Solid State/Nano Systems II

8:00AM K24.00001: Entanglement of Two Remote Mechanical Resonators* RALF RIEDINGER (Presenter), Harvard University, ANDREAS WALLUCKS, IGOR MARINKOVIĆ, TU Delft, SUNGKUN HONG, MARKUS ASPELMEYER, Universität Wien, SIMON GROEBLACHER, TU Delft — Entanglement is a key feature of quantum mechanics and plays an important role in many quantum information processing protocols. Here we report on the entanglement of two massive mechanical oscillators located on separate chips. Intriguingly, the silicon photonics devices employed in this experiment can serve as long-lived quantum memories and are directly interfaced to photons in the telecom wavelength range around 1550nm. We further report on the observation of entanglement between a flying telecom photon and a pair of such quantum memories.

Optical Backaction-Evading Measurement of a Mechanical Oscillator

ITAY SHOMRONI
(Presenter), LIU QIU, Ecole polytechnique federale de Lausanne, DANIEL MALZ, ANDREAS NUNNENKAMP, University of Cambridge, TOBIAS KIPPERBERG, Ecole polytechnique federale de Lausanne — Quantum mechanics imposes a limit on the precision of a continuous position measurement of a harmonic oscillator, as a result of quantum backaction arising from quantum fluctuations in the measurement field. A variety of techniques to surpass this standard quantum limit have been proposed, such as variational measurements, stroboscopic quantum non-demolition and two-tone backaction-evading (BAE) measurements. The latter proceed by monitoring only one of the two non-commuting quadratures of the motion. This technique, originally proposed in the context of gravitational wave detection, has not been implemented using optical interferometers to date. Here we demonstrate continuous two-tone BAE measurement in the optical domain of a localized GHz frequency mechanical mode of a photonic crystal nanobeam cryogenically and optomechanically cooled close to the ground state, employing quantum-limited detection. We observe up to 0.67dB (14%) reduction of total measurement noise, thereby demonstrating the viability of BAE measurements for optical ultrasensitive measurements of motion and force in nanomechanical resonators.

This work was supported by funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No. 709147 (GeNoSOS).

Cavity cooling of levitated nanospheres by coherent scattering

UROS DELIC (Presenter), MANUEL REISENBAUER, Faculty of Physics, University of Vienna, DAVID GRASS, Duke University, NIKOLAI KIESEL, MARKUS ASPELMEYER, Faculty of Physics, University of Vienna — Although cavity cooling of levitated nanospheres has been demonstrated in recent years, regime of strong optomechanical cooperativity C>1 is yet to be reached, leading to full quantum control of nanosphere motion. A common obstacle in many experiments is stable levitation of nanospheres in ultra-high vacuum (UHV). However, stable trapping has been achieved in an optical dipole trap in several experiments through the use of three-dimensional parametric feedback. We exploit this by combining such a trap with an optical cavity and demonstrate cavity optomechanics with a silica nanosphere in UHV. We confirm the trapping of nanospheres of nominal radius through a novel method using the variable coupling to a cavity mode. We achieve C=0.02, showing a five orders of magnitude improvement of cooperativity from our previous work. We then modify this setup to drive the cavity mode solely by scattered photons from tweezer laser. In addition, cavity enhanced scattered photons provide a more effective, three-dimensional cooling of the nanosphere motion, immediately allowing us to reach strong cooperativity in high vacuum.

A coherent nanomechanical oscillator driven by single-electron tunneling

YUTIAN WEN (Presenter), NATALIA ARES, FELIX SCHUPP, T. PEI, GEORGE ANDREW DAVIDSON BRIGGS, Department of Materials, University of Oxford, EDWARD LAIRD, Department of Physics, Lancaster University — We study the strong electromechanical coupling between a vibrating carbon nanotube and a single-electron transistor (SET) defined along its length. The current through the SET is both a sensitive transducer for the motion, and a source of strong feedback that leads to mechanical oscillations. Using a novel time-resolved measurement technique, we characterize the coherence of these oscillations, finding an auto-correlation time as long as 100 microseconds. This system resembles an electromechanical maser, with the pumping provided by the electrical bias and the phonon cavity provided by the mechanical resonance. While the linewidth of the free-running oscillator is limited by slow frequency fluctuations, we show two ways to stabilise it: by locking its frequency to an injection tone, and by adjusting the mechanical tension in a phase-locked loop. With feedback applied, the mechanical linewidth can be stabilised to within 2 Hz at a 230 MHz oscillation frequency.

8:48AM K24.00005: Coupled Piezoelectric and Optomechanical Resonators for RF-to-optical Frequency Conversion* MARCELO WU (Presenter), BISWARUP GUHA, Chemistry, University of Maryland, NIST, KRISHNA COIMBATORE BALRAM, Electric and Electronic Engineering, Bristol University, KARTIK A SRINIVASAN, Physical Measurement Laboratory, National Institute of Standards and Technology — The development of quantum computing technologies currently faces interconnectivity barriers. A leading platform for quantum processors uses superconducting microwave or radio-frequency (RF) circuits encased inside dilution refrigerators at millikelvin temperatures. Long-range communication is thus a major challenge due to loss of signal outside cryogenic environment. Recently, RF-to-optical photon converters have attracted significant interest for their use in linking RF signals to an optical signal that can propagate in high-speed low-loss optical fiber networks. We propose an on-chip nanoscale converter that connects RF signals to mechanical degrees of freedom using a piezoelectric resonator and then bridges to the optical domain using an optomechanical resonator. This effective electro-mechano-optical modulator is built on a GaAs material platform which exhibits strong photoelastic effect for optomechanical coupling. We demonstrate new device designs that compensate for the inherently low piezoelectric effect in GaAs and progress in the fabrication of an integrated piezo-optomechanical device.

9:00AM K24.00006: Laser heating of a charged gold nanosphere levitated in an ion trap at high vacuum* JOYCE COPPOCK (Presenter), SAMUEL KLUETER, JOSÉ HANNAN, Physics, University of Maryland, College Park, BRUCE E KANE, Laboratory for Physical Sciences — Levitation of a nanoparticle in high vacuum decouples the particle from its environment and enables sensitive thermodynamic measurements; specifically, a levitated particle can be heated in a controlled manner via illumination with a laser. We confine an electrically charged gold nanosphere in a quadrupole electric field trap at pressures as low as 1x10^-8 Torr and illuminate it with a linearly polarized 532 nm laser. Accurate measurements of the particle's charge-to-mass ratio, combined with observations of single discharge events, give a precise determination of its mass. We observe that the particle begins to evaporate at sufficiently high laser powers; from the evaporation rate, we can deduce its internal temperature. In this talk, we present evidence of the heating of 250 nm gold spheres to temperatures in the range of 1000-1250 K, near the melting temperature of 1337 K. Further heating of the particle should enable trapping and observation of a molten droplet.

*This work was supported by the Laboratory for Physical Sciences.

9:12AM K24.00007: Engineering dissipation dilution of strained nanomechanical resonators* SERGEY FEDOROV (Presenter), NILS JOHAN ENGELSEN, MOHAMMADJAFAR BEREYHI, ALBERTO BECCARI, AMIR HOSSEIN GHADIMI, RYAN SCHILLING, DALZIEL WILSON, TOBIAS KIPPPENBERG, Ecole polytechnique federale de Lausanne — Dissipation dilution by tensile strain enables micro- and nano- mechanical resonators that have quality factors (Q) exceeding those of bulk vibrations in the same material by orders of magnitude. For a long time, uniform beam- and membrane- shape resonators made of high-stress stoichiometric silicon nitride have been the system of choice to attain high Q and low effective mass—key parameters in force sensing and cavity optomechanics. Recently it was discovered that dissipation dilution (and hence Q) can be increased substantially in non-uniform resonators through techniques such as “soft clamping”, engineering local strain and “tapered clamping”. We show that soft clamping combined with strain engineering can be applied to nanobeams to produce record-high quality factors up to 800 million at room temperature and Q × frequency exceeding 10^15 Hz. The complementary tapered clamping approach results in enhanced Q for the fundamental flexural mode, unachievable with soft clamping. Time permitting, we will also present results on dissipation dilution engineering of membranes and cavity optomechanics with engineered resonators.

*This work was supported by the EU Horizon 2020 Research and Innovation Program under grant agreement no.732894 (FET Proactive HOT) and DARPA grant HR0011181003.
Directional transmission or amplification of microwave signals is indispensable in various applications involving sensitive measurements. Using a device including two on-chip superconducting resonators and two metallic drumhead mechanical oscillators, we experimentally demonstrate how to use this generic cavity optomechanical system to non-reciprocally amplify microwave signals. Pumping this device at four distinct microwave frequencies allows to design applications including sensitive metrology, ground state cooling of mechanical motion, and slowing of light.

**This work is supported by DARPA/MTO's PRISM: AIMS program through a grant from SPAWAR (N66001-16-1-4026) and Air Force Office of Scientific Research (AFOSR) MURI grant (FA9550-15-1-0029).**

**9:36AM K24.00009: Radio-frequency optomechanical characterization of a silicon nitride drum**

**ANNA PEARSON (Presenter), Department of Materials, University of Oxford, KIRAN KHOSLA, Blackett Laboratory, Imperial College London, MATTHIAS MERGENTHALER, GEORGE ANDREW DAVIDSON BRIGGS, Department of Materials, University of Oxford, EDWARD LAIRD, Department of Physics, Lancaster University, NATALIA ARENS, Department of Materials, University of Oxford — On-chip actuation and readout of mechanical motion is key for characterizing mechanical resonators and exploiting them for new applications. We capacitively couple a silicon nitride membrane to an off-resonant radio-frequency cavity formed by a lumped element circuit. Despite a low cavity quality factor of about 7.4 and off-resonant, room temperature operation, we are able to parametrize several mechanical modes and estimate their optomechanical coupling strengths. This enables fast characterization of a device without requiring a superconducting cavity, thereby eliminating the need for cryogenic cooling. We also observe optomechanically induced transparency and absorption which is crucial for a number of applications including sensitive metrology, ground state cooling of mechanical motion, and slowing of light.

**9:48AM K24.00010: Realization of directional amplification in a microwave optomechanical device**

**LAURE MERCIER DE LÉPINAY (Presenter), ERNO DAMSKÄGG, CASPAR OCKELOEN-KORPPI, MIKA SILLANPÄÄ, Applied Physics, Aalto University — Directional transmission or amplification of microwave signals is indispensable in various applications involving sensitive measurements. Using a device including two on-chip superconducting resonators and two metallic drumhead mechanical oscillators, we experimentally demonstrate how to use this generic cavity optomechanical system to non-reciprocally amplify microwave signals. Pumping this device at four distinct microwave frequencies allows to design two transmission paths for excitations from one microwave port of the device to another, that can be made to interfere constructively or destructively depending on the signal's propagation direction. As a result, we demonstrate amplification in one direction by 9 decibels and a simultaneous isolation in the opposite direction by 21 decibels.**

**This work was supported by the Academy of Finland (contracts 250280, 308290, 307757, 312296), by the European Research Council (615755-CAVITYQPD), and by the Aalto Centre for Quantum Engineering. 10:12AM K24.00012: Coupling of single photon emitters in hBN to microcavities*  
NICHOLAS PROSCIA (Presenter), HARISHANKAR JAYAKUMAR, ZAV SHOTAN, GABRIEL LOPEZ-MORALES, Physics, City College of New York, XIAOCHEN GE, WEIDONG ZHOU, University of Texas, Arlington, CARLOS A. MERILES, VINOD M MENON, Physics, City College of New York —Hexagonal Boron Nitride (hBN) was recently found to be a source of single photon emitters (SPE) which exhibit desirable properties such as narrow room-temperature linewidths, spectral tunability and operation under ambient conditions. Despite these advantageous properties, scalable integration of these emitters into chip-based cavities has proven elusive. Here, we demonstrate coupling of hBN defect emission to Si3N4 microdisk cavities by exploiting the topography of the cavity structure to engineer strain and thereby activate SPEs which near field couple to the cavities. We find the cavity coupled emission to have a Purcell enhancement of 1.3, close to the cavity's theoretical Purcell factor of 1.6. The present work is a first step towards cavity enhanced SPEs in this material system and paves the way for deterministic cavity coupling of SPEs that operate at room temperature.

*This work is supported by the NSF CREST IDEALS center, NSF MRSEC program (DMR-1420634) and the NSF EFRI 2-DARE program (EFMA -1542863) and was partially carried out at the CUNY ASRC NanoFabrication Facility.

10:24AM K24.00013: Valley-Mechanical Coupling in a Monolayer Semiconductor  
HAOKUN LI (Presenter), KING YAN FONG, HANYU ZHU, QUANWEI LI, SIQI WANG, SUOI WANG, XIANG ZHANG, University of California, Berkeley — The interaction of macroscopic mechanical object with electron charge and spin plays a vital role in today's information technology and fundamental studies of the quantum-classical boundary. Recently emerged valleytronics encodes information to the valley degree-of-freedom and promises exciting applications in communication and computation. We realize valley-mechanical coupling in a monolayer MoS2 resonator and demonstrate transduction of valley information to the mechanical states. The valley and mechanical degrees-of-freedom are coupled through the magnetic moment of the valley carriers under a magnetic field gradient. We identify the valley-actuated mechanical motion by optical interferometry and attain a transduction confidence level near unity. Our experiment lays the foundation for a new class of valley-controlled mechanical devices and facilitates realization of hybrid quantum valley-mechanical systems

10:36AM K24.00014: Interference effects in cavity optomechanics with hybridized membranes  
ONDREJ CERNOTIK (Presenter), CLAUDIU GENES, Max Planck Institute for the Science of Light, AURELIEN DANTAN, Department of Physics and Astronomy, University of Aarhus — Radiation pressure forces in cavity optomechanics allow for efficient cooling of motion, the manipulation of photonic and phononic quantum states, as well as generation of optomechanical entanglement. The standard mechanism relies on the cavity photons directly modifying the mechanical state. Hybrid cavity optomechanics provides an alternative approach by coupling mechanical objects to quantum emitters, either directly or indirectly via the common interaction with a cavity field mode. In these systems, the interference between forces from the cavity field and the emitters can give rise to novel optomechanical phenomena. We analyze two such hybrid optomechanical systems where a vibrating membrane is doped by quantum emitters or patterned with a photonic crystal structure. In particular, we demonstrate that, in the former system, a three-body interaction between the cavity field, emitters, and mechanical motion can be used to improve cooling of the mechanical motion [1]. Second, we show that, when an esnemble of emitters or a photonic crystal structure in the membrane strongly modifies the membrane reflectivity, the cavity linewidth can be significantly reduced and the system can reach the sideband resolved regime.

10:48AM K24.00015: Trapping Ultracold Fermionic Atoms in a Ring Bowtie Cavity  
KEVIN WRIGHT (Presenter), YANPING CAI, DANIEL ALLMAN, Dartmouth College — We have trapped ultracold fermionic atoms (6Li) in a ring cavity for the first time. The cavity is in a symmetric ring bowtie configuration with all glass-construction for compatibility with UHV environments and experiments requiring large magnetic fields for tuning atomic interactions. The high finesse and excellent passive mechanical stability of the cavity facilitate the creation of smooth, stable trapping potentials, with depths of up to 1 mK. The atoms can also be placed in a crossed-beam dipole trap, a 1D optical lattice, or a 2D optical lattice by varying the configuration of the cavity pump fields. After reporting on the performance of this first cavity, we will describe plans to use cavities of this type to study coupled atom-cavity systems in previously unexplored configurations

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K25 DAMOP DCMP: Disorder and Localization in AMO Systems II: Many-body Localization  
BCEC 160A - Michael Kolodrubetz, University of Texas at Dallas - Tag(s): Focus
MICHAEL SCHECTER (Presenter), THOMAS IADECOLA, SANKAR DAS SARMA, University of Maryland, College Park — We uncover a new non-ergodic phase, distinct from the full MBL phase, in a disordered two-leg ladder of interacting hardcore bosons. The dynamics of this emergent phase is determined by the many-body configuration of the initial state and features the coexistence of localized and extended many-body states at fixed energy density. We show that eigenstates in this phase can be described in terms of interacting emergent Ising spin degrees of freedom suspended in a mixture with inert charge-like degrees of freedom (doublons), and thus dub it a mobility emulsion (ME). We argue that grouping eigenstates by their doublon density reveals a transition between localized and extended states that is invisible as a function of energy density. We further demonstrate that the dynamics of the system following a quench may exhibit either thermalizing or localized behavior depending on the doublon density of the initial product state. These results establish a new paradigm for using many-body configurations as a tool to study and control nonergodic dynamics which can be realized in existing disordered Bose-Hubbard ladders.

*This talk is supported by the Laboratory for Physical Sciences and Microsoft.

ULRICH SCHNEIDER (Presenter), Cavendish Laboratory, University of Cambridge — Quasiperiodic potentials, in particular Aubry-Andre-type models, have routinely been employed by us and others as substitutes for real random disorder in the study of many-body localization with ultracold atoms. Far away from the transition, the resulting localized phases are indeed expected to be essentially identical. However, quasiperiodic potentials are not random but long-range ordered. Hence their physics must ultimately be very different. For instance, they do not contain any rare region and, as a result, the nature of the localization transition could be entirely different.

I will briefly review our experimental realization of many-body localization of interacting fermions in the presence of quasiperiodic disorder in 1D and 2D, with a particular focus on slow relaxation close to the localization transition. Furthermore, I will discuss a recent extension to 2D quasicrystals with high rotational symmetries. Matter-wave diffraction experiments in our eightfold symmetric optical quasicrystal directly reveal the presence of a fractal structure in momentum space. I will close with first measurements of the localization transition in these potentials.

Nanosystems Initiative Munich (NIM)

DI LUO, XIONGJIE YU, BRYAN CLARK (Presenter), Physics, University of Illinois at Urbana Champaign — A prime characterization of many-body localized (MBL) systems is the entanglement of their eigenstates; in contrast to the typical ergodic phase whose eigenstates are volume law, MBL eigenstates obey an area law. In this work, we show that a spin-disordered Hubbard model has both a large number of area-law eigenstates as well as a large number of eigenstates whose entanglement scales logarithmically with system size (log-law). This model, then, is a microscopic Hamiltonian which is neither ergodic nor many-body localized. We establish these results through a combination of analytic arguments based on the eta-pairing operators combined with a numerical analysis of eigenstates. In addition, we describe and simulate a dynamic time evolution approach starting from product states through which one can separately probe the area law and log-law eigenstates in this system.

9:00AM K25.00004: Probing Entanglement in a Many-Body-Localized System*  ROBERT SCHITTKO (Presenter), ALEXANDER LUKIN, MATTHEW RISPOLI, MING E TAI, Harvard University, ADAM KAUFMAN, JILA, University of Colorado and National Institute of Standards and Technology, SOONWON CHOI, VEDIKA KHEMANI, JULIAN LEONARD, MARKUS GREINER, Harvard University — An interacting quantum system that is subject to disorder may cease to thermalize due to localization of its constituents, thereby marking the breakdown of thermodynamics. The key to our understanding of this phenomenon lies in the system's entanglement, which is experimentally challenging to measure. We realize such a many-body-localized system in a disordered Bose-Hubbard chain and characterize its entanglement properties through particle fluctuations and correlations. We observe that the particles become localized, suppressing transport and preventing the thermalization of subsystems. Notably, we measure the development of non-local correlations, whose evolution is consistent with a logarithmic growth of entanglement entropy - the hallmark of many-body localization. Our work experimentally establishes many-body-localization as a qualitatively distinct phenomenon from localization in non-interacting, disordered systems.

9:12AM K25.00005: Many-body localization as a large family of localized ground states  MAXIME DUPONT (Presenter), University of California, Berkeley, NICOLAS MACÉ, NICOLAS LAFLORENCIE, CNRS and University of Toulouse — It is well-known that Many-Body Localized (MBL) eigenstates are only area-law entangled, even at high energy, although it is the usual hallmark of ground states of short-range Hamiltonians. It is therefore legitimate to ask whether zero-temperature physics may have some connections with MBL states. Building on this simple idea, we ask whether an arbitrary MBL state could also be the ground state of another Hamiltonian? This question falls in the more general following problem: given a single eigenstate, does it uniquely encode the underlying Hamiltonian? Using large scale DMRG simulations [1], we show that in the presence of disorder, a localized ground state is a very good approximation for an MBL excited state of a different Hamiltonian that differs only by its local disorder configuration. Following similar ideas, we also investigate [2] the ergodic - MBL transition at high energy using standard shift-invert exact diagonalization techniques.

9:24AM K25.00006: Kosterlitz-Thouless scaling at many-body delocalization phase transitions  PHILIPP DUMITRESCU (Presenter), Center for Computational Quantum Physics, Flatiron Institute, SIDDHARTH A PARMESWARAN, Rudolf Peierls Centre for Theoretical Physics, University of Oxford, ANNA GOREMYKINA, Department of Theoretical Physics, University of Geneva, MAKSYM SERBYN, IST Austria, ROMAIN VASSEUR, Department of Physics, University of Massachusetts, Amherst — We propose a scaling theory for the many-body localization (MBL) phase transition in one dimension, building on the idea that the transition proceeds via a `quantum avalanche'. The critical properties are captured at a coarse-grained level by a Kosterlitz-Thouless renormalization group flow. Based on this scaling picture, there are different scenarios for the behavior of fractal rare thermal inclusions within the MBL phase. We propose that the near-critical MBL phase could host rare thermal regions that are power-law distributed in size. This points to the existence of a second transition within the MBL phase, at which these power-laws change to a stretched exponential form. Large scale numerical simulations of a phenomenological models capturing the critical properties near the MBL transition support this picture.

9:36AM K25.00007: Quantum coherence, phases of matter and many-body localization*  LORENZO CAMPOS VENUTI, PAOLO ZANARDI (Presenter), University of Southern California — Quantum coherence is one of the most fundamental traits of quantum mechanics. The coherence generating power (CGP) is the ability of a quantum unitary map of generating coherence. It is defined as the average coherence produced by the map applied to the set of incoherent states. In this talk I will report upon an unexpected link between these information theoretic concepts, and well known condensed matter quantities. Given two point in the phase diagram of a system one can ask about the CGP of the adiabatic intertwiner connecting the two points. The CGP turns out to be the inverse participation ratio, a quantity used to detect many-body localization (MBL) while for close-by points the CGP is exactly given by the d.c. dielectric polarizability. Using known results we are able to show that, in the thermodynamic limit, the CGP becomes maximal in the ergodic phase and submaximal in the MBL phase while the differential coherence diverges in the ergodic and subdiffusive phase while it tends to a constant in the MBL phase.

9:48AM K25.00008: Global and short-range entanglement properties in excited, many-body localized spin chains*
COLIN WEST (Presenter), Physics, University of Colorado at Boulder, TZU-CHIEH WEI, C.N. Yang Institute for Theoretical Physics, Stony Brook University — We explore the use of short-range entanglement measures, such as concurrence and negativity, and global entanglement measures such as geometric entanglement, as indicators of many-body localization (MBL) in the spectra of disordered spin systems. From the perspective of entanglement monogamy, the two types of entanglement behave oppositely in the thermalized and MBL phases. In a recent work, the concurrence of subsystems, a measure of local entanglement, was used in a study of many-body localization in a one-dimensional spin-1/2 system (Bera and Lakshminarayan, 2016). We show numerically that the negativity displays notably similar behavior for this system, with the advantage that it can also be extended to systems of higher local dimension. We then demonstrate this extension in practice by using it to predict the existence of an MBL phase in a disordered spin-1 system. In terms of global entanglement, the geometric entanglement of both spin-1/2 and spin-1 systems is also shown to behave as a complementary indicator of the MBL phenomenon.

10:00AM K25.00009: Multiscale entanglement clusters at the many-body localization phase transition*
LOIC HERVIOU (Presenter), Department of Physics, KTH Royal Institute of Technology, SOUMYA BERA, Department of Physics, Indian institute of Technology Bombay, JENS BARDARSON, Department of Physics, KTH Royal Institute of Technology — We study numerically the formation of entanglement clusters across the many-body localization phase transition. We observe a crossover from strong many-body entanglement in the ergodic phase to weak local correlations in the localized phase, with contiguous clusters throughout the phase diagram. Critical states close to the transition have a structure compatible with fractal or multiscale-entangled Griffith states, characterized by entanglement at multiple levels: small strongly entangled clusters are weakly entangled together to form larger clusters. The critical point therefore features subthermal entanglement and a power-law distributed cluster size, while the localized phase present an exponentially decreasing distribution. These results are consistent with some of the recently proposed phenomenological renormalization-group schemes characterizing the many-body localized critical point, and may serve to constrain other such schemes.

*This work was supported by the ERC Starting Grant No. 679722 and the Knut and Alice Wallenberg Foundation 2013-0093. This research was supported in part by the National Science Foundation under Grant No. NSF PHY-1748958.

10:12AM K25.00010: Universality class of many-body localization transition on 1D system with both random and quasiperiodic potentials
SHIXIN ZHANG (Presenter), HONG YAO, Tsinghua University — Whether MBL transitions in quasiperiodic (QP) and random systems belong to the same universality class or two distinct ones has not been decisively resolved so far. Here we investigate MBL transitions in one-dimensional (d=1) QP systems as well as in random systems by state-of-the-art real-space renormalization group (RG) calculation. Our real-space RG shows that MBL transitions in 1D QP systems are characterized by the critical exponent \( \nu \approx 2.4 \), which respects the Harris-Luck bound (\( \nu > 1/d \)) for QP systems. Note that \( \nu \approx 2.4 \) for QP systems also satisfies the Harris-CCFS bound (\( \nu > 2/d \)) for random systems, which implies that MBL transitions in 1D QP systems are stable against weak quenched disorder since randomness is Harris irrelevant at the transition. By investigating the system with both QP and random potentials via real-space RG, we directly show that the QP-induced MBL criticality is robust against small randomness. Consequently, our real-space RG results imply that there are indeed two stable universality classes of MBL criticalities. We further discuss the possible scenario of the global phase diagram with both types of MBL transitions.

10:24AM K25.00011: Constructing local integrals of motion in the many-body localized phase*  
VIPIN KERALA VARMA (Presenter), VADIM OGANESYAN, College of Staten Island, DAVID PEKKER, University of Pittsburgh, ABHISHEK RAJ, SARANG GOPALAKRISHNAN, College of Staten Island — We consider a many-body localized spin system and its description by the so-called l-bit Hamiltonian. We outline a renormalization flow procedure to construct the extensive set of conserved quantities, and demonstrate that their locality results in exponentially decaying interactions in this effective model. The associated localization length of this decay is shown to manifest properties very similar to the noninteracting case of Anderson localization: normality of its distribution across samples, and its direct qualitative correspondence to the local spectral properties. A numerical simulation of a magnetic spin-echo protocol quantitatively reproduces these theoretically computed length scales. We therefore argue that these local integrals of motion help to practically identify the many-body localized phase.

*NSF DMR Grant No. 1508538 and US-Israel BSF Grant No. 2014265.

10:36AM K25.00012: Apparent slow dynamics in the ergodic phase of a driven many-body localized system without extensive conserved quantities  
TALÍA LEZAMA MERGOLD LOVE (Presenter), Condensed Matter, Max-Planck-Institut für Physik komplexer Systeme, SOUMYA BERA, Department of Physics, Indian Institute of Technology Bombay, JENS BARDARSON, Physics, KTH Royal Institute of Technology — We numerically study the dynamics on the ergodic side of the many-body localization transition in a Floquet model with no global conservation laws. We describe and employ a numerical technique based on the fast Walsh-Hadamard transform that allows us to perform an exact time evolution for large systems and long times. As in models with conserved quantities we observe a slowing down of the dynamics as the transition into the many-body localized phase is approached. More specifically, our data is consistent with a subballistic spread of entanglement and a stretched-exponential decay of the return probability, with the appropriately defined exponents, for a fixed system size, seeming to smoothly go to zero at the transition. However, with access to larger system sizes, we observe a clear flow of the exponents towards faster dynamics and can not rule out that the slow dynamics is a finite-size effect. Furthermore, we observe examples of non-monotonic dependence of the exponents with time, with dynamics initially slowing down but accelerating again at even larger times, reminiscent of what is observed in large scale simulations of random regular graphs and consistent with the slow dynamics being a crossover phenomena with a localized critical point.

10:48AM K25.00013: Phase diagram and observables of many-body localization in transmon circuit arrays  
TUURE ORELL (Presenter), University of Oulu, ALEXIOS MICHAILDIS, MAKSYM SERBYN, IST Austria, MATTI SILVERI, University of Oulu — Disordered interacting quantum systems can undergo a phase transition from ergodic to many-body localized phase. Most of the previous theoretical studies on this subject concentrate on spin systems, and this phenomenon has been observed e.g. in optical lattices with ultra-cold atoms. In this work, we investigate the potential use of superconducting transmon circuits as a platform for experimental studies of the many-body localization [1]. We study numerically one-dimensional disordered arrays of up to 14 transmons, and find that the phase transition occurs at experimentally realizable values of disordered on-site potentials and is robust against experimentally relevant perturbations such as weak next-nearest neighbor and higher-order Kerr interactions. Based on the simulations of the system dynamics, we find that the temporal fluctuations of transmon occupations could be used as an observable for probing the many-body localization in transmon circuits.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K26 DQI: Superconducting Qubits: Noise and Decoherence I  
BCEC 160B - David Pappas, National Institute of Standards and Technology Boulder
8:00AM K26.00001: Measuring charge and flux noise correlations with a superconducting qubit  
BRADLEY CHRISTENSEN (Presenter), CHRIS D WILEN, ALEXANDER OPREMCAN, University of Wisconsin - Madison, JJ NELSON, Syracuse University, FRANCISCO SCHLENKER, LARA FAORO, LEV B IOFFE, University of Wisconsin - Madison, BRITTON L PLOURDE, Syracuse University, JONATHAN L DUBOIS, Lawrence Livermore National Laboratory, ROBERT F MCDERMOTT, University of Wisconsin - Madison — Superconducting qubits are a promising approach towards scalable quantum computing. Coherence times in state-of-the-art devices are now in excess of 100 us. While these times are impressive, achieving the necessary fidelities for suitably scalable surface code algorithms requires better coherence times, and as such, a better understanding of the microscopic origin of the fluctuators that gives rise to different noise sources (e.g., flux noise, charge noise, and dielectric noise).

Recent evidence suggests that significant contribution to charge and flux noise arise from surface defects. Thus, a natural question to further understand the specific mechanism of the noise is if charge and flux noise originate from the same set of surface defects. To this end, we have designed and fabricated a charge-sensitive transmon device. Here we discuss the results of Ramsey-based power spectral density measurements on charge-parity noise (due to quasiparticle tunneling), charge noise, as well as a Ramsey-based cross power spectral density measurement between charge and flux noise. These results indicate valid microscopic models of the fluctuators that give rise to charge and flux noise.

8:12AM K26.00002: Piezoelectric loss in superconducting quantum circuits: Part 1*  
TAEKWAN YOON (Presenter), YIWEN CHU, PRASHANTA KHAREL, VIJAY JAIN, Yale Univ, WILLIAM RENNINGER, University of Rochester, LUIGI FRUNZIO, PETER RAKICH, ROBERT J SCHOELKOPF, Yale Univ — In recent studies, it has been shown that strong coupling between a superconducting qubit and phonons can be achieved. [1,2] These results imply that any unintended electromechanical coupling in the system could lead to loss in superconducting circuit systems. In my talk, I will present a highly sensitive technique for measuring electromechanical coupling in a material at cryogenic temperatures and in the GHz regime. The measurement is based on RF driving of phonons through electromechanical coupling and optical readout through Brillouin scattering. I will present measurements done on an inversion symmetric material, the progress on relevant materials for superconducting circuits, and discuss its implications for qubit coherence times.

*US Army Research Office grant W911NF-18-1-0212, DOE Office of Science grant DE-SC0019406, Max Planck Research Award from the Alexander von Humboldt Foundation, ONR YIP (N00014-17-1-2514), NSF MRSEC (DMR-1119826), AFOSR (FA9550-09-1-0484 and FA9550-15-1-0270), and the Packard Fellowship for Science and Engineering.

8:24AM K26.00003: Piezoelectric loss in superconducting quantum circuits: Part II*  
VIJAY JAIN (Presenter), YIWEN CHU, TAEKWAN YOON, LUIGI FRUNZIO, ROBERT J SCHOELKOPF, Applied Physics, Yale University — Recent demonstrations of strong coupling between a superconducting qubit and an acoustic wave resonator [1,2] implies the adoption of sound as a versatile quantum resource. The qubits used in these experiments exhibited reduced coherence times as compared with the state of the art in circuit-QED. While many factors contribute to determining a qubit’s coherence, unintentional electromechanical coupling between the circuit and piezoelectric material may be appreciable. In this talk, we will present a technique for measuring the microwave loss due to the presence of known piezoelectric materials. Since electromechanical coupling has an expected frequency dependence, we use the overtones of a stripline resonator to measure the intrinsic loss resulting from piezoelectric materials placed in the field of the resonator. The frequency dependence of this effect may enable us to distinguish it from microwave dielectric loss.

*We acknowledge support from US Army Research Office Grant Nr. W911NF-18-1-0212 and the Max Planck Research Award from the Alexander von Humboldt Foundation.
Observation of Low Thermal Excited State Population of Transmon Qubit

YIZHOU HUANG (Presenter), JEN-HAO YEH, RUI ZHANG, SHAVINDRA P PREMARATNE, FREDERICK C WELLSTOOD, Department of Physics, University of Maryland, College Park, BENJAMIN PALMER, Laboratory for Physical Sciences — We have measured the thermal excited-state population of a 3D Transmon qubit from 12 mK up to 150 mK. The Al/AlOx/Al qubit had a g-to-e transition frequency of 3.6 GHz, an e-to-f transition frequency of 3.4 GHz, and T1 of 17 microseconds. The device was mounted in a rectangular Al cavity with a transition frequency of 7.9 GHz and the cavity input line had custom-made attenuators ensuring that noise on the input line was well-filtered and thermalized[1]. The residual excited state population of the qubit was measured by measuring the response of the system when driving Rabi oscillations between the e and f states, with no initial preparation pulse applied to the qubit[2] for one of the pulse sequences. With the refrigerator at 12 mK, we found that the residual excited state population of the qubit in the e state was 0.17% with uncertainty of 0.02%, corresponding to a remarkably small effective qubit temperature of just 28 mK. For refrigerator temperatures T above 40 mK, the effective temperature Tn of the qubit was very close to T.

An analysis method for two superconducting resonators with common defects

NEDA FOROUZANI (Presenter), University of Maryland, Laboratory for Physical Sciences, BAHMAN SARABI, Laboratory for Physical Sciences, OMID NOROOZIAN, EDWARD WOLLACK, SAMUEL H MOSELEY, NASA Goddard Space Flight Center, KEVIN DANIEL OSBORN, Laboratory for Physical Sciences —

We report on a novel device consisting of a pair of superconducting circuit resonators with nearly degenerate resonances. The resonators share the same capacitor C which is engineered as an electrical capacitor bridge such that the capacitances for the resonators share the same defects. One of the resonators is made tunable using the nonlinearity of titanium nitride's kinetic inductance and is current biased, such that the detuning from degeneracy can be controlled. The design allows us to study virtually the same ensemble of atomic-sized two-level tunneling systems (TLSs) coupled to both resonators when degenerate. Slightly off resonance they should be affected by correlated noise but also allow measurement through separate readout lines. In this talk we analyze the device with a new 4 port, 2 resonator scattering theory. This will allow the extraction of two related TLS losses, many resonator couplings related by device symmetry, and an analysis of the noise.

Investigating superconducting qubit loss channels in a quantum acoustical device

BRADLEY MOORES (Presenter), LUCAS SLETTEN, K. W. LEHNERT, JILA, University of Colorado Boulder — The loss channels that limit superconducting qubit coherence times are presently not well understood. Mounting evidence shows that qubits couple to dissipative two-level system baths in dielectrics. In contrast, a less explored loss channel is from phonon radiation that is intrinsic to the Josephson junction superconductor-insulator boundary. Most dielectrics have a vanishing piezoelectric effect in the bulk from inversion symmetry, but this is not the case at surfaces. Theory predicts that the loss rate from this piezoelectric effect can be comparable to the lifetimes of state-of-the-art transmon qubits. Here we investigate phonon radiation from Josephson junctions to put an upper bound on its limitations on the transmon's coherence time.

Charge-parity dynamics in offset-charge-sensitive transmons: Part 1

SPENCER DIAMOND (Presenter), KYLE SERNIAK, MAX HAYS, VALLA FATEMI, GIJS DE LANGE, SHYAM SHANKAR, LUIGI FRUNZIO, ROBERT J SCHOELKOPF, LEONID GLAZMAN, Yale Univ, MANUEL HOUZET, CEA Grenoble, MICHEL H. DEVORET, Yale Univ —

Understanding and mitigating the effects of nonequilibrium quasiparticle excitations is an important step towards improving the performance of superconducting qubits. By designing transmon qubits in the offset-charge-sensitive regime, one can achieve direct dispersive detection of quasiparticle tunneling events. We utilize these devices to measure quasiparticle tunneling rates as a function of various experimental parameters such as RF filtering and qubit design. This talk will focus on experimental methods.

*Work supported by: ARO, ONR, NSF, AFOSR, and YINQE
9:24AM K26.00008: Charge-parity dynamics in offset-charge-sensitive transmons: Part 2*  
KYLE SERNIAK (Presenter), SPENCER DIAMOND, MAX HAYS, VALLA FATEMI, GIJS DE LANGE, SHYAM SHANKAR, LUIGI FRUNZIO, ROBERT J. SCHOLEKOPF, LEONID GLAZMAN, Yale Univ, MANUEL HOUZET, CEA Grenoble, MICHEL H. DEVORET, Yale Univ — Understanding and mitigating the effects of nonequilibrium quasiparticle excitations is an important step towards improving the performance of superconducting qubits. By designing transmon qubits in the offset-charge-sensitive regime, one can achieve direct dispersive detection of quasiparticle tunneling events. We utilize these devices to measure quasiparticle tunneling rates as a function of various experimental parameters such as RF filtering and qubit design. This talk will focus on experimental results.

*Work supported by: ARO, ONR, NSF, AFOSR, and YINQE

9:36AM K26.00009: Non-equilibrium quasiparticles in superconducting circuits: photons vs. phonons*  
GIANLUIGI CATELANI (Presenter), JARA Institute for Quantum Information (PGI-11), Forschungszentrum Jülich, Germany, DENIS M. BASKO, Laboratoire de Physique et Modélisation des Milieux Condensés, CNRS Grenoble, France — We study the effect of non-equilibrium quasiparticles on the operation of a superconducting device (a qubit or a resonator), including heating of the quasiparticles by the device operation. Focusing on the competition between heating via low-frequency photon absorption and cooling via photon and phonon emission, we obtain a remarkably simple non-thermal stationary solution of the kinetic equation for the quasiparticle distribution function. We estimate the influence of quasiparticles on relaxation and excitation rates for transmon qubits, and relate our findings to recent experiments.

*This work was supported in part by the Internationalization Fund - Seed Money initiative of Forschungszentrum Jüllich.

9:48AM K26.00010: Superconducting quasiparticle traps for CPW resonators  
ASHISH ALEXANDER (Presenter), CHRISTOPHER WEDDLE, CHRISTOPHER RICHARDSON, Laboratory of Physical Sciences, University of Maryland, College Park, MD — Excess quasiparticles limit the quality factor of the superconducting resonators by presenting an ohmic path for energy dissipation. It has been shown that normal metal in contact with the superconductor can act as a quasiparticle trap by confining quasiparticles away from the superconductor. Similarly, a small band gap superconductor in contact with a larger band gap superconductor can also act as a quasiparticle trap by confining quasiparticles away from the larger bandgap superconductor into the smaller one. Here aluminum (Al) and titanium nitride (TiN) are used as two superconductors. Finite difference method (FDM) simulations of the coupled phonon and quasiparticle systems of both superconductors suggest that the quasiparticle traps on the ground plane may be effective for setback distances less than 200 µm away from TiN waveguide features. Experimentally, a thin layer of Al is grown in-situ on TiN using molecular beam epitaxy (MBE) with a negligible dielectric layer between the two superconductors to increase the trapping efficiency of the Al. Currently work focuses on fabricating quarter wavelength resonators in TiN with different setbacks of the Al trap. The optimum setback of Al from the active region of the TiN resonator will be explored.

10:00AM K26.00011: Resolving the Location of Parasitic Defects in Superconducting Qubits*  
ALEXANDER BILMES (Presenter), GEORG WEISS, Physikalisches Institut, Karlsruhe Institute of Technology, RAMI BAREND'S, JULIAN KELLY, ANTHONY E MEGRANT, JOHN M MARTINIS, Google - Santa Barbara, ALEXEY V. USTINOV, JÜRGEN LISEN Feld, Physikalisches Institut, Karlsruhe Institute of Technology — New techniques to identify the location of decoherence-inducing material defects known as Two-Level-Tunneling systems (TLS) in superconducting qubits are demonstrated. We expose a transmon qubit circuit to a DC-electric field generated by electrodes surrounding the sample chip, and study the TLS response by monitoring their resonance frequencies using qubit swap spectroscopy. We find that about 50% of all detectable TLS do not couple to the applied E-field, as it is expected from TLS hosted in the Josephson junction tunnel barrier, but unlikely for TLS residing in surface oxides or at substrate interfaces. In contrast, all TLS respond to the mechanical strain generated by a piezo actuator. This indicates that surface TLS contribute about equally to qubit decoherence as those in qubit junctions. Moreover, by comparing measured and simulated coupling strengths to each DC-electrode, we obtain information about the possible locations and hosting interfaces of the observed surface TLS. This analysis directly indicates which circuit interfaces must be improved in order to enhance qubit coherence.

Reducing dissipation for superconducting qubits

NASSER ALIDOUST (Presenter), ANI NERSISYAN, STEFANO POLETTI, RICCARDO MANENTI, RUSS RENZAS, EYOBB SETE, CATVU BUI, KIM VU, TYLER WHYLAND, YUVRAJ MOHAN, SAM STANWYCK, JAYSS MARSHALL, KAMAL YADAV, ANDREW BESTWICK, MATTHEW J REAGOR, Rigetti Computing — Extending qubit lifetimes ($T_1, T_2$) remains a core challenge in developing large-scale quantum computers with superconductors. In this talk, we discuss a variety of substrate cleaning and subtractive patterning techniques responsible for increasing $T_1$ for superconducting qubits. For these analyses, we have developed fabrication flows based on subtractively-patterned niobium that yield resonators with average internal quality factors of $Q_{int} \approx 1 \times 10^6$ across several wafers and chips. We show options for integrating Josephson junctions into these process flows to make functional qubits with high coherence times.

Spurious mode suppression using micromachined pillars in superconducting quantum devices

PETER A SPRING (Presenter), JOSEPH RAHAMIM, BRIAN VLASTAKIS, ANDREW D PATTERTON, TAKAHIRO TSUNODA, SOPHIA SOSNINA, MARTINA ESPOSITO, SALHA JEBARI, KITTI RATTER, GIOVANNA TANCREDI, PETER LEEK, Condensed Matter Physics, University of Oxford — As quantum circuits scale in size, the enclosures used to house them will contain spurious resonant electromagnetic modes detrimental to the circuits unless preventative steps are taken. A standard solution in microwave circuits is the use of through-chip vias. Here we present an alternative that moves the through-chip electrical connection off the substrate and to the enclosure, which suppresses substrate and enclosure modes simultaneously. We achieve this by placing a substrate in a rectangular cavity incorporating an array of micromachined pillars, such that the minimum mode frequency is set by the pillar spacing and not the enclosure dimensions. To accommodate the pillars the substrate is machined. We investigate the compatibility of both CNC and laser machining of holes in silicon with superconducting qubit fabrication. We present proof of principle experiments on enclosures incorporating pillars, and produce simulations with more complex arrangements of pillars in larger-scale devices.

Phononic Losses in Superconducting Coplanar Waveguide Resonators on Piezoelectric Substrates

MARCO SCIGLIUZZO (Presenter), LAURE BRUHAT, ANDREAS BENTGSSON, JONATHAN BURNETT, PER DELSING, Microtechnology and Nanoscience, MC2, Chalmers University of Technology — In recent years there has been an increasing number of experiments involving superconducting qubits on piezoelectric substrates to investigate quantum acoustics. In this context Coplanar Waveguide (CPW) resonators provide a well established way for qubit manipulation and readout. However CPW resonators on piezoelectric substrates perform poorly, with two orders of magnitude lower internal quality factor ($Q$) compared with similar devices on low loss dielectrics.

In this work we present an investigation of the phononic loss channel for CPW resonators fabricated on a piezoelectric substrate. With the help of finite element method (FEM) simulations, we calculate the energy loss due to electromechanical conversion, and derive an upper limit for the internal $Q$. We fabricate quarter wavelength CPW resonators on GaAs and measure their internal $Q$ as function of frequency, power and temperature. We obtain a linear increase of the internal $Q$ with respect to frequency as expected for a frequency independent electromechanical coupling. Moreover we find a weak power dependence and a negligible temperature dependence around 10mK, excluding two level systems and nonequilibrium quasiparticles as the main source of losses.

Tunable High-Q Photonic Bandgap Microwave Cavity

ANKUR AGRAWAL (Presenter), AKASH DIXIT, DAVID SCHUSTER, AARON CHOU, University of Chicago — A woodpile structure made out of dielectric rods exhibits an omnidirectional photonic bandgap (PBG) which forbids the propagation of electromagnetic wave with energy within a certain range in all directions. We designed an electromagnetic cavity by creating a defect inside the crystal, such that its frequency lies within the forbidden bandgap. Very high Q-factors can be achieved since the light has no way to escape because of the bandgap and is only limited by the dielectric loss in the material. We predict the quality factor of such a cavity to be close to $10^8$ near 10 GHz. The cavity frequency is tuned by sliding the rods in and out. One of the potential applications is in the axion dark matter search, which is currently limited by the use of low $Q$-factor copper cavities due to the presence of a strong magnetic field. We predict the $Q$-factor of a PBG cavity to increase in the presence of a large magnetic field due to the shift in the two-level system energies to a higher level.

**Session K27 DQI: Quantum Machine Learning II** BCEC 160C - Maria Schuld, University of KwaZulu-Natal - Tag(s): Focus

**8:00AM K27.00001: The Impact of Quantum Noise in Neuromorphic Systems** GERASIMOS ANGELATOS (Presenter), HAKAN TURECI, Electrical Engineering, Princeton University — The quantum dynamics of driven-dissipative systems with a stable classical fixed-point are well understood, however dynamics far from equilibrium and in regimes without a fixed-point are less studied. Considerable theoretical challenges arise because such situations often involve strong transient excitation while the role of quantum fluctuations remains significant. This scenario is realized in neuromorphic optical systems which respond to a weak input above threshold with a robust large amplitude pulse. The quantum dynamics of neuromorphic systems can thus not be described by the standard small fluctuation expansion around a classical steady-state, and a full quantum modeling is out of question due to large transients. We present a general theoretical approach based on quantum stochastic differential equations which captures quantum noise about classical trajectories and apply it to two physical realizations of neuromorphic dynamics: an excitable laser and a superconducting circuit. Contrary to previous findings, fundamental quantum noise drives large fluctuations in pulse response times, while the amplitude response remains robust. In addition, quantum noise softens the bifurcation to a self-sustained pulsation regime by exciting the system in the absence of an input.

**8:12AM K27.00002: Performance of the Quantum Approximate Optimization Algorithm on the Maximum Cut Problem** GAVIN CROOKS (Presenter), NICHOLAS C RUBIN, Rigetti Quantum Computing — The Quantum Approximate Optimization Algorithm (QAOA) is a promising approach for programming a near-term gate-based hybrid quantum computer to find good approximate solutions of hard combinatorial problems. However, little is currently known about the capabilities of QAOA, or of the difficulty of the requisite parameters optimization. We explore these issues with the aid of QuantumFlow, a simulation of a gate based quantum computer that uses TensorFlow to rapidly optimize variational quantum circuits. Our investigations support the prospects that QAOA will be an effective method for solving interesting problems on near-term quantum computers.

**8:24AM K27.00003: Machine Learning Detection of Bell Nonlocality in Quantum Many-Body Systems** DONG-LING DENG (Presenter), Institute for Interdisciplinary Information Sciences, Tsinghua University — Machine learning, the core of artificial intelligence, is one of today's most rapidly growing interdisciplinary fields. Recently, its tools and techniques have been adopted to tackle intricate quantum many-body problems. In this talk, I will introduce machine learning techniques to the detection of quantum nonlocality in many-body systems, with a focus on the restricted-Boltzmann-machine (RBM) architecture. Using reinforcement learning, I will demonstrate that RBM is capable of finding the maximum quantum violations of multipartite Bell inequalities with given measurement settings. This result builds a novel bridge between computer-science-based machine learning and quantum many-body nonlocality, which will benefit future studies in both areas.

*This work is supported by Laboratory for Physical Sciences, Microsoft, and the start-up fund from Tsinghua University.

**8:36AM K27.00004: Benchmarking superconducting qubits with generative model learning** KATHLEEN HAMILTON (Presenter), EUGEN DUMITRESCU, Oak Ridge National Laboratory, HOLLY STEMP, University of Surrey, RAPHAEL POOSER, Oak Ridge National Laboratory — Our work is focused on the identification and development of simple machine learning tasks that can act as hardware benchmarks to compare the relative performance of NISQ devices. Using MMD training and stochastic optimization of circuit parameters, we show how a recently introduced class of generative models (the Quantum Circuit Born Machine [1]) can quantify the performance of noisy superconducting qubits. We identify three sources of error that limit the performance of these models on noisy qubits: decoherence, gate fidelities and measurement errors. We construct several shallow depth circuit ansatz and using metrics which are related to fidelity we demonstrate how different errors affect model performance. We also investigate the effect of applying error mitigation to the final trained circuit versus incorporating error mitigation into the circuit training workflow.

*This work was supported as part of the ASCR Testbed Pathfinder Program at Oak Ridge National Laboratory under FWP #ERKJ332
8:48AM K27.00005: Local-measurement-based quantum state tomography via neural networks  BEI ZENG (Presenter), University of Guelph — Quantum state tomography is a daunting challenge of experimental quantum computing even in moderate system size. One way to boost the efficiency of state tomography is via local measurements on reduced density matrices, but the reconstruction of the full state thereafter is hard. Here, we present a machine learning method to recover the full quantum state from its local information, where a fully-connected neural network is built to fulfill the task with up to seven qubits. In particular, we test the neural network model with a practical dataset, that in a 4-qubit nuclear magnetic resonance system our method yields global states via 2-local information with high accuracy. Our work paves the way towards scalable state tomography in large quantum systems.

9:00AM K27.00006: Variational Quantum Neural Programming  PIERRE-LUC DALLAIRE-DEMERS (Presenter), Zapata Computing — Variational algorithms used for quantum simulations are naturally resistant to some errors and are therefore well suited for NISQ devices. Their application in quantum machine learning has yielded methods for data classification, compression and generation such as the quantum autoencoder. Using inspiration from neural programming in classical machine learning, we show how a quantum program can be learned through gradient descent. Quantum programs are usually defined operationally over a variable number of qubits while variational quantum algorithms are typically meant to operate on fixed-size quantum registers. We define a class of differentiable ansatz that can operate on an arbitrary number of qubits and be used to reproduce algorithms such as the quantum Fourier transform and phase estimation using only a set of examples on few qubits. We generalize this class of ansatz to explore the space of shallow algorithms.

9:12AM K27.00007: Quantum machine learning: Challenges and Opportunities*  [Invited]  LEONARD WOSSNIG (Presenter), SIMONE SEVERINI, Computer Science, University College London — In this talk I will pose the general framework of learning and then introduce the different topics which jointly define the area of quantum machine learning. Since machine learning is an intrinsically data driven approach, dependencies and assumptions play a major role. I will therefore introduce different input and output assumptions and discuss corresponding data access models before giving a high level explanation of the different techniques which have been proposed. I will finally discuss current and future challenges and opportunities of the field.

*I thankfully acknowledge the support through a Research Fellows Enhancement Award grant of the Royal Society.

9:48AM K27.00008: A Universal Training Algorithm for Quantum Deep Learning*  GUILLAUME VERDON (Presenter), JASON PYE, Institute for Quantum Computing, MICHAEL BROUGHTON, School of Computer Science, University of Waterloo — Quantum variational algorithms have seen a recent surge of interest, yet their connection to classical deep neural networks has so far remained elusive. In this talk, we will establish how to port over classical neural networks as quantum parametric circuits, and we will further introduce a quantum-native backpropagation principle which can be leveraged to train any quantum parametric network. We will present two main quantum optimizers leveraging this quantum backpropagation principle: Quantum Dynamical Descent (QDD), which uses quantum-coherent dynamics to optimize network parameters, and Momentum Measurement Gradient Descent (MoMGrad), which is a quantum-classical analogue of QDD. We will briefly cover multiple applications of QDD/MoMGrad to various problems of quantum information learning, and how to use these optimizers to train classical neural networks in a quantum fashion. Furthermore, we will show how to efficiently train hybrid networks comprised of classical neural networks and quantum parametric circuits, running on classical and quantum processing units, respectively.

Talk based on [arXiv:1806.09729].

*The authors acknowledge financial support from NSERC. This research was supported in part by Perimeter Institute for Theoretical Physics.
Development of quantum algorithms for data analysis and machine learning has gained much attention recently. For practical applications of such algorithms in the big data era, the quantum advantage must be retained in noisy settings. One intriguing example in which the quantum algorithm outperforms the classical counterpart in the presence of noise is the problem of learning a parity function defined by a hidden bit string, known as learning parity with noise (LPN). However, a learner is most likely to receive noisy classical data, rather than noisy quantum data as considered in the original quantum LPN algorithm. Then, whether the quantum technique is still preferred remains an interesting open problem. Here, we present a quantum-classical reinforcement learning algorithm to solve the LPN problem efficiently for classical data. The algorithm uses classical training data to prepare an input quantum state suitable for the original quantum LPN algorithm. Based on the outcome of the quantum algorithm, a reward and an action are classically determined to update the input quantum state for the next learning cycle. Our method uses an exponentially smaller number of training samples than the direct application of the original quantum LPN algorithm to classical data.

We describe a Markov chain monte carlo simulation of quantum circuits based on decomposing the circuit in question as a sum of Clifford gates. The idea is to leverage the classical simulability of Clifford dynamics to cases where the circuit is no longer simulable. The runtime scales quadratically with the 1-norm of the vector of expansion, and the runtime is comparable with state-of-the-art simulators for an important class of circuits; the so-called Clifford+T circuits. The simulation method can be extended to two other problems: estimating transition probabilities and estimating the partition function of an n-qubit Hamiltonian. We give theoretical error and runtime estimates, and introduce a few sub-algorithms which can improve the performance in some cases.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K28 DQI: Quantum Measurement and Sensing I

8:00AM K28.00001: Quantum metrology in the presence of dissipation with superconducting qubits.* [Invited] KATER MURCH (Presenter), Physics, Washington University in St. Louis — While quantum systems can offer significant advantages over classical systems in metrology, often the quantum states that confer such advantages are degraded by decoherence. I will discuss experiments that explore strategies to mitigate this degradation through continuous quantum measurement and feedback. Furthermore, dissipation also yields potential for further metrological advantages that are associated with exceptional point degeneracies in non-Hermitian systems. I will discuss how such degeneracies can be realized in single dissipative qubits and present investigations of enhanced measurement sensitivity in single quantum systems.

*This work was supported the ONR Grant No. 12114811 and the NSF Grant No. PHY-1607156

8:36AM K28.00002: Non-Hermitian quantum sensing: exceptional point and non-reciprocal approaches HOI-KWAN LAU (Presenter), AASHISH CLERK, University of Chicago — Unconventional properties of non-Hermitian systems, such as the existence of exceptional points, have recently been suggested as a resource for sensing [1,2]. The impact of noise and utility in quantum regimes however remains unclear. We describe here a full analysis of quantum parametric sensing using coupled mode systems described by effective non-Hermitian Hamiltonians; our approach rigorously accounts for quantum noise effects [3]. Focusing on two-mode devices, we derive fundamental bounds on the signal power and signal-to-noise ratio for any such sensor. We use these to demonstrate that enhanced signal power requires gain, but not necessarily any proximity to an exceptional point. Further, when noise is included, we show that non-reciprocity is a powerful resource for quantum sensing: it allows one to exceed the fundamental bounds constraining any conventional, reciprocal sensor. Non-reciprocal quantum sensors could be implemented in a variety of systems, including superconducting quantum circuits and quantum optomechanical systems.

8:48AM K28.00003: Saturating the quantum Cramér-Rao bound using LOCC*  SISI ZHOU (Presenter), Yale Quantum Institute, Yale University, CHANG-LING ZOU, Key Laboratory of Quantum Information, University of Science and Technology of China, LIANG JIANG, Yale Quantum Institute, Yale University — The quantum Cramér-Rao bound (QCRB) provides an ultimate precision limit allowed by quantum mechanics in parameter estimation. Given any quantum state dependent on a single parameter, there is always a positive-operator valued measurement (POVM) saturating the QCRB. However, the QCRB-saturating POVM cannot always be implemented efficiently, especially in multipartite systems. In this talk, we show that the POVM based on local operations and classical communication (LOCC) is QCRB-saturating for arbitrary pure states or rank-two mixed states with varying probability distributions over fixed eigenbasis. We also analyze the robustness of our LOCC protocol against noise and show how it can be made noise-resilient. Finally, a four-qubit system is studied as an example of a non-trivial LOCC protocol saturating the QCRB. For details, see ArXiv: 1809.06017.

9:00AM K28.00004: Ramsey interferometry in correlated quantum noise environments*  LEIGH NORRIS (Presenter), FELIX BEAUDOIN, LORENZA VIOLA, Dartmouth College — We quantify the impact of spatiotemporally correlated Gaussian quantum noise on frequency estimation by Ramsey interferometry. While correlations in a classical noise environment can be exploited to reduce uncertainty relative to the uncorrelated case, we show that quantum noise environments with frequency asymmetric spectra generally introduce additional sources of uncertainty due to uncontrolled entanglement of the sensing system mediated by the bath. For the representative case of collective noise from bosonic sources, and experimentally relevant collective spin observables, we find that the uncertainty can increase exponentially with the number of probes. As a concrete application, we show that correlated quantum noise due to a lattice vibrational mode can preclude superclassical precision scaling in current amplitude sensing experiments with trapped ions. This work was recently reported in PRA (Rapid Communications) 98, 020102 (2018).

9:12AM K28.00005: Hamiltonian engineering for quantum sensing  YI-XIANG LIU (Presenter), Massachusetts Institute of Technology, ASHOK AJOY, University of California Berkeley, JORDAN HINES, PAOLA CAPPELLARO, Massachusetts Institute of Technology — Quantum sensing utilizes the interaction between the quantum sensor and the object to be detected. However, limited by the intrinsic system Hamiltonian or experimental capabilities, the implementable Hamiltonian evolution may not be optimal to reveal the information of the target object. Inspired by digital quantum simulation, here we present a general framework in which we use Trotter-like combinations of unitaries to engineer better Hamiltonians for sensing and provide an efficient protocol to reduce the approximation error. We show the application of Hamiltonian engineering to nano-scale magnetic resonance imaging.

9:24AM K28.00006: Provably optimal controls for magnetometry in cluttered environments  VIRGINIA FREY (Presenter), Univ of Sydney, LEIGH NORRIS, LORENZA VIOLA, Dartmouth College, MICHAEL JORDAN BIERCUK, Univ of Sydney — The extreme fragility of quantum systems makes them ideally suited for sensing applications such as magnetometry, biological imaging and noise characterization for quantum computing. However, interpreting a qubit-based sensor’s output is generally complicated by background clutter arising from both out-of-band spectral leakage, and ambiguity in signal origin when the implemented qubit drive is imperfect. Here we present a novel sensing protocol based on the optimal band-limited Slepian functions that overcomes both of these challenges. We construct Slepian-based controls using a finite-difference method that preserves the relevant spectral concentration while removing nonlinearities in the sensor response which arise when targeting ambient noise signatures that couple to the sensor’s signal through an additive dephasing Hamiltonian term, such as magnetic field fluctuations. We experimentally implement a tomographic measurement framework which separates multi-axes contributions using projective measurements on a single trapped ion magnetometer. Experiments validate the spectral concentration of the new finite-difference controls and allow for simultaneous, narrowband spectrum reconstruction of both environmental dephasing and control noise fields.
ROBERT DELANEY (Presenter), ADAM PREED, JILA, REED ANDREWS, HRL Laboratories, LLC, KONRAD LEHNERT, JILA — Quantum mechanics places strict limits on how precisely the two motional quadratures of an object can be simultaneously measured. To noiselessly reconstruct an unknown quantum state of motion, a single quadrature measurement can be repeated over all of phase space, and the density matrix describing the quantum state can be reconstructed via quantum state tomography. Here we demonstrate a pulsed measurement of the motion of a micromechanical oscillator embedded in a superconducting electromechanical circuit. The measurement can be tuned from a nearly quantum-limited simultaneous measurement of both quadratures, to a single quadrature measurement with added noise of -10 dB relative to vacuum fluctuations in one quadrature, resulting in a total measurement efficiency of 92%. The high efficiency measurement is used to accurately reconstruct the density matrix of a dissipatively squeezed mechanical oscillator (-3.3 dB relative to vacuum fluctuations), demonstrating that the measurement is suitable for tomography of arbitrary quantum states of the mechanical oscillator.

DANY LACHANCE-QUIRION (Presenter), SAMUEL PIOTR WOLSKI, YUTAKA TABUCHI, SHINGO KONO, KOJI USAMI, YASUNOBU NAKAMURA, Research Center for Advanced Science and Technology, The University of Tokyo — Opportunities for quantum sensing of quanta of collective spin excitations in a ferromagnet, called magnons, are now possible thanks to the demonstrations of both strong resonant and dispersive couplings between a superconducting qubit and the uniform precession mode, or Kittel mode, of a ferromagnetic sphere [1,2]. Based on operations on the qubit conditional on the state of the Kittel mode, single-shot detection of a single magnon with an efficiency reaching about 50% is demonstrated using the protocol of Ref. [3]. The detection efficiency is mainly limited by the qubit readout fidelity. Furthermore, a magnon detection sensitivity of about $10^{-3}$ magnons/√Hz is demonstrated using a standard Ramsey interferometry technique. These two complementary quantum sensing methods could find applications in quantum technologies based on magnonics and the detection of axions in dark matter searches.

KATHERINE INZANI (Presenter), SINEAD GRIFFIN, Lawrence Berkeley National Laboratory — The direct detection of light dark matter (DM) relies on harnessing low-threshold events in target materials. One such event is the scattering of an electron across a small gap, where our target material’s threshold will determine the range of masses of DM particles we are sensitive to. In this work we investigate spin-orbit semiconductors as DM detection targets. We report the results of a high-throughput search for new small-gapped semiconductors, and estimate their reach as DM targets using first-principles methods. We also discuss how the calculated material properties influence the detector size and geometry.

AKASH DIXIT (Presenter), DAVID SCHUSTER, University of Chicago, AARON CHOU, Fermilab, ANKUR AGRAWAL, SRIVATSAN CHAKRAM, RAVI NAIK, University of Chicago — The axion is a potential solution to the strong CP problem in QCD and could account for the abundance of dark matter observed in the universe. In the presence of an applied magnetic field, the axion field will source a current used to drive a resonant cavity to single photon occupation. A transmon qubit operating as a microwave photon sensor is a viable readout system at frequencies where the added noise of quantum limited amplifiers overwhelsms the signal rate. The use of a direct dispersive quantum non-demolition measurement of the photon number decouples the measurement back action from the experimental uncertainties. In this regime background and dark counts become the dominant sources of detector error. For a transmon qubit operating as a photon counter, the dark rate is typically 1-10% and is orders of magnitude greater than the anticipated signal rate. In order to mitigate the effect of individual bit flip errors of the detector we operate multiple detectors in the same cavity volume. The error rate of the joint N-qubit detector could potentially have exponentially suppressed error rates as compared to the single detector. We will report theoretical performance and progress towards characterizing fidelity and correlations of multqubit detectors.
10:24AM K28.00011: Quantum noise limits for a class of nonlinear amplifiers* JEFFREY EPSTEIN (Presenter), Physics, University of California, Berkeley, JOSHUA COMBES, Rigetti Computing — We introduce a class of nonlinear amplifier input-output relations that allow the measurement of any normal operator using linear measurements with only vacuum fluctuations added at the output. In the limit of large gain, such devices would effectively implement perfect measurements of nonlinear operators in the same way that linear amplifiers permit effectively perfect linear measurements even when paired with realistic, noisy measurement devices. We analyze the application of these amplifiers to photon number measurements and state estimation.

10:36AM K28.00012: One from many: Scalar estimation in a multiparameter context* JONATHAN GROSS (Presenter), Institut quantique, Université de Sherbrooke, CARLTON MORRIS CAVES, Center for Quantum Information and Control, University of New Mexico — Achievable sensitivity bounds are difficult to formulate for quantum multiparameter estimation. We consider a specialized case: many parameters of a Hamiltonian are unknown and one seeks an estimate for a scalar function of the Hamiltonian. This problem exhibits genuine multiparameter behavior, though it is superficially similar to single-parameter estimation. By uniting saturable single-parameter quantum bounds with geometric reasoning we prove the conditions, necessary and sufficient, for saturating the fundamental and attainable bound in this context.

*National Science Foundation Grant Nos. PHY-1521016 and PHY-1314763.

10:48AM K28.00013: Optimal measurements in simultaneous multi-parameter estimation of quantum systems* JING YANG (Presenter), Department of Physics and Astronomy, University of Rochester, SHENGSHI PANG, Fermi lab, YIYU ZHOU, Institute of Optics, University of Rochester, ANDREW N JORDAN, Department of Physics and Astronomy, University of Rochester — Simultaneous estimation of multiple parameters is a well-known challenge in quantum metrology. The underlying difficulty is to identify the common optimal measurements for all the parameters, which typically do not coincide or commute. For a general probe state and a projective measurement of arbitrary rank, we find the necessary and sufficient conditions under which the measurement gives rise to the multi-parameter quantum Cramer-Rao matrix bound. We also give an application of these conditions to the specific problem of estimating three-dimensional separation of two point incoherent sources of equal intensities from single photon measurements. By considering the hard-aperture and paraxial approximated pupil function, we find a local optimal measurement for simultaneous estimation of the small three dimensional separation. Furthermore, regardless of the magnitude of longitudinal separation, a local optimal measurement for simultaneously estimating the small transverse separation is also found. The saturation conditions of the multi-parameter quantum Cramer-Rao bound may be further explored in quantum sensing and imaging.

Wednesday, March 6, 2019 8:00 AM - 9:30 AM

Session K29 APS: Tutorial for Authors & Referees BCEC 162A

8:00AM K29.00001: Tutorial for Authors & Referees — Publication is an essential part of scholarly research and integral to most scientists’ careers. A good understanding of the authoring and reviewing processes will help authors navigate their way to a published manuscript. In this tutorial, editors from Physical Review Letters and Physical Review will provide advice on topics such as how to write a good paper, how best to respond to reviews, and how to write informative referee reports.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K30 GSOFT DPOLY DBIO: Organization and Dynamics of Functional Liquid Crystals, Polymers, and Biological Assemblies II BCEC 162B - Roy Beck, Tel Aviv University - Tag(s): Focus
**8:00AM K30.00001: DYNAMIC SELF-ASSEMBLY OF VIRUS CAPSIDS** [Invited] URI RAVIV (Presenter), Hebrew University of Jerusalem — The assembly and disassembly of virus capsids, composed of many subunits, are fundamental steps in the viral life cycle. The complete set of possible capsid intermediates is immense, yet the concerted assembly process is done with high fidelity and leads to stable capsids that can efficiently encapsulate and protect genetic material, and when needed, dissociate and release their cargo. Virus capsids are therefore stable and flexible dynamic structures. To better understand and predict the outcomes of these apparently contradictory processes, we precisely analyzed the structure, kinetics, and thermodynamic stability of the experimentally tractable virus assembly reaction, in vitro. High-resolution modern synchrotron solution X-ray scattering measurements of assembly reactions provided statistically reliable and rich structural data. We rigorously analyzed the data by integrating our home-developed state-of-the-art scattering data analysis software D+ (https://scholars.huji.ac.il/uriraviv/software/d-software) with simulations and theory of macromolecular self-assembly. Our accurate and comprehensive analysis provided new insight into the mechanisms of viral self-assembly and the boundaries where thermodynamic products can be realized and function, and when kinetically trapped metastable states may form. This insight could be important for designing antiviral therapeutics as well as noncapsules or nanoreactors.

**8:36AM K30.00002: Counterion-dependent Dynamics of Nanoconfined Water in Lyotropic Liquid Crystalline Mesophases** MAHESH MAHANTHAPPA (Presenter), University of Minnesota — Understanding how the interfacial chemical functionalities influence nanoconfined water dynamics could potentially inform the design of next-generation permselective and ion-transporting membranes for energy applications. However, lacking access to well-defined systems with tunable interfacial chemistries and nanoconfined geometries has hampered conclusive studies of water dynamics therein. Derived from the water concentration-dependent self-assembly of small molecule surfactants, lyotropic liquid crystals (LLCs) offer a platform for studying confined water dynamics in nanopores (diameters ~0.7-2.5 nm) lined with well-defined chemical functionalities. In this contribution, we describe the synthesis and aqueous phase behavior of ionic gemini dicarboxylate surfactants, which form technologically-useful, normal double gyroid phases in which water is nanoconfined between two carboxylate-lined, convex interfaces. Quasielastic neutron scattering (QENS) measurements indicate that the gyroid water dynamics are significantly slower than in bulk water, and that the observed dynamics are very sensitive to the nature of the charge-compensating counterion (Na+, K+, Me₄N+) associated with the carboxylate surfactant headgroup.

---

**8:48AM K30.00003: Phase transformations in lipids confined to colloidally stable nanoscale particles** JACOB RUEBEN (Presenter), Materials Science and Engineering, University of Illinois at Urbana-Champaign, HOKUN KIM, Korea Institute of Science and Technology, CECILIA LEAL, Materials Science and Engineering, University of Illinois at Urbana-Champaign — Lipids – biological, amphiphilic molecules with ability to self-organize into bilayer structures – have found lasting therapeutic application in drug-laden nanoparticles. Of recent interest is the internal structure of these nanoparticles, which influences their endosomal escape in cellular delivery pathways. Lipid nanoparticles with bicontinuous cubic internal structure show improved gene knockdown efficiency over more traditional liposomal particles [1]. Inverse hexagonal-phase lipid materials show further improved fusogenic properties, but are toxic due to pore formation with the plasma membrane [2]. Here we report a lipid-based material with phase-triggering character to avoid such toxicity limitations. In this system, a change from bicontinuous cubic to inverse hexagonal within the nanoparticles can potentially be triggered at any delivery step without requiring endosomal acidification. Instead, local heating is achieved via near-infrared radiation of incorporated gold nanorods, inciting localized surface plasmon resonance. The formulated lipid systems are characterized with cryogenic TEM and small-angle X-ray scattering (SAXS).

9:00AM K30.00004: Modeling the Properties of Liquid Crystal Electrolytes with Replica Exchange Molecular Dynamics*  
MICHAEL QUEVILLON (Presenter), ARSENII PANTELEEV, JONATHAN WHITMER, University of Notre Dame — Ionic liquid crystals exist at the intersection of ionic liquids and liquid crystals; properties from both classes of materials can be utilized in various applications, from nonlinear optical and photonic devices to dye-sensitized solar cells. One intriguing use has been suggested where the ionic liquid crystals act as anisotropic battery electrolytes, where the liquid crystalline order provides global structure and the ionic liquid character provides a medium through which charge transport is facilitated. The ionic liquid crystals in question have bulky ionic groups and mesogenic “tails” with little or no effective charge, qualitatively similar to charged surfactants. This class of materials is relatively unprobed experimentally, as many are nontrivial to synthesize. We leverage atomistic molecular dynamics simulations of these systems as a preliminary way to study their phase behavior, utilizing replica exchange methods to pinpoint and elucidate the observed phase transitions.

9:12AM K30.00005: Mechanisms to Twist-Bend and Splay-Bend Nematic Phases  
NANDITA CHATURVEDI (Presenter), RANDALL D KAMIEN, University of Pennsylvania — Twist bend phases of liquid crystals have been studied extensively experimentally. However, the mechanism behind their emergence remains debated. Theoretical models have predicted the existence of twist-bend and splay-bend phases as stable states arising from a common mechanism. With the recent experimental observation of splay-bend phases, we look at bond orientational order, such as planar hexatic order, as a way to arrive at splay-bend and twist-bend phases. We find that phase chirality, and the nematic symmetry play a key role in looking at possible interactions of nematic order and bond orientational order.

9:24AM K30.00006: Length segregation in mixtures of spherocylinders induced by imposed topological defects*  
ELSHAD ALLAHYAROV (Presenter), Theoretical Chemistry, University of Duisburg-Essen, HARTMUT LOEWEN, Theoretical Physics II, University of Dusseldorf — We explore length segregation in binary mixtures of spherocylinders of lengths \( L_1 \) and \( L_2 \) which are tangentially confined on a spherical surface of radius \( R \). The orientation of spherocylinders is constrained along an externally imposed direction field which is either along the longitude or the latitude lines of the sphere. We show that the integer orientational defects at the poles induce a complex segregation picture also depending on the length ratio factor \( y=L_2/L_1 \) and the total packing fraction \( \eta \) of the spherocylinders. In longitude preoriented cases shorter rods tend to accumulate at the poles whereas longer rods occupy central equatorial area of the spherical surface. In latitude preoriented cases longer rods are predominantly both in the cap and in the equatorial areas and shorter rods are localized in between. A reference situation with a defect-free flat plane does not show any length segregation at similar \( y \) and \( \eta \). We also develop an Onsager-like density functional theory which is capable to predict length segregation in ordered mixtures. At low density, the results of this theory are in good agreement with the simulation data.

9:36AM K30.00007: Temperature-induced coordinated transformation of block copolymer micelles on fcc lattices to hcp structures  
SANGWOO LEE (Presenter), LIWEN CHEN, Rensselaer Polytechnic Institute — We discovered coordinated phase transformation of the strongly-segregated block copolymer micelles in aqueous solution on fcc lattices to hcp structures. The fcc structures formed by direct dissolution of poly(1,2-butadiene-b-ethylene oxide) diblock copolymer in water were gently shear-aligned and contained in sealed thin-wall capillaries. Heating the shear-aligned fcc crystallites to a higher temperature induced highly-coordinated hcp crystallites aligned in the same direction which we believe cannot happen by a nucleation and growth mechanism due to the high symmetry of fcc crystals. Careful analysis of the hcp structures suggests that the phase transformation occurred by sliding specific two-dimensional hexagonal micelle layers of the shear-aligned fcc crystallites likely with the smallest cross-section area.
9:48AM K30.00008: A mean field approach to determine the statistics of bundles of wormlike chains  
GREG MORRISON (Presenter), University of Houston — Crosslinked bundles of macromolecules play an important role in a variety of biologically relevant systems, including the flagella that provide locomotion and the microtubules and actin filaments that compose the cytoskeleton. In this talk, I describe a novel method of studying the statistics of weakly-bending, weakly-shearing bundles of stiff polymers using a mean field approach. I show that the imposition of the constraints of inextensibility and inter-filament separation on average leads to an analytically tractable free energy determined by a single wormlike Hamiltonian coupled to an effective Hamiltonian of a cylindrically confined chain, the latter representing the crosslinking between filaments. This gives rise to a bundle free energy that deviates from a typical wormlike chain, depending on a deflection length that couples the filament stiffness and bundle radius. The free energy of an intrinsically twisted bundle is determined for stiff bundles as well, which produces a significant change in the dependence of the free energy on filament stiffness and cross-sectional width. This mean field approach provides new insight into the statistics of bundled macromolecules with a variety of geometric constraints, useful in a number of biological contexts.

10:00AM K30.00009: Configurable Self-Assembly of Block Copolymers at the Liquid-Liquid Interface*  
FELIPE JIMENEZ (Presenter), HA-KYUNG KWON, MONICA OLVERA DE LA CRUZ, Northwestern University — Self-assembly of charged block copolymers has a range of potential applications such as fabrication of reconfigurable patterns in liquid-liquid systems, thin-film nanopatterning, bottom-up nanofabrication, demulsifying and antifoaming in extraction methods, drug delivery, protein encapsulation, among many others. Here we investigate the configurations of amphiphilic block copolymers at the water-chloroform interface using molecular dynamics simulations. The copolymers are constituted by one hydrophilic block and one hydrophobic block. A fraction of monomers ($f_q$) in the hydrophilic block bear a positive elementary charge which is balanced by free counterions. Our model represents the block copolymer poly(styrene)-poly(2-vinylpyridine) (PS-b-P2VP) with a degree of quaternization ($f_q$). A variety of structures going from circular domains to elongated stripes is observed by varying the polymer charge fraction and the hydrophilic/hydrophobic ratio. The adsorption and the structural changes are driven by a combination of effects such as the dielectric mismatch at the liquid-liquid interface, ionic correlations, hydrophilic-hydrophobic forces, and solvation effects.

10:12AM K30.00010: Block and gradient copoly(2-oxazoline) micelles: striking different on the inside  
SERGEY FILIPPOV (Presenter), Harvard University, BART VERBRAEKEN, Department of Organic and Macromolecular Chemistry, Ghent University, PETER KONAREV, DMITRI SVERGUN, EMBL c/o DESY, NATALYA S. VISHNEVSKAYA, CHRISTINE M. PAPADAKIS, Physik-Department, Technische Universität München, SARAH ROGERS, ISIS Facility, Rutherford Appleton Laboratory, AUREL RADULESCU, Forschungszentrum Jülich GmbH, Jülich Centre for Neutron Science JCNS, TIMOTHEE COURTIN, JOSÉ C. MARTINS, Department of Organic and Macromolecular Chemistry, Ghent University, LARISA STAROVOYTOVA, Institute of Macromolecular Chemistry, POTEMKIN POTEMKIN, Physics Department, Lomonosov Moscow State University, RICHARD HOOGENBOOM, Department of Organic and Macromolecular Chemistry, Ghent University — Herein, we provide a direct proof for differences in the micellar structure of amphiphilic diblock and gradient copolymers, thereby unambiguously demonstrating the influence of monomer distribution along the polymer chains on the micellization behavior[1]. The internal structure of amphiphilic block and gradient co poly(2-oxazolines) based on the hydrophilic poly(2-methyl-2-oxazoline) (PMeOx) and the hydrophobic poly(2-phenyl-2-oxazoline) (PPhOx) was studied in water and water-ethanol mixtures by Small-Angle X-ray Scattering (SAXS), Small-Angle Neutron Scattering (SANS), Static and Dynamic Light Scattering (SLS/DLS), and $^1$H NMR spectroscopy. Contrast matching small angle neutron scattering (SANS) experiments revealed that block copolymers form micelles with a uniform density profile of the core. In contrast to popular assumption, the outer part of the core of the gradient copolymer micelles has a distinctly higher density than the middle of the core. We attribute the latter finding to back-folding of chains resulting from hydrophilic-hydrophobic interactions, leading to a new type of micelles that we refer to as micelles with a “bitterball-core” structure.

10:24AM K30.00011: Ionic Phase-segregated Liquid Crystal/Polymer Electrolyte for Lithium-ion Transport*
JIACHENG LIU (Presenter), SUNIL UPADHYAY, MATTHEW WINKLER, YUTING XIA, JENNIFER LYN SCHAEFER, University of Notre Dame — Solid polymer electrolytes have been widely studied for applications in lithium-ion batteries due to the potential for improved thermal and electrochemical stability.[1] Poly(ethylene oxide) (PEO) based electrolytes are the most widely studied solid polymer electrolyte. The conductivity of liquid-free PEO-based electrolytes is limited by ethylene oxide chain segmental motion.[2] In the present work, we seek to investigate lithium-ion transport via a different mechanism, lithium-ion transport through ionic domains. Ionic liquid crystal (LC) model small molecules and related single-ion conducting side-chain polymer electrolytes were synthesized. Small-angle X-ray scattering shows that both the LCs and polymers present segregated ionic phases. Impedance spectroscopy measurements indicate that both materials present Vogel-Tammann-Fulcher temperature-dependent conductivity. Current efforts are focused on macroscopic alignment of ionic phase for mitigation of grain boundary effects and studying the effect of anion structure on lithium-ion transport.

10:36AM K30.00012: Rotational Symmetry Breaking of Complex Polymeric Macromolecules*
JUSTIN LITTLE (Presenter), ROBJEN BRUINSMA, Physics and Astronomy, University of California, Los Angeles, ALEXANDER GROSBERG, Department of Physics, New York University — A generalized version of Flory mean-field theory, supported by numerical simulations, indicates that polymeric macromolecules in good solvent with branches and cycles can show a sequence of spontaneous rotational symmetry breaking transitions as a function of increasing strength of the self-repulsion (J. Kelly, A. Grosberg and R. Bruinsma, submitted to PRL). We present here the analysis of the effect of including thermal fluctuations in the mean-field theory on the nature of these transitions for specific polymeric structures.

*We thank the NSF-DMR under Grant 1006128 and the Simons Foundation for funding.

10:48AM K30.00013: Scalable Production of Internally-Structured and Surface-Active Polymer Colloids via Flash NanoPrecipitation
VICTORIA LEE (Presenter), ROBERT K PRUD'HOMME, RODNEY PRIESTLEY, Princeton University — Production of polymer nanocolloids with complex internal structures or anisotropic surface functionality on large scales has been a challenge which has hindered their implementation in applications from drug delivery and biosensing to oil and gas recovery. We have developed Flash NanoPrecipitation (FNP) as a scalable process which can be used to generate kilograms of such polymer colloids per day. This solvent-exchange process relies on the rapid mixing of a polymer solution with an antisolvent stream to produce supersaturated conditions which result in monodisperse polymer colloids. Additional complexity can be achieved using the same low-cost equipment by taking advantage of the phase separation of chemically distinct polymers. Janus, core-shell, patchy, and lamellar morphologies have been produced by incorporating a blend of homopolymers or block copolymers into the system, and hydrophilic coronas can be generated via the use of amphiphilic block copolymers. Amphiphilic Janus colloids have recently been created by combining the phase separation behavior of hydrophobic polymers with the adsorption of amphiphilic block copolymers on one domain. These colloids are surface-active in oil-water mixtures and show promise as Pickering emulsion stabilizers.

Session K31 DCP: Biomagnetic Chemical Sensing (QIS3) BCEC 203 - Michael Berman, Air Force Office of Science Research - Tag(s): Focus

8:00AM K31.00001: Quantum Biochemical Compasses [Invited] CHRISTIANE TIMMEL (Presenter), Oxford University — tbd
8:36AM K31.00002: Observations of Coherence in Bacterial Reaction Centers Using Two-Dimensional Electronic Spectroscopy*  
VERONICA POLICHT (Presenter), ANDREW NIEDRINGHAUS, JENNIFER P OGILVIE, Department of Physics, University of Michigan — Bacterial reaction centers (BRC) are photosynthetic proteins which perform electronic energy and charge transfer at ultrafast timescales (fs - ps) with near unity quantum efficiency in wild type proteins. Several recent observations of coherences in BRCs and other photosynthetic proteins have proposed that coherent superposition states are partly responsible for the impressive functionality of these systems. In attempting to answer this question, conflicting origin assignments of the coherences have been proposed. In order to develop our understanding of coherences we have performed Two-dimensional electronic spectroscopy on BRCs from purple bacteria *Rh. capsulatus* and its predominant pigment Bacteriochlorophyll a (BChla). We are able to identify strong intramolecular vibrational contributions in both systems as well as signs of vibronic coherence in the BRC. We additionally resolve the weak upper-excitonic peak of the strongly coupled special pair in the BRC, made visible due to resonance of vibrational modes with excitonic energy gaps. We simulate the signatures of vibronic coherence using a reduced BRC model. These results should inform future efforts to model electronic structure of the BRC.

*We gratefully acknowledge funding from the National Science Foundation (No. 1305450).

8:48AM K31.00003: Optical Tweezers: from Biophysics to Chemical Physics.  
MARIA KAMENETSKA (Presenter), Physics and Chemistry, Boston University, JACOB BLACK, ALEXANDER PAROBEK, ZIAD GANIM, Chemistry, Yale University — Optical Tweezers have resulted in transformative mechanistic understanding of biological processes by allowing unambiguous and reproducible measurements on single molecules. Using this technique, we can trap and isolate a single molecule away from surface heterogeneities and manipulate it with nanometer resolution and piconewton control. The application of this powerful technique to solution-phase chemistry and materials characterization has been hampered by the inability to achieve stable trapping in organic solvents. Here, I present our recent advances in extending optical tweezers to experiments on single molecules in a variety of solvents. Furthermore, I report on our preliminary measurements of optically-induced forces and demonstrate that force-detected absorption spectroscopy allows for nanoscale mapping of absorption profiles.

9:00AM K31.00004: The interplay between magnetism and chemical binding  
SUDIPTO CHAKRABARTI (Presenter), Weizmann Institute of Science — Single molecule spintronics aim to identify new spin transport effects near the limit of electronic component's miniaturization. While the focus in this field is on magneto-transport properties, not much is known about the effect of magnetism on the structure of molecular conductors. Here, we reveal a new phenomenon: the direction of applied magnetic field can affect the properties of a metal-molecule chemical bond. Specifically, we show that magnetic field direction affects the formation of metal-single molecule-metal junctions and the stability of the metal-molecule bond. Our findings reveal the interplay between magnetism and chemical binding at the level of a single chemical bond.

9:12AM K31.00005: Infrared spectroscopic nano-imaging of molecular coupling and dynamics in poly-tetrafluoroethylene  
SVEN A DOENGES (Presenter), BERND METZGER, JUN NISHIDA, ERIC A MULLER, MARKUS B RASCHKE, Department of Physics, Department of Chemistry, and JILA, University of Colorado - Boulder, Boulder, CO, United States — In organic materials, local morphology and environment determine material properties through intra- and intermolecular coupling. Vibrational spectroscopy can be used as a sensitive probe to variations in molecular structure, coupling, and dynamics. However, conventional far-field spectroscopic imaging spatially averages over the molecular ensemble, obscuring the effects of the local chemical environment. Here, we use broadband and ultrafast scattering scanning near-field optical microscopy (s-SNOM) to image nanoscale heterogeneity in the technologically important polymer of polytetrafluoroethylene (PTFE). Probing symmetric and antisymmetric coupled C-F stretch vibrations, from their variations and correlations in vibrational solvatochromism we reveal spatial sub-ensembles and their arrangements from nanometer to micron length scale of ordered and disordered domains in as cast, stretched, and rubbed PTFE films. The work demonstrates the use of vibrational marker resonances as intrinsic labels and molecular rulers as sensitive probes of their local structural environment associated with materials functional properties.
9:24AM K31.00006: Scanned Probe Microscopy Studies of MoS2 Catalysis on Insulating Substrates*  STEVEN ARIAS (Presenter), TAN DAO, SHAWNA HOLLEN, University of New Hampshire — Molybdenum Disulfide (MoS2) is one of the most commonly used commercial hydrodesulfurization (HDS) catalysts, but a microscopic understanding of the active sites and reaction mechanisms has been difficult to develop. Understanding these reactions on an atomic scale provide guidance to catalyst design. Improving HDS catalyst design will also rely on our knowledge of the catalyst on industrially relevant, insulating substrates. We will present data from scanning tunneling microscopy and non-contact atomic force microscopy on exfoliated MoS2 flakes on a silicon dioxide substrate. To determine active sites for HDS, we introduce thiophene molecules that adsorb to the MoS2. This system provides the first opportunities for atomic scale catalysis studies on industrially-relevant substrates.

*Acknowledgment is made to the Donors of the American Chemical Society Petroleum Research Fund for support (or partial support) of this research.

9:36AM K31.00007: Investigating Tunneling Controlled Reactions with Ring Polymer Molecular Dynamics  XINYANG LI (Presenter), PENGFEI HUO, Chemistry, University of Rochester — Here we present an ab-initio on-the-fly rate constant computation on the decay of methylhydroxycarbene with Ring polymer molecular dynamics (RPMD). Experiments show that hydroxycarbenes can decay rapidly through a high but thin barrier instead of a lower but broader barrier at 11 K. We investigate the tunneling of the transferring proton with RPMD which can accurately describe nuclear quantum effects. Quantum free energy profiles and transmission coefficients are computed in order to construct the full rate constants. We compute RPMD reaction rates at various temperatures which agree with previous experiments and theoretical studies.

9:48AM K31.00008: Self-assembling Ordered Arrays of Virus-like Particles Mediated by Linkers*  NICHOLAS BRUNK (Presenter), Intelligent Systems Engineering, Indiana University Bloomington, MASAKI UCHIDA, TREVOR DOUGLAS, Department of Chemistry, Indiana University Bloomington, VIKRAM JADHAO, Intelligent Systems Engineering, Indiana University Bloomington — Virus-like particles (VLPs), themselves self-assembled from protein subunits, can be exploited to generate hierarchical functional materials for applications in catalysis and photonics. We present an integrated experimental and computational method to understand and control higher-order VLP assembly into three dimensional, ordered arrays that is applicable to a variety of VLP-linker systems. Specifically, we study the assembly of bacteriophage P22 VLPs mediated by oppositely-charged, macromolecular dendrimers. The integrated approach demonstrates VLPs self-assemble into ordered arrays in the presence of dendrimers as the ionic strength is lowered below a threshold value. This threshold may be tuned by genetically engineering the VLP surface charge. At threshold, the common lattice structure exhibits the same long-range order and a similar configuration of bridging dendrimers, regardless of the VLP surface charge. The experimentally-validated model identifies key electrostatic and kinetic mechanisms, predicting dendrimer concentration as a control parameter for modulating assembly. The integrated approach opens new design and control strategies to fabricate active hierarchical materials.

*This work is supported by the National Science Foundation through Awards 1720625 and 1753182.

10:00AM K31.00009: Scaling relations quantify the hierarchical self-assembly of capillary-densified nanofiber arrays into shape-tunable architectures  ASHLEY KAISER (Presenter), ITAI Y STEIN, KEHANG CUI, BRIAN L WARDLE, Massachusetts Institute of Technology — Capillary-mediated densification is a facile and versatile method to create high-density, hierarchical structures from nanofiber (NF) arrays, such as aligned carbon nanotubes, whose exceptional intrinsic properties motivate their use as shape-tunable materials. Here, scaling relations are presented that accurately predict the morphology of capillary-densified NF arrays exhibiting multiple spatial scales, including long-range cellular networks formed from bulk-scale arrays, and solid, micron-scale pins formed via the densification of patterned arrays within the critical pattern size separating cell vs. pin formation. Both experiments and models show that the effective elastic modulus of the densifying NF arrays governs the resulting geometries, including the cell width and area, cell and pin wall thickness, and the NF volume fraction within the densified walls, which increase monotonically with array height. Further structural tunability, including the densification of mm- to cm-tall NF arrays, is possible by altering the NF-substrate adhesion strength. Collectively, these results could enable the broad use of capillary densification to predictably pattern hierarchical NF arrays for applications in optoelectronics, composite reinforcement, and advanced thermomechanical devices.
10:12AM K31.00010: Optical properties of free base tetrasulfonatofenil porphyrin (H2TPPS4), and tetrapyridyl porphyrin (H2TPyP) with ruthenium group

EHSAN ZOLGHADR (Presenter), KESHAV SHARMA, University of Alabama, JEFFERSON MARCIO SANCHES LOPES, Federal University of Pará, RENATO NEIVA SAMPAIO, University of North Carolina at Chapel Hill, ALZIR AZEVEDO BATISTA, Federal University of São Carlos, AMANDO SIUITI ITO, University of São Paulo, NEWTON M BARBOSA NETO, Federal University of Pará, PAULO T ARAUJO, University of Alabama — Recently we proposed new insight to the absorption and fluorescence (FL) of free base tetrapyridyl porphyrin (H2TPyP). In this project, we extend our study to the free base tetrasulfonatofenil porphyrin (H2TPPS4), and to supramolecular structure composed by H2TPyP and four ruthenium groups ([RuCl(terpy)(PPh3)2]PF6). Despite the fact that literature has reported the transitions observed in porphyrins’ absorption and fluorescence spectra, a more accurate interpretation has been evasive and still needed for H2TPPS4 and [RuCl(terpy)(PPh3)2]PF6 systems. We found that these systems follow our recent findings for H2TPyP where each of the absorption Q-bands consist of two quasi-degenerated bands namely Qx1, Qx2 and Qy1, Qy2, respectively. We also explore the FL and its polarization degree (polarization components) via the Stokes spectroscopy method. Using the Stokes method, we found that the FL polarization degree depends on the concentration of the molecules in the solvent. In order to elucidate the polarization mechanisms, further investigations are being conducted via polarization-resolved, temperature-dependent and lifetime spectroscopy experiments.

10:24AM K31.00011: Spin Crossover Predictions in Transition Metal Complexes using the Density Corrected DFT*

LUIS SORIANO (Presenter), ALBERTO VELA, Center for Research and Advanced Studies of the National Polytechnic Institute — The phenomenon of spin-crossover (SCO) in transition metal complexes is of great importance in the development of magnetic materials whose properties are used in visualization, memory, and electrical devices, to mention a few. This phenomenon has been amply studied with Density Functional Theory (DFT) using a broad variety of exchange-correlation (XC) functionals with disappointing outcomes. Such functionals seem incapable of predicting reliably the energy differences between the high- and low-spin configurations. Recently, an approach called HF-DFT, which consists of evaluating the energy of a selected XC functional with the Hartree-Fock (HF) density, has been applied successfully to several problems, including SCO in some iron complexes with small ligands, yielding results that are close to coupled cluster (CC) and Diffusion Monte Carlo calculations, at a much lower computational cost. In this work we show that HF-DFT, using DFT optimized geometries, also offers an excellent alternative to describe SCO in manganocenes with ligands in the cyclopentadienyl rings going from hydrogen to tert-butyl. The results are in excellent agreement with available CCSD calculations.

10:36AM K31.00012: Resonance Energy Transfer on a Metallic Thin Film: Characteristic Distance and the Origin of Plasmon Enhancement*

LIANG-YAN HSU (Presenter), Institute of Atomic and Molecular Sciences, Academia Sinica, JHIH-SHENG WU, physics, Georgia State University — Resonance energy transfer (RET) around metallic structures has received considerable attention during the past few years. In this study, we analyze the mechanisms of RET on a metallic thin film in the framework of macroscopic quantum electrodynamics and investigate the distance dependence of RET enhancements. Our theoretical analysis shows that the mechanisms of RET can be separated into mirror dipoles, surface plasmons, and retardation. Besides, we find the characteristic distance of RET coupled with surface plasmon polaritons and it can be modified by varying the thickness of thin film, indicating that RET can be significantly enhanced at a short range.

Session K32 DCP: Accurate Methods for Vibrational Analysis (C) BCEC 204A - Julien Bloino - Tag(s): Focus
8:00AM K32.00001: Collocation Methods for Computing Vibrational Spectra* [Invited] TUCKER CARRINGTON (Presenter), ROBERT WODRASZKA, Queen's University — When the potential energy surface (PES) does not have a special form (e.g. a sum of products), it is common to use quadrature to compute a vibrational spectrum. Direct-product quadrature grids are most popular. The size of a direct-product grid scales exponentially with the number of atoms and it is not possible to store values of the PES for molecules with more than 5 atoms. One option is to use a Smolyak quadrature grid. In this talk, I shall present collocation methods with Smolyak-type grids. Collocation has advantages: 1) point selection is less important; 2) no integrals, no quadratures, no weights; 3) easy to use with complicated kinetic energy operators; 4) it can be used with any (the best possible) coordinates and basis functions; 5) in many cases fewer collocation than quadrature points are required; 6) the length of the vectors one must store is reduced. Collocation can be used with the Multiconfiguration Time-Dependent Hartree (MCTDH) approach. The collocation-based MCTDH method I shall present can be used with general potential energy surfaces. This is imperative if one wishes to compute very accurate spectra. When the basis is good, the accuracy of collocation solutions to the Schrödinger equation is not sensitive to the choice of the collocation points. The original collocation-MCTDH (C-MCTDH) method [J. Chem. Phys. 148, 044115 (2018)] uses, as is also true in standard MCTDH, a direct product basis. Because we do not rely on having a sum-of-products potential energy surface, we also have a direct product grid. By using generalized hierarchical basis functions, that span the same space as the single particle functions we introduced in the first C-MCTDH paper, and a Smolyak grid, we have developed C-MCTDH approach that makes it possible to prune both the basis and the grid.

8:36AM K32.00002: On a New Path to Computing the Vibrational Spectra of PAHs* [Invited] RYAN FORTENBERRY (Presenter), Department of Chemistry & Biochemistry, University of Mississippi, JOSHUA P. LAYFIELD, Department of Chemistry, University of St. Thomas (MN), TIMOTHY J LEE, MS 245-3, NASA Ames Research Center — Polycyclic aromatic hydrocarbons are big, largely amorphous, and ubiquitous. This makes them both incredibly important (notably for environmental science and astrophysics) and incredibly difficult to precisely describe the infrared spectral features of a single unique PAH specimen type in the laboratory. Quantum chemical computations have recently demonstrated the ability to produce vibrational frequencies for a selection of molecules to as good as within 1.0 cm⁻¹ of experiment and can do so conclusively for a single molecule since only one chemical system is input into the computations. However, these computations are incredibly costly making them applicable only to small molecules. Recent work in our group has shown that newer quantum chemical theory such as explicitly correlated methods (F12b) can be utilized effectively to produce experimentally-comparable vibrational frequencies at a reduced cost, but this still only extends the sizes of the molecules to be studied potentially up to benzene. However, reparameterized semi-empirical methods designed solely to treat hydrocarbons are showing promise in predicting the spectra of small molecules with a significant savings in time. Successes include c-C₃H₂, C₃H₅⁺, and HOCO⁺ among others. These methods are currently being extended to PAHs.

9:12AM K32.00003: Ab initio methods targeting strong electron- and nuclear-correlation in spectroscopy* [Invited] MARKUS REIHER (Presenter), ETH Zurich — The density matrix renormalization group (DMRG) has emerged as an important alternative to multi-configurational self-consistent-field calculations in molecular spectroscopy, replacing standard complete active space approaches for large orbital spaces. We implemented a spin-adapted matrix-product-state (MPS) and -operator formulation of the DMRG, which serves as a flexible and efficient basis for the development of an MPS state-interaction approach for optical spectroscopy and of a short-time resonance Raman spectroscopy model. We extended our approach to vibrational spectroscopy and I will discuss how the DMRG can be exploited to optimize vibrational wave functions expressed as matrix product states.

*Support from ETH Zurich and the Swiss National Science Foundation is gratefully acknowledged.
9:48AM K32.00004: Computational Methods for Excited State Time-Resolved Vibrational Spectroscopies  
ALESSIO PETRONE (Presenter), FEDERICO COPPOLA, FULVIO PERRELLA, NADIA REGA, Chemical Sciences, University of Naples Federico II — Time-resolved Infrared (IR) and Raman\(^1\) spectroscopies, have become increasingly important in modern chemical, biological, and materials research. This modern focus is primarily due to their capability to study non-equilibrium structural dynamics of ultrafast chemical phenomena.\(^2\)

A computational approach based on both \textit{ab-initio} molecular dynamics and transient vibrational analysis is presented to establish a time-dependent density functional theory (TDDFT) based protocol able of describing simultaneously transient IR and Raman active vibrational modes. This work relies on the recent method development for the evaluation of higher-order TDDFT properties and multiresolution time-frequency analysis.\(^3\)

Excited state photo dynamics of prototypical molecules in gas phase will be used as test cases, showing the evolution of the vibrational \textit{signatures} upon the excitation. This protocol is critical to understand how nuclear motions can mediate the photo-dynamics of several photo-active systems.

10:00AM K32.00005: Gadolinium Cation (Gd\(^+\)) Reaction with CO\(_2\): Potential Energy Surface Mapped from Experiment and Theory  
MARIA DEMIREVA (Presenter), PETER B ARMENTROUT, University of Utah — Understanding the activation of CO\(_2\) is of interest because of the role of CO\(_2\) as a greenhouse gas and its potential use as a carbon source in chemical synthesis. In gas phase experiments, the interactions and thermochemistry of CO\(_2\) with metals can be probed without complicating effects from solvent or substrate molecules. Such studies can provide details about the activation processes at a molecular level. This information can potentially be extended to more complicated systems and be valuable in the design of new and improved catalysts. Here, guided ion beam tandem mass spectrometry is used to investigate the energy dependent reaction of gas-phase lanthanide gadolinium cation (Gd\(^+\)) with CO\(_2\) to form GdO\(^+\) and CO. Results show that ground state products are formed in an exothermic and barrierless process, with an electronically excited product ion produced efficiently at high collision energies. Additional experiments on the reverse process as well as Gd\(^+\)(CO\(_2\)) and O\(\text{Gd}^+(\text{CO})\) intermediates allow for an experimental potential energy surface to be determined. Electronic structure calculations help identify the structures and electronic states of these species and help explain the reactivity observed. Periodic trends in reactivity will be briefly discussed.

AMRO DODIN (Presenter), ADAM P. WILLARD, Chemistry, MIT — The statistics of open quantum systems are determined by the interplay of classical uncertainty, describing the lack of knowledge of the initial preparation of the system and bath, and quantum uncertainty, originating from the wave-mechanical nature of quantum states. In this presentation, a classical probability distribution on quantum state space will be defined that separately encodes classical and quantum sources of uncertainty. The dynamics of such distributions will then be explored, revealing similar properties to Hamiltonian classical mechanics. In particular, the dynamics of closed systems is shown to be incompressible and time reversible, proving a quantum analog to the classical Liouville’s theorem and framing quantum microreversibility equivalently to classical systems. This enables the application of tools from classical mechanics, statistical physics and fluid mechanics to quantum systems with applications in quantum information science and quantum thermodynamics.
10:24AM K32.00007: Vibronic Structure and Photoelectron Angular Distribution in the Photoelectron Spectrum of ICN

SOUMITRA MANNA (Presenter), SABYASHACHI MISHRA, Department of Chemistry, Indian Institute of Technology Kharagpur — In some molecular systems, the complex vibronic structure of photoelectron bands demand extensive theoretical and computational efforts to delineate the interactions between vibrational degrees of freedom and electronic motion, further complicated by coupling of orbital and spin momenta of the electrons. The photoelectron spectroscopy of ICN has been a very challenging problem that has received a lot of attention. However, a conclusive interpretation of the spectrum, in particular, the complex spin-vibronic structures of the B 2Π3/2 and B 2Π1/2 states, has remained elusive. In this presentation, we will explain the complex vibronic structure of ICN by analyzing the Dyson orbitals corresponding to the ionized electrons. The simulated spectra have been found to successfully reproduce the position and intensities of the main four photoelectron bands along with the associated vibronic structures. The shape resonances seen in the experimental asymmetry parameters and the trends of ionization cross-section with increasing electron kinetic energies are explained in terms of the partial wave analysis of the departing photoelectron and the contribution of allowed photoelectron angular momentum channels to the ensuing photoelectron wave function.

10:36AM K32.00008: Quantum Dynamics of Fluorescence Coupled with Surface Plasmon Polaritons and Intramolecular Vibrations

SIWEI WANG (Presenter), Chemistry, Princeton University, LIANG-YAN HSU, Institute of Atomic and Molecular Sciences, Academia Sinica, GREG SCHOLES, Chemistry, Princeton University — We study quantum dynamics of molecular fluorescence on a metal surface based on macroscopic quantum electrodynamics and explore the Purcell factor including non-Markovian effect (beyond Fermi's golden rule). The method we present is general for molecular fluorescence in a variety of plasmonic nanostructures (not limited to metal surfaces). Furthermore, the proposed method allows us to express memory kernels in terms of the parts of surface plasmon polaritons and molecular vibrations and enables us to calculate the kernels via classical electrodynamics, e.g., finite-difference time domain method. We find that, under different strengths of exciton-polariton couplings, the interplay of surface plasmon polaritons and molecular vibrations can lead to distinct characteristics in dynamics. Our study also provides a direction for exploring the effect of vibrational coherence on plasmon-enhanced molecular fluorescence.

BCEC 204B - Ali Gokirmak

8:00AM K33.00001: Evidence of Charge Trapping Giving Rise to Resistance Drift of Metastable Amorphous Ge2Sb2Te5

RAIHAN SAYEED KHAN (Presenter), SADID MUNEER, NAFISA NOOR, HELENA SILVA, ALI GOKIRMAK, University of Connecticut — Phase change memory (PCM) is a high speed, high density, scalable non-volatile memory that utilizes the resistivity contrast between amorphous (high resistivity) and crystalline (low resistivity) phases of chalcogenides like Ge2Sb2Te5 (GST) [1]. The large resistivity window enables programming to intermediate states and hence multi bit storage; however, PCM suffers from spontaneous resistance drift after amorphization [2,3] potentially resulting in overlapping resistance levels. It is difficult to be understand resistance drift from room temperature measurements as multiple processes may be occurring simultaneously, presenting a need for cryogenic measurements. We monitor resistance drift in GST line cells for up to ~10^4 s from 175K to 300K at 25K intervals with varying light exposure. The resistance drift coefficients decrease with decreasing temperature. Light exposure alters cell resistivity at a time scale longer than expected from thermal effects at these temperatures, suggesting a charge-trapping mechanism.

8:12AM K33.00002: Heat transfer as coupling mechanism in VO$_2$-based neurons* JAVIER DEL VALLE GRANDA (Presenter), YOAV KALCHEIM, PAVEL SALEV, IVAN SCHULLER, University of California, San Diego — Neuromorphic computing is a new computation paradigm which imitates the architecture of biological brain. One of the basic tasks is to find materials that mimic the functionality of the two basic components of neural networks: neurons and synapses. Resistive switching offers a unique opportunity to do this. Non-volatile resistive switching has been extensively studied and successfully used to mimic synaptic behavior. On the other hand, finding resistive-switching based neurons has remained an elusive task. Current hardware neurons are based on complex, not-scalable CMOS circuits. In this work, we show how volatile resistive switching in VO$_2$ can be used to do such task. We use heat as a memory mechanism to implement “leaky integrate and fire”, a basic neural functionality. By keeping VO$_2$ nanodevices at the edge of firing and using heat transfer as coupling mechanism, we show signal self-amplification when voltage spikes are transferred form one neuron to the next. This result is key towards the construction of completely scalable, resistive-switching based neuromorphic hardware.

8:24AM K33.00003: Electrical Characterization of Ge$_2$Sb$_2$Te$_5$ Phase Change Memory Cells at Cryogenic Temperatures to Investigate the Physical Phenomena that Give Rise to Resistance Drift of the Amorphous Phase* ABM HASAN TALUKDER (Presenter), RAihan SAYEED KHAN, SADID MUNEER, KIMBERLY NGUYEN, MADISON NADOLNY, ALI GOKIRMAK, HELENA SILVA, University of Connecticut — Electrical measurements of metastable amorphous Ge$_2$Sb$_2$Te$_5$ in the temperature range of 300 - 675 K using a waveform tailored to melt, quench and characterize cells in a single shot [1] have resulted in characterization of temperature dependent carrier activation energies that follow a parabolic behavior with a peak value of ~377 meV at ~465 K [2]. Measurements of cells amorphized at cryogenic temperatures give insights about the physical phenomena that give rise to resistance drift of the amorphous phase as well as the activation energy in a broader temperature range. We have performed electrical measurements in 85 – 300 K temperature range and observed resistance drift over time. As the viscosity of the material is expected to be extremely high at 85 K, we expect charge trapping to be the dominant factor for drift in amorphous Ge$_2$Sb$_2$Te$_5$.

8:36AM K33.00004: Characteristics and applications of carbon-based ReRAM* PEI-FANG CHUNG (Presenter), MONSHU HO, Physics, National Chung Hsing University — In this work, we anticipate the performance of fullerene molecules could provide a new prototype of the Carbon-based ReRAM model owing to its outstanding electric and magnetic characteristic. Few layers of fullerene molecules ($C_{84}$) ultrathin film were assembled thermally on Si (111)-7×7 substrates under ultra-high vacuum. The top-electrode Pt (50nm) was deposited by RF magnetron sputtering on $C_{84}$ film. The surface electronic states and magnetic characteristics of $C_{84}$ film were studied by UHV-STM and MFM. The STS has revealed the wide band gap of fullerene molecule in which the LDOS can be tuned by different cover density and different combination of fullerene molecules. The ferromagnetic domain has been discovered along the domain boundaries on proposed Si substrate due to the quantum confinement along with localized unpaired electrons in fullerene molecules. The resistance switching behavior of the memory devices were attributed to the formation and rupture of conductive filaments. Thus, we characterized the binding feature and the photoelectric properties with Raman, XPS and VT-PL. We could declare fullerene molecules have potential as a promising candidate for next generation nonvolatile memory and other semiconductor applications.

Finite Element Modeling of Ovonic Switching* JAKE SCOGGIN (Presenter), HELENA SILVA, ALI GOKIRMAK, ECE, UConn — Ovonic switching in amorphous semiconductors was first reported in the 1960s [1] and has since spawned phase change memory, ovonic threshold switches, and a rich debate on the physical phenomena underlying the rapid transition from low to high electrical conductivity in these materials once a sufficient field is applied [2]. We model ovonic switching as a field-assisted thermal phenomenon in 2-D, 2-D rotational, and 3-D finite element simulations. We vary fields, geometries, and transient conditions and obtain I-V characteristics in good agreement with experimental data. We also show 2-D simulations of ovonic switches as current-limiting access devices for reset and set of phase change memory cells in a crossbar array using our finite element phase change model [3], [4].

On attractor states in the dynamics of pulse-driven memristors YURIY PERSHIN (Presenter), Physics and Astronomy, University of South Carolina, VALERIY SLIPKO, Institute of Physics, Opole University — We predict the existence of attractor states in the dynamics of certain pulse-driven memristors (resistors with memory) and memristive networks [1]. A general approach to identify the attractor points in two-terminal memristive circuits driven by alternating polarity voltage or current pulses has been developed and applied to several model cases including the ideal and threshold-type memristors, as well as certain memristive networks. Potential applications of dynamical memristor attractors include the memristor initialization, associative memory, and validation of memristor models, to name a few. In particular, based on specific cases we have demonstrated that the presence or absence of attractor dynamics can be directly related to the window function used in the memristor model. This result paves the way towards a simple experimental test of memristor models, which is just one of several promising applications of dynamical memristor attractors.

Finite Element Simulation of Phase Change Memory Cell* MD TASHFIQ BIN KASHEM (Presenter), JAKE SCOGGIN, SADID MUNEER, HELENA SILVA, ALI GOKIRMAK, University of Connecticut — We perform finite element simulations of read, reset and set operations on Ge2Sb2Te5 phase change memory cells using the model developed in [1], [2]. An electrical circuit model is included to utilize a transistor as an access device. Thermoelastic effects (Thomson and Peltier heat) are incorporated in the current continuity and heat transfer physics which are solved self-consistently to obtain potential and temperature distributions across the device. We use temperature dependent material parameters (Seebeck coefficient, thermal conductivity and electrical resistivity) to precisely model electrothermal phenomena in the cell. We perform successive read, reset and set operations and analyze nucleation, growth and amorphization as well as temperature and resistance profiles during the simulations.

Enhanced Reset Variability in Phase Change Memory for Hardware Security Applications

NAFISA NOOR, SADID MUNEER, RAHAN SAYEED KHAN, ALI GOKIRMAK, HELENA SILVA (Presenter), Electrical and Computer Engineering, University of Connecticut, Storrs, CT 06269, USA — Phase change memory (PCM) relies on the change of resistance of a chalcogenide material, that can be reversibly switched between amorphous and crystalline states by applying appropriate electrical pulses. We have experimentally shown enhanced variability during the amorphization hexagonal close packed (hcp) Ge$_2$Sb$_2$Te$_5$ line cells by using long-narrow cell dimensions and voltage pulses with narrow rise and fall times. Percolation-blocked conduction in long-narrow cells, parasitic capacitive current, and thermal runaway at the onset of melting from the initial hcp state are the possible physical mechanisms behind the significant increase of reset uncertainty, which is useful for implementing hardware security primitives$^{1-4}$.

A simple and highly-scalable artificial neuron using an Ovonic Threshold Switch (OTS)*

SUYOUN LEE (Presenter), MILIM LEE, SEONG WON CHO, JOON YOUNG KWAK, HYUNSU JU, Korea Institute of Science and Technology, YEONJIN YI, Institute of Physics and Applied Physics, Yonsei University, BYUNG-KI CHEONG, Korea Institute of Science and Technology — A scalable and low power-consuming artificial neuron is an essential building block for developing a brain-inspired computing system. Among various features of a biological neuron in the mammalian cortex, the spike-frequency adaptation and chaotic activities are very important ingredients for the realization of the energy-efficient signal processing, learning, and adaptation to environments, which are hard to be achieved up to now. In this work, we have demonstrated those features in a simple artificial neuron device composed of an Ovonic Threshold Switch (OTS) and a few passive electrical components. Furthermore, with our OTS-based neuron device employing the reservoir computing technique combined with delayed feedback dynamics, spoken-digit recognition task has been performed with a considerable degree of recognition accuracy. These results show that our OTS-based artificial neuron device is promising for the application in the development of a large-scale brain-inspired computing system.

Development of Self-rectifying TaO$_y$/Nanoporous TaO$_x$ Memristor Synapse for Suppressing Non-neural Signal in the Large-scale Neuromorphic Array System

SANGHYEON CHOI (Presenter), SEONGHOON JANG, KU-KIST Graduate School of Converging Science & Technology, Korea University, JUNG-HWAN MOON, Department of Materials Science and Engineering, Korea University, JONG CHAN KIM, HU YOUNG JEONG, UNIST Central Research Facilities and School of Materials Science and Engineering, Ulsan National Institute of Science and Technology (UNIST), PEONGHWAN JANG, KYUNG-JIN LEE, Department of Materials Science and Engineering, Korea University, GUNUK WANG, KU-KIST Graduate School of Converging Science & Technology, Korea University — Memristor that consists of a metal-oxide layer sandwiched between two conductors is being greatly envisioned as a platform to imitate the principal of biological synapses due to its nonlinear and dynamic electrical properties depending on the history of applied electrical programming$^{[1]}$. In this study, we fabricated the nanoporous (NP) TaO$_x$ memristor device by an anodic treatment in the room temperature and utilized the device as the two-terminal artificial synapses$^{[2]}$. The device exhibits a stable self-rectifying I-V switching behavior with $\sim10^4$ nonlinearity, which can effectively prevent the undesired neural signals in the densely-integrated synaptic array. Based on analog shift of the Ohmic-contact site by diverse electrical stimuli, the essential synaptic functions were successfully mimicked. A 16 × 16 crossbar array with only our device was fabricated and statistically evaluated. In addition, we investigated the effect of the nonlinearity of the synaptic device on the accuracy of the pattern recognition using artificial neural network simulation. Taken all together, we believe the designed device can provide a route toward the large-scale neuromorphic computing technology.

10:00AM K33.00011: Current-induced resistivity switching in VO₂ micro-electronic oscillators  MILINDA PATTANAYAK (Presenter), Department of Physics & Astronomy, Nano Tech Center, Texas Tech University, MD NADIM F HOQUE, ZHAOYANG FAN, AYRTON A BERNUSSI, Department of Electrical and Computer Engineering, Nano Tech Center, Texas Tech University — Functional metal oxides are a class of emerging materials with novel applications in tunable and reconfigurable microelectronics beyond the CMOS technology. Vanadium dioxide (VO₂) is one such material that is attracting considerable attention for its reversible insulator-to-metal phase transition (IMT). Under electrically controlled IMT process VO₂ devices exhibit electrical switching and negative differential resistance (NDR). Such attributes make VO₂ the ideal candidate for designing tunable micro oscillators for emerging applications such as neuro-morphic computing. We designed, fabricated, and characterized planar VO₂ micro-channel devices with different dimensions. The intrinsic parasitic capacitance of the fabricated devices allowed for stable spontaneous electrical oscillations under current actuation. Our novel approach for controlling the current in the NDR region eliminates the need of an external pulsed power source or external passive components to generate self-sustained electrical oscillations. Such reduction in circuitry complexity is significant for prospective large scale on-chip integration of micro- or nano- oscillators that simplifies the power source design and the connection between oscillators and metal interconnects carrying power to the oscillators.

10:12AM K33.00012: Scalable Free-Space Optical Neural Networks* LIANE BERNSTEIN (Presenter), ALEXANDER SLUDDS, RYAN HAMERLY, DIRK R. ENGLUND, Massachusetts Institute of Technology — The transformative impact of deep neural networks (DNNs) in many fields has motivated the development of hardware accelerators to improve speed and power consumption. We present a novel photonic approach based on homodyne detection where inputs and weights are encoded optically and can be reprogrammed and trained on the fly. This architecture is naturally adapted to free-space optics where both fully-connected and convolutional networks can be implemented and scaled to millions of neurons. By utilizing passive optical fan-out and performing arithmetic coherently with optical interference, this scheme circumvents fundamental limits of irreversible electronic processing. We study the effect of detector shot noise on neural-network accuracy to establish a “standard quantum limit” for this system. This bound, which can be as low as 50 zJ/FLOP, suggests performance below the Landauer (thermodynamic) limit is theoretically possible with photonics.

10:24AM K33.00013: Synaptic Barristor Based on Phase-Engineered Two-Dimensional Heterostructures  WOONG HUH (Presenter), SEONGHOON JANG, JAE YOON LEE, DONGHUN LEE, JUNG MIN LEE, HONG-GYU PARK, Korea University, JONG CHAN KIM, HU YOUNG JEONG, UNIST, GUNUK WANG, CHUL-HO LEE, Korea University — Heterostructures built from various two-dimensional (2D) layered materials are emerging material platforms for low-power and high-performance electronic devices because of their high-quality heterointerfaces. Here, we report a new class of artificial synaptic architecture, a three-terminal device consisting of a monolithically integrated WOₓ memristor and a variable-barrier WSe₂/graphene Schottky diode, termed as a 'synaptic barristor'. The device can implement essential synaptic characteristics, such as short-term plasticity and long-term plasticity. Owing to the electrostatically controlled barrier height in the ultrathin vdW heterostructure, the device exhibits gate-controlled memristive switching characteristics with tunable programming voltages of 0.2–0.5 V. Notably, by electrostatic tuning with a gate terminal, we can additionally regulate the degree and tuning rate of the synaptic weight independent of the programming impulses from source and drain terminals. These capabilities enable the accelerated consolidation and conversion of synaptic plasticity, functionally analogous to the synapse with an additional neuromodulator in biological neural networks. Our demonstration represents an important step toward highly networked and energy-efficient neuromorphic circuits.
10:36 AM K33.00014: Resolving the Metal-Insulator Transition Mechanism of NbO2 for Memristor Applications

MATTHEW WAHILA (Presenter), GALO PAEZ, CHRISTOPHER SINGH, SHAWN SALLIS, Binghamton University, JERZY T. SADOWSKI, Center for Functional Nanomaterials, BROOKS TELLEKAMP, ALAN DOOLITTLE, Georgia Institute of Technology, WEI-CHENG LEE, LOUIS F. J. PIPER, Binghamton University — Electroformed NbOx films show potential for memristor applications, however, their memristive mechanism is not understood. NbO2 filaments with a temperature-dependent MIT have been theorized to be the culprit,[1,2] but this has not been proven due in part to a lack of understanding regarding the MIT nature. Crystalline NbO2 undergoes an MIT with accompanying structural transition at ~810°C, but there are competing claims as to whether it is Mott, Peierls, or cooperative Mott-Peierls like VO2.[3,4] We have investigated crystalline NbO2 using synchrotron-based temperature-dependent and variable energy XPS, µ-LEED, and LEEM/PEEM, and have conclusively found it be a gradual 2nd-order Peierls transition. The gradual nature is then attributed to weakening Nb-Nb dimers causing the formation of a pseudogap as temperature increases. Moreover, calculations fully reproduce experimental spectra without explicit consideration of correlations, indicating minimal Mott character.

*This material is based upon work supported by the Air Force Office of Scientific Research under award number FA9550-18-1-0024.

10:48 AM K33.00015: Nb-doped TiO2: Effect of interstitial oxygen atom on charge state of Nb

WEI YAN, XIAOJIE LIU (Presenter), Center for Quantum Sciences and School of Physics, Northeast Normal University — The structural and electronic properties of Nb doped Rutile TiO2 are investigated by first-principles calculations based on density functional theory. Several doping models including 2(NbTi)+Oi, NbTi+Oi, 2(NbTi), and NbTi are investigated. We find that all the doped systems preserve the semiconductor character but have an impurity state inside the band gap. Therefore, the band gaps of the doped systems are reduced by 0.15~1.41 eV, compared to that of the pure rutile TiO2. These results suggest that Nb-doped TiO2 would have higher photocatalytic activity than pure TiO2. The origin of the gap state is different in different doping models. The calculation results show that interstitial oxygen atom play an essential role in manipulating the valence state of Nb impurity. The charge density analysis show that Nb atom in 2(NbTi)+Oi and NbTi+Oi systems can be pentavalent since the Nb atom loses much more electrons due to the interaction with the interstitial oxygen atoms. On the other hand Nb atoms in the NbTi and 2(NbTi) doped systems would be tetravalent.

Session K34 FIAP FECS: Future of Physics and Evolving Careers of Physicists BCEC 205A - Maria Longobardi, University of Geneva - Tag(s): Careers, Industrial, Invited, Undergraduate
8:00AM K34.00001: Emergence by design in artificial spin ice* [Invited] CRISTIANO NISOLI (Presenter), Theoretical Division, Los Alamos National Laboratory — Intriguing phenomena generally emerge from the collective behavior of numerous simple interacting degrees of freedom. Indeed, physicists typically first discover new systems and then proceed to describe them via higher level models that often deliberately neglect the detail of the building blocks. Instead, they concentrate on the relevant symmetries and interactions of an emergent description [1]. Today, advances in nano and micro fabrication, characterization, and control, can invert that approach. We can realize artificial systems whose interacting, elementary degrees of freedom can be tailor-designed for exotic behaviors in their collective, low-energy kinetics. That is the case of artificial spin ice materials [2], which can now be variously manufactured in arrays of magnetic nano-islands [3], trapped colloids [4], vortices in nano-patterned superconductors [5], or possibly with skyrmions in liquid crystals. They can produce new phenomena often non seen in natural materials, such as complex kinetics of magnetic charges and magnetic monopoles [6], new forms of frustration [7], classical forms of topological order [8], dimensionality reduction [9], or ergodicity breaking in absence of quenched disorder. With the goal of eliciting contributions in this field by early career scientists and students we will briefly summarize the fiend and then report on the more recent results.

*LDRD LANL

8:36AM K34.00002: Imaging Quantum Materials* [Invited] MARIA IAVARONE (Presenter), Physics, Temple University — Future technological breakthroughs require innovations aimed at predicting, designing, developing and manufacturing complex materials with multiple functionalities. Materials research is key to answer these societal needs. In quantum materials, the collective behavior of electrons generates a wide range of novel physical properties. Understanding this behavior together with the ability to control the electronic properties of solids has already led to landmark discoveries in condensed matter physics. These discoveries have opened pathways to novel electronic applications of the new materials and devices. The availability of characterization tools, such as scanning probes, which visualize exotic quantum states with high sensitivity and resolution, allows scientists to improve their ability to design, synthesize and understand materials with exotic functionalities. Examples of applications of some of the scanning probe techniques to the field of superconductivity and two-dimensional materials will be presented.

*The work is supported by the Center for Complex Materials from First Principles (CCM), an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award #SC0012575 and by U.S. Department of Energy, Office of Science, Basic Energy Science DE-SC0004556.

Session K35 DQI: Semiconducting Qubits: Interface Characterization BCC5 205B - Patrick Harvey-Collard, Delft University of Technology - Tag(s): Focus

8:00AM K35.00001: A silicon metal-oxide-semiconductor quantum dot patterned with nano-imprint lithography* JOHN ROONEY (Presenter), NICHOLAS PENTHORN, JOSHUA S CHOENFIELD, HONGWEN JIANG, Physics, University of California, Los Angeles — We have transferred the metal gate pattern of a nanoscale depletion mode quantum dot onto a Si/SiO2 substrate with nano-imprint lithography (NIL), eliminating the use of e-beam lithography (EBL) and, consequently, reducing the effects of charge impurities. Critical features with 50 nm scale and separation can be dependably reproduced without making substantial changes to the device design. By studying charge transport through a quantum point contact and quantum dot, the prevalence of impurities was diminished in NIL devices when compared to similar EBL counterparts. Furthermore, 1/f charge noise was measured with an average of 1.4 µeV/√Hz at 1 Hz, equivalent to previous measurements made on EBL devices. This work offers a path toward reliable quantum dot operation in MOS by improving fabrication techniques to reduce charge impurities.

*This work was funded by the U.S. Army Research Office (ARO) through Grant No. # W911NF-17-1-0242

8:12AM K35.00002: Vibrational modes at the Si/SiO2 interface detected by pulse electron spin resonance* MARCO FANCIULLI (Presenter), Department of Materials Science, University of Milano-Bicocca, Milan, Italy, MATTEO BELLI, MDM Laboratory, IMM, CNR, Agrate Brianza, Italy, ROGÉRIO DE SOUSA, Department of Physics and Astronomy, University of Victoria, Victoria, British Columbia, Canada — Electron spin relaxation mechanisms for dangling bonds (Pb centers) at the Si/SiO2 interface in silicon nanowires produced by metal assisted chemical etching have been investigated by pulse electron spin resonance. The increased interface area in the nanowires provides the signal to noise ratio required to detect non-exponential decay of spin magnetization The spin-lattice relaxation rates are reported in the temperature range 4-300 K and the experimentally observed temperature dependence is explained in terms of the excess vibrational modes which manifest as tunneling two level systems (TTLS) giving rise to the so called “boson peak” of the amorphous interface. The experiment together with a theory of the spin relaxation mechanism which involves TTLSs provide a novel method to address the boson peak and other issues related to the role of the TTLSs in determining noise and decoherence in qubits and other sensitive devices.

8:24AM K35.00003: Fidelity of strongly driven electric dipole spin resonance* YASUHIRO TOKURA (Presenter), University of Tsukuba — Coherent control of a single spin confined in a quantum dot (QD) by the microwave electric field (electric dipole spin resonance; EDSR) is an active field of recent research. One of the required mechanisms to couple the orbital motion to the spin degree of freedom is to utilize the slanting magnetic field [1]. J. Yoneda et al.[2] had reported EDSR with a large Rabi frequency up to 100 MHz by optimizing the design of the micro-magnet as well as inducing larger power of microwave. In the largest achievable microwave amplitude, the Rabi frequency is saturated from the expected linear dependence with the microwave amplitude and the fidelity of the Rabi oscillation becomes degraded. Possible origin of this saturation is the non-parabolicity of the confinement potential [3]. In this report, we study the effect of the noise by strongly-driven orbital motion on the fidelity of the spin. In particular, the first (second)-order spin-orbital coupling induces enhanced spin-relaxations (decoherence) with increasing microwave amplitude.

Low power electric dipole spin resonance in silicon: theory

MONICA BENITO (Presenter), University of Konstanz, JASON R PETTA, Princeton University, GUIDO BURKARD, University of Konstanz, XANTHE CROOT, XIAO MI, Princeton University — Control of individual electron spins is one of the cornerstones of spin-based quantum technology. The application of ac magnetic fields allows to drive coherent spin rotations in electrons placed in gate-defined quantum dots, but there is a strong incentive to avoid magnetic driving since it is technically demanding and limits the Rabi frequency due to sample heating issues. Electric dipole spin resonance techniques, which harness some type of spin-orbit coupling to electrically control the electron spin state, provide a more robust possibility [1,2]. Since the intrinsic spin-orbit coupling for electrons in silicon is very weak, the development of novel efficient tools for spin control applicable to silicon based quantum devices is desirable [2-5]. Here, we present a theoretical investigation of an efficient novel mechanism in silicon quantum dots to induce single electron coherent spin rotations relying on an external magnetic field gradient.

Low power electric dipole spin resonance in silicon: experiment

XANTHE CROOT (Presenter), Department of Physics, Princeton University, Princeton, NJ 08544, USA, MONICA BENITO, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany, XIAO MI, Department of Physics, Princeton University, Princeton, NJ 08544, USA, GUIDO BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany, JASON R PETTA, Department of Physics, Princeton University, Princeton, NJ 08544, USA — Spin-based quantum information processing requires exquisite single spin control. While electron spin resonance is a natural means of controlling spin qubits in gate-defined quantum dots, generating localized ac magnetic fields large enough to drive coherent oscillations is challenging. As an alternative, electric dipole spin resonance (EDSR) can be employed [1]. Spin-orbit coupling often mediates EDSR: however, intrinsic spin-orbit coupling in silicon is small. To overcome this, on-chip micromagnets can be used to generate synthetic spin-orbit interactions [2], with EDSR having now been demonstrated in silicon [3, 4]. Here we present experimental results using a new technique for low-power EDSR in silicon with micromagnets, in a step towards scalable power budgets for large-scale spin-based quantum processors.

Charge offset drift in single electron devices containing aluminum oxide

RYAN MATTHEW STEIN (Presenter), Material Science and Engineering, University of Maryland, College Park, YANXUE HONG, Electrical and Computer Engineering, University of Maryland, College Park, BINHUI HU, ANDREW J MURPHY, NEIL ZIMMERMAN, JOSHUA POMEROY, MICHAEL DAVID STEWART, National Institute of Standards and Technology — Single electron devices (SEDs) suffer from a long-time instability, referred to as charge offset drift (ΔQ0), that hampers integration of SEDs in applications such as quantum metrology and computing. Previous measurements of ΔQ0 show SEDs containing aluminum oxide (AlOx) have been less stable than comparable SEDs containing only silicon dioxide (SiO2). Here, we have fabricated two different types of SEDs: all-metal Al/AlOx/Al tunnel junction-based devices and tunable barrier silicon metal-oxide-semiconductor (MOS) devices. The all-metal SEDs contain plasma-oxidized AlOx as the tunnel barrier. The charge offset stability measured on these devices is better than any other reported metallic SEDs, displaying a very small linear ΔQ0 of 0.1e over 7.5 days and two times lower standard deviation. The MOS SEDs are made on a silicon-on-insulator (SOI) substrate with a thermal SiO2 gate oxide, Al gates, and thermal AlOx as an isolation oxide. Four of the five MOS SEDs measured show a linear charge offset drift of less than 0.07 e over 7 days and standard deviations less than 0.02 e. These results suggest the stability of devices made with AlOx may be significantly better than previously thought and that other factors, such as geometry, are playing as large a role as materials.
9:12AM K35.00007: Probing decoherence at an atom-defect quantum interface† XUE HAN (Presenter), ALEC CAO, ALEC JENKINS, DOLEV BLUVSTEIN, University of California, Santa Barbara, SHUO MA, Physics, Princeton University, KUNAL MUKHERJEE, DAVID MINOT WELD, ANIA CLAIRE JAYICH, University of California, Santa Barbara — The atomic-scale quantum properties of interfaces play a central role in the ubiquitous surface-mediated decoherence that currently limits a wide variety of quantum technologies. We have constructed a novel instrument for quantitatively studying decoherence at active quantum surfaces. This hybrid quantum system combines neutral atoms adsorbed onto a diamond surface in ultrahigh vacuum conditions and subsurface nitrogen vacancy (NV) centers. We present measurements of the decoherence and relaxation rates of shallow NV centers interacting with atomic adsorbates deposited at thicknesses varying from angstroms to nanometers. As adsorbate atoms are added, we observe a significant reduction in spin relaxation time. We present progress towards a detailed understanding of coherence at this model quantum interface, with important consequences for a broad range of quantum interfaces.

*DOE BES Quantum Information Sciences program

9:24AM K35.00008: Ultra-thin body buried oxide 28nm FD-SOI platform for silicon quantum dots† CLAUDE ROHRBACHER (Presenter), SOPHIE ROCHELLE, JULIEN CAMIRAND LEMYRE, ALEXANDRE BÉDARD-VALLÉE, PASCAL LEMIEUX, Institut quantique, Universite de Sherbrooke, PHILIPPE Galy, THOMAS BEDECARRATS, FRANCK ARNAUD, Technology and Design Platforms Research and Development Center, STMicroelectronics, DOMINIQUE DROUIN, Departement de Genie Electrique et Informatique, Universite de Sherbrooke, MICHEL PIORO-LADRIERE, Institut quantique, Universite de Sherbrooke & Canadian Institute for Advanced Research — Silicon spin qubits, with their long coherence time and their compatibility with CMOS industrial technology shows great promise for large scale quantum computing and co-integration. Here we present a UTBB FD-SOI platform that is designed to operate as a transistor and host quantum dots. This platform is composed of NMOS structures with wire gate and split enhancement gate geometries, and is entirely fabricated inside STMicroelectronics’ standard process line. We explore various regimes in gate voltage space and demonstrate reproducible operation of multiples devices at 1.5 K and 10m K. We identify various regime for formation of quantum dots including electrostatic single and double quantum dots. We also present a cryogenic characterization of classical FD-SOI transistors that involves variation of mobility, kink effect and split C-V analysis down to 10 mK. These results set a pathway towards improved FD-SOI devices and quantum dots fully fabricated in standard process line.

9:36AM K35.00009: Magnetotransport of metal-oxide-semiconductor devices fabricated on highly enriched 28Si ARUNA RAMANAYAKA (Presenter), KE TANG, HYUN-SOO KIM, Joint Quantum Institute, JOSEPH HAGMANN, National Institute of Standards and Technology, RYAN MATTHEW STEIN, Joint Quantum Institute, MICHAEL DAVID STEWART, CURT A RICHTER, JOSHUA POMEROY, National Institute of Standards and Technology — Isotopically enriched 28Si is regarded as an ideal environment for quantum computation (QC) as elimination of unpaired nuclear spins can result in low error rates for QC. At NIST we have developed a method to grow isotopically enriched 28Si, which provides the unique advantage of targeting a desired enrichment anywhere between natural abundance and the highest possible enrichment > 99.99998 % 28Si isotopic fractions. To explore the electrical properties of 28Si, we fabricate gated Hall bar devices and study the magnetotransport at magnetic fields (B) 12 T and temperatures (T) ranging from 1.2 K to 10 K. The magnetoresistance at |B| ≤ 0.25 T shows maximum mobilities of ≈ 1700 cm²/(V×s) and ≈ 6000 cm²/(V×s) at an electron density of ≈ 2.5×10¹² cm⁻² for devices fabricated on 28Si and natSi, respectively. We use the T dependence of weak-localization and Shubnikov-de Haas oscillations to deduce the dominant scattering mechanisms in these devices. We believe that the lower mobility observed for the devices fabricated on 28Si is due to the dilute adventitious C, N and O detected in 28Si. We will also discuss the preliminary results of fabrication and measurement of gate defined quantum dot devices in 28Si epilayers.
New Linear-Optical Approach to Quantum Information Processing and Quantum Simulation
ALEXANDER SERGIENKO (Presenter), DAVID SIMON, SHUTO OSAWA, Boston University — Linear optical networks formed from beam splitters and phase shifters have been shown capable of carrying out all quantum information processing tasks, but at the cost of rapid growth in resources as the complexity of the task increases. Here, we show that the use of recently introduced directionally unbiased optical multiports (N≥3), where input ports can double as output ports, can achieve results with much more compact setups and with substantial savings in resources. The behavior of such multiports is highly flexible, with a variety of possible behaviors being controlled by a set of parameters that can be changed or tuned in real time. Here we give an overview of the properties and potential applications of these multiports. Applications include their use as high-dimensional coins and lattice sites for quantum walks, new type of logical gates for two-photon entangled states, and elements of optical simulators for solid state systems. We illustrate that the band structures and electronic behavior of a variety of solid state systems, including those with nontrivial topological behavior, can be simulated using relatively compact linear-optical systems based on such directionally unbiased multiports.

Manipulation of entanglement sudden death in an all-optical experimental setup
ASHUTOSH SINGH (Presenter), URBASI SINHA, Raman Research Institute — Entanglement sudden death (ESD) is the phenomenon wherein a multipartite entangled state disentangles in finite time even when individual qubits decohere only asymptotically in time due to noise. Prolonging the entanglement is essential for the practical realization of entanglement-based quantum information and computation protocols. For this purpose, local NOT operation in the computational basis on one or both qubits has been proposed to combat the amplitude damping noise. Here, we aim to discuss an all-optical-experimental implementation of the NOT operations that can hasten, delay, or avert ESD, all depending on when it is applied during the process of decoherence for the polarization entangled photonic qubit system[1]. Further, the preparation and characterization of a polarization entangled photon source instrumental in obtaining the exciting experimental results on the manipulation of ESD along with the attendant theory will be presented.

Implementation and Simulation of Electrostatically Controlled Quantum Dots in CMOS Technology
DIRK LEIPOLD (Presenter), equal1, HANNES LEIPOLD, USC, LUTZ LEIPOLD, equal1, ELENA BLOKHINA, PANAGIOTIS GIOUNANLIS, KRZYSZTOF POMORSKI, ROBERT STASZEWSKI, UCD, IMRAN BASHIR, GEORGE MAXIM, MIKE ASKER, equal1, CAGRI CETINTEPE, ALI ESMAILIYAN, HONGYING WANG, TEERACHOT SIRIBURANON, UCD — A new architecture of a charge qubit suitable for implementation in large scale CMOS circuits is presented. We demonstrate techniques for time-independent / time-dependent simulations of quantum states and transport in such quantum dots. The time-independent technique makes use of a semi-analytical approach in the Schrödinger formalism combining the calculations of the electric field in CMOS structures with a piece-wise potential approximation of eight or more potential wells. The time-dependent technique leverages the semi-analytical approach to obtain the evolution of eigen states in explicit form. The techniques are upgraded to calculations based on the density matrix. This approach allows estimations of transition frequencies, leakage of the wavefunction between quantum states, and decoherence due to finite potentials and asymmetries of CMOS structures. Based on the height of the barrier between the wells, the behavior can be interpreted as semi-classical single electron transport, CNOT quantum gate operation, or quantum annealing. The presented approach allows the design of quantum gates compatible with conventional CMOS technologies and operating at 4K. The structure was standard foundry solution. We describe the implementation including integrated control structure

Session K36 DPOLY: Recent Progress in Polymer Crystallization
BCEC 205C - Toshikazu Miyoshi, The University of Akron - Tag(s): Invited
Observation of scrolled single crystals of even-even nylons helped solve the decades long issue of their negative unbalanced surface stresses in the lamellae fold surfaces. These stresses induce twisted and scrolled lamellae, and very recent examples include the impact and identification of helical hand in crystal structures and the origin of branching, scrolled crystals. Their analysis helps reach some very finer details of the crystalline polymers' buildup. Older these constraints lead to unusual features of their diffraction pattern (e.g. specific streaks) or morphology (e.g. lamellar branching, scrolled crystals). Their analysis helps reach some very finer details of the crystalline polymers' buildup. Older and very recent examples include the impact and identification of helical hand in crystal structures and the origin of unbalanced surface stresses in the lamellae fold surfaces. These stresses induce twisted and scrolled lamellae.

Observation of scrolled single crystals of even-even nylons helped solve the decades long issue of their negative spherulites' architecture.

Shape-Symmetry Incommensurate Polymer Crystals

Crystallization is ubiquitous in nature and semicrystalline polymers are of crucial importance in our daily life. Because of their long chain nature, polymers crystallize via a more complex pathway, leading to profound metastable states and morphology. This talk will focus on polymer crystals whose shape is incommensurate with three-dimensional translational symmetry. Examples are helix, tubes and spheres. Not only can this shape-symmetry incommensurateness arise from the intrinsic characteristics of the crystal such as unbalanced chain folding and/or local stress, it also can be imparted by nanoscale confinement. Both cases will be discussed, and emphasis will be given to the formation mechanism, associated properties and possible applications of these unique polymer single crystals.

In Situ Real-Time Observation of Polymer Folded-Chain Crystallization by Atomic Force Microscopy at the Molecular Level

The crystallization process of a folded-chain crystal (FCC) was clearly visualized at the molecular level in situ and in real time for the first time [1]. We deposited an amorphous isotactic poly(methyl methacrylate) monolayer on mica, and the crystallization of the monolayer under high humidity was followed by atomic force microscopy. Detailed crystallization behaviors, especially, the stepwise growth of the FCC with blocks shorter than the chain, chain slipping in the FCC, the formation of an anisotropic nucleus and its growth, and the formation of a small nucleus with a short lifetime, were clearly visualized at the molecular level. The stepwise growth of the FCC differed from that expected by the classical Lauritzen-Hoffman theory and was consistent with recent reports that indicated the formation of some ordered states in the amorphous phase. In addition, the crystallization process of a poly(lactide), which formed an extended-chain crystal (ECC) in a monolayer was also visualized, and will be discussed.

The self-assembly, melting behavior and crystallization kinetics of polyethylenes with moieties placed at an exact equal distance along the backbone will be presented with especial focus on recent studies of the crystalline properties of precision polyethylenes with halogens (as pendant), and acetics (in-chain) groups under rapid and isothermal crystallization from the melt. The observed discrete minima in the temperature coefficient of the crystallization kinetics correlates with transitions between polymorphic structures that differ in packing symmetry. The minima or retardation of crystallization kinetics may be due to self-poisoning at the growth front or to differences in nucleation and growth between two polymorphs at the transition temperature. Control over different layered crystalline structures, demonstrate the ability of these novel systems to generate new polyethylene-based materials based on nanostructures at the lamellar and sub-lamellar level not feasible in classical branched polyethylenes.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K37 GMAG DCMP DCOMP: Triangular Lattices

8:00AM K37.00001: Hierarchy of Exchange Interactions in the Triangular-Lattice Spin Liquid YbMgGaO₄ [Invited]
FAHAD MAHMOOD (Presenter), XINSHU ZHANG, Johns Hopkins University, MARCUS DAUM, Georgia Institute of Technology, ZHILING DUN, University of Tennessee, JOSEPH PADDISON, Georgia Institute of Technology, NICHOLAS LAURITA, Johns Hopkins University, TAO HONG, Oak Ridge National Laboratory, HAIDONG ZHOU, University of Tennessee, PETER ARMITAGE, Johns Hopkins University, MARTIN MOURIGAL, Georgia Institute of Technology — The spin-1/2 triangular lattice antiferromagnet YbMgGaO₄ has attracted attention recently as a quantum spin-liquid candidate with the possible presence of off-diagonal anisotropic exchange interactions induced by spin-orbit coupling. Whether a quantum spin liquid is stabilized or not depends on the interplay of various exchange interactions with chemical disorder that is inherent to the layered structure of the compound. We combine time-domain terahertz spectroscopy and inelastic neutron scattering measurements in the field-polarized state of YbMgGaO₄ to obtain better insight of its exchange interactions. Terahertz spectroscopy in this fashion functions as a high-field electron spin resonance and probes the spin-wave excitations at the Brillouin zone center, ideally complementing neutron scattering. A global spin-wave fit to all our spectroscopic data at fields over 4 T, informed by the analysis of the terahertz spectroscopy linewidths, yields constraints on the disorder-averaged g factors and exchange interactions. Our results paint YbMgGaO₄ as an easy-plane XXZ antiferromagnet with the combined and necessary presence of subleading next-nearest neighbor and weak anisotropic off-diagonal nearest-neighbor interactions. Moreover, the obtained g factors are substantially different from previous reports. This work establishes the hierarchy of exchange interactions in YbMgGaO₄ from high-field data alone and thus strongly constrains possible mechanisms responsible for the observed spin-liquid phenomenology.
8:36AM K37.00002: Hidden order and its quantum excitations in the triangular-lattice magnet TmMgGaO₄
YAO SHEN (Presenter), CHANGLE LIU, YAYUAN QIN, SHOUDONG SHEN, Fudan University, YAODONG LI, Physics, University of California Santa Barbara, ROBERT BEWLEY, Rutherford Appleton Laboratory, ASTRID SCHNEIDEWIND, Jülich Centre for Neutron Science, GANG CHEN, JUN ZHAO, Fudan University — Certain magnetic materials exhibit exotic hidden-order phases, which are not directly accessible to conventional magnetic measurements due to the lack of internal field. Thus, experimental identification and theoretical understanding of a hidden order are difficult. Here we combine neutron scattering and thermodynamic probes to study the newly discovered rare-earth triangular-lattice magnet TmMgGaO₄. Magnetic Bragg peaks at K points are observed in the elastic neutron diffraction measurements. More interesting, however, is the observation of sharp and highly dispersive spin excitations that cannot be explained by a magnetic dipolar order, but instead is the direct consequence of the preformed multipolar order that arises from a rather weak crystal field splitting and is “hidden” in the conventional magnetic measurements. We demonstrate that the observed unusual spin correlations and thermodynamics can be accurately described by a transverse field Ising model on the triangular lattice with an intertwined dipolar and ferro-multipolar order.

8:48AM K37.00003: Investigating the Dynamic Magnetic Properties of Triangular Antiferromagnet YbZnGaO₄
WILLIAM STEINHARDT (Presenter), SACHITH DISSANAYAKE, ZHENZHONG SHI, Duke University, NICHOLAS BUTCH, Center for Neutron Research, National Institute of Standards and Technology, DAVID E GRAF, National High Magnetic Field Laboratory, YAOHUA LIU, Neutron Scattering Division, Oak Ridge National Laboratory, HONGCHENG LU, CASEY MARJERRISON, SARA HARAVIFARD, Duke University — Recently the antiferromagnetic triangular-lattice family of materials RMM'O₄ (where R = rare earth, M and M' = transition or main group) has attracted much attention, due to their disordered ground state and possible link to quantum spin liquid state. In this talk we present results from our recent field-dependent single-crystal diffuse and inelastic neutron scattering experiments, as well as thermal- and magneto-transport measurements performed on YbZnGaO₄.

9:00AM K37.00004: Elastic and Inelastic Neutron Scattering Study of the Triangular Lattice Ising Antiferromagnet TmMgGaO₄
MARCUS DAUM (Presenter), ZHILING DUN, Georgia Institute of Technology, HAIDONG ZHOU, University of Tennessee, Knoxville, MARTIN MOURIGAL, Georgia Institute of Technology — The LnMgGaO₄ family of materials (with Ln= Yb³⁺, Er³⁺, and Tm³⁺) has been the focus of recent studies in frustrated magnetism due to the combination of anisotropic exchange interactions from strong spin obit coupling, geometrical frustration, and inherent site disorder of Mg²⁺ and Ga³⁺. In order to further understand the original compound, YbMgGaO₄, we have begun to investigate how the non-Kramers ion Tm³⁺ differs from Yb³⁺ when placed in a similar crystal structure. TmMgGaO₄ displays a strong Ising behavior and magnetic scattering at the K-point of the triangular Brillouin zone at T= 0.05K. In this talk, I will present recent neutron scattering results on single-crystals of TmMgGaO₄ that elucidate the temperature and magnetic field dependence of spin correlations in that material.

*This work was supported by NSF Grant DMR 1750186.

9:12AM K37.00005: Gapless chiral spin liquid in spin-1/2 triangular Heisenberg model
SHOUSHU GONG (Presenter), Department of Physics, Beihang University, MAC LEE, DONNA SHENG, California State University, Northridge — We study the ground state of spin-1/2 triangular-lattice antiferromagnet with first- (J₁), second- (J₂), and third-neighbor (J₃) interactions, using large-scale density matrix renormalization group on cylinder geometry. By increasing the couplings, we establish a quantum phase diagram of the system. Besides the previously identified magnetic phases and J₁-J₂ spin liquid, we find a new gapless chiral spin liquid (CSL) phase with growing J₃, which emerges at the neighbor of the J₁-J₂ spin liquid. This CSL spontaneously breaks time-reversal symmetry by showing a robust three-spin scalar chiral order and the chiral edge mode in the entanglement spectrum. The finite-size scaling of spin triplet gap strongly suggests gapless spin excitations, which is further supported by the logarithmic behavior of the subsystem length dependence of entanglement entropy that leads to a finite central charge. The fitted central charge grows rapidly with increasing system width, which does not support a U(1) Dirac spin liquid but indicates an emergent spinon Fermi surface. This CSL realizes an example of interacting topological phase with chiral edge mode and gapless bulk excitations.
9:24AM K37.00006: Anisotropic-exchange magnets on a triangular lattice: dual spin liquids* ALEXANDER
CHERNYSHEV (Presenter), PAVEL MAKSIMOV, ZHENYUE ZHU, STEVEN ROBERT WHITE, University of California, Irvine — We establish a correspondence of the anisotropic-exchange model to an extended Kitaev-Heisenberg model. With the help of Klein dualities, deeper connections between different parts of the parameter space are established. Using these insights, we have performed DMRG studies of the quantum $S=1/2$ anisotropic-exchange model in previously unexplored parts of the phase diagram. The most important implication of the correspondence is that it necessitates an existence of a spin liquid that is Klein dual to the spin liquid found by us earlier. In our present DMRG study, we do confirm existence of this dual spin-liquid phase. With the structure factor $S(q)$, we also confirm that the dual spin liquid can be seen as a result of a melting of the dual 120° phase, same way as the earlier spin liquid is a molten 120° phase. The confirmation of the dual spin liquid strengthens our case for both of them.

*Supported by U.S. Department of Energy, Office of Science, Basic Energy Sciences, Award No. DE-FG02-04ER46174

9:36AM K37.00007: Anisotropic-exchange magnets on a triangular lattice: spin waves and accidental degeneracies* PAVEL MAKSIMOV (Presenter), ZHENYUE ZHU, STEVEN ROBERT WHITE, ALEXANDER CHERNYSHEV, University of California, Irvine — We present an overview of the phase diagram, spin-wave excitations, and finite-temperature transitions of the anisotropic-exchange magnets on a nearest-neighbor triangular lattice. We investigate transitions between five principal classical phases: ferromagnetic, Néel, its dual, and the two stripe phases. Transitions are identified by the spin-wave instabilities and by the Luttinger-Tisza approach. In the stripe phases, quantum fluctuations are mostly negligible, leaving the ordered moment nearly saturated even for $S = 1/2$. However, for a 2D surface of the full 3D parameter space, the spin-wave spectrum in one of the stripe phases exhibits an accidental degeneracy. As a result, the ordering transition temperature in a wide region of the phase diagram is suppressed. This accidental degeneracy is due to a correspondence to an extended Kitaev-Heisenberg model with emergent symmetries.

*Funded by DOE No. DE-FG02-04ER46174

9:48AM K37.00008: Pressure-tuning of the quantum spin Hamiltonian of a triangular lattice antiferromagnet SERGEI ZVYAGIN (Presenter), Dresden High Magnetic Field Laboratory, Helmholtz-Zentrum Dresden-Rossendorf, DAVID E GRAF, National High Magnetic Field Laboratory, Florida State University, TAKAHIRO SAKURAI, Research Facility Center for Science and Technology, Kobe University, SHOJIRO KIMURA, HIROYUKI NOJIRI, Institute for Materials Research, Tohoku University, JOACHIM WOSNITZA, Dresden High Magnetic Field Laboratory, Helmholtz-Zentrum Dresden-Rossendorf, HITOSHI OHTA, Molecular Photoscience Research Center, Kobe University, TOSHIO ONO, Department of Physical Science, Osaka Prefecture University, HIDEKAZU TANAKA, Department of Physics, Tokyo Institute of Technology — Quantum antiferromagnets on a triangular lattice are prototype materials to investigate the phenomena of geometrical frustration in quantum matter. Apart from highly unusual magnetic properties, they possess a very rich phase diagram ranging from a simple unfrustrated square lattice to a quantum spin liquid, yet to be confirmed experimentally. One major obstacle in this area of research is the lack of materials with appropriate (ideally tuned) exchange coupling parameters. Here, we demonstrate an alternative approach where, instead of the chemical composition, the spin Hamiltonian of a triangular lattice antiferromagnet is tuned by hydrostatic pressure. The combination of tunnel-diode-oscillator and electron spin resonance techniques allows us to accurately monitor the spin-Hamiltonian parameters in Cs$_2$CuCl$_4$, revealing a significant increase of its exchange coupling ratio from 0.3 to 0.42 at a pressure of 1.8 GPa. A number of emerging field-induced transitions were observed in the high-pressure phase.
10:00AM K37.00009: Partial Magnetic Order in the Anisotropic Triangular Lattice System CeCd₃As₃  SARAH DUNSIGER (Presenter), TRIUMF, KOLAWOLE AKINTOLA, Department of Physics, Simon Fraser University, ANDRE COTE, Kwantlen Polytechnic University, ALEX FANG, SHAYAN GHEIDI, JEONGHUN LEE, SHYAM SUNDAR, EUNDEOK MUN, JEFF SONIER, Department of Physics, Simon Fraser University — CeCd₃As₃ is one member of a family of rare earth ternary compounds which crystallize into a hexagonal ScAl₃C₃-type structure, where the magnetic Ce-ions form a quasi two dimensional anisotropic triangular lattice. Such model geometrically frustrated systems have been proposed as candidates for quantum spin liquid behavior [1].

We report a muon spin relaxation investigation of the low temperature partially ordered phase and associated spin fluctuations of this material. The growth of an anomalous and sizable magnetic contribution to the specific heat below 10 K in CeCd₃As₃ has been found to correspond to enhancement in the spin lattice relaxation rate, which onsets on a temperature scale 20x the ordering transition. Tuning the conductivity through chemical substitution, we discuss the roles of geometric magnetic frustration, Kondo and Ruderman-Kittel-Kasuya-Yosida (RKKY) interactions in interpreting the response of this Ce based intermetallic compound.

10:12AM K37.00010: Frustrated antiferromagnetic(AFM) order in CeCd₃As₃* KEENAN AVERS (Presenter), Physics, Northwestern University, ROMAN MOVSHOVICH, Condensed Matter and Magnet Sciences, Los Alamos National Laboratory, WILLIAM HALPERIN, Physics, Northwestern University, JOE D THOMPSON, PRISCILA ROSA, Condensed Matter and Magnet Sciences, Los Alamos National Laboratory — The relatively unexplored compound CeCd₃As₃ crystallizes in the P6₃/mmc space group, and has geometrically frustrated triangular arrangements of magnetic cerium atoms in the a/b plane. Magnetization measurements indicate strong out of plane AFM interactions. Our heat capacity, C(T), measurements on a single crystal reveal a sharp peak at Tₙ = 420 mK in zero field, consistent with an out of plane AFM phase transition. Applying a magnetic field within the easy-plane raises Tₙ to 490 mK at 2 T demonstrating lifting of frustration. At high fields Tₙ is suppressed to zero, and C(T) no longer resembles that of an AFM. Instead we observed an excess of entropy at the lowest temperatures measured. These results indicate competition between AFM order and frustration at low fields, and a field induced highly degenerate ground state at stronger fields.

*Work was conducted at Los Alamos National Laboratory under the auspices of the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering. KEA and WPH acknowledge the U.S. Dept. of Energy DE-FG02-05ER46248, and the Northwestern Center for Applied Physics and Superconducting Technology. A portion of this work was supported by the Los Alamos Laboratory Directed Research and Development program

10:24AM K37.00011: Magnon topology and thermal Hall effect in trimerized triangular lattice antiferromagnet* KYUNGSU KIM, KI LEE (Presenter), Seoul National University, SUK BUM CHUNG, Department of Physics, University of Seoul, JE-GUIEN PARK, Seoul National University — Magnon band topology and magnon transverse responses have been studied in two-dimensional magnetisms for the last few years. The magnon band topology of the most well-known frustrated two-dimensional spin model antiferromagnetic triangular lattice has got less attention than its cousin Kagome systems because of the spin-chirality cancellation which prohibits thermal Hall effect.

In this work, we study the band topology and thermal Hall effect of triangular lattice antiferromagnet with the nearest-neighbor exchange and external field using linear spinwave theory. We clarify that the effect PT symmetry forces thermal Hall effect in distortion-free triangular lattice antiferromagnets to zero even when a perpendicular external magnetic field is applied. We show, however, that (anti-)trimerization distortion in antiferromagnetic triangular lattice removes the symmetry and gives nontrivial magnon band topology and the finite thermal Hall effect. Finally, we estimate the thermal Hall effect of triangular antiferromagnets with such distortions YMnO₃ and LuMnO₃.

Selective measurements of intertwined multipolar orders: Non-Kramers doublets on a triangular lattice

CHANGLE LIU (Presenter), Department of Physics, Fudan University, YAODONG LI, Department of Physics, University of California, Santa Babara, GANG CHEN, Department of Physics, Fudan University — Motivated by the rapid experimental progress on the spin-orbit-coupled Mott insulators, we propose and study a generic spin model that describes the interaction between the non-Kramers doublets on a triangular lattice and is relevant for triangular lattice rare-earth magnets. We predict that the system supports both pure quadrupolar orders and intertwined multipolar orders in the phase diagram. We explore the magnetic excitations to reveal the dynamic properties of the systems. Due to the peculiar properties of the non-Kramers doublets and the selective coupling to the magnetic field, we further study the magnetization process of the system in the magnetic field. We point out the selective measurements of the static and dynamic properties of the intertwined multipolarities in the neutron scattering, NMR, and μSR probes and predict the experimental consequences. The relevance to the existing materials such as TmMgGaO₄, Pr-based, and Tb-based magnets, and many ternary chalcogenides is discussed. Our results not only illustrate the rich physics and the promising direction in the interplay between strong spin-orbit-entangled multipole moments and the geometrical frustration, but also provide a general idea to use noncommutative observables to reveal the dynamics of the hidden orders.

Physical properties of the trigonal binary compound Nd₂O₃

GABRIELE SALA (Presenter), MATTHEW BRANDON STONE, BINOD RAI, ANDREW MAY, CLARINA DELA CRUZ, GEORGE EHLERS, VASILE O GARLEA, MARK D LUMSDEN, Oak Ridge National Laboratory, HASITHA SURIYA ARACHCHIGE, Department of Physics and Astronomy, University of Tennessee, VICTOR R. FANELLI, Oak Ridge National Laboratory, DAVID GEORGE MANDRUS, Department of Material Science & Engineering, University of Tennessee, ANDY CHRISTIANSON, Oak Ridge National Laboratory — Nd₂O₃ is a structurally and chemically simple material which crystalizes in a trigonal structure, with Nd³⁺ ions surrounded by cages of 7 oxygen anions. Here we study the physical properties of Nd₂O₃ with neutron diffraction, inelastic neutron scattering, heat capacity, and magnetic susceptibility measurements. The inelastic neutron scattering measurements reveal that the crystal field spectrum consists of four excitations spanning the energy range 3-60 meV. The ground state eigenfunction consists of XY-spins in the ab plane. Fits to the magnetic susceptibility data indicate a Curie-Weiss temperature of θCW=-23.7(1) K. Neutron diffraction measurements show that long range antiferromagnetic order occurs below Tₐ=550 mK implying a frustration index of θCW / Tₐ ~43. These results suggest that Nd₂O₃ may be a model system for competing interactions between magnetic moments subject to strong spin-orbit coupling.

Session K38 GMAG DMP: 2D Magnetism II

Spin Transfer Torques in Monolayer WSe₂/PMA Heterostructures

STEVE NOVAKOV (Presenter), Physics, University of Michigan, NGUYEN VU, Materials Science and Engineering, University of Michigan, BHAKTI JARIWALA, AZIM KOZHAKHMETOV, Department of Materials Science and Engineering, Pennsylvania State University, GUANYU ZHOU, CHRISTOPHER HINKLE, Materials Science & Engineering, University of Texas - Dallas, JOSHUA ROBINSON, Department of Materials Science and Engineering, Pennsylvania State University, JOHN HERON, Materials Science and Engineering, University of Michigan — Transition metal dichalcogenides (TMD), with composition MX₂ (M={Mo, W}, X={S, Se, Te}), are promising candidates for a variety of spintronics applications due to their intrinsic band properties [1]. In comparison to 3D spin Hall effect (SHE) materials, (typically conductive 5d/4f transition metal compounds such as Pt and W) semiconducting TMDs promise spin/charge conversion with a higher efficiency and tunability, which has been shown in heterostructures with insulating magnets [2]. Additionally, TMDs may allow for more efficient switching of magnets with perpendicular magnetic anisotropy (PMA) than 3D SHE systems due to stronger out of plane spin torques [3]. We report on the growth and spin torque measurements of PMA and monolayer WSe₂ heterostructures. The PMA film stacks were grown by pulsed laser deposition and the WSe₂ was deposited with molecular beam epitaxy and chemical vapor deposition. The heterostructures were patterned into Hall bar devices and subject to angle and field resolved spin torque measurements to characterize the torque geometry and switching efficiency.

*SRC nCore New Limits
**Imaging the Electronic Structure of Magnetic and Non-Magnetic Atomic Impurities in Monolayer Semiconductors**

CALEB ZERGER (Presenter), ALEX CONTRYMAN, HONG LI, XIAOLIN ZHENG, HARI MANOHARAN, Stanford University — It has been predicted that a two dimensional dilute magnetic semiconductor (2D DMS) can be formed by suitably doping monolayer transition metal dichalcogenides with magnetic materials. Here we present scanning tunneling microscopy (STM) and spectroscopy (STS) data on these doped monolayers. We identify and characterize multiple impurity types resulting from the doping procedure, observing both magnetic and non-magnetic impurities. Using a full spectral mapping in position and energy space, and through comparison to density functional theory calculations, we can associate these impurity states with different impurity types and incorporation sites. For example, we have found transition metal substitutional dopants and a dichalcogenide substitutional dopant. Specific dopant arrangements demonstrate strong spin splitting, a necessary ingredient towards achieving a 2D DMS state in monolayer semiconductors.

**Magneto-Optical Kerr Effect microscopy on the intercalated transition metal dichalcogenides Fe₉TaS₂* ARIELLE LITTLE (Presenter), DYLAN REES, SPENCER DOYLE, CAOLAN JOHN, ERAN MANIV, JAMES G. ANALYTIS, JOSEPH ORENSTEIN, University of California, Berkeley — The layered transition metal dichalcogenide TaS₂ exhibits a broad range of phases including CDW states and superconductivity [1]; the polymorph 1T-TaS₂ has even been predicted to host a spin liquid [2]. Also of interest is the doping of such materials with metallic ions. In TaS₂ the intercalation of Iron between layers stabilizes ferromagnetic order. The magnetic properties vary drastically with the amount of intercalant, x [3]. For example, for x=0.33 chiral superlattice structures form [4]. Here we employ scanning Magneto-Optical Kerr Effect (MOKE) microscopy to image the onset of magnetic order and in some instances optical birefringence in compounds with intercalation from x=0.26 to 0.33. In the x=0.33 compound we report a sharp structural phase transition coincident with the magnetic transition and image the resulting domains on a 10-μm scale.

---

**Thermodynamic "valley noise" in monolayer semiconductors: access to intrinsic valley relaxation timescales** MATEUSZ GORYCA (Presenter), Los Alamos National Laboratory, NATHAN WILSON, Department of Physics, University of Washington, PRASENJIT DEY, Los Alamos National Laboratory, XIAODONG XU, Department of Physics, University of Washington, SCOTT CROOKER, Los Alamos National Laboratory — The new class of atomically-thin transition-metal dichalcogenide (TMD) semiconductors such as monolayer MoS₂ and WSe₂ has focused broad attention on the concept of “valleytronics”, founded on the idea of encoding information in an electron’s valley degree of freedom. A key parameter is therefore the intrinsic timescale of an electron’s inter-valley relaxation, and recent optical pump-probe studies have shown long (microsecond) valley relaxation of resident carriers in monolayer TMDs [1,2]. However, a significant drawback of all such pump-probe experiments is that they are by design perturbative: the optical pumping that drives the carrier polarization away from equilibrium also inevitably introduces “dark” excitons, whose presence may mask the intrinsic valley relaxation of resident carriers.

Here we present a completely alternative approach for measuring valley dynamics, based on the idea of passively “listening” to the random spontaneous scattering of carriers between K and K’ valleys that occurs even in strict thermal equilibrium. We demonstrate that the stochastic valley noise is measurable by optical means and, in accord with the fluctuation-dissipation theorem, encodes the true intrinsic timescales of valley relaxation, free from any pumping, excitation, or other perturbative effects [3]. Using this new fluctuation-based methodology we measure very long valley relaxation dynamics of both electrons and holes in a single electrostatically-gated WSe₂ monolayers. Noise spectra reveal long intrinsic valley relaxation with a single sub-microsecond time scale. Moreover, they validate both the relaxation times and the wavelength dependence observed in conventional pump-probe measurements, thereby resolving concerns about the role of dark excitons and trions in studies of long-lived valley relaxation.

9:12AM K38.00005: Gap opening at the Rashba-split states of Janus transition metal dichalcogenides induced by two-dimensional ferromagnetic semiconductor CrI₃* TAO HU (Presenter), WEI REN, Shanghai University — The Janus transition metal dichalcogenides intrinsically have Rashba spin splitting due to the presence of the out-of-plane mirror-symmetry breaking and strong spin-orbit coupling (SOC). Using first-principles calculations, we show that a van der Waals (vdW) heterostructure consisting of WSeTe and CrI₃ has inherently coexistence of Rashba and Zeeman spin splitting near the Brillouin zone center (Γ). The Rashba spin splitting states of WSeTe open an exchange gap of 29 meV when it is placed on the top of two-dimensional (2D) ferromagnetic semiconductor CrI₃. The spin-polarized subbands of Rashba-split states are separated at the Γ point because of the existence of effective perpendicular magnetic field stemmed from CrI₃. In the crossover region of Rashba and Zeeman spin splitting, the spin orientations of the two subbands are locked to the momenta. A single-circle Fermi contour could emerge if the Fermi level is tuned to locate exactly within the gap between the two subbands. Our results provide important insight into the manipulation of spin states for future spintronics applications of 2D vdW heterostructures.

9:24AM K38.00006: Influence of the spatial fluctuations of the Rashba field and magnetization on the electron and spin transport in 2D systems* ANNA DYRDAL (Presenter), Institut für Physik, Martin-Luther Universität Halle-Wittenberg, D-06099 Halle, Germany, SYLWIA KUDLA, VITALII DUGAEV, Department of Physics and Medical Engineering, Rzeszow University of Technology, Al. Powstancow Warszawy 6, 35-959 Rzeszow, Poland, EVGENY SHERMAN, Department of Physical Chemistry, Universidad del País Vasco UPV-EHU, 48080, Bilbao, Spain, JOZEF BARNAS, Faculty of Physics, Adam Mickiewicz University in Poznan, ul. Umultowska 85, 61-614 Poznan, Poland, JAMAL BERAKDAR, Institut für Physik, Martin-Luther Universität Halle-Wittenberg, D-06099 Halle, Germany — In a general case, spin-orbit coupling contains regular (spatially uniform, periodic) and a random component. Local imperfections, such as a random distribution of donors or impurities, may lead to local modifications of the spin-orbit coupling. Similarly, magnetization in the system may reveal spatial fluctuations as well. Such fluctuations modify transport properties of the system and induce a variety of observable effects [Physica E 42, 2157 (2010); Nat. Phys.12, 920(2016)]. We will present the theoretical description of the selected transport characteristics (electric and spin conductivity and anomalous Hall effect) induced or modified due to the presence of random Rashba field or magnetization fluctuations in 2D systems such as semiconductor heterostructures or topological insulators. We will show an important role of the transport relaxation time for charge and spin currents, that leads to a nontrivial temperature dependence of the conductivity [S.Kudla et al., PRB 97, 245307(2018)]. We will also consider the influence of magnetization fluctuations on the anomalous Hall effect in topological insulators.

9:36AM K38.00007: Electrically switching the valley polarization of 2D semiconductor LIZHONG LI (Presenter), SHENGWEI JIANG, Applied and Engineering Physics, Cornell University, ZEFANG WANG, Department of Physics, Penn State University, JIE SHAN, KIN FAI MAK, Applied and Engineering Physics, Cornell University — Controlling the valley degree of freedom in transition metal dichalcogenide(TMD) semiconductors is essential to the application of valleytronic devices. The strong magnetic coupling between monolayer TMD semiconductor WSe2 and few layer CrI₃, a recently discovered 2D magnet, provides a novel approach for lifting the valley degeneracy and switching the valley polarization. In this talk we present our result on gate controlled valley polarization in CrI₃/WSe₂ heterostructures. Due to the short-range magnetic proximity interaction, WSe₂ shows clear valley polarization controlled by the spin orientation of CrI₃. We demonstrate that the magnetic coupling between WSe₂ and CrI₃ could be effectively tuned by gate voltage, allowing reversible and efficient electrical switching of the valley polarization in WSe₂.
9:48AM K38.00008: Electrical gate control of photon-spin and photon-charge conversions in van der Waals heterostructures* [Invited] YUNQIU (KELLY) LUO (Presenter), ROLAND KAWAKAMI, Ohio State University — Semiconductor heterostructures of dissimilar materials are inherently limited by their interface quality, lattice mismatch, and intrinsic defects. These obstacles are overcome in van der Waals (vdW) heterostructures forming atomically sharp interfaces even between very different 2D materials. Our recent work demonstrates the efficient optically-created spin-polarized charge transfer across monolayer MoS2/graphene vdW interface, including complete control of spin polarization with photon helicity and photon energy up to room temperature. However, the underlying mechanisms and the qualitative trends in both photon-spin and photon-charge conversions remain elusive. To investigate origins of photon-charge conversion, we build a dual-gated MoS2/graphene field-effect device which allows multi-variable control of photon energy, bias voltage, and top and bottom gates. We observe an intriguing bias enhancement of photoconductivity, which behaves oppositely across graphene Dirac point. We further investigate the origins of photoconductivity using both above and below MoS2 band gap photon excitation. Gate dependence and photon intensity dependence indicate strongly towards the dominance of graphene photothermoelectric effect for below gap excitation, while an interplay of MoS2 photovoltaic effect and graphene photothermoelectric effect mediates above gap excitation. DFT and analytical models connect the role of bias voltage as an independent density of states modulation, which enhances the charge tunneling efficiency across the vdW barrier. In the end, we will briefly discuss the ultrafast photon-spin transfer across monolayer WSe2/graphene interface, as well as an outlook to the challenges and future of photon-spin and photon-charge conversions based on vdW hybrid systems.

10:24AM K38.00009: Unconventional transport in low-density two-dimensional Rashba systems* JOEL HUTCHINSON (Presenter), JOSEPH MACJEJKO, University of Alberta — Rashba spin-orbit coupling appears in 2D systems lacking inversion symmetry, and causes the spin-splitting of otherwise degenerate energy bands into an upper and lower helicity band. In this talk, we explore how impurity scattering affects transport in the ultra-low density regime where electrons are confined to the lower helicity band. A previous study has investigated the conductivity in this regime using a treatment in the first Born approximation. In this work, we use the full T-matrix to uncover new features of the conductivity. We first present results for the conductivity within a semiclassical Boltzmann framework and show that it exhibits an unconventional density dependence due to the unusual features of the group velocity in the single particle dispersion, as well as quantized plateaus as a function of the logarithm of the electron density. We support this with results from the Kubo formula and find that these plateaus persist in the full quantum theory. We suggest that this quantization may be seen in a pump-probe experiment.

10:36AM K38.00010: Magnetism of a Magnetic-ion-intercalated Transition Metal Dichalcogenide with a Chiral Structure KAI DU (Presenter), JAE WOOK KIM, FEI-TING HUANG, SEONG JOON LIM, Rutgers University, New Brunswick, KASUN GAMAGE, JUNJIE YANG, Central Michigan University, MYUNG-GEUN HAN, Brookhaven National Laboratory, SANG-WOOK CHEONG, Rutgers University, New Brunswick — Chiral magnets are materials where various intriguing spin orders including skyrmions, chiral soliton lattice, and topological domain walls can be found in the presence of the structural chirality. On the other hand, the hunting for exotic magnetic systems that are possible to fabricate functional two-dimensional devices for applications is also in high demand. In this work, we demonstrate that a magnetic-ion-intercalated transition metal dichalcogenide (TMD) is a layered chiral magnet according to our magnetic measurements and Lorenz transmission electron microscopy studies. Using transmission electron microscopy and magnetic force microscopy, we investigated its chiral structural domains and magnetic domains, respectively. Their domain topologies and relations will also be discussed.
Spin-Phonon Coupling, Spin Waves, and Other Magnetic Phenomena in Layered XPS₃ Materials via Raman Spectroscopy

AMBER MCCREARY (Presenter), Nanoscale Device Characterization Division, Physical Measurement Laboratory, National Institute of Standards and Technology, JUN CAO, Department of Chemistry, Boston University, XI LING, Department of Chemistry, Division of Materials Science and Engineering, and The Photonics Center, Boston University, ROBERT D MCMICHAEL, ANGELA HIGHT WALKER, Nanoscale Device Characterization Division, Physical Measurement Laboratory, National Institute of Standards and Technology — Raman spectroscopy is a powerful, non-destructive optical method to probe the fundamental physics of two-dimensional (2D) layered materials through inelastic scattering. An amazing amount of information is quantified from the spectra such as layer thickness, disorder, edge and grain boundaries, strain, etc. More interestingly for 2D materials is that Raman efficiently probes the evolution of the electron-phonon and spin-phonon interactions as a function of temperature, laser energy, polarization, and magnetic field. Using our unique magneto-Raman capabilities, we study the magnetic properties of the metal phosphorus trisulfide family (XPS₃, where X = Fe, Mn, and Ni) which are layered antiferromagnetic semiconductors. While the three materials have the same crystal structure, their varying spin structures result in distinct behavior as a function of temperature and magnetic field, which will be presented herein. In FePS₃, we investigate the splitting and shifting of a non Γ-point phonon mode below the Neel temperature that is not present in MnPS₃, as well as the emergence of a spin wave with anomalous symmetry behavior. In addition, we have studied the apparent two-magnon mode in NiPS₃ under various conditions.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K39 GMAG DMP: Spin Pumping

8:00AM K39.00001: Enhanced spin pumping into superconductors provides evidence for superconducting pure spin currents [Invited] CHIARA CICCARELLI (Presenter), University of Cambridge — Unlike conventional spin-singlet Cooper pairs, spin-triplet pairs can carry spin. Triplet supercurrents were discovered in Josephson junctions with metallic ferromagnet spacers, where spin transport can occur only within the ferromagnet and in conjunction with a charge current. Ferromagnetic resonance injects a pure spin current from a precessing ferromagnet into adjacent non-magnetic materials. For spin-singlet pairing, the ferromagnetic resonance spin pumping efficiency decreases below the critical temperature (Tc) of a coupled superconductor. Ciccarelli and collaborators present ferromagnetic resonance experiments in which spin sink layers with strong spin–orbit coupling are added to the superconductor. Their results show that the induced spin currents, rather than being suppressed, are substantially larger in the superconducting state compared with the normal state; although further work is required to establish the details of the spin transport process, they show that this cannot be mediated by quasiparticles and is most likely a triplet pure spin supercurrent.

8:36AM K39.00002: Probe of spin dynamics in superconducting NbN thin films via spin pumping* YUNYAN YAO (Presenter), QI SONG, International Center for Quantum Materials, School of Physics, Peking University, YOTA TAKAMURA, JUAN PEDRO CASCALES, Plasma Science and Fusion Center and Francis Bitter Magnet Laboratory, Massachusetts Institute of Technology, WEI YUAN, YANG MA, YU YUN, XINCHENG XIE, International Center for Quantum Materials, School of Physics, Peking University, BEIJING, JAGADEESH MOODERA, Plasma Science and Fusion Center and Francis Bitter Magnet Laboratory, Massachusetts Institute of Technology, WEI HAN, International Center for Quantum Materials, School of Physics, Peking University, BEIJING — The emerging field of superconductor (SC) spintronics has attracted intensive attentions recently. Many fantastic spin-dependent properties in SCs have been discovered, including large magnetoresistance, long spin lifetimes, and the giant spin Hall effect, etc. Regarding the spin dynamics in superconducting thin films, few studies have been reported yet. Here, we report the investigation of the spin dynamics in an s-wave superconducting NbN film via spin pumping from an adjacent insulating ferromagnet GdN film. A profound coherence peak of the Gilbert damping of GdN is observed slightly below the superconducting critical temperature of the NbN, which agrees well with recent theoretical prediction for s-wave SCs in the presence of impurity spin-orbit scattering. This observation is also a manifestation of the dynamic spin injection into superconducting NbN thin film. Our results demonstrate that spin pumping could be used to probe the dynamic spin susceptibility of superconducting thin films, thus pave the way for future investigation of spin dynamics of interfacial and two-dimensional crystalline SCs.

*National Basic Research Programs of China (973 program Grant Nos. 2015CB921104 and 2014CB920902) and National Natural Science Foundation of China (NSFC Grant No. 11574006).
8:48AM K39.00003: Efficient spin current generation from new, low-loss Mg(Al,Fe)2O4 films into heavy metals
LAUREN RIDDIFORD (Presenter), JACOB WISSER, Geballe Laboratory for Advanced Materials, Stanford University, SATORU EMORI, Physics, Virginia Tech, PENG LI, Geballe Laboratory for Advanced Materials, Stanford University, DEBANGSU ROY, EGECAN COGULU, Physics, New York University, OLAF M VAN T ERVE, Naval Research Laboratory, YONG DENG, SHAN X WANG, Materials Science, Stanford University, BEREND JONKER, Naval Research Laboratory, ANDREW D KENT, Physics, New York University, YURI SUZUKI, Geballe Laboratory for Advanced Materials, Stanford University — Low-damping magnetic insulators are essential to the growing field of spintronics since they can generate and transfer spin currents without associated charge currents. We have recently developed a new ferrimagnetic insulator, MgAl0.5Fe1.5O4 (MAFO), which has Gilbert damping as low as 1x10^-3. Through resonant excitation of the MAFO layer, we observed significant spin pumping from MAFO films into adjacent Pt and β-W layers by enhanced Gilbert damping and electrical voltage peaks that appear at ferromagnetic resonance (FMR). There is a reversal of the transverse voltage signal in MAFO/Pt and MAFO/β-W, which is consistent with the opposite signs of the spin Hall angle in these two materials and indicates the signal is due to the inverse spin Hall effect and not to proximity-induced anisotropic magnetoresistance (AMR). Further, angular dependent magnetoresistance (ADMR) measurements reveal that the spin Hall magnetoresistance (SHMR) is 7-10 times larger than the AMR contribution, so spin pumping effects dominate the magnetic dynamics of the bilayers. From FMR and ADMR measurements, we deduced a spin-mixing conductance of ~3x10^14 Ω^-1 m^-2 in MAFO/Pt. Together, these measurements indicate that MAFO is an excellent candidate for efficient spin current-based heterostructures and devices.

9:00AM K39.00004: Ferromagnetic Resonance and Spin Transport in Epitaxial Manganite/Ruthenate Bilayers
PURNIMA BALAKRISHNAN (Presenter), Stanford University, SATORU EMORI, Virginia Tech, YURI SUZUKI, Stanford University — Spin current generation by spin-pumping from a ferromagnet into a non-magnetic metal has been of great interest recently. However the role of the interface in the efficient pumping of spin current into the non-magnetic metal has not been addressed extensively. We address this issue by studying coherent interfaces in epitaxial oxide bilayers. Here we report recent results on spin pumping in pulsed-laser deposited bilayers of the ferromagnetic metal La2/3Sr1/3MnO3 (LSMO) and the paramagnetic metals SrRuO3 (SRO) and CaRuO3 (CRO). X-ray diffraction indicates excellent crystallinity of the bilayers. CRO layers are under tensile strain on LSMO films grown on LSAT substrates, in contrast to SRO layers which are under compressive strain. Ferromagnetic resonance measurements of LSMO films indicate that the Gilbert damping parameter can be as low as 1x10^-3. This damping increases with the addition of an epitaxial ruthenate overlayer of SRO or CRO consistent with spin pumping. From the ruthenate thickness dependence of the Gilbert damping, we estimate that the spin diffusion length is larger in CRO than in SRO. We will also discuss the role of proximity-induced magnetism on spin transport in bilayers with SRO versus CRO, which has no ferromagnetic transition.

MIJIN LIM (Presenter), HYUN-WOO LEE, Physics, Pohang University of Science and Technology(POSTECH), Pohang 37673, Korea — Spin conservation at an interface influences several spin transport phenomena such as spin-to-charge conversion and spin-orbit torque. If spin flips at the interface, the spin information may be lost, which is called a spin-memory loss. [1] We claim that large atomic spin-orbit coupling(SOC) and interfacial inversion symmetry breaking(ISB) are important elements of spin-flip scattering in the heterostructure that consists of a nonmagnetic metal with strong SOC and a ferromagnet. To study those effects, we calculate the change of spin information during the reflection/transmission using the tight-binding method. Here, we report two main findings. The first is about the spin-flip resulting from the SOC-induced entanglement of spin and orbital degree of freedom. The other is that the inversion symmetry breaking at an interface, which allows specific inter-orbital hopping [2], generates an additional spin-flip. We argue that these processes contribute to the interfacial spin-memory loss and spin transparency in spintronics devices. [1, 3]

*Samsung Science & Technology Foundation (Grant No. BA-1501-07)
9:24AM K39.00006: Enhancement of spin-motive force in systems with broken inversion symmetry* YUTA YAMANE (Presenter), RIKEN — The exchange interaction between the conduction electron spin and the local magnetization is responsible for spin-transfer torque, which provides an promising way of manipulating the magnetization by charge current. The same interaction can also mediate an electric-voltage generation by dynamical magnetic textures, i.e., spin-motive force (SMF). A SMF reflects spatiotemporal variation of the magnetization, and thus offers a powerful method to probe and explore various dynamical magnetic textures.

The experimentally observed SMFs thus far are typically 100nV-1μV. To achieve larger SMF is deemed indispensable towards realization of spintronic devices actively exploiting SMF. In this work we address this problem demonstrating that, in the presence of Dzyaloshinskii-Moriya Interaction (DMI), the SMF due to field-induced domain-wall motion can be dramatically enhanced[1]. The presence of DMI leads to extra spatial rotation of the magnetization, which turns out to play a crucial role in the enhancement of SMF. Our results suggest a new perspective on inversion-symmetry-broken systems as a suitable stage for pursuit of larger SMF.

*This research was supported by Research Fellowship for Young Scientists from Japan Society for the Promotion of Science.

9:36AM K39.00007: Optically generated spin currents in platinum/magnetic insulator bilayer structures* JOSEPH MURPHY (Presenter), SUBASH KATTEL, University of Wyoming, JINJUN DING, TAO LIU, MINGZHONG WU, Colorado State University, WILLIAM RICE, University of Wyoming — The generation and detection of pure spin current provides a pathway for solid-state devices to avoid Joule heating losses arising in electrical architectures.

Despite the promise of loss-free, spin-based devices, integrated spin current technology into real-world applications has proven difficult.

Here, we use a Pt/Y₃Fe₅O₁₂ (YIG) bilayer device to detect light from 390 nm to 2200 nm using the spin Seebeck effect (SSE).

We find that the nanometer-thick platinum layer is crucial for both spin current generation and detection.

We use a phase-sensitive, field-modulation technique to determine the temperature gradient across the YIG, \(\nabla T\), created by optical illumination, \(I\), to be \(\nabla T/I = 0.0975^\circ\text{C} \cdot \text{m}/\text{W}\).

From our measured values of \(\nabla T\) and \(\nabla V\), we obtain the SSE coefficient of YIG to be \(S_{\text{spin}} = -\nabla V/\nabla T = -1.1 \text{nV/K}\); this value is consistent with reported literature values for other SSE materials.

This work reveals the possibility of using spin current generation and detection for broadband light optoelectronics.

*JRM, SK and WDR acknowledge support from NASA through Grant No. WY-80NSS17M0049 and through the University of Wyoming School of Energy Resources.

9:48AM K39.00008: Nonlinear magnon study by microwave perpendicular pumping ferromagnetic resonance in thin films* TAO QU (Presenter), ANEESH VENUGOPAL, JAMES ETHERIDGE, KARTHIK SRINIVASA, WILLIAM PERIA, BETHANIE STADLER, PAUL CROWELL, RANDALL VICTORA, University of Minnesota — To investigate the nonlinear effects arising from magnon coupling to microwaves and their application to the new functionality of monolithically integrated magnetic components on semiconductor substrates, it is important to exploit non-linear ferromagnetic resonance in magnetic insulator materials. We have studied the nonlinearity caused by the three magnon scattering mechanism in GHz ferromagnetic resonance in simulation and analytically. The thicknesses of the studied YIG films are varied in the range of nanometers to several micrometers. A realistic micromagnetic simulation is implemented to capture the physical mechanisms coupling magnons of sub-micrometer wavelengths and microwaves of centimeter wavelength using CUDA parallel high-performance computing. Using the Holstein-Primakoff transformation and equation of motion in the theoretical model, we obtain the analytical magnon dispersion and the power threshold function. The power threshold for the three-magnon process is sensitive to the material properties. We find that the non-linearity is due primarily to incoherent magnon modes propagating in the thin film plane, while the modes propagating out of the film plane exist, but with much smaller occupation numbers.

*We thank DARPA and XSEDE for funding this project.
10:00AM K39.00009: Spin pumping in a material with metal-insulator transition  TAQIYYAH SAFI (Presenter), LUQIAO LIU, Massachusetts Institute of Technology — Ferromagnetic resonance driven spin pumping is a powerful tool to study the generation and detection of pure spin currents. Using spin pumping, people have characterized the spin orbit interaction induced charge—spin conversion in various materials, including paramagnetic, ferromagnetic and antiferromagnetic metals, semiconductors, as well as superconductors. It is interesting to ask whether the charge to spin conversion efficiency undergoes any significant change in a material with spontaneous phase transitions. In this talk we will present our work on spin pumping in VO₂, a prototype metal-insulator transition (MIT) material. By exciting ferromagnetic resonance in an adjacent magnetic insulator, we are able to inject spin current into VO₂ and quantify the variation in spin pumping voltage during the phase transition. We find that large spin pumping voltages exist in both metallic and insulating phase of VO₂, despite of the huge resistance change across this transition. To this end, we will present our work on the variation of spin mixing conductance and the spin Hall angle across the phase transition region.

10:12AM K39.00010: Topological Transport of Vorticity in Heisenberg Magnets  JI ZOU (Presenter), Physics, Univ of California - Los Angeles, SE KWON KIM, Physics, University of Missouri, YAROSLAV TSERKOVNYAK, Physics, Univ of California - Los Angeles — We study a robust topological transport carried by vortices in a thin film of an easy-plane ferromagnetic insulator between two metal contacts. A vortex, which is a nonlocal topological spin texture in two-dimensional magnets, exhibits some beneficial features as compared to skyrmions, which are local topological defects. In particular, the total topological charge carried by vorticity is robust against local fluctuations of the spin order-parameter magnitude. We show that an electric current in one of the magnetized metal contacts can pump vortices into the insulating bulk. Diffusion and nonlocal Coulomb-like interaction between these vortices will establish a steady-state vortex flow. Vortices leaving the bulk produce an electromotive force at another contact, which is related to the current-induced vorticity pumping by the Onsager reciprocity. The voltage signal decays algebraically with the separation between two contacts, similarly to a superfluid spin transport. Finally, the vorticity and closely related skyrmion type topological hydrodynamics are generalized to arbitrary dimensions, in terms of nonsingular order-parameter vector fields.

10:24AM K39.00011: Observation of NMR spin pumping*  YUKI SHIOMI (Presenter), University of Tokyo, JANA LUSTIKOVA, SHINGO WATANABE, Tohoku University, DAICHI HIROBE, Institute for Molecular Science, SABURO TAKAHASHI, Tohoku University, EIJI SAITO, University of Tokyo — We report spin pumping from nuclear magnetic resonance (NMR), in which nuclear spin dynamics emits a spin current, a flow of spin angular momentum of electrons. By using the canted antiferromagnet MnCO₃, in which typical nuclear spin-wave formation is established due to the reinforced hyperfine coupling, we find that a spin current is generated from an NMR.

*This research was supported by JST ERATO ‘Spin Quantum Rectification Project’ (JPMJER1402), JSPS KAKENHI (no. 17H04806, no. JP18H04215, no. 18H04311, no. JP16j03699 and no. 17H02927) and MEXT (Innovative Area ‘Nano Spin Conversion Science’ (no. 26103005)).

10:36AM K39.00012: Tunable Quantum Dynamics in a Disordered Magnet  CHRISTOPHER TANG (Presenter), DANIEL SILEVITCH, Caltech, GABRIEL AEPPLI, Paul Scherrer Institutue, THOMAS F ROSENBAUM, Caltech — Quantum memories depend on maintaining coherence in minimally-interacting qubits. In an attempt to engineer such memories, we decouple coherent many-body excitations from their environment in the dilute Ising magnet LiHo₀.₀₄₅Y₀.₉₅₅F₄ by driving the system into a non-linear regime with a Floquet drive. In this material, clusters of dozens to hundreds of spins bind together and can be excited resonantly by a strong ac magnetic field. The structure of these clusters can be studied via a Fano resonance technique using pump-probe magnetic susceptibility measurements, revealing lifetimes and coherent quantum interference between different excitation channels. In addition, we can tune the dynamics of the quantum degrees of freedom by tuning the strength of the pump ac magnetic field, or by introducing a static transverse field that serves to quantum-mechanically mix spin states. At special values of these two fields, zero-crossings of the Fano asymmetry parameter are observed, which are associated with a dissipationless response at the drive frequency. At these points, certain spin-clusters are minimally coupled with their environment, due to quantum interference between different excitation channels. The lifetimes of these excitations can be measured directly in the time-domain.
The behavior of spin propagation in metals in various measurement schemes is shown to be qualitatively different than a simple exponential decay - due to the backflow effect on spin diffusion in the presence of interfaces. We utilize the spin sensitivity of Nb superconducting point contacts to evaluate the spin current depolarization in a normal metal. The spin current was injected from bulk Co$_2$Mn$_{0.5}$Fe$_{0.5}$Si Heusler alloys into gold films of variable thickness. While our phenomenological theoretical results are consistent with gradually decaying spin polarization as the film thickness increases, the spin diffusion length in Au is found to be 285 nm, more than two times larger than without taking the backflow effect into account.

Session K40 GMAG DMP: Control of Magnetic Oxides

**8:00AM K40.00001: Control of Quantum States in 4d/5d Transition Metal Oxides** [Invited] GANG CAO (Presenter), Department of Physics, University of Colorado at Boulder — A delicate balance between spin-orbit and other competing interactions inherent in 4d/5d materials offers a unique range of opportunities to uncover exotic states and physical properties that are intimately coupled to the crystal structure [1]. This unique feature provides us fertile ground to control quantum states by tuning the lattice of single crystals. Here we present and discuss two recent examples and their fundamental significance: (i) Pressure-induced transition from interlayer ferromagnetism to intralayer antiferromagnetism in Sr$_4$Ru$_2$O$_{10}$ [2], and (ii) Electrical-current control of structural and physical properties in canted antiferromagnetic iridates [3].

**This work was supported by NSF grant DMR-1712101**

**8:36AM K40.00002: Electric field control of magnetic domains in Y-type hexaferrite single crystals at room temperature** VILMOS KOCSIS (Presenter), TARO NAKAJIMA, Center for Emergent Matter Science (CEMS), RIKEN, MASAAKI MATSUDA, Oak Ridge National Laboratory, AKIKO KIKKAWA, YOSHIO KANEKO, JUNYA TAKASHIMA, Center for Emergent Matter Science (CEMS), RIKEN, KAZUHISA KAKURAI, Comprehensive Research Organization for Science and Society (CROSS), TAKA-HISA ARIMA, University of Tokyo, FUMITAKA KAGAWA, Center for Emergent Matter Science (CEMS), RIKEN, YUSUKE TOKUNAGA, University of Tokyo, YOSHINORI TOKURA, YASUJIRO TAGUCHI, Center for Emergent Matter Science (CEMS), RIKEN — In the trigonal Y-type hexaferrites the magnetoelectric properties are attributed to the emergence of the so-called FE3 phase with co-existing ferrimagnetic and ferroelectric orders [1]. Recently, in the Al-doped Y-type hexaferrite, (Ba,Sr)$_2$Co$_2$Fe$_{11}$Al$_x$O$_{22}$, this multiferroic phase has been observed as a metastable phase close to room temperatures even in the absence of magnetic field [2,3].

In this presentation we report that in bulk Ba$_{0.8}$Sr$_{1.2}$Co$_2$Fe$_{12-x}$Al$_x$O$_{22}$ with x=0.9, the ferrimagnetic and ferroelectric domains have considerable coupling even at room temperature. Cross-control of the magnetic and electric degrees of freedoms, i.e. the direct (P-H) and inverse (M-E) magnetoelectric effect have been observed up to room temperature. Using magnetic force microscopy, control of the magnetic domain pattern by the application of electric field is directly visualized. We demonstrate that magnetization switching is realized via the propagation of two kinds of domain walls; parallel and perpendicular to the applied electric field.

8:48AM K40.00003: Magnetically Controlled Surface Acoustic Waves on Multiferroic BiFeO$_3$* RYO SASAKI (Presenter), YUTA ISHII, Department of Basic Science, University of Tokyo, YOICHI NII, Institute for Materials Research, Tohoku University, TOSHIMITSU ITO, National Institute of Advanced Industrial Science and Technology (AIST), YOSHINORI ONOSE, Institute for Materials Research, Tohoku University — We fabricate a surface acoustic wave (SAW) device on a multiferroic BiFeO$_3$ crystal while SAW devices are usually fabricated on nonmagnetic piezoelectrics and commercially available as bandpass filters. By using the time-domain technique, we demonstrate the SAW excitation on BiFeO$_3$. The amplitude and phase of the SAW signal are modulated by the external magnetic field reflecting the multiferroicity of BiFeO$_3$. The magnetic controllability of the multiferroic SAW device seems useful for the further functionalization of the SAW device.

9:00AM K40.00004: Pressure-induced magnetic behavior in Ca$_2$Mn$_2$O$_5$-type A$_2$B$_2$O$_5$ oxides YONGJIN SHIN (Presenter), JAMES M RONDINELLI, Northwestern University — Brownmillerite oxides with the chemical formula A$_2$B$_2$O$_5$ are derived from stoichiometric ABO$_3$ perovskites and exhibit ordered oxygen vacancies (OOVs). The OOVs transform the octahedral BO$_6$ units into different BO$_6$-x polyhedra, which allows for large changes in the crystal field split orbital structure and subsequent changes in functional properties. The magnetic order of transition metal oxides is governed by the correlation between these orbitals and corresponding electronic configurations. For example, Sr$_2$Mn$_2$O$_5$ (SMO; $d^4$) in the Ca$_2$Mn$_2$O$_5$-type square pyramidal network yields E-type antiferromagnetic (AFM-E) order, consistent with the Goodenough-Kanamori rules, whereas Sr$_2$Fe$_2$O$_5$ (SFO; $d^5$) exhibits AFM-G order within the same structure. Here, we investigate with first principles calculations the effect of hydrostatic pressure on the Ca$_2$Mn$_2$O$_5$-type structure, which drives contrasting behavior in SMO and SFO. We show the AFM-E order in SMO is further stabilized under pressure while SFO exhibits a magnetic transition to a FM state at ~24 GPa arising from a spin crossover. Lastly, we evaluate the pressure effect induced by biaxial strain in OOV structures and discuss the feasibility of such phase transition in thin film geometries.

9:12AM K40.00005: Pressure-induced transition from an antiferromagnetic insulator to a ferromagnetic metal in Ca$_2$Ru$_{1-x}$M$_x$O$_4$ (M=Cr, Mn and Fe)* HAO ZHENG (Presenter), Department of Physics, University of Colorado, Boulder, CO 80309, FENG YE, SONGXUE CHI, Quantum Condensed Matter Division, Oak Ridge National Laboratory, TN 37831, HENGDI ZHAO, YIFEI NI, YU ZHANG, GANG CAO, Department of Physics, University of Colorado, Boulder, CO 80309 — The comparable magnitudes of the Coulomb interaction and 4$d$-bandwidth can leave ruthenates precariously balanced on the border between metallic and insulating behavior, and/or on the verge of long-range magnetic order. Ca$_2$RuO$_4$ is an antiferromagnetic (AFM) Mott insulator with Neel temperature at $T_N = 110$ K and a first-order metal-insulator transition at $T_{MI} = 357$ K. It is recognized that Ca$_2$RuO$_4$ and its derivatives are highly sensitive to the lattice degrees of freedom. Here we report that application of modest pressure (< 2.5 GPa) readily destabilizes the AFM Mott state and precipitates a ferromagnetic metallic state at low temperatures in Ca$_2$Ru$_{1-x}$M$_x$O$_4$ (M=Cr, Mn and Fe). Transport and magnetic properties including neutron diffraction at pressure will be presented and discussed along with other related systems.

*This work was supported by the National Science Foundation via grant DMR-1712101.

9:24AM K40.00006: Strain-induced heteronuclear charge disproportionation in EuMnO$_3$* ULRICH ASCHAUER (Presenter), NATHALIE VONRÜTI, Departement of Chemistry and Biochemistry, University of Bern, NICOLA SPALDIN, Materials Theory, ETH Zürich — Charge disproportionation transitions commonly link high-temperature phases, in which cations of a given element have the same oxidation state, to low-temperature phases, where charge transfers between ions of this element results unequal oxidation states. Based on density functional theory calculations we here propose the concept of heteronuclear charge disproportionation, for which charge transfers occurs between different elements located on different crystallographic sites. Using EuMnO$_3$ as a test case, we show that the transition from Eu$^{3+}$Mn$^{3+}$O$_3$ to Eu$^{2+1}$Mn$^{4+}$O$_3$ can be triggered by pressure or epitaxial strain. We will highlight experimentally accessible signatures of this transition and discuss other crystal chemistries that could show similar phase transitions and resulting novel physics.

9:36AM K40.00007: Evidence of the Multiferroic Character of the EuO$_{1-x}$-BaTiO$_3$ Heterojunction* SYED QAMAR

ABBAS SHAH (Presenter), Physics and Astronomy, The University of Nebraska-Lincoln, GAURAB RIMAL, Physics and Astronomy, Rutgers University, Piscataway, GUANHUA HAO, ANDREW J YOST, Physics and Astronomy, The University of Nebraska-Lincoln, JINKE TANG, Physics and Astronomy, The University of Wyoming-Laramie, PETER A DOWBEN, Physics and Astronomy, The University of Nebraska-Lincoln — EuO$_{1-x}$ combines several interesting properties: large magneto-optical effects, colossal magnetoresistance, and enhanced Curie temperature due to bound magnetic polarons. EuO$_{1-x}$ is also one of a very few ferromagnetic insulators and, as an ultra thin film, very sensitive to interface effects. Investigation into the affect of ferroelectric substrates on the ferromagnetic properties of EuO$_{1-x}$ can provide deep insights into how one can manipulate magnetism by changing interface charge populations. Utilizing pulsed laser deposition, a thin film (20nm) of ferroelectric BaTiO$_3$ was grown on top of a thin film (15nm) of ferromagnetic EuO$_{1-x}$. X-ray diffraction indicates the presence of high quality crystalline thin films of EuO$_{1-x}$ and BaTiO$_3$. Magneto optical Kerr effect (MOKE) spectroscopy and magnetoresistance measurements indicate a temperature dependent signature of anti-ferromagnetic magnetoelectric coupling of the ferroelectric/ferromagnetic heterostructure. This study sheds new light on the modulation of magnetoelectric coupling at a device interface.

*This research was supported by the National Science Foundation, through Grant Nos. NSF-ECCS 1740136 and 1508541, as well as by the NCORE, a wholly owned subsidiary of the Semiconductor Research Corporation (SRC).

9:48AM K40.00008: Magnetic structure of hexagonally stabilized (Lu,In)FeO$_3$ KWANGHEE CHO (Presenter), HAKBEOM KIM, SOONYONG PARK, Chung-Ang University — Hexagonal LuFeO$_3$ has recently attracted considerable attention as promising candidates for room-temperature multiferroics, in which ferroelectricity and magnetism coexist in a single phase. However, most studies have been performed in a thin film form due to the instability of the bulk hexagonal LuFeO$_3$. Herein, we report that in LuFeO$_3$ a single hexagonal phase can be stabilized in both polycrystalline and single-crystalline bulk form with a wide range of Indium substitution in Lutetium site. Neutron diffraction results on magnetic spin structures and crystal structures of the Indium substituted LuFeO$_3$ will be discussed.

10:00AM K40.00009: Meta—stability and Transient Phases Triggered by Optically Excited Quasi—particles in Strongly Correlated Systems.* MYRON KAPETANAKIS (Presenter), Physics, University of Alabama at Birmingham, PANAGIOTIS LINGOS, Physics, University of Crete, JIGANG WANG, Physics & Astronomy, Ames Lab & Iowa State University, ILLIAS PERAKIS, Physics, University of Alabama at Birmingham — The interplay between electronic, magnetic and lattice degrees of freedom in colossal magnetoresistant manganites results in a rich phase diagram that provides an ideal model system for phase transition studies. Here we investigate the possibility of phase transitions induced by ultrafast optical laser pulses. We use a generalized tight—binding model, based on Hubbard operators, to describe the interaction between itinerant carrier and localized magnetic moment in multi—electron configurations. Optically—induced quasi—particle excitations introduce inhomogeneities, charge redistributions and spin fluctuations resulting in the formation of meta—stable states that trigger a non-equilibrium ultrafast dynamics. We discuss a theoretical description of optical switching mechanism between coexisting phases and highlight the role of photo—induced non—linearities on quantum femtosecond magnetism.

10:12AM K40.00010: Photo-excitation of Mott and charge transfer insulators DENIS GOLEZ (Presenter), PHILIPP WERNER, Department of physics, University of Fribourg, MARTIN ECKSTEIN, Department of physics, Friedrich-Alexander-Universität Erlangen-Nürnberg — I will compare the dynamics after the photo-excitation in Mott and charge-transfer insulators (CTIs). The later is described within the three-band Emery model and a non-equilibrium extension of GW+EDMFT. In contrast to Mott insulators a strong renormalization of the charge-transfer gap and a substantial broadening of bands is present in CTIs. The comparison with different experimental pump-probe techniques, like time resolved ARPES and optical conductivity, shows qualitative agreement and exemplify that dynamical correlations are essential for a proper description of the photo-doped state. I will provide an outlook how to extend these tools to an ab-initio description of strongly correlated materials out of equilibrium.

10:24AM K40.00011: Modulating Charge-Orbital Ordering in SmBaMn$_2$O$_6$ Single Crystals with Tuneable Strain. HAN ZHANG (Presenter), LIN HAO, JUNYI YANG, Physics, University of Tennessee, SHUA SANCHEZ, JIUN-HAW CHU, University of Washington, HAIDONG ZHOU, JIAN LIU, Physics, University of Tennessee — SmBaMn$_2$O$_6$ is a perovskite manganese oxide with A-site ordering where competing interactions lead to a series of phase transitions. The observed orderings include charge-orbital-ordering, antiferromagnetic ordering, ferromagnetic canting and spin re-orientation. The Structural phase transition associated charge-orbital-ordering clearly indicate a strong relation between the lattice, charge and orbital. A systematic study with tunable strain along lattice directions is done to study how the latter two interact with lattice, as well as how the interplay contributes to the macroscopic properties.
10:36AM K40.00012: Field-induced antiferromagnetic cone structure in multiferroic BiFeO3  MASAKI MATSUDA
(Presenter), SACHITH DISSANAYAKE, Oak Ridge National Laboratory, YASUKO OZAKI, TOSHIMITSU ITO, AIST, XINZHI LIU, MACIEJ
BARTKOWIAK, OLEKSANDR PROKHENKO, Helmholtz-Zentrum Berlin — BiFeO3, a rare multiferroic compound that shows
antiferromagnetism and ferroelectricity simultaneously above room temperature ($T_N$~640 K), has been studied intensively.
Recently, a new magnetic phase has been found between the cycloidal and canted antiferromagnetic phase in magnetic
field [1]. We performed neutron diffraction measurements in high static magnetic fields up to 19 T on HFM/EXED facility at
BER II research reactor in Helmholtz Zentrum Berlin. We successfully observed weak incommensurate peaks around 13 T
which split along the magnetic field direction [1,1,-2] at the (1/2, 1/2, 1/2) main peak. The magnetic field and temperature
region, where the incommensurate peaks appear, is consistent with that in the phase diagram obtained by the
magnetization measurements [1]. We confirmed that the magnetic structure in the intermediate phase is the
antiferromagnetic cone structure which is predicted theoretically. We will show the detailed magnetic structure (magnetic
wave vector and cone angle) and discuss the relation between the magnetic structure and the magnetoelectric effect. [1] S.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K41 GMAG DMP: Chiral Magnetism and Structures I  B Cec 209 - Daniele Pinna, Johannes Gutenberg
Universität Mainz - Tag(s): Focus

8:00AM K41.00001: Rise of Chiral Spintronics [Invited]  SEE-HUN YANG (Presenter), IBM Research - Almaden — Chirality is one
of the fundamental asymmetries in nature. Recently chiral nature of magnetic and nonmagnetic structures have been
enormously highlighted and arisen to be very useful for potential application to not only spintronics but biology and
pharmaceutical industries For example, it has been reported that the combination with spin-orbit interaction such as spin
Hall effect can be very efficient in manipulation of magnetic elements [1], and spin currents in chiral molecules induced by
chirality interacts with magnetic structures [2]. I will present recent remarkable progress in emergent novel phenomena
associated with chiral properties from not only emergent magnetic nanostructures but chiral molecules: spin-orbit torques
from perpendicularly magnetized ultrathin films [2], exchange coupling torque [3] and entirely new phase of chiral
exchange drag [4] from synthetic antiferromagnets, and separation of chiral molecules by magnetic structure: enantiomer
[5]. In the end I will discuss potential applications and promising outlooks from these new findings.

8:36AM K41.00002: Unit cell thick ferrimagnetic Mn$_3$Z Heusler Domain Wall motion  PANAGIOTIS CH. FILIPPOU
(Presenter), IBM Almaden Research Center, JAEWOO JEONG, New Memory Technology Lab, Samsung Electronics, YARI FERRANTE,
SEE-HUN YANG, TEYA TOPURIA, MAHESH G. SAMANT, IBM Almaden Research Center, STUART S PARKIN, Max Planck Institute for
Microstructure Physics Halle — Antiferromagnets and ferrimagnets are of particular interest for spintronic devices. In this
talk, we present the Domain Wall (DW) motion of Mn$_3$Z (Z=Ge, Sn, Sb) Heuslers, using the chemical templating layer (CTL)
concept. Unit cell thick, ferrimagnetic, binary Heusler compounds, have low magnetization and high perpendicular
magnetic anisotropy in their tetragonally distorted forms, can sustain current driven DW motion in nanowire racetracks of
-129 ms$^{-1}$ with the lowest current density to initiate motion of 2.8 $10^6$ A cm$^{-2}$. The direction of the DW motion is
determined by the bulk spin polarization of the Heusler. Moreover, the DW motion shows contribution by chiral spin orbit
torques when studied under in-plane fields. We discuss the complex mechanism of the DW motion in Heusler films and
identify a bulk Dzyaloshinskii-Moriya interaction and a spin Hall effect deriving from the CTLs.
One example of the extraordinary abilities of the Mn$_3$Z Heusler family, is shown by systematically tuning by an order of
magnitude the bulk DMI field strength, by varying the composition of the Heusler alloy. These results are the first
demonstration of DW motion in ultra-thin Heusler alloys with complex and tunable magnetic properties and is an
important step to enable Heusler spintronics applications.

The preimages of the spin texture and numerical calculations of $Q_H$ show that the hopfion has $Q_H = 1$. Furthermore, another non-trivial state that includes a monopole–antimonopole pair (MAP) is also stabilized in this system. By applying an external magnetic field, hopfion and MAP states with the same polarization can be switched between each other. The topological transition between the hopfion and the MAP state involves a creation (annihilation) of the MAP and twist of the preimages. Our work paves the way to study non-trivial 3D topological spin textures and stimulates more investigations in the field of 3D spintronics.

Transport signatures of interfacial exchange coupling and chiral spin textures in magnetic insulator thin films*  QIMING SHAO (Presenter), ECE, UCLA, YAWEN LIU, Physics, UCR, ALEXANDER GRUTTER, Neutron-Condensed Matter Science Group, NIST, GUOQIANG YU, ECE, UCLA, SE KWON KIM, Physics, UCLA, XIAOYU CHE, ECE, UCLA, CHI TANG, Physics, UCR, YAROSLAV TSERKOVNYAK, Physics, UCLA, JING SHI, Physics, UCR, KANG L. WANG, ECE, UCLA — Ferrimagnetic insulators (FMIs) attract tremendous interest for spintronic applications due to high characteristic frequency, low Gilbert damping, and absence of Ohmic loss. First, we demonstrate the critical role of dimensionality on the SOT efficiency by systematically studying the FMI layer thickness dependent SOT efficiency in tungsten/thulium iron garnet (W/TmIG) bilayers. Current-induced switching in FMI thin films is demonstrated with a thickness up to 15 nm [1]. Second, we use temperature dependent Hall measurements to identify contributions of spin Hall, magnetic proximity, and sublattice effects to the anomalous Hall signal in various heavy metal/ferrimagnetic insulator heterostructures. This approach enables detection of both the magnetic proximity effect onset temperature and magnetization compensation temperature and provides essential information regarding the interfacial exchange coupling. At last, we show the transport signatures of chiral spin textures, topological Hall effect, in the platinum/ferrimagnetic insulator bilayer. [1] Q. Shao, et al., Nat. Commun., 9, 3612 (2018)

Z2 topological invariant for magnon spin Hall systems  HIROKI KONDO (Presenter), YUTAKA AKAGI, HOSHO KATSURA, Department of Physics, University of Tokyo — The classification and characterization of different phases of matter based on the topology of band structures has recently attracted much attention. It is known that some of the topological phenomena in electron systems are carried over to bosonic systems [1]. However, the topological invariant of bosonic systems with time-reversal symmetry has not yet been identified, as Kramers' theorem cannot be applied to them. To address this issue, we first introduce the pseudo-time-reversal operator which ensures the existence of “Kramers pairs” of bosons. Then, we define the Z2 topological invariant for magnon spin Hall systems [2] using the Berry connection and curvature for bosons, which are different from those of electrons [3]. Furthermore, we propose two magnetic models with magnon bands carrying the nontrivial Z2 topological invariant. We also demonstrate that the presence (absence) of helical edge states corresponds to the nontrivial (trivial) value of the Z2 topological invariant.

Observation of long-wavelength modulation in chiral Mn1/3NbS2*  SUNIL KARNA (Presenter), DAVID P YOUNG, FRANK N. WOMACK, Physics and Astronomy Department, Louisiana State University, YAN WU, HUIBO CAO, LISA DEBEER-SCHMITT, Oak Ridge National Laboratory, PHILIP W ADAMS, JOHN DITUSA, Physics and Astronomy Department, Louisiana State University — We have investigated the magnetic properties of Mn1/3NbS2, through neutron diffraction and magnetic susceptibility measurements. Mn1/3NbS2 crystallizes in the non-centrosymmetric hexagonal space group P6322 and is built from NbS2 layers intercalated by Mn ions. The Mn atoms are situated in the octahedral holes between trigonal prismatic layers of 2H-NbS2. The magnetic susceptibility and magnetization indicate a magnetic transition at $T_N \sim 45$ K with an anisotropy that is similar to that observed in Cr1/3NbS2. Neutron diffraction reveals increased scattering near the structural Bragg peaks. However, our data indicate that the magnetic scattering had a wider q-dependence than the nuclear Bragg peaks suggesting a long wavelength modulation of the magnetic ordering along the c-axis.

*This material is based upon the work supported by the U.S. Department of Energy under EPSCoR Grant No. DE-SC0012432 with additional support from the Louisiana Board of Regents.
10:12AM K41.00010: Investigating the stability of incommensurate spin textures in GaV4S8  ELEANOR CLEMENTS (Presenter), University of South Florida, GANESH POKHAREL, DAVID GEORGE MANDRUS, Department of Materials Science and Engineering, University of Tennessee Knoxville, HARIHARAN SRIKANTH, MANH-HUONG PHAN, University of South Florida — The polar noncentrosymmetric GaV4S8 hosts a Néel skyrmion lattice (SkL) below Tc ~ 13 K. The Néel SkL extends over a broad range of temperature and magnetic field relative to the SkL in the chiral B20 helimagnets. It has been proposed that the modulated phases evolve into a ferromagnetic ground state at temperatures below ~ 5 K. By exploiting the magnetocaloric effect, we analyze the temperature and field evolution of the magnetic entropy change to gain insight into the stabilization mechanism of the magnetic phases close to Tc, which are thought to be governed by thermal fluctuations. We also investigate the behavior of the magnetic entropy change at low temperatures approaching the magnetic ground state.

10:24AM K41.00011: Non-trivial topology in 2D magnetic systems without skyrmions*  JIE-XIANG YU (Presenter), University of New Hampshire, WENTAO HOU, Boston College, MORGAN A DALY, JIADONG ZANG, University of New Hampshire — The magnetic skyrmion is a kind of two-dimensional(2D) topological non-trivial spin textures which can be identified by an integer number, called topological charge. However, our study on 2D chiral magnets, however, showed that one topological charge does not necessarily correspond to one skyrmion and the non-trivial topology can be found in a disordered phase. Here, we further investigate non-trivial topology in various systems where no-skyrmion is expected in low magnetic field region. In 2D spin-frustrated systems, such thermally driven topology is dominated in a wide range of magnetic fields; In the antiferromagnetic system with staggered Dzyaloshinskii-Moriya interactions, giant response of topological charge is found in a canted spin-ordering phase. Both two systems are related to real systems so that we expect the topological properties can be observed by thermal magnon and/or anomalous Hall effect.

*Our studies are supported by U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES) under Award No. DE-SC0016424 and Extreme Science and Engineering Discovery Environment (XSEDE) under Grant No. TG-PHY170023.

10:36AM K41.00012: Direct imaging of topological phase discontinuities in chiral spin textures via electron ptychography beyond diffraction-limited resolution*  ZHEN CHEN (Presenter), Applied and Engineering Physics, Cornell University, EMRAH TURGUT, Department of Physics, Oklahoma State University, KRISHNAN CHANDER, KAYLA NGUYEN, Applied and Engineering Physics, Cornell University, MATTHEW STOLT, SONG JIN, University of Wisconsin–Madison, DAN RALPH, Department of Physics, Cornell University, GREGORY FUCHS, DAVID ANTHONY MULLER, Applied and Engineering Physics, Cornell University — Real-space imaging of magnetic structures can provide crucial information for understanding many magnetic phenomena. Here, utilizing a new electron microscope detector, EMPAD, we resolve the internal fine structure of skyrmions in single crystal FeGe using Lorentz STEM and electron ptychography. We have unambiguously uncovered the topological phase discontinuities near the skyrmion lattice dislocation and boundaries. We also demonstrate a significant resolution improvement using electron ptychography, allowing magnetic imaging beyond the diffraction limit imposed by the electron optics. Magnetic domain images from ultrathin metallic multilayer films show the outstanding detection limit of our new imaging method. This new direct imaging technique can be applied to determine complex chiral spin structures in a wide variety of materials.

10:48AM K41.00013: Multiple magnetic phases in chiral Mn1/3NbS2  BING SHEN (Presenter), School of Physics, Sun Yat-Sen University, China — The chirality in materials always leads to the intriguing functionalities. In a magnetic system, the spin texture can be chiral due to the competition of Dzyaloshinskii-Moriya (DM) interaction and ferromagnetic coupling. The unique magnetic structure could be modulated into a particlelike order by applying field such as a magnetic soliton. In this talk, we present the systematic magneto-transport study on the chiral magnetic Mn1/3NbS2 single crystal, a proposed candidate of chiral magnetic solation semimetal. With tuning temperature and applied field, the system undergoes several magnetic states. An anisotropic magnetic phase diagram is revealed in this the layered materials.

Session K42 DQI: Applications of Noisy Intermediate Scale Quantum Computers IV  BCEC

210A - Peter Johnson - Tag(s): Focus
8:00AM K42.00001: Tensorial tools for quantum computing* YANNICK MEURICE (Presenter), University of Iowa — Tensorial methods have been playing an increasingly important role in the context of spin models and lattice gauge theory. In most examples, the variables of integration are compact and character expansion (for instance Fourier analysis for U(1) models) can be used to rewrite the partition function and average observables as discrete sums of contracted tensors. This reformulations have been used for RG coarse-graining but they are also very useful for quantum computing. Their build-in Trotter procedure allows us to write quantum circuit or propose analog simulations. We discuss recent applications and FAQs about the tensor reformulations such as boundary conditions, Grassmann variables, Ward identities, effects of truncations and gauge invariance.

*Department of Energy Office of Science Award Numbers: DE-SC0019139 and DE-SC0010113.

8:12AM K42.00002: How many qubits are needed for quantum computational supremacy?* ALEXANDER DALZELL (Presenter), Caltech, ARAM HARROW, DAX ENSHAN KOH, ROLANDO LA PLACA, Massachusetts Institute of Technology — Quantum computational supremacy arguments, which describe a way for a quantum computer to perform a task that cannot also be done by a classical computer, typically require a computational assumption related to the limitations of classical computation. One common assumption is that the polynomial hierarchy (PH) does not collapse, a stronger version of the statement that P =/= NP, which leads to the conclusion that any classical simulation of certain families of quantum circuits requires time scaling worse than any polynomial in the size of the circuits. However, the asymptotic nature of this conclusion prevents us from calculating exactly how many qubits these quantum circuits must have for their classical simulation to be intractable on modern supercomputers. We refine these quantum computational supremacy arguments and perform such a calculation by imposing fine-grained versions of the non-collapse assumption. Based on these conjectures we conclude that IQP circuits with 180 qubits, QAOA circuits with 360 qubits and boson sampling circuits (i.e. linear optical networks) with 90 photons are large enough for producing samples from their output distributions to be intractable on current technology.

8:24AM K42.00003: Verifying quantum supremacy by doubling the circuit depth* ANIMESH DATTA (Presenter), SAMUELE FERRACIN, THEODOROS KAPOURNIOTIS, University of Warwick — Any fruitful use of the noisy intermediate-scale quantum computing devices being developed relies crucially on our ability to verify the correctness of their outputs. This verification must be achievable within these noisy intermediate-scale devices. We present a verification protocol in the circuit model where the “desired” computation is verified running several independent “trap” computations, each of which requires (i) no more qubits than the desired computation and (ii) a circuit-depth twice that of the desired computation. Our protocol exploits the fact that single qubit gates are often the best components in noisy intermediate-scale quantum devices. We begin with the assumption that only the single-qubit gates are prefect, and then extend our protocol to account for all operations in intermediate-scale quantum computing devices being noisy. Our protocol applies to sampling problems that underlie quantum supremacy. In particular we provide a verification scheme, with a doubling of the circuit depth, to bound the variation distance between ideal and noisy probability distributions resulting from random circuit sampling - a candidate for quantum supremacy.

8:36AM K42.00004: Variational Quantum Factoring ERIC ANSCHUETZ, JONATHAN OLSON, ALAN ASPURU-GUZIK, YUDONG CAO (Presenter), Zapata Computing — Integer factorization has been one of the cornerstone applications of the field of quantum computing since the discovery of an efficient algorithm for factoring by Peter Shor. Unfortunately, factoring via Shor's algorithm is well beyond the capabilities of today's noisy intermediate-scale quantum (NISQ) devices. In this work, we revisit the problem of factoring, developing an alternative to Shor's algorithm, which employs established techniques to map the factoring problem to the ground state of an Ising Hamiltonian. The proposed variational quantum factoring (VQF) algorithm starts by simplifying equations over Boolean variables in a preprocessing step to reduce the number of qubits needed for the Hamiltonian. Then, it seeks an approximate ground state of the resulting Ising Hamiltonian by training variational circuits using the quantum approximate optimization algorithm (QAOA). We benchmark the VQF algorithm on various instances of factoring and present numerical results on its performance.
8:48AM K42.00005: Variational quantum eigensolver of interacting bosons with NISQ devices  ANDY C. Y. LI (Presenter), ALEXANDRU MACRIDIN, PANAGIOTIS SPENTZOURIS, Fermilab — Interacting boson systems are of broad interest in different fields of physics. Their simulation on classical computers is in general very challenging. The recent advances in variational-quantum-eigensolver (VQE) algorithms offer new scalable ways to investigate these systems with noisy intermediate scale quantum (NISQ) devices. In this work, we present a proof-of-principle experiment of a boson VQE algorithm implemented on Rigetti’s 8Q-device. Our experiment determines the low-energy eigenspectrum of the Rabi model -- a simple boson model with interactions mediated by an atom. Our results illustrate that scalable quantum simulations of interacting boson systems using NISQ devices have a promising future.

9:00AM K42.00006: A Quantum Algorithm for Symmetry-Exploitation in Exact Diagonalization of Quantum Many-Body Systems  ALBERT SCHMITZ, University of Colorado, Boulder, SONIKA JOHRI (Presenter), Intel — Grover's search algorithm can be extended to a minimization procedure on a quantum computer. Here, we find a new application for this procedure – the symmetry-based size reduction of matrices corresponding to quantum many-body Hamiltonians before they are diagonalized. This is currently a memory/computational bottleneck on classical computers. In this case, the minimization problem cannot tolerate an approximate minimum ruling out variational quantum algorithms, and adiabatic minimization is unsuitable since there is no notion of a finite energy gap protecting the ground state during the evolution from the starting to the final state. Instead, Grover's minimization procedure provides a reliable means to obtain a quadratic speedup over classical algorithms. We discuss both the theory and full circuit implementation of Grover minimization as applied to this problem. We find that the oracle for this problem only scales as poly-log in the size of the search space, in contrast to many oracles in proposed applications for Grover's algorithm which scale polynomially. Further, we design an error mitigation scheme that significantly reduces the effects of noise on the computation, making it a plausible candidate for the Noisy Intermediate Scale Quantum era.

9:12AM K42.00007: Variational Quantum Optics  AGUST&iacute;N DI PAOLO (Presenter), Université de Sherbrooke, Institut quantique and Département de Physique, PANAGIOTIS BARKOUTSOS, IVANO TAVERNELLI, IBM Research - Zurich, ALEXANDRE BLAIS, Université de Sherbrooke, Institut quantique and Département de Physique — Quantum processors of intermediate scale have been used to simulate quantum chemistry by means of the variational quantum algorithm (VQA). VQAs have been shown to be robust against noise and can handle limited connectivity by using hardware-efficient state-preparation protocols. This makes VQAs a promising tool for near-term application of quantum co-processors in the hybrid quantum-classical computation paradigm. In this talk, we extend the applicability of variational quantum algorithms to bosonic Hamiltonians with applications to quantum optics.

9:24AM K42.00008: Study network-related optimization problems using quantum alternating optimization ansatz  ZHIHUI WANG (Presenter), Quantum Artificial Intelligence Laboratory, NASA Ames Research Center, MUSTAFA ADNANE, Quantum Artificial Intelligence Laboratory, Universities Space Research Association, NASA Ames Research Center, ELEANOR RIEFFEL, BRYAN O’GORMAN, Quantum Artificial Intelligence Laboratory, NASA Ames Research Center, STUART HADFIELD, RICCARDO MENGONI, DAVIDE VENTURELLI, Quantum Artificial Intelligence Laboratory, Universities Space Research Association, NASA Ames Research Center — Network-related connectivity optimization problems are underlying a wide range of applications and are of high computational complexity. We consider studying network optimization problems using quantum heuristics. In particular, we consider Quantum Alternating Operator Ansatz, an extension of the Quantum Approximate Optimization Algorithms, in which a cost-function based unitary and a non-commuting mixing unitary are applied alternately. We present mappings for a few network optimization problems, including variants of finding the optimal spanning-tree or spanning-graph of a graph. We give special focus on the design of mixers based on the constraints in the problem such that the system evolution remains in a subspace of the full Hilbert space where all constraints are satisfied. In the spanning-tree problem, one such constraint is that a mixer applied to a spanning tree needs also be a spanning tree. This involves checking the connectivity of a subgraph, which is a global condition common for most network-related problems. We show how this feature can be efficiently represented in the mixer in a quantum coherent way, based on manipulation of a descendant-matrix and an adjacent matrix. We further develop a mixer for the spanning-graphs based on the spanning-tree mixer.

9:36AM K42.00009: Adiabatic Quantum Chemistry Simulations with Superconducting Qubits  NIKOLAJ MOLL (Presenter), GIAN SALIS, MARC GANZHORN, DANIEL EGGER, STEFAN FILIPP, IBM Research - Zurich, MARCO ROTH, RWTH Aachen University, SEBASTIAN SCHMIDT, ETH Zurich — The simulation of a quantum system with a classical computer without any approximations is intractable even for moderate system sizes. It has been recognized early that using a controllable quantum system as a simulator could solve this for increasing system sizes. We propose a scalable quantum simulator based on driven superconducting qubits where the interactions are generated parametrically by polychromatic magnetic flux modulation of a tunable bus element. In this system, the XX- and YY-type interactions as well as transverse fields are independently tunable over a large parameter range. We experimentally demonstrate an adiabatic simulation using two superconducting qubits and one tunable bus element. The time required to reach the ground state of the Hamiltonian lies in the few microseconds range and therefore is well within the capability of currently available superconducting circuits.
**9:48AM K42.00010: Faster classical sampling from distributions defined by quantum circuits** [invited] IGOR MARKOV (Presenter), ANEEQA FATIMA, University of Michigan, SERGEI ISAKOV, SERGIO BOIXO, Google — As quantum computers become more capable, the question of when they surpass state-of-the-art classical computation for a well-defined computational task is attracting much attention. The leading candidate task for this milestone entails sampling from the output distribution defined by a random quantum circuit. We develop algorithms and software for massively-parallel simulation. In particular, we propose two new ways to trade circuit fidelity for computational speedups, so as to match the fidelity of a given quantum computer --- a task previously thought impossible. We report massive speedups for the sampling task over prior software from Microsoft, IBM, Alibaba and Google, as well as supercomputer and GPU-based simulations. By using publicly available Google Cloud Computing, we price such simulations and enable comparisons by total cost across hardware platforms. We simulate approximate sampling from the output of a circuit with 7x8 qubits and depth 1+40+1 by producing one million bitstring probabilities with fidelity 0.5%, at an estimated cost of $35184. Simulating circuits of depth to 1+48+1 would cost one million dollars.

**10:24AM K42.00011: Subspace-search variational quantum eigensolver for excited states** KEN M NAKANISHI (Presenter), Physics, The University of Tokyo, KOSUKE MITARAI, Engineering Science, Osaka University, KEISUKE FUJII, Physics, Kyoto University — The variational quantum eigensolver (VQE), a variational algorithm to obtain an approximated ground state of a given Hamiltonian, is an appealing application of near-term quantum computers. To extend the framework to excited states, we here propose an algorithm, the subspace-search variational quantum eigensolver (SSVQE). This algorithm searches a low energy subspace by supplying orthogonal input states to the variational ansatz and relies on the unitarity of transformations to ensure the orthogonality of output states. The k-th excited state is obtained as the highest energy state in the low energy subspace. The proposed algorithm does not employ any ancilla qubits. The disuse of the ancilla qubits in our algorithm is a great improvement from the existing proposals for excited states, which have utilized the swap test, making our proposal a truly near-term quantum algorithm. We further generalize the SSVQE to obtain all excited states up to the k-th by only single optimization procedure. From numerical simulations, we verify the proposed algorithms. This work greatly extends the applicable domain of the VQE to excited states and their related properties like a transition amplitude without sacrificing any feasibility of it.

**10:36AM K42.00012: Holistic Error Mitigation Frameworks For Near-Term Computations** EUGEN DUMITRESCU (Presenter), RAPHAEL POOSER, ALEXANDER MCCASKEY, TITUS MORRIS, PAVEL LOUGOVSKI, Oak Ridge National Laboratory — It is necessary to mitigate physical errors in order for NISQ computations to compute quantities with reasonable accuracy. Therefore NISQ programming stacks must include a robust error mitigation infrastructure supplementing principal quantum programs at compile time and operating at a high level of abstraction. We introduce an error mitigation framework consisting of routines built into a software stack aiming to return corrected data from programs run on NISQ devices. As a demonstration, we implement a variety of protocols which increase the accuracy of variational quantum eigensolver-style hybrid algorithms running on multiple NISQ devices.

*This work was supported as part of the ASCR-Testbed Pathfinder Program at Oak Ridge National Laboratory under FWP #ERKJ332

**10:48AM K42.00013: Quantum Kitchen Sinks: An algorithm for machine learning on near-term quantum computers** CHRISTOPHER WILSON (Presenter), Institute for Quantum Computing, University of Waterloo, JOHANNES OTTERBACH, OpenAI, NIKOLAS TEZAK, ROBERT S SMITH, PETER KARALEKAS, ANTHONY POLLORENO, SOHAIB ALAM, GAVIN CROOKS, MARCUS DA SILVA, Rigetti Computing — Noisy intermediate-scale quantum (NISQ) computing devices are an exciting platform for the exploration of the power of near-term quantum applications. We describe a near-term quantum application for machine learning tasks by building upon the classical algorithm known as random kitchen sinks. Our technique, called quantum kitchen sinks, uses quantum circuits to nonlinearly transform classical inputs into features that can then be used in a number of machine learning algorithms. We demonstrate the power and flexibility of this proposal by using it to solve binary classification problems for synthetic datasets as well as handwritten digits from the MNIST database. Simulations show, in particular, that small quantum circuits provide significant performance lift over standard linear classical algorithms, reducing classification error rates from 50% to <0.1%, and from 4.1% to 1.4% in these two examples, respectively. We show comparable performance for these examples in experiments with superconducting qubits.

Session K43 DCMP: Breakthroughs in Quantum Dynamics BCEC 210B - Anatoli Polkovnikov - Tag(s): Invited
8:00AM K43.00001: Spatio-temporal quenches for fast preparation of ground states of critical models* [Invited]
KARTIEK AGARWAL (Presenter), McGill University, SHIVAJI SONDHI, RAVINDRA BHATT, MATTEO IPPOLITI, Princeton University, PRAHAR MITRA, Institute for Advanced Study — The difficulty of preparing highly entangled quantum states poses an important challenge in engineering artificial quantum systems for the purposes of computation and simulation. Adiabatic methods which slowly evolve unentangled states to entangled states are typically slow and particularly fail at criticality where the gap between eigenstates vanishes. The search for novel non-adiabatic methods for quantum state preparation is a topic of current research interest, and immense experimental relevance. I will describe the state of the art in the field and discuss our proposal(s) using spatio-temporal quenches to efficiently prepare the ground states of arbitrary interacting critical theories in one dimension and beyond.

8:36AM K43.00002: Localization and Thermalization in Nuclear Spin Chains [Invited] PAOLA CAPPELLARO (Presenter), Massachusetts Institute of Technology — TBD

9:12AM K43.00003: Many body localization with long range interactions* [Invited] RAHUL NANDKISHORE (Presenter), University of Colorado, Boulder — Many-body localization (MBL) has emerged as a powerful paradigm for understanding nonequilibrium quantum dynamics. Folklore based on perturbative arguments holds that MBL arises only in systems with short-range interactions. I will present nonperturbative arguments indicating that MBL can arise in systems with long-range (Coulomb) interactions, through a mechanism dubbed “order enabled localization.” In particular, one can show using bosonization that MBL can arise in one-dimensional systems with \( -r \) interactions, a problem that exhibits charge confinement. One can also show that (through the Anderson-Higgs mechanism) MBL can arise in two-dimensional systems with \( \log(r) \) interactions, and perhaps even in three-dimensional systems with \( 1/r \) interactions. The extension to three dimensions requires developing a theory of localization of extended quantum objects. The arguments are asymptotic (i.e., valid up to rare region corrections), yet they open the door to investigation of MBL physics in a wide array of long-range interacting systems where such physics was previously believed not to arise. They also open the door to using MBL to stabilize driven superconductivity.

9:48AM K43.00004: Exploring Quantum Thermalization Near Integrability in a Dipolar Quantum Newton's Cradle* [Invited] BENJAMIN LEV (Presenter), YIJUN TANG, Stanford University, SARANG GOPALAKRISHNAN, Physics, CUNY, MARCOS RIGOL, Physics, Pennsylvania State University, WIL KAO, KUAN-YU LI, Stanford University, KRISHNANAND MALLAYYA, Physics, Pennsylvania State University — Isolated quantum many-body systems with integrable dynamics generically do not thermalize starting from generic initial states when taken far from equilibrium. As one perturbs such systems away from the integrable point, thermalization sets in, but the nature of the crossover from integrable to thermalizing behavior is an unresolved and actively discussed question. We explore this question by studying the dynamics of the momentum distribution function in a dipolar quantum Newton’s cradle consisting of highly magnetic dysprosium atoms. This is accomplished by creating an ultracold one-dimensional Bose gas with strong magnetic dipole-dipole interactions. These interactions provide tunability of both the strength of the integrability-breaking perturbation and the nature of the near-integrable dynamics. We provide the first experimental evidence that thermalization close to a strongly interacting integrable point occurs in two steps: prethermalization followed by near-exponential thermalization. Moreover, the measured thermalization rate is consistent with a parameter-free theoretical estimate, based on identifying the types of collisions that dominate thermalization. By providing tunability between regimes of integrable and nonintegrable, chaotic dynamics, our work sheds light both on the mechanisms by which isolated quantum many-body systems thermalize, and on the temporal structure of the onset of thermalization. Wednesday, March 6, 2019 8:00 AM - 11:00 AM
8:00AM K44.00001: Quantum Oscillations in Kondo Insulators* [Invited]  LU LI (Presenter), University of Michigan — In metals, orbital motions of conduction electrons on the Fermi surface are quantized in magnetic fields, which is manifested by quantum oscillations in electrical resistivity. This Landau quantization is generally absent in insulators. Here, we report a notable exception in an insulator — ytterbium dodecaboride (YbB₁₂). The resistivity of YbB₁₂, which is of a much larger magnitude than the resistivity in metals, exhibits distinct quantum oscillations. These unconventional oscillations arise from the insulating bulk, even though the temperature dependence of the oscillation amplitude follows the conventional Fermi liquid theory of metals with a large effective mass. Quantum oscillations in the magnetic torque are also observed, albeit with a lighter effective mass.

The development of the torque magnetometry technique in intense magnetic fields was supported by the U.S. Department of Energy (DOE) under award DE-SC0008110. Some results are obtained with equipment supported by the National Science Foundation Major Research Instrumentation award under DMR-1428226 (the equipment of the thermodynamic and electrical transport characterizations).

8:36AM K44.00002: Fermi surfaces in Kondo insulators [Invited] SUCHITRA SEBASTIAN (Presenter), University of Cambridge — TBD

9:12AM K44.00003: A Physical-Chemical Understanding of Samarium Hexaboride [Invited] TYREL MCQUEEN (Presenter), Johns Hopkins University — TBD

9:48AM K44.00004: Mixed valence insulators with neutral Fermi surfaces* [Invited] SENTHIL TODADRI (Presenter), Massachusetts Institute of Technology — A number of recent experiments have suggested the possibility that the low-temperature insulating bulk of mixed valence systems like SmB₆ and YbB₁₂ hosts electrically neutral gapless excitations. I will describe a new phase of matter—composite exciton Fermi liquid—a mixed valence insulator with a three dimensional fermi-surface of a neutral fermion, that we name the "composite exciton". I will describe the mechanism responsible for the formation of such excitons, discuss the phenomenology of the composite exciton Fermi-liquid and discuss existing and possible future experiments.

*Research supported US Department of Energy grant DE-SC0008739, and partly by the Simons Foundation.

10:24AM K44.00005: Quantum Oscillation from in-gap states in Kondo insulators [Invited] HUITAO SHEN (Presenter), Massachusetts Institute of Technology — Recent experiments on quantum oscillation in heavy fermion materials, such as SmB₆ and YbB₁₂, has gained great many interests in the community of strongly correlated electrons. Its physical origin has been hotly debated.

In this talk, we present the most direct explanation to this novel phenomenon—quantum oscillation comes from in-gap quasiparticles. The quantum oscillation found in these narrow gap insulators, where the scattering rate controls Lifshitz-Kosevich (LK) factor instead of Dingle factor, is quite the opposite to the case of normal metals, where the scattering rate controls Dingle factor instead of LK factor. This novel result is an important prediction of our theory and differs clearly with other theories. We provide an analytical formula that can be used by experimentalists to fit and interpret their data. Our calculation based on the ARPES data agrees very well with the quantum oscillation experiments.

Wednesday, March 6, 2019 8:00 AM - 10:48 AM
Viscoelastic Thin Films SHEETAL RANGA (Presenter), RABIBRATA MUKHERJEE, Department of Chemical Engineering, Indian Institute of Technology Kharagpur —

Self-organized instability patterns in thin films are of great interest in diverse scientific and technological applications. We investigated the surface instability in a viscoelastic film engendered by externally applied electric field perpendicular to the film surface in a capacitor geometry. Here the main destabilizing force is electrostatic pressure and the restoring effects arising out of stretching of the crosslinked elastomeric film. The external field polarizes the air-polymer interface and the film surface destabilizes itself to align in the direction of the applied field to minimize the energy forming different morphologies. We report here complete bonding-debonding sequence and morphological transformation. During bonding, the patterns appear only when the field strength \( U \) exceeds critical voltage \( U_c \), which depends on the shear modulus, gap spacing, and film thickness etc. With an increase in \( U \), initially columns appear which further evolves into labyrinths and holes before the film surface comes in complete conformal contact with the top electrode. During debonding, the patterns appear following exactly opposite morphological sequence. Though the patterns are completely switchable by electric field we have observed hysteresis during de-bonding.

Transition from spin dewetted droplets to continuous film in a semi-crystalline Polyethylene Oxide thin film SOUMYAMOULI PAL (Presenter), RABIBRATA MUKHERJEE, Department of Chemical Engineering, Indian Institute of Technology Kharagpur — Polymeric thin films are increasingly being utilized for technological applications, such as coatings, functional surfaces, etc. Dewetting and crystallization both play a significant role in determining the film morphology and ultimate film properties. When polyethylene oxide (PEO) is spin coated from a nonpolar solvent (chloroform), crystallization proceeds via formation of spherulites, which correlate well with Avrami kinetics. Spontaneous rupture of the dispersed solution layer during spin coating results in isolated periodic morphologies of the solute at low concentrations (\( C_n \)). Here, the morphology of PEO thin films coated on pre-patterned PDMS substrate transforms from spin-dewetted droplets to elongated threads to continuous films with an increase in \( C_n \). We investigated the effects of RPM variation during spin coating on the transition of spin-dewetted morphologies from droplets at lower RPM to continuous film at higher RPM. We further show that within the spin-dewetted regime, with a decrease in solute concentration and increase in RPM, droplet periodicity (\( \lambda_D \)) reduces and number density of droplets increases. Spherulite structures were observed in both spin-dewetted aligned droplets and continuous films; however, lamellar structures were observed in elongated threads.

Influence of residual stress on dewetted morphology of spin coated polymer thin films ALOK PATRA (Presenter), ANUJA DAS, RABIBRATA MUKHERJEE, Department of Chemical Engineering, Indian Institute of Technology Kharagpur — Spontaneous instability in polymer thin film leading to its rupture and subsequent formation of polymer droplets is called Dewetting. In this regard, it is essential to investigate the fundamental properties of polymer leading to dewetting and its effect on the dewetted morphology. We report the dependence of dewetted morphology of polymer thin film on residual stress generated during spin coating. Unlike applied stress, residual stress arises due to polymer chain entanglement while the polymer is in solution state and endures high centripetal force. The spin-coated polymer film is at a metastable equilibrium state generating a residual stress among the polymer chains. We produce different residual stress in polymer thin film of same thickness by spin coating at different rotation speeds. Based on the degree of stress present, the dynamics of dewetting as well as morphology varies. From this we exhibit the contrast by dewetting the thin film by different techniques: Thermal annealing, solvent vapor and good solvent mediated dissolution. The contrast in the morphology is shown as a measure of droplet periodicity (\( \lambda_D \)) and diameter (\( D_D \)). Consequently, we can qualitatively predict the degree of residual stress in thin film by its dewetted morphology without further characterization.

Structure and dynamics of pseudo-partial wetting precursor films EMILIE VERNEUIL, FRANCOIS LEQUEUX, HELENE MONTES, CLAIRE SCHUNE (Presenter), MARC YONGER, SIMM, ESPCI Paris — Wetting of liquids on high energy solids where the spreading parameter is positive is expected to lead to nanometer-thick precursor films spreading out of the macroscopic liquid body. In this film, Van der Waals interactions induce either disjoining or conjoining Derjaguin pressure that respectively tend to separate the film interfaces or to bring them together.

We report for the first time systematic observations of droplets and their precursor films of high polarisability polymer melts on silica, which lead to a pseudo-partial wetting situation: at equilibrium, the droplet coexists with its film, in which the Derjaguin pressure is conjoining. By ellipsometry, we clearly evidence the unique structure and dynamics of these precursor films compared to total wetting films. Whereas in total wetting, the precursor film ends with a sharp step and consists of dense macromolecules, the profile of pseudo-partial wetting films is diffusive and the molecules form a quasi-two-dimensional gas with a diffusion coefficient specific to each polymer. These results were extended to a series of common organic polymers and rationalized within the framework of Van der Waals interactions, and short range surface interactions.
Theoretical insights into the hydrophobicity of low index CeO$_2$ surfaces

MARCO FRONZI (Presenter), International Research Centre for Renewable Energy, Xi’an Jiaotong University, HUSSEIN ASSADI, Center for Green Research on Energy and Environmental Materials, National Institute for Materials Science, DORIAN HANAOR, Chair of Advanced Ceramic Materials, Institute for Materials Science and Technology, Technische Universität Berlin — The hydrophobicity of CeO$_2$ surfaces is examined here. Since wettability measurements are extremely sensitive to experimental conditions, we propose a general approach to obtain contact angles between water and ceria surfaces of specified orientations based on density functional calculations. In particular, we analysed the low index surfaces of this oxide to establish their interactions with water. and we found the CeO$_2$ (111) surface to be the most hydrophobic, whereas the CeO$_2$ (110) surface is mildly hydrophilic. Also, we found that the O terminated (100) surface was unstable unless fully covered by molecularly adsorbed water. We identified a strong attractive interaction between the hydrogen atoms in water molecules and surface oxygen, which gives rise to the hydrophilic behaviour of (110) surfaces. The findings here shed light on the origin of the intrinsic wettability of rare earth oxides in general and CeO$_2$ surfaces in particular and also explain why CeO$_2$ (100) surface properties are so critically dependant on applied synthesis methods.

Inferring Boundary Viscosity Values from Shear Deformation of Molecularly Thin Films

KISHAN MAKWANA (Presenter), Physics, University of Oxford, Oxford OX1 3PN, UK, SANDRA TROIAN, MC128-95, CALTECH, Pasadena, CA 91125 — Derjaguin and co-workers in 1946 introduced a shear technique for inferring the boundary viscosity of ultrathin liquid films. Air blown through a slender horizontal slit is used to apply a constant shear stress to the free surface of an initially flat and uniform film. Newtonian films tend to distort streamwise into a wedge shape whose slope decreases in time. The viscosity of the film can then be extracted from the wedge slope. High resolution measurements of the deformed film shape are normally obtained by interferometry for microscale films or ellipsometry for molecular scale films. Over the years, it has become evident that liquid nanofilms can exhibit a shear response that deviates significantly from this ideal linear behavior. Various physical mechanisms have been proposed to help resolve discrepancies between theory and experiment. Here we present finite element simulations of the liquid deformation process to evaluate help assess the influences of different mechanisms. Based on quantitative comparison to experimental data, we describe which candidate mechanisms best fit the trends observed.

Dependency of ice adhesion strength on surface wettability and roughness

MARINA MACHADO DE OLIVEIRA (Presenter), SUBASH KATTEL, JOSEPH MURPHY, JOHN ACKERMAN, WILLIAM RICE, VLADIMIR ALVARADO, University of Wyoming — Ice adhesion mechanisms are poorly understood contributing to the limited effectiveness of current ice mitigation techniques. The ideal solution is to prevent ice accretion via suppression of ice adhesion on ice-phobic surfaces, which requires understanding ice-phobicity at a more fundamental level. Given the breadth of published results, we designed an experimental matrix to isolate the effects of roughness and dynamic water spreading on ice adhesion. To this end, we conducted detailed surface roughness maps and novel dynamic contact angle measurements on stainless steel, aluminum, and non-metallic materials. We varied temperature to evaluate a variety of conditions encountered in practice such as clear ice, mixed ice and rime ice. Dynamic hysteresis of the contact angle and adhesion are clear functions of the forcing frequency and amplitude as well as surface roughness in pendant drop experiments. These results are a step towards finding physics-based solutions to ice accretion challenges.

9:24AM K45.00008: Rapid Detection of Thalassaemia Carriers by Image Analysis of Dried Patterns of Blood and Plasma Droplets  
MANISH AYUSHMAN (Presenter), MANIKUNTALA MUKHOPADHYAY, SUNANDO DASGUPTA, Chemical Engineering, Indian Institute of Technology Kharagpur — The drying of drops of biological fluids such as blood/plasma leads to the formation of several interesting and complex patterns. Specific diseases can give rise to distinct drying patterns where the final pattern will depend on a number of factors such as plasma content and the morphology of the red blood cells. Thalassaemia is the most common single gene disorder in which the production of haemoglobin is impaired. At present, the gold standard method, used for carrier detection in hospitals, requires expensive instruments, skilled manpower and significant time, making it difficult to be used as an on-site method. A rapid, portable and automated technology for thalassaemia carrier screening is hence of significant importance. The carrier samples were separated from the healthy ones based on their blood and plasma droplet drying patterns. Image analysis based tools were used to identify the distinct signatory features in the patterns of the respective samples and correlated to the results obtained from the gold standard method. The proposed technique can be instrumental in developing a rapid, less laborious and cost effective ‘on-field’ screening method thus enabling the initial screening of the carriers from the large population.

9:36AM K45.00009: Creeping of Salt Solutions: Influence of Surfactants  
MOHSIN QAZI (Presenter), HERISH SALIM, ETIENNE JAMBON-PUILLET, DANIEL BONN, NOUSHINE SHAHIDZADEH, Institute of Physics, University of Amsterdam — Salt creeping, the growth of crystals from evaporating salt solutions beyond the solution boundary, is a very common and fascinating phenomenon. It has a significant impact in industrial processes involving high salt concentrations, for the sodification of agricultural soils and for the preservation of salt-contaminated buildings and artworks1. In spite of its importance, salt creeping remains poorly understood and there are consequently hardly or no measures to control the phenomenon2. We present new experiments using a custom-made setup, that allows to reproduce the creeping phenomenon in the laboratory and study the influence of environmental conditions and additives. We show that during evaporation of salt solutions, the creeping starts only when the contact angle reaches a well-defined critical value, allowing us to propose a mechanism for the creeping dynamics. In addition, a nucleation promoting surfactant promotes creeping whereas a nucleation inhibitor prevents it.

9:48AM K45.00010: Transient dynamics of viscous drop impact on immiscible liquid bath: A holistic analysis*  
KUMARI TRINAVEE (Presenter), SIRSHENDU MISRA, NAGA SIVA KUMAR GUNDA, SUSHANTA MITRA, Mechanical and Mechatronics Engineering, University of Waterloo — Droplet entry problems offer extensive opportunities to understand the non-trivial multifluid interaction and the resulting complex evolution of phase boundary. Although droplet entry problems on identical or miscible liquid pool has been prolifically studied, its immiscible counterpart is rather unexplored. In this work, we present our holistic approach coupling experimental observation with theoretical and numerical validation to better understand the dynamics of droplet impact for an oil droplet impinged on a water pool. Our focus is laid on understanding the topologically complex temporal evolution of the oil/water liquid interface. Images acquired from a high-speed camera has been processed to obtain the interface acceleration which in turn is used to calculate an assistive force field responsible for the pinch-off. An analysis involving the change in total energy in the penetration process for a flow field with negligible viscous dissipation has been presented. The experimental results are validated with a volume of fluid based numerical model developed in-house. Additionally, we investigated the equilibrium droplet shape beyond penetration and its dependence on the properties of surrounding fluid, which still is an unexplored area in literature.

Investigation of the interaction between graphene membranes suspended and liquid by nano-infrared spectroscopy*

LEONEL MEIRELES (Presenter), Universidade Federal de Minas Gerais, INGRID DAVID BARCELOS, CNPEM, Laboratório Nacional de Luz Síncrotron, GUSTAVO ARRIGHI FERRARI, PAULO ALEXANDRE DE ALMEIDA NEVES, Universidade Federal de Minas Gerais, RAUL OLIVEIRA FREITAS, CNPEM, Laboratório Nacional de Luz Síncrotron, RODRIGO GRIBEL LACERDA, Universidade Federal de Minas Gerais — The chemical properties of biological systems in their native living environment has been a constant ambition in life sciences. Infrared spectroscopy is a unique analytical tool that enables identification of chemical compounds by their natural molecular-vibrational signatures in a label-free mode. Here we report the development of a robust fluidic platform specifically designed for nanoscale resolved infrared spectroscopy of biomaterials in liquid environments. An advantage of our proposed fluidic chip is the use of an atomic-thin graphene layer as an optical window for accessing the liquid stream inside the micro-channels written in the silicon wafer. We demonstrate the feasibility of the platform for scattering scanning near-field optical microscopy for measuring the infrared fingerprint of typical biological fluids based on Dimethyl Sulfoxide, Phosphate, Citric Acid, and Human Serum Albumin. We foresee our development to serve as a template for future studies involving fundamental questions on the chemistry of in-solution nanoscale bio-systems.

*We thank the financial support given by CAPES, Fapemig, (Rede 2D), CNP, INCT/Nanomaterials de Carbono and for Brazilian Synchrotron Light Laboratory (LNLS) for the beamline time.

Underliquid wetting behavior of graphene: Is the hypothesis of wetting transparency valid?*

SIRSHENDU MISRA (Presenter), NAGA SIVA KUMAR GUNDA, SUSHANTA MITRA, Department of Mechanical and Mechatronics Engineering, University of Waterloo — Since the inception of wetting transparency hypothesis, understanding the wetting behavior of graphene and its dependence on the choice of underlying support layer fostered significant attention from scientific community. However, wetting studies on submerged graphene coated substrates are relatively scarce despite promising practical applications (e.g. water harvesting, oil-water separation etc.). Here we attempt to understand the wetting characteristics of a monolayer of graphene coated on a glass substrate when submerged in a liquid bath. A wide range of droplet and surrounding liquid combinations have been investigated to assess the dependency on the interaction potentials. In general, partial transparency towards wetting is observed and the degree of the same is seen to demonstrate a non-trivial dependence on the polar and dispersive interaction potentials between the participating entities with the competition between wetting affinities of the droplet and the surrounding liquid with respect to the coated substrate displaying the most prominent effect. Taking cue from Trinavee et al. (Langmuir 2018, 34, 11695−11705), a modified theoretical model involving formation of an intermediate thin film is proposed to explicate this underliquid wetting phenomenon.

*WIN Nanofellowship

Isotherm kinetics and rapid sorption activity of mesoporous vdW 2D sheets decorated with magnetic nanobeads*

MEENAKSHI TALUKDAR (Presenter), PRITAM DEB, Tezpur University — Two-dimensional (2D) van der Waals (vdW) adsorbent sheets represent as an emerging class of materials overcoming the limitations for oil adsorption. Here, the interaction between adsorbent and adsorbate can be realised by the adsorption isotherm of the adsorption process [Phys. Rev. Lett. 120, 264502, 2018]. Besides, the kinetics of the adsorption process is an important characteristics in understanding the rate of adsorption mechanism in vdW sheets [Rev. Mod. Phys. 89, 035005, 2017]. In addition to the standard isotherm and kinetics retention of the physical phenomena of the host magnetic nanocomposite system, our study has reported a promising adsorbent material for efficient and rapid oil recovery providing feasible solution towards the upcoming oil consumption [arXiv 2018.03037, 2018]-[Indian Patent Application 201831009592, 2018].

*Tezpur University
Effect of Catalysis-clustering on Gas-sensing Performance*

NACIR TIT (Presenter), MUHAMMAD ALI, ALAA SHAHEEN, Physics, UAE University — We present a theoretical investigation, based on a combined of density-functional theory (DFT) and non-equilibrium Green’s-functional (NEGF) formalism, to study the effect of catalysis-clustering on the sensor response. Specifically, the scope is to compare the adsorption and transport properties after chemisorption of CO2 molecules on iron (Fe) ad-atoms deposited on graphene nano-ribbons (GNR) in two different ways: (i) Five Fe ad-atoms deposited on GNR in scattered fashion; and (ii) A cluster of five Fe atoms deposited on GNR. The results of IV-curves calculations confirm stronger deviations in the case of scattered Fe ad-atoms and, consequently, stronger sensor response. This work suggests stronger sensitivity and selectivity to be reached by scattering ad-atoms of the transition-metal catalysis and with an optimization of their density. As the sensor response is based on the deviation of conductance from before to after the exposure to the gas, our results have indeed a direct application to fabricate solid-state based gas sensors working with high sensitivity at room temperature, to detect toxic and hazardous gases such as CO2.

Session K46 DMP: Complex Oxide Interfaces & Heterostructures -- Interfacial two dimensional electron gas

8:00AM K46.00001: Two dimensional t2g electron gas at the oxide interface* [Invited] ALEXANDER DEMKOV (Presenter), University of Texas at Austin — The discovered revolutionary class of polar oxide heterostructures holds tremendous promise for exploiting the physical properties of the novel 2DEG formed at the oxide/oxide interface. SrTiO3 is a widely used substrate for the growth of other functional oxide thin films. The reactivity of the substrate with respect to the film during deposition, particularly with regard to redox reactions, has typically been glossed over. We have recently demonstrated by depositing a variety of metals and measuring the in situ core level spectra of both the metal and SrTiO3 that, depending on the oxide formation energy and work function of the metal, there will be an interfacial layer of oxygen-deficient SrTiO3 at the interface with the top oxide film. I will focus on the integrated highly spin-split ferromagnetic semiconductor EuO onto perovskite SrTiO3 (001). A careful deposition of Eu metal by molecular beam epitaxy resulted in EuO growth via oxygen out-diffusion from SrTiO3. This in turn leaves behind a highly conductive interfacial layer through generation of oxygen vacancies. Below the Curie temperature of 70 K of EuO, this spin-polarized two-dimensional t2g electron gas at the EuO/SrTiO3 interface displays very large positive linear magnetoresistance.

*Air Force Office of Scientific Research (FA9550-12-10494)

8:36AM K46.00002: Engineering BaTiO3 Based Ferroelectric Materials with Reactive Molecular Dynamics Simulations* DUNDAR YILMAZ (Presenter), DOOMAN AKBARIAN, Pennsylvania State University, PANCHAPAKESAN GANESH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, ADRI C VAN DUIN, Pennsylvania State University — Ferroelectric materials such as barium titanate (BaTiO3) have wide applications in nano scale electronic devices due to their outstanding properties. In this study, we developed a ReaxFF reactive force field for BaTiO3 which can reproduce the ferroelectric/non-ferroelectric phases, ferroelectric and thermal hysteresis loops of the BaTiO3 crystal structure and O-vacancy, Ba-O and Ti-O divacancy formation energies and their migration. This ReaxFF description can be straightforwardly extended to a wide range of material interfaces. The force field predicted that a 4.8 nm sample thickness is required to observe the ferroelectric hysteresis effect. Also, we found that oxygen vacancies (OVs) in the BaTiO3 cluster reduce the polarization and the phase transition temperature. Our BaTiO3 ReaxFF reactive force field showed an outstanding ability of predicting the domain walls in BaTiO3. We investigated effect of the defect (O-vacancy, divacancy) densities as well as the thickness on the ferroelectric hysteresis loops of the BaTiO3 thin film structures to lead design efforts of novel BaTiO3 based ferroelectric materials.

Engineered Helicity of One-Dimensional LaAlO$_3$/SrTiO$_3$ Nanowires

MEGAN BRIGGEMAN (Presenter), JIANAN LI, Physics and Astronomy, University of Pittsburgh, MENGCHEN HUANG, Physics, University of California-Santa Barbara, ANTHONY TYLAN-TYLER, Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, JUNGWOO LEE, CHANG-BEOM EOM, Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Physics and Astronomy, University of Pittsburgh — Quantum transport in 1D geometries is fascinating in its own right, but it can also be regarded as a building-block for a variety of quantum devices. We have developed a flexible platform for creating 1D nanostructures at the LaAlO$_3$/SrTiO$_3$ interface using a conductive-AFM lithography technique [1]. Straight nanowire segments behave as electron waveguides with subband occupation that can be tuned with a gate and an external magnetic field [2]. We can periodically perturb this waveguide, with 10 nm periodicity, in two ways. “Kronig-Penney” type modulation results in periodic vertical displacement of the electron waveguide, and sinusoidal lateral displacement of the nanowire can also be achieved. Combining the two perturbations in quadrature yields a helical nanowire which exhibits striking oscillatory transmission as a function of both magnetic field and chemical potential. We discuss these results in terms of an engineered axial in-plane spin-orbit interaction within the spiral electron waveguide.

Determination of Spin-Orbit Scattering Lifetime at the Interface of LaAlO$_3$/SrTiO$_3$ from the Superconducting Upper Critical Fields

WEI-LI LEE (Presenter), AKHILESH SINGH, TSUNG-CHI WU, MING-YUAN SONG, MING-CHIN CHEN, CHI-SHEN LI, Institute of Physics, Academia Sinica — The intrinsic mechanism of the spin-orbit coupling at the LaAlO$_3$/SrTiO$_3$ interface remains a debatable issue. Rashba-type spin-orbit coupling is an appealing candidate that has been demonstrated by several magnetotransport results. On the other hand, the atomic spin-orbit coupling was also shown to play an important role, particularly when the Fermi level is close to the Lifshitz point. Unlike previous works, we focus on the measurements of the anisotropic and superconducting upper critical fields in gated LaAlO$_3$/SrTiO$_3$ devices. By rigorous fittings of the $H_{c2}$-$T$ curves using both the Werthamer-Helfand-Hohenberg theory and Klemm-Luther-Beasley model, the spin-orbit scattering lifetime can be determined with high precision in superconducting state. We found that the extracted spin-orbit lifetime monotonically increase with the transport lifetime that spanned over two orders of magnitude in the regime with sheet density higher than that at Lifshitz point. Those results suggest the dominant role of Elliott-Yafet type spin-relaxation. Comparison to the weak localization fittings will be presented and discussed.

*We acknowledge the funding support from MoST Taiwan (MOST 105-2112-M-001 -012 -MY3).

Nanoscale Inhomogeneous Energy Landscape in LaAlO$_3$/SrTiO$_3$ Heterostructures

ADITI NETHWEWALA (Presenter), MEGAN BRIGGEMAN, JIANAN LI, YUHE TANG, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, JUNGWOO LEE, CHANG-BEOM EOM, Department of Material Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — The energy landscape of LaAlO$_3$/SrTiO$_3$ (LAO/STO) heterostructures plays an important role in determining the transport phenomena. An inhomogeneous energy landscape can lead to the breakdown of 2D transport and the emergence of 1D transport. Thus, knowledge of the energy landscape of the system can play a significant role in understanding correlated electron systems. Here we report a minimally invasive probing technique to map the energy landscape of LAO/STO heterostructures. Using conductive atomic force microscope (c-AFM) lithography [1], we write nanoscale cross-shaped electron waveguides, or “nanocrosses”. Low temperature magnetotransport measurements reveal signs of spatial inhomogeneity. Anisotropic magnetoconductance and anomalous Hall resistance also indicate inhomogeneity. The nanocross geometry provides a powerful tool for exploring the energy landscape of the system and its implications under one frame.

9:24 AM K46.00006: Two-dimensional type-II Dirac fermions in a LaAlO3/LaNiO3/LaAlO3 quantum well

LINGLING TAO (Presenter), EVGENY Y TSYMBAL, Institute of Physics — The type-II Dirac fermions that are characterized by a tilted Dirac cone and anisotropic magnetotransport properties have been recently proposed theoretically and confirmed experimentally. Here, we predict the emergence of two-dimensional (2D) type-II Dirac fermions in LaAlO3/LaNiO3/LaAlO3 quantum-well structures. Using first-principles calculations and model analyses, we show that the Dirac points are formed at the crossing between the dx2−y2 and dz2 bands protected by the mirror symmetry. The energy position of the Dirac points can be tuned to appear at the Fermi energy by changing the quantum-well width. For the quantum-well structure with a two-unit-cell-thick LaNiO3 layer, we predict the coexistence of the type-II Dirac point and the closed nodal line. The results are analyzed and interpreted using a tight-binding model and symmetry arguments. Our findings offer a practical way to realize 2D type-II Dirac fermions in oxide heterostructures.

9:36 AM K46.00007: Density-functional prediction of a spin-orbital entangled two-dimensional electron gas at LaAlO3/SrIrO3 (001) interface

CHURNA BHANDARI (Presenter), SASHI SEKHAR SATPATHY, University of Missouri — With the recent advances on the epitaxial growth techniques, epitaxy grown ultrathin films of SrIrO3 have brought in a considerable research interest as they exhibit thickness dependent metal-insulator transition and other interesting transport properties. SrIrO3 is a Mott insulator below three or four layers of SrIrO3 grown on the SrTiO3 substrate. Using density-functional methods, we study the (001) interface between the non-polar SrIrO3 and the polar LaAlO3 material, where the LaO layer is in contact with the IrO2 layer. We predict the formation of a spin-orbital entangled 2DEG at the interface due to the polar catastrophe, analogous to the n-type LaAlO3/Sr2IrO4 interface. The predicted 2DEG is very well localized at a single layer of Ir near the interface occupying the J\text{eff} = 1/2 conduction bands (upper Hubbard band). The 2DEG leads to a ferromagnetic interface, which is different from the antiferromagnetic bulk.

*This research was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Grant No. DE-FG02-00ER45818.

9:48 AM K46.00008: Silicon-Integrated Transition Metal Oxide Thin Film Quantum Structures

J. ELLIOTT ORTMANN (Presenter), University of Texas at Austin, SUNAH KWON, University of Texas at Dallas, AGHAM POSADAS, University of Texas at Austin, MOON KIM, University of Texas at Dallas, ALEXANDER DEMKOV, University of Texas at Austin — While the SrTiO3/LaAlO3 (STO/LAO) system has garnered widespread attention since the discovery of a two-dimensional electron gas at the interface of these two band insulators, recent efforts have instead focused on its optical properties. The huge 2.4 eV conduction band offset between STO and LAO allows for charge confinement in STO quantum wells and the optical and electrical modulation of carriers between confined states. Such heterostructures could find use in a multitude of next-generation electrical, optical, and electro-optical devices. However, the technological relevance of such devices hinges on the ability to successfully integrate high-quality STO/LAO quantum structures with silicon. Here, we demonstrate the monolithic integration of high-quality STO/LAO multiple quantum wells on silicon (001) with molecular beam epitaxy. We present electron diffraction, X-ray diffraction and electron microscopy studies establishing the excellent uniformity and crystalline quality with which such heterostructures can be fabricated. Finally, we present examples of how silicon-integrated STO/LAO quantum structures could be used in device fabrication.

10:00 AM K46.00009: Transport regimes of a split gate superconducting quantum point contact in the two-dimensional LaAlO3/SrTiO3 superfluid

HOLGER THIERSCHMANN (Presenter), EMRE MULAZIMOGLU, MANCA NICOLA, Quantum Nanoscience, Delft University of Technology, SRJJIT GOSWAMI, QuTech, Delft University of Technology, TEUN M Klapwijk, ANDREA CAVIGLIA, Quantum Nanoscience, Delft University of Technology — Ever since the observation of the quantized resistance in a point contact in GaAs/AlGaAs heterostructures it has been a long standing goal to achieve similar experimental conditions also in superconductors. Being formed with split gate technology, these structures represent in an ideal manner equilibrium reservoirs which are connected only through a few electron mode channel. Here we demonstrate the formation of a superconducting quantum point contact (SQPC) with split gate technology in a two-dimensional superconductor, utilizing the unique gate tunability of the superfluid at the LaAlO3/SrTiO3 interface. When the constring is tuned through metallic split gates we identify three regimes of transport: First, SQPC for which the supercurrent is carried only by a few quantum transport channels. Second, superconducting island strongly coupled to the equilibrium reservoirs. Third, charge island with a discrete spectrum weakly coupled to the reservoirs.

*We acknowledge funding by the Netherlands Organisation for Scientific Research, Dutch Foundation for Fundamental Research on Matter, the ERC (METIQUM, grant no. 339306, EU H2020 programme/ERC Grant 677458), Quantox of QuantERA ERA-NET cofund in Quantum Technologies and the Russian Science Foundation (RSF) Project No.17-72-30036.

MICHAEL VEIT (Presenter), DI YI, Stanford University, REMI ARRAS, University of Toulouse, ROSSITZA PENTCHEVA, University of Duisburg-Essen, YURI SUZUKI, Stanford University — Emergent metallic behavior at the interface of the Mott insulator LaTiO3 and the band insulator SrTiO3 has been explained in terms of charge redistribution at the interface combined with strain-induced electronic structure modification. We have previously studied ultra-thin (3 unit cell thick) films of LaTiO3 on SrTiO3 substrates and found evidence for unexpectedly large spin-orbit coupling from quantum oscillations with an associated Berry phase, weak anti-localization in the magnetoresistance, and anisotropic in-plane magnetoresistance. In order to tune this material, we have electrically gated these films both on the back side of the SrTiO3 substrate and on top of the LaTiO3 film with an electrolytic gate. Most interestingly, we found a maximum in the resistance that is quantized to the quantum of conductance (2e^2/h). This is independent of the dimensions of the sample. Additionally, by studying samples with four and six contact geometries, we measure nonlocal transport similar. These features are present up to a surprisingly high temperature of 230K. We attribute these observations to helical edge states at the LaTiO3/SrTiO3 interface.

**10:24AM K46.00011: Anisotropic magnetoresistance for (111) SrTiO3 surfaces within Boltzmann transport theory**

NAZIM BOUDJADA (Presenter), ILIA KHAIT, ARUN PARAMEKANTI, University of Toronto — 2D electron gases formed at (111) surfaces and interfaces of SrTiO3 are highly sensitive to application of in-plane magnetic fields. Motivated by recent magnetoresistance experiments which report different crystalline symmetry components appearing at different gate voltages, we derive a multi-orbital single-layer Hamiltonian which includes spin-orbit coupling, orbital Rashba and broken inversion symmetry at the surface. The anisotropic magnetoresistance is calculated by solving the Boltzmann equation. An explanation for the experimental results observed for SrTiO3 is devised.

**10:36AM K46.00012: Adding depth resolution to resonant inelastic X-ray scattering by means of standing-wave excitation**

CHENG-TAI KUO (Presenter), SHIH-CHIEH LIN, Department of Physics, University of California, Davis, YINGYING PENG, Department of Physics and Seitz Materials Research Laboratory, University of Illinois, Urbana, YU-CHENG SHAO, Advanced Light Source, Lawrence Berkeley National Laboratory, GABRIELLA MARIA DE LUCA, DANIELE DI CASTRO, CRN-SPIN, ISMAEL GRAFF, Departamento de Fisica, Universidade Federal do Parana, NICHOLAS B BROOKES, European Synchrotron Radiation Facility, YI-DE CHUANG, Advanced Light Source, Lawrence Berkeley National Laboratory, MARK HUIJBEN, University of Twente, LUCIO BRAICOVICH, GIACOMO GHIRINGHELLI, Politecnico di Milano, CHARLES FADLEY, Department of Physics, University of California, Davis — Resonant inelastic X-ray scattering (RIXS) is a photon-in/photon-out synchrotron-based spectroscopy that uniquely probes the charge transfer, dd, magnetic, phonon and other excitations in correlated oxides and other systems. RIXS is considered to be a probe of bulk properties, reaching depths of the order of 1000 Å. It is thus desirable to give RIXS more quantitative depth resolution, for example to investigate interfaces in oxide heterostructures, which are known to show emergent properties (e.g. interface-induced ferromagnetism at the La_{1.85}Sr_{0.15}CuO_4/La_{0.67}Sr_{0.33}MnO_3 (LSCO/LSMO) heterostructures, 2D electron gases at LaAlO_3/SrTiO_3 (LAO/STO) heterostructure) not present in the single constituents. Here, we demonstrate that, by using standing-wave (SW) excitation from multilayer heterostructures, interface-specific RIXS information can be obtained. We present the results of SW-RIXS measurements on LSCO/LSMO and LAO/STO superlattices. SW effects are clearly observed on the RIXS excitations for these systems and we found to have different depth distribution. SW-RIXS will open up a new spatial dimension to this already powerful technique.

Chemically specific termination control of oxide interfaces via layer-by-layer mean inner potential engineering

HAOYING SUN (Presenter), ZHANGWEN MAO, TIANWEI ZHANG, LU HAN, TINGTING ZHANG, Nanjing University, XIANGBIN CAI, Department of Physics, Hong Kong University of Science and Technology, XINGFEI LI, YIPENG ZANG, WEI GUO, JIANHUI SONG, DIANXIANG JI, CHENYI GU, CHAO TANG, ZHENGXIN GU, Nanjing University, NING WANG, Department of Physics, Hong Kong University of Science and Technology, YE ZHU, Department of Applied Physics, The Hong Kong Polytechnic University, DARRELL G. SCHLOM, Department of Materials Science and Engineering, Cornell University, YUEFENG NIE, Nanjing University, XIAOQING PAN, Department of Chemical Engineering and Materials Science and Department of Physics and Astronomy, University of California, Irvine

Creating oxide interfaces with precise chemical specificity at the atomic layer level is desired for the engineering of quantum phases and electronic applications, but highly challenging, owing partially to the lack of in situ tools to monitor the chemical composition and completeness of the surface layer during growth. Here we report the in situ observation of atomic layer-by-layer inner potential variations by analysing the Kikuchi lines during epitaxial growth of strontium titanate, providing a powerful real-time technique to monitor and control the chemical composition during growth. A model combining the effects of mean inner potential and step edge density (roughness) reveals the underlying mechanism of the complex and previously not well-understood reflection high-energy electron diffraction oscillations observed in the shuttered growth of oxide films. General rules are proposed to guide the synthesis of atomically and chemically sharp oxide interfaces, opening up vast opportunities for the exploration of intriguing quantum phenomena at oxide interfaces.

Session K47: Photovoltaics -- Solar Energy Conversion I

Photovoltaics for High Specific Power: Increasing Markets and Decreasing Package Weight

NANCY HAEGEL (Presenter), National Renewable Energy Laboratory — Emerging markets for lightweight, flexible, and portable power, including unmanned aerial vehicles, portable charging, remote-site power generation, vehicle-integrated and building facades, could benefit from photovoltaic technologies with high specific power (W/kg). Thin-film and emerging technologies offer advantages for lightweight, flexible power, including decreased cost and package weight and the opportunity to utilize new materials and lift-off techniques. We have assessed the role of the substrate, packaging, and interconnects to provide a quantitative assessment of designs to maximize specific power. Including all required components and weight limitations associated with safety and reliability, we estimate a lower bound for a durable lightweight module of ~ 300-500 g/m². For a thin film device with 15% efficiency, this would yield up to 500 W/kg and up to 1200 W/kg for a 35% for a high efficiency III-V multijunction device [1].

*Work supported by the U.S. Department of Energy under Contract No. DE-AC36-08-GO28308 with the National Renewable Energy Laboratory (NREL). Funding provided by the U.S. Office of Naval Research and through NREL's Lab Directed Research and Development initiative.

Stability and the Electronic Properties of Silicon-rich Silicon Carbide Structures by First Principle Calculations

NOURA ALKHALDI (Presenter), SAJIB BARMA, MUHAMMAD NURUL HUDA, University of Texas at Arlington — Silicon carbide has been used in a variety of applications such as solar cells material due to its high stability. Obtaining silicon-rich silicon carbide materials are necessary to tune the band gap for efficient solar light absorptions. In addition, thermodynamically stable Si-rich SiC materials can be used in solar cell applications without requiring the expensive pure grade silicon or pure grade silicon carbide materials. We have used density functional theory (DFT) calculations to examine different phases of silicon-rich silicon carbide to predict stable structures. Different configurations of silicon and carbon atoms in silicon-rich silicon carbide structures have been considered because the configurations play a significant role in getting stable results. The electronic structures have been studied, and the total energies have been calculated as well as the formation energies. These results will be presented. The results show that higher-order hexagonal-phases are more favorable structures than other silicon-rich silicon carbide structures due to their more covalent nature of bonding compared to the cubic counterpart.

8:24AM K47.00003: Toward the rational design of organic solar photovoltaics: A DFT study of substituent effects on P3MT

DAVID PERRY (Presenter), The University of Akron, SANDILE MAMBA, GUISEPPE PELLICANE, School of Chemistry and Physics, University of KwaZulu-Natal, MESFIN TSIGE, The University of Akron — Organic polymers containing conjugated thiophene rings are among the candidates for the electron-donor materials in organic solar cells. Since material synthesis, device fabrication, and definitive characterization of those devices is tedious and expensive, it is desirable to apply computational methods to a systematic variation of the material chemistry to predict which materials will have the best properties and, potentially, which will yield the highest photon conversion efficiency. Reported here is a model study in which DFT calculations of poly-3-methyl thiophene (P3MT) with a range of 12 different substituents. For each candidate polymer, DFT calculations at the B3LYP-D2/6-31G(d,p) level were extrapolated to the long-chain limit. The following properties relevant to application in a photovoltaic device were estimated from the calculations: (i) the bandgap, (ii) the LUMO energy, and (iii) the steric hindrance to coplanarity of adjacent rings. While (ii) was found to be well correlated with the electron-donating property of the various substituents, (i) and (iii) were much less so indicating a design space in which these three critical properties could, to some extent, be varied independently.

8:36AM K47.00004: Quantitative Nanoscale Mapping of Photovoltaic Properties in Hybrid Organic/Inorganic Solar Cells

HAIAN QIU (Presenter), Department of Physics, Applied Physics, and Astronomy, Binghamton University, JONG HYUN SHIM, JUNGHYUN CHO, Materials Science and Engineering Program, Binghamton University, JEFFREY M. MATIVETSKY, Department of Physics, Applied Physics, and Astronomy, Binghamton University — Conductive atomic force microscopy (C-AFM) has been widely used to map local charge transport in functional materials and photovoltaic active layers. Recently, we have developed and employed C-AFM-based point-by-point current-voltage (PPIV) mapping to quantitatively investigate electrical properties such as local charge carrier mobility and to visualize local spatial variations in photovoltaic parameters such as open-circuit voltage, power conversion efficiency, and charge photogeneration rate. In this talk, we will present two examples in which PPIV mapping is employed to elucidate the influence of local morphology on photovoltaic properties in hybrid organic-inorganic systems. In the case of P3HT: ZnO nanorod active layers, photovoltaic properties are strongly dependent on the local P3HT hole transport layer thickness. Charge generation rate and charge collection probability maps reveal that photocurrent is mainly limited by charge collection. For inverted perovskite solar cells, PPIV photovoltaic characteristic maps exhibit an increased open-circuit voltage at crystal grain boundaries, indicating an important role played by these features.

8:48AM K47.00005: Degradation Mechanisms in Perovskite Solar Cells Probed by Low-Frequency Carrier Kinetics

VINOD SANGWAN (Presenter), MENGHUA ZHU, SARAH CLARK, KYLE LUCK, Materials Science and Engineering, Northwestern University, Evanston, IL 60208, TOBIN MARKS, MERCOURI KANATZIDIS, Chemistry, Northwestern University, Evanston, IL 60208, MARK HERSAM, Materials Science and Engineering, Northwestern University, Evanston, IL 60208 — Hybrid organic-inorganic perovskite solar cells have emerged as leading candidates for third-generation solar cell technology. Despite their superlative power conversion efficiencies (PCEs), hysteresis and degradation limit their applications, thus motivating detailed studies of the underlying physical mechanisms. We introduce correlated low-frequency noise and impedance spectroscopy characterization that reveals carrier kinetics in perovskite solar cells. We employ cells with different hole transport layers that also elucidate tradeoffs between solar cell performance metrics and stability. We focus on the technologically relevant planar cell structure using an emerging SnO2 electron transport layer and two widely used hole transport layers: poly(triarylamine) (PTAA) and Spiro-OMe TAD. PTAA and Spiro-OMe TAD cells with moderate PCEs of 5–12% show a Lorentzian feature at ~200 Hz corresponding to a single fluctuator. Spiro-OMe TAD cells with high PCE (>15%) show four orders of magnitude larger 1/f noise amplitude with a distinctive peak, which is indicative of a cyclostationary process that is correlated with an inductive loop in impedance spectra. The observed current fluctuations are consistent with trapping and de-trapping of methylammonium ions near the SnO2 interface.
9:00AM K47.00006: Domain boundaries in the dipolar order in the perovskite material CH$_3$NH$_3$PbI$_3^*$  
SAHEL ASHHAB (Presenter), MARCELO CARIGNANO, MOHAMED E. MADJET, Qatar Environment and Energy Research Institute (QEERI), Hamad Bin Khalifa University (HBKU), Qatar Foundation, Qatar — We investigate the ordering of the CH$_3$NH$_3$ dipoles in the material CH$_3$NH$_3$PbI$_3$. The dipoles are arranged in a simple cubic lattice. We perform numerical simulations in which we set the boundary conditions such that opposite sides of the simulated sample are ordered in different directions, hence simulating a domain boundary. We calculate the lowest energy state under this constraint. We find that at the level of dipole-dipole interactions, the dipole orientations tend to gradually transform between the two orientations at the two ends of the sample. When we take into consideration the finite spatial size of the CH$_3$NH$_3$ molecules and go beyond the point dipole approximation, we find that the domain boundary becomes sharper. For the parameters of CH$_3$NH$_3$PbI$_3$, our results indicate that the optimal energy structure has a boundary region of a width on the order of a single unit cell.

*This work was made possible by NPRP grant # 8-086-1-017 from the Qatar National Research Fund (a member of Qatar Foundation).

9:12AM K47.00007: Efficient first-principles calculation of phonon assisted photocurrent in large-scale solar cell devices  
MATTIAS PALSGAARD, KURT STOKBRO (Presenter), TROELS MARKUSSEN, Denmark, Synopsys, TUE GUNST, MADS BRANDBYGE, Physics, Technical University of Denmark — We present a straightforward and computationally cheap method to obtain the phonon-assisted photocurrent in large-scale devices from first-principles transport calculations[1]. The photocurrent is calculated using nonequilibrium Green's functions with light-matter interaction from the first-order Born approximation while electron-phonon coupling (EPC) is included through special thermal displacements (STD). We apply the method to a silicon solar cell device and demonstrate the impact of including EPC in order to properly describe the current due to the indirect band-to-band transitions. The first-principles results are successfully compared to experimental measurements of the temperature and light intensity dependence of the open-circuit voltage of a silicon Photovoltaic (PV) module[1]. We use the method to predict the solar cell efficiency of new Janus type 2D devices[2] and show that they outperform the silicon PV module. This work represents a recipe for computational characterization of future PV devices including the combined effects of light-matter interaction, phonon-assisted tunneling and the device potential at finite bias from the level of first-principles simulations.

9:24AM K47.00008: Highly efficient Non-Fullerene Organic Solar Cell with Fine Tuned Hole Transporting Layer  
QIN HU (Presenter), University of Massachusetts Amherst, ZHONG ZHENG, Chinese Academy of Sciences, WENKAI ZHONG, Lawrence Berkeley National Laboratory, JIANHUI HOU, HUIQIONG ZHOU, Chinese Academy of Sciences, FENG LIU, Shanghai jiaotong University, THOMAS RUSSELL, University of Massachusetts Amherst — Non-fullerene organic solar cells have experienced rapid development in the past few years with their impressive optoelectronic properties and great potential in practical applications. Here, we present a facile and effective strategy to improve the device performance through hole-transporting layer (HTL) modification. By optimizing Wox (nanoparticles): PEDOT:PSS composition, the surface free energy of the HTL is improved, hence influences the crystallization mechanism of PBDB-T:IT4F bulk-heterojunction (BHJ) active layer. In-situ grazing incident X-ray diffraction (GIXD) is applied to monitor the crystallization kinetics and morphology formation of the active layer based on different HTLs. The crystal coherence lengths and lamellar stacking distance as well as the phase separation are adjusted by various HTLs. In addition, the optimized HTL can promote more balanced carrier transport ability, leading to reduced non-radiative recombination and higher fill factor. The crystallization to structure, and film property to device performance relationship are established. A power conversion efficiency of 14.2% is achieved based on laboratorial spin-coating process, while an efficiency of 11.9% is obtained via industrial comparable slot-die printing fabrication.

9:36AM K47.00009: Conduction Band Matching in CdSe - Metal Oxide Quantum Dot Solar Cells: The Competition Between Energetics and Electron Transfer Kinetics*  
MATTHEW BECKER (Presenter), SAM AYALA, Saint Mary's College — Quantum dot solar cells were constructed by pairing CdSe quantum dots with metal oxides whose conduction band is very close to that of the CdSe. We hypothesized that the reduced loss of energy due to the closely matched conduction bands would result in a higher open circuit voltage. It was found that the band-matched solar cells perform more poorly and that the improved electron kinetics resulting from a large difference between CdSe and metal oxide conduction band energies seems to have a larger influence on the efficiency of these quantum dot solar cells.

*We wish to acknowledge and thank the Neuhoff Summer Science Communities Grant for providing seed funding for this project.
9:48AM K47.00010: How did solar energy get so cheap, and how much cheaper can it get?  HARRY APOSTOLERIS (Presenter), Khalifa University, MARCO STEFANCICH, Dubai Electricity and Water Authority, MATTEO CHIESA, Khalifa University — In the last several years, the cost of electricity from photovoltaics has fallen to the point where it is now the cheapest source of electricity across large parts of the world. Understanding how this happened is essential to guiding future research in solar energy technology. We have conducted a detailed analysis of the technological and economic factors that led to the realization of ultra low solar electricity prices in the United Arab Emirates, Saudi Arabia, Chile, Mexico and the southwestern US. We show that the primary influences are the declining cost of hardware (PV modules, inverters, trackers) and the low cost of capital available to these projects, combined with local factors such as labor costs and reductions in soft costs. In this presentation we will demonstrate the relative impact of these factors in different locations using a bottom-up LCOE model, and discuss their likely future trends (i.e. future evolution of hardware prices, or the expected impact of interest rate variations on the cost of financing). In this way we aim to provide a "big picture" context for today’s solar energy research.

10:00AM K47.00011: Electrostatic Potential Fluctuations in Thin-Film Photovoltaics†  HARVEY GUTHREY (Presenter), JOHN MOSELEY, MOWAFAK AL-JASSIM, National Renewable Energy Laboratory (NREL) — Increasing the conversion efficiency of photovoltaics based on thin-film absorbers materials requires minimizing the open circuit voltage (Voc) deficit (difference between the band gap and Voc) and producing films with sufficient charge carrier concentrations. However, inherent to these materials are high concentrations of intrinsic point defects and intentional extrinsic defects that can result in 1) significant charge carrier compensation thus reducing the carrier concentration and 2) fluctuations in the local electrostatic potential that define the band structure resulting in increased charge carrier recombination and low Voc values. Understanding both the magnitude and spatial distribution of such potential fluctuations is necessary in order to refine material and device fabrication processes to achieve the highest photovoltaic conversion efficiency. In this contribution, we demonstrate how cathodoluminescence microscopy can be used to monitor such changes in CdSeTe and CuInGaSe2 thin-films with sub-100nm spatial resolution. In addition we discuss the physical mechanisms behind how atomic-scale compositional variations relate to the magnitude and spatial distribution of electrostatic potential fluctuations in these materials.

*U.S. D.O.E. Contract No. DE-AC36-08GO28308

10:12AM K47.00012: Detection of shot noise in perovskite solar cells and related devices†  KEVIN DAVENPORT (Presenter), MARK HAYWARD, LOGAN DRAPER, ANDREY ROGACHEV, University of Utah — Hybrid organic-inorganic perovskite solar cells are one of the most promising emerging technologies with the capability to compete with established silicon devices. The effective commercial rollout of perovskite-based devices, however, requires a fundamental understanding of the material’s electrical transport properties. We have performed current noise spectroscopy on a series of methylammonium lead triiodide perovskite solar cells. Under illumination, the noise power spectrum exhibits two main components: a 1/f6 flicker noise and a frequency-independent white noise. Our main finding is that this white noise is associated with photo-generated shot noise. The extracted Fano factor (0.6 < F < 1) indicates that the observed shot noise is full scale and that the photo-generated carriers have no significant barriers to escape the device. We have performed a similar series of measurements on amorphous silicon solar cells as well as super yellow PPV polymer-based LEDs, the results of which will also be presented.

10:24AM K47.00013: Spectral mapping of open circuit voltage of Cu(In,Ga)Se2 thin-film solar cells via surface photovoltage and its implications for hole carrier transport  JURAN KIM (Presenter), Department of Physics, Ewha Womans University, KIHWAN KIM, JIHYE GWAK, JAE HO YUN, Photovoltaic Laboratory, Korean Institute of Energy Research (KIER), WILLIAM JO, Department of Physics, Ewha Womans University — Due to its suitable physical properties, Cu(In,Ga)Se2 (CIGS) thin-film solar cells are commercialized and expanding its application fields. Thus, the needs for bendable CIGS solar cells are also rising. Up to date, flexible CIGS solar cells have reached power conversion efficiency (PCE) over 20%, but their performance is still limited for low open-circuit voltage. It is related to electron-hole (e-h) carrier transport. Therefore, we need to comprehend carrier behavior in the solar cells and their band structure by analyzing surface photovoltage (SPV) of CIGS thin-films on flexible substrates. By 3-step process and NaF post-deposition treatment we obtained 4 different PCE of 0, 6, 12, and 17%, altering substrate temperatures. Confocal micro-Raman spectroscopy provides phase distribution inside of the materials and the surface. Kelvin probe force microscopy (KPFM) displayed upward surface potential barrier near grain boundaries, helping e-h separation. SPV results was obtained by photo-assisted KPFM under three different wavelength lasers (640, 532, and 405 nm) with different skin depths. These optoelectrical properties from confocal micro-Raman and SPV variation induced by the phase difference can elucidate how non-uniformity affects carrier transport in the solar cell materials.
10:36AM K47.00014: Modeling realistic grain boundaries in CdTe  ERIC SCHWENKER (Presenter), ARUN KUMAR MANNODI KANAKKITHODI, FAITH SEN, LI AN CHEN, SPENCER HILLS, Argonne National Laboratory, JINGLONG GUO, Physics, University of Illinois at Chicago, MOON KIM, Materials Science and Engineering, University of Texas at Dallas, ROBERT KLIE, Physics, University of Illinois at Chicago, MARIA CHAN, Argonne National Laboratory — Grain boundaries (GBs) are performance-limiting in CdTe photovoltaics. Towards understanding and improving GBs, especially in the presence of impurities or alloying elements such as Se and Cl, it is important to perform first principles density functional theory (DFT) modeling on realistic structural models. We develop and use a code FANTASTX (Fully Automated Nanoscale To Atomistic Structure from Theory and eXperiment) which aims at creating atomistic structures which are consistent with scanning transmission electron microscopy (STEM) images as well as are energetically reasonable. We will discuss the electronic structures of realistic CdTe GBs, the effects of impurities on the electronic structure, and the implications for photovoltaic performance.

10:48AM K47.00015: Quasiparticle Band Structure of Iron Pyrite*  GABE LOPEZ-CANDALES (Presenter), WEIYI XIA, Physics, University at Buffalo, YIYANG SUN, Aerospace Engineering and Mechanics, University of Minnesota, PEIHONG ZHANG, Physics, University at Buffalo — Being a non-toxic and abundant material, iron pyrite (FeS2) is an attractive material for photovoltaic applications with a very high quantum efficiency and absorption coefficient. Despite much research effort, the fundamental band gap of FeS2 is still not accurately determined. The measured fundamental band gap of FeS2 ranges from 0.84 to 1.2 eV. Surprisingly, straightforward density functional theory calculations within the generalized gradient approximation (GGA) predict a band gap of 0.46 eV, whereas the supposedly more accurate Heyd-Scuseria-Ernzerhof (HSE) hybrid functional predicts a band gap of 2.6 eV. Perhaps more intriguing is that it was reported [1] that quasiparticle calculations within the GW approximation predicts a band gap of 0.3 eV for FeS2. In this work, we report fully converged G0W0 quasiparticle band structure of FeS2 using a recently developed accelerated method [2]. Contrary to the previous claim, our results predict a 0.81 eV (dipole forbidden) band gap at the Gamma point and a dipole allowed transition energy of about 1.07 eV. Our work illustrates the importance of the convergence issue in GW calculations.

Session K48 DFD GSOFT GSNP: Thin Films, Surface Flows, Interfaces and Microfluidics I

BCEC 251 - Baiou Shi, Penn State Erie - Tag(s): Focus

8:00AM K48.00001: When Salty Water Meets a Hydrophobic Surface  ADELE POYNOR (Presenter), ANTHONY FLORIMBIO, CAYTON HORNBERGER, ZACHARY ZOLL, Allegheny College — The investigation of how water meets a hydrophobic surface suggests that a very low-density layer, called the depletion layer, forms to mitigate the loss of hydrogen bonds at the surface. Salt disrupts the hydrogen-bonding network of water and therefore is expected to affect the formation of the depletion layer. We study this interface using the quantum optical technique of Surface Plasmon Resonance (SPR) for self-assembled monolayers (SAMs) in different aqueous salt solutions.

8:12AM K48.00002: Constant-rate capillary rise in wettability-controlled tubes  BAUYRZHAN PRIMKULOV (Presenter), AMIR PAHLAVAN, RUBEN JUANES, Massachusetts Institute of Technology — Displacement of a viscous liquid by a less-viscous liquid from the solid surfaces is relevant to many practical applications, including flow through porous chemical reactors, immiscible pollutant transport in soils, and hydrocarbon recovery. We study the spontaneous imbibition of water in capillary tubes partially filled with oil slugs of fixed length. High viscosity contrast of viscous-oil with water results in a tunable constant-rate capillary rise. The capability to control both the displacement rates and wettability makes this an attractive system to explore, and the results of the study bear a direct connection to the multiphase flow in porous media, where wettability plays a critical role.
Capillary Flow Dynamics in Open Triangular Grooves: From Flatland to Curvy 3D Trajectories

NICHOLAS WHITE (Presenter), SANDRA TROIAN, MC 128-95, CALTECH, Pasadena, CA 91125 — Capillary flow in straight open triangular grooves finds widespread use in applications such as point-of-care biomedical devices, heat pipes for cooling microelectronics and spacecraft propellant management. Advances in 3D printing and other patterning techniques can now be used to fabricate compact open curved channels in 3D. This capability introduces the potential for multi-layer and multi-functional operation of many types of microfluidic and optofluidic chips. Romero and Yost (1996) and Weislogel (1996) first elucidated how the streamwise gradient in capillary pressure due to the change in curvature of the fluid interface due to local variations in film thickness induces rapid wicking of slender films into straight and open triangular grooves. Here we present an analytic model which extends that original work to arbitrarily curved open triangular grooves in 3D. Despite the complex flow trajectories which can ensue, a first order perturbation analysis yields a compact equation for the moving interface. This finding should be of use to the design and implementation of next generation 3D fluidic devices.

Capillary Forces Computation for Nano-suspension Droplet Spreading: Molecular Dynamics Simulations

BAIOU SHI (Presenter), Penn State Univ, Behrend, WEIZHOU ZHOU, EDMUND B WEBB III, Lehigh University — With the development of nano-technology, nano-suspension provides us a path to synthesize and disperse nano-particles in fluids, and it has been widely utilized in pharmaceutical and semiconductor industries. Recently, many studies via both experiments and simulations have focused on nano-suspension droplets dynamic spreading and further evaporation on solid surfaces. However, the underlying physics and especially the fundamental driving forces controlling the kinetics of nano-suspension wetting and spreading is still unknown. In this talk, results from molecular dynamics simulations are presented with emphasis on computing capillary forces between advancing liquid fronts and suspended particles. Meanwhile, the effect of nano-particle size, particle loading, and interaction strength examined from atomic scale simulations will be presented. For increasing particle size, a dramatic change of wetting behavior from de-pinning to pinning is observed and also interpreted as the increasing capillary force between suspended nano-particles and the three-phase interface. By tuning down the interaction between the particle and the underlying substrate, de-pinning is observed instead of the exhibiting pinning behavior.

Water Filtration in Carbon Nanotubes Resulting From Electronic Friction at the Walls

JEFFREY SOKOLOFF (Presenter), Northeastern University — In this talk, a mechanism for removal of salt from salt water is discussed, which results from friction due to Ohm's law heating, resulting from motion of an electron charge induced in the tube walls by the water molecules' dipoles and the ions' charges. The filtration occurs because this friction is larger for salt ions than for water molecules. Friction due to Ohm's law heating might also provide an explanation for the observation by Secchi, et. al., that the flow velocity of water in carbon nanotubes increases rapidly as the tube radius decreases from 50 to 15nm, which does not occur for boron nitride nanotubes which are insulators. This friction is large enough to produce the observed slip-lengths. One possibility is that the nanotubes in this experiment were metallic, whose conductivity becomes large as their radius decreases, due to ballistic conduction. Another possibility is that when the tube circumference drops below the electron mean free path, the wall switches from behaving as a two dimensional conductor to behaving as a one dimensional conductor for which the electrons are more strongly localized. For sufficiently small conductivity, small distortions of the localized states can provide the dominant contribution to the induced charge, rather than current flow.
9:00AM K48.00006: Laser streaming: A novel photoacoustic streaming principle and its application in microfluidic driving  SHUAI YUE (Presenter), Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, China, YANAN WANG, Department of Electrical and Computer Engineering, University of Houston, US, QIUHUI ZHANG, Department of Electrical Information Engineering, Henan University of Engineering, China, FENG LIN, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, China, NZUMBE EPIE, Physics Department and Texas Center for Superconductivity, University of Houston, US, SUCHUAN DONG, Department of Mathematics, Purdue University, US, XIAONAN SHAN, Department of Electrical and Computer Engineering, University of Houston, US, DONG LIU, Department of Mechanical Engineering, University of Houston, US, WEI-KAN CHU, Physics Department and Texas Center for Superconductivity, University of Houston, US, ZHIMING WANG, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, China, JIMING BAO, Department of Electrical and Computer Engineering, University of Houston, US — We report the discovery of a new optofluidic principle and demonstrate the generation of a flow by a pulsed laser beam through a glass window. A plasmonic nanoparticle-decorated cavity had been fabricated by focusing a laser on the interface of a glass and aqueous solution of Au nanoparticles. A flow emerges and remains after the colloidal solution is completely replaced by pure water. Hydrophone signals indicate that the flow is driven via acoustic streaming by a long-lasting ultrasound wave which is resonantly generated by the laser and the cavity through the photoacoustic effect. The principle of this light-driven flow via ultrasound, i.e., photoacoustic streaming by coupling photoacoustics to acoustic streaming had been applied by focusing beams on ion-implanted quartz plate. Manipulating and programming laser beams can easily create a micro single pump, a moving pump, and multiple pumps on any point of the quartz plate without any moving structures. The underlying pumping mechanism of photoacoustic streaming is verified by high-speed imaging of the fluid motion after a single laser pulse. These programmable, fabrication-free micropumps open up a new generation of micropump technology and new opportunities for easy integration and versatile applications.

9:12AM K48.00007: Alignment-dependent growth of unstable patterns in liquid crystals  QING ZHANG (Presenter), Mechanical Engineering, Massachusetts Institute of Technology, SHUANG ZHOU, Department of Physics, UMass Amherst, IRMGARD BISCHOFFBERGER, Mechanical Engineering, Massachusetts Institute of Technology — The displacement of a more viscous fluid by a less viscous one in a quasi-two dimensional geometry leads to the formation of complex fingering patterns. In isotropic systems, disordered dense-branching morphologies arise from repeated tip-splitting of the evolving finger. In anisotropic systems, by contrast, the growth morphology changes to a highly ordered dendritic growth characterized by stable needle-like protrusions decorated with regular side-branches. We investigate such morphology transitions between dendritic growth and dense-branching growth in an intrinsically anisotropic liquid, a lyotropic chromonic liquid crystal in the nematic phase. We show that the transition depends on three parameters; the interface velocity, the concentration of liquid crystal and the viscosity ratio between the less-viscous inner fluid and the more-viscous outer liquid crystal. Remarkably, we find that different aspects of the patterns are experiencing environments of different viscosities; the characteristics of the locally-determined most unstable wavelength are governed by a viscosity that is 20 times lower than that governing the relative length of the fingers. We discuss how these two different viscosities are related to the local alignment of the liquid crystal.

9:24AM K48.00008: Electrokinetics in pH-responsive polyelectrolyte-brush-grafted nanochannels: Effect of the appropriate Strong Stretching Theory representation of the polyelectrolytes*  SIDDHARTHA DAS (Presenter), HANNOOR SINGH SACHAR, VISHAL SANKAR SIVASANKAR, University of Maryland, College Park — Functionalization nanochannels with polyelectrolyte (PE) brushes, contrary to the classical notion, has recently been established to augment electroosmotic (EOS) transport in nanochannels under special conditions where charges of the brushes are localized at the non-grafted ends of the PEs. Here we shall re-visit these calculations as well consider the more readily encountered situations where the entire PE molecule is charged in presence of the most rigorous framework where the PE brushes are modeled using the Strong Stretching Theory (SST) that accounts for the excluded volume (EV) effects and the effect of considering a generalized mass action law. These considerations would significantly affect the monomer distribution (which in turn would affect the drag force imparted by PE brushes) and the resulting EDL (electric double layer) electrostatics (which in turn would affect the EOS body force). This model would be the first rigorous theory for the electrohydrodynamics in the PE-brush-functionalized nanochannels accounting for the appropriate coupled thermodynamic representation of the PE brush configurations and the EDL electrostatics.

*This work has been supported by the Department of Energy Office of Science grant DE-SC0017741.

9:36AM K48.00009: Direct measurement of capillary attraction between floating disks  IAN HO (Presenter), GIUSEPPE PUCCI, DANIEL M HARRIS, School of Engineering, Brown University — It is well known that two particles trapped at a fluid interface may interact due to the deformation they induce on the free surface. In the present work, we present direct measurements of the force between centimetric superhydrophobic disks resting on an air-water interface. Using a novel experimental setup, we characterize how the attraction force depends on the disk mass, diameter, and relative spacing. Our measurements are compared with theoretical predictions. Future directions will be discussed.
observe that the thermal force spectrum is a monotonically increasing function of frequency. A theoretical description involves extracting the spectrum of the thermal force. We compare our experimental measurements with a theoretical description that assumes a long and thin beam fluctuating in a viscous fluid with a frequency dependent thermal driving force. Since the Langevin force excites fluctuations of the resonator in proportion to the square of the linear response function, it is then possible to extract the spectrum of the thermal force. We compare our experimental measurements with a theoretical description that assumes a long and thin beam fluctuating in a viscous fluid with a frequency dependent thermal driving force. We observe that the thermal force spectrum is a monotonically increasing function of frequency.

*We acknowledge support from US NSF through Grant No. CBET-1604075

10:00AM K48.00011: Thickness Dependent Nanofluidic Transport in Nanopores and Nanochannels MOHAMMAD HEIRANIAN (Presenter), N. R. ALURU, University of Illinois at Urbana-Champaign — Due to the high performance water transport through ultrathin membranes, nanopores and nanochannels have drawn a great deal of attention in a variety of applications, such as water desalination, power generation and biosensing. Classically, the transport rate scales inversely with the thickness. However, transport in carbon-based nanopores and nanochannels far exceeds the classical transport governed by the Hagen-Poiseuille (HP) equation, suggesting large transport enhancement factors with respect to the permeation predicted by HP. Here, using molecular dynamics simulations we characterize the thickness dependence by studying the hydrodynamical properties of pores and channels in graphene and finite-length CNTs. Transport in graphene and short CNTs is shown to be dominated by a high interfacial friction and viscosity at the pore/channel entrance. A corrected Hagen-Poiseuille (CHP) model, based on viscosity and friction from Green-Kubo relations, successfully predicts the non-equilibrium pressure driven flows for different sizes of channels. The previously reported enhancement factors (of the order of 1000) approach unity when the permeations are normalized by that of the CHP. The results of our study will help better understand nanoscale flows in nanopores and nanochannels.

10:12AM K48.00012: An electro-coflow based microfluidic route to generation of alginate microcapsules* VENKAT GUNDABALA (Presenter), MD DANISH EQBAL, Chemical engineering, Indian Institute of Technology Bombay — Among various platforms for generation of microgels and microcapsules, microfluidics offers controlled routes for their generation. In this work, a novel interface-based microfluidic device is designed with capability for application of electric fields, and is used to generate alginate microparticles and capsules. Sodium alginate droplets generated through electro-coflow mechanism, cross a liquid-liquid interface and subsequently polymerize into polymeric particles. For microcapsules, double emulsions with an oil core and sodium alginate shell are used. The application of electric fields results in a significant reduction in the drop size and in turn in the particle/capsule size. The study shows a complete on-chip generation of microcapsules with size control achieved through application of external electric fields.

* Venkat Gundabala would like to thank DST (Department of Science and Technology) for research financial support through grant SB/S3/CE/081/2013 and IIT Bombay for travel support

10:24AM K48.00013: Dynamical measurements of receding contact angle for evaporating drops* CHLOE LINDEMAN (Presenter), NICHOLAS SCHADE, SIDNEY ROBERT NAGEL, University of Chicago — We study the receding contact angle of drops during evaporation. Drops of a dyed solution are allowed to evaporate for some time $\tau$ before they are removed via a small hole in the substrate. We record the contact angle as the fluid is removed and extract the receding contact angle — that is, the angle at which the drop first depins — as a function of $\tau$ and dye concentration. For low $\tau$ (i.e., immediate drop removal), the receding contact angle depends only weakly on concentration. For $\tau$ on the order of a few minutes, the receding contact angle decreases with a growing dependence on concentration. This suggests that the concentration of solute near the drop edge grows due to the flows induced by evaporation as in the coffee-ring effect. Surprisingly, even pure water exhibits a significant $\tau$-dependent receding contact angle.

8:00AM K49.00001: Impact of Antifoam on Rheological Properties of Polynorbornene Membranes for Biobutanol Separation*

SIYUAN LI (Presenter), BRYAN VOGT, Polymer Engineering, The University of Akron — Butanol is a promising alternative to ethanol for bio-based fuel, but its efficient separation from the fermentation broth can be challenging. Poly(butylnorbornene-ran-hydroxyhexafluoroisopropyl norbornene) (BuNB-r-HFANB) is promising for butanol separation from water. Here, we seek to understand how additives in typical fermentation broths interact with this polymer. The sorption of Antifoam 204 in butanol-water solutions in BuNB-r-HFANB films was characterized by quartz crystal microbalance with dissipation (QCM-D). From the QCM-D data, the dependence of concentration on swelling ratio and rheological properties (complex shear modulus and phase angle) of the films was elucidated. By examination of different film thicknesses, it was determined that the antifoam is incorporated within the film. At 100 ppm of antifoam, the swelling ratio increases by a factor of 170, while the phase angle increases to ~90° (liquid-like). The swelling is nearly unchanged at 10 ppm, but decreases markedly at 1 ppm. This suggests that the polymer is saturated by the antifoam even when only present at 10 ppm. These results illustrate the potential impact of dilute additives on new polymers for pervaporation membranes.

*This work was financially supported by the NSF under grant no. CMMI-1462284.

8:12AM K49.00002: The effect of filler distribution in the enhancement of the energy storage in nanocomposites*

ELSHAD ALLAHYAROV, Theoretical Chemistry, University of Duisburg-Essen, LEI ZHU, GUOQIANG ZHANG (Presenter), Macromolecular Science, Case Western Reserve University — Mixing dielectric polymers with high permittivity nano-sized inclusions affects their electrical properties. These nanocomposites are extensively used in actuation applications via employing electrostriction properties of the matrix, and in electrostatic energy storage applications employing high polarization fields of the fillers. In both cases existing theoretical studies mostly utilize mixing rule approaches that consider a homogeneous filler distribution in the matrix. Consequently, the effective permittivity of the composite never exceeds the the permittivity of the filler. We show that much higher effective permittivities can be achieved by manipulating the morphology of the inclusion distribution in the matrix. Simulation results for the field distribution reveal an enhancement of the field localization and dipole-dipole correlation effects in some proposed morphologies. By considering several possible clustering scenarios we found that a cylindrical clustering along the applied field has a potential to achieve an order of magnitude increase in the effective permittivity. The issue of chained filler configurations which lower the breakdown field threshold for the material is also addressed.

8:24AM K49.00003: Analyses of hierarchical structures in vulcanized SBR rubber by using contrast variation USANS and SANS

YUKI WATANABE (Presenter), Graduate School of Engineering, Kyoto University, MIKIITO TAKENAKA, Institute for Chemical Research, Kyoto University, SHOTARO NISHITSUJI, Graduate School of Organic Materials Science, Yamagata University, SATOSHI KOIZUMI, Graduate School of Science and Engineering, Ibaraki University, DAISUKE YAMAGUCHI, Institute for Integrated Cell-Materials Sciences, Kyoto University — The hierarchical structures of poly(styrene-ran-butadiene) (SBR) rubbers vulcanized with sulfur in swollen state were investigated by using ultra small angle neutron scattering (USANS) and small angle neutron scattering (SANS) technique. The scattering intensity can be described by the equation consisting of two Debye-Bueche equations and Ornstein-Zernike-Debye equation indicating that the inhomogeneous structure with the size of 500 to 900 Å exits, in addition to the inhomogeneous structures with the size of 70 to 100 Å with the networks. As the results of the analyses of contrast variation USANS and SANS, The origin of the inhomogeneous structures with the size of 500 to 900 Å was found to consist of ZnO added as activator of sulfur vulcanization, and we was able to yield the size of ZnO being in the order of 1000 Å quantitatively from the partial structure factor of ZnO.
Assignment of the Polymerization Peak in Polystyrene Melt

HE CHENG (Presenter), TAISEN ZUO, GUISHENG JIAO, ZEHUA HAN, China Spallation Neutron Source, Chinese Academy of Sciences, JUNPENG ZHAO, the department of polymer science and engineering, south china university of technology — Polymerization peak at around 0.75 Å⁻¹ in polystyrene (PS) melt was first reported by Katz in 1927, it is origin is still not clear. Here, by combined neutron total scattering, high concentration labelling and molecular dynamic simulation, we visualize the most-probable all-atom positions in polystyrene melt, and assign it to be the inter-chain backbone distance. In our experiments, both the neutron and x-ray total scattering profiles from 0.02 to 30 Å⁻¹ of PS-h8, PS-d8, PS-d5 and their mixtures (1:1 by molar) at different temperatures above their glass transition temperatures were measured. The low q scattering profiles in high concentration labelling mixtures are from the thermo fluctuations, while the intermediate and high q scattering profiles are assigned to the inter- and intra- chain atom-atom correlations.

Dynamics of Belousov Zhabotinsky Reaction Based Systems Via Nonlinear Stability Analyses

VANDANA RAJPUT (Presenter), PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology Gandhinagar — Controlling the dynamics of self-oscillating dynamical systems that are far from equilibrium has been a grand challenge for science and engineering. Belousov Zhabotinsky (BZ) reactions, a nonlinear chemical oscillator, has been used to design intrinsically powered self-oscillating dynamical systems. It has been known that the chemical oscillations in BZ reactions are due to the occurrence of Hopf bifurcation (HB). Here, reagent concentrations in the BZ system have been treated as the bifurcation parameter and we perform stability analyses to characterize the dynamics of the BZ system. Specifically, we calculate the first Lyapanov exponent to distinguish quantitatively between the subcritical and supercritical HB. In addition, we also calculate the second Lyapanov exponent to show that for a narrow range of bifurcation parameter, the sustained oscillations in the BZ system transforms in decayed oscillations with sensitive dependence on the initial condition. The transformation of this behavior occurs below a curve called Limit Point of Cycles which is a characteristic of Bautin bifurcation. The outcomes of our study can be utilized to characterize the behavior of dynamical systems and establish design rules for controlling their behavior.

Directional Motion of Sodium Polyacrylate Gels Initiated by Ca²⁺-Induced Contraction is coupled to an NaCl Gradient

SUSAN KOZAWA (Presenter), Case Western Reserve University, LOREN KREIDER, Indiana Institute of Technology, ANITA VENKATASWAMY, ANNE WALKER, GARY WNEK, Case Western Reserve University — It is known that Na-polyacrylate gel threads contract in the presence of CaCl₂ but we have rather unexpectedly, initiate contraction at or very near the gap, rather than from the side immersed in CaCl₂ while the other side is immersed in NaCl. The main mechanism for ion transport initiates through diffusion; the lowest crosslinked gel allows for bulk diffusion while the higher crosslinked gels primarily propagate surface diffusion. Through surface diffusion, the binding mechanism propagates in a linear fashion, from the CaCl₂ towards the NaCl. The more interesting phenomena, the bulk diffusion, allows the ion gradients to meet within the middle of the gel. We propose this allows time for the chains to condense in the presence of NaCl, which allows for the entropically favored binding to Ca²⁺, immediately collapsing chains and allowing the facilitated binding down either end of the gel. Due to this, we are able to induce overall movement of the gel thread. While the phenomena is correlated to diffusion, the rates are mainly determined by polyelectrolyte dynamics. In all cases, original gel dimensions can be recovered upon treatment with chelators such as sodium triphosphate, an analog to ATP.

Multiscale investigation of polyelectrolyte gel-based electronic devices

Vasilii Triandafilidi

Presenter), Joerg Rottler, Savvas Hatzikiriakos, University of British Columbia — Gel-based electronic devices (sensors and diodes) are attracting attention due to their low cost, favorable mechanical properties, and biocompatibility. We have performed coarse-grained molecular dynamics and continuum simulations of model polyelectrolyte gels used in such devices to study the relationship between voltage and ion distribution on the nanoscale. For sensors, we consider a system consisting of a negatively charged backbone and positive floating counterions. By interfacing two regions with different degree of ionizations, we compute the electrostatic potential difference and show that it obeys a modified Nernst-Donnan equation when accounted for counterion condensation. The pressure is found to be proportional to the Donnan-Potential, which provides a molecular basis for the piezoionic effect observed in experiments. For gel-based diodes, we interface two gels with oppositely charged ions, study its rectifying behavior with molecular simulations and challenge the results obtained through a description based on the Poisson-Boltzmann approximation.

Change in Hierarchical Structure of Segmented Polyurethane Elastomers under Mechanical Deformation

Ken Kojio (Presenter), Institute for Materials Chemistry and Engineering, Kyushu University, Chigusa Nagano, Shiori Masuda, Chao-Hung Cheng, Shuhei Nozaki, Graduate School of Engineering, Kyushu University, Kazutaka Kamitani, Atsushi Takahara, Institute for Materials Chemistry and Engineering, Kyushu University — Polymer materials possess a hierarchical structure such as orientation, conformation, crystal structure, microdomain structure, and so on. When external stimulus is applied to polymers, these various structures would respond depending on the size. In this study, lattice strains obtained from the crystal structure of hard segment domain and microphase-separated structure of segmented polyurethane (SPU) elastomers were evaluated under mechanical deformation by wide-angle X-ray diffraction (WAXD) and small-angle X-ray scattering (SAXS) measurements. SPU elastomers were synthesized with poly(oxytetramethylene) glycol, trans-1,4-bis(isocyanatomethyl) cyclohexane (1,4-H6XDI), and 1,4-butanediol. Change in molecular aggregation structure of the SPU with 20 and 30 wt% hard segment contents were investigated. Both strains (eSAXS and eWAXD) obtained from SAXS and WAXD linearly increased with increasing strain. Compared to HX-20, HX-30 exhibited larger eSAXS and eWAXD in both deformation modes. This is because strain can be easily propagated to whole samples due to well-developed hard segment domains formed in HX-30. eSAXS and eWAXD values obtained by biaxial deformation were larger than for uniaxial one, indicating that the biaxial deformation produces severer condition to the samples.

Thermal analysis of fully zwitterionic copolymers for safer electrochemical energy storage

Andrew Clark (Presenter), Department of Physics and Astronomy, Tufts University, Morgan E Taylor, Matthew J Panzer, Department of Chemical and Biological Engineering, Tufts University, Peggy Cebé, Department of Physics and Astronomy, Tufts University — Current ionic liquid electrolytes used in lithium ion batteries are both volatile and flammable. A safer alternative to liquid electrolytes is to use solid conductive polymer gel electrolytes. In this study, the thermal properties of a group of zwitterionic copolymers designed for electrochemical energy storage are investigated using temperature modulated differential scanning calorimetry (TMDSC) and thermogravimetry (TG). Investigating the thermal properties will reveal how the zwitterionic moieties can affect transition phenomena. Sulfobetaine vinylimidazole (SBVI) and 2-methacryloyloxyethyl phosphorylcholine (MPC) were dissolved in an ionic liquid solution in varying molar ratios and subsequently polymerized to produce fully zwitterionic random copolymers. TG reveals two degradation steps at 290 °C and 390 °C due to MPC degradation and one step at 350 °C due to SBVI degradation. TMDSC at 5 °C/min was used to identify the glass transition of these materials, showing a decrease in Tg from 60 °C to -35 °C with increasing addition of SBVI. A melting endotherm at -18 °C was observed on heating, attributed to the presence of residual ionic liquid.

9:48AM K49.00010: DFT studies of the structural, electronic, and electrochemical properties of copolymers containing ferrocene and imidazole  BENJAMIN TAYO (Presenter), Physics, Pittsburg State University, ERIC MULLINS, Physics, Kansas State University — Ferrocene-based polymers have been used in various applications such as sensors, solar cells, batteries, and photo-oxidation of thin films. Copolymers containing ferrocene and imidazole are unique because of electronic interactions between the ferrocene and neighboring imidazole moiety, leading to the formation of charge transfer complexes in the polymer. Recent electrochemical and UV-Vis studies in the presence of various electrolytes containing metal ions have revealed significant modifications in their properties, e.g., red shifts, and the appearance of multiple oxidation waves in cyclic voltammetry studies. Even though these modifications have been attributed to the ability of the imidazole to coordinate with metal ions, increasing its electron deficiency, thereby enhancing oxidation of the nearby ferrocene moiety if it is in close proximity to it, the equilibrium geometry of the polymer complex is unknown. This talk will discuss the results of DFT studies that was used to address these concerns, for instance determination of equilibrium geometry, and frontier energy levels. We will also discuss the correlation of molecular orbital density plots to the electrochemical properties, specifically the formation of donor-acceptor complexes within the polymer.

10:00AM K49.00011: Viscoelastic Phase Separation as a Route towards Continuously Processed Organic Solar Cells*  JING HE (Presenter), DILHAN M KALYON, STEPHANIE S LEE, Stevens Institute of Technology — Controlling the solution structure of polymer nanocomposite systems prior to thin film deposition is a promising strategy to enhance the efficiency of organic solar cells in a manner compatible with continuous processing methods. Using a model system comprising P3HT and PCBM dissolved in o-DCB, rheological characterization was employed to characterize the thermoreversible gelation of these solutions upon rapid cooling to sub-ambient temperatures. Temperature-variable confocal microscopy imaging of P3HT fluorescence revealed the formation of micron-sized solvent “holes” during cooling, a signature of viscoelastic phase separation. This phenomenon originates from the dynamic asymmetry between the polymer chains and solvent molecules and was found to arrest during the early stages of phase separation due to P3HT interchain crystallization. Cryogen-based scanning electron microscopy images of the gels further uncovered an interfibrillar network with characteristic pore sizes tens of nanometers in diameter. These interconnected polymer structures with hierarchical porosity were deposited as thin films via doctor blading, resulting in a 45% enhancement of light conversion efficiency compared to organic solar cells comprising active layers deposited from uncooled solutions.

10:12AM K49.00012: (Near-) Ambient Pressure XPS for Studying Surface Reconstruction of Hydrated Polymers*  MIKAYLA BARRY (Presenter), EMILY C DAVIDSON, University of California, Santa Barbara, ETHAN J CRUMLIN, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California, Santa Barbara — Polymer restructuring in response to environmental conditions has made surface characterization of polymers designed for use in hydrated applications difficult. Analysis techniques that provide nanoscale surface composition (e.g. X-ray Photoelectron Spectroscopy (XPS)) have been largely limited to use in vacuum, where the surface presentation no longer matches that of hydrated polymers. Consequently, characterization of the hydrated surface has been relegated to contact angle goniometry and vibrational spectroscopy techniques such as Raman and Sum Frequency Generation (SFG). We present the first synchrotron (Near-) Ambient Pressure XPS (AP-XPS) studies performed on polymer surfaces in contact with water vapor. Water adsorption on polydimethylsiloxane-based polymers was found to increase substantially for those containing even minimal amounts of amphiphilic side chains. The presence of hydrogen-bonding side chains also correlated with greater increases in water adsorption and decreases in silicon-character oxygen (associated with the polymer backbone) at 6 Torr relative to non-hydrogen-bonding side chains.

10:24AM K49.00013: Self-assembly of Functionalized Nanoparticles in Ordered Phases of Block Copolymers
SUPRIYA GUPTA (Presenter), PARESH CHOKSHI, Chemical Engineering, Indian Institute of Technology Delhi — An emerging application of polymer nanocomposites is to generate self-assembly of nanoparticles leading to novel nanoscale materials with enhanced properties. As particle-based techniques, e.g. molecular simulation, are computationally intensive, we employ the self-consistent field theory (SCFT) combined with density functional theory (DFT) to examine the localization of nanoparticles in ordered domains of block copolymers. The nanoparticles are grafted with polymer chemically identical to either block of the copolymer. To ensure finite size of the particles and excluded volume interactions between species, the free energy is described using DFT. We study the localization of nanoparticles in lamellar and cylindrical morphologies. For lamellar phase, nanoparticles assemble either at the interface between two blocks or at the center of a block domain depending upon particle concentration and grafting density. In cylindrical phase, nanoparticles self-assemble at the center of the cylinders. The role of grafting density, particle size and composition on self-assembly behavior of particles in block copolymer is examined. The comprehensive understanding of factors affecting localization of nanoparticles enable us to control the particulate assembly for desirable material properties.

10:36AM K49.00014: Effect of Synthetic Parameters on Molecular Architecture and Adhesive Performance for Acrylic Emulsion Copolymers
SIPEI ZHANG (Presenter), OWEN (WEN-SHUE) YOUNG, MELINDA EINSLA, JOSEPHINE ELDREDGE, VINITA YADAV, CYNTHIA R. LESLIE, KEBEDE BESHAH, ALAN NAKATANI, ASGHAR PEERA, WILLIAM GRIFFITH, SARAH R. ZOLYNKI, HIMAL RAY, CACHAE PEARSON, SASWATI PUJARI, SEHBAN OZAIR, Dow Chemical Company — It is well known that both the composition and architecture of a polymer affect its performance as a pressure sensitive adhesive (PSA). However, the specific relationships of glass transition temperature (T_g), degree of branching, crosslinking density, and molecular weight with PSA properties are often complicated, and the variables can be difficult to isolate. Here we present a study examining the effects of acrylic monomer, feed time, and styrene content on the molecular architecture of emulsion-based copolymers with systematically varied composition, and their relationships with adhesive performance. The polymer architecture is elucidated using dynamic mechanical analysis (DMA), gel permeation chromatography (GPC), gel fraction/swell ratio (GF/SR), and 13C nuclear magnetic resonance (NMR) spectroscopy. It was found that the primary acrylic monomer had the most significant effect on polymer architecture, followed by styrene content, and then feed time. The resulting impact on adhesive and cohesive strength will also be discussed.

10:48AM K49.00015: Dramatic Mechanical Response of Polymer-metal Inclusions Based Metamaterials
RITUPARNA GHOSH (Presenter), Department of Instrumentation & Applied Physics, Indian Institute of Science, SOURAV DAS, Department of Metallurgical and Materials Engineering, Indian Institute of Technology Kharagpur, ABHA MISRA, Department of Instrumentation & Applied Physics, Indian Institute of Science — A periodic lattice of metal sphere (steel ball) is arranged in polydimethylsiloxane (PDMS) polymer matrix in multidimensional architecture. At multiple strains there is gradual increases in both the stress and energy absorption capability. Three-dimensional architecture demonstrated maximum loading capacity retaining its elastic behaviour. An enhancement of ~ 50% in absorption capability and stress at 40% strain is recorded as compared to one and two-dimensional architectures. The three-dimensional architecture also showed strain rate independent highly reversible behaviour for 1000 compression cycles at 30% strains and exhibit excellent mechanical stability. However, a dramatic drop in stress by ~ 100% was observed at higher strain (> 50%) in three-dimensional architecture as compared to other metamaterials. Point contacts between multiple disjoint steel balls, which form a periodic chain like structure play the key role in achieving enhanced strength and energy absorption and have importance in numerous mechanical applications where high strength and energy absorption are the prime requirement.

8:00AM K50.00001: Trapped Photons Induced Ultra-high External Quantum Efficiency and Photoresponsivity with Millisecond Response in Hybrid Graphene/Metal-Organic Framework Broadband Wearable Photodetectors

KRISHNA PRASAD BERA (Presenter), Institute of Physics, Academia Sinica —

Metal-Organic frameworks (MOFs) are the promising new class of hybrid materials that has the tremendous attraction in sensing, gas storage, and drug delivery during past two decade due to its unique tunable properties and fascinating architectures. Optoelectronic application of MOF is challenging due to its high porosity and poor electrical conductivity. Combining the superior properties of the MOF along with ultra-high carrier mobility of graphene, we have fabricated and characterize the highly sensitive, broadband, and wearable photodetector on a polydimethylsiloxane substrate. The external quantum efficiency of the hybrid photodetector is found to be > 5×10^8%, under the excitation of 325 nm laser of intensity ~ 0.5 µWcm⁻², which exceeds all the reported values of similar devices. The porosity of the MOF and ripple structure graphene assist the trapping of photons at the light-harvesting layer. The device photoresponsivity is found to be > 10^6 AW⁻¹ with a response time of < 70 ms, which is ~100 times faster than the current standards of the graphene-organic hybrid photodetectors. In addition, utilizing the excellent flexibility of the graphene layer the wearability of the devices is demonstrated, which can be stretched up to 100% of its original dimension.

8:12AM K50.00002: ULTRAFAST ENERGY DISSIPATIONS AND QUANTUM EFFICIENCIES OF CONJUGATED POLYMERS BY SEGMENTAL STRESSES

HSUAN LU (Presenter), CHANG MOU YANG, TZUNG MIN WENG, Material Science, National Tsing Hua University — Quantum efficiencies of conjugated polymers (CPs) were found to increase dramatically by elevation of segmental stresses, therefore, we explore the emission behavior in the time scales comparable to segmental motions to unveil the relationship. We stretched CP (MEH-PPV) to ~300%, resulting photoluminescence (PL) enhancements of 20-60 folds depending on the stress level. By using up-conversion time-resolved confocal PL spectroscopy, we found the absorbed energy quickly dissipates via segmental rotations and vibrations, leading to PL red shifts. The damping via rotations was ~10 times faster than vibrations but stopped after ca. 2 ps, while the latter continued functioning, but abated slowly to diminishment. The segmental stresses can reduce or even switch off the rotation damping but yielded no influences on vibrations. The latter was found in fact heat dissipation, while the rotations, driven by local electrostatics from excitation, can trigger self-trapping and the 2 ps represents the time limit before escape from self-trapping for recombination. This model explains satisfactorily how segmental stresses interacting with CP backbones to result dramatic efficiency enhancements.

8:24AM K50.00003: Quantum-Entangled Triplet-Triplet Excitons in Acene Dimers and their role in Singlet Fission*

SOURATOSH KHAN (Presenter), SUMITENDRA MAZUMDAR, University of Arizona — Singlet fission (SF) in which a photoexcited spin singlet dissociates into a pair of low energy triplet excitons has been claimed in covalently linked acene dimers. Internal covnversion to a quantum entangled triplet-triplet state prior to dissociation makes the process spin-allowed. However, recent experiments based on electron spin resonance as well as transient absorption spectroscopy have both shown this intermediate biexciton to be stable against further decoherence thereby raising questions on SF itself. A disconnect between theory and experimental results have led us to calculate the excited state energies and their optical properties using a correlated electron model (Pariser-Parr-Pople Hamiltonian). We formulate a broad theory of quantum entanglement of triplet-triplet state in symmetric and asymmetric dimers. Based on our calculations, we conclude that i) spectroscopic differences in the ESA signals between free and bound triplets exist beyond the visible, ii) entanglement between the triplets is reduced as proximity between acene units is reduced or in the presence of significant steric hindrance, and iii) ESA from singlet exciton shows absorption in the short-wave infrared due to a transition to an optically forbidden even parity state.

Comparative studies on fluorescent emission of organic semiconductors between optical and electrical pumping* TAIKI MIURA (Presenter), Department of Physics, Graduate School of Science, Tohoku University, THANGAVEL KANAGASEKARAN, WPI-AIMR, Tohoku University, HIDEKAZU SHIMOTANI, SYUN ONUKI, Department of Physics, Graduate School of Science, Tohoku University, KATSUMI TANIGAKI, WPI-AIMR, Tohoku University — Light-emitting devices of organic semiconductors (OSCs), such as organic light-emitting diodes, have widely been used in daily life. Especially, light-emitting organic field effect transistors (LE-OFETs) are considered as candidates for efficient light-emitting devices, such as OSC lasers, in the future. However, the detailed understanding of electroluminescence (EL) by electrical pumping has not fully been understood when it is compared to photoluminescence (PL) by optical excitations. For realizing such a highly performed light-emitting device, the fundamental understanding on the difference between EL and PL is necessary. Here, we report accurate comparative studies on the difference between PL- and EL-mode in the case of single-crystal thin films of BP3T. The result shows that the spectrum shapes are different between PL- and EL-mode and quenching of fluorescent emissions occurs in high current region in the EL-mode. In order to realize highly efficient light-emitting OFETs towards OSC lasers in the future, such annihilation would become a significant obstacle.

Theoretical Study on Charge-Transfer Excitations of Buckycatcher-Fullerene Complexes MIHARU HAYASHI, TOMOMI YASOSHIMA, AZUSA MURAOKA (Presenter), Japan Women's University — In particular, p/p stacking compounds have become of interest in new materials for photocatalysis, solar energy and phosphorescent organic light-emitting diodes. We investigate theoretically the photo-induced charge transfer in supramolecular chemistry. Buckycatcher (BC) molecules, bowl-shaped polycyclic hydrocarbons, have attracted attention as a new type of π-conjugated compound. BC molecules with two corannulene or two sumanane subunits can form a complex (BC/C60) with C60 because of the π-π interaction between the convex surface of the C60 and the concave faces of corannulene subunits of the BC. We have performed DFT and TD-DFT calculations on the structures and excitation spectrum of BC molecules and BC/C60 complexes. The most stable structures are BC/C60 in which the p–p stacking of the two corannulene subunits of BC and C60 takes a concave–convex arrangement; therefore, the van der Waals contact is maximized. It is found that the charge-transfer-type excitations from BC to C60 start at the ultraviolet light region. The BC/C60 complexes and their derivatives are potential candidates as key elements for photovoltaic devices and other molecular electronic devices.

The impact of atomic substitution on the photophysics of contorted hexabenzocoronene derivatives GUY OLIVIER NGONGANG NDJAWA (Presenter), TIA S. LEE, NICHOLAS DAVY, JENI SORLI, GREG SCHOLES, LYNN LOO, Princeton University — The photophysical properties of organic semiconductors are strongly influenced by the spin states, lifetimes, populations, and energies of the lowest photoexcited species (S1 or T1). By favoring or limiting the rate of intersystem crossing (ISC), the relative population and lifetime of singlet and triplet excitons can be controlled through molecular design. The incorporation of heavy atoms, such as transition metals, have been reported to enhance spin-orbit coupling in organic systems. Here, we explore the role of peripheral moieties with heteroatoms on the photophysical properties of contorted hexabenzocoronene (cHBCs) derivatives. These chemical alterations may impose steric or enhance spin-orbit coupling, significantly increasing the rate of ISC. With benzofuran moieties, cTBFDBC exhibits the highest degree of molecular contortedness in the series, which is correlated with a high rate of ISC. With much heavier benzothiophene moieties, cTBTDBC uniquely exhibits room temperature and higher phosphorescence yield compared to cTBFDBC, which we correlate to a high degree of spin-orbit coupling induced by the heavy sulfur atom. These findings offer valuable guidelines for enhancing the optoelectronic properties of cHBCs using simple molecular substitution approaches.
9:12AM K50.00007: Coherence and Electron Transport in Pi-Stacked Acceptor-Donor-Acceptor Molecular Triads*
KEVIN KOHLSTEDT (Presenter), MICAELA MATTA, THOMAS ALDRICH, TOBIN MARKS, GEORGE C SCHATZ, Northwestern University — There has been a concerted effort to design non-fullerene acceptors (NFAs) for organic photovoltaic devices, in a large part, due to the processability and stability problems of fullerenes, but concomitantly there is a desire to further understand ultrafast charge generation in donor-acceptor organic molecules. Recently, covalently bonded molecular triads have shown substantial increases in device efficiency when blended with mid-gap polymers. There has been some advances in understanding the details of electron transport with NFA molecules, but there has yet to be quantitative investigation into the relationship of molecular organization in NFA device with its transport capabilities. Here, we present a detailed study of NFA aggregates that show slipped-stacked geometries and strong binding energies between the intermolecular layers. A consequence of strongly coupled LUMO orbitals is intermolecular delocalization leading to transport coherence. We find that for some slip-stacked arrangements favor coherent transport, while others do not, and we propose design strategies to get NFA packings with strong electronic couplings.

9:24AM K50.00008: Alloy or Blend: Analysis of a Ternary Organic Photovoltaic
XINJING HUANG (Presenter), Applied Physics, University of Michigan, XIAO LIU, EECS, University of Michigan, KAN DING, Physics, University of Michigan, STEPHEN ROSS FORREST, EECS, University of Michigan — The power conversion efficiency of organic solar cells can be enhanced by employing ternary blend bulk heterojunctions, which have been found to have an open-circuit voltage ($V_{OC}$) that depends on the blend ratio of acceptors/donors. It has been proposed that the variation in $V_{OC}$ is due to the formation of molecular alloy between blended acceptors/donors. However, we assert that the formation of a “molecular alloy” should exhibit new electronic states distinguished from those of its constituents. Here, we study the electronic states and energy levels in the P3HT:(ICBA:PC$_{61}$BM) ternary blend system. We find that the ICBA:PC$_{61}$BM acceptors shows the same highest occupied molecular orbital levels and exciton energies as that of ICBA, indicating no new exciton state emerges from the blend. In the ternary blend, the charge transfer states are composed of a linear superposition of those in the corresponding binaries. From these results, no evidence of new emergent electronics state is found which would support the existence of a molecular alloy. Indeed, our results point to the conclusion that blends of these non-interacting molecules differ substantially from our understanding of a conventional alloy. In this talk, we will consider the general criteria in identifying a molecular alloy.

9:36AM K50.00009: Design of Ethanol/Water Soluble Polymers/Fullerenes for Aqueous Processed Organic Solar Cells and Importance of Water Contents for Enhancement of Processability and Device Performance
SEUNGJIN LEE (Presenter), CHANGYEON LEE, YOUNGKWON KIM, JONNHYEONG CHOI, Department of Chemical and Biomolecular Engineering, KAIST, HAN YOUNG WOO, Department of Chemistry, Korea University, BUMJOON KIM, Department of Chemical and Biomolecular Engineering, KAIST — Most of the efficient organic electronic devices have been fabricated using toxic halogenated and/or aromatic organic solvents, which are not desirable in the industrial-scale solution process. Herein, we present a new series of ethanol/water soluble fullerene derivatives with different forms of oligoethylene glycol (OEG) side chains to be utilized in fabricating eco-friendly polymer solar cells (eco-PSCs). Intriguingly, the addition of a typical anti-solvent, water, to ethanol is found to markedly enhance the solubility of the non-ionic OEG side chain-based conjugated polymer (PPDT2FBT-A) and the newly designed fullerene mono-adducts (PC$_{61}$BO12, PC$_{61}$BO15, and PC$_{61}$BO27). A water-ethanol co-solvent with a 1:1 molar ratio provided an increased solubility of PPDT2FBT-A from 2.3 to 42.9 mg mL$^{-1}$ and that of PC$_{61}$BO12 from 0.3 to 40.5 mg mL$^{-1}$. Owing to the improved processability, efficient eco-PSCs with a power conversion efficiency of 2.05% were successfully fabricated. To date, this value is the highest among the devices based on the active layer of water/ethanol-soluble conjugated materials. Our results not only provide important guidelines for the design of electroactive materials, but also signifies the importance of water addition in fabricating environmentally benign eco-PSCs.
Defective conjugated polymers for organic electronics*

MICHAEL SOMMER (Presenter), Institute of Chemistry, Chemnitz University of Technology — This contribution discusses recent progress in the area of the synthesis of conjugated polymers for organic electronics. A first focus is on the role of chemical defects that form during synthesis. Depending on monomer structure, synthetic method and reaction conditions, homocouplings form at varying extent in donor-acceptor copolymers. This deviation from the usually suggested, strictly alternating structure lowers performance and causes a low level of reproducibility. In PCDTBT, homocouplings lower the short circuit current of photovoltaic devices and may be considered as one source for the broad range of reported power conversion efficiencies. The second part includes n-type copolymers from the naphthalene diimide and diketopyrrolopyrrole families. Defect formation, molecular weight control and energy level tuning is elucidated and correlated with charge carrier mobility and photovoltaic performance. A central conclusion is that the general understanding of the occurrence and importance of chemical defects in conjugated polymers has improved, but their entire elimination remains to be solved rendering batch to batch reproducibility a challenge.

Reduced mixed phase interface causes increased charge transfer state separation in polymer solar cells*

THOMAS FERRON (Presenter), MATTHEW C WALDRIP, MICHAEL POPE, BRIAN COLLINS, Washington State University — Investigations into organic solar cells have shown that molecular mixing within domains and interfaces significantly impacts device performance. However, studies often use performance metrics that blur fundamental structure-function mechanisms – in particular, the role of the mixed phase in charge generation versus charge extraction. Here, we present a study based on time-delayed collection field to separately quantify each fundamental step in the charge generation process. Additionally, we utilize a novel resonant X-ray scattering analysis to quantify the state of the nanostructure as it exists within real devices. We find that in a model semicrystalline system, decreasing the mixed interface between donor and acceptor domains has minimal impact on charge transfer (CT) state generation while greatly enhances CT state separation. With both a high correlation (>99%) and a granular quantification of all dynamics, we eliminate competing processes in working devices to determine a causal relationship between the mixed phase volume and the efficiency of charge separation. Our results here support that a reduction in the interfacial mixed phase establishes a steep energy gradient between pure phases to aid charge generation in organic solar cells.

Title: Understanding Quasi-random Nanostructures of the Bulkheterojunctions(BHJ) in Organic Solar Cell Active Layers with Spectral Density Function (SDF)

RABINDRA DULAL (Presenter), University of Wyoming, UMAR FAROOQ GHUMMAN, AKSHAY IYER, Mechanical Engineering, University of Northwestern, JOYDEEP MUNSHI, GANESH BALASUBRAMANIAN, Mechanical Engineering and Mechanics, Lehigh University, WEI CHEN, Mechanical Engineering, University of Northwestern, TEYU CHIEN, University of Wyoming — Bulkheterojunctions in organic photovoltaic solar cell (OPVC) active layers are believed to be determining the performance of the OPVCs. The domain features measured in the active layer exhibits quasi-random nanostructures. Though it is believed that the quasi-random nanostructures in the BHJ play a decisive role on determining the performance, it is unclear how to quantify this quasi-random nanostructures into a quantity that could be used to guide the synthesis. In this work, we will present mathematical description of SDF for two dimensional images followed by a simplified fitting equation for general SDF analysis. The simplified fitting equation will extract the information of domain sizes (average and deviation), and domain distances (average and deviation). Validation of this equation is tested by simulated model data. After testing with the simulated data, this equation is applied to two dimensional cross-sectional scanning tunneling microscopy and spectroscopy (XSTM/S) data and small angle X-ray diffraction data measured on the active layer made of poly(3-hexylthiophene) (P3HT) and [6,6]-phenyl C61 butyric acid methyl ester (PCBM). It will be argued that this method could be applied to various types of data exhibit similar two-domain quasi-random features.
Multiscale Modeling of Organic Photovoltaics*  THOMAS ALLEN (Presenter), PETER JACOB ROSSKY, Rice University — Obtaining a detailed understanding of how molecular configurations impact device performance in polymer-based solar cells is a key problem on the road to enabling improved rational design of these devices. Since direct observation of the relevant morphology is experimentally challenging, computer simulation has become an important tool in gaining insight into correlations between structure and performance in organic photovoltaics. Here, we report on the development and usage of a recent coarse-grained model of poly-3-hexylthiophene (P3HT), parameterized based on an information-theoretic Bayesian approach. On this basis, we discuss insights into not only how to build polymer models, but also which types of observables must be captured in the model in order to faithfully represent device morphology. Additionally, we consider spatial and temporal challenges present even in coarse-grained simulation and sampling and some approaches to alleviate them.

Session K51 DBIO: Information Processing in Sensory Systems

8:00AM K51.00001: Making an effort to listen: mechanical amplification by ion channels and myosin molecules in hair cells of the inner ear [Invited]  JIM HUDSPETH (Presenter), Howard Hughes Medical Institute, Rockefeller University — As the gateway to human communication, the sense of hearing is of enormous importance. Hearing commences with the capture of sound energy by hair cells, the ear's sensory receptors, which convert that energy into electrical signals that the brain can then interpret. Each hair cell is a cylindrical epithelial cell surmounted by a hair bundle, an erect cluster of 20-300 rigid, actin-filled rods termed stereocilia. Mechanical force deflects the hair bundle and thereby excites the hair cell and its associated nerve fibers.

Uniquely among our sensory receptors, the hair cell is not a passive recipient of stimuli, but instead uses an active process to enhance its inputs. This active process amplifies mechanical stimuli by as much as a thousandfold, greatly increasing our sensitivity to weak sounds. Amplification is accompanied by frequency tuning, which yields a frequency resolution of less than 0.2 %, one thirtyieth of the interval between piano keys. The active process produces a compressive nonlinearity that renders the ear sensitive to sounds over a millionfold range of amplitude or a trillionfold range of power. Finally, the active process can be so exuberant as to become unstable; as a result, in a very quiet environment most normal ears spontaneously emit sound!

As a result of the cooperative gating of mechanically sensitive ion channels, a hair bundle is dynamically unstable: the relation between the bundle's displacement and the force required to accomplish it possesses two stable fixed points separated by a region of negative stiffness. This situation fosters amplification or oscillation when the hair bundle is pushed into its region of instability by molecular motors, specifically the myosin molecules associated with adaptation of the transduction apparatus to sustained stimuli. Experiments on individual hair bundles indicate that the bundle's operation near this instability—a Hopf bifurcation—accounts for the four characteristics of the active process.

8:36AM K51.00002: Differential Resilience to Perturbation of Circuits with Similar Performance* [Invited]  EVE MARDER (Presenter), Volen Center and Biology Department, Brandeis University — Experimental work on the crustacean stomatogastric ganglion (STG) shows a 2-6 fold variability in the expression of ion channel and receptor genes and in the conductance densities for many of the processes that are important for circuit dynamics. Old and new computational work with conductance-based single neurons and small network models shows that similar network performance can arise from diverse underlying parameter sets. Together, these lines of evidence suggest that each individual animal, at any moment in its life-time, has found a different solution to producing “good enough” motor patterns for normal behavior. This poses the question of the extent to which animals with different sets of underlying circuit parameters can respond reliably and robustly to environmental perturbations and neuromodulation. Consequently, we study the effects of temperature, pH and neuromodulation on the pyloric rhythm of crabs. While all animals respond remarkably well to large environmental perturbations, extreme perturbations that produce system “crashes” reveal the underlying parameter differences in the population. Studies of multiple computational models with similar behaviors under control conditions reveal interesting dynamics when perturbed.

9:12AM K51.00003: Algorithms and neural circuits in olfaction* [Invited] VENKATESH MURTHY (Presenter), Molecular & Cellular Biology, Harvard University — Animals sense the chemical world to guide their behaviors. Fluctuating mixtures of odorants, often transported in fluid environments, are detected by an array of chemical sensors and parsed by neural circuits to recognize odor objects that can inform behavioral decisions. Unlike other sensory systems, the olfactory system lacks an obvious topographic organization, and neural connectivity across brain regions is seemingly unstructured. These anomalies offer an opportunity to uncover common principles across different sensory systems. We exploit a variety of biophysical, neurophysiological and behavioral methods to understand how odorant features are encoded in the activity of neurons and transformed in different stages of processing. We then use conceptual and computational models to seek algorithmic explanations for how animals solve specific olfactory tasks. In an illustrative set of studies, we have found that mice can be trained to recognize individual odorants embedded in unpredictable and variable background mixtures with high degree of success [doi: 10.1038/nn.3775]. Despite nonlinear interactions and variability in the representations of odor mixtures by odorant receptors, a simple linear feedforward decoding is sufficient to explain the performance of mice in this task [doi: 10.1016/j.neuron.2016.08.007]. Current experiments are aimed at understanding how the mouse brain represents information about odor mixtures to aid odor object identification and categorization.

*Work in the Murthy lab is supported by grants from the NIH, NSF and Harvard University.

9:48AM K51.00004: Information Processing in the Somatosensory System* [Invited] DANIEL O’CONNOR (Presenter), Department of Neuroscience, Johns Hopkins University School of Medicine — Touch perception arises from a closed-loop process in which animals move their sensors in order to actively seek out informative mechanical input, which is then processed to direct further movements. My laboratory uses the mouse whisker system to explore the neural basis of active touch perception, at essentially all levels of the nervous system. Information processing during active touch is constrained by the coding properties of neurons in the skin that transduce mechanical stimuli into action potentials. I will discuss recent work from my laboratory that addresses how specific types of mechanosensory neurons encode (a) mechanical features of the environment during active touch, and (b) self-motion kinematics. These two streams of information allow tactile input to be interpreted with respect to sensor position. After mechanical features of the environment are encoded into action potentials and sent to the central nervous system, multiple factors determine how these neural signals are routed within circuits of the brain to impact perception. I will discuss a second line of work in my lab that addresses how identically encoded sensory inputs can produce quite different perceptual outcomes. By monitoring and manipulating neural activity at multiple levels of the nervous system during behavior, we have gained insight into the mapping between mechanosensation and perception.

*NIH grants R01NS089652 and 1R01NS104834-01.

10:24AM K51.00005: Neural processing and computation in the visual system* [Invited] DAMON CLARK (Presenter), Molecular, Cellular, Developmental Biology, Yale University — Visual systems detect many features of natural scenes, but one of the best studied is how they detect motion, which is a widespread computation across animals. To estimate visual motion speed and direction, the visual system must integrate information nonlinearly over space and over time. Models to estimate visual motion have two essential features: a delay step that delays certain signals with respect to others; and a nonlinear step that integrates signals over space and time to create the motion estimate. The computation itself can be framed as an inference problem, in which spatiotemporal light intensity measurements are combined to estimate a latent variable of image velocity. I will present recent work on understanding how motion is computed in the small brain of the fruit fly Drosophila, where genetic tools allow us to dissect the roles of individual neurons in circuit computations. I will focus on the mathematical operations that describe the transformation from light intensity to motion signals, and how that algorithm performs with different visual inputs. I will also focus on processing steps that appear similar across visual systems. These parallels suggest that there may be a narrow range of motion estimation algorithms that perform well given the constraints of biological systems and the regularities of natural scenes.

Session K52 DPOLY: Polymer Nanocomposites II: Block Copolymers and More BCEC 253B - Pinar Akcora, Stevens Institute of Technology - Tag(s): Focus
In recent decades, block copolymer (BCP)-inorganic nanocomposite co-assembly has emerged as a highly tunable route to the synthesis of crystallographically ordered, mesoporous inorganic materials. These materials have found numerous applications in catalysis, energy conversion and storage, and other areas. One notable area in which BCP-directed assembly has made few inroads, however, is the production of electronic-grade materials suitable for studies of emergent phenomena, i.e. quantum metamaterials. For example, superconductors with mesoscale ordering are expected to have properties different from their bulk counterparts. The exploration of these properties has been limited by the lack of tunable, robust synthesis methodologies. We have developed a route to gyroidal NbN superconductors from poly(isoprene-b-styrene-b-ethylene oxide)-Nb$_2$O$_5$ nanocomposites using high-temperature annealing in ammonia gas. In recent work, we have developed synthesis routes using methane gas that enable the synthesis of carbonitrides with superconductor quality comparable to bulk samples and tunable morphology across the BCP phase diagram. These morphologies exhibit differences in the transition onset and magnetization behavior, potentially the first hallmarks of quantum metamaterial behavior.

**8:24AM K52.00003: Nanoparticle Templating via Block Copolymer Self-Assembly**

DEBORAH LIU (Presenter), DANIEL KROGSTAD, University of Illinois at Urbana-Champaign — Many applications of polymer nanocomposites require an ordered configuration. To address this challenge, our group is studying the templating of nanoparticles by block copolymers within a thermoset resin. However, much remains to be understood about the fundamental phase behavior of block copolymers when blended with a thermoset. In this presentation, we will discuss our recent work characterizing the self-assembly behavior of an asymmetric block copolymer blended in an epoxy resin. The nanostructures formed as a function of block copolymer weight fraction within the thermoset resin are characterized by SAXS and TEM, and the evolution of these structures during epoxy curing is evaluated. The effect of increasing weight fraction of block polymer on the thermal characteristics of the cured network are probed using DSC. In addition, we present preliminary work on the abilities of these nanostructures to template gold nanoparticles. The suitability of these materials for high performance applications is also discussed.

**8:36AM K52.00004: Entropy-driven assembly in multicomponent nanocomposite**

LE MA (Presenter), University of California, Berkeley, PETER ERCIUS, Lawrence Berkeley National Laboratory, TING XU, University of California, Berkeley — Hierarchically structured nanocomposites show unique collective properties from nanoparticle (NP) assemblies. Successfully structure control in nanocomposite remains as bottleneck to advance the field. Block copolymer (BCP) and supramolecular systems have been effective in achieving nanoscopic dispersion of fillers. However, NPs with size larger than 30% of the BCP specific domain size tend to aggregation due to the large conformational entropy penalty. This limitation in the particle size restricts the NP incorporation for targeted functionality. Here, we will discuss a new approach to modulate thermodynamic contribution from various components with a special focus of maximizing translational entropy. The present studies suggested that manipulating entropic contribution in multiple components system will lead to new path and opportunity toward structure control and access functionality.

Electrically Conductive Block Copolymer Nanocomposites for Large-Scale Coating Applications*

JUNPYO KWON (Presenter), KATHERINE EVANS, ROBERT OLIVER RITCHIE, TING XU, University of California, Berkeley — Electrically conductive coatings have been widely applied to convert insulators to electronics for sensing, energy harvesting, or actuator applications. However, commercially available conductive paints have issues regarding low mechanical properties and fatigue resistance. Furthermore, mass production is limited due to the extremely high price of conductive fillers and complicated manufacturing processes. Here, we introduce a low price block copolymer and carbon black nanocomposite possessing superb mechanical flexibility and electrical conductivity. Attractively, its mechanical and electrical properties can be recovered with a thermal annealing process after applying cyclic loadings with high frequencies. The nanocomposite can be coated on a variety of substrates, such as fabric, wood, glass, and plastic. This self-healing composite could be used to design wearable electronics, soft robotics, and strain sensors, which require high flexibility.

The effect of chemical structure on the morphology, ion transport, and modulus of hybrid inorganic-organic diblock copolymer electrolytes*

KEVIN GAO (Presenter), GURMUKH SETHI, SAHELI CHAKRABORTY, IRUNE VILLALUENGA, NITASH BALSARA, University of California, Berkeley — Poly(ethylene oxide)-b-polyhedral oligomeric silsequioxane (PEO-POSS) mixed with lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) salt is a nanostructured hybrid organic-inorganic diblock copolymer electrolyte that may enable lithium metal batteries. The organic poly(ethylene oxide) block solvates lithium ions and facilitates ion transport while the inorganic polyhedral oligomeric silsequioxane (POSS) block provides mechanical rigidity, decoupling typically antagonistic mechanical and ion conducting properties. PEO-POSS with different alkyl chain substituents on the POSS monomer's silica cage were synthesized to study the effect of chemical structure on morphology, ion transport, and modulus. Ionic conductivity, salt diffusion coefficient, and steady-state cation transference number were measured for a range of salt concentrations. In general, increasing the alkyl chain length was found to promote ordering and increase mechanical stiffness, while decreasing ionic conductivity.

Ionomer Nanocomposites: The Interplay Between Structural Dynamics and Water Transport

APOORVA BALWANI (Presenter), ALLISON JANSTO, Chemical & Biomolecular Engineering, Clemson University, ANTONIO FARAONE, NIST Center for Neutron Research, National Institute of Standards and Technology, ERIC DAVIS, Chemical & Biomolecular Engineering, Clemson University — Ionomer nanocomposites are gaining popularity as proton exchange membranes (PEMs) in vanadium redox flow batteries due to reduced vanadium ion crossover as compared to traditional PEMs. Understanding the impact of silica nanoparticles (SiNPs) on the structural dynamics and transport kinetics of these nanocomposites can provide vital insights into the mechanism of crossover reduction. Presently, segmental and swelling dynamics of a series of ionomer nanocomposite membranes were characterized using neutron spin echo and time-resolved Fourier transform infrared attenuated total reflectance (tFTIR-ATR) spectroscopy. We found that both viscoelastic relaxations and segmental dynamics in the ionomer network were impeded by the presence of SiNPs. Further, the dynamics of the membranes were highly dependent on the surface chemistry of the SiNPs, for both cationically or anionically charged surfaces. In addition to swelling dynamics, tFTIR-ATR was used to evaluate water sorption kinetics, which were found to be strongly coupled with the viscoelastic relaxation in these hybrid membranes. Anomalous, multi-stage water sorption kinetics were observed and attributed to different stages of structural rearrangement in the ionomer network during membrane hydration.
9:24AM K52.00008: Metal Organic Framework assisted ionic conductivity in solid polymer electrolyte for application in lithium-ion battery  NAGMA ZERIN (Presenter), JANNA MARANAS, XUEYI ZHANG, Pennsylvania State University — Solid polymer electrolytes are safer alternatives to the current flammable liquid electrolytes used in lithium-ion batteries. We are using crystalline PEO6/LiX (X= anion) as the potential polymer electrolyte. In this structure, pairs of PEO chains wrap around each other to form cylindrical tunnels. Inside the tunnel each Li+ coordinates with six ether oxygens. The anions are located outside the tunnel. Low molecular weight PEO6 has been found to be more conductive than its amorphous counterpart. However, it is not useful for practical applications as at room temperature this structure is like viscous liquid. Although increasing molecular weight improves the structural stability of PEO6, it doesn't improve conductivity. High molecular weight PEO6 chains fold into lamellae, preventing direct pathway for lithium ion conduction. We propose that incorporating high aspect ratio nanofillers, containing Lewis acidic surface sites, with PEO6 can resolve the issue. Using metal organic framework as the nanofiller, we have obtained conductivity greater than 10^{-5} S/cm at 30°C.

9:36AM K52.00009: EFFECT OF FILLER CONTENT ON ENHANCEMENT OF THERMAL CONDUCTIVITY OF ALIGNED POLYMER GRAPHENE NANOCOMPOSITES  FATEMA TARANNUM (Presenter), JIVTESH GARG, University of Oklahoma — In this work a systematic study of the effect of increment of filler content on enhancement of thermal conductivity(k) of aligned polymer-graphene nanocomposites has been conducted. Using Angstrom Method, it is found that aligned graphene nanoplatelets (GnPs) significantly increase the heat-conducting properties of pure polyethylene (PE) compared to randomly oriented nanoplatelets. The increment in amount of GnPs from 9 weight% to 13 weight% is studied. A combination of melt extrusion processing and compression molding is used to obtain an even dispersion of the filler in the polymer matrix. Alignment of PE and GnPs is observed through confocal laser scanning microscopy. Comparison with effective medium theory reveals the measured thermal conductivity enhancement to be larger than theoretical predictions. Cause of this discrepancy between measurement and theory will be discussed.

9:48AM K52.00010: Molecular Simulations of the Motion of Polymer-Tethered Nanoparticles in Unentangled Polymer Melts  TING GE (Presenter), MICHAEL RUBINSTEIN, Mechanical Engineering and Materials Science, Duke University, GARY GREST, Sandia National Laboratories — Polymer-tethered nanoparticles are commonly added to a polymer matrix to yield superior material properties. Critical to the fabrication and processing of such a composite is the mobility of polymer-tethered nanoparticles. We study the motion of polymer-tethered nanoparticles in unentangled polymer melts using molecular simulations, which offer a precise control of the grafted chain (tail) length N_{tail} and the number Z of tails per particle. For loosely-grafted particles with small Z, the diffusion coefficient decreases with increasing N_{tail}, exhibiting a crossover from particle-dominated to tail-dominated diffusion. If the diffusion is tail-dominated, there are two sub-diffusive regimes in the mean squared displacement \langle \Delta r^2(t) \rangle of particles before diffusion. The sub-diffusion at small t arises from the dynamical coupling of the particle and the melt chains, while the one at large t results from the participation of the particle in the dynamics of the tails. For densely-grafted particles with large Z, \langle \Delta r^2(t) \rangle can be approximated as that of a larger particle. The friction coefficient of the tails is smaller than the prediction based on Rouse dynamics of tails. These results suggest that the particle and tails move as one object with the tails hydrodynamically coupled to each other.

10:00AM K52.00011: Impact of hydrogen bonding interactions on graft-matrix wetting and structure in polymer nanocomposites*  ARJITA KULSHRESHTHA (Presenter), ARTHI JAYARAMAN, University of Delaware — Properties of polymer nanocomposites (PNCs) are linked to their morphology which is dictated by the dispersion/aggregated state of nanoparticles in a polymer matrix. Grafting polymeric ligands onto the nanoparticle surface offers a greater control over morphology by allowing for tuning of effective interactions between graft and matrix polymers. One way to tailor interactions between graft and matrix chemistries is by the introduction of inter-molecular hydrogen bonds between graft and matrix polymers. In this talk, we present our work on the development of a coarse-grained (CG) model that allows us to capture hydrogen bonding type directional and specific interactions between graft and matrix polymers. Using this CG model, we run molecular dynamics (MD) simulations to elucidate the effect of these directional and specific interactions on the PNC morphology by comparing grafted layer wetting, graft and matrix chain conformations and free volume for each graft monomer between PNCs with isotropic graft-matrix interaction and PNCs with hydrogen bonding type graft-matrix interaction. We explore effects over a large design space comprising of grafting density, polymer flexibility, and strengths of isotropic graft-matrix attraction and hydrogen bonding interaction.

*DOE (#DE-SC0017753)
10:12AM K52.00012: Influence of Nanoparticle Surface Chemistry on Properties of Iron Oxide–Poly(ethylene oxide) Nanocomposites*  DONOVAN WEIBLEN (Presenter), GRACE GIONTA, Materials Science and Engineering, Rensselaer Polytechnic Institute, DENIZ RENDE, Center for Materials, Devices, and Integrated Systems, Rensselaer Polytechnic Institute, PINAR AKCORA, Chemical Engineering and Materials Science, Stevens Institute of Technology, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — Heating using magnetically susceptible nanoparticles has shown promise in biomedical applications in areas such as tissue engineering and drug delivery. In the current work, the effect of surface coating on iron oxide nanoparticles heated via an alternating magnetic field (AMF) was explored. Two coatings were investigated in addition to bare nanoparticles: poly(ethylene glycol), PEG, coated and amine coated 50–nm–diameter iron oxide nanoparticles. These nanoparticles were dispersed in concentrations varying from 0.010–0.750% by weight in poly (ethylene oxide), PEO. PEO was chosen due to its known biocompatibility and use in the healthcare industry. A significant increase in temperature was observed considering the low loading of particles in all samples. Analysis of heating curves revealed an unusual result. The amine coated particles had a much more significant and rapid response than either the uncoated or PEG coated nanoparticles. Heating properties of samples were also investigated as a function of AMF parameters and iron oxide surface chemistry.

*This material is based upon work supported by the National Science Foundation under Grant No. CMMI-1825254

10:24AM K52.00013: Functional polymer nanocomposites : structural issues in relation to the piezoelectric response*  SOPHIE BARRAU (Presenter), ADELINE MARIN, JULIETTE DEFEBVIN, JOËL LYSKAWA, PATRICE WOISEL, JEAN-MARC LEFEVBRE, UMET, University of Lille, France, ANTHONY FERRI, ANTONIO DA COSTA, RACHEL DESFEUX, UCCS, University of Artois, France — Poly(Vinylidene Fluoride) (PVDF) is a semi-crystalline polymer with complex polymorphism that has attracted considerable interest, owing to the electroactive properties displayed by its polar β and γ phases. Regarding PVDF-based nanocomposites, two strategies are considered in the following :
- The first one deals with the incorporation of piezoelectric inorganic nanofillers (BaTiO3), with primary issues related to nanoparticle dispersion and monitoring of interfacial cohesion, together with promoting the development of the highly polar β phase in the PVDF matrix. It is shown that the piezoelectric response may be modulated as a function of filler content, going through a zero value at some critical filler fraction.
- Alternatively, the introduction of carbon nanotubes in the PVDF matrix is achieved, with the result that the nanotubes induce the formation of the γ polar phase in their vicinity. The local structural organization of the α and γ phases in the PVDF nanocomposite is probed by atomic force microscopy and specific attention is paid to the local electroactive properties through the use of piezoelectric force microscopy (PFM).

*This work was partly supported through grant ANR-16-CE08-0025, ANR NanoPic from the French National Research Agency.

10:36AM K52.00014: Optical Properties of Plasmonic Nanoparticles Polymer Nanocomposites*  ASSAD ULLAH KHAN (Presenter), YICHEN GUO, XI CHEN, GUOLIANG LIU, Virginia Tech — Plasmonic nanoparticles–polymer nanocomposites are used in functional optical materials and devices where light management is essential. However to modulate the optical properties of these nanocomposites, control over the orientation and spatial distribution of the nanoparticles within polymer matrix is very critical. Here we synthesized two-dimensional (2D) Ag nanoplates (AgNPs) with plasmon resonance across the visible and near infrared (NIR) light range via a multi-step approach. Layer-by-layer (LbL) assembly was utilized to control the orientation and density of the AgNPs in the nanocomposite films. The composite thin-films effectively controlled the light transmittance and reflectance across the visible and NIR range. In contrast to the conventional polymer nanocomposites in which the polymer grafted nanoparticles were randomly mixed within the matrix, the thin-film polymer nanocomposites comprise a single layer (~10 nm), or any desired multiple layers, of planarly oriented plasmonic AgNPs separated by a polymer with tunable interlayer thickness. The plasmonic composites filter light selectively and will have enormous effect on energy-efficient tinted glass.

*This material is based upon work supported by the National Science Foundation under Grant No. DMR-1752611.
8:00AM K53.00001: The Topology and Mechanics of the Formation of Fracture Surface Patterns* [Invited] JAY FINEBERG (Presenter), Hebrew University of Jerusalem, ITAMAR KOLVIN, Physics, University of California Santa Barbara, MOKHTAR ADDA-BEDIA, Laboratoire de Physique, ENS Lyon — How and why are patterns formed on broken surfaces? Faceted fracture surfaces are commonly formed by slow tensile cracks in amorphous materials; hence their formation cannot reflect microscopic order. While fracture mechanics predict that slow crack fronts should be straight and form mirror-like surfaces, facet-forming fronts propagate simultaneously within different planes separated by steps. Why are steps stable, what determines their path and how do they couple to crack front dynamics? By integrating real-time imaging of propagating crack fronts with surface measurements, we demonstrate that steps are topological defects; crack front separation into disconnected overlapping segments provides the condition for step stability. Crack dynamics are enslaved to steps; steps drift at a constant angle to the local front propagation direction while their increased dissipation couples to long-ranged elasticity to determine front shapes. We see how 3D topology couples to 2D fracture dynamics to provide a fundamental picture of how patterned surfaces are generated. We also show that crack front curvature may feed back to deflect step paths via nonlinear focusing of crack fronts, causing steps to converge to form a micro-branch. Thus, our results supply the basis for a unified picture of pattern formation on fracture surfaces.

8:36AM K53.00002: Topological adhesion [Invited] ZHIGANG SUO (Presenter), Harvard University — TBD

9:12AM K53.00003: Fracture mechanics of self-healing hydrogels [Invited] CHUNG YUEN HUI (Presenter), Cornell University — TBD

9:48AM K53.00004: Active superelasticity in three-dimensional epithelia of controlled shape* [Invited] XAVIER TREPAT (Presenter), ICREA at the Institute for Bioengineering of Catalonia — Fundamental biological processes are carried out by curved epithelial sheets enclosing a pressurized lumen. How these sheets develop and withstand three-dimensional deformations has remained unclear. By combining measurements of epithelial tension and shape with theoretical modeling, here we show that epithelial sheets are active superelastic materials. We produce arrays of epithelial domes with controlled geometry. Quantification of luminal pressure and epithelial tension reveals a tensional plateau over several-fold areal strains. These extreme tissue strains are accommodated by highly heterogeneous cellular strains, in seeming contradiction with the measured tensional uniformity. This phenomenology is reminiscent of superelasticity, a behavior generally attributed to microscopic material instabilities in metal alloys. We show that this instability is triggered in epithelial cells by a stretch-induced dilution of the actin cortex and rescued by the intermediate filament network. Our study unveils a new type of mechanical behavior -active superelasticity- that enables epithelial sheets to sustain extreme stretching under constant tension.

10:24AM K53.00005: Towards a Unified Model of Soft Adhesives [Invited] MATTEO CICCOTTI (Presenter), Soft Matter Science and Engineering Laboratory (SIMM), ESPCI Paris — Pressure Sensitive Adhesives (PSA) have been widely used in adhesive tapes, stickers, tags in industry and day-to-day use, for decades. PSAs are rate-dependent materials, extremely soft, hence highly deformable. Their bonding strength depends critically on small scale features such the surface properties of the substrates. Understanding quantitatively their behavior has been a enormous challenge. Quite surprisingly, a same adhesive can be described by different models with little connection within each other depending on the adhesion tests used. In this talk, I will present a new modeling strategy to these soft materials [Creton and Ciccotti, Soft Matter, (2016)] based on the identification of the mesoscale mechanisms (cavitation, fibrillation, ...) along with the evaluation of the contribution of the large strain rheology of the PSA into the total work of debonding. I will discuss some original experimental investigations providing insights into the pertinent links between the peel, tack and shear of model PSAs.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K54 DPOLY GSOFT GSNP: Confined Polymer Glasses II: Dynamics, Surface Effects, and Architecture BCEC 254A - George Floudas, University of Ioannina - Tag(s): Focus
8:00AM K54.00001: β-NMR Studies of the Depth Dependence of Secondary Relaxations in Polystyrene Thin Films

IAIN MCKENZIE (Presenter), Physical Sciences Division, TRIUMF, YU CHAI, Physics and Astronomy, University of Waterloo, DAVID CORTIE, Physics and Astronomy, University of British Columbia, JAMES FORREST, Physics and Astronomy, University of Waterloo, DEREK FUJIMOTO, Physics and Astronomy, University of British Columbia, VICTORIA KARNER, Chemistry, University of British Columbia, ROBERT F KIEFL, Physics and Astronomy, University of British Columbia, CDP LEVY, Accelerator Division, TRIUMF, W ANDREW MACFARLANE, Ryan MCFADDEN, Chemistry, University of British Columbia, GERALD D MORRIS, MATTHEW PEARSON, Physical Sciences Division, TRIUMF, ADAM RAEGEN, SHIPEI ZHU, Physics and Astronomy, University of Waterloo — β-detected nuclear magnetic resonance (β-NMR) of implanted $^8$Li$^+$ has been used to probe the depth dependence of secondary relaxation processes in thin films of atactic polystyrene (PS). β-NMR measurements of the average $^8$Li spin-lattice relaxation rate were used to determine the depth dependence of the fluctuation rate of the fast γ-relaxation process in PS films at 317 K, which is well below its glass transition temperature [I. McKenzie et al. Soft Matter, 14, 7324 (2018)]. A novel hole-burning (selective saturation) β-NMR technique has been used to measure the depth dependence of the fluctuation rate of the much slower β-relaxation process at the same temperature. Both the fluctuation rates of the β- and γ-relaxation processes are larger near the free surface than in the bulk and both return to the bulk value over a length scale of several nm.

8:12AM K54.00002: Reducing the Tg-Confinement Effect in Polystyrene Films by Use of Carbon Substrates and Changing the Direction of the Effect in Polystyrene-Carbon Model Nanocomposites

JOHN TORKELSON (Presenter), LAWRENCE CHEN, Northwestern University — Using ellipsometry and fluorescence, we have shown that single-layer polystyrene (PS) films supported on carbon substrate exhibit suppression of the classic $T_g$-confinement effect due to favorable polymer-substrate interactions. Additionally, a bilayer film/fluorescence study has shown that in a bulk PS film, the 15 nm layer at the carbon interface exhibits a $T_g$ nearly 10 K higher than bulk. The ability of PS to favorably interact at the interface with the graphitic substrate (versus silicon dioxide) was demonstrated qualitatively via a dewetting study. Because PS does not naturally wet the native oxide layer on silica, a thin 30 nm-thick, 30 kg/mol PS film readily dewets when annealed at 433 K. However, dewetting of supported thin PS films is greatly suppressed using substrates with favorable interfacial interaction with PS. Model nanocomposites were also made by sputtering a graphitic layer above PS films supported on carbon, sandwiching the film between two graphitic surfaces and providing a consolidated film with constant interlayer distance between the two hard surfaces after annealing. Single-layer PS films in this model nanocomposite geometry exhibit enhanced $T_g$ with decreasing nanoscale thickness due to pi-pi bonding interactions of PS with the graphitic substrates.

8:24AM K54.00003: Polymer dynamics under 2D nanometer confinement

GEORGE FLOUDAS (Presenter), MPI-P, University of Ioannina, CHRISTOS POLITIDIS, STELIOS ALEXANDRIS, University of Ioannina, MARTIN STEINHART, University of Osnabrueck — The effect of confinement on polymer dynamics and the associated liquid-to-glass temperature, $T_g$, has been an issue of great interest in polymer physics. In this study, we investigate the effect of nanometer confinement on the dynamics of several polymers including cis-1,4-polyisoprene with molecular weights both below and above the entanglement limit. As confining medium we employ self-ordered nanoporous alumina (AAO) with diameters, $d$, ranging from 400 nm to 25 nm resulting in a broad $2R_g/d$ range. We employ Broadband Dielectric Spectroscopy (BDS) and Temperature-Modulated Differential Scanning Calorimetry (TMDSC). BDS revealed consistently faster segmental dynamics under confinement with respect to the bulk, leading to a decrease in $T_g$ with increasing degree of confinement ($2R_g/d$). This is discussed in terms of the role of interfacial energy. In addition, we provide evidence for an intermediate process with an Arrhenius temperature dependence whose dielectric strength increases with increasing degree of confinement. These results are discussed in view of recent theoretical and experimental progress in understanding polymer imbibition in nanopores.
Irreversible adsorption: new insights on molecular mobility, thermodynamics and interfacial interactions* [Invited] SIMONE NAPOLITANO (Presenter), DAVID NIETO SIMAVILLA, Polymer and Soft Matter Dynamics, Universite libre de Bruxelles (ULB) — Irreversibly adsorbed polymer layers represent an intriguing class of novel nanomaterials with unexpected properties, strongly deviating from what observed in unbounded polymer melts. These extremely thin films are obtained via a small number of successive steps, easily reproducible: a polymer melt is placed in contact with an adsorbing substrate and nonadsorbed chains are washed away in a good solvent. Importantly, tuning the thickness of the adsorbed layer, an operational parameter equivalent to the number of chains adsorbed on a unit surface, allows modifying the interfacial free volume content and, hence, the performance of polymer coatings without affecting the interfacial chemistry.

Here, we discuss on the physics behind the formation of irreversibly adsorbed layers onto solid substrate. By analyzing the outcome of experiments and simulations, we show how changes in thermal energy and interaction potential affect the equilibrium and the nonequilibrium components of the kinetics. We verify that the monomer pinning mechanism is independent of surface coverage, while the progressive limitation of free sites significantly limits the adsorption rate. Importantly, in neat disagreement with current ideas on surface science, the equilibrium adsorbed amount – and, hence, interfacial interaction potential – is affected by nanocconfinement (1).

Thinner films show a neat drop in adsorbed amount, implying a reduction in interfacial interactions between polymer and substrate upon confinement at the nanoscale level. We demonstrate that this phenomenon is totally ascribable to the smaller amplitude of the dispersive forces in thinner films, that can be parametrized via the Hamaker constant, and discuss on the impact of our new findings on previous experiments on multilayers systems.

Confinement Effects on Dye Translational Diffusivity in Polystyrene Thin Films Depend on Polymer Molecular Weight: Connection to Fragility-Confinement Effects TONG WEI (Presenter), Department of Chemical and Biological Engineering, Northwestern University, TIAN LAN, Department of Material Science and Engineering, Northwestern University, JOHN TORKELSON, Department of Chemical and Biological Engineering, Northwestern University — The impact of confinement on the translational diffusivity, \(D_{\text{dye}}\), of small-molecule dye 9,10-bis(phenylethynyl)anthracene is studied in supported, thin films by fluorescence. Relative to bulk films and near \(T_g\), \(D_{\text{dye}}\) is reduced by 80 - 90\% in 100-nm-thick, high molecular weight (MW) PS (400 kg/mol) films. In contrast to \(T_g\), which reflects the slow portion of the cooperative segmental relaxation distribution, \(D_{\text{dye}}\) reflects the fast relaxation regions, which can be many orders of magnitude faster than slow regions. \(D_{\text{dye}}\) results are associated with fragility, which reflects the relaxation distribution breadth, and its confinement effects: with sufficient confinement, the relaxation distribution narrows (and high MW PS fragility decreases) with the fast relaxation tail becoming slower, leading to a decrease in \(D_{\text{dye}}\). In yet thinner films, the slow relaxation regions become faster, decreasing \(T_g\). Because low MW PS (6 kg/mol) exhibits a lower bulk fragility than high MW PS, confinement has a much-reduced effect on low MW PS fragility, and both fragility and \(D_{\text{dye}}\) in 100-nm-thick low MW PS films are unchanged from bulk.

Comparing Refractive Index and Density Changes with Decreasing Film Thickness in Thin Supported Films Across Different Polymers YIXUAN HAN (Presenter), CONNIE ROTH, Physics Dept, Emory University — Density or specific volume changes in thin films have been investigated in relation to glass transition and other property changes with decreasing film thickness. Often such density changes are inferred from values of the refractive index through the Lorentz-Lorenz equation. Our group’s previous work on supported polystyrene (PS) films concluded that recently reported large changes in apparent film density are likely erroneous because assumptions in the derivation of the Lorentz-Lorenz relation become invalid for thin films less than ~20 nm. Unexpected non-monotonic changes in refractive index with decreasing thickness were observed for PS films as measured by spectroscopic ellipsometry. Here we compare these PS results to similar measurements of refractive index on poly(2-vinylpyridine) (P2VP) and poly(methyl methacrylate) (PMMA) supported films, polymers typically associated with attractive substrate interactions. Surprisingly, we find P2VP shows identical thickness-dependent refractive index changes to PS, with a more muted behavior for PMMA. We explore whether such trends arise from alignment of monomers near the substrate interface by measuring substrates with different surface chemistries.
9:36AM K54.00007: Prediction of the Structural Relaxation Time from Vibrational Dynamics in Thin Films  ANDREA GIUNTOLI (Presenter), Wesleyan University, MATTEO BECCHI, SISSA, DINO LEPORINI, University of Pisa — The structural relaxation time of glass forming liquids correlates with the cage vibrational dynamics at the picosecond, making it possible to predict one from the other despite a separation of more than ten orders of magnitude in the time scales. This result, found in computer simulations, has been extended over the years to all kind of glassformers in bulk systems. Thin films, though, present additional complications due to finite size effects and complex surface interactions, causing shifts in the glass transition temperature and strong gradients in mobility across the film for reasons that are not fully understood yet. In spite of that, we show that the particle-sized layers of a thin supported film comply without any adjustment with the same scaling observed in bulks, by varying temperature, film thickness and distance from the substrate in a coarse grained molecular dynamics simulation. This result provides new predicting tools for both simulations and experiments and its implications shed light on the physics of confined liquids approaching the glass transition.

9:48AM K54.00008: How does star polymer architecture affect dynamical heterogeneity? JINPENG FAN (Presenter), HAMED EMAMY, Department of Physics, Wesleyan University, ALEXANDROS CHREMOS, JACK DOUGLAS, Materials Science and Engineering Division, National Institute of Standards and Technology, FRANCIS STARR, Department of Physics, Wesleyan University — The formation of an amorphous solid by polymers is one of the most important features for polymer applications. While glass formation of linear chain polymers has been widely explored, comparatively little is known about glass formation of star polymers. We study the dynamical heterogeneity and cooperative nature of star polymer melts via molecular dynamics simulations. In particular, we quantify how the number of arms and the length of those arms affect the collective string-like motion of monomers. We find that, while the star geometry can significantly affect the size and time scale of collective motions, the relationship between the size scale of the collective motions and the overall relaxation time follows the same Adam-Gibbs like relationship previously found to describe simple linear polymers.

10:00AM K54.00009: How does polymer architecture affect the fragility of ultra-thin films? AMBER STOREY (Presenter), WENGANG ZHANG, JACK DOUGLAS, National Institute of Standards and Technology, FRANCIS STARR, Wesleyan University — It is widely understood that the glass transition temperature and fragility of thin polymer films can drastically differ from that of the bulk polymer. In this talk, our focus is to show how polymer architecture affects glass formation in thin films, with an emphasis on changes of fragility. We use molecular dynamics simulations to contrast the behavior of coarse-grained supported polymer films of PEO (which has no sidegroup) and PMMA (which does have a sidegroup). The differences between these polymers are most noticeable in the vicinity of the supporting substrate and free interface, where packing consideration are more affected by the polymer architecture.

10:12AM K54.00010: Structure and Dynamics of Bio-Based Polymers in the Bulk and under Confinement KYRIAKH CHRISSOPOULOU (Presenter), KRISTALENIA ANDROULAKI, SPIROS ANASTASIAKIS, FORTH-IESL and Univ. of Crete, MASSIMILIANO LABARDI, Univ. of Pisa — The structure and the dynamics of two bio-based polyester polyols are investigated in the bulk and close to surfaces when the polymers are intercalated within the galleries of a hydrophilic sodium montmorillonite, Na⁺-MMT. The morphology of the neat polymers as well as the structure of the nanohybrids are investigated with X-ray diffraction and their thermal properties are studied by differential scanning calorimetry. One of the investigated polyesters is amorphous whereas the second one is a semi-crystalline polymer with an intriguing thermal behavior. Hybrids have been synthesized in a broad range of compositions and intercalated structures are always obtained. Dielectric relaxation spectroscopy was utilized to study the polymer dynamics. It revealed multiple relaxation processes for the neat polymers both below and above their glass transition temperatures whereas, in the nanocomposites, similarities and differences are observed depending on the specific mode of dynamic process. The results are compared with the ones of hyperbranched polymers of similar chemistry but non-linear architecture. This research has been co-financed by the Greek General Secretariat for Research and Technology (Action: Roadmap of Research Infrastructures, project INNOVATION EL, MIS: 5002772).
Existence of irreversibly adsorbed polymer chains in thin polymer films has a huge impact on the wetting, glass transition, aging and polymer chain mobility. Adsorption of polymer chains on the solid substrates is possible due to a delicate balance between enthalpic gain through segment-substrate interactions and reduction in conformational entropy. In this work we have used 4-arm star, 8-arm star, centipede and comb polystyrene (PS) architectures to understand the role of entropy on the structure of irreversibly adsorbed polymer layers using ellipsometry, X-ray reflectivity and atomic force microscopy. Normalized equilibrium adsorbed layer thickness for all architectures is larger than that of the linear PS and for 8-arm star PS it is above 1Rg. Substrate surface energy affects both the adsorbed layer thickness and the density of the layers. Adsorbed star polymers formed thicker and denser layers on HF etched substrates compared to hydrophilic substrates. It is also interesting to note that the adsorbed layer thickness increases with as-cast film thickness initially and reaches a plateau for thicknesses above 200 nm.

**8:00AM K55.00001: Monte Carlo Modelling of Phase Separation in Polymer Blends That Contain Branched Molecules**

EMMA WOOD (Presenter), NIGEL CLARKE, Physics and Astronomy, University of Sheffield — Thermoplastic-toughening of thermosetting epoxy resins is becoming increasingly prevalent, particularly for aerospace composites. As the mechanical properties of these materials are highly dependent on morphology, it is extremely important to understand phase separation within blends of branched and linear polymers. Unfortunately, the Flory-Huggins model has significant limitations for systems containing branched polymers. Entropies of branched polymers are often much lower than for linear polymers of the same molecular weight, but the mean field approach of the Flory-Huggins model does not account for this. The impact of polymer conformation on energetic interactions is also ignored. Here, we have developed a simulation approach capable of overcoming these difficulties and calculating free energy for polymers with branched architectures. We have also used Monte Carlo methods to directly simulate concentration fluctuations within industrially relevant blends, and have therefore gained insight into their phase separation characteristics.

**8:12AM K55.00002: Interface repulsion and arrest of coarsening in thin films of homopolymer blends due to thermal oscillations**

MARCUS MUELLER (Presenter), LOUIS PIGARD, Institute for Theoretical Physics, University of Gottingen, Germany — In equilibrium the interface potential that describes the interaction between two AB interfaces in a binary blend of A and B homopolymers is attractive, and this interface attraction gives rise to a coarsening of the blend morphology even in the absence of interface curvature. Using continuum models we demonstrate that the time-periodic variation of the Flory-Huggins parameter (or temperature or solvent concentration) qualitatively alters this behavior, i.e., for suitable parameter we find that AB interfaces repel each other and adopt a well-defined distance. We explore for which oscillation periods and amplitudes this interface repulsion occurs and how the preferred interface distance depends on these parameters. Using particle-based simulations we explicitly demonstrate that this dissipative self-assembly of a homopolymer blend results in a lamellar structure with multiple planar interfaces in a thin film geometry.

**8:24AM K55.00003: The application of Renormalization Group Theory to polymers**

ANNA SINELNIKOVA (Presenter), Department of Physics and Astronomy, Uppsala University, MAXIM ULYBYSHEV, Institut für Theoretische Physik, Julius-Maximilians-Universität, ANTTI J NIEMI, Nordita, Stockholm University — The definition of phases in polymer physics traditionally relies on scaling laws: different critical exponents correspond to different phases. This method requires the length to be varied for a certain polymer chain. This is impossible to do for proteins or other heteropolymer structures where the number of atoms is one of the characteristics of the system. To solve this problem we employ the ideas of Renormalization Group (RG) theory. We propose a scaling procedure and a novel observable through which RG flow determines the phases of polymers. In addition, this method gives rise to the idea of multiphases in heteropolymers: the chain exists in different phases on different length scales. For example, a helical protein can be seen as a collapsed coil at large scales but as a straight rod at scales corresponding to its secondary structure.

**8:36AM K55.00004: Coarse-grained Modeling for Polymer Solutions via the Mori-Zwanzig formalism**

SHU WANG, WENXIAO PAN (Presenter), University of Wisconsin - Madison — In this talk, we present a new method to establish implicit-solvent coarse-grained (CG) modeling for polymer solutions to conserve the dynamical properties of polymers. In the CG modeling, tens to hundreds of atoms were grouped as one CG particle; and the CG dynamic equations were rigorously derived from the atomistic data. The solvent-mediated dynamics of polymers was accurately captured via the generalized Langevin equation (GLE) with a non-Markovian memory kernel based on the Mori-Zwanzig formalism. The computational cost for direct evaluation of the non-Markovian memory kernel and generation of colored noise was significantly reduced by exploiting the equivalence between the non-Markovian dynamics and Markovian dynamics in an extended space. A higher-order time-integration scheme was developed to further accelerate the CG simulations. To assess, validate, and demonstrate the established CG modeling, we have applied it to simulate four different types of polymer solution systems. We find that the proposed CG modeling effectively conserves the velocity autocorrelation function and diffusivity of polymers and enables two orders of speedup in computer time, compared with the reference molecular dynamics simulations.

Simulating Diblock Copolymer Micelles in Binary Explicit Solvents  
DONG MENG (Presenter), JING ZONG, Mississippi State University — Amphiphilic block copolymers form nanoscale assemblies when dissolved in a selective solvent. Such self-assembled structures have wide-ranging applications as drug delivery vehicles and nanoreactors, etc. A powerful method to manipulate the assemblies is to vary the composition of solvent mixtures. Unlike single solvent solution, computational studies of amphiphilic block copolymers in solvent mixtures are rarely reported due to high computational cost associated with the necessity of treating solvents explicitly. Here, the Field-Accelerated Monte Carlo [1] simulation is employed in the expanded grand canonical ensemble to study the micelle formation of diblock copolymers in binary solvents: one selective solvent and one good solvent for both blocks. We investigate effects of molecular weight and solvent composition on micelle morphology, critical micelle concentration, and micelle size and aggregation number. It is found that distribution of the good solvent is highly inhomogeneous, concentrating at micelle interface and partitioning unevenly outside/inside micelle cores. Solvent intake by micelle cores increases with polymer molecular weight, affecting the way micelle size and aggregation number change with solvent composition.

Assessment of an Anisotropic Coarse-Grained Model for Cis-Polybutadiene Obtained by a Bottom-up Approach  
IOANNIS TANIS (Presenter), CLAIRE LEMARCHAND, CEA,DAM,DIF, 91297 Arpajon, France, ROUSSEAU BERNARD, Laboratoire de Chimie Physique, UMR 8000 CNRS, Université Paris-Sud, Orsay, France, LAURENT SOULARD, CEA,DAM,DIF, 91297 Arpajon, France — As it has been shown in previous coarse-grained simulations of polymer systems, the spherical representation utilized for the coarse-grained beads cannot capture anisotropic effects that play a crucial role on the structural features as well as on the dynamic response of such systems [1-2]. On these grounds, the aim of this study is to extract a coarse-grained potential for cis-polybutadiene in the melt state by taking into account the shape of the polymer beads. A conservative potential depending on the distance and the relative orientation of the polymer beads is deduced from atomistic molecular dynamics (MD) simulations. The translational dynamics of the beads is tracked using the position and momentum of their center-of-mass, whereas their rotational dynamics is modeled by representing their orientation through the use of quaternions. The efficacy of this approach to reproduce static features of the polymer melt is assessed in coarse-grained simulations and is also compared with respective isotropic models.

New Insights into the Glass Transition from Computational Prediction and Evolutionary Design*  
[Invited] DAVID SIMMONS (Presenter), Chemical and Biomedical Engineering, University of South Florida — In most polymers, the glass transition is one of the most important phenomena determining performance properties including mechanical response, processability, and transport behavior. For this reason, understanding and controlling the glass transition is a longstanding goal of polymer science and soft condensed matter physics. However, the vast range of timescales associated with glass formation, coupled with a lack of an agreed-upon theoretical description of the problem, have posed major challenges to achieving this goal. Here I describe a new approach to this problem, combining efficient molecular dynamics simulations, physics-based heuristics, machine learning, and evolutionary algorithms to predict, understand, and design the glass transition.

9:48AM K55.00008: Thermodynamics and kinetics of diblock copolymer micelles: chain architecture effect*
PRHASHANNA AMMU, ELENA DORMIDONTTOVA (Presenter), Polymer Program, Institute of Materials Science and Physics
Department, University of Connecticut, Storrs CT, 06269 — Diblock copolymers are actively used in various application, thus
understanding the factors affecting thermodynamics and kinetics of self-assembly is of obvious importance. Computer
modelling is a useful tool to analyze and compare behavior of various complex systems including diblock copolymers. Using
dissipative particle dynamics simulations we investigate the effect of chain architecture on diblock copolymer self-
assembly and the chain exchange kinetics using the example of diblock copolymers with a ring-shaped core or corona
block in comparison with their linear diblock copolymer counterpart. We found a striking difference in both the
equilibrium micelle size and kinetics of chain exchange in these systems. Furthermore, mixed micelles containing block
copolymers of both types exhibit an unexpected synergism of chain exchange, which is not present in mixed micelles
composed solely of linear chains. The origin of this effect and its implication for micelle self-assembly and practical
applications of self-assembled nanostructures will be discussed.

10:00AM K55.00009: Simulation of Free Surface of Block Copolymers*
DANIIL BOCHKOV (Presenter), Mechanical Engineering, University of California, Santa Barbara, GADDIEL OUAKNIN, Chemical Engineering, Stanford University, FREDERIC GIBOU, Mechanical Engineering, University of California, Santa Barbara — Due to their self-assembling properties, block
copolymers are used in a variety of engineering applications, from patterning of microchips to targeted drug delivery. The
study of these materials has been significantly accelerated by the powerful self-consistent field theory (SCFT), which has
been particularly effective at studying polymer self-assembly in bulk or in confinements with a-priori known geometry. However,
in many situations the surface of polymer material is free to deform (e.g., polymer/air interface) and its shape must be
determined simultaneously while solving the SCFT equations. In this talk, we present a computational framework for simulating free surfaces block copolymers based on an analytical shape sensitivity analysis. Specifically, we consider an
incompressible polymer melt described by the SCFT equations and derive an analogue of the Young-Laplace equation for
block copolymers. Selective interactions of surrounding materials with distinct polymer chain blocks are taken into
account by a new approach for imposing boundary conditions, consistent with the incompressibility property. To
demonstrate the capabilities of this methodology, we present examples of suspended and substrate-supported diblock
copolymer droplets.

10:12AM K55.00010: Systematic and Many-Chain-Simulation-Free Coarse Graining of Polymer Melts: Structure-
Based Coarse Graining of the Kremer-Grest Model
YAN WANG (Presenter), QIANG WANG, Colorado State Univ — Our
group recently proposed the systematic and simulation-free strategy for coarse graining of polymeric systems, where the
well-developed polymer reference interaction site model (PRISM) theory, instead of the many-chain molecular simulation
(MCMS), is used to obtain the structural and thermodynamic properties of both the original and coarse-grained (CG)
systems. Our strategy is much faster than those using MCMS, thus effectively solving the transferability problem of coarse
graining. It also avoids the problems caused by the finite-size effects and statistical uncertainties of MCMS, particularly for
the original system, which are the reasons why its coarse graining is needed. Here we apply our strategy to the structure-
based coarse graining of the well-known Kremer-Grest model for homopolymer melts, where the self-consistent PRISM
theory is used to avoid the assumption of ideal-chain conformations in the original system. This paves the way to
quantitatively applying our strategy to more realistic polymers and their multiscale modeling.

10:24AM K55.00011: Extensional Rheology of Neat and Contaminated Ring Polymer Melts*
THOMAS O’CONNOR (Presenter), Sandia National Laboratories, TING GE, MICHAEL RUBINSTEIN, Duke University, GARY GREST, Sandia National
Laboratories — Molecular simulations are applied to study unconcatenated ring polymer melts in uniaxial extensional flow.
Melts of neat rings and neat linear chains with the same length, and rings contaminated with a small fraction of linear
chains are elongated to steady-state for a wide range of Rouse Weissenberg numbers. The rate dependence of the steady-
state stress and viscosity are compared for the three systems and correlated with changes in microscopic chain
conformations. Extensional flows stretch and orient both ring and linear chain conformations along the extension axis.
However, linear chains can stretch to twice the length of a ring with the same molecular weight. The significantly stronger
response of linear chains to extensional flow suggests a small fraction of linear chain contamination might dominate the
extensional viscosity of a nominally neat ring melt. Simulations of ring melts contaminated with varying fractions of linear
chains are used to predict the experimental signature of linear contamination.

Laboratories.
10:36AM K55.00012: Stress Relaxation in Highly Oriented Melts of Entangled Polymers*  
AUSTIN HOPKINS (Presenter), Physics and Astronomy, Johns Hopkins University, THOMAS O'CONNOR, Sandia National Laboratories, MARK OWEN ROBBINS, Physics and Astronomy, Johns Hopkins University — Molecular dynamics simulations are used to study stress and conformational relaxation in entangled polymer melts deformed far from equilibrium by uniaxial extensional flow. Melts are elongated to a Hencky strain of 6 at Rouse Weissenberg numbers from 0.16-25, producing states with highly aligned chains. Then flow is ceased and the system is allowed to relax until twice the equilibrium disentanglement time. The relaxation of the stress is correlated with changes in the conformation of chains and the geometry of the tube confining them. The primitive path length of chains relaxes towards its equilibrium value on the equilibrium Rouse time and the orientation of the primitive path then relaxes on the equilibrium disentanglement time. Both results are counter to predictions of several recent models that suggest a large reduction in the entanglement density that persists for the disentanglement time, raising fundamental questions about the nature of entanglement in aligned molten polymers.

10:48AM K55.00013: Plasticizing polymers with small-molecule additives: a not so simple picture revealed by a simple molecular model  
KUSHAL PANCHAL, OLUSEYE ADEYEMI, Department of Chemical Engineering, McMaster University, ROOZBEH MAFI, Canadian General-Tower Ltd., LI XI (Presenter), Department of Chemical Engineering, McMaster University — Processing and manufacturing of many polymer products require the addition of plasticizers for tuning the flow properties of the melt as well as the thermo-mechanical properties of the product (lower Tg and improved material flexibility and ductility). These effects are often collectively described as plasticizers reducing the inter-chain friction and "softening" the material. However, a detailed molecular mechanism has not been fully revealed. We use molecular simulation to show that these effects are often not monotonically correlated. Most notably, additives that are better at reducing Tg may not be as effective at reducing the material stiffness. Indeed, our simulation shows that by simply changing the size of plasticizers, the Tg and Young's modulus vary in opposite directions. In-depth analysis of the free volume distribution and molecular mobility indicates that plasticizers have different effects on the dynamics at different length and time scales. Ongoing research focuses on the plasticizer effects on polymer viscoelasticity. Findings of this study reveal the rich complexity of the plasticization phenomena. In particular, the notion of "plasticization" is indeed a collection of a wide range of physical phenomena that are only loosely correlated at best.

Session K56 GSNP: Jamming and Glassy Behavior  
BCEC 255 - Andrea Liu, University of Pennsylvania

8:00AM K56.00001: Isostatic jamming of two-dimensional monodisperse system under quenched disorder*  
WEN ZHANG (Presenter), SHIYUN ZHANG, NING XU, Department of Physics, University of Science and Technology of China — The existence of amorphous packings in two-dimensional monodisperse system is a classical unsolved problem. By minimizing the enthalpy of packings of frictionless particles, we obtain isostatic jammed packings under quenched disorder at desired pressures. Quenched disorder is introduced by pinning a fraction of particles $N_f=nfN$. The result shows that there is a unique critical pinning density, $n_{fc}$, at which packings become completely disorder. The static correlation length $\xi_6$ diverges at the same $n_{fc}$ for different pressure $p$, which suggests new ways to investigate the jamming transition in two-dimensional monodisperse system. Finally, we confirm the existence of isostatic jammed packings with packing fraction $\Phi_{jw}=0.845$, and jamming scaling is still satisfied in two-dimensional monodisperse system.

We thank the Supercomputing Center of University of Science and Technology of China for the computer time.
We numerically study the equilibrium dynamics of a 3D binary hard-sphere (HARD) system and a 3D Kob-Andersen Lennard-Jones (KALJ) system. We provide a quantitative description of dynamical heterogeneity in terms of fluctuations in the local relaxation rates. We extract a recently defined two-point correlator, \( s(q, t) \), that probes those fluctuations. The time decay of \( \chi_{\phi}^2(t) = \lim_{q \to 0} s(q, t) \) is characterized by a certain time scale \( \tau_{ex} \), which we identify as the exchange time of the slow and fast regions, or equivalently the lifetime of the heterogeneities. We calculate the exchange time \( \tau_{ex} \) as a function of either the temperature (for KALJ) or packing fraction (for HARD). We find that, in HARD systems, close to the glass transition, \( \tau_{ex} \) becomes an order of magnitude longer than the \( \alpha \)-relaxation time \( \tau_\alpha \) and \( \tau_{ex}/\tau_\alpha \) increases with packing fractions. However, in KALJ systems, \( \tau_{ex} \) is approximately twice \( \tau_\alpha \) and \( \tau_{ex}/\tau_\alpha \) has no significant dependency on temperature. We also measure the two-point correlation length \( \xi_{\phi}^2(t) \) of the relaxation rates. We find that near the glass transition \( \xi_{\phi}^2(t) \) grows approximately logarithmically with time up to a maximum at time around \( 2\tau_\alpha \), and it decays at long times.
A marginal system is one for which there exists an infinitesimal deformation that will lead to instability. Frictionless sphere packings at jamming, as well as infinite packings above jamming, seem to meet this definition. Further, the scaling of the excess contact number with pressure is consistent with the mean-field expectation of marginal stability. However, the prefactor in three-dimensional systems is slightly larger than predicted. This discrepancy in the prefactor, termed the "marginality gap", is expected to vanish in the mean-field limit. We investigate numerically the Mari-Kurchan model of jammed packings, in which a Gaussian random shift is added to each separation of pairs of particles in the pair potential. By tuning the amplitude of the random shift, we study the range from jammed packings to the mean-field limit to see how the marginality gap evolves.

Jamming as a Multicritical Point*

The discontinuous jump in the bulk modulus B at the jamming transition is a consequence of the formation of a critical contact network of spheres that resists compression. We introduce lattice models with underlying under-coordinated compression-resistant spring lattices to which next-nearest-neighbor springs can be added. In these models, the jamming transition emerges as a kind of multicritical point terminating a line of rigidity-percolation transitions. Tuning the under-coordinated lattice to the jamming critical point yields a faithful description of jamming and its relation to rigidity percolation.

Can a large jammed packing be assembled from smaller ones?

The principle of equivalence of ensembles asserts that, in the thermodynamic limit, a system with periodic boundary conditions behaves identically to a subsystem of the same size, cut out from a larger system. We compare these two ensembles on finite length scales in the case of amorphous jammed packings of soft spheres at zero temperature. Focusing on the statistics of the contact fluctuations, we find that systems with periodic boundary conditions have significantly smaller fluctuations compared to the subsystems. This difference is largest near the jamming transition. Moreover, these two ensembles converge only at a surprisingly large system size. The crossover to the thermodynamic limit defines a length scale for each ensemble. Surprisingly, these diverge, as a function of the distance to the transition, with two different exponents. We argue that this disparity is the result of the system being above the upper critical dimension and that, based on the values of the exponents, the upper critical dimension can be measured.

Response to controlled perturbations in frictional granular jamming

Jamming in frictional granular media results in metastable configurations due to stability imparted by frictional contacts against sliding. We experimentally study the frictional energy difference $\Delta E$ between an unperturbed and a perturbed configuration subject to uni-axial compression under identical conditions in a two-dimensional system comprised of a bidispersed set of disks whose friction we tune through contact roughness $d$. The homogeneous system-wide acoustic perturbations are independently tuned with amplitude $A$ and frequency $f$. We find the frictional stress $\sigma$ released from perturbation follows a stretched exponential form $\sigma = \sigma_0 \exp\left[\frac{\Delta E}{T_{\text{eff}}}\right]^{\beta}$, where $\sigma_0$ is the unperturbed stress, $T_{\text{eff}} = \frac{1}{2}M (A_{\text{RMS}} f_{\text{RMS}})^2$, $M$ is total mass of disks in the configuration, and $A_{\text{RMS}}$ and $f_{\text{RMS}}$ are the respective RMS perturbation amplitude and frequency; the stretched exponent $\beta$ is the only fit parameter. At low $T_{\text{eff}}$, we obtain a best fit around $\beta \sim 1/3$. As $T_{\text{eff}}$ increases and more frictional stress is relieved, the stretched exponent $\beta$ transitions smoothly and approaches an asymptotic value of $\beta \approx 1$ with an Activated or Arrhenius-like relaxation behavior. Eventually when $A_{\text{RMS}} \geq d$, all frictional stresses in the system are relieved and frictionless jamming behavior is recovered.

9:48AM K56.00010: Aging is a (log-)Poisson Process, not a Renewal Process¹

STEFAN BOETTCHER (Presenter), DOMINIC M ROBE, Physics, Emory University, PAOLO SIBANI, Institut for Fysik Kemi og Farmaci, Syddansk Universitet — Aging is a ubiquitous relaxation dynamic in disordered materials. It ensues after a rapid quench from an equilibrium `fluid" state into a non-equilibrium, history-dependent jammed state. We propose a physically motivated description that contrasts sharply with the trap model² or a continuous-time random walk (CTRW) with broadly distributed trapping times commonly used to fit aging data.³ A renewal process like CTRW proves irreconcilable with the log-Poisson statistic exhibited, for example, by jammed colloids as well as by disordered magnets. A log-Poisson process is characteristic of the intermittent and decelerating dynamics of jammed matter usually activated by record-breaking fluctuations (`quakes'). We show that such a record dynamics (RD) provides a universal model for aging, physically grounded in generic features of free-energy landscapes of disordered systems.⁴

10:00AM K56.00011: Direct Measurement of Force Configuration Entropy in Jamming* JAMES SARTOR (Presenter), ERIC CORWIN, University of Oregon — Thermodynamics connects the microscopic details of a system's entropy to bulk measurements of the system's properties. In granular systems, for which the thermal energy scale is so small as to be irrelevant, this has been proposed using temperature analogues such as compactivity and angoricity. We present a method of linking the measurements of such quantities to the entropy of the force network by measuring the multiplicity directly. For systems at the critical jamming point there is only one mechanically equilibrium force network compatible with the spring network representation of the system, so the force configurational entropy of a jammed system is zero. For each new contact formed, the dimensionality of the space of allowed force configurations increases by one. Within this space lies a subspace of positive-definite forces, which is compatible with a granular packing. We propose that the volume of this subspace is proportional to the multiplicity of the packing's force network configuration. To determine the constant of proportionality, we measure the angoricity over 6 decades of pressure using the method of overlapping histograms.

10:12AM K56.00012: Void Percolation Threshold and Critical Properties of the Random Lorentz Gas* PATRICK CHARBONNEAU, Duke University, ERIC CORWIN, Physics, University of Oregon, YI HU (Presenter), Chemistry, Duke University — Percolation and glass formation share interesting dynamical features, in which they both exhibit caging of tracers/particles. Although first noticed long ago, this analogy has grown in physical relevance since a simplified model of structural glasses (Mari-Kurchan) was found to display corrections to caging that are analogous to those observed in percolating systems. Interestingly, our recent study has shown that the glass-like caging transition is absent in lattice percolation for all dimensions. In order to better understand the origin of caging, we consider transport in an off-lattice percolation model. Specifically, we study the caging and critical scaling of transport in the random Lorentz gas, which can be mapped onto the Mari-Kurchan model and to void percolation. We first develop numerical strategies to determine precisely the void percolation threshold in high dimensions, and then study dynamical criticality around that threshold. Our results provide key insights into the dynamics of glass formers and transport in heterogenous media, more generally.

10:24AM K56.00013: Fluctuation Distributions of Energy Minima in Complex Landscapes* HORST-HOLGER BOLTZ (Presenter), University of Chicago, ANDREA LIU, Physics, University of Pennsylvania, JORGE KURCHAN, LPS, ENS Paris — We discuss the properties of the distributions of energies of minima obtained by gradient descent in complex energy landscapes. Specifically, we study the distribution of energies in minima of the spherical p-spin model and the distribution of jamming threshold packing fractions in jammed particle configurations as archetypal manifestations of disorder-induced complexity. We numerically find universal distributions that resemble the Tracy-Widom distributions often found in problems of random correlated variables, and non-trivial finite-size scaling. Deeper insight into this problem is achieved by realizing the importance of a first-passage process in the eigenvalues of the Hessian to the termination of the steepest descent process, which also manifests the link to problems where the Tracy-Widom distribution is established. This first-passage view of steepest descent dynamics is generic and therefore we expect similar phenomenology in many problems.

Shear response of jammed disk and sphere packings*  

KYLE VANDERWERF (Presenter), Yale Univ, MARK SHATTUCK, Department of Mechanical Engineering & Materials Science, City College New York, COREY SHANE O’HERN, Yale Univ — The response of purely repulsive disk and sphere packings to athermal, quasistatic simple shear near jamming onset is highly nonlinear. Previous studies have shown that the ensemble-averaged static shear modulus $G$ is nearly constant at small pressure $p$, and at a characteristic pressure $p^*$, $G$ begins to increase as a power-law: $G \sim p^a$, where $a=0.5$. Also, $p^*$ decreases with increasing system size $N$, such that $p^* \sim N^{-\beta}$, where $\beta=1$. Although scaling arguments have rationalized the scaling behavior of $p^*$ and $G$, there is currently no quantitative theoretical framework that can predict the values of $a$ and $\beta$. Here, we carry out numerical simulations of 2D bidisperse disk packings near jamming onset undergoing athermal, quasistatic simple shear at fixed pressure to explain these exponents. We show that $a$ and $\beta$ can be understood by examining the “geometrical families” of jammed packings, which are intervals of shear or pressure where the packings maintain the same network of interparticle contacts without rearrangements. We present a statistical model based on random switching of the packings from one geometrical family to another to predict the values of the exponents $a$ and $\beta$.

Densest vs. jammed packings of 2D bent-core trimers*  

AUSTIN GRIFFITH (Presenter), ROBERT HOY, University of South Florida — We identify the maximally dense lattice packings of tangent-disk trimers with fixed bond angles ($\theta = \theta_0$) and contrast them to both their nonmaximally-dense-but-strictly-jammed lattice packings as well as the disordered jammed states they form for a range of compression protocols. While only $\theta_0 = 0, 60^\circ$, and $120^\circ$ trimers can form the triangular lattice, maximally-dense maximally-symmetric packings for all $\theta_0$ fall into just two categories distinguished by their bond topologies: half-elongated-triangular for $0 < \theta_0 < 60^\circ$ and elongated-snub-square for $60^\circ < \theta_0 < 120^\circ$. The presence of degenerate, lower-symmetry versions of these densest packings combined with several incommensurable families of less-dense-but-strictly-jammed lattice packings act in concert to promote jamming. Systems jam via a two-stage, two-length-scale process. First, randomly-oriented crystalline grains form and grow to a size that increases with decreasing compression rate and depends strongly on $\theta_0$. Since these grains cannot be compressed further, they effectively behave as single nearly-rigid particles as compression continues. Jamming occurs when they can no longer rotate/translate away from one another upon colliding.

Session K57 GSNP DPOLY GSOFT: The Extreme Mechanics of Balloons

8:00AM K57.00001: The Extreme Mechanics of Balloons: From Interfacial Films to Inflated Membranes and Back*

[Invited] JOSEPH D PAULSEN (Presenter), Syracuse University — Deformable sheets are ubiquitous in nature and industry across a vast range of scales, from graphene to metal foil to the earth's crust. Thin sheets are also central to advanced applications including flexible electronics and deployable satellites or emergency shelters. Despite their ubiquity, there are still significant fundamental challenges in predicting how a thin elastic sheet will deform under confinement, from the selection of a macroscopic deformed shape all the way down to the fine details of the microstructural features. I will discuss a suite of experiments using interfacial films and inflated membranes to address problems spanning this entire range. First, I will describe how an ultrathin polymer film wrapped around a liquid droplet adopts highly nonsymmetric shapes as the droplet size is decreased, and how this overall shape selection may be understood using a simple model wherein the exposed liquid surface area is minimized [1]. This geometric model reveals a fundamental connection between interfacial films and mylar balloons. Inspired by this connection, we are conducting experiments using inflated membranes to discover how smooth sinusoidal wrinkles transition into sharp “crumples”, a striking behavior that was originally observed on interfacial polymer films in a spherical geometry [2]. We have now isolated these buckled structures on interfacial films in hyperbolic and cylindrical geometries, suggesting that such crumples are a generic building block for confined sheets.

8:36AM K57.00002: Mechanics of interconnected balloon networks  MATJAZ CEBRON (Presenter), MIHA BROJAN, Faculty of Mechanical Engineering, University of Ljubljana, ANDREJ KOSMRLJ, Department of Mechanical and Aerospace Engineering, Princeton University, Princeton, NJ 08544 — We investigate the mechanical stability of an array of interconnected thin balloons made from hyperelastic material that are filled with incompressible fluid. Each individual balloon has a nonmonotonic relation between the volume of enclosed fluid and the pressure difference between the inside and the outside of the balloon. While an individual balloon is unstable in the region with the negative slope on the pressure-volume diagram, such state of a balloon can get stabilized when it is interconnected with other balloons. We will present conditions that have to be satisfied for the mechanical stability for the whole network of balloons. Furthermore, we will discuss the dynamics of unstable configurations, which may exhibit an interesting sequence of liquid redistributions between the connected balloons, such that the volumes of balloons change nonmonotonically, before they settle in a new stable state.

8:48AM K57.00003: Beyond the smectic order: splay and amplitude modulations in wrinkle patterns  OLEH TOVKACH, BENJAMIN DAVIDOVITCH (Presenter), University of Massachusetts Amherst — Thin solid sheets and shells tend to suppress compressive stresses by developing wrinkles -- elongated periodic undulations around a smooth enveloping shape, whose characteristic “wavelength”, \( \lambda \), vanishes with the solid's thickness. While an energetically-favored spacing imparts a local smectic order to the pattern, the geometric constraints underlying the mere presence of wrinkles are often incompatible with a global smectic order – implying localized defects and other meso-scale deviations from an "ideal" array of parallel, elongated wrinkles.

We elucidate this generic phenomenon through numerical simulations of a prototypical model of geometrically incompatible confinement – a thin sheet attached to a ball of harmonic springs. In addition to localized defects of various types, we find that a prominent motif is meso-scale modulations of the wrinkle amplitude in domains characterized by smectic order. This finding motivates a coarse-grained theory that describes the variation of wrinkle patterns at scales much larger than their wavelength. In addition to a smectic-like order parameter, whose existence was pointed out previously, we show that such a theory must include other fields, resembling the Ginzburg-Landau theory of superconductors.

9:00AM K57.00004: Self-similar retraction of a shot rubber-band  ALEXANDROS ORATIS (Presenter), JAMES C BIRD, Boston University — Stretching and shooting rubber bands is a familiar experience for both children and adults, yet the initial dynamics are so quick that they are generally missed. When a cut elastic strip is stretched from its end and suddenly released, the dynamics depend on a balance of stretching and inertia. However when a rubber band is stretched, a region of high-curvature is created and it is unclear how this curvature affects the dynamics. Here, we demonstrate that during the retraction of a circular rubber band, a wavelength develops at the rear which increases in size as time progresses. Through a combination of experiments and modeling, we investigate the speed at which the back of the elastic retracts and observe a self-similar shape that depends on stretching, inertia, and bending. These retraction dynamics illuminate how a rubber band can pass by a thumb when discharged without hitting it.

9:12AM K57.00005: All-in-One Design of Soft Machines  TREVOR JONES (Presenter), JOEL MARTHELOT, PT BRUN, Princeton University — In our world filled with human innovation and technology we hardly scratch the surface of what has been formed in nature. While we have increased our control and capabilities of machines in the thrust for biomimicry, the use of soft structures to accomplish complex tasks is still primarily the handiwork of biology. To bridge the gap on nature, we introduce an all-in-one approach to building soft machines. Using the powerful rules of fluid mechanics and silicone elastomers, fluid-mediated networks can be “frozen” to provide unique functional materials. Here a Bretherton-like technique is explored as an elongated bubble deposits a polymer melt film on the inside of tubes. The residual film undergoes drainage as the polymer melts cures into an elastic solid. We characterize these elastic networks, comprised of pneumatic bending actuators, through experiments and predictive models of their constituent parts. By means of this deep integration between the non-linear actuation and the far from equilibrium shape-morphing we reverse engineer targeted soft machines.
Inflatable origami-inspired structures

DAVID MELANCON (Presenter), School of Engineering and Applied Sciences, Harvard University, CHUCK HOBERMAN, Graduate School of Design, Harvard University, BENJAMIN GORISSEN, CARLOS GARCIA MORA, YUNFANG YANG, School of Engineering and Applied Sciences, Harvard University, JASON KU, ERIK DEMAIN, Computer Science and Artificial Intelligence Laboratory, MIT, KATIA BERTOLDI, School of Engineering and Applied Sciences, Harvard University — Origami has long been used as a source of inspiration to design creative and esthetic constructions, from the iconic paper swan to facades of multi-story buildings. More recently, the rules of folding have been applied to fabricate architected materials with functional properties such as compactness, self-foldability, and multi-stability. These properties highlight the potential of origami to become a new design paradigm for rapidly deployable structures. Whereas multiple origami-inspired deployable surfaces have been reported in the literature, there is a lack of research on enclosed deployable geometries. In this work, we introduce a novel type of inflatable origami-inspired structure comprised of a polyhedron with triangular faces and elastic hinges. From simple geometry principles, this star-shaped structure possesses two compatible configurations – flat-folded and deployed – giving rise to a bi-stable behavior. The insights gained from the study of this simple geometry enable the understanding of the folding principles of a novel class of enclosed origami-inspired structures that can be deployed to different stable configurations through inflation.

Buckling of inflatable pouch seams

JAMES HANNA (Presenter), HEE DOO YANG, ALAN ASBECK, Virginia Tech — Inflating a mylar balloon results in a pattern of wrinkles around its seams, and a shape with similarities to those of stuffed paper folders, tea bags, empanadas, and other objects in which the perimeters of thin sheets are attached to form a closed surface around a maximal volume. Our present interest in this problem stems from working with inflatable pouches for soft robotic actuators, made by layering textiles, plastics, and adhesives. We examine circular pouches with annular seams. Inflation of the pouch effectively provides a contractile planar constraint on the interior of the rim, leading to buckling reminiscent of prior results on swelling gel strips attached to rigid bodies. The buckling wavelength coarsens with the width of the seam, until it saturates at four cycles. We examine the effects of seam width, pouch radius, and sheet thickness on the buckling wavelength, through experiments and scaling arguments.

Stress Focusing in Inflated Membranes: Threshold and Morphology

RAJ DE (Presenter), YOUSRA TIMOUNAY, JESSICA L STELZEL, JOSEPH D PAULSEN, Department of Physics, Syracuse University — Thin elastic films may undergo large-amplitude deformations even under small applied force, which makes their behaviors challenging to predict. A symmetry-breaking transition from smooth periodic wrinkles to sharp stress-focusing crumples was recently observed in experiments where an ultrathin polymer film was placed on a spherical water meniscus whose curvature was continuously increased [1]. However, a general set of conditions for crumple formation has remained elusive. We approach this problem on a different scale using ~10-cm-wide square membranes that we construct from polymer sheets, which we then inflate with air. As the internal pressure is gradually increased, sharp crumple form on the surface of the sheet, which then transition to smooth wrinkles at higher pressure. Remarkably, all our data may be described by a single trend for the transition pressure, which depends linearly on the stretching modulus of the film and is inversely proportional to the size of the bag, where we have varied the sheet thickness, Young’s modulus, and bag size over a wide range. Finally, we use a 3D scanner to study the topography of the membrane as we go through the crumpling transition. [1] King et al. PNAS 109 (2012).

From flat sheet to cone without cutting: the wrinkled cone

DOIREANN O’KIELY (Presenter), JOSEPH BLANC, FINN BOX, DOMINIC VELLA, University of Oxford — It is relatively straightforward to roll a sheet of paper into a cone, but in doing so we must “waste” some paper (either by cutting or overlapping the sheet). Here, we show how to create a cone from a very thin polystyrene sheet without cutting or overlapping – instead, the excess length generated by deforming the initially flat sheet is buffered locally by wrinkling. To realise this, we suspend a thin circular sheet on a soap film so that it is held by a small radial tension at the boundary. The sheet is deformed by indenting at the centre. Through wrinkling, the flat sheet deforms to a cone, and subsequent changes in the angle of the cone are accommodated by self-regulated adjustment of the wrinkles. Experimentally, the soap film used to apply the radial tension is deformed by (and hence opposes) wrinkling in the sheet. We discuss the implications of this for the wrinkle pattern selection.

*ERC Grant Agreement no. 637334
Inflating and programming flat inextensible curvilinear paths

EMMANUEL SIEFERT (Presenter), ETIENNE REYSSAT, JOSE BICO, BENOIT ROMAN, PMMH, CNRS/ESPCI/SorbonneU/U. Diderot — Mylar balloons are popular gifts in funfairs or birthday parties. Their conception is very simple: two pieces of flat thin sheets are cut and then sealed together along their edges. Inflation deforms the envelope as it maximises the volume of the balloon. However, while thin sheets are easy to bend or to compress (by forming wrinkles), they barely stretch, which imposes non-trivial geometrical constraints.

Here, we focus on the shape of inflated rings and, more generally, any sealed curvilinear path. We rationalise the shapes obtained for axisymmetric geometries, and in particular describe the location of wrinkles.

We find that inflation modifies the initial curvilinear flat path. How should we choose the initial cut to obtain a mylar balloon of a desired shape? Using our theoretical predictions, we develop a simple numerical tool to solve the inverse problem of programming any 2D curve upon inflation.

Dragonfly-inspired deployable structures: how to inflate and stay flat?

JOEL MARTHELOT, THOMAS DUPUIS, PIERRE-THOMAS BRUN (Presenter), CBE, Princeton University — Programming the final shape of a soft inflatable structure is a nontrivial challenge. Such a task is routinely accomplished in nature, for example when the wing of an emerging dragonfly deploys over just a couple of minutes. This expansion is guided by a network of veins where hemolymph is injected and subsequently solidifies to generate rigidity.

Inspired by dragonflies, we build a model experiment to investigate inflatable deployable structures composed of a tubular network of the veins. We first mimic differential growth to fabricate wrinkled tubular structures. They comprise a soft annular core surmounted by a stiffer and thinner annulus prepared so as to yield a wrinkling instability. We then study the mechanical response of a single wrinkled tubular structure under pressure. We then characterize the in-plane expansion of the structure and study its correlation to the network geometry and the pressure applied to the system. A systematic variation of the geometric and elastic parameters allows us to search for optimal design and operational conditions for a maximal extension while minimizing the input pressure.

Sub-millimeter air-filled toroidal bubbles featuring easily reversible and rapid shape change.

PAUL RUSSO (Presenter), XUJUN ZHANG, ANDREW GORMAN, PETER YUNKER, SAAD BHAMLA, H. QI, Georgia Institute of Technology — Researchers have experimentally observed and generated liquid-filled vesicles in the toroidal topology, but small, air-filled toroids have not been reported. Here we report a facile method to generate air-filled toroidal bubbles coated by a particularly rugged amphipathic protein membrane made from filamentous fungi. The "air donuts" fall into the sub-millimeter size and are believed to be the world's first air-filled toroidal bubbles in this size scale. The major and minor ring radii ratio of the "air donuts" has a value of $\sqrt{2}$, which is in agreement with the liquid-filled vesicle literature. During the formation of "air donuts" under certain easy-to-meet conditions, the bubbles' shapes transform from cylinders to spheres, and ultimately to toroids. The sphere-to-toroid transition is reversible, which is surprising from the topology point of view. The air-filled toroidal vesicles could provide opportunities in the field of aerosol (flavor and fragrance) delivery applications.

*Supported by the Georgia Tech Center for Research on Active Surfaces and Interfaces, a part of the Science and Technology of Advanced Materials and Interfaces initiative.

Control of adhesion through geometrical enhancements

NICOLAS GAILLARD, Nantes University, MICHAL BUDZIK (Presenter), MARCELO AZEVEDO DIAS, Department of Engineering, Aarhus University — We present an experimental and theoretical investigation of interface geometric effects in peel test configuration to study adhesion between a silicone-based rubber (Vinylpolyisiloxane or VPS) film and a 3D printed ABS polymer. Experiments are carried out in which the VPS film is peeled from the 3D printed material. Two loading cases, peel and shear modes (90 and 0 degree respectively), are investigated in detail. Initially, reference specimens, in which VPS is moulded directly on the ABS surface are tested. With reproducible results no significant effects of the loading rate and a significant effect of the loading direction are observed. Subsequently, VPS is moulded to the 3D printed base which included rectangular groves along the crack growth path. Two failure mechanism are introduced which are found to lead to enhancement of apparent fracture energy: (1) local variations in the bending rigidity of the VPS film, (2) deflection of the crack growth path at the corrugation. Effective mechanism of VPS pillars pull-out is observed. Both mechanisms result in the peak (apparent) fracture energies ca. 10 and 1.4 times higher than the reference specimens for the peel and shear modes respectively. Theoretical and analytical arguments are provided to explain the aforementioned scenario.

Session K58 GSOFT: Disordered and Glassy Systems I  BCEC 257A - Matthew Abernathy, United States Naval Research Laboratory

8:00AM K58.00001: Probing the local environment in colloidal glass  WENHAI ZHENG (Presenter), DAVID J PINE, New York University — We developed a method to probe the local environment in colloidal glass by measuring the rotational diffusion of elliptical tracer particles. Using tracers of various aspect ratios as passive micro-probes, we explored the response of the material to different local strains. Special design of the tracers enhances its optical anisotropy, which enables us to follow the 3-dimensional rotation of nearly spherical probes. We found as the volume fraction of the colloidal suspension approaches the glass transition point, the rotational diffusion of the ellipsoids slows down dramatically and differs significantly spatially, which reflects the heterogeneity of the local environment.

8:12AM K58.00002: Tracer Transport Probes Relaxation and Structure of Attractive and Repulsive Glassy Liquids  RYAN ROBERTS (Presenter), RYAN POLING-SKUTVIK, JEREMY C PALMER, JACINTA CONRAD, Chemical Engineering, University of Houston — Dynamic coupling of small penetrants to slow, cooperative relaxations within crowded cells, supercooled liquids, and polymer matrices has broad consequences for applications ranging from drug delivery to nanocomposite processing. Interactions between the constituents of these and other disordered media alter the cooperative relaxations, but their effect on penetrant dynamics remains incompletely understood. We use molecular dynamics simulations to show that the motions of hard-sphere tracer particles probe differences in local structure and cooperative relaxation processes in attractive and repulsive supercooled liquid matrices with equal bulk packing fractions and long-time diffusivities. Coupling of the tracer dynamics to collective matrix relaxations affects the shape of tracer trajectories, which are string-like within the repulsive matrix and compact in the attractive. These results reveal that the structure of relaxations controls penetrant transport and dispersion in cooperatively relaxing systems. We further explore this connection by calculating the tracer and matrix dynamic susceptibilities, characterizing cooperative rearrangements in the matrices, and simulating tracer diffusion in arrested glasses.

8:24AM K58.00003: Controlling fragility via geometry in hard particle glass-formers*  ERIN TEICH (Presenter), University of Pennsylvania, GREG VAN ANDERS, Queen's University, SHARON GLOTZER, University of Michigan — We demonstrate that fragility, a technologically relevant measure of glass-forming ability, may be tuned via slight changes to particle shape in monodisperse, super-compressed systems of hard particles. We simulate systems of tetrahedrally symmetric particles, interacting solely through volume exclusion via Monte Carlo sampling, and show that these glass-formers become stronger as the particle shape becomes increasingly tetrahedral. Moreover, we connect strength and local structure in these systems. Our results parallel similar findings for network glass-formers such as silica, in which short-range tetrahedral bonding yields glasses of exceptional strength, and we show that similar effects can arise from geometry alone.

*E.G.T acknowledges support from the National Science Foundation Graduate Research Fellowship Grant DGE 1256260 and a Blue Waters Graduate Fellowship.

8:36AM K58.00004: Exploring Glassy Physics using Athermal Simulations  FRANCESCO ARCERI (Presenter), ERIC CORWIN, CorwinLab, Department of Physics, University of Oregon — Thermal hard spheres simulations are widely used for probing the low temperature physics of glass formers. However, they suffer from the limitations of Monte-Carlo simulations, which are necessarily slow and not easily parallelizable. Although hard sphere interactions present infinitely strong repulsion upon contact, in the infinite pressure limit when the jamming transition occurs, mean-field theory predicts an effective potential, which is a logarithmic function of the gap between particles. This effective potential can be seen as a proxy for frequent collisions, acting as a measure of the allowed space each particle can travel before interacting with one of its neighbors. Thus, by studying the properties of this effective potential we can learn about the thermal system in a high pressure regime which is otherwise inaccessible. Using deterministic minimization schemes to find local minima of the free energy landscape, we can reach extremely dense configurations. We explore the features of such configurations, comparing their vibrational properties with their thermal counterparts as well as with mean field predictions. Furthermore, their dynamics have been tested using thermal simulations with the aim of using them as valid configurations of low temperature glasses.
Correlations Between Short- and Long-time Relaxation in Colloidal Supercooled Liquids and Glasses

CHANDAN KUMAR (Presenter), XIAOGUANG MA, Department of Physics, University of Pennsylvania, Philadelphia, PA, United States, PIOTR HABDAS, Department of Physics, Saint Joseph's University, Philadelphia, PA, United States, KEVIN B APTOWICZ, Department of Physics and Engineering, West Chester University, West Chester, PA, United States, ARJUN G YODH, Department of Physics, University of Pennsylvania, Philadelphia, PA, United States — The spatiotemporal dynamics of short- (β) and long-time (α) structural relaxation are measured experimentally as a function of packing fraction, φ, in a series of quasi-two-dimensional binary-sphere colloidal supercooled liquids and glasses. The relaxation times associated with both long-time dynamic heterogeneity and short-time intra-cage motion grow by orders of magnitude with increasing φ, and interestingly, the two relaxation times are strongly correlated and suggest power law behavior. Moreover, microscopic analysis of the spatiotemporal dynamics revealed that the fraction of overlapping clusters of most-mobile particles at the long and short timescale increases with φ. Furthermore, the minimum spatial separation between the closest non-overlapping clusters of most-mobile particles across the two distinct timescales shows an exponential distribution. This allows extraction of φ-dependent characteristic length scale that further connects dynamics on short- and long timescales and increases with packing.

How glass responses to laser excitation

BO LI (Presenter), KAI LOU, Center for Soft and Living Matter, Korea Institute of Basic Science, WALTER KOB, University of Montpellier, Laboratoire Charles Coulomb, STEVE GRANICK, Center for Soft and Living Matter, Korea Institute of Basic Science — Glass is a disordered solid that processes distinct dynamical and elastic properties compared with crystal. Elastically, how heterogeneous a glassy materials can be and to what extent such heterogeneity is determined by structure are long standing puzzles in glass science. In this experiment, we probed the responses of binary colloidal glasses towards the local excitations caused by laser pulses. We observed very similar excitation patterns when the laser was repeated in linear region; directly proving that the dynamical heterogeneity is strongly encoded with structure. In non-linear region, we discovered for the first time a non-monotonic dynamical length scale as a function of φ, resulting from the intriguing interplay between cooperative motion and local structure. Our results highlight the crucial role structure plays in the dynamics and elasticity of glasses.

Direct Observation of the Gardner/Marginal Glass Transition within a Colloidal Glass

ANDREW HAMMOND (Presenter), ERIC CORWIN, University of Oregon — It has recently been shown that in the infinite dimensional limit there exists a second phase transition, called the Gardner transition, within the glassy phase, dividing so-called stable glass and marginal glass. We have developed a technique to experimentally probe this phase of matter using a colloidal glass. We avoid the difficulties inherent in measuring the long time behavior of glasses by instead focusing on the very short time dynamics of the ballistic to caged transition. We track a single tracer particle within a sedimenting mixture and measure the resulting mean squared displacement (MSD). By analyzing the MSD we find two distinct transitions at different packing fractions: 1) the transition into the stable glass phase is marked by the appearance of a plateau whose magnitude shrinks with increasing density and 2) the transition into the marginal glass phase is marked by logarithmic growth towards that plateau. This provides the first experimental evidence for the existence of a marginal glass in 3d.

*I would like to acknowledge funding from the Simons Foundation No. 454939, and from the NSF DMR-1255370.
**Frequency-dependent moduli in a supercooled liquid in the close vicinity of the glass transition by molecular dynamics**

**BAOSHUANG SHANG (Presenter),** Laboratoire Interdisciplinaire de Physique, University of British Columbia, **PENGFEI GUAN,** Beijing Computational Science Research Center, **JEAN-LOUIS BARRAT,** Laboratoire Interdisciplinaire de Physique — Amorphous materials have a rich relaxation spectrum which is usually described in terms of alpha, beta, and possibly more complex relaxation mechanisms. In this work, we investigate the local dynamic modulus spectrum in a model glass just above glass transition temperature by performing a mechanical spectroscopy analysis using molecular dynamics. We find that the spectrum, at the local as well as on the global scale, can be well depicted by Cole-Davidson formula in the frequency range explored with simulations. Surprisingly, the Cole-Davidson stretching exponent does not change with the size of the local region that is probed. The local relaxation time displays a broad distribution, as expected based on dynamic heterogeneity concepts, but the stretching is obtained independently of this distribution. Furthermore, we find that the size dependence of local relaxation time and modulus can be well explained by the elastic shoving model.

**Memory in Solid-Solid Interfaces**

**SAMUEL DILLAVOU (Presenter),** SHMUEL RUBINSTEIN, Harvard University — The interface between two solid, static bodies - your chair and the floor, your cup and the table, two books in a stack - is in fact continuously evolving. Due to small-scale roughness, ostensibly flat surfaces typically have a real area of contact several orders of magnitude smaller than apparent area. As a result, these contact points experience enormous pressures, and slowly deform in time.

By measuring the evolution of the real area of contact, we demonstrate that these multi-contact interfaces (MCIs) store a memory of the pressures they experienced. Unlike simple relaxation, e.g. a spring and dashpot system, which depends only on its current state, MCIs evolve according to their entire loading history.

Understanding of MCIs is not only useful for knowing how much coffee has been in your cup; the real area of contact also determines the friction between two bodies. As a result, the coefficient of static friction also evolves according to this interfacial memory. These effects suggest that MCIs and frictional systems belong in a universality class of glassy systems characterized by disorder and slow relaxation.

**Extending the phase space of jamming from a jamming point to a jamming plane**

**YULIANG JIN (Presenter),** Institute of Theoretical Physics, Chinese Academy of Sciences, **HAJIME YOSHINO,** Osaka University — The concept of jamming has attracted great research interest due to its broad relevance in soft matter such as liquids, glasses, colloids, foams, and granular materials, and its deep connection to the sphere packing problem and phase transitions. Here we show numerically that the phase space of frictionless jammed states can be extended from the well-known jamming point, to a jamming line by using deeply super-cooled liquid states as initial configurations, which can be further extended into a jamming plane by adding shear strains. While all jammed states are isostatic and belong to the same universality class, their various anisotropy and amorphous order can be mapped out on the jammed plane. The jamming point is isotropic, with the minimum amorphous order (or maximum randomness), which, in the thermodynamic limit, sets a sharp lower bound for the jamming density of frictionless packings.

10:00AM K58.00011: Large, growing length scale controls the melting mechanism of stable glasses*

LUDOVIC BERTHIER, Laboratoire Charles Coulomb, University of Montpellier, CNRS, PATRICK CHARBONNEAU, Chemistry, Physics, Duke University, ELIJAH FLENNER (Presenter), Chemistry, Colorado State University, CHRISTOPHER J. FULLERTON, Physiology, Anatomy and Genetics, University of Oxford — Exceptionally stable vapor-deposited glass films melt via a constant velocity front initiated at the surface, whereas ordinary liquid cooled glass films melt homogeneously. The melting time for stable glass films increase linearly with film thickness until a crossover thickness \( l_c \), which can be as large as a micrometer. For films thicker than \( l_c \) the melting time is constant, suggesting that a bulk transformation mechanism is then prominent. Here we use the swap Monte Carlo algorithm to prepare stable glass films that we subsequently melt films using molecular dynamics simulations, in order to study the microscopic differences between the two melting mechanisms of glass films. Several of our stable films completely melt via a front initiated at the surface for lower melting temperatures, but melt via a bulk mechanism at higher melting temperatures. For intermediate melting temperature we directly determine \( l_c \), and then we use bulk melting simulations to approximate \( l_c \) to lower melting temperatures. We find that \( l_c \) grows with increasing stability and decreasing melting temperature. Using parameters corresponding to toluene, we determine that the crossover length for our most stable glass is comparable to that measured in experiments.

10:12AM K58.00012: Quantifying the Structure of Space-Filling Disordered Cellular Patterns with Hyperuniformity Disorder Length Spectroscopy

ANTHONY CHIECO (Presenter), DOUGLAS DURIAN, University of Pennsylvania — A system is hyperuniform if the spectral density decays like \( \chi(q)\sim q^{-\epsilon} \) with \( \epsilon > 0 \) as \( q \) goes to zero. In real space the area fraction variance for randomly placed measuring \( L \times L \) windows can be written \( \sigma^2(L)\sim <a>^2 h(L)/L^3 \) where \( <a> \) is the average particle area and \( h(L) \) is the hyperuniformity disorder length, which is defined by the distance from the window boundary where number density fluctuations occur [1]. The spectrum of \( h(L) \) versus \( L \) quantifies the degree of structural order; smaller \( h(L) \) indicates more order, and at large \( L \) hyperuniform patterns have constant \( h(L)=h_e \). Here, we compare \( \chi(q) \) and \( h(L) \) spectra for cellular patterns given by Voronoi construction around points that are (1) uncorrelated (Poisson), (2) low discrepancy (Halton), and (3) displaced from a lattice by Gaussian noise (Einstein), as well as (4) the centroids of bubbles in a quasi-2d foam. All four types are hyperuniform and have \( \chi(q)\sim q^{-4} \) for small \( q \). The \( h_e \) values indicate that Poisson, Halton, Einstein, and foams are ranked least to most ordered. The foam has \( h_e=0.082<\alpha>^{1/2} \) and the same value of \( h_e \) is found for the other cellular patterns if analyzed in terms of the Voronoi cell centroids; for comparison, \( h_e=0.084<\alpha>^{1/2} \) is found at jamming for bidisperse disks [1].

10:24AM K58.00013: Competition of Crystallization and Vitrification*

MUHAMMAD HASYIM (Presenter), KRANTHI K MANDADAPU, Chemical and Biomolecular Engineering, University of California - Berkeley — The competition between vitrification and crystallization in glass-forming materials manifests as a non-monotonic behavior in the time-temperature transformation (TTT) diagrams. A coarse-grained model, referred to as the Arrow-Potts model, is constructed to explore the physics behind this competition. Using Monte Carlo simulations, the model is shown to produce two regimes of crystal nucleation and coarsening. At high temperatures, crystallization is dominated by the nucleation of compact and fluctuating crystalline clusters. At low temperatures, crystal coarsening proceeds through hierarchical relaxation pathways within the supercooled liquid, producing fractal ramified crystalline clusters. To explain and unify these two regimes, the Kolmogorov-Avrami theory is used as a framework to combine nucleation theory and a random walk theory for crystal coarsening kinetics, both of which govern the high-T and low-T regimes respectively. Finally, we demonstrate how the universal character of low-T crystallization is characterized by scaling exponents which are crucial to accurately account for the timescales observed in the TTT diagram.

TIANXING MA, ADITHYA SRIDHAR, KYLE BUZNITSKY, MATTHEW SIGNORELLI, JONATHAN SINGER (Presenter), Mechanical and Aerospace Engineering, Rutgers University — Focused laser spike (FLaSk) dewetting has been used as a method for the patterning of soft matter thin films for several decades. Through the use of a focused laser beam, a localized heat source is provided along with an extreme thermal gradient. The material melted by the local heating is simultaneously moved down the thermal gradient and forms highly characteristic trench-ridge morphologies. Through micron-scale dot exposures on a universal heating substrate designed in our lab, coupled with optical microscopy, we have studied the characteristic radii of the dewetted ridge feature for various glassy thin films with different molecular weights and glass transition temperatures as a function of time. This was approached through a combination of experiments, simulations, and analytical models. Not only were we able to identify features of the dewetting that revealed differences between the polymer system, but the FLaSk process could give independent information on surface and bulk behavior. In this way, it has been shown that FLaSk dewetting as a metrology method can be employed for high-throughput analysis of thin film materials in high shear, high temperature testing regimes that would otherwise be difficult to reach.

10:48AM K58.00015: How to extract memories from a relaxing granular material
KIERAN MURPHY (Presenter), JONATHON KRUPPE, HEINRICH M JAEGER, University of Chicago — Recent experiments on crumpled sheets have found they can store multiple memories of past loading, and that one can simply watch the system relax over long timescales to read off its memories [1]. The model used to explain the observed nonmonotonic relaxation approximates the system as a population of exponentially relaxing modes with a specific distribution of timescales, though the physical manifestation of the modes in these systems remains ambiguous.

Here we show a granular packing can also exhibit history-dependent and nonmonotonic stress relaxation. We then expand upon the framework to understand glassy dynamics in disordered systems with the following results and insights. First, the history dependence of the relaxation is found to be tied to the shear stresses supported by the granular packing but not isotropic compressive stresses. Second, we extend the above model to incorporate finite duration loading. Third, with frictional contacts in the granular packing as the relaxing elements, each sliding glacially slowly, we move beyond relaxation experiments to explain features in the data of shape-dependent plasticity [2] as well as volumetric compaction and hysteresis during cyclic loading.

Session K59 GSOFT: Rheology of Active Fluids: From Active Polymers to Living Matter
BCEC

8:00AM K59.00001: Symmetric shear bands and collective swarming of bacterial suspensions* [Invited] XIANG CHENG (Presenter), Chemical Engineering and Materials Science, University of Minnesota — Active fluids are a novel class of non-equilibrium complex fluids with examples across a wide range of biological and physical systems such as flocking animals, swimming microorganisms, vibrated granular rods, and suspensions of synthetic colloidal swimmers. Different from familiar non-equilibrium systems where free energy is injected from boundaries, an active fluid is a dispersion of large numbers of self-propelled units, which convert the ambient/internal free energy and maintain non-equilibrium steady states at microscopic scales. Due to this distinct feature, active fluids exhibit fascinating and unusual flow behaviors unseen in conventional complex fluids. Here, by combining high-speed confocal microscopy, rheological measurements and biochemical engineering, we experimentally investigate the flow behaviors of E. coli suspensions, a premier example of active fluids. In particular, we show the microscopic dynamics of bacterial suspensions associated with the abnormal rheology and the emergence of collective swarming. Using theoretical tools of fluid mechanics and statistical mechanics, we develop a quantitative understanding of these interesting behaviors. Our study shows the general organizing principles of active fluids that can be exploited for designing “smart” fluids with controllable fluid properties. Our results also provide new insights into the fundamental transport processes of microbiological systems.

8:36AM K59.00002: Activity effects on the non-linear mechanical properties of fire ant aggregations  
MICHAEL TENENBAUM (Presenter), ALBERTO FERNANDEZ-NIEVES, School of Physics, Georgia Institute of Technology — Individual fire ants are inherently active as they are a living organism that convert stored chemical energy into motion. However, each individual ant is not equally disposed to motion at any given time. In an active aggregation, most of the constituent ants are active, and vice versa for an inactive aggregation. Here we look at the role activity plays on the non-linear mechanical behavior of the aggregation through large amplitude oscillatory shear measurements. We find that the level of viscous non-linearity can be decreased by increasing the activity or by increasing the volume fraction. The level of elastic nonlinearity is not affected by either activity or volume fraction. Applying too large of an applied strain amplitude removes the effect of activity but preserves the effect of the volume fraction. We also compare this to viscosity measurements where we see that the level of nonlinearity decreases with activity as well.

8:48AM K59.00003: Spontaneous migration of cellular aggregates: from giant keratocytes to running spheroids  
FRANCOISE BROCHARD-WYART (Presenter), Curie Institute — We introduce the broad field of entangled active matter. Unlike swarms of fish and flocks of birds, cells are bound by transient links and behave as active viscoelastic pastes. Here, we investigate the collective migration of cell on adhesive gels, using 3D cellular aggregates as a model system. Aggregates spread by expanding outwards a cell monolayer, which may partially dewet, causing the aggregate to move. Varying the substrate rigidity induces different modes of aggregate motion: “Giant Keratocytes”, where the lamellipodium is a cell monolayer that expands at the front and retracts at the back; “Penguins”, characterized by bipedal locomotion; and “Running Spheroids”, for non-spreadin aggregates. We characterize these diverse modes of collective migration by quantifying the flows and force field responsible of the bipedal stick-slip motion. We propose two possible mechanisms to explain the spontaneous migration of cellular aggregates: i)chemical modification of the substrate in analogy to reactive droplets. We show that it is possible to mimic a keratocyte with a droplet of oil containing a surfactant. The reactive droplet adopts a croissant shape also seen for keratocyte fragments and ii) symmetry-breaking arising from cell polarization in analogy to active droplets.

9:00AM K59.00004: Activity Driven Bend Instability under an External Field*  
BIBI NAJMA (Presenter), POOJA CHANDRAKAR, S.ALI AGHVAMI, GUILLAUME DUCLOS, Physics, Brandeis University — Active fluids exhibit complex dynamics such as collective motion, internally generated flows, and spontaneous pattern formation on account of their fundamental nonequilibrium nature. Here, we use a 3D active material composed of extensile microtubule bundles and kinesin motor clusters to investigate how the activity driven bend instability is stabilized by an external flow. With no external flow, the internal stresses generated by kinesin motors drive the system far-from equilibrium causing a proliferation of periodic pattern of bend instabilities with a characteristic spatial period \( \lambda \). We observe that the striated pattern of undulations evolves into a turbulent regime with complex flow patterns. Our study reveals that the growth of unstable modes can be controlled by an externally imposed shear flow. We determine the critical value of the flow above which the bend instability is suppressed with the appearance of a uniform steady state where microtubule are aligned by the external flow. Below the critical flow, the growth of the unstable modes is stabilized and the microtubules form a steady undulated pattern that does not evolve into a turbulent regime.

9:12AM K59.00005: Impact of Motile Bacteria on Viscous Fingering  
JANE CHUI (Presenter), Massachusetts Institute of Technology, HAROLD AURADOU, Université Paris-Saclay, KAREN FAHRNER, HOWARD C BERG, Harvard University, RUBEN JUANES, Massachusetts Institute of Technology — Viscous fingering is a hydrodynamic instability that occurs when a less viscous fluid displaces a more viscous one. Instead of progressing as a uniform front, the less viscous fluid forms fingers to create complex patterns. Understanding how these patterns and their associated gradients evolve over time is of critical importance in characterizing the mixing of two fluids. Here, we investigate the impact of replacing the less viscous fluid with an active suspension of motile bacteria, relevant to applications such as microbial enhanced oil recovery and bioremediation.

In this series of experiments, a suspension of motile \( E. \) coli capable of collective swimming is injected into a microfluidic Hele-Shaw cell under viscous fingering conditions. Using fluorescent microscopy, we observe changes within the mixing zone compared to inactive fluids, such as “rafting,” where some of the bacteria group together and form a patterned interface between the two fluids. Combined with rheological measurements conducted with a Couette rheometer, we quantify the impact these active suspensions have on the formation of viscous fingering patterns and mixing efficiency between the two fluids, and conversely, report details of the collective swimming behavior in the presence of a viscous-gradient front.
9:24AM K59.00006: Looking into the rheology active microtubule suspensions* [Invited] DANIEL BLAIR (Presenter), DAVID A GAGNON, CLAUDIA DESSI, Physics and Institute for Soft Matter, Georgetown University, ZVONIMIR DOGIC, Physics, University of California Santa Barbara — Active suspensions are inherently out-of-equilibrium and can possess anomalous bulk rheological properties. Previous experimental and numerical studies suggest organisms with extensile swimming behavior (e.g. Escherichia coli) can decrease the apparent viscosity of a fluid, while those with contractile swimming behavior (e.g. Chlamydomonas reinhardtii) can increase the apparent viscosity of a fluid. In this talk we will present combined experimental results on the rheology and dynamics of an active suspension of microtubules and kinesin motors driven by ATP. We use a custom-built confocal rheometer to provide simultaneous macroscale rheological measurements and fluorescent imaging of local microtubule dynamics. We find increasing ATP concentration, and therefore increasing activity, yields a significant decrease in the apparent viscosity of the suspension. Simultaneously, using velocimetry techniques, we find significant increases in local velocity fluctuations and deformation rates, suggesting underlying microscale mechanisms for the observed macroscale rheology. We will present a simple model that captures the connection between the local mechanics and the global viscoelasticity.

*Templeton Foundation Grant #57392

10:00AM K59.00007: Interrogation and manipulation of active nematic films using colloidal probes DAVID RIVAS (Presenter), Johns Hopkins University, ROBERT HENRY, University of Maryland, DANIEL H REICH, Johns Hopkins University, TYLER SHENDRUK, University of Oxford, ROBERT LEHENY, Johns Hopkins University — We report studies of the interactions between active nematic films and disk-shaped colloids. The active nematics are driven by molecular motors that cause the constituent microtubular bundles to slide past each other, generating extensional flows that continuously create pairs of +1/2 and -1/2 defects. Rotating magnetic microdisks in proximity to the films produce hydrodynamic flows that compete with the films' intrinsic flow, leading to significant effects on the director field and defect landscape. Near the disks, the self-propelled +1/2 defects take on a preferred direction that is tangential to the direction of imposed stress, creating orientational ordering of the defect motion. At sufficient rotation rates, a more significant alteration of the director field is observed wherein a vortex-like structure within the director field with topological charge of +1 forms. Additionally, we are able to use the disks as effective microrheological probes to gain insight into the physical properties of the film. For example, by analyzing the velocity profile in the film produced by the spinning disk, we obtain an estimate of the film's viscosity.

10:12AM K59.00008: Shearing Living Liquid Crystals* HEND BAZA (Presenter), Department of Physics and Advanced Materials Liquid Crystal Institute, Kent State University, TARAS TURIV, Advanced Materials Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, O D LAVRENOVICH, ANTAL ISTVAN JAKLI, Department of Physics and Advanced Materials Liquid Crystal Institute, Kent State University — Flagellated bacteria of pusher type, such as B. subtilis and E. coli, change the rheological properties of the surrounding isotropic medium. B. subtilis dispersed in a water-based lyotropic chromonic liquid crystals (LCLCs), form a "living liquid crystal" (LLC). Here, we explore the response of the LLC to shear, in particular, how the effective viscosity of LLC changes with the shear rate and how the flow-aligning effect of shear and liquid crystal-mediated elasticity compete with the activity of bacteria that destabilize the orientational order. Studies with an optical rheometer and polarizing optical microscope demonstrate that upon cessation of shear, the activity of bacteria leads to a progressive development of periodic director undulations (with the wave vector parallel to the shear direction), nucleation and multiplication of disclination pairs that produce the regime of topological turbulence. When the gap height increases, disclinations transform from short segments connecting opposite plates to elongated segments in the plane of the cell. The studies reveal a wealth of intriguing phenomena when the system transforms from 2D to 3D-like confinement.

On the relationship between velocities, tractions, and intercellular stresses in the migrating epithelial monolayer

YOAV GREEN, JEFFREY FREDBERG (Presenter), JAMES P. BUTLER, Harvard T. H. Chan School of Public Health — Cells migrate collectively in physiological phenomena including cancer metastasis, development, and asthmatic airway remodeling. Within an epithelial monolayer, for example, each constituent cell exerts intercellular stresses on neighboring cells, and exerts traction forces on its substrate. While traction forces exerted by a monolayer have been measured for more than a decade, their relationship to measured cellular velocities remains unknown. Additionally, the relationship between intercellular stresses and tractions also remains unresolved. In passive systems, traction stresses and velocities are linked in principle through a constitutive law. The simplest and commonly assumed form of such a law is a Newtonian fluid, which implies a linear relationship between stress and strain rate. In this talk, I will address the question: To what extent are tractions related to velocities through such a linear constitutive law? Using a newly derived theoretical model, I will show that the tractions predicted from the measured velocity field are uncorrelated with the measured tractions. This implies that current methods for intercellular stress recovery need to be corrected where one such rectification is the inclusion of an active stress term, for which we derive a novel constraint.

Rheological response and direct visualization of collective patterns formation leading to shear-bands formation in a suspension of active E.coli at the super-fluidity transition*

ERIC CLEMENT (Presenter), PMMH, ESPCI, VINCENT M MARTINEZ, JOCHEN ARLT, ICMCS, University of Edinburgh, CARINE DOUARCHE, ADAMA CREPPY, HAROLD AURADOU, FAST, University of Paris-Sud, ANGELA DAWSON, JANA SCHWARZ-LINEK, WILSON POON, ICMCS, University of Edinburgh — Suspensions of motile Escherichia coli were found to display a "negative viscosity increment" at low shear rate viz., adding such bacteria lowers the shear viscosity of the system (H.M.Lopez, J. Gachelin, C. Douarche, H.Auradou, E. Clément, Phys. Rev. Lett. 115, 028301 (2015)). Furthermore at higher concentrations a regime of zero viscosity, akin to a "superfluidity" transition, can be reached. Here, for a strain of very active bacteria, we report a full exploration of the rheological response changing confinement, shear rate and concentration, both in a low-shear Couette rheometer and in a cone-plane rheometer. The last allows a direct visualization of the collective organization under shear and the exploration of the different regimes leading the "superfluidity transition" in relation with the dynamics of shear-band formation.

The active force spectrum of a microswimmer - modeling and experiments*

WYLIE AHMED (Presenter), California State University, Fullerton — Chlamydomonas reinhardtii are a widely-studied microswimmer that propel themselves by converting chemical energy to mechanical motion of their flagellum in a breast stroke motion. Fluid dynamics approaches have revealed much about the importance of hydrodynamics at the micron-scale and its role in microswimmer transport. However, the stochastic dynamics which are dominated by active non-thermal fluctuations are not well understood. We use optical tweezers and the photon momentum method to directly measure the stochastic forces generated by a trapped Chlamydomonas microswimmer. We model the microswimmer using the generalized Langevin equation approach with active stochastic forcing. Our combined experimental and theoretical approach, based on microrheological techniques, isolates the active force spectrum generated by Chlamydomonas to quantify their nonequilibrium dynamics. We seek to use this framework to test recent developments in stochastic thermodynamics.

Session K60 FECS FIP: Topology Matters: Structure-Property Relationships On Different Length Scales 8CEC 258A - Daniel Dessau, University of Colorado, Boulder - Tag(s): Invited
8:00AM K60.00001: Artificial Ferroic Systems: Magnetic Monopoles, Chirality and Bloch Point Singularities [Invited]
LAURA HEYDERMAN (Presenter), ETH Zurich - Paul Scherrer Institute — In artificial ferroic systems [1], novel functionality is engineered through the combination of designed ferroic structures and the control of the interactions between the different components. We probe their behaviour with large-scale facility methods including synchrotron x-rays and low energy muon spectroscopy, which give unparalleled information on microscopic magnetic phenomena. In hybrid mesoscopic structures incorporating two different ferromagnetic layers, the static and dynamic behaviour result from the mutual imprint of the magnetic domain configurations. Here, vortex core reversal can be induced by displacing the core across a domain boundary with a magnetic field. This reversal occurs via the creation of a pair of Bloch point singularities [2].

In artificial spin ice, consisting of arrays of dipolar-coupled nanomagnets arranged in frustrated geometries, a number of interesting emergent phenomena occur. For example, we have observed the creation and separation of emergent magnetic monopoles in an applied magnetic field [3]. In thermally-active systems with superparamagnetic elements, there is a geometry-dependent evolution of magnetic configurations into the lowest-energy states [4], and this dynamic process can be chiral [5]. We have also demonstrated that these magnetic metamaterials can support thermodynamic phase transitions [6, 7]. Finally, we have developed synchrotron x-ray methods to obtain chemical, structural and magnetic information in 3D, and have directly observed the curling magnetic structure surrounding Bloch points [8].

8:36AM K60.00002: Topological soft matter: from metamaterials to polymers [Invited] JAYSON PAULOSE (Presenter),
Physics, University of Oregon —
The classification of physical systems using topology has ushered in a new paradigm for condensed matter physics. Although topologically nontrivial states, with their accompanied features of exotic edge behaviour and robustness to disorder, were first predicted and observed in electronic systems, they have since been realized in a variety of classical systems. Soft matter provides a particularly rich playground for topological physics across diverse length scales. At the macroscopic scale, topology can be used to control tangible features such as vibrational response and mechanical rigidity, bringing elegant mathematical concepts literally to our fingertips. At microscopic scales, the messiness inherent to thermally fluctuating matter provides challenges as well as opportunities for realizing topologically nontrivial behaviour. Across these varied scales, topology holds promise as a tool to create artificial materials with desirable features that are robust to disorder and imperfections. I will demonstrate the breadth and richness of topological soft matter by describing two examples from either end of the spectrum. At the macroscale, I'll survey a class of mechanical metamaterials in which rigidity can be controlled both locally and globally using topology. At the microscale, I'll how strong interactions and thermal fluctuations can be harnessed to generate robust equilibrium patterns in a system of fluctuating lines, with potential applications in polymer patterning and manipulation of magnetic fields in superconductors.
9:12AM K60.00003: Geometrical Frustration Beyond Magnets* [invited] JOSEPH PADDISON (Presenter), University of Cambridge, ZHILING DUN, MARCUS DAUM, School of Physics, Georgia Tech, ANDREW CAIRNS, PETER THYGESEN, Department of Chemistry, University of Oxford, MATTHEW J CLIFFE, University of Cambridge, MATTHEW G. TUCKER, YAOHUA LIU, Oak Ridge National Laboratory, HELEN PLAYFORD, DAVID KEEN, ISIS Neutron and Muon Source, KARENA CHAPMAN, KEVIN BEYER, Argonne National Laboratory, ARKADIY SIMONOV, MICHAEL HAYWARD, RONGHUAN ZHANG, AMBER THOMPSON, Department of Chemistry, University of Oxford, DOMINIK DAISENBERGER, Diamond Light Source, FX COUDERT, Institut de Recherche de Chimie Paris, CNRS / Chimie ParisTech, HAIDONG ZHOU, University of Tennessee, MARTIN MOURIGAL, School of Physics, Georgia Tech, ANDREW GOODWIN, Department of Chemistry, University of Oxford — Geometrical frustration – the inability of a system to satisfy all of its interactions simultaneously because of geometrical constraints – can suppress conventional ordering and promote the formation of exotic states that are disordered, yet strongly correlated. Materials in which magnetic spins occupy lattices built from corner or edge-sharing triangles have provided many examples of novel magnetic behavior due to frustration. In this talk, I will discuss how frustration of structural (nonmagnetic) degrees of freedom – charge states, orbital orientations, or chain displacements – can determine the structures and properties of materials. I will also discuss how the nonmagnetic frustrated interactions can be mapped to equivalent “toy” spin Hamiltonians, including those that are challenging to realize experimentally in magnets. I illustrate these points using three real examples of nonmagnetic frustration. First, I discuss how the solid phases of silver(I) and/or gold(I) cyanides, in which polymeric chains occupy a triangular lattice, can host structural analogs of the spin vortices of triangular $XY$ magnets [1]. Second, I discuss the pyrochlore oxide $Y_2Mo_2O_7$, and explain how orbital dimerization of Jahn-Teller active $Mo^{4+}$ ions on the frustrated pyrochlore lattice may yield an orbital-ice analog of spin-ice and water-ice states [2]. Finally, I discuss the triangular-lattice-based system $YbMgGaO_4$ [3,4] – of interest because of proposed quantum-spin-liquid-like behaviour of its magnetic $Yb^{3+}$ ions – and show how the charge difference between nonmagnetic $Mg^{2+}$ and $Ga^{3+}$ generates a structurally-frustrated state, with implications for the proposed quantum-spin-liquid behaviour.

9:48AM K60.00004: Experimental realization of higher order topological states in classical systems [invited] ALEXANDER KHANIKAEV (Presenter), City College of CUNY — TBD

10:24AM K60.00005: Self-assembled 1D nanostructures on semiconductor surfaces [invited] MARIA LONGOBARDI (Presenter), University of Geneva — Self-assembled one-dimensional (1D) nanostructures have attracted considerable attention in the last decades since their low dimensional architecture offers the possibility to realize atomically precise patterns on semiconducting surfaces. Moreover, the gapped substrate allows the study of the exotic properties of the 1D physics. Bismuth nanolines and their derived Haiku structure are, in this scenario, a unique 1D structures self-assembled on the $Si(001)$ surface. They can grow several micrometers long, almost defect free, in dense arrays or isolated. Their length and tunable density make them suitable for realizing large area functionalized patterns. Although these systems were deeply investigated over the years, their electronic structures have yet not well understood.

Here, an STM/STS study combined with DFT simulation of the electronic properties of the Bi nanolines and derived Haiku structures is presented. High-resolution STM micrographs reveal a rich variety of periodic electronic features as a function of bias voltage. The atomic structures of Bi nanolines and the interplay between Bi and the Si substrate, essential to understanding the electronic and transport properties, are investigated in great details and reproduced in good agreement by the DFT simulations.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM

Session K61 GSOFT DBIO GSNP: Active Matter V BCEC 258B - Rui Zhang, University of Chicago - Tag(s): Focus
8:00AM K61.00001: Pushers, pullers, splitters: molecular processes governing the dynamics of active emulsions.*

[Invited] CORINNA MAASS (Presenter), KYLE A BALDWIN, BABAK VAJDI HOKMABAD, Max Planck Institute for Dynamics and Self-Organization — Active emulsions are a versatile microswimmer model system. We study a system of spherical oil droplets gradually dissolving in aqueous surfactant solutions, which move autonomously via self-sustaining Marangoni gradients at the oil-water interface. Owing to this interfacial driving, the droplets are direct experimental analogues to hydrodynamic squirmer models, with the interfacial velocity profile depending on the kinetics of surfactant micelles taking up oil from the swimming droplet. We have observed both hydrodynamic and chemical fields around the droplets and found that the system's geometry, length scales and solubilisation timescales govern various effects: pusher to puller type hydrodynamics; persistent to unsteady swimming; and, for large squeezed droplets, interfacial instabilities leading to deformation and division states.

8:36AM K61.00002: Light-driven Assembly of Motile Colloidal Clusters from Immotile Building Blocks

FALKO SCHMIDT (Presenter), University of Gothenburg, BENNO LIEBCHEN, HARTMUT LOEWEN, Heinrich-Heine-Universität Düsseldorf, D-40225 Düsseldorf, Germany, Institut für Theoretische Physik II: Weiche Materie, GIOVANNI VOLPE, University of Gothenburg — Active matter, consisting of self-propelled units locally injecting energy into the system, opens new horizons for the creation of functional soft materials with designable properties. Experiencing a constant energy input, allows active matter to self-assemble into phases with a complex architecture and functionality such as living clusters which dynamically form, reshape and break-up but would be forbidden in equilibrium material by the entropy maximization (or free energy minimization) principle. The challenge to control this active self-assembly has evoked widespread efforts typically hinging on an engineering of the properties of individual motile constituents. Here, we provide a different route, where activity occurs as an emergent phenomenon only when individual building blocks bind together, in a way which we control by laser light. Using experiments and simulations of two species of immotile microspheres, we exemplify this route by creating active molecules featuring a complex array of behaviors, becoming migrators, spinners and rotators. The possibility to control the dynamics of active self-assembly via light-controllable nonreciprocal interactions will inspire new approaches to understand living matter and to design active materials.

8:48AM K61.00003: Failures of defining Effective temperature in an active colloidal system

CHONG SHEN (Presenter), H DANIEL OU-YANG, Lehigh University — Active colloidal systems contain active particles, which convert energy from the environment into directed or persistent motion. Effective temperature, defined from active diffusion, fluctuation, and sedimentation profile, is used sometimes for quantifying the activity of active particles. However, non-thermal fluctuations were found to lead to failures when using effective temperature under some conditions, for examples, at short times and in strong confinement. The reason and conditions under which would the failure appear is not clear even for a single active particle.

We investigate from experimentation and numerical simulation the Effective temperature in a quadratic potential. We found the maximum probability distribution in histograms of position is at a characteristic length away from the center, which can't be described with $T_{\text{eff}}$ and Boltzmann distribution. The average potential energies were not proportional to the effective temperatures. We also found that the fluctuation power spectral density (PSD) plots have two characteristic frequencies, which can't be explained with $T_{\text{eff}}$ and fluctuation-dissipation theorem. Our experiments and numerical simulation provide how the effective temperature fails to describe the system.

9:00AM K61.00004: Fluidic Metamaterials for Controlled Transport of Active Colloids

SHAHRZAD YAZDI (Presenter), JUAN L. ARAGONES, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — In metamaterials, one can design novel properties by tuning the links between constituent elements. Here, we leverage hydrodynamic interactions as designed links to engineer a fluidic metamaterial for non-equilibrium colloidal control. Our system consists of an active particle in a viscous fluid confined in a periodic array of posts. Controlled hydrodynamic and electrostatic interactions of the particle with posts give rise to interesting transport modes, reminiscent of those in Floquet-Bloch systems. We present a wide range of non-equilibrium transport states for various lattice structures and external field parameters. Using Brownian dynamics, we examine the robustness of transport states to thermal fluctuations and design defects. This novel system gives insight into design of new materials for smart transport of colloidal particles.
9:12AM K61.00005: Propulsion of catalytic Janus spheres in viscosified solutions  
MATTEO RICCI (Presenter), EDMUND TANG, PURBA CHATTERJEE, Rensselaer Polytechnic Institute — Many applications of Janus motors involve moving objects through complex environments that are mixtures of components. The flow properties of these mixtures could be Newtonian or non-Newtonian. In other applications, additives may be introduced as a way of controlling the motion of motors. The first step in understanding how the fluid mixtures alter their motion is to examine propulsion in fluids where additives change the shear viscosity while the fluid remains Newtonian. We show how solution viscosity affects Janus motor propulsion keeping all other factors (motor size, fuel concentration, temperature, etc.) constant. The velocity is shown to decay approximately inversely with viscosity. Further, the type of viscosifier used affects the interaction between fuel molecules and motor, which affects propulsion. This is part of the overall goal of understanding how solution properties impact propulsion independent of a particular application. When qualifying the propulsion in crowded environments, it is important to understand how to accurately quantify the response. We have used computer simulations to quantify the errors associated with particle tracking when extracting the propulsion of Janus motors.

9:24AM K61.00006: Interrupted Motility Induced Phase Separation for aligning active colloids.  
MARJOLEIN VAN DER LINDEN, DIRK AARTS, Department of Chemistry, Physical and Theoretical Chemistry Laboratory, University of Oxford, OLIVIER DAUCHOT (Presenter), Gulliver Lab UMR 7083, CNRS — Switching on large activity in a rather dense system of active Janus colloids, we observe fast clustering, followed by clusters aggregation towards full phase separation. The phase separation process is however interrupted when large enough clusters start breaking apart. Following the cluster size distribution as a function of time, we identify four successive dynamical regimes. Tracking both the particle positions and orientations, we characterize the structural and alignment ordering present in the growing clusters, and thereby unveil the mechanisms at play in these regimes. In particular, we identify how alignment between the neighboring particles is responsible for the interruption of the full phase separation. This experimental study, which provides the first large-scale observation of phase separation in active colloids, combined with particle scale analysis of the local mechanisms, points at the new physics observed when both alignment and short-range repulsion are present.

9:36AM K61.00007: The velocity of self-propelled Pt-coated colloids is determined by the substrate.  
STEFANIA KETZETZI (Presenter), RACHEL PAMELA DOHERTY, DANIELA JUTTA KRAFT, Leiden University — Active colloids are typically self-propelling near a substrate. However, the effect of the substrate on the self-propulsion remains unexplored. Here, we investigate whether the substrate influences the self-propulsion by performing systematic experiments on different substrates. Interestingly, we find that the colloid velocities are considerably different on different substrates. We consider various physicochemical properties as the origin for this observation. Our results are useful for future modeling and might be helpful in understanding the details of the still debated self-propulsion mechanism.

9:48AM K61.00008: Light Driven Fuel-Free Thermocapillary Microswimmers*  
MATAN YAH BEN ZION (Presenter), YAEILIN CABA, ALVIN MODIN, PAUL M CHAIKIN, New York University — Surface tension is a powerful agent for driving biological and artificial micron-sized particles. Surface tension gradients however, typically require a chemical reaction, making a capillary based swimmer fuel dependent. By combining a light absorbing bead with a fluid droplet we made a dimer that is propelled by light, and requires no chemical fuel. The 6 μm swimmers’ motility records over 10 μm/s and show good with measured thermocapillary and hydrodynamic parameters. We discuss the swimmers’ manipulation and interactions.

10:00AM K61.00009: Tuning the motility of self-propelled droplets: from persistent to stochastic*  
ADRIEN IZZET (Presenter), New York University, PEPIJN MOERMAN, Chemistry, Utrecht University, KATHERINE A NEWHALL, Mathematics, University of North Carolina-Chapel Hill, JASNA BRUJIC, New York University — Active droplets produce isotropic concentration gradients in the solution. These solute-mediated interactions depend on the size of the droplet and on the composition of the solvent, as shown in the case of di-ethyl phthalate (DEP) droplets in an aqueous solution of sodium dodecyl sulphate (SDS) [P. G. Moerman et al. PRE 96, 032607 (2017)]. When the fluctuations of these interactions are sufficient to break the symmetry of this dissolution gradient, a self-sustained motion is initiated. These droplets exhibit different motility profiles, from ballistic to diffusive. We use the rotational diffusion model to describe the motility of these swimmers. For a given droplet size, we tune the concentration of surfactant in the solution in order to control the droplet solubility. We show that contrary to Janus particles, the persistence length of the trajectory decreases when adding more fuel (surfactant) in the system: the sensitivity to fluctuations of local fuel concentration increases.
10:12AM K61.00010: Exploring the origin of self-induced vertical oscillations of dust particles in a plasma  JOSHUA MENDEZ (Presenter), GURAM GOGIA, JUSTIN BURTON, Department of Physics, Emory University — Micron-size charged particles can be easily levitated in a low-density plasma environment. Such “dusty plasmas” are often used to investigate traditional condensed matter and statistical physics at the single-particle level. We have recently observed a novel phenomenon where hundreds of particles can switch between crystalline and gas-like states over minutes-long time scales (Gogia et al., PRL, 2017). The constituent-level source of energy for this “active matter” system is sustained, large-amplitude vertical oscillations of the individual particles. Delayed charging, charge fluctuations, and variations in the plasma number density have been previously invoked to explain such behavior, however, we show that these mechanisms are unlikely to drive the oscillations we observe. Langmuir probe measurements suggest the plasma environment around the grains is time-invariant. Furthermore, grains carry charges on the order of $10^4$ electrons, suggesting that square-root N fluctuations would be too small to drive such large amplitude oscillations. We hypothesize that particle oscillations arise not from electrostatic effects, but from a complicated interaction between the ion wakes streaming out in the lee of the particles and the underlying electrode at low pressures.

10:24AM K61.00011: Diffusive ferromagnetic roller gas: velocity and displacement statistics*  GAŠPER KOKOT (Presenter), ALEXEY SNEZHKO, Materials Science Division, Argonne National Laboratory — Active colloids can display collective motion that is non-directional on average, akin to gas molecules. We experimentally observe and investigate such behavior for ferromagnetic colloidal rollers powered by a vertical alternating magnetic field. We show that the system has a bimodal velocity distribution. Furthermore, the displacement statistics transition from bimodal to quasi-Gaussian distributions (Gaussian core with power-law tails) for all densities. Overpopulated tails are observed at low densities. The system demonstrates the normal diffusive behavior for both active particles and inert glass beads of the same size. The density dependence of the diffusion constant shows a striking difference between active and inert particles. Our work provides insight into statistical properties of active Brownian-like non-equilibrium systems.

*The research was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

10:36AM K61.00012: Collective dynamics and active turbulence in swarms of synchronized self-assembled spinners*  KOOHEE HAN (Presenter), GAŠPER KOKOT, ALEXEY SNEZHKO, Materials Science Division, Argonne National Laboratory — Active magnetic colloids have proven to be an excellent model system to explore emergent out-of-equilibrium dynamics and structures. We demonstrate that ferromagnetic microparticles, suspended at an air/water interface and energized by an external rotating magnetic field, form dynamic ensembles of synchronized self-assembled spinners. The balance between the magnetic and viscous torques determines the size of an individual self-assembled spinner, which can be controlled by the frequency and strength of the applied magnetic field. Each spinner generates local hydrodynamic flows such that the collective interactions of the multiple spinners allow the formation of dynamic crystal lattices. We investigate active diffusion of passive cargo particles in such spinner ensembles and analyze the structure of the underlying self-induced surface flows. We show that induced flows exhibit properties of an active turbulence. The energy spectra of the active turbulence in such synchronized spinner ensembles reveal reverse energy cascade with the exponent significantly different from the classical 2D turbulence.

*The research was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division.

10:48AM K61.00013: Solid-liquid transition in layers of deformable active droplets*  BENJAMIN LOEWE (Presenter), Syracuse University; University of California Santa Barbara, DAVIDE MARENDUZZO, University of Edinburgh, M. CRISTINA MARCHETTI, University of California Santa Barbara — Layers of epithelial tissue have been modeled either as collections of spherical active particles or via the Vertex Model (VM) that describes cells as irregular polygons tiling the plane. The VM is appropriate to describe confluent layers where there are no gaps between cells and does not incorporate variations in the cell packing fraction that is by construction set to one. In contrast, the particle model can account for variation in packing fraction, but does not allow for deformations of individual cells. Both models predict a solid-liquid transition of cellular tissue tuned either by cell shape (VM) or by cell density (particle model). To bridge between these two models, we describe cells as deformable self-propelled droplets each characterized by a scalar field representing the cell's density. We then examine the collective behavior of N droplets modeled as N interacting phase fields. Using this model, we examine the interplay of cell deformability, cell density and cell motility in controlling the solid-liquid transition. We quantify the melting of the hexagonal ground state, as well as the stability of metastable states.

8:00AM K62.00001: Exoplanets: from Discovery to Characterization and Beyond* [Invited] SARA SEAGER (Presenter), Massachusetts Institute of Technology — Thousands of exoplanets are known to orbit nearby stars with evidence that nearly all stars in our Milky Way Galaxy have planets. Beyond their discovery, a new era of “exoplanet characterization” is underway with an astonishing diversity of exoplanets driving the fields of planet formation and evolution, interior structure, atmospheric science, and orbital dynamics to new depths. Exoplanets with masses and average densities that have no solar system counterparts are mysteries in their formation pathways as well as their interior composition and structure. The push to find smaller and smaller planets down to Earth size is succeeding and motivating the next generation of planetary models and telescopes to have the capability to find and identify planets that may be like Earth.

8:36AM K62.00002: Phase transitions in mantle silicates and the internal structure of terrestrial exoplanets [Invited] KOICHIRO UMEMOTO (Presenter), Earth-Life Science Institute, Tokyo Institute of Technology — The highest-pressure form in the Earth of the major mantle silicate MgSiO₃-bridgmanite is post-perovskite (PPv). Knowledge of the fate of PPv at higher pressures relevant for super-Earth-type planets is fundamental for us to start modeling the internal structure and dynamics of these planets. In this talk I will review the sequence of phase transitions we discovered in pure MgSiO₃ up to 4 TPa, as well as in aggregates of MgSiO₃+MgO and MgSiO₃+SiO₂ with variable Mg/Si abundances. New phases in the (MgO)ₙ(SiO₂)ᵦ system have been discovered [1-5]. Such phases involve dissociation and recombination reactions in the MgSiO₃+MgO+SiO₂ system, some of them very surprising, but all ending-up in the dissociated elementary oxides, MgO+SiO₂, above 3.1 TPa [1]. These transitions produce density discontinuities in planetary interiors and the consequences of these transitions for the internal structure of terrestrial planets [6] with up to 20 Earth masses will be discussed.

9:12AM K62.00003: Mass-dependent Dynamics of Terrestrial Exoplanets Using ab initio Mineral Properties [Invited]
ARIE VAN DEN BERG (Presenter), Utrecht University, DAVID A. YUEN, Applied Physics and Applied Mathematics, Columbia University, KOICHIRO UMEMOTO, ELSI, Tokyo Institute of Technology, MICHAEL JACOBS, Metallurgy, Technical University Clausthal, RENATA WENTZCOVITCH, Applied Physics and Applied Mathematics and Department of Earth and Environmental Sciences, Lamont Doherty Earth Observatory, Columbia University — We present new modelling results for the internal structure and convective dynamics of large terrestrial (rocky) exoplanets. For up to 20 Earth masses (Me) our results show pressure and temperature (P,T) of several Terapascal (TPa) and 10000 Kelvin in the silicate mantle.
Recent mineral physics predictions show stepwise dissociation into SiO₂ and MgO of the main magnesium-silicate mineral of Earth's mantle under these P,T conditions (Umemoto et al., 2017).
Using material properties from these models we have modelled the internal structure of planets in the range 1-20 Me with an Earth-like core mass fraction of 0.3. We found that full dissociation into oxides occurs in planets with M > 13 Me, where at the core mantle boundary P > 2.4 TPa.
Our Rayleigh-Benard mantle convection results for planet mass 1-20 Me show strong differences in the internal structure and the convection dynamics between different cases.
First, due to increasing pressure the number of phase transitions increases from zero in the smallest case to four, for cases > 13 Me. Furthermore, we observe three regimes of convective dynamics, with: 1) smaller planets (< 4 Me), showing vigorous convection, 2) intermediate cases (< 12 Me), with sluggish penetrative convection, concentrated in a single shallow zone of higher flow velocity, and 3) large planets, (> 12 Me), with vigorous convection in top and bottom zones, separated by a high viscosity mid-mantle with sluggish convection.
These regimes are directly related to the pressure dependence of mantle viscosity, first increasing then decreasing due to pressure weakening. Here the planet mass is the control variable because it sets the mantle pressure range.
For the larger planet cases with a bottom layer of oxides, and reduced viscosity, we observe vigorous convection and small scale structure in the deepest part of the mantle that interacts with the dissociation phase boundary. This impacts the heat-flux from the core and the viability of core dynamo processes.

9:48AM K62.00004: Phase Transitions Beyond Post-Perovskite in Neighborite (NaMgF₃) to 1.6 Mbars* [Invited]
THOMAS DUFFY (Presenter), RAJKRISHNA DUTTA, Princeton University, ERAN GREENBERG, VITALI PRAKAPENKA, University of Chicago — Neighborite, NaMgF₃, is used as a model system for understanding ultra-high pressure phase transitions in ABX₃ systems such as MgSiO₃. In this work, we have studied the high-pressure behavior of NaMgF₃ to 1.6 Mbars using the laser-heated diamond anvil cell technique coupled with synchrotron x-ray diffraction. Our work reveals a complex sequence of high-pressure phases beyond post-perovskite in this ABX₃ system. The phase transition sequence in NaMgF₃ is: NaMgF₃ (perovskite) → NaMgF₃ (post perovskite) → NaMgF₃ (Sb₂S₃-type) → NaF (B2-type) + NaMg₂F₅ (P2₁/c) → NaF (B2) + MgF₂ (cotunnite-type). Our results demonstrate the existence of a post-post-perovskite phase, followed a two-stage dissociation into binary fluorides. This work is the first experimental report of a dissociation of a post-perovskite in any known ABX₃ system. A similar sequence of transition is predicted to occur in MgSiO₃ at ultrahigh pressures where it has implications for the mineralogy and dynamics large, rocky extra-solar planets.

10:24AM K62.00005: Laser Focus on Planets* [Invited] GILBERT COLLINS (Presenter), Laboratory for Laser Energetics, Mechanical Engineering, and Physics and Astronomy, University of Rochester — A new laboratory exploration of the deep interior states and processes for solar and extrasolar planets is underway. Kilojoule to Megajoule laser compression data and first principles calculations combined with recent observational planet discoveries provide fresh perspectives for the qualities and implications of these massive objects throughout the universe. Recent experimental results for silicates and water reveal dramatic chemical changes emerge at millions of atmosphere pressure and several thousand Kelvin, giving rise to polymeric silicates and superionic water. New equation of state data for iron to tens of millions of atmospheres provides insight into the deep interior core conditions for extrasolar terrestrial planets. At still higher pressures, approaching atomic pressures (294 Mbar = 29.4 TPa) atoms can be brought together closer than a deBroglie wavelength and even in some cases the Bohr radius where core as well as valence electrons (keV as well as eV energy levels) engage in bonding and where a new quantum behavior emerges.

Wednesday, March 6, 2019 8:00 AM - 11:00 AM
mechanical outcome of knitted fabrics. Techniques, the innate properties of the yarn and the stitch microstructure has a direct effect on the global geometric and elasticity of the resulting fabric. This puts a new spin on additive manufacturing – not only can stitch pattern control the local and global geometry of a textile, but the topology of knitted stitches has a profound impact on the geometry and elasticity of the resulting fabric. This puts a challenge has been realized in the ancient technology known as knitting. This process for making functional materials 2D and 3D with many functional materials, the key to knitting's extraordinary properties lies in its microstructure.

At the 1D level, knits are composed of an interlocking series of slip knots. At the most basic level there is only one manipulation that creates a knitted stitch – pulling a loop of yarn through another loop. However, there exist hundreds of books with thousands of patterns of stitches with seemingly unbounded complexity.

The topology of knitted stitches has a profound impact on the geometry and elasticity of the resulting fabric. This puts a new spin on additive manufacturing – not only can stitch pattern control the local and global geometry of a textile, but the creation process encodes mechanical properties within the material itself. Unlike standard additive manufacturing techniques, the innate properties of the yarn and the stitch microstructure has a direct effect on the global geometric and mechanical outcome of knitted fabrics.

8:36AM K63.00002: Avalanche dynamic in a knitted fabric*  SAMUEL POINCLoux, Ecole Normale Superieure, Mokhtar Adda-Bedia, Departement de Physique, Ecole Normale Superieure de Lyon, Frederic Lechenault (Presenter), Ecole Normale Superieure — A knitted fabric is a topologically constrained elastic yarn following a periodic path. The mechanical behavior of the fabric appears to be drastically different from the yarn it is made of. To explain this discrepancy, we introduced a network model which features three ingredients, a dominant bending energy, an unaltered topology and yarn length conservation. This model provides a quantitative comparison with experiments done on a model knitted fabric, both in the force-elongation relation and in the deformation field. However, yarn-yarn friction at the crossing points induces fluctuations around the average force and deformation response. The fluctuations are identified as sudden drops of the force correlated with localized slipping lines in the network. Power law distribution of event size and morphological scale invariance suggest an avalanching mechanism producing those fluctuations. A mechanism is indeed identified with local slips propagating and mediated through anisotropic elastic redistribution.

8:48AM K63.00003: A general geometric framework for knitted fabric elasticity  Michael Dimitriyev (Presenter), Krishma Singal, Elisabeta Matsumoto, Georgia Institute of Technology — Knitting is a process in which yarn, an essentially filament-like material, is shaped in space to form a fabric, an essentially sheet-like material, via stitching together a lattice of slip-knots. Due to fabric-level dependence on the stitch pattern, a single yarn can be used to create a large variety of fabric geometries and material responses. Moreover, the elasticity of knits remains poorly understood, as evidenced by the lackcluster performance of spring-lattice models. We seek a continuum elastic model that predicts the three-dimensional shape of knitted fabric. This model should have the flexibility to be adapted to describe a wide range of stitch patterns and elasticity models. To this end, we have developed a geometric framework for relating the yarn path to the emergent surface geometry of the fabric. The generality of our approach allows for a systematic coarse-graining of yarn degrees of freedom, without a priori specification of a model of yarn elasticity. Thus, we are able to arrive at a stitch pattern-dependent, continuum elastic model of knits by assuming a simple phenomenological model of yarn, whilst allowing for the possibility of including more realistic yarn mechanics and experimental comparison.

9:00AM K63.00004: A topological perspective on knitted fabrics  Shashank Markande (Presenter), Elisabeta Matsumoto, Georgia Institute of Technology — A knitted textile structure can be thought of as a series of slip knots stacked next to each other in multiple rows. In a given row, each loop is held in place by a loop in the preceding row. As a first step towards building a topological theory for knitted textile structures, we take advantage of the doubly periodic structure coming from the ordering of stitches into rows and columns. A two-periodic planar structure has two generators of translational symmetry. We get a minimal unit cell that tiles the original structure by modding out by these elements of symmetry. The resulting embedding of a curve inside the unit cell is equivalent to a knot sitting in the thickened two-torus. To study this class of knots, we aim to construct a knot invariant or link invariant based on the process of knitting -- using two needles to form slip knots in yarn -- to make an arbitrary two-periodic knitted textile structure. Such a knot invariant inherits an algebraic structure that reflects how and which elementary operations are used to make a given knitted textile structure and, as a result, tells us whether a given doubly periodic structure can be realized by knitting.
**9:12AM K63.00005: Top Down Modeling of Complex Knit Structures: Beyond Jersey Knits**

CHELSEA KNITTEL (Presenter), University of Oxford, RANDALL D KAMIEN, Physics and Astronomy, University of Pennsylvania, OANA GHITA, KEN EVANS, College of Engineering, Mathematics and Physical Sciences, University of Exeter, GENEVIEVE DION, Drexel University — Modeling of knit textiles is popular in fields such as mechanical engineering and physics, where researchers are working to understand effects of yarn and loop geometries on fabric properties. Often, this can be computationally expensive, allowing only for modeling of planar fabrics such as jersey, made from all knit stitches. We see potential however, in complex self-folding structures, made with knit and purl stitches, as a means of engineering metamaterial textile properties. To aid in modeling of these structures, we have developed a topological framework for the knit structure using families of bicontinuous surfaces which allow us to geometrically understand the physics of the characteristic boundary condition curling of jersey knits. We then consider complex self-folding as a result of competition between these boundaries, affected by contributing magnitudes of forces from course and wale directions. By characterizing these forces, we are developing a system of predicting this folding, through understanding of generalized behaviors that repeat regardless of material or machine. By studying interactions between segments of knit and purl stitches, rather than loops or yarns, we can more quickly understand this behavior, to engineer novel textile properties.

**9:24AM K63.00006: Stable elastic knots with no self-contact**

DEREK MOULTON (Presenter), University of Oxford, SÉBASTIEN NEUKIRCH, Université Pierre et Marie Curie, PAUL GRANDGEORGE, École polytechnique fédérale de Lausanne — Knots are widespread, universal physical structures, from shoelaces to Celtic decoration to the many variants familiar to sailors. They are often simple to construct and aesthetically appealing, yet remain topologically and mechanically quite complex. Knots are also common in biopolymers such as DNA and proteins, with numerous and significant biological implications.

While self-contact is an inevitable feature of tight knots, here we go the other direction and ask whether a knotted filament with zero points of self-contact may be realized physically. Our focus is on the simple hand-held experiment of an elastic rod bent into a trefoil knot, with the ends held clamped. The question we consider is whether there exist stable configurations for which there are no points of self-contact. This idea can be fairly easily replicated with a thin strip of paper, but is more difficult or even impossible with a flexible wire. We search for such configurations within the space of three tuning parameters related to the degrees of freedom in the simple experiment. Mathematically, we show, both within standard Kirchhoff theory as well within an elastic strip theory, that stable and contact-free knotted configurations can be found, and we classify the corresponding parametric regions. Numerical results are complemented with an asymptotic analysis that demonstrates the presence of knots near the doubly-covered ring. In the case of the strip model, quantitative experiments of the region of good knots are also provided to validate the theory.

**10:00AM K63.00007: Untangling the mechanics of elastic knots**

PAUL JOHANNS (Presenter), PAUL GRANDGEORGE, Institute of Mechanical Engineering, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland, CHANGYEOB BAEK, Department of Mechanical Engineering, Massachusetts Institute of Technology (MIT), USA, ALASTAIR FLYNN, Institute of Mathematics, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland, TOMOHIKO SANO, Department of Physical Science, Ritsumeikan University, Japan, JOHN MADDOCKS, Institute of Mathematics, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland, PEDRO REIS, Institute of Mechanical Engineering, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland — In surgery, knots are used as ligatures to bind surgical thread during suturing. Even if breakage or unraveling of knotted configurations can be disastrous, suturing guidelines are mostly empirical. Knot theory, a well-established field of mathematics, tends to focus on idealized, non-elastic knots. Moreover, analytical models based on Kirchhoff's theory for elastic rods are limited to simple knots in loose configurations. However, functioning knots are in general tight and involve elastic deformation of the thread, self-contact and nontrivial frictional interactions. We tackle this problem by performing high precision experiments to acquire unprecedented experimental data on the geometry and deformation of simple open-knots. We make use of X-ray micro computed tomography to acquire volumetric information of knotted configurations on homogeneous elastomeric rods. Emphasis is placed on systematically exploring how the mechanical properties of the rod, friction, and the externally applied loads, all conspire to dictate the mechanical performance of knotted structures. We hope that the physical insight gained from this experimental characterization will form the bases for future predictive models for physical knots.

*Supported by the Fonds National de la Recherche, Luxembourg 12439430
10:12AM K63.00008: Not-knots as the building block of elastic knots* PAUL GRANDGEORGE (Presenter), PAUL JOHANNS, Institute of Mechanical Engineering, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland, CHANGYEOB BAEK, Department of Mechanical Engineering, Massachusetts Institute of Technology (MIT), USA, ALASTAIR FLYNN, Institute of Mathematics, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland, TOMOHIKO SANO, Department of Physical Science, Ritsumeikan University, Japan, JOHN MADDOCKS, Institute of Mathematics, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland, PEDRO REIS, Institute of Mechanical Engineering, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland — Knots are key for a wide variety of applications such as mooring ships to docks, ensuring the safety of a falling climber or fastening surgical suture threads. Even if knots have been used in hundreds of configurations for millennia, the understanding of their mechanical behavior remains mainly empirical. Past fundamental studies on knots include ideal knots, purely based on geometry and one-dimensional reduced elasticity models. For tight knots, intricate three-dimensional geometries, large deformations, and friction between rod strands are all present in setting a highly nonlinear and coupled behavior. To gain better insight into this complex class of problems, we study the ‘not-knot’: a simpler model system composed of a clasp of two bent elastic rods brought together in mechanical contact. We use X-ray computed tomography to probe the geometry of not-knots, as well as precise force-displacement measurements to quantify the interplay of bending curvature, elasticity, and friction. We believe that regarding complex tight knots as assemblies of simple not-knots will provide a solid foundation to develop much needed predictive models for knotted structures.

10:24AM K63.00009: From knots to weaved baskets: Unravelling the mechanics of a clasp between two contacting filaments through numerical experiments* CHANGYEOB BAEK (Presenter), Department of Mechanical Engineering, Massachusetts Institute of Technology (MIT), PAUL GRANDGEORGE, PAUL JOHANNS, Institute of Mechanical Engineering, Ecole Polytechnique Fédérale de Lausanne (EPFL), ALASTAIR FLYNN, JOHN MADDOCKS, Institute of Mathematics, Ecole Polytechnique Fédérale de Lausanne (EPFL), PEDRO REIS, Institute of Mechanical Engineering, Ecole Polytechnique Fédérale de Lausanne (EPFL) — Tight elastic knots and weaved structures tend to exhibit intricate modes of deformation with nontrivial regions of contact that call for a fully three-dimensional description. Given this complexity, there is a striking lack of predictive models for knotted or weaved structures, the design of which tends to rely mostly on accumulated experience and empirical craftsmanship. Here, we study the elementary, yet rich and informative, canonical case of ‘a clasp’ formed by two elastic rods in crossing contact. We first start with the case of rods that have an originally circular cross-section. We tackle this problem by performing finite element simulations of this clasp configuration and contrast our results with experimental data obtained using X-ray tomography of the corresponding physical structures. We compare our results to a well-established description for ideal claps of geometrically rigid strings (that exclude elasticity), finding that the latter acts as an underlying ‘backbone’ for the full elastic solution. Finally, we extend our framework to a clasp formed by strips of non-circular cross-sections, which is the building block in basket weaving.

*P. Johanns was supported by the Fonds National de la Recherche, Luxembourg 12439430.

10:36AM K63.00010: Detangling hair THOMAS PLUMB-REYES (Presenter), NICHOLAS CHARLES, LAKSHMINARAYANAN MAHADEVAN, Harvard University — Tangled hair is difficult to manage. We investigate the everyday problem of taming a tangle of hair with a comb by focusing on a minimal model of this system: a pair of chiral, elastic helical rods entangled to form a braid. As a single, stiff tine combs through the double-helix, it leaves two untangled filaments in its wake. We use experiments, theory and computation to characterize this problem with both mechanics and topology.

10:48AM K63.00011: Born in the Wrong Geometry: Longitudinal and transverse frustration in non-parallel filament bundles* DARIA ATKINSON (Presenter), CHRISTIAN SANTANGELO, GREGORY GRASON, University of Massachusetts Amherst — Assemblies of one-dimensional, filamentous materials are commonplace in physical systems, from microscopic materials, such as columnar liquid crystals and biopolymer bundles, to familiar, macroscopic materials like wires, cables, and ropes. The geometry of continuous filament bundles with cross sectional ordering in three dimensions is highly constrained, and we show that only two families of such filament bundles permit equidistant configurations of their constituent filaments: those with bend, but no twist, and those with twist, but no bend. The elastic response of bent and twisted bundles with no such ordered ground state, such as those formed by DNA plasmids under confinement, is then doubly geometrically frustrated: the presence of twist frustrates crystalline order in the cross-section, and the presence of bend couples this compromise structure to the filament tangents. In filaments, as in many frustrated systems, the global response to deformations can not be adequately described by a linear energy. We present a fully nonlinear theory for the elasticity of bundles with one-dimensional components which can slide freely along their tangents, and discuss the response of Euclidean filament packings to the imposition of non-equidistant geometries.

8:00AM K64.00001: Award for Outstanding Doctoral Thesis Research in Biological Physics Talk: Mechanics and energetics of the bacterial flagellar motor* [Invited] JASMINE NIRODY (Presenter), Center for Studies in Physics and Biology, Rockefeller University — The bacterial flagellar motor (BFM) is an ion-powered nanomachine that drives swimming in many bacteria. This protein complex is comprised of several transmembrane rings connected to a long flagellar filament by a flexible hook. Rotation is known to occur via an interaction between one or more membrane-embedded “stator” units, and protein spokes on the periphery of the spinning “rotor” ring. In this talk, I will touch on three features of the motor: (1) its fundamental mechanochemical cycle, (2) the dynamic remodelling of motor structure in response to its environment, and (3) the efficiency of the motor. First, taking into account all the structural and dynamic biophysical experimental evidence to date, we present a mechanically-specific, testable model of the motor's mechanism of torque generation. We validate this theoretical model of the BFM's mechanochemical cycle against experiments done on motors with a single stator. Second, we extend this base model to consider the behavior of multi-stator motors. Stator units have been shown to dynamically bind and leave the motor. We present several recent experiments that shine light on the nature of this complex process, which is influenced by several factors, including the ion gradient, external load, and motor speed. Finally, we also discuss experiments directly measuring the relationship between ion flux through the membrane and motor speed, towards answering the question of whether the motor is loosely or tightly coupled to ion flux — that is, whether each ion passage constitutes a fully efficient power stroke.

8:36AM K64.00002: Invariance properties of bacterial random walks inside domains with variable geometry and structural disorder [Invited] ROBERTO DI LEONARDO (Presenter), Università di Roma — Motile cells often explore natural environments characterized by a high degree of structural complexity. Moreover cell motility is also intrinsically noisy due to spontaneous random reorientation and speed fluctuations. The interplay of different noise sources gives rise to complex dynamical behavior that can be strongly sensitive to details and hard to model quantitatively. In striking contrast to this general picture we show that the mean residence time of swimming bacteria inside artificial complex microstructures can be quantitatively predicted by a generalization to active matter of a recently discovered invariance property of random walks. By systematically varying geometry and structural disorder we produce systems that exhibit strongly different distributions of path length and dwell time but whose mean values is invariant and can be predicted with precision by the sole free volume to surface ratio.

Biological implications include the possibility of predicting and controlling the colonization of complex natural environments using only geometric informations.

9:12AM K64.00003: Spontaneously oscillating synthetic cilia* ISABELLA GUIDO (Presenter), ANDREJ VILFAN, Ramin Golestanian, Eberhard Bodenschatz, Max Planck Institute for Dynamics and Self-Organization, KAZUHIRO OIWA, Advanced ICT Research Institute, National Institute of Information and Communications Technology (NICT) — Cilia and flagella produce rapid and regular bending waves responsible for the propulsion of organisms in fluids or for the promotion of fluid transport. It is known that the main contribution to their beating is due to motor proteins, dynein, which drives sliding of the microtubule doublets. However, the fundamental mechanism of the dynein-microtubule interaction is still a puzzle. Here we investigate their mechanical interaction and emergent behavior by analyzing a minimal synthetic system that we experimentally assemble with two microtubules and few dynein motors. We observe that the microtubule pair undergoes cyclical association/dissociation interaction through rhythmic bending, followed by a complete detachment of the microtubules and subsequent re-attachment. By considering the shearing force produced by the motors when they move along the adjacent microtubule and the finite elasticity of the system, we describe this beating cycle in terms of the curvature and dynein-microtubule binding force.

**9:24AM K64.00004: Quantitative in vivo measurements of cerebrospinal fluid flow through perivascular spaces in the brain**

JEFFREY TITHOF (Presenter), University of Rochester, HUMBERTO MESTRE, TING DU, WEI SONG, WEIGUO PENG, AMANDA M SWEENEY, GENARO OLVEDA, University of Rochester Medical Center, JOHN H THOMAS, University of Rochester, MAIKEN NEDERGAARD, University of Rochester Medical Center, DOUGLAS H KELLEY, University of Rochester — Recent discoveries have uncovered a novel route for the flow of cerebrospinal fluid (CSF) through the brain which is important for the removal of protein waste, such as amyloid-β. Characterizing this flow and the mechanisms which reduce it may offer new insight into the development of neurodegenerative diseases, such as Alzheimer's disease, which are correlated with accumulation of protein waste. CSF enters the brain along perivascular spaces (PVSs) — annular tunnels around arteries — and arterial pulsations are hypothesized to drive these flows, but this has never been quantitatively shown. We perform experiments to measure PVS flows by injecting microspheres into the CSF of living mice, imaging PVSs using two-photon microscopy, and performing particle tracking velocimetry. These measurements offer the first quantitative evidence demonstrating that CSF is driven through PVSs by arterial pulsations. Furthermore, by increasing blood pressure, we observe changes in the arterial pulsations and a net reduction in the CSF flow speed. Our results offer one potential causal mechanism which may contribute to reduced protein waste clearance and development of neurodegenerative diseases.

**9:36AM K64.00005: Flows and Stability of a 3D Active Nematic**

KEVIN SKOWRONSKI (Presenter), GUILLAUME DUCLOS, Brandeis University — Filamentous bacteriophage (fd virus) have an elongated, rod-like shape, and have served as a well-known model for lyotropic passive liquid crystals. At low concentrations, fd virus in suspension maintain an isotropic orientation; however, as the virus concentration is increased, the system undergoes a transition to a liquid crystalline phase where the nematic elasticity induces long range order. We can drive this material out of equilibrium by doping it with active filaments that consume chemical energy to self-propel, and probe for novel far-from-equilibrium behaviors. Here, we use microtubules, clusters of kinesin motors, ATP, and a depletant polymer that induces bundling of the microtubules. We combine this active microtubule system with a dense suspension of fd virus to create a 3D out-of-equilibrium composite liquid crystal. By varying the concentration of fd virus and microtubules in the system, we experimentally determine the extent to which the coupling between activity, nematic elasticity, and confinement influence the emergence of collective flows or control the stability, in both the isotropic and the nematic phases.

**9:48AM K64.00006: Live cell and in vitro mitotic spindles as arrested liquid crystal tactoids.**

SUMON SAHU (Presenter), Department of Physics, University of Massachusetts, Amherst, BIANCA EDOZIE, Department of Biochemistry and Molecular Biology, University of Massachusetts Amherst, PATRICIA WADSWORTH, Department of Biology, University of Massachusetts Amherst, JENNIFER ROSS, Department of Physics, University of Massachusetts, Amherst — Microtubule self-organization is a fundamentally important phenomenon from both physics and biological point of view. One interesting and important structure is the mitotic spindle, a football-shaped structure used to align and ultimately separate the chromosomes during cell division. Recent studies have claimed that the meiotic spindle is internally organized like a liquid crystal tactoid with many, short microtubules that are fluid-like and can coalesce like droplets. Using live cell experiments, we find that the regions of mitotic spindle near the chromosomes are more fluidized, but other regions are arrested. Using photoactivation, we can measure the dynamics of different regions of the spindle and the relative concentration of microtubule-associated proteins and motors as a function of the microtubule concentration. In addition, we use in vitro reconstitution experiments of microtubule polymerization in the presence of a microtubule cross linker, MAP65, and depletion agents that can form spindle-like structures. Using FRAP experiments, we found that these spindle-like assemblies are not fluid, but rather arrested, unlike liquid crystals. Using this combination of live cell and in vitro reconstitution, we are uncovering the physical organizations of the mitotic spindle.
10:00AM K64.00007: Actin assembly alone can drive inward and outward membrane deformations  CAMILLE SIMON (Presenter), REMY KUSTERS, VALENTINA CAORSI, Physico Chimie Curie UMR 168, Institut Curie, JOANNEY JEAN-FRANCOIS, ESPCI, CLÉMENT CAMPILLO, LAMBE, Université Evry, JULIE PLASTINO, PIERRE SENS, CÉCILE SYKES, Physico Chimie Curie UMR 168, Institut Curie — The cell membrane is able to deform inward, as during the initiation of endocytosis, or outward, as during the formation of filopodia. Interestingly, both deformations are generated by the same branched, Arp2/3-based, polymerizing actin network. How an inward or an outward deformation can be obtained in the same network structure? What are the physical parameters that will trigger the direction of membrane deformation? To address these questions, we use a reconstituted membrane system of liposomes and purified actin. We investigate the conditions under which the actin cytoskeleton induces inward or outward membrane deformations. We reveal that actin dynamics are the essential player of membrane deformations by photo-damaging the actin structure that relaxes membrane shape. Lowering membrane tension is key to produce filopodia-like structures. Oppositely, endocytic-like structures are robust features that only weakly depend on membrane tension. A pulse-chase two color actin experiment and the labeling of the proteins associated to actin reveal the details of network growth during inward or outward membrane deformation. Our results, supported by theoretical models, explain how such deformations depend on a mechanical balance between the membrane and the actin network.

10:12AM K64.00008: Local, biased polymerization kinetics lead to slow axonal transport of actin  NILAJ CHAKRABARTY (Presenter), Department of Physics and Astronomy, Ohio University, PANKAJ DUBEY, Department of Pathology and Laboratory Medicine, University of Wisconsin-Madison, YONG TANG, Department of Molecular and Cellular Physiology, Stanford University, ARCHAN GANGULY, KELSEY LADT, Department of Neurosciences, University of California, San Diego, CHRISTOPHE LETERRIER, CNRS, Aix-Marseille Universite, SUBHOJIT ROY, Department of Neuroscience, University of Wisconsin-Madison, PETER JUNG, Department of Physics and Astronomy, Ohio University — Actin, a key protein constituent of the neuronal cytoskeleton is conveyed along the axon at rates corresponding to slow axonal transport. However, the mechanism of this movement is unknown. Recent advances in live imaging of F-actin and super-resolution imaging has revealed that axonal actin is highly dynamic, undergoing focal assembly, disassembly and elongation bidirectionally along the axon. Actin filaments have an anterograde bias, are locally polymerized and grow with their barbed ends attached to stationary axonal endosomes. We generated the dynamics of axonal actin trail assembly using a model of stochastic filament nucleation and elongation which incorporates imaging data. We then devised a photoactivation simulation to track fluorescently labeled actin in the axon, which closely matches the pulse-chase experiment paradigm. Our simulations predict that local, biased polymerization of actin trails lead to global, anterograde actin transport at rates matching in-vivo pulse-chase experimental rates. Collectively, the simulations and experiments point to local assembly and biased polymerization forming the mechanistic basis of bulk transport. This mechanism is distinct from motor-driven polymer sliding and occurs without any significant contribution from microtubules.

10:24AM K64.00009: Impact of filament dynamics on actomyosin flows  DANIELLE SCHEFF (Presenter), MARGARET GARDEL, Department of Physics, University of Chicago — While myosin driven activity in actin networks has proven to be a good model system for studying active matter, actin filaments have internal dynamics that are less well understood. In cells, filaments continuously depolymerize on one end while repolymerizing on the other, an active process that can both relax stresses by depolymerizing stretched filaments and create forces by driving actin into the cell membrane. Here, we study how this activity affects the ability of actin networks to store energy and propagate forces. Using a minimal system we previously developed, we are able to add actin dynamics to systems composed of both short filaments, which form a liquid crystal, and long ones, which form a contractile-network when in the presence of myosin motors. Preliminary results suggest that filament dynamics cause actomyosin networks to contract uniaxially, implying that dynamic filaments contract through sliding, in contrast to stable filaments which contract through buckling. Simultaneously, dynamics redistribute actin allowing the network to maintain long-lasting contractile flows.
10:36 AM K64.00010: Noise induced escape in delay coupled mixed-reality systems
KLEMENTYNA SZWAYKOWSKA
(Presenter), IRA SCHWARTZ, JASON HINDES, United States Naval Research Laboratory — Networks of coupled subsystems are
common in many fields, from biology to epidemiology and robotics. The emergent behaviors of these systems depend on
the nature of the interaction and the communication network. It is now well-known that delay in communication between
individual agents significantly impacts dynamic pattern formation. In addition, noise propagation through coupling can
lead to complex system-wide behaviors. We consider a mixed-reality (MR) system in which delay-coupled real and
simulated agents fly together in formation, and show how noise acting on the real agents can induce a large transition in
the simulated agents. In order to address this problem, we first analyze a generic model of two weakly delay-coupled
dynamical systems. We show how noise in one system can drive a catastrophic state transition in the other, even as the
noisy system exhibits only small random oscillations; further, we show how the expected transition time scales as a
function of the coupling strength and communication delay. We use an analogous approach to study changes in the flight
formation of MR agents.

10:48 AM K64.00011: Modeling nonequilibrium self-assembly in the cell through reaction-diffusion simulation
MATTHEW VARGA, Johns Hopkins University, OSMAN YOGURTCU, Food and Drug Administration, MARGARET JOHNSON
(Presenter), Johns Hopkins University — In diverse cellular pathways including clathrin-mediated endocytosis (CME) and viral
bud formation, cytosolic proteins must self-assemble and induce membrane deformation. These essential processes
require localization to the membrane at particular times within the cell, relying in part on the nonequilibrium activity of
energy consuming kinases, phosphatases, and ATPases to produce robust and reversible assemblies. Current
computational tools for studying self-assembly dynamics are not feasible for simulating cellular dynamics due to the slow
time-scales and the dependence on energy-consuming events. We recently developed novel reaction-diffusion algorithms
and software that enable detailed computer simulations of nonequilibrium self-assembly over long time-scales. Our
simulations of clathrin-coat assembly in CME reveal how the formation of structured lattices impacts the kinetics of
assembly, and how localization to the membrane can stabilize large, dynamic assemblies not observed in solution. We also
recently developed a relatively simple theory to quantify how localization of protein binding partners to the membrane
can dramatically enhance binding, via reduction of dimensionality. Membrane localization can thus provide a trigger for
assembly.

Session K65 DBIO DPOLY GSNP GSOFT: Phase Separation in Biological Systems BCEC 260 - Jean-
Charles Walter, Université de Montpellier - Tag(s): Focus

8:00 AM K65.00001: Permeation of small molecules in phase separated lipid bilayer domains
MARTIN GIRARD
(Presenter), TRISTAN BEREAU, Max Planck Institute for Polymer Research — Membranes of cells are constituted of lipid bilayers,
which can phase separate into ordered domains called rafts. Recent atomic simulations have shown that ionic permeation
is enhanced at the gel-liquid interface of rafts near the melting temperature. Herein, we revisit permeation of small
molecules at raft interfaces using the coarse-grained MARTINI model. Namely, we study how the free energy of insertion
changes with the small molecule, lipid composition and temperature.

*We acknowledge funding from the Emmy Noether program of the Deutsche Forschungsgemeinschaft (DFG).
8:12AM K65.00002: Aggregation of cells dispersed in packed microgels  
CAMERON MORLEY, University of Florida, \( \text{KATHERINE KIWIMAGI, JESSE TORDOFF, RON WEISS, MIT, THOMAS ANGELINI (Presenter), University of Florida} \) — Mixtures of different types of living cells within cultured spheroids segregate in space, sometimes forming core-shell distributions. One long-standing potential mechanism behind this process is described by the differential adhesion hypotheses, which states that cells having differing levels of adhesivity will separate into groups. While this hypothesis has been tested in many ways, alternative driving forces have been proposed. To investigate an extreme limit of cell clustering and segregation, we perform studies using only one cell-type at a time, replacing all other cells with passive, non-adhesive microgel particles. Multiple cell types with tunable cadherin densities are dispersed in polyacrylamide microgels at different volume fractions and monitored over time. In this talk, we will present data on the kinetics of aggregation, the physical characteristics of clusters including fractal dimension, and the role of adhesion energy density on aggregates. By treating microgels as passive, non-adhesive “surrogate” cells, we envision testing theoretical models of active matter designed to study cell-cell phase separation, but in this case setting the appropriate parameters to zero.

8:24AM K65.00003: Evolutionary analysis of pollen patterns as a curious consequence of modulated phases  
ASJA RADJA (Presenter), University of Pennsylvania, \( \text{MAXIM O LAVRENTOVICH, Physics, University of Tennessee, ALISON SWEENEY, University of Pennsylvania} \) — Pollen grain surface morphologies are famously diverse; each species displays a unique, replicable pattern. The function of these microstructures is poorly understood, largely because it is difficult to describe these patterns in a well-defined, mathematical way. It has been shown that the templating of these patterns is created by a phase separation of a polysaccharide mixture on the cell surface. Here we present a characterization of the surface morphologies using a Landau theory of phase transitions to ordered states. We show that 10% of all morphologies can be characterized as equilibrium states with a well-defined wavelength of the pattern. The rest of the patterns have a range of wavelengths on the surface that can be recapitulated by exploring the evolution of a conserved dynamics model. We then perform an evolutionary trait reconstruction where we categorize all extant patterns into one of these two states, further binned by wavelength ranges. Surprisingly, we find that although the equilibrium states have evolved multiple times, evolution has not favored these ordered-polygonal like shapes and perhaps their patterning is simply a natural consequence of a phase separation process without cross-linkers.

8:36AM K65.00004: Spatial control of irreversible protein aggregation  
CHRISTOPH WEBER (Presenter), Biological Physics, Max Planck Institute for the Physics of Complex Systems, \( \text{THOMAS MICHAELS, L MAHADEVAN, Engineering and Applied Sciences, Harvard} \) — Liquid cellular compartments form in the cytoplasm and can regulate aberrant protein aggregation. Yet the mechanisms by which these compartments affect protein aggregation remain unknown. Here, we combine kinetic theory of protein aggregation and liquid-liquid phase separation to study the spatial control of irreversible protein aggregation in the presence of liquid compartments. We find that even for weak interactions aggregates strongly enrich inside the liquid compartment relative to the surrounding cytoplasm. This enrichment is caused by a positive feedback mechanism of aggregate nucleation and growth driven by a flux maintaining the phase equilibrium between the compartment and the cytoplasm. Our model establishes a link between specific aggregating systems and the physical conditions maximizing aggregate enrichment in the compartment. The underlying mechanism of aggregate enrichment could be used to confine cytotoxic protein aggregates inside droplet-like compartments but may also represent a common mechanism to spatially control irreversible chemical reactions in general.

8:48AM K65.00005: Density and viscosity measurements on the liquid condensates of FUS protein low-complexity domain  
CHAO JI (Presenter), \( \text{ERIC GIRARDI, NICHOLAS FAWZI, JAY TANG, Brown University} \) — Recent discoveries have revealed in living cells the formation of liquid droplets consisting of proteins, RNA & DNA. Changes in interactions among these biomolecules may result in devastating diseases, such as amyotrophic lateral sclerosis (ALS). Thus, investigating the physical properties of these liquid droplets in connection with liquid-liquid phase transition is relevant to biomolecular functions and potential therapeutic interventions. We report experiments on the dense liquid droplets formed by FUS (Fused in Sarcoma) low-complexity domain, a section of a protein involved in the development of ALS. By applying a ball drop method under a microscope, we found the density of the protein droplets greater than that of water by 10-15%, indicative of the protein concentration ~200mg/ml. The viscosity of the dilute phase containing FUS droplets is similar to that of water, but viscosity within FUS droplets is very high, ~4000 that of water. Additionally, we found FUS droplets wet solid surface poorly based on the contact angle measurement. These results confirm extremely high protein concentration and strong intermolecular cohesiveness within the condensate state.
Multicomponent Equilibrium Model for the Effects of Charge Regulation on Liquid-liquid Phase Separation of a Globular Eye Lens Protein*  
GEORGE M THURSTON (Presenter), JOHN F HAMILTON, DAVID ROSS, AARON FADDEN, Rochester Institute of Technology, CHRISTOPHER W WAHLE, Video Gaming Technologies, Inc., LEA VACCA MICHEL, JULIA FARAONE, SYMEON BUSHUNOW, Rochester Institute of Technology — We study how charge regulation affects liquid-liquid phase separation of bovine gammaB-crystallin. Our grand-canonical distribution model indicates that hundreds of charging patterns have enough probability to affect protein interactions. We measured times for rotational diffusion via nuclear magnetic resonance, and for translational diffusion to neighbors with quasielastic light scattering. Both times are orders of magnitude faster than time scales for some protonation state changes of titrating residues. Here, we apply chemical equilibrium conditions to a first-order perturbation model for the multicomponent, pattern-dependent free energy. Standard chemical potentials result from our existing dilute solution model. We estimate screened electrostatic, pattern-pair dependent interactions using a linearized Poisson-Boltzmann code that accounts for dielectric heterogeneity and includes all titratable groups. We estimate van der Waals interactions using a simplified protein geometry, and adopt an effective Hamaker coefficient by comparison with the experimental second virial coefficient. This model provides a framework for evaluating how charging pattern probabilities change with increasing concentration, and how they affect liquid-liquid coexistence.

*Supported by NIH R15EY018249

Mediator and RNA polymerase II forms phase-separated bodies and colocalizes with centrosomes during mitosis.*  
CHOONGMAN LEE (Presenter), WON-KI CHO, JAN-HENDRIK SPILLE, IBRAHIM CISSE, Department of Physics, MIT — In interphase, transcriptional proteins such as RNA polymerase II and Mediator are known to form phase-separated bodies to regulate an expression level of SE-controlled genes. However, a behavior of such proteins during mitosis, a cell cycle stage in which most transcriptional activities are silent, is still poorly understood. Here, we show that RNA polymerase II and Mediator form phase-separated bodies during mitosis. Unlike condensates in interphase which are formed based on clustered enhancer elements, condensates in mitosis are formed based on pericentriolar materials, which are phase-separated bodies in mitosis. We suggest that centrosomes play a role of not only microtubule-organizing centers but also protein storages for immediate transcriptional activities after mitosis.

*This work was supported primarily by the NIH director's New Innovator award (DP2CA19569 to I.I.C.) and also by the Pew Charitable Trusts through the Pew Biomedical Scholars Program grant (to I.I.C.)

Liquid-like protein condensates are glassy  
LOUISE JAWERTH (Presenter), Max Planck Institute for the Physics of Complex Systems, ELISABETH FISCHER-FRIEDRICH, ANTHONY HYMAN, Max Planck Institute of Molecular Cell Biology and Genetics, FRANK JULICHER, Max Planck Institute for the Physics of Complex Systems — Liquid-like protein condensates (LLPCs) are intracellular compartments that segregate material without the use of a membrane. The liquid-like behavior of the condensates is a defining characteristic and the viscosity, surface tension and other material properties determine how segregated species diffuse into and within condensates; they, thus, critically impact the biological function of the condensates. It has become increasingly clear that some LLPCs do not have time-independent material properties, but can, instead, transition to more solid, gel-like materials. Here, we present our efforts to quantify these new materials as they age in vitro. We measure the visco-elastic material properties of two proteins, PGL-3 and FUS, by means of a combination of active and passive microrheology. At early times, we find that the droplets behave much like simple liquids but gradually become less elastic. Surprisingly, the changing mechanical properties can all be scaled onto a single master curve using one characteristic time scale which grows as the sample ages. This and other features we observe bear a striking resemblance to the behaviors observed in materials with glass-like aging suggesting that LLPCs are in fact not simple liquids but, rather, a type of soft glass.
Effective long range interactions generated by polymer fluctuations induce bound particle phase separation*  

Gabriel David (Presenter), Jean-Charles Wallter, Laboratoire Charles Coulomb (L2C), CNRS, Univ. Montpellier, Montpellier, France, Chase Broedersz, Arnold Sommerfeld Center for Theoretical Physics and Center for Nanoscience, Ludwig-Maximilian-Universität München, D-80333 München, Germany, Jérôme Dorignac, Frédéric Geniet, Andrea Parmeggiani, Nils-Ole Walliser, John Palmeri, Laboratoire Charles Coulomb (L2C), CNRS, Univ. Montpellier, Montpellier, France — The confinement of chemical species within the cytoplasm is mandatory for the spatio-temporal organization of chemical activities in the cell. Cells indeed compartmentalize the intracellular space using either membrane-bound vesicles or membrane-less organelles. For the latter, cells may employ phase separation of chemical species in order to create localized high density regions in which specific reactions may occur. Such biological phase separation mechanisms often need polymeric scaffolds such as RNA or DNA to bind the chemical species. We propose a general theoretical 3D framework for such polymer-bound particles from which we derive an effective 1D lattice gas model with both nearest neighbor and long range interactions, the latter arising from polymer fluctuations. We argue that 1D phase transitions exist in such system for both Gaussian and self-avoiding polymers and, using a variational method that goes beyond mean field theory, we obtain the mean occupation/temperature phase diagram. To illustrate this model, we apply it to the biologically relevant case of the ParABS system, a prevalent bacterial DNA segregation system, to study the formation of ParBS complexes on DNA.

*This work is funded by the Agence Nationale de la Recherche (Labex Numev) and the CNRS Défi Inphyniti.

Motif Sequences and the Statistical Physics of Intracellular Phase Separation*  

Benjamin Weiner (Presenter), Princeton University, Yigal Meir, Ben Gurion University, Ned Wingreen, Princeton University — Intrinsically Disordered Proteins (IDPs) lack a unique folded structure, and yet perform diverse and important functions inside cells. Recent work suggests that some IDPs promote the formation of membrane-less organelles via phase separation, helping cells spatially organize their biomolecules. Classical theories of phase separation focus on homogeneous polymers, but IDPs have evolved particular sequences of interacting motifs. How does an IDP's motif sequence determine its physical properties? We propose a statistical physics model of IDPs to elucidate the relationship between motif sequence, conformational disorder, and biological function.

We find that motif sequences strongly influence the statistical properties of model IDPs. Intuitively, each sequence has its own set of spatial conformations which determine the relative entropy of inter- and intra-protein bonds. As a result, the concentration of IDPs required for phase separation depends strongly on the motif sequence. Our work demonstrates the emergence of spatial order from conformational disorder, a process which may play a key role in intracellular organization.

Phase separation and migration in 2D cell co-cultures  

Manuel Gomez-Bera (Presenter), Rochester Institute of Technology, Supravat Dey, University of Delaware, Moumita Das, Rochester Institute of Technology — During morphogenesis, whether in the context of the formation of embryos or of tumors, different types of cells live in close proximity. These cells often have different physical properties. Breast epithelial cells, for example, are generally more adhesive than their cancerous counterparts. This is due to the downregulation of the protein E-cadherin, which facilitates cell-cell adhesion, in cancer cells. Cancer cells are also often more deformable than non-cancerous cells of the same tissue type. We investigate how these differences impact the organization and migration within a binary cell population. To address this, we model and simulate this system as a two-dimensional binary mixture of soft, active particles with different mechanical and adhesive properties. We characterize the phase separation in the system by monitoring the organization and growth of cell clusters with time, and the dynamics in terms of tagged cell trajectories and speeds, mean squared displacements, and non-affine motion. Our results may provide interesting insights into tumor organization, and metastasis.
**10:12AM K65.00012: In vivo dynamics and phase state of natural lipid droplets**  
MARGARITA FOMINA (Presenter), EUGENE MAMONTOV, HUGH O’NEILL, Oak Ridge National Laboratory — All organisms store lipids as energy resource for metabolism. Such lipids are accumulated in the form of intracellular droplets. The lipid droplets (LDs) contain un- and saturated triglycerides. Uncovering biophysics of LDs is crucial for metabolism manipulation or reducing lipid storage. The type and organization of lipids affect their phase state and dynamics in the droplet. We studied LDs in fresh human and porcine subcutaneous fat tissues, as well as yeast cells using quasi-elastic neutron scattering, probing molecular motions in a time scale of 6-400 ps and a length scale of 3-20 Å. The detected two-component dynamics in the droplet is associated with lipid unrestricted diffusion (D~0.006 Å²/ps) and motions of its hydrocarbon chains (D~0.2 Å²/ps) in a restricted volume (5-12 Å). The dynamics of lipids is reduced below 305 K and 266 K in porcine and human tissues, respectively, due to a fluid-gel phase transition of lipids. However, LDs in the yeast cells remain in a fluid-like state within range of 280-310 K. We believe, phase behavior of LDs is different in the tissues and microorganism due to lipid composition. Lipid packing in the droplet is tight in the tissues, having saturated lipids, and loose in the yeast droplet, having equal proportions of un- and saturated lipids.

**10:24AM K65.00013: The role of motility in Myxococcus xanthus droplet formation and droplet geometries**  
CASSIDY YANG (Presenter), KATHERINE COPENHAGEN, JOSHUA SHAEVITZ, Princeton University — Myxococcus xanthus, a rod-shaped soil bacterium lacking long-range interactions, collectively bead from surfaces when starved to form 3D droplet-like aggregates known as fruiting bodies consisting of hundreds of thousands of cells. Active self-propulsive forces of individual bacteria generate local increased pressures that drive the dewetting process. Unlike passive fluids that form axisymmetric spherical cap-shaped droplets, these aggregates are symmetry breaking and are often elongated in an elliptic-like shape. To examine the role of motility in dewetting, we present here the dynamics of both stable and unstable droplet geometries during dewetting and the formation of these fruiting bodies for cells with different Pe numbers. Using sparsely labelled cells, we also track emergent collective flows within these droplets to characterize the internal hydrodynamics and cellular organization.

**10:36AM K65.00014: Mechanical Interplay of Chromatin and Liquid-Liquid Phase Separated Condensates**  
DANIEL LEE (Presenter), Lewis-Sigler Institute for Integrative Genomics, Princeton University, YI-CHE CHANG, Department of Chemistry, Princeton University, YONGDAE SHIN, Department of Mechanical and Aerospace Engineering, Seoul National University, DAVID SANDERS, DAN BRACHA, Department of Chemical and Biological Engineering, Princeton University, PIERRE RONCERAY, Princeton Center for Theoretical Sciences, Princeton University, NED WINGREEN, Lewis-Sigler Institute for Integrative Genomics, Princeton University, CLIFF BRANGWYNNE, Howard Hughes Medical Institute — DNA is organized into chromatin, a complex material which stores information and controls gene expression. One mechanism for biological organization, particularly in the crowded nucleus, is liquid-liquid phase separation (LLPS). Here, we use two optogenetic technologies to show that liquid condensates displace chromatin as they grow. We also demonstrate that these synthetic condensates localize to regions of low-density chromatin. We develop a minimal physical model to explain this stiffness selectivity, wherein droplets prefer low-density chromatin regions due to a lower mechanical energy of deformation. By utilizing these spatiotemporally-controllable optogenetic systems, we construct a phase diagram of an intrinsically disordered transcriptional regulator and estimate the stiffness of the chromatin network. Our work thus not only sheds light on the role of LLPS in chromatin organization but also uses the physical principles of phase separation to elucidate mesoscale features of the nucleus.

8:00AM K66.00001: Mathematical modeling studies on spatial profiles of cytotoxic T cells in solid tumors* XUEFEI LI (Presenter), Rice University, TINA GRUOSSO, MORAG PARK, McGill University, HERBERT LEVINE, Rice University — Infiltration of CD8⁺ T lymphocytes into solid tumors is associated with good prognosis in various types of cancer, including Triple Negative Breast Cancers (TNBC). However, the mechanisms underlying different infiltration-levels are largely unknown. Here, we have characterized the spatial profile of CD8⁺ T cells around tumor-cell clusters in TNBC. Combining mathematical modeling and data analysis, we propose that there exists a possible chemo-repellent inside tumor-cell clusters, which prevents CD8⁺ T cells from infiltrating into tumor-cell clusters. Furthermore, investigation into the properties of collagen fibers suggests that variations in desmoplastic elements does not limit infiltration of CD8⁺ T lymphocytes into tumor-cell clusters, which is consistent with the prediction of our mathematical modeling analysis whereby CD8⁺ T cells are predicted to infiltrate the fibrotic barrier.

*This work was supported by the NSF PHY-1427654, NSF DMS-1361411, The V Foundation, CQDM, the NIH, Merck, Sharpe & Dohme Corp./McGill Faculty of Medicine Grants for Translational Research, the Database and Tissue Bank Axis of the Réseau de Recherche en Cancer of the Fonds de Recherche du Québec-Santé, the Québec Breast Cancer Foundation, and the Charlotte and Leo Karassik Oncology fellowship.

8:12AM K66.00002: Tumor spheroids explode in the presence of interstitial flows revealed by a 3D microfluidic model* YU LING HUANG (Presenter), YUJIE MA, Biological & Environmental Engineering, Cornell University, CINDY WU, Chemical & Biomolecular Engineering, Cornell University, CARINA SHIAU, Biological Sciences, Cornell University, JEFFREY SEGALL, Department of Anatomy & Structural Biology, Albert Einstein College of Medicine, MINGMING WU, Biological & Environmental Engineering, Cornell University — Interstitial flows are ubiquitous in maintaining tissue homeostasis in living systems, and are known to be elevated in malignant tumors. However, most current in vitro assays are carried out in static conditions and do not include fluid flows. In our work, we developed a microfluidic model to study tumor spheroid invasion through 3D collagen architecture under well controlled flows. We discovered that tumor spheroids explode in the presence of flow in contrast to no flow condition. Possible mechanisms underlying this explosion will be discussed in my talk. Our work highlights the importance of biophysical parameters in regulating tumor cell invasion.

8:24AM K66.00003: The Role of Cell Migration Guidance Cues in Emergent Collective Behavior* RACHEL LEE (Presenter), University of Maryland School of Medicine, MATT J. HOURWITZ, PHILLIP ALVAREZ, University of Maryland, College Park, KEYATA N. THOMPSON, MICHELE I. VITOLO, University of Maryland School of Medicine, JOHN T FOURKAS, WOLFGANG LOSERT, University of Maryland, College Park, STUART S. MARTIN, University of Maryland School of Medicine — Studying the dynamics of collective systems can provide insight into how the motion of individual active agents can lead to unexpected emergent collective behavior. As tumors cells migrate to form metastases, a particularly lethal stage of cancer, the cells’ collective behavior is disrupted. Although current research largely focuses on individual cells, recent evidence shows that the most dangerous tumor cells retain the ability to move as collective strands or clusters that metastasize together. In this work, we use quantitative image analysis tools and live-cell imaging to investigate how guidance cues influence cells with different tumorigenicity, leading to distinct migration behavior.

*This research is supported by NIH grant T32-CA154274 and AFOSF grant number FA9550-16-1-0052.

8:36AM K66.00004: Breast cancer cell migration in the bone microenvironment* NATASHA COWLEY (Presenter), RHODA HAWKINS, Physics and Astronomy, University of Sheffield — We are investigating how material confining a cell affects cell motility and behaviour. In particular we look at how rigidity and geometry play a role by investigating the mechanical response of materials with different rigidities to cell generated forces. We model a cell as a viscous droplet with an active contractile boundary analogous to the actin cortex. We use the immersed boundary method to simulate a cell interacting with deformable elastic walls of various geometries. We look at the specific case of breast cancer metastasis to the bone. The majority of patients who die from cancer do so not from the primary tumour, but from the metastasis of cancer to other sites in the body. Breast cancer most commonly metastasises to the bone. We are examining how mechanical forces are involved in this process. Bone tissue is very varied in composition and vastly different from breast tissue. In order to model this varied niche we combine analytical calculations and our simulations, with AFM data from our collaborators. This will further our understanding breast cancer metastasis to the bone and it's motility in the bone microenvironment.

*EPSRC, University of Sheffield
8:48AM K66.00005: Physics of Cancer Metastasis  SEZIN GALIGOLU (Presenter), UNAM, Bilkent University, OZGE AKBULUT, Molecular Biology and Genetics, Bilkent University, ROUJIN GAFFARI, UNAM, Bilkent University, TAYFUN OZCELIK, OZGUR SAHIN, Molecular Biology and Genetics, Bilkent University, SERIM ILDAY, UNAM, Bilkent University — Metastasis is the cause of 90% of deaths related to the cancer. Cancer cells metastasize by entering the bloodstream, where they are dragged to distant parts of the body, and exiting the blood to colonize on another organ. Epithelial-Mesenchymal Transition (EMT) of cancer cells and vice versa (MET), have been proven to be the essential processes underlying metastasis through “static measurements” of biochemical cues. However, it has never been studied under dynamic conditions mimicking the actual physical environment: The blood vessel has an undulated, quasi-2D topology. Blood forms complex flows, e.g., laminar, turbulent, shear flows and their combinations inside this topology. In the bloodstream, the cancer cells are traveling along with many different cells and other entities, where they also face random obstacles. All of these factors are important for the successful completion of the metastasis process. Here, we show how epithelial, mesenchymal, drug-resistant breast cancer cells and healthy breast cells behave in such a dynamic, quasi-2D confined system under complex flows and when faced with random obstacles. We will test their adaptability under extreme physical conditions to conclude the physics of cancer metastasis.

9:00AM K66.00006: Shear stress increases acidic vesicles and proton pumps enhancing prostate cancer progression  ZEINA KHAN (Presenter), FAZLE HUSSAIN, Texas Tech University — Cells in the tumor microenvironment are subjected to increased interstitial fluid pressure due to the angiogenic growth of new leaky blood vessels which triggers lymphangiogenic growth for drainage. This subjects tumor cells to shear stresses of approximately 0.01-0.1 dynes/cm², two to three orders of magnitude smaller than wall shear stresses in blood vessels. While acidic membrane-bound vesicles, such as endosomes and lysosomes, and the V-ATPase proton pumps located on their membranes have been pursued as cancer markers, their role in cancer cell mechanotransduction and enhancing cancer aggressiveness is only recently emerging. We demonstrate that moderately metastatic prostate cancer cells respond to shear stress by increasing endosomes, lysosomes, and proton pumps, thereby activating both complexes of the mechanistic target of rapamycin pathway – mTORC1 and mTORC2 – controllers of autophagy, protein synthesis, glucose and lipid metabolism, and cell cytoskeletal changes. We will also report on shear stress-induced changes in migration and glucose metabolism, where increases accompany enhanced aggressiveness.

9:12AM K66.00007: Spatial heterogeneity of the mechanics of solid tumors  THOMAS FUHS (Presenter), ERIK W. MORAWETZ, FRANK SAUER, STEFFEN GROSSER, JOSEF A KÄS, Peter Debye Institute for Soft Matter Physics, Leipzig University — In solid tumors tissue that is stiffer than healthy tissue is formed by cells that are softer than healthy cells. We try to address this contradiction by spatially resolved investigation of the mechanics of solid tumors tissues. We are able to measure the elasticity of slices of solid tumors on the millimeter scale with micrometer spatial resolution by AFM. This avoids measuring only heavily selected regions or only single cells extracted from dissected tissue. At the same time we are able to precisely align our AFM data with immunohistological stains. We can correlate the spatial heterogeneity of the elasticity maps with the distribution of cytokeratin. We complete these measurements with elasticity data on the whole tissue scale obtained by magnetic resonance elastography and single cell data from optical stretcher measurements. Each set of measurements is performed with tissue and from the same tumor, minimizing the error through biological variance within a dataset. Through the combination of the measurements we are able to bridge the scales from single cells to tissue level, to see how the individual cells contribute to the whole.  

9:24AM K66.00008: Mechanical interactions in 3D tumor/fibroblast co-culture models of pancreatic cancer  ERIC STRUTH (Presenter), JONATHAN P CELLI, Department of Physics, University of Massachusetts Boston — Studies have shown that mechanical interactions between tumor cells and stromal components in the tumor microenvironment impact disease progression and therapeutic response. Tumors of the pancreas are associated with an abundance of stiff fibrous stroma impacting growth and drug delivery. Here we use time lapse imaging to study physical interactions between pancreatic ductal adenocarcinoma (PDAC) cells and stromal fibroblasts grown in 3D culture on laminin rich extracellular matrix (ECM). PDAC cells overlaid on ECM form compact multicellular 3D nodules. When fibroblasts are introduced there is a profound change in growth behavior culminating in the formation of large connected structures. We describe quantitative analysis of this behavior using particle image velocimetry. We contrast stromal interactions of PANC1 PDAC cells and a previously established associated drug-resistant sub-line, showing that drug naïve co-cultures and drug resistant co-cultures are quantifiably different in both distribution of per-frame average magnitude over time, as well as final spatial distribution of spheroids in the co-cultures. Going forward, the methodology for cultivating fibrotic PDAC tumors in vitro may comprise a useful platform for screening drug delivery approaches for this lethal disease.

9:36AM K66.00009: Mathematical analysis of the life-span shortening in mice induced by radiation* TAKAHIRO WADA (Presenter), Department of Pure and Applied Physics, Kansai University, TETSUHIRO KINUGAWA, YUICHIRO MANABE, Division of Sustainable Energy and Environmental Engineering, Osaka University, MASAKO BANDO, RCNP, Osaka University — At Institute for Environmental Sciences, Japan, they are conducting experiments to continuously irradiate mice with low dose-rate radiation. In one experiment, they sacrifice a certain number of mice every 100 days and count the number of cancers in the body. They found that, in the irradiated group, the occurrence of cancer happens earlier and the average number of cancer is larger. In the other experiment, they keep the mice until the natural death and they found that the life span is shortened with the increase in the dose rate.

We analyzed the data with a mathematical model. Let $F_C(t)$ be the probability that a mouse has cancers at time $t$ and $P_D(t, s)$ be the probability that a mouse dies by a time $t$ due to a cancer that occurred at time $s$. Then the survival probability at time $t$, $F_S(t)$, is given as $F_S(t) = 1 - \int dF_C(s)/ds P_D(t, s) ds$. In our analysis, $F_C(t)$ is given by the cancer occurrence data. Then by assuming a function form of $P_D(t, s)$, we calculate $F_S(t)$ to compare with the survival data. We found that we can reproduce the survival data by using a simple function for $P_D(t, s)$. We obtained a parameter which expresses the interval between the occurrence of cancer and the death.

9:48AM K66.00010: Multiscale simulation of Ras-Raf interaction SUMANTRA SARKAR (Presenter), ANGEL E GARCIA, Center for Nonlinear Studies, Los Alamos National Laboratory — Cells use a limited number of mutually interacting protein-protein interaction networks, called cell-signalling network to communicate with each other. The protein components of these signalling networks have been identified and their individual functions understood. However, how they interact with each other to produce a functional cell-signalling network is relatively poorly understood. An important cell signalling network involved in the growth and proliferation of cells is the MAPK pathway, which is activated through the formation of phosphorylated Ras-Raf protein complex. The formation of this complex at biologically relevant concentrations span multiple timescales, rendering traditional theoretical and experimental tools inadequate to study this problem in its entirety. Using recently developed accelerated simulation techniques, we have been able to overcome this barrier and have studied Ras-Raf interaction in biologically relevant concentrations and timescales. In this talk, I shall present new aspects of Ras-Raf kinetics revealed through these simulations and discuss their potential biological implications.

10:00AM K66.00011: Structure guided development of anti-cancer flexible-heteroarotinoid compounds* DONGHUA ZHOU (Presenter), MARYAM MASHAYEKHI, DIPENDRA BHANDARI, GIL REPA, Oklahoma State University-Stillwater — Flexible-heteroarotinoid compounds have been developed for their anticancer activities. The lead compound SHetA2 is able to inhibit growth of a variety of cancer cell lines and tumors in animal tests, without toxicity to normal tissues. The growth inhibition is about 84% for A2780 ovarian cancer cell cultures; the inhibition efficacy often decreases in real tissues. Therefore, it is desirable to improve efficacy and potency by designing better analogues. We identified the SHetA2 binding site on the receptor protein mortalin using NMR methods. SHetA2 disrupts the interaction of mortalin with other proteins that are upregulated in cancer cells but not in normal cells. Molecular modeling indicated that the binding strength of an analogue could be enhanced by increasing hydrophobicity of the chroman unit and substitution of a certain polar group. Five series of compounds were synthesized to validate the hypotheses. Several redesigned compounds did outperform the parent compound SHetA2, achieving inhibition efficacy of about 94% along with slightly better potency.

10:12AM K66.00012: Anti-cancer drug containing apolioprotein B lipoparticle reconstitution and tracking in living cell

WEI-PING CHANG (Presenter), CHUNG CHING LIN, HSUEH-LIANG CHU, Department of Biological Science and Technology, National Chiao Tung University, Taiwan, PO-YEN LIN, Division of Core Facilities Imaging, Institute of Cellular and Organismic Biology, Academia Sinica, Taiwan, YU-CHUAN LIANG, Agricultural Biotechnology Research Center, Academia Sinica, Taiwan, CALEB G. CHEN, Department of Hematology-Oncology, Mackay Memorial Hospital, Taiwan, CHIA-CHING CHANG, Department of Biological Science and Technology, National Chiao Tung University, Taiwan — Radicicol (Rad), an Hsp 90 inhibitor, is an antitumor drug which loses its antitumor activity during delivery process, in vivo. By adding Rad in the reconstituting apolioprotein B (apoB) process, a Rad containing reconstituted apoB lipoparticle (rABL) complex (Rad@rABL) can be reconstituted and characterized by photonic spectroscopies, differential scanning calorimetry and super resolution imaging. Interestingly, the Rad@rABL single molecule can be tracked within the living cell. The drug delivery route to the mitochondria in the Hep G2 cell line can be monitored. Moreover, the anticancer efficacy of Rad can be enhanced. In summary, rABL is an excellent and native self-assembly drugs carrier and living cell tracking agent.

10:24AM K66.00013: Predicting patient outcomes (TNBC) based on positions of cancer islands and CD8+ T cells using machine learning approach

GUANGYUAN YU (Presenter), XUEFEI LI, HERBERT LEVINE, Rice University — The infiltrations of T are different in patients, which could be a tool for the prognosis. High CD8+ T cell counts (both overall and inside cancer-cell islands) is associated with better patient outcome. However, a cut-off of the T-cell count has to be selected manually to separate groups of patients. In this work, we propose a method to classify the small patch of triple-negative breast cancer (TNBC) tumor and use the overall percentage of “good” patches as a marker to predict the prognosis, which is an automatic method of prognosis and could also be used for other cancers. The result shows that the machine learns the importance of cell count and cell infiltration and use the combination as an indicator for prognosis.

10:36AM K66.00014: The physics of normal and impaired mitochondrial electron transfer

PAVITHI WEERASINGHE (Presenter), MARTHA VILLAGRAN, Department of Physics and Texas Center for Superconductivity, University of Houston, AIJUN ZHANG, DALE J HAMILTON, Center for Bioenergetics, Houston Methodist Research Institute, BRIAN J MILES, Department of Urology, Houston Methodist, JAREK WOSIK, Department of Electrical and Computer Engineering and Texas Center for Superconductivity, University of Houston, JOHN H MILLER, Department of Physics and Texas Center for Superconductivity, University of Houston — The mitochondrial electron transport chain (ETC) produces most of our bodies’ energy in the form of ATP. Within the ETC, complex II, also known as succinate dehydrogenase (SDH), plays a unique role in that it converts succinate to fumarate as part of the Krebs cycle while simultaneously feeding energetic electrons to the ETC. The electrons travel along a chain of three Fe-S clusters in subunit B (SDHB) before entering the membranous domain containing a heme group and ubiquinone, which ultimately transports them to complex III. Some SDHB mutations in the form of amino acid replacements trigger aggressive growth of certain cancers, such as paraganglioma and pheochromocytoma. We will discuss our collaborative experimental and theoretical program, which includes measurements of human tissue and cell lines, and calculations of normal and mutated electron tunneling rates using Marcus theory. Our preliminary results suggest that some mutations disrupt SDHB electron pathways, causing many electrons to fail to reach their ubiquinone target and instead spill out to generate reactive oxygen species that increase tumorigenicity.

10:48AM K66.00015: Comparison of Subcellular Nanoparticle Size Distributions Across Cell Types with Light Transmission Spectroscopy

ALISON DEATSCH (Presenter), PATRICK SANSONE, NAN SUN, CAROL E TANNER, STEVEN THOMAS RUGGIERO, Physics, University of Notre Dame — The cellular cytoplasm is a complex environment with a wide breadth of both size and concentration of particles, making a comprehensive survey of the subcellular structures interesting and difficult. Using LTS, we measure optical extinction spectra over a wavelength range of ~220-1000 nm, then apply Mie Theory to obtain particle size distributions (PSD). We present improvements to previous spinach cell PSDs, as well as those of new cell types and a comparison of healthy and cancer cells. With a combination of advanced filtration and quantitative LTS (a method of obtaining the concentration directly from the magnitude of the absorption peaks in the extinction spectra), we have improved the measurement of particles <100 nm, allowing the accurate assessment of PSDs over a wide size range: from ~5 nm to 3000nm. These PSDs reveal a power law dependence of particle concentration, \( N(D) \propto D^{-\alpha} \), where \( N(D) \) is the number of particles of diameter, \( D \), per unit volume. This reflects the fractal nature of the cytoplasm as a self-similar system of spheres on many size scales, with the goal to enrich our understanding of the fundamental nature of particle packing in the cytoplasm.

Session L01 DCMP: Fractional Quantum Hall Effect: Composite Fermions BCEC 106 - Steven Simon, University of Oxford

11:15AM L01.00001: Fractional Quantum Hall Effect at $\nu=2+6/13$: The Parton Paradigm for the Second Landau Level AJIT COIMBATORE BALRAM (Presenter), Niels Bohr International Academy and the Center for Quantum Devices, Niels Bohr Institute, SUTIRTHA MUKHERJEE, Quantum Universe Center, Korea Institute of Advanced Study, KWON PARK, School of Physics and Quantum Universe Center, Korea Institute for Advanced Study, MAISSAM BARKESHLI, Physics, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, MARK RUDNER, Niels Bohr International Academy and the Center for Quantum Devices, Niels Bohr Institute, JAINENDRA JAIN, Physics, Pennsylvania State University — The unexpected appearance of a fractional quantum Hall effect (FQHE) plateau at $\nu=2+6/13$ [Kumar et al., Phys. Rev. Lett. 105, 246808 (2010)] offers a clue into the physical mechanism of the FQHE in the second Landau level (SLL). Here we propose a \texttt{\bar{3}\bar{2}111} parton wave function and demonstrate it to be a good candidate state for this phase. We make several predictions for experimentally measurable properties that can reveal the nature of this state and also distinguish it from the topologically distinct 6/13 state realized in the lowest Landau level. Taking these results together with the recent demonstration that the related \texttt{\bar{2}\bar{2}111} wave function is a good candidate for the ground state at $\nu=2+1/2$ [Balram et al., Phys. Rev. B 98, 035127 (2018)], we propose that the \texttt{\bar{n}\bar{2}111} family of parton wave functions naturally describes the experimentally observed sequence of SLL FQHE plateaus at 2+2/3, 2+1/2 and 2+6/13, and their hole partners.

11:27AM L01.00002: On the Interpretation of Thermal Conductance of the $\nu=5/2$ Edge STEVEN SIMON (Presenter), University of Oxford — Recent experiments [Banerjee et al, Nature 2018] have measured thermal conductance of the $\nu=5/2$ edge in a GaAs electron gas and found it to be quantized as $K \approx 5/2$ (in appropriate dimensionless units). This result is unexpected, as prior numerical work predicts that the $\nu=5/2$ state should be the Anti-Pfaffian phase of matter, which should have quantized $K = 3/2$. The purpose of this paper is to propose a possible solution to this conflict: if the Majorana edge mode of the Anti-Pfaffian does not thermally equilibrate with the other edge modes, then $K = 5/2$ is expected. I discuss several possible reasons for this nonequilibration, and discuss possible mechanisms in some detail. I further discuss what should be examined further to determine if this is the case.

*EPSRC grants EP/I031014/1 and EP/N01930X/1.
11:39AM L01.00003: Dirac Composite Fermions and Emergent Reflection Symmetry about Even Denominator Filling Fractions*  HART GOLDMAN (Presenter), EDUARDO HECTOR FRADKIN, University of Illinois at Urbana-Champaign — Motivated by the appearance of a “reflection symmetry” in transport experiments and the absence of statistical periodicity in relativistic quantum field theories, we propose a series of relativistic composite fermion theories for the compressible states appearing at filling fractions $\nu = 1/2n$ in quantum Hall systems. These theories consist of electrically neutral Dirac fermions attached to $2n$ flux quanta via an emergent Chern-Simons gauge field. While not possessing an explicit particle-hole symmetry, these theories reproduce the known Jain sequence states proximate to $\nu = 1/2n$, and we show that such states can be related by the observed reflection symmetry, at least at mean field level. We further argue that the lowest Landau level limit requires that the Dirac fermions be tuned to criticality, whether or not this symmetry extends to the compressible states themselves.

11:51AM L01.00004: Partial Equilibration of Integer and Fractional Edge Channels in the Thermal Quantum Hall Effect*  KWOK WAI MA (Presenter), DMITRI FELDMAN, Brown University — Since the charged mode is much faster than the neutral modes on quantum Hall edges at large filling factors, the edge may remain out of equilibrium in thermal conductance experiments. This sheds light on the observed imperfect quantization of the thermal Hall conductance at $v=8/3$ and can increase the observed thermal conductance by two quanta at $v=8/5$. Under certain unlikely but not impossible assumptions, this might also reconcile the observed thermal conductance at $v=5/2$ with not only the PH-Pfaffian order but also the anti-Pfaffian order.

*This research was supported in part by the National Science Foundation under Grant No. DMR-1607451

12:03PM L01.00005: Finite-thickness effect of the fractional quantum Hall states in the second Landau level*  PENGJIE WANG (Presenter), JIAN SUN, YIJIA WU, International Center for Quantum Materials, Peking University, HUA CHEN, Department of Physics, Zhejiang Normal University, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University, XINCHENG XIE, XI LIN, International Center for Quantum Materials, Peking University — Given the finite thickness of the samples in experiments, the in-plane magnetic field will squeeze the single-particle electron wave function in the direction perpendicular to the plane, effectively decrease the quantum well (QW) width and modify the electron interaction. However, this effect has only been reported in the non-Abelian candidate, 5/2 fractional quantum Hall (FQH) state, while other FQH states in the second Landau level (SLL), including the particle-hole conjugate of 5/2 FQH state, i.e. 7/2 FQH state, remain uninvestigated. We will present our energy gap measurements of the FQH states (7/3, 5/2, 8/3 and 7/2) in the SLL under tilted magnetic fields. A universal critical in-plane magnetic field of around 1.0 T is observed at different fillings, which corresponds to an in-plane magnetic length of around 26 nm. This critical value is comparable with the QW width of 28 nm in our sample, indicating the finite-thickness effect in the SLL. At higher in-plane magnetic fields, we found that the FQH states deviates from its strengthening tendency with in-plane field, further demonstrating the finite-thickness effect.

*The work was funded by NBPRC (2015CB921100), NSFC (11674009), Gordon and Betty Moore Foundation (GBMF4420), NSF MRSEC (DMR-1420541) and Keck Foundation.

12:15PM L01.00006: Strain-induced resistance anisotropy near the FQHE $v=5/2$ in two-dimensional GaAs single quantum wells*  ALEXANDER STERN (Presenter), Physics of Quantum Materials, Max Planck Institute for Chemical Physics of Solids, BRIAN CASAS, Department of Physics and Astronomy, University of California Irvine, JOHANNES POLLANEN, Department of Physics and Astronomy, University of California Irvine, JAMES EISENSTEIN, Department of Physics, California Institute of Technology, KENNETH WEST, LOREN PFEIFFER, Department of Electrical Engineering, Princeton University, JING XIA, Department of Physics and Astronomy, University of California Irvine — We report strain-dependent low temperature magnetotransport measurements of a two-dimensional electrons gas confined in GaAs single quantum wells. The samples are mounted to a piezoelectric-based strain device with which we can apply, and vary, tensile strain in the quantum well in situ. With this apparatus we have achieved strain as large as $-0.5\%$ in GaAs quantum wells at cryogenic temperatures. We find that with increasing strain with a high magnetic field applied causes the magnetoresistance of the two-dimensional electron system confined in the quantum well to develop anisotropic resistance near the FQHE $v = 5/2$. Additionally, we find that this strain and field induced resistance anisotropy is caused by a meta-stable phase that has a temperature dependent decay back to its isotropic state.

*The work at UC Irvine is supported by NSF Grant No. DMR-1350122
12:27PM L01.00007: Principal component analysis of quantum Hall wave functions  NA JIANG (Presenter), SIYAO KE, XIN WAN, Zhejiang University — The fractional quantum Hall effect demonstrates the robustness of topological properties in many-body systems. The effect of mass and interaction anisotropy can be understood in terms of a geometrical description. We present a study of the evolution of quantum Hall wave functions with interaction anisotropy by a statistical learning technique known as the principal component analysis (PCA). We show that the topological and geometrical aspects of a family of wave functions can be readily separated by the PCA. We discuss how to use the PCA to extract wave function metric and to determine the stability of a fractional quantum Hall phase.

12:39PM L01.00008: Hamiltonian theory for Quantum Hall systems in a tilted magnetic field: composite fermion geometry and robustness of activation gaps  KANG YANG (Presenter), University of Paris VI: Pierre-and-Marie-Curie University, MARK OLIVER GOERBIG, University of Paris-Sud, BENOÎT DOUÇOT, University of Paris VI: Pierre-and-Marie-Curie University — In 2011, Haldane showed the existence of an internal geometric degree of freedom in the description of incompressible fractional quantum Hall states. The static value of this metric tells us how the quantum Hall system reacts in the presence of anisotropy, e.g. in the electron-electron interaction. We implement this geometry into Shankar and Murthy's Hamiltonian theory, which provides an analytical framework for Jain's composite fermion (CF) picture according to which the fractional quantum Hall effect arises from an integer number of fully filled CF Landau levels. Here, we study a quantum Hall system in a tilted magnetic field. With a finite width of the system in the z-direction, the parallel component of the magnetic field induces anisotropy into the effective two-dimensional interactions. We find that this anisotropy introduces mixing of CF Landau levels and thus perturbs the Hartree-Fock CF state of the Hamiltonian theory. By changing the internal geometry of the CF, such a perturbation can be minimized by optimizing the underlying metric, and we calculate the corresponding activation gaps for different tilt angles. Our results show that the activation gaps are remarkably robust against the in-plane magnetic field in the lowest and first Landau levels.

12:51PM L01.00009: A Josephson relation for fractionally charged anyons.*  MAELLE KAPFER, PREDEN ROULLEAU, Service de Physique de l'Etat Condense, CEA Saclay, IAN FARRER, Department of Electronic and Electrical Engineering, University of Sheffield, DAVID A RITCHIE, Department of Physics, Cavendish Laboratory, CHRISTIAN GLATTLI (Presenter), Service de Physique de l'Etat Condense, CEA Saclay — Anyons (intermediate between bosons and fermions) occur in two-dimensional electron systems in high magnetic field as fractional excitations with charge \( e^* = e/q \) in the topological ordered states of the Fractional Quantum Hall Effect (FQHE). Owing to their importance for topological quantum phases and possible decoherence free quantum information approaches, understanding anyons is of utmost importance. However, experiments probing their dynamics are lacking. Here we report on a dynamical property of anyons: the long predicted Josephson relation \( f_J = e^* V / h \) for charge \( e^* = e/3 \) and \( e/5 \). It manifests as marked signatures in the Photo Assisted Shot Noise (PASN) versus voltage \( V \) when irradiating contacts at microwaves frequency \( f = f_J \). The validation of FQHE PASN models opens the way to realize time-resolved anyon sources based on levitons to perform time-domain anyon braiding.

*ANR FullyQuantum AAP CE30 grant

1:03PM L01.00010: Non-Magnetic Fractionally Quantized Conductance in Quasi-One Dimensional Semiconductor Structures*  MICHAEL PEPPER (Presenter), SANJEEV KUMAR, YILMAZ GUL, University College London, MAKSYM MYRONOV, Physics, University of Warwick, DAVID A RITCHIE, Physics, University of Cambridge, IAN FARRER, Electrical Engineering, University of Sheffield, HENRY MONTAGU, University College London — We have investigated quasi-one dimensional carrier transport using holes, (electrons), in Ge-SiGe, (GaAs-AlGaAs), heterostructures in the ballistic regime. At values of carrier concentration below about 5.1010 cm-2 the integer ground state disappears to be replaced by fractional values of conductance. This occurs when the confinement of the carriers is relaxed to be on the verge of two-dimensionality. For holes in Ge we find that, in units of \( e^2/h \), the fractional values of conductance are 1/2, spin degenerate, dropping to 1/4 in the presence of a parallel magnetic field and 1/16 which is spin polarized at zero field, (1). The accuracy of the quantization was 0.5%, possibly corresponding to fractional charges of \( e/2 \) and \( e/4 \).

For electrons in GaAs we find a rich structure, the dominant fractional values of conductance, consistently observed, are in the presence of a weak, asymmetric confinement. The values found are 2/5, 1/2 and 1/6. In the presence of a parallel magnetic field a number of other fractions started to appear, (2). These results will be discussed in relation to the formation of a zig-zag electron configuration with strong interactions between the two rows.

Melting of interference in the fractional quantum Hall regime: Appearance of neutral modes

MITALI BANERJEE (Presenter), R BHATTACHARYYA, MOTY HEIBLUM, DIANA MAHALU, VLADIMIR UMANSKY, Department of Condensed Matter Physics, Weizmann Institute of Science — The core reason for the absence of interference of fractional charges (in the lowest Landau level) has long been a subject of discussions. Certainly there is dephasing of quasiparticles, but the agent behind this havoc was never singled out experimentally. While interference of electrons has been routinely observed in the integer regime, it gradually reduced as the filling was reduced towards \( \nu = 1 \), where it fully quenched, not to recover in the fractional regime. Here, we have systematically studied the Aharonov-Bohm interference in a Mach-Zehnder interferometer (MZI) and correlated it with the appearance of upstream neutral modes. The latter were determined by an appearance of a conductance plateau of \( \nu = 1/3 \) in a quantum point contact (QPC), which carried shot-noise. As the bulk filling approached \( \nu = 1 \) a substantial drop in the visibility was observed, concomitantly with the appearance \( \nu = 1/3 \) noisy conductance plateau in the QPC (of the MZI) - pointing at the birth of neutral modes at the QPC. Such \( \nu = 1/3 \) conductance plateau persisted throughout the hole-conjugate regime, where interference was absent. We believe that unexpected edge reconstruction, favored in a rather soft edge potential at \( 2 > \nu \geq 1 \) gives birth to upstream neutral modes that dephase the interference.

Landau level subbands as a platform for many-body localization*

AKSHAY KRISHNA (Presenter), Electrical Engineering, Princeton University, MATTEO IPPOLITI, Physics, Princeton University, RAVINDRA BHATT, Electrical Engineering, Princeton University — Previous numerical results [1] have confirmed the theoretical argument [2] that many-body localization is not possible in a Landau level in the presence of interactions and arbitrary disorder. We examine the possibility of many-body localization in subbands (both topological and non-topological) derived from the lowest Landau level. In particular, we use two specific models – a suitably engineered flat band potential, and randomly placed point-like impurities, to create subbands into which we project the problem, including both interactions and disorder. We use exact diagonalization to compute the level spacing ratio as a diagnostic of localization. The results show the absence of localization in topological subbands and the possibility of a finite-disorder many-body localization transition in non-topological subbands. This represents a novel setting for the study of many-body localization in one and two dimensions.

Bulk properties of the 5/2 fractional quantum Hall state with Corbino geometry*

JIAN SUN (Presenter), PENGJIE WANG, ZHEYI ZHU, JIASEN NIU, Peking University, LOREN PFEIFFER, KENNETH WEST, Princeton University, XI LIN, Peking University — The nature of the ground state of the fractional quantum Hall (FQH) effects at half-filling in the second Landau level has been an interesting problem. In high-quality GaAs samples, the exact quantization of the 5/2 FQH state has been observed in van der Pauw geometry, but the fully bulk insulation of the 5/2 FQH state remains unrevealed. Corbino geometry, known for its edge-free nature, has been applied in studying the bulk physics of FQH states and charge density wave states recently. We will show our observation of bulk insulation in the 5/2 FQH state with Corbino geometry at an estimated low electron temperature of 12 mK. With in-plane electrical field, the stability of the 5/2 FQH state was explored. In our measurement, the 5/2 FQH state wasn't enhanced by a weak in-plane electrical field as suggested. Our observation indicates a fully charge insulating nature of the bulk at filling factor 5/2 and could be informative for the proposed thermal conductivity measurements to search the striped Pfaffian and anti-Pfaffian state.

1:51PM L01.00014: Half-filled Landau levels: a continuum and sign-free regularization of 3D quantum critical points*  MATTEO IPPOLITI (Presenter), Physics, Princeton University, ROGER MONG, Physics and Astronomy, University of Pittsburgh, FAKHER ASSAAD, Physics, Wuerzburg University, MICHAEL ZALETEL, Physics, University of California, Berkeley — We propose a method to regulate (2+1)-dimensional quantum critical points in which the ultraviolet cutoff is implemented by Landau level quantization, rather than by a lattice [1]. This allows numerical computations on arbitrary manifolds without introducing lattice defects. We focus on $N=4$ flavors (corresponding to the spin and valley degrees of freedom of electrons in graphene) at half filling, and introduce appropriate interaction anisotropies in flavor space to drive different types of magnetic order. We thus obtain a continuum regularization of the O(5) nonlinear sigma model (NLSM) with a topological term, which has been conjectured to flow to a deconfined critical point. We perform infinite-cylinder DMRG [2] simulations of this model and estimate the dimension of the O(5) vector to be $\Delta V \approx 0.55 - 0.70$, depending on the NLSM stiffness. This dependence may be a finite-size effect or further evidence of a weakly discontinuous transition. As the model is sign-problem-free, forthcoming quantum Monte Carlo simulations may be able to discriminate between these cases.

2:03PM L01.00015: Superconducting correlations in a fractional quantum Hall bilayer interface  JUKKA VAYRYNEN (Presenter), Microsoft Station Q Santa Barbara, MOSHE GOLDSTEIN, Tel Aviv University, YUVAL GEFEN, Weizmann Institute of Science — We consider a fractional quantum Hall bilayer system with an interface between quantum Hall states of filling fractions (0,1) and (1,1/3), motivated by recently fabricated systems by the Heiblum group (Weizmann). We show that disordered tunneling within one of the layers will drive the system to a stable fixed point with two counterpropagating charge modes which have attractive interactions. As a result, superconducting correlations on the edge become slowly-decaying. We discuss the observable effects of the phenomenon and derive general requirements for electron attraction in Abelian quantum Hall states.

Session L02 DMP: Topological Materials -- Optical and other Spectroscopy  BCEC 107A - Kenneth Burch, Boston College - Tag(s): Focus

11:15AM L02.00001: Magneto-infrared Spectroscopy of Topological Materials [Invited]  ZHIGANG JIANG (Presenter), Georgia Institute of Technology — The topological nature of a material is not only reflected on the surfaces or along the edges but also hidden inside the material in the bulk electronic structure. In this talk, I will describe how the bulk-sensitive magneto-infrared spectroscopy technique can be used to probe the electronic structure topology. I will use transition-metal pentatellurides (ZrTe$_5$ and HfTe$_5$, Dirac semimetals) and monopnictides (NbP, Weyl semimetals) as material examples. For the Dirac semimetals, we find that the observed Landau level transitions are similar to that in graphene but with a finite mass and the Zeeman effect opens the inverted band gap due to the large g-factor in the materials. For the Weyl semimetals, we find that the magnetic field opens a sizable gap at the charge neutrality point (Weyl annihilation) due to the finite coupling between the Weyl points and a new optical transition rule appears when the magnetic field breaks the axial symmetry. For both material systems, a semiquantitative agreement between the experiment and the effective Hamiltonian model calculation is achieved.

11:51AM L02.00002: Quantum oscillation evidence of topological semimetal phase in ZrSnTe  JIN HU (Presenter), University of Arkansas, YANGLIN ZHU, ZHIJIE TANG, Tulane University, ZHIQIANG MAO, Pennsylvania State University, DAVID E GRAF, National High Magnetic Field Laboratory, XIN GUI, WEIWEI XIE, Louisiana State University — The layered WHM - type ($W=Zr$/Hf/La, $H=Si$/Ge/$Sn$/Sb, $M=S$/Se/Te) materials represent a large family of topological semimetals, which provides an excellent platform to study the evolution of topological semimetal state with the fine tuning of spin-orbit coupling and structural dimensionality for various combinations of $W$, $H$ and $M$ elements. In this work, through high field de Haas–van Alphen (dHvA) quantum oscillation studies, we have found evidence for the predicted topological non-trivial bands in ZrSnTe. Furthermore, from the angular dependence of quantum oscillation frequency, we have revealed the three-dimensional Fermi surface topologies of this layered material owing to strong interlayer coupling.
Identification of candidate species for intercalation doping of ZrTe$_5^*$

NORMAND MODINE (Presenter), Sandia National Laboratories — ZrTe$_5$ is an interesting topological quantum material that is predicted to be a Dirac semimetal at the boundary between weak and strong topological insulator phases. In topological materials, it is highly desirable to control the doping of the material in order to adjust the Fermi level to coincide with features in the band structure. Since ZrTe$_5$ is a layered material, one approach to accomplishing this goal is “intercalation doping,” in which a dopant diffuses between the layers of the material. We have used van der Waals-corrected density functional theory to investigate the intercalation of a variety of atoms into ZrTe$_5$ with the goal of identifying promising candidates for intercalation doping. We have calculated bulk absorption energies and diffusion barriers, and where bulk interlayer diffusion rates are reasonably rapid, we have also calculated the corresponding surface properties. We conclude that Li and Pd are promising candidates for intercalation doping of ZrTe$_5$.

Measurements of out-of-plane magnetoresistance in ZrSiS, ZrSiSe, and HfSiS microstructures

KENT SHIRER (Presenter), KIMBERLY MODIC, TINO ZIMMERLING, MARKUS KOENIG, Max Planck Institute for Chemical Physics of Solids, LESLIE SCHOOP, Princeton University, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids — Topological nodal-line semimetals with the general formula XSiY (X = Zr, Hf and Y = S, Se, Te) have recently attracted much experimental and theoretical interest due to their properties, particularly their large magnetoresistances and high carrier mobilities. Due to the platelet-like nature of the XSiY crystals and their extremely low residual resistivities, measurements of the resistivity along the [001] direction are extremely challenging. To accomplish such measurements, microstructures of single crystals were prepared using Focused Ion Beam techniques. Microstructures prepared in this manner have very well-defined geometries and maintain their high crystal quality, verified by the quantum oscillations we observed. We will present magnetoresistance and quantum oscillation data for currents applied along both [001] and [100] in ZrSiS, ZrSiSe, and HfSiS and discuss the role microstructuring can play in the study of these materials.

Revealing Optical Transitions and Carrier Dynamics within the Bulk Band Structure of Bi$_2$Se$_3^*$

GIRIRAJ JNAWALI, SAMUEL M LINSER, IRAJ ABBASIAN SHOJAEI, SEYYEDESADAF POURNIA, HOWARD E JACKSON, LEIGH SMITH (Presenter), Department of Physics, University of Cincinnati, RYAN NEED, STEPHEN WILSON, Materials Department, University of California, Santa Barbara — Bismuth selenide (Bi$_2$Se$_3$) is a prototypical topological insulator which exhibits gapped states within the bulk and topologically protected conducting states on the surface. Here we use mid-infrared pump-probe spectroscopy on Bi$_2$Se$_3$ nanosheets exfoliated from Bridgeman grown single crystals to map the band-edge electronic structure and interrogate carrier relaxation processes over a wide energy range (0.3 to 1.2 eV). We observe direct optical transitions from spin-orbit split valence bands to the Fermi level above the lowest conduction band minimum. The photoexcited carriers thermalize rapidly to the lattice temperature within a couple of picoseconds due to optical phonon emission and scattering with the cold electron gas followed by slow electron-hole recombination within 150 ps at 10 K and 50 ps at 300 K. Knowledge of electronic structure and interaction of electrons and holes within the bulk band structure provides a foundation for understanding coupling of these states with the protected surface states.

12:39PM L02.00006: The thickness dependent optical nonlinearity of graphene/Bi$_2$Te$_3$ heterojunction* JIA CHI LAN (Presenter), JUN PENG QIAO, WEI-HENG SUNG, Photonics, National Sun Yat-sen university, CHUN HU CHEN, Chemistry, National Sun Yat-sen university, CHENG MAW CHENG, Condensed Matter Physics Group, National Synchrotron Radiation Research Center, CHAO-KUEI LEE, Photonics, National Sun Yat-sen university — The graphene like surface state of topological insulators (TIs) have been attracted plenty of attentions. However, ultra-low saturation absorption resulting from the intrinsic bulk state of TIs limits its application, such as pulse laser. In this work, thickness dependent optical nonlinearity of graphene/Bi$_2$Te$_3$ heterojunction saturable absorber is investigated. Unlike the low saturation intensity of Bi$_2$Te$_3$ (with order of tens W/cm$^2$), the saturation intensity of graphene/Bi$_2$Te$_3$ heterojunction increases dramatically at least 4 order of magnitude. In addition, the increasing modulation depth of around 60% is characterized and the high quality 1um Q-switched solid state laser based on graphene/Bi$_2$Te$_3$ heterojunction saturable absorber is accordingly performed. Finally, the possible mechanism of carrier dynamics between p-n heterojunction and guideline for material design are proposed and discussed as well.

12:51PM L02.00007: Measuring the Thermal Conductivity of Semiconductors and Semimetals Using Raman Spectroscopy* IRAJ ABBASIAN SHOJAEI (Presenter), GIRIRAJ JNAWALI, SEYYEDESADAF POURNIA, SAMUEL M LINSER, HOWARD E JACKSON, LEIGH SMITH, Department of Physics, University of Cincinnati, RYAN NEED, STEPHEN WILSON, Materials Department, University of California, Santa Barbara — We present a measurement of the thermal conductivity for Bi$_2$Se$_3$ and Te and semimetals at room temperature by using Raman scattering spectroscopy on a clean prepared sample on a SiO$_2$ substrate. Aluminum is deposited on either side of the flake and is used as a heat sink at room temperature. Using a He/Ne laser (633 nm), we measure the Raman shift of the sample as a function of laser power between 0.1mW and 1mW. The linear red shift of Raman modes due to heating of the sample provides a measure of the temperature of the sample around the incident laser area. We calculate the thermal conductivity of the sample by solving a simplified one dimensional heat diffusion equation, ignoring the heat conduction to the ambient air and substrate. Our results for Bi$_2$Se$_3$ suggest a value of 4 W/mK for the thermal conductivity, comparable to the measurements of others; using the same technique we plan make measurements of several Weyl semimetals (e.g. WTe$_2$ and NbIrTe$_4$).

*UC acknowledges NSF grants ECCS-1509706, DMR-1531373, and DMR-1507844. S.D.W. acknowledges the support of NSF DMR 1505549.

1:03PM L02.00008: Signature of chiral anomaly in TaP through phonon dynamics THANH NGUYEN (Presenter), MINGDA LI, FEI HAN, NINA ANDREJEVIC, Massachusetts Institute of Technology, SONGXUE CHI, JAIME FERNANDEZ-BACA, MASAAKI MATSUDA, Oak Ridge National Laboratory, AHMET ALATAS, ESEN ALP, Argonne National Laboratory — Recent theoretical predictions discussed the possibility of detecting chiral anomaly based on phonon spectra as the exotic electronic degrees of freedom in a Weyl semimetal play an important role to influence the phonon structure. I will discuss measurements made of phonon excitations on a high-quality single crystal sample of type-I Weyl semimetal TaP using inelastic neutron and x-ray scattering spectroscopies. These measurements indicate the presence of phonon softening near the Weyl nodes which is driven by the coupling between the chiral Weyl fermions and phonons. We also observe that this coupling differs between the W1 and W2 Weyl nodes. These results provide a method to extract valuable information about the sought-after electron-phonon coupling strength.

1:15PM L02.00009: Band structure of topological insulators via cyclotron resonance ANDREI PIMENOV (Presenter), Vienna University of Technology — In the quasi-classical approximation the cyclotron mass can be directly connected to the band structure. The analysis based on the cyclotron resonance (CR) is especially useful for thin film materials in which capping layers prevent standard approaches like ARPES. Here, using the CR experiments in the terahertz range, we obtain the band structure of topological insulators (TI) based on mercury telluride (HgTe) quantum wells. In three-dimensional HgTe TI the dispersion of surface carriers is close to parabolic and it dominates the cyclotron signal. In addition, several other features are observed that can be attributed the bulk carriers. In two-dimensional HgTe TI the dispersion of electrons is close to linear showing increasingly complicated character in the region of the hole-like carriers.

This results in the flat bands only having a weak effect on the bulk properties, while the impact of the Dirac cone at the Γ-point is also limited due to it being several hundred meV above EF. We will discuss detailed results of the Fermi surface topology measurements and prospects for tuning the EF to meet either the flat bands or the Dirac cone.

*This material is based upon work supported by the National Science Foundation Graduate Research Fellowship Program under Grant No. DGE 1256260. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

1:39PM L02.00011: Fermi Surfaces of Flat-Band Intermetallic APd3 (A = Pb, Sn)* KAYA WEI (Presenter), National High Magnetic Field Laboratory, KUAN-WEN CHEN, JENNIFER NEU, YOU LAI, GRETA CHAPPLE, Florida State University, YAN XIN, DAVID E GRAF, LUJIS BALICAS, RYAN BAUMBACH, National High Magnetic Field Laboratory, THEO SIEGRIST, Florida State University — DFT calculations for APd3 (A=Pb, Sn) recently revealed an interesting band structure [1] that includes: a dispersionless branch along the Γ-X line, that could result in a large DOS near EF, and Dirac-like surface states. To test these predictions, we synthesized single crystals of PbPd3 and SnPd3 using the Czochralski growth technique and performed magnetoresistance and torque magnetometry measurements in magnetic fields up to 45 T. Through analysis of quantum oscillations, we uncover Fermi surface topographies that suggest the EF is roughly 50 meV above the flat band for PbPd3. This results in the flat bands only having a weak effect on the bulk properties, while the impact of the Dirac cone at the Γ-point is also limited due to it being several hundred meV above EF. We will discuss detailed results of the Fermi surface topology measurements and prospects for tuning the EF to meet either the flat bands or the Dirac cone.

1:51PM L02.00012: Novel plasmons in quantum anomalous Hall systems* JIANHUI ZHOU (Presenter), High Magnetic Field Laboratory, Hefei Institutes of Physical Science, DI XIAO, Carnegie Mellon Univ, YUGUI YAO, FURU ZHANG, Beijing Institute of Technology — We find that the inverted band structure with the Mexican-hat dispersion could enhance the interband correlation leading to a strong intrinsic plasmon excitation. Its frequency ranges from several meV to tens of meV and can be effectively tuned by the external fields. The electron-hole asymmetric term splits the peak of the plasmon excitation into double peaks. The fate and properties of this plasmon excitation can also act as a probe to characterize the topological phases even in lightly doped systems. We numerically demonstrate the impact of band inversion on plasmon excitations in magnetically doped thin films of three-dimensional strong topological insulators, which support the quantum anomalous Hall states (QAHE). We also study the chiral edge plasmons in QAHE and find many new and remarkable features of chiral edge plasmons. Our work thus sheds some new light on the potential applications of topological materials in plasmonics.

2:03PM L02.00013: Optical circular dichroism in an antiperovskite Dirac semimetal KATSUHISA TAGUCHI (Presenter), TAKUTO KAWAKAMI, MASATOSHI SATO, YITP, Kyoto University — We theoretically study selective circular dichroism in an antiperovskite type Dirac semimetal, which hosts Dirac fermions with high total angular momentum J. We find that unconventional circular dichroism depends on J : In J =1/2 Dirac fermion, nonzero circular dichroism is generated in Jz · J'z = ±1, where Jz and J'z are the z-component of J of the conduction band minimum and the valance band maximum around Dirac points, respectively. It is noted that this ±1 reflects on the spin angular momentum of the polarization of the applied light. On the other hand, in J =3/2 Dirac fermion, the nonzero circular dichroism is triggered in Jz · J'z = ±3. Its origin is shown in this presentation.
11:15AM L03.00001: Topological Fermi-arcs and Weyl node connectivity in the ferromagnetic Weyl semimetal Co₃Sn₂S₂  NOAM MORALI, RAJIB BATABYAL (Presenter), PRANAB KUMAR NAG, Weizmann Institute of Science, ENKE LIU, QIUNAN XU, YAN SUN, Max Planck Institute for Chemical Physics of Solids, BINGHAI YAN, Weizmann Institute of Science, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, NURIT AVRAHAM, HAIM BEIDENKOPF, Weizmann Institute of Science — Topological “Fermi-arc” surface states are guaranteed to exist on certain surfaces of Weyl semimetals. They connect the surface projection of the bulk Weyl nodes. However, in the presence of multiple pairs of surface projected Weyl nodes the actual connectivity among them is ambiguous. We use scanning tunneling spectroscopy to verify the classification of ferromagnetic Co₃Sn₂S₂ as a Weyl semimetal as well as its time reversal broken origin. By studying three different surface terminations we show that Fermi arc connectivity and Fermi-arc contour in Co₃Sn₂S₂ changes with the specific surface potential. While on the Sn surface we find intra-Brillouin zone connectivity, on the Co surface the Fermi arcs connect Weyl nodes across the Brillouin zone edge. On the S termination the Fermi–arcs hybridise with non-topological bulk and surface states thus obscuring their connectivity.

11:27AM L03.00002: A bi-directional photovoltaic shift on the surface of topological insulators  TOMOKI YOSHIKAWA (Presenter), KAZUKI SUMIDA, Graduate School of Science, Hiroshima University, Japan, YUKIKAISHI, Institute for Solid State Physics, the University of Tokyo, Japan, JAIHAU CHEN, MUNISA NURMAMAT, Graduate School of Science, Hiroshima University, Japan, KONSTANTIN A. KOKH, OLEG E. TERESHCHENKO, Novosibirsk State University, Russia, SHIK SHIN, Institute for Solid State Physics, the University of Tokyo, Japan, AKIO KIMURA, Graduate School of Science, Hiroshima University, Japan — Topological insulators (TIs) possess spin-polarized Dirac states on the surface as a result of the non-trivial topology of the bulk band structure. The surface of TIs is considered as a promising spin-electronic application. Recently, it was suggested that a generation of spin-polarized photocurrent would be possible with bulk-insulating TIs by utilizing surface photovoltage (SPV) effect. To date, SPV effect was observed for the bulk-insulating TI, Bi₂Te₂Se. However, due to the limited controllability of bulk carrier, only a uni-directional shift of the surface potential has been demonstrated. A bi-directional SPV is important for taking control of the ambipolar surface current by light. Here, we have performed time- and angle- resolved photoemission spectroscopy on bulk-insulating TIs of n- and p-type Bi₂Te₃. The experiment was carried out with linearly polarized pump (hv=1.48 eV) and probe (5.92 eV) pulses generated by Ti: sapphire laser system operating at a repetition rate of 250 kHz.

11:39AM L03.00003: Spectromicroscopic Analysis of Surface and Bulk Band Structure at a Disordered Topological Insulator Surface  ERICA KOTTA (Presenter), LIN MIAO, YISHUAI XU, Physics, New York University, AARON BOSTWICK, CHRIS JOZWIAK, ELI ROTENBERG, ALS, Lawrence National Berkeley Laboratory, TAKEHITO SUZUKI, JOSEPH CHECKELSKY, Physics, Massachusetts Institute of Technology, LEWIS A WRAY, Physics, New York University — The technique of angle resolved photoemission spectroscopy (ARPES) is widely applied to measure electronic band structures and has become central to our understanding of quantum material electronic structures over the last few decades. Recent improvements in coherent VUV light sources have driven rapid developments in the focused beam spot for ARPES, down to the d<10um diameter scale with little sacrifice, and the d~100nm scale with reduced flux. For this talk I will present ARPES spectromicroscopy data which was used to map the surface band structure of a beam-sensitive topological insulator sample (disorder-enriched Bi₂Se₃). New data analysis methods are developed to obtain quantitative electronic structure information in spite of the flux sensitivity of the surface, revealing a complex structural environment in which fluctuations in the surface and bulk state energetics are found to be mostly decoupled.
Topological nodal-line semimetals in ferromagnetic rare-earth-metal monohalides

SI-MIN NIE (Presenter), Stanford University, HONGMING WENG, Institute of Physics, Chinese Academy of Sciences, FRITZ PRINZ, Stanford University — Topological semimetals, extending the topological classification from insulators to metals, have greatly enriched our understanding of topological states in condensed matter. Here we identify layered materials as promising candidates for hosting TNLSs. Based on first-principles calculations and effective model analysis, we propose that layered ferromagnetic rare-earth-metal monohalides LnX (Ln=La, Gd; X=Cl, Br) exhibit long pursued topological phases. Specifically, single-layer LaX and single-layer GdX are ideal two-dimensional (2D) Weyl semimetals and large-gap 2D quantum anomalous Hall insulators (QAHIs), with band gaps up to 61 meV, respectively. In addition, 3D LaX and 3D GdX are TNLSs with a pair of mirror-symmetry protected nodal lines and 3D QAHIs, respectively. The nodal lines in 3D LaX extending through the whole Brillouin zone (BZ) are fairly robust against strong spin-orbit coupling (SOC) and located close to the Fermi level, providing a novel platform toward exploring the exotic properties in nodal-line fermions as well as related device designs.

Weak topological insulator state in quasi-one-dimensional bismuth iodide observed by surface-selective nano-ARPES

RYO NOGUCHI (Presenter), Institute for Solid State Physics, University of Tokyo, TAKANARI TAKAHASHI, Materials and Structures Laboratory, Tokyo Institute of Technology, KENTA KURODA, Institute for Solid State Physics, University of Tokyo, MASAYUKI OCHI, Department of Physics, Osaka University, TETSURO SHIRASAWA, National Metrology Institute of Japan, National Institute of Advanced Industrial Science and Technology, CÉDRIC BAREILLE, MASATO SAKANO, MITSUHIRO NAKAYAMA, Institute for Solid State Physics, University of Tokyo, MATTHEW WATSON, Diamond Light Source, KOICHIRO YAJI, AYUMI HARASAWA, Institute for Solid State Physics, University of Tokyo, HIDEAKI IWASAWA, PAVEL DUDIN, TIMUR KIM, Diamond Light Source, MORITZ HOESCH, DESY, VIKTOR KANDYBA, ALESSIO GIAMPIETRI, ALEXEI VICTOROVICH BARINOV, Elettra-Sincrotrone Trieste, SHIK SHIN, Institute for Solid State Physics, University of Tokyo, RYOTARO ARITA, RIKEN Center for Emergent Matter Science, TAKAO SASAGAWA, Materials and Structures Laboratory, Tokyo Institute of Technology, TAKESHI KONDO, Institute for Solid State Physics, University of Tokyo — Recently, various materials have been confirmed to be topologically non-trivial by angle-resolved photoemission spectroscopy (ARPES) [1]. Despite intensive research on topological materials, a weak topological insulator (WTI) has so far remained hypothetical, since topological surface states (TSS) emerge only on the side surfaces, which are usually undetectable by conventional ARPES. We have overcome this difficulty by employing newly developed nano-ARPES. Its high spatial resolution allows us to perform surface selective measurements, which is necessary for the discovery of a WTI state in real 3D crystals.

In this contribution, we provide first experimental evidence for a WTI state in quasi-one-dimensional $\beta$-Bi$_4$I$_4$. The crystal has naturally cleavable top and side surfaces both stacked via van-der-Waals forces, and TSSs emerge only on the side surface as the WTI phase [2,3]. Our nano-ARPES results reveal quasi-1D Dirac-like surface state emerge only on the side surface while the top surface is topologically dark, which is the hallmark of the WTI state in $\beta$-Bi$_4$I$_4$ [4].

12:15PM L03.00006: Large magnetic gap at the Dirac point in a Mn-induced Bi$_2$Te$_3$ heterostructure* OLIVER RADER (Presenter), EMILE RIENKS, PARTHA M. MANDAL, Helmholtz-Zentrum Berlin, ONDREJ CAHA, JAN RUZICKA, Masaryk University Brno, ANDREAS NEY, HUBERT STEINER, VALENTYN V. VOLOBUYEV, HEIKO H. GROISS, Johannes Kepler Univ. Linz, SALEEM KHAN, JAN MINÁR, University of West Bohemia Pilsen, MIHAELA ALBU, Graz Center for Electron Microscopy, HUBERT EBERT, Ludwig-Maximilians-Universitat Munchen, GÜNTHER BAUER, Johannes Kepler Univ. Linz, ANDREI VARYKHALOV, JAIME SÁNCHEZ-BARRIGA, Helmholtz-Zentrum Berlin, STEFAN WIMMER, GUNTER SPRINGHOLZ, Johannes Kepler Univ. Linz — A magnetic gap at the Dirac point of topological insulators has so far never been observed directly. Here, we use low temperature ARPES to reveal the magnetic gap of Mn-doped Bi$_2$Te$_3$ films which is present only below T$_C$ of 10-12 K. Surprisingly, the gap is 5 times larger than predicted by density functional theory. We show that this enhancement is due to a remarkable structure modification induced by Mn doping. Instead of a disordered impurity system, it forms an alternating sequence of septuple and quintuple layer blocks, with Mn in the center of the septuple layers. Mn-doped Bi$_2$Se$_3$ forms a similar heterostructure, however, only a large, albeit nonmagnetic gap is formed. We explain both differences based on the higher spin-orbit interaction in Bi$_2$Te$_3$. The present findings provide crucial insights for pushing the lossless transport properties of topological insulators towards room temperature.

12:27PM L03.00007: Directly photoexcited Dirac and Weyl fermions in ZrSiS and NbAs JAEHUN KIM (Presenter), CHRISTOPHER P WEBER, Santa Clara University, LESLIE SCHOOP, Chemistry, Princeton University, STUART S P PARKIN, Max Planck Institute of Microstructure Physics, ROBERT NEWBY, Santa Clara University, ALEXANDR NATEPROV, Applied Physics, Academy of Sciences of Moldova, BETTINA LOTSCH, Max Planck Institute for Solid State Research, M. BALA MURALI KRISHNA, KESHAV M DANI, Femtosecond Spectroscopy Unit, Okinawa Institute of Science and Technology Graduate University, HANS BECHTEL, Advanced Light Source Division, Lawrence Berkeley National Laboratory, ERNEST ARUSHANOV, Applied Physics, Academy of Sciences of Moldova, MAZHAR ALI, Max Planck Institute of Microstructure Physics — We report ultrafast optical measurements of the Dirac line-node semimetal ZrSiS and the Weyl semimetal NbAs, using mid-infrared pump photons from 86 meV to 500 meV to directly excite Dirac and Weyl fermions within the linearly-dispersing bands. In NbAs the photoexcited Weyl fermions initially form a non-thermal distribution, signified by a brief spike in the differential reflectivity whose sign is controlled by the relative energy of the pump and probe photons. In ZrSiS electron-electron scattering rapidly thermalizes the electrons, and the spike is not observed. Subsequently hot carriers in both materials cool within a few picoseconds. This cooling, as seen in the two materials’ differential reflectivity, differs in sign, shape, and timescale. Nonetheless, we find that it may be described in a simple model of thermal electrons, without free parameters. The electronic cooling in ZrSiS is particularly fast, which may make the material useful for optoelectronic applications.

12:39PM L03.00008: Symmetry protected band crossings of spin-orbit coupled surface states of NbGeSb IGOR MARKOVIĆ (Presenter), OLIVER J CLARK, FEDERICO MAZZOLA, MATTHEW WATSON, University of St Andrews, PHILIP MURGATROYD, MATTHEW DYER, University of Liverpool, CHRISTOPHER ANDREW HOOLEY, University of St Andrews, JONATHAN ALARIA, University of Liverpool, PHILIP KING, University of St Andrews — The electronic structure of materials in the ZrSiS family of nonsymmorphic semimetals hosts, alongside their bulk Dirac line nodes, peculiar surface states created by the breaking of nonsymmorphic symmetry at the surface layer [1-3]. We study the surface electronic structure of NbGeSb (isotransitional to ZrSiS) using spin- and angle-resolved photoemission spectroscopy (ARPES) and density-functional theory (DFT). We observe two pairs of surface states, hosting large Rashba-like spin-splittings, split off from the bulk manifold. We find how these two branches intersect each other, forming a fourfold crossing structure along the Brillouin zone boundary. Surprisingly, we find a counter-intuitive hybridisation structure around these crossings, with three remaining protected and just a single hybridised anti-crossing. We demonstrate how a mirror symmetry line provides protection along the Brillouin zone face, opening new routes to realising complex intertwined spin textures of spin-orbit coupled surface states.

12:51PM L03.00009: Non-Hermitian Hopf-Link Exceptional Line Semimetals* YANG ZHESEN (Presenter), JIANGPING HU, Chinese Academy of Sciences — We study a new class of non-Hermitian topological phases in three dimension, where the topological robust band degeneracies are Hopf-link exceptional lines. As a concrete example, we investigate the non-Hermitian band structure of nodal line semimetals under non-Hermitian perturbations, where the Fermi surfaces can transit from 1d nodal lines to 2d twisting surfaces with Hopf-link boundaries. The topological invariants of these linked exceptional line phases are also proposed. Due to non-Hermitian skin effect, We also find a huge difference between the band structure of periodic and open boundary conditions. After complexification of the momentum in the Bloch Hamiltonian, we find the correct bulk-boundary correspondence in non-Hermitian system. The possible experimental realizations are also discussed.

1:03PM L03.00010: Fragility of Fermi arcs in Dirac semimetals* YUN WU (Presenter), NA HYUN JO, LIN-LIN WANG, CONNOR SCHMIDT, KATHRYN NEILSON, BENJAMIN SCHRUNK, PRZEMYSLAW SWATEK, ANDREW EATON, SERGEY L. BUD’KO, PAUL CANFIELD, ADAM KAMINSKI, Iowa State University — We use tunable, vacuum ultraviolet laser-based angle-resolved photoemission spectroscopy and density functional theory calculations to study the electronic properties of Dirac semimetal candidate PtBi2. In addition to bulk electronic states we also find surface states as expected from theory and band calculations. The topological surface states form Fermi pockets rather than double Fermi arcs that were observed in Na3Bi. The surface bands forming the Fermi pockets merge with bulk bands in proximity of the Dirac points, as expected. Our data confirms existence of Dirac states in PtBi2 and reveals the fragility of the Fermi arcs in Dirac semimetals. Because the Fermi arcs are not topologically protected in general, they can be deformed into Fermi pockets, as proposed by Kargarian et al.. Our results demonstrate validity of this theory in PtBi2.

1:15PM L03.00011: Intrinsic Fermi Arc Re-wiring in NbIrTe4 SANDY ADHITIA EKAHANA (Presenter), Oxford University-USE 4643, YAN SUN, Max Planck Institute for Iron Research GmbH, HIROMASA NAMIKI, Tokyo Institute Of Technology, HAIFENG YANG, Chinese Academy of Sciences (CAS), JUAN JIANG, Lawrence Berkeley National Laboratory, WUJUN SHI, Max Planck Institute for Iron Research GmbH, CHAOFAN ZHANG, National University of Defense Technology, YIWEI LI, DING PEI, Oxford University-USE 4643, TAKAO SASAGAWA, Tokyo Institute Of Technology, CLAUDIA FELSER, Max planck institute, BINGHAI YAN, Weizmann Institute of Science, ZHONGKAI LIU, ShanghaiTech, YULIN CHEN, Oxford University-USE 4643 — NbIrTe4 which is a semimetal that breaks inversion symmetry predicted to host only four Weyl points. This simplest configuration is confirmed by the measurement from the top and bottom surface of NbIrTe4 showing only a pair of Fermi arcs each. Furthermore, it is found that the Fermi arc connectivity on the bottom surface experiences re-wiring as it evolves from Weyl points energy to the ARPES Fermi energy level. This change is attributed to the hybridisation between the surface and the bulk states as their projection lie within the vicinity of each other. The finding in this work demonstrates that although Fermi arcs are guaranteed in Weyl semimetals, their shape and connectivity are not protected and may be altered accordingly.

1:27PM L03.00012: ARPES study on the electronic structure of VTe2 with double zigzag chains MITSUISHI NATSUKI (Presenter), YUSUKE SUGITA, SAEED BAHRAMY, MANABU KAMITANI, TATSUYA SONOBE, MASATO SAKANO, The University of Tokyo, TAKAHIRO SHIMOJIMA, RIKEN CEMS, KOJI HORIBA, HIROSHI KUMIGASHIRA, KEK-PF, KAZUAKI TAGUCHI, KOJU MIYAMOTO, TAICHI OKUDA, Hiroshima University, SHINTARO ISHIWATA, YUKITOSHI MOTOME, KYOKO ISHIZAKA, The University of Tokyo — Layered transition metal dichalcogenide (TMDC) has been a well-known system to host a variety of charge density waves (CDW) reflecting its quasi-two-dimensionality. More recently, there has been increasing interest in spin-orbit coupling effect and topological aspects of TMDC. VTe2 has a trigonal CdI2-type structure (so-called 17 phase) at high temperature, consisting of trigonal layers formed by edge-sharing VTe6 octahedra. Below ~485 K, it undergoes a peculiar structural phase transition to the monoclinic 17” phase. In this phase, VTe2 exhibits the 3×1×3 superstructure characterized by the formation of double zigzag chains of vanadium [1], which has been discussed in terms of CDW. In this talk, we report on the peculiar modification of the electronic structures via the 17-17” phase transition clarified by utilizing angle-resolved photoemission spectroscopy (ARPES) and first-principles calculations.

1:39PM L03.00013: New class of Chiral topological nodes in transition metal silicide CoSi  
ZHICHENG RAO (Presenter), Institute of Physics — Exotic chiral topological nodes with nonzero chern number and multiple degeneracy, distinct from conventional Dirac and Weyl nodes, could exist in crystalline semimetals with certain space group symmetries. The projections of these chiral topological nodes with opposite chern number are connected by topologically protected surface fermi arcs. Several other types of chiral topological nodes have been predicted by theorists, but the direct experiment evident is still lacked. Here, we will report that two types of new chiral nodes are revealed by using angel-resolved photoemission spectroscopy in transition metal silicide CoSi.

1:51PM L03.00014: Cyclotron antiresonance in the topological insulator Bi$_2$Te$_3$ studied in Voigt geometry  
SASA DORDEVIC (Presenter), The University of Akron, HECHANG LEI, CEDOMIR PETROVIC, Brookhaven National Laboratory, SEONGPHILL MOON, DMITRY SMIRNOV, National High Magnetic Field Laboratory — We have previously observed cyclotron antiresonance in a canonical 3D topological insulator Bi$_2$Te$_3$ in Faraday geometry. We now supplement those results with the recent measurements in Voigt geometry. Antiresonance is also present in this geometry, but an additional absorption feature is also detected, whose origin is currently unknown. Possible explanation of these effects will be discussed within the model which uses an unconventional form of the Lorentz force that external magnetic field exerts on charge carriers.

2:03PM L03.00015: Observation of Quasi-one-dimensional Edge State in ZrTe$_5$ by Angle-resolved Photoemission Spectroscopy  
DONG QIAN (Presenter), FENGFENG ZHU, WENXIANG JIANG, Shanghai Jiao Tong University — Single-layer ZrTe$_5$ was known as a two-dimensional topological insulator, while ZrTe$_5$ bulk crystal consisting of many ZrTe$_5$ layers has been argued as either a three-dimensional strong topological insulator or a weak topological insulator. Using high-resolution photon-energy dependent angle-resolved photoemission spectroscopy, we succeeded in observing a quasi-one-dimensional and linearly dispersive energy band near the Fermi level on the surface that is perpendicular to the two-dimensional ZrTe$_5$ layers. The observed quasi-one-dimensional band comes from the one-dimensional topological edge state of the ZrTe$_5$ layers. The weak dispersion of the quasi-one-dimensional band along the normal direction of ZrTe$_5$ layer indicates that the inter-edge coupling between the ZrTe$_5$ layers are not strong enough to form a three-dimensional strong topological insulator. Our findings provided the comprehensive information about the quasi-one-dimensional edge state and unambiguously indicated that ZrTe$_5$ bulk crystal is a three-dimensional weak topological insulator.

Session L04 DMP: Dirac/Weyl Semimetals -- Materials Prediction II BCEC 107C - Dmytro Pesin, University of Virginia - Tag(s): Focus

11:15AM L04.00001: Composite Dirac Semimetal  
ZIMING ZHU (Presenter), Hunan Normal University, ZHI-MING YU, WEIKANG WU, Singapore University of Technology and Design, WEI ZHANG, Fujian Normal University, FAN ZHANG, University of Texas at Dallas, SHENGYUAN YANG, Singapore University of Technology and Design — In this work, we investigate the possibility to construct a new topological state, which may be regarded as a combination of a WTI and a Dirac semimetal, hence it may be termed as a composite Dirac semimetal (CDSM). We start with an effective model, which can be derived from a tight-binding model defined on a stacked honeycomb lattice. By analyzing the possible band ordering at the high symmetry points on the rotation axis, we show that a CDSM state can be realized, for which one pair of low-energy bands cross at the Fermi level to form two symmetry-protected Dirac points, whereas another pair of bands have inverted band ordering along the high symmetry path. The hallmark of this state is that on the side surfaces, a pair of Fermi arcs connecting the projected Dirac points coexist with a pair of helical Fermi loops traversing the surface Brillouin zone (BZ). Without breaking any symmetry, the CDSM may undergo a topological phase transition to an insulating state via a band inversion scenario, accompanied by two pairs of helical surface Fermi loops. Finally, by using first-principles calculations, we show that the discussed physics can be realized in a realistic material system.
First-Principles Prediction of New Magnetic Weyl Semimetals: Cobalt-Based Shandites System

YUMA NAKAMURA, WEI LUO (Presenter), JINSEON PARK, Department of Physics and Astronomy, The University of Tennessee (Knoxville), MINA YOON, CNMS, Oak Ridge National Lab — The experimental confirmation of Co3Sn2S2 as the first magnetic Weyl semimetal (MWSM) paved the way to explore new magnetic Weyl semimetals. Cobalt-based shandite consists of T3M2X2 (T = Co; M = Ge, Sn, Pb; X = S, Se) in a rhombohedral arrangement with rotational symmetry, inversion symmetry, and a kagome layer formed by Co. Using a first-principles approach coupled with a global structure search algorithm, we explored energetically stable configurations of Co-based shandites and their alloys (T3M1M2X2, where M1/M2 = Ge, Sn, and Pb). We characterized their electronic properties by establishing a tight-binding Hamiltonian with parameters extracted from maximally localized Wannier functions, and identified new MWSMs. The Weyl points of new MWSMs are formed by p-orbitals of elements M located between the kagome layer and d-orbitals of Co on the kagome layer, where their location and energy level changes as a function of M. A wider class of new MWSMs that can be synthesized experimentally is proposed.

Pairing and charge order in a strongly-interacting Weyl system: Numerically exact results from auxiliary-field quantum Monte Carlo

PETER ROSENBERG (Presenter), NIRAJ ARYAL, EFSTRATIOS MANOUSAKIS, National High Magnetic Field Laboratory, Florida State University — The recent discovery of Weyl semimetals has generated intense interest in their properties. These materials have been predicted to exhibit a number of fascinating behaviors, including topological superconductivity. Here we study a model Weyl system subject to strong interactions using the numerically exact auxiliary-field quantum Monte Carlo technique. We focus on charge and pairing properties, in order to explore the interplay of Weyl physics, charge order, and superconductivity. These high-accuracy results will complement ongoing experimental efforts in Weyl systems, and help guide the search for exotic pairing phenomena in these systems, which can be realized in both real materials and ultra-cold atoms.

Mixed axial-torsional anomaly in Weyl semimetals

YAGO FERREIROS, Royal Institute of Technology, YARON KEDEM, EMIL J BERGHOLTZ, Stockholm University, JENS BARDARSON (Presenter), Royal Institute of Technology — We show that Weyl semimetals exhibit a mixed axial-torsional anomaly in the presence of axial torsion, a concept exclusive of these materials with no known natural fundamental interpretation in terms of the geometry of spacetime. This anomaly implies a nonconservation of the axial current—the difference in current of left- and right-handed chiral fermions—when the torsion of the spacetime in which the Weyl fermions move couples with opposite sign to different chiralities. The anomaly is activated by driving transverse sound waves through a Weyl semimetal with a spatially varying tilted dispersion, which can be engineered by applying strain. This leads to sizable alternating current in presence of a magnetic field that provides a clear-cut experimental signature of our predictions.

Evolution of the surface states of the Luttinger semimetal under compressive strain and broken inversion symmetry

EWELINA HANKIEWICZ (Presenter), JULIAN-BENEDIKT MAYER, MAXIM KHARITONOV, University of Wurzburg — Luttinger semimetal, the quadratic-node semimetal for  electrons under full cubic symmetry, is the parent highest-symmetry minimal model for a variety of topological and/or strongly correlated materials, such as HgTe, α-Sn, and iridate compounds. Recently, Luttinger semimetal has been demonstrated [1] to exhibit surface states of topological origin that can be attributed to approximate chiral symmetry. In the present work, we theoretically study the effect of the symmetry-lowering perturbations on these surface states within an analytical model. Under compressive strain lowering rotational symmetry, Luttinger semimetal becomes a Dirac semimetal with a pair of double-degenerate linear nodes. Breaking further inversion symmetry, the system turns into a Weyl semimetal, with each Dirac node split into four Weyl nodes. We analyze the corresponding evolution of the surface states, and its relation to the surface states of the full Kane model.

12:15PM L04.00006: The effect of interaction and gauge field in topological semimetals

CHAOXING LIU (Presenter), Pennsylvania State University, RUI-XING ZHANG, University of Maryland, PENG YE, Sun Yat-sen University, XIAOLIANG QI, Stanford University, HONGWEI JIA, WENLONG GAO, QINGHUA GUO, BIAO YANG, JING HU, YANGANG BI, Univ of Birmingham, YUANJIANG XIANG, Shenzhen University, SHUANG ZHANG, Univ of Birmingham — Topological semimetals possess topologically protected nodal points or lines with exotic physical properties. Here I focus on the effects of interaction and gauge field on topological Weyl or Dirac semimetals. I will first show that in a nanowire made of Dirac semimetals, interaction enables the emergence of boundary Majorana zero modes that are protected by rotation symmetry under magnetic fields [1]. Therefore, the Dirac semimetal nanowire provides an ideal platform for the realization of 1D interacting topological phase with Majorana physics, which does not require superconductivity and is thus number-conserving. Next I will describe the influence of generalized gauge fields in Weyl semimetals [2,3]. Due to the chirality of Weyl nodes, it was realized that more general form of gauge fields beyond conventional electromagnetic fields can be induced by magnetic fluctuation or strain in Weyl semimetals. As a consequence of gauge fields, zeroth Landau levels can be induced and only propagate in one direction (chiral). The presence of chiral zeroth Landau levels is the origin of chiral anomaly and allows for a robust bulk transport. Such generalization of gauge fields is recently demonstrated in an inhomogeneous Weyl metamaterial experimentally [3].

12:51PM L04.00007: Level statistics of disordered Weyl semimetals

XIANG RONG WANG (Presenter), Hong Kong University of Science and Technology, CHEN WANG, PENG YAN, School of Electronic Science and Engineering, University of Electronic Science and Technology of China — The level statistics and the fractal nature of electron wavefunction around Weyl nodes of disordered Weyl semimetals are numerically investigated. The nearest-neighbor level spacing follows a new universal distribution originally proposed for the level statistics of critical states in the integer quantum Hall systems or normal dirty metals (diffusive metals) at metal-to-insulator transitions, instead of the Wigner-Dyson distribution for diffusive metals. The wavefunction at a Weyl node occupies a fractal space of dimension 2.18, in contrast to the extended states that spread over the whole space (D=3). The finite size scaling of the inverse participation ratio (IPR) suggests that the correlation length of wavefunctions at Weyl nodes (E=0) diverges as ξ \sim |E|^{-\nu} with \nu=0.89. In the ergodic limit, the level number variance around Weyl nodes increases linearly with the average level number N.

1:03PM L04.00008: Emergent Weyl Nodes and Monopole Charge Density Wave State*  
YI LI (Presenter), ERIC BOBROW, CANON SUN, Johns Hopkins University — We study a new class of topological charge density wave states exhibiting monopole harmonic symmetries. When electron and hole Fermi surfaces carry different Chern numbers, the particle-hole pairing exhibits a non-trivial Berry phase inherited from band structure topology independent of concrete density-wave ordering mechanism. The associated density-wave gap functions become nodal, and the net nodal vorticity is determined by the monopole charge of the pairing Berry phase. The gap function nodes become zero-energy Weyl nodes of the bulk spectra of quasi-particle excitations. These states can occur in doped Weyl semimetals with nested electron and hole Fermi surfaces enclosing Weyl nodes of the same chirality in the weak coupling regime. Possible signatures of monopole harmonic charge density waves are proposed for scattering experiments.

1:15PM L04.00009: Non-Abelian Statistics in Momentum Space*  
QUANSHENG WU, EPFL Lausanne, ALEXEY A SOLUYANOV, University of Zurich, TOMAS BZDUSEK (Presenter), Stanford University — We develop a general theory describing the stability and conversions of a wide range of band-structure nodes. The technique readily applies to a plethora of nodes existing in semimetals and superconductor, while it also reveals various previously unknown nodal features. Especially, we find that band-structure nodes in PT-symmetric systems with negligible spin-orbit coupling carry a non-Abelian charge, thus suggesting non-trivial braiding rules in momentum space. The non-Abelian charge also poses constraints on admissible nodal-line composition in 3D systems, and on the topological transitions between various such compositions. We emphasize that the non-Abelian property arises without the need of electron interactions.

In this talk, I motivate our description of band-structure nodes based on homotopy theory, and demonstrate its power on several simple examples. Afterwards, I clarify the meaning of the non-Abelian charge arising in PT-symmetric systems, and show how it constraints nodal compositions in a simple metal, namely elemental scandium (Sc) under strain. Our predictions could be experimentally tested in photoemission experiments.

1:27PM L04.00010: Classification of composite Weyl fermions  
DANIEL GOSÁLBEZ MARTÍNEZ (Presenter), OLEG YAZYEV, École Polytechnique Fédérale de Lausanne (EPFL), Switzerland — Weyl nodes with chiral charge ±1 are classified as types I and type II according to the tilting of the conical band dispersion at the band degeneracy. Their Fermi surface, described by a quadratic form, is different for these two types. We extend this classification to the case of composite Weyl nodes with chiral charge larger than one. When the C4 and C6 rotation symmetries forbid the linear band dispersion on the plane perpendicular to the symmetry axis, new terms with quadratic and cubic momentum dependence must be included. Consequently, the Fermi surface produced by these band degeneracies are described by a 4 or 6 order algebraic surfaces. In this more complex situation, instead of classifying Fermi surfaces, we study numerically the possible Lifshitz transitions of the Fermi surface produced by a composite Weyl node as the chemical potential is varied. We use this methodology to study quadratic Weyl nodes generated by the C4 rotation symmetry. We find that such band degeneracies present four different types of morphologies, two analogous to the type-I and type-II case of the conical Weyl nodes, and two new distinct morphologies within the type-II class. We illustrate the existence of these new types of band degeneracies in real materials such as bcc iron.

1:39PM L04.00011: Computational search for magnetic Weyl semimetals in rare-earth compounds*  
LIN-LIN WANG (Presenter), Ames Laboratory, NA HYUN JO, YUN WU, BRINDA KUTHANAZHI, ADAM KAMINSKI, PAUL CANFIELD, Iowa State University — Weyl fermions are of interests for both basic science and future technology. Weyl points in electronic band structure can be generated by breaking inversion or/and time-reversal symmetry to realize linear crossings having monopoles of Berry curvature. Here we have used high throughput band structure calculations based on density functional theory to search for magnetic Weyl semimetals in rare-earth compounds. The existence of Weyl points is identified by calculating Berry curvature. We find that the magnetic Weyl points depend on the specific magnetic ordering structure.

*This work is supported by the Center for Advancement of Topological Semimetals, an Energy Frontier Research Center funded by the US DOE Basic Energy Sciences, through the Ames Laboratory under Contract No. DE-AC02-07CH11358. NHJ is funded by the Gordon and Betty Moore Foundation’s EPIQS Initiative through Grant GBMF4411.
1:51PM L04.00012: Optical Properties of Weyl Semimetals from First Principles
CHRISTINA GARCIA (Presenter), JENNIFER COULTER, PRINEHA NARANG, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Recent experiments have shown interesting optical behavior in Weyl semimetals, a topologically nontrivial class of materials. Weyl semimetals (WSMs) are characterized by linearly dispersive band touchings in the bulk states (in three dimensions) where electrons can be treated as massless Weyl fermions. This talk will focus on our evaluation of optical properties, hot carrier generation and dynamics in different Weyl semimetals using first principles calculations incorporating electron-phonon interactions. In particular, we explore TaAs, in which record-breaking second-harmonic generation and bulk photovoltaic effects have been recently reported. We will build upon our ab initio framework to include nonlinear optical properties for direct comparison with these exciting observations.

Wednesday, March 6, 2019 11:15 AM - 2:15 PM

Session L05 DMP: Topological Superconductivity: Theory
BCEC 108 - Gregory Fiete, University of Texas at Austin
- Tag(s): Focus

11:15AM L05.00001: Designing topological superconductors [Invited] LIANG FU (Presenter), Massachusetts Institute of Technology — I will discuss routes to creating topological (and other unconventional) superconductors by tuning the Fermi surface of materials with gating, electric/magnetic field and strain. Candidate systems include 2D materials with spin-orbit coupling, with tunable van Hove singularity, or with moire superlattice.

11:51AM L05.00002: Extension of symmetry-based indicators and its application* SEISHIRO ONO (Presenter), Institute for Solid State Physics, HARUKI WATANABE, Applied Physics, University of Tokyo — The goal of the study of topological phases is to achieve the complete classification of phases for all spatial and internal symmetries. The topological periodic table, the classification table of topological insulators for each internal symmetry class, is a milestone in this line of research. Recently, the method of “symmetry-based indicators (SI)” has been developed. It diagnoses the topology of band structures based on their symmetry representations. The prototypical example of SI is the Fu-Kane formula, which distinguishes topological insulators from normal insulators in terms of inversion parities. So far, as an internal symmetry, only the time-reversal symmetry has been taken into account in the calculation of SI. In this talk, we discuss how to incorporate with the chiral symmetry and the particle-hole symmetry.

*H.W. is supported by JSPS KAKENHI Grant No. JP17K17678.

12:03PM L05.00003: Classification of topological crystalline superconducting nodes on high-symmetry line* SHUNTARO SUMITA (Presenter), Department of Physics, Kyoto University, TAKUYA NOMOTO, Department of Applied Physics, The University of Tokyo, KEN SHIOZAKI, Yukawa Institute for Theoretical Physics, Kyoto University, YOUICHI YANASE, Department of Physics, Kyoto University — Recent development in exact classification of a superconducting gap has elucidated various unconventional gap structures [1-8], which have not been predicted by the classification of order parameter based on the point group [9]. One of the important previous results is that all symmetry-protected line nodes are characterized by nontrivial topological numbers [6, 7]. Another intriguing discovery is the gap structures depending on the angular momentum of electrons $j_z$ on threefold and sixfold rotational-symmetric lines [1, 3, 8]. Stimulated by these findings, we classify all crystal symmetry-protected nodes (including such $j_z$-dependent nodes) on high-symmetry $n$-fold ($n = 2, 3, 4, and 6$) axes, by using the combination of group theory and $K$-theory [10]. As a result, it is shown that the classification by group theory completely corresponds with the topological classification. Based on the obtained results, we discuss superconducting gap structures in several candidate superconductors.

12:15PM L05.00004: Weak-Pairing Higher Order Topological Superconductors*  MAO LIN (Presenter), YUXUAN WANG, TAYLOR HUGHES, University of Illinois at Urbana-Champaign — We consider a new class of superconductors, second-order topological superconductors (SOTSC), that have gapped, topological surfaces and gapless Majorana modes on lower-dimensional boundaries: corners of a 2D system or hinges for a 3D system. We propose two general scenarios that SOTSC can be realized spontaneously with weak-pairing instabilities. First, we show that p-wave pairing in a Dirac semimetal in 2D with four mirror symmetric Dirac nodes realizes SOTSC. Second, we show that p+id pairing on an ordinary Fermi surface realizes SOTSC as well. We show that these exotic states can be intrinsically realized in a metallic system with electronic interactions. In the latter case we find that the topological invariants describing the system can be written using simple formulae involving only the low-energy properties of the Fermi surfaces and superconducting pairing, and we also show it can be induced by proximity effect in a heterostructure of cuprate and superconductor.

12:27PM L05.00005: Exotic superconductivity with enhanced energy scales in materials with three band crossings*  YU-PING LIN (Presenter), RAHUL NANDKISHORE, Department of Physics, University of Colorado Boulder — Three band crossings can arise in three-dimensional quantum materials with certain space group symmetries. The low energy Hamiltonian supports one fermions and a flat band. We study the pairing problem in this setting. We write down a minimal BCS Hamiltonian and decompose it into spin-orbit coupled irreducible pairing channels. We then solve the resulting gap equations in channels with zero total angular momentum. We find that in the s-wave spin singlet channel (and also in an unusual d-wave 'spin quintet' channel), superconductivity is enormously enhanced, with a possibility for the critical temperature to be linear in interaction strength. Meanwhile, in the p-wave spin triplet channel, the superconductivity exhibits features of conventional BCS theory due to the absence of flat band pairing. Three band crossings thus represent an exciting new platform for realizing exotic superconducting states with enhanced energy scales. We also discuss the effects of doping, nonzero temperature, and of retaining additional terms in the k.p expansion of the Hamiltonian.

12:39PM L05.00006: Anomalous symmetry protected topological states in interacting fermion systems*  QING-RUI WANG, Physics, The Chinese University of Hong Kong, YANG QI, Physics, Fudan University, ZHENGCHENG GU (Presenter), Physics, The Chinese University of Hong Kong — The classification and construction of symmetry protected topological (SPT) phases have been intensively studied in interacting systems recently. To our surprise, in interacting fermion systems, there even exists a new class of the so-called anomalous SPT (ASPT) states which are only well defined on the boundary of a trivial fermionic bulk. The physical reason is that certain symmetry action might change the fermion parity locally, but is conserved if we introduce a bulk. We demonstrate the essential idea by considering anomalous topological superconductor with time reversal symmetry $T^2 = 1$. Finally, we also discuss the classification scheme of anomalous SPT states for interacting fermions with a total symmetry $G_f = G_b \times \mathbb{Z}_2$ and relevant experimental implications.

*ZCG acknowledges Direct Grant no. 4053300 from The Chinese University of Hong Kong and funding from Hong Kong’s Research Grants Council (ECS 24301516).
12:51PM L05.00007: Superconducting higher-order semimetals: Second-order Dirac superconductors and magnetic field induced higher-order topological superconductivity* SAYED ALI AKBAR GHORASHI (Presenter), XIANG HU, Physics, College of William and Mary, TAYLOR HUGHES, Physics Institute for Condensed Matter Theory, University of Illinois Urbana-Champaign, ENRICO ROSSI, Physics, College of William and Mary — We identify three dimensional superconductors that exhibit various forms of higher order topology. We show how such superconductors can be obtained through superconducting instabilities induced in higher order quadrupole topological semimetals [1]. In our models the normal-state degrees of freedom consist of two orbitals and spin in an electronic structure that forms a quadrupolar topological semimetal. We consider all possible s-wave superconducting pairing terms satisfying Fermi-Dirac statistics and obtain six different superconducting models. We find that four of the models have a non-zero residual quadrupole-like topology, and therefore topologically protected Majorana hinge states on the four hinges of the sample. The other two models have no quadrupolar topology yet, in the presence of an external magnetic field, exhibit helical hinge states localized at only two of the four hinges. For these two models we also find that the pair of corners exhibiting hinge states switches upon a change of sign of the magnetic field.

1:03PM L05.00008: Higher Order Topological Phases: A General Principle of Construction DUMITRU CALUGARU (Presenter), Max-Planck-Institut fur Physik komplexer Systeme, Dresden, Germany, VLADIMIR JURICIC, NORDITA, the Nordic Institute for Theoretical Physics, Stockholm University and KTH, Stockholm, Sweden, BITAN ROY, Max-Planck-Institut fur Physik komplexer Systeme, Dresden, Germany — In this talk, we discuss a general principle for constructing higher-order topological (HOT) phases [1]. We argue that if a D-dimensional first-order or regular topological phase involves m Hermitian matrices that anti-commute with additional p-1 mutually anti-commuting matrices, it is conceivable to realize an n\textsuperscript{th}-order HOT phase, where n=1,..., p, with appropriate combinations of discrete symmetry-breaking Wilsonian masses. An n\textsuperscript{th}-order HOT phase accommodates zero modes on a surface with co-dimension n. We exemplify these scenarios for prototypical three-dimensional gapless systems, such as a nodal-loop semimetal possessing SU(2) spin rotational symmetry, and Dirac semimetals, transforming under (pseudo-)spin-1/2 or 1 representation. The former system permits an unprecedented realization of a 4\textsuperscript{th}-order phase, without any surface zero modes. Our construction can be generalized to HOT insulators and superconductors in any dimension and symmetry class.

1:15PM L05.00009: Gauge Theory of the Superconductor-Insulator Transition* VALERII VINOKOUR (Presenter), Argonne National Laboratory, CRISTINA DIAMANTINI, LUCA GAMMAITONI, Dipartimento di Fisica e Geologia, University of Perugia, IGOR LUKYANCHUK, Laboratory of Condensed Matter Physics, University of Picardie, CARLO TRUGENBERGER, SwissScientific Technologies SA — The standard model of particle physics is extraordinarily successful at explaining much of the physical realm. Yet, one of its most profound aspects, the mechanism of confinement, that binds quarks into hadrons and is supposedly mediated by chromo-electric strings in a condensate of magnetic monopoles, is not thoroughly understood and lacks direct experimental evidence. We demonstrate that the infinite-resistance superinsulating state, a mirror analog of superconductivity, emerging at the insulating side of the superconductor-insulator transition (SIT) is a condensed matter realization of the quark confinement. We reveal that the mechanism ensuring the infinite resistance of superinsulators is the binding of Cooper pairs into neutral “mesons” by electric strings and establish a mapping of quarks onto Cooper pairs in superinsulators. We reveal a Cooper pair analog of the asymptotic freedom effect implying that systems smaller than the string scale appear in a quantum metallic state.

1:27PM L05.00010: Superconducting vortex from magnetic skyrmions*  SHU-PING LEE (Presenter), YI LI, Johns Hopkins University — We show topological superconductivity can arise at the interface of ferromagnetic skyrmion material in proximity to an s-wave superconductor in the presence of strong spin-orbit coupling. We study the Majorana zero modes localized at the interface of the heterostructure and propose a pathway towards a useful platform for the manipulation of Majorana fermions via controlling skyrmions.

*S.-P. Lee and Y. L. acknowledge the support by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, Grant No. DE-FG02-08ER46544. Y. L. also acknowledges the support from the Alfred P. Sloan Fellowship.

1:39PM L05.00011: Magnon-induced superconductivity in a topological insulator coupled to ferro- and antiferromagnetic insulators*  HENNING HUGDAL (Presenter), Norwegian University of Science and Technology, STEFAN REX, Karlsruhe Institute of Technology, FLAVIO NOGUEIRA, IFW Dresden, ASLE SUDBO, Norwegian University of Science and Technology — We study the effective interactions between Dirac fermions on the surface of a three-dimensional topological insulator due to the proximity coupling to the magnetic fluctuations in a ferromagnetic or antiferromagnetic insulator. Magnetic fluctuations can mediate attractive interactions between Dirac fermions of both Amperean and BCS type. In the ferromagnetic case, we find pairing between fermions with parallel momenta, so-called Amperean pairing, whenever the effective Lagrangian for the magnetic fluctuations does not contain a quadratic term. If a quadratic term is present, the pairing is instead of BCS type above a certain chemical potential. In the antiferromagnetic case, BCS pairing occurs when the ferromagnetic coupling between magnons on the same sublattice exceeds the antiferromagnetic coupling between magnons on different sublattices. Outside this region in parameter space, we again find that Amperean pairing is realized

1:51PM L05.00012: Reproducing topological properties with quasi-Majorana states  ADRIAAN VUIK, BAS NIJHOLT, ANTON AKHMEROV, Kavli institute of nanoscience, Delft University of Technology, MICHAEL WIMMER (Presenter), QuTech and Kavli institute of nanoscience, Delft University of Technology — Andreev bound states in hybrid superconductor-semiconductor devices can have near-zero energy in the topologically trivial regime as long as the confinement potential is sufficiently smooth. We show that in addition to the suppressed coupling between the quasi-Majorana states, also the coupling of these states across a tunnel barrier to the outside is exponentially different. As a consequence, quasi-Majorana states mimic most of the proposed Majorana signatures: quantized zero-bias peaks, the 4π Josephson effect, and the tunneling spectrum in presence of a normal quantum dot. We identify a quantized conductance dip instead of a peak in the open regime as a distinguishing feature of true Majorana states in addition to having a bulk topological transition. Because braiding schemes rely only on the ability to couple to individual Majorana states, the exponential control over coupling strengths allows to also use quasi-Majorana states for braiding.

2:03PM L05.00013: Fulde-Ferrell-Larkin-Ovchinnikov phases in Proximitized Josephson junctions  CHIEN-TE WU (Presenter), Electrophysics, National Chiao Tung University, FNU SETIAWAN, KATHRYN LEVIN, James Franck Institute, University of Chicago — Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phases, which are notoriously difficult to find in more homogeneous systems, have been observed in proximitized superconductors. Of particular interest are those heterostructures which are associated with topological phases[1,2]. In this talk, we establish the effects of spin-orbit coupling and show why these elusive phases are observable in the presence of proximitization. We focus on that FFLO phase which appears inside a substrate (subjected to an in-plane magnetic field) and formed in a Josephson junction configuration. To do so, we solve the Bogoliubov-de Gennes equations for the full multi-component system. The substrates consist of (1) a conical Holmium magnet with an effective 1D spin-orbit coupling, and (2) a two-dimensional electron gas.

Exploring electronic anisotropy with strain in CeRhIn$_5$*  
SEAN THOMAS (Presenter), ADAM P DIOGUARDI, JOE D THOMPSON, PRISCILA ROSA, ERIC BAUER, FILIP RONNING, Los Alamos National Laboratory — Strongly correlated material CeRhIn$_5$ hosts a helical antiferromagnetic ground state at zero applied field. When a magnetic field of ~30 T is applied slightly away from the c-axis, a new phase emerges within the antiferromagnetic state with an XY electronic nematic character [1]. Here, we use a combination of uniaxial and biaxial strain devices to investigate the nematic susceptibility of CeRhIn$_5$. A similar approach has been extensively used to investigate the nematic order in iron-based superconductors [2]. We will discuss signatures of the nematic susceptibility in the low-field region of the H-T phase diagram.

*Work at Los Alamos was performed under the auspices of the US DOE, Division of Materials Science and Engineering.

Spin density wave and possible Fulde-Ferrell-Larkin-Ovchinnikov states in CeCoIn$_5$*  
DUK YOUNG KIM, Institue of Basic Science, SKKU, South Korea, SHIZENG LIN, ERIC BAUER, FILIP RONNING, ROMAN MOVSHOVICH (Presenter), Los Alamos National Laboratory — We examine interplay between spin density wave (SDW) and the putative Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state in CeCoIn$_5$. We use thermal conductivity measurement along a-axis in magnetic field applied at various angles away from the c-axis within the bc plane of this tetragonal compound. We compare our results to those of our theoretical model which shows that SDW state in CeCoIn$_5$ is stabilized when the field is directed close to the ab plane. The SDW phase disappears when the field is rotated away from the ab plane. When the field is rotated toward the c axis, the FFLO state emerges while the SDW phase disappears. As a function of field, we observed the reduction of thermal conductivity for field close to the ab plane and the enhancement of thermal conductivity when field is close to the c axis, consistent with the theoretical expectations of additional contribution to the heat transport from the FFLO nodal planes.

Fermi surface evolution and crystal-field excitations in heavy-fermion compounds probed by time-domain terahertz spectroscopy*  
SHOVON PAL, CHRISTOPH WETLI, Department of Materials, ETH Zürich, FARZANEH ZAMANI, Physikalisches Institut, University of Bonn, OLIVER STOCKERT, MPI-CPFS Dresden, HILBERT V. LÖHNEYSEN, Physikalisches Institut and Inst. für Festkörperphysik, KIT Karlsruhe, MANFRED FIEBIG, Department of Materials, ETH Zürich, JOHANN KROHA (Presenter), Physikalisches Institut, University of Bonn — In heavy-fermion (HF) compounds, the existence of heavy quasiparticles (QPs) is signaled by an enlarged Fermi volume. The energy scale for heavy QP formation is believed to be the Kondo lattice temperature. Hence, the origin of a large Fermi volume observed at temperatures much higher than the Kondo lattice temperature has recently been a controversial issue. We measure the quasiparticle weight in the HF compound CeCu$_6-x$Au$_x$ (x=0, 0.1) by time-resolved THz spectroscopy for temperatures from 2 K up to 300 K. This method distinguishes contributions from the heavy Kondo band and from the crystal-electric-field satellite bands by different THz response delay times [1,2]. We find that the formation of heavy bands is controlled by an exponentially enhanced, high-energy Kondo scale once the crystal-electric-field states become thermally occupied. We corroborate these observations by temperature-dependent, high-resolution dynamical mean-field calculations for the multi-orbital Anderson lattice model and discuss the relevance for quantum critical scenarios.

*Funded in part by SNSF and DFG.
11:51AM L06.00004: Kondo effects in α and γ phases of Ce  JUNWON KIM (Presenter), DONG-CHOON RYU, Department of Physics, Pohang University of Science and Technology, HONGCHUL CHOI, Scuola Internazionale Superiore di Studi Avanzati, KYOO KIM, Max Plank Research Center, Pohang 37671, Korea, BYUNG IL MIN, Department of Physics, Pohang University of Science and Technology — The Kondo effect is one of the fascinating correlation phenomena in condensed matter physics. The monoatomic compound Ce, which is famous for the α - γ phase transition and the extremely rich phase diagram with at least seven allotropes, is a good sample for observing the Kondo effect and its change with respect to the temperature or pressure variations. In this research, we focused on the Kondo physics in α and y phase among the various phases of Ce. To capture the Kondo physics, we used the first principles Dynamical Mean-Field Theory (DMFT) approach combined with Density Functional Theory (DFT)[1,2]. Unlike the cases of using DFT only, we have observed in the DFT+DMFT scheme that Kondo resonances are formed distinctly for α and γ phases of Ce, which yields different band structures between two phases, especially at around EF. We theoretically discuss the temperature-dependent physical properties of both phases, and compare their band structures with photoemission experimental results.

12:03PM L06.00005: Magnetic complexity in RScT (R=Gd, Pr, T=Sb, Ge) based compound*  ARJUN PATHAK (Presenter), FRANCOIS GUILLOU, YAROSLAV MUDRYK, VITALIJ K PECHARSKY, Materials sciences and engineering, Ames Laboratory, US DOE, Ames IA — Ternary RTX intermetallics, where R = rare earth, T = transition metal, X = p-block element, are structurally and magnetically diverse and are among the most interesting intermetallic compounds to explore (Gupta et. al. JALCOM 618 (2015) 562). For example, GdScGe crystallizes in tetragonal CeScSi-type structure and undergoes a ferromagnetic (FM) transition at TC = 350K, while PrScGe (same CeScSi-structure type) has an antiferromagnetic (AFM) transition at TN = 88K and then a FM transition at TC = 80K. When germanium is replaced by antimony, the GdScSb compound crystallizes in a closely related tetragonal CeFeSi-type and orders AFM at TN ~55K. Here we present a systematic study of the interplay between crystal structure and magnetism in Gd1-xPrxScGe and GdSc(Ge1-xSbx). The substitution of heavy lanthanide, Gd, with light lanthanide, Pr, results in a complex magnetic ground state with a large exchange bias of HE ~ 1.06 kOe at T = 2K.

*The Ames Laboratory is operated for the U. S. DOE by Iowa State University of Science and Technology under contract No. DE-AC02-07CH11358. This work was supported by the Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division.

12:15PM L06.00006: The Ho₆Mo₄Al₄₃ structure type as a cage for Uranium and Plutonium*  KEVIN HUANG, National High Magnetic Field Laboratory, WILLIAM NELSON (Presenter), Physics, Florida State University, ALEXANDER CHEMEY, THOMAS ALBRECHT-SCHMITT, Chemistry, Florida State University, RYAN BAUMBACH, National High Magnetic Field Laboratory — Single crystals of A₆W₄Al₄₃ (A=U/Pu) were synthesized for the first time using a molten Al flux. This structure features large lattice constants (a=10.97, c=17.71Å) and cage-like W-Al polyhedra that surround the A ions. XRD suggests that, unlike for some other cage-like structures, the A ions do not exhibit soft lattice modes. Magnetic susceptibility measurements for U₆W₄Al₄₃ show Curie-Weiss behavior, where fits to the data yield an effective magnetic moment near 2.0 µB/U. At low-T the magnetic susceptibility deviates from the Curie-Weiss law and saturates to a constant value, as seen for other spin fluctuating materials. There is evidence from the electrical transport and heat capacity for the formation of a heavy Fermi liquid ground state due to Kondo lattice behavior. In contrast, Pu₆W₄Al₄₃ exhibits nearly T-independent Pauli paramagnetism, suggesting delocalization of the 5f electrons. We will discuss these results in the context of the Hill plot, where both compounds are found near the inter-actinide distance that separates delocalized and localized f-electron behavior.

*Work was performed at the NHMFL-FSU, supported by NSF coop. agreements DMR-1157490 and DMR-1644779 and the state of FL. We acknowledge support from US-DOE, BES, under Award No. DE-SC0016568 EFRC-CAST.
Multiple electronic instabilities and the anomalous thermodynamics of plutonium

NEIL HARRISON (Presenter), JONATHAN B BETTS, FEDOR BALAKIREV, MARCELO JAIME, PAUL H TOBASH, Los Alamos National Laboratory — Given plutonium’s importance in energy production, an understanding of its anomalous electronic and thermodynamic properties is essential for its safe handling and long term storage. In common with rare earth and other actinide elements and compounds, plutonium’s physical and chemical properties are determined by $f$-electrons, whose transformation from localized to itinerant behavior are known to drive a significant collapse in volume. However, the occurrence of a volume collapse on both reducing and increasing the temperature and its anomalously large magnitude, reaching as much as 25% at low temperatures, represent extreme departures from the behavior of other known metals. Here we discuss new magnetostriction measurements on $\delta$ Pu, made using an optical fiber Bragg grating technique adapted for use on encapsulated radiological materials, that plutonium’s exceptional thermodynamic behavior with temperature derives from its $f$-electron shell having multiple electronic instabilities.

*This work is supported by the LANL LDRD program.

Fermi Surface Topology and Correlation Effects in the Electronic Structure of Plutonium

ROXANNE TUTCHTON (Presenter), JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory — Due to its position at the boundary between the light and heavy actinides, the electronic structure of Pu has exotic physical properties that are complex and challenging to model. The difficulties in performing accurate theoretical calculations for this element stem from the liminal characteristics of Pu-$5f$ orbital electrons and understanding the role of the fluctuating magnetism in the electronic structure. Two methods for treating the magnetic behavior in Pu are currently debated. One is the “disordered local moment” model described by density functional theory (DFT) and the other is the “valence fluctuation” model as captured by dynamical mean-field theory (DMFT). Focusing on the $\delta$-phase of elemental Pu, we perform a careful comparison of Fermi surface topology calculations using DFT and DFT+$U$. The de Haas-van Alphen (dHvA) frequencies at the Fermi surface and band masses are calculated in both magnetic and nonmagnetic states. We also analyze the effective mass enhancement due to $5f$-electron correlation effects with DMFT. The comparison study will be helpful for future experiments to validate theoretical modeling.

*This work was performed under the auspices of the U.S. DOE National Nuclear Security Agency through the LANL LDRD program.

Isotropic Giant Magnetoresistance in URhIn$_5$

CARSTEN PUTZKE (Presenter), École Polytechnique Fédérale de Lausanne (EPFL), Institute of Materials, Lausanne, Switzerland, ETERI SVANIDZE, MAJA BACHMANN, MARKUS KOENIG, KENT SHIRER, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, JONAS DIAZ, École Polytechnique Fédérale de Lausanne (EPFL), Institute of Materials, Lausanne, Switzerland, TOBIAS FOERSTER, Highfield Magnetlaboratory Dresden, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany, ANDREAS LEITHE-JASPER, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, ERIC BAUER, FILIP RONNING, Los Alamos National Laboratory, Los Alamos, New Mexico, USA, YURI GRIN, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, PHILIP MOLL, École Polytechnique Fédérale de Lausanne (EPFL), Institute of Materials, Lausanne, Switzerland — We will show results of the resistivity anisotropy in focused ion beam (FIB)-fabricated microstructures of URhIn$_5$ and compare them to CeRhIn$_5$. Both systems order antiferromagnetically (AFM) at 94 K and 3.8K K, respectively. Marked differences are found in their response to magnetic field, despite their structural and electronical similarities. In CeRhIn$_5$, the AFM order leads to an increase in the ratio of in-plane to out-of-plane resistivity with a modulation of the angle-dependent magnetoresistance. In contrast, the onset of AFM order in URhIn$_5$ has no effect on the anisotropy of the system, but leads to a giant magnetoresistance (GMR), resembling semi-metals like Bi$^1$ and WTe$_2$$^2$, rather than other 115-heavy fermion systems. By performing detailed angle-dependent measurements of the magnetoresistance in the U-based system, we can show that the GMR originates mainly from orbital magnetoresistance, making it unique among $f$-electron containing system.
Large anomalous Hall effect in kagome antiferromagnet $U_3Ru_4Al_{12}$

TOMOYA ASABA (Presenter), ERIC BAUER, JOE D THOMPSON, FILIP RONNING, MPA-CMMS, Los Alamos National Laboratory — The Berry curvature in ferromagnets and antiferromagnets has been attracting huge interests due to the tunability of topological features via the magnetic structure. However, topological features in magnetic heavy fermion systems have been sparsely studied so far. In this study, we measured the anomalous Hall effect (AHE) of kagome heavy fermion antiferromagnet $U_3Ru_4Al_{12}$. A large intrinsic AHE at high fields was observed, suggesting the presence of a large Berry curvature due to Weyl fermion. Moreover, the fields required to obtain the large Berry curvature are significantly different between $B//a$ and $B//a^*$, providing a mechanism to control the topological response in this system. These results may not only help to understand the topological heavy fermion physics, but also shed light on this system as an ideal playground for studying field-tuned topological states.

Magnetic torque of uranium dioxide single crystals

KRZYSZTOF GOFRYK (Presenter), Idaho National Laboratory, YOU LAI, NHMFL-FSU, DANIEL ANTONIO, Idaho National Laboratory, RYAN BAUMBACH, DAVID E GRAF, NHMFL-FSU, MARCELO JAIME, NHMFL-LANL, ANDRES SAUL, Aix-Marseille University, MYRON B SALAMON, NHMFL-LANL, JAMES L SMITH, LANL — Uranium dioxide is one of the most studied actinide compounds due to its fundamental and applied importance. Recently, we have performed a low-temperature magnetostriction study of UO$_2$ in magnetic fields up to 95 T [Nature Comm. 8, 99 (2017)], and uncovered the appearance of linear magnetostriction, leading to a trigonal distortion and piezomagnetism (the first example of piezomagnetism in $f$-electron spin system). The unusually strong correlations between the magnetic moments in U-atoms and lattice distortions are a direct consequence of the non-collinear symmetry of the magnetic state that breaks time reversal symmetry in a non-trivial way that leads to the piezomagnetism. The microscopic nature of these interactions, however, remains unclear. During the talk, we will present magnetic torque measurements (up to 35 T) performed on oriented UO$_2$ single crystals. We will discuss implications of these results in the context of the origin of the piezomagnetic ground state in this material.

Magnetoelectric Quantum Oscillations and the Fermi Surface of UPt$_3$

BELLA VE SHIVARAM, LUDWIG HOLLEIS (Presenter), VERN ULRICH, University of Virginia — We report details of magnetoelectric quantum oscillations measured for several different angles of the magnetic field away from the $a$-axis as well as the $c$-axis in UPt$_3$ for temperatures down to 35 mK. The effective masses of the electrons in the observed orbits obtained from the temperature dependence of the amplitudes of the oscillations will be presented. The field dependence of the frequencies of the orbits will be discussed and the low field values will be compared with the known band structure predictions of UPt$_3$.

Field Angle Tuned Metamagnetism, Lifschitz Transitions and Hidden Order in UPt$_3$

BELLA VE SHIVARAM (Presenter), LUDWIG HOLLEIS, University of Virginia, MARCELO JAIME, JOHN SINGLETON, NHMFL, Los Alamos National Labs, VERN ULRICH, University of Virginia — We report ultrasound velocity measurements carried out on single crystals of UPt$_3$, in magnetic fields, $B$, applied at various angles between $c$-axis and the basal plane. For $B//c-axis, \theta=90^\circ$, we observe magneto-acoustic oscillations that commence at fields as low as 12T. These oscillations suddenly break into a very large amplitude at 24.8 T implying a Lifshitz transition. Continuing to higher fields these large amplitude oscillations disappear at 30 T beyond which much smaller oscillations with altered frequencies are observed. Magnetoelectric measurements performed at fields up to 65 T for $\theta=90^\circ$ reveal small features that are consistent with boundaries at similar magnetic field values. Further, the 30 T transition appears to merge with the angle dependent metamagnetic transition at the intermediate angle $\theta=50^\circ$. For field along this unique angle the magnetoelectric along c-axis vanishes precisely for all magnetic field values. High resolution magnetization measurements vs. field are, surprisingly, featureless and near linear when $\theta=90^\circ$.

The work at the University of Virginia was funded by NSF DMR 0073456. The National Magnet Laboratory in Tallahassee is supported by the National Science Foundation and the State of Florida.
1:51PM L06.00014: Anisotropic Magnetostriction Measurements in UPt₃ to 65 T*  BELLAVE SHIVARAM, University of Virginia, FRANZISKA WEICKERT (Presenter), MARCELO JAIME, NHMFL, Los Alamos National Labs — We present magnetostriction measurements obtained in pulsed magnetic fields up to 65 T at the NHMFL/Los Alamos in single crystals of UPt₃ for fields both parallel and perpendicular to the c-axis. While we reproduce published results at low fields the measurements at the highest fields for field parallel to the basal plane reveal a surprising downward trend in the magnetostriction. All these observations will be examined in the context of the single energy scale model of metamagnetism in heavy electron materials.

*The work at NHMFL/Los Alamos is supported by the National Science Foundation.

Wednesday, March 6, 2019 11:15 AM - 1:51 PM

Session L07 DCMP: Theory of Topological Phases  BCEC 109B - Itamar Kimchi, University of Colorado at Boulder

11:15AM L07.00001: Anomaly manifestations in topological insulator surfaces with strong correlations and disorder  ITAMAR KIMCHI (Presenter), YANG-ZHI CHOU, RAHUL NANDKISHORE, MICHAEL A HERMELE, LEO R RADZIHOVSKY, Physics, University of Colorado, Boulder — Three-dimensional topological insulators exhibit a bulk quantum anomaly that protects certain properties of their surface. For example, theoretical studies of weakly interacting strong and weak topological insulators show that their surface stays conducting, even with arbitrarily strong disorder, as long as the relevant symmetries are preserved on average. However, the combination of strong interactions and disorder offers theoretical questions which have not yet been addressed. Here we address this interplay and show that it can lead to a type of localized surface state, even while the disorder ensemble preserves all symmetries. We discuss how the quantum anomaly is manifested within the localized surface. These minimal manifestations of the quantum anomaly can constrain possible Lieb-Schultz-Mattis-type theorems for disordered systems.

11:27AM L07.00002: Free and Interacting SRE Phases of Fermions: Beyond the Ten-Fold Way*  YU-AN CHEN, ANTON KAPUSTIN, ALEX TURZILLO (Presenter), MINYOUNG YOU, Caltech — It is well-known that sufficiently strong interactions can destabilize some SPT phases of free fermions, while others remain stable even in the presence of interactions. It is also known that certain interacting phases cannot be realized by free fermions. We systematically study both of these phenomena in low dimensions and determine the map from free to interacting SPT phases for an arbitrary unitary symmetry G. In particular, in dimension zero and one we describe precisely which SPT phases can be realized by free fermions. We show that in dimension three there are no non-trivial free fermionic SPT phases with a unitary symmetry. We also describe how to compute invariants characterizing interacting phases for free band Hamiltonians with symmetry G (in any dimension) using only representation theory.

* U.S. Department of Energy, Office of Science, Office of High Energy Physics, Award Number de-sc0011632. The work of A. K. was partly performed at the Aspen Center for Physics, which is supported by National Science Foundation grant PHY-1607611. A. K. was also supported by the Simons Investigator Award.

11:39AM L07.00003: Emergent Dirac fermions in Composite-Fermi-Liquids.*  JIE WANG (Presenter), Princeton University, EDWARD H REZAYI, California State University, Los Angeles, FREDERICK D HALDANE, Princeton University — Composite Fermi Liquids (CFLs) are compressible states that can occur for 2D interacting fermions in the lowest Landau level at 1/2m Landau level fillings when m is an integer. They have been understood as Fermi seas of electromagnetic-flux-attached fermions due to Halperin, Lee and Read. At 1/2 filling, an alternative particle-hole symmetric description based on Dirac fermions was proposed by Son. In this talk, we numerically examined the Berry phase associated with transporting one composite fermion around the Fermi sea at filling 1/2 and 1/4. At one-half, a PI Berry curvature singularity was observed [1,2], supporting Son's effective theory. At one-quarter, we found a uniform Berry curvature and an additional PI strength at Fermi sea center. We explained the 1/4 phenomenon from CFL model wavefunctions. We also proposed a flux-attached Dirac fermion effective action [3], which generalized Son's theory from 1/2 filling to all other filling fractions. The Fermi-sea in this new theory is interpreted as formed by internal-gauge-flux-attached Dirac fermions.

*Department of Energy BES Grant de-sc0002140; Princeton U. compton fund.
11:51AM L07.00004: Fragile topological phases in interacting systems  DOMINIC ELSE (Presenter), HOI CHUN PO, Massachusetts Institute of Technology, HARUKI WATANABE, University of Tokyo — Topological phases of matter are defined by their nontrivial patterns of ground-state quantum entanglement, which is irremovable so long as the excitation gap and the protecting symmetries, if any, are maintained. Recent studies on noninteracting electrons in crystals have unveiled a peculiar variety of topological phases, which harbors nontrivial entanglement that can be dissolved simply by the addition of entanglement-free, but charged, degrees of freedom. Such topological phases have a weaker sense of robustness than their conventional counterparts, and are therefore dubbed "fragile topological phases." In this work, we show that fragile topology is a general concept prevailing beyond systems of noninteracting electrons. We identify the key ingredients for fragile topological phases, and demonstrate their existence not only in interacting systems of fermions, but also bosons.

12:03PM L07.00005: Gapped boundary theory of the twisted gauge theory model of three-dimensional topological orders  HONGYU WANG (Presenter), YINGCHENG LI, Physics Department, Fudan University, YUTING HU, Department of Physics and Institute for Quantum Science and Engineering, Southern University of Science and Technology, YIDUN WAN, Physics Department, Fudan University — We extend the twisted gauge theory model of topological orders in three spatial dimensions to the case where the three spaces have two dimensional boundaries. We achieve this by systematically constructing the boundary Hamiltonians that are compatible with the bulk Hamiltonian. Given the bulk Hamiltonian defined by a gauge group G and a four-cocycle \( \omega \) in the fourth cohomology group of G over U(1), we construct a gapped boundary Hamiltonian using \( \{K, \alpha\} \), with a subgroup \( K \subseteq G \) and a 3-cochain \( \alpha \) of K over U(1), which satisfies the generalized Frobenius condition. The Hamiltonian is invariant under the topological renormalization group flow (via Pachner moves). Each solution \( \{K, \alpha\} \) to the generalized Frobenius condition specifies a gapped boundary condition. We derive a closed-form formula of the ground state degeneracy of the model on a three-cylinder, which can be naturally generalized to three-spaces with more boundaries. We also derive the explicit ground-state wavefunction of the model on a three-ball. The ground state degeneracy and ground-state wavefunction are both presented solely in terms of the input data of the model, namely, \( \{G, \omega, K, \alpha\} \).

12:15PM L07.00006: SU(3) trimer resonating-valence-bond state on the square lattice  XIAOYU DONG (Presenter), California state University, Northridge, USA, JI-YAO CHEN, C. N. R. S. and Université de Toulouse, Toulouse, France, HONG-HAO TU, Technische Universität Dresden, Dresden, Germany — We propose and study an SU(3) trimer resonating-valence-bond (tRVB) state with C4v point-group symmetry on the square lattice. By devising a projected entangled-pair state (PEPS) representation, we show that all (connected) correlation functions between local operators in this SU(3) tRVB state decay exponentially, indicating its gapped nature. We further calculate the modular S and T matrices by constructing all nine topological sectors on a torus and establish the existence of Z3 topological order in this SU(3) tRVB state.

12:27PM L07.00007: Quantum phase transitions between gapped topological phases: a percolation approach  XIN DAI (Presenter), SAAD KHALID, ILYA A GRUZBERG, YUANMING LU, Physics, Ohio State University — We study continuous quantum phase transitions between two gapped topological orders, where a gapped boundary exists at the interface of the two phases. Using a percolation picture, we derive the effective Hamiltonian and the universality class of the quantum phase transition.

12:39PM L07.00008: Anyon exclusions statistics on surfaces with gapped boundaries  YINGCHENG LI (Presenter), YIDUN WAN, HONGYU WANG, YUTING HU, Fudan University — Anyon exclusion statistics, proposed by Haldane, generalizes the Bose-Einstein and Fermi-Dirac statistics. When fusion of anyons is involved, certain 'pseudo-species' anyons appear in the exotic statistical weights of non-Abelian anyon systems, whose meaning and significance remains an open problem. The relevant past studies had considered only anyon systems without any physical boundary. In this paper, we propose an extended anyon exclusion statistics on surfaces with gapped boundaries, introducing mutual exclusion statistics between anyons as well as the boundary components. We present a formula for the statistical weight of many-anyon states obeying the proposed statistics. We develop a systematic basis construction for non-Abelian anyons on any Riemann surfaces with gapped boundaries. The basis construction offers a standard way to read off a canonical set of statistics parameters and hence write down the extended statistical weight of the anyon system being studied. The basis construction reveals that a pseudo-species has different 'excitation' modes corresponding to good quantum numbers of subsystems of a non-Abelian anyon system. This is important because often (e.g., in topological quantum computing) we may be concerned about only the entanglement between such subsystems.
Lattice model constructions for gapless domain walls between topological phases

CHENFENG BAO, Perimeter Institute for Theoretical Physics, Waterloo, Ontario, N2L2Y5, Canada, SHUO YANG (Presenter), State Key Laboratory of Low-Dimensional Quantum Physics and Department of Physics, Tsinghua University, Beijing 100084, China, CHENJIE WANG, Perimeter Institute for Theoretical Physics, Waterloo, Ontario, N2L2Y5, Canada, ZHENGCHENG GU, Department of Physics, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong — Lattice models of gapless domain walls between twisted and untwisted gauge theories of finite group G are constructed systematically. As simple examples, we numerically studied the gapless domain walls between twisted and untwisted Z_N (with N=6) gauge models in 2+1D using the state-of-art loop optimization of tensor network renormalization algorithm. We also studied the physical mechanism for these gapless domain walls and obtained quantum field theory descriptions that agree perfectly with our numerical results. By taking the advantage of the systematic classification and construction of twisted gauge models using group cohomology theory, we systematically construct general lattice models to realize gapless domain walls for arbitrary finite symmetry group G. Such constructions can be generalized into arbitrary dimensions and might provide us with a systematical way to study gapless domain walls and topological quantum phase transitions.

Effect of Electron-Phonon Interactions on Dirac Fermions

YUXI ZHANG (Presenter), Department of Physics, University of California, Davis, GEORGE BATROUNI, Institut de Physique de Nice, Universite de Nice-Sophia Antipolis, WETING CHIU, Department of Physics, University of California, Davis, NATANAE DE CARVALHO COSTA, Universidade Federal do Rio de Janeiro, HUAIMING GUO, Department of Physics, Beihang University, RICHARD THEODORE SCALETTAR, Department of Physics, University of California, Davis — The effect of electron-electron interactions on Dirac fermions, and the possibility of an intervening spin liquid phase between the semi-metal and antiferromagnetic (AF) regimes, has been a focus of intense quantum simulation effort over the last five years. We use determinant quantum Monte Carlo (DQMC) to study the Holstein model on Honeycomb lattice and pi-flux lattice and explore the role of electron-phonon interactions on Dirac fermions. We show that they give rise to charge density wave (CDW) order, and present evidence that this occurs only above a finite critical interaction strength. We evaluate the temperature for the transition into the CDW which, unlike the AF transition, can occur at finite values owing to the discrete nature of the broken symmetry.

Charge-Density-Wave Transitions of Dirac Fermions Coupled to Phonons

CHUANG CHEN (Presenter), Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, XIAO YAN XU, Department of Physics, Hong Kong University of Science and Technology, ZI YANG MENG, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, MARTIN HOHENADLER, Institut für Theoretische Physik und Astrophysik, Universität Würzburg — The spontaneous generation of charge-density-wave order in a Dirac fermion system via the natural mechanism of electron-phonon coupling is studied in the framework of the Holstein model on the honeycomb lattice. Using two independent and unbiased quantum Monte Carlo methods, the phase diagram as a function of temperature and coupling strength is determined. It features a quantum critical point as well as a line of thermal critical points. Finite-size scaling appears consistent with fermionic Gross-Neveu-Ising universality for the quantum phase transition, and bosonic Ising universality for the thermal phase transition. The critical temperature has a maximum at intermediate couplings. Our findings motivate experimental efforts to identify or engineer Dirac systems with sufficiently strong and tunable electron-phonon coupling.

1:27PM L07.00012: Diagnosing fractionalization and anyonic statistics in magnetic insulators via noise magnetometry with spin qubits*  
SHUBHAYU CHATTERJEE (Presenter), Physics, University of California Berkeley, JOAQUIN RODRIGUEZ NIEVA, EUGENE DEMLER, Physics, Harvard University — Two-dimensional magnetic insulators exhibit a plethora of competing ground states, such as ordered (anti)ferromagnets, quantum spin liquids with topological order and anyonic excitations, and random singlet phases emerging in the presence of disorder and frustration. We propose that single spin qubits, which interact directly with the low-energy excitations of magnetic insulators, can be used as a diagnostic of magnetic ground states. Experimentally tunable parameters, such as qubit level splitting, sample temperature, and qubit-sample distance, can be used to measure spin correlations with energy and wavevector resolution. Such resolution can be exploited to distinguish between fractionalized excitations in spin liquids and spin waves in magnetically ordered states, or to detect anyonic statistics in systems with a finite energy gap.

1:39PM L07.00013: Chiral Tricritical Point: A New Universality Class in Dirac Systems  
SHUAI YIN (Presenter), SHAO-KAI JIAN, HONG YAO, Institute for Advanced Study, Tsinghua University — Tricriticality, as a sister of criticality, is a fundamental and absorbing issue in condensed-matter physics. It has been verified that the bosonic Wilson-Fisher universality class can be changed by gapless fermionic modes at criticality. However, the counterpart phenomena at tricriticality have rarely been explored. In this Letter, we study a model in which a tricritical Ising model is coupled to massless Dirac fermions. We find that the massless Dirac fermions result in the emergence of a new tricritical point, which we refer to as the chiral tricritical point (CTP), at the phase boundary between the Dirac semimetal and the charge-density wave insulator. From functional renormalization group analysis of the effective action, we obtain the critical behaviors of the CTP, which are qualitatively distinct from both the tricritical Ising universality and the chiral Ising universality. We further extend the calculations of the chiral tricritical behaviors of Ising spins to the case of Heisenberg spins. The experimental relevance of the CTP in two-dimensional Dirac semimetals is also discussed.

Session L08 DCMP: Superconductivity: Copper Oxide - Methods and Probes BCEC 150 - Timir Datta, University of South Carolina

11:15AM L08.00001: Circular photogalvanics study of BSCCO high temperature superconductors*  
SE JOON LIM (Presenter), Stanford University, MARTIN GREVEN, University of Minnesota, AHARON KAPITULNIK, Stanford University — Recent studies have reported that bulk inversion symmetry may be broken inside the pseudogap region of the phase diagram in YBa2Cu3Oy single crystals. Here, we report signatures of inversion symmetry breaking in another family of cuprate high temperature superconductors, Bi2Sr2CaCu2O8+δ, using circular photogalvanic measurements.

*This work is supported by the Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract DE-AC02-76SF00515 and the Gordon and Betty Moore Foundation's EPiQS Initiative through Grant GBMF4529.

11:27AM L08.00002: Three Laws of Electronic Thermal Conductivity of High Temperature Superconductors via Dipolon Theory  
RAM SHARMA (Presenter), University of Illinois at Chicago — Recently we predicted [1] a universal peak in electronic thermal conductivity (ETC) of high-Tc superconductors (HTSCs) via the dipolon theory [2-5]. Previously the dipolon theory has predicted the two high energy and one low energy kinks besides a new very low energy kink in HTSCs. Here we present the three laws of ETC which explain not only the origin but also the behavior of ETC in HTSCs: First Law: The ETC is due to the rate of increase of the quasiparticle energy distribution (ROIOTQED) with temperature particularly near the Fermi level. Second Law: The ROIOTQED becomes maximum at temperature \( T^{(p)} \) given by \( \Delta(0)/k_B T^{(p)} = 2.40 \). Third Law: Where there is a superconducting energy gap, there is a peak in the ETC at the temperature \( T^{(p)} \).

11:39 AM L08.00003: High Pressure 3D to 2D Tuning of Magnetism in Cuprates  
MARKUS HUECKER (Presenter), Condensed Matter Physics Department, Weizmann Institute of Science, GENDA GU, JOHN TRANQUADA, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, BERND BÜCHNER, Institute for Solid State Physics, IFW Dresden  
— Broken lattice symmetries often play an integral part in the selection process of the electronic ground state. A prime example is found in the La-214 cuprates, where lattice distortions result in a complex relationship between superconductivity, charge and magnetic orders. In an attempt to dissect this problem into its various parts, here we highlight the impact of lattice distortions on the pristine magnetism of a cuprate parent compound.

11:51 AM L08.00004: Uniaxial strain susceptibilities of superconducting Tc and charge order transition temperature from sound velocity measurements in YBCO*  
DAVID LEBOEUF (Presenter), SIHAM BENHABIB, MEHDI FRACHET, FRANCIS LALIBERTÉ, CYRIL PROUST, LNCMI - CNRS, TOSHINAO LOEW, JUAN PORRAS, MATHIEU LE TACON, BERNHARD KEIMER, max planck institut  
We study the uniaxial strain dependence of superconducting Tc in YBCO as a function of doping using ultrasounds. We focus on the strain dependence along the a-axis dTc/dε1 and along the b-axis dTc/dε2. For dopings 0.08<p<0.12 we find an anisotropic strain dependence with dTc/dε2 >> dTc/dε1. We attribute this anisotropy to a strain-tuned competition between superconductivity and 3D uniaxial CDW. This is supported by sound velocity measurement of the 3D CDW for longitudinal modes along a and b-axis. The elastic behaviour through this CDW transition is anisotropic with |dTCDW/dε2| >> |dTCDW/dε1|. The uniaxial CDW appears as an intrinsic instability even in zero magnetic field and in the zero strain limit probed here.  
For 0.12<p<0.15 where the uniaxial strain dependencies are maximum, we observe dTc/dε2 = dTc/dε1.  
An isotropic dTc/dεi is difficult to explain as being due to a competition to a uniaxial electronic order or as being due to the orthorhombic structure. It indicates that other mechanisms must be at play. This maximum in the strain dependence of Tc with in-plane isotropy could reflect an extrema in the electronic compressibility.

12:03 PM L08.00005: Noisy defects in a doped Mott insulator*  
FREEK MASSEE (Presenter), University of Paris-Sud, YINGKAI HUANG, MARK GOLDEN, University of Amsterdam, MARCO APRILI, University of Paris-Sud  
Detailed studies of the effect of single dopant atoms on the local electronic properties are crucial for a full understanding of the macroscopic characteristics of host materials ranging from semiconductors to high temperature superconductors. Due to limited time resolution of conventional scanning tunnelling microscopes, most atomic scale studies of the latter systems focussed on the time averaged effect of dopants on the electronic structure. I will present how, by using atomic scale shot-noise measurements in the high temperature superconductor Bi2Sr2CaCu2O8+, we visualize sub-nanometre sized objects where remarkable dynamics leads to an enhancement of the tunnelling current noise by at least an order of magnitude. From the position, current and energy dependence we deduce that these defects are oxygen dopant atoms whose local environment leads to charge dynamics that strongly affect the tunnelling mechanism. Possible effects on superconductivity will be discussed.  
*We acknowledge funding from H2020 Marie Sklodowska-Curie Actions (# 659247) and the ANR (ANR-16-ACHN-0018-01)

12:15 PM L08.00006: Steady-state superconductivity in electronic materials with repulsive interactions*  
OLIVER HART (Presenter), University of Cambridge, GARRY GOLDSTEIN, Rutgers University, CLAUDIO CHAMON, Boston University, CLAUDIO CASTELNOVO, University of Cambridge  
We study the effect of laser driving on a minimal model for a hexagonal two-dimensional material with broken inversion symmetry. Through the application of circularly polarised light and coupling to a thermal free electron bath, the system is driven into a nonequilibrium steady state with asymmetric, nonthermal carrier populations in the two valleys. We show that, in this steady state, interband superconducting correlations between electrons can develop independent of the sign of the electron-electron interactions. We discuss how our results apply, for example, to transition metal dichalcogenides. This work opens the door to technological applications of superconductivity in a range of materials that were hitherto precluded from it.  
*This work was supported in part by Engineering and Physical Sciences Research Council (EPSRC) Grants No. EP/P034616/1 and No. EP/M007065/1 (C.Ca. and O.H.), by NSF grant No. DMR-1733071 (G.G.), and by DOE Grant No. DE- FG02-06ER46316 (C.Ch.).
12:27PM L08.00007: Tuning the Josephson vortex lattice structure with pancake vortices in Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ single crystals* SIMON BENDING (Presenter), PETER J CURRAN, HUSSEN A MOHAMMED, Department of Physics, University of Bath, ALEXEI E KOSHELEV, Materials Science Division, Argonne National Laboratory, YUJI TSUCHIYA, Department of Electrical Engineering, Nagoya University, TSUYOSHI TAMEGAI, Department of Applied Physics, University of Tokyo — Vortex structures in the highly anisotropic superconductor Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ depend on the angle the applied field makes with the CuO$_2$ layers; stacks of pancake vortices form when the field is perpendicular to these and highly elliptical Josephson vortices form when it is parallel to them. For tilted magnetic fields, pancake and Josephson vortices coexist and interact in complex ways to form vortex chains and composite vortex lattices, reflecting the delicate balance between attractive and repulsive interactions. Scanning Hall microscopy has been used to map the rich tilted-field vortex phase diagram in an underdoped Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ single crystal. We find that the Josephson vortex lattice spacing has an unexpected non-monotonic dependence on pancake vortex density linked to a field-driven structural transformation with increasing out-of-plane fields. We establish the exact evolution of vortex-chain phases as the out-of-plane field is increased and identify especially stable structures spaced by an integer number of rows of interstitial pancake vortex stacks. Our experimental results are in good semi-quantitative agreement with a theoretical model.

12:39PM L08.00008: Enhancement of critical current density and mechanical properties of BiPb-2223 superconductor phase added with Nano-sized Gd-123 phase ALY ABOU-ALY (Presenter), NAYERA MOHAMMED, MAI BARAKAT, MOHAMMED HASSAN, RAMADAN AWAD, Physics Department, Alexandria University — Ball milled Nano-sized of Gd-123 superconductor phase was added to the high temperature superconductor (HTSC) BiPb-2223 phase with weight percentage 2.0 wt.%. The milling times t was varied up to 180 min. The samples have a general stoichiometry of (Gd$_{1.0}$Ba$_{2.0}$Cu$_{3.0}$O$_{8+\delta}$)$_{2.0}$/Bi$_{1.8}$Pb$_{0.4}$Sr$_{2.0}$Ca$_{2.0}$Cu$_{3.2}$O$_{10+\delta}$. The samples were prepared by the standard solid-state reaction method. The ball milled superconductor Gd-123 phase was characterized by X-ray powder diffraction (XRD) and transmission electron microscope (TEM) confirming the Nano-scale crystallite size. The prepared samples were characterized by XRD and the scanning electron microscope (SEM). Samples were examined by electrical resistivity and IV measurements in addition to Vickers micro hardness. No significant change in the superconducting transition temperature $T_c$ has been noticed for all samples. The highest relative volume fraction for BiPb-2223 phase was recorded for the sample with $t = 120$ min. The critical current density $J_c$ was increased from 326, for free sample, up to 1860 A/cm$^2$, for added sample, with grain size 17.52 nm. The micro hardness data was analyzed using several models. The modified proportional sample resistance (MPSR) model is the model that can describe the behavior of our samples successfully.

12:51PM L08.00009: Structural Phase Transitions: a Limiting Factor for Quantum Criticality and Superconductivity in La$_{1.6-x}$Nd$_{0.4}$Sr$_x$CuO$_4$* QIANLI MA (Presenter), MIRELA DRAGONMIR, JAMES P.I. CLANCY, McMaster University, ASHFIA HUQ, Oak Ridge National Laboratory, BRUCE GAULIN, McMaster University — One branch of the La-214 family of cuprate superconductors, La$_{1.6-x}$Nd$_{0.4}$Sr$_x$CuO$_4$, has been of great interest as it displays the full complexity of the canonical hole-doped high TC phase diagram. The strong dependence of the electronic properties on the crystal symmetry has motivated careful diffraction studies of the La$_{1.6-x}$Nd$_{0.4}$Sr$_x$CuO$_4$ structural phase diagram.

We present our recent findings on the structural transitions in the La$_{1.6-x}$Nd$_{0.4}$Sr$_x$CuO$_4$ system. Our group has synthesized single-phase polycrystalline samples with $x$ spanning from 0.01 to 0.40, and grew large single crystals of La$_{1.6-x}$Nd$_{0.4}$Sr$_x$CuO$_4$ for select $x$. To the best of our knowledge, such high Sr concentrations have not been achieved thus far. Systematic neutron and X-ray diffraction studies were performed at both low and high temperatures. These analyses allowed us to follow the sequence of structural phase transitions and to propose an updated La$_{1.6-x}$Nd$_{0.4}$Sr$_x$CuO$_4$ phase diagram that now covers Sr doping concentrations up to $x = 0.40$. Furthermore, our findings suggest that the persistence of the high temperature tetragonal structure, HTT, down to low temperatures when $x = 0.27$ might be a limiting factor for both superconductivity and the putative quantum critical point proposed for La$_{1.6-x}$Nd$_{0.4}$Sr$_x$CuO$_4$.

*NSERC
1:03PM L08.00010: d-wave Andreev reflection study of the ab-plane proximity effect in cuprate/manganite and cuprate/nickelate thin films* RAINNI CHEN (Presenter), CHAO ZHANG, CHRIS GRANSTROM, JOHN Y.T. WEI, Physics, University of Toronto — An anomalously long-range proximity effect was previously reported in c-axis thin-film heterostructures of ferromagnetic La$_{2/3}$Ca$_{1/3}$MnO$_3$ (LCMO) and superconducting YBa$_2$Cu$_3$O$_{7-\delta}$ (YBCO), and attributed to spin-triplet d-wave pairing [1]. However, there is debate over the existence of such long-range proximity effect, given the short c-axis coherence length of YBCO, and since scanning tunneling spectroscopy (STS) on c-axis LCMO/YBCO bilayers has failed to observe any direct evidence [2]. For YBCO/LCMO bilayers oriented along the a-axis, similar STS measurements have reportedly observed a proximity length scale of ~ 30 nm [3]. In this work, we extend these prior STS studies to YBCO/LCMO bilayers oriented along the <110> axis, a geometry that is expected produce the most robust d-wave Andreev resonance states. We also measure <110>-oriented LaNiO$_3$/YBCO bilayers, as a non-magnetic control. Our data are analyzed in terms of the overlayer thickness, in an effort to determine the actual length scale of the manganite/cuprate proximity effect in the ab-plane.

*This work was supported by NSERC, CFI, OIT, and CIFAR.

1:15PM L08.00011: Atomically thin high-temperature superconductors YUYING ZHU (Presenter), MENGHAN LIAO, JIN ZHANG, Tsinghua University, RUIDAN ZHONG, JOHN SCHNEELOCH, GENDA GU, Brookhaven National Laboratory, KAILI JIANG, DING ZHANG, XUCUN MA, QIKUN XUE, Tsinghua University — The emergent technique of van der Waals stacking has started to impact on high temperature superconductivity [1][2]. Here we report the realization of superconducting unprotected Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ (BSCCO) flakes down to 2.5 unit cells for studying high Tc superconductivity mechanism. We employ a novel solid state gating technique to effectively tune the carrier density of thin flakes, inducing the superconductor-insulator transition (SIT) in BSCCO. The corresponding evolution of the density of states (DOS) is unveiled by using planar tunnel junctions of graphite/BSCCO. The combination of gate tuning and tunneling spectroscopy shall be applicable to other two-dimensional materials.

1:27PM L08.00012: New Mechanism of Umklapp Scattering in Cuprate High-Tc Superconductors RONG LI (Presenter), ZHEN-SU SHE, Peking University — Cuprates display several novel symmetry-broken orders such as spin stripe, charge density wave (CDW). We propose a novel mechanism of dissipative umklapp scattering contributing to anomalous transport by fluctuating order beyond fermi surface reconstruction to electronic spectrum. Spatial-temporal fluctuating order is assumed to introduce umklapp scattering of holes, which yields a relaxation time proportional to square of order's periodicity ($l_o$) and a resistivity $\rho=\hbar/(\pi^2e^2ncl_o^2)$. This achieves a remarkable link between microscopic fluctuating orders and macroscopic transport, which yields a length mapping method (i.e. $l_o\propto \rho^{-1/2}$) to derive orders' periodicity from resistivity data. The theory is validated by data of three classes of samples in LSCO, Bi-2201 and Bi-2212. We show that at underdoped regime at 'knee' temperature (of $\rho$ vs $T$), $l_o$ is indeed close to $2a_0$, which is the periodicity of antiferromagnetism, while at overdoped regime $l_o$ is near $4a_0$, the CDW periodicity. In a vortex liquid, $l_o$ is found to vary as reduced vortex distance (-$B^{1/2}$), and in strange metal as reduced de Broglie wave length (-$T^{-1/2}$). These results demonstrate the universal validity of the new umklapp scattering mechanism and the length mapping method, providing a new tool to study order transitions.
1:39PM L08.00013: Reconfigurable SQUID Arrays  
SICHAO YU (Presenter), New York University Tandon School of Engineering, WILLIAM ANDREW MAYER, MATTHIEU DARTAILH, KAUSHINI WICKRAMASINGHE, JOSEPH YUAN, JAVAD SHABANI, Center for Quantum Phenomena, Department of Physics, New York University — Superconducting quantum interference devices (SQUID) are widely used for sensitive magnetic field detection. Traditional SQUID arrays based on Superconductor/Insulator junctions have limited flexibility as junction properties are not tunable. The realization of Superconductor/Semiconductor junctions allows for gate-tunable junction properties. This allows for complex tunable SQUID arrays that can be continuously adjusted with voltage gates. We numerically study tunable SQUID arrays with various circuit geometries. Potential applications of these arrays include increased sensitivity to spatial inhomogeneity of fields and variable spatial resolution. Another potential advantage that is numerically explored is leveraging time dependent gate voltages to filter noise and increase sensitivity.

1:51PM L08.00014: Scanning SQUID Microscopy on fractional flux quanta with on-chip field control  
PIM REITH (Presenter), MESA+ Institute for Nanotechnology, University of Twente, MICHAEL FALEY, PGi-5, Forschungszentrum Jülich, CHRISTOFORUS DIMAS SATRYA, ALEXANDER GOLUBOV, HANS HILGENKAMP, MESA+ Institute for Nanotechnology, University of Twente — Scanning Superconducting Quantum Interference Device (SQUID) Microscopy (SSM) is a scanning probe technique that utilizes the high magnetic field sensitivity of a SQUID to image local magnetic field of a sample surface. SSM played a vital role in showing the d-wave symmetry in cuprate superconductors by measuring fractional flux quanta, created spontaneously due to the cuprate acting as a π-shift element.

Now we continue on this by incorporating an on-chip bias line that can produce a local magnetic field. This allows us to control the flux state of nearby Nb-YBCO hybrid loops that exhibit fractional flux behavior. We have demonstrated the ability to freely change between the +1/2 Φ₀ and -1/2 Φ₀ states. Additionally, we study transitions into higher flux states (+3/2 Φ₀, ±5/2 Φ₀). These results are a crucial step to using controllable superconducting loops with π-shift elements in quantum annealing computing.

2:03PM L08.00015: Modeling Resonances in the Current-Voltage Characteristics of SQUID Susceptometers*  
SAMANTHA DAVIS (Presenter), Physics, Stanford University, JOHN KIRTLEY, GLAM, Stanford University, KATHRYN ANN MOLER, Physics and Applied Physics, Stanford University — In Scanning SQUID Microscopy, SQUID susceptometers are tools for achieving extremely precise magnetic imaging and local susceptibility measurements with high spatial resolution. Further development of scanning SQUID microscopy demands a thorough understanding of the properties of SQUID susceptometers. One mysterious behavior is the presence of resonances in the current-voltage characteristics of SQUID susceptometers for scanning applications. The origins and the effects of the resonances on the performance of these SQUIDs is unknown. To illuminate the origin and impact of the resonances, we have developed a model that successfully reproduces the experimentally-determined current-voltage characteristics of SQUIDs for one resonance. We explore the limitations of our model by calculating the noise characteristics of SQUIDs of different designs and comparing the results with experimental noise measurements. Looking forward, we aim to extend the model to encompass all the resonances that appear in experimental data. We will then use the model to optimize the signal-to-noise characteristics of scanning SQUID susceptometers.

Session L09 DCMP: Superconductivity: Proximity Effect and Josephson Junctions I  
Michael Ososfky, United States Naval Research Laboratory
11:15AM L09.00001: Quantum Vortex Melting and Superconductor Insulator Transition in a 2D Josephson Junction Array in a Perpendicular Magnetic Field via Diffusion Monte Carlo* PRAGALV KARKI (Presenter), YEN LEE LOH, University of North Dakota — In this study [1], we simulated a quantum rotor model describing a Josephson junction array (JJA) in the phase representation at zero temperature in a perpendicular magnetic field $B=0.1,0.2,0.3,0.4$ (in units of $h/4\pi ea^2$) on a $L_xL_y$ square lattice with spacing $a$ for $L=6,8,10,12$. The superconductor-insulator transition (SIT) is tuned by the ratio of charging energy to Josephson coupling, $U/J$. Abrupt drops in the magnetization values were observed in the bigger lattices at certain values of $B$ and $U/J$ caused by the formation of vortices. Increasing $U/J$ at a fixed $B$ field causes quantum vortex melting. The magnetization drops to zero around $U/J \sim 5$ indicating SIT. For $B=0.1$ the SIT occurs without an intermediate vortex state and the magnetization scales as $M \sim L^4$, whereas for $B=0.4$ the scaling is $M \sim L^4$ during the vortex melting. For $B$ between 0.1 and 0.4 the scaling is not clear. We used the diffusion Monte Carlo (DMC) method with a guiding wavefunction optimized using the variational Monte Carlo (VMC) method.

*ND EPSCoR through NSF grant #OIA-1355466

11:27AM L09.00002: Protected gap closing in Josephson junctions constructed on Bi$_2$Te$_3$ surface ZHAOZHENG LYU (Presenter), YUAN PANG, JUNHUA WANG, GUANG YANG, GUANGTONG LIU, FANMINING QU, LI LU, JIE FAN, ZHONGQING JI, XIUNIAN JING, institute of physics — On the road of searching for Majorana zero modes (MZMs) in topological insulator-based Josephson junctions, a highly-sought signature is the protected full transparency of electron transport through the junctions due to the existence of the MZMs, associated with complete gap closing between the electronlike and holelike Andreev bound states (ABSs). We fabricated Pb-Bi$_2$Te$_3$-Pb Josephson junctions and developed the method of using nonsuperconducting Pd electrodes to detect the ABS spectra in the junctions area. We generalized the Blonder-Tinkham-Klapwijk theory to describe the measured contact resistance of the Pd-Bi$_2$Te$_3$ interface. Our results provide direct experimental evidence of complete gap-closing and full transparent transport in single Josephson junctions constructed on the surface of Bi$_2$Te$_3$.

11:39AM L09.00003: A Mesoscopic Spectrometer Based on the Josephson Effect* JOEL GRIESMAR (Presenter), VINCENT BENZONI, FABIEN LAFONT, LEO PEYRUCHAT, JEAN-LOUP SMIRR, CAGLAR GIRIT, Flux Quantum Lab, CNRS USR 3573, College de France — A key element of mesoscopic topological systems, such as hybrid semiconductor-superconductor circuits, are Andreev Bound States, single quasiparticles localized at superconducting weak links. The characteristic transition energy of these states is twice the superconducting gap (90 GHz in aluminum). Conventional microwave techniques allow probing these states but only in a limited bandwidth. We propose a new broadband spectrometer operating at frequencies up to 180 GHz based on the Josephson effect which converts a DC voltage to microwave oscillations at a frequency proportional to this voltage. Using a symmetrical SQUID biased at half a flux quantum allows decoupling the spectrometer from environmental modes. In addition, careful design of the biasing circuit reduces the number of remaining modes and damps them. The fabricated mesoscopic spectrometer has a linewidth of 2 MHz, a bandwidth of 180 GHz and a minimal theoretical sensitivity of 5 kHz.

*This research was supported by IDEX grant ANR-10-IDEX-0001-02 PSL, a Paris Programme Emergence(s) Grant and the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (grant agreement 636744).

11:51AM L09.00004: Quantum Hall Supercurrent in a locally gated Graphene Josephson Junction - Part 1: Induction of Local Filling Factors and Quantum Hall Supercurrent* ANDREW SEREDINSKI (Presenter), ANNE M DRAELOS, ETHAN ARNAULT, MING-TSO WEI, Physics, Duke University, HENGMING LI, TATE FLEMING, Physics and Astronomy, Appalachian State University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, NIMS, FRANCOIS AMET, Physics and Astronomy, Appalachian State University, GLEB FINKELSTEIN, Physics, Duke University — We present a study of a graphene-based Josephson junction with local gates modulating the carrier density along either edge of the junction in a wide range. In magnetic fields in the 1-2 Tesla range, we populate the next Landau level, resulting in Hall plateaus with conductance that differs from the bulk filling factor. We observe robust supercurrent when the gating introduces counter-propagating quantum Hall edge states along either edge of the junction.

*The authors were supported by ARO Award W911NF-16-1-0122 and NSF awards ECCS-1610213 and DMR-1743907.
12:03PM L09.00005: Quantum Hall Supercurrent in a locally gated Graphene Josephson Junction - Part 2: Evolution of Interference patterns with Carrier Density and Field* ETHAN ARNAULT, ANDREW SEREDINSKI, ANNE M DRAELOS, MING-TSO WEI, Department of Physics, Duke University, HENGMING LI, TATE FLEMING (Presenter), Department of Physics, Appalachian State University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Material Lab, NIMS, FRANCOIS AMET, Department of Physics, Appalachian State University, GLEB FINKELSTEIN, Department of Physics, Duke University — We explore supercurrent induced along individual edges in a locally gated graphene-based Josephson junction in the quantum Hall regime. When supercurrents are present along both sides of the junction, they produce interference pattern as a function of magnetic field, bulk and edge carrier densities. This behavior allows us to infer information about the position of the edge states. We present electrostatic models relating the evolution of the interference patterns to the physical location of quantum Hall edge states in the device.

12:15PM L09.00006: Realization of Hybrid Superconductor–Semiconductor Systems by Homoepitaxial Growth of Non-equilibrium P-doped Si(111)* KASRA SARDASHTI (Presenter), Department of Science and Math, Fashion Institute of Technology, KAUSHINI WICKRAMASINGHE, Department of Physics, New York University, TRI NGUYEN, Department of Physics, City College of New York, WILLIAM ANDREW MAYER, MEHDI HATEFIPOUR, JOSEPH YUAN, JAVAD SHABANI, Department of Physics, New York University — To fulfill the long-term vision of reliable quantum computation, the ideal hybrid platform allows quantum information to be processed, stored and transmitted in the same materials system. Silicon can be a promising candidate for fault-tolerant hybrid quantum systems due to its multifunctionality, reliability and long coherence times. Superconducting Si could provide a viable pathway for realization of Si qubit circuits, by forming homogeneous Superconductor (SC)–Semiconductor–SC Josephson junctions. In this work, non-equilibrium p-doping of Si thin-films by homoepitaxial growth of Ga-rich Si on Si(111) is studied. Surface structure and morphology of the p-doped films were evaluated by reflection high-energy electron diffraction and atomic force microscopy. Doping levels and carrier concentrations were determined by temperature-dependent resistivity (ρ–T) measurements in van der Pauw configuration and on Hall bars. Upon increase in Ga incorporation, ρ–T characteristics of the p-doped films transitioned from insulating to quasi-reentrant superconductivity with $R_{min}/R_N$ of 0.82–0.89. Based on the known theories, mechanisms and strategies to go beyond the quasi-reentrant regime will be discussed.

*US Air Force Office of Scientific Research Young Investigator Award, FA9550-16-1-0348.

12:27PM L09.00007: Spin-orbit splitting of Andreev states revealed by microwave spectroscopy* LEANDRO TOSI (Presenter), CYRIL METZGER, MARCELO GOFFMAN, CRISTIAN URBINA, HUGUES POTHIER, Quantronics Group, SPEC, CEA-Saclay, SUNGHUN PARK, ALFREDO LEVY YEYATI, Departamento de Materia Condensada, Universidad Autonoma de Madrid, PETER KROGSTRUP, JESPER NYGÅRD, Center for Quantum Devices — The Josephson supercurrent that flows through a weak link between two superconductors is mediated by fermionic quasiparticle states localized at the weak link: the Andreev bound states. To explore the role of the spin of these states, we have performed their microwave absorption spectroscopy in superconducting weak links with strong spin-orbit coupling: an InAs-Al (core-full shell) epitaxially-grown nanowire. The spectra present distinctive features that we interpret as arising from zero-field spin-split Andreev states. A simple empirical model, which takes into account the Rashba spin-orbit interaction in a multichannel nanowire, explains these features and their evolution with magnetic field. Our results show that the spin of quasiparticles can be a relevant degree of freedom in Josephson weak links.

Anomalous interference in planar WTe₂ Josephson junctions

ANDREW PIERCE (Presenter), Department of Physics, Harvard University, JOHANNES GOOTH, Max Planck Institute for Chemical Physics of Solids, MICHAEL KOSOWSKY, Department of Physics, Harvard University, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, AMIR YACOBY, Department of Physics, Harvard University — Josephson junctions fabricated on materials with strong spin-orbit coupling (SOC) have driven substantial research efforts due to the possibility of realizing topological superconductivity (TSC) in such devices. Layered materials with strong SOC, especially those which can be isolated via mechanical exfoliation, are particularly attractive due to their natural compatibility with large in-plane magnetic fields. This talk discusses the evolution of the critical current of WTe₂ Josephson junctions as a function of in-plane magnetic field. Thin (<100 nm) samples of WTe₂ are of interest for applications to TSC as they provide strong SOC with the required type of Fermi-surface spin texture. Under certain conditions, the interference patterns observed in these devices diverge from the standard Fraunhofer-like pattern that follows from the simplest set of assumptions, suggesting the presence of important orbital effects.

Numerical modelling of capacitively-shunted Josephson junctions including quasiparticle excitations

WILLIAM COLE (Presenter), University of Maryland, College Park, CHAITANYA MURTHY, University of California, Santa Barbara, BERNARD VAN HECK, Microsoft Quantum, Microsoft Station Q, UCSB — We have developed a numerical framework for calculating the many-body spectrum of Cooper pair box hamiltonians where the Josephson potential is matrix-valued in the space of (non-conserved) quasiparticle occupation numbers. We will describe this general formalism and then demonstrate its applicability to various semi-realistic superconducting junctions of current interest, as specified by real-space Bogoliubov-de Gennes hamiltonians.

Manipulation of Phases and Supercurrents in S-TI-S Lateral Josephson Junction Networks

ERIK HUEMILLER (Presenter), Inprentus Precision Optics, CAN ZHANG, GUANG YUE, University of Illinois at Urbana-Champaign, SEONGSHIK OH, Physics, Rutgers, The State University of New Jersey, DALE J VAN HARLINGEN, University of Illinois at Urbana-Champaign — Quantum computing using topological Q-bits composed of Majorana Fermions (MF) shows promise for its robustness against disorder and its scalability with existing lithography infrastructure. In lateral Josephson junction networks, the MFs are localized to points in the junction where the phase difference of the superconducting order parameter across the junction is equal to an odd multiple of π. Quantum computations are performed by physically moving MFs pinned to odd π crossings around one another, encoding the quantum state of the system in the historical locations of the MFs relative to each other. Understanding the phase distributions around multi-junction nodes in the network is one key hurdle that needs to be overcome before the implementation of this architecture is a reality. Measurements and modeling of Nb-BiSe-Nb lateral Josephson junctions in three and four junction geometries will be presented. The results will be discussed with their implication for the realization of a topological quantum architecture.

Transport Studies in Gate-Tunable Multi-Terminal Josephson Junctions

GINO GRAZIANO (Presenter), School of Physics and Astronomy, University of Minnesota, JOON SUE LEE, California NanoSystems Institute, University of California, Santa Barbara, MIHIR PENDHARKAR, Department of Electrical and Computer Engineering, University of California, Santa Barbara, CHRIS PALMSTROM, Materials Department, University of California, Santa Barbara, VLAD S PRIBIAG, School of Physics and Astronomy, University of Minnesota — Josephson junctions with three or more superconducting leads are predicted to exhibit topological physics in the presence of few conducting modes within the interstitial normal material.[1][2] Such topological behavior manifests itself as signatures in the complex transport properties between the different terminals, with topological phase transitions occurring as a function of phase and voltage bias.[3] Here we study the superconducting and resistive properties of top-gated multi-terminal Josephson devices, based on an InAs 2DEG proximitized with epitaxial aluminum. The top gate is used to deplete the 2DEG, and resistances are analyzed under various bias currents and magnetic fields.

*This work was conducted under NSF DMR grant 16-10114
Spin-triplet supercurrents in Josephson junctions with Co/Py exchange-spring interfaces

EKTA BHATIA (Presenter), Physical Sciences, National Institute of Science Education and Research, HBNI, JAMES DEVINE STONEMAN, SACHIO KOMORI, ANAND SRIVASTAVA, ZOE BARBER, Department of material science and metallurgy, University of Cambridge, KARTIK SENAPATI, Physical Sciences, National Institute of Science Education and Research, HBNI, JASON ROBINSON, Department of material science and metallurgy, University of Cambridge — Conventional (spin-singlet) s-wave superconductivity (S) and ferromagnetism (F) are incompatible. However, it is now established that s-wave S can coexist with F through the conversion of spin-singlet to spin-triplet Cooper pairs at a magnetically inhomogeneous interface [1]. Here we report Josephson coupling in Nb/Co/Py/Nb Josephson junctions in which the total bilayer (Co/Py) thickness exceeds the singlet pair coherence length [1nm in Py [2]]. At a Co/Py interface, the interface exchange coupling is strong compared to the weak magnetic anisotropy of Py and so, depending on the direction and magnitude of an external magnetic field, an in-plane Bloch domain wall can form in Py creating the necessary magnetic non-collinearity for pair conversion [3]. We observe Josephson coupling for Py layer thicknesses up to 11 nm which greatly exceeds the singlet coherence length, strongly suggesting the propagation of spin-polarized triplet supercurrents. Furthermore, through magnetic field history we are able to programme the magnetic state, which offers the potential for active control of triplet supercurrents.

Non-local Josephson effect in Andreev molecules*

CAGLAR GIRIT (Presenter), JEAN-DAMIEN PILLET, VINCENT BENZONI, JOEL GRIESMAR, JEAN-LOUP SMIRR, CNRS USR 3573, Collège de France — We propose the Andreev molecule, an artificial quantum system comprised of two closely spaced Josephson junctions. As in a real molecule, the coupling between Josephson junctions in an Andreev molecule occurs through the overlap and hybridization of the junction's "atomic" orbitals, the Andreev Bound States. One of the striking consequences of molecular hybridization is that the supercurrent flowing through one junction depends on the superconducting phase difference across the other junction. The energy spectrum of Andreev molecules have gaps which open as the inter-junction separation is reduced. The current-phase relations are non-local and demonstrate the possibility of a non-zero supercurrent at zero phase difference, a \( \phi \)-junction. In order to synthesize and detect Andreev molecules, we propose experiments on devices fabricated only with conventional materials and standard nanofabrication techniques. Andreev molecules are a new class of superconducting quantum devices with potential applications in quantum information, metrology, sensing, and molecular simulation.

Phase transitions in current biased superconductors*

VADIM OGANESYAN, NEGIN MOHARRAMI ALLAFI (Presenter), Physics and Astronomy, CSI and GC, CUNY — We consider models of Josephson coupled superconducting wires and sheets in the presence of current biasing. We study signatures of a phase transition between fully locked ("locked") and unlocked ("soliton") phases akin to the conventional commensurate-incommensurate transition in mutual inductance and tunnelling spectroscopy.

*NSF DMR1508538 and DMR1420634
Probing the magnetic screening properties of superconductor-ferromagnet hybrids.*

NATHAN SATCHELL (Presenter), Department of Physics and Astronomy, Michigan State University, PATRICK QUARTERMAN, National Institute of Standards and Technology, REZA LOLOEE, Department of Physics and Astronomy, Michigan State University, BRIAN KIRBY, JULIE BORCHERS, National Institute of Standards and Technology, NORMAN OWEN BIRGE, Department of Physics and Astronomy, Michigan State University — Ferromagnetic Josephson junctions are a strong candidate for a dissipationless cryogenic memory alternative to dissipative CMOS technologies. Much attention has been focused on what happens to the supercurrent propagating through the Josephson junction, including the discovery of spin aligned triplet Cooper pairs in these systems [1]. In parallel, the magnetic screening properties of superconductors in electronic proximity to ferromagnetic materials have been studied, as an additional component of the screening is expected to be induced by the proximity effect [2]. These additional screening currents may account for several experimental observations, most notably in Co/Nb/Cu trilayers where an anomalous Meissner effect is reported by the low energy muon spin rotation technique [3]. In this work, we report our progress characterising the magnetic screening properties of isolated Nb (200 nm) and a bilayer of Ni (x nm)/Nb (200 nm) using polarized neutron reflectometry and the Fraunhofer characteristic of Josephson junctions.

Wednesday, March 6, 2019 11:15 AM - 1:51 PM

Session L10 DMP DCOMP: Fe-based Superconductors -- FeSe Intercalates and Interfaces

11:15AM L10.00001: Spectroscopic evidence of pair-mediated bosonic modes in superconductor FeSe/SrTiO3(100) film

MINJUN LEE (Presenter), MYUNCHUL OH, Seoul National University, JUNGSEOK CHAE, Institute for Basic Science, YOUNG KUK, Seoul National University — Single layer FeSe on SrTiO3(100) is atypical but noticed system in superconductivity. This has unique properties due to the substrate phonon. Unlike other bulk systems, the presence of the interface allows the substrate phonons to affect the superconducting layer. We have investigated substrate phonon effects on superconducting FeSe layer by using scanning tunneling spectroscopy and Eliashberg theory. We were able to measure acoustic, optical and substrate phonons in d²I/dV² spectroscopy. We found these phonon modes attribute to the paring of electrons in this superconducting layer. These results are analyzed by Eliashberg model and we will discuss the coupling strength of these bosonic features. We have found that the substrate phonon has major contribution to increase the transition temperature of this system.
11:27AM L10.00002: Replica bands in FeSe monolayers on STO [Invited]  FENGMIAO LI (Presenter), GEORGE ALBERT SAWATZKY, University of British Columbia, Vancouver, British Columbia, Canada V6T 1Z4, Stewart Blusson Quantum Matter Institute — The recent observation of replica bands in FeSe monolayers on STO in angle-resolved photoemission spectroscopy (ARPES) [1] has triggered intense discussions concerning the influence of FeSe electron coupling with STO phonon on the enhanced superconductivity. To obtain narrow replica bands tracing closely the dispersion of main bands rather than broad shake-off features or kinks, one has to require the coupling to be strongly peaked at q=0. However, whether the uniform electric field generated by q=0 STO phonon can strengthen the Cooper pairing in FeSe monolayer is still in discussion. We follow up with a new interpretation of the replica bands demonstrating they are largely due to the energy loss process of the escaping photoelectron, resulted from the well-known strong coupling of external propagating electrons to q=0 Fuchs-Kliewer (FK) surface phonons in STO [2]. Photoelectron energy loss on FeSe monolayer is calculated using the demonstrated successful semiclassical dielectric theory in describing low energy high-resolution electron energy loss spectroscopy (HREELS) [2]. We reduce the loss probability in HREELS by a factor 2 since the electron traveling path in ARPES is 1/2 of the HREELS one. Our calculation turns out to be able to reproduce the replica intensity and other experimental features in detail very well without the need for any fitting parameter [3]. This strongly suggests that the observed replica bands are mostly due to extrinsic photoelectron energy loss and not a result of the electron-phonon interaction of the Fe d electrons with the STO phonons. Therefore, the mechanism of the enhanced superconductivity in these monolayers remains an open question although other phonons than the FK types may still contribute.

12:03PM L10.00003: Quantum phase transition in monolayer FeSe films by tunable thickness of graphene substrate  WAN-TONG HUANG (Presenter), HAICHENG LIN, CHENG ZHENG, YUGUO YIN, SHUAI-HUA JI, XI CHEN, Tsinghua University — Insulator to superconductor transition in Fermi systems is one of the most fascinating issues, which goes beyond the BCS paradigm of superconductivity as the Fermi surface instability. Although exotic physics has been predicted theoretically, the experimental realization of such transition in solid-state systems has been more or less elusive. Here we show that the monolayer FeSe films grown on epitaxial graphene on nitrogen-doped SiC(0001) exhibit phase transition from insulator to superconductor. The Fermi energy of monolayer FeSe is remarkably low and can be tuned by the thickness of graphene through carrier doping. Furthermore, the Fermi energy is comparable to the superconducting gap, providing opportunity to probe exotic physics.

12:15PM L10.00004: Molecular Beam Epitaxy Growth of FeSe/SrTiO3 Heterostructures*  ZHENG REN (Presenter), HE ZHAO, ALEXANDER LAFLEUR, SHANG GAO, BRYAN RACHMILOWITZ, ILIJA ZELJKOVIC, Boston College — Monolayer of FeSe grown on SrTiO3 surface has shown to exhibit a large increase in superconducting transition temperature, from ~8K in bulk FeSe to above 100K (Ge J, et al. Nature Materials 14, 285-289(2015) ). Extensive studies performed on this system to date suggested that both electronic and phononic mechanism might be responsible for this enhancement of superconductivity. Therefore, a route towards increasing the Tc even further might involve using oxide substrates with carefully engineered chemical composition. We use molecular beam epitaxy to grow thin film SrTiO3 on commercial substrates with a precise control of the surface termination (SrO vs. TiO2). Furthermore, we discuss our preliminary results on comparing the structural and electronic properties of FeSe deposited on SrTiO3 thin films and bulk commercial substrates.

*We gratefully acknowledge the funding from DARPA N66001-17-1-4051.
**12:27PM L10.00005: Suppression of superconductivity and the magnetotransport behaviour in ultra-thin flakes of FeSe**

LIAM FARRAR (Presenter), Department of Physics, University of Bath, MATTHEW BRISTOW, Department of Physics, University of Oxford, AMIR HAGHIGHIRAD, Institute for Solid-State Physics, Karlsruhe Institute of Technology, ALIX MCCOLLAM, High Field Magnet Laboratory (HFML-EMFL), Radboud University, SIMON BENDING, Department of Physics, University of Bath, AMALIA COLDEA, Department of Physics, University of Oxford — The discovery of high temperature superconductivity in a monolayer of FeSe on SrTiO3 has ignited significant interest in understanding its two-dimensional superconductivity and the interfacial phenomena that determine its properties. To address these aspects, we examine the superconducting and electronic properties of exfoliated thin flakes of FeSe as a function of decreasing thickness, from bulk down towards 10 nm. We present a magnetotransport study in magnetic fields up to 38 T, which allows us to assess the changes in the multi-band electronic properties as a function of thickness. By reducing the thickness, the superconductivity of FeSe flakes is suppressed and the superconducting phase diagrams show significant changes in anisotropy.

*The research was supported by the Oxford Centre for Applied Superconductivity (CFAS), the John Fell Fund of the Oxford University and by EPSRC, UK (EP/L015544, EP/M020517/1, EP/I004475/1).

**12:39PM L10.00006: Coexistence of Magnetism and Superconductivity in Separate Layers of Iron-Based Superconductor Li_{1-x}Fe_{y}(OH)Fe_{1-y}Se**

CRAIG TOPPING (Presenter), School of Physics and Astronomy, University of St Andrews, FRANZISKA KIRSCHNER, STEPHEN BLUNDELL, Department of Physics, University of Oxford, PETER J. BAKER, ISIS Facility, Rutherford Appleton Laboratory, DANIEL WOODRUFF, FRANCESCA SCHILD, HUALEI SUN, SIMON CLARKE, Department of Chemistry, University of Oxford — The family of compounds of general formula Li_{1-x}Fe_{y}(OH)Fe_{1-y}Se, consisting of alternating Fe_{1-y}Se and Li_{1-x}Fe_{y}(OH) layers, have been found to superconduct with $T_c$'s of $\approx 40$ K. The hydroxide layer, containing roughly 20 % substitution of Li for Fe, has been shown to display magnetism well below the superconducting transition in the region of 10 K. This has been alternately reported as an ordering of the hydroxide layer Fe moments ferromagnetically and antiferromagnetically. Our study elucidates this magnetism by taking advantage of the flexible synthesis of these compounds allowing investigation of superconducting and non-superconducting variants in an effort to disentangle magnetism from superconductivity. Utilizing static and dynamic magnetometry, measurement of heat capacity and muon spin relaxation we propose the magnetism of the hydroxide layer to be glass-like and coexist with superconductivity.

**12:51PM L10.00007: Sign reversal of order parameter in single layer FeSe/SrTiO3 film**

HUIMIN ZHANG (Presenter), ZHUOZHI GE, LIAN LI, Department of Physics and Astronomy, West Virginia University — Single layer FeSe film grown on SrTiO3 substrate has drawn much interest for its novel interfacial effects, which have led to the highest superconducting temperature ($T_c$) to date amongst all Fe-based superconductors. While several paring symmetries, such as $s^{++}$-wave, nodeless $d$-wave, as well as $s_{2}$-wave have been suggested, the experimental determination of its superconducting paring symmetry remains elusive. Here we investigate the intrinsic impurity-induced in-gap bound states and quasiparticle interference (QPI) patterns in single layer FeSe/SrTiO3 by scanning tunneling microscopy/spectroscopy. We observed bound states induced by nonmagnetic impurities, which strongly suggests a sign-changing order parameter. Through detailed analysis of the phase-sensitive QPI patterns, we further confirm that the order parameter indeed changes sign within the electron pockets. This identification of a sign change pairing symmetry in single layer FeSe/SrTiO3 presents an important step towards the understanding of the mechanism of its high $T_c$ superconductivity.

*This research is supported by DOE (DE-SC0017632).
of superconducting paths connecting superconducting islands within Fe(Te$_{0.7}$Se$_{0.3}$) thin flakes to describe the behavior of model is supported by the observed thickness dependence of the superconducting transition. We propose a 2D network confirmed using the BKT transition for inhomogeneity model, as well as finite state effects (FSE). This inhomogeneous transition. Due to non-uniform Te/Se spatial distribution, we find that $R(T)$ behavior in flakes $<$10nm can be explained and $>$10nm flakes we find a systematic suppression of the superconductivity and broadening of the superconducting phase modulation caused by the ferromagnetism, which can lead to the decrease of the pairing and critical temperature. 

The presence of Hubbard on-site interaction. Using a single-band model for the superconductor-ferromagnet vacancies. We find that a robust surface ferromagnetism can emerge due to the periodic pattern of oxygen vacancies in FeSe/SrTiO$_3$, and demonstrates that quasiparticle scattering at boundaries can be a viable phase sensitive probe of pairing symmetry in Fe-based superconductors. 

This research is supported by NSF (DMR-1335215).

Evidence of Two-dimensional Superconducting Behavior in Atomically Thin Fe(Te$_{0.7}$Se$_{0.3}$) Flakes

ANDREW STEELY (Presenter), CHUNLEI YUE, YUN LING, ABIN JOSHY, Tulane University, ZHIQIANG MAO, Pennsylvania State University, JIANG WEI, Tulane University — We report detailed thickness-dependent transport studies on strain-free Fe(Te$_{0.7}$Se$_{0.3}$) thin flakes. Notably, we present evidence of two-dimensional superconducting behavior in flakes $<$10nm. For $>$10nm flakes we find a systematic suppression of the superconductivity and broadening of the superconducting phase transition. Due to non-uniform Te/Se spatial distribution, we find that $R(T)$ behavior in flakes $<$10nm can be explained and confirmed using the BKT transition for inhomogeneity model, as well as finite state effects (FSE). This inhomogeneous model is supported by the observed thickness dependence of the superconducting transition. We propose a 2D network of superconducting paths connecting superconducting islands within Fe(Te$_{0.7}$Se$_{0.3}$) thin flakes to describe the behavior of this natural percolating system.

*This work was supported by the DOE under grant DESC0014208 and by the Board of Regents Support Fund (BoRSF) under grant LEQSF(2015-18)-RD-A-23.

Hydrothermal design of magnetic heterolayer iron-based superconductors

BRANDON WILFONG (Presenter), XIUQUAN ZHOU, HUAFEI ZHENG, NAVNEETH BABRA, EFRAIN RODRIGUEZ, JOHNPIERRE PAGLIONE, University of Maryland, College Park — Recently, a new iron-based superconductor, (Li$_{1-x}$Fe$_x$OH)FeSe (critical temperature, $T_c = 43$ K), was reported. Pachmayr et al. and Lu et al. reported observation of ferromagnetism and antiferromagnetism, respectively, in this 43 K superconductor, but no magnetic peak(s) have been observed for this system in several neutron diffraction studies. Thus, our current work aimed at controlling this magnetism through selective doping of other transition metals onto the Li site within the (Li$_{1-x}$Fe$_x$OH)$5^+$ spacer layers. We have synthesized powder and single crystals (Li$_{1-x}$yFe$_x$M$_y$OH)FeSe samples ($M = Cr$, Mn, Co, Ni, Cu, Zn) through a hydrothermal ion-exchange reaction of KFe$_{2-2x}$M$_2$Se$_2$ precursors. These samples have been characterized by x-ray diffraction, electrical resistivity, and magnetic susceptibility to confirm their crystal structure, chemical composition and the influence of transition metal dopants on their superconductivity and magnetism. Neutron diffraction revealed correlation between magnetism and the crystal structure tuned by transition metal dopants in the spacer layers which coexists with superconductivity. Our work demonstrates coexistence of superconductivity and magnetism can be designed through chemical manipulation of heterolayer transition metal chalcogenides.

Engineering nanoscale superconductivity through the competition between ferromagnetism and superconductivity

MATTHEW REDELL (Presenter), WEI-CHENG LEE, Binghamton University — As electronic devices continue to decrease in size, it becomes increasingly more important to understand how to engineer nanoscale systems. Reduced dimensionality in superconductors allows fluctuations to play a greater role in the behavior of the system. For example, bulk iron selenide (FeSe) has a superconducting critical temperature of 8K, but the single layer FeSe grown on SrTiO$_3$ exhibits a significantly higher critical temperature. Motivated by these results, we have performed density functional theory (DFT) calculations for various systems of SrTiO$_3$ with different surface reconstructions for oxygen vacancies. We find that a robust surface ferromagnetism can emerge due to the periodic pattern of oxygen vacancies in the presence of Hubbard on-site interaction. Using a single-band model for the superconductor-ferromagnet heterostructure, we demonstrate that for nanoscale systems the superconducting properties are highly susceptible to modulation caused by the ferromagnetism, which can lead to the decrease of the pairing and critical temperature.
Wednesday, March 6, 2019 11:15 AM - 1:51 PM

Session L11 DMP DCMP FIAP: Materials for Quantum Information Science -- Engineering Quantum States  BCEC 152 - Tag(s): Focus

11:15AM L11.00001: InSb Nanowires for Quantum Devices  GHADA BADAWY (Presenter), SASA GAZIBEGOVIC, Applied Physics, Eindhoven University of Technology, SEBASTIAN HEEDT, FRANCESCO BORSOI, QuTech, Delft University of Technology, SEBASTIAN KOELLING, MARCEL VERHEIJEN, Applied Physics, Eindhoven University of Technology, LEO P KOUWENHOVEN, QuTech, Delft University of Technology, ERIK P. A. M. BAKKERS, Applied Physics, Eindhoven University of Technology — Indium-antimonide (InSb) nanowires (NWs) are considered prime candidates for hosting topological states, known as Majorana zero modes, a key ingredient for future fault-tolerant quantum computing. More specifically, the properties of InSb, such as its high electron mobility and strong spin-orbit coupling, grant it with the ability to deliver stringent requirements needed for bearing topological phases when combined with a superconductor.
Yet, synthesis of this superior material remains a challenge. InSb NWs have been so far synthesized on top of a “stem” of a foreign material, posing two main hurdles; incorporation of the stem material into the grown InSb segment and limiting the length of the InSb NW, restricting it to a maximum of about 3.5 μm. Here, we report growth of pure zinc blende InSb nanowires tens of microns long. These NWs demonstrate significantly higher electron mobility values than obtained for InSb NWs on stems. Thus, this technique meets the strict length and purity prerequisites for realizing Majorana devices and provides flexibility for intricate device designs.

11:27AM L11.00002: In-plane Selective Area InSb Networks for Scalable Majorana Devices  ROY OP HET VELD (Presenter), Applied Physics, Eindhoven University of Technology, DI XIU, QuTech, Delft University of Technology, MARCEL VERHEIJEN, Applied Physics, Eindhoven University of Technology, MIHIR PENDHARKAR, JOON SUE LEE, Dept. of ECE, University of California Santa Barbara, STAN PETERS, SEBASTIAN KOELLING, Applied Physics, Eindhoven University of Technology, LEO P KOUWENHOVEN, Qutech, Delft University of Technology, CHRIS PALMSTROM, Dept. of ECE, University of California Santa Barbara, HAO ZHANG, QuTech, Delft University of Technology, ERIK P. A. M. BAKKERS, Applied Physics, Eindhoven University of Technology — Theoretical proposals predict that networks of Indium Antimonide (InSb) nanowires are suitable for Majorana based quantum computing.
Here we show In-plane Selective Area Networks (InSANe) of InSb nanowires grown catalyst free with a high crystal quality. Although InSb has a large lattice mismatch with Indium Phosphide (InP) (high bandgap substrate material), we manage to synthesize single crystal networks. Transmission electron microscopy (TEM) analysis confirms a zincblende InSb nanowire with a single twin defect at the interface with the underlying substrate. Low temperature transport measurements (e.g. Aharonov-Bohm interference) demonstrate a large electron coherence length of up to 10 μm. An epitaxial superconductor on these networks induces a hard superconducting gap and gives rise to a 2e-periodic Coulomb blockade, making this platform very promising for Majorana topological quantum computing.

11:39AM L11.00003: Fabrication and Characterization of Template-Defined Scalable InAs Nanowire Networks*  KRISTOPHER CERVENY (Presenter), University of Basel, MARTIN FRIEDL, Ecole Polytechnique Federale de Lausanne, TARAS PATLATIUK, CHRISTIAN SCHELLER, LORIN DIRSCHERL, University of Basel, DIDEM DEDE, ANNA FONTCUBERTA I MORRAL, Ecole Polytechnique Federale de Lausanne, DOMINIK ZUMBUHL, University of Basel — Semiconductor nanowires with strong Rashba-type spin-orbit interaction are a great platform to create and study novel quasiparticles, such as Majorana- and para-fermions. These excitations with non-Abelian statistics are of fundamental interest offering promising applications in topological quantum computing. Here, we report recent results on templated InAs nanowire networks grown on GaAs nanomembranes[1]. A fabrication process for contacting, encapsulation in an ALD dielectric, and electrostatic gating of wires grown on [111] and [100] GaAs substrates has been developed and implemented. The low-temperature conductance behavior of the devices has been analyzed as a function of applied magnetic field and gate voltage. The investigation aims at fundamental system properties like mean free path, coherence length, and spin-orbit length. Further, transport behavior over junctions between the nanowires - enabled by the crystal-lattice symmetries - has been explored. The work lays the foundation for the integration of superconductors in the devices, which provides a means for studying the behavior of hybrid structures with strong spin-orbit interaction.

11:51AM L11.0004: Scalable quantum photonics using quantum dots [Invited]  EDO WAKS (Presenter), University of Maryland, College Park —
In this talk I will describe an experimental realization of strong interactions between single photons mediated by a single electron trapped in a quantum dot. I will first present a quantum transistor where a single photon can control a single electron spin and vice versa 1. This switch realizes a transistor operating at the fundamental quantum limit, where in picoseconds timescales a single photon flips the orientation of a spin and the spin flips the polarization of the photon. I will show how this transistor creates strong interactions between single photons, and enables a single photon to switch a bright field composed of many photons. 2

Subsequently, I will also describe our efforts to incorporate these interactions in quantum photonic circuits to create complex nonlinear devices. I will show a technique to achieve on-chip tuning of quantum dots in order to create indistinguishable emitters coupled to cavities and waveguides 3–5. I will also describe new fabrication methods we are pursuing for hybrid integration of quantum dots with silicon photonics 4, as well as novel topological photonic structures that enable photons to propagate through chiral edge states 6, providing new possibilities for photonic quantum simulation.

12:27PM L11.0005: Improved control of quantum dots in Ge/SiGe quantum wells for spin qubit applications*  WILL HARDY (Presenter), Sandia National Laboratories, YI-HSIN SU, YEN CHUANG, Electrical Engineering, National Taiwan University, LEON MAURER, MITCHELL BRICKSON, ANDREW BACZEWSKI, Sandia National Laboratories, JIUN-YUN LI, Electrical Engineering, National Taiwan University, TZU-MING LU, DWIGHT R LUHMAN, Sandia National Laboratories — Much work on semiconductor spin qubits has focused on extending capabilities and understanding limitations of Si and GaAs. In parallel, alternative materials are being scrutinized for potential advantages in terms of coherence times, control, and extensibility, without sacrificing key features. One such quantum well system, undoped strained Ge/SiGe, appears promising as a candidate spin qubit host due to low disorder, small hole effective mass, and large spin-orbit coupling, and has already been used to demonstrate basic single quantum dots. We take the next steps toward hole spin qubits by preparing a double quantum dot in a one-layer gate structure, then using multilayer gate stacks to demonstrate improved quantum dot control.

12:39PM L11.0006: A solvable quantum model of dynamic nuclear polarization in quantum dots*  THOMAS NUTZ (Presenter), Physics, Imperial College London, EDWIN BARNES, SOPHIA ECONOMOU, Physics, Virginia Tech — Dynamic nuclear polarization (DNP) in quantum dots has given rise to a variety of unexpected and potentially useful effects, yet a consistent theoretical description with predictive power is still lacking. We present a quantum mechanical theory of optically induced DNP applicable to quantum dots and other interacting spin systems. The exact steady state of the optically driven coupled electron-nuclear system is calculated under the assumption of constant hyperfine coupling strengths (box model) for an arbitrary number of nuclear spins. Based on this analytical result we investigate the nuclear spin behaviour for different experimental parameter regimes and find that our model reproduces the flat-top and triangular absorption lineshapes (linedragging) seen in various experiments. Furthermore we predict a novel DNP effect. Under particular and achievable experimental conditions the nuclear spin system tends to polarize in such a way as to cancel the effect of the external magnetic field. The predicted sharply peaked nuclear spin polarization probability distributions centered at the value corresponding to degenerate electronic transitions would be of great significance for quantum technological applications.

12:51PM L11.00007: Plasmon mediated quantum communication between quantum dot clouds* RAVINDRA YADAV
(Presenter), Department of Physics, Indian Institute of Science, Bangalore, India, MATTHEW OTTEN, Center for Nanoscale Materials, Argonne National Laboratory, Lemont, IL 60439, USA, WEIJIA WANG, Applied Physics Program, Northwestern University, Evanston, Illinois 60208, United States, STEPHEN K GRAY, D. J. GOSZTOLA, GARY P WIEDERRECHT, Center for Nanoscale Materials, Argonne National Laboratory, Lemont, IL 60439, USA, TERI W. ODOM, Applied Physics Program, Northwestern University, Evanston, Illinois 60208, United States, JAYDEEP K BASU, Department of Physics, Indian Institute of Science, Bangalore, India — We report experimental and theoretical studies of the interaction of a quantum dot (QD) cloud [1] with a remote QD cloud mediated by surface lattice resonances (SLR) in two dimensional array of plasmonic nanoparticles[2]. By exciting one QD cloud and collecting the photoluminescence from a remote, unexcited QD cloud, we experimentally demonstrate long range, SLR mediated coupling between the two clouds. We explore the coupling between the two QD clouds through the SLR. Our results suggest an exciting new direction where coherent plasmonic systems can mediate interactions between remote QDs, having various applications in quantum information processing and quantum computation, such as realizing two qubit gate interactions between the QD clouds.

1:03PM L11.00008: Simulating topological insulators with donors and quantum dots* NGUYEN LE (Presenter), University of Surrey, ANDREW JAMES FISHER, University College London, ERAN GINOSSAR, University of Surrey — We explore the possibilities of simulating the Su-Schrieffer–Heeger (SSH) model of topological insulators with a one dimensional chain of donors or quantum dots. A measurement of the transverse tunneling current through one end of the chain is proposed for confirming the existence of the edge state in the topologically non-trivial phase. For donors and quantum dots the electron-electron interaction is typically larger than the hopping amplitude, resulting in strong correlation in the ground state. We investigate the effect of interaction on the spin correlation, entanglement, excitation energy spectrum and the Zak phase. We discuss bulk-edge correspondence between the Zak phase and the edge state in the correlated case. An external magnetic field can be used to induce a transition to the well-understood limit of the non interacting SSH model. This transition is accompanied by a strong enhancement of the edge state’s spatial localization, and hence can be identified by observing a sharp increase in the conductance signal.

1:15PM L11.00009: Kitaev chain with a quantum dot* CHUANCHANG ZENG (Presenter), CHRISTOPHER MOORE, APARAO MOHAN RAO, Department of Physics and Astronomy, Clemson University, TUDOR DAN STANESCU, Department of Physics and Astronomy, West Virginia University, SUMANTA TEWARI, Department of Physics and Astronomy, Clemson University — We solve analytically the problem of a finite length Kitaev chain coupled to a quantum dot (QD), which extends the standard Kitaev chain problem making it more closely related to the quantum dot-semiconductor-superconductor (QD-SM-SC) nanowire heterostructure that is currently under intense investigation for possible occurrence of Majorana zero modes (MZMs). Our analytical solution reveals the emergence of a robust near-zero-energy Andreev bound state (ABS) localized in the quantum dot region as the generic lowest energy solution in the topologically trivial phase. By contrast, in the bare Kitaev chain problem such a solution does not exist. The robustness of the ABS in the topologically trivial phase is due to a partial decoupling of the component Majorana bound states (MBBs) over the length of the dot potential. As a result, the signatures of the ABS in measurements that couple locally to the quantum dot, e.g., tunneling measurements, are identical to the signatures of topologically-protected MZMs, which arise only in the topological superconducting (TS) phase of the Kitaev chain.
