ZOLTAN TOROCZKAI (Presenter), FERENC MOLNAR, University of Notre Dame, ANA-RITA RIBEIRO GOMES, Neuroscience, l'Université Claude Bernard Lyon 1, MARIA ERCSEY-RAVASZ, Physics, Babes-Bolyai University, Cluj-Napoca, KENNETH KNOBLAUCH, HENRY KENNEDY, INSERM Stem Cell & Brain Research Institute U1208 — Although mammalian brains show a massive, 5 orders of magnitude variation in weight, they present common processing features, implying that cortical computing is built on a scalable architecture. We hypothesize the existence of network architectural organizational principles in the mammalian brain, critical for efficient and hierarchically modular information processing. Extending our empirical, consistent tract-tracing network databases, we confirm the validity of the Exponential Distance Rule (EDR) in the macaque cortex, showing that the EDR is an architectural network invariant. We have also developed and cross-validated novel, machine learning based imputation algorithms, suitable for dense interareal networks, exploiting the weighted, directed and the spatially embedded nature of these networks. As we show, these algorithms can efficiently be used to guide further tract-tracing experiments, for example by identifying potential injection targets that would generate the largest information gain, after every new injection.

3:30PM P23.00004: A 2D Stochastic Lattice Model Describing the Self-Assembly of Synaptic Membrane Protein Domains*  EVerest law (Presenter), Univ of Southern California — The regulation of neurotransmitter receptor domains on the postsynaptic membrane plays an important role in signal transduction across synapses. Inspired by the interactions between glycine receptors and gephyrin scaffolds, we present a stochastic lattice reaction-diffusion model explaining receptor domain formation. Using reaction and diffusion rates consistent with experimental observations, our model reproduces the receptor/scaffold copy numbers and domain areas observed in nanoscopy experiments. The Turing instability in our model intuitively explains the pattern formation observed, without assuming the existence of patterns a priori. The present work is an extension of previous work where the same model is only studied in 1D.

3:42PM P23.00005: Dynamics of the intrinsically disordered proteins and neurodegeneration* [Invited] Marek Cieplak (Presenter), Institute of Physics, Polish Academy of Sciences — The equilibrium dynamics of the intrinsically disordered proteins is thought to consist of transitions between many basins in the free energy landscape whereas structured proteins stay in the vicinity of one native basin. We demonstrate this picture explicitly by studying networks defined on the discretized plane: conformational end-to-end distances vs. radii of gyration. The bin sizes are defined by time scales that span orders of magnitude. The networks, derived from all-atom and coarse-grained molecular dynamics simulations, are nearly scale invariant. The bin representation also provides insights into the folding process of the structured proteins and identifies regions that hinder folding. Intrinsically disordered proteins often lead to neurodegenerative diseases through a variety of mechanisms. Here, we focus on one such mechanism: jamming of the proteasomal protein degradation by transient conformations that contain knots. We show that such conformations arise at least for sufficiently long polyglutamine tracts and α-synuclein. The polyglutamine tracts are fused within huntingtin protein that is associated with the Huntington neurodegenerative disease. We show that the presence of knots in the tracts obstructs translocation through a model proteasome, especially when the knots are deep. The knots in polyglutamine may form in tracts that exceed about 40 residues. This fact explains the existence of a similarly sized length threshold above which there is an experimentally observed toxicity at the monomeric level. We also discuss emergence of knots in α-synuclein – the protein associated with the Parkinson disease. We show that these knots are either shallow or deep and last for about 3 – 5 µs, as inferred from an all-atom explicit-solvent 20 and 30 µs trajectories. We argue that their presence enhances aggregation of α-synucleins. In collaboration with: M. Chwastyk, L. Mioduszewski, and B. de Aquino.

4:18PM P23.00006: Alpha rhythm shapes the correlation landscape of avalanche dynamics across resting wakefulness*  FABRIZIO LOMBARDI (Presenter), Institute of Science and Technology Austria, LUCILLA DE ARCANGELIS, University of Campania "L. Vanvitelli", HANS JURGEN HERRMANN, ESPCI Paris, OREN SHRIKI, Ben Gurion University — Brain rhythms and neuronal avalanches form a fascinating dichotomy in the universe of emergent brain dynamics. The former have characteristic times and amplitudes, whereas the latter are scale-free, i.e. they lack characteristic spatio-temporal scales. Yet, they coexist and can be independently measured across different physiologic states, such as sleep and resting wake. However, underlying dynamics and functional role of such emergent dichotomy, as well as the dynamic relationship between brain rhythms and avalanches, remain not understood. In this talk I will show that, while the scale-free properties are universal and preserved across sleep and wake, avalanche dynamics is intimately connected to the dominant brain rhythm characterizing each of those physiologic states, and shows unique features in the resting awake state. Our results indicate that the alpha rhythm induces a dynamic transition in the functional organization of neuronal avalanches, and crucially determines the relationship between consecutive avalanches to balance the spatio-temporal dynamics of spontaneous brain activity.

4:30PM P23.00007: Non-perturbative renormalization group analysis of strongly-coupled spiking networks  BRADEN BRINKMAN (Presenter), Neurobiology and Behavior, Stony Brook University — To fully explain how neural dynamics transmit information and perform computations, we need to understand the structure of the coordinated activity of neurons and their responses to external inputs. Given a model of neural dynamics and their synaptic connections, we would in principle achieve this goal by calculating the statistical and response functions of the network---a notoriously intractable task for all but the simplest models. While diagrammatic series have been successfully used to correct mean field predictions in weakly-coupled network models, they break down in networks with strong nonlinear behavior, demanding new approximation methods.

Here, we employ `non-perturbative renormalization group" methods to analyze strongly-coupled spiking networks. We show that the true mean firing rates of the network satisfy a nonlinear system of equations formally similar to the mean-field system but with a different effective nonlinearity. We explicitly derive a differential equation for this nonlinearity and solve it numerically. Our results predict the distribution of firing rates in simulated networks of neurons reasonably well, even in strong coupling regimes in which perturbative calculations begin to break down.
4:42PM P23.00008: Representation of nearby and infinitely far reference frames in the brain   SHONALI DHINGRA (Presenter), MINA SHAHI, MAYANK MEHTA, University of California, Los Angeles — While navigating the world, our brain needs to keep track of the space around us. A brain region called the Hippocampus plays a significant role in our perception of space. Our work shows that hippocampal cells recognize space as a vector! Hippocampal Place Cells have been shown to keep track of the subject's absolute position. Using GLM, we show that hippocampal cells also keep track of the direction of the rat's position with respect to various frames of reference. These frames include infinitely far frames, thus keeping track of the canonical Head Direction[1]. We also show that these cells utilize various frames of reference at finite distances from the rat's current position. We call the origin of these reference frames as Anchor Points. We see that these cells code for such anchor points in coherent and stable ways, and we call such tuning of these cells as Anchor Fields. We observe that visual cues are capable of affecting various properties of these anchor tunings, including position of Anchor Points, size of Anchor Fields, percentage of cells tuned, and the direction of tuning with respect to these anchor points. We posit that hippocampal cells utilize these tunings to create a vectorial map of space in our brains.

4:54PM P23.00009: How behavioral and evolutionary constraints sculpt early visual processing* [Invited] STEPHANIE PALMER (Presenter), University of Chicago — While efficient coding has been a successful organizational principle in visual neuroscience, to make a more general theory behavioral, mechanistic, and even evolutionary constraints need to be added to this framework. In our work, we use a mix of known computational goals and detailed behavioral measurements to add constraints to the notion of 'optimality' in vision. Accurate visual prediction is one such constraint. Prediction is essential for interacting fluidly and accurately with our environment because of the delays inherent to all brain circuits. In our work, we explore how our visual system makes these predictions, starting as early as the eye. We use techniques from statistical physics and information processing to assess how efficient, predictive vision emerges from these imperfect component parts. To test whether the visual system performs optimal predictive compression and computation, we compute the past and future stimulus information in populations of retinal ganglion cells, and in the vertical motion sensing system of the fly. In the fly, we anchor our calculations with published measurements of fast evasive flight maneuvers. This survival-critical behavior requires fast and accurate control of flight, which we show can be achieved by visual prediction via a specific wiring motif involving gap junction coupling. Developing a general theory of the evolution of computation is also a current research direction in our group. We use the repeated evolution of tetra-chromatic color vision in butterflies to test hypotheses about whether extant neural computations contain shadows of the evolutionary history of the organism.

2:30PM P24.00001: Flow-Arrest Transition in Granular Materials* [Invited] ISHAN SRIVASTAVA (Presenter), GARY GREST, JEREMY LECHMAN, Sandia National Laboratories, LEO SILBERT, Central New Mexico Community College — Flowing granular materials can abruptly arrest if the applied stresses are smaller than a friction-dependent critical value. Such a phenomenon is commonly observed in geophysical scenarios and industrial practice, often with deleterious consequences. However, the statistical and rheological properties of this non-equilibrium transition are not well-understood. In this talk, I will describe our stress-controlled granular simulations that indicate a highly stochastic nature of this transition with long-tailed distributions of flowing times before arrest, which diverge as a power law at a critical stress ratio. We construct a flow-arrest state diagram that clearly distinguishes between shear flow and shear arrest in granular systems in terms of microstructural and rheological properties, with inter-particle friction being an important ingredient. Furthermore, granular flows in the vicinity of this transition exhibit rheological features that are not captured by the traditional \( \mu(I) \) model, such as the presence of normal stress differences. I will describe our recently developed 3D constitutive model that captures these features and is fully compatible with more complex flow scenarios beyond simple shear, such as extensional and so-called triaxial flows.

3:06PM P24.00002: Shear thickening and jamming of dense suspensions: the importance of rolling friction ABHINENDRA SINGH (Presenter), University of Chicago, CHRISTOPHER NESS, University of Edinburgh, JUAN DE PABLO, HEINRICH M. JAEGGER, University of Chicago — The mechanism of shear thickening in dense suspensions has been linked to a stress-controlled transition from a lubricated ``frictionless'' to an unlubricated ``frictional'' rheology. Recent particle simulations that constrain the sliding motion between particles have been successful to reproduce both the discontinuous shear thickening (DST) and shear jamming (SJ) observed experimentally but cannot account for the surprisingly low SJ volume fraction (often below 50%) measured in real-life suspensions in which particles are rough. However, an additional way to build up and maintain stress-carrying paths across a suspension, particularly relevant to rough particles, is by constraining particle rolling. We show via simulations that using rolling friction together with sliding friction can significantly decrease the volume fraction required for the onset of DST and SJ leading to enhanced shear thickening. Moreover, rolling friction drastically affects the structure of the underlying network of frictional particle-particle contacts, while from a dynamical perspective it leads to an increase in the velocity correlation length, in part responsible for the increased dissipation.
Tuning Solvent Chemistry to Suppress Shear-Jamming in Dense Suspensions  
MICHAEL VAN DER NAALD (Presenter), LIANG ZHAO, GRAYSON JACKSON, HEINRICH M. JAEGER, University of Chicago — Mechanical stress can transform a free flowing suspension of solid particles in a Newtonian liquid into a shear jammed, solid-like state. While recent work highlighted how particle surface chemistry contributes to the shear jamming transition,[1] much less is known about the suspending liquid. We here report both steady state rheology and the transient impact response tracked by high-speed ultrasound imaging [2] for silica nanoparticles dispersed in polyethylene glycols (PEGs) of varied chain lengths. For suspensions with identical silica volume fractions and impact conditions, decreasing the solvent molecular weight (MW) suppresses shear jamming. We attribute these results to stronger solvation layers in low MW PEG which keep contacts between particles lubricated even under high stress.

Yielding and Rigidity of Sheared Columns of Hexapod Granules*  
YUCHEN ZHAO (Presenter), Department of Physics, Duke University, JONATHAN BARÉS, Laboratoire de Mécanique et Génie Civil, Université de Montpellier, JOSHUA SOCOLAR, Department of Physics, Duke University — Granular packings of non-convex or elongated particles can form free-standing structures like walls or arches. For some particle shapes, such as staples, the rigidity arises from interlocking of pairs of particles, but the origins of rigidity for non-interlocking particles remain unclear. We report on experiments and numerical simulations of sheared columns of “hexapods,” particles consisting of three mutually orthogonal rods whose centers coincide. We vary the length-to-diameter ratio, $\alpha$, of the rods and subject the packings to quasistatic direct shear. For small $\alpha$, we observe a finite yield stress. For large $\alpha$, however, column is rigid against shear, and stresses within it increase with increasing strain. Analysis of X-ray micro-computed tomography data collected during the shear, reveals that the stiffening is associated with a tilted, oblate cluster of hexapods near the nominal shear plane in which particle deformation and average contact number both increase. Simulation results show that geometric cohesion effects are negligible for small $\alpha$. For large $\alpha$ ($\alpha=10$), we directly observe that particles are collectively under tension even though they do not interlock pairwise. The tensile stress counteracts the tendency to dilate in direction normal to the shear plane.

Chaotic particle dynamics above and below yield in a 2D jammed material* LARRY GALLOWAY (Presenter), DOUG JEROLMACK, PAULO ARRATIA, University of Pennsylvania — Amorphous materials, often fail catastrophically, just beyond yield. This is a problem not just in design engineering (harnessing high strength glasses without the chance of ruinous breakdowns), but also in predicting the failure of non-constrained, natural systems (averting damage caused by mudslides). The yielding transition has previously been observed in both experiments and simulations to present via the emergence of specific particle trajectories, known as reversibly or irreversibly plastic. Here we present detailed quantification of Lagrangian properties (displacement lengths, arc-lengths, and enclosed area) of experimentally obtained particle trajectories for the purpose of illuminating where plasticity occurs in space and time both above and below yield. Our findings suggest plastic trajectories, both reversible and irreversible, predominantly occur in specific regions as a function of the strain amplitude, but not time. These findings imply that the yield transition is of the first order and that mean field and thermodynamic models are attainable. In this direction, we introduce a non-dimensional measure of plastic dissipation that applies both above and below yield and captures the rheological yield point.

The precursors to stick-slip events in sheared granular systems* CHAO CHENG (Presenter), RITUPARNA BASAK, New Jersey Inst of Tech, MIROSLAV KRAMAR, Department of Mathematics, University of Oklahoma, LOU KONDIC, New Jersey Inst of Tech —

The stick-slip transition of granular systems is related to earthquakes and avalanches, and therefore understanding the conditions leading to slip events is of general importance. Although stick-slip behavior has been studied extensively, what triggers a slip event still remains unclear. The purpose of our study is to explore the existence of precursors to slip events. For this purpose, we study a sheared system in a stick-slip regime via two-dimensional discrete element simulations. Particular focus is on the evolution of force networks before and during slip events. We will show that some features of force network evolution could be used to gain insight into the occurrence of a slip event.

4:06PM P24.00007: Jamming and tiling in fragmentation of rectangles  ELI BEN-NAIM (Presenter), Los Alamos Natl Lab, PAUL KRAPIVSKY, Boston University — We investigate a stochastic process where a rectangle breaks into smaller rectangles through a series of horizontal and vertical fragmentation events. We focus on the case where both the vertical size and the horizontal size of a rectangle are discrete variables. Because of this constraint, the system reaches a jammed state where all rectangles are sticks, that is, rectangles with minimal width. Sticks are frozen as they can not break any further. The average number of sticks in the jammed state, $S$, grows as $S \approx A/(2\pi \ln A)^{1/2}$ with rectangle area $A$ in the large-area limit, and remarkably, this behavior is independent of the aspect ratio. The distribution of stick length has a power-law tail, and further, its moments are characterized by a nonlinear spectrum of scaling exponents. We also study an asymmetric breakage process where vertical and horizontal fragmentation events are realized with different probabilities. In this case, there is a phase transition between a weakly asymmetric phase where the length distribution is independent of system size, and a strongly asymmetric phase where this distribution depends on system size.

4:18PM P24.00008: Contact breaking in packings of frictional disks  YAN CHEN (Presenter), PHILIP WANG, QIKAI WU, Yale University, MARK SHATTUCK, City College of New York, COREY SHANE O'HERN, Yale University — We employ discrete element modeling simulations of the geometrical asperity or "bumpy particle" model to study the nonlinear vibrational response of jammed packings of frictional disks. We first calculate the eigenmodes of the dynamical matrix for each bumpy-particle packing. We then perturb the packing by a given velocity along a single and multiple eigenmodes of the dynamical matrix, run the simulations at constant total energy, and measure the Fourier transform of the translational and rotational velocities of the particles. For small velocity perturbations, contacts do not break, and the peaks in the power spectrum occur at frequencies that match the eigenfrequencies of the dynamical matrix. We determine the characteristic temperature $T_c$ above which the interparticle contact network breaks, and compare the density of vibrational modes from dynamical matrix to the power spectrum for $T > T_c$. We show that perturbing along eigenmodes with primarily translational velocities gives rise to qualitatively different behavior of the vibrational response compared to that after perturbing along eigenmodes with primarily rotational content.
Modelling granular fragmentation in compacted systems

JOEL CLEMMER (Presenter), DAN STEFAN BOLINTINEANU, JEREMY LECHMAN, Sandia National Laboratories — The jamming of hard particles in the zero-pressure limit has been well studied, however many applications are far from this limit. As pressure increases, granular rearrangement is no longer the only mechanism for densification as grains deform and fracture. This breakdown of granular matter, or comminution, produces irregular shapes and sizes and changes macroscopic properties including rheology. We explore the compaction of brittle granular systems using large-scale discrete element simulations. Each grain is composed of many small, fundamental particles. These particles are interconnected by bonds which break under sufficient stress allowing grains to fragment into smaller grains. During loading, we monitor the evolution of stress, porosity, and distributions of grain size and shape. We characterize trends and explore the effect of strain rate and material properties. We also identify the pressure at which individual grains fracture and compare to theoretical models.

Electrostatic Attraction between Like-Charged Particles

BENJAMIN REGGIO (Presenter), SHUBHA TEWARI, Univ of Mass - Amherst — A point charge Coulomb force model provides an inadequate description of the interaction between finite-sized particles. Experiments find that dielectric particles of like charge can polarize one another, causing effective attractive forces between them that lead to clumping. To more accurately model the origin of these attractive forces, we study the effective interaction between two dielectric spherical shells with like charge as a function of their size and charge ratios, and the dielectric constant of each. We base our work on a model developed by Bichoutskaia et. al. [1] in which the authors map a phase diagram of attractive interactions between like-charged spheres at touching. We extend the phase diagram to finite separations between the particles, determining the boundary at which the force becomes repulsive. Though a closed form expression for the force between particles does not exist, we find an effective force in certain parameter regimes that can be used as an input in simulations of charged granular particles. The form of this force is found to vary depending on whether we are in the small size ratio or the small charge ratio regime.

4:54PM P24.00011: Unforgettable random walks: forces and displacements distributions in granular systems.*  
ANTON PESHKOV (Presenter), Department of Physics and Astronomy, University of Rochester, ZACKERY A BENSON, IREAP, University of Maryland, DEREK C RICHARDSON, Department of Astronomy, University of Maryland, WOLFGANG LOSERT, Affiliation: Departments of Physics, IPST and IREAP, University of Maryland — Granular systems are known to exhibit memory effects characterized by the remembrance of the past states and preparation history, which affect its future evolution. At the same time there exist a consensus that the force distributions of granular systems follow exponential and gamma distributions; a hallmark of the memory independent Brownian motion. Both of these assertions are mutually contradicting. We resolve this incongruity by experimentally and numerically verifying that the forces, as well as translational and rotational displacements of dense granular systems are governed by log-normal and power law distributions; consequence of a history dependent geometrical Brownian motion. We show the latter to be a natural product of contacts that reign between particles.

*This work was supported by National Science Foundation grant DMR5244620.

5:06PM P24.00012: Weakening, compaction and creep from vibration in sheared granular materials*  
STEPHANIE TAYLOR (Presenter), University of California, Santa Cruz, ABE CLARK, Naval Postgraduate School, EMILY BRODSKY, University of California, Santa Cruz — The strength and stability of granular materials like sands and powders corresponds to the strength and stability of soils, asphalt, building and industrial materials, gouge filled earthquake faults, hillslopes, and more. Passing vibrations and transient perturbations have been thought to play a role in determining dynamic friction during sliding in such systems as well as trigger failure in static grain packs. With laboratory experiments and discrete element method simulations, we show that low amplitude high frequency vibrations are capable of significantly reducing frictional resistance over a range of velocities in actively shearing systems. Near yield, coefficient of friction decreases with increasing acoustic energy raised to a power of -0.2. Susceptibility to creep, compaction and weakening depends on grain shape, vibration amplitude, frequency, system resonances and system pressure. Exposure to (and generation of) vibration during shear of granular materials is common in many industrial and transport processes, and granular materials’ susceptibility to vibrational weakening may play a pivotal role in these processes.

2:30PM P25.00001: String Contraction via Twisting: Ideal and Nonideal Behavior  JESSE HANLAN (Presenter), University of Pennsylvania, GABRIELLE DAVIS, Department of Physics, University of Maryland, DOUGLAS DURIAN, University of Pennsylvania — Strings are an ancient and extremely common tool for force delivery. They may also be used to deliver torque via twisting, according to tension times the rate of length contraction versus twist angle $\Theta$, and this is important for twisted string actuators in robotics as well as for button-on-a-string toys and hand-powered centrifuges. Idealized behavior for length contraction is predicted to be $L^2 = L_0^2 - (r\Theta)^2$ where $L_0$ is the initial string length and $r$ is its radius. Here we compare this model with data for single, double and triple stranded strings of parachute cords, rattail cord, nylon, kevlar, monofilament fishing line, and metal wire. We also examine deviation from ideality at small and large twist angles in order to probe the internal structure of our strings. At small angles, we see a systematic decrease in the effective cord radius compared to expectation, as individual strands compress into each other, while at large twist angles we see less contraction than expectation due to the coiling of the strands. In all cases, nonideal effects may be quantified by an effective string radius indicative of internal geometry and string-string interaction, which could play a role in the mechanics of real knots and fabrics.

2:42PM P25.00002: Contact geometry of equidistant tubes  HARMEET SINGH (Presenter), PAUL GRANDGEORGE, TOMOHIKO SANO, PEDRO REIS, JOHN MADDOCKS, École polytechnique fédérale de Lausanne — We consider equilibrium configurations of two flexible tubes arranged in space such that their centrelines are separated by a constant distance. Depending on their configuration, the two centrelines may exhibit single or double contact. We will discuss the contact geometry of one such configuration that exhibits double contact, called the orthogonal clasp, where the two centrelines are assumed to lie in orthogonal planes. Based on this example, we will motivate a “capstan” like equation governing tension decay along the centreline of a flexible tube wrapped around a rigid hook with friction.

2:54PM P25.00003: Fibered by fibers: the geometry and elasticity of frustrated filaments*  DARIA ATKINSON (Presenter), Univ of Mass - Amherst, CHRISTIAN SANTANGELO, Syracuse University, GREGORY GRASON, Univ of Mass - Amherst — Filamentous and columnar assemblies are a ubiquitous motif in materials, from microscopic and biological materials, like discotic liquid crystals and biopolymer bundles, to familiar macroscopic materials like yarns, cables, and ropes. Ordered ground states in filament bundles, however, are highly geometrically constrained. We show that only two families of filament textures permit equidistance between the constituent filaments: the developable domains, which can bend, but not twist, and the helical domains, which can twist uniformly, but not bend. The elastic response of non-equidistant filament bundles is then frustrated, and cannot adequately be described by a linearized energy. To describe nonequidistant configurations, we derive a geometrically nonlinear, coordinate invariant, gauge-like theory for the elasticity of filamentous materials. Within this framework, we discuss the impact of filament texture on bundle elasticity, and calculate the stable states for non-equidistant bundles with small curvature.

NSF DMR-1608862
3:18PM P25.00005: Disease outbreak as stochastic resonance: interplay between host-seeking behavior and heterogeneous human/vector interactions results in system amplification*  
JOSHUA PARKER (Presenter), U.S. Army Engineer Research and Development Center, DAVE PECOR, Smithsonian Institution, NICOLE WAYANT, U.S. Army Engineer Research and Development Center — We perform phase space analysis on a mathematical model of mosquito-borne disease that incorporates the full mosquito life cycle. We also include the cessation of host-seeking after obtaining a blood meal, and heterogeneous interactions between the human and mosquito populations. We find that under these conditions, stochastic resonance results in the emergence of a dynamic phase of episodic outbreak, where the proportion of the human and mosquito populations susceptible to disease exposure varies wildly from year to year. The results of this work suggest that interventions to screen vector and human populations from disease leads to intermittent exposure to infection, which may lead to these populations becoming more sensitive to outbreaks.

3:30PM P25.00006: Impact of initial seeds in cooperative contagion processes  
BYUNGJOON MIN (Presenter), Department of Physics, Chungbuk National University — Many types of contagion phenomena are often strongly influenced by cooperative effects among multiple pathogens. When a node has been infected with one of the diseases, the probability of the second disease’s transmission grows, compared to single pathogen spreading. It remains unclear how to predict epidemic outbreaks from the location of the initial seeds. In this work, we modulate the probability of infection depending on the state of nodes taking into account the cooperativity between different pathogens. Defining the transmission probabilities of the first and of the second infecting disease, we derive message-passing equations for cooperative contagion processes. By using the message-passing equations, we assess the impact of seeds in cooperative coinfections and also provide explanation how cooperative epidemic occurs.
3:42PM P25.00007: Degree-preserving Network Growth* SHUBHA RAJ KHAREL (Presenter), University of Notre Dame, TAMÁS RÓBERT MEZEI, Alfréd Rényi Institute of Mathematics, SUKHWAN CHUNG, University of Notre Dame, DÁNIEL SOLTÉSZ, PETER ERDOS, Alfréd Rényi Institute of Mathematics, ZOLTAN TOROCZKAI, University of Notre Dame — Real-world networks evolve over time via the addition or removal of vertices and edges. In current network evolution models, vertex degree varies or can even grow arbitrarily, yet there are many networks in which it saturates (e.g., social networks) or is fixed (e.g., chemical complexes), thus requiring an entirely different description. We introduce a novel class of models that encapsulates degree preserving dynamics in the simplest form, resulting in structures significantly different from previous ones. We discuss their properties as function of the evolution of the network’s matching number and present several generative models based on this framework, from growing uniform degree distribution graphs to growing random regular graphs, which, to our best knowledge, is the first model of this kind. Within this approach, we also introduce configuration-like models that realize given degree sequences, with tunable degree-mixing properties. Moreover, this process can generate scale-free networks with arbitrary exponents, but without involving any degree-based preferential attachment.

3:54PM P25.00008: Synchronization of Coupled Kuramoto Oscillators under Resource Constraints* KEITH WILEY (Presenter), University of Pennsylvania, PETER J MUCHA, University of North Carolina at Chapel Hill, DANIELLE BASSETT, University of Pennsylvania — A fundamental understanding of synchronized behavior in multi-agent systems can be acquired by studying analytically tractable Kuramoto models. Yet, such models typically diverge from many real systems whose dynamics evolve under marked resource constraints. Here we construct a system of coupled Kuramoto oscillators that consume or produce resources as a function of their oscillation frequency. At high coupling, we observe strongly synchronized dynamics, whereas at low coupling, we observe independent oscillator dynamics, as expected. For intermediate coupling which typically induces a partially synchronized state, we demonstrate that the system can exist in either an oscillatory synchronization state or a bistable synchronization state depending on whether the oscillators consume or produce resources, respectively. Relevant for systems as varied as coupled neurons and social groups, our study lays important groundwork for future efforts developing quantitative predictions of synchronized dynamics for systems embedded in environments marked by resource constraints.

Model reduction of large networked systems using the Manifold Boundary Approximation Method

BENJAMIN FRANCIS (Presenter), JACOB R NUTTALL, MARK TRANSTRUM, Brigham Young Univ - Provo, ANDRIJA SARIĆ, University of Novi Sad, ALEKSANDAR STANKOVIĆ, Tufts University — Complex systems are often described by a network. Models of these systems are often constructed from physical first principles by accounting for the interaction network among the components.

For large systems, model complexity grows faster than the richness of the available data, leading to many more tunable parameters than can be reliably estimated from measurements. The resulting models are often sloppy and amenable to effective descriptions in which mechanistic details are intentionally ignored in favor of the relevant collective degrees of freedom governing system behavior.

We consider the case of a small network model from electric power systems and show that sloppiness is manifest in both dynamic and network parameters.

Using techniques of information geometry, we derive reduced models of the network that act as effective theories in cases where only partial system measurements are available using the Manifold Boundary Approximation Method (MBAM).

Leveraging insights from this model, we apply a linearized version of MBAM to a much larger system.

We demonstrate that this method can identify the effective network of interactions, and discuss implications for modeling of other networked systems.

Path-dependent Dynamics Induced by Rewiring Networks of Kuramoto Oscillators with Inertia

WILLIAM QIAN (Presenter), EVANGELIA PAPADOPOULOS, ZHIXIN LU, DANIELLE BASSETT, University of Pennsylvania — In networks of coupled oscillators, it is of wide interest to understand how interaction topology affects synchronization. Many studies have gained key insights into this question by studying the classic Kuramoto oscillator model on static networks. However, new questions arise when network structure is time-varying or when the oscillator system is multistable, which can occur by adding an inertial term to the Kuramoto model. While the consequences of evolving topology and multistability have been examined separately, real-world systems such as the brain may exhibit these properties simultaneously.

This motivates investigation into how rewiring of network connectivity affects synchronization in systems with multistability, where different paths of network evolution may differentially impact collective behavior. To this end, we study the effects of evolving network topology on coupled Kuramoto oscillators with inertia. We find that certain fixed-density rewiring schemes induce significant changes to the level of global synchrony, and that these changes are robust to a wide range of network perturbations. Our findings suggest that the specific progression of network topology can play a considerable role in modulating the collective behavior of systems evolving on complex networks.
4:30PM P25.00011: Distribution of the Sizes of the Blackouts in Power Grids, Synthetic Models, and the Motter and Lai Model under different Dynamical Rules and Criteria of Overload  GABRIEL CWILICH (Presenter), SERGEY BULDYREV, Physics, Yeshiva University, YOSEF KORNBLUTH, Mechanical Engineering, Massachusetts Institute of Technology — Studies of the sizes of the blackouts in real grids and computer simulation models of them using the direct current approximation suggest that the resulting blackout sizes are distributed as a power law when using the standard criterion of resilience, the so-called N-1 condition: The grid must safely operate in the event of a failure of any single line. At any stage of the cascade, one of the lines whose load exceeds the maximum values imposed by the N-1 condition fails and immediately all the currents in the grids are redistributed adjusting to the new topology. On the contrary, when the grid is modeled with a uniform tolerance proportional to its initial current for all the nodes and one removes all the overloaded lines simultaneously at each stage of the cascade, the distribution of the sizes of the blackouts is bimodal as in a first the order phase transition, resulting in either a very small blackout or a very large blackout. Here we reconcile both approaches by looking at how the blackout distribution changes with model parameters and different dynamic rules of failure of the overloaded lines. We also study the Motter and Lai model of betweenness overload and find similar results, suggesting that the physical laws of flow are not the determinant factor in the problem.

4:42PM P25.00012: Generating individual aging trajectories with a network model  SPENCER FARRELL (Presenter), ARNOLD MITNITSKI, KENNETH ROCKWOOD, ANDREW RUTENBERG, Dalhousie Univ — Aging is characterized by the stochastic accumulation of damage. We model this process with a set of health attributes as nodes that interact in a network leading to mortality. Health decline and mortality occur stochastically with a set of complex rates that are trained along with the interaction network using data from observational aging studies. Our model generates synthetic-individuals with health trajectories and lifespan resembling real individuals. The trajectories and lifespans generated with this method also let us model both health events and health interventions so as to better understand their effects on the future health and lifespan of individuals.
4:54PM P25.00013: Modeling the Dynamics of Belief in Climate Change with Statistical Physics

ERNEST AIGNER, Wirtschaftsuniversität Wien, JACKIE BROWN, York University, KYLE FURLONG, MITRE, DAVID GIER, University of California, Davis, LUDVIG HOLMÉR (Presenter), Stockholm School of Economics, RITWIKA VALLOMPARAMBATH PANIKKASSERYSU, Physics, University of California, Merced — We simulate the dynamics of belief in climate change using agents on a social network who update their beliefs according to a classical XY Model Hamiltonian. The initial conditions of the model are set by contemporary empirical insights in the social distribution of climate beliefs (Hornsey et al. 2016). The social network dynamics are inspired by dispersion rules proposed by Galesic and Stein (2019) but extend with additional social and environmental rules. Environmental effects include extreme weather events and disasters. The frequency, spatial-distribution, and intensity of extreme weather events are calibrated with real world data on climate impacts (Siscoe et al. 2017). The model enables us to analyse the interactions between social belief dynamics in networks and climate impacts and suggest when and if a consensus about climate change will form in the wake of extreme climate-related weather events.

Session P26 DBIO DCP: Immune Sensing and Response

2:30PM P26.00001: Universality of biochemical feedback and its application to immune cells* [Invited] AMIR EREZ (Presenter), Princeton University, TOMMY A. BYRD, Purdue University, ROBERT M VOGEL, IBM T. J. Watson Research Center, GREGOIRE ALTAN-BONNET, National Institutes of Health, ANDREW MUGLER, Purdue University — Positive feedback is ubiquitous in biochemical networks and can lead to a bifurcation from a monostable to a bistable cellular state. One such example is the immune self/foreign decision, which is manifested in a complex biochemical cascade. We consider a coarse-grained view of this cascade, its output and response to inhibition, and propose a theory which maps the stochastic dynamics to thermodynamic state variables. Our mapping allows experimental data analysis without curve fitting and highlights previously unknown features in the data. Beyond steady state, our theory reveals critical slowing down and a universal scaling of the response to changing stimulus. Finally, motivated by the immunological synapse, where a pair of cells communicate with each other through molecule exchange, we consider a pair of sensing/responding cells and how they might communicate effectively.

3:06PM P26.00002: Optimal non-equilibrium decision making to store immune memory
OSKAR SCHNAACK (Presenter), Max Planck Institute for Dynamics and Self-Organization, ARMITA NOURMOHAMMAD, University of Washington — Our adaptive immune system consists of highly diverse immune receptors to mount specific responses against a multitude of pathogens. During an infection, a fraction of these receptors forms a memory for later encounters. Here, we address a key question: which of the immune receptors should be kept as memory so that they can mount a response against evolved forms of the original pathogen in future infections? To do so, we have developed a theoretical framework, where memory storage is a non-equilibrium decision-making process between an adaptive exploration to mount a specific response and exploitation of existing yet suboptimal memory that can be utilized immediately to suppress an infection. To achieve a long-term benefit for the host, we show that memory generation should involve feedback from receptors' affinity and should favor cross-reactive receptors with a moderate affinity over high-affinity receptors against the infecting pathogen. The recipe for memory generation should be tuned over the host's evolutionary timescale based on the pathogenic evolutionary rates. Our results are consistent with recent experiments that suggest cell fate decisions during memory generation are highly regulated to balance the affinity and cross-reactivity of immune receptors.

3:18PM P26.00003: Visualizing and controlling immune response to gut microbes*
BRANDON SCHLOMANN (Presenter), TRAVIS J WILES, ELENA S WALL, KAREN GUILLEMIN, RAGHUVEER PARTHASARATHY, Univ of Oregon — Trillions of bacteria reside in the intestine where they are largely kept away from epithelial surfaces. When this spatial confinement is broken, the resulting immune responses can be damaging and lead to disease. Understanding the processes that spatially restrict gut bacteria will open new avenues for microbiome-based therapies. I will present work that investigates interactions between immune cells and resident gut bacteria through live imaging of naturally transparent, larval zebrafish. We discovered that flagella-based swimming motility enables a native Vibrio species to govern its own spatial organization within the gut and stimulate a potent immune response. Mutants that cannot swim become aggregated and confined to the interior lumen of the gut. Loss of motility also leads to reduced expression of the proinflammatory cytokine TNFα in gut-associated macrophages and in the liver. Externally-inducible genetic switches enabled in situ manipulation of bacterial motility, and therefore external control of both bacterial spatial distribution and proinflammatory potential. Our findings reveal connections between the physical activity of bacteria, their spatial organization, and host inflammatory activity.

*This work was supported by the NIH, NSF, and Kavli Foundation.
Adoptive cell transfers have emerged as a disruptive approach to treat diseases in a manner that is more specific than using small molecule drugs. However, unlike traditional drugs, cells are living entities that can alter their function in response to subtle environmental cues. In this talk, I will present a class of particles, referred to as “backpacks”, that can regulate the phenotype of adoptively transferred macrophages in vivo. Backpacks are able to robustly adhere to macrophage surfaces and evade phagocytosis for several days. Once attached, backpacks can release encapsulated pro-inflammatory cytokines to potentiate antitumor (M1) phenotypes in macrophages, even in tumor-mimicking conditions. When injected intratumorally into mice bearing breast tumors, a potent immunosuppressive (M2) environment, backpacks allowed macrophages to maintain their M1 phenotypes. Conserved phenotypes led to significantly reduced metastatic burdens and slowed tumor growths compared to those of mice treated with an equal dose of free cytokine. Overall, controlled release of cytokines from backpacks may enable a new strategy to regulate phenotypes of adoptively transferred cells to aid in the treatment of a variety of inflammatory and autoimmune diseases.

Cells such as natural killer cells and macrophages can recognize and eliminate targets with aberrant surface ligand expression without antigen specificity. This innate mechanism of activation must be tightly regulated to prevent autoimmunity. We describe a quantitative model of the regulation of nonspecific activation that is grounded in Bayesian inference. Our model captures known behaviors of innate immune cells, including adaptation to changing environments and the development of hyposensitivity after prolonged exposure to activating signals. Our analysis reveals a tradeoff between precision and flexible adaptation to different environments. Maintaining the ability to adapt naturally leads to heterogeneous responses, even for hypothetical populations of immune cells and targets that have identical surface receptor and ligand expression. Collectively, our results describe an adaptive algorithm for self/nonself discrimination that functions even in the absence of antigen restriction and supports biological observations of single-cell heterogeneity in response to cell-cell interactions. The same model could also apply more broadly to the adaptive regulation of activation for other immune cell types.
A mathematical model of aging in the immune system

ERIC JONES (Presenter), University of California, Santa Barbara, JIMING SHENG, SHENSHEN WANG, University of California, Los Angeles, JEAN M CARLSON, University of California, Santa Barbara — The adaptive and innate branches of the vertebrate immune system work in close collaboration to protect organisms from harmful pathogens. As the organism ages the immune system undergoes immunosenescence, characterized by declined performance or malfunction in either branch, which can lead to various diseases and death. In this study we develop a mathematical model of the immune system that couples the innate and adaptive components of the immune system, allowing investigation of the mutual modulation of the innate and adaptive immune branches over time. Our results capture the clinically-observed chronic inflammatory response affiliated with aging (“inflamm-aging”), and find that the timing of this persistent inflammatory response is dependent on the history of pathogen encounters. By consolidating complex immune feedbacks into a mathematical model, our results inform the mechanisms responsible for immunosenescence and offer opportunities for their further exploration through quantitative modeling.

B cells use mechanical energy to distinguish affinity and speed up adaptation

HONGDA JIANG (Presenter), SHENSHEN WANG, Department of Physics and Astronomy, University of California, Los Angeles — Generation of potent antibodies relies on positive selection of germinal center (GC) B cells expressing high affinity receptors. Effective selection during the rapid evolutionary process called affinity maturation requires efficient ranking of affinity. Yet, the mechanism by which affinity discrimination is achieved and how it affects B cell evolution remains unclear. Growing evidence shows that B cells use mechanical forces to actively extract antigens from the surface of antigen-presenting cells. Here we study the stochastic process of antigen extraction using theory and simulations. We find that application of mechanical force alters the energy landscape of molecular interactions and consequently extends the range of distinguishable affinities. Integrating this extraction model on the molecular scale with GC dynamics on the population level, we demonstrate that exertion of cytoskeletal forces for antigen extraction can accelerate the rate of affinity maturation.
Aging in the immune system is a loss of balance

Jiming Sheng (Presenter), Physics and Astronomy, University of California, Los Angeles; Eric Jones, Jean M Carlson, Physics, University of California, Santa Barbara; Shenshen Wang, Physics and Astronomy, University of California, Los Angeles — The innate and adaptive arms of the vertebrate immune system work in close collaboration to protect organisms from harmful pathogens. As an organism ages its immune system undergoes immunosenescence, characterized by degraded performance or malfunction, in either arm, that leads to diseases and even death. However, a system-level mechanism of immunosenescence is not understood.

In this talk, I introduce a mathematical model of immune response that integrates the innate and adaptive components, which enables studies of their mutual modulation over an individual's lifetime. Our results capture the clinically-observed chronic inflammation associated with aging, demonstrating that this “inflamm-aging” could be of protective origin by compensating for weakened adaptive immunity. We show that the timing of onset of persistent inflammatory response depends strongly on the temporal pattern of pathogen encounter and uncover potential determinants of the timing. Finally we examine the bipartite role of adaptive immunity in a balance between removing pathogens and mitigating inflammation. In all, our work suggests that aging in the immune system exemplifies a failure of coordination between adaptive and innate immunity and the timing of failure is strongly shaped by the infection history.

Influenza virus geometry shapes the immune response against it

Assaf Amitai (Presenter), Massachusetts Institute of Technology MIT; Maya Sangesland, Daniel Lingwood, The Ragon Institute of Massachusetts General Hospital, The Massachusetts Institute of Technology and Harvard University; Arup K Chakraborty, Massachusetts Institute of Technology MIT — Influenza surface glycoprotein – Hemagglutinin (HA) is the main target of the immune system following exposure to the virus. Most antibodies elicited following vaccination or infection are created against the head, which is highly mutable. A vaccination approach that would target immune response towards evolutionarily conserved residues on hemagglutinin stem can elicit broadly neutralizing antibodies capable of fighting many flu strains.

Using mice experiments, in-silico models of designed immunogens (nanoparticles) and of antibody development against flu, we study how a targeted response against conserved stem residues can be elicited. We find that because of the high density of HA molecules on the virus, infection by the virus drives the proliferation of B cells targeting mutable residues while suppressing those targeting conserved sites. Strong response against the conserved residue can be achieved by vaccinating with nanoparticles presenting the stem part of HA alone, of flu strain different from those to which the system was already exposed to.
4:42PM P26.00010: Spurious higher-order correlations from non-linearities in a receptor-ligand model  RICHARD ZHU (Presenter), ARVIND MURUGAN, University of Chicago — Multi-body correlations arise frequently in analyses of biological systems, such as antibiotic interactions in cell growth rate, mutational interactions on protein function and ligand interactions in the immune system. In particular, it is common practice to measure the 1st and 2nd-moments of quantities of interest, and fit a maximum-entropy model to the data. We demonstrate that pairwise and higher-order interactions emerge naturally from mismatches between the fitted model and the underlying physical system, as well as ignorance of unmeasured quantities. We study a simple receptor-ligand model and demonstrate that spurious higher-order interactions can arise from simpler interactions combined with non-linearities not accounted for. Our analysis shows how careful accounting for the underlying biology is needed to conclude the existence or absence of complex interactions within the system.

4:54PM P26.00011: To die or not to die: Cell decision-making in the face of viral threat*  [Invited]  JENNIFER OYLER-YANIV (Presenter), California State University, Los Angeles — Paradoxically, the pro-inflammatory cytokine Tumor Necrosis Factor α (TNFα) simultaneously activates opposing pro-apoptotic and pro-survival signaling. We show that the activation of antagonistic pathways changes the properties of cell fate decision transitioning cells from a “slow and accurate” to “fast and error-prone” decision mode. Mathematical modeling predicts, and experiments in vitro and in vivo validate, that the regulation of the decision mode of non-immune cells by innate immune cell production of TNFα is key to prevent viral spread. Overall our results demonstrate how a collective phenotype emerges from the regulation of fundamental tradeoffs within cellular cognitive processes.

Wednesday, March 4, 2020 2:30 PM - 5:18 PM

Session P27 FIAP DCMP: Synthesis and Characterization of Electronic Thin Films  404 - Amber Reed, Air Force Research Lab - WPAFB
2:30PM P27.00001: Effect of Scandium Nitride Film Orientation on Growth and Electrical Properties

AMBER REED (Presenter), Air Force Research Lab - WPAFB, DAVID LOOK, Semiconductor Research Center, Wright State University, HADLEY SMITH, ZACHARY BIEGLER, RACHEL ADAMS, MADELYN HILL, TYSON BACK, JOHN CETNAR, Air Force Research Lab - WPAFB — Scandium nitride (ScN) is a degenerate semiconductor with great potential as a complementary material to enhance GaN performance in high-power and high-speed electronic applications. Electron mobilities up to 130 cm$^2$/Vs have been reported for (100)-ScN on (100)-MgO substrates. The values reported for (111)-ScN, however, are significantly lower. In this work, we investigate the effect of ScN orientation on film growth, composition and electrical properties. A series of thin ScN films were deposited on (111)-, (110)- and (100)-MgO substrates using reactive magnetron sputtering. X-ray diffraction showed that ScN grew with the same orientation as the MgO and crystalline growth and quality was dependent on growth conditions. Secondary ion mass spectroscopy showed that while the variation in the oxygen concentration was negligible, the fluorine and hydrogen concentrations differed between ScN orientations. Hall-effect measurements showed that mobility, carrier concentration, and resistivity were dependent on orientation. In this presentation we will discuss the correlation between the measured electrical properties and the ScN crystallinity and composition.

2:42PM P27.00002: High-Mobility Two-Dimensional Electron Gases at Al$_x$Ga$_{1-x}$N/GaN Heterostructures Grown by Plasma-assisted Molecular Beam Epitaxy

YUXING REN (Presenter), YONGJIN CHO, AUSTIN HICKMAN, REET T CHAUDHURI, PHILLIP DANG, MENYOUNG LEE, WENWEN ZHAO, ZEXUAN ZHANG, HUILI GRACE XING, DEBDEEP JENA, Cornell University — Polarization-induced high-mobility two-dimensional electron gases (2DEGs) at AlGaN/GaN heterostructures have been studied and used for ultrafast transistors. They offer an interesting platform to study quantum transport in the high electron effective mass regime. At room temperature, the mobility is dominated by optical phonon scattering, but at low temperatures, the mobility is determined by defect and imperfection based scattering mechanisms, and weakly by acoustic phonons. In this talk, we will present how gate control of the 2DEG density helps us identify the impact of dislocations on the mobility. We have used a range of samples in which the dislocation densities vary over 4 orders of magnitude. With the help of high magnetic field oscillation studies at low temperatures we extract the effect of dislocations on the low temperature scattering processes.

2:54PM P27.00003: Electrical Properties of Highly Functionalized Ultrathin, 2-Dimensional Hexagonal Boron Nitride* DANIEL CHOI (Presenter), National Research Council, STANISLAV TSOI, EVGENIYA LOCK, BORIS FEYLGELSON, United States Naval Research Laboratory — Hexagonal boron nitride (h-BN), an excellent dielectric material with a wide band gap value of ~6 eV, is widely used as insulating layer and gate dielectric in a wide variety of current electrical systems as well as emerging quantum based applications. Thus, much efforts have been invested in looking into modulating electrical properties of h-BN systems. However, much of the current state of the art h-BN studies have focused around larger flakes rather than thin films due to difficulty in uniform synthesis and surface chemistry, leading to low degree of functionalization. In this talk, we present electrical and tunneling properties of highly functionalized, ultrathin, 2D h-BN. Our h-BN are functionalized with TFPA-NH$_2$ and TFPA-SH molecules and electrical properties probed via conductive atomic force microscopy. Our approach reveals previously unachieved, high degree of functionalization, as well as electrical and tunneling properties of this novel system. Our results provide basis for understanding effects of high degree functionalization on h-BN thin films as well as additional incorporation method of h-BN into other 2D van der Waals heterostructure systems.

3:06PM P27.00004: Mobility fluctuation Controlled Linear Positive Magnetoresistance in 2D Semiconductor Bi$_2$O$_2$Se nano-plates PENG LI (Presenter), University of Waterloo, CHENHUI ZHANG, King Abdullah University of Science and Technology, GUOXING MIAO, University of Waterloo, XIXIANG ZHANG, King Abdullah University of Science and Technology — Bi$_2$O$_2$Se is a promising 2D semiconductor with ultrahigh mobility and excellent stability in ambient conditions. We report the observation of positive and linear magnetoresistance in both Se-poor and Se-rich Bi$_2$O$_2$Se nano-plates grown by chemical vapor deposition. In Se poor Bi$_2$O$_2$Se nano-plates, the pronounced Shubnikov-de Hass oscillations lie in the linear magnetoresistance background. The Se-poor Bi$_2$O$_2$Se nano-plates show a typical 2D conduction feature with a small effective mass of 0.032m$_0$. The average transport Hall mobility, i.e. less than 5500 cm$^2$V$^{-1}$s$^{-1}$, is significantly reduced, compared to the ultrahigh quantum mobility that is as high as 16260 cm$^2$V$^{-1}$s$^{-1}$. The spatial mobility fluctuation leads to the linear magnetoresistance, which are strongly supported by inhomogeneity in the scanning near-field microscopy images and Shubnikov-de Hass oscillation analyses. On the contrary, Se-rich Bi$_2$O$_2$Se samples with the transport mobility less than 300 cm$^2$V$^{-1}$s$^{-1}$ show a smaller linear magnetoresistance ratio, which is controlled by the average mobility. Our finding expands the understanding of this 2D semiconductor and explores its potential magnetoresistive device application.
3:18PM P27.00005: First-principles study of adatom interactions on the $\beta$-Ga$_2$O$_3$(010) surface*  
MENGEN WANG (Presenter), SAI MU, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara — Monoclinic $\beta$-Ga$_2$O$_3$ is a wide-gap (~4.8 eV)$^{1}$ semiconductor with a high breakdown field. This renders Ga$_2$O$_3$ a promising candidate for high-power electronics and deep ultraviolet detectors. However, the growth rate and crystal quality of Ga$_2$O$_3$ thin films are limited by etching of the Ga$_2$O$_3$ surface due to suboxide (Ga$_2$O) formation. It has been reported that the growth rate of Ga$_2$O$_3$ in molecular beam epitaxy can be enhanced by an additional indium supply.$^{2}$ However, the mechanism by which In impacts growth remains elusive. To address this puzzle, we use density functional theory to explore the adsorption and diffusion of Ga and O adatoms on the Ga$_2$O$_3$(010) surface. The low-energy adsorption structures are studied for various Ga coverages. We illustrate the effect of the co-adsorption of In and Ga on the adsorption energetics and the diffusion barriers of O atoms. Our study holds clues to understanding the growth and etching mechanism of the Ga$_2$O$_3$ surface.

*The work was supported by the GAME MURI of the Air Force Office of Scientific Research.

3:30PM P27.00006: Temperature coefficient of resistance (TCR) measurement on vanadium pentoxide (V$_2$O$_5$) nanoparticles*  
GANGA NEUPANE (Presenter), PARAMESWAR HARI, Univ of Tulsa — In this work, we varied molar concentrations (0.05M, 0.1M, 0.15M, and 0.2M) of vanadium pentoxide (V$_2$O$_5$) to synthesize nanoparticles by hydrothermal method. Structural properties were studied using X-ray diffraction spectroscopy (XRD) and Transmission electron microscopy (TEM). XRD and TEM confirmed the increase in particle size with increasing molar concentrations with no secondary phases. Optical properties were studied using Photoluminescence and absorption measurements. Bandgap energy of nanoparticles was found to decrease from 2.25 eV to 2.20 eV with increasing molar concentration. Elemental composition was analyzed by X-ray photoelectron spectroscopy (XPS). The electrical conductivity of nanoparticles was found to increases with increasing molar concentration and also with increasing annealing temperature. The resistivity of nanoparticles (0.05M, 0.1M, 0.15M, and 0.2M) with different temperatures from 293K to 393K was measured. The temperature coefficient of resistance (TCR) value of -2.39%/K and resistivity of 0.1 Ohm-cm for 0.2 M concentration of vanadium pentoxide nanoparticles were obtained. We will discuss the significance of TCR obtained in the microbolometer application.

*NASA EPSCoR  
The University of Tulsa
3:42PM P27.00007: Multiscale Modeling for MOCVD Synthesis and Characterization of Transition Metal Dichalcogenides*  NADIRE NAYIR (Presenter), YUANXI WANG, YUAN XUAN, Pennsylvania State University, KASRA MOMENI, Louisiana Tech University, MERT YIGIT SENGUL, YANZHOU JI, TANUSHREE HOLME CHOU DHURY, DANIELLE REIFSNYDER HICKEY, NASIM ALEM, JOAN M REDWING, VINCENT CRESPI, LONG Q. CHEN, ADRI C.T. VAN DUIN, Pennsylvania State University — MOCVD enables to synthesize high-quality TMD layers from vaporized precursors by providing flexibility in the selection of the precursors and their flow rate. Herein, we develop a multiscale approach as a combination of ReaxFF, continuum fluid dynamics, phase-field (PF) and machine learning (ML) to model the gas-phase kinetic of the MOCVD growth and to connect further the MOCVD control parameters to the morphology, size, and distribution of the synthesized TMD materials. The results of the model that we developed, first, for MOCVD gas-phase kinetic of 2D-WSe2 correlate well with the experimental thickness measurements of 2D-WSe2 and show that the model is capable of simulating the experimentally observed trend [1]. We further extend this model to the combination of ReaxFF, ML, and PF, in progress. A systematic representative data set is generated based on the ReaxFF potential to train an ML-model describing the edge energies and edge-growth rates of 2D-WSe2 flakes as a function of key parameters, then to incorporate them into the PF simulations. The target of this work is to bridge spatial scales that range from 10−9 to 10-3 m in space and explore the optimal growth conditions resulting in high-quality TMD materials.

*NSF DMR-1539916

3:54PM P27.00008: DISTORTED PHASE OF SINGLE LAYER JANUS MoSTe*  MEHMET YAGMURUKARDE S (Presenter), Department of Physics, University of Antwerp, CEM SEVIK, Anadolu University, FRANCOIS M PEETERS, Department of Physics, University of Antwerp — Recently synthesized monolayer of Janus MoSSe structure has attracted great attention on those out-of-plane anisotropic materials. Here, we investigate the electronic, vibrational, elastic, and piezoelectric properties of two dynamically stable crystal phases of monolayer Janus MoSTe, namely 1H-MoSTe and 1T'-MoSTe. The 1H-MoSTe phase is found to be an indirect band-gap semiconductor while 1T'-MoSTe is predicted as small-gap semiconductor. The calculated Raman spectrum of each structure shows unique character enabling us to clearly distinguish the stable crystal phases via Raman measurements. The systematic piezoelectric stress and strain coefficient analysis reveals that out-of-plane piezoelectricity appears in 1H-MoSTe and the noncentral symmetric 1T'-MoSTe has large piezoelectric coefficients. Static total-energy calculations show clearly that the formation of 1T'-MoSTe is feasible by using 1T'-MoTe2 as a basis monolayer. Therefore, we propose that the Janus MoSTe structure can be fabricated in two dynamically stable phases which possess unique electronic, dynamical, and piezoelectric properties.

*Flemish Science Foundation (FWO-VI)
4:06PM P27.00009: Synthesis and properties of hexagonal GaBN/BN heterostructure and quantum wells. 6.3.6* QINGWEN WANG (Presenter), JING LI, JINGYU LIN, HONGXING JIANG, Texas Tech Univ — Hexagonal boron nitride \((h\text{-}BN)\) is the only layer-structured or quasi-2D material with bandgap \(>6.0\) eV among the members of the III-nitride semiconductor family. The unique features of \(h\text{-}BN\) make it highly attractive in novel device applications, which includes high optical emission efficiency, possibility of \(p\)-type conductivity control, promising host for single photon emitter, as well high detection efficiency for thermal neutrons. Like all other compound semiconductors, achieving the ability of bandgap tuning through alloying will further expand the applications of \(h\text{-}BN\). Here, we report the synthesis of \(h\text{-}GaBN\) alloys using metal organic vapor deposition (MOCVD) growth. By utilizing \(h\text{-}BN\) epilayers as templates, we have successfully achieved \(h\text{-}GaBN\) alloys and \(h\text{-}GaBN/BN\) quantum wells with Ga-content up to 7%. The effects of phase separation and critical thickness have been investigated in detail and will be reported. The present study provides insights into possible ways to synthesize layered GaBN and would open up many new applications.

*This work is supported by ARO (W911NF-16-1-0268) and monitored by Dr. Michael Gerhold. Jiang and Lin are grateful to the AT&T Foundation for the support of Ed Whitacre and Linda Whitacre endowed chairs.

4:18PM P27.00010: Temperature influence in the electrical conductivity of graphite oxide platelets* DIEGO SANCHEZ (Presenter), JOHN PRIAS, HERNANDO ARIZA, Optoelectronics, Universidad del Quindío — Graphite oxide platelets from bamboo pyrolygenous acid (GO-BPA) synthesized by using the double thermal decomposition (DTD) method at 973 K as carbonization temperature, exhibit temperature influence in the electrical conductivity like a semiconductor material. Samples were characterized by using Raman, FTIR, XRD, XPS, HR-TEM and I-V curves (two and four-points at temperatures of 20 to 300 K) techniques. Electrical measurements suggest that increased temperature increases electrical conductivity like a semiconductor material. Conduction mechanism was described mainly by 3D-variable range hopping.

*We would like to thank the Interdisciplinary Institute of Sciences, the Doctorate program in Physical Sciences at Universidad del Quindío for the financial support.
4:30PM P27.00011: Thermal Expansion and Residual Strain in AlN Thin Film Sensor Materials  
ROBERT LAD (Presenter), MORTON G GREENSLIT, DAVID T PLOUFF, MAURICIO PEREIRA DA CUNHA, Univ of Maine — Aluminum nitride films are attractive materials for high temperature sensor devices because of their stable piezoelectric and semiconducting properties up to 800°C in air, above which the films degrade by oxidation. In this work, epitaxial AlN (002) films were grown at 930°C on c-cut sapphire substrates by N₂-plasma-assisted Al evaporation and were characterized up to 1000°C in air using an X-ray diffraction (XRD) sample hot stage. The coefficient of thermal expansion (CTE) and homogeneous strain were determined from accurate measurements of the c-axis lattice parameter for AlN and sapphire vs. thermal processing up to 800°C, and film oxidation was evaluated above 800°C from the relative decrease in the AlN (002) XRD intensity and degradation of the (002) pole figure. AlN films grown to 200nm thickness have c-axis compressive strain, but this residual strain can be relieved by thermal cycling between 25-700°C. The CTE value of 2.5x10⁻⁶/°C for the as-deposited films decreased as the film strain was released and is below the value of 5.3x10⁻⁶/°C reported for bulk AlN. Understanding the level of residual film strain and thermal expansion matching across the relevant interfaces is key for preventing delamination, cracking, and failure of sensor packaging or sensor function itself.

4:42PM P27.00012: Effects of growth parameters on faceting and defects in confined epitaxial lateral overgrowth*  
ARANYA GOSWAMI (Presenter), SIMONE TOMMASO ŠURAN BRUNELLI, BRIAN MARKMAN, Electrical and Computer Engineering Department, University of California, Santa Barbara, DAN J PENNACHIO, Materials Department, University of California, Santa Barbara, HSINYING TSENG, SUKGEUN CHOI, Electrical and Computer Engineering Department, University of California, Santa Barbara, AIDAN TAYLOR, Materials Department, University of California, Santa Barbara, JONATHAN KLAMKIN, MARK RODWELL, CHRIS J PALMSTROM, Electrical and Computer Engineering Department, University of California, Santa Barbara — Laterally grown III-V epitaxial semiconductor layers offer multiple advantages over conventional vertically-grown layers for fabricating novel semiconductor devices and III-V on Si integration for photonics. In confined epitaxial lateral overgrowth (CELO), pre-fabricated dielectric templates are used to control the growth and its direction. Such grown nano-structures however, often suffer from high densities of stacking faults and rotational twins, which limit the performance of the devices made using these materials. Here, we use scanning electron microscopy (SEM), transmission electron microscopy (TEM) and electron channeling contrast imaging (ECCI) to characterize these nano-structures grown by metal organic chemical vapor deposition (MOCVD) on patterned InP substrates. Using a combination of plan-view and cross-sectional TEM on the same nano-structure, we explore the influence of growth conditions (growth temperature and V/III ratio), template direction and substrate orientations on the evolution of facets and the nature of defects. We further show growth and characteristics of heterostructures and superlattice structures grown using CELO, as well as electrical measurements of these nanostructures.

4:54PM P27.00013: Controlled Fractal Growth of Transition Metal Dichalcogenides* PEIJIAN WANG (Presenter), HAO ZENG, Physics, State Univ of NY - Buffalo, SHAOMING HUANG, School of Materials and Energy, Guangdong University of Technology — We report controlled fractal growth of atomically thin transition metal dichalcogenides (TMDCs) by chemical vapor deposition, with morphological evolution from dendritic to triangular. Based on experimental observations, we tuned several important growth parameters, including the relaxation rate, adhesion coefficient, diffusion anisotropy and growth time to fabricate TMDCs with controllable fractal dimensions. Furthermore, a model based on the steps of nucleation, diffusion limited aggregation, and relaxation, was proposed to explain the morphological evolution. The computational simulation based on this model yielded good agreements with the experiments results. Our study sheds light on the growth mechanism of TMDs, which is fundamental to improving controllability of growth.

5:06PM P27.00014: Properties of SPEED Grown FTO Thin Films Deposited at Various Solution Concentrations and Ageing time* GBADEBO TAOFEEK YUSUF (Presenter), Science Laboratory Technology, Osun State Polytechnic — There have been various reports on the scarcity of indium element which is one of the constituents of indium tin oxide (ITO). Alternative TCO material is therefore necessary before the supply eventually runs out. This research therefore focused on fluorine-doped tin oxide thin films (FTO) as a possible alternative to the ITO. FTO thin films were grown using the Streaming Process for Electrodeless Electrochemical Deposition (SPEED) technique. The structural and optical properties of the films were determined at various fluorine to tin (F: Sn) concentrations and aging time. The results, as revealed by SEM and XRD analysis show that the properties of FTO films improve as the solution concentration and aging time were jointly increased to 0.85 and 12 hours. All FTO thin films except those deposited at solution concentration (F: Sn) of 0.55 and 4 hours aging time show optical transmission above 80 % in the Visible-UV region. This study has shown that the SPEED technique is a promising technique for depositing high-quality FTO thin films for solar photovoltaic applications.

**Session P28 FIAP: Fellows of FIAP** 405-407 - Michael Gordon, IBM Thomas J. Watson Research Center - Tag(s): Industry, Invited, Undergrad Friendly

2:30PM P28.00001: Semiconductor and Nanostructured Materials and Devices [Invited] NAZIR P KHERANI (Presenter), University of Toronto — TBD
3:06PM P28.00002: The Taming of the Superconducting Qubit: A Tale of Loss [Invited]  CONAL MURRAY (Presenter), IBM T.J. Watson Research Center — The potential of quantum computing to enable new ways of solving problems considered intractable on classical computing platforms relies on our understanding of how qubits operate. Qubit scaling follows different metrics than those associated with classical computing, driven by the requirement that the fragile states they possess can be retained for sufficiently long times. After a brief introduction into superconducting transmon qubits, I will discuss how dielectric loss impacts their relaxation times and how we can effectively model such behavior using analytical and computational approaches. The resulting analysis provides guidance into the design aspects associated with such qubits. A secondary issue that follows from manufacturing greater numbers of qubits involves unwanted communication among them. In particular, resonance modes generated in the substrate on which they reside can limit their operating frequencies. It is known that incorporating grounded, through-silicon vias can increase the corresponding cutoff frequency within the substrate. I will show how we can predict the resulting spectrum by considering the array of vias as an effective photonic crystal to arrive at a fundamental frequency dependent on the particulars of the via geometry.

3:42PM P28.00003: Addtive Manufacturing of Magnetic Materials for Clean Energy Applications* [Invited]  MARIAPPAN PARANTHAMAN (Presenter), Oak Ridge National Lab — The main goal of this research is to develop a process to print near-net shape NdFeB polymer bonded magnets and to minimize the cost associated with manufacturing. One of the ways in which we can achieve this goal is by using an additive manufacturing technique to create complex shapes and geometries of polymer bonded magnets from a computer aided design which requires no tooling but little post-field-annealing and reducing the amount of waste generated. We have successfully demonstrated the fabrication of near-net shape magnets with complex geometries and high energy product using over 70vol% of NdFeB in nylon polymer composite magnets. A higher energy product of over 18 MGOe have been achieved. We will discuss in detail about thow materials chemistry aspects are used to improve the mechanical, magnetic and thermal stability of printed magnets.

Session P29 DSOFT DBIO GSNP DPOLY: Active Matter and Liquid Crystals in Biological Systems I  501 - Zvonimir Dogic, University of California, Santa Barbara -

Tag(s): Focus
2:30PM P29.00001: Dipolar Extensile Dynamics in Microtubule-Based 2D Active Nematics
LINNEA LEMMA (Presenter), Physics Department, Brandeis University, ZVONIMIR DOGIC, Physics Department, University of California Santa Barbara — Theories describe 2D active nematics in terms of liquid crystals, hydrodynamics and chaotic fluids. However, the experimental system is inherently hierarchical and connecting the microscopic forces to the macroscopic flows remains an open challenge. Using an \textit{in vitro} 2D active nematic composed of microtubules and kinesin motors, we probe the microscopic dynamics under varying active stresses. We find that locally, flows are dipolar extensile whose strain rate can be tuned by ATP concentration. Additionally, we uncover a velocity distribution of microtubules along the director which indicates the importance of many body interactions in bridging the length scales of the system.

2:42PM P29.00002: Design of active nematic systems with controllable defect dynamics and flows [Invited] RUI ZHANG (Presenter), ALI MOZAFFARI, JUAN DE PABLO, University of Chicago — Active matter encompasses a wide spectrum of non-equilibrium condensed matter systems, the constituents of which convert energy into mechanical work. They exhibit intriguing collective behaviors, such as flocking and activity-induced phase transitions. In the particular case of anisotropic particles or molecules, these materials can enter an active nematic state, which displays intricate motions of topological defects, characteristic of nematic liquid crystals, accompanied by chaotic-like flows. Active nematics are encountered in numerous biological systems, ranging from cytoskeletal polymer extracts, to tissue cells and dense bacterial suspensions. The dynamics of active nematics are not fully understood, and efforts to control and manipulate the structure and flow of this class of materials have been limited. In this talk, I will summarize our recent progress in active nematics research, with an emphasis on the interplay between molecular interactions, elasticity, and hydrodynamic forces. In particular, I will discuss an experimentally realizable approach, which relies on spatiotemporal patterning of activity, to manipulate defects and flows in active nematics. I will show how simulations can be harnessed to guide design of well-controlled dynamics, paving the way towards engineering active matter for practical applications.
3:18PM P29.00003: Control of bacterial dynamics by splay and bend in nematic vortices*
RUNA KOIZUMI (Presenter), TARAS TURIV, Kent State Univ - Kent, MIKHAIL GENKIN, Cold Spring Harbor Laboratory, ROBERT LASTOWSKI, HAO YU, Kent State Univ - Kent, IRAKLI CHAGANAVA, Georgian State Teaching University of Physical Education and Sport, QIHUO WEI, Kent State Univ - Kent, IGOR ARONSON, Pennsylvania State University, OLEG D LAVRENTOVICH, Kent State Univ - Kent — Microswimmers exhibit collective behavior that can be controlled by an anisotropic environment such as a lyotropic chromonic liquid crystal. We explore the effect of splay and bend of the director field on the individual and collective behavior of motile *Bacilli subtilis*. The director field, imposed through photoalignment, is designed in the form of vortices of topological charge +1. Their geometry changes from pure radial to spiral and to the circular, representing thus deformations of a pure splay, splay-bend mix, and pure bend, respectively. In dilute dispersions, the bacteria follow the pre-imposed director field, but after their concentration reaches some threshold, they engage in a collective unipolar circulation. This collective behavior is controlled by the splay-to-bend ratio: vortices with dominating splay condense the bacterial swarms towards the center, while vortices with dominating bend push them away to the periphery. Vortices with splay-bend parity formed by 45-degree spiraling director produce the most stable swarming with a time-independent radius as long as the bacterial activity is constant. The change in swimming scenario as a function of splay-to-bend ratio is reminiscent of an unstable limit cycle.

*The work is supported by NSF DMS-1729509.

3:30PM P29.00004: Spatiotemporal Optimal Control of an Extensile Active Nematic Suspension*  
MICHAEL M NORTON (Presenter), Center for Neural Engineering, Pennsylvania State University, PIYUSH GROVER, Mechanical Engineering, University of Nebraska-Lincoln, APARNA BASKARAN, MICHAEL HAGAN, SETH FRADEN, Physics, Brandeis University — Active nematic suspensions are self-driven fluids that exhibit rich spatiotemporal dynamics characterized by director field buckling, defect nucleation/annihilation and chaotic trajectories of those defects. Towards developing experimental methods for controlling these dynamics, we consider an optimal control problem which seeks to find the spatiotemporal pattern of active stress strength required to drive the system towards a desired director field configuration. As an exemplar, we consider an extensile active nematic fluid confined to a disk. In the absence of control, the system produces two topological defects that perpetually circulate. Optimal control identifies a time-varying active stress field that drives the defects to orbit in the opposite direction.

*We acknowledge support from NSF MRSEC, Bioinspired Soft Materials, DMR-1420382
3:42PM P29.00005: Self propelling nematic microcapsules*  
CORINNA MAASS (Presenter), BABAK VAJDI HOKMABAD, Max Planck Institute for Dynamics and Self-Organization, KYLE A BALDWIN, SOFT Group, School of Science and Technology, Nottingham Trent University, CHRISTIAN BAHR, Max Planck Institute for Dynamics and Self-Organization — The ability to produce controllable, self propelling microcapsules is of great interest to synthetic biology and the design of smart microreactors. Inactive fluid shells are already widely used as artificial cell models, micro-reactors, and in food and drug applications. However, combining activity, stability, and control remains a significant challenge. Building on an established active emulsion platform, we have developed a new approach to the problem of encapsulation by using nematic active double emulsions, where a solubilization mechanism induces activity and the molecular nematicity provides stability. We show that using a nematic liquid crystal as the shell material with homeotropic anchoring at both interfaces will result in a nematoelastic force on a displaced core droplet and act as a topological barrier against the coalescence of the core droplet with the outer phase. We further present a peculiar self-propulsion mode where the interplay of spontaneous symmetry breaking and autochemotaxis results in a "shark-fin meandering" motion of the shell in a 2D-confined geometry and helical swimming in 3D. This behavior can be controlled or switched off by introducing chemical gradients, topographical guidance or by changing the shell topology.

3:54PM P29.00006: The Dynamics of Active Nematic Defects on The Sphere Surface*  
YIHENG ZHANG (Presenter), Beijing Normal Univ, MARKUS DESERNO, Carnegie Mellon Univ, ZHANCHUN TU, Beijing Normal Univ — A nematic liquid crystal confined to the surface of a sphere exhibits topological defects of total charge +2 due to the topological constraint. In equilibrium, the nematic field forms four +1/2 defects, located at the corners of a tetrahedron inscribed within the sphere, since this minimizes the Frank elastic energy. Here we study the active counterpart of such a system, in which a self-driven directional motion of the individual nematogens creates a large-scale flow that drives the system out of equilibrium. In this new state, defects exhibit complex dynamics which, depending on the strength of the active forcing, can be simple and periodic (for weak forcing) or chaotic (for strong forcing). We show that Onsager's variational principle offers an exceptionally transparent way to derive the exact dynamical equations of the defects in such an active spherical nematic, and we explain its mobility at the hydrodynamics level.

*We thank for the financial support from the National Natural Science Foundation of China (Grant No. 11675017).
4:06PM P29.00007: Emergent dynamics of large scale collective rotations in 2D active nematic  DAVID QUINT (Presenter), Department of Physics, University of California, Merced, DALI E CHAPMAN, Department of Molecular and Cellular Physiology, Stanford University, STEVEN P. GROSS, Department of Developmental and Cell Biology, University of California, Irvine, DANIEL BELLER, AJAY GOPINATHAN, JING XU, Department of Physics, University of California, Merced — Motivated by recent work on active nematics we employ here a microtubule and kinesin motor gliding assay system to examine dynamic collective order in 2D. Without the need for a depletion agent, our system exhibits the classic nematic order transition that depends on microtubule and active motor density. However in the regime of very flexible microtubules nematic order is lost, suggesting that this ordering is a consequence of both microtubule stiffness and density. We demonstrate that the ordered state exhibits large scale coherent rotations and that the introduction of a time varying director is necessary for proper characterization of the active nematic system. We show that the rate of this collective rotation of the nematic order is strongly dependent on activity induced microtubule fluctuations.

4:18PM P29.00008: Defect dynamics of 3D active nematic turbulence  ZIGA KOS (Presenter), Faculty of Mathematics and Physics, University of Ljubljana, JACK BINYSH, University of Warwick, SIMON COPAR, JURE APLINC, SLOBODAN ZUMER, Faculty of Mathematics and Physics, University of Ljubljana, GARETH ALEXANDER, University of Warwick, MIHA RAVNIK, Faculty of Mathematics and Physics, University of Ljubljana — Three-dimensional active nematics are exciting new materials characterized by a network of continuously evolving defect lines and loops [1]. We report on detailed numerical investigation of confined 3D active nematics [2]. At sufficient activity, such system transitions into active turbulence with irregular dynamics of multiple defect loops with distinct topological events of loop crossover, annihilation, splitting and merging occurring in time. The dynamics of a single active defect loop depends on the local crosssection of the director profile that can span from +1/2 or -1/2 winding numbers to twist profiles. Depending on the loop orientational profile, we observe spontaneous shrinking, growing, and bending of a single zero-charge loop [3]. Our work aims to provide insight into 3D active turbulence from the perspective of the topology of the emergent 3D defects and their self-induced dynamics.

Topological Defects in Cell Monolayers Guided by Topography

Kirsten EndreSEN (Presenter), Minsu Kim, Francesca Serra, Johns Hopkins University — Many types of cells display long-range alignment like nematic liquid crystals (LCs), and have topological defects. These defects are characterized by their topological charge, the number of rotations of the alignment around the defect. In 2D cell culturing, only +/- 1/2 defects are typically observed, although other defects exist in living systems. Topological defects in cell layers have been associated with increase in cell apoptosis [1] and clustering [2]. We induce alignment of cells via contact guidance into formations that impose arbitrary topological charges. We survey multiple cell types (EpH-4 and 3T6) to characterize their alignment, density, and dynamics near defects of various topological charges, and define LC parameters such as defect core sizes and elastic constants. We observe a large change in density of fibroblasts (3T6) near the topological defects, where our tunable confinement allows us to identify the isotropic defect cores.

This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. DGE-1746891.

Clustering, jamming, and topological defects in growing bacterial colonies at liquid interfaces

Blake Langeslay (Presenter), Gabriel Juarez, University of Illinois at Urbana-Champaign — Active nematic matter encompasses a broad variety of systems including confined vibrating rods, flocks of birds, and colonies of bacteria. Here, we present experimental results on growing colonies of rod-shaped bacteria confined in two dimensions by adsorption at an oil-water interface. Using microfluidics and time-lapse microscopy, we investigate the roles of motility and growth on cluster formation, topological defects, and jamming. As colonies grow on finite liquid interfaces, we observe cluster formation where regions of tightly packed bacteria that display notably low swimming velocities increase in number and size over time. As the surface coverage increases, a densely packed monolayer of bacteria with long-range orientation order is observed and topological defects are quantified. This setup functions as a useful model system for low-friction confinement of a growing active nematic comprised of discrete particles as well as carrying important implications for the study of biofilm formation at liquid interfaces.

Topological defects drive layer formation in bacteria colonies

Katherine Copenhagen (Presenter), Ricard Alert, Ned Wingreen, Joshua Shaevitz, Princeton University — The starvation-induced development of macroscopic fruiting bodies in Myxococcus xanthus begins with the formation of layered cell structures. Cells in these layers are densely packed, aligned via their rod shape, and retain their motility so that the population forms an active nematic liquid crystal. We investigate the origin of layering by looking at the formation of second layers and holes from cellular monolayers. These events occur at discontinuities in the cell direction field known as topological defects. Layers form at positive defects while holes open at negative defects. By measuring cell flows, we find an influx of cells towards positive defects and an outflux away from negative defects. We find that a model of monolayers as an active, dry extensible nematic with anisotropic friction can reproduce the measured flow fields and change in cell density at defects. Overall, we conclude that the conversion from a 2D cell layer to a 3D droplet is triggered by the formation of layers of cells at topological defects.
Pulsating air bubbles can swim in anisotropic fluids*  
SUNG-JO KIM (Presenter), EUJIN UM, JOONWOO JEONG, Ulsan National Institute of Science and Technology — Small-scale locomotion in fluids has been of great interest, from microorganisms to active matter and spermbots. Here we explore the swimming of a spherical bubble with a periodic change in its radius. Its spatial symmetry and the scallop theorem [1] tell us that the bubble with the reciprocal motion cannot achieve propulsion. In anisotropic fluids, however, the bubbles can swim. The spherical bubble dispersed in homogeneously aligned nematic liquid crystals (LCs) accompanies either a hyperbolic point defect or a disclination ring called a Saturn-ring. The pulsating bubble generates LC flow of which spatial and time-reversal symmetry are broken because of LC’s director configuration and viscoelastic response, respectively. The bubble with the point defect exhibits the net propulsion, while the swimming of the other one depends on the shape of the ring defect. We also introduce our theoretical understanding of this propulsion mechanism, with ideas to maximize swimming efficiency.

Session P30 DSOFT DPOLY: Soft Mechanics via Geometry III 502 - Michael Czajkowski, Georgia Inst of Tech
2:30PM P30.00001: Geometrically-frustrated wrinkle patterns 1: Defects and mesoscale structure*  
JOSEPH PAULSEN (Presenter), Physics, Syracuse University, OLEH TOVKACH, Physics,  
University of Massachusetts, Amherst, MONICA RIPP, Physics, Syracuse University, JUNBO CHEN, TENG  
ZHANG, Mechanical & Aerospace Engineering, Syracuse University, BENJAMIN DAVIDOVITCH, Physics,  
University of Massachusetts, Amherst — Thin films readily buckle to relax compression, creating  
wrinkle patterns that can have considerable morphological complexity. Some of this complexity  
stems from a basic geometric conflict, arising when wrinkles that would otherwise prefer a fixed  
wavelength are formed in geometries where the lines of tension are splayed, for example when  
wrinkles emanate radially from a point. We study such frustrated states within an annular region  
of an elastic sheet subjected to unequal tensions at its inner and outer boundaries. Using  
experiments and simulations, we demonstrate two distinct solutions: (i) states with  
approximately constant wavelength, enabled by “defects” in the wrinkle pattern where new  
wrinkles begin, and (ii) “defect-free” states consisting of a fixed number of wrinkles of non-  
constant wavelength. We show how these two morphological types reflect distinct minima of a  
suitable coarse-grained elastic energy. We further predict a mesoscopic lengthscale for patches  
of nearly-parallel wrinkles separated by defect-rich regions, in agreement with our observations.  
This work unravels an organizing principle with analogs in liquid crystalline and superconducting  
states of matter. (This is part 1 in a 3-talk series).

*Support from NSF-DMR and NSF-CMMI is gratefully acknowledged.

2:42PM P30.00002: Geometrically-frustrated wrinkle patterns 2: cascades versus defects*  
MENG XIN (Presenter), Univ of Mass - Amherst, DOIREANN O'KIELY, University of Oxford, BENJAMIN  
DAVIDOVITCH, Univ of Mass - Amherst, DOMINIC VELLA, University of Oxford — Cascades and  
localized defects are characteristic motifs of wrinkle patterns in  
elastic sheets, appearing when a array of uniformly-spaced wrinkled is incom-  
patible with a confining topography, boundary conditions, or gradients in the  
sheet's thickness or the stiffness of a supporting substrate. Inspired by a recent  
experimental study (J. Schleifer et al. Soft Matter 15 1405 (2019)), we employ  
numerical simulations to study the wrinkle patterns in a uniaxially-compressed  
sheet, floating on a liquid bath whose density in non-uniform, implying a gra-  
dient in the locally-favored value of the wrinkle wavelength in the direction  
orthogonal to the axis of compression. This simple model enables a systematic  
study of the basic mechanisms through which the wrinkle density and wave-  
length vary in space. Exploring the parameter regimes that correspond to weak  
and strong gradient of the liquid density, we show that the meso-scale features  
of the pattern may be determined by distinct physical mechanisms that involve  
cascade-like structures and localized defects

*NSF DMR 1822439
**2:54PM P30.00003: Geometrically-frustrated wrinkle patterns**

Experimental realisation of defect patterns

LUCIE DOMINO (Presenter), DOIREANN O'KIELY, DOMINIC VELLA, University of Oxford — In the previous talks, the role of geometry in forcing the creation of defects in wrinkle patterns has been discussed. Here, we present a series of experimental systems that exhibit different mechanisms for introducing new wrinkles, including smooth cascades and localised defects. We discuss the influence of the underlying preferred wrinkle pattern on which of these mechanisms is observed in reality. (This is part 3 in a 3-talk series).

*This research has received funding from the European Research Council under the European Union's Horizon2020 Programme

**3:06PM P30.00004: Curvature in Compressed Thin Cylindrical Shells Approaching the Isometric Limit**

NICOLE E VOCE (Presenter), CASSIDY ANDERSON, Physics and Astronomy, James Madison University, MARCELO DIAS, Engineering - Mechanical Metamaterials and Soft Matter, Aarhus University, KLEBERT FEITOSA, Physics and Astronomy, James Madison University — We study the buckling of a thin cylindrical shell constrained to slide onto an inner non-deformable pipe. Our goal is to characterize the relationship between the shell thickness and the localization of stresses by using curvature measurements. First, we induce surface buckling by immobilizing one end of the shell and applying force to the other end. Then, we obtain a virtual reconstruction of the surface from 3D optical scanning and compute the Gaussian curvature for every point on the mesh. We find that as the shell gets thinner, the distribution of Gaussian curvatures becomes broader. However, surprisingly, the mean of the Gaussian curvature distribution increases. Furthermore, measurements of areas enclosed by the parabolic lines around protruding vertices from the buckled surface show that the transitions between regions of positive and negative Gaussian curvature are more localized. Finally, the Gaussian curvature reveals the formation of substructures within the lobes around the vertices. These results demonstrate that the evolution of the cylindrical shell towards the isometric limit represented by the well-known Yoshimura pattern is non-trivial.

**3:18PM P30.00005: Topological Floppy Modes in Epithelial Tissue Network**

HAROLD LIU (Presenter), Univ of Michigan - Ann Arbor, DI ZHOU, Georgia Inst of Tech, LEYOU ZHANG, DAVID LUBENSKY, XIAOMING MAO, Univ of Michigan - Ann Arbor — The ordering, structure formation, and mechanical response in epithelial cells are essential to the functioning of many tissues. In this talk, we explore topological mechanics in a simple epithelial cell sheet described by a vertex model. We find that floppy modes in this model can become polarized based on the geometry of the cells, and domain boundaries with localized floppy modes can be observed. This simple model indicates a possible role for epithelial cell structure in directing mechanical responses. This topological mechanical polarization may be related to the mechanism of formation of Planar Cell Polarization (PCP), an intriguing phenomenon often seen in animal development, which is a polarization of a field of cells within the plane of a cell sheet to obtain directional information that is essential for diverse cellular processes.
3:30PM P30.00006: Twisting, buckling, and tension in elastic helices with multiple perversions* ADAM FORTAIS (Presenter), KARI DALNOKI-VERESS, McMaster Univ — A telephone cord and the coils of cucumber tendrils; these are two examples of elastic beam-like systems that take on the shape of soft, helical springs. By unwinding such a spring and holding its ends fixed, an elastic instability forms, causing the spring to form both chiralities of the helix, meeting at defects called perversions. We investigate this phenomenon in an idealized experiment using highly uniform, microscopic, elastic fibers with cylindrical cross-sections. We measure the force of extension as a function of geometry, material properties, and twist. Previous work has shown that multiple perversions may form as a result of a spring's prismatic cross-section. Here we observe that, surprisingly, multiple perversions still form, despite the uniform cylindrical cross-section of our fibers.

3:42PM P30.00007: Simulations of buckling and crumpling in twisted ribbons* MADELYN LEEMBRUGGEN (Presenter), Physics, Harvard University, JOVANA ANDREJEVIC, School of Engineering and Applied Sciences, Harvard University, ARSHAD KUDROLLI, Physics, Clark University, CHRISTOPHER RYCROFT, School of Engineering and Applied Sciences, Harvard University — A twisted ribbon exhibits at least five deformation phases, with transitions facilitated by tuning the tension applied or twist angle. When driven from one of these self-avoiding phases into a disordered regime of self-contact, the ribbon develops ridges as it folds or crumples. Here, we develop a computational model of this complex, dynamic process, which reproduces the transitions seen in experimental tests. Our simulations illuminate the details of folding and crumpling transitions induced via twisting; allow careful analysis of the ribbon's topography and curvature; and potentially reveal a state variable by which the disordered system may be quantified.

*We acknowledge support from the National Science Foundation under Grant No. DMR-1420570.
3:54PM P30.00008: Statistical mechanics of 2D sheets under uniaxial tension*  MOHAMED EL HEDI BAHRI (Presenter), ANDREJ KOSMRLJ, Princeton University — Atomically thin sheets, such as graphene, are widely used in nanotechnology. Recently they have also been used in applications including kirigami and self-folding origami, where it becomes important to understand how they respond to external loads. Motivated by this, we investigate how isotropic sheets respond to uniaxial tension by employing the renormalization group. Previously, it was shown that for freely suspended sheets thermal fluctuations effectively renormalize elastic constants beyond a characteristic thermal length scale (a few nanometers for graphene at room temperature), beyond which the bending rigidity increases, while the in-plane elastic constants reduce with universal power law exponents. Under uniaxial tension, we find that the bending rigidity along the axis of tension diverges with a different power law exponent beyond a stress-dependent length scale whereas the Young's modulus in the orthogonal direction renormalizes to zero. As a consequence, for moderate tensions we find a universal nonlinear force-displacement relation and the universal Poisson's ratio. For large tensions, in-plane fluctuations longitudinal with the axis of tension are suppressed and classical mechanics along this axis is recovered.

* Work was supported by the NSF Career award DMR-1752100

4:06PM P30.00009: Isigami: sheet reconfiguration driven by cone interactions*  BENJAMIN KATZ (Presenter), VINCENT CRESPI, Pennsylvania State University — A novel class of surfaces holds the possibility of reversible reconfiguration into a large family of distinct, stable shapes. This property stems in part from their topological defects—they have equal numbers of cones and saddles. Exploring these surfaces with an example constructed out of a graphene monolayer with the defects arranged in a kagome-like superlattice, we model its mechanical response with semiclassical molecular dynamics. The cones possess a two-fold degree of freedom in their up/down orientation, yielding a reconfigurable surface with a large number of metastable shapes. Enumerating a complete 'zoo' of such shapes for a small patch of this material reveals that not only are the interactions between these degrees of mechanical freedom long-range enough to produce a gaussian-like 'density of states' for given cone orientations, but also that the surface possesses other hidden degrees of freedom in certain orientations—further increasing the number of stable shapes it can hold. These shapes cover a broad range of physical forms and a scale comparable to important biomolecules, raising the possibility of biological applications.

*Research performed under a training fellowship for CoMET, an NRT at Penn State funded by NSF.
4:18PM P30.00010: Indentation of ellipsoidal and cylindrical shells: new insights from shallow-shell theory  WENQIAN SUN (Presenter), JAYSON PAULOSE, Univ of Oregon — Pressurized elastic shells are ubiquitous in nature, from pollen grains to the outer walls of yeast and bacterial cells. Indentation measurements provide a means of simultaneously probing the internal pressure and elastic properties of thin shells, which in turn can be relevant to understanding cellular function. We study the effects of geometry and pressure-induced stress on the indentation stiffness of ellipsoidal and cylindrical elastic shells using shallow shell theory. The key advance in our work lies in reducing the linear indentation response to a single integral with two dimensionless parameters which encode the asphericity and internal pressure. This integral can be numerically evaluated in all regimes, and is used to generate analytical expressions in various limits. Our results provide theoretical support for previous scaling and numerical results on the stiffness of ellipsoids, and give new insights to the linear indentation response of pressurized cylinders.

4:30PM P30.00011: Statistical mechanics of dislocation pileups  GRACE ZHANG (Presenter), DAVID R. NELSON, Harvard University — Dislocations experiencing applied stress in two dimensions can order when trapped in a single glide plane with aligned Burgers vectors. These dislocation queues, called dislocation pileups, are critical in the initiation and propagation of deformations in materials. We study the static and dynamical properties of this class of defect ordering, where the dislocations themselves form inhomogeneous quasilattices in one dimension, with spatially varying lattice spacings whose spatial profile depends on the form of the applied stress. We study these dislocation pileup lattices using an intriguing connection with recent generalizations of random matrix ensembles, and examine the crystallization of these dislocations at low temperatures. We use random matrix theory to probe the equilibrium statistical mechanics, which allows us to extract the spatial correlation functions and structure factors of two distinct types of dislocation pileups, those in uniform stress fields and those in stress fields linear in space. Our formalism provides an analytical formulation for these correlations generalizable to other inhomogeneous crystals in one dimension. Finally, we analyze the low temperature excitation spectrum of these dislocation pileups and the spatial properties of their excitation modes.
4:42PM P30.00012: Statistical ensemble inequivalence for flexible polymers under confinement in various geometries* PANAYOTIS BENETATOS (Presenter), Department of Physics, Kyungpook National University, Rep. of Korea, SANDIPAN DUTTA, Center for Soft and Living Matter, Institute for Basic Science, Rep. of Korea — The problem of statistical ensemble inequivalence for single polymers has been the subject of intense research. In a recent publication, we show that even though the force-extension relation of a free Gaussian chain exhibits ensemble equivalence, confinement to half-space due to tethering to a planar substrate induces significant inequivalence [S. Dutta and P. Benetatos, Soft Matter, 2018, 14, 6857-6866]. In this talk, we extend that work to the conformational response to confining forces distributed over surfaces. We analyze in both the Helmholtz and the Gibbs ensemble the pressure-volume equation of state of a chain with free ends in rectangular, spherical, and cylindrical confinement. We especially consider the case of a directed polymer in a cylinder. We also analyze the case of a tethered chain in various geometries. In general, confinement causes significant ensemble inequivalence. Remarkably, we recover ensemble equivalence at the limit of squashing confinement. Our work may be useful to the interpretation of single molecule experiments and caging phenomena.

4:54PM P30.00013: Soft actively contractile cylinders and spheres* MICHELE CURATOLO, PAOLA NARDINOCCHI, Structural Engineering and Geotechnics, Sapienza, University of Rome, Italy, LUCIANO TERESI (Presenter), Mathematics and Physics, University Roma Tre, Italy — In the last years, contractile gels have been the subject of intense research activity. Active gel microtubules have been produced to investigate how the dynamics of diffusion can be enhanced when gel activity is driven by molecular motors (Phil.Trans.R.Soc. A 372, 2014). Likewise, buckling shapes of thin sheets made of active polymers have been presented and discussed (Nature Communications 9, 2018). On a different side, microfluidic applications based on polymer microtubules have been investigated (Lab on a Chip 18, 2018).

In all those examples, active contraction of the gels as well as solvent release and flows contribute to the dynamics of the active gel structures and determine the smoothly or suddenly change of the original geometric shapes. Our mathematical model can describe some of the key features of these dynamics. We view active contraction as a change in the material metric of the structures, and describe it within a theory of stress-diffusion with remodeling of the polymeric network. The results of the model will be compared and contrasted with the observations of actual experiments on microtubules and microspheres.

Non trivial deformation structures in confined elastic membrane under stretching

DEBANKUR DAS (Presenter), TIFR Centre for Interdisciplinary Sciences, JÜRGEN HORBACH, Institut für Theoretische Physik II, Heinrich-Heine-Universität Düsseldorf, SURAJIT SENGUPTA, TIFR Centre for Interdisciplinary Sciences, TANUSRI SAHA-DASGUPTA, S.N. Bose National Centre, Kolkata — Two dimensional elastic networks when stretched, deform plastically by producing pleats; system spanning linear structures with width comparable to lattice spacing, where the network overlaps on itself. When a similar elastic membrane is confined within rigid walls and allowed to have out of plane fluctuations, similar unconventional deformation modes appear upon stretching. Within these structures, which we call ripplocations, the height field becomes multivalued. These distinct structures are separated by large free energy barriers from a phase with only smooth ripples, that are always present at non-zero temperatures. To understand these structures and their interrelation, we introduce an external field that couples to local non-affine fluctuations measured from the flat reference. Using sequential umbrella sampling Monte Carlo involving sophisticated, non Boltzmann sampling, we obtain conditions under which ripplocations are formed. We obtain a finite temperature phase diagram in the strain-field plane. We also describe experimental signatures such as typical stress strain curves for membranes by which transitions from rippled to ripplocated membranes may be probed.

Mechanical response of wrinkled structures

SIJIE TONG (Presenter), ANDREJ KOSMRLJ, Princeton University — Wrinkling instability of compressed stiff thin films bound to soft substrates has been studied for many years and the formation and evolution of wrinkles is well understood. Recently, the wrinkling instability has been exploited to create structures with tunable drag, wetting and adhesion. While these studies successfully demonstrated the proofs of concepts, the quantitative understanding is still lacking, because we don't know how wrinkled surfaces deform in response to interactions with environment. To address this issue, we systematically study how wrinkled structures respond to infinitesimal surface forces both in the vertical and horizontal directions. We find that the linear response diverges near the onset of wrinkling instability and then decays away from this critical threshold. The mechanical response near the critical threshold is dominated by the characteristic mode of wrinkles. In analogy with the critical phenomena in ferromagnets, we can introduce the critical exponents for the response of the characteristic mode of wrinkles, which are consistent with the Landau theory. Our theory can be further used to study the response of wrinkled structures to more complicated distributions of external forces and can thus provide insights for the above-mentioned applications.
2:30PM P31.00001: Multi-scale relaxation dynamics of arrested patchy particle gels  JAKE SONG (Presenter), Massachusetts Institute of Technology MIT, MARC PIQUETTE, Tufts University, FELIPE DE QUESADA, Massachusetts Institute of Technology MIT, MEHEDI RIZVI, North Carolina State University, QINGTENG ZHANG, SURESH NARAYANAN, Argonne National Laboratory, JOSEPH TRACY, North Carolina State University, EMANUELA DEL GADO, Georgetown University, NIELS HOLTEN-ANDERSEN, GARETH H MCKINLEY, Massachusetts Institute of Technology MIT — Patchy particle interactions enable the design of so-called ‘equilibrium gels’, a system where arrest is achieved without an underlying phase separation, resulting in structurally equilibrated gels which do not undergo coarsening-induced aging. Here, we study the multi-scale relaxation dynamics of a model patchy particle gel consisting of nanoparticles linked with end-functionalized polymers by using stopped-flow spectro-photometry, x-ray photon correlation spectroscopy, and linear viscoelastic measurements. We show that, despite the fast dissociation dynamics of an individual polymer linker from the nanoparticle, the relaxation of the system becomes slow and arrested at larger length-scales due to multi-functional associations between the nanoparticles. We show that the nanoscale primary clusters undergo a combination of super-diffusive and diffusive relaxation modes, which is contrasted by the sub-diffusive and stretched-exponential relaxation of the network at the macroscale. We show that the super-diffusive dynamics of the primary clusters are highly intermittent, which supports the interpretation that avalanche dynamics is a general feature associated with the microscopic dynamics of arrested soft materials, irrespective of the material's route to arrest.

2:42PM P31.00002: Nanosheets and Metallo-Hydrogel Formed by 2-nm Metal-Organic Cages based on Electrostatic Interaction*  YUQING YANG (Presenter), HUI LI, TIANBO LIU, JIAHUI CHEN, TING-ZHENG XIE, YI FENG, XINYU SUN, polymer science, the university of akron — Macroionic solutions, including metal-organic cages, would form the single layered hollow sperical blackberry-type structure based on counterion-mediated attraction. Here, we observed a hydrogel formation process from 2-nm emissive, low molecular-weight metal-organic cages at low concentrations (>15 mg/mL) based on counterion-mediated attraction and π-π/hydrophobic interactions. With addition of small electrolytes, the cages in aqueous solution will follow the counterion-mediated attraction and self-assemble into 2D nanosheets, like normal macroionic solutions. However, the unique molecular structure and the charge distribution of the cages make the bending of nanosheets into spheres difficult, leading to stable, standing alone MOC nanosheets in solution and their very large excluded volumes lead to gelation at very low (~1.5 wt%) cage concentrations, with the helps from hydrophobic and partially π-π interactions similar to the gelation of graphene oxides.

2:54PM P31.00003: Emergence of Multiscale Dynamics in Colloidal Gels   JAE HYUNG CHO  
(Presenter), Massachusetts Institute of Technology MIT, ROBERTO CERBINO, University of Milan, IRMGARD BISCHOFBERGER, Massachusetts Institute of Technology MIT — To gain insight into the kinetics of colloidal gel evolution at low particle volume fractions $\phi$, we utilize differential dynamic microscopy to investigate particle aggregation, geometric percolation, and the subsequent transition to nonergodic dynamics. We report the emergence of unexpectedly rich multiscale dynamics upon the onset of nonergodicity, which separates the wave vectors $q$ into three different regimes. In the high-$q$ domain, the gel exhibits $\phi$-independent internal vibrations of fractal clusters. The intermediate-$q$ domain is dominated by density fluctuations at the length scale of the clusters, as evidenced by $q$-independence of the relaxation time $\tau$. In the low-$q$ domain, the scaling of $\tau$ as $q^{-3}$ suggests that the network appears homogeneous. The transitions between these three regimes introduce two dynamical characteristic length scales, distinct from the cluster size.

3:06PM P31.00004: Size-Dependent Tracer Diffusion in Colloidal Gels*   BRIAN KANG RYU  
(Presenter), ROSEANNA ZIA, Department of Chemical Engineering, Stanford University — Colloid diffusion in porous media is ubiquitous in industrial and biophysical systems, such as the extracellular matrix hydrogels of cell tissues and the nucleoid region inside prokaryotic cells, where specific pore morphologies enable selective filtering. Obtaining a relation between pore size and colloid diffusion in porous media will lead to the development of models that will elucidate how cells regulate biomolecule transport. In this study, we seek a fundamental understanding of how the diffusion of tracer colloids of various sizes are hindered by a porous medium. We present our results from simulations of tracer colloids undergoing Brownian diffusion in the voids of a colloidal gel. Detailed characterization of tracer diffusion reveals that all tracers experience sub-diffusive motion over short to intermediate length scales. Small tracers eventually recover the diffusive regime over longer length scales while large tracers remain in a local cavity. We additionally present algorithms to identify the characteristic length scale that marks the onset of the recovery to normal diffusion and the cutoff tracer size that determines whether a tracer is too large to break through the void network.

3:18PM P31.00005: Connecting the viscoelastic response of nanosheet gels to the elastic properties of the particles* SEBASTIAN BARWICH, MATTHIAS MOBIUS (Presenter), School of Physics, Trinity College Dublin — Micron-sized nanosheets such as graphene, graphene oxide or clay platelets can be used to make conducting inks or as fillers in composites to enhance their mechanical properties. At high concentrations beyond rigidity percolation, nanosheet suspensions become yield stress fluids with a finite storage modulus. In this regime the elastic response of nano-sheet suspensions appears to be universal. The storage modulus plateau of few-layer graphene in NMP solvent, aqueous graphene oxide gels and clays exhibit a power law exponent close to 3 as a function of relative volume fraction.

We present a new analytical model that explains this behaviour and connects the bulk response to the elastic properties of single nanosheets and their size. This allows is to infer the magnitude of the bending stiffness of single nano-sheets from our rheological data.

This model opens up the possibility to infer elastic properties of different nanosheets from rheological data of the suspension rather than performing AFM experiments on single nanosheets. Furthermore, this model may explain the mechanical enhancement of nanosheet composites where a similar exponent can be observed.

*The authors aknowledge funding from Science Foundation Ireland (SFI) under grant 17/CDA/4704

3:30PM P31.00006: Tunable viscoelasticity of double gel networks: colloidal gels embedded in a hydrogel matrix IPPOLYTI DELLATOLAS (Presenter), JAE HYUNG CHO, THIBAUT DIVOUX, IRMGARD BISCHOFBERGER, Massachusetts Institute of Technology MIT — We create double gel networks consisting of a colloidal gel embedded within a hydrogel matrix. Depending on the relative strength between the two networks, we can tune the rheology to be either dominated by the colloidal gel, the hydrogel, or to exhibit features characteristic of both systems. This allows us to adjust both the sample modulus and the yielding behavior. Looking beyond the macroscopic mechanical characteristics, we discuss the changes in the microscopic dynamics of the colloidal gel occurring as the hydrogel network forms around it. We use differential dynamic microscopy and confocal fluorescence microscopy to access the variations in the structure and network fluctuations of the colloidal gel.
Tuning vaporization threshold of perfluorocarbon by interfacial melting in endoskeletal droplets

GAZENDRA SHAKYA (Presenter), Department of Mechanical Engineering, University of Colorado, Boulder, SAMUEL HOFF, SHIYI WANG, HENDRIK HEINZ, Department of Chemical and Biological Engineering, University of Colorado, Boulder, XIAOYUN DING, MARK BORDEN, Department of Mechanical Engineering, University of Colorado, Boulder — Perfluorocarbon (FC) droplets have been extensively used as phase-change contrast agents for biomedical ultrasound imaging and therapy. Several studies have aimed at understanding the vapor embryo nucleation and vaporization behavior of these droplets. However, these studies have not looked at tuning the thermodynamic limit of stability (spinodal) by using multiphase mixtures. We investigated the vaporization behavior of endoskeletal perfluoropentane ($C_5F_{12}$) droplets by incorporating solid FC and solid hydrocarbon (HC) skeletons. Multiple geometries were generated, including endoskeletal (solid-in-liquid) as well as exoskeletal (liquid-in-solid) droplets. Vaporization of these droplets was measured over a range of temperatures both optically using a microscope and acoustically with clinical ultrasound scanner. We show that $C_5F_{12}$ stability can be tuned by controlling the intermolecular interactions, as captured quantitatively by the exchange parameter. Using a simple statistical thermodynamics lattice model, we demonstrate that the presence of the FC strengthens the intermolecular attraction and the presence of HC breaks the intermolecular attraction between the liquid molecules, making it possible to finely tune the spinodal and consequently the vaporization temperature.

Flow of Quasi-2D Emulsion Droplets Through Small Openings*

ANISA HOFERT (Presenter), YONGLUN JIANG, ERIC WEEKS, Emory University — We examine how various parameters affect the flow rate of quasi-2D soft particles moving through tight openings. To observe this, we create thin hopper-shaped chambers which have a small exit for the particles to flow through. We fill the chambers with monodisperse oil-in-water emulsions with a soap surfactant. We use microscopy to observe the droplets moving through the chamber. We find faster flow rates when there are more droplets in the chamber (providing a larger pressure head) and with larger exit sizes. We fit the flow rate to a modified Beverloo equation with an extra term for the height of the particles pushing the droplets through the opening.

A granular material spreading as a liquid: growth dynamics of 3D aggregates of oil droplets

JEAN-CHRISTOPHE ONO-DIT-BIOT (Presenter), TANEL LORAND, KARI DALNOKI-VERESS, Physics and Astronomy, McMaster University — A continuous medium like a puddle has a characteristic critical height set by the capillary length, a balance between gravity and surface tension. In this study, monodisperse frictionless and lightly attractive oil droplets (radius approximately 10 microns) are produced one-by-one in an aqueous solution. Droplets are buoyant and accumulate underneath a glass slide which acts as the top of a liquid cell, forming 3D aggregates. The droplets initially accumulate vertically. As a critical height is reached, the aggregate collapses and spreads horizontally on the glass slide. Despite the aggregates being granular in nature, we find that the equilibrium shape of such aggregates follows the physics of continuous media. Indeed, the height of the aggregate reaches a critical value which is set by a balance between adhesion between the droplets and buoyancy. Both parameters can be tuned in the experiment to vary the geometry of the droplet aggregates. We developed a model that captures the shape of the aggregate with a simple parameter analogous to the capillary length.

Spreading of a 2D granular analogue of a liquid puddle: Predicting structure through a “granular capillary length”

JOHNATHAN HOGGARTH (Presenter), JEAN-CHRISTOPHE ONO-DIT-BIOT, KARI DALNOKI-VERESS, McMaster Univ — The structure of an accumulation of granular material, such as a pile of sand, is understood through the balance between gravity, which acts to limit the height, and inter-grain friction, which holds the particles together. In contrast, for the case of a continuous medium, the height of a puddle is dictated by the capillary length which balances gravity and surface tension. Here we develop an experimental model that allows us to probe the structure of a 2D pile of monodisperse microscopic oil droplets. The droplets are buoyant, adhesive, and friction is negligible. Oil droplets are deposited within a chamber and accumulate at a barrier. The droplets accumulate to a certain critical height at which point the pile collapses and spreads across the barrier. This process is reminiscent of the spreading of a liquid even though the pile is granular and 2D in nature. We define a parameter, analogous to the capillary length, which determines the height of the pile and is dictated by the balance between buoyant and adhesive forces. These parameters can be controlled experimentally in order to modify the height of the pile. We developed a simple model that can predict the shape of the pile based on the balance of adhesion and buoyancy.
4:30PM P31.00011: Characterizing the effects of Temperature and Ethanol Concentration on the louche of Absinthe. *  JESSICA BICKEL (Presenter), ANNA ELLIS, ANDREW H RESNICK, Cleveland State University — Oil flavored alcohols are traditionally served by mixing them with cold water to form a louche: a microemulsion that turns the drink opaque because of the interactions of the alcohol with water, which it dissolves, and the oil, which is disperses. When there is sufficient water the oil phase precipitates, forming the louche. Thus, characterization of the louche depends on the concentrations of water, alcohol and oil. Absinthe has not been as well characterized as other oil flavored alcohols such as Limoncello or Ouzo with no studies on either a ternary phase diagram or on the louche phase. This work examines the emergence of the louche phase in absinthe by measuring the optical transmittance of the solution as a function of both: (1) the concentration of ethanol and (2) the temperature, which can be separately varied. The laser transmission was measured through a temperature-controlled sample of absinthe. The change in transmission was recorded as water was added to the sample, revealing an inverse relationship between temperature and ethanol concentration at which louche forms. There are also two different steps in the louche suggesting two different micro-emulsions form depending on the concentrations.

4:42PM P31.00012: Surface active microgels: dual functioning soft stabilisers  DAVID CROSBY (Presenter), VINCENT MARTINEZ, TIFFANY WOOD, ALEX LIPS, WILSON POON, Univ of Edinburgh — Emulsions are stabilised by either surfactants or solid particles which sit at the interface between the phases. Particles irreversibly adsorb to an interface whereas surfactants detach under small perturbations. Due to their enhanced stability, particle-stabilised emulsions are used as a base for many products such as foods and pharmaceuticals. Furthermore, particles impart elasticity to interfaces, a quality which enhances the sensory performance of foods without the need for excessive amounts of fat [1]. Personal care products are another potential application as they require enhanced sensory properties and tuneable stability.

However, particle-stabilised interfaces can become unstable when dilated or compressed, processes which are common in processing. This instability, known as buckling, occurs when colloids jam together causing films to collapse.

We present work done on a commercial microgel system, composed of an amphiphilic polymer called Sepimax Zen (SZ). We show that SZ microgels stabilise an oil-water interface forming elastic films which are immune to buckling and can also be used to thicken suspensions.

4:54PM P31.00013: Clustering Colloids with Polymer Bridges  THEODORE HUECKEL (Presenter), New York Univ NYU, JOERI OPDAM, Eindhoven University of Technology, THOM SNOEREN, New York Univ NYU, REMCO TUINIER, Eindhoven University of Technology, STEFANO SACANNA, New York Univ NYU — Colloidal model systems are typically highly uniform, yet structurally simple. One design principle inspired from organic chemistry is to take rudimentary atomic building blocks and combine them into more complex and functional molecules. An analogous colloidal reaction is the heteroaggregation of core and shell particles into clusters that have new shapes, which can foster assembly in a directional fashion. Some colloidal pairings are naturally complementary, such as oppositely charged particles, but it is difficult to combine distinct like-charged suspensions in a similar manner. Highly tailored surface chemistry can bind particles together, however, severely impact throughput along the way. Here, a general approach to heteroaggregation is described where particles are speciated as either polymer-coated or bare and made to bind specifically to their counterpart through polymer bridging. Flexibly selecting from a variety of materials for the cores and shells creates a veritable zoo of different cluster products with large-scale production potential. Harnessing this colloidal bond has led to advancements in particle shape, surface pattern, and regioselective binding, which are all necessary control parameters for furthering our capabilities in synthetic self-assembling systems.

5:06PM P31.00014: Universal elasticity in nearly floppy soft matter  BRIAN TIGHE (Presenter), Delft University of Technology — In many soft matter systems, mechanics is governed by the balance between microscopic degrees of freedom and internal constraints on motion. Constraints on relative motion parallel to the bond between two particles, or between two nodes in a network, can be modeled with springs. However, other, non-central force constraints are often present as well — examples include constraints on sliding in frictional granular media and composites, constraints on bending in biopolymers and covalent glasses, and constraints on shape distortions in confluent tissues, foams, and emulsions. We consider the case where non-central force constraints are present, but carry a weaker energetic cost than their spring-like counterparts. We will show that the elasticity of these systems has universal features, independent of the origin of the non-central force constraint. These features can be explained in terms of the floppy modes that appear in the limit where non-central forces are "turned off." We derive scaling relations for the shear modulus and validate them numerically in three model systems — pre-tensioned spring networks, semi-flexible fibre networks, and composite packings of hard and soft particles.

Session P32 DPOLY DSOFT DCP DMP: Molecular and Polymer Glass Dynamics  504 - Mark Ediger, University of Wisconsin - Madison - Tag(s): Focus
Evidence for heterogeneous bulk melting dominating the transition of organic stable glasses

MARTA GONZALEZ-SILVEIRA (Presenter), ANA VILA-COSTA, MARTA RODRÍGUEZ-LOPEZ, AITOR F. LOPEANDÍA, JAVIER RODRIGUEZ-VIEJO, Physics Department, Autonomous University of Barcelona — For over a century, scientists have tried to understand the mechanisms behind the glass transition and the dynamics of glassy systems. Part of the difficulty arises from the time scales involved in these processes. The low stability of conventional glasses, obtained by cooling down a melted material, have determined for years how we study glass dynamics, focused basically on the aging regime, i.e., performing isothermal treatments below the limiting fictive temperature ($T_f$) of the glass, allowing the glass to evolve towards a more stable configuration. But the evolution of glasses above their $T_f$ in isothermal regime, what we could call softening of rejuvenation as the glass progressively loses stability, has been barely explored at temperatures not far above the conventional glass transition temperature of the material, $T_g$. The time scales in this case are extremely short for conventional glasses, and in order to study rejuvenation one would need either glasses of high stability (to increase the measuring time) or advanced instrumentation (able to work in very short times). This scenario has changed with the ability to prepare glasses of a wide range of stabilities by means of PVD and the development of fast scanning nanocalorimetry. By performing isothermal treatments at temperatures spanning more than 30 K above the conventional $T_g$ of the material we show that the rejuvenation process in stable glasses takes place via two different mechanisms: i) a homogeneous softening of the glass and ii) the formation of liquid patches in the bulk of the glass, which grow transforming the glass straight into the liquid, dominating the pace of the transformation and resembling the nucleation and growth process characteristic of the melting of crystals. Surprisingly, these two mechanisms are present even in glasses with stabilities close to those of the conventional glass, although clear differences can be found in the number of initial liquid patches and the transformation rate.

Solvent vapor annealing of stable glasses

SHIVAJEE GOVIND (Presenter), HAOQIANG ZHAO, PATRICK WALSH, ZAHRA FAKHRAAI, University of Pennsylvania — Stable glasses (SG) are highly dense, low energy glasses that are made by physical vapor deposition (PVD). Because of their desirable properties and wide range of applications, they are extensively studied glasses. However, measuring their dynamics can be difficult since they are produced directly into a SG state on a substrate during the process of PVD. We have introduced a novel and indirect method of measuring the dynamics of SG using solvent vapor annealing (SVA). Using this technique, together with in-situ ellipsometry, we have shown that even at low solvent vapor pressure, the surface of SG swells more quickly, in an analogous Fickian type diffusion, compared to that of the bulk. Above a certain threshold of vapor pressure, the bulk of the film swells linearly with time, which demonstrates a Case II type of diffusion. This shows the diffusion of the solvent molecule through the film is limited by the relaxation of the molecules such that the solvent uptake is governed by a two-layer model; one swollen with solvent and the other the dry medium. By monitoring the solvent front moving across the film, we compare the dynamics of the SG films of different stability produced at different deposition temperatures.

3:18PM P32.00003: Secondary Dynamics in Ultrastable Polystyrene Thin Films Studied by $\beta$-NMR

IAIN MCKENZIE, TRIUMF, DANAAN CORDONI-JORDAN, Chemistry, Simon Fraser University, DEREK FUJIMOTO (Presenter), Physics and Astronomy, University of British Columbia, VICTORIA KARNER, Chemistry, University of British Columbia, ROBERT F KIEFL, Physics and Astronomy, University of British Columbia, PHILIP C. P. LEVY, TRIUMF, W ANDREW MACFARLANE, RYAN M. L. MCFADDEN, Chemistry, University of British Columbia, GERALD MORRIS, MATT PEARSON, TRIUMF, ADAM RAEGEN, Physics and Astronomy, University of Waterloo, JOHN TICKNOR, Chemistry, University of British Columbia, JAMES A FORREST, Physics and Astronomy, University of Waterloo — Ultrastable, highly mono-disperse polystyrene (PS) thin films can be produced by physical vapor deposition. These films can exhibit properties similar to those of a normal glass that has been aged for thousands of years. $\beta$-detected nuclear magnetic resonance ($\beta$-NMR) of implanted $^8\text{Li}^+$ probes can be used to study dynamics in thin polymer films, which is not possible with conventional magnetic resonance techniques [I. McKenzie et al. Soft Matter 14, 7324 (2018)]. We have used $\beta$-NMR to study the temperature dependence of the secondary $\gamma$-relaxation process in an ultrastable PS film and a normal PS film that was produced by rejuvenating an ultrastable film by heating to $T_g + 25$ K for 2 minutes. The $\gamma$-relaxation is $\sim 38\%$ slower at 295 K, and the activation energy is $\sim 20\%$ larger in the ultrastable glass compared with the normal glass. Our interpretation of the results is that the denser packing in the ultrastable glass hinders motion of the phenyl rings.

*We acknowledge the support of the Natural Sciences and Engineering Research Council of Canada (NSERC).

3:30PM P32.00004: Uncovering $\beta$-relaxations in amorphous phase-change materials

SHUAI WEI (Presenter), RWTH Aachen University, SI-XU PENG, Huazhong University of Science and Technology, YUDONG CHENG, JULIAN PRIES, RWTH Aachen University, HAI-BIN YU, Huazhong University of Science and Technology, MATTHIAS WUTTIG, RWTH Aachen University — Relaxation processes are decisive for many relevant physical properties of amorphous materials. For amorphous phase-change materials (PCMs) employed in non-volatile memories, relaxation processes are, however, difficult to characterize due to the lack of bulk samples. Here, instead of bulk samples, we use powder mechanical spectroscopy for powder samples to detect the prominent excess wings – a characteristic feature of $\beta$-relaxations – in a series of amorphous PCMs at temperatures below the glass transition. By contrast, $\beta$-relaxations are vanishingly small in amorphous chalcogenides of similar composition, which lack the characteristic features of phase-change materials. This conclusion is corroborated upon crossing the border from PCMs to non-PCMs, where $\beta$-relaxations drop significantly. Such a distinction implies that amorphous PCMs belong to a special kind of covalent glasses whose locally fast atomic motions are preserved even below the glass transitions. These findings also suggest a correlation between $\beta$-relaxation and crystallization kinetics of PCMs, which may have technological implications for phase-change memory functionalities.
3:42PM P32.00005: A direct static scattering evidence on the dynamic nature of glass formation process in polystyrene*  HE CHENG (Presenter), GUIHENG JIAO, TAISEN ZUO, CHANGLI MA, ZEHUA HAN, JUNRONG ZHANG, Chinese Academy of Sciences, JUNPENG ZHAO, south china university of technology, CHARLES C HAN, Chinese Academy of Sciences — The combination of neutron total scattering, high concentration labelling and molecular dynamics (MD) simulation enable us to visualize the temperature dependence most-probable all-atom positions in atactic polystyrene (PS), and find out the dynamic nature of its glass forming. The scattering profiles from MD simulation are in agreement with all of the neutron scattering curves, as well as the X-ray scattering data in literatures at different temperatures. Two main scattering peaks at ~0.6 Å⁻¹ and 1.4 Å⁻¹ can thus be allocated. The peak at ~0.6 Å⁻¹ is from the segment-segment interaction, which is a combination of backbone-backbone and backbone-phenyl interactions. And the peak at 1.4 Å⁻¹ is mainly from phenyl-phenyl interaction. Below glass formation temperature, both peaks keep almost constant. Their heights jump during glass formation, revealing the melting of the configuration variation and development of dynamic heterogeneity.

3:54PM P32.00006: Effects of aromatic side-group structure on thermal transitions of polyzwitterions* ANDREW CLARK (Presenter), YAJNASENI BISWAS, AYSE ASATEKIN, MORGAN E TAYLOR, MATTHEW J PANZER, Tufts Univ, CHRISTOPH SCHICK, Physics, University of Rostock, PEGGY CEBE, Tufts Univ — Aromatic structures can have a pronounced effect on the glass forming properties of ionic liquids and polymers. Polyzwitterions are polymers with side groups that contain a covalently linked anion and cation. Depending upon side chain structure, this can lead to high glass transition temperatures, occurring near the onset of degradation. In this study we are using fast scanning calorimetry to investigate how aromatic structures in the side-group alters the glass formation of polyzwitterions. Poly(sulfobetaine vinylimidazole) (PSBVI) and poly(sulfobetaine-4-vinylpyridine) (PSB4VP) were synthesized and cast into films. Both polymers contain identical sulfonate anions allowing for a good comparison of the effect of aromatic structure variations in the side-group. The glass transition could not be observed prior to degradation in either polymer using conventional slow scan DSC. Using fast scanning calorimetry, degradation was avoided by heating and cooling at 2000 K/s which allowed the first measurement of the glass transition process in these materials. We found that PSBVI has a T_g of 250 °C while PSB4VP has T_g at 215 °C. Analysis of the fragility reveals that PSBVI is a stronger glass former than PSB4VP.

*NSF DMR-1608125, DAAD, Tufts Collaborates Seed Grant, NSF CBET-1802729
Rigorous analysis of the linear viscoelastic behavior of thermo-rheologically complex amorphous materials

GRIGORI MEDVEDEV (Presenter), JAMES M CARUTHERS, Purdue Univ — It is well-known that linear viscoelastic response of amorphous materials, including both low molecular weight and polymeric, as probed in mechanical and dielectric relaxation experiments is thermo-rheologically complex. A common approach to analyzing viscoelastic data is to use a combination of phenomenological functions such as stretched exponential, Havriliak-Negami, etc. manifesting as distinct peaks in the relaxation spectrum. Unfortunately, not only the location on the time axis but also the shape and the spectral strength of these peaks is required to change with temperature rendering such representation merely a curve fit. A brute force Prony series expansion has also been tried, where the relaxation times are typically assumed to be evenly spaced on the logarithmic scale. The resulting set of Debye peaks of varying strength also lacks physical interpretation. We propose a different approach where all processes have the same strength, but the corresponding relaxation times are dictated by the data. When broad temperature interval comprising sub-Tg and above Tg regions is investigated a complete relaxation map emerges. Examples of the relaxation map will be shown for several materials, including epoxy systems of varying architecture.

Relaxation processes in polymer glasses: a hierarchical approach

PETER OLMSTED (Presenter), Department of Physics and Institute for Soft Matter Synthesis and Metrology, Georgetown University, DANIEL L BAKER, MATTHEW REYNOLDS, JOHAN MATTSSON, Department of Physics & Astronomy, University of Leeds, ROBIN MASUREL, Department of Physics and Institute for Soft Matter Synthesis and Metrology, Georgetown University — The glass transition temperature Tg in polymers increases with increasing molecular weight M, but the detailed Tg(M) dependence in polymers is not well understood. Here, we present experimental results of the M-dependence of both the structural (alpha) relaxation process, which controls the glass transition, and faster (beta and gamma) secondary relaxation processes for a range of polymers of varying chain flexibility. Based on our results, we propose a hierarchical relaxation scenario that links these relaxations and controls Tg in polymers, where the fundamental metric is linked to ‘local’ flexibility. We identify regimes in M where intra and inter-molecular relaxation dynamics play different roles in defining the dynamics (and thus Tg). We argue that dihedral barriers play a crucial role in controlling the dynamics, which gives rise to distinct differences in behaviour from what is observed in glass-formers with simpler ‘rigid’ structures, or in simplified bead-spring models of polymers.

4:30PM P32.00009: Unusual Viscoelasticity in Polyrotaxane Glasses  KARAN DIKSHIT (Presenter), CARSON J BRUNS, University of Colorado, Boulder — This work characterizes the viscoelastic properties of glasses made from polyrotaxanes, a class of mechanically interlocked polymers possessing a bead-on-a-string structure. The rheology of polyrotaxane-based glasses in the devitrified state reveals an absence of elastic plateau over a large range of frequencies. The motivation for this investigation stems from a need to understand the processability of polyrotaxanes. These “molecular necklaces”, without any modification, are crystalline due to the presence of strong hydrogen bonding between the cyclodextrin-based molecular beads. Similar to cellulose, which also exhibits strong hydrogen bonding, these materials do not flow when heated. Chemical modification of the cyclodextrins leads to the breakdown of hydrogen bonding which, in turn, reduces crystallinity and renders the polyrotaxanes amorphous and glassy. XRD and DSC data confirm the amorphous nature of these polymers and reveal their glass transition temperatures. Understanding the rheology of these polyrotaxane glasses will help characterize their mechanical behavior over different temperatures and time scales while identifying optimal processing conditions for applications in advanced materials.

4:42PM P32.00010: Volume recovery and physical aging of pressure-densified glasses  DANIEL FRAGIADAKIS (Presenter), ADAM HOLT, CHARLES M. ROLAND, United States Naval Research Laboratory — When a glass is formed by cooling under high pressure, the resulting pressure densified glass exhibits a higher density and different thermal and mechanical properties than the corresponding glass prepared by conventional cooling at low pressure. Understanding, manipulating, and exploiting the full potential of pressure densified glasses offers the possibility of better properties. The effects of pressure densification on 1,3,5-tri(1-naphthyl)benzene (TNB) are assessed from volumetric and calorimetric measurements. The pressure densified glass (PDG) exhibits anomalous physical aging. Rather than evolving monotonically towards the equilibrium density, there is an overshoot to a lower density state. Only when the density of the PDG becomes equivalent to the corresponding CG does the density begin a slow approach towards equilibrium. Using molecular dynamics simulations of a simplified model of TNB, we show that the effects of vitrification pressure and subsequent volume recovery and aging of the glass are comparable to experimental results for real TNB. A two-parameter description of the underlying non-equilibrium structure, entailing a fictive temperature and fictive pressure, appears adequate to interpret the “anomalous” aging behavior of pressure-densified TNB.
Understanding aging phenomena by the free-energy-landscape approach

TAKASHI ODAGAKI (Presenter), Research Institute for Science Education & Kyushu University — Aging phenomena have been observed in many non-equilibrium systems such as polymers and glasses, where physical properties depend on the waiting time before observation. It is not known what causes the aging, nor what information can be extracted from them. Exploiting the free-energy-landscape (FEL) theory[1], which explains dynamic and thermodynamic properties of non-equilibrium systems in a unified framework, I argue the physical origin of the aging phenomena for the first time. The FEL depends on temperature and, thus, will respond to a temperature modulation with delay. I consider physical quantities observed after a waiting time $t_w$ when the temperature is modulated at time $t = 0$ and show that the delayed response of the FEL manifests itself in an additional aging. As an example, I investigate aging phenomena of dielectric relaxation represented by a two-level model. I show that the relaxation function and the linear susceptibility show non-trivial dependence on $t_w$ from which one can deduce the relaxation time of the FEL.

Lifetime of Rate Domains: Comparison of Simulations and Single-Molecule Experiments in o-Terphenyl

HARVEEN KAUR, Chemistry and Biochemistry, Univ of South Carolina, KEEWOOK PAENG, LAURA KAUFMAN, Chemistry, Columbia University, MARK BERG (Presenter), Chemistry and Biochemistry, Univ of South Carolina — Supercooled liquids have domains with different relaxation rates. The lifetime of those domains is not well understood. The usefulness of single-molecule measurements has been limited by conventional, molecule-by-molecule analysis, which suffers from excessive noise. An alternative, ensemble-based analysis using multidimensional correlation functions is applied to single-molecule dichroism results in o-terphenyl near $T_g$ ($T_g$+4.5–1.5 K, $T_{rot}$ = 3–15 s). It yields a detailed rate-exchange correlation function, which is biphasic. The slow, main component is 22 times slower than the alpha-relaxation time, implying that single-particle relaxation does not fully equilibrate the liquid. A small, fast phase of rate exchange is attributed to molecules on the boundaries of rate domains. The same analysis was applied to a ms-long, all-atom simulation of o-terphenyl from the D. E. Shaw group [J. Phys. Chem. B 117, 12898 (2013)]. It is at a higher temperature (272.5 K, $T_{rot}$ = 16 μs), but it is still well below the mode-coupling temperature (290 K). There are clear differences from the results near $T_g$, suggesting that time–temperature superposition does not hold for rate exchange.

This material is based upon work supported by the National Science Foundation under CHE-1707813.
5:18PM P32.00013: Unified description of the Arrhenian and super-Arrhenian behavior of OTP by the excess internal energy model  JAMES M CARUTHERS (Presenter), JACK YUNGBLUTH, GRIGORI MEDVEDEV, BRET SAVOIE, Purdue Univ — As previously reported (Caruthers, Medvedev 2018), the excess internal energy model, $1/U_x$, unlike the excess entropy model of Adam and Gibbs, is able to describe the mobility of liquids in the super-cooled state as a function of temperature and pressure. The $1/U_x$ model prediction of the temperature effect on mobility was validated for 21 molecular glass formers and of the temperature and pressure – for ortho-terphenyl (OTP) – the only material for which there was sufficient data. In the current work MD simulations were performed on model OTP in the high temperature region that includes the onset of the super-Arrhenian behavior. The excess internal energy was obtained at pressures from 0.1 MPa to 5 GPa. The translational and rotation diffusivities were determined at these temperatures and pressures. The MD mobility data (including extremely long time 0.1 MPa simulations from Eastwood et al. 2013) were combined with experimental data, where it was shown that in both the high temperature Arrhenian region and the lower temperature super-Arrhenian region the mobility is a linear function of $1/U_x$, albeit with different proportionality constants; the transition between the Arrhenian and super-Arrhenian behaviors is relatively sharp at a critical internal energy $U_{x,α}$.

Session P33 DPOLY DSOFT: Hierarchical Structural Emergence in Elastomer Nanocomposites: Dispersion, Dynamics, Structure, Modeling, and Simulation II 505 - Greg Beaucage, Univ of Cincinnati - Tag(s): Focus

2:30PM P33.00001: WITHDRAWN ABSTRACT —
2:42PM P33.00002: Quantification of dispersion for weakly and strongly correlated fillers in polymer nanocomposites*  ALEX M MCGLASSON (Presenter), KABIR RISHI, GREG BEAUCAGE, MICHAEL CHAUBY, Univ of Cincinnati, VIKRAM KUPPA, University of Dayton — The dispersion of nanoparticles in viscous polymers is dictated by kinetics; interaction potentials between particles; and interfacial compatibility between the matrix and dispersed phases. An analogy has been made between thermally dispersed colloids and kinetically dispersed nanoparticles for cases where only weak interactions exist between particles allowing for a mean field description under the Ginzburg criterion such as for carbon black dispersed in polybutadiene. For these cases the pseudo- second virial coefficient can be used to quantify the quality of dispersion. However, this approach fails for nanoparticles with surface charges or other specific interactions that display strong correlations such as precipitated silica in styrene-butadiene rubber. Here, these strongly correlated systems are investigated in the context of the mean-field systems in order to gain a comparative description of dispersion using the network mesh size and a derived virial coefficient. In the proposed approach, the correlations in nanoaggregates are described by a combined semi-empirical function based on the Born-Green theory and a distribution function that accounts for the non-uniform accumulated strain in nanocomposites.

2:54PM P33.00003: Recent Study of Small-Angle Neutron Scattering Spectrometer Suanni on Elastomer Nanocomposites* YUE SHUI, LIZHAO HUANG, TINGTING WANG, GUANGAI SUN, JIAN GONG, JIE CHEN, DONG LIU (Presenter), Key Laboratory of Neutron Physics and Institute of Nuclear Physics and Chemistry (INPC), China Academy of Engineering Physics (CAEP) — The small-angle neutron scattering (SANS) spectrometer Suanni at CMRR has been brought into operation since 2014 [1]. The SANS-Suanni can achieve a maximum-q up to 10.5 nm⁻¹. In this report, we will discuss some applications on the polymeric materials. By combining extensional rheological and in situ SANS techniques, the correlation between chain deformation and morphology of flow-induced crystallization has been studied [2]. The structure decomposition of silica-filled silicone rubber via the contrast variation SANS technique was presented. SANS results suggested unambiguously the existence of a bound rubber layer with thickness of ca. 8.5 nm [3]. Recently, the correlation between macroscopic mechanical properties and microscopic structures of an optimized silica fraction in silicone rubber was investigated. An optimum filler fraction ranges from 40~50 phr was found, in which the best performances of reinforcement and themorpholog were shown. [4].

3:06PM P33.00004: WITHDRAWN ABSTRACT —
3:18PM P33.00005: Effect of Initial Dispersion State on the Structure and Property of Polymer Nanocomposites*  
GA YOUNG KIM (Presenter), SO YOUN Y KIM, Ulsan Natl Inst of Sci & Tech — In the colloids-polymer mixture system, the microstructure of particles and polymers are strongly dependent upon their interactions, which can vary systemically with the component concentrations. When the colloidal system is concentrated by solvent evaporation with drying, the continuous change of component concentrations also causes a continuous change in the interparticle interaction. Previous studies have been conducted to control the rate of evaporation or drying conditions of the system. In this study, we show how the initial dispersion of the colloidal system can influence the final structure and property of the polymer nanocomposites. To vary the initial dispersion state, we first set different initial dispersion concentrations to find the effect of polymer and particle volume fractions on the interaction. Second, we provide different equilibrium time for particles to be aggregated. Ensemble-averaged microstructures were analyzed by SAXS measurement and rheological properties were analyzed by rheometer.

3:30PM P33.00006: Thermodynamic model for dispersion in nanocomposites.*  
GREG BEAUCAGE (Presenter), KARSTEN VOGTT, KABIR RISHI, Univ of Cincinnati, HANQIU JIANG, The China Spallation Neutron Source (CSNS), Institute of High Energy Physics, ANDREW MULDERIG, Univ of Cincinnati — Dispersion of nanoparticles can involve thermally driven diffusion of particles or kinetically driven mixing. On the nano- to colloidal scale a virial expansion of osmotic pressure can be used to quantify dispersion. Scattering can be used to measure the osmotic compressibility associated with concentration fluctuations which are related to the second virial coefficient. These fluctuations might be created thermally or by kinetic mixing. For multi-hierarchical materials such as aggregates which cluster to form a macroscopic network, each level of structure contributes to the free energy. This can be quantified in terms of the total number of free particles contributed by each of the levels of structure. For different levels in a hierarchy the energy of aggregation can be associated with an aggregation equilibrium or an apparent equilibrium. The resulting number of particles can be related to the energy of aggregation. This approach is demonstrated for three systems, pigments dispersed with nonionic surfactants; worm-like micelles; and condensation polymerization.

3:42PM P33.00007: Scattering Studies on Hierarchically Self-Organized Filler Particles in Polymers [Invited] MIKIHITO TAKENAKA (Presenter), Kyoto Univ, SHOTARO NISHITSUJI, Yamagata University, TAKEJI HASHIMOTO, Kyoto Univ — In this study, we investigated the self-organization of nanoparticles dispersed in polymer melts under applied mechanical energy imposed to mixtures that are composed of a bulk of the particle powder and a bulk of the polymer melt. Using various scattering methods that enable the exploration of structures that exist over a length scale that spans from ~0.1 nm to ~20 mm, we elucidated that the self-organized particles had hierarchical structures with various hierarchical levels as follows: primary particles (PPs), aggregates of the PPs fused together, clusters of the aggregates, and partially interdigitating mass-fractal structures built up by the clusters.

4:18PM P33.00008: First principles Study of Interaction of Polymer Molecules with Flat Carbon Nanotubes GEETA SACHDEVA (Presenter), RAVINDRA PANDEY, Department of Physics, Michigan Technological Univ, GREGORY M. ODEGARD, Department of Mechanical Engineering and Engineering Mechanics, Michigan Technological Univ — Polymer composites possess an integrated combination of structures and properties associated with the host matrix and fiber material (e.g. carbon nanotubes), and thus holding the potential as high strength materials. In general, the load transfer from the matrix to the fiber depends upon the strength of bonding at the interface which characterizes the mechanical strength. In this talk, we present the results based on density functional theory for the composite consisted of epoxy/BMI resins and flat carbon nanotubes with an aim to provide atomistic description of the interface which determines the mechanical strength of the polymer composite.

4:30PM P33.00009: Multiscale Modeling of Fracture in Epoxy/CNT Nanocomposites HAYDEN HOLLENBECK (Presenter), CHENGYUAN WEN, RALPH ROMERO, TABASSUM AHMED, NESLIHAN GENCKAL, NISHANT SHIRODKAR, GARY SEIDEL, SHENGFENG CHENG, Virginia Tech — Modeling fracture in a polymer nanocomposite with molecular resolution is a big challenge. We have developed a multiscale modeling framework on the basis of coarse-grained molecular dynamics (CG-MD) simulations and peridynamics to study fracture initiation and propagation in epoxy/CNT nanocomposites. The CG model constructed via a hierarchical coarse-graining scheme enables us to model an epoxy network at micrometer scale and still capture its mechanical properties including various moduli. A jointed-tube model is developed for CNTs that overcomes the corrugation issue in traditional CG potentials between CNTs and polymers. Peridynamics simulations of CG CNT bundles dispersed in CG epoxy are used at the microscale to generate statistical distributions of moduli and fracture properties to be used in macroscale peridynamics simulations of fracture toughness tests. The calculations are validated against physical experiments at a given macroscale volume fraction. Successful validation of our hybrid hierarchical-concurrent modeling framework integrating CG-MD and peridynamics models paves the way to designing epoxy/CNT nanocomposites with desired fracture properties via tuning CNT loading and dispersion state.

4:42PM P33.00010: Molecular Dynamics Investigation of the Structural and Mechanical Properties of Off-Stoichiometric Epoxy Resins  CHANG WOON JANG (Presenter), JOHN LAWSON, NASA Ames Research Center — We carried out molecular dynamics (MD) simulations to measure the mechanical properties of various off-stoichiometric polymers regarding amine to epoxy ratios (r) and to understand the stiffness of the polymers in terms of their structures. The aerospace-grade API-60 epoxy resin is used as an adhesive bond for assembling large-scale composite structures via the co-curing-ply bonding method. This method will produce a reliable and certifiable composite joint without additional fasteners. Calculated Young's modulus was measured from the uniaxial tension simulation with several high strain rates, and the experimental modulus was estimated by extrapolating the simulation results. We found that the stiffness was associated with molecular packing caused by chemical cross-linking. We also found that the number of network clusters gradually decreased as the ratio approached r = 1.0, which made the tighter cluster and the system much stiffer with an increase in the molecular weight and the degree of cross-linking. Structural properties such as Rg, MSD were measured to figure out the degree of stiffness with respect to the r.

4:54PM P33.00011: Deformation of Epoxy Nano-Composites  SURESH AHUJA (Presenter), materials, xerox corporation — Polymeric materials show properties which come from the interplay of phenomena at various length and time scales. The presence of layered silicates in polymers (PNC) changes the viscoelastic behavior of the unfilled matrix from liquid-like to solid-like because of the formation of a three-dimensional percolating network of exfoliated or intercalated stacks. This gel-like behavior is a direct consequence of the highly anisotropic nature of the nano-clays which prevents their free rotation and the dissipation of stress. Particle to particle interactions is the dominant mechanism in fumed silica nanocomposites whereas particle to polymer interaction is the dominant one in colloidal silica nanocomposites at identical filler concentrations.

Nano clays organically treated were mixed with Epoxy in a high shear mixer. Viscosity, normal stresses and dynamic viscoelastic measurements at various temperatures were determined. Relaxation modulus as function of time at different temperatures was used to get power law fits. Relaxation modulus at different crosslinking level in the nanocomposite shows large difference from nanocomposite with un-crosslinked epoxy. These structures by X-ray diffraction and TEM showed significant exfoliation.
Effect of interface modifiers on the cure, mechanical and viscoelastic properties of hierarchical carbon nanotube composites.  AJAY KRISHNAMURTHY (Presenter), RAN TAO, QI AN, AARON M FORSTER, National Institute of Standards and Technology — Addition of carbon nanotubes (CNTs) to traditional fiber-reinforced polymer composites (FRPs) has led to significant improvements in multifunctional capabilities of these materials. However, achieving these superior properties require incorporating relatively large CNT mass fractions (greater than 1%) where methods of dispersing CNTs in polymer matrix fail. Directly grafting CNTs onto fiber surfaces prior to resin infusion is a viable alternative and here this is achieved by using an electrophoretic deposition (EPD) process. To deposit the CNTs on fiber surfaces, they are first oxidized and mixed with a polyelectrolyte (such as polyethyleneimine (PEI)) which upon protonation is used to drive the CNTs onto fiber surfaces. In our previous study, we observed that the presence of small percentages of PEI affects the viscoelastic properties and the hydrogen dynamics of the composite. Here we aim to isolate the effect of PEI in the absence of CNTs and glass fibers and study its effect on the cure kinetics, mechanical properties and viscoelastic characteristics of the resin system. The cure process is understood using differential scanning calorimetry, the viscoelastic characteristics using dynamic mechanical thermal analysis and the mechanical properties using tensile testing.

Adhesion Strength of Block Copolymer Modified Epoxy Adhesives

VINCENT PANG (Presenter), University of Minnesota, ZACHARY JOHN THOMPSON, GUY D. JOLY, 3M Company, FRANK S BATES, LORRAINE F. FRANCIS, University of Minnesota — Epoxies are widely used as coatings and structural adhesives in the aerospace, automotive, and consumer goods industries. Prior studies have shown that the addition of block copolymers (BCPs) to epoxy resins can increase bulk fracture toughness, but little work has been done to understand the adhesive properties of these modified epoxy systems. In this work, the influence of self-assembled BCP nanostructures on the adhesion strength of epoxy thermosets was evaluated. Poly(ethylene-alt-propylene)-b-poly(ethylene oxide) BCP modifiers of various molecular weights and weight fractions were mixed into an epoxy resin, forming well dispersed nanoscale structures. Two self-assembled morphologies were studied: spherical micelles and bilayer vesicles. For both nanostructure morphologies, the modified epoxies exhibited significant improvements in bulk fracture toughness, with no reduction in elastic modulus. Single-lap-joint shear tests showed a significant (~50%) increase in the adhesion strength when spherical micelle modified epoxies were used on surface roughened aluminum. In contrast, vesicle-forming modifiers were detrimental, with a 36% reduction in adhesion strength. Possible mechanisms for the adhesion strength results will be discussed.

*This work was funded by the 3M Company.

Session P34 DPOLY DSOFT: Characterization of Non-Equilibrium or Exotic Structures of Polymers 506 - Douglas Tree, Brigham Young Univ - Provo - Tag(s): Focus
2:30PM P34.00001: Non-equilibrium laser annealing derived mesostructured silicon templated in mesoporous thin film network structures from block copolymer self-assembly

FEI YU (Presenter), QI ZHANG, ULRICH WIESNER, Cornell University — Block copolymer self-assembly derived network structures are combined with non-equilibrium transient laser heating to serve as nanotemplates for directing structures of inorganic materials, which otherwise are difficult to achieve mesoscale order. Amphiphilic block copolymers swelled by carbon precursors self-assemble into equilibrium bicontinuous gyroidal phases via solvent vapor annealing. After pyrolysis in nitrogen, the resulting mesoporous gyroidal carbon thin films are backfilled with amorphous Si (a-Si). The poor tolerance of carbon toward high temperature in air and the high melting points of inorganic materials present an enormous challenge in preparing crystalline mesostructured Si in the carbon templates. The carbon templates' stability is significantly enhanced, however, using nanosecond laser heating. Melting and recrystallization of Si (a-Si melts at \( \sim 1250 \) °C) during this ultrafast, highly non-equilibrium process allow conformal template backfilling so that crystallized Si inherits the templates' mesostructural order. Such non-equilibrium nanostructure formation approaches in conjunction with equilibrium self-assembly process open up opportunities for novel materials in catalysis and photonics.

*Funding from the National Science Foundation (DMR-1707836) is appreciated.

2:42PM P34.00002: Probing Block-Copolymer Self-Assembly Kinetics with In-Situ Spectroscopic Ellipsometry*

CONNOR BILCHAK (Presenter), GUILLERMO CONTREAS, SHIVAJEE GOVIND, Department of Chemistry, University of Pennsylvania, SHAWN MAGUIRE, RUSSELL COMPOSTO, Department of Materials Science and Engineering, University of Pennsylvania, ZAHRA FAKHRAAI, Department of Chemistry, University of Pennsylvania — Understanding the assembly of block copolymers during various processing procedures is critical for the development of functional materials, as well as providing information on the underlying polymer physics. However, direct observation of the assembly process in-situ is exceedingly challenging and time-consuming. In this work, we develop and implement a novel characterization method to monitor the assembly of cylinder- and lamellar- forming block copolymers using spectroscopic ellipsometry, which tracks the optical anisotropy that results from microphase separation of the assembled domains. Measurements of the birefringence are well-correlated with surface AFM images and are in good agreement with the birefringence expected from simple geometric arguments. Furthermore, the fast sampling rate (1 sec) permits in-situ measurements of the polymer self-assembly during both thermal and solvent vapor annealing in a single, rapid measurement, and correlate with the . Ellipsometry thus presents a means to not only obtain information to inform future experimental parameters for obtaining ordered phases, but also may be utilized as a novel technique to study the assembly kinetics of soft materials.

2:54PM P34.00003: A fluorescence-based method for determining order-disorder transition temperatures in block copolymers  MUZHOU WANG (Presenter), ZHE QIANG, LINGQIAO LI, JOHN TORKELSON, Northwestern University — We present a technique for observing the order-disorder transition (ODT) in block copolymers through changes in the temperature-dependent behavior of an optically fluorescent probe. This technique provides potential advantages over existing strategies such as scattering and rheology, as it is non-invasive and can be directly applied to thin films. Pyrene molecules were covalently attached to the styrene block of a PS-b-PMMA copolymer through addition of trace levels of functionalized monomer during synthesis by controlled radical polymerization. We observed a discontinuous change in the intensity ratio of the pyrene vibronic emission bands as the polymer was heated through its ODT. As this intensity ratio is sensitive to the chemical environment surrounding these molecules, we hypothesized that this change occurs as the pyrenes are in contact with only PS when the polymer is ordered, but experiences an averaged effect of both PS and PMMA in the disordered state. We then applied this ODT measurement technique to thin films, where an increase in $T_{ODT}$ is observed when the substrate preferentially interacts with the PMMA and the film thickness is sufficiently small. Further experiments tuned this effect by modulating the surface energy of the substrate.

3:06PM P34.00004: Evolution of disordered hyperuniformity in block copolymers thin films by homopolymer dilution  URI GABINET (Presenter), CHANGYEON LEE, CHINEDUM OSUJI, University of Pennsylvania — Disordered hyperuniform materials display long range order despite their seemingly random structure – long range density fluctuations are suppressed as reflected in a vanishing structure factor at zero wavevector. Close-packed micelles of block copolymers (BCPs) display such behavior. Here, we explore the degree of structural order in BCP thin films and manipulation of such order, through the lens of disordered hyperuniformity. We explore the effect of gradually increasing disorder by increasing the nearest-neighbor distance between micelles by homopolymer addition. The hyperuniformity of the system is evaluated as a function of BCP concentration via numerical image analysis of AFM or SEM images of the BCP films. We observe a continuous transition from a DH state to randomly disordered, as characterized by the change in scaling of particle number density with increasing BCP dilution. These results offer a new perspective on structural order in BCP thin films and add to the understanding of the evolution and emergence of hyperuniform states in disordered materials. The findings are also relevant for improved engineering of nanoscale arrays based on BCP templates towards ‘designer made’ DH materials.
3:18PM P34.00005: Fluctuation/Correlation Effects in Symmetric Diblock Copolymers: On the Disordered Phase  YAN WANG (Presenter), Chemical and Biological Engineering, Colorado State University, JING ZONG, Chemical Engineering, Mississippi State University, DELIAN YANG, Synopsys, QIANG WANG, Chemical and Biological Engineering, Colorado State University — While the polymer self-consistent field theory has gained great success in describing various inhomogeneous polymeric systems, particularly the self-assembled morphologies of block copolymers, for spatially homogeneous systems it reduces to the Flory-Huggins theory and gives the simplest, yet often qualitatively incorrect, predictions. We compare, without any parameter-fitting, the thermodynamic and structural properties of the disordered phase of symmetric diblock copolymers obtained from fast off lattice Monte Carlo (FOMC) simulations [Q.Wang and Y.Yin, J.Chem.Phys.130,104903(2009)], reference interaction site model (RISM) and polymer reference interaction site model (PRISM) theories, and Gaussian-fluctuation theory for the same model system of discrete Gaussian chains interacting with soft, finite-range repulsion used in the dissipative particle dynamic simulations. We compared the internal energy, entropy, Helmholtz free energy, pressure, constant-volume heat capacity, chain/block dimensions, and various structure factors in the systems, which unambiguously and quantitatively reveal the consequences of various theoretical approximations and validity of these theories in describing the fluctuations/correlations in disordered diblock copolymers.

3:30PM P34.00006: Multiscale Modeling of Multicompartment Micelle Consisting of Block Copolymers*  MACKENZIE MALLARD, SEUNG MIN LEE, SEUNG SOON JANG (Presenter), Georgia Inst of Tech — In this work, we present a procedure for estimating the Flory-Huggins χ-parameter for use in atomistic and mesoscale molecular simulations for multicompartment micelle consisting of multiblock copolymers. In particular, we propose improvements upon traditional Flory-Huggins theory by considering coordination number correction, dielectric screening, and molecular volume normalization. We apply this technique to several test systems. Our results demonstrate that the newly developed procedure offers high precision and consistency in predicting the Flory-Huggins χ-parameter for miscibility analysis. In addition, we discuss the application of multicompartment micelle for nano-reactor. For this, 1) we characterize the transport of small molecules through the multicompartment micelle; 2) we introduce photo-responsive chemical structure to transform the structure of micelle. From this study, we conclude that a set of well-determined χ-parameters enables the molecular design of multiblock copolymer for variety of applications utilizing molecular self-assembly.

*We thank the U.S. Department of Energy, Office of Basic Energy Sciences, for funding this work through Catalysis Contract DE-FG02-03ER15459.
**3:42PM P34.00007: Direct Observation of Block Copolymer Micelle Fragmentation in Ionic Liquids**  
JULIA T EARLY (Presenter), University of Minnesota, KEVIN YAGER, Brookhaven National Laboratory, TIMOTHY LODGE, University of Minnesota — Recently, attention has been directed to quantifying the relaxation kinetics of block copolymer micelles, such as micelle fragmentation and fusion. Studies on block copolymer micelle fragmentation typically involve indirect techniques such as small angle scattering and *ex-situ* transmission electron microscopy. In this work, the direct observation of fragmentation in 1,2-polybutadiene-*block*-poly(ethylene oxide) (PB-PEO) micelles in the ionic liquid 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide was achieved using high-temperature liquid-phase transmission electron microscopy. The kinetics of PB-PEO fragmentation were also studied for various molecular weights in one ionic liquid using time-resolved small-angle X-ray scattering and dynamic light scattering. By combining these experimental techniques, a detailed analysis of the effect of molecular weight on micelle fragmentation kinetics, along with the observation of intermediate structures during fragmentation events, was conducted. These experiments provide further insights into the equilibration kinetics of block copolymer micelles via fragmentation and the mechanism of fragmentation itself.

**3:54PM P34.00008: The Effects of the Size of Crystal Domains to the Polymorphism of Close-Packed Micelles**  
SANGWOO LEE (Presenter), LIWEN CHEN, Chemical and Biological Engineering, Rensselaer Polytechnic Institute, HAN SEUNG LEE, Characterization Facility, University of Minnesota, MIKHAIL ZHERNENKOV, National Synchrotron Light Source-II, Brookhaven National Laboratory — Polymorphism is technologically important, but its mechanistic origin is not well understood. We recently investigated the transitional structures of strongly-segregated block copolymer micelles in water in the liquid-to-solid and solid-to-solid transitions. In both transition processes, we found that the polytypes of close-packed block copolymer micelles are regulated by the size of crystal domains. In the liquid-to-solid phase transition, the crystallization of micelles proceeds by forming metastable hexagonal close-packed (HCP) structures that transform into stable face-centered cubic (FCC) structures via intermediate randomly stacked two-dimensional hexagonal close-packed (RHCP) structures. In the solid-to-solid transformation, the martensitic shear transformation of metastable FCC structures could be initiated by heating that reduces the size of metastable FCC crystal domains. These observations suggest that the polymorphism of crystalline solids is likely regulated by the size of crystal domains.
4:06PM P34.00009: Quasiperiodic Ordering of Minimally Hydrated Ionic Surfactant Micelles*  
ASHISH JAYARAMAN (Presenter), CARLOS BAEZ-COTTO, TYLER J MANN, MAHESH MAHANTHAPPA, University of Minnesota — Minimally hydrated surfactant micelles, by analogy to hard spheres, pack into high-symmetry body-centered cubic, face-centered cubic and hexagonally closest-packed structures. Recently, hydrated dianionic surfactant micelles were shown to self-assemble into low-symmetry Frank-Kasper (FK) σ and A15 morphologies. These FK phases are well-known periodic approximants of dodecagonal quasicrystals (DDQC), which possess 12-fold rotational symmetry yet lack translational symmetry. We report the formation of a well-ordered DDQC formed by oil-swollen aqueous dispersions of alkylphosphonate surfactants. Our studies show that the DDQC formation is strongly path dependent, and that different processing approaches to the same final composition instead yield periodic σ and A15 approximants. These findings coupled with the observations of irreversible thermal transformation of the DDQC into a σ phase suggest the metastability of these soft quasicrystals. This discovery illustrates avenues to tune the subtle free-energy balance prevalent among complex micellar phases and exemplifies the universality of quasiperiodic order in soft matter self-assembly.

4:18PM P34.00010: Processing Path-Dependent Complex Micelle Packings of Hydrated Diblock Polymer Amphiphiles [Invited] MAHESH MAHANTHAPPA (Presenter), University of Minnesota — Water drives the self-assembly of short diblock polymer amphiphiles into spatially periodic lyotropic liquid crystalline (LLC) mesophases, including lamellae, polycontinuous networks, hexagonally-packed cylinders (HEX), and 3D sphere packings. Beyond high symmetry body-centered cubic (BCC) and cubic close-packed micellar phases, diblock oligomers also form tetrahedrally closest-packed Frank-Kasper (FK) A15 phases. In spite of the low molecular weight of the constituent amphiphile, we recently demonstrated that judicious thermal processing of an A15 LLC enables formation of a surprisingly long-lived, non-equilibrium state. Specifically, heating an A15 phase drives transitions to BCC and HEX phases at elevated temperatures. Quenching these LLCs unexpectedly drives formation of a remarkably well-ordered, tetragonal FK sigma phase comprising 30 quasispherical micelles per unit cell as a metastable state, which takes ~150 days at 22 °C to revert to the original A15 structure. The formation and metastability of the sigma phase is contingent on sample quench rate, quench depth, and annealing temperature. These slow order-order phase transformation kinetics stem from a complex interplay of temperature-dependent phase nucleation and growth rates, which are coupled to the molecular-level rate of particle size reconfiguration and mesoscale rate of spatial rearrangement of the micelles. These findings highlight the importance of processing path-dependence on the observed mesophases of self-assembled soft materials.
Expanding spherical regions of block copolymers via designed chain architectures* YICHENG QIANG, WEI-HUA LI (Presenter), Macromolecular Science, Fudan Univ — Recently, the self-assembly of block copolymers into spherical phases has attracted renewed interest due to the discovery of Frank-Kasper spherical phases. Experiment and theory unravel that the formation of Frank-Kasper phases mainly results from the expansion of spherical region. However, it is generally believed that the spherical domains self-assembled from AB-type block copolymers are composed of the minority blocks. Breaking this generic rule so that the spherical domains are formed by the majority blocks requires new mechanisms to drastically expand the stable region of spherical packing phases. Herein, we propose a useful mechanism, and thus we design a series of dendron-like AB-type block copolymers. Our self-consistent field theory calculations predict that all these dendron-like copolymers exhibit a spherical region extending to $f > 0.5$. In particular, the maximal spherical region even approaches $f \sim 0.7$. Interestingly, such a phase diagram exhibits multiple reentrant transitions of Frank-Kasper phases.

Exotic Phase Behaviors of Purposely Designed Dendron-Like Block Copolymers* YICHENG QIANG (Presenter), WEI-HUA LI, Department of Macromolecular Science, State Key Laboratory of Molecular Engineering of Polymers, Fudan University — Within a series of purposely designed dendron-like AB-type block copolymers, self-consistent field theory (SCFT) calculations reveal that the regions of spherical phases can be extended to a volume fraction over 0.5, along with the vanishing of most traditional phases and the emergence of bicontinuous P phase as well as some exotic cylindrical phases. By changing the control parameter $\tau$ from 0 to $\infty$, these dendron-like copolymers can be reduced to dendritic block copolymers or miktoarm $AB_n$ block copolymers, respectively, which both exhibit similar phase behaviors to that of the simplest AB diblock copolymer. To demonstrate how spherical regions change non-monotonically as $\tau$, we construct a large set of phase diagrams for different $\tau$ values. We observe many exotic phase behaviors in these phase diagrams, especially about the change of the stability regions of different spherical phases including the classical BCC phase and complex Frank-Kasper phases.

2:30PM P35.00001: Modeling of complexation of oppositely charged polyelectrolytes in aqueous solutions*    MOHSEN GHASEMI (Presenter), Univ of Michigan - Ann Arbor, SEAN FRIEDOWITZ, JIAN QIN, Stanford University, RONALD LARSON, Univ of Michigan - Ann Arbor — The association of oppositely charged polyelectrolytes in aqueous solutions can lead to formation of polyelectrolyte complexes (PECs) whose properties are governed by many physiochemical parameters. PECs can be divided into overcharged complexes, where one type of polyelectrolyte charge is present in excess, and neutral ones, which contain equimolar ratios of polyanion and polycation. Using a theory, which captures the effects of chain connectivity and ion-specificity of charged species, here we rationalize why in non-stoichiometric mixtures, excess polyelectrolyte appears in the PEC and we pinpoint theoretical underpinnings of the overcharging phenomenon. Further, using the same theory, we investigate “doping” of stoichiometric PECs, in which salt concentration is increased, leading to the breaking of ion-pairs between oppositely charged groups of polyelectrolytes and their replacement with counterions. We find that the predictions of the level of counterion replacement during doping follow a similar trend to data from doping experiments. The development of such theories to could lead to methods of rational design of practical applications of PECs.

2:42PM P35.00002: ``Looping-back'' complexation in stoichiometrically asymmetric polyelectrolyte solutions    SEAN FRIEDOWITZ (Presenter), JUNZHE LOU, YAN XIA, JIAN QIN, Stanford Univ — The complexation of ionic polymers is typically studied in model systems lacking compositional heterogeneity that is often unavoidable in realistic systems. We address this by examining the coacervation behavior of synthetic, homologous polyions over a range of stoichiometric asymmetry between polyanions and polycations. An unexpected, narrow ``looping-back'' coexistence window is observed at low salt concentrations, and is captured by a theoretical model incorporating reversible ion-binding and chain connectivity, revealing the importance of the competition between charge neutrality and mixing entropy. Partitioning of both small ions and polyions between the supernatant and coacervate phases is measured, and theoretically analyzed.
The first report on a synthetic polyelectrolyte, polyacrylic acid, was published by W. Kern (1939). Ten years later, Fuoss and Sadek reported the first complex between two synthetic, oppositely-charged polyelectrolytes. At the time, it seemed evident that “strong electrostatic interactions would lead to mutual precipitation.” However, Michaels could not measure an enthalpy of complexation and concluded it was driven by entropy or the “escaping tendency of microions.” With more sensitive calorimetric measurements, complexation enthalpies were again ascribed to the coulombic forces assembling the component polyelectrolytes. In this talk I will show how polyelectrolyte coacervates, complexes and multilayers rely on the loss of counterions, an entropic driving force, to assemble. This overall driving force is moderated by an enthalpic contribution attributed to changes in the structure of water around counterion-compensated polyelectrolyte repeat units. The experimentally-determined relative ion concentrations within and external to a PEC are predicted by the Donnan equilibrium.

*This work was supported by the National Science Foundation, Division of Materials Research

Polyelectrolyte complexation opens new territory for polymer self-assembly. Micelles with complex cores are formed from neutral-charged block copolymers complexing with oppositely charged homopolymers and copolymers. The resulting objects bear a physical resemblance to micelles formed from solvophobic self-assembly of block copolymers. However, the details of formation, exchange, dissociation and scaling laws are all different. These characteristics will be discussed. The cores of these micelles can be used as depots and delivery vehicles for oppositely charged macromolecules. When these macromolecules are biologically active, such as proteins and nucleic acids, polyelectrolyte complex micelles can be used as therapeutic delivery vehicles. We have studied such micelles with nucleic acid-containing cores in detail with some unexpected results. At high concentrations of these micelles, when they begin to impinge on one another, they form as series of ordered phases with varying structures from bcc to hexagonal to lamellar. This set of structures and their associated properties will be discussed at length.

Measurements on a common linear oppositely-charged polyelectrolyte complex, potassium-poly(styrene sulfonate) and poly(diallyl dimethyl ammonium bromide), shows liquid-liquid phase separation upon heating, or lower critical solution temperature behavior. The experimental accessibility of the binodal temperature occurs for a narrow range of monovalent salt concentration. We will report new results on the kinetics of phase separation studied by scattering techniques as a function of quench depth from the binodal. The growth rate of concentration fluctuations will be discussed and compared to available theories.
3:54PM P35.00006: Quantification of the lower critical solution temperature phase diagram of polyelectrolyte complex coacervates  YUANCHI MA (Presenter), SAMIM ALI, YIMIN MAO, DEBRA AUDUS, VIVEK PRABHU, National Institute of Standards and Technology, Gaithersburg, MD — Measurements on a common aqueous oppositely-charged polyelectrolyte complex, potassium-poly(styrene sulfonate) and poly(diallyl dimethyl ammonium bromide), shows liquid-liquid phase separation upon heating, or lower critical solution temperature behavior. The experimental accessibility of the apparent critical temperatures occurs for a narrow range of monovalent KBr salt concentration. We will show new static and dynamic light scattering and small-angle neutron scattering results and discuss how the correlation length, osmotic compressibility, and relaxation times change as the coexistence curve is approached by increasing temperature. The measurements of the binodal and spinodal curves from these associating polyelectrolyte solutions are compared to available mean field models.

4:06PM P35.00007: An Anomalous Small Angle X-ray Scattering Study of Counterion Distribution around Macroion*  JIAHUI CHEN (Presenter), Univ of Akron, MRINAL BERA, NSF’s ChemMatCARS Sector 15, The University of Chicago, TIANBO LIU, Univ of Akron — Counterion condensed around marcoion is important for solution behavior. While other techniques can hardly achieve, anomalous small angle X-ray scattering (ASAXS) can provide numbers and spatial distribution of counterions around macroion. (Mo_{132}), a negatevely charged sphere of ~3 nm diameter, was used as model of macroions to investigated by ASAXS. The result shows: 1. Extra Rb^{+} can neutralize most of negative charges and induce coagulation. 2. Extra Sr^{2+} can effectively screen the electrostatic interaction between macroions, while contrary to DLVO or Debye-Huckel theory, it only loosely associate with macroion and cannot induce coagulation. While the Coulomb force dominate the interactions between macroions and counterions in most cases, the energy penalty of break the hydration shell of divalent cation upon counterion-macroion association is important.

*The ASAXS were conducted at NSF’s ChemMatCARS, which is supported by the Divisions of Chemistry and Materials Research, National Science Foundation, under grant number NSF/CHE 1834750. Use of the Advanced Photon Source, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science by Argonne National Laboratory, was supported by the U.S. DOE under Contract No. DE-AC02-06CH11357.
The Complexation of oppositely charged polyelectrolytes through electrostatic interaction is ubiquitous in both natural and synthetic systems. One of the microscopic properties of interest in polyelectrolyte complexes (PEC) is the polymer chain conformation of a labeled chain. Recent literature studies on polycation/polyanion chain conformation in PECs using small-angle neutron scattering reported Gaussian chain statistics. Such scaling behavior is unlike polymer chains dissolved in good solvents, which show Gaussian statistics only at very high polymer concentrations (semidilute state). This behavior appears to be independent of chain length, salt concentration, and polymer concentration. We performed coarse-grained Langevin dynamics simulations of symmetric and flexible PECs and counterions, with and without salt added. As we gradually increase polymer concentration, the polymer chains transition from a globule-like state and level off to a Gaussian chain conformation. Qualitatively, similar behavior was also observed in the presence of salt. The polycations and polyanions have been observed to be highly overlapped in both cases. Such a qualitative agreement with experiments is observed because of the strong electrostatic driving force for complexation.

Constraint Release in Entangled Liquid Coacervates Made from Oppositely Charged Polyelectrolytes

Mixtures of oppositely charged polyelectrolytes can phase separate to form a polymer rich coacervate phase, important in many technological applications and biological systems. Many studies focus on formation of the coacervate, but less work has focused on predicting their dynamics. We developed a scaling theory predicting the dynamics of unentangled and entangled liquid coacervates, finding that the structure of asymmetric coacervates results in a dynamic coupling between the high and low charge density polymers. The high charge density polymer can either reptate along the tube formed by other high charge density chains or along the tube formed by low charge density chains. In the latter, topological constraints imposed by the low charge density chains onto the high charge density chains vary with time by reptation of low charge density chains through the process called constraint release. In this work, we develop a scaling model to predict the effects of constraint release on entangled asymmetric coacervates, finding that the dynamic coupling broadens regimes dominated by tube rearrangement as compared to symmetric coacervates. Furthermore, constraint release weakens the concentration dependence of viscosity in regimes dominated by reptation of the high charge density chains.
Solid-to-Liquid Phase Transition in Polyelectrolyte Complexes: Structural Evolution, Dynamics, and Phase Behavior

SIQI MENG (Presenter), JEFFREY M TING, HAO WU, MATTHEW TIRRELL, Pritzker School of Molecular Engineering, University of Chicago — The physical states of polyelectrolyte complexes (PECs), formed by mixing together solutions of oppositely charged polyelectrolytes, can span from glassy solids to low viscosity liquids. Transformation between these two states can be readily achieved by altering salt concentration and temperature, but our understanding towards this process is still incomplete. To fill this gap, we here study a model PEC system comprising two controllably synthesized styrenic polyelectrolytes. We first employed rheology to determine phase and evaluate mechanical properties of this PEC under different conditions. Surprisingly, we detected a counterintuitive trend that in the solid regime, these complexes became stiffer as temperature and salt concentration increased. Above certain threshold, viscoelastic liquid responses appeared. Next, we used small-angle X-ray scattering and cryogenic electron microscopy to unveil the structural evolution of this PEC. Additionally, thermogravimetric analysis was adopted to quantitatively probe water composition and phase behavior. Together, structures, dynamics and phase behavior demonstrated excellent agreement and dictated an integrated mechanism for the physical responses of this PEC system during solid-to-liquid phase transition.

Free Energy Profile of Complexation of two oppositely charged Polyelectrolytes

SOUMIK MITRA (Presenter), ARINDAM KUNDAGRAMI, IISER Kolkata — We report a study of the complexation process of two oppositely charged polyelectrolyte (PE) chains in dilute solution interacting through screened Coulomb potential within the DLVO framework. The two PE chains, as well as the neutral complex, are considered to be hypothetical spheres whose radii quantitatively denote the sizes of the respective chains, and the system is characterized by its free energy, calculated within the uniform spherical expansion approximation. Detailed comparative study of the effect of entropy gain of free counterions due to complexation and enthalpy change due to the reorganization of ion-pairs into two types—both of the monomer-counterion type and oppositely charged monomer-monomer type—is shown. We have looked into both salt-free and salty conditions and how it affects the complex formation process. Several factors drive the mutual adsorption of the two PEs to form a neutral coacervate. The full free energy profile of complexation, including the intermediate stages, is found to be monotonic at all conditions. A free energy landscape for the pathway of the complexation process may also be employed in studying the quantitative time scales in the kinetics of complex coacervation of two PEs.

5:06PM P35.00012: Scaling relation of Complex Coacervate Core Micelles  
TAEYOUNG HEO  
(Presenter), Hongik University, DEBRA AUDUS, National Institute of Standards and Technology,  
SOOHYUNG CHOI, Hongik University — Complex coacervation is a liquid-liquid phase separation  
when two oppositely charged polyelectrolytes are mixed in an aqueous solution. Because of the  
nature of electrostatic interaction, the coacervates are highly responsive to solution condition  
such as ionic strength. In this study, complex coacervate core micelles (C3Ms) are prepared by  
simple mixing of AB and A'B diblock copolyelectrolyte solutions in an aqueous solution where A  
and A' are oppositely charged blocks, and B is PEO block. Owing to the coacervate cores, C3Ms  
have been used for stimuli-responsive vehicles in the field of food, cosmetics and biomedical  
industry. For wider utilization of C3Ms, understanding the scaling relation is significant. We have  
developed the scaling relation for C3Ms such as core dimension as a function of charged block  
length and ionic strength, and compared to experimental data obtained by light, x-ray, and  
neutron scattering measurements. These results are discussed in terms of current understanding  
of complex coacervates including free energy and interfacial tension.

5:18PM P35.00013: Ionic-group-dependent phase behavior of polyelectrolyte coacervates  
SOJEONG KIM  
(Presenter), MINHWAN LEE, WON BO LEE, Seoul Natl Univ, SOOHYUNG CHOI, Hongik  
University — Complex coacervates are polymer-rich phases generated by liquid-liquid phase  
separation when oppositely charged polyelectrolytes are mixed in aqueous solutions. Since the  
previous Voorn-Overbeek model does not account for the chain connectivity and chemistry-  
specific details, advanced models have been suggested up to now. However, experimental data  
of well-defined model system is rare to compare with the theoretical description. In this study, 4  
polyelectrolytes are prepared (e.g., strong/weak and polyanion/polycation) from identical parent  
polymer using anionic polymerization, and thus 4 pairs of polyelectrolyte complex coacervates  
are investigated to map out the phase diagrams as a function of the pair of ionic group. It is  
found that the phase diagram shows distinctive features including salt resistance, the area of a  
two-phase region and the shape of binodal curves depending on the pairs of polyelectrolytes. In  
addition, atomistic MD simulations give molecular-level insight into the interaction of two  
charged moieties and especially show a clear difference in the ability to form hydrogen bonds.  
We believe chemistry specific parameters play an important role in control phase behavior and  
these findings shed new light on the biologically important topic of complex coacervation.

2:30PM P39.00001: Heterogeneous proton-coupled electron transfer at nanoparticle and electrode interfaces [Invited] SHARON HAMMES-SCHIFFER (Presenter), Yale University — Interfacial proton-coupled electron transfer (PCET) reactions play a vital role in a wide range of energy conversion processes. A general theory of PCET that includes the quantum mechanical effects of the active electrons and transferring protons, as well as the motions of the proton donor-acceptor mode and solvent environment, has been developed. This formulation enables the calculation of rate constants and kinetic isotope effects for homogeneous as well as heterogeneous processes at nanoparticles and electrode surfaces. This theory has been applied to experimentally studied photoreduced ZnO nanocrystals reacting by PCET with the nitroxyl radical TEMPO. The calculations indicate that the electron transfers from the conduction band of the ZnO nanocrystal to TEMPO concertedly with proton transfer from a surface oxygen of the ZnO nanocrystal to the oxygen of TEMPO. Proton diffusion from inside the nanocrystal to reactive sites on the surface was found to explain the experimentally observed nonexponential kinetics. This PCET theory has also been applied to experimentally studied proton discharge from triethylammonium to a gold electrode in acetonitrile. These experiments demonstrated an isotope-dependent Tafel slope or, equivalently, a potential-dependent kinetic isotope effect. The calculations explain the potential-dependent kinetic isotope effect in terms of contributions from excited electron-proton vibronic states that depend on both isotope and applied potential. Proton discharge to a gold electrode in acidic and alkaline aqueous solution has also been studied. These applications highlight the importance of using a vibronically nonadiabatic theory that quantizes the transferring proton and includes the effects of hydrogen tunneling and excited electron-proton vibronic states. These studies are also assisting in the interpretation of experimental data and the design of more effective catalysts for energy conversion processes.

3:06PM P39.00002: Excitation Dynamics in Water under Proton Irradiation: Time-dependent Maximally-Localized Wannier Function Approach* CHRIS SHEPARD (Presenter), DILLON C YOST, YI YAO, YOSUKE KANAI, Univ of NC - Chapel Hill — Proton irradiation of liquid water has many important medical applications, including proton beam therapy. However, understanding the quantum dynamical details of the electronic excitations of water induced by the energetic protons has long been intangible. Using the approach of propagating maximally localized Wannier functions (MLWFs) in real-time TDDFT, we study the molecular-level dynamics of the electronic excitations\(^1\). These time-dependent MLWFs (TD-MLWFs) are localized in space, offering a convenient ‘chemical moiety’ picture of liquid water and allow for understanding of the electron dynamics in terms of bond centered and lone pair electrons of water molecules. The spatially-localized nature of the TD-MLWFs allows us to study the secondary electronic excitations from the electrons initially excited by the proton. The MLWF gauge also enables usage of the length-gauge to describe the homogeneous electric field to model photo-excitation, and analyze proton and photo- irradiation on equal footing.

3:18PM P39.00003: Time-dependent exciton wave functions from TDDFT*  JARED R. WILLIAMS (Presenter), CARSTEN A. ULLRICH, Physics and Astronomy, Univ of Missouri - Columbia — Time-dependent density-functional theory (TDDFT) is a computationally efficient alternative to the Bethe-Salpeter equation for calculating optical spectra in insulators and semiconductors, including excitonic effects. We show how time-dependent exciton wave functions can be obtained from TDDFT via the time-dependent Kohn-Sham transition density matrix. The method is illustrated using one-dimensional model solids.

*This work was supported by NSF Grant No. DMR-1810922.

3:30PM P39.00004: Transient X-ray absorption spectra in solids from generalized Kohn-Sham real-time TDDFT.*  SRI CHAITANYA DAS PEMMARAJU (Presenter), SLAC - Natl Accelerator Lab — Simulating transient X-ray absorption spectra in solids with TDDFT requires at a minimum, a balanced treatment of both localized core and possibly delocalized valence excitations. To this end range-separated hybrid exchange-correlation functionals offer improved accuracy by mitigating self-interaction errors across multiple length-scales [1,2]. In this work the velocity-gauge formulation of real-time TDDFT is combined with multiply-range-separated hybrid functionals to simulate transient soft X-ray near-edge absorption spectra in solids where excitonic effects are important. Immediately following laser excitation by few femtosecond pump pulses, soft X-ray probe spectra are shown to exhibit characteristic features of population induced bleaching and transient energy shifts of exciton peaks. Simulation results are assessed for accuracy by comparison with experimental data on prototypical solid state systems.

3:42PM P39.00005: TD-DFT without wavefunctions  KAILI JIANG (Presenter), XUECHENG SHAO, MICHELE PAVANELLO, Rutgers University, Newark — We present an extension of Orbital-Free Density Functional Theory (OFDFT) to the time domain (TD-OFDFT). The method hinges upon approximating the wavefunction of the system by a single effective orbital augmented by a position-dependent phase factor. We find that such a simplified picture still delivers good optical spectra and response properties for metal clusters, surfaces and bulk systems. Specifically, we show that the method delivers plasmonic collective electronic excitations of metal clusters in reasonable agreement with Kohn-Sham TD-DFT. Because of the simplicity of the model, and the efficient codebase [1], the simulations are extremely computationally efficient delivering converged results in wall-times two or more orders of magnitude smaller than conventional Kohn-Sham TD-DFT.

3:54PM P39.00006: Pre-equilibrium stopping power mechanisms in proton-irradiated aluminum sheets* ALINA KONONOV (Presenter), ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — Although ion-irradiation is a standard tool for imaging and altering materials' surfaces, most existing knowledge concerning an energetic ion's interaction with solids is limited to bulk materials. As an ion approaches and traverses a surface, it is expected to exchange charge with the material and transition into bulk conditions resembling a steady-state. To gain insight into this so-called pre-equilibrium behavior, we use real-time time-dependent density functional theory to simulate protons with 6 - 60 keV of kinetic energy impacting few-layer aluminum sheets. We find up to 25% stopping power enhancement in aluminum sheets compared to bulk, particularly near the entrance surface, and we examine several possible explanations for this behavior including pre-equilibrium projectile charge dynamics, polarization induced in the sheet during the proton's approach, and surface plasmon excitations. Our analysis suggests that surface plasmons are a plausible source of stopping power enhancement, while the contribution of the other potential mechanisms is either small or inconclusive. Such pre-equilibrium behavior has particularly important implications for optimizing focused ion beam techniques for 2D materials.

4:06PM P39.00007: Quantitative electronic stopping power from localized basis set* IVAN MALIYOV (Presenter), XIXI QI, JEAN-PAUL CROCOMBETTE, FABIEN BRUNEVAL, Service de Recherches de Métallurgie Physique, CEA-Saclay — In charged particle irradiation, the electronic excitations are the prevailing phenomenon. The energy transfer from the projectile to the electrons of the target material is measured by the so-called electronic stopping power. Today, it can be obtained from time-dependent density functional theory [1]. Most implementations rely on a plane-wave approach, however, at the expense of very cumbersome calculations.

In this work, we show that localized orbitals, especially Gaussian-type orbitals, can be an practical alternative [2]. They can yield electronic stopping powers in quantitative agreement with the plane-wave results, while retaining the computational burden relatively low. These positive results are only possible with the use of Gaussian basis sets specially designed for the stopping power evaluation. With this tool, we investigate the discrepancy between TDDFT calculations and experiment at large velocity, the role of core excitations in the total stopping power. We rule out the wide-spread centroid path approximation as soon as some core excitations are involved.

4:18PM P39.00008: New Simulation Method for Temperature Dependent Magnetic Circular Dichroism with Non-Perturbative Treatment of Magnetic Field*  SHICHAO SUN (Presenter), XIAOSONG LI, University of Washington — Magnetic circular dichroism (MCD) is an important experimental tool for probing open shell molecules, but the simulation is challenging. First, simulating MCD involves multiple perturbations, such as magnetic field, spin-orbit coupling and circularly polarized light. Second, the ground state Zeeman splitting comparable with kT makes MCD temperature dependent. Scientists used to parameterize temperature dependence, and evaluate the perturbation by sum over states or excited state gradient method. However, such perturbations increase the computational cost and fail in strong magnetic field. We developed a non-perturbative treatment of magnetic fields and spin-orbit coupling in linear response non-collinear TDDFT formalism, which simplifies the perturbation. It is especially advantageous for strong magnetic field. In order to resolve the temperature dependence of MCD, excitations are weighted by temperature dependent occupation number. This method is applied in Mo(CN)$_8^{3-}$ and gives correct MCD-temperature dependence.

*The development of two-component electronic structure method is funded by the US Department of Energy (DE-SC0006863). The development of non-perturbative spectroscopic methods is supported by the National Science Foundation (CHE-1856210).

4:30PM P39.00009: Polarization dependence of optical excitations in anisotropic metal/insulator heterostructures*  MARKUS ERNST GRUNER, ROSSITZA PENTCHEVA (Presenter), Department of Physics, University of Duisburg-Essen — In the framework of real-time time-dependent density functional theory (RT-TDDFT) we unravel the layer-resolved dynamics of a Fe$_1$/(MgO)$_3$(001) multilayer after optical excitations. Short optical pulses with two polarization directions of light and a frequency smaller than the band gap of bulk MgO induce strong anisotropic dynamic response: Substantial transient changes to the electronic structure, which persist after the duration of the pulse, are only observed for in-plane polarized electric fields. We find the largest effect in the Fe-layer, but time-dependent changes in the occupation numbers are visible in all layers, promoted by the presence of interface states. The time evolution of the layer-resolved occupation numbers indicates transfer from in-plane to out-of-plane orbitals that support the propagation of optically induced excitations into the interface region. We also see a small net charge transfer away from oxygen towards the Mg sites even for MgO layers, which are not directly in contact with the metallic Fe.

4:42PM P39.00010: Dissociation Path Competition of Radiolysis-Ionization induced Molecule Damage under Electron Beam Illumination  ZENGHUA CAI, SHIYOU CHEN (Presenter), East China Normal University, LIN-WANG WANG, Lawrence Berkeley National Laboratory — The radiolysis ionization under electron beam illumination induces dissociation and damage of organic and biological molecules, which causes the inability of transmission electron microscopy (TEM) in imaging the related materials. We developed a procedure based on the real-time time-dependent density functional theory (rt-TDDFT) for simulating the radiolysis damage processes of molecules, which can describe the ionization cross sections of electronic states and the fast dissociation processes caused by the hot carrier cooling and the Auger decay on deep levels. For the radiolysis damage of C$_2$H$_6$O$_2$, our simulation showed unexpectedly that there is strong competition among three different dissociation paths, including the fast dissociation caused by the hot carrier nonadiabatic cooling; the fast dissociation caused by Auger decay induced double ionization and Coulomb explosion; the slow dissociation caused by the increased kinetic energy. As the energy of incident electron beam changes, the time scales of these dissociation paths and their prudency in causing the molecule damage change significantly. These results explained the measured mass spectra of the C$_2$H$_6$O$_2$ dissociation fragments, and revealed the dissociation paths in the TEM imaging of organic and biological materials.

4:54PM P39.00011: Generalized nanoquanta exchange-correlation kernel and nonhydrogenic Rydberg series of excitonic binding energies in monolayer WS$_2$  VOLODYMYR TURKOWSKI (Presenter), JOSE MARIO GALICIA-HERNANDEZ, Department of Physics, University of Central Florida, Orlando, FL 32816, GREGORIO HERNANDEZ-COCOLETZI, Instituto de Fisica Ing. Luis Rivera Terrazas, Benemerita Universidad Autonoma de Puebla, Puebla 72550, Mexico, TALAT S. RAHMAN, Department of Physics, University of Central Florida, Orlando, FL 32816 — We have formulated a methodology to derive a generalized nanoquanta (nanoquanta+) TDDFT exchange-correlation (XC) kernel that is capable of describing excitonic properties of extended systems. Compared to the standard nanoquanta XC kernel, the generalized one takes into account screening effects more accurately through the usage of exact (beyond one-loop) electron susceptibility in the formalism. As we demonstrate for the example of monolayer WS$_2$, such an improved XC kernel allows one to reproduce accurately the experimentally-observed nonhydrogenic Rydberg series in the excitonic spectrum, [1] which has so far not been possible with other familiar kernels. We also calculate the effective electron-hole potential that enters the TDDFT eigen-energy equation of excitons, and demonstrate that the reason for the nonhydrogen Rydberg energy series is a non-Coulomb structure of the potential. We discuss the general properties of the nanoquanta+ kernel and compare them to that of other XC kernels employed for extracting properties of excitons.

Wednesday, March 4, 2020 2:30 PM - 5:18 PM
2:30PM P40.00001: Matter in Extreme Environments: Novel Chemistry under Pressure

MAOSHENG MIAO (Presenter), Chemistry and Biochemistry, California State University, Northridge — Thanks to the developments of high-pressure techniques and quantum mechanics based crystal structure prediction methods, numerous novel compounds with atypical compositions have been obtained or predicted in the past decade. Differing from conventional solid materials, many of these new compounds consist of various homonuclear chemical species such as dimers, trimers, pentagonal and heptagonal rings, polymer chains, atomic layers, and three-dimensional networks, unexpectedly telling a story of rich chemistry under pressure. More strikingly, pressure can alter the chemical characteristics of elements by activating the core electrons, the unoccupied orbitals and the quantum orbitals at the interstitial sites, leading to many new surprising phenomena. In this talk, I will outline the novel compounds and the new chemical phenomena within one conceptual framework based on the change of quantum states of electrons under high pressure. In contrast to the conventional view and chemical intuition, the quantum mechanics features of electrons such as directional bonds, inhomogeneous distribution, lower symmetry etc. are actually magnified by the increasing pressure, giving rise to rich moieties and variations in novel inorganic compounds. One striking example is that the core electrons can be activated to form bonds, violating a primary principle of chemistry. Other examples include electrons detaching from all atoms to play the role of anions at the interstitial sites (electrides), noble gases behaving as anions because their outer-shell $d$ orbitals gain electrons, and noble gases reacting with ionic compounds without forming any chemical bonds. The influence of this new picture on future studies that is destined to higher pressures, more complex compositions and applicable materials is discussed.

Theoretical phase diagram of boron carbide $B_xC$ from ambient to high pressure ($P$) and high temperature ($T$): the “single phase” regime in the light of the density functional theory (DFT) results*

antoine jay, Laboratoire d'analyse et d'architecture des systèmes, CNRS, Toulouse, olivier hardouin duparc, jeleña sjakste, cnrs, laboratoire des solides irradiés, nathalie vast (Presenter), cea-saclay, laboratoire des solides irradiés — the phase diagram of boron carbide is calculated within the DFT as a function of $T$ and $P$ up to 80 GPa, accounting for icosahedral, graphite- and diamond-like atomic structures [1]. Only some icosahedral phases turn out to be thermodynamically stable with atomic carbon concentrations ($c$) of resp. 8.7% ($B_{10.5}C$), 13.0% ($B_{6.7}C$), 20% ($B_{4}C$) and 28.6% ($B_{2.5}C$). Their respective ranges of stability under pressure and temperature are calculated, and the theoretical $T$-$P$-$c$ phase diagram boundaries are discussed. At ambient conditions, the introduction in the phase diagram of the new phase $B_{10.5}C$, with an ordered crystalline motif of 414 atoms, is shown to bring the theoretical solubility range of carbon in boron close to the experimental one. The introduction of configurational entropy heavily changes the convex hull at finite temperature. We discuss the occurrence of the “single phase regime” in the light of these new results.

Novel tunable band gap BC8/ST12 Si$_x$Ge$_{x-1}$ alloys: insights from first-principles calculations*

johnes wagner (Presenter), helmholtz-centre potsdam (gfz), maribel nunez valdez, goethe university frankfurt am main & helmholtz-centre potsdam (gfz) — the cubic $Ia\-3$ (BC8) and tetragonal $P4_{3}2_{1}2$ (ST12) modifications of Si and Ge are promising candidates for applications in optoelectronic, thermoelectric or plasmonic devices. However the indirect and narrow band gaps are a limiting factor of the pure phases. Si-Ge alloys in these modifications could overcome this drawback and enable tailoring for specific use-cases. To that end, high pressure BC/ST12 Si$_x$Ge$_{x-1}$ solid solutions for $0 \leq x \leq 1$ have been synthesized and reported to be stable at ambient conditions[1]. Here we employ ab initio calculations to further investigate the electronic properties of these alloys as a function of $x$. We show how atomic site occupancy affects the band gap and which atomic arrangements stabilize intermediate compositions. We find that the ST12 phase is energetically favorable up to $x$=0.75 and that the indirect band gap of the ST12 Ge end-member can be tuned to become direct for $0.05 \leq x \leq 0.2$. Furthermore, we obtain the effective band structure of intermediate random alloys by calculating special quasi random structures (SQS) for selected compositions.

3:30PM P40.00004: First-Principles Simulation of Strain Effects on Lanthanum Monopnictides
CHIA-MIN LIN (Presenter), WEI-CHIH CHEN, CHENG-CHIEN CHEN, Department of Physics, Univ of Alabama - Birmingham — Rare-earth monopnictides have attracted significant attention due to their exotic electronic and topological properties with potential thermoelectric and spintronic applications. Here, we theoretically investigate strain effects on lanthanum monopnictides LaX (X = N, P, As, Sb, and Bi) by first-principles simulations using hybrid density functionals with spin-orbit coupling. In particular, the phonon properties, electronic bandstructures, and topological natures of these materials under compressive and tensile strains are computed. It is shown that strain engineering is an effective approach to manipulating the properties of LaX for improved performance and device applications.

3:42PM P40.00005: A First-Principles Exploration of Na$_x$S$_y$ Binary Phases at 1 atm and Under Pressure
NISHA GENG (Presenter), TIANGE BI, NILOOFAR ZARIFI, Chemistry, University at Buffalo, YAN YAN, School of Science, Changchun University, EVA ZUREK, Chemistry, University at Buffalo — Interest in Na-S compounds stems from their use in battery materials at 1 atm, as well as the potential for superconductivity under pressure. Evolutionary structure searches coupled with Density Functional Theory calculations were employed to predict stable and low-lying metastable phases of sodium poor and sodium rich sulfides at 1 atm and within 100–200 GPa. At ambient pressures, four new stable or metastable phases with unbranched sulfur motifs were predicted: Na$_2$S$_3$ with C2/c and Imm2 symmetry, C2 -Na$_2$S$_5$ and C2 -Na$_2$S$_8$. Van der Waals interactions were shown to affect the energy ordering of various polymorphs. At high pressure, several novel phases that contained a wide variety of zero-, one-, and two-dimensional sulfur motifs were predicted, and their electronic structures and bonding were analyzed. At 200 GPa, P4/mmm -Na$_2$S$_8$ was predicted to become superconducting below 15.5 K, which is close to results previously obtained for the β-Po phase of elemental sulfur. The structures of the most stable M$_3$S and M$_4$S, M = Na, phases differed from those previously reported for compounds with M = H, Li, K.
Tuning Magnetic and Electronic Properties in Exotic Silver(II) Fluorides Using Pressure

WOJCIECH GROCHALA (Presenter), ADAM GRZELAK, JAKUB GAWRACZYNSKI, Center of New Technologies, University of Warsaw, DOMINIK KURZYDLOWSKI, Faculty of Mathematics and Natural Sciences, Cardinal Stefan Wyszynski Univ., ZORAN MAZEJ, Dept. of Inorg. Chem. and Techn., Jozef Stefan Institute, VITALI PRAKAPENKA, Center for Advanced Radiation Sources, University of Chicago, MARIANA DERZSI, Center of New Technologies, University of Warsaw, VIKTOR STRUZHUKIN, Geophysical Laboratory, Carnegie Institution for Science, PAOLO BARONE, SPIN, CNR, JOSE LORENZANA, Dept. of Physics, ISC-CNR and Univ. of Rome — Silver(II) fluorides exhibit unique structural, electronic and magnetic features which render them similar to parent compounds of high-TC oxocuprate superconductors. These encompass the reduced structural and magnetic dimensionality, the persistence of the Jahn-Teller effect, substantial covalence of chemical bonding between metal and nonmetal (d-p hybridization), potent magnetic superexchange via nonmetal atom, insulating charge-transfer character within the Zaanen-Sawatzky-Allen classification, small energy band gap at the Fermi level, comparable Debye frequencies, etc. Here I will discuss the behaviour of some of these materials (including doped systems) at elevated pressure conditions as obtained from combined experimental and theoretical studies. Influence of high pressure on bonding, as well as electronic and magnetic properties, will be discussed. Possibility to achieve metallization and superconductivity will also be addressed.

**4:30PM P40.00007: The change of basic chemical behavior of elements under high pressure**

*YUANHUI SUN (Presenter), MAOSHENG MIAO, California State University, Northridge —

The chemistry at ambient condition has implicit boundaries rooted in the atomic shell structure: The inner-shell electrons and the unoccupied outer-shell orbitals do not involve as major component in chemical reactions and in chemical bonds. The chemical properties of atoms are determined by the electrons in the outermost shell; hence, these electrons are called valence electrons. These general rules govern our understanding of chemical structures and reactions. Using first principles calculations, we demonstrate that under high pressure, the above doctrines can be broken. Our previous studies showed that both the inner shell electrons and the outer shell empty orbitals of Cs and other elements can involve in chemical reactions. The formation of CsF\(_n\) (\(n > 1\)) compounds demonstrates that Cs atom can behave like a \(p\)-block element under high pressure.[1] Besides, we found that Hg in Hg-F compounds transfers charge from the \(d\) orbitals to F atoms, thus behaving as a transition metal.[2] We have extended the above study and found that the involvement of core electrons in forming chemical bonds is a common phenomena while the external pressure is high enough.

**4:42PM P40.00008: Ultrahigh-pressure induced decomposition of silicon disulfide into high coordination number silicon-sulfur compounds**

*YUANZHENG CHEN (Presenter), School of Physical Science and Technology, Southwest Jiaotong University, Chengdu 610031, China., XIAOLEI FENG, SIMON A. T. REDERN, Department of Earth Sciences, University of Cambridge, Cambridge, CB2 3EQ, UK, HANYU LIU, College of Physics, Jilin University, Changchun 130012, China — SiS\(_2\) is thought to occur in inter-stellar dust and is of interest more generally among the silicon chalcogenides as a comparator to SiO\(_2\), an important component of terrestrial planets. However, the high-pressure behaviors of silicon sulfides are unclear. Here, using an efficient structure search method, we systematic explore the structural evolution of different Si-S stoichiometries up to 250 GPa. We find that SiS\(_2\) is only stable below 155 GPa, which then decomposes into two previously-unreported compounds, SiS and SiS\(_3\), at higher pressures. SiS adopts a high symmetry \(Pm\)-3\(m\) structure consisting of 8-fold coordinated silicon in face-sharing SiS\(_8\) polyhedra, while SiS\(_3\) crystallizes in \(R3m\) structure containing 9-fold coordinated SiS\(_9\) polyhedra. Analysis suggests the new Si 8-fold coordination environment could be a common feature for group IV-VI compounds under high pressure. Our findings provide key insights on the nature of the Si-S compounds under ultrahigh pressure.

4:54PM P40.00009: A novel all-nitrogen molecular crystal as promising high-energy density material LEI ZHAO (Presenter), California State University, Northridge, SHIJIE LIU, School of Physics and Engineering, Henan University of Science and Technology, YUANZHENG CHEN, School of Physical Science and Technology, Southwest Jiaotong University, WENCAI YI, Department of Physics, Qufu Normal University, FENGLONG GU, School of Chemistry and Environment, South China Normal University, YONGHAO ZHENG, School of Optoelectronic Science and Engineering, University of Electronic Science and Technology of China, BINGBING LIU, State Key Laboratory of Superhard Materials, Jilin University, MAOSHENG MIAO, California State University, Northridge — In the decades-long search for energy-dense materials capable of greater energy output, many studies have focused on nitrogen rich compounds, which have the advantages of relative stability at ambient conditions, high-energy output when broken down, and a clean gas product (N₂) that is inert, non-toxic, and a non-contributor to the greenhouse effect. The most stable form of nitrogen under ambient condition is N₂ molecular crystal, because of its exceedingly stable triple bond in nature. Besides N₂, there is not any report of other all nitrogen molecular crystals either at ambient condition or under high pressure, except a recently reported N₈ crystal. Here, using ab initio calculations combined with an intelligence structure-searching, we report the discovery of a thermodynamically stable nitrogen molecular crystal, which has perfect packing and more energetic stability at lower pressure range, compared with the N₈ crystal. While decompose at ambient pressure, this all nitrogen molecular crystal can release great amount of energy (~2.90 kJ/g).

5:06PM P40.00010: Structure and Stability of Oxyfluorides and Oxychlorides and Their Relations to Catalytic Activities in Oil Refining Reactions DALAR KHODAGHOLIAN (Presenter), California State University, Northridge — Metal oxides have long been used as catalysts or supporters of catalysts in petroleum refining processes. Mixing anions such as fluorine into the structures of these compounds can greatly enhance their structural stability. Therefore, metal oxyfluorides are potential candidates for such catalysts due to their stability, atomic and electronic properties. The stability of several compositions of these compounds has been investigated, combining different anions or replacing them partially or fully. Since synthesizing mixed anion compounds is challenging, automatic crystal structure search together with density functional theory, particle swarm optimization algorithm and geometry relaxation calculations have been performed to obtain information regarding the stability and properties of these compounds. Plotting convex hull has revealed that FeOF, Fe₂OF₄, and AlOF have low formation energies, therefore can be used in synthesizing the catalyst materials. Based on structures obtained, electronic properties of these structures have been studied. Also, the effects of pressure on these compounds have been explored. Under pressures such as 10 GPa, fluorine rich compound Fe₂OF₄ and AlOF become highly destabilized, leaving FeOF more likely to be a candidate compound under higher pressures.
P40.00011: Physical property modulation in 2D TMDs homo- and hetero-structures via pressure engineering  

JUAN XIA (Presenter), University of Electronic Science and Technology of China — 2D TMDs and their van der Waals heterostructures (vdWs HSs), exhibit attractive optical and optoelectronic properties thanks to the different band alignments and interlayer interactions. Their sensitivity to interlayer distance allows effective tuning of material properties through external modulation of lattice parameters. Therefore, it is of both fundamental and practical importance to explore interlayer excitons in vdWs HSs, especially their dynamic response and underlying mechanisms to different tuning techniques. So far, only limited changes in lattice parameters have been achieved, hampering effective tuning of physical properties in vdWs HSs. In this talk, we demonstrate effective tuning of the excitonic states by controlling the interlayer distance in TMDs vdWs HSs, and further tune the interlayer spacing and thus the band structure using hydrostatic pressure. In addition, we perform DFT calculations and achieve good agreement with the experimental observations, revealing a pressured-induced changeover in the band structure of the HSs. This may offer new insights into the strong interlayer interaction and electron-phonon coupling in TMDs via pressure engineering, which can be exploited for designing new excitonic devices based on 2D vdWs HSs.

Session P41 GMAG DMP FIAP DCOMP: Spins in Non-magnetic Semiconductors 707 - Raphael Daveau, Cornell University

2:30PM P41.00001: Band structure probe of near Surface InAs Quantum Wells*  

BRENDEN A MAGILL (Presenter), GITI KHODAPARAST, Virginia Tech, SUNIL K THAPA, CHRISTOPHER J STANTON, Univ. of Florida, JOSEPH YUAN, MEHDI HATEFIPOUR, WILLIAM MAYER, MATTHIEU DARTIALH, KASRA SARDASHTI, KAUSHINI S WICKRAMASINGHE, JAVAD SHABANI, New York University, Y. H. MATSUDA, ZHUO YANG, YOSHIMITSU KOHAMA, Univ. of Tokyo — Near surface InAs quantum wells (QW) have recently attracted a great deal of interest as tools to explore mesoscopic and topological superconductivity. These shallow QWs can interact strongly with superconducting layers which can be epitaxially grown on their surfaces. In this talk, we present a combined experimental and theoretical approach to study the band structure of these QWs. The effective mass and g-factors in these QWs were determined using high field cyclotron resonance (CR). Unlike GaAs, narrow gap systems like InAs have large nonparabolicity in their band structures. The band parameters extracted from our CR experiments are consistent with those obtained from Shubnikov de Hass measurements and agree remarkably well with the theoretical calculations. Our band structure models include strong mixing of the conduction and valence bands which leads to a large non-parabolicity. The calculations accurately describe the experimental observations and allowing us to accurately map the effective mass and g-factor as a function of magnetic field, Landau level index, and the well width for different near surface InAs QWs.

2:42PM P41.00002: Weak-antilocalization Induced by Spin-orbit Interaction in Two-dimensional Tellurium* CHANG NIU, ZHUOCHENG ZHANG (Presenter), GANG QIU, YIXIU WANG, WENZHUO WU, PEIDE (PETER) YE, Purdue Univ — Tellurium (Te) is an intrinsic p-type semiconductor with a narrow bandgap of 0.35eV, whose hexagonal crystal structure is formed by van der Waals interaction between each helical atom chains. Through controllable atomic layer deposition (ALD) grow dielectric doping, we can access transport properties of Te conduction band. Here we report experimental results regarding weak-antilocalization (WAL) effect in n-type two-dimensional (2D) Te films at cryogenic temperatures. The gate and temperature dependence on WAL shows D'yakonov-Perel (DP) mechanism plays the main role in spin relaxation and electron-electron (e-e) interaction is dominant for phase relaxation, which matches well with Iordanskii, Lyanda-Geller, and Pikus (ILP) theory. Also, phase coherence length of Te extracted from WAL feature reaches 573nm at T=1K and transition from weak-localization (WL) to weak-antiocalization (WAL) is observed by tuning the gate bias, indicating its potential for future tunable spintronic applications.

*This work was supported by NSF/AFOSR 2DARE Program, ARO, and SRC.
The synthesis of 2D Te materials is supported by the National Science Foundation under Grant CMMI-1762698.

2:54PM P41.00003: Magneto-optical properties of n-type InAsP films in ultrahigh magnetic fields* SUNIL K THAPA (Presenter), CHRISTOPHER J STANTON, University of Florida, BRENDEN A MAGILL, RATHSARA R HERATH MUDIYANSELAGE, GITI KHODAPARAST, Virginia Tech, Y. H. MATSUDA, ZHUO YANG, YOSHIMITSU KOHAMA, University of Tokyo, SUKGEUN CHOI, CHRIS J PALMSTROM, Univ. of California, Santa Barbara — InAsP ternary alloys have immense prospect for optoelectronic and quantum communication devices due to their variable band gap of 0.35-1.35 eV and tunability in the g-factors. We present a theoretical/experimental study of the magneto-optical properties of n-type InAs\(_x\)P\(_{1-x}\) films (x=0.07,0.34) in ultrahigh magnetic fields in the Faraday's geometry at T=300 K using k.p method with modified 8-band Pidgeon-Brown model. The calculated Landau-level Fan diagram for x=0.34 suggests a near-zero g-factor. Moreover, the Field-dependent Fermi levels and the absorption coefficients show a very strong corroboration with the Cyclotron Resonance (CR) measurements, both in position and the strength. In this study, we also employed ultrafast Time Resolved Differential Reflectivity (TRDR) and ultrafast time resolved Magneto-optic Kerr Effect (MOKE) to provide information on the carrier and spin relaxation dynamics.

*This material is based upon work supported by the Air Force Office of Scientific Research under award number FA9550-17-1-0341, and DURIP funding (FA9550-16-1-0358).
3:06PM P41.00004: Ultralong spin coherence in MAPbI$_3$ single crystals revealed by ultrafast optics  
YUE YAO (Presenter), MATTHEW SHEFFIELD, HESHAN HEWA WALPITAGE, ISAAC P BROWN HEFT, University of Utah, YE LIU, ZHENYI NI, JINSONG HUANG, University of North Carolina at Chapel Hill, YAN LI, University of Utah — Hybrid organic-inorganic perovskites (HOIPs) have demonstrated remarkable optoelectronic properties with their unprecedented rate of increase in solar cell efficiency, and their applications have been quickly extended to many areas, including light emitting diodes, lasing, and photo detection. Recent studies have also revealed their great potential in spintronics because of spin-dependent optical transitions, long spin lifetimes, and predicted large spin-orbit coupling effects for potential spin manipulation. Our previous study revealed long spin lifetimes ($T_{2^*}$) exceeding 1 ns at 4 K on MAPbI$_3$ polycrystalline films despite the presence of large spin-orbit coupling. Here, in order to exclude the influence of the polycrystalline structure and obtain intrinsic spin dynamics, we investigate spin dynamics on high quality MAPbI$_3$ single crystals by time-resolved Faraday rotation (TRFR). The spin lifetime improved by an order of magnitude when compared to polycrystalline films, which suggests the long spin lifetime is an intrinsic property of MAPbI$_3$. Combining the TRFR measurements with circularly-polarized photoluminescence, we analyze the interplay between carrier dynamics and spin dynamics upon optical excitation of spin-polarized carriers in this HOIP.

3:18PM P41.00005: Probing the cubic crystal anisotropy and spin-orbit interaction in GaAs heterostructures using hole quantum point contacts  
KARINA HUDSON (Presenter), ASHWIN SRINIVASAN, Univ of New South Wales, DMITRY MISEREV, Department of Physics, University of Basel, QINGWEN WANG, OLEH KLOCHAN, Univ of New South Wales, IAN FARRER, Department of Electronic and Electrical Engineering, University of Sheffield, DAVID A RITCHIE, Cavendish Laboratory, University of Cambridge, ALEX HAMILTON, Univ of New South Wales — Understanding the form of the spin-orbit interaction (SOI) in semiconductors such as GaAs is a prerequisite for engineering of topological superconducting and insulating states in these materials. Zeeman spin-splitting transport measurements in p-type 1D quantum point contacts (QPCs) are an effective probe of the SOI. Previous measurements have shown that there is a strong anisotropy in the in-plane g-factors in hole QPCs due to SOI ($g_{||} > g_{\perp}$), which can be explained as arising from a second $k^2B$ Zeeman term in addition to the established $k^4B$ Zeeman term$^1$. Here we present the first study of the effect of cubic crystal anistropies on the anisotropy of the g-factor. By rotating the QPC with respect to the crystal axes, we change the effect of the cubic crystal terms. We find the anisotropy of the g-factor is strongly dependent on QPC orientation, and present a theoretical framework describing the SOI terms arising from cubic crystal anisotropy. We identify four additional Zeeman terms that describe the dependence of the anisotropy of the in-plane g-factors with respect to QPC orientation. Our model shows that SOI is highly dependent on crystal asymmetries with implications for topological systems such as artificial graphene.

3:30PM P41.00006: Origin of Rashba-Dresselhaus effect in a Pb-free ferroelectric nitride perovskite. SUBHADEEP BANDYOPADHYAY (Presenter), INDRA DASGUPTA, School of Physical Science, Indian Association for the Cultivation of Science — First principles electronic structure calculations have been employed to investigate the Rashba-Dresselhaus spin splitting of the bands in a Pb-free non-toxic ferroelectric nitride perovskite. Our first principles results are supplemented with effective k.p model analysis. A systematic study of orthorhombic and rhombohedral phases of this system reveal the importance of symmetry in realizing the nature of the splitting of bands around the time reversal invariant k-points. In the orthorhombic structure it shows linear Rashba-Dresselhaus splitting where nonsymmorphic symmetries play an important role in enhancing the band splitting in the \( k_z = \pi/c \) plane. While the rhombohedral phase shows existence of unique higher order Rashba-Dresselhaus term which mixes with the linear Rashba-Dresselhaus term to produce unusual pattern of out-of-plane spin component in the spin texture that may find application in spintronics.

3:42PM P41.00007: Efficient spin to charge conversion at strained amorphous-Si thin film interfaces RAVINDRA G BHARDWAJ, ANAND KATAIHA, PAUL C LOU, SANDEEP KUMAR (Presenter), University of California, Riverside — Interfacial asymmetry in conjunction with strain engineering can provide an alternate pathway to achieve efficient and controllable spin to charge conversion. This hypothesis is experimentally verified using spin-Seebeck effect measurement in case of B-doped amorphous-Si thin film interface. The spin-Seebeck voltage and spin-Hall angle in amorphous-Si is found to be an order of magnitude larger than the corresponding value for Pt thin film spin detector. Further, the spin-Seebeck effect is greatly enhanced in the multilayer heterostructures and it diminishes when the strain effects in the sample are reduced. The inhomogeneous strain induces strong interfacial Rashba-Dresselhaus spin-orbit coupling in the two-dimensional electron gas at the metal-Si interface. The resulting intrinsic inverse spin-Hall effect is the underlying cause of efficient spin to charge conversion, which is of the same order as the topological surface states. This study gives a new direction of research for spin-caloritronics applications using strain engineering and amorphous materials.
3:54PM P41.00008: Dephasing in quasi-1D wires: Non-Markovian noise and correlations due to itinerant spin interactions*

MATTHEW FOSTER (Presenter), SETH M DAVIS, Rice Univ —

Motivated by the interest in many-body localization, we revisit the problem of dephasing due to electron-electron scattering in quasi-1D (many channel) wires. The effectively Markovian bath due to Coulomb interactions dephases at any nonzero temperature [1]. The effect of short-ranged (e.g. spin exchange) electron-electron scattering is more subtle. The latter induces a non-Markovian, diffusive noise kernel. Formally the field theory describing the dephasing in the presence of a purely diffusive bath has an upper critical spatial dimension of \( d = 4 \), and is strongly coupled in \( d = 1 \) [2]. We show that a perturbative expansion in the diffusive noise kernel is well-defined but unphysical at long times. We also consider the case of both Coulomb and spin-exchange scattering, using the former to physically regularize the latter. In this case we find "rephasing" contributions at second order that are in contrast to the Markovian limit [3]. We discuss possible experimental signatures.

4:06PM P41.00009: Radial spin texture in elemental tellurium with chiral crystal structure*

MASATO SAKANO, Univ of Tokyo, MOTOAKI HIRAYAMA, RIKEN, TAKANARI TAKAHASHI, Tokyo Institute of Technology, SHUNTARO AKEBI, MITSUHIRO NAKAYAMA, KENTA KURODA, Univ of Tokyo, KAZUAKI TAGUCHI, TOMOKI YOSHIKAWA, KOJI MIYAMOTO, TAICHI OKUDA, Hiroshima University, KANTA ONO, High Energy Accelerator Research Organization, HIROSHI KUMIGASHIRA, Tohoku University, TOSHIYA IDEUE, YOSHIHIRO IWASA, MITSUISHI NATSUKE (Presenter), KYOKO ISHIZAKA, SHIK SHIN, Univ of Tokyo, TAKASHI MIYAKE, AIST, SHUICHI MURAKAMI, TAKAO SASAGAWA, Tokyo Institute of Technology, TAKASHI KONDÔ, Univ of Tokyo — Trigonal tellurium has a chiral crystal structure which is characterized by a lack of mirror symmetry and an inversion center, resulting in the inequivalent right- and left-handed structures. To reveal the spin textures of chiral crystals, here we investigate the spin and electronic structure in \( p \)-type semiconductor elemental tellurium by using spin- and angle-resolved photoemission spectroscopy. Our data demonstrate that the highest valence band crossing the Fermi level has a spin component parallel to the momentum of electron around the Brillouin zone corners. Significantly, we have also confirmed that the spin polarization is reversed in the crystal with the opposite chirality. The results indicate that the spin textures of the right- and left-handed chiral crystals are hedgehog-like, leading to unconventional magnetoelectric effects and nonreciprocal phenomena.

*This research was partly supported by CREST projects (Grant No. JPMJCR16F2, No. JP-MJCR14F1) from Japan Science and Technology Agency (JST) and JSPS KAKENHI (Grants-in-Aid for Scientific Research) (Grant No. JP18H03678, JP19H00651).
4:18PM P41.00010: Prediction of momentum dependent spin splitting in antiferromagnetic compounds without spin-orbit coupling*  LINDING YUAN (Presenter), ZHI WANG, University of Colorado, Boulder, JUN-WEI LUO, Chinese Academic of Science, ALEX ZUNGER, University of Colorado, Boulder — The Conventional way of creating spin splitting entails the involvement of spin orbit coupling (SOC). The latter entails heavy elements that lead to weak bonds and undesirable defects. Can one generate spin splitting without relying on SOC? We identify the magnetic symmetry conditions that produce AFM prototypes having spin splitting even at TRIM points without external magnetic field and even when SOC is set to zero. The resulting spin splitting in AFM arises from the coupling between electron spin and the position coordinates which is k dependent and of the same order as the Thomas term. Band structures of specific compounds are worked out within DFT showing the effects.

*Funded by DOE-BES- MSE to CU Boulder

4:30PM P41.00011: Response of Bloch Electrons to Electric Fields  WILLIAM KERR (Presenter), Wake Forest Univ — We consider the response of spinful Bloch electrons to external electric fields; the electrons’ unperturbed Hamiltonian is the one given by Dresselhaus [1], including the spin-orbit interaction. We write matrices for the system observables with respect to the Bloch basis states of the unperturbed Hamiltonian, truncate them to two bands, and use them to obtain their Heisenberg equations of motion. The equation for the velocity contains not only the anomalous velocity term obtained by Karplus and Luttinger [2] [expressed in terms of the now-familiar (position operator) Berry connection [3]], but also additional terms involving “quasi-connections” from the momentum and spin operators. We apply the equations of motion resulting from this procedure to a two-dimensional model of a ferromagnet with the Dresselhaus linear-in-wavevector spin-orbit interaction and an exchange field term. We find for this model that the anomalous velocity is dominated by the term coming from the spin operator rather than the position operator.

Introducing spin-polarized carriers in semiconductor lasers reveals an alternative path to realize room-temperature spintronic applications, beyond the usual magnetoresistive effects[1]. Through carrier recombination, the angular momentum of the spin-polarized carriers is transferred to photons, thus leading to the circularly polarized emitted light. Surprisingly, a large birefringence[2], considered detrimental in both conventional and spin-lasers, has been demonstrated to lead to ultrafast operation with an order of magnitude faster modulation frequency [3] than in the best commercial lasers. By using transparent rate equations we explain how the birefringence can provide key differences in the modulation frequency of the intensity and polarization of light emitted from a laser. We reveal that for such ultrafast operation it is important to have a short spin relaxation time in the active region of the semiconductor lasers, typically made of quantum wells.

Colloidal Nanoplatelet is a two-dimensional semiconductor nanocrystal heterostructure that allows for wavefunction engineering by controlling their composition and or thickness. With the inclusion of a shell doped with magnetic ions around a non-magnetic core, there exists a carrier mediated exchange interaction between the excitonic spin density and the Mn spins. Through the exchange interaction, magnetic effects such as Zeeman splitting and the excitonic photoluminescence circular polarization can be controlled by varying the shell thickness and or Mn content [1,2]. The previous works did not take into account on how the exitonic wavefunction is affected by the addition of the magnetically doped shell. Here, we present a model that includes the carrier mediated exchange interaction and study its effect on the excitonic wavefunction. [1] S. Delikanl et al., ACS. Nano 2015 9, 12, 12473-12479 [2] F. Muckel et al., Nano Lett. 2018, 18, 2047–2053.
Correlated States and Frustration in Magnetic Quantum Dots with Multiple Occupancy*  

TIAGO CAMPOS (Presenter), State Univ of NY - Buffalo, JAMES PIENTKA, St Bonaventure Univ, ALEX MATOS ABIAGUE, Wayne State Univ, JONG E HAN, IGOR ZUTIC, State Univ of NY - Buffalo — Magnetically doped semiconductor quantum dots (QDs) provide an enhanced control of magnetic ordering as compared to their bulk-like counterparts [1]. Unlike in the bulk structures, adding a single carrier in a magnetic QD can have important ramifications. An extra carrier can both strongly change the total carrier spin and the temperature of the onset of magnetization. Recent experiments reveal how multiple carrier occupancy is optically controlled in Mn-doped II-VI QDs [2] and motivate studies of strongly-correlated states in these systems. While Wigner molecules, as the nanoscale manifestation of correlation effects in Wigner crystals, have been extensively studied in nonmagnetic QDs, their generalizations in magnetic QDs are largely unexplored [3]. Using exact diagonalization and conditional probability density we reveal peculiar manifestations of strongly-correlated states in Mn-doped QDs. The spatial control of Mn-dopants provides a platform to examine the role of magnetic frustration and the shell-structure formation with the change in the strength of Coulomb interaction.

Theory of Excitonic Phases in an Electron-Hole Double-Layer System with Relativistic Spin-Orbit Interaction  

YEYANG ZHANG (Presenter), KE CHEN, RYUICHI SHINDOU, Peking Univ — We propose helicoidal and helical excitonic insulator phases in a Coulomb-coupled two-dimensional electron-hole double layer (EHDL) system with relativistic spin-orbit interaction. Previously, it was proposed that layered InAs/AlSb/GaInSb heterostructure is an ideal experimental platform for searching excitonic dense phases, while its electron layer has non-negligible Rashba interaction. We clarify that due to the Rashba term, the spin-triplet (spin-1) and spin-singlet (spin-0) excitonic fields in the EHDL system forms either helicoidal or helical structure, depending on its coupling with an in-plane Zeeman field. We provide a comprehensive understanding of electric and magnetic properties of these condensed phases as well as their low-energy collective modes.

Session P42 GMAG DMP: Complex Oxide Interfaces & Heterostructures - Skyrmions and Novel Magnetism  

709/711 - Sanghoon Kim
2:30PM P42.00001: Topological Hall Effect in SrTiO$_3$/SrIrO$_3$/SrRuO$_3$ Superlattices*  JOSE FLORES (Presenter), ADAM S AHMED, BINBIN WANG, NURIA BAGUES SALGUERO, DAVID W. MCCOMB, FENGYUAN YANG, Ohio State Univ - Columbus — Ferromagnet(FM)/heavy-metal(HM) bilayers films have been found to able to host topological magnetic structures like skyrmions stabilized by exchange and interfacial Dzyaloshinskii-Moriya interactions. Electrical measurement by the topological Hall effect (THE) has been a primary method of detection of these features. Perovskites multilayers are an excellent platform for investigating these systems due to the wide range of electrical and magnetic properties and very low lattice mismatch allowing for the growth of high-quality films. Here we investigated the topological hall effect in STO(001)/SrRuO$_3$/SrIrO$_3$/SrTiO$_3$ superlattices where SrTiO$_3$ acts as a spacer layer that seperates the FM/HM layers SrRuO$_3$/SrIrO$_3$. As the spacer thickness was increased, the magnitude of the topological Hall resistivity decreased suggesting interlayer coupling. Superlattices with thinner spacer layers show a transition between two topological hall peaks corresponding to before and after the magnetization has switched and an intermediate temperature where both signal are observed. This behavior appears to be unique to the superlattices and is not seen in bilayer structures.

2:42PM P42.00002: Tunable real- and momentum-space topological properties in SrRuO$_3$ ultrathin films  LINGFEI WANG (Presenter), TAE WON NOH, Department of physics and astronomy, Seoul National University — In perovskite-structured SrRuO$_3$ (SRO), a fine balance between the electron-electron correlation and spin-orbit coupling gives rise to a variety of exotic topological properties. Here, we will show our recent results about tunable real-and momentum-space topological properties in SRO ultrathin films. First, we report the discovery of ferroelectrically tunable skyrmions in ultrathin BaTiO$_3$/SRO bilayer heterostructures. The ferroelectric proximity effect at the BaTiO$_3$/SRO heterointerface can trigger a sizable Dzyaloshinskii-Moriya interaction, thus stabilizing a real-space topological spin texture: magnetic skyrmion. By locally manipulating the ferroelectric polarization, we can achieve local, switchable, and nonvolatile control of both skyrmion density and thermodynamic stability. Second, we will focus on the highly tunable anomalous Hall effect (AHE) in SRO single layers. We found the AHE exhibit a clear sign reversal as the SRO film thickness decreases to 4 unit-cells due to the changes in momentum-space Berry curvatures. By harnessing the step-flow growth, we can induce an artificial thickness inhomogeneity and a two-channel AHE in SRO films. We developed several experimental methods for distinguishing the skyrmion-induced topological Hall effect from the two-channel AHE.
2:54PM P42.00003: Investigating the Skyrmion Phase Diagram in Polycrystalline Chemically Substituted Cu\(_2\)OSeO\(_3\) with Small Angle Neutron Scattering*  PAUL NEVES (Presenter), Department of Physics, University of Maryland, College Park, DUSTIN GILBERT, National Institute of Standards and Technology Center for Neutron Research, SHENG RAN, I-LIN LIU, SHANTA SAHA, JOHN COLLINI, Department of Physics, University of Maryland, College Park, MARKUS BLEUEL, National Institute of Standards and Technology Center for Neutron Research, JOHNPIERRE PAGLIONE, Department of Physics, University of Maryland, College Park, JULIE ANN BORCHERS, NICHOLAS BUTCH, National Institute of Standards and Technology Center for Neutron Research — The chiral helimagnet Cu\(_2\)OSeO\(_3\) is now understood to host a variety of interesting magnetic phases. The stability of these phases is sensitive to many parameters, including magnetic field and temperature history, magnetic field direction, and chemical tuning. Here, we discuss results studying the magnetic phase diagram of chemically substituted polycrystalline (Cu\(_{1-x}\)M\(_x\))\(_2\)OSeO\(_3\), M = (Ag, Zn), and Cu\(_2\)(O\(_{1-x}\)S\(_x\))\(_2\)SeO\(_2\) with bulk magnetization and small angle neutron scattering (SANS). Notably, we perform SANS measurements after rotation of our powdered samples in a magnetic-field to resolve 6-fold symmetric skyrmion lattice diffraction patterns. This allows us to gleam information about the skyrmion lattice order and magnetocrystalline anisotropy. Bulk magnetization suggests an enhancement of skyrmion temperature stability in the Ag and S substituted samples, while SANS suggests a generic decrease in the ability of field rotation to align skyrmion lattices in chemically disordered systems. Additionally, we are unable to confirm the presence of a second skyrmion phase in Zn substituted samples.

3:06PM P42.00004: Theoretical investigations of Topological Hall Effect at Manganite/Iridate Oxide Interfaces*  NARAYAN MOHANTA (Presenter), Oak Ridge National Lab, ELBIO DAGOTTO, Department of Physics and Astronomy, University of Tennessee at Knoxville, SATOSHI OKAMOTO, Oak Ridge National Lab — We study topological Hall effect at the interface between La\(_{1-x}\)Sr\(_x\)MnO\(_3\) and SrIrO\(_3\). We show that the ferromagnetism at the manganite layer, in conjunction with the Dzyaloshinskii-Moriya (DM) interaction which arises at the interface due to broken inversion symmetry and strong spin-orbit coupling from the iridate layer produces a skyrmion crystal (SkX) phase in the presence of an external magnetic field. Using the Monte Carlo technique and a two-orbital spin-fermion model for manganites, we obtain phase diagrams which reveal, at low temperatures, a clear SkX phase and also a low-field spin-spiral phase. Increasing temperature, a skyrmion-gas phase, precursor of the SkX phase upon cooling, was identified. The topological Hall effect primarily appears in the SkX phase. We also show that a planar topological Hall effect can robustly appear at oxide interfaces from conical spin spirals at oxide interfaces, without skyrmions, when the magnetic field is applied parallel to the interface plane.

3:18PM P42.00005: Investigation of Domain Walls in Single Crystal Cr$_2$O$_3$ Using Nitrogen Vacancy Scanning Magnetometry  NATASCHA HEDRICH (Presenter), KAI WAGNER, BRENDA SHIELDS, Department of Physics, University of Basel, Klingelbergstrasse 82, Basel 2056, Switzerland, TOBIAS KOSUB, DENYS MAKAROV, Helmholtz-Zentrum Dresden-Rossendorf e.V., Institute of Ion Beam Physics and Materials Research, 01328, Dresden, Germany, PATRICK MALETINSKY, Department of Physics, University of Basel, Klingelbergstrasse 82, Basel 2056, Switzerland — Magnetolectric antiferromagnets are promising candidates for spintronic devices that have been used to demonstrate electrical reading and writing [1]. Chromia, in particular, has drawn attention due to its room temperature ordering. While domain structures in thin-film Cr$_2$O$_3$ have been studied in detail [2], domains in single crystals prove more elusive and less well understood. Second harmonic generation and magnetic force microscopy have been used to study these structures, but these techniques have provided primarily qualitative images [3,4]. Here, we present a quantitative study of domain walls in single crystal chromia using nitrogen vacancy (NV) magnetometry, performed with all-diamond scanning probes, where we make use of the sub 1 uT/$\sqrt{\text{Hz}}$ sensitivity and sub 50 nm spatial resolution of these structures to investigate the domain wall properties at the nanoscale. Our measurements demonstrate the unique possibility offered by NV magnetometry to study single crystalline antiferromagnetic systems and reveal fundamental properties of the crystal and its spin textures.

3:30PM P42.00006: Spin Dynamics in the Antiferromagnetic Oxy- and Fluoro- Pnictides: LaMnAsO, LaMnSbO, and BaMnAsF*  FARHAN ISLAM (Presenter), PINAKI DAS, YONG LIU, ELIJAH GORDON, LIQIN KE, Ames Laboratory, Iowa State University, DOUGLAS L ABERNATHY, Oak Ridge National Laboratory, ROBERT MCQUEENEY, DAVID VAKNIN, Ames Laboratory, Iowa State University — Inelastic neutron scattering (INS) from polycrystalline LaMnAsO, LaMnSbO, and BaMnAsF are analyzed using $J_1$-$J_2$-$J_c$ Heisenberg model in the framework of the linear spin-wave theory. All three systems show clear evidence that $J_1$ and $J_2$ are both antiferromagnetic (AFM) with a ratio of $2J_2/J_1 < 1$. Thus, the competing interactions do not lead to the stripe structure, preserving the square lattice checkerboard AFM structure. The inter-plane coupling $J_c$ in all three systems is on the order of $\approx 3\times10^{-4}J_1$, rendering the magnetic properties of these systems quasi-two-dimensional. The substitution of Sb for As significantly lowers the in-plane exchange coupling, which is also reflected in the Néel temperature $T_N$. Although BaMnAsF shares similar MnAs sheets as LaMnAsO, their $J_1$-$J_2$ values are substantially different. Using density functional theory, we calculate exchange parameters $J_{ij}$ to rationalize the differences between these systems.

3:42PM P42.00007: Magnetic structure and spin dynamics of a buckled-honeycomb antiferromagnet Co4Ta2O9

SUNGYUN CHOI (Presenter), VALERY KIRYUKHIN, Department of Physics and Astronomy, Rutgers University, New Brunswick, MATTHIAS J GUTMANN, DAVID J VONESHEN, ISIS Neutron and Muon Source, SHANGKE PAN, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University, New Brunswick — Controlling magnetism by the electric field is one of the most important topics in correlated materials, which could be realized via magnetoelectric (ME) coupling. The discovery of ME in Cr2O3 [1] initiates intense research on related ME materials for practical applications. However, there are not many real materials that show strong ME coupling due to rather strict symmetrical conditions: the absence of the inversion and time-reversal symmetry.

The interest was renewed when the Co4Nb2O9 study found a large ME coupling with an antiferromagnetic ordering [2]. Keeping this interest, we present a combined measurement of magnetic susceptibility, neutron diffraction and inelastic neutron scattering on Co4Ta2O9 [3]. We determined a magnetic order by single-crystal neutron diffraction and also performed inelastic neutron scattering to prove spin dynamics. We will discuss the implication of our results on the magnetic structure and spin excitations in the context of the magnetoelectricity of this material.

3:54PM P42.00008: Direct visualization of domain dynamics in Ni$_2$MnTeO$_6$ antiferromagnet using X-ray Bragg diffraction Phase contrast Imaging.*

MIN GYU KIM (Presenter), SUNGYUN CHOI, Rutgers University, Piscataway, HU MIAO, Brookhaven National Lab., CHOONGJAE WON, Pohang University of Science and Technology, JUNJIE YANG, New Jersey Institute of Technology, WEN HU, CLAUDIO MAZZOLI, Brookhaven National Lab., SANG-WOOK CHEONG, Rutgers University, Piscataway, ANDI BARBOUR, STUART B WILKINS, IAN KEITH ROBINSON, MARK DEAN, Brookhaven National Lab., VALERY KIRYUKHIN, Rutgers University, Piscataway — Magnetic phase transitions provide one of the important testbeds in condensed matter physics. Development of the magnetic domains lies at the heart of any such transitions. Generally, antiferromagnetic (AFM) domains can evolve with temperature, through the phase transition from the paramagnetic phase to the ordered state, or between states with different AFM orders. However, the study of such dynamics of AFM domain was impossible due to the lack of temporal resolution in the existing techniques. Using recently developed X-ray Bragg diffraction Phase contrast Imaging (XBPI) technique that can visualize AFM domains and domain walls in real-time and real-space, we present the growth and merging of the AFM domains in real-time as a function of temperature in Ni$_2$MnTeO$_6$ where two AFM states with different Q vectors exist.

4:06PM P42.00009: Random Telegraph Noise in Ferromagnetic Garnets∗ ROBERT SPONSEL (Presenter), E. DAN DAHLBERG, University of Minnesota — Magnetic noise in ten garnet samples is reported. The magnetic noise, fluctuations in the transmitted light intensity using the Faraday effect to observe the magnetization, was measured when the samples were driven by an applied AC magnetic field. The data were taken as a function of the area sampled, the magnitude of the AC magnetic field, and the AC frequency (40-250 Hz). In zero applied magnetic field, the magnetization of the samples consisted of either stripe or serpentine domains. The measured noise is white at fields somewhat below and somewhat above the coercive field for all length scales. Intermediate fields, close to the coercive field of a sample, exhibit a Lorentzian power spectral density (PSD) as would be expected for random telegraph noise (RTN). This PSD was seen at all length scales. Surprisingly, the Lorentzian noise exhibits the same characteristic frequency at all positions measured in a given sample. With increasing area the magnitude of the Lorentzian noise decreases following a 1/area relation consistent with the Lorentzian noise arising from many uncorrelated RTN oscillators. The results will be discussed in terms of random pinning of domains to create complex domain structures.

4:18PM P42.00010: Magnetic structure and electronic properties in Layered BaMn$_2$Sb$_2$ and Ba$_2$Mn$_3$Sb$_2$O$_2$∗ QIANG ZHANG (Presenter), Louisiana State University, Baton Rouge, LA 70803 USA and Neutron Scattering Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA*, ZHENYU DIAO, Louisiana State University, Baton Rouge, LA 70803 USA, HUIBO CAO, Neutron Scattering Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, AHMAD IKHWAN US SALEHEEN, RAMAKANTA CHAPAI, DONGLIANG GONG, SHANE STADLER, RONGYING JIN, Louisiana State University, Baton Rouge, LA 70803 USA — We present the structural, electronic, and magnetic properties of BaMn$_2$Sb$_2$ and Ba$_2$Mn$_3$Sb$_2$O$_2$ single crystals, both with the layered structure analogous to high-temperature Fe- and/or Cu-based superconductors. While the Mn moment in the MnSb$_4$ tetrahedral environment forms a long-range G-type antiferromagnetic (AFM) ordering in both BaMn$_2$Sb$_2$ ($T_{N1}$ ≈443 K) and Ba$_2$Mn$_3$Sb$_2$O$_2$ ($T_{N1}$ ≈314 K), a short-range AFM order is found in the intercalated MnO$_2$ layer at a much lower temperature ($T_{N2}$ ≈60 K) coexisting with long-range G-type order in MnSb$_4$ layer in Ba$_2$Mn$_3$Sb$_2$O$_2$. The directions of the ordered moments in these two magnetic sub-lattices of Ba$_2$Mn$_3$Sb$_2$O$_2$ are perpendicular to each other. The G-type AFM order in MnSb$_4$ layers in both compounds is distinct from the stripe-like order in Fe-based superconductors, but the in-plane magnetic structure in MnO$_2$ layers of Ba$_2$Mn$_3$Sb$_2$O$_2$ is found to be similar to that in the Cuprates. Our study reveals the significant and distinct roles of the CuO$_2$- and FeAs$_4$-type transition metal layers in the structure, novel magnetic and electronic properties.

**4:30PM P42.00011: Calculated magnetic exchange interactions in the Dirac magnon material Cu3TeO6**  
DI WANG (Presenter), XIANGYAN BO, FENG TANG, XIANGANG WAN, Nanjing Univ — Recently, topological aspects of magnon band structure have attracted much interest, and especially, the Dirac magnons in Cu3TeO6 have been observed experimentally. In this work, we calculate the magnetic exchange interactions J's using the first-principles linear-response approach and find that these J's are short range and negligible for the Cu-Cu atomic pair longer than 7 Å. Moreover, there are only five sizable magnetic exchange interactions, and according to their signs and strengths, modest magnetic frustration is expected. Based on the obtained magnetic exchange couplings, we successfully reproduce the experimental spin-wave dispersions. The calculated neutron scattering cross section also agrees very well with the experiments. We also calculate Dzyaloshinskii-Moriya interactions (DMIs) and estimate the canting angle of the magnetic noncollinearity based on the competition between DMIs and J’s, which is consistent with the experiment. The small canting angle agrees with that current experiments cannot distinguish the DMI-induced nodal line from a Dirac point in the spin-wave spectrum. Finally, we analytically prove that the “sum rule” conjectured in W. Yao et al. [Nat. Phys. 14, 1011 (2018)] holds but only up to the 11th-nearest neighbor.

**4:42PM P42.00012: Elucidation of spin reorientation and short-range ferromagnetic correlations in double perovskite Ho2FeCoO6**  
THOMAS HEITMANN (Presenter), MU Research Reactor, Univ of Missouri - Columbia, MO 65211 USA, HARIPRIYA G R, K. SETHUPATHI, V. SANKARANARAYANAN, Low Temperature Physics Laboratory, Department of Physics, Indian Institute of Technology, Madras, Chennai-600036, India, R. PRADHEESH, the Racah Institute of Physics, the Hebrew University of Jerusalem, Jerusalem, 91904 Israel, HARIKRISHNAN S NAIR, Department of Physics, University of Texas at El Paso, El Paso, TX 79968 USA — We report on energy resolved neutron diffraction and inelastic neutron scattering studies of double perovskite Ho2FeCoO6. The B-site moments have been shown previously to order antiferromagnetically near 250 K with a spin reorientation transition at 45 K. We use energy resolved neutron diffraction of a Ho2FeCoO6 powder to establish the order parameter of these two phases and to characterize a diffuse scattering signal observed surrounding q ≈ 1.3 Å⁻¹. The diffuse part is determined to result from short-range ferromagnetic correlations of the Ho-moments. The development of Ho correlations coincides in temperature with the spin reorientation transition so it is likely that exchange between sublattices is becoming important in this temperature range. We have also explored this system via inelastic scattering and report on a crystalline electric field that is detected at E = 9.8 meV. Both the diffuse and inelastic signals were found to be absent in non-A-site magnetic La2FeCoO6 confirming the origin of these effects as the Ho sublattice.
4:54PM P42.00013: Precursor effects to the Verwey transition of Fe₃O₄: a MaxEnt-μSR study.* CARLOS MORANTE (Presenter), CAROLUS BOEKEMA, San Jose State University — The magnetic fields of Fe₃O₄ have been previously studied using muon-spin rotation (μSR). [1,2] The Verwey transition at Tᵥ (~123 K) and a transition at T₃ (~247 K) are observed. Using Maximum Entropy (MaxEnt, ME) the single-crystal Fe₃O₄ μSR data are analyzed with improved precision. [3] Extra signals are found, indicating 2 signals at room temperature (RT) and 2 at 205 K. [4] These frequencies are found at B_{ext} // <110> and B_{ext} smaller than the demagnetization B. At RT, the upper signal follows the trend seen in the Tᵥ-T₃ region. At 205 K, the lower signal follows the extension above T₃. Short-range ordering could be interpreted as precursor effects to the Tᵥ transition. [1,2] This short-range ordering relates to the “extra” 3d-electron (3d*) behavior. We re-examine the T dependence of fields with B (720 Oe) // <110>. Our Fe₃O₄ MEμSR study of the 3d* spin-phonon interaction could lead to a better understanding of the magnetism of this Mott-Wigner glass. 5:06PM P42.00014: Spin waves above and below the Verwey transition in TbBaFe₂O₅*

DANIEL PAJEROWSKI (Presenter), Oak Ridge National Lab, DANIEL K. PRATT, National Institute of Standards and Technology, STEVEN E HAHN, WEI TIAN, GARRETT E GRANROTH, ALEXANDER KOLESNIKOV, Oak Ridge National Lab, ALEXEY A TASKIN, YOICHI ANDO, Osaka University, ROBERT MCQUEENEY, Iowa State University — TbBaFe₂O₅+δ (TBFO) is a mixed valence compound with antiferromagnetic order (T_N = 450 K) that changes along with the crystal structure and conductivity upon cooling below a Verwey-like transition (Tᵥ = 280 K). This type of double-cell-layered-perovskite is useful to study putative charge ordering in fractional valence systems because the crystal structure develops unique sites for the different valence states. While the static magnetic structure of TBFO is known, in this study we investigate the magnetic interactions. Single crystal inelastic neutron scattering experiments at T = 4 K < Tᵥ and T = 320 K > Tᵥ show spin-waves that are modeled with linear spin wave theory to extract magnetic anisotropy and superexchange parameters. Below Tᵥ there is a sizable magnon gap due to an easy-axis magnetic anisotropy that closes above Tᵥ resulting from the evolution to easy-plane anisotropy. The magnetic interactions are found to be highly three-dimensional and change across Tᵥ. Above Tᵥ, where the conductivity is greater, a damping term is required to model the spin waves.

*Research conducted at ORNL’s Spallation Neutron Source was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U. S. Department of Energy.
Localized electron spins can couple magnetically via the Ruderman-Kittel-Kasuya-Yosida interaction even if their wave functions lack direct overlap. Theory predicts that spin-orbit scattering leads to a Dzyaloshinskii-Moriya type enhancement of this indirect exchange interaction, giving rise to chiral exchange terms. Here we present a spin-polarized scanning tunneling microscopy study of transition metal oxide chains on the (001) surfaces of Ir and Pt. Our STM results confirm that deposition of Co, Fe, Mn, and Cr on the (2×1) oxygen-reconstructed Ir(001) surface leads to the formation of quasi-one-dimensional chains with a (3×1) unit cell. In contrast, preparation on Pt(001) required deposition onto the cold substrate with subsequent annealing in an oxygen atmosphere. In particular, for MnO$_2$ chains we found highly complex spin structures. Whereas we find an almost antiferromagnetic Mn–Mn coupling along the chains, the inter-chain coupling across the non-magnetic substrates turns out to be chiral. We will show that some of the magnetic structures observed for MnO$_2$ can be viewed as highly anisotropic Skyrmions.
2:30PM P43.00001: Inverse Design of Soft Materials: Crystals, Quasi Crystals, Liquid Crystals*  [Invited] MARJOLEIN DIJKSTRA (Presenter), Debye Institute for Nanomaterials Science, Utrecht University — In 1960, Feynman challenged us to think “from the bottom up” and to create new functional materials by directing and manipulating the arrangements of individual atoms ourselves. With recent advances in the synthesis of colloidal nanoparticles and the bottom-up fabrication of nanostructured materials using colloidal self-assembly, we are tantalizingly close to realizing this dream. In this talk, I will show using theory and simulations how one can structure matter over multiple length scales using hierarchical self-assembly. The prediction and design of these structures remains an important challenge for nanomaterials science. I will present a method to predict which structures are stable assuming the shape and interactions between the constituent particles are known, and I will show that particle shape alone can already give rise to a wide variety of structures such as (plastic) crystals [1,2], quasi crystals [3], and liquid crystals [4,5], which can be classified using machine learning techniques. Subsequently, I will show how one can reverse-engineer the particle shape to stabilize highly exotic liquid crystal phases.

3:06PM P43.00002: Hard Particle Colloidal Clathrates with Rotating Guest  SANGMIN LEE (Presenter), SHARON C GLOTZER, Chemical Engineering, University of Michigan — Clathrate crystal consisting of polyhedral cages is usually found in gas hydrate or intermetallic systems where the size of particles forming the structures is mostly atomic or molecular length scale. In this work, we report a design strategy of hard colloidal particles that self-assemble into various colloidal clathrate crystals with single or multiple rotating guests. Monte Carlo simulations show that a single component system of hard truncated triangular bipyramids (TBPs) self-assembles into five different clathrates with rotating guests depending on the truncation of the TBP. Truncation of the TBP creates a cavity at the center of the clathrate cage-like motifs, and the cavity is occupied by guest particles when the size of the cavity reaches a comparable size of the guest. Thermodynamic stability of the clathrates is confirmed by Frenkel-Ladd free energy calculations. The dynamics of the guests can be categorized as free rotation, rotation around a fixed axis, or quantized rotation and rattling, with the mode determined by guest/cavity size ratio, prolateness of the cavity and shape of the guest. In addition, when the TBPs are mixed with other hard shapes, clathrates encapsulate these different guest particles.
3:18PM P43.00003: Symmetry-based discovery of multicomponent, two-dimensional colloidal crystals  NATHAN MAHYNSKI (Presenter), National Institute of Standards and Technology, EVAN PRETTI, Lehigh University, VINCENT SHEN, National Institute of Standards and Technology, JEETAIN MITTAL, Lehigh University — We present a systematic method for computing the ground state phase behavior of multicomponent colloidal materials. In two-dimensions there are exactly 17 “wallpaper groups” which represent distinct combinations of isometries of the Euclidean plane. Using properties of these groups, we develop an algorithm to cover the plane with a fixed number of arbitrary components in all ways that satisfy a desired stoichiometric ratio. These combined symmetry-stoichiometry rules dramatically reduce the number of possible configurations, which generally suffer from a so-called “combinatorial explosion” otherwise making extensive, random structure searching computationally infeasible. With subsequent continuum relaxation, this enumeration approach can predict crystal structures in silico for multicomponent colloidal mixtures. We use this approach to investigate the ground state phase behavior of multicomponent systems inspired by DNA-coated colloidal mixtures, with a focus on stable, low-density “open” crystals. We demonstrate the approach for binary and ternary mixtures at zero ambient pressure to explore how complexity can be achieved through the combination of several components with simple interactions rather than a single component with a more complicated interaction potential.

3:30PM P43.00004: Why integer valence point-charge model works so well  RUOSHI JIANG (Presenter), Tsung-Dao Lee Institute, XIANG LI, Shanghai Jiao Tong University, XINYAO ZHANG, Tsung-Dao Lee Institute — Integer valence counting works extremely well in determining stability of chemical compounds. It comes as a surprise that the same integer valence counting also works very well in comparing energies of different lattice structures of the same composition, even though an incomplete (non-integer) charge transfer is expected in realistic systems. Then, why is the point charge model reasonably accurate (even more than employment of real partial charge)? Here, by partitioning the charge density via atom-centered Wannier functions, we justify the integer valence counting approach through a systemic analysis of multi-pole expansion of the Coulomb energy. Our results demonstrate the dominance of the point charge contribution over the finite moment ones, and reveal the important role of local point group symmetry in suppressing first few low-order moments. While the inaccuracy grows expectedly as the system’s covalency increases from LiF, ZnO, GaAs to Si, surprisingly a reasonable accuracy is still achieved by an effective ionic assignment even for Si (as Si$^{4+}$Si$^{4-}$). Our formulation also illuminates the removal of the infamous self-interaction in such a simple approach, further explaining its unexpected success in numerous applications.
3:42PM P43.00005: Integrated Particle and Field-Theoretic Simulations: A Multiscale Approach to Complex Soft Matter Formulations*  NICK SHERCK (Presenter), KRIS T DELANEY, SCOTT SHELL, GLENN H FREDRICKSON, University of California, Santa Barbara — Our work investigates the phase-behavior of complex polymeric solutions leveraging the strengths of both particle and polymer field-theoretic simulations. Mesostructured polymeric solutions are difficult to simulate using traditional particle-explicit approaches due to the disparate time and length scales, while the predictive capability of field-theoretic simulations is hampered by the need to specify emergent parameters (e.g., chi parameters) with nonobvious connections to molecular architecture. To overcome the weaknesses of both, we discuss an original way to use small-scale, atomistic simulations to parameterize statistical field theory models. Subsequently, field-theoretic simulations can probe behavior at larger length scales in polymeric solutions efficiently while maintaining a connection to the underlying polymer chemistry. This synergistic approach to polymer simulations opens the door to explore–de-novo–a wide variety of polymeric solution phase behavior. We demonstrate the predictive capability of this approach by reproducing the high-temperature, aqueous, PEO phase diagram, without any experimental data.

3:54PM P43.00006: First principles investigations of orthorhombic-cubic phase transition and its effect on thermoelectric properties in cobalt-based ternary alloys.  HEM KANDPAL (Presenter), Chemistry, Indian Institute of Technology Roorkee — We screened six cobalt-based 18-VEC systems CoVSi, CoNbSi, CoTaSi (Si-group) and CoVGe, CoNbGe, CoTaGe (Ge-group) by the first-principles approach, with the motivation of stabilizing these orthorhombic phases into the cubic symmetry -- favorable for thermoelectrics. We account the cubic ground state of the Si-group to the interplay of internal pressure and covalent interactions. The principle of reducing covalent interactions will provide insight and could be vital in speeding the search of missing cubic half-Heusler alloys. Meanwhile, the calculated transport properties of all the systems on p-type doping, except CoVSi, are more promising than the well-known CoTiSb. We also provide conservative estimates of the figure of merit, exceeding the CoTiSb. Based on our findings, we suggest possible new phases of ternary compounds for thermoelectric applications.
4:06PM P43.00007: Unexpected Photonic Band Gaps in 3D Crystal Structures*  ROSE CERSONSKY (Presenter), Macromolecular Science and Engineering Program, University of Michigan, JAMES A. ANTONAGLIA, BRADLEY DICE, Department of Physics, University of Michigan, SHARON C GLOTZER, Department of Chemical Engineering, University of Michigan — Photonic crystals are materials composed of mixed dielectric media that result in the reflection of all electromagnetic waves within a range of wavelengths commensurate with the length scale of the crystal. Such complete photonic band gaps allow for light to be controlled through materials design. Since first theorized in 1987, much effort has been made to define and synthesize photonic crystal structures. In the decades since, many photonic structures have been discovered, often by using naturally occurring crystal structures as templates for design. However, these studies have yet to answer the question: what features of a 3D structure will produce a complete photonic band gap? Here, we present data on over 150,000 potential photonic crystals, and show that complete photonic band gaps are possible for many unexpected structures that have yet to be explored. Our simulations suggest that when designing novel photonic materials, the toolbox of structural templates may be larger and richer than previously thought, widening the field of target crystal structures.

4:18PM P43.00008: A mesoscale lattice model and atomistic simulations of controlled drug release*  KULVEER SINGH, RATNA SANDEEP KATIYAR, SOUMITRA SATAPATHI, PRATEEK JHA (Presenter), Indian Institute of Technology Roorkee — Excipients such as polymers are used for the delivery of poorly soluble drugs to enhance drug bioavailability by limiting drug aggregation/crystallization. I will discuss two distinct approaches, which target different time and length scales of the excipient design problem. First, a two-dimensional lattice model is developed of “ants” (drug) performing a random walk in a lattice containing “walls” (excipient). Ants can be “blind” or “friendly”, corresponding to hydrophilic or hydrophobic drug molecules, respectively. Second, atomistic molecular dynamics simulations are performed on an example system containing acrylic acid oligomers as excipient and doxorubicin as the drug. We mimic drug release by matrix swelling in atomistic simulations using a sequential water removal approach that is a crude but simpler alternative of grand canonical ensemble simulations. Drug release by polymer erosion and drug release in a non-swellable, non-eroding matrix is mimicked in our simulations by variations in polymer/drug concentrations. Together, these two simulation approaches provides design rules for choosing polymer-drug combinations for controlled release.

**4:30PM P43.00009: Van der Waals Metamaterials**

SYEDA MINHAL GARDEZI (Presenter), HARRIS PIRIE, WILLIAM DORRELL, NATHAN C DRUCKER, FAN DU, JENNIFER E. HOFFMAN, Harvard University — Van der Waals (vdW) heterostructures are a fertile frontier for discovering emergent condensed matter phenomena. They are constructed by stacking elements of a large library of two-dimensional materials, which couple together through vdW interactions. However, fully exploring the vast number of possible combinations within this library is a daunting task. Here we introduce vdW metamaterials to rapidly prototype and screen their quantum counterparts. These layered metamaterials reshape the flow of ultrasound to mimic electron motion. We first present a method to recreate the vdW interaction between layered phononic metamaterials using interlayer coupling membranes, which we can tune to create acoustic analogs of well-known vdW heterostructures, including all configurations of bilayer and trilayer graphene. We then twist coupled metamaterial layers to induce interesting phononic behavior mimicking twisted bilayer graphene. We anticipate vdW metamaterials will inform future electronic devices. Equally, they allow the transfer of useful electronic behavior to acoustic systems, such as flat bands in magic-angle twisted bilayer graphene, which may advance super-resolution ultrasound imaging.

**4:42PM P43.00010: Development of an implicit solvent model for the interfacial configuration of colloidal nanoparticles and application to the interfacial self-assembly of truncated cubes**

UNMUKT GUPTA (Presenter), FERNANDO A ESCOBEDO, Cornell University — This study outlines the development of an implicit solvent model that reproduces the behavior of colloidal nanoparticles at a fluid-fluid interface. The center-point of this formulation is the generalized Quaternion-based Orientational Constraint (QOCO) method. The model captures 3 major energetic characteristics that define the nanoparticle configuration – position (orthogonal to the interfacial plane), orientation, and inter-nanoparticle interaction. The framework encodes physically relevant parameters that provide an intuitive means to simulate a broad spectrum of interfacial conditions. For a wide range of shapes, we are able to replicate the behavior of an isolated nanoparticle at an explicit fluid-fluid interface, both qualitatively and quantitatively. Using the family of truncated cubes as test-bed, we analyze the effect of change in the degree of truncation on the potential landscape. Furthermore, we model the self-assembly of an array of cuboctahedra to provide corroboration to the experimentally observed honeycomb and square lattices. Finally, by exploring a broader range of interfacial conditions, we identify and suggest the assembly mechanism for a set of novel superlattice configurations.

First-principles study on the stable hydrogen configuration in SrVO$_2$H

MASAYUKI OCHI (Presenter), KAZUHIKO KUROKI, Department of Physics, Osaka University — Mixed-anion compounds, which contain multiple anionic species in a single phase, such as oxyfluorides and oxyhydrides, have been gathering growing attention as a new platform of materials science [1]. While it is an attracting idea to employ the anionic degrees of freedom for tuning the cation environment, much less is known about mixed-anion compounds than oxides. In particular, understanding and controlling the stable configuration of multiple anions in crystal is one of the most challenging issues. For example, hydrogen atoms are aligned along one direction in some oxyhydrides such as SrVO$_2$H [2-3], but are randomly distributed in some oxyhydrides such as SrCrO$_2$H [4]. In this study, we investigate the stable hydrogen configuration in SrVO$_2$H by performing first-principles calculation of the total energy for several hundreds of possible crystal structures with different hydrogen configurations. In this talk, we will discuss what determines the stability of the hydrogen configuration in this material. References: [1] H. Kageyama et al., Nat. Commun. 9, 772 (2018). [2] F. D. Understanding Li-ion Diffusion Through Artificial SEI Coating Layers

ANGELA HARPER (Presenter), Univ of Cambridge, STEFFEN EMGE, Chemistry, University of Cambridge, ANDREW J MORRIS, Metallurgy and Materials, University of Birmingham — Li-ion batteries show promise for storing large amounts of energy, yet, they are limited by the capacity of the graphite anode. High capacity alternatives, such as Li or Si, pose additional issues due to volume expansion and dendrite growth. In both Si and Li, Al$_2$O$_3$ coatings can be used as a protective layer on the anode [1,2]. We apply a combined theoretical and experimental study to both predict and confirm the structure of this interface, a combination which has been applied numerous times in this field [3]. Using Al K-edge X-Ray absorption spectroscopy calculated with DFT, we have shown how individual layers of Al$_2$O$_3$ grow via atomic layer deposition, and how the structure of the layers is dependent on the number of layers. This result was confirmed experimentally, and suggests that the performance of this coating layer is dependent on the number of layers grown. Finally, we calculate the Li$^+$ diffusivity across the interface, and show how the interface changes during ion diffusion. These results provide both a computational and experimental explanation for the enhanced performance of Al$_2$O$_3$ coated high-capacity anodes.

Fingerprints based biasing for finding complex reaction pathways. *

DEB DE (Presenter), MARCO KRUMMENACHER, BASTIAN SCHAEFER, STEFAN A C GOEDECKER, University of Basel — Determining the pathway of a reaction/transformation is of great importance in chemistry, physics and materials sciences. However, due to the indistinguishability of atoms, finding complex reaction and transformation pathways, containing a large number of intermediate states, is difficult within the existing methods at the density functional theory level. We have resolved this issue by introducing a bias that is invariant under atomic index permutations and that can target a single well defined configuration as the final configuration of a chemical reaction or physical transformation. In this way we can overcome the index mapping problem. The forces arising from the bias, by construction, do not depend on the indexing of the atoms. We have thus reduced the combinatorial atomic indexing problem, that has an exponential scaling, to a global minimization problem on a biased PES involving an indexing invariant penalty function. The later problem can be solved easily in practice. The penalty function we propose is universal and can be applied to any reaction or transformation. We expect that this method will give atomistic insight into complex reaction pathways i.e. in catalysis as well as complex phase and shape transformations.

Session P44 DCOMP DMP: Electrons, Phonons, Electron Phonon Scattering, and Phononics III - 704 - Olivier Delaire, Duke University - Tag(s): Focus
2:30PM P44.00001: Theoretical Spectroscopy of 2D Materials: Exciton-phonon coupling in resonant Raman and luminescence spectroscopy* [Invited] LUDGER WIRTZ (Presenter), FULVIO PALEARI, Department of Physics and Materials Science, University of Luxembourg, ALEJANDRO MOLINA-SANchez, QuantaLab, International Iberian Nanotechnology Laboratory, PIER LUIGI CUDAZZO, Department of Physics and Materials Science, University of Luxembourg, SVEN REICHARDT, Department of Materials, University of Oxford — 2D materials are known to exhibit very pronounced excitonic effects due to the confinement of electrons and holes in a layer and due to the weak dielectric screening of the electron-hole interaction. In spectroscopy involving vibrational degrees of freedom, the exciton-phonon coupling must therefore be included in order to obtain a qualitative understanding of the spectra and in order to obtain quantitative results. We present our methods for the calculation of exciton-phonon coupling via a finite displacement [1] and via a diagrammatic approach [2,3], both using many-body perturbation theory.

We present results for the phonon-assisted luminescence spectrum of bulk hexagonal boron nitride (hBN), where the combination of indirect band gap and strong excitonic effects leads to a complex peak structure due to coupling of excitons with various phonon branches [1]. Furthermore, we present calculations of resonant Raman intensities with the combined inclusion of both excitonic and non-adiabatic effects. In bulk hBN, which has high phonon-frequencies due to the light atoms, we demonstrate the emergence of strong quantum interference between different excitonic resonances due to non-adiabatic effects. In MoS\textsubscript{2} and MoTe\textsubscript{2}, our calculations explain the observed different intensity dependences of the A\textsubscript{1}' and E' modes on the energy of the exciting laser [3].

3:06PM P44.00002: Strong phonon-assisted Auger recombination in PbSe* XIE ZHANG (Presenter), JIMMY SHEN, CHRIS VAN DE WALLE, University of California, Santa Barbara — It is commonly believed that direct Auger recombination dominates in narrow-gap semiconductors. With the example of the prototypical narrow-gap semiconductor PbSe, we demonstrate that this is not necessarily the case. By explicitly calculating both the direct and phonon-assisted indirect Auger recombination coefficients of PbSe from first principles, we show that a number of puzzling anomalies in the Auger recombination in PbSe can be well understood. These insights shed new light on the impact of electron-phonon coupling on Auger recombination in IV-VI semiconductors, which is critical for improved device design.

3:18PM P44.00003: Fully Anharmonic, Non-Perturbative First-Principles Theory of Electronic-Vibrational Coupling in Solids

MARIOS ZACHARIAS, MATTHIAS SCHEFFLER, CHRISTIAN CARBOGNO (Presenter), Fritz Haber Institute of the Max Planck Society, Berlin — The coupling between nuclear vibrations and the electronic structure plays a pivotal role for many material properties, including optical absorption and electronic transport. In this regard, however, today’s state-of-the-art methodologies rely on two approximations [1]: the harmonic (phonon) approximation for the nuclear motion and the linear response description of the electronic structure with respect to harmonic displacements. In this work, we overcome both these approximations by performing fully anharmonic ab initio molecular dynamics (aiMD) calculations and by accounting for the non-perturbative, self-consistent response of the wavefunctions along the aiMD trajectory. By this means, we obtain fully anharmonic, vibronically renormalized spectral functions, from which macroscopic material properties like temperature-dependent band gaps and electronic transport coefficients are obtained. We validate our approach using silicon as an example, for which the traditional electron-phonon coupling formalism is recovered. Using cubic SrTiO$_3$ as example, we further demonstrate that anharmonic electronic-vibrational coupling effects not captured in traditional formalisms play a decisive role in complex materials like perovskites.

3:30PM P44.00004: Phonon-mediated Optical and Electronic Transport Properties of BAs*

KYLE BUSHICK (Presenter), KELSEY MENGLE, SIEUN CHAE, ZIHAO DENG, EMMANOUIL KIOUPAKIS, Univ of Michigan - Ann Arbor — While boron arsenide (BAs) has attracted attention for its ultrahigh thermal conductivity, open questions remain about its use in semiconducting devices. To address this problem, we apply density functional and many body perturbation theory to understand its electronic and optical properties and guide device applications. Since BAs has an indirect band gap of approximately 2 eV and a direct gap of 4.1 eV, absorption of visible light is exclusively mediated by phonons. We therefore calculate the indirect and direct optical absorption spectra to assess its potential in photovoltaics and examine how excitonic effects alter the absorption. Our results are in excellent agreement with experimental data. We also calculate the effect of strain on the band alignment and the electron and hole mobilities, and show that bi-axial tensile strain increases the mobilities of both carriers by over 50%. Finally, we determine the band offsets of BAs heterostructures with nearly lattice-matched ZnSnN$_2$ and InGaN to guide heterostructure design. Our work elucidated the functional properties of BAs for technologically relevant device applications.

3:42PM P44.00005: Electron and Phonon Hydrodynamics in Antimony  ALEXANDRE JAOUI (Presenter), BENOIT FAUQUE, KAMRAN BEHNIA, ESPCI Paris — We present a study of the electrical and thermal resistivities in millimetric samples of the semimetal Sb down to sub-Kelvin temperatures. By applying a large magnetic field, we can clearly separate the electronic and phononic thermal resistivities. The Wiedemann-Franz (WF) law is recovered at low temperature ($T \approx 4K$) in all samples. Yet, a size-dependent departure from the WF law is observed at higher temperatures. We show that this deviation is due to a mismatch between the prefactors of the thermal and electrical $T^2$-resistivities. By analogy with the case of normal-state liquid $^3$He, where fermion-fermion collisions generate a thermal conductivity inversely proportional to temperature [1], we can associate the larger $T^2$-thermal resistivity to the momentum-conserving electronic collisions [2]. In this scenario, the size-dependence of the ratio of the thermal to the electrical $T^2$-prefactors in Sb points to a hydrodynamic flow of electrons [3]. Furthermore, in the 1K-7K range, we also report on a large increase of the thermal diffusivity of phonons, in the same samples, i.e. a signature that the flow of phonons is partially hydrodynamic.

3:54PM P44.00006: Unraveling a New Heat Transport Regime at The Nanoscale.* GIUSEPPE BARBALINARDO (Presenter), ZEKUN CHEN, SHUNDA CHEN, DAVIDE DONADIO, University of California, Davis — The understanding of heat transport in nanoscale semiconductors is of fundamental importance because of its huge technological impact in electronics and renewable energy harvesting and conversion. A particularly interesting question is related to the understanding of how thermal properties of dielectrics, like silicon, change when their size of the order of a few hundred nanometers, which is the characteristic size of state of the art electronic circuits. In this size range heat transport is in a regime in between ballistic and diffusive, which is inaccurately described by either approximation.

In this work, we analyze the current state of the art of heat transport in semiconductor nanostructures. We identify substantial gaps in the theoretical treatment of the quasi-ballistic transport regime, and we propose a new atomistic model to compute the thermal conductivity of nanoscale systems, including both quantum and finite boundaries effects. Our novel approach is implemented in a computational environment, which gives to the powerful framework of anharmonic lattice dynamics, the ability to perform high accuracy predictions for finite size systems, and provide a rigorous alternative to non-equilibrium molecular dynamics.

4:06PM P44.00007: Electron wind force in an atomistic non-equilibrium molecular dynamics simulation*  DAVIDE MANDELLI, Istituto Italiano di Tecnologia, FRANCO PELLEGRINI (Presenter), Ecole Normale Superieure Paris, GIUSEPPE E. SANTORO, ERIO TOSATTI, International School for Advanced Studies — We demonstrate electronic friction on metals by addressing the reverse process – the force imparted on the atoms by the flow of an electronic current in the metal. By well established Ehrenfest dynamics we implement a quantum-classical simulation of the motion of a chain of classical atoms forming a contactless monatomic ring, where electrons flow by nearest neighbor hopping between atomic-like orbitals in an electric field generated by a linearly growing external magnetic field threading the ring. In the real time dynamics, electron-phonon scattering events take the form of Landau-Zener processes, each of them imparting momentum to the classical atoms, that can vibrate and also dissipate to a bath. The realistic features of electron conduction and resistivity are recovered in this model, plus a microscopic description of the current-induced momentum transfer to the atoms which vibrate and to the whole chain which drifts. When one additional adatom is added to the chain, the quantum mechanics of the wind force and the resulting electromigration drift are controlled by the weak hybridization of the adatom orbital to the chain atomic orbitals where the current flows, suggestive of a rather general mechanism.

4:18PM P44.00008: Thickness-dependent electron-phonon coupling and transport in metals from first principles  SUSHANT KUMAR (Presenter), RAVISHANKAR SUNDARARAMAN, Rensselaer Polytechnic Institute — Recent strides in thin-film deposition technology have made the next generation of ultrathin plasmonic devices and ultrascaled metallic interconnects plausible. It has led to a renewed interest in the study of properties of metals and semiconductors in the low dimensional limit. Here, starting with a single layer, we systematically investigate the effect of thickness on the electronic properties and electron-phonon (e-ph) coupling of ultrathin metallic films. Such ab initio studies have typically been challenging because of the inability of the state-of-the-art DFT codes to correctly predict the phonon dispersion curves of finite thickness materials, especially in the $q \to 0$ limit. We propose a new computationally-inexpensive correction scheme for the phonon force matrix based on rotational invariance of the elasticity tensor. This scheme facilitates accurate computation of phonon bandstructures and e-ph coupling for arbitrary film geometries. Using this capability, we determine the variation of electronic transport properties as a function of layer number, fully accounting for effects such as phonon confinement. These ab initio calculations give us an insight into the effect of surface and interfacial strain on the e-ph scattering in thin metallic films.
**4:30PM P44.00009: Phonon interactions in rock salt and fluorite structures**  
LYUWEN FU (Presenter), MARK ALAN MATHIS, ENDA XIAO, CHRIS MARIANETTI, Columbia Univ — Space group irreducible derivatives of the Born Oppenheimer potential are computed from density functional theory for materials with the rock salt and fluorite structures, including PbTe and ThO2. We utilize our recently developed group theoretical approach which allows the extraction of the irreducible derivatives from finite displacement calculations on the smallest possible supercells using the smallest possible number of calculations. Quadratic (i.e. phonons), cubic, and quartic irreducible derivatives have been computed. The fidelity of the irreducible derivatives is tested via comparison to strain derivatives of the phonons. Both dynamics and thermodynamics are evaluated using our irreducible Taylor series, yielding observables such as phonon linewidths, thermal conductivity, thermal expansion, mean square displacements, etc. Results on PbTe and ThO2 are compared to experiment.

**4:42PM P44.00010: Predictive calculations of electron and heat transport in ultra-wide-band-gap semiconductors**  
EMMANOUIL KIOUPAKIS (Presenter), KELSEY MENGLE, Univ of Michigan - Ann Arbor — Ultrawide-band-gap semiconductors are used for energy-efficient power electronics, but there is a pressing need to improve on current materials. Beta gallium oxide (β-Ga2O3) outperforms materials such as Si, SiC, and GaN due to its wide band gap and corresponding large breakdown field. However, three drawbacks of β-Ga2O3 are its lack of p-type doping, its low thermal conductivity, and its inferior electron mobility. Using first-principles calculations we calculate the electron-phonon coupling of β-Ga2O3 to understand the origin of the limits to the electron mobility and thermal conductivity. We also explore rutile germanium dioxide (r-GeO2) as a semiconductor for power-electronic applications. The calculated band gap and optical absorption spectrum is in good agreement with optical measurements. We also determine the phonon-limited carrier mobilities and lattice thermal conductivity as a function of temperature and crystal orientation. We find that the electronic and thermal transport properties of r-GeO2 outperform current materials, while it can also be ambipolarly doped. Our results highlight the potential of r-GeO2 for power electronics.

*This work was supported by NSF DMR-1534221 DGE-1256260. Computational resources provided by the DOE NERSC facility.*
Optical absorption in gallium oxide

HARTWIN PEELAERS (Presenter),
Department of Physics and Astronomy, University of Kansas, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara — Transparent conducting oxides (TCOs) are a technologically important class of materials used in optoelectronic devices, as TCOs balance two conflicting properties: transparency and conductivity. The requirement of transparency is typically tied to the band gap of the material being sufficiently large to prevent absorption of visible photons. This is a necessary but not sufficient condition: indeed, the high concentration of free carriers, required for conductivity, can also lead to optical absorption. This absorption can occur through direct absorption to higher-lying conduction band states, or by an indirect process, for example mediated by phonons or charged impurities.

We performed a detailed first-principles study of these absorption processes in Ga$_2$O$_3$ [1,2], a material with promising applications in high-power devices and UV photodetectors. Our results elucidate the fundamental limitations of optical absorption in Ga$_2$O$_3$ and shed light on experimental observations.

*Work supported by DOE and AFOSR.

Low and high field transport in 2-dimensional electron gas in β-(Al$_x$Ga$_{1-x}$)$_2$O$_3$/Ga$_2$O$_3$ heterostructures

AVINASH KUMAR (Presenter), UTTAM SINGISETTI, State Univ of NY - Buffalo — β-Ga$_2$O$_3$ is an emerging wide-bandgap semiconductor for potential application in power and RF electronics. The 2-dimensional electron gas (2-DEG) in β-(Al$_x$Ga$_{1-x}$)$_2$O$_3$/Ga$_2$O$_3$ heterostructures show the promise for high speed transistors. We will present both the low- and high- field 2-DEG transport properties in the AlGa$_2$O$_3$/Ga$_2$O$_3$ heterostructure. A self-consistent Poisson-Schrodinger simulation of heterostructure is used to obtain the subband energies and wavefunctions. Intra-subband, inter-subband, 2D-3D, 3D-2D and 3D-3D scattering rates are calculated for all the different scattering mechanisms. The electronic structure, assuming confinement in a particular direction, and the phonon dispersion is calculated based on first principle methods under DFT and DFPT framework. Phonon confinement is not considered for the sake of simplicity. The different scattering mechanisms that are included in the calculation are phonon (polar and non-polar), remote impurity, alloy and interface-roughness. We include the full dynamic screening in polar optical phonon scattering. We will use Full Band Monte Carlo to calculate the velocity-field profile in different crystal directions. We will also report the low field mobility by solving the Boltzmann transport equation using Rode's iterative method.
Phonon RIXS calculations using Green's function Momentum Average technique

KRZYSZTOF BIENIASZ (Presenter), MONA BERCIU, Stewart Blusson Quantum Matter Institute, University of British Columbia, STEVEN JOHNSTON, University of Tennessee in Knoxville —

Spectroscopic experiments are the most extensively used probes for characterizing the physical properties of condensed matter. However, their understanding often requires a theoretical calculation of the spectra in question, usually starting from some simplified model of the underlying system. One of the problems that are key to the understanding of many properties of materials is the physics of phonons and their interaction with the conduction electrons. These are the issues lying at the base of conventional superconductivity and it is hoped that their better understanding in high temperature superconductors might help elucidate some of the mysteries still surrounding those materials. The RIXS spectroscopy is a novel, emerging technique, that only recently started to approach the resolving power necessary to observe the phononic features. Thus, theoretical predictions concerning phonon RIXS are now becoming timely in this rapidly progressing field of research. Our aim is to use the Momentum Average Green's function technique and apply it to the problem of phonon RIXS calculations, thus going beyond the current dichotomy of exact diagonalization vs. perturbative expansion methods that are the two dominating methodologies in RIXS theory.

Session P45 DCOMP GDS DSOFT DPOLY: Emerging Trends in Molecular Dynamics Simulations and Machine Learning IV 706 - Maria Chan, Argonne Natl Lab -

Tag(s): Focus
KURT KREMER (Presenter), Max Planck Institute for Polymer Research — Most biological systems and a huge class of everyday products ranging from simple plastics to complex functional systems and to most foods are made of soft matter. Its generic properties are mostly governed by the statistical mechanics of strongly fluctuating huge molecules, such as polymers. For this the plain fact that polymer chains cannot cross through each other introduces significant constraints and is of central importance, e.g. for polymer rheology where entanglements dominate the dynamics or for chromosome territories in the cell nucleus in biophysics, where “topological repulsion” plays a role. Such constraints can be permanent, as for gels and networks or ring polymers or temporary but long lived as in polymer melts or for chromosome organization in the cell nucleus. By manipulating entanglements new non-equilibrium materials can be made. Based on computer simulations new morphologies are predicted, and are tested experimentally. Currently there is no comprehensive analytic theory, which links topological constraints to material properties. The talk will give an overview of recent developments and point to some challenging opportunities based on advances in computational physics of soft matter and experiment.

Transfer learning is a subfield of machine learning that leverages proficiency in one or more prediction tasks to improve proficiency in a related task. For chemical applications, transfer learning models represent a promising approach for addressing intrinsic data scarcity by utilizing potentially abundant data across adjacent domains. For chemical applications, it is still largely unknown how correlation between the prediction tasks affects performance, the limitations on the number of tasks that can be simultaneously trained in these models before incurring performance degradation, and if transfer learning positively or negatively affects ancillary model properties. In this talk we investigate these questions using an autoencoder latent space as a latent variable for transfer learning models trained on the QM9 dataset that have been supplemented with quantum chemistry calculations. We explore how property prediction can be improved by utilizing a simpler linear predictor model, forces the latent space to reorganize linearly with respect to each property. The linear organization of the latent space has further applications to novel structure generation by increasing the quality of generated species and facilitating targeted structure searching.

3:18PM P45.00003: Neural Network Based Molecular Dynamics to Study Polymers
CHRISTOPHER KUENNETH (Presenter), RAMAMURTHY RAMPRASAD, School of Materials Science and Engineering, Georgia Institute of Technology — Polymers are an important class of materials that display morphological complexity and diverse inter-atomic interactions. These two factors have defied large-scale and long-time quantum-accurate atomic-level simulations of polymer dynamics. Traditional simulation methods utilize parameterized classical potentials or force fields which often lack accuracy, transferability, and versatility. Moreover, although these methods are known to fail in notable circumstances, it is not clear how the traditional methods can be systematically improved using the known failures. Neural network based models for molecular dynamics, the subject of this study, are capable of learning from reference quantum mechanical data. Once learned, these models can emulate the parent quantum calculations in accuracy, but be about a billion orders of magnitude faster. Neural network based molecular dynamics simulations can thus reach length-scales and time-scales previously inaccessible using quantum mechanical methods. In this work, we develop a new class of first-ever neural network models for the prototypical case of hydrocarbons and provide several meticulous and diverse validation tests. Challenges that remain are discussed and pathways to overcome such challenges are presented.

3:30PM P45.00004: Applications of Automatic Differentiation to Materials Design* ELLA KING (Presenter), CARL GOODRICH, Harvard University, SAM SCHOENHOLZ, EKIN DOGUS CUBUK, Google, MICHAEL PHILLIP BRENNER, Harvard University — Developments in automatic differentiation (AD) have opened the door to an array of new possibilities throughout the physical sciences. However, AD in materials design has largely been out of reach. Simulations of novel materials were far too computationally intensive for a tool that requires running hundreds of thousands of simulations. Recent work has begun to integrate molecular dynamics simulations with AD, bringing the developments in AD to a new and exciting domain. We demonstrate the power of AD in materials design by building on a seminal paper by Torquato. The prior work begins with a specific model pair potential, and varies four parameters to achieve a honeycomb lattice. Through AD, we are able to start from an entirely arbitrary pair potential, optimize that potential, and ultimately reach a honeycomb lattice with fewer defects.

3:42PM P45.00005: Trainable Molecular Dynamics Models CARL GOODRICH (Presenter), ELLA KING, Harvard University, SAMUEL SCHOENHOLZ, EKIN DOGUS CUBUK, Google, MICHAEL PHILLIP BRENNER, Harvard University — The development of automatic differentiation is motivated by the desire to train computational models with non-trivial architectures that more accurately reflect the underlying structure of the data. This is especially desirable when studying complex physical phenomena, which are governed by fundamental principles (e.g. conservation of energy) that are well understood. By applying automatic differentiation to well-established physics simulations, one can in principle obtain machine trainable models with the physics built in. We will discuss the first steps towards Trainable Molecular Dynamics Models (TMDMs): how they work, their significant potential for scientific and technological discovery, and initial discoveries of non-trivial self-assembly pathways.
3:54PM P45.00006: Hydrogen-Oxygen Combustion: Data-Driven Generation of Quantum-Accurate Interatomic Potentials*  
ALLAN AVILA (Presenter), University of California, Santa Barbara, 
LUKE BERTELS, University of California, Berkeley, IGOR MEZIC, University of California, Santa Barbara, 
MARTIN P HEAD-GORDON, University of California, Berkeley — Although quantum scale simulations of hydrogen-oxygen combustion offer an accurate description of the process, a multi-atom quantum simulation of combustion is unfeasible as it would not terminate in a scientist's lifetime. Multi-atom simulations of combustion are feasible at the molecular scale, however, the potential bond energies are inaccurate and results often fail to match quantum data. We demonstrate how the programmable potentials methodology can be utilized to develop quantum accurate molecular level potentials for several intermediate reactions involved in hydrogen-oxygen combustion. Sparse Electronic Structure Theory (EST) simulation data is utilized to train our programmable potentials. The developed potentials are then inputted into the molecular dynamics simulation package LAMMPS for verification. Our results demonstrate that the developed programmable potentials generalize beyond the sparse EST training dataset. Most importantly, the developed potentials lead to feasible and quantum-accurate molecular dynamics simulations of hydrogen-oxygen combustion.

4:06PM P45.00007: Toward optimal descriptors for accurate machine learning of flexible molecules  
VALENTIN VASSILEV GALINDO (Presenter), IGOR POLTAVSKYI, ALEXANDRE TKATCHENKO, University of Luxembourg Limpertsberg — Robust machine learning (ML) models should be able to reliably predict global molecular potential-energy surfaces (PES) including equilibrium and “far-from-equilibrium” geometries. However, existing molecular ML models are substantially biased towards “close-to-equilibrium” geometries. Indeed, the difficulty of the learning task increases with increasing flexibility of a molecule, due to a vast manifold of configurations with a complex interplay of covalent and non-covalent interactions to be learned.

Our objective is to test how the ability to accurately reproduce PES depends upon the choice of a molecular descriptor. We use azobenzene, aspirin and salicylic acid molecules as our test systems, and the sGDML code¹ for building ML force-fields. We found that the descriptors which demonstrate excellent performance for “close-to-equilibrium” parts of PES are inefficient for building global PES models. To resolve this challenge, we propose new descriptors that allow building accurate and data-efficient ML models for flexible molecules.

4:18PM P45.00008: Towards transferable parametrization of Density-Functional Tight-Binding with machine learning  LEONARDO MEDRANO SANDONAS (Presenter), MARTIN STOEHR, ALEXANDRE TKATCHENKO, Physics and Materials Science Reasearch Unit, University of Luxembourg — Machine learning (ML) has been proven to be an extremely valuable tool for simulations with ab initio accuracy at the computational cost between classical interatomic potentials and density-functional approximations. Similar efficiency can only be achieved by semi-empirical methods, such as density-functional tight-binding (DFTB). One of the limiting factors in terms of the accuracy and transferability of DFTB parametrizations is the so-called repulsive potential, which plays a considerable role for the prediction of energetic, structural, and dynamical properties. Few attempts of using ML-techniques to address this issue have been proposed recently but, up to now, evidence of transferability and scalability is still scarce. Using the QM7-X database of small organic molecules, we demonstrate that the DFTB repulsive energy can be effectively learned by means of ML-approaches including neural networks and kernel ridge regression. We further show how the resulting DFTB+ML model can also be used for more complex systems like molecular dimers and crystals, and modeling techniques like (global) structure search or vibrational analysis. DFTB+ML thus opens a route to the simultaneous access to reliable electronic and structural/dynamical properties of diverse molecular systems.

4:30PM P45.00009: Active learning of fast Bayesian force fields with mapped gaussian processes - application to stability of stanene  YU XIE (Presenter), JONATHAN VANDERMAUSE, LIXIN SUN, ANDREA CEPELLOTTI, BORIS KOZINSKY, Harvard University — Machine learning force-fields can reach accuracy comparable to ab-initio molecular dynamics and simulate much larger systems. Gaussian process (GP) regression has remarkable advantage due to its built-in uncertainty quantification based on Bayesian posterior inference, which can be used to monitor the quality of predictions. A limitation is that the prediction cost grows linearly with the training set size, making accurate GP predictions slow. To solve this, we exploit the special structure of an n-body kernel function to construct interpolation functions based on the trained GP, mapping both forces and uncertainties. To demonstrate the capability of this mapped GP Bayesian force field (BFF) method, we perform active learning and large-scale simulation of stanene. We reveal the decomposition mechanism of stanene and identify the range the phase transition temperature. The application shows that we can reach classical potential prediction speed while keeping quantum accuracy, at the same time incorporating uncertainty quantification. We present progress in implementing automated active learning workflows for training BFFs, aimed at large-scale simulations of rare event dynamics in complex materials.
4:42PM P45.00010: Nuclear quantum delocalization enhances non-covalent intramolecular interactions: A machine learning and path integral molecular dynamics study  
HUZIEL SAUCEDA (Presenter), Tech Univ Berlin, VALENTIN VASSILEV GALINDO, Physics and Materials Science Research Unit, University of Luxembourg, STEFAN CHMIELA, KLAUS-ROBERT MÜLLER, Tech Univ Berlin, ALEXANDRE TKATCHENKO, Physics and Materials Science Research Unit, University of Luxembourg — It is of common knowledge that nuclear quantum effects generates delocalized molecular dynamics. In this study, we present evidence that nuclear delocalization can enhance electronic and electrostatic interactions that promote localized dynamics. These results were obtained from the reconstructed potential-energy surfaces using the symmetrized gradient-domain machine learning (sGDML) framework[1] trained on coupled cluster with single, double, and perturbative triple excitations (CCSD(T)) data combined with path integral molecular dynamics simulations. The physical process responsible for this phenomenon is the effective reduction of the interatomic distances between non-covalently bonded atoms or functional groups. This potentiates intramolecular interactions such as the \( n\to\pi^* \) and electrostatic interactions[2]. These results diverge from the general assumption that nuclear quantum effects just tend to lower energetic barriers or to smoother the energy landscape, opening new avenues into possible explanations of complex processes in chemistry and biology.

4:54PM P45.00011: Active learning identifies optimal \( \pi \)-conjugated peptide chemistries for optoelectronics*  
KIRILL SHMILOVICH (Presenter), ANDREW L FERGUSON, University of Chicago — In this work we perform active learning discovery within an embedded chemical space of \( \pi \)-conjugated peptides using coarse-grained molecular dynamics simulation to discover molecules with emergent optoelectronic behavior. Molecules with oligopeptide wings flanking a \( \pi \)-conjugated core have surfaced as an extensible building block for self-assembling electronic devices due to overlaps between \( \pi \)-orbitals in supramolecular assemblies leading to optical and electronic properties with the potential to operate in bio-compatible frameworks. However, a combinatorial explosion in the molecular design space of possible peptide sequences render brute force trial-and-error discovery impossible through either experiment or simulation. By deploying an activate learning procedure over a variational autoencoder learned space of \( \pi \)-conjugated peptides molecules are iteratively selected for computational screening by balancing exploration of undersampled regions and exploitation in high confidence regions of chemical space. This protocol efficiently navigates this large chemical space to ultimately identify promising \( \pi \)-conjugated peptide chemistries with optimal optoelectronic behavior for further computational testing and experimental synthesis.

5:06PM P45.00012: A Self-consistent Artificial Neural Network Inter-atomic Potential for Li/C Systems  
YUSUF SHAIDU (Presenter), RUGGERO LOT, International School for Advanced Studies, FRANCO PELLEGRINI, Laboratoire de Physique Statistique, École Normale Supérieure, Université PSL, EMINE KUCUKBENLI, Harvard University, STEFANO DE GIRONCOLI, International School for Advanced Studies — Graphene-based structures, due to their large surface area, have been suggested as suitable anode materials for Li-ion batteries. In a previous study[1] we examined Li adsorption on graphene at finite temperature with a site-based potential and identified the temperature and Li coverage at which a transition can be expected from disperse Li ion to clustered Li atoms configuration on graphene surface. To extend this study to a wide range of Li coverage on realistic anode materials, a more flexible and accurate Li-C potential is needed. In this talk we first present a self-consistent approach to construct a neural network potential for Carbon using the PANNA code[2]. Our potential performs excellently in ranking the energies of distinct sp3 networks and reproduces the equation of state of graphite, diamond and graphene, as well as elastic and vibrational properties of these phases. We then extend our potential to Li/C systems incorporating long range electrostatics and test its performance on a wide range of Li adsorbed carbon allotropes.

5:18PM P45.00013: Active Learning Driven Machine Learning Inter-Atomic Potentials Generation: A Case Study for Hafnium dioxide*  
GANESH SIVARAMAN (Presenter), Argonne Leadership Computing Facility, Argonne National Laboratory, ANAND NARAYANAN KRISHNAMOORTHY, MATTHIAS BAUR, CHRISTIAN L. HOLM, Institute for Computational Physics, University of Stuttgart, MARIUS STAN, Applied Materials Division, Argonne National Laboratory, GÁBOR CSÁNYI, Department of Engineering, University of Cambridge, CHRIS BENMORE, X-ray Science Division, Argonne National Laboratory, ALVARO VAZQUEZ-MAYAGOITIA, Computational Science Division, Argonne National Laboratory — We propose a novel active learning scheme to automate the configuration selection to fit the Gaussian Approximation Potential (GAP). The proposed scheme consists of an unsupervised active sampler coupled to a Bayesian optimization to evaluate the GAP model. We apply this scheme to \textit{ab initio} molecule dynamics trajectories of Hafnium dioxide. We will show that this scheme leads to a much lower number of training configuration that arrives at near \textit{ab initio} energy fit accuracy as evaluated by an error metric. With the active learned GAP model, we performed molecule dynamics (MD) simulation. We show that the MD simulation calculated x-ray structural factors are in the good agreement with experiments.

Session P46 GMAG DMP DCOMP: Unconventional Order and Phase Behaviors in Complex Oxides 708 - Arun Paramekanti, Univ of Toronto - Tag(s): Focus
2:30PM P46.00001: Collective Spin and Charge Behavior in Ni\textsuperscript{1+}-Rich Layered Nickelates\*  
[Invited] JOHN MITCHELL (Presenter), Argonne Natl Lab — For more than 30 years nickel oxides have been explored in vain as potential cuprate-like superconductors. The recent report of superconductivity in a nickelate film by Hwang et al (Nature 572, 624 (2019)) brings new urgency to this quest. Unlike that of their cuprate analogs, the electronic phase diagram of layered nickelates, R\textsubscript{2-x}Sr\textsubscript{x}NiO\textsubscript{4} (R=rare earth) is populated not by metals and superconductors, but rather with insulating charge- and spin-stripe phases. The absence of superconductivity can be rationalized by factors such as d-p mixing, lack or planar orbital polarization, among others. Each of these traces ultimately to the markedly different electronic configuration of d\textsuperscript{8} Ni\textsuperscript{2+} in octahedral coordination vis-à-vis d\textsuperscript{9} Cu\textsuperscript{2+} in an essentially square planar environment. Ni\textsuperscript{1+}-containing solids are rare and difficult to synthesize. However, a family of such materials with square planar Ni does exist, with formula R\textsubscript{n+1}Ni\textsubscript{n}O\textsubscript{2n+2}, where the Ni\textsuperscript{1+} fraction is given by (n-1)/n. Indeed, the reported nickelate superconductor thin film derives from the Sr-doped ‘infinite layer’ endmember of this series, Nd\textsubscript{0.8}Sr\textsubscript{0.2}NiO\textsubscript{2}. Here we discuss the phase behavior of the n=3 member of this series, R\textsubscript{4}Ni\textsubscript{3}O\textsubscript{8}(R=La,Pr) made possible by advances in high pressure crystal growth. Specifically, we show the emergence in this system of several characteristics of cuprates that have been missing in nickelates, including strong in-plane x\textsuperscript{2}-y\textsuperscript{2} orbital polarization, significant 3d-2p mixing at E\textsubscript{F}, and competition between metallic and antiferromagnetic insulating stripe phases. We present an expanded phase diagram of the reduced, layered nickelates and suggest ways in which these materials might be made into superconductors.

3:06PM P46.00002: An \textit{ab initio} study of electron-hole pairs in the insulating single layer cuprates and nickelates\*  
CHRISTOPHER LANE (Presenter), JIAN-XIN ZHU, Los Alamos National Laboratory — Advanced density functionals have proven to be an indispensable tool in studying correlated materials exhibiting the delicate interplay between complex charge and non-collinear magnetic order. We perform a comparison study of the electronic and magnetic structure of a prototypical high-temperature superconductor La\textsubscript{2}CuO\textsubscript{4} with the isostructural single-layer nickelate La\textsubscript{2}NiO\textsubscript{4}. We find key differences in the low-energy electronic structure, where in particular, La\textsubscript{2}NiO\textsubscript{4} exhibits an enhanced Hund’s coupling. Additionally, utilizing our accurate \textit{ab initio} ground state, we obtain the excitonic dispersion for each material. Excitons in La\textsubscript{2}CuO\textsubscript{4} are delocalized and can freely move in the CuO\textsubscript{2} plane without disturbing the antiferromagnetic order. In contrast, in La\textsubscript{2}NiO\textsubscript{4} we find the low-lying excitonic states to be extremely localized, producing a nearly flat dispersion. Our results are in excellent agreement with RIXS observations, and give insights into the excited state dynamics of the cuprates and nickelates. Finally, we will briefly connect our results to the newly discovered superconducting infinite-layer nickelates.

3:18PM P46.00003: Low Temperature Specific Heat of Doped SrTiO$_3$: Doping Dependence of the Effective Mass and Kadowaki-Woods Scaling Violation*  ERIC MCCALLA, McGill University, MARIA NAVARRO GASTIASORO, GUY CASSUTO, RAFAEL FERNANDES, CHRIS LEIGHTON (Presenter), University of Minnesota — We discuss wide-doping-range (8 x 10$^{17}$ to 4 x 10$^{20}$ cm$^{-3}$ Hall electron density) low temperature specific heat measurements on single crystal SrTiO$_3$:Nb, correlated with electronic transport data and tight-binding modeling [1]. Lattice dynamic contributions to specific heat are shown to be well understood, albeit with unusual sensitivity to doping, likely related to soft modes. Electronic contributions to specific heat provide effective masses that increase substantially, from 1.8 to 4.8$m_e$, across the two SrTiO$_3$ Lifshitz transitions. It is shown that this behavior can be quantitatively reconciled with quantum oscillation data and calculated band structure, establishing a doping-independent mass enhancement factor of 2.0. With the doping-dependent $\tau^2$ resistivity prefactor and Sommerfeld coefficient known, Kadowaki-Woods scaling has been tested over the entire doping range. Despite Fermi liquid behavior in electronic specific heat, standard Kadowaki-Woods scaling is dramatically violated, highlighting the need for new theoretical descriptions of $\tau^2$ resistivity in SrTiO$_3$.

3:30PM P46.00004: Influence of structural distortions on the magnetic order of rare-earth titanates*  ANA NAJEV (Presenter), Faculty of Science, Department of Physics, University of Zagreb, DAMJAN PELC, SAJNA HAMEED, JOSEPH JOE, MARTIN GREVEN, School of Physics and Astronomy, University of Minnesota, MIROSLAV POZEK, Faculty of Science, Department of Physics, University of Zagreb — Perovskite oxides feature fundamentally and technologically alluring properties such as magnetism, superconductivity and colossal magnetoresistance. How structural distortions and disorder influence the electron system in these materials is an important open question. Rare-earth titanates show promise in shedding new light on this problem through the study of their magnetic ground states, which are controlled by distortions induced by different-sized rare-earth ions. The compounds exhibit an interplay among charge, orbital, spin and lattice degrees of freedom, which produces a complex phase diagram that includes ferromagnetic and antiferromagnetic phases (e.g., in $Y_{1-x}La_xTiO_3$) and metal-insulator transitions (e.g., $Y_{1-x}Ca_xTiO_3$, $La_{1-x}Sr_xTiO_3$). We have conducted NMR measurements on select rare-earth titanates. Our results point to unusual local behavior well above magnetic ordering temperatures, which is not seen by macroscopic probes. Additionally, we have modified the structural distortions by uniaxial pressure and investigated their effect via magnetic susceptibility measurements.

3:42PM P46.00005: Multipolar orders in Kondo materials [invited] Sungbin Lee, Korea Adv Inst of Sci & Tech, Arun Paramekanti (Presenter), Univ of Toronto — Recent experiments on a series of Pr-based heavy fermion cage compounds have found evidence of complex quadrupolar and octupolar orders emerging from interactions between localized non-Kramers doublets. This talk will discuss our recent work, employing Landau theory and Monte Carlo simulations, showing that incorporating multispin interactions is important to understanding such ordered states. We argue that such interactions might become increasingly important near the small-to-large Fermi surface transition.

4:18PM P46.00006: Changes in phonon dispersion across metal-insulator transition in a Pr-containing cobaltite* Daniel Phelan (Presenter), Matthew Krogstad, Materials Science Division, Argonne National Laboratory, Nathaniel Schreiber, Department of Materials Science and Engineering, Cornell University, Raymond Osborn, Materials Science Division, Argonne National Laboratory, Ayman Said, Advanced Photon Source, Argonne National Laboratory, Hong Zheng, Stephan Rosenkrantz, Materials Science Division, Argonne National Laboratory — A group of praseodymium-containing cobaltites are known to undergo 1st order metal-insulator transitions that are correlated to valence shifts that involve both Pr and Co cations. We have measured the dispersion of acoustic phonons in a single crystal of (Pr$_{0.85}$Y$_{0.15}$)$_{0.7}$Ca$_{0.3}$CoO$_{3-\delta}$ in both the metallic and insulating states and have observed differences which arise at the phase transition temperature. We interpret changes in the mode energies in terms of changes in the elastic constants. Anomalous damping of the phonons is observed near the phase transition. Elastic diffuse scattering, symptomatic of precursory behavior in the metallic phase is observed.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Science, Materials Science and Engineering Division. This research used resources of the Advanced Photon Source, a US Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Argonne National Laboratory under Contract No. DE-AC02-06CH11357.
4:30PM P46.00007: Phonon density of states of the infinite layer nickelate Nd$_{0.8}$Sr$_{0.2}$NiO$_2$*

STEPHAN ROSENKRANZ (Presenter), DANIEL PHELAN, BIXIA WANG, HONG ZHENG, Materials Science Division, Argonne National Laboratory, DOUGLAS L ABERNATHY, Neutron Scattering Division, Oak Ridge National Laboratory, JOHN MITCHELL, RAYMOND OSBORN, Materials Science Division, Argonne National Laboratory — One of the main mysteries of high-temperature superconductivity in oxides is why this has so far only been observed for cuprates, but not for other oxides with transition metals exhibiting similar electronic properties. The recent report of superconductivity up to 15K in a thin film nickelate with similar crystal and electronic structures to that of the cuprates, suggests that these infinite-layer nickelates could harbor superconductivity with the same underlying pairing mechanism as the cuprates. Here we report inelastic neutron scattering measurements performed on a bulk sample of Nd$_{0.8}$Sr$_{0.2}$NiO$_2$, the same nominal composition for which superconductivity was observed in thin film form grown on a SrTiO$_3$ substrate. We will discuss the implications of our results, in particular the measured phonon density of states, on possible superconducting mechanisms in this compound.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division. Work at ORNL’s Spallation Neutron Source was sponsored by the U.S. DOE, Office of Basic Energy Sciences, Scientific User Facilities Division.

4:42PM P46.00008: Study of competing order parameters and relaxation dynamics in La$_{1/3}$Sr$_{2/3}$FeO$_3$ using first-principles  
NAM NGUYEN (Presenter), VIJAY SINGH, HYOWON PARK, Univ of Illinois - Chicago — La$_{1/3}$Sr$_{2/3}$FeO$_3$ is a strongly correlated material exhibiting the strong interplay between spin, charge, and lattice degrees of freedom. It is an antiferromagnetic Mott insulator at low temperature below 200K accompanying a charge ordering with the Fe-O bond disproportionation. The charge ordering driven by magnetism shows the Fe$^{3+}$/Fe$^{5+}$/Fe$^{3+}$/Fe$^{3+}$/Fe$^{5+}$/Fe$^{3+}$ structure along the [111] direction, and it disappears above 200K as the magnetic order is suppressed. Using first-principles calculations, we identify two charge ordering structures can occur in this material. With close energetics near the ground state and study electronic and structural orders along the energy path obtained using method of climbing image nudged elastic band. We then solve the time-dependent Landau equation along the Free energy path and study the non-equilibrium dynamics of those competing order parameters. Our results can provide an insightful explanation to the slow dynamics of this material observed in the recent ultra-fast experimental measurement.
4:54PM P46.00009: Synthesis and characterization of bulk polycrystalline Nd\textsubscript{1-x}Sr\textsubscript{x}NiO\textsubscript{3} and 
Nd\textsubscript{1-x}Sr\textsubscript{x}NiO\textsubscript{2}\textsuperscript{*}  

BIXIA WANG (Presenter), HONG ZHENG, STEPHAN ROSENKRANZ, DANIEL PHELAN, 
JOHN MITCHELL, Argonne Natl Lab — Recently, superconductivity has been reported for Sr-doped nickelate NdNiO\textsubscript{2} thin films [1]. This intriguing result represents a realization of the long-sought superconductivity in oxides that possess low-valence nickel cations in square planar coordination. In this work, we have synthesized bulk polycrystalline Nd\textsubscript{1-x}Sr\textsubscript{x}NiO\textsubscript{3} and Nd\textsubscript{1-x}Sr\textsubscript{x}NiO\textsubscript{2} compounds. The electrical, magnetic and structural properties of these compounds are discussed.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Science, Materials Science and Engineering Division.

5:06PM P46.00010: Quantum Materials for Energy Efficient Neuromorphic Computing: 
Defective La\textsubscript{1-x}Sr\textsubscript{x}CoO\textsubscript{3-d}\textsuperscript{*}  

SHENLI ZHANG (Presenter), GIULIA GALLI, University of Chicago — We present a first principle study of La\textsubscript{1-x}Sr\textsubscript{x}CoO\textsubscript{3-d}, a promising candidate material to build devices for neuromorphic computers. In particular we investigate how the generation of oxygen vacancies can drive a metal-to-insulator transition in the system, with focus on the interplay between structural, electronic and magnetic properties.

Using DFT+U and the Quantum Espresso package (https://github.com/QEF/q-e/releases/tag/qe-6.1.0), we found that increasing the oxygen vacancy concentration from 0 % to ~11 % leads to a change of the cobalt’s oxidation state and of the magnetic state of the system, accompanied by a variation of the octahedral tilt angle and lattice parameters. Altogether these changes determine the opening of the fundamental gap. For x = 0 (no Sr doping) and d varying from 0 to 0.5, we observe a structural transformation from a perovskite phase (semiconductor) to a brownmillerite phase (insulator), consistent with experiments.

*This work was supported as part of the Quantum-Materials for Energy Efficient Neuromorphic-Computing (Q-MEEN-C), an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award # DE-SC0019273.
P46.00011: Protonation-induced magnetic phase transition in SrRuO$_3$* WEIDONG LUO (Presenter), ZIJUN TIAN, School of Physics and Astronomy, Shanghai Jiao Tong University, ZHUOLU LI, SHENGCHUN SHEN, PU YU, Department of Physics, Tsinghua University — In transition metal oxides, the subtle modulation of charge carrier triggers the emergence of exotic electronic and magnetic properties. In the ferromagnetic metal SrRuO$_3$, experiment has shown a systematic and reversible control of both carrier density and crystalline symmetry through the ionic liquid gating induced protonation. The insertion of protons dopes the SrRuO$_3$, leading to a ferromagnetic to paramagnetic phase transition. In order to understand the protonation induced structural and magnetic phase transformations in SrRuO$_3$, we performed first-principles calculations. The proton intercalation leads to a significant splitting of the degenerated Ru t$_{2g}$ bands, resulting in dramatically modified density of states. The lattice also shows a significant expansion with the intercalation of proton, consistent with the XRD results. The observed ferromagnetic to paramagnetic transition in SrRuO$_3$ can be understood within the Stoner model.

Wednesday, March 4, 2020 2:30 PM - 5:06 PM

Session P47 GMAG: Magnetism of 2D Semiconductors, Dichalcogenides and Graphene 710/712 - Scott Crooker, Los Alamos Natl Lab

2:30PM P47.00001: Magnetic interactions in the 2D layered van der Waals semiconductor CrPS$_4$ STUART CALDER (Presenter), Oak Ridge National Lab, AMANDA HAGLUND, University of Tennessee, YAOHUA LIU, DANIEL PAJEROWSKI, HUIBO CAO, TRAVIS WILLIAMS, VASILE O GARLEA, Oak Ridge National Lab, DAVID MANDRUS, University of Tennessee — Compounds with two-dimensional layers weakly connected by van der Waals bonding offer routes to enhanced quantum behavior in the bulk as well as in reduced layer materials achieved through exfoliation analogous to graphene. The presence of magnetic ions in the layers can provide new fundamental insights and possible functionality. Consequently the search and investigation of such "beyond graphene" materials has proved a recent focus for research efforts. CrPS$_4$ is such a semiconducting magnetic van der Waals material, however has undergone only limited experimental investigations to date. Here we present a series of neutron scattering measurements that allow the magnetic structure to be determined and exchange interactions extracted. The results reveal the subtle role of competing interactions, which manifest in a non-trivial magnetic transition and a tunable magnetic structure with small applied fields. Our results in the bulk compound provide intriguing insights that can be applied to an understanding of the behavior of reduced layer CrPS$_4$. 
2:42PM P47.00002: High Curie temperature and strain-induced spin reorientation transition in two dimensional CrPbTe3* IMRAN KHAN, JISANG HONG (Presenter), Pukyong National Univ — We investigated the strain-induced magnetic properties of two-dimensional CrPbTe3 (CPT) monolayer belonged to the members of Cr based two-dimensional family. We explored the possibility of fabrication of 2D layer through the mechanical stability, dynamical stability, formation energy, cohesive energy, and thermal stability calculations. We found ferromagnetic ground state and the pristine CrPbTe3 monolayer had an indirect band gap of 0.25 eV with an in-plane magnetic anisotropy of -1.37 meV/cell. The Curie temperature was 110 K and this is much larger than that of CrI3, CrSiTe3, and CrGeTe3. Under the 4 % tensile strain, the band gap was increased to 0.45 eV and also the Curie temperature was enhanced to 150 K. We found strain-induced semiconductor-metal transition under the compressive strain and also the spin reorientation transition from in-plane to perpendicular magnetic anisotropy at 4 % compressive strain and the perpendicular magnetic anisotropy energy was almost three times larger than that of the CrGeTe3 layer. Our finding may suggest that the CrPbTe3 system can be utilized for spintronics and straintronic applications.

*This research was supported by the National Research Foundation of Korea (NRF) (2019RA21B5B01069807).

2:54PM P47.00003: Magnetic Properties of Proton Irradiated van der Waals Magnets* SRINIVASA RAO SINGAMANENI (Presenter), LUIS M MARTINEZ, HECTOR ITURRIAGA, OLMOS RUBYANN, University of Texas, El Paso, QIANG WANG, West Virginia University, SHAO LIN, Texas A&M, YU LIU, CEDOMIR PETROVIC, Brookhaven National Laboratory — The advent of two-dimensional (2D) van der Waals (vdWs) magnetic crystals such as ABTe3 (A = Fe, Cr, Mn; and B = Si, Ge) creates new possibilities in exploring their magnetic properties as they are easily exfoliable. They retain their magnetic nature, chemical stability and structural integrity down to monolayers and, are readily tuned by various kinds of external stimuli, and opened enormous opportunities in controlling their magnetic states through coupling with external perturbations. Irradiation with protons has been shown to be an effective versatile method in inducing and manipulating the magnetic and electronic properties. In this work, we present and discuss the magnetic properties of proton irradiated vdWs magnets such MnSiTe3 and CrSiTe3 as a function of proton fluence (10^15 to 10^18/cm^2). Our findings show that it is possible to tune the saturation magnetization by about 53% in both these crystals. As evidenced from complementary measurements, spin-lattice coupling is strongly modified upon proton irradiation and that could cause the observed changes in the magnetic properties.

*Nuclear Regulatory Commission, 31310018M0019.
3:06PM P47.00004: Optical Characterizations of Magnetic Phases in Two-Dimensional Ferromagnetic Semiconductor CrSBr  KIHONG LEE (Presenter), AVALON DISMUKES, EVAN TELFORD, CORY DEAN, XIAOYANG ZHU, XAVIER ROY, Columbia University —
The advent of two-dimensional (2D) magnetic materials has not only altered our understanding of magnetism in low-dimensional systems, but invites numerous applications in nanoscale transport, optoelectronics, and quantum devices. However, the library of materials has been limited to metals and insulators with strong air-sensitivity, limiting the potential scope of utilization. Here, we present 2D ferromagnetic semiconductor CrSBr, which possesses in-plane magnetic anisotropy and interlayer antiferromagnetic coupling. Magnetic phase transitions in CrSBr are probed with second- and third-harmonic generations in various thicknesses to the monolayer limit. With decreasing number of layers, CrSBr displays unconventional increase in magnetic transition temperature. Linear spectroscopy and transport measurements demonstrate the semiconducting nature of the material. Lastly, Raman spectroscopy reveals complex magnetic phases in bulk CrSBr, some of which are suppressed at the atomically thin limit.

3:18PM P47.00005: Magnetic anisotropy of two-dimensional ferromagnetic insulator MnBi$_2$Te$_4$*  YANG LI (Presenter), WENHUI DUAN, Department of physics, Tsinghua university —
MnBi$_2$Te$_4$ has attracted great interest recently due to its magnetic and topological properties. Based on the density functional theory calculation, we systematically study the magnetic anisotropy of the monolayer MnBi$_2$Te$_4$, which is vital for establishing the long-range magnetic order in two-dimensional system. We find the exchange interaction in monolayer MnBi$_2$Te$_4$ almost has no contribution to the magnetic anisotropy, as a result of the weak p-d hybridization between Mn and Te. The magnetic anisotropy originates from the single-ion anisotropy, leading to a ferromagnetic Curie temperature of about 20 K. Interestingly, the emergence of the single-ion anisotropy cannot be induced solely by the spin-orbit coupling of Mn atoms, but also involves the spin-orbit coupling of ligand Te. This behavior is very different from that in monolayer CrI$_3$ and CrGeTe$_3$. Our findings may provide a comprehensive understanding of the magnetic behavior in monolayer MnBi$_2$Te$_4$ and motivate further research on its potential applications.

Ferrimagnetic excitations in the layered hexagonal compound $\text{Mn}_3\text{Si}_2\text{Te}_6^*$

MATTHEW STONE (Presenter), GABRIELE SALA, JIAO LIN, ANDREW MAY, Oak Ridge National Laboratory — The layered ferrimagnet $\text{Mn}_3\text{Si}_2\text{Te}_6$ orders below $T_c=78$ K. The $S=5/2$ Mn sites are arranged in alternating honeycomb and triangular lattice layers. Each honeycomb layer is ferromagnetically ordered with the moments pointing in a singular direction in the ab-plane. The triangular lattice layer has the moments also pointing in the ab-plane but in the opposite direction. A net moment is generated due to an imbalance in the Mn content within the different layer types. We examine single crystal inelastic neutron scattering measurements of the excitations in $\text{Mn}_3\text{Si}_2\text{Te}_6$ below $T_c$. We use super-resolution image correlation techniques to refine the resolution convolved spin-wave spectrum in order to determine the exchange interactions in this system. We find significant exchange interactions orthogonal to the ab-plane, produce a network of geometrically frustrated interactions. The potential for Dirac nodes in the dispersion of the coupled ferromagnetic hexagonal layers will also be considered.

Large scale synthesis of monolayer ferromagnetic $\text{Fe}_3\text{GeTe}_2^*$

RYAN ROEMER (Presenter), CHONG LIU, KE ZOU, University of British Columbia — Until now, the two-dimensional ferromagnets remain limited to exfoliated micron-sized samples. Large-scale thin films are desirable for the fabrication of integrated devices for spintronic and memory storage applications. We show, by molecular beam epitaxy, the synthesis of high-quality $\text{Fe}_3\text{GeTe}_2$ (FGT) films, a promising candidate that carries ferromagnetic states at room temperature upon ionic liquid gating. The FGT unit cell consists of two weakly coupled quintuple layer substructures with hexagonal symmetry, confirmed by surface x-ray diffraction.

*Quantum Electronic Science & Technology (QuEST) scholarship
Magnetism tunability in wafer-scale few-layered van der Waals ferromagnetic Fe₃GeTe₂ films

SHANSAN LIU (Presenter), KE YANG, ZIHAN LI, Department of Physics, Fudan Univ, WENQING LIU, Department of Electronic Engineering, Royal Holloway University of London, ENZE ZHANG, HUA WU, FAXIAN XIU, Department of Physics, Fudan Univ — Two-dimensional (2D) ferromagnetic materials have been discovered with tunable magnetism and nodal-line properties. 2D magnetism modulation in exfoliated nanoflakes via electrostatic gating introduces the boosted Tₘ. One of the most intriguing challenges, however, is still the realization of high Tₘ materials that are tunable, robust. Here, we report the effective manipulation of magnetic properties of wafer-scale 2D ferromagnetic Fe₃GeTe₂ films by changing the sample composition and utilizing the proximity effect in ferromagnetic/antiferromagnetic heterostructures. With the film thickness decreasing, Tₘ drops continuously from 220 K (bulk-like) down to 130 K (few-layer). By varying the sample compositions, Tₘ will monotonously increase as the ratio changing. Tₘ behaves a rising trend as the ferromagnetic/antiferromagnetic heterostructure period increases. Our experiments have confirmed the room-temperature Tₘ and the phase transition, which are consistent with the DFT calculations. The large-scale high-Tₘ film growth and controllable ferromagnetism of Fe₃GeTe₂ promise the practical spintronic applications. It also opens unprecedented opportunities to explore rich physics in heterostructures of van der Waals ferromagnets with 2D superconductors and topological materials.

Magnetic interactions in two-dimensional single-layer transition-metal dichalcogenides*

TATSUYA SHISHIDOU (Presenter), MICHAEL WEINERT, University of Wisconsin - Milwaukee — The transition-metal dichalcogenides (TMD), a class of two-dimensional layered van der Waals materials, have attracted extensive interest because of the wide variety of physical properties that they exhibit. An important recent addition is the intrinsic ferromagnetic order found in atomic single layers of VSe₂ [1] and MnSe₂ [2] that persists above room temperature. This discovery opens up exciting opportunities [3] to study strong spin fluctuations in reduced dimensionality, as well as to engineer novel spintronic devices. In this talk, using a density-functional spin-spiral approach [4], we address the magnetic interactions in two-dimensional TMD films in the ultrathin limit.

4:18PM P47.00010: High Curie temperature in magnetically doped tungsten diselenide
SABYASACHI TIWARI (Presenter), MAARTEN L VAN DE PUT, Department of Materials Science and Engineering, The University of Texas at Dallas, BART SOREE, imec, WILLIAM G VANDENBERGHE, Department of Materials Science and Engineering, The University of Texas at Dallas — Two-dimensional (2D) magnets have attracted immense attention recently because of their possible use in future energy-efficient spintronic devices. A class of 2D magnetic materials are transition-metal dichalcogenides (TMDs) that are substitutionally doped with magnetic transition metals like Cr, Fe, and Mn. Especially, TMDs based on heavy elements like tungsten (W) and selenium (Se). In this work, we investigate magnetism in magnetically doped WSe$_2$ monolayers using Density Functional Theory (DFT). In particular, we simulate the magnetic phase transition using Monte-Carlo simulations of a classical Heisenberg Hamiltonian, built for randomly doped samples of WSe$_2$. Specifically, we investigate the effect of dopant-atom clustering on the magnetic properties of doped monolayer WSe$_2$. To take into account the effect of the clustering of the dopant atoms, we introduce a functional form for the exchange interaction and obtain the parameters of our classical Heisenberg Hamiltonian from total energy DFT calculations. From the Monte-Carlo calculations, we extract the doping-density-dependent Curie temperature for each dopant atom. Finally, we show a high Curie temperature of about 300 K in Fe/Mn-doped WSe$_2$ at a doping concentration of 7-8%.

4:30PM P47.00011: Magnetic Response of Graphene Flakes*
SEAN DEYO (Presenter), SELMAN P HERSHFIELD, Physics, University of Florida — The orbital diamagnetism and spin paramagnetism of graphene flakes is computed as a function of size, shape, boundary type, and temperature, using a nearest-neighbor tight binding Hamiltonian. In general the orbital magnetization per atom grows as the size of the flake increases, but not necessarily monotonically. Flakes with "open" boundaries, where open means there are atoms on the edges of the flake with only one nearest neighbor, exhibit a smaller magnetization than flakes with "closed" boundaries, where closed means every atom has at least two nearest neighbors. The orbital susceptibility increases with temperature for open flakes, whereas the closed flakes show little change at low temperatures.

The paramagnetic spin response also depends on the boundaries. In particular, for certain types of edge defects states near zero energy are created. The wave functions of these states are not localized to the boundary. They produce a paramagnetic response that looks like an isolated spin so that the net magnetization of the flake is paramagnetic at low fields and diamagnetic at higher fields. Such magnetization vs. B plots have been observed.

*We thank the University of Florida's University Scholars Program for funding this research.
4:42PM P47.00012: Computational challenges in the characterization of magnetism for atomically precise nanographenes on noble metal substrates.*  
CARLO ANTONIO PIGNEDOLI (Presenter), KRISTJAN EIMRE, SHANTANU MISHRA, Empa, Swiss Federal Laboratories for Materials Science and Technology, DOREEN BEYER, Faculty of Chemistry and Food Chemistry & Center for Advancing Electronics Dresden, Technical University of Dresden, Dresden, Germany, OLIVER GRÖNING, PASCAL RUFFIEUX, ROMAN FASEL, Empa, Swiss Federal Laboratories for Materials Science and Technology — On-surface synthesis techniques have demonstrated high flexibility and atomic precision in the fabrication of carbon-based nanomaterials, with recent examples ranging from graphene nanoribbons hosting topological quantum phases\(^1\) to specifically shaped nanographenes (NGs).\(^2\)-\(^5\) NGs may exhibit a magnetic, open-shell structure as a result of their peculiar topology, which makes them highly attractive for applications in molecular electronics. Furthermore, unpaired spins in open-shell NGs may be used to perform spin logic operations. I will discuss present challenges for ab-initio simulations in understanding recent experiments reporting evidence of magnetism for specific nanographenes supported on gold substrates. I will present both, cases of non-Kekulé NGs where sublattice imbalance is responsible for magnetism, and of NGs where - despite absence of sublattice imbalance - topological frustration in the underlying π-electron network generates uncompensated radicals.

Increased Curie temperature and enhanced perpendicular magneto anisotropy of Cr$_2$Ge$_2$Te$_6$/NiO heterostructure*  

ANDRES LLACSAHUANGA ALLCCA (Presenter), Physics and Astronomy, Purdue University, HIROSHI IDZUCHI, XING-CHENG PAN, KATSUMI TANIGAKI, Advanced Institute for Material Research, Tohoku University, YONG CHEN, Physics and Astronomy, Purdue University — Van der Waals (vdW) materials with ferromagnetic properties down to few layers such as CrI$_3$ and Cr$_2$Ge$_2$Te$_6$ have recently attracted a lot of attention due to their potential in spintronic applications. However, the Curie temperature (T$_C$) of these vdW has remained relatively low. Here, we report increased T$_C$ and enhanced perpendicular magnetic anisotropy in Cr$_2$Ge$_2$Te$_6$ (CGT) flakes interfaced with antiferromagnetic insulator NiO for a wide range of CGT thicknesses (5-200 nm).

Measurements of the same flake by polar magneto optic Kerr effect (MOKE) microscopy before and after coating NiO reveal a hysteresis loop with a square shape and larger coercive field for the CGT/NiO heterostructure. Furthermore, the maximum T$_C$ observed for CGT/NiO reached ~120K, almost double the T$_C$ of CGT alone (~60K). These observations suggest that interfacing van der Waals ferromagnets with other materials could provide a venue to engineer their magnetic properties. [1]

**P47.00014: 2D Layered Ferromagnet: the Emergence of Skyrmions in Transition Metal Dichalcogenides**

*YUNBO OU (Presenter), Francis Bitter Magnet Laboratory, Plasma Science and Fusion Center, Massachusetts Institute of Technology, NORBERT MARCEL NEMES, Unidad Asociada ICMM-CSIC "Laboratorio de Heteroestructuras con Aplicación en Espintronica", Complutense University of Madrid, JOSE LUIZ MARTINEZ, Instituto de Ciencia de Materiales de Madrid ICMM-CSIC, MIRKO ROCCI, HANG CHI, Francis Bitter Magnet Laboratory, Plasma Science and Fusion Center, Massachusetts Institute of Technology, DANIEL LARSON, Department of Physics, Harvard University, AUSTIN AKEY, Center for Nanoscale Systems, Harvard University, WENBO GE, Department of Physics and Astronomy, Rutgers University, DHAVALA SURI, Francis Bitter Magnet Laboratory, Plasma Science and Fusion Center, Massachusetts Institute of Technology, DAVID CHARLES BELL, School of Engineering and Applied Sciences, Harvard University, WEIDA WU, Department of Physics and Astronomy, Rutgers University, EFTHIMIOS KAXIRAS, Department of Physics, Harvard University, JAGADEESH MOODERA, Department of Physics, Massachusetts Institute of Technology — Recently there is great attraction drawn towards Van der Waals (vdW) ferromagnet since the discovery of ferromagnetism in monolayer CrI$_3$. Due to the extraordinary topology driven properties, magnetic transition metal dichalcogenides (TMDCs) appear to behave more exotically. In this work, utilizing molecular beam epitaxy, a stable CrTe$_2$, one of TMDCs, films are fabricated down to monolayer (ML) level. Ferromagnetism is exhibited even down to the 2D insulating limit - 1 ML film. Surprisingly, the topological Hall effect (THE), which manifests the real space topology of magnetic structure in TMDCs, is observed in thicker films (> 6 ML) up to 130 K, a first such observation. Electric transport data and magnetometry data indicate a high possibility of presence of magnetic Skyrmions, real space nanometer-sized quasi-particles with topological spin textures. Although they are found in many systems even at room temperature, but not in TMDCs, until now. The discovery of magnetism in monolayer CrTe$_2$ and topological magnetic structure in thicker CrTe$_2$ not only enriches the 2D magnet family and the capability of TMDCs, but also pave a way for all vdW materials based spintronic devices.

2:30PM P48.00001: Study on the pressure-induced superconducting phases of antimony*
ZHENG WU (Presenter), LIANGZI DENG, MELISSA GOOCH, SHUYUAN HUYAN, PAUL C. W. CHU, Texas Center for Superconductivity and Department of Physics, University of Houston — Pressure-induced superconductivity in antimony was investigated electrically using a diamond anvil cell up to 61 GPa. A semimetal to metal transition was observed in the pressure range of 22 to 28 GPa at room temperature, which coincides with the transition from an incommensurate tetragonal host-guest structure to a body-centered cubic (bcc) structure. The high pressure metal phase was found to be superconducting and the transition temperature ($T_c$) was non-monotonous with regard to the applied pressure while in the bcc structure. The empirical rule, lighter elements having higher $T_c$s in a homologous series in non-transition elements in the periodic table, was found not to hold for bcc Sb when compared with Bi. A controlled pressure quench of the superconducting phase in the incommensurate composite phases at temperatures up to 77 K was also performed and the zero resistance was retained in the quenched phase with the midpoint of the superconducting transition above 3.4 K and a transition width of 0.2 K.

2:42PM P48.00002: Andreev quantum dot chain in an InSb nanowire  HAO WU (Presenter), PO ZHANG, JUN CHEN, University of Pittsburgh, SASA GAZIBEGOVIC, ROY OP HET VELD, GHADA BADAWY, ERIK BAKKERS, Eindhoven University of Technology, SERGEY M FROLOV, University of Pittsburgh — We built a chain of quantum dots in a semiconductor nanowire to study the Kitaev model of a one dimensional topological superconductor. Three quantum dots are electrostatically confined in an InSb nanowire. Each dot is strongly coupled to a superconducting NbTiN electrode. We observe Andreev bound states in each of these quantum dots and study their magnetic field dependence with fields parallel to the nanowire axis. Having two normal contacts at the wire ends and three superconducting leads, we are able to perform non-local measurements. We study spatial separation of Andreev bound states in this three dots chain with various inter-dot coupling strengths. Our experiments may provide insights on non-locality of zero modes in Majorana wires.
2:54PM P48.00003: Quantum Hall Effect in an Epitaxial Nitride Semiconductor/Superconductor Heterostructure*  PHILLIP DANG (Presenter), GURU BAHADUR KHALSA, Cornell University, D. SCOTT KATZER, NEERAJ NEPAL, BRIAN DOWNEY, VIRGINIA D. WHEELER, U.S. Naval Research Laboratory, ALEXEY SUSLOV, National High Magnetic Field Laboratory, ANDY XIE, EDWARD BEAM, YU CAO, CATHY LEE, Qorvo, HUILI XING, Cornell University, DAVID MEYER, U.S. Naval Research Laboratory, DEBDEEP JENA, Cornell University — The quantum Hall effect (QHE) is a paragon of topological protection in electronic states, exhibiting exceptional precision in resistance, while superconductivity allows exceptional precision in voltage due to flux quantization. To create seamless heterostructures of these two electronic phases is highly desirable for the discovery of new physics and use in quantum information science. To this end, we design an all-epitaxial superconductor/semiconductor nitride heterostructure, based on GaN two-dimensional electron gases (2DEGs) and superconducting NbN, using an industrial device process that is compatible with silicon and nitride semiconductor technology. The heterostructure is demonstrated to simultaneously exhibit the integer QHE in the GaN 2DEG and superconductivity in the NbN. Such a demonstration in an all-epitaxial nitride heterostructure is the first of its kind and paves the way for new quantum technologies.

3:06PM P48.00004: Transport properties of double quantum dots coupled to a superconductor  PO ZHANG (Presenter), HAO WU, University of Pittsburgh, SABBIR AHMED KHAN, PETER KROGSTRUP, University of Copenhagen, DAVID PEKKER, SERGEY M FROLOV, University of Pittsburgh — Superconductor/semiconductor hybrid systems have drawn a lot of attention due to their rich physics and the potential to demonstrate topologically protected qubits. We experimentally investigate transport properties of a double dot electrostatically defined in an InAs nanowire by metallic gates under the wire. Superconductivity is provided by epitaxial Al shell grown in-situ after nanowire growth. The shell induces a hard gap and sharp spectral features of Andreev bound states in the nanowire. The source of the double dot is a normal metal while the drain is a superconductor. We study the spectra of the resulting normal-Andreev double dot and search for the recently proposed Andreev blockade upon which current is blocked in the triplet (1,1) configuration which is unable to form a Cooper pair and enter the drain superconductor.
Angular dependence of the magnetoresistance in HgBa$_2$CuO$_{4+\delta}$.*

KATHERINE SCHREIBER (Presenter), ERIC BAUER, NEIL HARRISON, MUN KEAT CHAN, Los Alamos Natl Lab — The Fermi surface in the cuprates is known to undergo significant changes with temperature and doping, from Fermi arcs to small pockets reconstructed by charge density wave order. In general the shape of the Fermi surface for a particular phase reveals information about its place in the phase diagram; for example, the symmetries broken by the charge density wave. Such information is valuable to understanding the relationship of these phases to high temperature superconductivity. The pseudogap phase is of particular interest because superconductivity and the charge density wave emerge from this phase as temperature is lowered.

Here we present measurements of the angular dependence of the c-axis magnetoresistance in the pseudogap regime of underdoped single layer cuprate HgBa$_2$CuO$_{4+\delta}$. We have performed transport measurements up to 65 T at many angles of the c-axis with respect to the applied field. From this data we are able to extract details about the structure of the Fermi surface in the pseudogap regime and discuss its morphology.

Hall effect measurements under high pressure for Pr$_2$Ba$_4$Cu$_7$O$_{15-\delta}$

FUMIHIRO ISHIKAWA (Presenter), Faculty of Science, Niigata University, MASAYA SAWADA, Graduate School of Science and Technology, Niigata University, AYAKO OHMURA, Faculty of Science, Niigata University, TAKASHI NAKA, National Institute for Materials Science, ANTHEUNIS DE VISser, Univ. of Amsterdam — It is well known that the Pr-substitution for Y-site in YBa$_2$Cu$_3$O$_{7-\delta}$ and YBa$_2$Cu$_4$O$_8$ dramatically suppresses the superconducting transition temperature $T_c$ and superconductivity in CuO$_2$ planes disappears. However, Pr$_2$Ba$_4$Cu$_7$O$_{15-\delta}$ (Pr247) oxide shows superconductivity with $T_c = 15$ K after reduction treatment [1]. Pr247 has the same crystal structure as Y$_2$Ba$_4$Cu$_7$O$_{15-\delta}$ with an alternative repetition of the single and double chains along the c-axis. As-sintered sample of Pr247 shows metallic conductivity at low temperatures owing to the conduction in the CuO double chains. Reduction treatment on Pr247 caused the electron carrier density change by controlling the amount of oxygen deficiency. Applying high pressure on superconductive Pr247 suppresses the superconductivity. This is well explained by the one-dimensional conduction mechanism based on Tomonaga-Luttinger liquid theory [2]. High pressure study on Hall effect reveals the effect of pressure on electron carrier concentration for Pr247.

Influence of plastic deformation on the transport and magnetic properties of strontium titanate

SAJNA HAMEED (Presenter), DAMJAN PELC, ZACHARY ANDERSON, School of Physics and Astronomy, University of Minnesota Twin Cities, CHRIS LEIGHTON, Chemical Engineering and Materials Science, University of Minnesota, MARTIN GREVEN, School of Physics and Astronomy, University of Minnesota Twin Cities — Strontium titanate (SrTiO$_3$, STO) is one of the most important transition metal oxides: it is a model perovskite with a structural phase transition, and also one of the most commonly used single crystal substrates for epitaxial growth of oxide thin films. Superconductivity in STO occurs at unusually low carrier densities at temperatures well below 1 K and is not understood, even five decades after its discovery.

Building on our recent work on oxide superconductors [1], we explore another interesting property of STO: its high ductility at room temperature, which allows us to plastically deform single crystals using uniaxial pressure. We report on the influence of this compressive plastic deformation on the transport and magnetic properties of STO, with particular emphasis on the superconducting state.

Work supported by the Department of Energy through the University of Minnesota Center for Quantum Materials under DE-SC0016371.

Anomalous transverse magnetoresistance in superconductor/ferromagnet multilayers

XAVIER PALERMO, SALVATORE MESORACA, NICOLAS REYREN, ANKE SANDER, SOPHIE COLLIN, FLORIAN GODEL, KARIM BOUZEHOUANE, Unité Mixte de Physique CNRS/Thales, Palaiseau, France, JACOBO SANTAMARIA, GFMC, Universidad Complutense de Madrid, Spain, VINCENT CROS, Unité Mixte de Physique CNRS/Thales, Palaiseau, France, ALEXANDRE BUZDIN, LOMA, Université de Bordeaux, France, JAVIER VILLEGAS (Presenter), Unité Mixte de Physique CNRS/Thales, Palaiseau, France — We have studied the magnetoresistance of metallic multilayers composed of a low-$T_c$ superconductor (MoSi) and different ferromagnets (from single Co layers to combinations of these with heavy-elements) which present variable magnetic anisotropy and domain structure. In some cases, the longitudinal magnetoresistance shows a strong magnetic hysteresis that results from the interaction of flux quanta in the superconductor and the stray field from the ferromagnet's domains. Interestingly, that behavior is accompanied by an anomalous transverse magnetoresistance whose parity depends on the direction of the magnetic field relative to the ferromagnet's easy axis. We will discuss the different scenarios allowing for an understanding of these effects.

4:06PM P48.00009: Higgs mode and tr-ARPES in Non-equilibrium Superconductors with a Moving Condensate*  ANKIT KUMAR (Presenter), ALEXANDER F KEMPER, North Carolina State University — When a superconducting state is perturbed, one of the resulting excitations gives rise to the amplitude oscillation mode known as the Higgs mode. The existence of the Higgs mode in a perturbed broken-symmetry state is one of the fundamental phenomena in condensed matter systems. However, the Higgs mode is hard to measure experimentally due to the spin-less and charge-less nature of the condensate. Recently, it was proposed that the Higgs mode in superconductors can be coupled to light in the linear regime if there is a non-zero supercurrent present in the system. Motivated by that, we study the dynamics of the Higgs mode in the presence of supercurrent. We find that the supercurrent creates an asymmetry of the electron distribution in the momentum space which leads to a momentum-dependent superconducting spectral gap. When we pump the system with an ultra-fast light pulse, the frequency of the Higgs mode gains momentum dependence. We analyze the dynamics of the Higgs mode through the electron spectral function which can be measured using angle-resolved photoemission spectroscopy (ARPES), and propose that the presence of supercurrent may help in the observation of the Higgs mode through time-resolved ARPES.

4:18PM P48.00010: Magnetoconductance of planar cuprate superconductor/graphene junctions*  KEVIN SEURRE (Presenter), VINCENT HUMBERT, Unité mixte de physique CNRS-Thales, Palaiseau, France, DAVID PERCONTE, Cold temperature laboratory, Universidad autonoma de Madrid, Madrid, Spain, CHRISTIAN ULYSSE, C2N-CNRS, Palaiseau, France, ANKE SANDER, JUAN TRASTOY QUINTELA, BRUNO DLUBAK, PIERRE SENEOR, JAVIER VILLEGAS, Unité mixte de physique CNRS-Thales, Palaiseau, France — Graphene/superconductor junctions have been extensively studied using low-Tc superconductors, but studies involving high-Tc temperature cuprates are scarce despite their interest for instance the rich physics expected from the d-wave order parameter. Here we study planar high-Tc superconductor/graphene junctions fabricated by transferring CVD graphene onto optimally doped c-axis PDL grown YBaCuO_{7-x} films, which are patterned using electron lithography and ion irradiation. Transport measurements at low temperature revealed an interesting, anomalous behavior of the magnetoconductance, which first increases at low magnetic fields before remaining constant or decreasing depending on the samples. This effect highly depends on temperature and voltage bias applied to the junction. We will discuss the different scenarios allowing for an understanding of this behavior.

*Work supported by the ERC grant n° 647100 “SUSPINTRONICS”
4:30PM P48.00011: Non-Majorana quantized zero-bias conductance peaks in semiconductor nanowire devices
MAKSIM GOMANKO (Presenter), PENG YU, Univ of Pittsburgh, GHADA BADAWY, SASA GAZIBEGOVIC, ROY OP HET VELD, ERIK BAKKERS, Eindhoven University of Technology, JUN CHEN, SERGEY M FROLOV, Univ of Pittsburgh — Quantized zero bias conductance peaks are predicted and reported in InSb nanowire devices coupled to NbTiN superconductors under certain conditions that are compatible with Majorana zero modes. These conditions include induced superconductivity, spin-orbital coupling, and an external magnetic field. We observed quantized zero bias conductance peaks at one end of similar nanowire devices, without observing matching zero bias peak of any height on the other side. These results imply either a topological segment shorter than the superconducting segment which is 400 nm, or a non-Majorana origin of the observed quantized zero-bias peaks.

4:42PM P48.00012: Versatile and selective platform for high-quality hybrid semiconductor-superconductor nanowire devices.*
NICK LOO (Presenter), GREG P. MAZUR, Delft University of Technology, SEBASTIAN HEEDT, MARINA QUINTERO PEREZ, Microsoft station Q Delft, FRANCESCO BORSOI, Delft University of Technology, ALEXANDRA FURSINA, Microsoft station Q Delft, MAY AN VAN DE POLL, Delft University of Technology, KEVIN VAN HOOGDALEM, Microsoft station Q Delft, GHADA BADAWY, SASA GAZIBEGOVIC, ERIK BAKKERS, Department of Applied Physics, Eindhoven University of Technology, LEO P. KOUWENHOVEN, Microsoft station Q Delft — Majorana bound states and topological superconductivity are highly anticipated candidates for decoherence-free quantum computation. To achieve this goal, high-quality semiconductor-superconductor hybrid systems are the most promising platform. Here, we combine high-mobility semiconductor nanowires with selective deposition of a superconducting material, resulting in state-of-the-art hybrid devices. We benchmark our devices by investigating InSb/Al Josephson junctions. In voltage-bias spectroscopy, we observe multiple Andreev reflections indicating a highly-transparent interface. Furthermore, in current-bias spectroscopy we observe remarkably high critical currents. Finally, we emphasize that we have developed a versatile platform which can easily be used to investigate different material combinations. In addition, it can be used to create sophisticated quantum circuits for the purpose of demonstrating the proof of principle of a topological qubit.

4:54PM P48.00013: Design and discovery of CaKRu$_4$P$_4$: a new member of the generalized 1144 structure.* MINGYU XU (Presenter), Iowa State University, PALASYUK ANDRIY, Ames Lab, SERGEY L. BUD’KO, BOQUIN SONG, KAI-MING HO, PAUL C CANFIELD, Iowa State University — AeAFe$_4$As$_4$ (Ae=Ca, Sr; A=K, Rb, Cs) compounds were discovered as a new structural type [1] which has alternate stacking of the Ae and A layers. The AeAFe$_4$As$_4$ structure is stabilized by the combination of large $\Delta c = (c^{A122} - c^{Ae122})$ and small $\Delta a = (a^{A122} - a^{Ae122})$, where a and c are lattice parameters of the AFe$_2$As$_2$ and AeFe$_2$As$_2$ parent structures. In this presentation we extent this idea to similar, phosphorus-based 122 compounds with large $\Delta c$ and small $\Delta a$ values, identifying CaKRu$_4$P$_4$ as a promising candidate. The stability of a CaK1144 type ruthenium phosphide was also recently predicted by combining first principle calculations [2]. We synthesize polycrystalline CaKRu$_4$P$_4$ by solid state reaction of CaRu$_2$P$_2$ and KRu$_2$P$_2$. The crystallographic structure and physical properties of CaKRu$_4$P$_4$ will be presented.

2:30PM P49.00001: Plutonium in high magnetic fields. MARK WARTENBE (Presenter), PAUL H TOBASH, NEIL HARRISON, JOHN SINGLETON, LAUREL E WINTER, Los Alamos National Laboratory — High magnetic field studies of plutonium have been limited up until now. The complex behavior of plutonium’s 5f electrons are thought to be responsible for the elements unusual behavior, making it possibly the strangest element in the periodic table. Here we review data from a new set of various experiments involving high magnetic field and extremes of temperature. High magnetic fields are especially effective in probing electronic states and is the highlighted method of this study. We present the data in the context of gaining in site into the 5f electrons physics of the material and its ephemeral magnetic moment.
2:42PM P49.00002: Ab initio study of the properties of liquid uranium for temperatures up to 2050 K* LUIS GONZALEZ (Presenter), BEATRIZ GONZALEZ DEL RIO, DAVID GONZALEZ, Univ de Valladolid — Uranium compounds are used as fissile materials in nuclear reactors. Nowadays the most used nuclear fuel is UO$_2$, but in generation-IV reactors other compounds are being considered, such as UC and UN [1].

Upon possible loss of coolant accidents, the core of the reactor would get heated up to very high temperatures, and it is essential to understand the behaviour of the nuclear fuel in such conditions for proper risk assessment. UO$_2$ and UC would eventually melt, but UN would not reach a melting process since at high temperatures it is thermochemically unstable, and decomposes into gaseous N$_2$ and liquid U.

The experimental study of liquid U is difficult and scarce. For instance, there is no experimental information about its static structure factor. In this contribution we analyze the properties of liquid U, studied through ab initio methods, for three temperatures in the temperature range between its melting point (1405 K) and 2050 K. We show results for the static structure and also for several dynamic properties, including atomic diffusion and viscosity.

2:54PM P49.00003: Theoretical investigations of the tritium diffusion pathways in γ-LiAlO$_2$ pellets HARI P PAUDEL, TING JIA, YUHUA DUAN (Presenter), Natl Energy Technology Lab — In tritium-producing burnable absorber rods (TPBAR), γ-LiAlO$_2$ is used in the form of an annular ceramic pellet enriched with $^6$Li isotope and is located between the zircaloy-4 liner and nickel-plated zircaloy-4 tritium getter with a gas gap in between. When irradiated in a pressurized water reactor (PWR), the $^6$Li pellets absorb neutrons and produce tritium ($^3$H) through $^6$Li + n → $^3$H + α. However, accurate analysis of the $^3$H transport through the ceramic pellets and the barrier/cladding system is hampered by the lack of fundamental data about the hydrogen isotope solubility and diffusivity. For TPBARs to enable effective tritium production in PWRs and to improve the performances of these components, we are investigating the $^3$H solubility and diffusion pathways in the bulk and surface of γ-LiAlO$_2$ with different concentrations of lithium defects. The calculated results for bulk and low-index surfaces properties, thermal conductivity, $^3$H activation energy barriers, and the diffusion coefficients in γ-LiAlO$_2$ are in good agreement with the available experimental values. With a better knowledge of $^3$H transport properties within γ-LiAlO$_2$ pellets through our modeling, its performances and higher $^3$H production rate can be further evaluated experimentally with a higher confidence.
3:06PM P49.00004: Complex Phase Behavior of U$_3$O$_8$  ANDREW MISKOWIEC (Presenter), JENNIFER NIEDZIELA, TYLER SPANO, Oak Ridge National Lab, SARAH FINKELDEI, University of California - Irvine, RODNEY HUNT, MICHAEL AMBROGIO, Oak Ridge National Lab — Oxidation of UO$_2$ produces U$_3$O$_8$. During oxidation, the unit cell undergoes a significant expansion (approx. 17%). This reaction must be considered in technological applications of UO$_2$ (such as nuclear fuel). U$_3$O$_8$ itself has multiple crystal phases, including an orthorhombic Amm2 phase that occurs below 300 °C, and a hexagonal P-62m phase above 300 °C. Although these phases are nearly isomorphic, one fact is that the Amm2 phase has two crystallographic uranium sites, and the oxidation configuration is 2U(V) + U(VI). But, the P-62m phase has only one crystallographic site, and so each of the three uranium atoms must carry 16/3 charge. We present preliminary investigations into possible resolutions of this observation, including temperature dependent Raman and x-ray diffraction measurements. Coupled with density functional theory calculations, we show an intimate relationship between phonon softening and local U-O structural re-arrangements. In particular, softening of one strong Raman-active mode near 420 cm$^{-1}$ appears to be the driving effect in the orthorhombic-to-hexagonal phase transition. We also explore the possibility of coupling between this phonon and the electronic structure and whether this phonon facilitates an electron-hopping mechanism.

3:18PM P49.00005: Crystal-field states of UO$_2$ probed by directional dependence of nonresonant inelastic x-ray scattering*  MARTIN SUNDERMANN (Presenter), Institute of Physics II, University of Cologne, GERRIT VAN DER LAAN, Magnetic Spectroscopy Group, Diamond Light Source, ANDREA SEVERING, Institute of Physics II, University of Cologne, LAURA SIMONELLI, ALBA Synchrotron Light Source, GERARD H LANDER, European Commission, Joint Research Centre (JRC), MAURITS HAVERKORT, Institute for Theoretical Physics, Heidelberg University, ROBERTO CACIUFFO, European Commission, Joint Research Centre (JRC) — Core-level nonresonant inelastic x-ray scattering (NIXS) [1-3], also called x-ray Raman scattering, has been performed on single crystals of UO$_2$ to study the directional dependence of higher-order multipole scattering from the uranium O$_{4,5}$ edges (90-110 eV). By comparing the experimental results with theoretical calculations the symmetry of the ground state is confirmed directly as the crystal-field Γ$_5$ triplet state within the $J = 4$ manifold [4] as had been suggested by inelastic neutron scattering [5]. The results demonstrate that the directional dichroism of the NIXS spectra is sensitive to the CF strength and establish NIXS as a tool for probing crystal-field interactions quantitatively.

*NIXS data were taken at the beamline ID20 at the ESRF in Grenoble under proposal HC-743. M.S. and A.S. benefited from the financial support of the Deutsche Forschungsgemeinschaft (DFG) under grant SE-1441-5-1.
Excess Electrons on Reduced AnO$_2$ (111) Surfaces (An = Th, U, Pu) and Their Impacts on Catalytic Water Splitting

GAOXUE WANG (Presenter), ENRIQUE BATISTA, PING YANG, Los Alamos National Laboratory — Excess electrons from intrinsic oxygen vacancies play a key role in the surface chemistry and catalytic properties of metal oxides. This effect is particularly critical in actinide dioxides (AnO$_2$), the most common nuclear fuels, where radiation can induce the formation of vacancies. However, the behavior of excess electrons on AnO$_2$ surfaces has not been fully explored. In this talk, I will discuss our first-principle study of the electronic structure of excess electrons from oxygen vacancies on AnO$_2$ (111) surfaces. The low-energy electronic structure is searched via U-ramping and occupation matrix control. The excess electrons are found to localize at the vacancy site on ThO$_2$, move to the metal 5f orbitals on PuO$_2$ surface, with UO$_2$ as an intermediate case. In the presence of water, the excess electrons lead to the exothermic splitting of H$_2$O and formation of H$_2$ on ThO$_2$ and UO$_2$ surfaces, while on PuO$_2$ surface the formation of H$_2$ is thermodynamically unfavorable. This work has important implications in the surface chemistry and corrosion of AnO$_2$, and hence the handling and long-term storage of spent nuclear fuels.

LANL LDRD and Director's Postdoc Fellow

First Principles Investigation of the electronic and magnetic structure of Pu$_6$Fe

SARAH HERNANDEZ (Presenter), JOHN M WILLS, Los Alamos National Laboratory — Chemical impurities within δ-plutonium (Pu) arises due to the casting and processing of the material. One impurity, iron (Fe), is believed to segregate to the grain boundaries and forms an intermetallic compound ζ-Pu$_6$Fe. This compound was determined by X-ray diffraction (XRD) to be body-centered tetragonal with a space group of I4/mcm and to date, very little is known about its physical properties, other than it has a low melting temperature at 410°C. Using density functional theory, we can predict equilibrium properties and begin to understand the fundamental electronic and magnetic structure of Pu$_6$Fe. This work will present density functional theory calculations using the all-electron full-potential linearized augmented-plane-wave plus local orbital basis method as implemented in the WIEN2k code. Calculations included a non-magnetic, ferromagnetic, and anti-ferromagnetic arrangement at the respective optimized structures with no-spin-orbit-coupling, spin-orbit-coupling, and spin-orbit-coupling with orbital polarization to gauge the different level of theories.

This work is funded by LDRD.
3:54PM P49.00008: Magnetic torque of USb single crystals  XIAXIN DING (Presenter), KESHAV SHRESTHA, Idaho National Laboratory, INGRID ZIMMERMANN, ROSS MCDONALD, FRANZISKA WEICKERT, NEIL HARRISON, MARCELO JAIME, MYRON B SALAMON, Los Alamos National Laboratory, J-C. GRIVEAU, DG Joint Research Centre, Germany, JAMES L SMITH, Los Alamos National Laboratory, KRZYSZTOF GOFRYK, Idaho National Laboratory — Over 40 years, uranium monoantimonide (USb) has been investigated by a variety of experimental and theoretical methods. This compound crystallizes in the cubic NaCl-type of crystal structure and is known to order antiferromagnetically with a non-collinear triple-k magnetic structure below $T_N \sim 214$ K. This high-symmetry complex magnetic structure consists of three equivalent $<0 0 1>$-type of wave vectors, with spins that point along $<1 1 1>$ direction. During the talk we will present results of our recent magnetic torque measurements performed on high-quality single crystals of USb at temperatures below and above $T_N$. The measurements have been carried out in both DC and pulsed magnetic fields up to 60 T. The results obtained are crucial in understanding of magnetic interactions, anisotropy, and their coupling to the lattice in this material. We will discuss implications of these results.

4:06PM P49.00009: 5f-electron localization in metallic PuPdSn*  KRZYSZTOF GOFRYK (Presenter), Idaho National Laboratory, J-C. GRIVEAU, ERIC COLINEAU, ROBERTO CACIUFFO, DG Joint Research Centre, Directorate G-Nuclear Safety and Security, Karlsruhe, Germany, JAMES L SMITH, Los Alamos National Laboratory — While the effect of electronic correlations is relatively well studied in Ce, Yb and U based materials, there is still lack of knowledge on how these collective phenomena impact magnetic, transport, and thermodynamic properties in transuranium intermetallics. Depending upon the strength of the interactions, many unusual properties such as complex magnetism, Kondo effect, heavy fermion ground state, valence fluctuations, and/or unconventional superconductivity have been observed in these materials. Here we present our detailed studies on the structural, magnetic, thermal, and transport properties of PuPdSn. This compound crystalizes in the hexagonal ZrNiAl-type of structure [space group P62m]. It orders antiferromagnetically at $T_N = 21$ K that is followed by another AF-like transition at 9.6 K. The low-temperature linear specific heat coefficient is small, $\gamma \sim 8$ mJ/mol K$^2$. All the results obtained strongly suggest the presence of well localized 5f-states in this material, which is rare among U and Pu intermetallics.

*We are grateful to R. Jardin and J. Rebizant for sample preparation and characterization. This work is supported by DOE's Early Career Research Program.
Equiatomic GdNi and HoNi are ferromagnetic materials with a Curie temperature $T_c = 69$ K and $T_c = 36$ K, respectively. These compounds exhibit a large magnetocaloric effect and are suitable for low temperature magnetic refrigerator applications. We investigate the electronic structure of GdNi and HoNi using Hard X-ray photoemission spectroscopy (HAXPES). HAXPES of the Gd and Ho 3d, 4d, 4s and 5p core level spectra confirm the atomic multiplets of Gd$^{3+}$ and Ho$^{3+}$.

Valence band HAXPES of GdNi and HoNi shows Ni 3d features at the Fermi level, confirming a partially filled 3d band, while the Gd 4f/ Ho 4f states occur at high binding energies away from the Fermi level. For GdNi, we have also carried out XAS and XMCD studies in the ferromagnetic phase at $T = 25$ K. We analyze the Gd $M_{4,5}$-edge and Ni $L_{2,3}$-edge spectra using atomic multiplet and cluster model calculations, respectively. The Gd $M_{4,5}$-edge XMCD spectrum is consistent with a ground state configuration of $S = 7/2$ and $L=0$. The Ni $L_{2,3}$-edge XMCD results indicate that the antiferromagnetically aligned Ni moments exhibit a small but finite magnetic moment ($m_{\text{tot}} \sim 0.19 \mu_B$). The results indicate that the Ni 3d band is not fully occupied and invalidates the charge-transfer model for GdNi and HoNi.
Magnetic frustration and magnetic correlations in YbMn$_2$Sb$_2$ single crystals

RAQUEL RIBEIRO (Presenter), JULIAN MUNEVAR, FABIANA R ARANTES, LETICIE MENDONÇA-FERREIRA, MARCOS A AVILA, Univ Federal do ABC, ELVEZIO MORENZONI, Paul Scherrer Institut — The crystal growth and the structural, transport and magnetic characterization of the magnetically frustrated YbMn$_2$Sb$_2$ single crystals are reported. The crystals show a trigonal symmetry, where corrugated honeycomb layers of MnSb are separated by Yb atoms. No structural transition was observed down to 22 K. The resistivity measurements show a predominantly insulating behavior. The combined resistivity, dc and ac susceptibility, and heat capacity measurements confirm successive transitions at 230 K, 116 K and 40 K, being the transition at $T_N = 116$ K due to the Mn$^{2+}$ lattice antiferromagnetic ordering. Muon spin rotation experiments ($\mu$SR) reveal a more complicated scenario, with a complex temperature dependence of the magnetic volume fraction and a several order of magnitude variation of the relaxation rate, with its maximum at approximately 40 K.

Study of the Band Structure and the Origin of the XMR Effect in La$_{1-x}$Ce$_x$Bi

YUJIE HAO (Presenter), XIAO-MING MA, BIN LI, YANPING GUO, FENG YUE, RUI'E LU, CHANG LIU, Southern University of Science and Technology — Extremely high magnetoresistance (XMR) [1] in the rare earth monopnictides LnX (Ln = La, Ce, X = Sb, Bi) has recently received considerable interest [2-3]. These compounds with simple rock salt structure and electronic band structure are ideal model systems to search for the origin of the XMR effect. In this work, La$_{1-x}$Ce$_x$Bi single crystals with $x$ ranging from 0 to 0.2 is studied. By combining transport, magnetic and angle-resolved photoemission measurements, we performed a systematic investigation on the magnetotransport property and electronic structure of La$_{1-x}$Ce$_x$Bi. We clearly observe that the XMR effect in LaBi is gradually suppressed with increasing Ce doping level. The field-induced resistivity upturn and plateau disappear before the XMR effect is completely suppressed. On the other hand, the band structures near the Fermi surface barely changed with increasing Ce doping level. According to our results, whether the XMR effect originates from particular bands near the Fermi surface still needs further investigation.

P49.00014: The interplay of electronic, magnetic and structural properties of GdB₆ from first principles*  
SHAOWEN XU (Presenter), Physics Department, International Centre of Quantum and Molecular Structures, Shanghai University, Shanghai, 200444 China — Gadolinium hexaboride (GdB₆) is a well-known field emitter material that has been investigated for more than three decades. We perform a systematical density-functional theory (DFT) study of GdB₆ by using the generalized-gradient approximation and considering the electron interaction parameter U. The basic structural and electronic properties are carefully revised, as well as a strong U-value dependence in determining the antiferromagnetic (AFM) magnetic structures of Gd 4f electronic states. We found a small U (0~3eV) showing the most consistent experimental ground-state properties, which gives rise to a magnetic structure with a ground state of C-AFM and a second stable E-AFM. Moreover, we find the distortion modes of boron octahedron play an important role in the interaction between spin and lattice structures in this system. These results will deepen our understanding of the boron-based correlated rare earth compounds.

Maxim Dzero, Kent State Univ - Kent

2:30PM P50.00001: Floquet control of indirect exchange interaction in periodically-driven magnetic lateral heterostructures*  
MAHMOUD M. ASMAR (Presenter), WANG KONG TSE, Physics and Astronomy, University of Alabama — Controlling the indirect exchange interaction between ferromagnetic impurities is pivotal for spintronic information transfer and storage. We present a theory for the RKKY interaction in a monochromatically irradiated magnetic lateral heterostructure (MLH). The MLH is composed of a left-side ferromagnet, a two-dimensional electron gas, and a right-side ferromagnet. Using the Keldysh-Floquet formalism, we calculate the time-averaged spin susceptibility and RKKY interaction mediated by the irradiated MLHs. Our results show that the emergence of non-equilibrium Floquet states under periodic driving leads to two qualitatively different RKKY regimes: 1) when the n ≤ 0 Floquet bands intersect the Fermi level, the sign and period of oscillation of the RKKY interaction are controllable by the frequency and amplitude of the laser; 2) when the n ≤ -1 Floquet bands intersect the Fermi level, the RKKY coupling does not display oscillations and remains ferromagnetic, resembling the exchange interaction mediated by insulating spacers. Our work demonstrates the feasibility of optically controlling the indirect exchange interaction with coherent laser fields.

Nonequilibrium susceptibility in photoinduced Floquet states

ATSUSHI ONO (Presenter), SUMIO ISHIHARA, Department of Physics, Tohoku University — We investigate the nonequilibrium spin susceptibility in an electron system subject to a time-periodic electric field [1]. The spin susceptibility is formulated on the basis of the Floquet Green’s function method, and is calculated numerically in a wide range of amplitude and frequency of light. When the frequency is larger than the bandwidth, the susceptibility is enhanced by the dynamical localization effect, and their peak positions in the momentum space are shifted due to the Fermi surface deformation. In the case of the small frequency and amplitude, a multiple-peak structure emerges in the susceptibility, originating from the electron-hole excitation in and between the Floquet sidebands. To confirm those numerical results and provide the interpretation, a perturbative expression of the susceptibility is derived for small electric-field amplitude.

Promoting spontaneous symmetry breaking through Floquet band engineering

ILIYA ESIN (Presenter), GAURAV KUMAR GUPTA, Technion - Israel Institute of Technology, EREZ BERG, Weizmann Institute of Science, MARK RUDNER, Niels Bohr Institute, University of Copenhagen, NETANEL LINDNER, Technion - Israel Institute of Technology — In itinerant electronic systems, spontaneous symmetry breaking results from an interplay between interactions and density of states: a large density of states allows electrons to form long-range correlations by reducing the associated kinetic energy cost. The prospect of realizing new correlated states of electrons motivates us to seek methods for engineering band structures exhibiting large densities of states. We show that "Floquet engineering" via application of strong electromagnetic fields provides means for obtaining the necessary density of states to realize a novel nonequilibrium spontaneous symmetry breaking transition. We show that the transition occurs in the steady-state of the system achieved due to interplay between the coherent external drive, electron-electron interactions, and dissipative processes due to coupling to phonons and the electromagnetic environment. We obtain the phase diagram of the system using numerical calculations that match predictions obtained from a phenomenological treatment and discuss the conditions on the system and the external drive under which spontaneous symmetry breaking occurs. Our results imply that Floquet engineering of the density of states provides a new route for obtaining correlated states of electrons "on-demand".
Observation of Floquet prethermalization in dipolar spin chains

PAI PENG (Presenter), CHAO YIN, XIAOYANG HUANG, Massachusetts Institute of Technology MIT, CHANDRASEKHAR RAMANATHAN, Dartmouth College, PAOLA CAPPELLARO, Massachusetts Institute of Technology MIT — Periodically driven (Floquet) quantum systems provide a promising platform to study physics out of equilibrium, such as time crystalline phase and Floquet topological structure. However, the drive generically heats up the system to infinite temperature. Still, it was shown theoretically that the heating rate is exponentially small in the driving frequency, giving rise to a long-lived prethermal stage that exhibits all the intriguing properties of Floquet systems.

Here we present nuclear magnetic resonance observation of Floquet prethermalization in dipolar spin chains. We first show that the system quickly converges to a prethermal state that agrees with the equilibrium statistics of a time-independent “prethermal” Hamiltonian (PTH). We then observe the exponentially slow heating of quasi-conserved quantities, by measuring the time-autocorrelation of the PTH itself. Intriguingly, we find that at timescale when the PTH is no longer conserved, the system may still possess other symmetries.

The results improve our understanding of thermalization in driven quantum systems and demonstrate the possibility to realize novel Floquet phases of matter and robust Floquet engineering in the prethermal regime.

Approaching a Floquet Time Crystal phase in the periodically driven O(N) model

MUATH NATSHEH (Presenter), New York Univ NYU, ANDREA GAMBASSI, SISSA, Italy, ADITI MITRA, New York Univ NYU — Results are presented for the dynamics of the periodically driven O(N) model starting from a prescribed initial state. This model is known to host ferromagnetic phases that, depending on microscopic parameters, are period doubled or period synchronized, the former being an example of a Floquet Time Crystal. Employing numerical simulations, and analytic calculations within a large-N approach, we study how an initial paramagnetic phase evolves into the Floquet time crystal phase following a quench. We identify regimes where the transient dynamics is characterized by an effective mass that approaches steady state as a universal power-law. Results for the one-loop corrections to correlations functions in this transient regime are presented. Analogies to transient dynamics at the critical point of the static O(N) model are highlighted. The possibility of universality in the transition from the paramagnetic and Floquet time crystal phase is discussed.

3:30PM P50.00006: Quantum butterfly effect in polarized Floquet systems with conservation laws*  
XIAO CHEN (Presenter), RAHUL M NANDKISHORE, ANDREW LUCAS, University of Colorado, Boulder — We explore quantum dynamics in Floquet many-body systems with local conservation laws in one spatial dimension, focusing on sectors of the Hilbert space which are highly polarized. We numerically compare the predicted charge diffusion constants and quantum butterfly velocity of operator growth between models of chaotic Floquet dynamics (with discrete time translation invariance) and random unitary circuits which vary both in space and time. We find that for any non-zero polarization per length (in the thermodynamic limit), the random unitary circuit correctly predicts the butterfly velocity but incorrectly predicts the diffusion constant. We argue that this is a consequence of quantum coherence on short time scales. Our work clarifies the settings in which random unitary circuits provide correct physical predictions, and the origin of the slow down of the butterfly effect in highly polarized systems.

3:42PM P50.00007: Floquet Conformal Field Theory*  
RUIHUA FAN (Presenter), YINGFEI GU, ASHVIN VISHWANATH, Harvard University, XUEDA WEN, Massachusetts Institute of Technology — Conformal field theory provides an ideal platform to discuss examples of Floquet dynamics in an analytic and exact way. Earlier work solved for the Floquet dynamics using a particular driving Hamiltonian (the sl(2,R) generators) and restricted initial state (eigenstates). In this talk, we will generalize the original set-up to go beyond the sl(2,R) algebra and also discuss driving a thermal state. We will discuss the entanglement pattern and energy profile in these generalized set-ups and also describe some non-universal features of the Floquet dynamics.

3:54PM P50.00008: Positivity of the Spectral Densities of Retarded Floquet Green Functions*  JAMES FREERICKS (Presenter), Physics, Georgetown University, MONA KALTHOFF, Physics, University of Hamburg, GOETZ S UHRIG, Physics, University of Dortmund — Periodically driven nonequilibrium many-body systems are interesting because they have quasi-energy spectra, which can be tailored by controlling the external driving fields. We derive the general spectral representation of retarded Green functions in the Floquet regime, thereby generalizing the well-known Lehmann representation from equilibrium many-body physics. The derived spectral Floquet representation allows us to prove the non-negativity of spectral densities and to determine exact spectral sum rules, which can be employed to benchmark the accuracy of approximations to the exact Floquet many-body Green functions.

4:06PM P50.00009: Floquet dynamics under spatially inhomogeneous drive*  ZHOUSHEN HUANG (Presenter), AASHISH CLERK, IVAR MARTIN, Argonne Natl Lab — Floquet engineering has been shown to be a promising mechanism in realizing quantum information manipulations. While spatially homogeneous drives allow for block diagonalization in momentum, and have thus often been invoked in theoretical studies, in realistic systems, translation symmetry is typically broken. In this work, we discuss features of Floquet systems under inhomogeneous spatial drives, in the context of band theory, such as nondispersing traveling wave packets, simplification of dynamical Hilbert space, and a machine learning scheme which can predict time dynamics of arbitrary temporal driving profiles.

*Argonne LDRD
4:18PM P50.00010: Long-lived interacting phases of matter protected by multiple time-translation symmetries in quasiperiodically-driven systems  DOMINIC ELSE (Presenter), Department of Physics, Massachusetts Institute of Technology MIT, WEN WEI HO, Department of Physics, Harvard University, PHILIPP DUMITRESCU, Center for Computational Quantum Physics, Flatiron Institute — We show how a large family of interacting nonequilibrium phases of matter can arise from the presence of multiple time-translation symmetries, which occur by quasiperiodically driving an isolated quantum many-body system with two or more incommensurate frequencies. These phases are fundamentally different from those realizable in time-independent or periodically-driven (Floquet) settings. Focusing on high-frequency drives with smooth time-dependence, we rigorously establish general conditions for which these phases are stable in a parametrically long-lived `preheating' regime. We develop a formalism to analyze the effect of the multiple time-translation symmetries on the dynamics of the system, which we use to classify and construct explicit examples of the emergent phases. In particular, we discuss time quasi-crystals which spontaneously break the time-translation symmetries, as well as time-translation symmetry protected topological phases.

4:30PM P50.00011: Non-equilibrium steady state solutions of time-periodic driven Luttinger liquids* SERENA FAZZINI (Presenter), University of Kaiserslautern, Germany, PIOTR CHUDZINSKI, School of Mathematics and Physics, Queens Univ. Belfast, CHRISTOPH DAUER, IMKE SCHNEIDER, SEBASTIAN EGGERT, University of Kaiserslautern, Germany — The recent development of Floquet engineering has made periodic driving a versatile tool for achieving new phases not accessible in static equilibrium systems. We now study the exact Floquet steady states of the periodically driven Tomonaga-Luttinger liquid without resorting to any high frequency approximations. We show that the time-dependent Schrödinger equation can be solved analytically for a large class of driven interacting 1D systems, which give the resulting non-equilibrium steady states. Remarkably, we observe regions of instabilities as a function of total momentum where the solution is not of Floquet form, which implies a loss of time translational invariance and therefore heating of excitations. For small driving amplitudes the instabilities are close to the naively expected resonance condition $nu=2vq$, but for stronger driving the heating regions separate a rich structure of bands of steady state solutions. Physical consequences are discussed.

4:42PM P50.00012: Spontaneously broken discrete time translation symmetry in driven quantum Brownian motion*  JYONG-HAO CHEN (Presenter), Physics, University of California, Berkeley, MASAKI OSHIKAWA, ISSP, University of Tokyo — Spontaneously broken discrete time translation symmetry (DTTS) in Floquet systems, often be dubbed as discrete time crystal or Floquet time crystal, draws a lot of attention in recent years. While most experimental realizations and theoretical studies of the DTTS breaking involve many-body localization to avoid heating, the effect of dissipation is an obvious alternative to prevent heating. In this work, we consider the quintessential model of quantum dissipation — the Caldeira-Leggett model and take into account the presence of a periodically driven external potential. Employ a perturbative approach within the framework of Feynman-Vernon influence functional enables us to demonstrate analytically that DTTS breaking would occur in such a simple model. The interplay between the driving frequency, the strength of dissipation, and the temperature are studied in detail. A crossover between the quantum and classical limit is examined as well. Owing to the ubiquitousness of the ordinary Caldeira-Leggett model, our findings pave a new avenue toward exploring the novel phenomena of DTTS breaking in broad systems.

4:54PM P50.00013: Dynamic Control of Metal-Insulator Transitions Out of Equilibrium*  JOSEPH KLEINHENZ (Presenter), IGOR KRIVENKO, Physics, University of Michigan, GUY COHEN, Chemistry, Tel Aviv University, EMANUEL GULL, Physics, University of Michigan — Dynamic switching between different phases of quantum matter offers many exciting theoretical and practical possibilities. We present recent results from our studies of switching across the Mott metal-insulator transition in the Hubbard model within the framework of non-equilibrium DMFT. We find that the metal to insulator transition is relatively easy to drive but for many quenches the insulator to metal transition occurs over a very long timescale. We present quench protocols that are able to overcome this difficulty and demonstrate controllable switching across the phase boundary in both directions.

5:06PM P50.00014: Photo-induced superconductivity in the Kondo lattice  TOMONORI SHIRAKAWA (Presenter), SHOHEI MIYAKOSHI, SEIJI YUNOKI, RIKEN — The non-equilibrium dynamics can induce many interesting phenomena in strongly correlated quantum systems. For example, recent experiments have observed the photoinduced superconducting-like behavior in some of the high-$T_c$ cuprates and the alkali-doped fullerenes even above $T_c$. In this context, we have previously studied theoretically the photo-excited states from the Mott insulating state in the Hubbard model and found that the pulse irradiation can induce the enhancement of superconducting correlations, which is attributed to eta-pairing formation [1]. Here, we show that the same mechanism can be applied to the Kondo lattice model, an effective model for heavy fermion systems, by demonstrating that the photo-irradiation indeed enhances the eta-pairing correlations. As in the Hubbard model, the non-linear optical process is essential to increase the number of photo-induced eta-pairs and thus enhance the superconducting correlations.

2:30PM P51.00001: Fully tunable Magic Angle Twisted Bilayer Graphene Josephson Junction

DANIEL RODAN-LEGRAIN (Presenter), YUAN CAO, JEONG MIN PARK, Massachusetts Institute of Technology MIT, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology MIT — Superconductivity and correlated insulating states have recently been observed in ‘magic-angle’ twisted bilayer graphene (MATBG) heterostructures at twist angles close to 1.1 degrees, featuring nearly-flat bands owing to strong interlayer coupling. MATBG offers a new playground to study superconductivity and strongly correlated physics with an unprecedented degree of tunability. One of the elemental superconducting devices are Josephson Junctions, where two superconductors are coupled by a non-superconducting weak link. In this work, we exploit such tunability to create a fully tunable 2D Josephson Junction allowing to independently control the electronic state of the weak link and the rest of the junction via multiple electrostatic gates. The MATBG electrodes can thus be brought into a superconducting state, either in the hole regime or the electron regime, while the narrow junction at the center of the device can be tuned into any possible state of the phase diagram of MATBG (from metal, band insulator, charge neutrality, correlated insulator, superconductor). Such devices may pave the way towards new geometries in the study of strongly correlated systems, tunable superconducting qubits, and fully-integrated 2-dimensional electronics for the future nanodevice technology.

2:42PM P51.00002: Chiral twist on the high-T\textsubscript{c} phase diagram in moiré heterostructures\textsuperscript{*}

YU-PING LIN (Presenter), RAHUL NANDKISHORE, Department of Physics, University of Colorado, Boulder —

We show that the large orbital degeneracy inherent in moiré heterostructures naturally gives rise to a ‘high-\text{\textsubscript{T_c}}’ like phase diagram with a chiral twist - wherein an exotic quantum anomalous Hall insulator is flanked by chiral $d+id$ superconducting domes. Specifically, we analyze repulsively interacting fermions on hexagonal lattices near Van Hove filling, with an SU(4) flavor degeneracy. At this point, a nested Fermi surface and divergent density of states give rise to strong $\ln^2$ instabilities to correlated phases, the competition between which can be controllably addressed through a combination of weak coupling parquet renormalization group and Landau-Ginzburg analysis. We uncover an unambiguous and rich behavior, wherein at weak coupling the leading instability is to a Chern insulator, characterized by a spontaneous breaking of time reversal symmetry and a quantized Hall response. Upon doping this phase gives way to a chiral $d+id$ superconductor. We further consider deforming this minimal model by an orbital splitting, and discuss the resulting RG flow and phase diagram. Our analysis thus bridges the minimal model and the practical moiré bands, thereby elucidates transparently how the correlated phases arise.

\textsuperscript{*}Supported by the Army Research Office under Grant No. W911NF-17-1-0482.
We present a systematic classification and analysis of possible pairing instabilities in graphene-based moiré superlattices. Motivated by recent experiments on twisted double-bilayer graphene showing signs of triplet superconductivity, we analyze both singlet and triplet pairing separately, and describe how these two channels behave close to the limit where the system is invariant under separate spin rotations in the two valleys, realizing an SU(2)$_+$ $\times$ SU(2)$_-$ symmetry. Further, we discuss the conditions under which singlet and triplet can mix via two nearly degenerate transitions, and how the different pairing states behave when an external magnetic field is applied. We find that an approximate SU(2)$_+$ $\times$ SU(2)$_-$ symmetry can generically account for the linear increase of the critical temperature with small magnetic fields, and we map out the possible forms of the phase diagram as a function of temperature and magnetic field. Finally, we also detail the differences in the classification when the additional microscopic or emergent symmetries relevant for twisted bilayer graphene and ABC trilayer graphene on hexagonal boron nitride are taken into account.

*This research was funded by the NSF (Grant DMR-1664842) and the German National Academy of Sciences Leopoldina (Grant LPDS 2016-12).

We use scanning tunneling microscopy to explore several non-encapsulated twisted bilayer graphene devices with different nominal twist angles. In this talk, I present quantitative results of the homogeneity on different length scales.

3:18PM P51.00005: Tunable electron interactions in moiré graphene: extinction of Mott order in the presence of screening  ALI FAHIMNIYA (Presenter), MIT, DMITRI EFETOV, PETR STEPANOV, ICFO Barcelona, LEONID LEVITOV, MIT — Magic-angle twisted bilayer graphene (TBG) is a strongly-correlated system that hosts different ordered states, notably Mott-insulating and superconducting, stabilized by the electron-electron (e-e) and electron-phonon (el-ph) interactions. Understanding the individual roles of these interactions, as well as their interplay, is a central question of the moiré graphene physics. To that end, we explore the robustness of the Mott order in the presence of a screened e-e interaction, as is the case in currently studied heterostructures comprised of TBG, hexagonal boron nitride (hBN), and graphite layers. Screening of electron charges in TBG by image charges in graphite weakens e-e interactions as the hBN spacer width decreases. The suppression of the Mott order due to enhanced screening sets in at the hBN widths on the order of the Wannier orbital radius (~10nm) and is followed by complete extinction of the Mott order. At the same time, el-ph coupling strength remains unchanged. The experiments, too, show a drastic change of the Mott insulator phase upon varying hBN width but find that the superconducting phase survives in the absence of long-range e-e interactions. Comparison of theory and experiment sheds new light on the origin of Mott order and superconductivity in the TBG system.

3:30PM P51.00006: Tunable bandwidths and gaps in twisted double bilayer graphene system on the verge of correlations*  PRATAP ADAK (Presenter), SUBHAJIT SINHA, UNMESH GHORAI, L. D. VARMA SANGANI, Tata Institute of Fundamental Research (TIFR), KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Tsukuba, RAJDEEP SENSARMA, MANDAR M DESHMUKH, Tata Institute of Fundamental Research (TIFR) — Recently, superlattices in graphene have gained much interest due to its ability to tune its band structure. In particular, it has been demonstrated that when two copies of monolayer graphene are stacked with a ‘magic’ angle twist between them, flat bands appear. Flat bands give birth to a plethora of electronic interaction governed phenomena like superconductivity, ferromagnetism, etc.

When two copies of bilayer graphene are put on top of each other with a relative twist, it allows electrical control over the flatness of the bands and the gaps between them. Even before studying interaction driven physics, it is useful to study the tunability of bands in such a system. We perform transport measurements on dual gated twisted double bilayer graphene device (TDBG) and use simple model calculations to understand important experimentally observed features. Specifically, we will discuss how the bandwidth of the bands can be tuned electrically and how an electron-hole asymmetric model can explain some observations. A discussion on some observations which may be precursors to correlation will conclude the presentation.

*We acknowledge funding from Department of Atomic Energy, India and Department of Science and Technology, India.
Observation of charging peaks near the flat band in magic-angle twisted bilayer Graphene

NIKHIL TILAK (Presenter), XINYUAN LAI, Department of Physics and Astronomy, Rutgers University, 136 Frelinghuysen Road, Piscataway, NJ 08855 USA, YUHANG JIANG, JINHAI MAO, Department of Physics and Astronomy, University of Chinese Academy of Sciences, CMSJ+7X, Huabeiizhen, Huairou, Beijing, China, MINGYU XU, RAQUEL DE ALMEIDA RIBEIRO, PAUL C CANFIELD, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa, 50011, USA, EVA ANDREI, Department of Physics and Astronomy, Rutgers University, 136 Frelinghuysen Road, Piscataway, NJ 08855 USA — Magic-angle twisted bilayer Graphene (MA-tBLG) has emerged as a highly tunable platform to study correlation physics. Numerous transport experiments have shown the existence of correlated insulating states, unconventional superconductivity and emergent ferromagnetism as the filling of the flat moire bands in MA-tBLG is tuned. More recently, several Scanning Tunneling Microscopy/Spectroscopy (STM/STS) experiments have also observed correlated-insulator like behavior, charge order and broken C3 symmetry in this system. Here, using Low temperature STM/STS measurements, we report the observation of sharp charging peaks which appear in the LDOS as the Fermi level is tuned close to the edges of the flat band. We perform a systematic study of these states to see their evolution in space using STS mapping. The observation of these states hints at the formation of local compressible regions surrounded by a gapped incompressible region because of tip induced band bending.

Experimental Observation of Tunable Chern insulator and Ferromagnetism in ABC-Trilayer Graphene on hBN Moiré Superlattice

GUORUI CHEN (Presenter), University of California, Berkeley, AARON SHARPE, ELI J FOX, Stanford, YAHUI ZHANG, MIT, SHAOXIN WANG, LILI JIANG, University of California, Berkeley, BOSAI LV, Shanghai JiaoTong University, HONGYUAN LI, University of California, Berkeley, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, ZHIWEN SHI, Shanghai jiaoTong University, SENTHIL TODADRI, MIT, DAVID GOLDHABER-GORDON, Stanford, YUANBO ZHANG, Fudan University, FENG WANG, University of California, Berkeley — Haldane theorized that Chern insulators with integer QH effects could appear in lattice models with complex hopping parameters even at zero magnetic field. The ABC-trilayer graphene/hexagonal boron nitride (TLG/hBN) moiré superlattice provides an attractive platform to explore Chern insulators because it features nearly flat moiré minibands with a valley-dependent electrically tunable Chern number. Here we report the experimental observation of a correlated Chern insulator in a TLG/hBN moiré superlattice. We show that reversing the direction of the applied vertical electric field switches TLG/hBN’s moiré minibands between zero and finite Chern numbers, as revealed by dramatic changes in magneto-transport behavior. The Hall resistance is well quantized at h/2e2, i.e. C = 2, for B > 0.4 T. The correlated Chern insulator is ferromagnetic, exhibiting significant magnetic hysteresis and a large anomalous Hall signal at zero magnetic field. Our discovery of a C = 2 Chern insulator at zero magnetic field should open up exciting opportunities for discovering novel correlated topological states, possibly with novel topological excitations, in nearly flat and topologically nontrivial moiré minibands.
Spin-triplet superconductivity and ferromagnetism in moire systems: A case study for twisted double bilayer graphene

YI-TING HSU (Presenter), FENGCHENG WU, University of Maryland, College Park — Recent experiments have observed possible ferromagnetism and spin-triplet superconductivity in twisted double bilayer graphene that comprises a pair of AB-stacked bilayer graphene under a displacement field. We show that ferromagnetism and spin-triplet pairing can naturally be the dominant instabilities in such systems as a general consequence of the valley-dependent van Hove physics when the nesting is weak. Specifically, by performing a renormalization group analysis for all possible pairing, magnetic, and charge instabilities, we find ferromagnetism or spin-triplet pairing to be dominant throughout a broad parameter space of interactions and low-energy band structure properties we consider. Finally, we discuss the possibility of topological superconductivity and relevance to the experimental findings.

Ferromagnetism in twisted bilayer graphene

AARON SHARPE (Presenter), ELI J FOX, ARTHUR W BARNARD, JOE FINNEY, Stanford Univ, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, MARC KASTNER, DAVID GOLDHABER-GORDON, Stanford Univ — When two sheets of graphene are stacked at a small twist angle, the resulting flat superlattice minibands are expected to strongly enhance electron-electron interactions. These enhanced interactions have led to the observation of interesting correlated electronic states, such as superconductivity, where metallic behavior would otherwise be expected. Here we present evidence that near three-quarters (3/4) filling of the conduction miniband these enhanced interactions drive the twisted bilayer graphene into a ferromagnetic state. We suggest that the system is a Chern insulator. We further present magneto transport measurements in tilted field that may hold clues to the nature of the magnetism.

Ferromagnetism in narrow bands of moiré superlattices

CECILE REPELLIN, DONG ZHIHUAN (Presenter), Department of Physics, Massachusetts Institute of Technology, YAHUI ZHANG, Department of Physics, Harvard University, SENTHIL TODADRI, Department of Physics, Massachusetts Institute of Technology — Many graphene moiré superlattices host narrow bands with non-zero valley Chern numbers. We provide analytical and numerical evidence for a robust spin and/or valley polarized insulator at total integer band filling in nearly flat bands of several different moiré materials. In the limit of a perfectly flat band, we present analytical arguments in favor of the ferromagnetic state substantiated by numerical calculations. Further, we numerically evaluate its stability for a finite bandwidth. We provide exact diagonalization results for models appropriate for ABC trilayer graphene aligned with hBN, twisted double bilayer graphene, and twisted bilayer graphene aligned with hBN. We also provide DMRG results for a honeycomb lattice with a quasi-flat band and non-zero Chern number, which extend our results to larger system sizes. We find a maximally spin and valley polarized insulator at all integer fillings, which can be destabilized by interaction-induced effective dispersive terms. These results still hold in the case of zero valley Chern number. We give an intuitive picture based on extended Wannier orbitals, and emphasize the role of the quantum geometry of the band, whose microscopic details may enhance or weaken ferromagnetism in moiré materials.
Transport experiments in twisted (double) bilayer graphene

PETER RICKHAUS, FOLKERT DE VRIES (Presenter), ELIAS MARIN PORTOLES, GIULIA ZHENG, Physics, ETH Zurich, MING-HAO LIU, National Cheng Kung University, Taiwan, JOSE LADO, Aalto University Helsinki, JOHN WALLBANK, Centre for Ecology and Hydrology, Oxfordshire, SERGEY SLIZOVSKIY, The University of Manchester, MARCIN KURPAS, University of Silesia in Katowice, RICCARDO PISONI, HISKE OVERWEG, YONGJIN LEE, ANNIKA KURZMANN, MARIUS EICH, CHUYAO TONG, REBEKKA GARREIS, CAROLIN GOLD, MICHELE MASSERONI, Physics, ETH Zurich, KLAUS RICHTER, University of Regensburg, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, Japan, THOMAS IHN, KLAUS ENSSLIN, Physics, ETH Zurich — We study signatures in electronic transport in twisted (double) bilayer graphene. Specifically, we are interested in the coupling and decoupling between single- and bilayer graphene layers as a function of twist angle. For large twist angles, the wavefunction of the layers are decoupled. Using twisted double bilayer graphene, we determine the intrinsic energy difference between inner and outer layers of the stack. Such a crystal field opens a gap in the groundstate [1]. Since the two layers are strongly capacitively coupled but their wavefunctions can be independently tuned, the geometric capacitance between the layers is heavily affected by the finite thickness of graphene, which we determine [2]. We also show transport data at small angles, where the layers are strongly coupled. At tiny twists, we detect a topological network [3] in twisted bilayer graphene and correlated states in twisted double bilayer graphene. Finally, we study the crossover between the coupled and decoupled regime, where the wavefunctions start to spread over all layers.

4:54PM P51.00013: Colossal mid-infrared photoresponse in small-twist-angle bilayer graphene* BINGCHEN DENG (Presenter), CHAO MA, Yale University, QIYUE WANG, University of Texas at Dallas, SHAOFAN YUAN, Yale University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, FAN ZHANG, University of Texas at Dallas, FENGNIAN XIA, Yale University — Small-twist-angle bilayer graphene has drawn much attention recently due to its exotic transport properties such as superconductivity and correlated insulating phase. The Brillouin zone folding and the formation of flat moiré bands significantly modify the density of states (DOS). Here we demonstrate the colossal and gate-tunable mid-infrared (5 ~ 12 μm) photoresponse leveraging the enhanced DOS and the emergence of superlattice-induced bandgaps. At liquid nitrogen temperature, we achieve a maximum extrinsic responsivity of 26 mA W⁻¹ at 12 μm in a 1.81° twist angle bilayer graphene, when the Fermi level is tuned to the middle of the superlattice gap in the electron branch. Together with transport study, we reveal the bolometric origin of the photoresponse. Moreover, the colossal photoresponse critically relies on the formation of superlattice gaps as it is vanishingly small in ultrasmall twist angle (< 0.5°) device, where the gaps are absent in our measurement range. Our results show the desirable properties and promising applications of twisted bilayer graphene for mid-infrared optoelectronics.

5:06PM P51.00014: Nano-photocurrent mapping of twisted bilayer graphene SAI SUNKU (Presenter), ALEXANDER MCLEOD, Columbia Univ, TOBIAS STAUBER, ICMM-CSIC, HYOBIN YOO, Harvard Univ, DORRI HALBERTAL, GUANGXIN NI, AARON STERNBACH, Columbia Univ, BOR-YUAN JIANG, UC San Diego, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, PHILIP KIM, Harvard Univ, MICHAEL M FOGLER, UC San Diego, DMITRI BASOV, Columbia Univ — We report a combined nano-photocurrent and infrared nanoscopy study of twisted bilayer graphene. We show that the photocurrent as a function of carrier density changes sign at twist-induced insulating states. We use this property to identify domains of varying local twist angle in our sample. Consistent with the photocurrent study, infrared nano-imaging experiments reveal optical conductivity features dominated by twist-angle dependent interband transitions. Nano-photocurrent imaging can be broadly applied to moiré superlattices occurring in various other van der Waals heterostructures.
**5:18PM P51.00015: Nano-optical study of Moire superlattice domains in twisted graphene heterostructures**

DORRI HALBERTAL (Presenter), NATHAN FINNEY, SAI SUNKU, SHAOWEN CHEN, CHARLES ZHANG, NICOLA CURRELI, MATTHEW A YANKOWITZ, ALEXANDER MCLEOD, GUANGXIN NI, ALEXANDER KERELSKY, CARMEN RUBIO VERDU, LEO MCGILLY, ABHAY NARAYAN, CORY DEAN, JAMES C HONE, DMITRI BASOV, Physics, Columbia University — Twisted graphene heterostructure have attracted a considerable amount of attention, realizing a plethora of physical phenomena including strongly interacting correlated states, superconductivity, magnetism and more. In this work we used several nano-optical techniques to study the formation and reconstruction of domain walls in several twisted graphene heterostructures. The techniques are uniquely suited to provide a nanometric spatial map of the domains, over an entire flake scale, which allowed us to study domain formation and internal structure on all relevant scales, and to gain insight into the reconstruction problem in several system of interest, including the twisted bilayer graphene and the twisted double bilayer graphene.

**2:30PM P52.00001: Detecting Stable Surface Adsorbates with Bayesian Optimization**

JARI JÄRVI (Presenter), MILICA TODOROVIC, PATRICK RINKE, Department of Applied Physics, Aalto University — Determining stable structures of organic molecules at inorganic surfaces requires both quantum mechanics and thorough exploration of the potential energy surface (PES). This is prohibitively expensive with density-functional theory (DFT). We combine DFT with artificial intelligence (AI) for global atomistic structure search of stable adsorbates. Bayesian Optimization Structure Search (BOSS) [1] is a new AI tool, which accelerates the structure search via a strategic sampling of the PES. BOSS minimizes the number of expensive DFT simulations to compute the complete PES. This allows a clear identification of the most stable minimum energy structures and the barriers between them.

We apply BOSS to study the adsorption of a camphor molecule on the Cu(111) surface as a function of molecular orientation and translations. We identify the optimal structure and 8 unique types of stable adsorbates, in which camphor chemisorbs via oxygen (global minimum) or physisorbs via hydrocarbons to the Cu(111) surface. This study demonstrates that the new cross-disciplinary tools, like BOSS, allow us to identify complex interface structures and properties, and tune the functionality of advanced materials.

2:42PM P52.00002: Unusual self-assembly of chloroaluminium phthalocyanine on graphite
HAIYANG MA (Presenter), JINFENG JIA, Shanghai Jiao Tong Univ, RUIQIN ZHANG, Physics, City University of Hong Kong — We report an unusual self-assembled layer structure of chloroaluminium phthalocyanine (ClAlPc) molecules on highly ordered pyrolytic graphite (HOPG), in which a close-packed well-ordered monolayer is separated from the substrate by a relatively disordered buffer layer, as revealed using scanning tunneling microscopy (STM). Our close-packed monolayer has a nearly rectangular lattice, instead of the distinctly different square lattice for the more commonly observed well-ordered bilayer structure. This may be due to the dominance of intermolecular interactions within the monolayer when the influence from the substrate is shielded by the buffer layer. Density Functional Theory (DFT) calculations and Reduced Density Gradient (RDG) analysis indicate that the dominant intermolecular interaction within the unusual layer is likely the London dispersion force.

2:54PM P52.00003: Coherent X-ray measurement of local step-flow propagation during growth on polycrystalline organic semiconductor thin film surfaces*  RANDALL HEADRICK (Presenter), JEFFREY G ULBRANDT, Department of Physics and Materials Science Program, University of Vermont, PECO MYINT, Division of Materials Science and Engineering, Boston University, JING WAN, Boston University, YANG LI, Department of Physics and Materials Science Program, University of Vermont, ANDREI FLUERASU, YUGANG ZHANG, LUTZ WIEGART, National Synchrotron Light Source II, Brookhaven National Laboratory, KARL F LUDWIG, Division of Materials Science and Engineering and Department of Physics, Boston University — Vapor deposition of C\textsubscript{60} on a graphene coated surface is investigated in real-time by utilizing coherent hard X-rays. X-ray Photon Correlation Spectroscopy is performed in grazing incidence to achieve surface-sensitivity. Local step-flow is monitored through the observation of oscillatory correlations in the later stages of growth after crystalline mounds have formed. Coherent X-rays do not average over complex structures, and this allows us to monitor growth on polycrystalline surfaces without loss of information. The results show that the step-flow velocity is nonuniform, and we model the velocity of each step-edge as being a simple function of the lengths of the terraces above and below it. Sensitivity to local step-flow is enhanced by coherent mixing of X-rays scattered from the average mound structure with those scattered from the step array. This effect is a version of heterodyne scattering, where the scattering from the average step array can be considered to be a quasi-static reference signal. This work shows that the use of coherent X-ray scattering provides an approach to better understand surface dynamics and fluctuations during crystal growth.

3:06PM P52.00004: Realizing nearly-free-electron like conduction band in a molecular film through mediating intermolecular van der Waals interactions* [Invited] MIN FENG (Presenter), School of Physics and Technology and Key Laboratory of Artificial Micro- and Nano-Structures of Ministry of Education, Wuhan University — The degree of electron delocalization in organic semiconductors is critical for their adoption in electronic and optoelectronic applications. Electron delocalization, however, is usually facile through chemical bonds in conjugated organic materials, but is rarely optimal when the noncovalent intermolecular vdW forces define the self-assembly and the intermolecular electronic coupling. As a typical vdW material, C_{60} molecules form solids through the attractive vdW force, thus are characterized with flat electronic bands with inconsequential dispersions and hopping transport, which is unfavourable for their practical applications.

To enhance intermolecular electronic hybridization, we introduce a method to mediate the vdW interactions between C_{60} molecules through a substrate control of intermolecular interactions. We show by STM and theory that the black phosphorus (BP) substrate organizes C_{60} molecules into a compressed monolayer that optimizes the intermolecular π-π couplings, resulting in a nearly-free-electron (NFE) like LUMO band in C_{60} monolayers, acquiring an effective mass of 0.53-0.70 and has carrier mobility of ~200 to 440 cm^2V^{-1}s^{-1}. The fact that the π-π vdW interactions does trigger the NFE like electronic band formation implies that templating of intermolecular interactions by vdW forces on otherwise weakly interacting substrates provides a promising strategy for tailoring remarkable electronic properties in organic materials for electronics and optoelectronics.

3:42PM P52.00005: Predicting $\chi$ of polymer blends using atomistic "morphing" simulations

SHREYA SHETTY (Presenter), ENRIQUE D GOMEZ, SCOTT MILNER, Pennsylvania State University — The Flory Huggins interaction parameter $\chi$ governs phase behavior in polymer blends and block copolymers. We have previously used molecular dynamic (MD) simulations and thermodynamic integration during the morphing of one species to another, to compute the excess free energy of mixing in coarse-grained, bead-spring model of polymer blends. Using this method, we have studied the effect on $\chi$ of factors like stiffness mismatch, chain architecture and Lennard Jones interactions. In this work, we use united-atom MD simulations and the morphing method to calculate $\chi$ for real polymer blends: (1) poly(ethylene) - poly(ethylene oxide), (2) poly(styrene) - poly(2-vinyl pyridine), (3) poly(isoprene) - saturated (polyisoprene) and (4) poly(styrene) - poly(α-methyl styrene). These examples require different kinds of morphing- LJ interactions and partial charges of atoms (cases 1 and 2), transform double bond to single bond (case 3) and disappearance of atoms (case 4). All simulations used force field parameters adopted from TRAPPE. Our $\chi$ values from simulations are in reasonable agreement with experiment, but are sensitive to force field parameters used in the simulation.

3:54PM P52.00006: Visualizing Molecular Orientational Ordering and Electronic Structure in Cs$_n$C$_{60}$ thin films

SHA HAN (Presenter), Physics, Tsinghua University, MENGXUE GUAN, Chinese Academy of Sciences, CANLI SONG, Physics, Tsinghua University, YILIN WANG, Shandong University, MINGQIANG REN, Physics, Tsinghua University, SHENG MENG, Chinese Academy of Sciences, XUCUN MA, QIKUN XUE, Physics, Tsinghua University — Alkali-doped fullerides exhibit a wealth of unusual phases that remain controversial by nature. Here a cryogenic scanning tunneling microscopy and first-principles calculation are combined to investigate the sub-molecular structural and electronic properties of expanded fullerene C$_{60}^{n^-}$ films on inert graphene with various cesium (Cs) doping. By varying the discrete charge states and film thicknesses, we reveal a large tunability of orientational ordering of C$_{60}^{n^-}$ anions, yet the tunneling conductance spectra are robustly characteristic of energy gaps, hallmarks of the Jahn-Teller distortions and electron correlations. The Fermi level lies halfway within the insulating gap for stoichiometric Cs doping level of $n = 1, 2, 3$ and $4$, apart from which it moves toward the band edges with concomitant electronic states in the gap. Our findings establish the universality of Jahn-Teller instability, and clarify the relationship among the doping, structural and electronic structures in Cs$_n$C$_{60}$ fullerides.

Facet Specific Adsorption as a Route to Remediation of Chlorinated Organic Contaminants

HAO GUO (Presenter), Univ of Akron, EMILY GERSTEIN, University of Wisconsin-Milwaukee, KSHITIJ C JHA, MESFIN TSIGE, Univ of Akron — The deployment of Palladium (Pd) based technologies in contaminant removal would require multiples of improvement in reactivity specific to a given feed. Control in Pd nanostructure has shown as an approach that would allow scalable realization of gains in it. We report the behavior of two common chlorinated organic contaminants, trichloroethylene (TCE) and 1,3,5-trichlorobenzene (TCB), on three facets of Pd in terms of their adsorption, structural organization. We separate the adsorption organic molecules to atop, bridge and hollow types. Effects of temperature are additionally provided to correlate to adsorption isotherms. The Pd {110} surface templates an interlocked structure for both TCE and TCB, while having the least favorable adsorption energies. The Pd {111} surface provides stability to TCB. All the energy calculation has been done for each adsorption type and is consistent with the result of Potential of Mean Force (PMF).

Evidence for an accumulation layer at the donor-acceptor interface in organic solar cells

XINRUI ZHU (Presenter), CHRISTINA MCGAHAN, ALEXI C. ARANGO, KATHERINE AIDALA, Physics, Mount Holyoke College — Expected band bending at typical donor-acceptor interfaces in solar cells suggests an accumulation layer could develop for sufficiently high bias, though this is rarely discussed in the photovoltaic literature. There is evidence from bilayer organic field effect transistors as well as organic light emitting transistors that high mobility interfacial accumulation layers exist [1], as well as a report on unexpectedly long diffusion lengths in a solar cell [2]. Our model of dark current in solar cells, which carefully considers multiple physical contributions to the total current, suggests the role of an accumulation layer in supporting observed high current densities. Here we present bulk electrical measurements on bilayer transistors, along with scanning Kelvin probe force microscopy capable of measuring band bending and density of states. Materials studied include CuPC/NTCDA bilayer transistors.

Controlling energy level alignment at a chromophore/TiO$_2$ interface using a co-adsorbed helical peptide*  

JONATHAN VIERECK (Presenter), Physics and Astronomy, Rutgers University, YUAN CHEN, RYAN HARMER, ELENA GALOPPINI, Chemistry, Rutgers University - Newark, SYLVIE RANGAN, ROBERT ALLEN BARTYNISKI, Physics and Astronomy, Rutgers University — The sensitization of wide band gap transition metal oxide semiconductors by chromophores has become ubiquitous in the field of photovoltaic devices. Since performance hinges on the charge transfer across the interface, which in turn depends upon the alignment of the chromophore frontier orbitals with respect to the substrate band edges, it is crucial to find ways of controlling this energy alignment.

Here, we present a novel and versatile approach of controlling this energy alignment via a “mixed-layer” solution sensitization process, where a monolayer of a dipole containing helical peptide is prepared on a single crystal TiO$_2$(110) surface and successively exposed to a solution of a Zinc Tetrphenylporphyrin (ZnTPP) derivative. Using UV and X-ray photoemission spectroscopies, we find that (1) repeated exposure to the ZnTPP derivative progressively displaces the peptides on the surface, and (2) the highest occupied molecular orbital and N 1s core level of the ZnTPP derivative within the mixed layer are located 300 meV lower in energy than their respective counterparts on a pure ZnTPP-derivative monolayer. These results are consistent with a simple parallel plate capacitor model of the intermixed peptide dipole layer.

Investigating the monolayer structure of caffeine molecules on Au(111)*

MALTE SCHULTE (Presenter), Experimental Physics 1, TU Dortmund University, ANDREAS JEINDL, Institute for Solid State Physics, TU Graz, ISMAIL BALTACI, MARIE SCHMITZ, Experimental Physics 1, TU Dortmund University, PETER ROESE, ULF BERGES, DELTA, TU Dortmund University, OLIVER T. HOFMANN, Institute for Solid State Physics, TU Graz, CARSTEN WESTPHAL, Experimental Physics 1, TU Dortmund University — Polymorphism is an important property of pharmaceutical ingredients in terms of their bioavailability. As a bottom-up approach we investigated the formation of monolayers of caffeine molecules on a Au(111) surface to understand caffeine's polymorph behavior.

In this work we analyzed the structure formation of caffeine molecules on Au(111) by scanning tunneling microscopy (STM), low-energy electron diffraction (LEED), x-ray photoelectron spectroscopy (XPS), and density functional theory (DFT) calculations. All investigations were conducted at monolayer coverage at room temperature.

By combining these powerful surface science techniques, we demonstrate successful formation of caffeine monolayers including molecular alignment in two mirrored directions of the Au(111) surface. We propose a structure model for the two found surface domains in a three-molecular unit cell. This contributes to an understanding of the driving forces for surface structure formation which is essential for potential applications.

4:54PM P52.00011: Spiropyran/Merocyanine adsorption on a Gold Surface  ANDREAS RIEemann (Presenter), LUCAS BROWNING, HUNTER GOFF, NELSON TATE, Western Washington Univ — Spiropyran is a photochromic, three-dimensional molecular switch which can be converted to Merocyanine, a planar isomer of Spiropyran where the central C-O bond has been broken. The adsorption behavior of a specific molecule, namely naphtho-merocyanine on an Au(111) substrate has been investigated using Scanning Tunneling Microscopy (STM) and computational chemistry methods. The experiments show a strong preference of dimer formation of the merocyanine molecule. Topographical and spectroscopic measurements are used to identify two distinguished configurations, an elongated dimer and a compact dimer. With the help of DFT and Molecular Mechanics calculations these two configurations as well as the specific merocyanine isomer can be identified and energy calculations including adsorption geometries could be performed. This is a first step in investigating possible pathways toward the switching behavior of merocyanine and spiropyran on this substrate.

5:06PM P52.00012: Investigating Electronic structure at Nano-Bio Interface to optimize Excitonic Solar cell architecture  SUBHABRATA DAS (Presenter), Langmuir Center of Colloids and Interfaces, Columbia Univ, XIAOJiANG YU, Synchrotron Light Source, National University of Singapore, LIANG CAO, Shanghai Institute of Applied Physics, Chinese Academy of Sciences, ABHIRUP PATRA, Chemistry, University of Pennsylvania, XINGyu GAO, Shanghai Institute of Applied Physics, Chinese Academy of Sciences, MARK BREESE, Synchrotron Light Source, National University of Singapore, PONISSERIL SOMASUNDARAN, Langmuir Center of Colloids and Interfaces, Columbia Univ, ZHAONING SONG, Physics and Astronomy, University of Toledo, BERNARDO BARBIELLINI, Physics, LUT University of Technology, VENKATESAN RENUGOPALAKRISHNAN, Chemical Biology, Northeastern University — A study of the Bacteriorhodopsin/TiO₂ and Bacteriorhodopsin/Perovskite interfaces associated with the photoactive chromophore in bacteriorhodopsin (bR) and its various mutant (D96N, triple glutamic mutations E9Q/E194Q/E204Q) forms allowed the explanation of the effective coupling existing between the π electrons of the chromophore and the local environment of the Schiff base when adsorbed to a substrate (Das et al., ACS applied materials & interfaces 11.34 (2019)). X-ray Photoemission Spectroscopy (XPS) and X-ray Absorption Spectroscopy (XAS) experiments have been used to explain some of the optical properties for various substrates such as Mesoporous TiO₂ and Perovskite. Density functional calculations (DFT) for both the ground state and the excited state has been carried in parallel with the experimental measurements. We discussed how to compensate the charge offset, to restore the Valence Band and XPS of C1s while mapping the occupied and unoccupied states around both sides of the Fermi level. In specific, we calculated the electronic band structure of the bR Chromophore using DFT+U methodology. The goal of this investigation is to optimize future Solar cell architecture (Das et al., The Journal of Physical Chemistry C (2019)).
P52.00013: Light-induced molecular dipole reordering in halide perovskites* YA-PING CHIU (Presenter), HUNG-CHANG HSU, National Taiwan University, BO-CHAO HUANG, Academia Sinica, SHU-CHENG CHIN, National Taiwan University, CHENG-RONG HSING, DUC-LONG NGUYEN, Academia Sinica, MICHAEL SCHNEDLER, Forschungszentrum Jülich, RAMAN SANKAR, Academia Sinica, RAFAL E. DUNIN-BORKOWSKI, Forschungszentrum Jülich, CHING-MING WEI, Academia Sinica, CHUN-WEI CHEN, National Taiwan University, PHILIPP EBERT, Forschungszentrum Jülich — Light-induced molecular dipole's orientation has been suggested to be a critical degree of freedom to affect the performance of hybrid perovskite-based optoelectronic devices. In this work, we utilized light-illuminated cross-sectional scanning tunneling spectroscopy to map simultaneously the organic cation's dipole orientation and the corresponding electrostatic potential with atomic resolution. Our discovery provides real space experimental evidence of the dipole reordering under illumination to create a deep one-dimensional potential energy well. The result may be directly responsible for the efficient carrier transport and suppressed carrier recombination of hybrid perovskite as an excellent photovoltaic and optoelectronic material.

Session P53 DCMP: Physical properties of carbon nanotubes, 1D structures derived from 2D materials, and nanowires Mile High Ballroom 1F - Masa Ishigami, Univ of Central Florida
2:30PM P53.00001: Band-Gap-Dependent Electronic Compressibility of Carbon Nanotubes in the Wigner Crystal Regime  
NEDA LOTFIZADEH (Presenter), University of Utah, DANIEL R. MCCULLEY, MITCHELL SENGER, Oregon State University, HAN FU, University of Chicago, ETHAN D. MINOT, Oregon State University, BRIAN SKINNER, Ohio State University, VIKRAM V DESHPANDE, University of Utah — Electronic compressibility, the second derivative of ground-state energy with respect to total electron number, is a measurable quantity that reveals the interaction strength of a system and can be used to characterize the orderly crystalline lattice of electrons known as the Wigner crystal. Here, we measure the electronic compressibility of individual suspended ultraclean carbon nanotubes in the low-density, Wigner crystal regime. Using low-temperature quantum transport measurements, we determine the compressibility as a function of carrier number in nanotubes with varying band gaps. We observe two qualitatively different trends in compressibility versus carrier number, both of which can be explained using a theoretical model of a Wigner crystal that accounts for both the band gap and the confining potential experienced by charge carriers. We extract the interaction strength as a function of carrier number for individual nanotubes and show that the compressibility can be used to distinguish between strongly- and weakly- interacting regimes.

2:42PM P53.00002: Beating the Detailed Balance Limit in Ideal Carbon Nanotube pn diodes*
PRATHAMESH DHAKRAS (Presenter), College of Nanoscale Science and Engineering, SUNY Polytechnic Institute, EVERETT COMFORT, Intel, JI UNG LEE, College of Nanoscale Science and Engineering, SUNY Polytechnic Institute — The detailed balance (DB) limit developed by Shockley-Queisser has been the guiding principle for the design of modern solar cells. According to the DB limit, a single junction pn diode exhibits the maximum open-circuit voltage (\(V_{OC}\)) when it operates in the ideal diode limit. An ideal pn diode is characterized by an ideality factor \(n=1\) which correlates to a specific generation and recombination (GR) process in a diode. Though \(V_{OC}\) is directly proportional to \(n\), typically a higher \(n\) does not correspond to a larger \(V_{OC}\). This is due to higher GR process for diodes with \(n\) that directly correspond to an increased diode leakage current, which reduces the diode's open-circuit voltage. Here, we exploit a previously overlooked parameter, the diode ideality factor \(n\), to increase the \(V_{OC}\) above the ideal diode limit. We use dynamic gate modulation in a single-walled carbon nanotube diode to engineer a digitally tunable effective ideality factor that is decoupled from the diode leakage current. We show that the open-circuit voltage can be tuned in direct proportion to \(n\) and achieve a \(V_{OC}\) that is 3 times higher than that given by the DB limit of an ideal pn diode.

2:54PM P53.00003: Electrical Transport of One-Dimensional Atomic Tellurium Nanowires Scaling Down to Two Nanometer Limit  PAI-YING LIAO (Presenter), JINGKAI QIN, GANG QIU, MENGWEI SI, Purdue Univ, SIQI ZHANG, YOKE KHIN YAP, Department of Physics, Michigan Technological University, PEIDE (PETER) YE, Purdue Univ — Due to the capability of forming air-stable thin films with high carrier mobility up to 800 cm$^2$ V$^{-1}$ s$^{-1}$ at room temperature, tellurium (Te) as a chalcogen has shown its excellent potential in the field of semiconductor devices. As a narrow-bandgap p-type semiconductor, bulk Te has a direct bandgap of $\sim$0.35 eV. Besides, Te has a unique crystal structure composed by helical chains. Each Te atom is covalently bonded with the other two adjacent Te atoms to form a spiral chain, and bulk crystal is consist of numerous chains stacked by van der Waals interaction. Here, we systematically studied the electronic transport properties of 1D Te devices scaling down to 2 nm limit in diameter. Since the native oxidation and degradation of 1D Te nanowires (NWs), the limit of bare Te NWs to exhibit stable electronic signal is around 6-7 nm. In order to further explore the performance of thinner Te NWs, we grew Te atomic chains into boron nitride nanotubes (BNNTs) and realized its field effect successfully down to 2 nm limit. Due to the encapsulation of BNNTs, the on-state current can even be dramatically increased. Moreover, the phonon responses of 1D Te NWs have also been investigated from bulk form down to a single atomic chain limit by encapsulation of carbon nanotubes (CNTs).

3:06PM P53.00004: Fabrication and characterization of ultrathin Ta$_2$(Pd or Pt)$_3$Se$_8$ nanowires*  ABIN JOSHY (Presenter), YUN LING, Tulane Univ, XUE LIU, Physics and Applied Physics, Nanyang Technological University, ANDREW STEELY, GAVIN R BLAIR, Tulane Univ, LIUBOV YU ANTIPINA, PAVEL B. SOROKIN, Technological Institute for Superhard and Novel Carbon Materials, ANA M. SANCHEZ, University of Warwick, ZHIQIANG MAO, Pennsylvania State University, JIANG WEI, Tulane Univ — Miniaturization of semiconductor devices has been a prime focus of the electronics industry to address the requirements of next-generation electronic devices. One possible solution to tackle this problem is semiconducting one-dimensional (1D) van der Waals(vdW) wires. Here we present quasi 1D semiconducting Ta$_2$(Pd or Pt)$_3$Se$_8$(TPS) crystals, composed of weakly bound molecular ribbons. Inter-ribbon bonding energy(0.34eV/atom) of TPS bulk is 17 times weaker than the intra ribbon bonding energy(5.7eV/atom). In this work, we used cost-effective and easily processable liquid phase exfoliation technique to achieve molecularly thin wires. The thinnest nanowire we have readily achieved is around 1 nm, corresponding to a bundle of one or two molecular ribbons. Optimum solvent for the dispersion is investigated and found Di-acetone alcohol gives strong dispersion. High-resolution TEM, SEM and AFM studies were done to investigate the morphology and crystallinity of the ultrathin wires obtained. Our electrical transport measurements have shown that these thin wires are gatable and preserve the intrinsic bulk characteristics. The fabricated 1D transistors exhibit high switching performance and excellent ambient environment stability.

3:18PM P53.00005: Carbon nanotube photocurrent quantum yield greater than 100%*
MITCHELL SENG (Presenter), DANIEL R. MCCULLEY, Physics, Oregon State University, ANDREA
BERTONI, Istituto Nanoscienze, Consiglio Nazionale delle Ricerche, VASILI PEREBEINOS, Electrical
Engineering, University at Buffalo, ETHAN D. MINOT, Physics, Oregon State University — Carbon
nanotubes (CNTs) have been identified as a candidate material to surpass the Shockley-Queisser
limit, however, early measurements of photocurrent quantum yield (PCQY) in CNT photodiodes
found PCQY < 100%. We studied CNT photodiodes made from individual suspended CNTs with
the goal of elucidating the role of nanotube diameter, dielectric environment, axial electric field,
and the optical excitation energy. When photons of energy approximately twice the band gap are
absorbed in the intrinsic region of a CNT photodiode, it is possible to extract a photocurrent that
 corresponds to more than one electron-hole pair per absorbed photon. We observed this high-
quantum-yield process by increasing CNT diameter to > 2.6 nm and increasing the axial electric
field to > 10 V/µm (a previously unstudied regime). Higher energy optical excitation gives even
higher PCQY. The observed dependence on diameter and dielectric environment is consistent
with theoretical models for exciton binding energy and exciton dissociation rates. Our work
suggests there are conditions for which efficient exciton dissociation co-exists with efficient
impact ionization.

No. 1709800.

3:30PM P53.00006: Temperature-Dependent Thermoelectric Transport in Polymer-Sorted
Semiconducting Carbon Nanotube Networks with Different Diameter Distributions*
MARTIN STATZ (Presenter), Univ of Cambridge, SEVERIN SCHNEIDER, FELIX BERGER, University of
Heidelberg, LIANGLUN LAI, WILLIAM ADAM WOOD, Univ of Cambridge, JANA ZAUMSEIL, University of
Heidelberg, HENNING SIRRINGHAUS, Univ of Cambridge — We report carrier density and
temperature dependent field-effect mobility and on-chip Seebeck coeff. measurements of small
diameter (6,5) (0.76 nm), ttmgb treated (6,5) and large diameter plasma torch (RN, 1.17-1.55 nm)
SWCNT networks with different network densities to provide insights into their charge transport
mechanisms and potential for thermoelectric applications. The Seebeck coeff. offers insights into
transport energetics, potential contributions from electron-electron and electron-phonon
interactions and the relative contributions of inter- versus intra-CNT transport.¹ A pure
percolation theory and VRH description cannot explain both transport coefficients and instead
intra-CNT transport depending on chirality needs to be considered as well. In the high network
density regime, the density influences neither electric nor thermoelectric transport strongly,
indicating both are dominated by tubes rather than tube-tube junctions. Despite generally lower
mobilities, (6,5) SWCNTs show comparable power factors to RN networks. These findings provide
design guidelines towards narrow DoS distr., large diameter SWCNT networks for both electronic
and thermoelectric applications.²

**3:42PM P53.00007: Applying Machine Learning to Thermal Conductance**

ALEXANDER KERR (Presenter), KIERAN MULLEN, Homer L Dodge Department of Physics and Astronomy, Univ of Oklahoma, DANIEL T GLATZHOFER, Department of Chemistry and Biochemistry, Univ of Oklahoma, LIANGLIANG HUANG, School of Chemical, Biological and Materials Engineering, Univ of Oklahoma — Machine learning provides a new approach in materials design. Recent years have seen the use of generative models to algorithmically produce candidate molecules for a variety of tasks. One such model is the variational autoencoder (VAE), which can map discrete information to a continuous, low-dimensional space. We study the ability of these methods to design nanostructures for thermal conductivity: from idealistic harmonic chains to functionalized carbon nanotubes (CNTs). Designing the latter’s side-chains is of particular interest for overcoming the severe Kapitza resistance of CNTs and accessing their promising thermal properties. We also highlight the ability of a genetic algorithm (GA) enhanced with a discriminating neural network to optimize molecules for their thermal conductance. Because discriminating GAs are forced to consider a diverse field of molecules, they are an effective way to generate a varied dataset for analysis. It can be shown that molecules sampled in this manner are clustered based on their thermal properties in the latent space learned by the VAE. In addition, studying the GA trajectory may reveal design rules that can narrow the search for good conductors.

**3:54PM P53.00008: Carbon Nanotube Alignment Dynamics under Electric Fields in Different Solutions**

ATIQUR RAHMAN, AHMED ZUBAIR (Presenter), Electrical and Electronic Engineering, Bangladesh University of Engineering and Technology — Controlled macroscopic assembly of carbon nanotubes (CNTs) while preserving their excellent optoelectronic properties still remain a key challenge. Here, we investigated the molecular dynamics of single-wall carbon nanotube (SWCNT) alignment inside various viscous media under electric fields. An analytical model based on dielectrophoresis induced torque considering the viscosity and conductivity of the medium was used to obtain molecular dynamics of the SWCNTs. An alternating current (AC) electric field was applied to SWCNT containing liquid solutions of several solvents/surfactants such as DIW, DMF, DPSF, SDS, and DOC. Time required for the SWCNTs to get aligned to the applied AC electric field were calculated for different initial conditions for all the solutions. The effects of CNT length, CNT diameter, and frequency of the electric field on the SWCNT network formation were theoretically studied. Longer and thinner SWCNTs prompted to faster alignment in SWCNT network. Furthermore, the effect of concentration of surfactant on arrangement time was examined. Slower SWCNT alignment was observed in medium with higher viscosity. The findings of this report will be helpful for establishing an effective technique of producing large-scale aligned CNT films for diverse applications.
4:06PM P53.00009: Achieving Global Alignment of Single-Wall Carbon Nanotube Films through Electrostatic Control*  JOSHUA S. WALKER (Presenter), Physics, University of Wyoming, JEFFREY A. FAGAN, ADAM BIACCHI, National Institute of Standards and Technology, VALERIE KUEHL, Chemistry, University of Wyoming, THOMAS A SEARLES, Howard University, ANGELA HIGHT WALKER, National Institute of Standards and Technology, WILLIAM D. RICE, Physics, University of Wyoming — Single-wall carbon nanotubes (SWCNTs), known for their exceptional mechanical, thermal, electrical, and optical properties, present a platform for next generation opto- and thermo-electronics. The difficulty, however, lies in the ability to reproducibly form aligned SWCNT films from aqueous nanotube solutions, which continues to be a significant scientific and technological challenge. Although multiple research groups have achieved high nematic ordering from SWCNT solutions, the mechanism driving this alignment, as well as optimization of it, remains elusive. Here, we use an automated filtration platform and superhydrophobic glass to create globally aligned films from solution-based SWCNTs. We show how SWCNT alignment is impacted by the filtration flow rate and SWCNT electrostatic environment. Additionally, we find that the SWCNT nematicity can be enhanced via buffing of the polymeric membrane coating and hindered by reducing the Debye interaction length of the SWCNTs, both of which show the importance of electrostatics in the alignment mechanism. These results have direct implications for achieving and optimizing the alignment of single- and few- chirality SWCNT films.

4:18PM P53.00010: Electron-phonon and phonon-phonon interaction in low-dimensional carbon materials  IOANNIS CHATZAKIS (Presenter), Physics and Astronomy, Texas Tech University — Low-dimensional (e.g. atomically thin) materials continue to gain prominence in applications ranging from electronics to photonics and alternative energy generation systems. Critical to efficiently developing these systems is the understanding of the fundamental processes related to the dynamics of charge carriers, phonons, and other excitations (i.e. excitons, polaritons). In this talk, I will focus on electron-phonon interactions in low dimensional carbon materials. Through these interactions the electrons lose all their excess energy above the band edge and become thermally equilibrated with the most strongly coupled optical phonon modes. Subsequently the optical phonons modes through unharmonic phonon-phonon scattering processes decay to lower-energy phonon modes.
4:30PM P53.00011: A Raman study of G-bands in isolated and bundled triple-walled carbon nanotubes  JIA WERN HUE (Presenter), Department of Physics & Astronomy, The University of Alabama, THOMAS CH HIRSCHEMANN, Attocube Systems AG, YOONG AHM KIM, School of Polymer Science and Engineering, Chonnam National University, NEWTON M BARBOSA NETO, Instituto de Ciências Exatas e Naturais – Programa de Pós-graduação em Física, Universidade Federal do Pará, PAULO T ARAUJO, Department of Physics & Astronomy, The University of Alabama — The G-band is a Raman-active phonon mode, caused by tangential and longitudinal stretching of the two dissimilar carbon atoms in the unit cell. This mode is well studied in other forms of carbon, e.g. graphite, graphene, single-walled and double-walled carbon nanotubes. Building on that knowledge, a study on bundled and isolated triple-walled carbon nanotubes (TWNT) is presented. Of particular interest is how many G-band peaks are present, their lineshapes, and how the G-band frequencies of the constituent tubes are affected from being in a TWNT system compared to if they were just SWNTs.

4:42PM P53.00012: High pressure Raman spectroscopy of Linear carbon chain encapsulated in isolated multiwall carbon nanotube*  KESHAV SHARMA (Presenter), Univ of Alabama - Tuscaloosa, NATHALIA L.M. COSTA, ALEXANDRE ROCHA PASCHOAL, Departamento de Física, Universidade Federal do Ceará, Fortaleza, PAULO T ARAUJO, Univ of Alabama - Tuscaloosa — Elusive measurements of the Longitudinal optical (LO) phonon mode frequency of isolated Cn@MWCNT systems (linear carbon chains encapsulated by multi-wall carbon nanotubes) were studied under extreme high pressure via Resonance Raman spectroscopy. The pressure-dependent frequency softening with increasing pressure is discussed in terms of a simple force constant model in which the spring constants present a dependence with pressure. The model allowed us to easily obtain both the Young's modulus and the Gruneisen parameter associated to such LO mode. In particular, the Gruneisen parameter was found to be much higher than that of Graphene and CNTs. Additionally, the LO phonon lifetime was found to be decrease with increasing stress.

*The authors want to acknowledge The Sociedade Brasileira de Física (SBF) and the American Physical Society (APS) for the Brazil-U.S. Physics Ph.D. Student and Postdoc Visitation Program award.
4:54PM P53.00013: Raman Spectra of Vertical Graphene Nanosheets*  CHUNYU LU  (Presenter), ABDULRAHMAN AL-HAGRI, NITUL RAJPUT, MATTEO CHIESA, Khalifa University — Raman spectroscopy studies have been demonstrated their importance in providing a quantitative measure on different carbon-based samples, such as graphene, carbon nanotube, and sp3 amorphous carbon. Recently, plasma-enhanced chemical vapor deposition grown vertical graphene nanosheets (VGNs) have attracted much attention owing to their abundant edges, surface, and enhanced electrochemical activity, which are potentially applicable to a wide of fields. However, due to its complexity of the vertical structures, the knowledge gained in previous carbon-based materials has not fully been extended to VGNs. In this work, we review the recent advance of Raman characterization results on PECVD-grown VGNs. With the insights from interference in graphene nanosheets and their electrical field distribution, we are able to extend the knowledge from the Raman spectroscopy of conventionally flat graphene layer to vertical graphene nanosheets. A feasible way to distinguish and evaluate the quality and structures of the VGNs from Raman spectra is presented in combination with the transmission electron microscopy characterization.

*the Cooperative Agreement between the Khalifa University, UAE and the Massachusetts Institute of Technology, MA, USA, Reference Number FR2017-000001.

5:06PM P53.00014: Manipulating high-harmonic generation in single walled carbon nanotubes*  KAZUHIRO YANAGI (Presenter), HIROYUKI NISHIDOME, Tokyo Metropolitan Univ, KOHEI NAGAI, KENTO UCHIDA, YOTA ICHINOSE, YOHEI YOMOGIDA, KOICHIRO TANAKA, Physics, Kyoto university — High-harmonic generation (HHG), which is the generation of multiple optical harmonic light, is an unconventional nonlinear optical phenomenon beyond the perturbation regime. The HHG in solid state materials is strongly influenced by the presence of nonlinearity in transport and optical transitions, but how to engineer these parameters has not yet been elucidated. Here, we demonstrate manipulation of HHG by tuning the electronic structure and carrier densities using single-wall carbon nanotubes with tuned electronic structures and Fermi levels. We reveal systematic changes in the HH spectra of carbon nanotubes with a series of electronic structures from a zero band-gap metal to a semiconductor. We demonstrate enhancement or reduction of harmonic generation by more than one order of magnitude by tuning electron and hole injection into the semiconductor carbon nanotubes through static electric field application.

5:18PM P53.00015: Polymer Host for Optical and Terahertz Spectroscopy of Low-Aggregation Nanoparticle Films*  HENRY WLADKOWSKI (Presenter), JULIAN A. DUARTE, Univ of Wyoming, JEFFREY A. FAGAN, National Institute of Standards and Technology, JEFFREY L BLACKBURN, National Renewable Energy Laboratory, SHASHANK RAM NANDYALA, JON M PIKAL, WILLIAM D. RICE, Univ of Wyoming — Preparation techniques for producing films of individualized nanoparticle for low-temperature optical spectroscopy are often challenging to execute and specific for a particular nanoparticle system. Here, we present a rapid, facile, and low-cost technique for producing 100 μm-thick nanoparticle-polymer films that exhibit high uniformity, low aggregation, excellent optical transparency, and low terahertz absorption. These films are both robust at cryogenic temperatures and exhibit a high laser damage threshold of 0.3 TW/cm², which make them ideal for pulsed laser measurements. Additionally, we show that free-standing flexible films can be made from 0D quantum dots and 1D single-wall carbon nanotubes (SWCNTs). Using absorption, Raman scattering, and photoluminescence excitation spectroscopy we show that SWCNT individualization is maintained from solution to film. Finally, we perform optical pump, terahertz probe measurements on SWCNT films to demonstrate pulsed spectroscopic investigation across a broad electromagnetic regime. This polymer host presents spectroscopists with a straightforward method for producing free-standing and flexible nanoparticle films with low aggregation.

Wednesday, March 4, 2020 2:30 PM - 5:30 PM

Session P54 DCMP: Geometric and Fluid Properties of Quantum Hall States  Mile High Ballroom 2A

2:30PM P54.00001: Free surface boundary dynamics of compressible and dissipationless fluids with Hall viscosity  SRIRAM GANESHAN (Presenter), Simons Center for Geometry and Physics, GUSTAVO MONTEIRO, The City College of New York, ALEXANDER ABANOV, Simons Center for Geometry and Physics, TANKUT CAN, Initiative for the Theoretical Sciences, The Graduate Center, CUNY — In this talk, we consider non-dissipative and compressible two-dimensional broken parity fluids with odd viscosity and magnetic field with a free surface boundary condition. We solve the linearized hydrodynamic equations for the deepwater case and derive the dispersion of chiral surface waves. We show that in the long-wavelength limit the flow profile exhibits an oscillating vortical boundary layer near the free surface. The thickness of the layer is controlled by the length scale given by the ratio of odd viscosity to the sound velocity. In the incompressible limit, the vortical boundary layer becomes singular with the vorticity within the layer diverging as the velocity of sound. The boundary layer is formed by odd viscosity coupling the divergence of velocity to vorticity. It results in non-trivial chiral free surface dynamics even in the absence of external forces. The structure of the odd viscosity induced boundary layer is very different from the conventional free surface boundary layer associated with dissipative shear viscosity.
2:42PM P54.00002: Variational principle for free surface boundary dynamics of dissipationless fluids with Hall viscosity  GUSTAVO MONTEIRO (Presenter), SRIRAM GANESHAN, The City College of New York, ALEXANDER ABANOV, Simons Center for Geometry and Physics, TANKUT CAN, Initiative for the Theoretical Sciences, The Graduate Center, CUNY — In this talk, we present the variational principle for non-dissipative and compressible two-dimensional broken parity fluids with odd viscosity with a free surface boundary condition. In the absence of shear viscosity, the boundary layer is formed by odd viscosity coupling the divergence of velocity to vorticity. The dissipationless nature of the boundary layer allows us to construct an effective action that gives both bulk hydrodynamic equations and free surface boundary conditions. The free surface boundary conditions require an additional boundary term in the action which resembles a 1+1D chiral boson field coupled to the background geometry. We discuss generalizations of this action to quantum Hall fluids and nearly incompressible fluids.

2:54PM P54.00003: Hall viscosity in systems with discrete symmetry: point group and lattice anisotropy*  PRANAV RAO (Presenter), BARRY BRADLYN, University of Illinois at Urbana-Champaign — Inspired by recent experiments on graphene, we examine the non-dissipative viscoelastic response of anisotropic two-dimensional quantum systems. We pay particular attention to electron fluids with point group symmetries, and those with discrete translational symmetry. We extend the Kubo formalism for viscosity to systems with internal degrees of freedom and discrete translational symmetry, highlighting the importance of properly considering the role of internal angular momentum. We analyze the Hall components of the viscoelastic response tensor in systems with discrete point group symmetry, focusing on the hydrodynamic implications of the resulting forces. We show that though there are generally six Hall viscosities, there are only three independent contributions to the viscous force density. To compute these coefficients, we develop a framework to consistently write down the long-wavelength stress tensor and viscosity for multi-component systems, and apply our formalism to a few examples.

*This material is based upon work supported by the National Science Foundation Graduate Research Fellowship Program under Grant No. DGE 1746047
3:06PM P54.00004: Geometric response of fractional quantum Hall states to anisotropy*  
AKSHAY KRISHNA (Presenter), Princeton University, MATTEO IPPOLITI, Stanford University, FAN CHEN,  
RAVINDRA NAUTAM BHATT, Princeton University — Fractional quantum Hall states possess a  
geometric degree of freedom that is usually hidden in the case of rotationally symmetric  
Hamiltonians. When this symmetry is broken, for example by means of an anisotropic electron  
band mass or electron-electron interaction, the many-body wavefunction optimizes over this  
degree of freedom to obtain the lowest energy. This is manifested as a partial transference of the  
anisotropy of Hamiltonian to observable properties of the ground state. In some cases, the  
fractional quantum Hall phase is unstable to the application of anisotropy and there is a  
transition to a broken symmetry phase. We use a combination of exact diagonalization and the  
infinite density matrix renormalization group (iDMRG) algorithm to quantify the extent of the  
anisotropic response and find a remarkable dependence on filling fraction, Landau level index,  
interaction type and particle statistics [1].  
*This work was supported by DOE BES Grant DE-SC0002140.

3:18PM P54.00005: Non-trivial edge profile of the Laughlin wave function*  
GABRIEL JOSE GOULART CARDOSO (Presenter), ALEXANDRE ABANOV, Department of Physics and Astronomy, Stony  
Brook University, JEAN-MARIE STÉPHAN, CNRS, University of Lyon 1 — The wave function proposed by  
Laughlin in 1983 led to a great advance in understanding the many-body quantum physics of the  
Fractional Quantum Hall Effect (FQHE). Laughlin's plasma analogy maps the distribution of  
electron densities in the FQHE state to the one of the classical 2-dimensional One-Component  
Plasma (2DOCP), with the temperature of the 2DOCP corresponding to the filling fraction of the  
FQHE state. We explore this connection further to investigate the non-trivial behavior of the  
electron density close to the edge of a FQHE droplet. Using a mix of recent Monte Carlo results  
and analytical methods we show that the observed profile of overshoot plus damped oscillations  
of the density near the edge can be explained in terms of the partial crystallization of the  
corresponding 2DOCP close to a boundary. We analyze the dependence of this effect on the  
proximity to the boundary and on the FQHE filling fraction.

3:30PM P54.00006: Contactless pulsed tunneling spectroscopy of exciton superfluid phase in a quantum Hall bilayer*  HEUN MO YOO (Presenter), Massachusetts Institute of Technology MIT, K. W. BALDWIN, KENNETH WEST, LOREN PFEIFFER, Princeton University, RAYMOND ASHOORI, Massachusetts Institute of Technology MIT — A quantum Hall (QH) bilayer with sufficiently small interlayer separation $d$ is predicted to host an exciton superfluid phase. Here, we use a contactless pulsed tunneling technique to search for novel superfluid properties of the QH bilayer. As our method does not require ohmic contacts to the layers, it permits access the entire range of density imbalances ($\Delta \nu$) at a total filling factor $\nu_T = 1$. At a small magnetic field ($d/l_B = 1.49$), zero-bias interlayer tunneling is maximized at $\Delta \nu = 0$ and is consistent with prior DC tunneling measurements. On the other hand, at a larger magnetic field ($d/l_B = 1.82$), we observe the maximum of zero-bias tunneling near a full density imbalance $\Delta \nu = 1$. The observed behavior near $\Delta \nu = 1$ contradicts the simple theoretical expectation, based on the pseudospin stiffness going to zero, that the system would evolve into a trivial $\nu = 1$ QH-state in one layer. In addition to the full density imbalance dependence, future pulse tunneling measurements can reveal high-frequency dynamical response of the exciton superfluid phase.

3:42PM P54.00007: Observation of a new reentrant integer quantum Hall state in the N=0 Landau level*  GABOR CSATHY (Presenter), VIDHI SHINGLA, Purdue Univ, KENNETH WEST, LOREN PFEIFFER, Princeton Univ — We report the observation of a reentrant integer quantum Hall state in the $N = 0$ Landau level near the Landau level filling factor $\nu = 2 - 1/5$. Unlike similar reentrant states in high $N \geq 2$ Landau levels, the reentrant state reported here is interpreted as a Wigner solid that is the particle-hole conjugate of the reentrant Wigner solid forming at $1/5 < \nu < 2/9$. Our results indicate that Wigner solids in the GaAs/AlGaAs system commonly straddle the partial filling factor $1/5$ and paint a complex picture of the competition of the Wigner solid with fractional quantum Hall states.

*Measurements at Purdue University were supported by NSF grants DMR 1505866 and 1904497. Sample growth efforts at Princeton University were supported by Gordon and Betty Moore Foundation Grant No. GBMF 4420, and the National Science Foundation MRSEC Grant No. DMR-1420541.
3:54 PM P54.00008: Collective excitations of quantum Hall states under tilted magnetic field

KANG YANG (Presenter), Department of Physics, Stockholm University, MARK OLIVER GOERBIG, Laboratoire de Physique des Solide, Paris-Sud University, BENOÎT DOUÇOT, Sorbonne University — We study the neutral excitations of quantum Hall systems under external anisotropy introduced by tilting the magnetic field. In the isotropic case, the neutral collective excitation can be worked out through the conserving method of composite fermions satisfying integer quantum Hall effects in the Hamiltonian theory. We show how such a computation can be carried out perturbatively for an anisotropic interaction. We find that unlike the charge gap, the neutral collective gap is much more easily destroyed by the parallel component of the magnetic field. We also address the issue about the convergence of the collective spectrum to the activation gap.

4:06 PM P54.00009: Hall viscosity in abelian gauge theories*

UMANG MEHTA (Presenter), DAM THANH SON, University of Chicago — We investigate the Hall viscosity of U(1) gauge theories. Starting with the Maxwell-Chern-Simons theory, by explicitly constructing the ground state wave functional, we show that the Hall viscosity is zero. We also add Lorentz-breaking parity-odd terms to the Lagrangian and observe that the Hall viscosity remains zero. We argue that the result is general and discuss the implications for the Hall viscosity of the composite fermions in the fractional quantum Hall effect.

4:18 PM P54.00010: Pseudopin transition of two-dimensional hole systems in hydraulic pressure*

YANG LIU (Presenter), KE HUANG, Peking Univ, LOREN PFEIFFER, KENNETH WEST, K. W. BALDWIN, Electrical engineering, Princeton university, XI LIN, Peking Univ — We preform transport measurement of high quality two-dimensional hole systems in a pressure cell at low temperatures. We find that the hydraulic pressure can induce phase transition to fractional quantum Hall effect near $\nu = 3/2$. The discovered phenomenon is consistent with spin polarization transitions when the energy separation between the lowest two Landau levels is quenched by the large hydraulic pressure. Our finding reveal subtle dependence of spin degree of freedom on hydraulic pressure in hole systems.

4:30PM P54.00011: Anomalous nematic states in half-filled Landau levels in tilted magnetic fields

MICHAEL ZUDOV (Presenter), XIAOJUN FU, QIANHUI SHI, University of Minnesota, GEOFF C GARDNER, JOHN WATSON, MICHAEL MANFRA, Purdue University, K. W. BALDWIN, LOREN PFEIFFER, KENNETH WEST, Princeton University — In this talk we examine the effect of in-plane magnetic fields on anomalous nematic phases in half-field high Landau levels which are characterized by unexpected minima (maxima) in \( R_{xx} \) \( (R_{yy}) \) and plateau-like features in \( R_H \) emerging at low temperatures. In particular, we have found that these features quickly disappear upon application of in-plane magnetic field, regardless of its orientation with respect to the native anisotropy axis, and that conventional quantum Hall stripe phase is restored.

*The work at Minnesota (Purdue) was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award \# ER 46640-SC0002567 (DE-SC0020138). 4:42PM P54.00012: Interlayer exciton condensates in high Landau levels in bilayer WSe2

QIANHUI SHI (Presenter), EN-MIN SHIH, DANIEL A RHODES, BUMHO KIM, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, ZLATKO PAPIC, University of Leeds, JAMES C HONE, CORY DEAN, Columbia University — Exciton condensates (EC) have been realized in the quantum hall regime in GaAs double quantum wells and graphene double layers separated BN, appearing in the lowest Landau level (LL) with index \( N = 0 \). In these systems, the barrier thickness has to be carefully chosen in order to preserve strong interlayer Coulomb interaction but suppress tunneling at the same time. In bilayer WSe2, the spin-valley locking together with the valley misalignment in natural AB stacking, results in suppressed interlayer tunneling and allows independent control of the layer population. We observe signatures consistent with interlayer EC when the two layers have matched LL orbital wavefunctions. Unlike previous systems with intentional tunnel barrier, the natural bilayer has the interlayer spacing \( d \) as small as the lattice constant and the strong interlayer Coulomb interaction allows EC to be realized in \( N > 0 \) LLs. Compared to EC in the lowest LL, EC in high LLs turn out to be more robust in the low \( d/l_B \) limit (\( l_B \) is the magnetic length), and the charge gap demonstrates an opposite dependence against interlayer density imbalance.

*Supported by US Department of Energy (DE-SC0016703).
4:54PM P54.00013: Properties of Reentrant Integer Quantum Hall States in High Landau Levels*  
DOHYUNG RO (Presenter), NIANPEI DENG, MICHAEL MANFRA, Purdue Univ, LOREN PFEIFFER, KENNETH WEST, Princeton University, GABOR CSATHY, Purdue Univ — Reentrant integer quantum Hall states in two-dimensional electron gases are commonly associated with electronic bubble phases, novel electronic solids predicted by Hartree-Fock theories. Various measurements were all consistent with the Hartree-Fock theory, with the exception of predictions of proliferation of such ground states in high Landau levels. This has recently changed with observations of double reentrance in the N=3 Landau level. We will discuss the filling factor and the temperature dependence of magnetotransport of the reentrant integer quantum Hall states in the N=3 Landau level. Our findings significantly strengthen the bubble interpretation of the reentrant integer quantum Hall states and provide insight into details of the competition of electron-electron interaction and disorder effects in the formation of the electronic bubbles.

*Our work was supported by the NSF grant DMR 1904497. Sample growth work of M.J.M. was supported by the DOE contract no. DE-SC0006671, while that of K.W.W. and L.N.P. by the National Science Foundation MRSEC Grant DMR-1420541 and the Gordon and Betty Moore Foundation Grant GBMF 4420.

5:06PM P54.00014: From Casimir Effect to Quantum Atmosphere*  
QINGDONG JIANG (Presenter), Stockholm Univ, FRANK WILCZEK, MIT — By altering the propagation of virtual photons, materials can influence the behavior of objects in their vicinity. They can cause forces on macroscopic bodies (Casimir effect), or perturb the spectra of nearby molecular complexes. I'll briefly show how to make repulsive Casimir force by using chiral materials, but mainly discuss how symmetry breaking states of matter can transmit symmetry breaking effects to spectra. I'll discuss a few such effects, which involve the “axion electrodynamics” relevant to topological insulators, quantitatively. Then I'll describe an operator framework whereby effects of this kind can be analyzed systematically, qualitatively, and discuss possible experimental implications.

*This work was supported by the Swedish Research Council under Contract No. 335-2014-7424. Frank Wilczek’s work is supported by the U.S. Department of Energy under grant Contract No. DE-SC0012567 and by the European Research Council under grant 742104.

5:18PM P54.00015: Spinning Radiation from Topological Insulator*  
EMROZ KHAN (Presenter), EVGENII NARIMANOV, Purdue Univ — Axion coupling in topological insulator (TI) gives rise to unusual electromagnetic phenomena such as induction of image magnetic monopole, Faraday rotation etc. Here we show this coupling also leads to emergence of spin angular momentum (SAM) in the thermal radiation from TI (Phys. Rev. B 100, 081408(R)). A slab of TI with a thin magnetic coating would radiate light with the same degree of circular polarization in all directions, in contrast to conventional thermal emitters with structured interface. Through the control of emission of SAM, TIs may, therefore, find potential applications in generation of structured light from thermal sources.

*The authors acknowledge support for this work from the National Science Foundation under Grant No. DMREF- 1629276 and the Gordon and Betty Moore Foundation.
2:30PM P55.00001: THz Emission Spectroscopy of Surface Photogalvanic Effects in a Chiral Weyl Semimetal  
DARIUS TORCHINSKY (Presenter), BAOZHU LU, Temple Univ, DYLAN REES, University of California, Berkeley, KAUSTUV MANNA, HORST BORRMANN, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, JOSEPH ORENSTEIN, University of California, Berkeley — Topological materials, and Weyl semimetals in particular, exhibit diverse optical effects. If inversion symmetry is broken, second order responses are allowed, expanding the number of methods that can be used to probe the optical properties of a material. These second order effects are also allowed at material interfaces, providing a unique tool to study their topologically important surface states. Here, we present photogalvanic effect data collected via terahertz emission spectroscopy on a chiral Weyl semimetal as a function of polarization and incident wavelength and discuss how our data reveal signatures of the topologically relevant surface states.

2:42PM P55.00002: Non-linear Optical Response of an Exactly Soluble Model of Topological Insulators*  
PETER RISEBOROUGH (Presenter), Temple Univ — We examine an exactly soluble model of time-reversal and inversion symmetric Topological Insulators and calculate the linear optical conductivity. For frequencies smaller than the bulk gap, the response is quantized and yields information on the surface Weyl cones and their energies. The inclusion of many-body interactions changes the result and may cause an instability due to the spontaneous emission of spin-one k=0 excitations, if the Fermi-energy is in close proximity to the vertex of the Weyl cone. For topological insulators, the low-frequency conductivity is caused by metallic states and the conductivity is highly non-local. The non-linear response functions are shown to diverge at low-frequencies, due to the 1/√ω coupling that lead to the well-known infra-red divergences found in Brehmstrahlung. We show that the infra-red divergences in the response functions due to the interaction with the surface states at both surfaces of the slab, cancel analogously to Furry's Theorem. Cancellation of the divergences seems to requires that the non-local Maxwell's equations are solved and the systematic inclusion many-body interactions.

2:54PM P55.00003: Circular photogalvanic effect in interacting Weyl semimetals
ALEKSANDR AVDOSHKIN (Presenter), VLADYSLAV KOZII, JOEL MOORE, University of California, Berkeley — The circular photogalvanic effect (CPGE) is a photocurrent that depends on the sense of circular polarization. In a disorder-free, non-interacting chiral Weyl semimetal, the magnitude of the effect is approximately quantized with a material-independent quantum e^3/h^2 for reasons of band topology. We study the first-order corrections due to the Coulomb and Hubbard interactions in a continuum model of the Weyl points. We find that the inclusion of interactions generically breaks the quantization yet the corrections are non-divergent. The corrections are similar in spirit to the case of interaction corrections to the (non-topological) linear conductivity of graphene. Thus, we conclude that, unlike the quantum Hall effect or the chiral anomaly in field theories, the quantization of the CPGE is not protected but has perturbative corrections in interaction strength.

3:06PM P55.00004: Electronic band structure and free carrier properties of strained tin-germanium alloys on InSb from FTIR ellipsometry*
RIGO CARRASCO (Presenter), STEFAN ZOLLNER, New Mexico State Univ, ARNOLD KIEFER, BRUCE CLAFLIN, Wright-Patterson Air Force Base, STEPHANIE CHASTANG, JINSONG DUAN, GORDON GRZYBOWSKI, KBR Wyle — From Fourier-transform infrared ellipsometry, we provide spectroscopic evidence about the valence band structure of α-tin. The mid-infrared dielectric function of α-tin grown pseudomorphically by molecular beam epitaxy shows a strong peak near 0.41 eV. The peak can be attributed to the allowed intra-valence band transitions from the Γ(7) (electron-like) to the Γ(8) +υ heavy hole valence band and/or interband transitions from the Γ(7) band to the Γ(8) +c light “hole” conduction band. Possible sources for the strength of the peak and its temperature dependence will be discussed. Our results are significant, because intra-valence band transitions have not previously been reported as a peak in ellipsometry spectra. This peak cannot be described as a van Hove singularity with a critical point lineshape. It should be universal, i.e., common to all zero-gap semiconductors. We will also show the dependence of this peak on composition and strain in Ge_{1-x}Sn_{x} alloys with up to 6% Ge. At photon energies below 0.4 eV, FTIR ellipsometry spectra are dominated by the Drude response of free carriers and a discussion on the species of the carriers will be provided.

3:18PM P55.00005: SHG spectroscopy of the surface states of a chiral Weyl semimetal

DYLAN REES (Presenter), University of California, Berkeley, BAOZHU LU, Department of Physics, Temple University, KAUSTUV MANNA, CLAUDIA FELSER, Max-Planck-Institute for Chemical Physics of Solids, Nöthnitzer Straße-40, 01187 Dresden, Germany, JOSEPH ORENSTEIN, University of California, Berkeley, DARIUS TORCHINSKY, Department of Physics, Temple University — Second harmonic generation (SHG) is an optical effect that has recently been extensively used to study the electronic band structure as well as lattice and electronic symmetry of various inversion-symmetry breaking solid state materials, including topological systems. Since the surface of any material is a locus of inversion symmetry breaking, SHG spectroscopy has traditionally been used to selectively probe the surface electronic properties of materials. We present an SHG study of a chiral Weyl semimetal as a function of incident photon energy to study SHG response deriving solely from the surface and discuss what our analysis of the nonlinear tensor elements reveals on the topological nature of the material.

3:30PM P55.00006: Kerr and Faraday rotations in a Weyl semimetal in a strong magnetic field

JEAN-MICHEL PARENT (Presenter), RENE COTE, ION GARATE, Universite de Sherbrooke — One striking property of the Landau level spectrum of a Weyl semimetal (WSM) is the existence of a chiral Landau level (CLL) in which the electrons propagate unidirectional along the magnetic field. This linearly dispersive level influences the optical properties of WSMs. For example, it was shown that a complete optical valley polarization is achievable in a time-reversal symmetric WSM placed in a strong magnetic field [1]. This effect originates from interband transitions involving the CLL and requires a tilt of the Weyl cones in the Hamiltonian. In this talk, we show how the presence of the CLL changes the behavior of the Kerr and Faraday rotations of an electromagnetic wave incident on a WSM in a strong magnetic field with respect to a non-topological metal. To calculate the optical conductivity tensor \( \sigma_{\alpha\beta}(\omega) \), we use the minimal model of a WSM developed in Ref. [1] with four tilted Weyl nodes related by mirror and time-reversal symmetry. We present the dependency of the Kerr and Faraday angles on the tilt angle of the cones, the position of the Fermi level, the thickness of the WSM and the magnetic field intensity in both the resonant and non-resonant frequency regimes.

Connecting second-order optical response with the band structure geometry of Weyl semimetals*

TOBIAS HOLDER (Presenter), DANIEL KAPLAN, BINGHAI YAN, Weizmann Institute of Science — Nonlinear optical response is well studied in the context of semiconductors and has gained a renaissance in studies of topological materials in the recent decade. In non-magnetic materials the response is believed to root in the Berry curvature of the material band structure. Here, we revisit the general formalism for the second-order optical response with finite lifetimes, focusing on the consequences of the time-reversal-symmetry breaking. We identify three physical mechanisms to generate a dc photocurrent, i.e. the Berry curvature, the quantum metric and the diabatic motion. All three effects are non-zero when time-reversal symmetry is broken. They can be understood intuitively from the anomalous acceleration; the first two terms are respectively the antisymmetric and symmetric parts of the quantum geometric tensor. The last term is due to the dynamical antilocalization that refers to the phase accumulation between time-reversed fermion loops.

*This research was supported by the Willner Family Leadership Institute for the Weizmann Institute of Science, the Benoziyo Endowment Fund for the Advancement of Science, Ruth and Herman Albert Scholars Program for New Scientists, and the European Research Council (Grant No. 815869).

Probing quantum criticality using nonlinear Hall effect in a metallic Dirac system*

VLADIMIR JURICIC (Presenter), HABIB ROSTAMI, NORDITA — Interaction driven symmetry breaking in a metallic (doped) Dirac system can manifest in the spontaneous gap generation at the nodal point buried below the Fermi level. Across this transition linear conductivity remains finite making its direct observation difficult in linear transport. In this talk, we will show how the nonlinear Hall effect can be used as a direct probe of this transition when inversion symmetry is broken [1]. Specifically, for a two-dimensional Dirac material with a tilted low-energy dispersion, we first predict a transformation of the characteristic inter-band resonance peak into a non-Lorentzian form in the collisionless regime. Furthermore, we find that inversion-symmetry breaking quantum phase transition is controlled by an exotic tilt-dependent line of critical points. As this line is approached from the ordered side, the nonlinear Hall conductivity is suppressed owing to the scattering between the strongly coupled incoherent fermionic and bosonic excitations. Our results should motivate further studies of nonlinear responses in strongly interacting Dirac materials.

*H.R. acknowledges the support from the Swedish Research Council (VR 2018-04252).
Observation of bulk-to-surface optical transition in topological insulator Bi$_2$Se$_3$

JIWON JEON, KWANGNAM YU, JIHO KIM, Univ of Seoul, JISOO MOON, SEONGSHIK OH, Department of Physics and Astronomy, Rutgers, the state university of New Jersey, EUNJIP CHOI (Presenter), Univ of Seoul — We performed broadband optical transmission measurements of Bi$_2$Se$_3$ and In-doped (Bi$_{1-x}$In$_x$)$_2$Se$_3$ thin films, where in the latter the spin-orbit coupling (SOC) strength can be tuned by introducing In. An optical absorption peak located at E=1eV in Bi$_2$Se$_3$ becomes completely suppressed at the critical x=0.06 in correlation with the topological surface state (SS) quenched at the same x due to TI-NTI transition. When Bi$_2$Se$_3$ is electrically gated, the 1eV-peak becomes stronger(weaker) when electron is depleted from (accumulated into) the SS. These observations combined together demonstrate that under the 1eV photo illumination, electron is excited from a bulk band into the SS of Bi$_2$Se$_3$. The bulk-to-surface optical transition or equivalently the optical population of the SS, is the first kind of such phenomena observed in TI's, is not only of fundamental significance but also offers an opportunity for optoelectronic application.

Chiral Magnetic Photocurrent in Dirac and Weyl Materials

SAHAL KAUSHIK (Presenter), DAMITRI E KARZEEV, EVAN PHILIP, State Univ of NY - Stony Brook — Circularly polarized light (CPL) can induce an asymmetry between the number of left- and right-handed chiral quasiparticles in Dirac and Weyl semimetals. We show that if the photoresponse of the material is dominated by chiral quasiparticles, the total chiral charge induced in the material by CPL can be evaluated in a model-independent way through the chiral anomaly. In the presence of an external magnetic field perpendicular to the incident CPL, this allows to predict the linear density of the induced photocurrent resulting from the chiral magnetic effect. The predicted effect should exist in any kind of Dirac or Weyl materials, with both symmetric and asymmetric band structure. An estimate of the resulting chiral magnetic photocurrent in a typical Dirac semimetal irradiated by an infrared laser of intensity $\sim 5 \times 10^6$ W/m$^2$ and a wavelength of $\lambda \sim 10 \mu$m in an external magnetic field $B \sim 2$T yields a current $J \sim 50$ nA in the laser spot of size $\sim 50 \mu$m. This current scales linearly with the magnetic field and wavelength, opening up possibilities for applications in photonics, optoelectronics, and THz sensing.

4:30PM P55.00011: The Low Energy Second Harmonic Generation Spectrum of the Chiral Multifold Fermion System RhSi  
BAOZHU LU (Presenter), Temple Univ, DYLAN REES, University of California, Berkeley, KAUSTUV MANNA, HORST BORRMANN, Max Planck Institute for Chemical Physics of Solids, ADOLFO G GRUSHIN, Neel Institute (CNRS), CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, JOSEPH ORENSTEIN, University of California, Berkeley, DARIUS TORCHINSKY, Temple Univ — Lacking any mirror symmetries, the Weyl nodes of the multifold fermion system RhSi are offset in energy, permitting a spectroscopic study of the optical properties of a single node. The lack of any mirror symmetry also implies that RhSi lacks an inversion center and thus can support second order nonlinear optical processes in its bulk. Here, we present a spectroscopic study of one of these processes, the bulk second harmonic generation response as a function of incidence photon energy and measure the single SHG susceptibility tensor element $\chi_{xyz}$ over the 275 - 900 meV range. We describe how our results directly probe the nonlinear optical response of the isolated Weyl at the $\Gamma$ point in the Brillouin zone and discuss our findings in the context of the linear optical response of the material.

4:42PM P55.00012: Nonlinear optical response of graphene family materials near topological phase transitions*  
RAJESH MALLA (Presenter), Center for Nonlinear Studies and Theoretical Division, Los Alamos National Laboratory, WILTON J DE MELO KORT-KAMP, Theoretical Division, Los Alamos National Laboratory —  
The graphene family materials behave as topological insulators due to non-negligible spin-orbit coupling. The gaps at each Dirac cone can be tailored when static electric fields and/or non-resonant circularly polarized lasers are applied to the system. Various electronic phases, characterized by Chern numbers, have been explored by changing the external fields. In this work we study the interaction of graphene family materials with ultrashort (~10's of femtosecond) linearly polarized optical pulses both in time and frequency domain. In order to observe the nonlinear response of these materials, we develop a non-perturbative approach to solve the massive Dirac equation for each valley and spin. Then we compute the longitudinal and transverse currents to investigate signatures of the ultrafast dynamics of the material. We demonstrate that the asymmetry of different Dirac cones plays a crucial role in the nonlinear response of the graphene family materials near topological phase transition boundaries.

4:54PM P55.00013: Femtosecond to Nanosecond Lifetimes in Optically-Excited Nodal-Line Semimetals

ROBERT KIRBY (Presenter), GREG SCHOLES, LESLIE SCHOOP, Princeton University — Topological semimetals, such as the Dirac semimetal Cd$_3$As$_2$, have been proposed as superior materials for the next generation of highspeed optoelectronic devices due to their previously-observed ultrafast response times and high carrier concentrations [1]. Nodal-line semimetals, such as ZrSiX, should be even better suited to these applications because they have a much higher carrier concentration in Dirac bands, since those bands extend over lines or loops in k-space instead of just around a single point. In this talk, we will discuss our ultrafast optical measurements of the response of ZrSiX ($X = S, Se, Te$) to narrowband near-infrared pulses. Unlike other studies into this class of materials, multiple time scales are observed in the response, from the femtosecond- to nanosecond-scale. The spectral and kinetic features are connected to the structure and bandstructure of the materials, particularly surrounding the nodal-line straddling the Fermi level.

5:06PM P55.00014: Colliding Electrons and Holes in Semiconductors to Reconstruct Berry Curvature

* JOSEPH COSTELLO (Presenter), SEAMUS O’HARA, DARREN VALOVCIN, Physics, University of California, Santa Barbara, QILE WU, MACKILLO KIRA, Electrical Engineering and Computer Science, University of Michigan, LOREN PFEIFFER, Electrical Engineering, Princeton University, MARK STEPHEN SHERWIN, Physics, University of California, Santa Barbara — Electron-hole recollisions occur when a probe laser beam excites electron-hole pairs in a semiconductor that is driven by sufficiently strong THz-frequency electric fields [1]. The THz accelerates the electron-hole pairs and causes recollision, leading to the release of photons at higher energy than the probe in a process called high order sideband generation (HSG).

The intensity and polarization of each sideband depends on the relative polarizations of the probe and THz [2]. One cause of this dynamical birefringence is quantum interference between electron-hole recollision pathways under non-Abelian Berry curvature from the coupling between valence bands. In this talk I will present HSG experiments done in GaAs and demonstrate how to extract parameters relating to hole dynamics. This procedure opens the door to measurements of the complete electronic structure of semiconductors, including Berry curvature, Bloch wavefunctions, and effective Hamiltonian parameters.

2:30PM P56.00001: Polar Kerr effect measurements of UTe₂ using Sagnac interferometry.*
DI WEI (Presenter), Stanford University, JIAN ZHANG, Fudan University, SHENG RAN, JOHNPIERRE PAGLIONE, NICHOLAS BUTCH, University of Maryland, College Park & NIST, AHARON KAPITULNIK, Stanford University — The heavy fermion compound UTe₂ was recently found to superconduct with Tᵋ = 1.6K, showing paramagnetic behavior and closely resembling the family of uranium based ferromagnetic superconductors [Ran et al., Science, 2019]. This initial study presented strong evidence of spin-triplet superconductivity, likely mediated by ferromagnetic fluctuations, which have been shown to occur below Tᵋ in μSR experiments [Sundar et al., arXiv, 2019]. Additionally, a recent scanning tunneling microscopy experiment claims signatures of chiral modes inside of the superconducting gap, raising the possibility of topological superconductivity [Jiao et al., arXiv, 2019]. A direct measurement of possible time-reversal symmetry (TRS) breaking effects in this system can provide insight on the exact order parameter of UTe₂, as well as evidence for the possible topological nature of the system. We present measurements of the polar Kerr effect using Sagnac interferometry in search for a possible TRS breaking state, and to examine ferromagnetic fluctuations in the Meissner and vortex states of this material.

2:42PM P56.00002: Electrodynamic response of the unconventional superconductor UTe₂*
SIRAK MEKONEN, DAVID BARBALAS, DIPANJAN CHAUDHURI, Johns Hopkins University, SHENG RAN, WESLEY T FUHRMAN, University of Maryland, College Park, NICHOLAS BUTCH, NIST Center for Neutron Research, National Institute of Standards and Technology,, PETER ARMITAGE (Presenter), Johns Hopkins University — Evidence was recently reported that UTe₂ is a nonunitary spin-triplet superconductivity, which features a high (for this material family) transition temperature of 1.6 K and a remarkably large and anisotropic upper critical field exceeding 40 T. Here we report results of measurements on the electrodynamic response of this compound down to low frequencies and temperatures. We investigate the finite frequency response of this system and search for evidence for the ferromagnetic fluctuations that have been seen in the optical response of other exotic superconductors close to ferromagnetism.

*Work at Johns Hopkins was supported as part of the Institute for Quantum Matter, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award No. DE-SC0019331. Crystal growth work at UMD was supported by NIST. Wesley T. Fuhrman is grateful for the support of the Schmidt Science Fellows program, in partnership with the Rhodes Trust.
Electronic structure of ferromagnetic superconductor UGe$_2$ in comparison to UTe$_2$

JONATHAN DENLINGER (Presenter), Lawrence Berkeley National Laboratory, JAMES W ALLEN, U. of Michigan, A. D. HUXLEY, JACQUES FLOUQUET, CEA-Grenoble — The newly discovered spin-triplet superconductor UTe$_2$ [1] has a strong suggestive relationship to the family of ferromagnetic superconductors UGe$_2$, URhGe and UCoGe. Here we update studies [2] of the electronic bandstructure of UGe$_2$, experimentally measured by angle-resolved photoemission (ARPES) near the U 5$d$-5$f$ resonance, with comparisons to DFT calculations of ThGe$_2$ decomposed into subunit building block structures. A signature imprint of a 2D diagonal square-net plane of Ge atoms on the formation of large diamond-shaped Fermi surface contours is shown to agree well with ARPES and with dHvA orbit sizes. Similar theoretical decomposition of the UTe$_2$ structure into zig-zag U-Te chains and a plane of Te linear chains with strong $p$-orbital bonding-antibonding splitting identifies the origins of the underlying orthogonal quasi-1D band structures near the Fermi level, in agreement with recent ARPES measurements [3].

Systematics of uranium-based superconducting materials.

ETERI SVANIDZE (Presenter), Max Planck Inst — A large number of uranium-based materials are exotic – they show complex magnetic orders, coexistence of superconductivity with magnetism, enhanced effective electron masses, quantum critical behavior, and topological states. All of these peculiar phenomena are thought to arise from electrons’ dual nature, which is also believed to lie at the origin of high-temperature superconductivity. Among unconventional uranium-based systems, the most intriguing are in fact superconductors – UBe$_{13}$, URu$_2$Si$_2$, and UPt$_3$ [1-3]. In this talk, I will provide a brief historic overview of superconductivity in uranium-based compounds, and address several pertinent questions [4]: Is superconductivity in uranium-based materials always unconventional? Why are superconducting temperatures in uranium-based compounds so low, compared to other compounds, based on actinide or lanthanide elements? Is there a way to pinpoint crystallographic motifs, which are favorable for the emergence of superconducting state?

3:18PM P56.00005: Revealing the intrinsic properties of the heavy-fermion superconductor UBe\textsubscript{13} PRIMOZ KOZELJ (Presenter), ULRIKE STOCKERT, MARKUS KOENIG, ANDREAS LEITHE-JASPER, YURI GRIN, ELENA HASSINGER, ETERI SVANIDZE, Max Planck Institute for Chemical Physics of Solids — Even though UBe\textsubscript{13} was one of the first reported heavy-fermion superconductors, it continues to receive a considerable amount of attention due to its unconventional ground state [1 - 3]. While single crystals of UBe\textsubscript{13}, grown out of Al flux, have been available early on [1], it was recently shown that their physical properties are highly affected by the Al incorporation into the lattice [4]. Even though the amount of Al atoms in the UBe\textsubscript{13} structure is rather small (< 1 - 2 at. %), it leads to dramatic changes in the physical properties. Our work provides a novel way in which polycrystalline samples of UBe\textsubscript{13} can be studied. These samples, which are inherently free of Al inclusions, provide a comprehensive examination of the inherent crystallographic defects both at the atomic- and the micro-scale. We show that these defects have a rather strong influence on the critical temperature $T_c$, the Sommerfeld coefficient $\gamma$, and the size of the specific heat anomaly.

3:30PM P56.00006: Aluminium impurities in single crystals of the heavy-fermion superconductor UBe\textsubscript{13} ANDREAS LEITHE-JASPER (Presenter), ALFRED AMON, ETERI SVANIDZE, PAUL SIMON, MATEJ BOBNAR, IRYNA ZELENINA, MARCEL NAUMANN, PRIMOZ KOZELJ, ELENA HASSINGER, YURI GRIN, Max Planck Institute for Chemical Physics of Solids, MPG — We studied the influence of Al incorporation on the heavy fermion superconductor UBe\textsubscript{13} to explain the sample dependence of physical properties. Al which substitutes Be in the crystal structure of flux-grown UBe\textsubscript{13} single crystals can be detected by combining X-ray diffraction, nuclear magnetic resonance and X-ray spectroscopy. The minute amounts of Al (1-2 at. %) in the structure are located by atomic resolution transmission electron microscopy. Specific heat measurements complement this study and reveal strong influence of the incorporated Al on the physical properties of UBe\textsubscript{13}. 

3:42PM P56.00007: Generalized Spin Fluctuation Feedback in Heavy Fermion Superconductors* ADIL AMIN (Presenter), DANIEL AGTERBERG, University of Wisconsin - Milwaukee — Experiments reveal that the superconductors UPt$_3$, PrOs$_4$Sb$_{12}$ and U$_{1-x}$Th$_x$Be$_{13}$ undergo two superconducting transitions in the absence of an applied magnetic field. The prevalence of these multiple transitions suggests a common underlying mechanism. A natural candidate theory which accounts for these two transitions is the existence of a small symmetry breaking field, however such a field has not been observed in PrOs$_4$Sb$_{12}$ or U$_{1-x}$Th$_x$Be$_{13}$ and has been called into question for UPt$_3$. Motivated by arguments originally developed for superfluid $^3$He we propose that a generalized spin fluctuation feedback effect is responsible for these two transitions. In this talk, we show that a phenomenological theory which couples spin fluctuations to superfluidity correctly predicts that a high temperature broken time-reversal superfluid $^3$He phase can emerge as a consequence. This phenomenological approach is then applied to these three superconductors revealing that this naturally leads to a high-temperature time-reversal invariant nematic superconducting phase, which can be followed by a second transition into a broken time-reversal symmetry phase, as observed.

*Adil Amin and D.F.A acknowledge financial support through the UWM research growth initiative.

3:54PM P56.00008: Magnetic Field Dependent Low-Temperature Specific Heat in UCo$_{1-x}$Fe$_x$Ge* SANGYUN LEE (Presenter), ERIC BAUER, FILIP RONNING, ROMAN MOVSHOVICH, Los Alamos National Laboratory — We have investigated low-temperature specific heat of UCo$_{1-x}$Fe$_x$Ge with $x$ spanning a narrow region around the concentration $x=0.23$ of the purported Ferromagnetic Quantum Critical point (FM QCP), at temperatures from 60 mK to 2 K and in magnetic field up to 9 T. All investigated samples show a rise in specific heat at low temperature when external field is applied, interpreted as being due to the Co nuclear Schottky anomaly, as the magnitude of the low temperature anomaly scales with the Co content. The Schottky anomaly is absent when the external field is zero, and $x$ is close to 0.23, indicating paramagnetic ground state in these samples. The shallow rise of the Sommerfeld coefficient $\gamma = C/T$ with decreasing temperature for $x=0.22$ and $x=0.23$ samples is consistent with previously reported higher temperature specific heat data, which were interpreted as an evidence of an FM QCP. In this talk, we discuss about quantum criticality of UCo$_{1-x}$Fe$_x$Ge system.

4:06PM P56.00009: Quantum phase transition and superconductivity in ferromagnetic heavy-fermion systems*  
HAOYU HU (Presenter), ANG CAI, QIMIAO SI, Rice University —  
Ferromagnetic Kondo lattice systems have been shown to display the phenomenon of Kondo destruction [1], raising the prospect of quantum criticality in ferromagnetic heavy fermion systems in parallel with their antiferromagnetic counterparts [2]. The issue becomes particularly pressing given the recent developments on UTe2. This system shows strong evidence for spin-triplet superconducting pairing and indications of quantum criticality in the normal state [3,4]. In this work, we study a periodic Anderson model with ferromagnetic RKKY interactions. We treat the model within the extended dynamical mean-field theory [5] and solve the self-consistency equations with the continuous-time quantum Monte Carlo method [6]. We present the results on the underlying quantum phase transition and the superconducting pairing correlations, showing that the system has a strong tendency to triplet pairing.

*Supported by NSF grant DMR-1920740 and Welch Foundation grant C-1411.

4:18PM P56.00010: Angle Dependence of the Field-Induced Phases in UPt$_2$Si$_2$*  
GRETA CHAPPELL (Presenter), DAVID E GRAF, KAYA WEI, YOU LAI, WILLIAM NELSON, BENNY SCHUNDELMIER, CHRIS MANN, RYAN BAUMBACH, Florida State Univ —  
The low temperature antiferromagnet ($T_N = 32$ K) UPt$_2$Si$_2$ exhibits complex magnetic field-induced phases. Previous studies have established magnetic phase diagrams for applied fields along the $a$- and $c$-axes and suggest that the metamagnetic phase transitions (PT) may be associated with an evolution of the Fermi surface [1,2]. Here, we examine the PT angle dependence with RF skin depth and torque magnetometry experiments at temperatures $T < 1$ K and in fields $H < 45$ T. We find that AFMI $\rightarrow$ III evolves with nearly $1/\cos\theta$ dependence, III $\rightarrow$ V is hysteretic and nearly angle independent, and an additional PT in region V that also follows a $1/\cos\theta$ dependence. We shall discuss these results and the implications for the metamagnetism in UPt$_2$Si$_2$ and similar uranium-based materials.

*Work performed at NHMFL is supported by the National Science Foundation through DMR-1644779 and the State of FL. A portion of work is supported by the Center for Actinide Science and Technology, an EFRC funded by the US DOE under DE-SC0016568.
**4:30PM P56.00011: Field induced phases in UCr$_2$Si$_2$**

YOU LAI (Presenter), Los Alamos National Laboratory, JONAS DIAZ, GRETA CHAPPELL, National High Magnetic Field Laboratory, PHILIP MOLL, Institute of Materials (IMX), EPFL, RYAN BAUMBACH, National High Magnetic Field Laboratory, ROSS MCDONALD, Los Alamos National Laboratory — In the broader family of (Ln-An)Cr$_2$Si$_2$ (Ln = lanthanide and An = actinide), UCr$_2$Si$_2$ is unique, where the system undergoes a structural (tetragonal to monoclinic) and antiferromagnetic phase transitions at $T_S = 210$ K and $T_N = 27$ K, respectively, and the U ions carry a magnetic moment. Here, we present an extensive study of the behavior in high magnetic fields. We have performed pulsed field torque magnetometry and resistivity measurements on single crystalline samples UCr$_2$Si$_2$ grown first time by molten flux method. Along the crystallographic c axis, at low temperatures, we find a metamagnetic-like transition in fields of the order 10 T, possibly indicating a first-order transition, the field induced phase transition moves to higher field and reaches maximum while the field is along the $<101>$ diagonal of the tetragonal lattice. From our analysis of the data we can distinguish new high-field phases above the AFM ground state, which indicate the UCr$_2$Si$_2$ is possibly similar to what is seen for URu$_2$Si$_2$ and UPt$_2$Si$_2$, where the emergence of these new phase is due to the Fermi surface effects.
Spectroscopic investigation of UFe$_2$Si$_2$, URu$_2$Si$_2$, UNi$_2$Si$_2$, and UPd$_2$Si$_2$: from Pauli paramagnetism to antiferromagnetism via the hidden order state.* ANDREA SEVERING (Presenter), Institute of Physics II, University of Cologne, ANDREA AMORESE, Max-Planck Institute for Chemical Physics of Solids Dresden, MARTIN SUNDERMANN, Institute of Physics II, University of Cologne, MAURITS HAVERKORT, Institute of Theoretical Physics, University of Heidelberg, YINGKAI HUANG, van der Waals Zeeman Institute, Amsterdam University, MARIA SZLAWSKA, DARIUSZ KACZOROWSKI, Polish Acadademy of Science, RAN SHENG, M BRIAN MAPLE, Department of Physics, University fo California, San Diego, ERIC BAUER, Los Alamos National Laboratory, ANDREAS LEITHE-JASPER, LIU TJENG, Max-Planck Institute for Chemical Physics of Solids Dresden — We have carried out hard x-ray photoelectron spectroscopy (HAXPES) measurements at the U 4$f$ core level and non-resonant inelastic x-ray scattering (NIXS) at the U O$_{4.5}$ edge of UT$_2$Si$_2$ compounds that all form in the tetragonal ThCr$_2$Si$_2$ structure but exhibit different ground state properties: UFe$_2$Si$_2$ is a Pauli paramagnet; URu$_2$Si$_2$ is the famous hidden order compound of which the order parameter is still fiercely debated despite 30 years of intense experimental and theoretical studies [1]; UPd$_2$Si$_2$ and UNi$_2$Si$_2$ are antiferromagnets with T$_N$ well above 100 K and sizeable ordered magnetic moments [2].

We have determined the degree of the 5$f$-electron localization (HAXPES [3]) as well as the symmetry of the 5$f$ ground state wave function (NIXS [4]) across these very different compounds. This enabled us to identify their systematics and to place them in an effective Doniach phase diagram.

**4:54PM P56.00013: Origin of the gap-like behavior in pure and doped URu$_2$Si$_2$: A combined study via quasiparticle scattering spectroscopy and resistivity measurements**

SHENZHI ZHANG (Presenter), GRETA CHAPPELL, RYAN BAUMBACH, National High Magnetic Field Lab, Florida State University, NAVEEN POUSE, M BRIAN MAPLE, physics, University of California, San Diego, LAURA GREENE, WAN KIYU PARK, National High Magnetic Field Lab, Florida State University — Using Quasiparticle scattering spectroscopy (QPS), we track the temperature dependence of the hybridization gap in URu$_{2-x}$Fe$_x$Si$_2$ and URu$_2$Si$_2$P$_x$ (URSP) [1,2,3] in all substitutions, whether the hidden order (HO) appears or not. This poses a challenge to the Fermi surface gapping scenario, due to the absence of drastic changes in the conductance spectra across the HO transition. As an alternative way to explain the gap-like behavior, we adopt a model based on gapped bosonic excitations in the ordered state [4]. With an unusual temperature dependence of their stiffness, the temperature-dependent resistivity can be reproduced well including the jump at the HO transition. The extracted gap increases with increasing Fe-content, which agrees with the behavior of the $E_1$ gap in inelastic neutron scattering under pressure. This implies that the $E_1$ gap might originate from the same gapped bosonic excitations.

**5:06PM P56.00014: Structural studies of Fe-doped URu$_2$Si$_2$ near the hidden order transition using X-ray crystallography**

XIAOLAN SUN (Presenter), University of Illinois at Urbana-Champaign, JOHN A MYDOSH, Leiden University, NAVEEN POUSE, M BRIAN MAPLE, University of California, San Diego, SANGJUN LEE, PETER ABBAMONTE, University of Illinois at Urbana-Champaign — The origin of hidden order (HO) in URu$_2$Si$_2$ has been debated for the past thirty years. An interesting observation in recent years is the phase transition into a large moment antiferromagnetic (LMAF) state under either high pressure or Fe substitution for Ru. We used low-temperature x-ray crystallography to study the structure of URu$_2$Si$_2$, both with and without Fe doping. We observed changes in the intensities of the Bragg peaks suggesting the HO transition is associated with a breaking of spacegroup symmetry not accompanied by a change in lattice parameters. The pattern of atomic displacements changes markedly when crossing into the LMAF phase via Fe doping. No structural superlattice reflections were observed, consistent with past studies. We will discuss how our results constrain the subgroups and physical origin of the HO and LMAF phases.

*This work was supported by DOE Office of Basic Energy Sciences grant no. DE-FG02-06ER46285.
Magnetostriction of URu$_{2-x}$Fe$_x$Si$_2$ in High Magnetic Fields

Alexander Breindel (Presenter), University of California, San Diego, Sheng Ran, University of Maryland, Naveen Pouse, Inho Jeon, University of California, San Diego, Marcelo Jaime, Los Alamos National Laboratory, M Brian Maple, University of California, San Diego — URu$_2$Si$_2$ is a compound of great interest due to its hidden order (HO) phase whose order parameter has remained a mystery for more than three decades. It has been discovered that the substitution of Fe for Ru produces a transition from the HO to an antiferromagnetic (AFM), similar to what occurs under the application of pressure. This provides an opportunity to study URu$_2$Si$_2$ in both the HO and AFM phases at atmospheric pressure using experimental techniques that cannot readily be performed under pressure. In that vein, we conducted high field magnetostriction measurements on URu$_{2-x}$Fe$_x$Si$_2$. Our results support the findings of other high field measurements on URu$_{2-x}$Fe$_x$Si$_2$. However, we do not see a signature of the HO transition in our data, suggesting that our probe is not sensitive to the HO transition.

*The National High Magnetic Field Laboratory is supported by the NSF through NSF/DMR-1157490/1644779 and the State of Florida. Research at UCSD was supported by the US DOE BES under Grant No. DE-FG02-04-ER46105 (materials synthesis and characterization) and the US NSF under Grant No. DMR-1206553 (low temperature measurements) This research is also funded by a QuantEmX grant from ICAM and the Gordon and Betty Moore Foundation through Grant GBMF5305 to Alexander Breindel

Session P57 DMP: Electronic and Optical Properties of 2D Materials III
Mile High Ballroom 3A - Wencan Jin, Auburn University - Tag(s): Focus

2:30PM P57.00001: Valleytronics and excitonics in 2D materials. [Invited] Tony Heinzel (Presenter), Applied Physics and Photon Science, Stanford University — Selected by Focus Topic Organizer (Liuyan Zhao, Robert Hovden)
3:06PM P57.00002: High-temperature exciton condensation in two-dimensional atomic double layers [Invited]  
ZEFANG WANG (Presenter), Cornell University, DANIEL A RHODES, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Tsukuba, Japan, JAMES C HONE, Columbia University, JIE SHAN, KIN FAI MAK, Cornell University — Bose-Einstein condensate is the ground state of matter of a dilute gas of bosons, such as atoms cooled to temperatures close to absolute zero. With a much smaller mass than atoms, excitons have been predicted to condense at significantly higher temperatures. The small exciton binding energy in conventional semiconductors has so far limited the condensation temperature to below 1 K. In the past several years, a new class of two-dimensional (2D) semiconductors with much larger exciton binding energy has emerged. In this talk, I will discuss the development of transition metal dichalcogenide double layer structures and electrical injection of interlayer excitons up to $10^{12} \text{ cm}^{-2}$ in the system. We study the electron-hole double layers through the interlayer tunneling and electroluminescence (EL). We observe a threshold dependence of the EL intensity on exciton density, accompanied by a super-Poissonian photon statistics near the threshold, and a large EL enhancement peaked narrowly at equal electron-hole densities. These results provide compelling evidence for interlayer exciton condensation in atomic double layers.

3:42PM P57.00003: Comparative KPFM measurements on doped monolayer MoS$_2$*  
CHRISTINA MCGAHAN (Presenter), Mount Holyoke College, PIN-CHUN SHEN, YUXUAN LIN, Massachusetts Institute of Technology, ASHLEY CAVANAGH, Mount Holyoke College, TOMAS PALACIOS, JING KONG, Massachusetts Institute of Technology, KATHERINE AIDALA, Mount Holyoke College — Tuning the electrical properties of monolayer MoS$_2$ through doping allows better control and flexibility over future device design. Here we present electrical measurements on sulfur-rich and oxygen-rich MoS$_2$ flakes using kelvin probe force microscopy (KPFM) and a field effect transistor sample geometry, allowing us to resolve spatial variations. Preliminary KPFM measurements show that oxygen-rich MoS$_2$ has a larger work function than sulfur-rich MoS$_2$ and that the work function of monolayer MoS$_2$ differs from that of multilayer MoS$_2$. The trend in work functions between differently doped MoS$_2$ flakes observed via KPFM is consistent with the trend in threshold voltages extracted from bulk current-voltage measurements on the flakes as well as the trend in work functions calculated via density functional theory. The sensitivity of the shift in work function of the MoS$_2$ flakes from an applied gate voltage suggests that local density of states measurements can be extracted with KPFM to experimentally examine the energy levels of the differently doped monolayer MoS$_2$ flakes.

*NSF-DMR 1231319, NSF-1541959, NSF-DMR 1708970, NSF 0939514
3:54PM P57.00004: Tomonaga-Luttinger Liquid in MoSe₂ Twin Domain Boundaries*  YIPU XIAXUNQIU ZHANG, Physics Department, The University of Hong Kong, YUANJUN JIN, Physics Department, Southern University of Science and Technology, WINGKIN HO, Physics Department, The University of Hong Kong, HU XU, Physics Department, Southern University of Science and Technology, MAOHAIXIE (Presenter), Physics Department, The University of Hong Kong — In epitaxial MoSe₂ monolayer grown by molecular-beam epitaxy, dense networks of twin domain boundaries (DBs) have been observed [1]. They behave as metals. Being sandwiched between semiconducting pristine MoSe₂ domains, they represent an ideal one-dimensional (1D) system for studying the physics of 1D metals, such as the Peierls type instability and collective excitations of Tomonaga-Luttinger liquid (TLL). Indeed, there have already been reports of charge density waves (CDW) [2] and the TLL [3] in such systems. In this work, we report a low-temperature scanning tunneling spectroscopy study revealing the quantum confinement effect and signatures of the TLL in the 4|4P-type DB defects in MoSe₂. Notably, CDW is not observed at temperatures down to ~ 5 K. This finding is consistent with a recent study of another type (4|4E) 1D defect in MoS₂ [4].

*The work is supported by a Collaborative Research Grant (No. C7036-17W) from the Research Grant Council of Hong Kong Special Administrative Region, China.

4:06PM P57.00005: Probing Excitonic Resonances of Metal Films on Suspended 2D Membranes Using Electron Energy Loss Spectroscopy*  TODD BRINTLINGER (Presenter), JOSE FONSECA, JAMES CLIFFORD CULBERTSON, MAXIM ZALALUTDINOV, RHONDA MICHELE STROUD, JEREMY ROBINSON, United States Naval Research Laboratory — We characterize Oriented Porous mEtallic Networks (OPEN) with aberration-corrected scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS). These OPEN films are synthesized by annealing metal films on 2D layers, which causes lattice registry between the metal layer and the 2D materials. We are studying the morphological influence that MoS₂ monolayers have on relatively thick (13-25nm) gold thin films during annealing. Ex-situ annealing experiments of MoS₂/Au on SiO₂ substrates shows that the Au films can become textured (oriented), as revealed through electron beam scattering diffraction, and that the Au film can locally dewet beneath the MoS₂ layer to form a porous metal layer with suspended MoS₂ membranes. Further, 60 kV STEM imaging and EELS show that the metal and 2D lattices are aligned, with several EELS resonances in the low loss range. One resonance at ~ 2 eV is associated with the so-called A and B excitons. We will discuss the origin of these resonances, and how both the metal overlayer and disordered carbon contamination affect them.

*The authors acknowledge funding from the Office of Naval Research (Naval Research Laboratory Basic Research Program).
4:18PM P57.00006: Out-of-plane charge transport anomalies in polytypes of NbS$_2$*  
KONSTANTIN SEMENIUK (Presenter), EDOARDO MARTINO, CARSTEN PUTZKE, Ecole Polytechnique Federale de Lausanne, DAVID LEOBEUF, Laboratoire National des Champs Magnétiques Intenses, HELMUTH BERGER, PHILIP MOLL, LASZLO FORRO, Ecole Polytechnique Federale de Lausanne — Tuning interlayer coupling in quasi-two-dimensional materials is a powerful tool for realising novel electronic states for potential applications in electronic and optical devices. Crucial information regarding the underlying interactions can be obtained by probing the c-axis resistivity$^1$. We present the case of the 2H and 3R polytypes of NbS$_2$, which have the same in-plane structure but different stacking of the layers and as a result exhibit very contrasting charge transport properties. By utilising focused-ion-beam-assisted sample preparation we were able to unambiguously probe the in-plane and out-of-plane resistivities of the compounds. The corresponding anisotropies are substantially lower than has been thought before. Furthermore, we show a number of previously unobserved features, including non-monotonic temperature dependence of resistivity and negative longitudinal magnetoresistance. We suggest that the stacking faults, occurring naturally in the studied compounds$^2$, are the primary cause of the aforementioned behaviours.

4:30PM P57.00007: Identification of select populations of single photon emitters in hexagonal boron nitride based on their zero phonon line and linewidth broadening footprint  
HAMIDREZA AKBARI (Presenter), WEI-HSIANG LIN, BENJAMIN VEST, HARRY ATWATER, Applied Physics, Caltech — Single photon emitters (SPE) in hexagonal boron nitride (hBN) have shown promising electrical and optical properties for utilization in quantum light source applications. The unpredictability of defect properties in hBN remains a significant challenge in order to reproducibly and more deterministically identify bright and robust emitters. In this presentation, we first investigate the characteristics of zero phonon line spectra (ZPLs) from defects found in hBN samples fabricated by chemical vapor deposition techniques. Depending on the growth conditions, the ZPL distribution of defects from the same sample can be significantly reduced. This suggests that defects exhibiting similar properties might be identified. Based on these observations, we carry out an in-depth study of the spectral properties and emission line broadening mechanisms for different sets of defects showing similar spectral features. In particular, we perform both low temperature spectroscopy of photoluminescence down to 4K and luminescence decay lifetime measurements. Mechanisms of line broadening for the different populations of defects will be discussed. These elements build a better understanding of the zoology of defects in hBN and of their potential and limitations for quantum light applications.
4:42PM P57.00008: Unraveling the Mystery of the 1.5 layer Raman Response in Exfoliated MoS2. ANDREY KRAYEV (Presenter), HORIBA Scientific, MATĚJ VELICKÝ, Chemistry and Chemical Biology, Cornell University — Recently a new method of exfoliation of large area monolayers of transition metal dichalcogenides (TMDC) was proposed. Confocal Raman characterization of exfoliated monolayers of MoS2 showed A' peak splitting, the components of this split peak corresponding to a standard A' peak of the monolayer and A1g peak of the bi-layer correspondingly. We further performed tip enhanced Raman Scattering (TERS) imaging of these exfoliated crystals. Thanks to greatly improved spatial resolution of TERS imaging, we discovered that some areas of what seemed to be a uniform monolayer, actually contained a network of tiny islands (few tens of nm across) having spectral signature closely matching TERS response of the bilayer while TERS spectra of areas in between these islands closely resembled standard Raman spectrum of the monolayer. Thanks to these observations we came to the conclusion that the gold-assisted exfoliation of MoS2 may result in inhomogeneous crystals featuring a network of tiny bilayer islands, and consequently, greatly increased crystal edge length per unit of area, a feature that may be useful for (photo)catalytic applications of TMDCs.

4:54PM P57.00009: Correlating 3D atomic defects and electronic properties of 2D transition metal dichalcogenides with picometer precision* XUEZENG TIAN (Presenter), DENNIS S KIM, University of California, Los Angeles, SHIZE YANG, Oak Ridge National Laboratory, CHRISTOPHER CICCARINO, Harvard University, YONGJI GONG, Rice University, YONGSOO YANG, YAO YANG, University of California, Los Angeles, BLAKE DUSCHATKO, Harvard University, YAKUN YUAN, University of California, Los Angeles, PULICHEL M AJAYAN, Rice University, JUAN-CARLOS IDROBO, Oak Ridge National Laboratory, PRINEHA NARANG, Harvard University, JIANWEI MIAO, University of California, Los Angeles — The field of research in two-dimensional (2D) transition metal dichalcogenides (TMD), has experienced extraordinary growth. To understand the structure-property relationship of these materials at the fundamental level, we must know their 3D atomic structure with high precision.

Here, we developed scanning atomic electron tomography (sAET) to localize the 3D atomic coordinates in 2D materials and heterostructures with picometer precision. Using a Re-doped MoS2 monolayer sample, we demonstrated a general sAET method to overcome several limitations and determined the 3D coordinates of individual atoms with precision down to 4 pm. We identified 3D crystal defects such as dopants, vacancies and atomic-scale ripples and measured the 3D atomic displacement and the full strain tensor of the Re-doped MoS2. Furthermore, the experimental 3D atomic coordinates were used as direct input to DFT to correlate crystal defects with the electronic band structure at the single-atom level. sAET is generally applicable to the determination of the 3D atomic coordinates of various 2D materials, heterostructures and thin films.

PRIBIAG, School of Physics and Astronomy, University of Minnesota — Tellurium is a narrow bandgap
semiconductor with high hole mobility of several hundred cm²(Vs)⁻¹. It has attracted great
interest due to its unique crystal structure, consisting of 1D helical chains interconnected by van
der Waals type bonds. A recent development is the successful synthesis of two-dimensional
tellurium, or tellurene, using a solution-based process. Various interesting transport phenomena
have been experimentally demonstrated since then, such as anisotropic magnetoresistance,
quantum Hall effect and gate-tuned insulator-metal transition, revealing its potential for
fundamental studies and future applications of nanoscale devices. We discuss the fabrication and
electrical measurements of few-layer and bulk tellurium flakes grown by the solution method. We
study anisotropic and nanoscale transport of the material.

Session P58 DCP: Journal of Chemical Physics Editor's Choice Awards
Mile High Ballroom 3B - Tag(s): Invited, Undergrad Friendly

2:30PM P58.00001: Electron transfer in confined electromagnetic fields* [Invited]  ALEXANDER
SEMENOV (Presenter), ABRAHAM NITZAN, University of Pennsylvania — The interaction between
molecular (atomic) electron(s) and the vacuum field of an optical cavity has drawn significant
attention thanks to the rapid developments in nano-optics. Such interaction which is a subject of
cavity quantum electrodynamic can substantially affect transport properties of molecular
systems. In this work we consider non-adiabatic electron transfer process in the presence of a
cavity mode. We present a generalized framework for the interaction between a charged
molecular system and a quantized electromagnetic field of a cavity and apply it to the problem of
electron transfer between a donor and an acceptor placed in a confined vacuum electromagnetic
field. The effective system Hamiltonian corresponds to a unified Rabi and spin-boson model
which includes a self-dipole energy term. Two limiting cases are considered: one where the
electron is assumed to be much faster than the cavity mode and another in which the electron
tunneling time is significantly larger than the mode period. In both cases a significant rate
enhancement can be produced by coupling to the cavity mode in the Marcus inverted region. The
results of this work offer new possibilities for controlling electron transfer processes using visible
and infrared plasmonics

3:06PM P58.00002: Laser-based imaging of gas phase molecules [Invited] ARNAUD ROUZÉE (Presenter), Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy — Watching a molecule at work, the so-called making a molecular movie, is a long standing goal in the physical chemistry community. With the recent advent of X-ray free electron lasers and relativistic electron guns, femtosecond diffractive imaging studies with intense short-wavelength pulses and with ultrafast electron bunchs became possible. In this talk, I will discuss alternative routes based on strong field ionization by intense femtosecond laser pulses to image molecular structures and dynamics. Two techniques, namely laser-induced Coulomb explosion imaging and laser-induced electron diffraction, will be presented and recent applications of these techniques to the retrieval of molecular structure and ultrafast molecular dynamics will be provided.

3:42PM P58.00003: Diffusion, plasticity, and excess entropy in complex colloidal fluids* [Invited] XIAOGUANG MA (Presenter), University of Pennsylvania — Excess entropy is the difference between the “true” system entropy and that of an equivalent ideal gas. Rosenfeld first observed that the diffusivity and viscosity of simple liquids scale exponentially with excess entropy. This intriguing discovery had motivated numerous studies of excess entropy scaling in a wide variety of materials spanning different particle type, size, density, interaction, temperature, and even shear rate, most of which are computer simulation work. In this talk, I will discuss our recent experiments utilizing excess entropy concept to understand the dynamics of complex fluids. In the first experiment, we investigate the structure and dynamics in dense colloidal fluids with tunable short-range attractions. From particle trajectory data we measure the two-body excess entropy and the long-time diffusion coefficients from samples with different packing fractions and attraction strengths. These results are found to follow Rosenfeld's excess entropy scaling that is independent of sample packing fraction and attraction strength. In the second experiment, we study plastically deformed colloidal solids. We directly imaged the dynamics and micro-structure induced by plastic shear flow in a series of amorphous solids under oscillatory shear. Data reveal novel scaling relationships between plastic flow, viscous response, and excess entropy. These findings extend the application of excess entropy concept from equilibrium to nonequilibrium systems.

Markov state models have become popular in the computational biophysics community as a technique for identifying stationary and kinetic information of protein dynamics from molecular dynamics (MD) simulation data. We extended the applicability of automated Markov state modeling to simulation data of molecular self-assembly by constructing collective coordinates from molecular descriptors that are invariant to permutations of molecular indexing. Understanding molecular self-assembly is of critical importance if we want to deepen our understanding of neurodegenerative diseases where the aggregation of disordered peptides or misfolded proteins is thought to be the main culprit. I will present the Markov state models that we obtained for the self-assembly of different peptides and demonstrate that the Markov state models clearly map out the different aggregation pathways, something which has not been possible with standard MD analysis tools.

Spin waves in the antiferromagnetic topological insulator MnBi$_2$Te$_4^*$

BING LI (Presenter), Ames Laboratory, Ames, IA 50011, USA; Iowa State University, Ames IA 50011, USA, SIMON RIBEROLLES, LIQIN KE, ELIJAH GORDON, Ames Laboratory, Ames, IA 50011, USA, DANIEL PAJEROWSKI, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, ANDREAS KREYSSIG, Ames Laboratory, Ames, IA 50011, USA; Iowa State University, Ames IA 50011, USA, BENJAMIN UELAND, Ames Laboratory, Ames, IA 50011, USA, JIAQIANG YAN, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, ROBERT MCQUEENEY, Ames Laboratory, Ames, IA 50011, USA; Iowa State University, Ames IA 50011, USA — MnBi$_2$Te$_4$ is proposed to be the first antiferromagnetic (AF) topological insulator (TI). The natural intergrowth of magnetic and TI layers, and the ground state tunability via a magnetic field provide a unique platform for studying the interplay between magnetism and topological electronic states, which give rise to the quantum anomalous Hall effect and axion electrodynamics. Here we present results from our inelastic neutron scattering (INS) study on MnBi$_2$Te$_4$ single crystals, where we determined the strength of the magnetic interactions and anisotropy in the AF state ($T_N = 24$ K). By comparing our INS data to the dynamic spin susceptibility calculated using a linear-response density functional theory, we find that magnetic interactions extending further than the Mn nearest-neighbor distance are necessary to understand the observed spin wave dispersion.

Electronic states and magnetic response of MnBi$_2$Te$_4$ surface by scanning tunneling microscopy and spectroscopy

YONGHAO YUAN (Presenter), XINTONG WANG, Department of Physics, Tsinghua University, HAO LI, School of Materials Science and Engineering, Tsinghua University, JIAHENG LI, YU JI, ZHENQI HAO, Department of Physics, Tsinghua University, YANG WU, Department of Mechanical Engineering, Tsinghua University, KE HE, YAYU WANG, YONG XU, DUAN WENHUI, WEI LI, QIKUN XUE, Department of Physics, Tsinghua University — The newly discovered intrinsic magnetic topological insulator, MnBi$_2$Te$_4$, has demonstrated novel quantum phenomena. Quantized Hall conductance and topological axion state have been realized in its thin flakes. However, the measured band structures show deviations from calculation results and the reason is still in debate. In our studies, low-temperature scanning tunneling microscopy experiment is carried out to investigate its surface states and magnetic response. Unexpected electronic structures are obtained from quasiparticle interference patterns on the topmost layer, which show deviations from the prediction of out-of-plane A-type antiferromagnetic structure. Such differences presumably originate from the re-orientation of magnetic moments near the surface. Moreover, 5% of Mn substitutions at Bi sites are observed. They not only give rise to fluctuating electronic structures, but also affect the magnetism of the material. Our findings shed new lights on the magnetic property of MnBi$_2$Te$_4$ and the design of magnetic topological insulators.
2:54PM P59.00003: Gapless surface Dirac cone and its possible origin in antiferromagnetic topological insulator MnBi$_2$Te$_4$*  YU-JIE HAO, PENGFEI LIU, YUE FENG, XIAO-MING MA, Physics, Southern University of Science and Technology, EIKE F. SCHWIER, MASASHI ARITA, SHIV KUMAR, Hiroshima Synchrotron Radiation Center, Hiroshima University, CHAOWEI HU, Physics and Astronomy, University of California, Los Angeles, RUI'E LU, MENG ZENG, YUAN WANG, ZHANYANG HAO, HONG-YI SUN, Physics, Southern University of Science and Technology, KE ZHANG, Hiroshima Synchrotron Radiation Center, Hiroshima University, JIAWEI MEI, Physics, Southern University of Science and Technology, NI NI, Physics and Astronomy, University of California, Los Angeles, LIUSUO WU, Physics, Southern University of Science and Technology, KENYA SHIMADA, Hiroshima Synchrotron Radiation Center, Hiroshima University, CHAOYU CHEN, QIHANG LIU, CHANG LIU (Presenter), Physics, Southern University of Science and Technology — The recent discovered antiferromagnetic topological insulators in the Mn-Bi-Te family have rapidly drawn broad interest since its cleaved surface state is believed to be gapped, hosting the unprecedented axion states. However, we show by ARPES that a gapless Dirac cone at the (0001) surface of MnBi$_2$Te$_4$ exists inside the bulk band gap. Such unexpected surface state remains unchanged across the bulk Néel temperature, and is robust against severe surface degradation, indicating additional topological protection. Through symmetry analysis and \textit{ab initio} calculations we consider different types of surface magnetic reconstruction as possible origins giving rise to such linear dispersion. Our results reveal that the intrinsic magnetic topological insulator hosts a rich platform to realize various topological phases, and thus pushed forward the comprehensive understanding of magnetic topological materials.

Intrinsic magnetic topological insulators are stoichiometric materials with both magnetic ordering and topological electronic states. Due to its inherent magnetism, this class of materials processes rich topological quantum phases that induced by symmetry breaking, while maintaining good crystallinity and high purity of the material. We report the MBE synthesis and characterization of an intrinsic magnetic topological insulator MnBi$_2$Se$_4$. The MnBi$_2$Se$_4$ thin films are deposited with alternating layer growth of Bi$_2$Se$_3$ and a-MnSe(111). The high quality of the material is shown with cross-sectional TEM. Dirac surface state is demonstrated with angle-resolved photoemission spectroscopy above its magnetic ordering temperature. SQUID magnetometry measurement on films with different thicknesses shows layered-antiferromagnetic ordering in this material. Low-field SQUID measurement also shows a hysteresis loop, with magnetic moments preferred to stay within the lattice plane. The ferromagnetic signal is attributed to uncompensated magnetic moments at the surface. Its magnetic characterization is also confirmed with XMCD measurement. Furthermore, magnetometry measurement also shows that the magnetic ordering in MnBi$_2$Se$_4$ persists down to the monolayer limit.
3:18PM P59.00005: Scanning tunneling microscopy and spectroscopy investigation of the antiferromagnetic topological insulator MnBi$_2$Te$_4^*$  HONG LI (Presenter), HE ZHAO, Boston College, CHAOWEI HU, SCOTT MACKEY, Physics and Astronomy, UCLA, ZIQIANG WANG, Boston College, NI NI, Physics and Astronomy, UCLA, ILIJA ZELJKOVIC, Boston College — The interplay of topology and magnetism within the same material can give rise to exotic electronic phases, such as the quantum anomalous Hall state and the axion insulator state. Recently discovered MnBi$_2$Te$_4$ is believed to be the first intrinsic antiferromagnetic topological insulator. Using low temperature scanning tunneling microscopy and spectroscopy, we study the surface of high-quality single crystals of MnBi$_2$Te$_4$. From STM topographs, we visualize the spatial distribution of accidental Mn substitutions in the topmost Te layer. Moreover, by imaging the scattering of electrons on the surface, we track the evolution of the electronic band structure and compare it with angle-resolved photoemission spectroscopy experiments. Our measurements provide a nanoscale insight into the chemical inhomogeneity and the electronic structure of this novel system.

3:30PM P59.00006: Strongly Gapped Topological Surface States in MnBi$_2$Te$_4$(Bi$_2$Te$_3$)$_n$ Family*  KYLE GORDON (Presenter), University of Colorado, Boulder, CHAOWEI HU, Physics, University of California, Los Angeles, PENGFEI LIU, Physics, Shenzhen Institute for Quantum Science and Technology, BARUN GHOSH, Physics, Indian Institute of Technology-Kanpur, ANDREW LINN, HAOXUANG LI, DUSHYANT NARAYAN, University of Colorado, Boulder, JINYU LIU, Physics, University of California, Los Angeles, HONGYI SUN, Physics, Shenzhen Institute for Quantum Science and Technology, BAHADUR SINGH, Physics, Northeastern University, AMIT AGARWAL, Physics, Indian Institute of Technology-Kanpur, SUYANG XU, Physics, Massachusetts Institute of Technology, HSIN LIN, Physics, Academia Sinica, TAY-RONG CHANG, Physics, National Cheng Kung University, QIHANG LIU, Physics, Shenzhen Institute for Quantum Science and Technology, NI NI, Physics, University of California, Los Angeles, DANIEL DESSAU, University of Colorado, Boulder — The MnBi$_2$Te$_4$(Bi$_2$Te$_3$)$_n$ family of materials are potential candidates for magnetic topological insulators (MTIs) that may show the Quantum Anomalous Hall Effect (QAHE). This class of materials are heterostructures of MnBi$_2$Te$_4$ and Bi$_2$Te$_3$ layers that are stacked together via van der Waals forces, with n number of Bi$_2$Te$_3$ layers interstitially placed between MnBi$_2$Te$_4$ layers. In this talk, we present Angular Resolved Photoemission Spectroscopy (ARPES) experiments on MnBi$_4$Te$_7$, MnBi$_6$Te$_{10}$, and MnBi$_8$Te$_{13}$, demonstrating the topological nature of each material. Furthermore, we deconvolve the surface spectra due to each possible surface termination for each stacking arrangement, demonstrating a rich transition from the gapless MnBi$_2$Te$_4$ surface, through a gapped Bi$_2$Te$_3$-like surface, and ending with an approximate pure Bi$_2$Te$_3$ surface.

Competing Interactions in the Antiferromagnetic State of the Axion Insulator Candidate MnBi₂Te₄

VINCENT MORANO (Presenter), VERONICA STEWART, Johns Hopkins University, YIMING QIU, CRAIG BROWN, National Institute of Standards and Technology, TYREL MCQUEEN, COLLIN LESLIE BROHOLM, Johns Hopkins University — A new class of materials, antiferromagnetic topological insulators, has been predicted to realize the bulk axion insulator with a large and in some cases quantized magneto-electric coefficient. Hexagonal MnBi₂Te₄ is a candidate material and here we report neutron scattering experiments conducted at the NIST Center for Neutron Research to understand its magnetism. We confirm A-type antiferromagnetic order (alternating FM basal planes with spins along the hexagonal axis) with T_N=24 K. Inelastic scattering reveals an excitation spectrum with a bandwidth of 4.5 meV and gap \( \Delta <0.6 \) meV. Modelling these data using spin-wave theory, we obtain an effective spin Hamiltonian for MnBi₂Te₄ that features competing ferro- and antiferromagnetic interactions within the basal plane.

*This work was supported as part of the Institute for Quantum Matter, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award No. DE-SC0019331.

Investigation on the topological surface states of a superlattice-like magnetic topological insulator MnBi₄Te₇

XUEFENG WU (Presenter), YU ZHANG, XIAO-MING MA, CHUNSHENG ZHOU, KEDONG WANG, QIHANG LIU, CHANG LIU, YUE ZHAO, physics, Southern University of Science and Technology — The recently verified intrinsic magnetic topological insulator MnBi₂Te₄ has attracted tremendous research interest, as it is considered to be a promising platform for emergent quantum phenomena such as the quantum anomalous Hall effect, and the axion insulator state, etc. In a superlattice-like bulk of alternating MnBi₂Te₄ and Bi₂Te₃ layers, the antiferromagnetic exchanged coupling can be effectively weakened. Here, we investigate the surface states of MnBi₄Te₇ crystal via angle-resolved photoemission spectroscopy (ARPES) and scanning tunneling microscopy (STM) techniques. Two different band structures are observed, both showing the Dirac point located at \(-280\) mV below the Fermi level and gapless feature at Dirac point. The two different band structures can be associated with the MnBi₂Te₄-terminated and Bi₂Te₃-terminated surfaces by STM study. We further analyze the quasi-particle interference scattering at various energies, which exhibit distinct \( \Gamma\)-\( M \) features corresponding to the scattering of topological surface states, showing good correspondence to ARPES data. Our results can help to understand the electronic structure and related phenomena in the emerging intrinsic magnetic topological insulators.
Dynamic magnetic properties of a magnetic topological insulator material MnBi₄Te₇

KAVITA MEHLAWAT (Presenter), ALEXEY ALFONSOV, ANNA ISAEVA, BERND BUECHNER, VLADISLAV KATAEV, Leibniz IFW Dresden, Helmholtzstr. 20, D-01069 Dresden, Germany — A van der Waals compound MnBi₄Te₇ belongs to the family of (Bi₂Te₃)ₙ(MnBi₂Te₄), (n = 0, 1, 2) heterostructures and is a candidate magnetic topological insulator [1]. It is the first magnetic material that features both, the intrinsic net magnetization and a band inversion. Static magnetic susceptibility (χ) and magnetization (M) measurements as a function of the applied field (H) on MnBi₄Te₇ single-crystals show an antiferromagnetic state at Tₑ = 13 K and a ferromagnetic-like hysteresis occurring upon cooling below 5 K [1]. We performed electron spin resonance (ESR) spectroscopy measurements in wide frequency and temperature ranges to explore the dynamic magnetic properties of MnBi₄Te₇. From high-frequency ESR measurements, we obtain evidence that MnBi₄Te₇ is an easy-axis type ferromagnet and ferromagnetic spin correlations persist up to T = 30 K on the time scale of an ESR experiment (10⁻¹⁰ - 10⁻¹¹ s).

Topological Electronic Structure and Its Temperature Evolution in Antiferromagnetic Topological Insulators

LEXIAN YANG (Presenter), Tsinghua University, ZHONGKAI LIU, ShanghaiTech University, YONG XU, Tsinghua University, YULIN CHEN, Oxford University — Magnetic topological insulators represent a novel state of topological quantum materials with unique blends of non-trivial band topology and magnetism. Recently, Intrinsic magnetic topological insulator MnBi₂Te₄ is shown to exhibit rich topological effects such as quantum anomalous Hall effect and axion electrodynamics, which attracts tremendous research interests. Here, we carried out comprehensive and high-resolution angle-resolved photoemission spectroscopy studies on MnBi₂Te₄, and identified its topological electronic structure. In contrast to theoretical predictions and previous studies, we observe topological surface states with a diminished gap forming a characteristic Dirac cone. In addition, the temperature evolution of the energy bands reveals their interplay with the magnetic phase transition by showing interesting differences between the bulk and surface states, respectively. Our results provide important insights into not only the exotic properties of MnBi₂Te₄, but also the generic understanding of the interplay between magnetism and topological electronic structure in magnetic TQMs.

*Supported by the National Natural Science Foundation of China (Grant No. 11774190 and No. 11674229).
Characterization of the Layered Antiferromagnetic Topological Insulator MnBi2Se4 Using Scanning Tunneling Microscopy

ROBERT WALKO (Presenter), Ohio State Univ - Columbus, TIANCONG ZHU, University of California, Berkeley, ALEXANDER BISHOP, ROLAND KAWAKAMI, JAY A GUPTA, Ohio State Univ - Columbus — Recently, topological insulators have been an area of interest due to the existence of symmetry protected states. Those with broken time reversal symmetry are particularly interesting because they have been predicted to host several intriguing phenomena such as the quantum anomalous hall effect, magneto-electric effects, and topologically protected surface and edge states. MnBi2Se4 (MBS) is a predicted topological insulator formed of van der Waals separated septuple layers (SL) with a layered anti-ferromagnetic structure, which breaks time-reversal symmetry and could therefore potentially realize some of those phenomena. For this study, a Se capped 20SL MBS film was grown on a sapphire substrate using molecular beam epitaxy. After other measurements were taken ex-situ the sample was then de-capped and transferred via vacuum suitcase to a low-temperature (5K) scanning tunneling microscope (STM). In our STM images, we observed a triangular lattice with an average lattice constant of 3.85Å. Additionally, we see a semiconducting nature in scanning tunneling spectroscopy with a band gap of approximately 700meV.

Engineering MnBi2Te4 thin films by chemical dopants and tailoring structure

LIGUO ZHANG (Presenter), HAICHENG LIN, FENGREN FAN, YAN SUN, CLAUDIA FELSER, Max-Planck Institute for Chemical Physics of Solids — As the first realized intrinsic magnetic topological insulators, MnBi2Te4 (MBT) has been extensively studied and shows rich novel transport properties and magnetic properties. As MBT is layered material with antiferromagnetic coupling between adjacent layers, it is a challenge to realize the quantum anomalous Hall effect in MBT. With molecular beam epitaxy technique, we prepared MBT thin films and tried to modify the magnetic coupling by constructing multilayer structures and co-doping method. In this work we systematically studied the magneto-electrical transport properties with the bottom gate tuning method. In the multilayer films stacked with other magnetically doped topological insulators, we observed a diversity behaviors of magnetoresistance and Hall effect in different samples, which are likely due to the variable magnetic orders. Besides, we also discovered an evident evolution in Sb-doped MBT films with varying the ratio of Bi/Sb. Our study indicates that the magnetic order can be tuned in MBT based films and it paves a promising way to control different exotic topological states.
**Surface magnetism of antiferromagnetic topological insulator**

*MnBi$_2$Te$_4$*  WEIDA WU (Presenter), PAUL SASS, Physics and Astronomy, Rutgers University, New Brunswick, JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Lab — MnBi$_2$Te$_4$ is a promising candidate of antiferromagnetic (AFM) topological insulator which might host fascinating quantized anomalous Hall effect or axion insulator state in few molecular layers$^{1,2}$. These quantum phenomena are induced by the mass gap on Dirac surface states opened by the A-type AFM order (alternating ferromagnetic layers)$^3$ with uniaxial anisotropy in MnBi$_2$Te$_4$. However, recent high resolution angle resolved photoemission spectroscopy studies reveal gapless surface states, indicating paramagnetic or non-uniaxial A-type AFM orders$^{4-7}$. Yet there is no direct evidence of such surface magnetism. Recently we demonstrated magnetic imaging of AFM domain walls in MnBi2Te4 family using our homemade cryogenic magnetic force microscope (MFM)$^8$. In this talk, we will present MFM studies of MnBi2Te4 single crystals to address the nature of surface magnetism.

5:06PM P59.00014: Quantum transport in a dual-gated antiferromagnetic topological insulator* KENJI YASUDA (Presenter), ERIC SORIANO, XIRUI WANG, Massachusetts Institute of Technology MIT, JIAQIANG YAN, Oak Ridge National Laboratory, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology MIT — Magnetic topological insulator provides an exciting arena to investigate the interplay between magnetism and spin-momentum-locked Dirac surface state [1]. The recent discovery of the intrinsic antiferromagnetic topological insulators, MnBi2Te4, MnBi4Te7, and MnBi6Te10 has enabled us to study the quantum anomalous Hall effect and axion insulator in exfoliated crystals [2,3]. Especially interesting is the electric-field effect on the crystals due to the expected finite topological magnetoelectric effect. We here report the quantum transport properties of dual-gated antiferromagnetic topological insulator devices, which allow the independent control of the carrier density and the electric field.

*This work was partially supported as part of the Center for the Advancement of Topological Materials, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science.

5:18PM P59.00015: Realizing intrinsic magnetic topological insulators with gapped topological surface states in MnBi2-xSb_xTe4* WONHEE KO (Presenter), MAREK KOLMER, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Laboratory, ANH PHAM, MINGMING FU, FELIX LUEPKE, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, SATOSHI OKAMOTO, Materials Science and Technology Division, Oak Ridge National Laboratory, PANCHAPAKESAN GANESH, ZHENG GAI, ANPING LI, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — The interplay between magnetism and topology of materials could create a variety of exotic topological quantum states, including the quantum anomalous Hall (QAH) effect showing dissipationless chiral edge states, the topological axion states displaying quantized magnetoelectric effects, and Majorana fermions, obeying non-Abelian statistics. All of these quantum states are hopefully realizable in MnBi2Te4. However, the Fermi level is usually in the bulk conduction band of the materials, which is not ideal for revealing these topological properties in transport. Here we show that by doping MnBi2Te4 with Sb, the Fermi level can be shifted while the non-trivial topology is maintained. Scanning tunneling microscopy (STM) is utilized to observe electronic band structure by quasi-particle interference, which reveals surface states in the bulk band gap and a surface band gap at the Dirac point. The transport from multiprobe-STM further displays a surface dominant transport. Our results show that the MnBi2-xSb_xTe4 is an intrinsic magnetic topological insulator that would offer an ideal platform to observe various exotic topological phenomena.

*This research was performed at the Center for Nanophase Materials Sciences which is a DOE Office of Science User Facility.
2:30PM P60.00001: Recent progress of Majorana zero mode in iron-based superconductors

[Invited] HONG DING (Presenter), Chinese Academy of Sciences — In this talk I will report our recent progress of Majorana zero mode in iron-based superconductors. Following our original findings of superconducting topological surface state [1] and Majorana zero mode (MZM) [2] of Fe(Te, Se), we have recently observed a half-integer level shift of vortex bound states [3] and quantized Majorana conductance [4] in this material, which are hallmarks of MZMs. In addition, we have also found that most of iron-based superconductors [5], including monolayer Fe(Te, Se)/STO [6], have similar topological electronic structures. One of them, CaKFe$_4$As$_4$, an Fe-As bilayer superconductor (Tc ~ 35K), is found to possess MZM and other bound states that can be well reproduced by a simple theoretical model [7]. Our observations offer a new, robust platform for realizing and manipulating MZMs, which may be used for quantum computing at a relatively high temperature.

3:06PM P60.00002: Superconducting and topological properties of CoX (X = As, Sb and Bi)*
JIAQING GAO, SHUNHONG ZHANG, WENJUN DING (Presenter), PING CUI, ZHENYU ZHANG, ICQD, University of Science and Technology of China — Recent studies have revealed high transition temperature ($T_c$) topological superconductivity in FeSe-based superconductors in either monolayer or bulk form. Here we use first-principles approaches to demonstrate that the systems of CoX (X = As, Sb, and Bi) are not only isovalent to FeSe, but also adopt the same layered structure, thereby may serve as new promising platforms to realize high-$T_c$ superconductivity. Our detailed band structure analyses further show that these systems are topologically nontrivial, and can be exploited for materialization of topological superconductivity. Moreover, all these layered CoX structures can be stabilized on SrTiO$_3$(001), which not only could enhance $T_c$, but also preserve the topological nature. These findings characterize CoX as appealing new systems to achieve high-$T_c$ superconductivity and topological properties.

3:18PM P60.00003: Effect of Zeeman coupling on the Majorana vortex modes in iron-based topological superconductors
POUYAN GHAEMI (Presenter), The City College of New York, AREG GHAZARYAN, Physics, Institute of Science and Technology Austria, PEDRO LOPES, Physics, University of British Columbia, PAVAN HOSUR, Physics, University of Houston, MATTHEW GILBERT, Electrical and Computer Engineering, University of Illinois at Urbana-Champaign — In the superconducting regime of FeTe(1−$x$)Sex, two types of vortices which are distinct by the presence or absence of zero energy states in their core are observed. To understand their origin, we examine the interplay of Zeeman coupling and superconducting pairings in three-dimensional metals with band inversion. Zeeman fields are found to suppress the intra-orbital spin-singlet pairing, known to localize the states at the ends of the vortices on the surface. On the other hand, an orbital-triplet pairing is shown to be stable against Zeeman interactions, leads to delocalized zero-energy Majorana modes. In contrast, the finite-energy vortex modes remain localized at the vortex ends for both types of pairings. Phenomenologically, this manifests as an observed disappearance of zero-bias peaks within the cores of topological vortices upon increase of the applied magnetic field. The presence of magnetic impurities in FeTe(1−$x$)Sex, which are attracted to the vortices, would lead to such Zeeman-induced delocalization of Majorana modes in a fraction of vortices that capture a large enough number of magnetic impurities. Our results provide an explanation to the dichotomy between topological and non-topological vortices recently observed in FeTe(1−$x$)Sex.
**3:30PM P60.00004: Exploring Higher-Order Topological Physics in FeTe\textsubscript{0.55}Se\textsubscript{0.45}**

MASON GRAY (Presenter), MEAGHAN DOYLE, JAZZMIN R VICTORIN, NARENDRA KUMAR, Boston College, RUIDAN ZHONG, Brookhaven National Laboratory, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, University of Tsukuba, GENDA GU, Brookhaven National Laboratory, KENNETH BURCH, Boston College — Higher order topological superconductors (HOTSC) are a new class of topological materials in which the “bulk-boundary correspondence” is generalized to higher dimensions. FeTe\textsubscript{0.55}Se\textsubscript{0.45} is an ideal candidate to search for and manipulate such higher-order topological modes due to its intrinsic non-trivial topology and anisotropic superconductivity. In this work, we expand upon recent experimental studies which provide evidence for higher-order modes in FeTe\textsubscript{0.55}Se\textsubscript{0.45}. Furthermore, we explore predictions for HOTSC in this recently emerging platform by studying the response of FeTe\textsubscript{0.55}Se\textsubscript{0.45} to various angles of applied magnetic field.

*National Science Foundation Award No. DMR-1709987

**3:42PM P60.00005: Topological Crystalline Superconductivity in Dirac Semimetal Phase of Iron-based Superconductors**

TAKUTO KAWAKAMI (Presenter), Osaka Univ, MASATOSHI SATO, Kyoto Univ — Recently, topological states of iron-based superconductors have attracted much attention. In Fe(Se, Te) and LiFeAs, triple band inversions occur between a $p_z$ orbital and three $d$ orbitals [1,2]. ARPES experiments showed that one of the inversions near the Fermi level forms topological insulating gap [1]. Furthermore, another inversion at higher energy causes a band touch with linear dispersion [2]. Therefore, these systems with carrier doping can be Dirac semimetal.

Motivated by these experiments, we theoretically investigated unconventional superconductivity of this Dirac semimetal in iron-based superconductors [3]. We found that the Cooper pair between the electrons with d- and p-orbitals in this system yields odd-parity superconductivity. In the presentation we will discuss its topological property and typical surface states, such as Majorana flat band, Majorana quartet, and Möbius twisted surface states.

Observation of conductance plateau of Majorana zero modes in Fe(Te,Se)

LINGYUAN KONG (Presenter), SHIYU ZHU, LU CAO, HUI CHEN, Institute of Physics, Chinese Academy of Sciences, MICHAL PAPAJ, Massachusetts Institute of Technology, SHIXUAN DU, YUQING XING, WENYAO LIU, DONGFEI WANG, CHENGMIN SHEN, FAZHI YANG, Institute of Physics, Chinese Academy of Sciences, JOHN SCHNEELOCH, RUIDAN ZHONG, GENDA GU, Brookhaven National Laboratory, LIANG FU, Massachusetts Institute of Technology, YUYANG ZHANG, HONG DING, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences —

Recently, iron-based superconductor turns to be a promising platform for studying Majorana quasiparticles. The sharp and isolated zero-bias conductance peaks (ZBCPs) were observed clearly by high-resolution scanning tunneling microscopy. The wavefunction behavior of the ZBCPs and the global behavior of vortex bound states series were well studied. It implies that the observed ZBCPs are most probably Majorana zero modes (MZMs), and its topological nature renders the global $\pi$-phase shift of vortex bounds states.

There is another long-sought-after fingerprint for MZMs, i.e. $2e^2/h$-quantized Majorana conductance induced by resonant Andreev reflection. That resonance nature is ensured by the particle-hole equivalence of MZMs and introduces a plateau feature of zero-bias conductance at zero temperature. Due to the large energy level spacing in the vortex core, the iron-based superconductor turns to be a good platform to check that expectation. Here, I will report our recent tunnel-couple tunable STM measurement on a topological vortex of Fe(Te,Se). We find that the conductance of ZBCP has plateau behavior with its value close to or even reach $2e^2/h$, while other finite energy vortex bound states do not have such exotic behavior.

FeTe$_{1-x}$Se$_x$: Magnetism, electronic coherence, superconductivity, and surface state

YANGMU LI (Presenter), NADER ZAKI, Brookhaven National Laboratory, DAVID MICHAEL FOBES, Los Alamos National Laboratory, ZHIJUN XU, National Institute of Standards and Technology, GENDA GU, RONGWEI HU, CEDOMIR PETROVIC, Brookhaven National Laboratory, ANDREI T SAVICI, VASILE O GARLEA, Oak Ridge National Laboratory, PETER JOHNSON, JOHN TRANQUADA, IGOR ZALIZNYAK, Brookhaven National Laboratory — Local inhomogeneity has a great impact on the electronic band structure and magnetic properties of correlated quantum materials. We apply neutron spectroscopy, together with spatially-resolved chemical and electrical analysis, to a topological superconductor candidate, FeTe$_{1-x}$Se$_x$. Combining with photoemission spectroscopy, we obtain detailed physical and chemical information, which points to an underlying connection among magnetism, electronic coherence, superconductivity, and the topological surface state.

4:18PM P60.00008: High-T\textsubscript{c} Superconductor Fe(Se,Te) Monolayer: an Intrinsic, Scalable and Electrically-tunable Majorana Platform*  
XIANXIN WU (Presenter), Physics department, Pennsylvania State University, XIN LIU, Physics department, Huazhong University of Science and Technology, RONNY THOMALE, Physics department, University of Wuerzburg, CHAOXING LIU, Physics department, Pennsylvania State University — A monolayer of the high-T\textsubscript{c} superconductor FeTe\textsubscript{1-x}Se\textsubscript{x} has been predicted to realize a topologically non-trivial state with helical edge modes at its boundary, providing a novel intrinsic system to search for topological superconductivity and Majorana zero modes. Evidence in favor of a topological phase transition and helical edge modes has been given in recent experiments. We propose to create Majorana zero modes by applying an in-plane magnetic field to the FeTe\textsubscript{1-x}Se\textsubscript{x} monolayer and by tuning the local chemical potential via electric gating. We demonstrate that, for appropriate parameter regimes, Majorana zero modes can exist at several different locations, including the corner between two perpendicular edges, the domain wall of chemical potentials at one edge, and certain type of tri-junction in the 2D bulk. The scalability and electrical tunability of our proposal render FeTe\textsubscript{1-x}Se\textsubscript{x} monolayer a promising Majorana platform which is in reach of contemporary experimental capability.

*The Office of Naval Research (Grant No. N00014-18-1-2793), DOE grant (DE-SC0019064) and Kaufman New Initiative research grant of the Pittsburgh Foundation. The work in Wuerzburg is supported DFG-SFB 1170 and by the Wuerzburg-Dresden Cluster of Excellence on Complexity and Topology in Quantum Matter.

4:30PM P60.00009: Zero-Energy Modes on Superconducting Bismuth Islands Deposited on Fe(Te,Se)*  
HAI-HU WEN (Presenter), Physics Department, Nanjing University — Topological superconductivity is one of the frontier research directions in condensed matter physics. One of the unique elementary excitations in topological superconducting state is the Majorana fermion (mode) which is its own antiparticle and obeys the non-Abelian statistics, and thus useful for constructing the fault-tolerant quantum computation. The evidence for Majorana fermions (mode) in condensed matter state is now quickly accumulated. Here we report the easily achievable zero-energy mode on the tunneling spectra on Bi islands deposited on the Fe(Te,Se) superconducting single crystals. We interpret this result as the consequence of proximity effect induced topological superconductivity on the Bi islands with strong spin-orbit coupling effect. The zero-energy mode is argued to be the signature of the Majorana modes in this size confined system.

*This work was supported by National Key R&D Program of China, Natural Science Foundation of China.
Yu-Shiba-Russinov states around an excess iron in FeSe$_{0.4}$Te$_{0.6}$

TADASHI MACHIDA (Presenter), RIKEN, YUE SUN, Department of Physics and Mathematics, Aoyama Gakuin University, SUNSENG PYON, Department of Applied Physics, The University of Tokyo, SHUN TAKEDA, Laboratory for Materials and Structures, Tokyo Institute of Technology, YUHKO KOHSAKA, TETSUO HANAGURI, RIKEN, TAKAO SASAGAWA, Laboratory for Materials and Structures, Tokyo Institute of Technology, TSUYOSHI TAMEGAI, Department of Applied Physics, The University of Tokyo — Zero-energy bound states have been detected at interstitial excess irons in the iron-based superconductor Fe(Se,Te) by using a scanning tunneling microscope (STM) [1], and its relationship to the Majorana quasiparticles (QP) has been discussed [2]. However, higher energy resolution of the order of ~10 μeV is necessary to make clear the origin of the bound states at the excess irons. Here, we performed high-energy resolution (~20 μeV) tunneling spectroscopy around excess irons, using a dilution-refrigerator STM [3]. We found that most of the excess irons indicate only finite energy peaks. We also found excess irons with the zero energy peak, but it splits into a pair of finite energy peaks with increasing the distance from the excess irons and with changing the set-point conductance. These findings suggest that the bound states at the excess irons are not Majorana QP in origin but associated with the conventional Yu-Shiba-Russinov state.

Field-free platform for Majorana modes in superconductors

SONGTIAN SONIA ZHANG (Presenter), JIAJIN YIN, Princeton University, GUANGYANG DAI, Chinese Academy of Sciences, KUN JIANG, Boston College, TAY-RONG CHANG, National Cheng Kung University, LINGXIAO ZHAO, Chinese Academy of Sciences, HSIN LIN, Academia Sinica, GUOQING CHANG, Princeton University, GENFU CHEN, Chinese Academy of Sciences, RAMAN SANKAR, National Taiwan University, CHANGQING JIN, Chinese Academy of Sciences, ZIQIANG WANG, Boston College, ZAHID HASAN, Princeton University — Superconducting materials exhibiting topological properties are emerging as an exciting platform to realize fundamentally new excitations from topological quantum states of matter. Finding a systematic and controllable path to generate nonabelian Majorana zero energy excitations has been the central task in this research direction. Here, we explore the possibility of a field-free platform by depositing magnetic impurities on the surface of candidate topological superconductors. We use scanning tunnelling microscopy to probe localised states induced at the Fe atoms on the atomic scale at sub Kelvin temperatures and find that each Fe adatom generates a striking zero-energy bound state inside the superconducting gap. Our findings point to magnetic adatoms evaporated on bulk superconductors with topological surface states as a new platform for exploring Majorana zero modes under field-free conditions.

**P60.00012: Topological superconducting and Majorana zero mode in a new Fe-As bilayer superconductor**  WENYAO LIU (Presenter), Chinese Academy of Sciences — By combining the topological band structure and superconductivity, Fe-based superconductor Fe(Te,Se) is found to host a Majorana Zero Mode (MZM) inside its vortex core. However, the strong intrinsic inhomogeneity induced by the difference between Te and Se atom constraints further researching and practical application of MZM in this material. Recently, we found a Fe-As bilayer superconductor (Tc~35 K), CaKFe$_4$As$_4$, which could host the topological nontrivial surface state and homogeneous bulk meanwhile. Here I will introduce our observation in CaKFe$_4$As$_4$. Our ARPES and STM results mention that MZM and other bound states are derived from the topological surface state, which can be well reproduced by a simple theoretical model for topological superconducting, thus CaKFe$_4$As$_4$ is promising to be a new and more practical Majorana platform.

**2:30PM P61.00001: Valence bond glass state in the 4d$^1$ Mo$^{5+}$ fcc antiferromagnet Ba$_2$LuMoO$_6$**  OTTO MUSTONEN (Presenter), HEATHER MUTCHE, Materials Science and Engineering, University of Sheffield, PETER BAKER, HELEN WALKER, ISIS Pulsed Neutron and Muon Source, CHARLOTTE PUBH, Materials Science and Engineering, University of Sheffield, FIONA COOMER, Johnson Matthey Battery Materials, CHENG LIU, SIAN E DUTTON, Cavendish Laboratory, University of Cambridge, EDMUND J CUSSEN, Materials Science and Engineering, University of Sheffield — Ba$_2$LuMoO$_6$ is a 4d$^1$ Mo$^{5+}$ fcc antiferromagnet in the double perovskite structure. Here we show that it is a valence bond glass; similar to the well known isostructural Ba$_2$YMoO$_6$ compound. Muon spin rotation and relaxation measurements on Ba$_2$LuMoO$_6$ revealed the lack of magnetic order or spin freezing down to 60 mK, in contrast to Ba$_2$YMoO$_6$ where spin freezing occurs at 1 K. Inelastic neutron scattering measurements revealed a singlet-triplet gap of 28 meV similar to Ba$_2$YMoO$_6$. These results are interpreted as the formation of a valence bond glass, where spin singlets form in a disorganized manner. Some orphan spin do not form singlets and remain paramagnetic even at 60 mK.

**2:42PM P61.00002: Tuning electron correlation strength by charge doping of 5d\(^1\) double perovskites**

ERICK GARCIA (Presenter), Brown University, PAOLA CATERINA FORINO, University of Bologna, RONG CONG, CHARLES SNIDER, Brown University, PHUONG TRAN, PATRICK WOODWARD, The Ohio State University, VESNA F MITROVIC, Brown University, SAMUELE SANNA, University of Bologna — Competing interactions between spin-orbit coupling (SOC) and strong electron correlations have recently led to widespread studies of various emergent novel quantum phases. Double perovskites, particularly those containing 5d transition metal ions, present a useful opportunity to study such interactions since they display comparable magnitudes of electron correlations, crystal field, and SOC. Here, we present a systematic study of the electron doped powder Mott insulator Ba\(_2\)Na\(_{1-x}\)Ca\(_x\)OsO\(_6\) through the Na/Ca partial substitution using \(^{23}\)Na nuclear magnetic resonance at various doping concentrations. These results complement our previous muon spin relaxation (μSR) and superconducting quantum interference device (SQUID) measurements. Ba\(_2\)Na\(_{1-x}\)Ca\(_x\)OsO\(_6\) displays a crossover from an exotic canted ferromagnetic state driven by multipolar ordering at \(x = 0\) to an antiferromagnetic state at \(x = 1\). Moreover, the magnetic transition increases monotonically from 5 K to 40 K with increasing Ca concentration. The experimental results will be compared to theoretical work and their implications will be discussed.

*This work was supported by NSF grant DMR-1608760 and DMR-1905532.

**2:54PM P61.00003: NMR study on single crystal Ba\(_2\)LiOsO\(_6\)**

CHARLES SNIDER (Presenter), RONG CONG, ERICK GARCIA, Brown University, SAMUELE SANNA, University of Bologna, SANATH RAMAKRISHNA, Florida State University, ARNEIL P REYES, National High Magnetic Field Laboratory, JIAQIANG YAN, Oak Ridge National Lab, VESNA F MITROVIC, Brown University — Nuclear magnetic resonance (NMR) measurements on single crystals of Ba\(_2\)LiOsO\(_6\) were carried out to test the universality of theoretical models based on anisotropic exchange interactions \[^1\]. The results are compared with NMR findings on its isostructural and isovalent compound Ba\(_2\)NaOsO\(_6\). Ba\(_2\)LiOsO\(_6\) displays significant line broadening at low temperature, but no well-defined line splitting like its Na counterpart \[^2\]. In addition, the spin-lattice relaxation and linewidth of its spectrum undergoes an abrupt change at 6 T. The implications of these findings will be discussed.

*We acknowledge funding from NSF grant DMR-1608760 and DMR-1905532.
On the charge transfer energy in iridates: a hard x-ray photoelectron spectroscopy study

DAISUKE TAKEGAMI (Presenter), DEEPA KASINATHAN, KLAUS WOLFF, SIMONE G ALTENDORF, CHUN-FU CHANG, KATHARINA HOFER, ANNA MELÉNDEZ-SANS, YUKI UTSUMI, Max Planck Institute for Chemical Physics of Solids, FEDERICO MENEGHIN, Politecnico di Milano, THAI DUY HA, Department of Electrophysics, National Chiao Tung University, CHIEN-HAN YEN, Department of Physics, National Tsing Hua University, KAI CHEN, Institute of Physics II, University of Cologne, CHANG-YANG KUO, Y. F. LIAO, KU-DING TSUEI, National Synchrotron Radiation Research Center, RYAN MORROW, SABINE WURMEHL, Leibniz Institute for Solid State and Materials Research IFW Dresden, B.E. PRASAD, Max Planck Institute for Chemical Physics of Solids, MARTIN JANSEN, Max Planck Institute for Solid State Research, ALEXANDER KOMAREK, PHILIPP HANSMANN, LIU HAO TJENG, Max Planck Institute for Chemical Physics of Solids — We have investigated the electronic structure of iridates in the double perovskite crystal structure containing either Ir$^{4+}$ or Ir$^{5+}$ using hard x-ray photoelectron spectroscopy (HAXPES). The experimental valence band spectra can be well reproduced using tight binding calculations including only the Ir 5$d$, O 2$p$ and O 2$s$ orbitals with parameters based on the down-folding of the density-functional band structure results. We found that regardless the A and B cations, the A$_2$BIrO$_6$ iridates have essentially zero O 2$p$ to Ir 5$d$ charge transfer energies. They are extremely covalent systems with the consequence is that the magnetic exchange interactions become very long-ranged, thereby hampering the materialization of the Kitaev model. Nevertheless, it still would be possible to realize a spin-liquid system using the iridates with a proper tuning of the various competing exchange interactions.

We acknowledge supported by the Deutsche Forschungsgemeinschaft through SFB 1143 (project-id 247310070) and Grant No. 320571839.

Monte Carlo simulation of a strong SOC model for d$^1$ double perovskite

RONG CONG (Presenter), JOHN BRADLEY MARSTON, VESNA F MITROVIC, Brown University — Recent NMR experiments have revealed exotic quantum phases in the magnetic Mott insulator with strong spin orbit coupling (SOC) Ba$_2$NaOsO$_6$[1]. To investigate the possible spin and orbital order patterns consistent with the NMR observations, we performed Monte Carlo simulations of a microscopic model for d$^1$ double perovskites magnetic Mott insulators with multipolar spin interactions[2] . We obtained the low temperature phase diagram involving both spin and orbital degrees of freedom by magnetic annealing. We found that the zero temperature phase diagram consists of a fluctuating xyAFM, a canted FM[100] and a magnetic quadrupolar state each with distinct corresponding orbital ordering pattern. Furthermore, the xyAFM and the quadrupolar state are also found at intermediate temperatures as a result of enhanced thermal fluctuations. We demonstrate that the ground state evolves from the canted FM[100] state to the quadrupolar state as electric quadrupole-quadrupole interaction increases.

We acknowledge funding from NSF grant DMR-1608760, DMR-1905532 and NSF grant No. ACI-1548562.
3:30PM P61.00006: Ground state in the novel dimer iridate $\text{Ba}_{13}\text{Ir}_6\text{O}_{30}$ with Ir$^{6+}(5d^3)$ Ions*

HENGDI ZHAO (Presenter), University of Colorado, Boulder, FENG YE, Neutron Scattering Division, Oak Ridge National Laboratory, HAO ZHENG, BING HU, YIFEI NI, YU ZHANG, ITAMAR KIMCHI, GANG CAO, University of Colorado, Boulder — We have synthesized and studied a new iridate, $\text{Ba}_{13}\text{Ir}_6\text{O}_{30}$, with unusual Ir oxidation states: 2/3 Ir$^{6+}(5d^3)$ ions and 1/3 Ir$^{5+}(5d^4)$ ions. Its crystal structure features dimers of face-sharing IrO$_6$ octahedra, and IrO$_5$ monomers, that are linked via long, zigzag Ir-O-Ba-O-Ir pathways. Nevertheless, $\text{Ba}_{13}\text{Ir}_6\text{O}_{30}$ exhibits two transitions at $T_{N1} = 4.7$ K and $T_{N2} = 1.6$ K. This magnetic order is accompanied by a huge Sommerfeld coefficient 200 mJ/mole K below $T_{N2}$, signaling a coexisting frustrated/disordered state persisting down to at least 0.05 K. This iridate hosts unusually large $J_{\text{eff}}=3/2$ degrees of freedom, which is enabled by strong spin-orbit interactions (SOI) in the monomers with Ir$^{6+}$ ions and a joint effect of molecular orbitals and SOI in the dimers occupied by Ir$^{5+}$ and Ir$^{6+}$ ions. Features displayed by the magnetization and heat capacity suggest that the combination of covalency, SOI and large effective spins leads to highly frustrated ferrimagnetic ordering, a novelty of this new high-spin iridate.

*This work was supported by the National Science Foundation via grant DMR-1712101 and No. DMR-1903888.
3:42PM P61.00007: Spin-orbital-entangled quantum magnet on a honeycomb lattice [Invited]
TOMOHIRO TAKAYAMA (Presenter), Max Planck Inst — In heavy transition-metal compounds containing 4d or 5d elements, strong spin-orbit coupling often yields spin-orbital-entangled $J_{\text{eff}}$-states for $d$-electrons. The magnetic interactions between such states may give rise to an exotic ground state due to their bond-sensitive character. In particular, quantum liquid state of spin-orbital-entangled objects have been expected to emerge in a simple honeycomb lattice.

Honeycomb-based iridates with $J_{\text{eff}} = 1/2$ pseudospins have been intensively investigated as a potential realization of Kitaev spin liquid. Although the honeycomb iridates such as Na$_2$IrO$_3$ and α-Li$_2$IrO$_3$ are shown to undergo magnetic ordering likely due to the additional magnetic interactions other than Kitaev-type exchange, a quantum liquid state has been identified in the hydrogen-exchanged material H$_3$LiIr$_2$O$_6$. No magnetic order or spin-glass freezing is not seen in H$_3$LiIr$_2$O$_6$ down to 50 mK. However, clear evidence for Kitaev-type spin liquid is lacking so far, and the prime driving force for the liquid state remains elusive. In order to investigate the critical role of hydrogen, we synthesized an isotopic material D$_3$LiIr$_2$O$_6$. D$_3$LiIr$_2$O$_6$ displays a large isotope effect in structural and magnetic properties; the antiferromagnetic Weiss temperature increases from 100 K for H$_3$LiIr$_2$O$_6$ to 170 K for D$_3$LiIr$_2$O$_6$. Nevertheless, the quantum liquid state was found to be robust. We argue that the disordered OH/OD bonds likely play a role to stabilize the quantum liquid state.

Another exotic honeycomb magnet is expected for systems with $d^4$ configuration. In the case, the spin-orbit coupling produces nonmagnetic $J_{\text{eff}} = 0$ singlet ground state. However, the $d^4$ ions magnetically interact with each other via the excited $J_{\text{eff}} = 1$ levels, and such magnetic interactions are also shown to inherit bond-dependent character. We argue that a honeycomb ruthenate Ag$_3$LiRu$_2$O$_6$ has the spin-orbit induced singlet ground state and discuss the possible pressure-induced electronic phase transitions.

4:18PM P61.00008: Jahn-Teller effect and spin-orbit coupling in $t_{2g}$ systems* SERGEY STRELTSOV (Presenter), Institute of Metal Physics, DANIEL KHOMSKII, Univeristy of Cologne — In this talk we will discuss a very general problem of interplay between the Jahn-Teller (JT) effect and the spin-orbit coupling (SOC). It will be shown that the result of competition strongly depends on the specific situation: for some cases, such as $d^4$ and $d^5$, but also $d^2$ configurations, strong SOC may sometimes reverse, but finally completely suppresses JT distortion, whereas in other cases, notably $d^3$, SOC generates JT effect in the configuration which is usually considered as “orbitally dead”.

**4:30PM P61.00009: Thermodynamics of Spin-Orbital Coupled Magnets: The Case of Dimers and Timers**  STEPHEN WINTER (Presenter), YING LI, ROSER VALENTI, Institute for Theoretical Physics, Goethe University Frankfurt — Recently, there has been great interest in 4d and 5d magnetic insulators with strong spin-orbit coupling (SOC) - which have shown the potential to realise low-energy spin Hamiltonians featuring a variety of complex anisotropic couplings of fundamental interest. In this contribution, we focus on the theoretical description of recently reported spin-liquid candidate materials based on mixed valence $M_2O_9$ dimers [1] and $M_3O_{12}$ trimers [2,3]. The challenge of modelling these materials lies in their complex local electronic structures, which should manifest in e.g. complex spin-orbital ground states, instabilities towards charge order, and strong structural sensitivity of the magnetic response. We focus, in particular, on experimental signatures and consequences of various possible ground states as a function of SOC strength and electronic filling. Of particular experimental importance is the inapplicability of Curie-Weiss analysis due to the non-commutability of SOC with magnetic fields.

**4:42PM P61.00010: Effect of disorder in Kitaev materials** [Invited]  NATALIA PERKINS (Presenter), University of Minnesota, JOHANNES KNOLLE, Physics, Technical University of Munich, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, WEN-HAN KAO, University of Minnesota — Recent years have seen remarkable progress in identifying candidate materials that can realize Kitaev quantum spin liquid [1]. In particular, a significant experimental and theoretical effort has been devoted to the study of magnetic properties of 4d and 5d systems, such as iridates and ruthenates, in which the interplay of strong spin-orbit coupling and electronic correlations gives rise to highly anisotropic and spatially dependent Ising-like interactions between effective moments $J=1/2$. Many of these materials show the presence of various forms of disorder, such as site disorder (magnetic or non-magnetic impurities), bond disorder and layer stacking faults. This is why these systems offer a remarkable playground for new phenomena that can be realized as a cooperative manifestation of disordered topological condensed matter systems. Recently we argued [2] that a minimal model of a bond disordered Kitaev quantum spin liquid can account for most of the salient experimental findings in $H_3LiIr_2O_6$ [3]. However, other implications of disorder might be crucial to account for all observations in this material. Here we discuss how include vacancies in this consideration and consider combined effect of bond disorder and vacances at finite temperature properties of the Kitaev quantum spin liquid.

Resonant elastic x-ray scattering on the molecular orbital in Li$_2$RuO$_3$

SEOKHWAN YUN (Presenter), Department of Physics and Astronomy, Seoul National University, BEOM HYUN KIM, Korea Institute for Advanced Study, KI HOON LEE, Department of Physics and Astronomy, Seoul National University, DAN G. PORTER, Diamond Light Source, Harwell Science and Innovation Campus, SERGIO DI MATTEO, Universite de Rennes, SOONMIN KANG, JAEHONG JEONG, Department of Physics and Astronomy, Seoul National University, ALESSANDRO BOMBARDI, Diamond Light Source, Harwell Science and Innovation Campus, JE-GUEN PARK, Department of Physics and Astronomy, Seoul National University — In solid, the $d$-orbital electrons of transition metal (TM) elements are generally described in the atomic orbital limit because an overlap between adjacent orbitals is much smaller than other perturbations like $d$-$p$ hybridization or Coulomb $U$. However, when ionic radii increase with the rise of periodicity or adjacent ions are getting closer like ones in edge-sharing or face-sharing octahedra, the enhanced overlap of orbitals can lead the molecular behavior of orbital clusters.

Li$_2$RuO$_3$ has a layered honeycomb structure composed of edge-sharing RuO$_6$ with strong dimerization. It enhances the orbital overlap so induces the spin-singlet, molecular orbital state. We measured the Bragg-forbidden (010) reflection in Li$_2$RuO$_3$ single crystal using resonant elastic x-ray scattering to identify the spatial distribution of the molecular orbitals. The peak was measured at the $\sigma$-$\pi$ polarization change, but it is not a magnetic reflection as Li$_2$RuO$_3$ has no long-range magnetic order. We observed a distinct phase difference in the polarization dependence between Ru 2$p$-4$d$ ($t_{2g}$) and 2$p$-4$d$ ($e_{g}$) process. It also shows a fine structure from the crystal-field effect only at Ru $L_3$ edge but not at $L_2$ edge. This result elucidates the local shape of the molecular orbital of the Ru dimer.

Session P62 DMP: Electron-Phonon Coupling and Transport in Nanostructures

Mile High Ballroom 4C - Shixiong Zhang, Indiana Univ - Bloomington - Tag(s): Focus
It has been known for some time that a perfect (delta-function) energy filter allows, in principle, thermal-to-electric energy conversion near ideal (Carnot) efficiency. [1,2] I will introduce this concept and report on a recent experiment where we realized a near-ideal quantum-dot heat engine in devices based on single nanowires, realizing power production at maximum power with Curzon-Ahlborn efficiency, and reaching more than 70% of Carnot efficiency at maximum efficiency settings [3]. This proof-of-performance of efficient energy harvesting from electrons is directly relevant to the concept of hot-carrier or thermophotovoltaics, where the aim is to boost energy conversion efficiency by harvesting heat from non-equilibrium electrons [4]. I will present our progress towards implementing this principle in heterostructure nanowires. [4]

3:06PM P62.00002: Cooling and self-oscillation in a nanotube electromechanical resonator
CARLOS URGELL (Presenter), WEI YANG, SERGIO DE BONIS, CHANDAN SAMANTA, ICFO-The Institute of Photonic Sciences, MARIA JOSÉ ESPLANDIU, Catalan Institute of Nanoscience and Nanotechnology, QUAN DONG, YONG JIN, Centre de Nanosciences et de Nanotechnologies, ADRIAN BACHTOLD, ICFO-The Institute of Photonic Sciences — Nanomechanical resonators are used with great success to couple mechanical motion to other degrees of freedom, such as photons, spins and electrons [1,2]. The motion of a mechanical eigenmode can be efficiently cooled into the quantum regime using photons [2,3,4], but not other degrees of freedom. Here, we demonstrate a simple yet powerful method for cooling, amplification and self-oscillation using electrons. This is achieved by applying a constant (d.c.) current of electrons through a suspended nanotube in a dilution refrigerator. We demonstrate cooling to 4.6±2 quanta of vibrations. We also observe self-oscillation, which can lead to prominent instabilities in the electron transport through the nanotube. We attribute the origin of the observed cooling and self-oscillation to an electrothermal effect. This work shows that electrons may become a useful resource for cooling the mechanical vibrations of nanoscale systems into the quantum regime.

3:18PM P62.00003: Theory of hot-carrier generation and relaxation in plasmonic nanoparticles
YU ZHANG (Presenter), Theoretical Division, Los Alamos National Laboratory — Hot-carrier generation from surface plasmon decay has attracted much recent attention due to its promising applications in physical, chemical, materials and energy science. However, the detailed mechanisms of plasmonic hot-carrier generation and relaxation are less studied or treated by the semiclassical model. In this work, we develop and apply a quantum-mechanical model and coupled master equation method to study the generation, relaxation, and extraction of hot-carriers. And the connection with the semiclassical model is discussed. The initial distribution of hot-carriers and lifetimes of hot-carriers induced by different excitation are investigated. The relaxation due to electron-electron and electron-phonon scatterings are treated on the equal footing. Heat generation from hot-carriers decay is also described. We also generalize the model to study the extraction of hot-carriers to attached molecules or semiconductors. The quantum yield of extracting hot-carriers from the plasmonic nanoparticles is found to be size-dependent.

*The work at Los Alamos National Laboratory (LANL) was supported by the LANL Directed Research and Development Funds (LDRD). LANL is operated by Triad National Security, LLC, for the NNSA of the U.S. DOE (Contract No. 89233218NCA000001).
3:30PM P62.00004: Nanoimaging of surface waves in 2D materials  DMITRI VORONINE (Presenter), Univ of South Florida — Propagating surface waves such as surface-plasmon polaritons and exciton-polaritons have recently been of interest in a variety of optical, electronic and quantum communication applications. Nano-optical imaging of surface waves in two-dimensional (2D) transition-metal dichalcogenide (TMD) materials has been realized in several cavity-coupled systems. In this work, new nanoimaging schemes based on tip-enhanced photoluminescence (TEPL) and Kelvin-probe force microscopy (KPFM) are presented, revealing the optical and electric components of surface waves in 2D TMD heterostructures, respectively. These results could be used in novel nanophotonic coupling schemes for quantum emitters in 2D materials.

3:42PM P62.00005: Coupled electron-phonon thermal transport across metal-nonmetal interfaces and superlattices  CHENG SHAO (Presenter), JUNICHIRO SHIOMI, Univ of Tokyo — Understanding the thermal transport across metal/nonmetal interface is of great importance for applications like electronic and thermoelectric devices. In nonmetal phonons are the dominant heat carriers; while in metal both electrons and phonons conduct heat. The nonequilibrium carrier populations and the complicated coupling channels at the interfaces make our current understanding yet to be completed. In this work, we utilize the fully coupled Monte Carlo simulations to study thermal transport across the metal-nonmetal interfaces and superlattice. The mode-wise electron and phonon relaxation times and their coupling strengths are obtained from first-principles calculations, while the phonon transmissions at interfaces are obtained from the Green's function methods. The simulation results show that the thermal transport at metal/nonmetal interface can be enhanced by inserting an intermediate metal layer with high electron-phonon coupling strength. For metal-nonmetal superlattice structure, thin metal layers with weak electron-phonon coupling can largely impede the thermal transport. The simulation results reveal the importance of mode-wise scattering channel and the nonequilibrium between electron, acoustic phonon, and optical phonon at the interface to thermal transport.
Modification of Electron-Phonon Coupling by Micromachining and Suspension*  
OLLI SAIRA (Presenter), Brookhaven National Laboratory, MATTHEW MATHENY, California Institute of Technology, LIBIN WANG, JUKKA P PEKOLA, Aalto University, MICHAEL ROUKES, California Institute of Technology — Weak electron-phonon interaction in metals at low temperatures forms the basis of operation for cryogenic hot-electron detectors. Standard power laws, describing the heat flow in the majority of experiments, have been identified and derived theoretically. However, a full picture encompassing experimentally relevant effects such as reduced dimensionality, material interfaces, and disorder is in its infancy, and has not been tested extensively.

Here [1], we study the electron-phonon heat flow in a thin gold film on a suspended SiO$_2$ platform at temperatures below 100 mK using supercurrent thermometry. We observe a half-integer power law that has been recently predicted by theory [2], defying conventional results for bulk (semi-infinite) systems. The novel thermometry method we employ addresses some of the shortcomings of conventional nanoscale thermal measurement schemes. Similar behavior has been reported in earlier work [3].

*We acknowledge support from the U.S. Army Research Laboratory and the U.S. Army Research Office (contracts W911NF-13-1-0390 and W911NF-18-1-0028) and Academy of Finland (contract 312057).
4:06PM P62.00007: Influence of Highly Non-Equilibrium Electron-Phonon Transport on Heat Conduction across Metal-Insulator Superlattice  Kyoungjung Kim (Presenter), Mechanical Engineering, Univ of Tokyo, Yosuke Kurosaki, Naoto Fukatani, Shin Yabuuchi, Research & Development Group, Hitachi Ltd., Yosuke Ira, Cheng Shao, Mechanical Engineering, Univ of Tokyo, Jun Hayakawa, Research & Development Group, Hitachi Ltd., Junichiro Shiomi, Mechanical Engineering, Univ of Tokyo — Nanostructuring is often utilized to improve figure-of-merit of thermoelectric materials by reducing thermal conductivity (TC). There, thermal boundary conductance at nanostructure interfaces is important, and population of heat carriers can be highly non-equilibrium. One strategy to further reduce TC is to utilize metal–semiconductor interfaces, such as in metal-semiconductor superlattice with the electron-phonon scattering mean free path being comparable or longer than the nanostructure length-scale. There, the nonequilibrium interfacial regions are expected to make phonons the dominant heat carrier even in the metal part, which should contribute to the reduction of TC. In this study, we take metal-insulator(MgO) superlattice as a model case and measure the TC by the time-domain thermoreflectance method. We prepare two kinds of samples with different metal layers (AuSi or Ta) with relative difference in the electron-phonon coupling strength. As a result, for both kinds of samples, TC of superlattice was reduced as the unit-layer of the superlattice was made thinner. While the reduction of TC is expected due to the increase in the number of interfaces, the different trends of reduction between AuSi and Ta samples suggest roles of non-equilibrium phonon-electron transport.

4:18PM P62.00008: Ultrafast investigation of electronic and vibrational dynamics of via pump-degenerate four-wave mixing  Joseph Avenoso (Presenter), Univ of Delaware, Daniela Zahn, Ralph Ernstorfer, Fritz Haber Institute, Lars Gundlach, Univ of Delaware — Phonon dynamics and their coupling to electronic excitations in bulk tungsten disulfide is investigated. Pump-degenerate four-wave mixing is used to measure the femtosecond dynamics of the phonons, which when combined with transient absorption spectroscopy, provides an energy-resolved picture of phonon dynamics and their lifetimes. Measurements suggest the LA(M) phonon mitigates electron scattering from the K point to the Σ valley in under 100 fs. Pump-degenerate four-wave mixing is hereby shown to be an effective tool to compliment momentum-resolved methods for studying coupling in tungsten disulfide and other transition metal dichalcogenides.
4:30PM P62.00009: Acoustoelectric charge transport at the LaAlO$_3$/SrTiO$_3$ interface by surface acoustic waves*  YIGITCAN UZUN (Presenter), SANDER SMINK, M. P. DE JONG, HANS HILGENKAMP, WILFRED G. VAN DER WIEL, Univ of Twente — Surface acoustic waves (SAWs) are capable of transporting free charge carriers along their propagation path, resulting in an acoustoelectric current or voltage. This has been explored intensively in AlGaAs/GaAs heterostructures. Here, we integrate SAWs with the LaAlO$_3$/SrTiO$_3$ 2-dimensional electron system, which is known to exhibit high mobility at low temperature, magnetism and superconductivity under the appropriate conditions. Despite the non-piezoelectric nature of SrTiO$_3$ (and LAO) we can make use electrostriction for SAW generation. We measure the acoustoelectric effect both at room temperature and at 150 K, and observe a considerable enhancement at lower temperatures. Our results suggest robust coupling between the SAWs and the interfacial free electrons, which opens the way for applying the same approach in other non-piezoelectric (complex-oxide) systems.

The authors also acknowledge financial support of the Netherlands Organisation for Scientific Research (NWO) through a Vrij Programma grant (QUAKE, 680.92.18.04/7566) and the DESCO programme.

4:42PM P62.00010: Hot-carrier induced above-threshold light emission in plasmonic tunnel junctions*  LONGJI CUI, YUNXUAN ZHU (Presenter), MAHDIYEH ABBASI, ARASH AHMADIVAND, BURAK GERISLIOGLU, PETER JAN ARNE NORDLANDER, DOUGLAS NATELSON, Rice Univ — Light emission from electrically driven tunnel junctions, mediated by localized surface plasmons, have attracted much recent interests, showing that the emitted photon energies are limited by the applied voltage bias. Recent works have reported the above-threshold light emission in which the emitted photons have energies significantly above the applied voltage. However, the physical mechanism underlying this phenomenon, is elusive. Here we report systematic measurements of light emission from tunneling junctions made of different plasmonic materials and proposed a hot-carrier induced light emission mechanism. The characteristics and dynamics of the hot carriers is found to be set by the non-radiative plasmonic process. The reported light emission and electrically driven hot carrier generation opens new possibility in plasmonic chemistry and optoelectronic energy conversion applications.

*Robert A. Welch Foundation Grant No. C-1636; J Evans Atwell Welch Postdoctoral Fellowship
4:54PM P62.00011: Ultrafast hot carrier injection in Au/GaN: the role of band bending and the interface band structure* FAN ZHENG (Presenter), LIN-WANG WANG, Lawrence Berkeley National Laboratory — Plasmon photochemistry can potentially play a significant role in photocatalysis. To realize this potential, it is critical to enhance the plasmon excited hot carrier transfer and collection. However, the lack of atomistic understanding of the carrier transfer across the interface, makes it challenging to design more efficient system. In this work, we apply the non-adiabatic molecular dynamics simulation to study hot carrier dynamics in the system of Au nanocluster on top of GaN surface. By setting up the initial excited hole in Au, the carrier transfer from Au to GaN is found to be on a sub-pico second time scale. After the hole has cooled down to the band edge of GaN, we find some of the charges can return back to Au. By applying different external potentials to mimic the Schottky-barrier band bending, the returning charge can be reduced effectively. Finally, with the understanding of the carrier transfer's pathway, we suggest that a ZnO layer between GaN and Au can effectively block the "cold" carrier from returning back to Au but still allow the hot carrier to transfer.

*This work is funded by the Joint Center for Artificial Photosynthesis, supported through DOE under Award number DE-SC0004993. NERSC and Oak Ridge Leadership Computing Facility provide computational support.

5:06PM P62.00012: Tunable plasmonic hot carrier dynamics in noble metal alloys ADELA HABIB (Presenter), RAVISHANKAR SUNDARARAMAN, Rensselaer Polytechnic Institute — Noble metal alloys exhibit promise as a tunable plasmonic material with an 'on-demand optical response' [1]. However, the performance of these metal alloys for plasmonic hot carrier harvesting remains unknown. In particular, disorder in the alloys is expected to lead to increased scattering and inhibit transport of low energy carriers in metal alloys, but the corresponding situation for hot carriers is not yet known. Moreover, hot carrier generation and injection across a metal-semiconductor interface depend sensitively on the band structure [2], and alloys may provide an opportunity to tune the band structure for increasing injection. This talk will present first-principles predictions of hot carrier generation and transport properties of ordered and random structures of gold-silver alloys. The density of states and phase space for both optical excitation and hot carrier scattering depend critically on composition and disorder, providing an additional knob for generating and harvesting hot carriers with desired energy distributions.

Recent developments in nanotechnology enable us to control and observe electron transfer with high accuracy fulfilling needs for quantum metrology. One of its important instances is an electron pump driven by a time periodic bias voltage between source and drain electrodes attached to a microscopic system such as a quantum dot (J. P. Pekola et al., Rev. Mod. Phys. 85, 1421 (2013)). In conventional studies, the electron pump has been mostly formulated in an adiabatic regime, where the time-dependent bias is described by an infinitely slow modulation of electrochemical potentials of electrodes (T. Yuge et al., Phys. Rev. B 86, 235308 (2012)). This formalism is, however, practically useless because the pumped current generated by the infinitely slow modulation is zero in a strict sense. The purpose of the present study is to provide a more realistic formalism describing the pumping under a finite speed continuous modulation of the bias voltage. To this end, we propose an extended formalism of the pumping based on the full counting statistics with quantum master equation taking into account a temporal shift of single-particle energy of electrons in source and drain induced by the voltage modulation.

Session P63 DMP DCOMP FIAP: Defects: Structure and Strain 1 Mile High Ballroom 4D - Kunal Mukherjee, University of California, Santa Barbara - Tag(s): Focus

2:30PM P63.00001: Defects in Chalcogenide Compound Semiconductors for Photovoltaics [Invited] ANGUS ROCKETT (Presenter), Colorado Sch of Mines — This talk briefly reviews recent progress in solar cell energy generation to set the stage. The most promising include the thin film chalcogenide compound based devices. The talk then reviews the characterization and understanding of defects in the two primary materials classes used in solar cells (photovoltaics), CdTe and CuInSe$_2$ and related compounds. The characterization methods discussed include scanning tunneling microscopy, nuclear magnetic resonance, and capacitance methods including scanning microwave impedance microscopy. The implications of the results for device performance are described.
Does lattice expansion really occur in defected low-temperature GaAs?

MARY CLARE ESCANO (Presenter), Research Center for Development of Far-Infrared Region, University of Fukui, Japan, TIEN QUANG NGUYEN, Institute of NanoScience Design, Osaka University, Japan, HIDEAKI KASAI, National Institute of Technology, Akashi College, Japan, MASAHIKO TANI, Research Center for Development of Far-Infrared Region, University of Fukui, Japan — A prominent example of lattice expansion caused by point defects is that of GaAs grown at low temperature (LT-GaAs). A linear correlation between the lattice expansion and concentration of As-antisite ($\text{As}_{\text{Ga}}$) point defect is obtained experimentally by XRD. However, using full first-principles method (DFT-LDA) on a large 512-atom supercell of GaAs bulk, we found that, in the limit of small concentrations of $\text{As}_{\text{Ga}}$ (less than 1%), the lattice does not expand but the As-As bond length near the defect increased. DFT-LDA method is tested vis-a-vis the more sophisticated DFT-hybrid functionals and the former yields the same lattice changes as the latter. We propose that the observed expansion maybe due to the increased bonds near the defect. We also found that $\text{As}_{\text{Ga}}$ point defects do not prefer isolated structure even at low concentration. Using molecular dynamics simulation, we confirm that the above results hold true even at room temperature. Study of electronic properties reveals that, in this low concentration regime, abrupt changes in density of states near the fermi level occur. These findings pose impact in the use of LT-GaAs for optoelectronic/terahertz devices, where fundamental understanding of defect concentration's relation with material structure/functionality is vital.

Off-centered Pb Interstitials in PbTe*

SUNGJIN PARK (Presenter), BYUNGKI RYU, Korea Electrotech Res Inst — The nature of off-stoichiometry of PbTe has not been fully understood yet though many studies existed by investigating its intrinsic defects. We reinvestigated the formation of intrinsic defects of PbTe by DFT study. From this, Te vacancy ($V_{\text{Te}}$) was the major defect under Pb-rich condition. Due to experiments that reported the increase of the lattice parameter as the Pb excess content grew up, a controversy between the DFT and the experimental results existed since the existence of $V_{\text{Te}}$ could not explain the volume increase. So we assumed Pb interstitial ($\text{Pb}_{\text{Int}}$) as the major defect in PbTe instead $V_{\text{Te}}$ because it not only exhibited the second-lowest formation energy, but also could be responsible for the lattice parameter increase. From this, all possible $\text{Pb}_{\text{Int}}$ positions in PbTe were first investigated to understand its off-stoichiometry. As a result, we found new stable positions of $\text{Pb}_{\text{Int}}$ other than the conventional one at the subcubic center. Moreover, among the various locations, $\text{Pb}_{\text{Int}}$ toward the nearest Te and Pb dimer with $\text{Pb}_{\text{Int}}$ were the ground and a metastable state. Finally, we believed that the many local minima of $\text{Pb}_{\text{Int}}$ might be responsible for the off-stoichiometry of PbTe during the sintering of thermoelectric PbTe.

3:30PM P63.00004: Quantifying Cation Disorder in ZnGeP$_2$ Thin Films Using Resonant Energy X-ray Diffraction  
REKHA SCHNEPF (Presenter), Colorado School of Mines, BEN LEVY-WENDT, Stanford University, BROOKS TELLEKAMP, National Renewable Energy Lab, BRENDEN ORTIZ, CELESTE MELAMED, Colorado School of Mines, LAURA SCHELHAS, KEVIN STONE, MICHAEL TONEY, SLAC National Accelerator Laboratory, ERIC TOBERER, Colorado School of Mines, ADELE TAMBOLI, National Renewable Energy Lab — II-IV-V$_2$ materials, ternary analogs to III-V’s, are emerging for their potential applications in devices such as LEDs and solar cells. Controlling cation ordering in II-IV-V$_2$'s offers the potential to tune properties at nearly fixed compositions and lattice parameters. Cation disorder is prevalent in many II-IV-V$_2$'s and has a profound effect on properties – however, quantification of disorder remains difficult. In this work, we investigate two different methods to quantify cation ordering in ZnGeP$_2$ thin films: a stretching parameter calculated from lattice constants ($c/a$), and an order parameter determined from the cation site occupancies ($S$). We use high resolution X-ray diffraction (HRXRD) to determine $c/a$ and resonant energy X-ray diffraction (REXD) to extract $S$. REXD is critical to distinguish elements with similar Z-number (e.g. Zn and Ge) through X-ray diffraction. We found that samples with a $c/a$ corresponding to the ordered chalcopyrite structure had only partially ordered $S$ values. The optical absorption onset for these films occurred at lower energy than expected for fully ordered ZnGeP$_2$, indicating that $S$ better captures disorder in these samples. This work highlights the importance of nuanced techniques (e.g. $S$) when analyzing more complex ternary systems.

3:42PM P63.00005: Phonon Dispersion in Anisotropic Dilute Alloys by Weighted Dynamical-Matrix Approach  
MINA AZIZIHA (Presenter), SAEED AKBARSHAHI, Physics and Astronomy, West Virginia University, SAYANDEEP GHOSH, PRATIVA PRAMANIK, Physics, Indian Institute of Technology, JAMES PATRICK LEWIS, ALDO H ROMERO, Physics and Astronomy, West Virginia University, SURESH PITTALA, Physics, Indian Institute of Science, SUBHASH THOTA, Physics, Indian Institute of Technology, MOHINDAR S SEEHRA, MATTHEW BRUCE JOHNSON, Physics and Astronomy, West Virginia University — The calculation of phonon frequencies in dilute anisotropic alloys is not a simple undertaking and the successful methodologies are not well developed. We propose weighted dynamical-matrix (WDM) approach for calculating optical phonon spectra that is applicable to such complex alloys for a large range of alloying elements. Our WDM approach forms the dynamical-matrix for random alloys using the weighted average of parent structures mass and calculated force constants that allows us to calculate the phonon spectra. This WDM approach is computationally efficient and easily implemented. We demonstrate its use for the effect of Fe-doping on the phonon modes in dilute alloy of CuAl$_{1-x}$Fe$_x$O$_2$ delafossite powders whose structural and magnetic properties have been reported previously$^{1,2}$ and the phonon frequencies are measured using Raman and FTIR spectroscopies. The observed phonon modes are in good agreement with our WDM approach calculations. These results are consistent with the lattice expansion accompanying the Fe-doping, weakening the bonds. Also, Fe-doping effect on optical properties of these alloys is explored and explained by the first-principle calculated band structures.

Simulations of Nitrogen Incorporation into GaAsN Alloys: The Role of Lattice Relaxation*

EMILY OLIPHANT (Presenter), Physics, University of Michigan and Idaho State University, RACHEL GOLDMAN, Physics and Materials Science and Engineering, University of Michigan, LIANG QI, TIMOTHY JEN, ALBERT TSUI, Materials Science and Engineering, University of Michigan, DRIMIK CHOWDHURY, Mathematics, University of Michigan, YONGQIANG WANG, Materials Science and Technology Division, Los Alamos National Laboratory — Due to the significant band gap narrowing induced by dilute fractions of N in III-V semiconductors, dilute nitride semiconductor alloys are of significant interest for long-wavelength optoelectronics. However, rapid thermal annealing (RTA) is often needed to achieve suitable transport properties and emission efficiencies. Therefore, identification of the local N environments and the influence of RTA on those environments is needed. For GaAsN, it has been suggested that N shares an As site with either As or N, with N-As and N-N pairs (split interstitials) aligned along [010] and [111] directions, respectively. However, the effect of lattice relaxation in the vicinity of incorporated N has not been considered. Here, we utilize density functional theory to compute minimum energy positions of NAs and surrounding neighbors. To identify N incorporation sites, we compare nuclear reaction analysis (NRA) spectra with Monte Carlo-Molecular Dynamics simulations along the [100], [110], and [111] directions. The measured NRA spectra exhibit the highest (lowest) yields in the [111](100) directions. Similar trends are observed for simulations of (N-As)As, confirming the presence of interstitial complexes, predominantly (N-As)As, in GaAsN.

Diffusion of Acceptor Dopants in Atomically Precise Devices*

JEFFREY IVIE (Presenter), EVAN ANDERSON, SCOTT W SCHMUCKER, LISA A TRACY, DEANNA CAMPBELL, DAVID SCRYMGEOUR, AARON KATZENMEYER, JUAN P MENDEZ, PING LU, XUJIAO GAO, DAN R. WARD, EZRA BUSSMANN, TZU-MING LU, SHASHANK MISRA, Sandia National Laboratories — Atomically precise (AP) electrical devices, fabricated using hydrogen depassivation lithography in a scanning tunneling microscope, offer a potential pathway to ultra-efficient transistors. Almost all previous work regarding AP devices has been focused on understanding the properties of phosphorus-based donor devices integrated into intrinsic or donor-implanted substrates. Equivalent knowledge for integration on to substrates having acceptor dopants is critically lacking. Here, we present our work in understanding the diffusion processes of acceptor dopants during CMOS compatible AP processing, which demonstrates highly counterintuitive behavior compared to donor dopants. We speculate on the origin of this diffusion mechanism, which is neither thermally-driven nor concentration gradient-driven.

*This work was supported by the Laboratory Directed Research and Development Program at Sandia National Laboratories and was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. SNL is managed and operated by NTESS under DOE NNSA contract DE-NA0003525. The views expressed in the article do not necessarily represent the views of the DOE or the U.S. Government.
**4:18PM P63.00008: p-Type Doping of Pyrite FeS$_2$**  
BRYAN VOIGT (Presenter), WILLIAM MOORE, Chemical Engineering & Materials Science, University of Minnesota, DEBMALYA RAY, Chemistry, University of Minnesota, MICHAEL MANNO, Chemical Engineering & Materials Science, University of Minnesota, JEFF D JEREMIASON, Chemistry, Gustavus Adolphus College, LAURA GAGLIARDI, Chemistry, University of Minnesota, ERAY AYDIL, CHRIS LEIGHTON, Chemical Engineering & Materials Science, University of Minnesota — Pyrite FeS$_2$ is a potentially ideal absorber for thin film solar cells as it is composed of earth-abundant, inexpensive elements, has a suitable band gap (0.95 eV), and is strongly absorptive. Lack of doping control, however, has precluded $p$-$n$ homojunctions. Heterojunction solar cells have disappointing efficiencies (≤3 %), likely limited by a leaky surface inversion layer. The ability to controllably $n$- and $p$-dope FeS$_2$ would make possible a homojunction solar cell that could, uniquely, avoid this surface inversion entirely. Recently, we established S vacancies as $n$-dopants in FeS$_2$ and achieved transport control in bulk crystals. Here, we demonstrate $p$-doping by introducing phosphorus (P) during growth. Increasing P concentrations above ~40 ppm triggers a majority carrier inversion from $n$- to $p$-type. Thermal activation energy, room temperature hole density, and mobility in $p$-type crystals are ~170 meV, $\sim 10^{18}$ cm$^{-3}$, and 1 cm$^2$V$^{-1}$s$^{-1}$, respectively. Density functional theory confirms that P substitution for S creates an acceptor level 100’s of meV from the valence band, in agreement with experiment. With $p$-type control thus achieved, $p$-$n$ FeS$_2$ homojunctions now become possible.

*This work was supported by the customers of Xcel Energy through a grant from the Renewables Development Fund.

**4:30PM P63.00009: Insulator-Metal Transition in Co-Doped Pyrite FeS$_2$ Single Crystals**  
BHASKAR DAS (Presenter), BRYAN VOIGT, MOUMITA MAITI, WILLIAM MOORE, MICHAEL MANNO, University of Minnesota, ERAY AYDIL, New York University, CHRIS LEIGHTON, University of Minnesota — Iron pyrite (FeS$_2$) is a low-cost, earth-abundant, non-toxic semiconductor with attractive electronic and optical properties, both for fundamentals, and applications (e.g. photovoltaics). Sulfur vacancies ($V_S$)[1] and Co[2] are the only well-established $n$-dopants in FeS$_2$. $V_S$ are deep donors, however, preventing facile study of phenomena such as the insulator-metal transition (IMT), while surface conduction complicates transport at low Co doping. In this work the problem of surface conduction is circumvented via a contacting scheme that provides access to the bulk, enabling wide-$T$-range transport studies of Co-doped FeS$_2$ single crystals. An IMT is found at ~4X$10^{17}$cm$^{-3}$ Hall density, with Efros-Shklovskii variable-range hopping and/or activated transport below this, and electron-electron interaction-corrected metallic conductivity above it. A number of unexpected features also occur, however, including non-monotonic $T$ dependence of the Hall coefficient, resistivity anomalies at intermediate $T$, and non-saturating non-parabolic positive magnetoresistance. These will be discussed in detail.

*Work supported by the customers of Xcel Energy through grant from the Renewables Development Fund.
Toward Deterministic Doping of Silicon via Dopant Containing Homopolymer

MICHELE PEREGO (Presenter), GABRIELE SEGUINI, ELISA ARDUCA, ANDREA NOMELLINI, FRANCESCO CARUSO, IMM-CNR, KATIA SPARNACCI, DIEGO ANTONIOLI, VALENTINA GIANOTTI, RICCARDO CHIARCOS, MICHELE LAUS, Università del Piemonte Orientale — Manipulation of isolated impurity atoms in semiconductors fostered a vision of novel classical and quantum single atom devices. The main roadblock toward their exploitation is the lack of strategies to control the positioning of dopant impurities within the semiconductor lattice by a methodology compatible with current semiconductor technology. Recently, we developed a doping strategy using self-assembled monolayers of polymers terminated with P-containing moieties, used as dopant-carrying molecules.(1,2) Their self-limiting “grafting-to” reaction from melt determine the areal density of the grafted molecules and consequently the number of P atoms in the dopant source. Subsequent injection and activation of P atoms into the Si substrate is achieved by high temperature annealing.(1) Control of the lateral distribution of P atoms over the substrate could be achieved by integrating these materials with suitable lithographic techniques. In this talk, we will review our results on this topic providing preliminary data on the development of a deterministic doping strategy based on self-assembly materials.

Epitaxial growth, structure, and properties of MgZrN$_2$, an emerging nitride semiconductor

SAGE BAUERS (Presenter), National Renewable Energy Laboratory, JOHN S MANGUM, Metallurgical and Materials Engineering, Colorado School of Mines, JOHN PERKINS, STEPHAN LANY, ANDRIY ZAKUTAYEV, National Renewable Energy Laboratory — Inorganic nitrides are important technological materials, many of which belong to one of two families: hexagonal main-group metal nitride semiconductors and cubic transition-metal nitride superconductors. We break this dichotomy with our discovery of several new semiconducting Mg-TM-N (TM=Ti, Zr, Hf, Nb, Ta) nitrides which adopt rocksalt crystal structures. Ab-initio calculations on this family of mid-gap semiconductors reveal extremely large dielectric constants (up to 80 $\varepsilon_0$), and a striking tolerance to structural defects relative to other ternary nitrides. This talk will focus on Mg$_x$Zr$_{2-x}$N$_2$. We find that this material forms over a broad metal composition range. At stoichiometric MgZrN$_2$ compositions, this material behaves as a heavily-doped n-type semiconductor exhibiting a negative temperature coefficient of resistivity and thermally-activated carriers. The transport properties can be radically tuned with Mg:Zr ratio from metallic (Zr-rich) to non-degenerately-doped (Mg-rich). X-ray diffraction and electron microscopy reveal that MgZrN$_2$ can be epitaxially grown on both GaN and MgO substrates. The combination of elemental abundance, compelling properties, and structural compatibility highlights the potential of these materials for integration with known nitrides.
5:06PM P63.00012: Proton radiation-induced enhancement of conductivity of composite amorphous/nanocrystalline silicon thin films* ZVIE RAZIELI, NATHAN BOSCH, School of Physics and Astronomy, University of Minnesota, LAGY T BABY, Department of Physics, Florida State University, LIS STOLIK VALOR (Presenter), School of Physics and Astronomy, University of Minnesota, RACHEL YOHAY, Department of Physics, Florida State University, ROGER W RUSACK, JAMES KAKALIOS, School of Physics and Astronomy, University of Minnesota — While most semiconductor devices are susceptible to radiation damage, we report here observations of an enhancement of the conductivity of undoped composite hydrogenated amorphous silicon thin films containing silicon nanocrystalline inclusions (a/nc-Si:H) following irradiation with high-energy protons. A series of films with varying nc content, synthesized in a unique dual-chamber co-deposition system, were irradiated with 16 MeV protons from a superconducting linear accelerator for fluences ranging from $2 \times 10^{13}$ cm$^{-2}$ to $10^{15}$ cm$^{-2}$. For the highest irradiation doses, the dark conductivity is enhanced by over an order of magnitude. Unlike the persistent photoconductivity effect observed in amorphous semiconductors, the radiation-induced enhancement is permanent and is not removed by annealing, remaining unchanged at least eight months after irradiation. Various mechanisms are tested to explain the irradiation-induced conductivity enhancement, but none are found to be able to fully account for our observations.

P63.00013: Impurity diffusion induced dynamic electron donors in semiconductors* WEN-HAO LIU, JUN-WEI LUO (Presenter), SHU-SHEN LI, State Key Laboratory of Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences, LIN-WANG WANG, Materials Science Division, Lawrence Berkeley National Laboratory — Low-energy impurity diffusion in a host material is often regarded as an adiabatic process. Here, we present that the diffusion process in semiconductors can involve nonadiabatic electron excitations, rendering it to be a more complicated process. Impurity diffusion in a device at working temperature can pump one electron up from localized impurity state into the host conduction band and causes the impurity to be a dynamic donor since it temporarily loses its electron to the host. This nonadiabatic process, against a common belief, fundamentally change the diffusion behavior, including its barrier height and diffusion path. Although we mainly demonstrate this process with Au metal impurity in bulk Si through time-dependent density functional theory simulations, we believe this could be a rather common phenomenon as it is shown that the similar phenomena also exist in Zn, Cd impurities diffusion in bulk Si, and Ti diffusion in TiO2. We believe this study can open up a new direction of inquiry for such diffusion behavior in semiconductor.

Wednesday, March 4, 2020 2:30 PM - 5:30 PM
GUOXIANG HU, Center for Nanophase Materials and Sciences, Oak Ridge National Laboratory, CHANDLER BENNETT, QIYANG LU, Materials Science and Technology Division, Oak Ridge National Laboratory, OLLE HEINONEN, Materials Science Division, Argonne National Laboratory, PAUL KENT, Center for Nanophase Materials and Sciences, Oak Ridge National Laboratory, HO NYUNG LEE, JARON KROGEL, Materials Science and Technology Division, Oak Ridge National Laboratory, PANÇHAPAKEŞAN GANESH (Presenter), Center for Nanophase Materials and Sciences, Oak Ridge National Laboratory — A subclass of ABO$_x$ perovskites undergoes metal-to-insulator transitions (MITs) when n-doped either via oxygen vacancies concomitant with ordering, chemical substitution or strain. For example, the oxygen-rich perovskite SrCoO$_3$ is a ferromagnetic metal, while the oxygen-deficient brownmillerite SrCoO$_{2.5}$ is an anti-ferromagnetic insulator. The precise mechanism driving the MIT, and its relation to the electronic-structure of the metallic phase, remains unknown. Here we hypothesize that metallic ABO$_3$ that are more susceptible to a MIT via n-doping are self-hole doped negative charge transfer metals; n-doping fills these pre-existing holes and gives rise to an insulating state. Magnetism is a secondary effect that may or may not assist in the gap opening. Moreover, this tendency to remain self-hole doped determines a universal electronic response to modulations in stoichiometry/composition/pressure. In this work, we use *ab-initio* density functional theory (DFT), DFT+U, DFT+hybrid as well as many-body quantum Monte Carlo (QMC) calculations to shed light on the hypothesis, with comparison to experiments where possible.

Pressure-induced metal-insulator transition in degenerately doped ferroelectrics*  CHENGLIANG XIA (Presenter), YUE CHEN, The University of Hong Kong, HANGHUI CHEN, NYU-ECNU Institute of Physics, New York University Shanghai — We perform first-principles calculations to study oxygen vacancies in two important types of ferroelectric oxides (LiNbO₃ as the prototype of R3c-type ferroelectrics and BaTiO₃ as the prototype of perovskite-type ferroelectrics). Under ambient conditions, with a low concentration of oxygen vacancies, both LiNbO₃₋δ and BaTiO₃₋δ become metallic; the polar distortions are reduced in both compounds but do not disappear. However, under pressures, the polar distortions in BaTiO₃₋δ are completely suppressed and the system remains metallic with itinerant electron uniformly distributed on Ti atoms. By contrast, the polar distortions in LiNbO₃₋δ increase under pressures and above a critical pressure, the system turns into an insulating state. The increased polar displacements in LiNbO₃₋δ reduce the band width even though the overall volume decreases under pressures, which localizes the itinerant electrons onto a defect state and eventually leads to a metal-insulator transition.

Can free charge carriers enhance polarization?*  SHUTONG LI (Presenter), TURAN BIROL, University of Minnesota — Ferroelectricity and metallicity has long been thought to be mutually exclusive because of the screening of the long range coulomb force. After the observation of ferroelectric-like transitions in metals recently, there has been a surge of interest in the study of `ferroelectric metals‘ and the stabilizing forces of structural polarization therein. Nevertheless, addition of carriers to semiconducting or insulating ferroelectrics is still usually thought to be detrimental to ferroelectricity. In this talk we show, by using first principles calculations, that ferroelectric polarization can actually be strengthened by introduction of free carriers in a series of oxide ferroelectrics. We consider introduction of carriers through electrostatic gating, which can alter the carrier concentration without changing the level of disorder.

3:06PM P64.00004: Dielectric Conduction in the Post-breakdown Region Predicted Using a Charge Transport Model  YUEMING XU (Presenter), JOEL L PLAWSKY, TOH-MING LU, Rensselaer Polytechnic Institute — A Charge Transport Model was developed originally in our group to predict time-dependent dielectric breakdown (TDBB) in the back end of line (BEOL) interconnects. Both ramped voltage stress tests (RVS) and constant bias stress tests (CVS) data could be simulated with a same set of fitting parameters by the model.

To investigate what happens post-breakdown, we removed the industrially defined breakdown condition that was used to stop the simulation and with adjustments to the voltage response of both the Schottky barrier height and of the electron at the metal/dielectric interface, the model has now been extended into the post-breakdown region. The revised model can now predict the entire current vs. time history from the breakdown to ohmic behavior post-breakdown.

The linear I-V behavior agrees with the experimental observations of the current behavior of various resistive random-access memories (ReRAM) at low resistive state (LRS) after the generally required ‘Forming’, which is essentially a dielectric breakdown process. The extended charge transport model, therefore, provides a possible explanation for the ReRAM conduction mechanism at LRS by treating it as an incompressible electronic flow system.

3:18PM P64.00005: A high-throughput search of antiferroelectric perovskites.*  HUGO ARAMBERRI (Presenter), Luxembourg Inst of Science and Technology, JORGE INIGUEZ, Luxembourg Inst of Science and Technology; University of Luxembourg — Despite the perovskite family of compounds showing a plethora of polymorphs with rich ferroic behaviors, the quest for an antiferroelectric perovskite oxide with a simple displacive behavior remains fruitless (but for maybe PbZrO3). By means of first principles calculations, we carry out a high-throughput study of non-magnetic perovskites (ABO3), comparing their leading instabilities in their vibrational spectra and their known experimental polymorphs. Most remarkably, this search has allowed us to identify a family of perovskite-derivative compounds that display a rich variety of polar and non-polar polymorphs and seem promising candidates for antiferroelectric behavior.

3:30PM P64.00006: Frustrated Dipole Order Induces Noncollinear Proper Ferrielectricity in Two Dimensions*  LING-FANG LIN (Presenter), YANG ZHANG, ADRIANA MOREO, ELBIO DAGOTTO, University of Tennessee, SHUAI DONG, Southeast University — Achieving novel physical properties in two-dimensional (2D) materials should enable numerous functionalities in nanoscale devices. In recent years, interest in high-performance 2D ferroelectric materials has also grown rapidly across multiple scientific and engineering disciplines. Here, dioxydihalides MO\textsubscript{2}X\textsubscript{2} materials (where M= Mo and W; X= Cl and Br) are studied based on density functional theory calculations. For dioxydihalides MO\textsubscript{2}X\textsubscript{2} monolayers, we predict that they should display noncollinear ferrielectricity, induced by competing ferroelectric and antiferroelectric soft modes [1]. More importantly, this intrinsic noncollinearity of dipoles generates unique physical properties, such as Z\textsubscript{2}xZ\textsubscript{2} topological domains, atomic-scale dipole vortices/anti-vortices, and negative piezoelectricity. Our investigations should open the door to a new branch of 2D materials in the pursuit of intrinsically strong noncollinear ferrielectricity.

*Supported by the National Natural Science Foundation of China (Grants No. 11834002 and No. 11674055) and the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES), Materials Science and Engineering Division.

3:42PM P64.00007: A room-temperature ferroelectric semimetal  PANKAJ SHARMA (Presenter), University of New South Wales; ARC Centre of Excellence in Future Low-Energy Electronics Technologies, UNSW, Sydney, NSW, Australia — Ferroelectricity has often been associated with and observed in materials that are insulating or semiconducting rather than metallic because conduction electrons in metals screen out the static internal fields arising from a long-range dipolar order. In the 1960s, Anderson and Blount proposed materials with these seemingly incompatible characteristics, i.e., metals with a polar axis termed ferroelectric metals. Since then, ferroelectric metals were merely a theoretical construct until recent experimental observations suggesting otherwise. Despite the progress, electrically switchable intrinsic electric polarization, together with the direct observation of ferroelectric domains, has not yet been realized in a bulk crystalline metal, although incomplete screening by mobile conduction charges should, in principle, be possible.

Here, we provide evidence that native metallicity and ferroelectricity coexist in bulk crystalline van der Waals WTe\textsubscript{2}. We show that, despite being a Weyl semimetal, WTe\textsubscript{2} has switchable spontaneous polarization and a natural ferroelectric domain structure at room temperature. This new class of materials has tantalizing potential for functional nanoelectronics applications.
3:54PM P64.00008: The Role of Oxide Surface Structure and Polarity in Flexoelectricity*
CHRISTOPHER MIZZI (Presenter), LAURENCE D. MARKS, Northwestern University — Interest in flexoelectricity has grown significantly over the past decade owing to its universality and importance at the nanoscale. Unlike many other oxide properties, a material's macroscopic flexoelectric response is predicted to be highly surface sensitive. This surface sensitivity has been demonstrated with first principles calculations on (100) SrTiO$_3$ bulk terminations [PRB 90, 201112(R) (2014)]. However, experimentally observed oxide surfaces often possess structural and chemical differences from the corresponding bulk material, the effects of which remain unclear in the context of flexoelectricity. Using density functional calculations, we compare the flexoelectric response of a number of low-energy (100) SrTiO$_3$ reconstructions to assess the impact of surface stoichiometry and periodicity on flexoelectricity. Additionally, we address the role of polar surfaces with calculations on (100) and (111) MgO surfaces. Our calculations on experimentally observed oxide surface structures corroborate previous work highlighting the importance of surfaces in flexoelectricity and have important implications for flexoelectric measurements and thin film growth.

4:06PM P64.00009: Uniqueness of the Polarization in Crystals and Nanostructures*
SHOHAM SEN (Presenter), YANG WANG, Carnegie Mellon Univ, PRADEEP SHARMA, Mechanical Engineering, University of Houston, KAUSHIK DAYAL, Carnegie Mellon Univ — Ionic crystals such as solid electrolytes and complex oxides are central to modern technologies for energy storage, sensing, actuation, and other functional applications. An important fundamental issue in the atomic and quantum scale modeling of these materials is the question of defining the macroscopic polarization. In a periodic crystal, the usual definition of the polarization as the first moment of the charge density in a unit cell is found to depend qualitatively and quantitatively on the choice of the unit cell.

We examine this issue using a rigorous approach based on the framework of two-scale convergence. By examining the continuum limit of when the lattice spacing is much smaller than the characteristic dimensions of the body, we prove that accounting for the boundaries consistently provides a route to uniquely compute electric fields and potentials despite the non-uniqueness of the polarization. Specifically, different choices of the unit cell in the interior of the body leads to correspondingly different partial unit cells at the boundary; while the interior unit cells satisfy charge neutrality, the partial cells on the boundary need not; the net effect is that these changes compensate each other.

*We thank the DOD MURI program for financial support.
4:18PM P64.00010: Multiferroic Quantum Criticality [Invited] AWADHESH NARAYAN (Presenter), Indian Institute of Science — Phase transitions are ubiquitous in nature -- water turning to steam is an everyday example. A special kind of phase transition can occur at zero temperature by changing a non-thermal control parameter. Such a quantum phase transition is the driver for exotic quantum critical physics that extends to elevated temperatures [1]. In this talk, I will begin by introducing quantum phase transitions in magnets, which have been widely explored [2]. I will next discuss, the very recently established, ferroelectric quantum critical behavior [3]. Finally, I will present the concept of multiferroic quantum criticality -- in which both magnetic and ferroelectric quantum criticality occur in the same system -- that we have recently proposed [4]. I will describe the associated experimental signatures and material systems to realize it, and highlight possible future directions.

4:54PM P64.00011: Dynamical hybrid improper ferroelectricity in incipient ferroelectric SrTiO\textsubscript{3} * MINGQIANG GU (Presenter), JAMES RONDINELLI, Northwestern University — SrTiO\textsubscript{3} (STO) has been intensively studied, in part, because of its ‘incipient’ ferroelectricity. A small perturbation, such as strain, stress, chemical variation, or surface truncation, can induce a paraelectric to ferroelectric phase transition. Recent optical pump-probe experiments found that even THz light excitations can trigger the transition in STO. The underlying mechanism for the light-mediated ferroelectricity remains controversial; explaining it is crucial for both ultrafast manipulation and control. Here, we explain this process as a form of dynamical hybrid improper ferroelectricity. The inversion symmetry is lifted by the trilinear coupling between a polar mode, a zone-center antiferrodistortive mode, and a zone-boundary in-phase rotation mode activated under THz pumping. With density functional theory calculations, we compute the free energy profiles of the coupled modes. With the fitted coupling coefficients, we estimate the time evolution of the inversion symmetry lifting and compare our model with the experimental results. Our understanding extends the scope of improper ferroelectricity, and may open a new route to manipulate inversion symmetry of other materials in the time domain.

Multiferroic Switching Dynamics in BiFeO$_3$  

ERIC PARSONNET (Presenter), YEN-LIN HUANG, University of California, Berkeley, CHIA-CHING LIN, TANAY GOSAVI, Intel Corporation, ALEXANDER QUALLS, University of California, Berkeley, IAN YOUNG, Intel Corporation, LANE WYATT MARTIN, JEFFREY BOKOR, RAMAMOORTHY RAMESH, University of California, Berkeley — With room temperature coupling between magnetic and electric degrees of freedom, BiFeO$_3$ (BFO) has attracted much attention as a leading candidate for magnetoelectric applications. There has been extensive work studying quasi-static magnetoelectric coupling in BFO, but the magnetoelectric coupling dynamics, their fundamental speed limits and intrinsic mechanisms of switching have yet to be explored. We are studying time-domain switching dynamics of the ferroelectric state as the first step in understanding magnetoelectric dynamics. Such studies are challenging, often limited by the platform on which the experiment is performed. Using short electrical pulses with rise time $\sim$100ps and pulse widths of the order of 10ns, we are able to probe the switching of the ferroelectric state on timescales much shorter than previous studies. The data reveal low-nanosecond switching, faster than any formerly reported switching times in (La)BFO. We probe the effects of chemical composition on magnetoelectric switching by studying two model systems, namely BFO and La-doped BFO. We study to what extent multiferroic switching conforms to existing models for classical ferroelectric switching and analyze deviations in the context of magnetoelectric coupling.

Multiferroic LuFeO$_3$ on GaN, Studies of Band Offsets and a Polar-Polar Interface  

JOSEPH CASAMENTO (Presenter), DARRELL SCHLOM, HUILI GRACE XING, DEBDEEP JENA, Cornell University — The ability to integrate epitaxial ferroelectrics on GaN, an established wide bandgap semiconductor platform, has been recently demonstrated [Li et al, Advanced Materials Interfaces 5, 1700921 (2018)] by pulsed laser deposition (PLD) of Pb$_x$Zr$_{1-x}$TiO$_3$. LuFeO$_3$, a room temperature ferroelectric and low temperature (~147K) multiferroic material, has been integrated with LuFe$_2$O$_4$ layers in a superlattice that demonstrated near room temperature (~281K) magnetoelectric multiferroic behavior [Mundy et al, Nature 537, 7621 (2016)]. Its hexagonal crystal symmetry makes it promising for epitaxial integration with III-nitrides. Here, we report the molecular beam epitaxy (MBE) growth, ferroelectricity, and band offsets of hexagonal LuFeO$_3$ on GaN. Piezoresponse force microscopy (PFM) results of LuFeO$_3$-n type GaN interface indicate ferroelectric switching behavior. X-ray photoelectron spectroscopy (XPS) of core levels of LuFeO$_3$-GaN interfaces was utilized to determine the valence band offset. Preliminary results indicate a valence band offset of $\sim$1.3 eV. Assuming a bandgap of $\sim$ 1 eV for LuFeO$_3$, this gives a conduction band offset of $\sim$ 1 eV. These studies highlight a potential avenue of epitaxial LuFeO$_3$-GaN based multiferroic-semiconductor heterojunctions for memory and logic applications.

Session P65 DCMP: 2D Materials: Twisted Bilayers

Mile High Ballroom 4F - Peter Jacobse, University of California, Berkeley
Tunable correlated insulator behavior in twisted double bilayer graphene

Sergio de la Barerra (Presenter), Samuel Aronson, Yuan Cao, Daniel Rodan-Legrain, Oriol Rubies-Bigorda, Pablo Jarillo-Herrero, Raymond Ashoori, Massachusetts Institute of Technology MIT — Recent evidence for correlated physics in moire superlattice systems has motivated numerous theoretical studies and predictions relating flat bands, interactions, topology, and the underlying dependence on twist angle. In particular, twisted structures of two Bernal-stacked graphene bilayers display transport signatures of correlated insulating states at quarter- and half-filling of the superlattice bands that appear at finite displacement fields. Here, we explore the detailed evolution of these features in the electronic structure via sensitive measurements of the electronic compressibility. By varying carrier density and displacement field in a dual-gate capacitor geometry, we tune the bands into the various incompressible regimes to shed light on the possible correlations. By applying in- and out-of-plane magnetic fields, we probe the spin character and Landau level spectrum of the moire bands and comment on the correspondence to existing theoretical predictions.

Ferromagnetism and its stability from the one-magnon spectrum in twisted bilayer graphene

Yahya Alavirad (Presenter), Jay Sau, University of Maryland, College Park — We study ferromagnetism and its stability in twisted bilayer graphene. We show that in the perfectly flat band limit and at filling fractions $\pm 3/4$, the saturated ferromagnetic (spin and valley polarized) states are ideal ground state candidates in the large band-gap limit. By assuming a large enough substrate (hBN) induced sub-lattice potential, the same argument can be applied to filling fractions $\pm 1/4$. We estimate the regime of stability of the ferromagnetic phase around the chiral limit by studying the spectrum of one-magnon excitations. The instability of the ferromagnetic state is signaled by a negative magnon excitation energy. This approach allows us to deform the results of the idealized chiral model towards more realistic systems. Furthermore, we use the low energy part of the exact one-magnon spectrum to calculate the spin-stiffness of the Goldstone modes throughout the ferromagnetic phase. The value of spin-stiffness can determine the energy of charged skyrmions. We further calculate the spectrum of the gapped single valley-flip excitations. The valley-mode gap can be used to estimate the transition temperature of quantum anomalous Hall state.

2:54PM P65.00003: Recovery of massless Dirac fermions at charge neutrality in strongly interacting twisted bilayer graphene with disorder*  
ALEX THOMSON (Presenter), JASON F. ALICEA, Caltech — Stacking two graphene layers twisted by the `magic angle' generates flat energy bands, which in turn catalyzes various strongly correlated phenomena. At charge neutrality, transport measurements reveal superficially mundane semimetallicity in some samples yet robust insulation in others. We propose that the interplay between interactions and disorder admits either behavior, even when the system is strongly correlated and locally gapped. We argue that strong interactions supplemented by weak, smooth disorder stabilize a network of gapped quantum valley Hall domains with spatially varying Chern numbers determined by the disorder landscape --- even when an entirely different order is favored in the clean limit. Sufficiently small samples that realize a single domain are insulating. Conversely, multi-domain samples exhibit re-emergent massless Dirac fermions formed by gapless domain-wall modes, yielding semimetallic behavior. Our results highlight the crucial role that randomness can play in ground-state selection. We discuss experimental tests of our proposal.

3:06PM P65.00004: Evolution of charge modulation in twisted bilayer graphene near the magic angle*  
XINYUAN LAI (Presenter), NIKHIL TILAK, Rutgers University, New Brunswick, YUHANG JIANG, JINHAI MAO, University of Chinese Academy of Sciences, MINGYU XU, RAQUEL DE ALMEIDA RIBEIRO, PAUL C CANFIELD, Iowa State University, EVA ANDREI, Rutgers University, New Brunswick — Twisting and stacking two layers of graphene with a twist-angle near "magic angle" flattens the energy band and significantly slows down the movement of charge carriers. The resulting strong electron-electron interactions favors the emergence of novel correlated phases, including a charge ordered stripe phase\[1\]. Using STM on magic-angle twisted bilayer graphene with a gate tunable doping dependence, we study the evolution of the band structure with doping and its effect on the charge ordered state. When the flat band is empty or full it produces a pronounced STS spectroscopy peak which corresponds to a peak in the density of states. Bringing the Fermi level within the flat band we observe a correlation induced pseudogap at the Fermi energy accompanied by a spatial variation of the charge distribution that breaks the C3 symmetry. We will report on the evolution of the charge ordered phase with temperature, magnetic field and on its relation to the pseudogap.

*Work supported by DOE-FG02-99ER45742, NSF DMR 1708158
Emergent quantum phases driven by electronic interactions can manifest in materials with narrowly dispersing, i.e. “flat”, energy bands. Recently, flat bands have been realized in a variety of graphene-based heterostructures using the tuning parameters of twist angle, layer stacking and pressure, and resulting in correlated insulator and superconducting states. Here we report the experimental observation of similar correlated phenomena in twisted bilayer tungsten diselenide (tWSe$_2$), a semiconducting transition metal dichalcogenide (TMD). Unlike twisted bilayer graphene where the flat band appears only within a narrow range around a “magic angle”, we observe correlated states over a continuum of angles, spanning 4° to 5.1°. Hall measurements supported by ab initio calculations suggest that the strength of the insulator is driven by the density of states at half filling, consistent with a 2D Hubbard model in a regime of moderate interactions. At 5.1° twist, we observe evidence of superconductivity upon doping away from half filling, reaching zero resistivity around 3 K. Our results establish twisted bilayer TMDs as a model system to study interaction-driven phenomena in flat bands with dynamically tunable interactions.

Emergent quantum phases driven by electronic interactions can manifest in materials with narrowly dispersing, i.e. “flat”, energy bands. Recently, flat bands have been realized in a variety of graphene-based heterostructures using the tuning parameters of twist angle, layer stacking and pressure, and resulting in correlated insulator and superconducting states. Here we report the experimental observation of similar correlated phenomena in twisted bilayer tungsten diselenide (tWSe2), a semiconducting transition metal dichalcogenide (TMD). We observed that a Mott-like insulator appears at half band filling that can be sensitively tuned with displacement field over a continuum of angles, spanning 4° to 5.1°. We further study the system under high magnetic field. The interleaved Landau fans coming from band edge and full-filling of Moiré cell show the first observed Hofstadter butterfly pattern in TMD. The strength of correlated insulating state is modulated by magnetic field in an unusual way and the extra Landau fan coming from half-filling shows complex patterns. These exotic features allow us to study the interplay between topology, electronic correlations and magnetism in the flat band platform.
3:42PM P65.00007: Magic continuum in twisted bilayer WSe$_2$: critical phenomena and phase transitions  AUGUSTO GHIOTTO (Presenter), LEI WANG, EN-MIN SHIH, Columbia Univ, LEDE XIAN, Max Planck Institute for the Structure and Dynamics of Matter, DANIEL A RHODES, CHENG TAN, Columbia Univ, MARTIN CLAASSEN, Simons Foundation, DANTE M. KENNES, Max Planck Institute for the Structure and Dynamics of Matter, BUMHO KIM, YUSONG BAI, Columbia Univ, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, XIAOYANG ZHU, JAMES C HONE, Columbia Univ, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter, CORY DEAN, ABHAY PASUPATHY, Columbia Univ — Emergent quantum phases driven by electronic interactions can manifest in materials with narrowly dispersing, i.e. “flat”, energy bands. Recently, flat bands have been realized in a variety of graphene-based heterostructures using the tuning parameters of twist angle, layer stacking and pressure, and resulting in correlated insulator and superconducting states. 3:54PM P65.00008: Designing quantum geometry and nonlinear responses in van der Waals homostackings  HUITAO SHEN (Presenter), YANG ZHANG, SUYANG XU, LIANG FU, Massachusetts Institute of Technology — The recent discovery of magic-angle twisted bilayer graphene has attracted tremendous interest. Despite the excitement, an important open question is that whether layer stacking can enable other new dimensionalities that can be utilized to discover fundamentally new physics and functionalities. In this talk, I will show that van der Waals (vdW) homostackings can be used to very effectively design the quantum geometry and nonlinear or nonreciprocal responses of many vdW materials. Specifically, carefully designed homostackings can generate strong Berry curvature in the electronic structures of 2D materials. As a result, exotic nonlinear responses such as nonlinear Hall and circular photogalvanic effects are enabled in materials. Moreover, homostackings can turn many vdW materials, even graphene and transition metal dichalcogenides, into being ferroelectric, paving the way for realizing nonvolatile memory devices. The results are applicable to a wide range of vdW materials and therefore provide a new means to discover, control and harness emergent quantum phenomena in 2D devices.
In twisted bilayer systems, the breaking of the mono-layer Bravais lattice translation symmetry induces off-diagonal couplings between monolayer Bloch States. In an effort to model the coarse-grained couplings we establish new integral results for the two dimensional Fourier Transforms of generalized Slater-Koster hopping amplitudes, for various radial scaling functions, in the form of a series which rapidly converges over the entire parameter space.

Applied with a first-order gradient expansion of the strain fields, we evaluate this continuum model approach in relation to commensurate band structure calculations for a variety of appropriate Van-der Waals bilayer structures.

*Office of Naval Research

4:18PM P65.00010: Phonons in Twisted Transition Metal Dichalcogenide Bilayers ("Twistnonics"): Ultra-soft Phasons, and a transition from Superlubric to Pinned Phase

INDRAJIT MAITY (Presenter), MIT H. NAIK, PRABAL K MAITI, SRIRAM RAMASWAMY, HULIKAL KRISHNAMURTHY, MANISH JAIN, Indian Institute of Science - Dept of Physics — The tunability of the interlayer coupling by twisting one layer with respect to another layer of two-dimensional materials provide a unique way to manipulate phonons and related properties. We refer to this engineering of phononic properties as "Twistnonics". We study the effects of twisting on low-frequency shear (SM) and layer breathing (LBM) modes in transition metal dichalcogenide (TMD) bilayer using atomistic classical simulations. We show that these low-frequency modes are extremely sensitive to twist and can be used to infer the twist angle. We find unique “ultra-soft” phason modes (frequency ≤ 1 cm⁻¹) for any non-zero twist, corresponding to an effective translation of the moiré lattice by relative displacement of the constituent layers in a non-trivial way. Unlike the acoustic modes, the velocity of the phason modes is quite sensitive to twist angle. As twist angle decreases, (θ ≤ 3°, & ≥ 57°) the ultra-soft modes represent the acoustic modes of the “emergent” soft moiré scale lattice. Also, new high-frequency SMs appear, identical to those in stable bilayer TMD (θ = 0°/60°). Our study reveals the possibility of an intriguing θ dependent superlubric to pinning behavior and of the existence of ultra-soft modes in all two-dimensional materials.
4:30PM P65.00011: Particle-Hole Duality, Emergent Fermi Liquids and Fractional Chern Insulators in Moiré Flatbands

AHMED ABOUELKOMSAN (Presenter), Department of Physics, Stockholm University, ZHAO LIU, Zhejiang Institute of Modern Physics, Zhejiang University, EMIL BERGHOLTZ, Department of Physics, Stockholm University — We consider the core problem of Coulomb interactions within fractionally filled Moiré flat bands and demonstrate that the dual description in terms of holes, which acquire a non-trivial hole-dispersion, provides key physical intuition and enables the use of standard perturbative techniques for this strongly correlated problem. We find that the single-hole dispersion has a profound impact on the phase diagram: in experimentally relevant examples such as ABC stacked trilayer and twisted bilayer graphene aligned with boron nitride, it leads to emergent Fermi liquid states at band filling fractions down to $1/3$ and $2/3$ respectively. At even lower filling fractions, the electron density still faithfully tracks the single-hole dispersion while exhibiting distinct non-Fermi liquid behaviour. We also show that fractional Chern insulators can form in twisted bilayer graphene aligned with boron nitride at band filling $1/3$.

4:42PM P65.00012: Valley Jahn-Teller effect in Twisted Bilayer Graphene

MATTIA ANGELI (Presenter), ERIO TOSATTI, MICHELE FABRIZIO, SISSA — The surprising insulating and superconducting states of narrow-band graphene twisted bilayers have been mostly discussed so far in terms of strong electron correlation, with little or no attention to phonons and electron-phonon effects. We found that, among the 33492 phonons of a fully relaxed $\theta=1.08^\circ$ twisted bilayer, there are few special, hard, and nearly dispersionless modes that resemble global vibrations of the moiré supercell (‘moiré phonons’). One of them, doubly degenerate at $\Gamma$, couples very strongly with the valley degrees of freedom, also doubly degenerate, realizing a so-called Exe Jahn-Teller (JT) coupling. The JT coupling lifts very efficiently all degeneracies which arise from the valley symmetry, and may lead, for an average atomic displacement as small as 0.5 mÅ, to an insulating state at charge neutrality. In addition, freezing the same phonon at a zone boundary point brings about insulating states at most integer occupancies of the four ultraflat electronic bands.

Electron pairing instability in magic angle twisted bilayer graphene*
MING XIE (Presenter), ALLAN MACDONALD, University of Texas at Austin — Superconductivity is one of the most intriguing properties observed recently in magic angle twisted bilayer graphene. Its origin is evidently closely tied to the nearly flat low energy bands at magic angle, which possess both spin/valley flavor symmetries and unique topological properties. The precise mechanism of pairing remains unclear however. Here we make an unbiased assessment of different pairing models, taking both Coulomb interactions and effective interactions induced by electron-phonon coupling into account. We find that it is essential to account for the screening of Coulomb interactions by remote metallic gates which increase the momentum dependence of Coulomb interactions and open the door to unconventional pairing channels. I will also comment on orbital suppression of superconductivity by an in-plane magnetic field, and on the possibility of using the magnetic-field dependence of superconductivity to identify the pairing mechanism.

Session P70 DCMP DMP: Metals: Magnetism, Semi-metals and Topology 208 - Hans Hallen, North Carolina State University

Computing Transport Coefficients of Many-Body Hamiltonians by Equilibrium Averages*
ASSA AUERBACH (Presenter), Physics, Technion - Israel Institute of Technology, ILIA KHAIT, Physics, University of Toronto, NOGA BASHAN, Physics, Technion - Israel Institute of Technology — DC transport coefficients of most strongly interacting Hamiltonians demand insurmountable computational challenges, e.g. large system sizes, long real-time evolution, and poorly controlled analytic continuation of quantum Monte Carlo data. In contrast, continued fractions expansions and the use of our new formulas for Hall-type resistivities, require only computations of equilibrium averages. These are amenable to well controlled methods, e.g. imaginary-time quantum Monte Carlo, high temperature series, and variational wavefunctions. We review continued fractions dynamical conductivity and Hall and Thermal Hall coefficients calculations for the Bose and Fermi Hubbard models, and the disordered Heisenberg chain.

Investigation of the universal scattering rate in PdCrO$_2$ by high energy electron irradiation*  
**ELINA ZHAKINA** (Presenter), PHILIPPA MCGUINNESS, VERONIKA SUNKO, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, MARCUS KONCZYKOWSKI, Ecole Polytechnique, Palaiseau, France, SEUNGHYUN KHIM, MARKUS KOENIG, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — PdCrO$_2$ is an extremely pure magnetic delafossite metal. It combines both possibilities for the motion of electrons in a solid: a nearly free electron metal and a Mott insulating state. The resistivity of PdCrO$_2$ exhibits a $T$-linear dependence between 150 K and 300 K. In the region of the $T$-linear resistivity, the scattering rate per kelvin is well approximated by the ratio $k_B/h$. A number of other materials reveal similar results, in spite of large differences in the microscopic origins of the scattering [1].

To investigate the universal behaviour of the scattering rate, we conducted a study of the influence of point defects on the resistivity of PdCrO$_2$, the results of which we report here. We introduced point defects to FIB microstructures of PdCrO$_2$ by irradiating them with high-energy electrons. Comparing the results with those on PdCoO$_2$, we confirm that the increase in the resistivity is dominated by defects in Pd layers. Matthiessen's rule is obeyed in the $T$-linear region, indicating that the inelastic scattering events could be considered independent from the elastic ones.

Quantum Paracrystalline Shear Resonances in Metals  
**JUN YONG KHOO** (Presenter), Max Planck Institute for the Physics of Complex Systems, PO-YAO CHANG, National Tsing Hua University Taiwan, FALKO PIENTKA, INTI SODEMANN, Max Planck Institute for the Physics of Complex Systems — Unlike classical fluids, a quantum fermi liquid can support a long-lived and propagating shear sound wave, reminiscent of the transverse sound in crystals, despite lacking any form of long-range crystalline order. This mode is expected to be present in moderately interacting metals where the quasiparticle mass is renormalised to be more than twice the bare mass, but, it is hard to excite and detect because it does not involve charge density fluctuations, in contrast to the conventional plasma mode. We propose two strategies to excite and probe this unconventional mode. One is the appearance of sharp dips in the AC conductance of narrow channels when the frequency matches the energy dispersion of the shear sound. Another is the coupling of the mode to charge fluctuations under weak magnetic fields, that could allow to excite it using near field techniques such as those employed to excite plasma modes in two-dimensional metals.
3:06PM P70.00004: Polarizability and magnetoplasmons for the $\alpha$-T$_3$ model* GODFREY GUMBS (Presenter), DIPENDRA DAHAL, Physics and Astronomy, Hunter college, ANTONIOS BALASSIS, Fordham University, ANDRII IUROV, Medgar Evers college, DANHONG HUANG, Kirtland Air Force Research Lab — Godfrey Gumbs, Dipendra Dahal, Antonios Balassis, Andrii Iurov, and Danhong Huang

*The dynamical polarizability is calculated at zero temperature and then employed in the dielectric function to determine the dispersion relation for magnetoplasmons for the $\alpha$-T$_3$ model. In the absence of magnetic field, the low-energy spectrum consists of a pair of a pair of Dirac cones and a dispersionless (flat) band in the K and K' valleys, i.e., two inequivalent Dirac points in the first Brillouin zone. However, the corresponding wave functions are valley-dependent. The Dirac-Weyl Hamiltonian for this structure with pseudospin S=1 is characterized by a parameter alpha which is a measure of the coupling strength between an additional atom at the center of the honeycomb lattice for the A and B atoms on the rim. We present results for a doped layer in the integer quantum-Hall regime for fixed alpha and various magnetic fields, and chosen magnetic field and different alpha in the random-phase approximation.

3:18PM P70.00005: The origin of sub-room temperature ferromagnetism in VSe$_2$ monolayer: reduced dimension and electron correlation* TAEKJUNG KIM (Presenter), SIHEON RYEE, Department of Physics, Korea Advanced Institute of Science and Technology (KAIST), SANGKOOK CHOI, Condensed Matter Physics and Materials Science Department, Brookhaven National Laborator, MYUNG JOON HAN, Department of Physics, Korea Advanced Institute of Science and Technology (KAIST) — Recently 1T-VSe$_2$ has been reported as one of the first room-temperature two-dimensional ferromagnets. However, this conclusion remains elusive both theoretically and experimentally. In this presentation we apply LDA+DMFT (local density approximation plus dynamical mean-field theory) approach to study the magnetic properties of bulk and monolayer VSe$_2$. Our results indicate that bulk 1T-VSe$_2$ is a paramagnetic material as well-known but the monolayer is ferromagnetically ordered. The calculated Curie temperature is ~250K. From the detailed analysis on the electronic structure and the local spin susceptibility, we attribute the formation of local moment and the monolayer ferromagnetism to the concerted effect of quasiparticle pre-localization caused by reduced dimensionality and the electronic correlation. Further analysis shows that this ferromagnetism is vulnerable to the formation of interlayer interaction or extra charge doping, which provides the useful insight to understand the controversial experiments.

3:30PM P70.00006: Modulation of magnetism across the van der Waals interfaces

HIDEKI MATSUOKA, MOHAMMAD SAEED BAHRAMY, YUE WANG, SATOSHI YOSHIDA, KYOKO ISHIZAKA, YOSHIHIRO IWASA, MASAKI NAKANO (Presenter), Univ of Tokyo — A van der Waals (vdW) heterostructure provides an indispensable material platform in modern condensed-matter researches. There, weak interlayer bonding nature ensures formation of an atomically-abrupt heterointerface beyond fundamental constraint imposed by lattice matching condition, while strong electronic coupling enables creation of an emergent electronic ground state that is missing in individual materials. Here we fabricated vdW heterostructures by molecular-beam epitaxy, where a new type of 2D magnet, vanadium selenide epitaxial thin film\(^1\), was incorporated. In the presentation, we will show transport properties of those magnetic heterostructures, and discuss the interface proximity effect on 2D magnetism. [1] M. Nakano et al, Intrinsic 2D ferromagnetism in V\(_5\)Se\(_8\) epitaxial thin films. arXiv:1910.01959.

3:42PM P70.00007: High-Temperature Ferromagnetic Resonance in FePt Thin Films

CHUANPU LIU (Presenter), Colorado State University, KUMAR SRINIVASAN, ANTONY AJAN, Western Digital Corporation, ETHAN MCCOLLUM, MINGZHONG WU, Colorado State University — Understanding of damping processes in ferromagnetic thin films at temperatures (T) near the Curie temperature (T\(_c\)) has significant implications for heat-assisted magnetic recording and magnetic sensors operating at elevated temperatures. Recent ferromagnetic resonance (FMR) studies [PR Applied 10, 054046 (2018)] using out-of-plane fields showed that there are two major relaxation processes in granular L1\(_0\)-odered FePt thin films at 10-45 K below T\(_c\); two-magnon scattering and spin-flip magnon-electron scattering; with a decrease in T, the FMR linewidth increases due to the enhancement of the two-magnon scattering. This presentation reports high-T FMR studies on continuous FePt thin films with cubic structures, rather than L1\(_0\) structures. The films are 6-nm thick and have T\(_c\)≈680 K; the FMR measurements were performed over 300-620 K in out-of-plane fields. As opposed to the L1\(_0\) FePt films, the cubic FePt films show an FMR linewidth that decreases with a decrease in T. This T dependence suggests that the spin-flip magnon-electron scattering is dominant over the two-magnon scattering; the two-magnon scattering is weak because it is expected to be absent in continuous films under out-of-plane fields.
3:54PM P70.00008: Structure and Magnetism of New Metastable Fe₈Co₈N₂ Compound*

BALAMURUGAN BALASUBRAMANIAN, RABINDRA PAHARI, Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska, SHAH VALLOPPILLY, XINGZHONG LI, Nebraska Center for Materials and Nanoscience, University of Nebraska, RALPH SKOMSKI, XIAOSHAN XU, Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, DAVID SELLMYER (Presenter), Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska — Recently, the discovery of new magnetic materials with high magnetocrystalline anisotropy $K_1$, large saturation magnetic polarization $J_s$, and high Curie Temperature $T_c$ has been accelerated by efficient computational and non-equilibrium fabrication methods [1-4]. Guided by theoretical predictions [4], we have produced a new Fe₈Co₈N₂ compound in the form of nanoparticles using a cluster-deposition method and characterized it by XRD, XPS, STEM, EDS and magnetometry measurements. The nanoparticles have a stoichiometry of about Fe₈Co₈N₂ and exhibit a uniform elemental distribution of Fe, Co and N. A Rietveld refinement of XRD data shows that the new compound crystallizes in a tetragonal structure [space group I4/m (87), $a = 6.188$ Å and $c = 5.669$ Å]. Fe₈Co₈N₂ exhibits appreciable magnetic properties, $K_1 = 16$ Mergs/cm³, $J_s = 17.6$ kG, and $T_c = 650$ K, which are promising for a wide range of applications including information and energy processing.

4:06PM P70.00009: Topology on a new facet of bismuth*  HSIN LIN (Presenter), Academia Sinica, CHUANG-HAN HSU, National University of Singapore, XIAOTING ZHOU, TAY-RONG CHANG, National Cheng Kung University, QIONG MA, NUH GEDIK, Massachusetts Institute of Technology, ARUN BANSIL, Northeastern University, SUYANG XU, LIANG FU, Massachusetts Institute of Technology — Bismuth-based materials have been instrumental in the development of topological physics, even though bulk bismuth itself has been long thought to be topologically trivial. A recent study has, however, shown that bismuth is in fact a higher-order topological insulator featuring one-dimensional (1D) topological hinge states protected by three-fold rotational and inversion symmetries. In this talk, we uncover another hidden facet of the band topology of bismuth by showing that bismuth is also a first-order topological crystalline insulator protected by a two-fold rotational symmetry. As a result, its (1\(\bar{1}0\)) surface exhibits a pair of gapless Dirac surface states. Remarkably, these surface Dirac cones are unpinned in the sense that they are not restricted to locate at specific \(k\) points in the (1\(\bar{1}0\)) surface Brillouin zone. These unpinned 2D Dirac surface states could be probed directly via various spectroscopic techniques. Our analysis also reveals the presence of a distinct, previously uncharacterized set of 1D topological hinge states protected by the two-fold rotational symmetry. Our study thus provides a comprehensive understanding of the topological band structure of bismuth.

4:18PM P70.00010: The relation between ferromagnetism and structure in half-metallic transition metal oxides*  MOHAMMAD SAGHAYEZHIAN (Presenter), ZHEN WANG, HANGWEN GUO, RONGYING JIN, Louisiana State University, Baton Rouge, YIMEI ZHU, Brookhaven National Lab, JIANDI ZHANG, E WARD PLUMMER, Louisiana State University, Baton Rouge — Interface-driven magnetic properties such as exchange bias and inverted hysteresis are highly sought after in modern functional materials, where at least two magnetically active layers are required. Ability to achieve these functionalities in a single layer thin film (monolithic) reduces the dimensionality while enriching the magnetism. Here we uncover a previously unseen part of the phase diagram of a monolithic epitaxial thin film of \(\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3\) on \(\text{SrTiO}_3\) which exhibits inverted hysteresis, spontaneous magnetic reversal and exchange bias due to a structural gradient in oxygen octahedral network. We have mapped the phase diagram of this material and discovered that at a specific oxygen pressure and above a critical thickness, a complex magnetic behavior appears. Atomic-scale characterization shows that this peculiar magnetism is closely linked to continuous structural gradient that creates three distinct regions within the film, each with a different magnetism onset. Extracting oxygen octahedral geometry by electron microscopy, we found that the Curie temperature is directly correlated with the bond angle. This study illustrates the importance of octahedral geometry in the magnetic properties of the materials.

**4:30PM P70.00011: Anomalous suppression of higher-order nonlinearities in 3D Dirac semimetals**  
JEREMY LIM (Presenter), YEE SIN ANG, LAY KEE ANG, Science and Math cluster, Singapore University of Technology and Design, LIANG JIE WONG, School of Electrical and Electronic Engineering, Nanyang Technological University — Three dimensional Dirac semimetals are often thought to share the same essential physics as 2D Dirac materials. Here, we present a counter-intuitive feature of 3D Dirac semimetals that sets them apart from their 2D counterparts: the absence of field-induced intraband nonlinearities beyond the third order at zero temperature at or near a critical field strength. Our closed-form intraband current expressions show that this effect is robust against changes in incident field polarization and phase, and remains significant at finite temperatures. Our theory is in excellent agreement with nonperturbative numerical simulations of the field-induced electron dynamics. Additionally, we identify regimes where 3D Dirac semimetals effectively function as bulk versions of 2D Dirac semimetals with the potential for superior performance in terms of high-harmonic generation. Our work fills a vital gap in understanding the nonlinear response of bulk Dirac electrons, and paves the way for the development of chip-integrable, nanophotonic devices and optoelectronics based on Dirac materials.

**4:42PM P70.00012: Topological Semimetal in a Chiral Crystal with Large Chern Numbers, Multifold Band Crossings, and Long Fermi-arcs**  
MAIA G VERGNIORY (Presenter), Donostia International Physics Center — Topological semimetals (TSs) in structurally chiral crystals (which possess a handedness due to a lack of mirror and inversion symmetries) are expected to display numerous exotic physical phenomena, such as new fermionic excitations with large topological charge, long Fermi-arc surface states, unusual magnetotransport and lattice dynamics, as well as a quantized response to circularly polarized light. Despite multiple recent photoemission studies of predicted material candidates, this maximal Chern number, measured by counting the number of Fermi-arcs, has not yet been observed experimentally. Using angle-resolved photoelectron spectroscopy and ab-initio calculations, here we show that the chiral topological semimetal candidate PdGa displays the required multifold nodes, which are connected by long surface Fermi-arcs. Due to large spin-orbit coupling and the high crystallinity of our sample surfaces, we are for the first time able to resolve 4 independent Fermi-arcs, proving experimentally that the observed multifold nodes – which are a generic feature of many chiral metals – display the maximal Chern number magnitude of 4.

4:54PM P70.00013: Polar and Phase Domain Walls in Weyl Semimetallic MoTe$_2$: New Paradigm for Topological Interfacial States* FEI-TING HUANG, SEONG JOON LIM, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, SOBHIT SINGH, JINWOONG KIM, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, LUNYONG ZHANG, Laboratory for Pohang Emergent Materials and Max Plank POSTECH Center for Complex Phase Materials, Pohang University of Science and Technology, Pohang 37673, Republic of Korea, JAEOOK KIM, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, M.-W CHU, Center for Condensed Matter Sciences, National Taiwan University, Taipei 106, Taiwan, China, KARIN M RABE, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, SANG-WOOK CHEONG (Presenter), Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — Much of the dramatic growth in research on topological materials has focused on topologically protected surface states. While the domain walls of topological materials such as Weyl semimetals with broken inversion or time-reversal symmetry can provide a new paradigm for exploring topological interfacial states, such investigations have received little attention to date. Utilizing in-situ cryogenic transmission electron microscopy combined with first-principles calculations, we discover intriguing domain-wall structures in MoTe$_2$, both between polar variants of the low-temperature(T) Weyl phase, and between this and the high-T higher-order topological phase. We demonstrate how polar domain walls can be manipulated with electron beams, and show that phase domain walls tend to form superlattice-like structures along the c axis. Scanning tunneling microscopy indicates a possible signature of a conducting hinge state at phase domain walls. Our results open new avenues for investigating topological interfacial states and unveiling multifunctional aspects of domain walls in topological materials.

5:06PM P70.00014: Giant extrinsic anomalous Hall effect in the Kagome, Dirac Antimonide KV$_3$Sb$_5$ YAOJIA WANG (Presenter), Max planck institute of Microstructure physics — The electronic anomalous Hall effect (AHE), where charge carriers acquire a velocity component orthogonal to an applied electric field, is one of the most fundamental and widely studied phenomena in physics. There are several different AHE mechanisms known falling into intrinsic and extrinsic regimes. The skew scattering mechanism (extrinsic) applies to high conductivity materials and has traditionally focused on ferromagnetic metals. Here we report the observation of a giant extrinsic AHE in KV$_3$Sb$_5$, an exfoliable Dirac semimetal with a spin 1/2 Kagome layer of Vanadium atoms. Our exfoliated flake devices reach low resistivity $\sim$1.6 $\mu\Omega$ cm at low temperature and even though KV$_3$Sb$_5$ shows no magnetic ordering down to 0.25 K, the anomalous Hall conductivity (AHC) reaches $\sim$10000 $\Omega^{-1}$cm$^{-1}$ with a skew constant of 0.013, nearly an order of magnitude larger than Fe. Surprisingly, the AHE scales with the square of the longitudinal conductivity, defying expectations from skew scattering theory. This observation invites a wider variety of materials to be investigated for giant anomalous AHE including metallic magnetically frustrated materials and cluster magnets as well as posing new fundamental questions about high conductivity AHE mechanisms.
Quantum squeezing and coherence of magnons detected by spin transport

WOLFGANG BELZIG (Presenter), Univ Konstanz, AKASHDEEP KAMRA, Department of Physics, NTNU, QuSpin — We predict the emergence of novel magnetic quasiparticles, mediated by magnetic dipolar interactions, even for a uniform ground states. These quasiparticles exhibit a spin ranging from zero to above 1 [1]. Of particular interest is our finding that the eigenmodes in an easy-axis antiferromagnet are spin-zero quasiparticles instead of the widely believed spin-1 magnons [2]. These unusual properties originate from a competition between quantum mechanical squeezing (increasing the spin) and hybridization (decreasing the spin). We show that spin-current noise measurement can reveal this fundamental quantum phenomenon [1] in full analogy to the effective charge known from shot noise measurements. Antiferromagnetic magnons are shown to exhibit giant antanglement, which might be used as quantum battery [3]. Finally, we show that by adding two normal metal spin current detectors, the magnon coherence can be tested by measuring the cross correlations [4] in analogy to the well-known second-order coherence.

Session Q35 APS: Staged Reading of the Play: Einstein's Wife Hyatt Centennial
FG - Tag(s): Outreach, Undergrad Friendly

8:00PM Q35.00001: Staged Reading of the Play: Einstein's Wife [Invited] — Sponsored by the Forum on the History of Physics
This new play Einstein’s Wife by the playwright scientist-historian David C. Cassidy is based on the true story of the courtship, marriage, and ultimately separation of Albert Einstein and his first wife Mileva Maric. Mileva confronts the challenges of disability and discrimination, love, fate, and marriage to Albert Einstein.
In the late 1800s, Mileva Maric, a young Serbian woman facing the exclusion of women from higher education in much of Europe, travels to Zurich, Switzerland where she meets another first-year physics student, Albert Einstein. Mileva and Albert soon fall in love and eventually marry, a romance and marriage spanning Albert’s ascent to the top of his profession by the eve of World War I. But fate is unkind to Mileva, challenging her love and career and bringing upon the lovers both triumph and tragedy. Based on actual events, letters, and poems. The play Einstein’s Wife was written and developed by David C. Cassidy in collaboration with Break A Leg Productions, NY and its artistic director, Teri Black. The play director is Susan Lyles, Artistic Director and Founder of the And Toto too Theatre Company. Some of the play’s actors as well the playwright will be available for a talkback discussion after the play reading.
Produced by Brian Schwartz, CUNY and Smitha Vishveshwara, University of Illinois, Urbana-Champaign. Co-Sponsored by: the Forum on Outreach and Engaging the Public, the Forum on Physics and Society, the Forum on Education, the Topical Group on Physics Education Research, the Committee on the Status of Women in Physics, the Division of Materials Physics, and the Division of Condensed Matter Physics.

8:00AM R01.00001: Non-Hermitian topological photonics and light steering* [Invited] LIANG FENG (Presenter), HAN ZHAO, XINGDU QIAO, TIANWEI WU, BIKASHKALI MIDYA, University of Pennsylvania, STEFANO LONGHI, Physics, Politecnico di Milano — Photonic topological insulators provide a route for disorder-immune light transport, which holds promise for practical applications. Flexible reconfiguration of topological light pathways can enable high-density photonics routing, thus sustaining the growing demand for data capacity. By strategically interfacing non-Hermitian and topological physics, we demonstrate arbitrary, robust light steering in reconfigurable non-Hermitian junctions, in which chiral topological states can propagate at an interface of the gain and loss domains. Our non-Hermitian–controlled topological state can enable the dynamic control of robust transmission links of light inside the bulk, fully using the entire footprint of a photonic topological insulator.

8:36AM R01.00002: Floquet engineering with resonant drive and Application to symmetry-protected topological phases  KAORU MIZUTA (Presenter), Kyoto University, KAZUAKI TAKASAN, University of California, Berkeley, NORIO KAWAKAMI, Kyoto University — Recently periodically driven (Floquet) systems have attracted much interested, and Floquet engineering, control of phases by a periodic drive, is one of the most vigorous fields in Floquet systems. However, in conventional Floquet engineering, only high-frequency drives (=drives whose energy scale is much smaller than the frequency) are mainly utilized since it is based on high-frequency expansion theory, only applicable to Floquet systems under high-frequency drives. Therefore, we extend the conventional high-frequency expansion theory to the cases in the presence of resonant drives (= drives whose local energy scale is comparable to the frequency) and propose a new scheme of Floquet engineering done by high-frequency and resonant drives [1]. We clarify that the effective Hamiltonian describing long-time dynamics acquires an emergent $Z_N$ symmetry, and hence our scheme enables us to simultaneously control phases and add a symmetry to the system. With our Floquet engineering, we also propose a way to realize/control topological phases protected by a $Z_2 \times Z_2$ symmetry only in the presence of a $Z_2$ symmetry [2].

[References]
In my talk I will present a definition of topological invariants for driven dissipative lattices that relies on the singular value decomposition of non-Hermitian coupling matrices, $H$, or, equivalently, on the eigenstates of an effective Hamiltonian, $H_{\text{eff}} = \sigma^+ H + H^\dagger \sigma^-$. I will show that topological non-trivial phases of $H_{\text{eff}}$ correspond to steady-states in which the driven dissipative lattice behaves as a directional amplifier. Thus, our work leads to a connection between topological band theory and amplification in photonic lattices, which also leads to a physically motivated classification of topological phases non-Hermitian lattices. I will briefly sketch an implementation of our ideas with periodically driven superconducting circuits.

*I acknowledge support from Spanish project PGC2018-094792-B-100 (MCIU/AEI/FEDER, EU)
Quantum quench is nonequilibrium dynamics and its interplay with band topology gives rise to intriguing dynamical topological phenomena. We introduce the concept of loop unitary

\[ U_l \]

and its homotopy invariant

\[ W_3 \]

to fully characterize the quench dynamics of arbitrary two-band insulators in two dimensions, going beyond existing scheme based on Hopf invariant which is only valid for trivial initial states. The theory traces the origin of nontrivial dynamical topology to the emergence of

\[ \pi \]

-defects in the phase band of

\[ U_l \]

, and establishes that

\[ W_3 = C_f - C_i \]

, i.e. the Chern number change across the quench. We further show that the dynamical singularity is also encoded in the winding of the eigenvectors of

\[ U_l \]

along a lower dimensional curve where dynamical quantum phase transition occurs, if the pre- or post-quench Hamiltonian is trivial. The winding along this curve is related to the Hopf link, and shown to give rise to torus links and knots for quench to Hamiltonians with Dirac points. Our framework which can be generalized to multiband systems and other dimensions paves the way to study quench dynamics and its associated topology.

9:12AM R01.00005: Quantum many-body scars from virtual entangled pairs*  SAMBUDDHA CHATTOPADHYAY (Presenter), Harvard University, HANNES PICHLER, California Institute of Technology, MIKHAIL LUKIN, WEN WEI HO, Harvard University — We study weak ergodicity breaking in a one-dimensional, non-integrable spin-1 XY model. We construct for it an exact highly excited eigenstate, which despite having a non-zero energy density, can be represented analytically by a finite bond-dimension matrix product state (MPS) with area-law entanglement. Upon a quench to a finite Zeeman field, the state undergoes periodic dynamics with perfect many-body revivals, in stark contrast to other generic initial states which instead rapidly thermalize. Remarkably, we find that the dynamics can be completely understood in terms of the evolution of entangled virtual spin-1/2 degrees of freedom, which in turn underpin the presence of an O(L) tower of strong-eigenstate thermalization hypothesis (ETH)-violating many-body eigenstates: quantum many-body scars. The scars we find are therefore of novel origin, and we provide insight into their nature and entanglement structure.

9:24AM R01.00006: Haldane Phase in Spin-1 Bose-Hubbard Model with Flat Band*  HONG YANG (Presenter), HAYATE NAKANO, HOSHO KATSURA, Univ of Tokyo — The Haldane phase has been widely discussed in spin chains. A famous rigorous example is the AKLT model. However, in itinerant spin systems which have both unfrozen spin and charge degrees of freedom, the Haldane phase has been rarely investigated, to say nothing of any rigorous results. Here we study the spin-1 Bose-Hubbard model on a sawtooth lattice with flat band. At half-unit filling with fine-tuned interaction strength, we prove that the ground state can be exactly written down in the form of a matrix product state (MPS) similar to that of the AKLT model. The ground state correlation lengths, edge states, string order parameters, etc. are analytically given for both spin and charge degrees of freedom. The entanglement spectrum also analytically shows perfect two-fold degeneracy. Moreover, with general interaction strength, when a parameter (related to hopping and on-site potential of the lattice) is sufficiently large, perturbation theory yields the spin-1 bilinear-biquadratic model as the effective spin model, which can be either symmetry-protected-topological (Haldane) or trivial, depending on the interaction strength.

Detecting fractional Chern insulators in optical lattices through quantized displacement

ILYOUN NA (Presenter), Physics, University of California, Berkeley, JOHANNES MOTRUK, Lawrence Berkeley National Laboratory — The realization of interacting topological states of matter such as fractional Chern insulators (FCIs) in optical lattices with synthetic gauge fields has recently come within experimental reach. However, detecting their occurrence might prove difficult since transport measurements akin to those in solid state systems are challenging to perform in cold atom setups and alternatives have to be found. We consider a $\nu = 1/2$ FCI state realized in the lowest band of a Harper-Hofstadter model of hardcore bosons in a harmonic trapping potential. We demonstrate the stability of the topological state for a wide range of confining strengths by density matrix renormalization group simulations. Using matrix-product state algorithms, we study the time evolution when applying an effective electric field for the particles on top of the harmonic confinement. The movement of the particle cloud allows an accurate determination of the fractionally quantized Hall conductivity which provides an experimentally measurable signal to detect the topological nature of the state. Below a critical field strength, the particle displacement shows oscillations around the quantized value which abate as the field strength decreases.

Robustness of quantum scarred states to the presence of disorder and external drives

IAN MONDRAGON-SHEM (Presenter), Argonne National Laboratory, MAXIM G VAVILOV, Department of Physics, University of Wisconsin - Madison, IVAR MARTIN, Argonne National Laboratory — Recent experiments in Rydberg atom quantum simulators have found unexpected coherent and persistent oscillations in an ergodic system at infinite temperature. The origin of such oscillations has been explained in terms of quantum scarred states that are embedded in an ergodic spectrum. We examine the robustness of such quantum scarred states to the presence of inhomogeneous potentials as well as the action of external drives. We focus on models that exhibit approximate SU(2) symmetries, such as the PXP model, and explore conditions under which the dynamics of the system remains non-ergodic. To do this, we evaluate diagnostic quantities such as the revival probability, the spatial entanglement, and the average spin dynamics. Finally, we discuss similarities with the disordered Heisenberg spin chain in a regime in which anomalous non-ergodic dynamics can also be obtained.
10:00AM R01.00009: Topological effects in interacting Su-Schrieffer-Heeger chains  HELENA DRUEEKE (Presenter), DIETER BAUER, University of Rostock, Germany — The Su-Schrieffer-Heeger (SSH) model [1] describes a linear chain with two distinct topological phases. We investigate the behavior of two interacting particles in this one-dimensional system by simulating the equivalent system of a single particle in a two-dimensional system. Even though the two particles repel each other, doublon states, where both particles are on the same lattice site, are possible. By performing time-dependent simulations, we investigate transitions between the two topological phases of the two-dimensional SSH-like system. We focus on the doublon and surface states and the relation between them.

Optical waveguides are a possible experimental realization of such two-dimensional systems [2]. Realizing energetically separated surface and doublon states would allow the routing of light along specific paths within a bundle of waveguides. This could lead to increased bandwidth for fiber-optic communications.

10:12AM R01.00010: Topological photonic resonator for chiral quantum optics*  SABYASACHI BARIK (Presenter), AZIZ KARASAHIN, SUNIL MITTAL, EDO WAKS, MOHAMMAD HAFEZI, University of Maryland, College Park — Topological photonics has enabled unprecedented applications in the field of optics. The resulting topological structures exhibit chiral edge states that are robust to disorder and sharp bends. By coupling these photonic states to quantum emitters, one can generate directional light emission. Even though the previous works have investigated directional light emission in one-dimensional edge states, the extension of this concept to resonator structures has remained elusive. Here we demonstrate chiral light-matter interactions in a topological resonator. We use valley-Hall topological edge states to realize a helical resonator. Such a helical resonator is created at the interface of two distinct topological regions that supports two counter-propagating light modes with opposite polarizations. We show the chiral coupling of the resonator to a quantum emitter. Moreover, we achieve an intensity enhancement of 3.4 due to resonant coupling. Such robust resonators could provide a platform for studying novel many-body dynamics and designing complex nano-photonic circuits.

R01.00011: Effective field theories at the edges of topological insulators  MANUEL VALIENTE (Presenter), XIN CHEN, Tsinghua University — We consider interacting two-dimensional time reversal invariant topological insulators with time reversal preserving (non-magnetic) disorder near their edges. These systems are known to fail to exhibit quantized spin currents even when the fermion-fermion interactions are weak, as was recently shown within Hartree-Fock theory (Novelli et al., Phys. Rev. Lett. 122, 016601). Here, we investigate the microscopic origin of the lack of quantization by considering the most relevant few-body processes at the edges of the system, and find that fermion-impurity resonances are responsible for backscattering. We build two different effective field theories for the interacting edge modes in the system near the Fermi energy that eliminate the bulk in two different ways: 1) by keeping the inhomogeneity explicitly and 2) by accounting for the width of the resonance in the dispersion relations.

10:24AM R01.00012: Dynamical Quantum Phase Transitions in U(1) Quantum Link Models in (1+1)d and (2+1)d*  YI-PING HUANG (Presenter), DEBASISH BANERJEE, MARKUS HEYL, the Max Planck Institute for the Physics of Complex Systems — Quantum link models (QLMs) are extensions of Wilson-type lattice gauge theories which realize exact gauge invariance with finite-dimensional Hilbert spaces. QLMs not only reproduce standard features of Wilson lattice gauge theories in equilibrium, but can also host new phenomena such as crystalline confined phases. The local constraints due to gauge invariance also provide kinetic restrictions that can influence substantially the real-time dynamics in these systems. We aim to characterize the nonequilibrium evolution in lattice gauge theories through the lens of dynamical quantum phase transitions, which provide general principles for real-time dynamics in quantum many-body systems. Specifically, we study quantum quenches for two representative cases, U(1) QLMs in (1+1)D and (2+1)D, for initial conditions exhibiting long-range order. Finally, we discuss the connection to the high-energy perspective and the experimental feasibility to observe the discussed phenomena in recent quantum simulator settings such as trapped ions, ultracold atoms, and Rydberg atoms.

**8:00AM R02.00001: Experimental and numerical studies on phase change under dynamic loadings: application to Tin.** [Invited] CAMILLE CHAUVIN (Presenter), Commissariat à l'énergie atomique et aux énergies alternatives — Polymorphic (structural) phase transformations of metals under dynamic high pressures is an area of fundamental scientific research at CEA which are studied through both experimental and theoretical/computational means. Experiments have long suggested that non-equilibrium behavior (kinetics) is an important part of the dynamic compression response of materials undergoing phase transformations. Both this deeper understanding, and quantitative data on specific metals, are needed to improve material models used in state-of-the-art hydrocodes. Only in recent years have experimental capabilities advanced sufficiently enough, in terms of diagnostics as well as drivers, that kinetics effects in dynamic phase transformations can begin to be quantified in a more rigorous manner. Empirical kinetic models can in a lot of cases reproduce the experimental velocity profiles but without clearly identifying the nature of the transition.

At CEA, we have developed preheating devices for gas gun and for HPP driver a promising testing on x-ray diffraction under shock. We propose to present our preliminary results to explore the phase diagram of Tin and how these experimental data help to understand kinetic models and EOS.

**8:36AM R02.00002: Unusual strength in tin under dynamic compression**

CAMELIA STAN (Presenter), ALEX ZYLSTRA, Lawrence Livermore Natl Lab, MATTHEW P HILL, Atomic Weapons Establishment, TOM LOCKARD, HYE-SOOK PARK, PHILIP POWELL, DAMIAN C SWIFT, JAMES M MCNANEY, Lawrence Livermore Natl Lab — Tin is a soft metal that undergoes several phase transitions at high pressure and temperature (1). These structural changes should lead to significant changes in both material microstructure and physical properties upon compression. Here, we use the Rayleigh-Taylor instability to measure its strength within the high-pressure BCC phase. A pre-machined rippled pattern seeds the instability, wherein a low density fluid pushing against a high density fluid causes growth of surface perturbations. We use a CH layer as the low density material, and the “push” is provided by the Omega EP laser facility, University of Rochester, which generates a ramped compression drive of ~1.5 Mbar in the sample. Ripple growth is measured using face-on radiography, and strength is interpreted based on the rate of growth relative to the undriven portion of the sample. We find that the growth rate is much less than that predicted in hydrodynamic simulations using a Steinberg-Guinan model. This suggests that BCC tin has unusually high strength, interpreted here as a resistance to plastic deformation. Lazicki, A et al. Phys. Rev. Lett. 115, (2015).

8:48AM R02.00003: Coupled Experiment and Theory to Explore the Limits of Material Strength at High Strain Rates  MITCHELL WOOD (Presenter), JAMES STEWART, JOSEPH D OLLES, Sandia National Laboratories — Experiments to study materials at high pressure are challenging and time consumptive, therefore we turn to modeling tools to refine and predict outcomes beforehand. Efficient models balance absolute physical accuracy against approximate but computationally lightweight constitutive inputs. By using a relatively small number of high fidelity simulations we have be able to broaden the predictive power of the shock response in metals and polymers. Analysis of these simulations has produced parameterizations of material strength, which can be used as constitutive inputs for continuum hydrodynamics codes. For shocked Cu, MD simulations show a yield strength from Richmyer-Meshkov Instability(RMI) jet growth of approximately 450MPa that depends on the details of the free surface geometry. This value is close to the yield strength of 500MPa parameterized from experiments at the Dynamic Compression Sector at Argonne National Lab. The same analysis applied to MD simulations of PMMA jetting resulted in no clear determination of yield strength, implying a more complex RMI process in polymeric materials. Simulations of both materials demonstrate the need for explicit strain rate dependence for future improvements in strength models used in continuum codes.

9:00AM R02.00004: Dynamic Strength in Polymers  JENNIFER JORDAN (Presenter), RACHEL HUBER, DANA DATTELBAUM, Los Alamos National Laboratory, DANIEL T. CASEM, CCDC Army Research Laboratory — Dynamic strength in polymers has been related to the underlying polymer structure in studies by Bourne, Millett, and co-workers. However, the majority of this work focused on changing the polymer chemistry. In this study, the effect of polymer structure, e.g. crystallinity, on dynamic polymer strength is investigated. The current understanding of polymer strength will be reviewed and recent results will be presented.

9:12AM R02.00005: Rayleigh-Taylor strength experiments in the high pressure and high strain rate regime on NIF*  HYE-SOOK PARK (Presenter), NATHAN R BARTON, ANDREW KRYGIER, BRUCE ALLEN REMINGTON, ROBERT E RUDD, PHILIP POWELL, SHON T. PRISBREY, DAMIAN C SWIFT, CHRISTOPHER WEHRENBERG, ALEX ZYLSTRA, JAMES M MCNANEY, Lawrence Livermore Natl Lab, MATTHEW P HILL, AWE — A solid material can be placed in the high energy density regime by compressing it to pressures >1 Mbar using a laser driven plasma piston drive. We create a ramped laser drive that keeps the material in the solid state during compression without shock melting. Understanding plastic deformation dynamics of materials under these extreme conditions is of high interest to a number of fields, including meteor impact dynamics and advanced inertial confinement fusion. We infer the strength of Ta, Pb [1,2] and Fe at high pressures (upto 8 Mbar), high strain rates (~10⁷ s⁻¹) and high strains (> 30%) by measuring the growth of Rayleigh-Taylor instabilities (RTI) under ramped compression. We find that the RTI growth for materials in the solid state, compressed under high pressure and high strain rates, is reduced compared to the no-strength case. We will describe the experimental results from NIF and compare them to various strength models.

9:24AM R02.00006: Experimental studies of material strength in the high energy density regime*  PHILIP POWELL (Presenter), ANDREW KRYGIER, HYE-SOOK PARK, NATHAN R BARTON, CHANNING M HUNTINGTON, BRUCE ALLEN REMINGTON, ROBERT RUDD, SHON T. PRISBREY, DAMIAN SWIFT, CHRISTOPHER WEHRENBERG, ALEX ZYLSTRA, JAMES M MCNANEY, Lawrence Livermore Natl Lab — A solid material can be placed in the high energy density regime by compressing it to pressures > 1 Mbar using a laser driven plasma piston drive. We create a ramped laser drive that avoids shock melting, maintaining the material in the solid state during the full compression. Understanding plastic deformation dynamics of materials under these extreme conditions is of great interest in a number of fields, including meteor impact dynamics and advanced inertial confinement fusion. We infer the strength of Ta, Pb [1,2] and Fe at high pressures (up to 8 Mbar), high strain rates (~10^7 s^{-1}) and high strains (> 30%) by measuring the growth of Rayleigh-Taylor instabilities (RTI) under ramped compression. We find that the RTI growth for materials in the solid state, compressed under high pressure and high strain rates, is reduced compared to the no-strength case. We describe recent experimental results from NIF and compare them to various strength models. [1] H. -S. Park et al., Phys. Rev. Lett. 114, 065502 (2015). [2] A. Krygier et al., Phys. Rev. Lett., accepted (2019).

9:36AM R02.00007: Influence of Defects on the Shock Hugoniot of Tantalum*  SARYU FENSIN (Presenter), Los Alamos Natl Lab, ERIC N HAHN, University of California, San Diego — Using molecular dynamics simulations, we investigate the effect of vacancies and dislocations on the dynamic response of single crystal tantalum to shock loading. A Hugoniostat technique is employed, for which a series of states along the Hugoniot are sampled by many individual simulations. We show that defects have a limited effect on the shock/particle velocity relationship and that the shock pressure/volume relationship can be well predicted by taking into account the changes in the initial density and sound speeds of the samples. The principal effect of initial defects is the activation of heterogeneous dislocation nucleation and expedited dislocation multiplication during shock. The heat generated by plastic work, caused by defects moving through the lattice, is substantial. The result is significantly divergent final shock temperatures for different initial defect concentrations and pronounced changes in the resultant shock melting temperatures. The motion of dislocations also leaves behind a inconsequential concentration of vacancies that is quantified.

* Molecular dynamics simulations utilized resources were provided by the LANL Institutional Computing Program and funding was provided by Science Campaign 1.
9:48AM R02.00008: Experiments studying the flow strength of tantalum up to 30 GPa
FRANK CHERNE (Presenter), MATTHEW HUDSPETH, MICHAEL PRIME, BRIAN JENSEN, Los Alamos National Laboratory — In the recent years, there has been a number of experiments performed looking at different platforms or techniques to probe the strength of tantalum. The focus of this research has been to apply a shock/double shock drive conditions to determine the flow strength in tantalum up to about 30 GPa. The elastic/plastic response of tantalum and its interaction with typical lower impedance window materials complicates the design of these experiments. In this work, we present the results where we applied the shock/reloading technique to determine the flow strength of tantalum at initial loading stress states up to 30 GPa. Simulations with and without a PTW strength model are also compared to the experimental data.

10:00AM R02.00009: Simulating Tantalum Strength Measurements on the National Ignition Facility, Z-Machine, and Gas Gun Platforms* CORBETT BATTAILE (Presenter), Sandia National Laboratories, NATHAN R BARTON, Lawrence Livermore National Laboratory, JUSTIN BROWN, MATTHEW D LANE, HOJUN LIM, Sandia National Laboratories, PHILIP POWELL, Lawrence Livermore National Laboratory, MICHAEL PRIME, Los Alamos National Laboratory — The yield strengths of body-centered-cubic refractory metals (e.g. molybdenum, niobium, tantalum, and tungsten) can depend strongly on temperature, pressure, and strain rate. A variety of constitutive models have been proposed to describe these effects, but most are calibrated and/or validated in specific regimes of interest. In this work we used three recently-developed strength models, namely the Livermore Multiscale Model, the Preston-Tonks-Wallace model, and the Kink Pair model, to describe the response of tantalum subjected to elevated temperatures, pressures, and strain rates. We applied these models to predict strength measurements from Lawrence Livermore's National Ignition Facility, Los Alamos' gas gun facilities, and Sandia's Z-Machine, in order to explore a wide range of loading regimes. In this presentation we will outline each approach, and discuss validation results for the models' predictions of the strength of tantalum across a wide range of temperatures, pressures, and strain rates on these high-energy-density platforms.

*Sandia is managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a subsidiary of Honeywell International, for the US DOE's NNSA under contract DE-NA-0003525.
10:12AM R02.00010: Nonisentropic Release of a Shocked Solid  PATRICK HEIGHWAY (Presenter), MARCIN SLIWA, DAVID R MCGONEGLE, University of Oxford, CHRISTOPHER WEHRENBERG, Lawrence Livermore National Laboratory, CYNTHIA BOLME, Los Alamos National Laboratory, JON HENRY EGGERT, Lawrence Livermore National Laboratory, ANDREW HIGGINBOTHAM, York Plasma Institute, AMY E LAZICKI, Lawrence Livermore National Laboratory, HAEJA LEE, BOB NAGLER, SLAC National Accelerator Laboratory, HYE-SOOK PARK, ROBERT RUDD, RAYMOND SMITH, Lawrence Livermore National Laboratory, MATTHEW SUGGIT, University of Oxford, DAMIAN SWIFT, Lawrence Livermore National Laboratory, FRANZ TAVELLA, SLAC National Accelerator Laboratory, BRUCE ALLEN REMINGTON, Lawrence Livermore National Laboratory, JUSTIN STEPHEN WARK, University of Oxford — Shock release is the fundamental process that takes place when a material at high pressure undergoes rapid decompression. It is commonly accepted that rarefaction of this sort takes place isentropically, and is thus attended by substantial cooling due to the thermoelastic effect. However, this treatment fails to account for the fact that rapidly releasing material within the first few microns of the free surface typically exhibits material strength of order gigapascals, and therefore suffers copious plastic-work heating. Moreover, an isentropic treatment of release neglects the energy that can be recovered via the annihilation of crystal defects that ensues during rarefaction. Here, we present molecular dynamics simulations of shock and release in micron-scale tantalum crystals that exhibit release temperatures far exceeding those expected under the standard assumption of isentropic release. We show via an energy-budget analysis that this is due primarily to heating from material strength that largely counters thermoelastic cooling. The simulations are corroborated by experiments where the release temperatures of laser-shocked tantalum foils are deduced from their thermal strains via femtosecond x-ray diffraction, and are found to be close to those behind the shock itself.

10:24AM R02.00011: A model for twinning and plasticity in tantalum under shock conditions  NICOLAS BRUZY (Presenter), AURÉLIEN VATTRÉ, CHRISTOPHE DENOUAL, CEA de Bruyeres-le-Chatel — During deformation of tantalum at high strain rates, a competition takes place between plastic slip and twinning. The higher the strain rate, the harder it is to activate slip systems and twinning becomes predominant. In view of investigating this transition, a phase field model for phase changes including crystal plasticity, written in the finite strain format, is derived. It relies on the Reaction Pathway formalism, which is tailored for dynamic loadings since elastic and inelastic effects are properly split. First, all accessible variants are identified using point group symmetries of the parent phase. In the case of tantalum, two levels of transformation are considered (with 1+36 accessible variants in total), which makes it possible to reproduce secondary twinning. Then, the variants are taken as local minima of an energy landscape from which transformational energy and kinetic relations are obtained. A crystal plasticity model is further embedded at each variant to run polyphase plastic computations. Shock simulations on tantalum bars are performed using a 3D total Lagrangian code with an element-free Galerkin least-squares formulation. Results in terms of both variants repartition and plastic activity are consistent with past experimental works.
10:36AM R02.00012: Study of Hugoniot Elastic Limit in Tantalum single crystal using elastic precursor decay at normal and elevated temperature: Molecular Dynamics study
ANURADHA SINGLA (Presenter), ADITI RAY, Bhabha Atomic Res Ctr — Crystalline solids subjected to extremely high strain rates, as happens in shock wave propagation, is an important branch of material science. Knowledge of HEL is of fundamental importance in shock wave studies. Among BCC metals, Ta has several technological advantages due to its excellent mechanical property and thermodynamic phase stability at extreme conditions. This makes it useful in designing high impedance flyers for equation of state studies.

MD simulation of Ta has been performed in an effort to study formation of two-wave structure and its attenuation over distance. This leads to determination of HEL as a function of peak stress and sample thickness in two principle orientations. The work is mainly focused on studying decay of elastic precursor with advancement of shock along sample at normal and elevated temperature. The precursor decay for sub-micron sized sample has been modeled with empirical fitting relation. The fit predicts experimental result and other MD results for above-micron sized sample. This indicates that computationally intensive simulation for longer lengths can be avoided. Also, strong crystal anisotropy effect has been observed in onset of elastic-plastic wave.

R02.00013: Anisotropic shock response of single-crystalline β-phase tin* ROBERT SCHARFF (Presenter), NMO, Nevada National Security Site — Mesoscale simulations of the dynamic response of polycrystalline metals to shockwave compression can provide unique insight into the nature of the various physical mechanisms responsible for material failure. This approach requires a constitutive description for individual grains and boundaries, including defects such as dislocations, within an explicit representation of the microstructure geometry and evolving deformation fields. Computational models of the single-crystal constituents cannot be unambiguously constrained by traditional measurements of the shock or stress-strain response of polycrystalline metals. Instead, these models require comprehensive measurements of the anisotropic shock response of single crystals for their calibration and validation. We present a coordinated experimental and simulation campaign on the shock response of single-crystalline β-phase tin demonstrating a remarkable anisotropic elastic-plastic response of the metal.

*This work was done by Mission Support and Test Services LLC, under Contract No. DE-NA0003624 with the U.S. Department of Energy, and supported by the Site-Directed Research and Development Program. DOE/NV/03624—0391.
8:00AM R07.00001: Optimal approximate quantum error correction for quantum metrology*  SISI ZHOU (Presenter), Physics, Yale University, LIANG JIANG, Pritzker school of molecular engineering, University of Chicago — For a generic set of Markovian noise models, the estimation precision of a parameter associated with the Hamiltonian is limited by the $1/\sqrt{t}$ scaling where $t$ is the total probing time, in which case the maximal possible quantum improvement in the asymptotic limit of large $t$ is restricted to a constant factor. However, situations arise where the constant factor improvement could be significant, yet no effective quantum strategies are known. Here we propose an optimal approximate quantum error correction (AQEC) strategy asymptotically saturating the precision lower bound in the most general adaptive parameter estimation scheme where arbitrary and frequent quantum controls are allowed. We also provide an efficient numerical algorithm finding the optimal code. Finally, we consider highly-biased noise and show that using the optimal AQEC strategy, strong noises are fully corrected, while the estimation precision depends only on the strength of weak noises in the limiting case.

8:12AM R07.00002: Multi-parameter metrology with the Holevo Cramer Rao bound; an explicit 2-qubit 3-parameter bound*  JAMIE FRIEL (Presenter), FRANCESCO ALBARELLI, ANIMESH DATTA, Univ of Warwick — Quantum metrology is essential for the rigorous analysis and optimisation of all quantum-limited experiments. Since no experiment is ever truly a single parameter one what is required is multi-parameter quantum metrology. It invokes the central axiom of quantum mechanics, that of incompatible observables. Hitherto, SLD quantum Fisher information matrix (QFIM) has largely been the Cramer-Rao bound of choice for examining multi-parameter metrology. In this work we show that the QFIM is an inadequate metric for multi-parameter problems. Further, we show that the Holevo Cramer-Rao (HCRB) bound is not only easier to calculate both numerically and analytically than previous thought but it is also essential for multi-parameter problems.

We point out new insights obtained from evaluating the HCRB for much larger Hilbert spaces than before, enabled by the convexity of the problem. We also show that previously known techniques allow us to calculate an explicit bound for 3D-magnetometry with 2 qubits, which again leads to new insight and further emphasises the pitfalls of the QFIM.

*Centre for Doctoral Training in Diamond Science and Technology, EP/L015315/1
8:24AM R07.00003: Parametrically-enhanced quantum sensing with effective non-Hermitian lattice dynamics  ALEXANDER MCDONALD (Presenter), AASHISH CLERK, University of Chicago — Systems whose dynamics are described by a non-Hermitian effective Hamiltonian have been suggested as platforms for improved sensing. Several experiments have already demonstrated the utility of exceptional points, a uniquely non-Hermitian feature, in setups consisting of a few resonant modes [1-3]. The phenomena exhibited by coupled multi-mode non-Hermitian systems, such as the non-Hermitian skin effect [4] and the existence of abnormally large susceptibilities, are also promising sensing resources. Here, we show how to harness the unusual lattice physics to build quantum sensing platforms with remarkable properties. In particular, the quantum Fisher information of our measurement scheme grows exponentially with system size, even when bounding the number of photons used for the measurement. This is achieved without coupling to dissipative baths or postselection. Our setup is realizable in a number of experimental platforms, including superconducting quantum circuits and quantum optical setups.

8:36AM R07.00004: Metrology near exceptional points from superconducting circuits with loss*  PATRICK HARRINGTON (Presenter), MARYAM ABBASI, Washington University, St. Louis, YOGESH JOGLEKAR, Indiana University - Purdue University Indianapolis, KATER MURCH, Washington University, St. Louis — The underlying mechanism of sensors, amplifiers, and metrological devices is a strong response to small perturbations. Such strong responses are expected for classical systems governed by non-Hermitian Hamiltonians. We use post-selection to create an effective non-Hermitian Hamiltonian for a superconducting quantum circuit and measure the sensitivity of the circuit to a coherent drive for different system parameters. We find that the quantum Fisher information about the drive amplitude diverges at the exceptional point, indicating enhanced sensitivity. However, enhanced sensitivity is achieved at the cost of additional experimental data due to post-selection statistics. With this experiment, we highlight the interplay of dissipation, dephasing, and loss near exceptional points of non-Hermitian open quantum systems and, we observe the role of quantum measurement backaction for quantum sensing.

8:48AM R07.00005: Macroscopic Quantum Tunneling Devices for Nanoscale Attonewton Force Sensing  
BENJAMIN SAFVATI (Presenter), YI-TING CHEN, MORGAN BRUBAKER, HARI C. MANOHARAN, Stanford Univ — The precision enabled by ultra-high vacuum, low temperature scanning tunneling microscopy for atomic manipulation has allowed the design of nanostructures that exhibit quantifiable quantum dynamics. This work presents a novel nanoscale probe of atomic-scale forces and enables new detection methods of the energy landscape in a Fermi gas. In a two-dimensional electron gas, the geometry of the boundaries on the surface will produce uniquely non-local alterations in the electronic wave function. By creating a device in which a single atom or molecule can macroscopically tunnel between degenerate states in a double potential well, we are able to detect quantum forces that break the degeneracy by measuring an asymmetry in the tunneling rates between each side. Our new method of two-dimensional nanoscale force measurement is able to detect forces with attonewton sensitivity, and the device's design permits the probing of quantum forces due to proximal nanostructures with atomic resolution. Designer boundary conditions can amplify the measured forces and further illustrate the non-local nature of quantum force fields. We will discuss ways to extend device sensitivity even further, below the attonewton level.

9:00AM R07.00006: Dissipation-based quantum sensing of magnons*  
SAMUEL WOLSKI (Presenter), DANY LACHANCE-QUIRION, YUTAKA TABUCHI, Research Center for Advanced Science and Technology, The University of Tokyo, SHINGO KONO, Center for Emergent Matter Science, RIKEN, KOJI USAMI, YASUNOBU NAKAMURA, Research Center for Advanced Science and Technology, The University of Tokyo — Magnons are the quanta of collective spin excitations. We introduce a novel technique for quantum sensing of magnons by leveraging the quantum coherence of a superconducting qubit which interacts with a magnetostatic mode. This is enabled by the realization of a strong dispersive coupling between the uniformly precessing magnetostatic mode in a ferromagnetic sphere and a superconducting qubit in a hybrid system [1,2]. A finite magnon population induces additional dephasing in the qubit, and can thus be inferred by probing the qubit coherence via Ramsey interferometry. A magnon detection sensitivity of around $10^{-3}$ magnons/√Hz is demonstrated, in good agreement with numerical simulations. The dissipation-based nature of our quantum sensor is confirmed by the dependence of the sensitivity on the detuning used in the Ramsey interferometry. The use of quantum sensing techniques in magnonics could find applications in fields such as magnon spintronics and magnetic field sensing.

9:12AM R07.00007: Quantum sensing with superconducting microwave circuits*  
MATTI PARTANEN (Presenter), KIRILL FEDOROV, STEFAN POGORZALEK, MICHAEL RENGER, QI-MING CHEN, ACHIM MARX, FRANK DEPPE, RUDOLF O GROSS, Walther-Meissner-Institut, Munich, Germany — Quantum mechanics offers intriguing opportunities for sensing applications with accuracies beyond the classically obtainable limits. An especially interesting approach is based on using entangled microwave photons for radar applications [Las Heras et al., Sci. Rep., 7, 9333 (2017)]. Here, we discuss a novel frequency-degenerate scheme for quantum sensing with superconducting microwave circuits. Our method is based on continuous variables that provide a convenient platform for quantum communication [Pogorzalek et al., Nat. Commun., 10, 2604 (2019)]. The same microwave regime is utilized in conventional radars owing to the transparency window of the atmosphere. Hence, our scheme suffers no conversion losses and, therefore, is promising for future real-world applications.

9:24AM R07.00008: Quantum-Enhanced Noise Radar  
NIZAR MESSAoudi (Presenter), CHUNG WAI SANDBO Chang, A.M. Vadiraj, Insitute of Quantum Computingan Electrical and Computer Engineering, University of Waterloo, JEROME BOURASSA, Istitut Quantique, Universite de Sherbrooke, BHASYAM BALAJI, Radar Sensing and Exploitation Section, Defence R&D Canada, C.M. WILSON, Insitute of Quantum Computingan Electrical and Computer Engineering, University of Waterloo — Quantum Illumination (QI) promises improvement in the sensitivity of target detection technologies. The approach takes advantage of strong correlations that can be created in electromagnetic beams using quantum processes, through a form of entanglement. Notably, QI has proven to be very robust to the presence of noise and loss, suggesting that it may have practical applications. We have made a proof-of-principle demonstration of a novel QI protocol: quantum-enhanced noise radar (QENR). In QENR, we use a parametric amplifier to produce a two-mode squeezed (TMS) state, which exhibits continuous-variable entanglement between signal and idler beams. This state is the input to the radar system. Compared to existing proposals for QI, our protocol does not require joint measurement of the signal and idler. This greatly enhances the practicality of the system by eliminating the need for a quantum memory to store the idler. We compare the performance of a TMS source to an ideal classical source that saturates the classical bound for correlation, finding a quantum enhancement approaching a factor of 10. One of the main challenges to making QENR practical is bringing the quantum microwaves out of the cryostat. We will discuss progress towards overcoming this challenge.
Parametric quantum amplifiers are of paramount importance for quantum information processing with superconducting circuits. A promising route to design quantum amplifiers is based on parametric modulation of coupled modes, where the required mode-mixing processes are realized by utilizing Josephson junction-based tunable couplers. All designs face the challenge of higher-order nonlinearities, resulting in a limitation of the dynamical range of the amplifier. However, even without any higher-order nonlinearities, the amplification process is itself nonlinear, e.g., it involves the mixing of three waves: the pump, the idler and the signal. Only for weak enough signal intensity the pump can be considered stiff and the amplification process becomes linear. Once the signal strength grows this approximation does not hold true anymore. The nonlinear nature of the mixing process leads to back-action, limiting the dynamical range of the amplifier.

Here we present possible ways to face these challenges, and how to avoid unwanted back-action effects in engineered quantum systems. Furthermore, we discuss routes for optimizing the design of quantum-limited parametric amplifiers that one can avoid pump-depletion effects completely.
Near quantum limited Josephson traveling wave amplifiers I, Fabrication and characterization

LUCA PLANAT (Presenter), ARPIT RANADIVE, RÉMY DASSONNEVILLE, JAVIER PUERTAS, SEBASTIEN LEGER, CÉCILE NAUD, OLIVIER BUISSON, WIEBKE GUICHARD, Institut Neel, DENIS M BASKO, Laboratoire de Physique et Modélisation des Millieux Condensés, NICOLAS ROCH, Institut Neel — Efficient low noise amplification is a crucial component for any system dealing with low amplitude signals. Currently, Josephson parametric amplifiers (JPAs) can attain quantum limited amplification for microwave signals. However, JPAs based on resonant structures are limited to low bandwidth and saturation power. These limitations can be overcome using Josephson meta-materials forming traveling wave parametric amplifiers (TWPAs).

In part I, we will present in detail, our simplified aluminum-based two-step fabrication technique for TWPAs with low footprint[1], and discuss their linear characterization[2]. This technique paves the way for on-chip integration of broadband amplifiers with quantum devices.

In part II, we will present the performance of these amplifiers, exhibiting a large and near quantum limited gain over bandwidth larger than 2GHz; and conclude with a discussion on techniques for mitigating some of the limitations.

Heisenberg-limited single-mode quantum metrology in a superconducting circuit  WEITING WANG (Presenter), YUKAI WU, YUWEI MA, WEIZHOU CAI, LING HU, XIANGHAO MU, YUAN XU, Tsinghua University, ZIJIE CHEN, University of Science and Technology of China, HAIYAN WANG, YIPU SONG, Tsinghua University, HAIDONG YUAN, Chinese University of Hong Kong, CHANGLING ZOU, University of Science and Technology of China, LUMING DUAN, LUYAN SUN, Tsinghua University — Quantum metrology is one of the most promising near-term applications of quantum technology. Reaching a quantum advantage in metrology usually requires hard-to-prepare two-mode entangled states such as NOON states. Instead of exploring quantum entanglement in the two-mode interferometers, a single bosonic mode also promises a measurement precision beyond the shot-noise limit (SNL) by taking advantage of the infinite-dimensional Hilbert space of Fock states. In this talk, we demonstrate such a single-mode phase estimation that approaches the Heisenberg limit (HL) unconditionally in a superconducting circuit by preparing the superpositions of Fock states (|0> + |N>) up to N=12. We realize a 9.1 dB improvement over the SNL at N=12, which is only 1.7 dB away from the HL. Our experimental architecture can be combined with quantum error correction techniques to fight against decoherence, and thus promises quantum-enhanced sensing in practical applications.
RAFAL DEMKOWICZ-DOBRZANSKI (Presenter), Faculty of Physics, University of Warsaw — A comprehensive overview of the most recent advances in theoretical methods of quantum metrology will be presented, that in particular benefit from the quantum information related concepts such as quantum error-correction or matrix product states formalism. The theory developed allows to determine whether the Heisenberg scaling of precision is possible for a quantum sensor subject to a general Markovian noise. The theory takes into account all the possible quantum strategies, including entangling the sensor with ancillary systems, adaptive strategies such as e.g. quantum error correction protocols. Moreover, effective algorithms, based on the matrix product states/matrix product operator formalism, are developed that allow to identify the optimal metrological protocols in presence of noise (also correlated noise) in the limit of large number of probes, inaccessible by the state-of-the-art methods. These results are highly relevant for modern developments of quantum enhanced sensing protocols, including NV-center magnetometry, squeezed states enhanced optical and atomic interferometry or stabilization protocols for atomic clocks.

Simultaneous Measurement of 53 Superconducting Transmons on the Sycamore Processor

ZIJUN CHEN (Presenter), OFER NAAMAN, DANIEL T SANK, PAUL KLIMOV, CHRIS QUINTANA, JULIAN KELLY, ANTHONY E MEGRANT, Google Inc - Santa Barbara, HARTMUT NEVEN, Google Inc, JOHN M MARTINIS, Google Inc - Santa Barbara —

Progress in low-noise amplifiers, device design, and device calibration has enabled high fidelity readout in transmon qubits. However, challenges arise when scaling up to large numbers of qubits, where deleterious effects such as crosstalk and unwanted interactions can degrade readout fidelity. In this talk, I will discuss how we overcame some of these challenges to achieve simultaneous readout of 53 qubits on Google's Sycamore processor, enabling the demonstration of quantum supremacy. [1].

Single-shot readout and state preparation of a fluxonium qubit without the use of a parametric amplifier

DARIA GUSENKOVA (Presenter), MARTIN SPIECKER, RICHARD GEBAUER, LUKAS GRUENHAUPT, PATRICK WINKEL, FRANCESCO VALENTI, IVAN TAKMAKOV, DENNIS RIEGER, ALEXEY V. USTINOV, WOLFGANG WERNSDORFER, OLIVER SANDER, IOAN-MIHAI POP, Karlsruhe Institute of Technology —

High-fidelity qubit readout is an essential requirement for the implementation of quantum algorithms. A commonly used readout technique involves the dispersive interaction between a qubit and a resonator, which encodes the qubit state into the phase and amplitude of the microwave readout tone. In theory, the state discrimination can be substantially improved if the resonator is populated with high photon numbers [1]. In practice however, the optimal photon number, at which the best readout fidelity is obtained, is usually in the range of a few photons [2, 3], and parametric amplifiers with near quantum-limited noise are needed to overcome the noise of even the best commercial high electron mobility transistor amplifiers.

Using a fluxonium qubit with a granular aluminum superinductance [4], we demonstrate single shot qubit measurements without a parametric amplifier, at a readout power corresponding to hundreds of circulating photons. The dispersive shift decreases with photon number, and the qubit decay rate increases, resulting in a tradeoff between applied power and readout fidelity.

Measurement of quantum jumps of a fluxonium qubit using a Dimer Josephson Junction Array Amplifier operated at high power  

IVAN TAKMAKOV (Presenter), PATRICK WINKEL, Karlsruhe Institute of Technology, FARSHAD FOROUGHI, NEEL, MARTIN SPIECKER, LUKAS GRUENHAUPT, DARIA GUSENKOVA, Karlsruhe Institute of Technology, LUCA PLANAT, NEEL, DENNIS RIEGER, ALEXEY V. USTINOV, WOLFGANG WERNSDORFER, IOAN-MIHAI POP, Karlsruhe Institute of Technology, NICOLAS ROCH, NEEL — Josephson parametric amplifiers have become an essential element in cQED dispersive readout measurement schemes, enabling single-shot qubit readout. Over the last decade there was significant progress in the increase of their saturation power [1,2,3,4], which now reaches several thousand photons per μs. We demonstrate high saturation power in a Dimer Josephson Junction Array Amplifier [4] operating with a quantum efficiency of 60%. We use this parametric amplifier to perform dispersive readout of a fluxonium qubit with a superinductor made of granular aluminum [5]. We present quantum jump measurements acquired using up-to 100 circulating photons in the readout resonator, which allowed qubit state discrimination in tens of nanoseconds.

Towards autonomous digital feedback on a superconducting qubit  

ZIYI ZHAO (Presenter), ERIC ROSENTHAL, JILA and University of Colorado, Boulder, MAXIME MALNOU, NIST, Boulder, CHRISTIAN M. F. SCHNEIDER, University of Innsbruck, LEILA VALE, GENE C. HILTON, NIST, Boulder, GERHARD KIRCHMAIR, University of Innsbruck, JIANSONG GAO, NIST, Boulder, K. W. LEHNERT, JILA and University of Colorado, Boulder — Quantum error correction requires conditional operations predicated on measurement results. Such feedback schemes in superconducting qubit systems, however, can be hardware intensive. They may require dedicated control hardware at ambient temperature and consume precious high-bandwidth connections between temperature stages. Here we present preliminary data on the state preparation and stabilization of a superconducting qubit where we keep the measurement information at the base temperature stage of the cryostat, and then use it to conditionally \( \pi \) pulse a qubit. This scheme avoids the aforementioned problems and can ease the development of stabilized quantum networks within a scalable architecture.
**8:48AM R08.00005: Isolating a qubit from amplifier backaction by coordinated switching**

ERIC ROSENTHAL (Presenter), JILA and the University of Colorado, Boulder, CHRISTIAN M. F. SCHNEIDER, University of Innsbruck, MAXIME MALNOU, NIST, Boulder, ZIYI ZHAO, FELIX LEDITZKY, JILA and the University of Colorado, Boulder, BENJAMIN J. CHAPMAN, Physics and Applied Physics, Yale, XIZHENG MA, DANIEL A PALKEN, JILA and the University of Colorado, Boulder, LEILA R. VALE, GENE C. HILTON, NIST, Boulder, GERHARD KIRCHMAIR, University of Innsbruck, JIANSONG GAO, NIST, Boulder, GRAEME SMITH, K. W. LEHNERT, JILA and the University of Colorado, Boulder — We demonstrate a cQED qubit measurement scheme in which the qubit is isolated from amplifier backaction without ferrite circulators. We swap a readout signal from the qubit cavity to an ancillary cavity by temporarily coupling them. The state of the ancillary cavity is then amplified by parametrically pumping past bifurcation into one of two large amplitude states that are correlated with the qubit state. Isolation and efficiency are comparable to readout using a ferrite circulator, but are achieved using a chip-scale device compatible with the integration of superconducting qubits. Because the measurement result is contained in the digital state of a superconducting bifurcation amplifier, it is possible to use this scheme to create autonomous feedback loops at the cryostat base temperature. The integrated nature of this readout suggests an avenue toward the scalable measurement of larger quantum networks.

**9:00AM R08.00006: On-chip single-pump interferometric Josephson Isolator**  
BALEEGH ABDO (Presenter), OBLESH JINKA, NICHOLAS T BRONN, SALVATORE OLIVADESE, MARKUS BRINK, JERRY M. CHOW, IBM TJ Watson Research Center — Nonreciprocal microwave devices, such as circulators and isolators, play several critical roles in superconducting quantum processors. They route readout signals in a directional manner, protect the quantum system against noise coming from the output chain, and enable reflection measurements by separating input from output. However, the reliance of these devices, on magnetic materials and strong magnets for breaking reciprocity, makes them disadvantageous in scalable superconducting architectures. In this work, we realize and measure an on-chip Josephson isolator, which is formed by coupling two nondegenerate Josephson mixers in an interferometric scheme. Isolation is created, in the active device, by operating the two mixers in frequency conversion mode using balanced, same-frequency microwave pumps, whose phase difference is \( \pi/2 \). The applied pumps are generated using an on-chip quadrature hybrid, which equally splits the single pump feeding the device and imposes the required phase difference between the split drives.
9:12AM R08.00007: Novel Measurements for Annealing Capable Flux Qubits* WADE DEGOTTARDI (Presenter), DAVID J. CLARKE, SERGEY NOVIKOV, JAMES I BASHAM, JEFFREY GROVER, STEVEN M DISSELER, DAVID FERGUSON, Northrop Grumman - Mission Systems — Quantum Flux Parametron (QFP) based measurements have demonstrated the ability to implement high fidelity z-basis readout for high coherence capacitively shunted flux qubits (CSFQs) at the end of an anneal. This talk discusses alternative QFP readout procedures including: (i) at early times in the anneal, (ii) for other non z-loop currents, and (iii) for Josephson phase slip qubits (JPSQs). It is shown how the POVM (positive-operator valued measure) that characterizes the qubit measurement in these novel regimes can be derived from the final QFP POVM by modeling the dynamics of the coupled QFP-qubit system.

9:24AM R08.00008: Realizing large, tunable dispersive shifts with parametric couplings ZHIHAO XIAO (Presenter), University of Massachusetts Lowell, LEONARDO M RANZANI, LUKE GOVIA, Raytheon BBN Technologies, RAYMOND W SIMMONDS, JOSE AUMENTADO, National Institute of Standards and Technology Boulder, ARCHANA KAMAL, University of Massachusetts Lowell — In recent years, parametric couplings are being deployed in a variety of applications, ranging from parametric gates, state preparation to quantum annealing. Unlike their traditional applications such as parametric amplification, these new functionalities require much stronger parametric coupling strengths that can dominate qubit decay and measurement rates. The theoretical framework to capture the effect of such strong time-dependent couplings, however, remains rudimentary. In this work, we analyze the primary building block of such a platform --- a single qubit parametrically coupled to a single-mode resonator. We establish that even this simple system can support a rich structure in dispersive shifts, that can be rendered large and tunable by choosing suitable parametric coupling drive amplitudes and frequencies. In addition, this platform can enable enhanced cavity squeezing by multi-tone parametric pumping. Our scheme can be realized with state-of-the-art circuit-QED architecture, and we discuss our early experimental efforts to support this approach.
Remote entanglement via two mode squeezed light

XI CAO (Presenter), Physics and Astronomy, University of Pittsburgh, GANGQIANG LIU, Applied Physics, Yale University, TZUCHIAO CHIEN, CHAO ZHOU, PINLEI LU, MICHAEL JONATHAN HATRIDGE, Physics and Astronomy, University of Pittsburgh — Remotely entangling qubits which do not interact directly is very desirable for quantum information processing. One method for remote entanglement is to read out two qubits in parallel with their outputs entering the signal and idler mode of a phase-preserving amplifier. The amplifier squeezes away which-path information and can project the qubits into a Bell state. However, this measurement also produces an outcome-dependent phase kick on the qubits’ state. Thus, losses and inefficient amplification can prevent the generation of entangled states [1, 2]. However, we have recently demonstrated a new scheme which uses two-mode squeezed light (TMSL) in an interferometer formed by two phase-preserving amplifiers to measure a qubit. We find that the phase back-action of TMSL measurement alters the phase back-action relative to coherent readout, depending on the amplifiers’ relative phase. Here we present a two qubit, TMSL interferometric entangling readout. We will show how TMSL affects the back-action of the entangling readout and discuss the prospects for the use of TMSL to make the scheme more tolerant of hardware imperfections.

9:48AM R08.00010: Fast high fidelity quantum non-demolition superconducting qubit readout* [Invited] RÉMY DASSONNEVILLE, Neel Institute, University Grenoble Alpes, CNRS, THOMAS RAMOS, Institute of Fundamental Physics, IFF-CSIC, VLADIMIR MILCHAKOV, LUCA PLANAT, ETIENNE DUMUR, FARSHAD FOROUGHI, JAVIER PUERTAS, SEBASTIEN LÉGER, KARTHIK SRIKANTH BHARADWAJ, JOVIAN DELAFORCE, CÉCILE NAUD, WIEBKE GUICHARD, Neel Institute, University Grenoble Alpes, CNRS, JUAN JOSE GARCIA-RIPOLL, Institute of Fundamental Physics, IFF-CSIC, NICOLAS ROCH, OLIVIER BUISSON (Presenter), Neel Institute, University Grenoble Alpes, CNRS — The most common technique of qubit readout in cQED relies on the transverse dispersive coupling between a qubit and a microwave cavity. However, despite important progresses, implementing fast high fidelity and QND readout remains a major challenge. Indeed, inferring the qubit state is limited by the trade-off between speed and accuracy due to Purcell effect and unwanted transitions induced by readout photons in the cavity. To overcome this, we propose and experimentally demonstrate a new readout scheme based on a transmon molecule inserted inside a 3D-cavity_[1,2]. The full system presents a transmon qubit mode coupled to a readout mode through an original non-pertubative cross-Kerr coupling. The readout mode, called polariton mode, results from the hybridization between the microwave cavity and the transmon molecule circuit. The direct cross-Kerr coupling is a key point of our readout scheme since it protects the qubit from Purcell effect. This first implementation, though perfectible, already enables a very efficient single-shot QND readout of the qubit in only 50ns, with a QND-ness of 99% and a fidelity of 97.4%.

10:24AM R08.00011: Frequency-domain pulse engineering for fast qubit readout and resonator reset* RICCARDO BORGANI, MATS THOLEN, SHAN WILLIAMS JOLIN, DANIEL FORCHHEIMER, DAVID HAVILAND (Presenter), KTH Royal Inst of Tech — The state of a superconducting qubit is typically determined by measuring the dispersive shift $\chi$ of a superconducting resonator with coupling rate $\kappa$ to a transmission line. Large $\chi/\kappa$ ratio is beneficial for high-fidelity readout. While small $\kappa$ protects the qubit from the noisy environment, it has the big disadvantage of limiting the speed of measurement. In particular, photons linger in the resonator for a time of several $1/\kappa$, causing decoherence of the qubit and blocking subsequent measurement. Here we present a microwave pulse scheme which, regardless of the state of the qubit, populates the readout resonator, measures the state of the qubit, and empties the resonator, all in a time much faster than $1/\kappa$. The pulse is designed in the frequency domain by shaping its spectral content at the dressed-resonance frequencies. The pulse envelope is derived through inverse Fourier transform, rather than relying on brute-force numerical optimization. We evaluate the performance of the pulse scheme in different regimes of $\chi/\kappa$ through both simulation and experiment, and we comment on the theoretically achievable single-shot fidelity of the method.

10:36AM R08.00012: High efficiency measurement of a superconducting qubit using a directional, phase-sensitive, parametric amplifier

FLORENT LECOCQ (Presenter), National Institute of Standards and Technology Boulder, LEONARDO M RANZANI, Raytheon BBN Technologies, GABRIEL PETERSON, SHLOMI KOTLER, KATARINA CICAK, X. Y. JIN, RAYMOND W SIMMONDS, JOHN TEUFEL, JOSE AUMENTADO, National Institute of Standards and Technology Boulder — The measurement of a superconducting quantum bit is often performed by encoding its state in a single quadrature of a microwave field. Ideal measurement efficiency of this observable could in principle be achieved by noiselessly amplifying the information-carrying quadrature, but in practice is limited by technical losses due to circulators, cables and connectors used in state-of-the-art amplification chains.

In this talk we will discuss how one can approach ideal measurement efficiency by directly connecting a 3D transmon to a non-reciprocal phase-sensitive amplifier [1]. After describing the setup and tuning of the amplifier, we will extract the measurement efficiency by comparing the qubit dephasing rate to the measurement rate.

10:48AM R08.00013: High fidelity dispersive qubit readout in circuit QED without using a Josephson Parametric Amplifier

SUMAN KUNDU (Presenter), KISHOR V SALUNKHE, ANIRBAN BHATTACHARJEE, SUMERU HAZRA, MEGHAN P. PATANKAR, R VIJAY, DCMP&MS, Tata Institute of Fundamental Research, Mumbai — In the cQED architecture, the Josephson parametric amplifier (JPA) enables high fidelity readout by providing minimal degradation of the signal-to-noise ratio (SNR) of the amplified readout signal. While the SNR can also be increased by increasing readout power and integration time, the fidelity typically gets limited due to unwanted transitions both within and outside the computational subspace. Here, we present and demonstrate an alternate design where qubit-cavity coupling does not rely on the dispersive approximation of the Jaynes-Cummings Hamiltonian. This multi-modal circuit is reminiscent of the quantronium qubit design but with two differences: the qubit is of the transmon type and the cavity is linear. The device is implemented in the 3D cQED architecture and we use a rectangular waveguide to couple the readout cavity to the measurement line. We achieve a readout fidelity of 97.8% for 800ns integration time with a histogram overlap error of only 0.3% without using a JPA. The best fidelity obtained with the JPA was 98.9% for a 300 ns integration time with an overlap error of less than 0.01%. We will conclude by discussing the variation of readout fidelity with measurement power and compare with a conventional transmon readout in cQED.
8:00AM R09.00001: Randomized benchmarking for qudit Clifford gates* BARRY SANDERS (Presenter), Institute for Quantum Science and Technology, University of Calgary, MAHNAZ JAFARZADEH, Physics Department, Urmia University, YADONG WU, Institute for Quantum Science and Technology, University of Calgary — We introduce unitary-gate randomized benchmarking (URB) for qudit gates by extending single- and multi-qubit URB to single- and multi-qudit gates. Specifically, we develop a qudit URB procedure that exploits unitary 2-designs. Furthermore, we show that our URB procedure is not simply extracted from the multi-qubit case by equating qudit URB to URB of the symmetric multi-qubit subspace. Our qudit URB is elucidated by using pseudocode, which facilitates incorporating into benchmarking applications.

8:12AM R09.00002: Quantum-Computing Architecture based on Large-Scale Multi-Dimensional Continuous-Variable Cluster States in a Scalable Photonic Platform* BO-HAN WU (Presenter), Physics, Univ of Arizona, RAFAEL ALEXANDER, Center for Quantum Information and Control, Univ of New Mexico, ZHESHEN ZHANG, Department of Materials Science and Engineering, Univ of Arizona — Quantum computing is a disruptive paradigm widely believed to be capable of solving classically intractable problems, but the route toward full-scale quantum computers is impeded by immense challenges associated with the scalability of the platform and the required fidelity of various components. One-way quantum computing is an appealing approach that shifts the burden from high-fidelity quantum gates and quantum memories to the generation of high-quality entangled resource states and high fidelity measurements. Here, we bridge two fields—Kerr microcombs and continuous-variable (CV) quantum information—to formulate a one-way quantum computing architecture based on programmable large-scale CV cluster states. The architecture accommodate hundreds of simultaneously addressable entangled optical modes multiplexed in frequency and an unlimited number of sequentially addressable entangled modes in time. One-, two-, three-dimensional CV cluster states can be deterministically produced, which allows for fault-tolerant one-way quantum computing with known error-correction strategies. This architecture opens a promising avenue for quantum computing at a large scale.

8:24AM R09.00003: Proposed Universal Deutsch Gate Circuitry Using GaAs/InAs Quantum Dots PAUL BAILEY (Presenter), JEAN-FRANCOIS VAN HUELE, Brigham Young Univ - Provo — The Deutsch gate is a universal quantum logic gate, meaning that any quantum computing task can be completed using a combination of Deutsch gates. Although a proposal exists to build a Deutsch gate using Rydberg atoms [X-F Shi, Phys. Rev. Applied 9, 051001], to our knowledge no Deutsch gate has been experimentally realized so far. We propose to combine two GaAs/InAs quantum dots with photon polarization in a larger circuit comprised of linear optical elements to create a spin-spin-photon polarization three qubit Deutsch Gate similar to a proposal for a CNOT gate [Bouwmeester et al., Phys. Rev. Lett. 104, 160503]. We display the circuit and discuss the intricacies of designing this gate and reflect on the general feasibility of gate design.
Quantum-classical transition in analog quantum supremacy subject to Markovian decoherence*

RAZIEH MOHSENINIA (Presenter), Univ of Southern California, MILAD MARVIAN, Massachusetts Institute of Technology, DANIEL A LIDAR, Univ of Southern California — Instantaneous Quantum Polynomial time circuits are a promising way to demonstrate quantum supremacy. We study the robustness of quantum supremacy in an analog Hamiltonian version of such circuits in the presence of a Markovian environment whose noise operators commute with the system Hamiltonian. We find a transition from a regime of quantum supremacy to classical simulability that occurs at a finite critical decoherence rate, that depends on the system size.

Optimal recognition of exact free-fermion solutions for spin models*

ADRIAN CHAPMAN (Presenter), STEVEN FLAMMIA, Univ of Sydney — Finding exact solutions to spin models is a fundamental problem of many-body physics. A workhorse technique for many such exact solution methods is mapping to an effective description by noninteracting particles. The paradigmatic example of this method is the exact solution for the one dimensional XY model by mapping to free-fermions via the Jordan-Wigner transformation. We connect the general problem of recognizing models which can be exactly solved in this way to the graph-theoretic problem of recognizing line graphs, which has been solved optimally. Our solution method captures an entire class of spin models which are as exactly solvable as the Kitaev honeycomb model. We give an example of a previously unsolved spin model and demonstrate its exact solution by our method. We close by showing how these techniques can be used to design new fermion-to-qubit mappings.

Quantum Algorithms for Approximate Dynamic Programming

POOYA RONAGH (Presenter), University of Waterloo — We present a quantum algorithm for finding approximate solutions to dynamic programming problems using the multiplicative weight update method. Up to polylogarithmic factors, our algorithm provides a quadratic quantum advantage in terms of the number of states of a given dynamic programming problem, at the expense of the appearance of other polynomial factors representative of the number of actions of the dynamic programming problem, the maximum value of the instantaneous reward, and the time horizon of the problem. We also prove lower bounds for the query complexity of quantum algorithms and classical randomized algorithms for solving dynamic programming problems, and show that no greater-than-quadratic speedup in either the number of states or number of actions can be achieved for solving dynamic programming problems using quantum algorithms.
9:12AM R09.00007: A Novel Tensor Network Algorithm for Simulating Large Quantum Circuits*
JUSTIN REYES (Presenter), Univ of Central Florida, LEI ZHANG, STEFANOS KOURTIS, CLAUDIO CHAMON, ANDREI E RUCKENSTEIN, Physics, Boston University, EDUARDO R MUCCIOLO, Univ of Central Florida — Simulations of quantum circuits often involve an exponential number of resources, suffering from the so called "curse of dimensionality." Because of this, obtaining measurement information from states output by high-depth circuits is challenging. To overcome this limitation, we employ a novel tensor network methodology to compute expectation values that resembles the Keldysh formalism. This algorithm, which we term ICD (Iterative Contraction Decomposition), iteratively alternates between sequences of tensor contractions and global sweeps of tensor pair Schmidt decompositions. We demonstrate our algorithm's ability to determine measurement outcomes for random circuits of up to 40 qubits with circuit depths of 80 steps.

9:24AM R09.00008: Gate(s)-wise Optimization for Variational Quantum Eigensolvers*
LUCAS SLATTERY (Presenter), BENJAMIN VILLALONGA, BRYAN CLARK, University of Illinois at Urbana-Champaign — The variational quantum eigensolver (VQE) is a promising hybrid framework for solving chemistry and physics problems on noisy intermediate-scale quantum (NISQ) computers of the near future. VQE uses a NISQ device to prepare classically intractable parameterized quantum states. These states include ground states of chemistry and condensed matter models, as well as the solution to other optimization problems. A VQE method combines sampling from the NISQ device with a classical optimization routine to find target states. To optimize, most VQE algorithms use quantum circuits to measure gradients of a cost function in order to perform a gradient descent step. We provide and benchmark an alternative to gradient descent VQE methods with the potential for avoiding local minima and faster convergence. We demonstrate proof-of-concept results for local hamiltonians by optimizing one gate at a time.

The resilience of quantum random access memory to generic noise*

CONNOR HANN (Presenter), GIDEON LEE, STEVEN GIRVIN, Yale University, LIANG JIANG, University of Chicago — Quantum random access memory (qRAM)—a memory which stores classical data but allows queries to be performed in superposition—is required for the implementation of numerous quantum algorithms. While naive implementations of qRAM are highly susceptible to decoherence and thus not scalable, it has been argued that the bucket brigade qRAM scheme [Phys. Rev. Lett. 100 160501 (2008)] possesses a remarkable resilience to noise. In this scheme, the infidelity of a memory call scales only logarithmically with the size of the memory. In prior analyses of the scheme, however, this favorable scaling followed directly from the use of restricted noise models, thus leaving open the question of whether experimental implementations would actually enjoy the purported scaling advantage. We prove that, quite surprisingly, the favorable scaling holds for general noise models (including depolarization) and hence should be achievable in realistically noisy devices. As a corollary, we show that the benefits of the bucket-brigade scheme persist even when quantum error correction is used, in which case the scheme offers improved resilience to logical errors and better hardware efficiency.

QuSP: The Quantum Simulator Package*

MATTHEW JONES (Presenter), LINCOLN CARR, Colorado School of Mines — With the advent and recent popularity of quantum computing (QC) architectural design, there has never been greater focus on quantum simulators and how they might inform the associated design decisions. There are many libraries and tools that hope to bridge the gap between optimal design patterns and the intuition that informs those patterns, but there are very few platforms that streamline this iterative process. With the guidance of the Science Gateways Community Institute, and backed by OpenMPS, a highly generalizable matrix product state simulation toolkit, we will address the aforementioned gap with QuSP, the Quantum Simulator Package. By building a clean, hosted graphical interface for performing quantum simulator simulations, leveraging both the high performance computing resources of the Colorado School of Mines and XSEDE, we will bridge this gap. QuSP provides a guided user experience to defining a system, its evolution, and any metrics a user might want to track through that evolution.

*Funded by NSF
10:00AM R09.00011: Cost of Classical Strong Simulation of the T-Gate Magic State*  LUCAS KOCIA (Presenter), MOHAN SAROVAR, Sandia — The stabilizer rank of qubit T-gate magic state has been postulated to grow slowest with increasing number of qubits, suggesting that the T-gate is in this sense the most efficient state outside the Clifford subtheory that can be simulated by classical strong simulation that nevertheless extends this subtheory to quantum universality. Unfortunately, the T-gate magic state's stabilizer rank scaling is not formally known and has only been found numerically for up to seven qubits. We examine this problem from the perspective of the cost of strong classical simulation of discrete Wigner functions in systems with odd dimension and compare with the known results for qubits. To accomplish this, we develop and exploit relationships between the number of critical points of quantum states' Wigner functions in a periodized stationary phase approximation and spanning decompositions of stabilizer states that are closely related to the stabilizer rank. We report on the trends we observe.

10:12AM R09.00012: Alibaba Cloud Quantum Development Platform: Large-Scale Classical Simulation of Quantum Circuits  FANG ZHANG, CUPJIN HUANG, Alibaba Quantum Laboratory, MICHAEL NEWMAN, Departments of Physics and Electrical and Computer Engineering, Duke University, JUNJIE CAI, HUANJUN YU, ZHENGXIONG TIAN, BO YUAN, HAIHONG XU, JUNYIN WU, Alibaba Group, XUN GAO, JIANXIN CHEN (Presenter), MARIO SZEGEDY, YAOYUN SHI, Alibaba Quantum Laboratory — We report our work on the Alibaba Cloud Quantum Development Platform(AC-QDP). AC-QDP provides a set of tools for aiding the development of both quantum computing algorithms and quantum processors, and is powered by a large-scale classical simulator deployed on Alibaba Cloud. In this note, we report the computational experiments demonstrating the classical simulation capability of AC-QDP. We use as a benchmark the random quantum circuits designed for Google's Bristlecone QPU \cite{GRCS}. We simulate Bristlecone-70 circuits with depth 1+32+1 in 0.43 second per amplitude, using 1449 Alibaba Cloud Elastic Computing Service (ECS) instances, each with 88 Intel Xeon(Skylake) Platinum 8163 vCPU cores @ 2.5 GHz and 160 gigabytes of memory. By comparison, the previously best reported results for the same tasks are 104 and 135 seconds, using NASA's HPC Pleiades and Electra systems, respectively (\cite{arXiv:1811.09599}). Furthermore, we report simulations of Bristlecone-70 with depth 1+36+1 and depth 1+40+1 in 5.6 and 580.7 seconds per amplitude, respectively. To the best of our knowledge, these are the first successful simulations of instances at these depths.
10:24AM R09.00013: Alibaba Cloud Quantum Development Platform: Applications to Quantum Algorithm Design  
CUPJIN HUANG, MARIO SZEGEDY (Presenter), FANG ZHANG, JIANXIN CHEN, XUN GAO, YAOYUN SHI, Alibaba Quantum Laboratory —
We report our work on the Alibaba Cloud Quantum Development Platform (AC-QDP). The capability of AC-QDP’s computational engine was already reported in \cite{arXiv:1805.01450, arXiv:1907.11217}. In this follow-up article, we demonstrate with figures how AC-QDP helps in testing large-scale quantum algorithms (currently within the QAOA framework). We give new benchmark results on regular graphs. AC-QDP’s QAOA framework can simulate thousands of qubits for up to 4 layers. Then we discuss two interesting use cases we have implemented on the platform: 1. Optimal QAOA sequences for small-cycle free graphs; 2. Graph structure discovery.

10:36AM R09.00014: Quantum linear system solver based on time-optimal adiabatic quantum computing and quantum approximate optimization algorithm*  
DONG AN (Presenter), LIN LIN, University of California, Berkeley — The condition number dependence is a crucial aspect of quantum linear system solvers. We demonstrate that with an optimally tuned scheduling function, adiabatic quantum computing (AQC) can solve a quantum linear system problem with $O(\kappa/\varepsilon)$ runtime, where $\kappa$ is the condition number, and $\varepsilon$ is the target accuracy. This achieves at least quadratic speedup over the standard vanilla AQC and reaches the complexity lower bound with respect to $\kappa$. The success of the time-optimal AQC implies that the quantum approximate optimization algorithm (QAOA) can also achieve the $O(\kappa)$ complexity with respect to $\kappa$. Our method is applicable to general non-Hermitian matrices (possibly dense), but the efficiency can be improved when restricted to Hermitian matrices, and further to Hermitian positive definite matrices. Numerical results indicate that QAOA can yield the lowest runtime compared to the time-optimal AQC, vanilla AQC, and the recently proposed randomization method. The runtime of QAOA is observed numerically to be only $O(\kappa \text{*poly}(\log(1/\varepsilon)))$.

*This work was partially supported by the Department of Energy under Grant No. DE-SC0017867, the Quantum Algorithm Teams Program under Grant No. DE-AC02-05CH11231 (L.L.), and the Google Quantum Research Award (D. A. and L.L.).
10:48AM R09.00015: Quantum optimal algorithm for general polynomials  KEREN LI (Presenter), Peng Cheng Laboratory, PAN GAO, Tsinghua University — Gradient descent algorithms, which is a first-order iterative algorithm, is widely used for optimization problems. To obtain the local minimum of a objective function, one calculates the gradients at the current point in a d-dimension space and then move the function along the negative gradient. This procedure requires $O(poly(d))$ calculation operations, which hinders the performance of the algorithm in a high dimensional optimization situation. Here, by learning a framework of a quantum iterative optimization algorithm and introducing an adapted encoding scheme, we develop the quantum gradient operation for an in-homogenous polynomial objective function with a unit norm constraint. Under certain circumstances, the calculation operations required for the algorithm decreases and is linear with the $O(poly(log(d)))$. Besides, we experimentally demonstrate it on a 4-qubit Nuclear Magnetic Resonance(NMR) quantum system and show the feasibility in polynomial optimization. Since the potential value in high dimensional optimization problems, this algorithm is supposed to influence the interdisciplinary research including Quantum Information and Artificial Intelligence, such as Support Vector Machine, Logistic regression, (quantum) Neural network.

Thursday, March 5, 2020 8:00 AM - 9:36 AM

Session R15 DFD GSNP: Granular, Porous Media, & Multiphase Flows I

210/212 - Anthony Chieco, University of Pennsylvania

8:00AM R15.00001: Flow of emulsions in heterogeneous media*  MARINE LE BLAY (Presenter), DENIS BARTOLO, Univ. Lyon, ENS de Lyon, Univ. Claude Bernard, CNRS, Laboratoire de Physique, F-69342, Lyon, France — We elucidate the collective dynamics of particles hydrodynamically driven through disordered environments. We build on model microfluidic experiments where we track the individual dynamics of hundreds of thousands oil droplets advected by an aqueous fluid through random lattices of pinning sites. Increasing the driving flow, we identify a sharp transition between a creeping regime and a mobilization regime where a finite fraction of the droplets proceed through a sparse network of branched and reconnected rivers. This dynamical transition is a critical phenomenon characterised by diverging time and length scales at the onset of mobilization. We however demonstrate that criticality is not accompanied by the correlated motion of particles in avalanches events. Mobilization requires at most the coordinated motion of ten particles at a time, but these erratic rearrangements are geometrically correlated over system spanning scales along a smectic river network. We conclude by commenting on the similarities and profound differences with the plastic depinning transition of flux lines in super conductors, or grains in eroded sand beds.

8:36AM R15.00002: Controlling capillary fingering using pore size gradients in disordered media  NANCY LU (Presenter), CHRISTOPHER BROWNE, DANIEL AMCHIN, Chemical and Biological Engineering, Princeton University, JANINE K NUNES, Mechanical and Aerospace Engineering, Princeton University, SUJIT DATTA, Chemical and Biological Engineering, Princeton University — Capillary fingering is a displacement process that can occur when a non-wetting fluid displaces a wetting fluid from a homogeneous disordered porous medium. Here, we investigate how this process is influenced by a pore size gradient. Using microfluidic experiments and computational pore-network models, we show that the non-wetting fluid displacement behavior depends sensitively on the direction and the magnitude of the gradient. The fluid displacement depends on the competition between a pore size gradient and pore-scale disorder; indeed, a sufficiently large gradient can completely suppress capillary fingering. By analyzing capillary forces at the pore scale, we identify a non-dimensional parameter that describes the physics underlying these diverse flow behaviors. Our results thus expand the understanding of flow in complex porous media and suggest a new way to control flow behavior via the introduction of pore size gradients.

8:48AM R15.00003: Fluid Flow Mechanisms in Shale Organic Nanopores  FELIPE PEREZ VALENCIA (Presenter), DEEPAK DEVEGOWDA, Univ of Oklahoma — From a fluid dynamics perspective, production of hydrocarbons from unconventional reservoirs represents a challenge because (1) the fluids are located in porous organic matter in shale rocks where the pore sizes range from a few to a couple hundred nanometers, (2) the permeability of shale rocks is on the order of nanodarcy (1 darcy ≈ 10^{-12} m^2), and (3) the behavior of the fluids and their interactions with the pore surface are poorly understood. In this work we use molecular dynamics simulations to create molecular models of organic matter (kerogen) that host a hydrocarbon mixture that is liquid at normal conditions of pressure and temperature. Our models account for the chemical functionality and pore geometry of kerogen and serve as rigid frameworks to study the mechanisms by which the different species of the mixture flow from organic pores to a microfracture.

Our simulations indicate that the two phases free- and adsorbed-fluid coexist in the pores, and the mechanisms by which the molecules of each phase flow are different. While the free phase can expand and diffuse, the strong interaction between adsorbed molecules and the pore surface gives rise to surface diffusion and retards or impedes the arrival of the longer, heavier and aromatic molecules to the microfracture.

9:00AM R15.00004: Colloidal transport in porous media: Pore-scale interplay of advection, deposition, and erosion  NAVID BIZMARK (Presenter), Princeton Institute for the Science and Technology of Materials, Princeton University, JOANNA SCHNEIDER, RODNEY PRIESTLEY, SUJIT DATTA, Chemical and Biological Engineering, Princeton University — There is significant interest in applying colloids to remediate contaminated soils or aquifers. However, the transport of such colloids to porous subsurface regions is complex due to the interplay of particle adsorption, surface erosion, and pore-space advection. Here, we use a transparent model porous medium to directly image in 3D the interplay between adsorption and erosion events at the pore scale. Analysis of these processes allows us to determine the net particle deposition rate and further to predict the macroscopic net particle deposition profile. These findings show how the pore-scale dynamics can be controlled for macroscopic aims in remediation practices.
9:12AM R15.00005: CFD-DEM Study of Anomalous Collapse of Interacting Bubbles into an Incipiently Fluidized Bed  AZIN PADASH (Presenter), CHRISTOPHER M BOYCE, Columbia University — Computational fluid dynamics – discrete element method (CFD-DEM) recreates the collapse phenomenon of the recent magnetic resonance imaging (MRI) study (Boyce et al., Phys. Rev. Fluids, 2019, 034303) in which one bubble collapses when two bubbles are injected side-by-side into an incipiently fluidized bed, and the other bubble does not collapse and reaches the surface of the bed. Our simulation results reveal the underlying physics behind the collapse phenomenon which was ambiguous in the 2D imaging plane of the experimental results. The 3D visualization of voidage field and gas velocity field from simulations demonstrates that bubble collapses and it does not move out of the imaging plane of the study. Also, our results confirm the hypothesis of the MRI study where there should be a slight difference in size of the bubbles, which causes the gas flow to channel more favorably to the larger bubble. Therefore, the smaller bubble does not receive enough gas flow to channel through it and support its roof which leads to its collapse.

9:24AM R15.00006: Colloid-Enhanced Mobilization of Immiscible Fluids in Porous Media  JOANNA SCHNEIDER (Presenter), Chemical and Biological Engineering, Princeton University, NAVID BIZMARK, Princeton Institute for the Science and Technology of Materials, Princeton University, RODNEY PRIESTLEY, SUJIT DATTA, Chemical and Biological Engineering, Princeton University — More than 50% of the United States receives its drinking water from porous groundwater aquifers that are susceptible to contamination from industrial processes. The persistence of these contaminants after their initial introduction requires specialized remediation techniques. Here, we show that injection of colloidal particles improves contaminant removal from a porous medium compared to ambient flow alone. Specifically, by tailoring colloidal properties and injection conditions, we find that particles deposit on the solid surfaces of the porous medium, enhancing the local fluid pressure and pushing out trapped non-aqueous contaminants. We also develop a model to describe how changing permeability impacts mobilization and compare the model’s predictions to experimental results. Importantly, this approach avoids the need for repeated pumping and treatment, representing a major advancement in simplicity and cost over current approaches.
R15.00007: Complex Conductivity in Saturated Porous Media: Role of Membrane Polarization  QIUZI LI (Presenter), LANG FENG, Corporate Strategic Research, ExxonMobil Research and Engineering, STEVE CAMERON, Retired, HARRY DECKMAN, DENIZ ERTAS, Corporate Strategic Research, ExxonMobil Research and Engineering — We quantitatively explain the origin of complex conductivity of a porous medium made of non-conductive grains, saturated with a binary electrolyte. The medium is assumed to possess a heterogeneous immobile charge density, and to interact with ions in the electrolyte only through electrostatic interactions. We establish a theoretical framework relating spectral complex conductivity in these systems to the geometry and intrinsic properties of the materials, and validate the results with experiments on model systems. We conclude that complex conductivity arises due to concentration (membrane) polarization, which is driven by spatial inhomogeneity in the ionic transferences, i.e., the proportion of current carried by the cation vs. the anion. We obtain quantitative agreement between experiment and theory, not just for characteristic frequencies and amplitudes, but for the entire spectral shape of the phase angle between electric field and current density. The amplitude, scaling of the characteristic frequency with feature size, and the spectral shape of the phase angle differ markedly from complex conductivity associated with dispersed electronic conductors.

Thursday, March 5, 2020 8:00 AM - 10:48 AM

Session R16 DQI: Superconducting Qubits: Gates, Couplers and Crosstalk I 201 - Chen Wang, UMass

8:00AM R16.00001: Two-qubit gate with a parity-violated superconducting qubit*  ATSUSHI NOGUCHI (Presenter), Univ of Tokyo, SHINO KONO, Center for Emergent Matter Science, RIKEN, SHUMPEI MASUDA, Tokyo Medical and Dental University, KENTARO HEYA, SAMUEL PIOTR WOLSKI, Univ of Tokyo, HIROKI TAKAHASHI, Osaka University, TAKANORI SUGIYAMA, ALTO OSADA, DANY LACHANCE-QUIRION, YASUNOBU NAKAMURA, Univ of Tokyo — The second-order nonlinearity has been intensively studied over the decades in nonlinear optics for applications such as squeezed light sources and optical frequency combs. Three-wave mixing, the elementary process induced by the second-order nonlinearity, is also a key concept in the latest development of quantum transducers and has also been utilized for high-fidelity quantum manipulations of trapped ions with a parametric coupling. As is well known, a parity violation is required for the second-order nonlinearity. Here we propose a parity-violated superconducting qubit, which enables us to achieve a strong parametric coupling with a neighboring qubit based on the second-order nonlinearity. The qubit consists of a capacitively-shunted SNAIL [1] circuit under a finite flux bias. We demonstrate fast two-qubit gates (CZ, SWAP, and iSWAP) combined with echo pulses to suppress the effect of a residual longitudinal coupling and evaluate the average gate fidelities using an interleaved randomized benchmarking technique.

*This work is partly supported by JST PRESTO (JPMJPR1429), JST ERATO (JPMJER1601), and MEXT Q-LEAP (JPMXS0118068682).
8:12AM R16.00002: Characterization and Tuneup of High-Fidelity Two-Qubit Operations on a Parametrically Driven Gate*  
CHRISTOPHER WARREN (Presenter), ANDREAS BENGTSSON, GIOVANNA TANCREDI, XIU GU, ANTON FRISK KOCKUM, PHILIP KRANTZ, PER DELSING, JONAS BYLANDER, Chalmers Univ of Tech — Maintaining the fidelity of single- and two-qubit gates is a necessary requirement for building a quantum computer, especially in the NISQ era where every gate is critical. At the ideal limit without coherent or systematic errors, the gate fidelity fluctuates as $T_1$ fluctuates. It is important to be able to characterize the timescales over which system parameters may fall out of calibration, and the worst-performance cases should be reported. Here we present our work towards characterizing these effects, and we compare schemes for automating the recalibration process on a device consisting of fixed-frequency transmon qubits with a tunable coupler. The coupler is parametrically driven to selectively perform an iSWAP or CZ gate. Our results indicate that we are primarily limited by incoherent errors with single-qubit gates performing with >99.9% fidelity and two-qubit gates with fidelities >99.0%.

*Knut and Alice Wallenberg Foundation, Swedish Research Council, EU Flagship on Quantum Technology

8:24AM R16.00003: Efficient cavity control with SNAP gates  
THOMAS FOESEL (Presenter), Max Planck Inst for Sci Light, STEFAN KRASTANOV, Massachusetts Institute of Technology, LIANG JIANG, University of Chicago, FLORIAN MARQUARDT, Max Planck Inst for Sci Light — Microwave cavities coupled to superconducting qubits have been demonstrated to be a promising platform for quantum information processing. A major challenge in this setup is to realize universal control over the cavity. A promising approach are selective number-dependent arbitrary phase (SNAP) gates combined with cavity displacements. Whereas it could be proven that this is a universal gate set, a central question remained open: how can a given target operation be realized efficiently with a sequence of these operations.

In this talk, we present a practical scheme to address this problem. We will compare our results to previously known techniques: for many experimentally relevant applications, we find that the sequence length can be reduced by a factor of around 10 or higher. We will also sketch the working principle of our method.
Demonstrating a Continuous Set of Two-qubit Gates for Near-term Quantum Algorithms  
BROOKS FOXEN (Presenter), AI Quantum, Google, BEN CHIARO, MATTHEW MCEWEN, University of California, Santa Barbara, JOHN M MARTINIS, AI Quantum, Google — Quantum algorithms offer a dramatic speedup for computational problems in machine learning, material science, and chemistry. However, any near-term realizations of these algorithms will need to be heavily optimized to fit within the finite resources offered by existing noisy quantum hardware. Here, taking advantage of the strong adjustable coupling of gmon qubits, we demonstrate a continuous two-qubit gate set that can provide a 3x reduction in circuit depth as compared to a standard gate decomposition. We implement two gate families: an iSWAP-like gate to attain an arbitrary swap angle, θ, and a CPHASE gate that generates an arbitrary conditional phase, Φ. Using one of each of these gates, we can perform an arbitrary two-qubit gate within the excitation-preserving subspace allowing for a complete implementation of the so-called Fermionic Simulation, or fSim, gate set. We benchmark the fidelity of the iSWAP-like and CPHASE gate families as well as 525 other fSim gates spread evenly across the entire fSim(θ, Φ) parameter space achieving purity-limited average two-qubit Pauli error of 3.8 \times 10^{-3} per fSim gate.

Experimental implementation of universal nonadiabatic geometric quantum gates with a superconducting circuit  
ZIYUE HUA (Presenter), YUAN XU, Tsinghua University, TAO CHEN, South China Normal University, XIAOXUAN PAN, XUEGANG LI, JIA XIU HAN, WEIZHOU CAI, YU WEI MA, HAIYAN WANG, YI PU SONG, Tsinghua University, ZHENG YUAN XUE, South China Normal University, LUYAN SUN, Tsinghua University — Using geometric phase to realize noise-resilient quantum computing is an important method to enhance control fidelity. In this work, we experimentally realize a universal nonadiabatic geometric quantum gate set in a superconducting qubit chain. We characterize the realized single- and two-qubit geometric gates with both quantum process tomography and randomized benchmarking methods. The measured average fidelities for single-qubit rotation gates and two-qubit controlled-Z gate are 0.9977 and 0.977, respectively. Besides, we also experimentally demonstrate the noise-resilient feature of the realized single-qubit geometric gates by comparing their performance with the conventional dynamic gates with different types of errors in the control field. Thus, our experiment proves a way to achieve high-fidelity geometric quantum gates for robust quantum computation.
9:00AM R16.00006: Bounds on cross-resonance gate fidelity in an extended parameter regime  EMILY PRITCHETT (Presenter), ABHINAV KANDALA, DAVID MCKAY, IBM Tj Watson Research Center — The cross-resonance (CR) interaction is the primary method for enabling two-qubit gates in systems with fixed-frequency transmons using only microwave control. Eliminating the need for tunable circuit elements reduces the system's susceptibility to low-frequency noise, but the cost is more complicated coherent dynamics during the gate [1,2,3,4], both between the targeted qubit pair and to qubits that are nominally idle (spectators). We bound the two-qubit CR gate fidelity as set by unitary dynamics, showing its sensitivity to the parameters governing the two-qubit interaction (coupling strength, relative energies, anharmonicities, and total gate time) and to parameters required to build larger devices (frequency allocation of neighboring qubits). As we reach the limit of fidelities achieved by control of our current devices, consideration of this larger parameter space will let us design devices with higher performance.

9:12AM R16.00007: Superconducting qubit gates based on accelerated adiabatic evolution*  FNU SETIAWAN (Presenter), PETER GROSZKOWSKI, University of Chicago, Pritzker School of Molecular Engineering, HUGO RIBEIRO, Max Planck Institute for the Science of Light, Erlangen, AASHISH CLERK, University of Chicago, Pritzker School of Molecular Engineering — Quantum gates based on adiabatic evolution are in principle desirable because of their intrinsic robustness against small errors or imperfections in the control pulses. In practice however, the requirement of extremely long evolution times makes them very susceptible to dissipation and noise, resulting in poor fidelities. Recently, protocols based on shortcuts to adiabaticity have been used to design accelerated version of adiabatic quantum gates [1,2]. These gates can be fast while still possessing some of the robustness properties of purely adiabatic gates. We perform detailed theoretical studies and simulations exploring the performance of such gates in realistic superconducting qubit platforms. This includes single qubit gates in protected qubit architectures such as fluxonium, as well as two-qubit gates in cavity-coupled transmon architectures [3].

*Research was sponsored by the Army Research Office and was accomplished under Grant Number W911NF-19-1-0328
Microwave-activated entangling gates in high coherence superconducting qubits  
LONG NGUYEN (Presenter), AARON SOMOROFF, QUENTIN FICHEUX, YEN-HSIANG LIN, IVAN PECHENEZHSKIY, University of Maryland, College Park, YINQI CHEN, KONSTANTIN NESTEROV, MAXIM G VAVILOV, University of Wisconsin-Madison, VLADIMIR MANUCHARYAN, University of Maryland, College Park — We report experimental progress on microwave-activated entangling gates with capacitively coupled fluxonium qubits. When biased at the flux sweet-spot, individual qubit transition has long coherence (the best device has $T_2 > 400$ us) [1]. A control-Z gate can be implemented by sending a short $2\pi$-pulse at the frequency near the $1\rightarrow 2$ transition of the target qubit [2]. The gate transition has higher frequency and larger matrix element than the qubit transition, resulting in fast gate and minimal spurious phase errors. Another microwave entangling gate, similar to the cross-resonance gate in transmon [3], can be applied to the computational subspace. We discuss qubits' design and fabrication, initialization, readout, and benchmarking of the gates.

Demonstration of entangling gate for all-to-all connected superconducting qubits*  
MARIE LU (Presenter), JEAN-LOUP VILLE, SYDNEY SCHREPPLER, University of California, Berkeley, FELIX MOTZOI, LUKAS F BUCHMANN, Physics, Aarhus University, IRFAN SIDDIQI, University of California, Berkeley — Exploring highly connected networks of qubits is invaluable for implementing various quantum codes and simulations. All-to-all connectivity allows for entangling qubits with reduced gate depth. In the ion community, the Mølmer-Sørensen gate is routinely used to entangle over a dozen qubits with high fidelity. We report on the observed fidelity for a Mølmer-Sørensen-like interaction through the use of shared coplanar waveguide (CPW) resonators to couple multiple superconducting qubits. This gate allows us to selectively entangle any subset of the qubits coupled to the shared resonator.

*This research was supported by the LPS HiPS program under ARO grant W911NF1810178 and the L’Oreal USA for Women in Science Fellowship.

Multi-qubit gate mediated by a shared microwave resonator: Error analysis*  
JEAN-LOUP VILLE (Presenter), MARIE LU, SYDNEY SCHREPPLER, University of California, Berkeley, FELIX MOTZOI, LUKAS F BUCHMANN, Aarhus University, IRFAN SIDDIQI, University of California, Berkeley — Using microwave dressing of superconducting qubits, it is possible to implement a multi-qubit gate via a shared resonator. The gate investigated here is analogous to the Mølmer-Sørensen gate commonly used for trapped-ion qubits, but using the photon mode of the resonator instead of the phonon mode of the ions. The gate requires the use of two-photon transitions induced by bi-chromatic fields. We discuss in this talk the different sources of errors currently limiting the fidelity of the gate, relative to the coherence of the driving fields and the lifetimes of the dressed qubits.

*This work was funded by the LPS HiPS program under ARO grant W911NF1810178 and L’Oréal USA For Women in Science Fellowship Program.
Fidelity Optimization of the Cross-resonance Gate on a Multi-qubit Quantum Processor

RAVI KAUSHIK NAIK (Presenter), BRADLEY MITCHELL, AKEL HASHIM, JOHN MARK KREIKEBAUM, IRFAN SIDDIQI, University of California, Berkeley — In this work, we benchmark the performance of the cross-resonance gate in a multi-qubit setting, and evaluate gate fidelity as a function of circuit and control parameters, such as qubit detuning, effective coupling rate, and control pulse shape. We use numerical techniques to efficiently optimize gate parameter configurations. Lastly, we monitor the error syndromes of calibrated gates to investigate their sensitivity to environmental drift. This work outlines systematic calibration and operation of cross-resonance gates with model-guided optimization for general algorithmic utilization in near-term quantum computers.

*This research was supported by the LPS HiPS program under ARO grant W911NF1810178.

10:12AM R16.00012: A continuously tunable coupler for switching off adjacent qubit coupling in a superconducting circuit

XUEGANG LI (Presenter), TIANQI CAI, ZHILING WANG, XIAOXUAN PAN, YUWEI MA, WEIZHOU CAI, JIAXIU HAN, XIYUE HAN, YUKAI WU, HONGYI ZHANG, YIPU SONG, LUMING DUAN, LUYAN SUN, Institute for Interdisciplinary Information Sciences, Tsinghua University — Controllable interaction between superconducting qubits is desirable for large-scale quantum computation and simulation. We experimentally realize a simply designed and flux-tunable coupler with continuous tunability that can turn off the adjacent qubit coupling in a superconducting circuit. Based on this coupler, we demonstrate a new scheme for a two-qubit controlled-Z gate: two Xmon qubits, originally far detuned, are first gradually brought into resonance while adjusting the coupler to keep the qubit-qubit coupling off; then the qubit-qubit coupling is turned on by the tunable coupler for the necessary interaction; finally the two qubits are brought out of resonance to the idle points while keeping the coupling off. This scheme not only efficiently suppresses the leakage out of the computational subspace but also allows for a large qubit-qubit interaction strength. We achieve an average controlled-Z gate fidelity of 98.3%, characterized via quantum process tomography and dominantly limited by the system decoherence.
10:24AM R16.00013: Cancellation of unwanted ZZ interactions by superconducting qubit engineering*  
RONI WINIK (Presenter), Research Laboratory of Electronics, Massachusetts Institute of Technology, CATHERINE LEROUX, AGUSTIN DI PAOLO, Département de Physique, Université de Sherbrooke, JOCHEN BRAUMUELLER, MORTEN KJAERGAARD, ANTTI VEPSALAINEN, Research Laboratory of Electronics, Massachusetts Institute of Technology, DAVID K KIM, JONILYN YODER, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, MIT Lincoln Laboratory, ALEXANDRE BLAIS, Département de Physique, Université de Sherbrooke, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, WILLIAM OLIVER, Research Laboratory of Electronics, Department of Electrical Engineering & Computer Science, Department of Physics, Massachusetts Institute of Technology and MIT Lincoln Lab — We present a method to cancel the unwanted always-on ZZ interaction in transmon based qubit architectures by qubit engineering. We employ a new engineered qubit, which operates as a weakly anharmonic oscillator and has anharmonicity comparable to the transmon qubit, but with a positive sign. We test this concept on the cross-resonance-gate architecture [1] and outline various strategies for optimal chip design. Based on that, we design a new architecture for a superconducting quantum processor that has an inherent suppression of the unwanted ZZ interactions. Our work addresses on one of the major challenges in a commonly used architecture for superconducting quantum processors, and it enables higher fidelity multiqubit gates.

10:36AM R16.00014: Implementation of a conditional-phase gate by using in-situ tunable ZZ-interactions*  
JOHANNES HERRMANN (Presenter), MICHELE COLLODO, CHRISTIAN KRALGUND ANDERSEN, ANTS REMM, STEFANIA LAZAR, LIANGYU CHEN, NATHAN LACROIX, JEAN-CLAUDE BESSE, THEO WALTER, ANDREAS WALLRAFF, CHRISTOPHER EICHLER, Department of Physics, ETH Zurich — High fidelity two-qubit gates exhibiting low crosstalk are essential building blocks for gate-based quantum information processing. In superconducting circuits two-qubit gates are typically based either on RF-controlled interactions or on the in-situ tunability of qubit frequencies. Here, we present an alternative approach using a tunable ZZ-interaction between two-qubits, mediated by a flux-tunable coupler element. By adding a direct capacitive coupling path between the qubits, we are able to control the ZZ-coupling rate over three orders of magnitude. Using this coupling mechanism we implement a conditional-phase gate without relying on resonant exchange of excitations and characterize its performance in terms of gate fidelity, leakage and residual coupling in the idle configuration.

8:00 AM R17.00001: Multiplexing quantum modules in computational and communication systems.* [Invited] KAE NEMOTO (Presenter), National Institute of Informatics — There are many advantages to processing quantum information in a distributed fashion. The technology required to connect multiple quantum computers together provides an ideal way to naturally scale up one's computational resources. Such a feature is now standard in the classical domain; however, quantum information systems fundamentally differ from their classical counterparts in several ways. It is these differences that bring unique advantages to the distributed quantum information processing realm. Distributed quantum information systems are decomposed into modules, the fundamental building block of such systems. Adding more modules significantly increases the computational resource. The modules are simple enough to be able fully characterizable and merge quantum communication and computation approaches together. They give an architecture free technology. In this talk, we focus on these unique features of distributed quantum information processing and give a few examples of how we can implement various protocols and architecture for quantum computation and communications with an NV-based quantum module. Further we illustrate the unique advantage quantum multiplexing enables.

*This work was partly supported by MEXT KAKENHI Grant number 15H05870, 19H00662 and MEXT Quantum Leap Flagship Program (MEXT Q-LEAP) Grant Number JPMXS0118069605.

8:36 AM R17.00002: Designing Scalable Quantum Network Architectures MARTIN SUCHARA (Presenter), JOAQUIN F CHUNG MIRANDA, RAJKUMAR KETTIMUTHU, Argonne National Laboratory, ALEXANDER KOLAR, Northwestern University, XIAOLIANG WU, Illinois Institute of Technology, TIAN ZHONG, University of Chicago — Simulation-driven design is an essential tool in the development of quantum communication networks. In the past few years experimental quantum network demonstrations moved from table-top experiments to metropolitan-scale deployments and long-distance repeater network prototypes. As the number of optical components in these experiments increases, simulations simplify experiment planning and allow comparisons of alternative network architectures. In this work we use simulations to quantify the performance of networks with quantum router and repeater nodes. Our simulator of quantum network communication, called SeQUeNCe, performs simulations at the individual photon level with picosecond resolution. Faithful evaluations are achieved by modeling interactions between the physical layer, control protocols, and applications. We implement simplified models of optical components and the control protocol stack. End-to-end performance is evaluated for quantum key distribution and quantum state teleportation applications, and correctness of our models is partially validated by comparing against prior experimental results.
Routing in a quantum network

WILLIAM MUNRO (Presenter), NTT Basic Research Labs, NICOLE LO PIPARO, MICHAEL HANKS, KAE NEMOTO, National Institute of Informatics, Tokyo, Japan — It is now well known that quantum physics offers novel ways for information communication. It is expected that these principles will lead to a quantum enabled internet supporting new communication, computation and metrologocial tasks. Given the global nature of such an internet, it is clear that quantum repeaters will play an essential role in both its development and abilities. As such the efficient routing of quantum (and classical) signals will be paramount.

We discuss how the different repeater generations naturally require different routing approaches: the lower ones favoring a circuit switched approach with static routing while the third generation are ideal for a packet switched approach with dynamic routing. We illustrate how dynamic routing significantly boosts the networks performance especially when multiple users want to communicate simultaneously while allowing multiple simultaneous routes to be used by a single user. It is important to characterize the performance of the various approaches and so we introduce various cost metrics associated with the resources used within the repeaters nodes to normalize our communication rates by. Our results show the performance of the network heavily depends on efficient classical communication and the network associated with that.

A novel approach towards designing and structuring Quantum Communication devices and Quantum information processing

ADITYA CHINCHOLE (Presenter), Electronics and Telecommunication, Yeshwantrao Chavan College of Engineering — A completely new approach to quantum computation and simulation has been devised. Looking into various methods like Trapped ion, quantum communication with microwave photons, space division multiplexing optical fibre and comparing these methods to know the best suitable technique for information processing. A modified quantum information processing system is also stated in this paper. Efficient and simple techniques are also studied in depth for optical fibre communication.
9:12AM R17.00005: Towards inter-city entanglement generation using solid state spins in diamond.* ARIAN STOLK (Presenter), Delft University of Technology, JACO MORITS, ERWIN VAN ZWET, RONALD HAGEN, AD VERLAAN, TNO, MATTHEW WEAVER, RONALD HANSON, Delft University of Technology — Large scale networks where entanglement is generated and exploited between nodes are of great interest for both practical applications as well as fundamental tests of nature[1]. The NV-centre in diamond provides an excellent platform for realizing such a network, with recent work demonstrating fast entanglement generation[2] and entanglement between the NV-centre qubit and a telecom photon [3]. In this talk I will show latest experimental progress towards generating entanglement between two Dutch cities via 30km of fibre. This experiment will be the first link in a metropolitan scale quantum network in the Netherlands, which will serve as a test bed for the development of the Quantum Internet.

*This work was supported by the Netherlands Organisation for Scientific Research (NWO) through a VICI grant, and the European Research Council through an ERC Consolidator Grant.

9:24AM R17.00006: Entanglement Certification in Witness Experiments with Arbitrary Noise BAS DIRKSE (Presenter), MATTEO POMPILI, RONALD HANSON, Delft University of Technology, MICHAEL WALTER, University of Amsterdam, STEPHANIE WEHNER, Delft University of Technology — Entanglement is a fundamental property of quantum mechanical systems and an essential resource for quantum network applications. Carefully certifying entanglement is therefore an important task that is often achieved using entanglement witness experiments. Given only finite trials, the statistical confidence is typically expressed as the number of observed standard deviations of witness violations. This method implicitly assumes that the noise is well-behaved so that the central limit theorem applies.

In this work, we derive a method to certify entanglement without putting any assumptions on the state at each trial. This allows for arbitrarily correlated noise. We quantify the confidence using the p-value, the probability of obtaining data as extreme as the observed experimental data with only separable states. We give a formal abstract model of witness experiments that takes into account imperfect measurement devices and random number generators. We provide a simple method for sound data collection and show how to compute an upper bound to the p-value from the observed measurement data and device characteristics. We illustrate the use of our method with detailed examples based on realistic simulation of NV centres. This method applies to any witness experiment in general.
A Quantum Internet will enable new applications that are provably impossible with classical communication alone. However, the optical fibers used to carry the quantum information are inherently lossy. To overcome the exponential losses over distance so-called quantum repeaters are needed to amplify the signal.

For the purpose of a scalability analysis we investigate the performance of different architectures using atomic-ensemble technology in a large repeater chain spanning hundreds of kilometers. We go on to determine hardware requirements needed to cross the theoretical bound on secret key rate generation through direct transmission. By including multi-pair emission, a main source of error for these types of architectures, into our simulation we go beyond current analytical modeling of perfect photon pair sources. This allows us to assess the potential of different component technologies, such as photon sources and quantum memories, and quantify what improvements are necessary to bridge long distances.

With our simulation we provide a crucial stepping stone towards a blueprint for a pan-European quantum internet.

10:00AM R17.00009: Deterministic entanglement between non-interacting systems with linear optics*  LEIGH MARTIN (Presenter), Department of Physics, Harvard University, BIRGITTA K WHALEY, University of California, Berkeley — Measurement-based heralded entanglement schemes provide the primary method to entangle physically separated nodes in most quantum systems. However, the impossibility of performing a deterministic Bell measurement with linear optics bounds the success rate of these protocols to at most 50%. Here we show that the ability to perform feedback during the measurement process enables unit success probability in a single shot. Our primary feedback protocol, based on photon counting, retains the same robustness as the standard Barrett-Kok scheme, while doubling the success probability even in the presence of loss. Furthermore, it generalizes to creation of distributed $N$-particle Dicke states. In superconducting circuits, for which homodyne detectors are more readily available than photon counters, we give another protocol that can deterministically entangle remote qubits given realistic parameters. In constructing the latter protocol, we derive a general expression for locally optimal control that applies to any continuous feedback problem.

*The research is based upon work supported by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), via the U.S. Army Research Office contract W911NF-17-C-0050.

10:12AM R17.00010: Protocols for creating and purifying GHZ states*  SEBASTIAN DE BONE (Presenter), Delft University of Technology, RUNSHENG OUYANG, Tsinghua University, KENNETH GOODENOUGH, DAVID ELKOUSS, Delft University of Technology — The distribution of high quality Greenberger-Horne-Zeilinger (GHZ) states is at the heart of many applications in quantum information and the upcoming quantum internet, ranging from extending the baseline of telescopes to secret sharing. They also play an important role in error-correction architectures for distributed quantum computation, where EPR pairs are leveraged to create an entangled network of quantum computers.

Here, we investigate the creation of GHZ states over quantum networks. In particular, we introduce an algorithm based on dynamical programming to optimize over a large class of protocols that create and purify GHZ states. The new protocols outperform previous proposals for relevant scenarios, by reducing the resources necessary for GHZ creation, thus bringing the aforementioned applications closer to reality.

*This work was supported by the Netherlands Organization for Scientific Research (NWO/OCW), as part of the Quantum Software Consortium program (project number 024.003.037 / 3368).
10:24AM R17.00011: Constraints on continuous variable entanglement swapping in the presence of photon loss  ALEX KWIATKOWSKI (Presenter), University of Colorado, Boulder, EZAD SHOJAEE, SCOTT GLANCY, EMANUEL H KNILL, National Institute of Standards and Technology — In many procedures for entanglement swapping in the continuous variable domain the entangling measurement is quadrature measurement of linear mixtures of the two modes sent by the two parties that wish to swap entanglement. In the presence of sufficient photon loss, which we model as a fictitious beamsplitter with the environment on each of the two modes, we show that such a measurement cannot be used to swap entanglement. We show analytically that if the modes sent by the two parties suffer losses that average between them to 50% or more, then any passive linear circuit followed by quadrature measurement has a separable POVM on those modes and therefore cannot be used to perform entanglement swapping. We will also discuss the case where the constraints on the measurement are relaxed to include arbitrary Gaussian resources.

10:36AM R17.00012: Quantum Control through Optical Nonlinearities for Error Corrected One-way Quantum Repeaters  STEFAN KRASTANOV (Presenter), MIKHEL HEUCK, Massachusetts Institute of Technology MIT, KURT JACOBS, Army Research Laboratory, PRINEHA NARANG, Harvard University, DIRK R. ENGLUND, Massachusetts Institute of Technology MIT — The use of exclusively optical modes for quantum communication and quantum computing is intriguing due to its potential to work at room temperatures. However, restricting architectures to only optical modes (i.e. quantum harmonic oscillators with simple couplings), leaves very few knobs available for the control of such systems. We present how the couplings between multiple optical modes, mediated by material nonlinearities, enable the performance of error correction and logical operations for a number of small bosonic error correcting codes. This high level of control is achieved through designing arbitrary pulse shapes for the classical laser light used to trigger the resonant nonlinear interaction between multiple quantum modes. This would enable one-way quantum repeaters with error correction and is a necessary step for room-temperature quantum photonic information processing.
10:48AM R17.00013: Entanglement of a pair of quantum emitters under continuous fluorescence measurements* PHILIPPE LEWALLE (Presenter), CYRIL ELOUARD, SREENATH KIZHAKKUMPURATH MANIKANDAN, University of Rochester, XIAO-FENG QIAN, Stevens Institute of Technology, J H EBERLY, ANDREW N JORDAN, University of Rochester —
We examine the state and entanglement dynamics of two remote qubits, under continuous measurements of their spontaneous emission. Erasing information about which qubit emitted a particular contribution to the joint measurement signal is possible with both photodetection, and well-chosen quadrature measurements; in either case, measurements then effectively perform an entanglement swapping operation, taking entanglement created between each qubit and its emitted field mode, and generating correlations between the two remote qubits instead. We compare the quantum jump trajectories from photodetection with the diffusive quantum trajectories, which arise from quadrature measurements, demonstrating that they have equivalent average entanglement yield under ideal conditions. Outlook and next steps will be discussed.

Session R18 GSNP: Electron-Phonon Coupling and High-Temperature Superconductivity 205 - John Sous, Columbia Univ - Tag(s): Invited
8:00AM R18.00001: Reconsidering the electron-phonon problem and bounds on $T_c$ [Invited]
STEVEN KIVELSON (Presenter), Stanford Univ — We exploit the fact that the Holstein model of the electron-phonon problem can be treated without approximation using fermion-minus-sign-free determinant quantum Monte Carlo methods to establish results that can be compared quantitatively and unambiguously with approximate methods based on Migdal-Eliashberg (ME) theory. In the relevant limit in which the phonon frequencies are small compared to the Fermi energy (strong retardation), we find that ME theory is extremely accurate up to moderate values of the dimensionless electron-phonon coupling $\lambda$, and then breaks down relatively suddenly beyond a characteristic value, $\lambda^{*} \sim 1$, beyond which polaron physics is significant. One consequence of this is that – in contrast with earlier beliefs based on ME theory – the superconducting $T_c(\lambda)$ has its maximum value at $\lambda \approx \lambda^{*}$. This implies that there is an upper bound on $T_c$ from the electron phonon mechanism $T_c \leq A w_{\text{max}}$, where $w_{\text{max}}$ is the maximum phonon energy and we estimate that $A \approx 1/10$.

8:36AM R18.00002: Light bipolarons from strong Peierls electron-phonon coupling* [Invited]
MONA BERCIU (Presenter), Physics and Astronomy, University of British Columbia, JOHN SOUS, Physics, Columbia University, MONODEEP CHAKRABORTY, Centre for Theoretical Physics, Indian Institute of Technology, Kharagpur, ROMAN KREMS, Chemistry, University of British Columbia — It is widely accepted that phonon-mediated high-temperature superconductivity is impossible at ambient pressure, because of the very large effective masses of polarons and bipolarons at strong electron-phonon coupling. We challenge this by showing that strongly bound yet very light bipolarons appear for strong Peierls coupling. These bipolarons exhibit many unconventional properties; e.g., at strong coupling there are two low-energy bipolaron bands that are stable against strong Coulomb repulsion. Using numerical simulations and analytical arguments, we show that these properties result from the specific form of the phonon-mediated interaction, which is of “pair hopping” instead of regular density-density type. This unusual effective interaction is bound to have nontrivial consequences for the superconducting state expected to arise at finite carrier concentrations and should favor a large critical temperature.

9:12AM R18.00003: Superconductivity in Ultra-Low Density Dirac Materials Driven by a Ferroelectric Quantum Critical Point* [Invited] JONATHAN RUHMAN (Presenter), Physics, Bar Ilan University, VLADYSLAV KOZII, Condensed Matter Physics, Berkeley, ZHEN BI, Massachusetts Institute of Technology MIT — According to standard lore, low-density materials such as semimetals should not become superconducting. They are characterized by a small Fermi energy, which is comparable to the Debye frequency and moreover, their density of states is extremely small. Nonetheless, superconductivity is ubiquitous in topological materials, including YPtBi, Bi$_2$Se$_3$, Bi, Cd$_3$As$_2$, PbTe and SnTe, which raise the question regarding the microscopic picture of pairing in these systems. In this talk, I will discuss the option of pairing mediated by ferroelectric fluctuations close to a quantum critical point in a Dirac semimetal. I will show that such fluctuations lead to pairing, even when the Fermi energy is smaller than any bosonic frequency in the problem and possibly, even at charge neutrality.

9:48AM R18.00004: New Perspectives from Spectroscopy on the Bismuth Oxide Superconductors* [Invited] NICHOLAS PLUMB (Presenter), Swiss Light Source, Paul Scherrer Institute — Despite being known for decades, the perovskite bismuth oxide superconductors (max $T_c > 30$ K) were never experimentally probed to nearly the extent of more famous high-$T_c$ materials, such as cuprates and iron-based superconductors. This is a pity, because their phenomenology and underlying physics connect with a wide array of contemporary interests: not only unconventional/high-$T_c$ superconductivity, but also metal-insulator and insulator-superconductor transitions, (bi)polarons, CDWs/charge-order, disordered systems, and so on. Recently we have studied Ba$_{1-x}$K$_x$BiO$_3$ films using angle-resolved photoemission and resonant inelastic x-ray scattering. These experiments establish the unusual “bond disproportionated” nature of the parent compound and track its evolution into the superconducting doping region. The under- to optimally-doped region of the phase diagram is particularly fascinating. There spectra show a highly dispersive conduction band forming a well-defined Fermi surface, despite a total absence of sharp peaks that would typically accompany weakly interacting quasiparticles. We observe, moreover, two types of pseudogap-like spectral behaviors: The first extends over a broad energy scale and persists above room temperature; the other is set in a narrow region around $E_F$ and opens in a well-defined temperature range above $T_c$. I will discuss how these psuedogaps appear to be linked - namely that they represent the precipitation of ordered bipolaronic insulating regions out of a disordered polaronic liquid.

*This work is supported by the Swiss National Science Foundation under projects 200021_159678 and 200021_185037.
The nature of superconductivity in the dilute semiconductor SrTiO₃ has remained an open question for over half a century. Thin film heterostructures provide new opportunities to examine SrTiO₃ superconductivity using a newly developed method for engineering band alignments at oxide interfaces to access the electronic structure of Nb-doped SrTiO₃ using high-resolution tunneling spectroscopy. While we observe strong coupling to the highest-energy longitudinal optic phonon consistent with $\lambda \sim 1$, the superconducting gap is found to be in the weak-coupling limit of BCS theory, i.e. $\lambda_{BCS} \sim 0.1$. This discrepancy arises in the context of an unusual anti-adiabatic condition for superconductivity in SrTiO₃ (Fermi energy < Debye energy), which we find precisely bounds the superconducting dome.

This work was done in collaboration with Hyeok Yoon, Adrian Swartz, Hisashi Inoue, Yasuyuki Hikita, and Sri Raghu.

Session R19 GMAG: Magnetic interactions at complex oxide interfaces
207 - Alexander Grutter, National Institute of Standards and Technology - Tag(s): Invited
Efficient bias-driven magnetization control by orbital selection at a La$_{0.67}$Sr$_{0.33}$MnO$_3$ interface* [Invited] LE DUC ANH (Presenter), TAKASHI YAMASHITA, NOBORU OKAMOTO, HIROKI YAMASAKI, DAISEI ARAKI, MUNETOSHI SEKI, HITOSHI TABATA, MASAAKI TANAKA, SHINOBU OHYA, Univ of Tokyo — Bias-driven magnetization control of a ferromagnet, which utilizes the ability of controlling the magnetic anisotropy (MA) with an electric field, is crucial for spintronic applications due to its low power consumption. However, it remains a challenge to induce a large change in the MA of ferromagnetic materials that can rotate the magnetization. In this work, using La$_{0.67}$Sr$_{0.33}$MnO$_3$ (LSMO)/SrTiO$_3$ (STO)/LSMO magnetic tunnel junctions (MTJs), we demonstrate that a drastic change in the MA of LSMO can be induced when the chemical potential ($E_F$) at the LSMO/STO interface is moved between bands with different orbital symmetries. By this new approach, we successfully realize a deterministic and magnetic-field-free 90°-magnetization switching of LSMO solely by applying a small electric field of 0.05 V/nm on the tunnel barrier, with a negligibly small current density of $\sim 10^{-2}$ A/cm$^2$.

The studied MTJs are grown on an STO (001) substrate by molecular beam epitaxy. We probe the orbital symmetry of the carriers and the MA of the LSMO layers at each bias $V$ by measuring the magnetic-field-direction dependence of the tunneling conductance and that of the tunneling magnetoresistance (TMR), respectively. Using this approach, we show that, with applying $V$, the MA of the LSMO switches from a two-fold symmetry to a four-fold symmetry by shifting $E_F$ from the $e_g$ band to the $t_{2g}$ band [1]. This change of MA is strong enough to rotate the magnetization direction from [110] to [1-10] without any assisting magnetic field. Our findings indicate that highly efficient magnetization control can be realized by designing materials so that the $E_F$ lies close to the band edges of different-symmetry orbitals [2].

Spin-orbit coupling and local magnetism at a complex oxide interface

[Invited] VLAD PRIBIAG (Presenter), University of Minnesota — SrTiO$_3$-based thin-film heterostructures are a powerful platform for studying a wide array of electronic phases in two dimensions, at high carrier densities. This talk will discuss low-temperature electronic transport studies of NdTiO$_3$/SrTiO$_3$ interfaces, which reveal local ferromagnetic order and strong spin-orbit interaction. As the magnetic field angle is gradually tilted away from the sample normal, the data reveals an intriguing interplay between strong k-cubic Rashba-type spin-orbit coupling and a substantial magnetic exchange interaction from local magnetic regions. The resulting quantum corrections to the conduction are in excellent agreement with existing models and allow sensitive determination of the small magnetic moments (22 $\mu_B$ on average), their magnetic anisotropy and mutual coupling strength. This effect is expected to arise in other 2D magnetic materials systems and could provide a simple yet powerful tool for investigating local magnetism.

Film growth and structural characterizations were funded by the U.S. Department of Energy through the University of Minnesota Center for Quantum Materials, under Grant No. DE-SC-0016371. Portions of this work were conducted in the Minnesota Nano Center, which is supported by the National Science Foundation through the National Nano Coordinated Infrastructure Network (NNCI) under Award No. ECCS-1542202. Sample structural characterization was carried out at the University of Minnesota Characterization Facility, which receives partial support from NSF through the MRSEC program under Award No. DMR-1420013.
Interfacial control of chiral magnetic interactions and Hall effect in iridate-manganite superlattices* [Invited] ELIZABETH SKOROPATA (Presenter), JOHN A NICHOLS, JONG MOK OK, Oak Ridge National Lab, RAJESH V CHOPDEKAR, Lawrence Berkeley National Laboratory, EUN SANG CHOI, National High Field Magnet Laboratory, ANKUR RASTOGI, CHANGHEE SOHN, XIANG GAO, THOMAS FARMER, RYAN DESAUTELS, Oak Ridge National Lab, YONGSEONG CHOI, DANIEL HASKEL, JOHN WILLIAM FREELAND, Argonne National Laboratory, SATOSHI OKAMOTO, MATTHEW BRAHLEK, HO NYUNG LEE, Oak Ridge National Lab — One of the most intriguing outcomes of symmetry breaking and spin-orbit interactions in magnetic systems is the possibility to create non-collinear and chiral spin textures. The Dzyaloshinskii-Moriya interaction (DMI) results from strong spin-orbit coupling and broken inversion symmetry to generate magnetization rotations with fixed chirality. The discovery of magnetic skyrmions originating from strong DMI in metal thin films has led to an explosion of efforts to manipulate magnetic phases originating from interfaces. I will describe our progress to understand interface-induced magnetism in epitaxial $3d/5d$ iridate/manganite superlattices. Our previous work on high-quality epitaxially stabilized SrMnO$_3$/SrIrO$_3$ superlattices revealed charge-transfer induced interfacial collinear ferromagnetism and an anomalous Hall effect [1,2]. In LaMnO$_3$/SrIrO$_3$ superlattices, we find a large additional topological Hall effect arising from the interaction of charge carriers with a noncoplanar chiral spin texture induced by interfacial DMI [3]. I will describe how the interfacial atomic layer stacking and symmetry enabled by the nonmagnetic A-sites determine the competition between collinear and chiral magnetic interactions originating from the oxide interface. These results will be compared with magnetometry measurements, soft and hard x-ray experiments, which provide a comparison of the bulk and interface electronic and magnetic properties. Our findings provide insight to the manipulation of chiral magnetism from atomic-scale control of DMI at oxide interfaces.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.
Spin to charge conversion in the topological insulator HgTe and in STO-based two-dimensional electron gas* [Invited] JEAN-PHILLIPPE ATTANE (Presenter), Univ. Grenoble Alpes, CEA, IRIG, 38000 Grenoble (France) — While classical spintronics has traditionally relied on ferromagnetic metals as spin generators and spin detectors, a new approach called spin-orbitronics exploits the interplay between charge and spin currents enabled by the spin-orbit coupling in non-magnetic systems. However, the interconversion efficiency of the Hall effect is a bulk property that rarely exceeds ten percent, and does not take advantage of interfacial and low-dimensional effects otherwise ubiquitous in spintronics.

In this contribution, we first focus on strained mercury telluride, using spin pumping experiments at room temperature. We show that a HgCdTe barrier can be used to protect the HgTe topological surface states, leading to high conversion rates, with inverse Edelstein lengths up to 2.0±0.5 nm. These measurements, associated with the temperature dependence of the resistivity, suggest that these high conversion rates are due to the spin momentum locking property of HgTe surface states [1].

We then focus on the SrTiO3 (STO)-based 2D electron system, presenting experiments performed on NiFe/Al/STO heterostructures. We investigate the nature of the spin-to-charge conversion through a combination of spin pumping, magnetotransport, spectroscopy and gating experiments, finding a very highly efficient spin-to-charge conversion, with inverse Edelstein lengths beyond 20 nm. More importantly, we demonstrate that the conversion rate can be tuned in amplitude and rate by a gate voltage. We then discuss the amplitude of the effect and its gate dependence on the basis of the electronic structure of the 2DES and highlight the importance of a long scattering time to achieve efficient spin-to-charge interconversion.

The transition metal oxides exhibit a variety of interesting properties that are important for many practical applications, such as the dielectrics, magnetism, ferroelectricity, superconductivity, multiferroicity, etc. Such a rich plethora of functional properties primarily originate from the hybridized bands between the transition metal and the oxygen atoms. In artificially heterostructured oxide thin films, there exist the exciting new properties that are absent in the bulk materials, i.e. the emergent properties in oxide heterostructures. The understanding of the fundamental physics behind these emergent properties remains a huge challenge in condensed matter physics and attracts a lot of research interests in recent days. In this talk, I will introduce our recent advances in understanding the emergent magnetism in 2D oxide ferromagnets and a number of magnetic oxide heterostructures, from the symmetry aspects of the oxygen sublattice, including the octahedral rotations, tilts and the oxygen vacancies. Our study reveals the importance of the symmetry of the oxygen sublattice in shaping the emergent magnetism in low dimensional correlated oxide heterostructures.

*The National Key Research and Development Program of China (Grants No. 2016YFA0401004), the National Natural Science Foundation of China (Grants No. 51627901 and No. 11574287).
AYDOGAN OZCAN (Presenter), University of California, Los Angeles — Deep learning is a class of machine learning techniques that uses multi-layered artificial neural networks for automated analysis of signals or data. The name comes from the general structure of deep neural networks, which consist of several layers of artificial neurons, each performing a nonlinear operation, stacked over each other. Beyond its main stream applications such as the recognition and labeling of specific features in images, deep learning holds numerous opportunities for revolutionizing image formation, reconstruction and sensing fields. In fact, deep learning is mysteriously powerful and has been surprising optics researchers in what it can achieve for advancing optical microscopy, and introducing new image reconstruction and transformation methods. From physics-inspired optical designs and devices, we are moving toward data-driven designs that will holistically change both optical hardware and software of next generation microscopy and sensing, blending the two in new ways. Today, we sample an image and then act on it using a computer. Powered by deep learning, next generation optical microscopes and sensors will understand a scene or an object and accordingly decide on how and what to sample based on a given task – this will require a perfect marriage of deep learning with new optical microscopy hardware that is designed based on data. For such a thinking microscope, unsupervised learning would be the key to scale up its impact on various areas of science and engineering, where access to labeled image data might not be immediately available or very costly, difficult to acquire. In this presentation, I will provide an overview of some of our recent work on the use of deep neural networks in advancing computational microscopy and sensing systems, also covering their biomedical applications.

*NSF, HHMI and Koc Group are acknowledged for funding.
8:36AM R20.00002: Exploring Organic Ferroelectrics Using Data-driven Approaches*  
AYANA GHOSH (Presenter), Univ of Connecticut - Storrs, NICHOLAS LUBBERS, Computer, Computational and Statistical Sciences, Information Sciences, Los Alamos National Laboratory, SERGE M NAKHMANSON, Univ of Connecticut - Storrs, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory — Recent advances in the synthesis of polar molecular materials have produced practical alternatives to ferroelectric ceramics, opening up exciting new avenues for the incorporation of such compounds into modern electronic devices. However, in order to fully realize the prospects of polar polymer and molecular crystals for modern technological applications, it is paramount to acquire diverse datasets of potential organic ferroelectrics such that the mechanisms governing the emergence of ferroelectricity can be studied. Here we propose to use data-driven approaches to judiciously shortlist candidates from a wide range of chemical space with ferroelectric functionalities. First, this investigation will be governed by identification of chemical similarities between existing molecular compounds exhibiting similar ferroelectric behavior. Second, we investigate machine learning (ML) and deep neural network models for estimating charge transfer effects in organic chemistry. The dipole moment and ferroelectric properties estimated by ML can then be used to supplement the data-driven screening of possible organic ferroelectrics.

8:48AM R20.00003: Deep Learning Model for Finding New Superconductors  
TOMOHIKO KONNO (Presenter), National Institute of Information and Communications Technology, HODAKA KUROKAWA, FUYUKI NABESHIMA, YUKI SAKISHITA, RYO OGAWA, University of Tokyo, IWAO HOSAKO, National Institute of Information and Communications Technology, ATSUTAKA MAEDA, University of Tokyo — It is very difficult for both theories and computational methods to predict the superconducting transition temperatures Tc of superconductors for strongly correlated systems, in which high-temperature superconductivity emerges. Exploration of new superconductors still relies on the experience and intuition of experts, and is largely a process of experimental trial and error. In one study, only 3% of the candidate materials showed superconductivity. Here we report an interdisciplinary attempt for finding new superconductors based on deep learning. We represented the periodic table in a way that allows a deep learning model to learn it. Although we used only the chemical composition of materials as information, we obtained an R2 value of 0.92 for predicting Tc for materials in a database of superconductors. We obtained three remarkable results. The deep learning method can predict superconductivity for a material with a precision of 62%, which shows the usefulness of the model; it found the recently discovered superconductor CaBi2, which is not in the superconductor database; and it found Fe-based high-temperature superconductors (discovered in 2008) from the training data before 2008. These results open the way for the discovery of new high-temperature superconductor families.
9:00AM R20.00004: Deep Learning for Energetic Materials: Predicting Material Properties from Electronic Structure using Convolutional Neural Networks*  ALEX CASEY (Presenter), Mechanical Engineering, Purdue University, BRIAN BARNES, Army Research Laboratory, ILIAS BILIONIS, STEVEN F. SON, Mechanical Engineering, Purdue University — Developing numerical descriptions of complex objects, like molecular structure, is a difficult task. The accuracy of a machine learned model depends on the input representation. Ideally, input descriptors encode the essential physics and chemistry that influence the target property. Thousands of molecular descriptors have been proposed and proper selection of features requires considerable domain expertise. In contrast, deep learning networks are capable of learning rich data representations. This provides a compelling motivation to use deep learning networks to learn molecular structure-property relations from 'raw' data. We develop a convolution neural network capable of directly parsing the 3D electronic structure of a molecule described by spatial point data for charge density and electrostatic potential concatenated into a 4D tensor. The model is jointly trained on over 20,000 molecules that are potentially energetic materials (explosives) to predict dipole moment, total electronic energy, Chapman-Jouguet (C-J) detonation velocity, C-J pressure, C-J temperature, crystal density, HOMO-LUMO gap, and solid phase heat of formation. This work demonstrates the first use of complete 3D electronic structure for machine learning of molecular properties.

9:12AM R20.00005: Optimization of Molecular Characteristic using Continuous Representation of Molecules by Variational Autoencoder with Discriminator  KYOSUKE SATO (Presenter), KENJI TSURUTA, Graduate School of Natural Science and Technology, Okayama University — Efficient molecular search contributes to an essential speedup of the development of organic devices and, in turn to the improvement of their characteristics. In the present study, we focus on the deep learning variational auto-encoder (VAE) model[1], where molecules represented by SMILES strings can be efficiently converted to multivariable continuous space. The VAE consists of two neural networks: an encoder and a decoder. The one-hot representation of SMILES is input to the encoder and mapped to the latent variable space. Here we further improve the output rate of valid SMILES of decoder by introducing a discriminator attached to the VAE stream. Adopting a molecular-mechanics method to calculate 3D structure from SMILES, we can optimize physical properties of the molecule by other simulation methods such as density-functional-theory calculations even when there is not enough data set. The range of physical property space covered by the SMILES representation is thereby expanded and the data-driven optimization using Kernel Ridge Regression method can be performed within the search space. In the presentation, we show the effectiveness of this method for optimizing a molecular HOMO-LUMO gap as an example.

An Initial Design-based Deep Learning Procedure for the Optimization of High Dimensional ReaxFF Parameters*  
MERT SENGUL (Presenter), Materials Science and Engineering, The Pennsylvania State University, YAO SONG, LINGLIN HE, YING HUNG, TIRTHANKAR DASGUPTA, Department of Statistics, Rutgers University, ADRI C.T. VAN DUIN, Mechanical Engineering, Pennsylvania State University — Atomistic level investigations are a significant part of today’s materials discovery research; however, most of the modeling methods that can describe chemical reactions are restricted to small molecular systems due to computational costs. The ReaxFF, an empirical interatomic potential, is capable of simulating reactions in larger molecular systems; however, the application of ReaxFF requires a significant preprocessing. One of the preprocessing steps is the optimization of functional parameters that are used to calculate interatomic interactions. This optimization process is complex due to high dimensionality. Here, we propose a deep learning (DL)-based procedure to be used in ReaxFF parameter optimization. The procedure is composed of three stages, which are: 1) data set creation; 2) DL model fitting and 3) local-minima detection. This DL procedure eliminates unfeasible regions in parameter space, which originate from the unphysical atomistic interactions, and constructs a more comprehensive understanding of a physically meaningful parameter landscape. The performance of the procedure will be evaluated by its application to molecular systems.

Feature Extraction Using Semi-Supervised Deep Learning.*  
MUAMMAR EL KHATIB (Presenter), WIBE A DE JONG, Computational Research Division, Lawrence Berkeley National Laboratory — Features are defined as measurable properties that characterize observed phenomena and represent a key part of machine learning (ML) algorithms. In materials sciences, ML has successfully accelerated atomistic simulations using man-engineered features for tasks such as energy or atomic forces predictions. These features fulfill physics constraints such as rotational and translational invariance, uniqueness and, locality (the sum of local contributions reconstructs a global quantity). However, these ML models are known to perform poorly when operating out of the training set regime because features are not representative of the underlying structure of the data. This could be improved if features are extracted with advanced hybrid architectures e.g. a variational autoencoder that is trained with physics constraints introduced with an external task and a loss function. We will explore how the use of semi-supervised learning techniques can be a powerful tool for the extraction of features for atomistic simulations. All results shown herein can be reproduced with ML4Chem: a free software package for machine learning in chemistry and materials sciences.

Unsupervised feature extraction in simple physical models through mutual information maximization

LEOPOLDO SARRA (Presenter), FLORIAN MARQUARDT, Max Planck Inst for Sci Light — When studying systems with many degrees of freedom, a typical problem is to find the correct low-dimensional variables to describe them on a higher level of abstraction. However, sometimes it is not clear how to choose meaningful quantities. By defining relevant features as low dimensional variables that preserve the largest mutual information with the original coordinates of the system, we set up an unsupervised learning technique to automatically extract those features. A variational bound allows to estimate mutual information through deep neural networks. We show example applications to statistical mechanics and classical dynamics.

Integration of Neural Network-Based Symbolic Regression in Deep Learning for Scientific Discovery*

SAMUEL KIM (Presenter), Electrical Engineering and Computer Science, Massachusetts Institute of Technology, PETER LU, Physics, Massachusetts Institute of Technology, MICHAEL GILBERT, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, SRIJON MUKHERJEE, LI JING, Physics, Massachusetts Institute of Technology, VLADIMIR ČEPERIĆ, University of Zagreb, MARIN SOLJACIC, Physics, Massachusetts Institute of Technology — Symbolic regression is a powerful technique that can discover the underlying analytical equations describing data, which can lead to explainable models and generalizability outside of the training data set. Here we use a neural network for symbolic regression based on the EQL network and integrate it into other deep learning architectures such that the whole system can be trained end-to-end through backpropagation. We demonstrate this system on an arithmetic task involving MNIST digits and on prediction of dynamical systems. The architecture is able to simultaneously extract meaningful latent variables and find the underlying equations that generalize extremely well outside of the training data set compared to a standard neural network approaches, paving the way for scientific discovery.

Rapid machine learning-based solutions of partial differential equations on complex domains. VIKAS DWIVEDI (Presenter), BALAJI SRINIVASAN, Indian Inst of Tech-Madras — Conventional methods like FEM (finite element method) and FVM (finite volume method) are mesh-based. However, if the computational domain consists of a complicated polygon with very short line segments, then it puts serious restrictions on mesh generation methods like triangulation. Recently, Berg et. al [1] have developed a deep unified ANN algorithm to solve PDEs on complex computational domains. Their method is based on an ansatz for the solution which requires deep neural networks and an unconstrained gradient-based optimization method such as gradient descent or a quasi-Newton method. In this paper, we present physics informed extreme learning machine (PIELM), a new machine-learning algorithm, which solves this problem with a simpler neural network architecture and an extremely fast learning routine. We demonstrate the efficacy of our method by solving the Poisson and biharmonic equation on complex 2D and 3D geometries such as the gyroid, which has important engineering applications.

Probabilistically-autoencoded horseshoe-disentangled multidomain item-response theory models* JOSHUA CHANG (Presenter), SHASHAANK VATTIKUTI, CARSON C CHOW, National Institutes of Health - NIH — Item response theory (IRT) is a non-linear generative probabilistic paradigm for using exams in order to quantify latent traits. In multidimensional IRT, one requires a factorization of the test items. For this task, linear factor analysis methods are often used, making IRT a posthoc model. We propose skipping the initial factor analysis by using a sparsity-promoting horseshoe prior to perform factorization directly within the IRT model so that all training occurs in a single self-consistent step. By binding the generative IRT model to a Bayesian neural network (forming a probabilistic autoencoder), one obtains a scoring algorithm consistent with the interpretable Bayesian model. In some IRT applications the black-box nature of a neural network scoring machine is desirable. Within this problem, we investigate the translation of some regularization principles common in Bayesian modeling to neural networks.

10:36AM R20.00012: Turbulence-generating networks ARMANDO GARCIA (Presenter), University of Texas, El Paso, RAO GUDIMETLA, Air Force Research Laboratory, JORGE MUNOZ, University of Texas, El Paso — The propagation of light through the atmosphere is often simulated with screens that impose a phase difference on an incoming wave. The screens are applied in series and have phase power spectral densities that are consistent with the strength of the turbulence to be simulated. We propose a new method to simulate the effect of turbulence on light propagation that uses mathematical graphs (networks) that are agnostic of spatial dimension or angle information. The intensity variation in the final screen is a measure of turbulence strength and we used several machine learning methods to adjust the probability distribution functions (PDF) of the weights of the edges of the networks to achieve the desired variations. We compare our results to the phase screen method for the case of the Kolmogorov spectrum using statistical measures such as the structure function. Finally, we explore avenues for improving the computational cost of producing turbulence-degraded images with this method as well as extending it to anisotropic turbulence.

10:48AM R20.00013: SignalTrain: Modeling Time-dependent Nonlinear Signal Processing Effects Using Deep Neural Networks WILLIAM MITCHELL (Presenter), SCOTT HAWLEY, Physics, Belmont University — The advent of increased consumer computing power and graphics processing unit (GPU) usage over the last decade has made possible machine learning approaches to modeling problems once thought impractical. This work expands on prior research published on modeling nonlinear time-dependent signal processing effects associated with music production by means of a deep neural network\(^1\). The presented results show the progress in accurately modeling these effects through architecture and optimization changes, increasing computational efficiency, lowering noise, and extending to a larger variety of nonlinear audio effects. Unique contributions of this effort include the ability to emulate the individual settings or “knobs” you would see on an analog piece of equipment, and with the production of commercially viable audio, i.e. 44.1kHz sampling rate at 16-bit resolution.

Session R21 GERA: Thermoelectric Materials 302
**8:00AM R21.00001: Computational Investigation of Ternary Na-V-VI$_2$ Chalcogenides and Their Thermoelectric Properties**

ISHAN KHARE (Presenter), Ottawa Hills High School, OH 43606, NATHAN J SZYMANSKI, Department of Materials Science and Engineering, UC Berkeley, RICHARD IRVING, Department of Physics and Astronomy, The University of Toledo — Ternary chalcogenides have been of recent investigation for applications such as solar cells and thermoelectrics. We have computed the structural, energetic, electronic, optical, and thermoelectric properties of nine ternary Na-V-VI$_2$ chalcogenides, NaAX$_2$, where A represents As, Sb, Bi and where X represents S, Se, Te, using first principles methods based on density functional theory and beyond. Optimized lattice parameters have been computed using the generalized gradient approximation (GGA). Phonon density of states computed at zero-temperature shows that only four of the nine compounds, NaAsS$_2$, NaAsTe$_2$, NaSbS$_2$, and NaSbSe$_2$, are dynamically stable. Our computations for these structures show that their electronic and optical properties are highly anisotropic. In addition, thermoelectric properties such as Seebeck coefficient (S) and power factor were computed using Boltzmann statistics. The compounds are predicted to have promising thermoelectric properties at 300 K, indicating that these materials are desirable for thermoelectric applications. Particularly, NaAsTe$_2$ is predicted to have S = 425 μV/K. Experimental verification is suggested.

---

**8:12AM R21.00002: Enhanced thermoelectric efficiency in Bi$_2$Te$_3$ nanoplates and SnSe$_2$ films.**

JIHAN CHEN, INDU ARAVIND (Presenter), YU WANG, Univ of Southern California — We present a facile method to improve the thermoelectric efficiency of CVD grown 2D Bi$_2$Te$_3$ nanoplates through remediation of unintentional surface doping. The as-grown flakes of Bi$_2$Te$_3$ exposed to ambient conditions exhibit relatively small thermopowers. The high surface-to-volume ratio of these thin nanoplates makes them especially sensitive to surface doping, which is a common problem among nanomaterials in general. After surface passivation by deposition of 30nm of Al$_2$O$_3$ using ALD, the Seebeck coefficient of these flakes increases by a factor of 5X (from -34 to -169 μV/K). Here, the surface passivation can prevent the degradation of the thermoelectric properties caused by gas adsorption and surface oxidation processes, thus increasing the Bi$_2$Te$_3$ Seebeck coefficient.$^1$

We also report cross-plane thermoelectric measurements of SnSe and SnSe$_2$ films grown by the modulated element reactant (MER) approach. By performing post-growth annealing at a fixed Se partial pressure, a transition from SnSe-to-SnSe$_2$ is induced which results in a 16-fold increase (from -38.6 to -631μV/K) in the cross-plane Seebeck coefficient.$^2$

8:24AM R21.00003: High Thermoelectric Figure of Merit via Tunable Valley Convergence Coupled Low Thermal Conductivity in \(A^{II}B^{IV}C_{2}^{V}\) Chalcopyrites  MADHUBANTI MUKHERJEE (Presenter), GEORGE YUMNAM, ABHISHEK SINGH, Indian Institute of Science — Developing high performance thermoelectrics require designing strategy to obtain excellent electronic but poor phononic transport properties. Tetragonal chalcopyrites are of significant attention due to complex electronic structures affecting the transport properties. Conflicting requirements of achieving high Seebeck coefficient and electrical conductivity are simultaneously reached, by tuning crystal and electronic structures by isoelectronic substitution, leading to unprecedented enhancement in electronic transport properties of \(A^{II}B^{IV}C_{2}^{V}\) (\(II = \text{Be, Mg, Zn, and Cd}, \ IV = \text{Si, Ge, and Sn}; \ \text{and V = P and As}\)). Existing multiple valleys in conduction bands get converged by substitution of group IV dopants to offer enhanced powerfactors for n-type carriers. These substitutions improve convergence of valence bands having a direct correlation with tetragonal distortion (\(\eta\)) of these chalcopyrites. For small distortion in system (\(\eta\sim 1\)), complete convergence of bands is achieved, enhancing the p-type powerfactor. Excellent electronic transport and low thermal conductivity results in maximum ZT of 1.67 in CdGeAs\(_2\) for n-type doping. The approach developed to enhance the thermoelectric efficiency can be useful to design new thermoelectric materials.

*J. Phys. Chem. C* 2018, 122, 29150–29157

8:36AM R21.00004: Thermoelectric properties of n-type PbTe driven near ferroelectric phase transition by strain*  JIANG CAO (Presenter), School of Electronic and Optical Engineering, Nanjing University of Science and Technology, JOSE D. QUERALES-FLORES, DORDE DANGIC, Tyndall National Institute, STEPHEN B FAHY, University Colledge Cork, IVANA SAVIC, Tyndall National Institute — We recently showed that soft transverse optical (TO) phonons play the key role in high thermoelectric (TE) figure of merit (ZT) of PbTe: they strongly suppress its lattice thermal conductivity[1], but do not degrade its electronic transport properties[2]. In this work, using first principles calculations, we investigate how driving PbTe closer to the soft mode phase transition (PT) via strain affects the TE properties and ZT of n-type PbTe. We find that the lattice thermal conductivity decreases significantly when PbTe approaches the PT, which leads to considerable ZT enhancement. However, if PbTe is driven very close to the PT, the originally negligible electron-TO phonon scattering becomes the strongest scattering channel, due to an increased TO phonon amplitude and the electron-TO phonon scattering phase space. Such increased scattering strength rapidly degrades electrical transport and ZT very near the PT. We show how tuning the proximity to soft mode PT can increase the TE performance of PbTe and other materials with soft phonons that interact weakly with the electronic states relevant for transport.

*Science Foundation Ireland PI Award 15/IA/3160, and NSF of Jiangsu BK20180456.*
A high valley degeneracy of electronic bands in a material leads to its large efficiency of conversion between thermal and electrical energy, quantified by the thermoelectric figure of merit (ZT). Large ZT enhancements due to the alignment of the valence band maxima at L and Σ (or “valley convergence”) have been demonstrated in p-type PbTe and related materials [1], by tuning temperature and the doping concentration. However, it is still unclear why this strategy of improving ZT works well since the scattering processes between L and Σ valleys can deteriorate thermoelectric properties. Here, we introduce a first principle method to model electron-phonon scattering mechanisms in p-type PbTe [2]. The calculated room temperature thermoelectric parameters are in very good agreement with available experiments. Our model also allows accounting for the temperature dependence of the electronic band structure in thermoelectric transport calculations, which enables us to quantify the effect of L and Σ valley convergence at ~620 K [3] on the ZT values of p-type PbTe.

9:00AM R21.00006: Lessons from a thermoelectric transport trend study on half-Heusler alloys

KRISTIAN BERLAND (Presenter), Faculty of Science and Technology, Norwegian University of Life Sciences, OLE MARTIN LØVVIK, SINTEF — The thermoelectric properties of the 4-9-15 (Ti,Zr,Hf) (Co,Rh,Ir)(As,Sb,Bi) and 4-10-14 (Ti,Zr,Hf)(Ni,Pd,Pt)(Ge,Sn,Pb) series have been studied theoretically [J. App. Phys. 126, 145102 (2019)]. The electronic transport properties were calculated with density functional theory (DFT) and Boltzmann transport equations (BTE) at the hybrid functional level utilizing a recently developed k.p-based interpolation scheme [J. App. Phys 123, 205703 (2018)]. Phonon transport properties were calculated with the temperature-dependent effective potential (TDEP) method, including alloy and grain-boundary scattering.

Our trend study provides a number of key lessons:
1) Electronic band structures show much variation and there is, in particular, the potential for n-type Half Heusler with higher ZT.
2) The predicted thermoelectric properties are quite sensitive to the choice of exchange-correlation potential.
3) The thermal conductivity of a pure material is a poor indicator of the final thermal conductivity once other scattering mechanisms are included.
4) Sub-lattice alloying is generally more effective on the Z site than on the X site.

These findings provide valuable insights for more realistic high-thruput assessments of thermoelectric properties.

*THELMA, NOTUR

9:12AM R21.00007: Solving the Thermoelectric Trade-Off Problem with Metallic Carbon Nanotubes

YOTA ICHINOSE (Presenter), AKARI YOSHIDA, KANAKO HORIUCHI, KENGO FUKUHARA, Tokyo Metropolitan Univ, NATSUMI KOMATSU, WEILU GAO, Rice University, YOHEI YOMOGIDA, Tokyo Metropolitan Univ, MANAHO MATSUBARA, TAKAHIRO YAMAMOTO, Tokyo University of Science, JUNICHIRO KONO, Rice University, KAZUHIRO YANAGI, Tokyo Metropolitan Univ — Semiconductors are generally considered far superior to metals as thermoelectric materials because of their much larger Seebeck coefficients $S$. However, a maximum value of $S$ in a semiconductor is normally accompanied by a minuscule electrical conductivity $\sigma$, and hence, the thermoelectric power factor $P = S^2\sigma$ remains small. An attempt to increase $\sigma$ by increasing the Fermi energy ($E_F$), on the other hand, decreases $S$. This trade-off between $S$ and $\sigma$ is a well-known dilemma in developing high-performance thermoelectric devices based on semiconductors. Here, we show using metallic carbon nanotubes (CNTs) with tunable $E_F$ solves this long-standing problem, demonstrating higher thermoelectric performance than semiconducting CNTs. We studied the $E_F$ dependence of $S$, $\sigma$, and $P$ in a series of CNT films with systematically varied metallic CNT contents. In metallic CNTs, both $S$ and $\sigma$ monotonically increased with $E_F$, continuously boosting $P$ with increasing $E_F$. Particularly, in an aligned metallic CNT film, the maximum $P$ was ~5 times larger than that in the high-purity (>99%) semiconducting CNT film. We attribute these superior thermoelectric properties of metallic CNTs to the simultaneously enhanced $S$ and $\sigma$ of one-dimensional conduction electrons near the first van Hove singularity.
9:24AM R21.00008: When Band Convergence is Not Beneficial for Thermoelectricity*
JUNSOO PARK (Presenter), Lawrence Berkeley National Laboratory, MAXWELL DYLLA, YI XIA, JEFF SNYDER, Northwestern University, ANUBHAV JAIN, Lawrence Berkeley National Laboratory — Band convergence is known to generally benefit thermoelectric performance for its capability to increase carrier concentration for given Fermi level, i.e., increase conductivity for given Seebeck coefficient. With explicit treatment of electron-phonon scattering, we show that this is not necessarily the case and the degree of attainability of the said benefit depends on the dominant scattering mechanism and the manner in which bands converge. Multi-band convergence at a single k-point under deformation scattering is less beneficial (if at all) than multi-pocket convergence under polar-optical scattering at distant k-points. In the former case, one band gains while the other band loses phase space, and the increasingly disparate pocket lifetimes and mobilities can lower the Seebeck coefficient and render higher power factor inaccessible. In the latter case, the convergence preserves the scattering behavior, thereby successfully leading to higher power factor. We establish these by performing state-of-the-art first-principles studies on CaMg2Sb2-CaZn2Sb2 Zintl alloy and full-Heusler Sr2SbAu.

9:36AM R21.00009: Potential barrier/well engineering for improving the power factor in nanostructured thermoelectric materials*  
NEOPHYTOS NEOPHYTOU (Presenter), SAMUEL FOSTER, VASSILIOS VARGIAMIDIS, Univ of Warwick — Energy filtering is one of the most successful ways to improve the Seebeck coefficient in nanostructured materials and superlattices. Despite the fact that nanostructuring emerges as the most promising method to reduce thermal conductivity and improve ZT, to-date, energy filtering has not been widely utilized because it did not achieve sufficient improvements in the thermoelectric power factor. In this work, we present a theoretical analysis of a novel concept for efficient design of the potential well/barrier region such that very large power factor improvements are achieved. The concept proposed combines aspects of: i) energy filtering from potential barriers with thermionically emitted carriers, ii) highly degenerate doping conditions but with non-uniform distribution of dopants, and iii) reduced energy relaxation of carriers after they passed the barriers and propagate into the wells. We employ simple analytical models, but verify the main design ‘ingredients’ with more advanced Non-Equilibrium Green's Function (NEGF) quantum transport simulations and semiclassical Monte Carlo simulations.

*This work has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 Research and Innovation Programme (Grant Agreement No. 678763).
9:48AM R21.00010: Tuning Thermoelectricity in Molecular Junctions via Quantum Interference*  RUIJIAO MIAO (Presenter), Energy Storage and Distributed Resources, Lawrence Berkeley National Lab — Studies of molecular junctions, created by trapping a single molecule or multiple molecules between metallic electrodes, not only provide fundamental knowledge of charge transport at the atomic scale, but also offer unique opportunities in developing molecule-based devices for energy conversion. It has been theoretically proposed that quantum interference effects can be employed to obtain impressive thermoelectric performance in molecular junctions. Toward this goal, we took advantage of the destructive interferences which arise in conjugated molecules to allow high-energy electrons to pass while blocking low-energy electrons. Specifically, we investigated this effect in oligo(phenylene ethynylene) (OPE) derivatives with a para-connected central phenyl ring (para-OPE3) and meta-connected central ring (meta-OPE3). Experiments on both single molecules and monolayers reveal a two-fold increase in thermopower in meta-OPE3 (~20 μV/K) junctions compared with para-OPE3 (~10 μV/K) junctions, which agrees with our initio modeling. Our results illustrate how enhancements in thermopower can be achieved in molecular junctions via quantum interferences.

Department of Energy (DE-SC0004871, scanning probe microscopy)

10:00AM R21.00011: Including the finite temperature atomistic evolution into thermoelectric theory*  JOHN VILLANOVA (Presenter), SALVADOR BARRAZA-LOPEZ, Univ of Arkansas-Fayetteville — Thermoelectric (TE) materials have enjoyed much attention because of their promise for energy savings and targeted low-power cooling. Bulk monochalcogenides (SnSe) are some of the most effective TE materials [1,2]. Phonon anharmonicity and softening modes play an important role in improved TE performance [3], but so far, theoretical approaches to computing TE properties do not account for such softening explicitly. To address this shortcoming, we use molecular dynamics data for two-dimensional SnSe as inputs for the electronic structure and phonon dispersions at finite temperature. We capture an increase in phonon velocity at the Γ-point and enhanced hole conductivity at the structural transition temperature, accounting for the change in structure and anharmonicity in predicting TE performance explicitly. These ideas enhance our understanding of TE materials, and the procedure is applicable to bulk systems as well.

*This work was supported by an Early Career Grant from the DOE (DE-SC0016139). Calculations were performed on Cori at NERSC (DE-AC02-05CH11231).
10:12AM R21.00012: Copper occupation and dynamics in Cu rich tetrahedrite; an NMR study* NADER GHASSEMI (Presenter), YEFAN TIAN, Texas A&M Univ, XU LU, Department of Applied Physics, Chongqing University, JOSEPH H. ROSS, Texas A&M Univ, YANCI YAN, XIAOYUAN ZHOU, Department of Applied Physics, Chongqing University — Thermoelectric materials can generate electricity from heat. Recently tetrahedrite with the chemical structure of Cu$_{12}$Sb$_4$S$_{13}$ emerged as the most promising thermoelectric material for mid-temperature applications. Here we report $^{63}$Cu NMR measurements for the Cu-rich phase of Cu$_{12+x}$Sb$_4$S$_{13}$ ($x \approx 2$) and compared to Cu$_{12}$Sb$_4$S$_{13}$. Based on NMR, T$_1$ and T$_2$ measurements, the results demonstrate Cu-ion hopping below room temperature with an activation energy of $\sim$150 meV for the Cu-rich phase, consistent with superionic behavior. The NMR results also demonstrate the effects of Cu-ion mobility in the Cu$_{12}$Sb$_4$S$_{13}$ phase, but with a larger activation barrier. We identify a small difference in NMR Knight shift for the metallic phase of Cu$_{12}$Sb$_4$S$_{13}$, compared to the Cu-rich phase, and when compared to DFT calculations the results indicate a mix of hyperfine contributions to the metallic shift.

*This work was supported by the Robert A. Welch Foundation, Grant No. A-1526.

10:24AM R21.00013: Heat is Work, and Work is Heat: a first-principles approach to find improved thermoelectrics* PHIL HASNIP (Presenter), GENADI NAYDENOV, MATT I. J. PROBERT, University of York — Thermoelectric materials have the potential to dramatically improve the energy efficiency of many devices and industrial processes by converting waste heat into electricity. An ideal thermoelectric material has high electrical conductivity and low thermal conductivity, requirements which are often in conflict. Simulating thermoelectric properties is extremely challenging: predicting electronic properties requires first-principles material modelling, yet thermal conductivity must be modelled on long lengthscales which are beyond direct first-principles modelling.

In this talk I will introduce the fundamental physics of thermoelectrics and how they may be modelled accurately, using \textit{ab initio} quantum mechanical simulations coupled with classical models. I will also show how this combination of modelling techniques is being used to explain the behaviour of current materials as well as predicting entirely new thermoelectrics, paving the way for a new generation of cheap, efficient thermoelectric devices.

8:00AM R22.00001: The strange case of Dr Jekyll and Mr Hyde: The two faces of singular models. [Invited] PAUL WIGGINS (Presenter), Physics, Bioengineering and Microbiology, University of Washington — Why does systems biology work in spite of a blizzard of poorly-defined parameters and yet the detection of the Higgs boson requires five-sigma? Both these statistical analyses involve singular models, defined by structural unidentifiability (i.e. the absence of a one-to-one map between parameters and distribution functions). This singular structure leads to profound changes in the phenomenology of inference. In this talk, we will explore the phenomenology of learning from two physical perspectives: First, we explore the correspondence between statistical physics and statistics and demonstrate that there is equivalence between predictive performance and heat capacity, which gives new physical insight into why learning has universal scaling as well as explaining how and why these universal rules fail in the context of singular models. Finally, we explore insights from the Riemannian geometry of the model parameter space to determine what face a singular model will show: anomalously high or low learning performance.

8:36AM R22.00002: Learning dynamical information from static protein and sequencing data PHILIP PEARCE (Presenter), Harvard Medical School, FRANCIS G WOODHOUSE, ADEN W FORROW, University of Oxford, ASHLEY KELLY, HALIM KUSUMAATMAJA, Durham University, JORN DUNKEL, Massachusetts Institute of Technology — Many complex processes, from protein folding to neuronal network dynamics, can be described as stochastic exploration of a high-dimensional energy landscape. While efficient algorithms for cluster detection in high-dimensional spaces have been developed over the last two decades, considerably less is known about the reliable inference of state transition dynamics in such settings. Here, we introduce a flexible and robust numerical framework to infer Markovian transition networks directly from time-independent data sampled from stationary equilibrium distributions. We demonstrate the practical potential of the inference scheme by reconstructing the network dynamics for several protein folding transitions, gene-regulatory network motifs and HIV evolution pathways. The predicted network topologies and relative transition time scales agree well with direct estimates from time-dependent molecular dynamics data, stochastic simulations and phylogenetic trees, respectively. Owing to its generic structure, the framework introduced here will be applicable to high-throughput RNA and protein sequencing datasets and future cryo-electron-microscopy data.
8:48AM R22.00003: Associative Memory of Structured Knowledge  JULIA STEINBERG (Presenter), HAIM SOMPOLINSKY, Harvard University — A long standing challenge in biological and artificial intelligence is to understand how new knowledge can be constructed from known building blocks in a way that is amenable for computation by neuronal circuits. While previous work has focused primarily on working memory tasks of structured data, here we focus on the task of storage and recall of structured knowledge in long term memory. Specifically, we ask how a Hopfield type network can store and retrieve episodic memories where each episode is a set of associations between events. We model each knowledge structure as a set of binary relations between events and cues (cues may represent e.g., temporal order, spatial location, role in semantic structure). We use a binarized version of holographic reduced representation (HRR) to map such structures to fixed length vectors. We then train a recurrent network to store these vectors as fixed points. By a combination of signal-to-noise analysis and numerical simulations we demonstrate that our model allows for an efficient storage and recall of these knowledge structures in a way that allows the full retrieval of the memorized structure and their building blocks from partial retrieving cues. Our work contributes to the understanding of neural computations of structured knowledge.

9:00AM R22.00004: Can model reduction replace expert intuition for modeling complex biological systems?*  CODY PETRIE (Presenter), DANE BJORK, MARK TRANSTRUM, Brigham Young Univ - Provo — One of the challenges to modeling biological systems is the overwhelming complexity. Mathematical models that account for all the known interactions would have an unwieldy number of components and parameters. Traditionally, real-world models have been based on expert intuition that judiciously relate only those components believed to be relevant to a behavior of interest. These models typically reflect intuition and physical insights that are difficult to rigorously justify or convey. Here, we consider whether recent advances in model reduction may be able to automatically construct comparable simplified models in a semi-automatic, data-driven way. We report on a comparative study of model reduction of the Wnt signaling pathway, comparing automatic methods with expert intuition. Automatic model reduction is done using the Manifold Boundary Approximation Method (MBAM), based on information geometry and "sloppy model" analysis. We find that MBAM leads to simplified models that closely resemble those proposed based on expert intuition. Our results suggest that data-driven methods of model reduction may be a viable alternative to expert-derived models, and can be used to extract comparable physical insights into the behavior of complex biological systems.

*NSF-1753357
9:12AM R22.00005: Limits on the suppression of molecular fluctuations and oscillation dephasing in stochastic reaction networks  JIAWEI YAN (Presenter), JOHAN PAULSSON, Harvard Medical School — Many efforts in synthetic biology have been dedicated to designing ultra-reliable gene networks, but so far there has been little theory capable of providing guidance on the experimental design, because small differences in rate functions or topology can sometimes change the dynamics drastically. Here we aim to identify general principles in stochastic reaction networks that apply regardless of parameters and the form of rate functions. First we studied the noise suppression in multi-component networks and asked if it is possible to design systems where the components control and mutually suppress the noise in each other. Specifically, we find that in any \( N \)-component system, regardless of how each component affects other's production rates, it is impossible to suppress fluctuations below the uncontrolled equivalents for all components. We next examined whether there exist similar design principles in oscillatory behaviours in stochastic reaction networks. We studied a broad class of feedback, allowing arbitrary time delay and control functions, and found that even when all the rest of the feedback loop is optimal for generating sustained oscillations, the information loss from one single reaction step can lead to severe constraints in the autocorrelation and power spectrum.

9:24AM R22.00006: Kalman-like Self-Tuned Sensitivity in Biophysical Sensing*  KABIR HUSAIN (Presenter), WEERAPAT PITTAYAKANCHIT, Department of Physics, University of Chicago, GOPAL PATTANAYAK, MICHAEL RUST, Department of Molecular Genetics and Cell Biology, University of Chicago, ARVIND MURUGAN, Department of Physics, University of Chicago — Living organisms need to be sensitive to a changing environment while also ignoring uninformative environmental fluctuations. Here, we argue that living cells can navigate these conflicting demands by dynamically tuning their environmental sensitivity. We analyze the circadian clock in *Synechococcus elongatus*, showing that clock-metabolism coupling can detect mismatch between clock predictions and the day-night light cycle, temporarily raise the clock's sensitivity to light changes, and thus re-entraining faster. We find analogous behavior in recent experiments on switching between slow and fast osmotic-stress-response pathways in yeast. In both cases, cells can raise their sensitivity to new external information in epochs of frequent challenging stress, much like a Kalman filter with adaptive gain in signal processing. Our work suggests a new class of experiments that probe the history dependence of environmental sensitivity in biophysical sensing mechanisms.

Searching for the Relevant Properties of Binary Datasets: Is your Model Truly Pairwise?  
CLELIA DE MULATIER (Presenter), University of Pennsylvania, PAOLO PIETRO MAZZA, Institute for Theoretical Physics, University of Tübingen, MATTEO MARSILI, International Centre for Theoretical Physics — Uncovering the patterns hidden within noisy data is essential to science. Information theory provides a quantitative method to select the best of potential explanations for data, by optimizing the balance between goodness-of-fit and simplicity. Yet in practice finding “the” best model for a given dataset is impossible. A common practical issue is the huge number of potential models. But with a finite amount of data, the real limitation comes from the large degeneracy of models that perform nearly optimally. We illustrate this problem on examples of binary data using a heuristic procedure to perform an efficient search among all spin models with high order interactions. As good models tend to share a common sub-structure that is likely to capture relevant properties of the data, we focus our search on this structure rather than on finding the strictly best model. We show that minimally complex spin models are useful for this task. We obtain an analytic expression for their posterior probability, which makes them easy to fit and exactly comparable. We then show that working with equivalence classes of these models allows a) to find the spin basis in which the dependencies between basis variables are minimal and b) to quantify these dependencies and the relevance of each dimension.

Information efficiency of bacterial chemotaxis*  
HENRY MATTINGLY (Presenter), KEITA KAMINO, Yale University, XIAOWEI ZHANG, Peking University, BENJAMIN B MACHTA, THIERRY EMMONET, Yale University — Information transfer is central to the function of many biological systems. For example, the bacteria Escherichia coli climbs gradients of chemical attractants by modulating its rate of tumbling—randomly reorienting its swimming direction—when it senses time-changes in attractant concentration. But even in the absence of signal processing, the cell's tumble behavior is correlated with the signal it sees. The transfer entropy rate $I_{\phi \rightarrow M}$ from signal to tumble behavior removes these correlations and isolates the causal influence of the signal on the cell's tumble decisions. We show that climbing a gradient with drift speed $v_D$ requires an information rate of at least $I_{\phi \rightarrow M} = 12 \frac{D_r (v_D/v_0)^2}{v_0} (1-TB)$, where $D_r$ is the rate of rotational diffusion, $v_0$ is the run speed, and $TB$ is the fraction of time the cell is tumbling. To quantify E. coli cells' information rates, we measure, in single cells, signal transduction responses and fluctuations. Along with measurements of drift speeds, we determine how efficiently E. coli use information about the gradient during chemotaxis.

10:00AM R22.00009: Decision-making at a T-junction by gradient-sensing agents  TANVI GANDHI, JINZI MAC HUANG (Presenter), ANTOINE AUBRET, DESMOND YAOCHENG LI, SOPHIE RAMANANARIVO, MASSIMO VERGASSOLA, JEREMIE PALACCI, University of California, San Diego — At the beginning of life, searching for food and evading hazards are two essential activities for microorganisms to survive, and the way they navigate is through chemotaxis. The optimal chemotaxis in complicated terrains determines the fate of living creatures, and natural selection ensures the existence of such an optimization. In our study, we investigate the navigation of inert particles in a network that has multiple junctions. In micro-networks manufactured through photolithography, a background gradient of salt is established as the signal of chemoattractant by placing a source and a sink of salt. Colloidal particles then follow this signal through diffusiophoresis and move towards the source. Through stochastic modeling, we show that particles prefer to exit each junction at the end with higher concentration gradient. This preference is further enhanced when the particle size is larger, which leads to a way to magnify small signals in a network so that the colloidal particles larger than a critical size can always move towards the source of salt through the shortest path. Ultimately, we compare the navigation schemes of inert particles and living organisms, aiming to understand biological chemotaxis and shed light on future manufacturing of navigable microswimmers.

10:12AM R22.00010: Trading bits in the readout of positional information*  MARIANNE BAUER (Presenter), WILLIAM S BIALEK, THOMAS GREGOR, Princeton University, MARIELA D PETKOVA, Harvard University, ERIC WIESCHAUS, Princeton University — Expression levels of gap genes, crucial for fly development, have been shown to be precise, matching the spatial precision in the expression of downstream genes. If the transcriptional machinery can read these gap expression levels only imprecisely, subsequent precision could not be reproduced. Yet, assuming that levels can be read with infinite precision is unrealistic. Reading expression levels with limited precision can be phrased mathematically by limiting the number of bits which are available for each measurement. The question of how to use these bits to capture the maximum positional information is an instance of the information bottleneck problem. We show that to capture ~90% of the available information, we need more bits than intuitively biologically reasonable. We can allow for an increased number of bits per measurement by having molecules bind to multiple sites. This is a generalization of the information bottleneck problem. We show that one can capture almost all the available information with multiple “low precision” encodings, which may correspond physically to multiple binding sites or even enhancers.

10:24AM R22.00011: Single-Molecule Conductance and Conformational Analysis with Engineered Nano-Junctions for Nucleic Acid Sequencing  LEE KORSHOJ, SEPIDEH AFSARI, ANUSREE CHATTERJEE, PRASHANT NAGPAL (Presenter), University of Colorado, Boulder — DNA sequencing on the single-molecule level can be used to study cellular heterogeneity and stochasticity with reduced time, cost, and complexity compared to traditional sequencing methods. However, sample noise and signature overlap due to varying nucleotide conformations prevent accurate sequencing results. We address these issues by engineering nano-junctions for conductance measurements on conformationally constrained single nucleotides within electrostatically bound DNA molecules on a self-assembled cysteamine monolayer. From STM break junctions with biochemical moieties in individual nucleobases, the unique conductance signature of each nucleobase is analyzed with machine learning algorithms [1]. Additionally, conformational variation, or smear, is quantified from the distance over which molecular junctions are maintained during each conductance measurement [2]. We demonstrate >93% accuracy for DNA nucleotide recognition with 20 repeat measurements. These results are a significant improvement over contemporary methods and show the potential for using simple surface modifications and existing biochemical moieties in nucleobases for single-molecule, nanoelectronic nucleotide identification.

Session R23 DBIO GSNP: Evolutionary and Ecological Dynamics III: Evolution 304 - Thierry Mora, Ecole Normale Superieure - Tag(s): Focus

8:00AM R23.00001: Evolutionary dynamics of immune repertoires* [Invited] THIERRY MORA (Presenter), Ecole Normale Superieure — Our adaptive immune system protects us against a wide variety of pathogens using a broad repertoire of specific receptors expressed by B and T cells, whose concentrations adapt to past experiences to encode immune memory. In this talk I will discuss how the diversity of receptors is generated and how it evolves and self-organises over time to protect us efficiently. I will present models of population dynamics as well as design principles of optimal memory encoding, and will relate them to high-throughput sequencing data. I will also discuss diversity measures and the power-law nature of the distribution of clone sizes observed in the repertoire.

**8:36AM R23.00002: Evolutionary regain of lost network function**  
MIRNA KHEIR GOUDA, Laufer Center for Physical & Quantitative Biology, State Univ of NY - Stony Brook, MICHAEL MANHART, Institute of Integrative Biology, ETH Zurich, GABOR BALAZSI (Presenter), Laufer Center for Physical & Quantitative Biology, State Univ of NY - Stony Brook — Natural or synthetic genetic network modules can lose their function over long-term evolution if the function is costly. How populations can evolve to restore such broken function is poorly understood. To test the reversibility of evolutionary breakdown, we use a synthetic gene circuit (PF) integrated into yeast cells. In previous evolution experiments, mutations in a gene eliminated the fitness costs of PF activation, corrupting gene circuit function. Since PF activation also provides drug resistance, we grew such corrupted mutants in both drug and inducer, imposing selection to regain drug resistance and possibly PF function. We observe various adaptation scenarios with or without repairing lost gene circuit function. The data suggest interactions between intracellular gene network dynamics and evolutionary dynamics, with possible consequences for understanding the evolution of drug resistance and developing future synthetic biology applications.

**8:48AM R23.00003: Measuring mutations with droplet microfluidics**  
MIKE HENNESSEY-WESEN (Presenter), CALIN GUET, BJOERN HOF, Institute of Science and Technology Austria — Mutations are random errors in genetic material that create the diversity which underpins the development of all life. However, work done over recent years has suggested that certain mutations are not as random as once thought - several factors such as stress, chromosomal neighborhood, and transcription level have been implicated to affect genetic stability. Typically, quantitative measures of frequency and distribution of point mutations have either relied on fluctuation tests that make assumptions about the shape of mutation distributions, or on large volumes of data from multiple sources that can harbor unknown inconsistencies. We use a droplet-based, microfluidic platform to make real-time measurements of point mutations in bacteria under various conditions with high precision. We are able to alter various conditions of growth, such as heat/drug stress and transcriptional activity, and detect mutations without the use of a selective or metabolic screen, which makes our system a versatile tool for studying mutant occurrence. Our results offer a direct look into this often-simplified area of evolutionary dynamics.

9:00AM R23.00004: The Evolutionary Dynamics of Incubation Periods*

BERTRAND OTTINO-LOFFLER (Presenter), Condensed Matter Theory Group, Massachusetts Institute of Technology MIT, JACOB SCOTT, Translational Hematology and Oncology Research, Cleveland Clinic, STEVEN STROGATZ, Center for Applied Mathematics, Cornell University — The incubation period for typhoid, polio, measles, leukemia and many other diseases follows a right-skewed, approximately lognormal distribution. Although this pattern was discovered more than sixty years ago, it remains an open question to explain its ubiquity. Here, we propose an explanation based on evolutionary dynamics on graphs. For simple models of a mutant or pathogen invading a network-structured population of healthy cells, we show that skewed distributions of incubation periods emerge for a wide range of assumptions about invader fitness, competition dynamics, and network structure. The skewness stems from stochastic mechanisms associated with two classic problems in probability theory: the coupon collector and the random walk. Unlike previous explanations that rely crucially on heterogeneity, our results hold even for homogeneous populations. Thus, we predict that two equally healthy individuals subjected to equal doses of equally pathogenic agents may, by chance alone, show remarkably different time courses of disease.

9:12AM R23.00005: Evolution of systems with power-law memory: Do we have to die?*

MARK EDELMAN (Presenter), Department of Physics, Yeshiva University — Various features of the development of individual living species are programmed. Is death also programmed and what can be the underlying mechanism providing the inevitability of death? The presented hypothesis is based on the similarity of human evolution to the evolution of discrete nonlinear systems with power-law memory. Caputo fractional logistic map is a discrete system with power-law memory and quadratic nonlinearity. In the area of parameters where the fixed point is unstable, its evolution starts as the evolution of a system with a stable fixed point but then this fixed point becomes unstable, suddenly breaks, and turns into a period two point. Under random perturbations the time spans of the evolution as a fixed point before the break (lifespans) obey the Gompertz-Makeham law, which is the observed distribution of the lifespans of living species. The reasons for modeling the evolution of humans by fractional systems are the observed power law in human memory and the viscoelastic nature of organ tissues of living species. Models with power-law memory may explain the observed decrease at very large ages of the rate of increase of the force of mortality and they imply limited lifespans.

Spatial Expansions and Serial Bottlenecks Produce Different Topologies of Genealogical Trees

GABRIEL BIRZU (Presenter), Applied Physics, Stanford University, OSKAR HALLATSCHEK, Physics and Integrative Biology, University of California, Berkeley, KIRILL S KOROLEV, Physics, Boston University — What do the genealogies of expanding populations look like? While recent studies recognize the importance of genealogies for inferring and predicting evolutionary dynamics, very little is known about genealogies in expanding populations. Here, we show that range expansions can produce extremely different topologies of genealogical trees, which are very sensitive to the growth dynamics at the front. When growth is cooperative, genealogies are described by the Kingman coalescent—a backward-in-time analog to neutral evolution in which only pairwise mergers between lineages occur. Weakly cooperative and non-cooperative growth result in fundamentally different trees, with multiple lineages merging at the same time. We explain these results by deriving the distribution of the effective offspring number at the front, and show that the transition between the two topologies occurs when the variance of this distribution diverges. This divergence arises due to rare fluctuations of the front shape and position. Thus, evolutionary dynamics of range expansions cannot be approximated by a deterministic model of serial bottlenecks. Our results also show that range expansions provide a robust mechanism for non-Kingman genealogies, which previously have only been attributed to natural selection.

Early Multicellular Organisms Co-opt Cell-Level Characteristics into Group-Level Properties via the Principle of Maximum Entropy

THOMAS DAY (Presenter), DAVID B YANNI, SHANE JACOBEEEN, PETER YUNKER, Georgia Inst of Tech — In the earliest stages of the evolution of multicellularity, genetic changes occur at the individual cell level yet selection acts at the group level. New group level traits emerge when mutations affecting cell-level properties are co-opted into consistent group-level traits. However, it is unclear how readily coherent group-level properties emerge absent a regulatory developmental plan. It even seems likely that small fluctuations at the cellular level may elicit large fluctuations at the group level, destroying the chance for survival. Here we demonstrate that lab-evolved simple multicellular groups with permanent intercellular bonds follow the principle of maximum entropy. As a result, a large space of microstates (e.g. specific cell configurations) correspond to a smaller space of macrostates (e.g. cluster volume), thereby achieving robust, consistent macroscopic properties. We derive an equation of state that relates these macroscopic properties together and experimentally verify predictions from the equation of state, demonstrating that robust group-level properties readily emerge from individual cell traits. Finally, we speculate that the emergence of group-level properties is possible within any cluster with fixed bonds between mother and daughter cells.
Selection of mutants in a microbial population depends on multiple cellular traits. In serial-dilution evolution experiments, three key traits are the lag time when transitioning from starvation to growth, the exponential growth rate, and the yield (number of cells per unit resource). Here we investigate how these traits evolve in laboratory evolution experiments using a minimal model of population dynamics, where the only interaction between cells is competition for a single limiting resource. We find that the fixation probability of a beneficial mutation depends on a linear combination of its growth rate and lag time relative to its immediate ancestor, even under clonal interference. The relative selective pressure on growth rate and lag time is set by the dilution factor; a larger dilution factor favors the adaptation of growth rate over the adaptation of lag time. The model shows that yield, however, is under no direct selection.

Physical constraints on epistasis

KABIR HUSAIN, ARVIND MURUGAN (Presenter), University of Chicago — Living systems evolve one mutation at a time, but a single mutation can alter the effect of subsequent mutations. The underlying mechanistic determinants of such epistasis are unclear. Here, we demonstrate that the physical dynamics of a biological system can generically constrain epistasis. We analyze models and experimental data on proteins and regulatory networks. In each, we find that if the long-time physical dynamics is dominated by a slow, collective mode, then the dimensionality of mutational effects is reduced. Consequently, epistatic coefficients for different combinations of mutations are no longer independent, even if individually strong. Such epistasis can be summarized as resulting from a global non-linearity applied to an underlying linear trait, i.e., as global epistasis. This constraint, in turn, reduces the ruggedness of the sequence-to-function map. By providing a generic mechanistic origin for experimentally observed global epistasis, our work suggests that slow collective physical modes can make biological systems evolvable.
10:12AM R23.00010: Emergence of heritability of higher-level traits in a major transition
ANTHONY BURNETTI (Presenter), Biological Sciences, GEORGIA TECH, SEYED ALIREZA ZAMANI DAHAJ, Physics, GEORGIA TECH, MATTHEW HERRON, WILLIAM RATCLIFF, Biological Sciences, GEORGIA TECH — Increases in biological complexity and the origins of life’s hierarchical organization are described by the “major transitions” framework. A crucial component of this paradigm is that after the transition in complexity or organization, adaptation occurs primarily at the level of the new, higher-level unit. For collective-level adaptations to occur, though, collective-level traits—properties of the group, such as collective size—must be heritable. Using the ‘snowflake yeast’ model system of early multicellularity, we investigated the biophysical basis of emergent multicellular traits. We genetically engineered four yeast genotypes to have different cellular aspect ratios, which prior work has shown affects cellular packing and the size of the multicellular group. We then measured the heritability of both the cellular trait (aspect ratio) and emergent multicellular trait (group size at fracture) and compared them to our theoretical predictions. Extrapolating from these results, we show mathematically that, for a wide range of functions relating the group traits to cellular traits, the emergent group-level traits will have higher heritability than their corresponding cell-level traits.

10:24AM R23.00011: Lineage Branching During Recovery from Simulated Mass Extinction*
DAWN KING, TYLER HANKE, SONYA BAHAR (Presenter), University of Missouri - St. Louis — How do population lineages diversify to fill new ecological niches? What governs the dynamics of population recovery from near-extinction? These questions are particularly urgent in our current age of climate-driven mass extinction. We investigate these questions using a computational model of evolutionary dynamics in which simulated organisms reproduce by bacterial fission or assortative mating on a two-dimensional phenotype space. This model has been shown to undergo a directed-percolation-like nonequilibrium phase transition from survival to extinction as system parameters such as maximum mutation size or death rate are varied. Here, we use methods from coalescent theory to show that population lineages undergo a structural change near the extinction-survival transition, with a sharp divergence in the time to most recent common ancestor (TMRCA). We also simulate mass extinctions, both in the neighborhood of the phase transition and in the survival regime, by either increasing the death rate of organisms, or increasing the parameter that controls their competition. We then analyze lineages, TMRCA, and other measures of population structure during successful and unsuccessful recoveries from mass extinction events.

*This research was supported by the James S. McDonnell Foundation.
The evolution of multicellular organisms on earth is one of the most transformative events in the history of life. Despite its importance, we know little about the process by which nascent microscopic multicellular organisms overcome substantial mechanical constraints and dramatically increase their size. We experimentally study this process with the snowflake yeast model system: baker's yeast (S. cerevisiae) with a single mutation in ACE2 gene allows mother and daughter cells to remain attached via uncut chitin bonds. These yeast clusters are composed of a few hundred cells and grow to a maximum diameter of 200 microns. After a year of artificial selection for larger multicellular size, five populations of snowflake yeast surprisingly evolved to grow to a diameter of 1 mm. In this work we show how small changes at the cell level trait lead to emergent properties in the microscopic level and helped to overcome tremendous mechanical constraints on their size.

10:48AM R23.00013: Evolution of hardwired behavioral strategies through competitive population dynamics  
TONG LIANG (Presenter), Department of Physics and Astronomy, Stony Brook University, BRADEN A. W. BRINKMAN, Department of Neurobiology and Behavior, Stony Brook University — Normative approaches are commonly used to predict an organism's hardwired behaviors by optimizing utility functions such as sensory information or reward, which are loosely interpreted as proxies for evolutionary fitness. However, the validity of the assumption that utility function optimization confers true evolutionary success has seldom been explored. Here we develop mechanistic evolutionary models to investigate whether normative principles can predict the most evolutionarily advantageous strategies. With mean-field approximations and agent-based stochastic simulations, we show that the most competitive strategies that emerged from these models in environments of randomly distributed resources conform well with normative predictions, but only when organisms are sparsely distributed and interactions are rare. These results suggest that normative approaches can predict the evolutionarily most competitive innate behavioral strategies, at least when the optimized utility is directly relevant for the organisms' survival and accounts for environmental constraints. This work bridges the gap between normative approaches and the underlying fundamental evolutionary dynamics.
The ability to determine the structure of a protein to near-atomic resolution using x-ray crystallography and NMR spectroscopy has been vital for advances in structural biology. However, it is unclear whether or not the structures obtained from these two methods are the same to within experimental uncertainties, or if these characterization methods influence the structures in some way. To address this important question, we compiled a dataset of paired high-resolution x-ray crystal structures and high-quality NMR structures to determine whether there are any systematic differences between the structures solved using the two experimental techniques. Backbone fluctuations of core Cα atoms reveal that core residues from x-ray crystal structures occupy smaller regions of configuration space than core residues in NMR structures. We also find that the core residues of NMR structures are more densely packed than core residues in x-ray crystal structures. We explain this result by preparing packings of amino-acid-shaped particles with thermalized packing-generation protocols, and find that packings with higher thermalization resemble cores in NMR structures, while in the limit of no thermalization we recover packings that resemble the cores of x-ray crystal structures. This result suggests that the differences between NMR and x-ray crystal structures are caused by the varying degree of thermal fluctuations in the two characterization methods. NMR solution structures are allowed to fluctuate more, which compacts the core, but allows for greater exploration of core configurations. In contrast, x-ray crystal structures occupy only well-defined, smaller regions of configuration space.

Decoy Detection of Computational Protein Designs

ALEX GRIGAS (Presenter), ZHE MEI, JOHN TREADO, ZACHARY LEVINE, Yale University, LYNNE REGAN, University of Edinburgh, COREY SHANE O’HERN, Yale University — Decoy detection is one way to reframe protein folding, not in terms of folding a protein, but in terms of differentiating a well-folded protein from a poorly folded one. An effective decoy scoring metric would both improve prediction methods and indicate how prediction methods fail. The O’Hern group has been making progress in understanding protein structure by focusing on the core regions of proteins, which are inaccessible to solvent. Core structure is uniquely specified by purely repulsive atomic interactions, as hard-sphere interactions are able to predict core structure. In this work, we apply this framework to the decoy detection problem and find that state-of-the-art protein predictions in the CASP11, 12 and 13 competitions often have core regions that are overpacked, due to overlapping residues. Additionally, cores in the predicted protein structures are often too small and too solvent-exposed, suggesting that the prediction methods do not properly capture hydrophobic collapse. Finally, by scoring CASP predictions based on its core structure, we can effectively distinguish between high- and low-quality computational protein designs.

Low-Force Elasticity Reveals Complex Structure of an Intrinsically Disordered Protein

HOANG TRUONG (Presenter), IAN L MORGAN, OMAR SALEH, University of California, Santa Barbara — Intrinsically disordered proteins (IDPs) do not possess a well-defined three-dimensional structure, which presents a challenge to investigating their conformations. To overcome this challenge, we explore low-force polymeric elasticity as a means to quantify structural properties. Here, using a high-resolution single-molecule magnetic tweezer, we stretch a polypeptide construct derived from the neurofilament tail domains and study its conformations. At low forces, the construct behaves as an ideal coil instead of a self-avoiding coil. This is surprising given the IDP’s high net charge, suggesting the presence of weak long-range attractive interactions. In addition, the measured persistence length is longer than expected for a random polypeptide chain. This result suggests the IDP has residual structure, which stiffen the chain at low force. We further probe the response of long-range attraction and chain stiffening to changes in salts and denaturants. Our data reveals a rich elastic behavior and complex structure in a nominally disordered chain.

This work is supported by the National Science Foundation under grant number 1715627.
9:00AM R24.00004: ProSPr: Protein Structure Prediction via Interatomic Distances  
WENDY BILLINGS (Presenter), BRYCE E HEDELIUS, TODD MILLECAM, DAVID WINGATE, DENNIS DELLA CORTE, Brigham Young Univ - Provo — Substantial progress has been made in the past several years towards the accurate prediction of protein tertiary structures from primary sequence, aided greatly by the integration of machine learning. Current success is based on two-stage protocols: first, the training of a deep convolutional neural network (CNN) to predict macromolecular structure restraints, and second, the use of these restraints to construct a folded three-dimensional structure of the target protein. Such a two-stage folding protocol was used by DeepMind in the recent Critical Assessment of Structure Prediction (CASP13), which outperformed all established groups. However, DeepMind has not expressed a plan to publish the code of their AlphaFold protocol. Here we present ProSPr, a network representing the first part of the AlphaFold pipeline for predicting interatomic distances, and demonstrate its abilities in the contact prediction task relative to other state-of-the-art methods. We also investigate and report on the roles of certain input features in prediction quality. ProSPr is made freely available to the scientific community both as source code and a Docker container, which we anticipate will encourage the development of better techniques for assembling protein structures from restraints.

9:12AM R24.00005: Landscapes, Nonlinearity, and Biomolecular Energy Redistribution  
JUSTIN ELENEWSKI (Presenter), National Institute of Standards and Technology, KIRILL VELIZHANIN, Los Alamos National Laboratory, MICHAEL ZWOLAK, National Institute of Standards and Technology — Although selective energy redistribution is critical to the function of numerous biomolecules and functional nanomaterials, the processes mediating these dynamics remain a poorly understood facet of nonequilibrium thermodynamics. In this talk, I will discuss how topological features, nonlinearities, and energy landscape architecture can collude to define biomolecular heat propagation [1]. Our exhaustive all-atom simulations and novel local-in-time and space analysis - which is equally applicable to both theory and experiment - permit the multiscale dissection of energy migration in biomolecules. Unlike transport through small-molecule systems, we find that nonlinearity dominates over coherent processes at even at short length- and time-scales. Leveraging these observations, I will demonstrate how vibrational energy transport can probe otherwise inaccessible aspects of macromolecular dynamics and the interactions that underlie biological function.

Understanding the native fluctuations of protein cores

ZHE MEI (Presenter), JOHN TREADO, ZACHARY LEVINE, Yale University, LYNNE REGAN, University of Edinburgh, COREY SHANE O’HERN, Yale University — Understanding how thermal fluctuations affect protein structure is essential for characterizing the energy landscape of proteins, as well as determining the response to amino acid mutations. Protein structures obtained from liquid-state NMR, unlike those from x-ray crystallography, provide a number of model structures that satisfy the experimental constraints. Using a database of high-quality, paired NMR and x-ray crystal structures, we have shown that there are important differences between NMR structures and those solved by x-ray crystallography including differences in the root-mean-square deviations of the core C\textalpha atomic positions, identities of the core amino acids, and packing fractions of core residues. In this work, we carry out all-atom molecular dynamics simulations to study the fluctuating conformational dynamics of wildtype globular proteins, as well as mutants, in aqueous solvent at room temperature. We study the fluctuating conformations using several metrics including the radius of gyration \(R_g\), packing fraction, and \(C_{\alpha}\) atomic positions. We find that most often the MD simulations sample conformations that are representative of the NMR and x-ray conformations, but \(~40\%\) of the sampled structures are not consistent with the experimental structures, with larger \(R_g\) and lower packing fractions.

Steric Equation of State for Monoclonal Antibodies from Low to High Concentrations

HASSAN SHAHFAR (Presenter), Physics and Astronomy, University of Delaware, CHRISTOPHER J ROBERTS, Chemical and Biomolecular Engineering, University of Delaware — Steric interactions potentially play a significant role in packing behavior of proteins as one considers increasing concentrations, particularly for monoclonal antibodies (MAbs) due to their extended, anisotropic, and flexible structure. Steric contributions to the equation of state are key to balancing attractive contributions in crowded environments that result in phase separation. Steric protein-protein interactions are sensitive to the size and shape of proteins and can be considered as the minimal level of interactions to be captured in coarse-grained models. To date, all atom simulation was used to calculate only the role of steric only behavior of monoclonal antibodies on the second osmotic virial coefficients. A biased Monte Carlo algorithm (Mayer sampling) used to calculate the steric interactions up to the fifth virial coefficient using all atom simulations for representative MAb structures. The results are compared with different levels of coarse grained models to assess the accuracy of predictions of lower resolution models. The results show that, upon increasing concentration to approx. 10 volume percent, the deviation of the predictions of coarse grained models is pronounced, but can be mitigated by the choice of model.
10:12AM R24.00008: Origins of Critical Phenomena in the Folding Phase Diagram of Proteins* ANDREI GASIC (Presenter), MARGARET CHEUNG, Department of Physics, University of Houston; Center for Theoretical Biological Physics, Rice University — Proteins are folded polymers that are able to respond to slight environmental perturbations to preformation their biological function while also keeping a quasi-unique conformation. Such properties may be exhibited by a physical system near a critical point. Recent experimental and computational findings demonstrate that protein folding transitions in the temperature ($T$), pressure ($P$), and crowding volume-fraction ($\phi$) phase diagram have signatures of criticality, where distinct folding phases merge [A. G. Gasic et al., Phys. Rev. X (2019)]. Here we investigate the origin of this critical behavior using insight from polymer physics. Based on our theory, we show that the separation of $T$ between the folding and collapse transition temperatures ($T_F$ and $T_\Theta$, respectively) lead to a critical transition. We derive the relationship for the correlation length and show divergence approaching the critical regime. Structure-based model simulations of a protein in a crowded environment are used to validate our predictions. Our study illustrates the importance of the crowded cellular environment for a protein biological function.

10:24AM R24.00009: Dissimilar ligands bind in a similar fashion: guiding the ligand binding mode prediction* XIANJIN XU, XIAOQIN ZOU (Presenter), Univ of Missouri - Columbia — The Molecular Similarity Principle have achieved great successes in the field of drug design/discovery. Existing studies focus on similar ligands, while the behavior of dissimilar ligands remains hidden in darkness. In this study, a strategy was introduced for comparing the binding modes of ligands with different molecular structures for the first time. Our systematic analysis on a newly constructed dataset of protein-ligand complexes showed that ligands with similar structures tend to share a similar binding mode, which is consistent with the molecular similarity principle. More importantly, the results revealed that dissimilar ligands can also bind in a similar fashion. This finding would open a new avenue for rational drug design. Furthermore, a template-guided method was introduced for predicting protein-ligand complex structures. Encouragingly, even with the use of dissimilar ligands as templates, our method significantly outperformed bound docking of the molecular docking method.

An escape rate analysis for pulling experiments based on energy landscapes in two reaction coordinates

Sudeep Adhikari (Presenter), Kevin Stuart David Beach, Univ of Mississippi — The structural dynamics of biopolymers such as proteins are described in the context of their conformational energy landscapes. In optical-tweezer pulling experiments, features of the energy landscapes are extracted from the observed distribution of the critical force at which the polymer unfolds, and typically the analysis is based on a one-dimensional (1D) reaction coordinate, the extension. But a 1D analysis is inadequate when various possible folded configurations are degenerate in the end-to-end length. We present an analytical framework for the well escape rate in the context of an effective 2D landscape. We test our analysis against simulated pulling experiments and verify our ability to extract meaningful well parameters.

Session R25 GSNP DSOFT: Active Matter

8:00AM R25.00001: Propagating Activity Fronts in Columns of Fire Ants* Caleb Anderson (Presenter), Alberto Fernandez-Nieves, Guillermo Goldsztein, Georgia Inst of Tech — For the past three decades, the study of active matter has revealed rich physics and universal behaviors, such as collective motion, across a wide variety of biological and synthetic systems with seemingly disparate particle interactions. Here we present our surprise observation and measurements of stable activity fronts propagating through two-dimensional columns of thousands of fire ants. We then propose both computational and analytical models to explain the origin of these macroscopic non-linear fronts from simplified pairwise interactions between ants. Finally, we finish by comparing these fronts to other instances of collective motion observed in active systems.

*FLAMEL, NSF IGERT program

8:12AM R25.00002: Self- and air-driven fluidization of black soldier fly larvae Olga Shishkov (Presenter), David Hu, Daniel I Goldman, Georgia Inst of Tech — Active systems can be driven via internal activity of individual elements or via external mechanical forcing. Here we study a living system in which both internal and external activity can be varied. In laboratory experiments, we confine thousands of ~10 mm long black soldier fly larvae in an air fluidized bed (~4 larva lengths in diameter, 10 in height) and study the collective and individual dynamics. When larvae are not externally fluidized, due to their internal activity they self-pack and the height of the column of larvae decreases over time to a steady state value. In steady state, larval motion is distributed heterogeneously and transiently, with regions of motion and clustering appearing and disappearing throughout the bed volume. These dynamics can be altered by gentle flow of air to the bed: like fluidized beds of inactive (non-living) particles, steady-state larval collective volume (column height) increases with increasing air flow, and the persistence of the transient regions change. Further, external fluidization has the same effect as the addition of food, where activity also causes large-scale mixing.
8:24AM R25.00003: Stochastic thermodynamics for self-propelled particles* GRZEGORZ SZAMEL (Presenter), Colorado State University — We present a generalization of stochastic thermodynamics to systems of active particles, which move under the combined influence of stochastic internal self-propulsions (activity) and a heat bath. The generalization relies upon a formal similarity of an active system and a system consisting of two subsystems interacting with different heat reservoirs and coupled by a non-symmetric interaction. The resulting thermodynamic description closely follows the standard stochastic thermodynamics. In particular, total entropy production, $\Delta s_{\text{tot}}$, can be decomposed into housekeeping, $\Delta s_{\text{hk}}$, and excess, $\Delta s_{\text{ex}}$, parts. Both $\Delta s_{\text{tot}}$ and $\Delta s_{\text{hk}}$ satisfy fluctuation theorems. The average rate of the steady-state housekeeping entropy production can be related to the violation of the fluctuation-dissipation theorem via a Harada-Sasa relation. The excess entropy production enters into a Hatano-Sasa-like relation, which leads to a generalized Clausius inequality involving the change of the system's entropy and the excess entropy production.

8:36AM R25.00004: Odd viscosity in active materials: microscopic origin and 3D effects* TOMER MARKOVICH (Presenter), Center for Theoretical Biological Physics, Rice University, TOM LUBENSKY, Physics and Astronomy, University of Pennsylvania — Active materials are composed of many components that convert energy from the environment into directed mechanical motion, thus locally breaking time reversal symmetry (TRS). Examples of active materials go beyond living systems such as bacteria and is also realized in e.g. colloidal rollers. A striking phenomenon of breaking TRS is the possible appearance of odd viscosity. Onsager reciprocal relations require that when TRS holds the viscosity tensor is symmetric for exchanging its first and last pair of indices. However, when TRS is broken, Onsager relations predict an odd viscosity that is both odd under TRS and under the change of indices. Such odd viscosity is non-dissipative and should thus be derivable from a Hamiltonian theory. Active materials innately break TRS, which led to recent studies of odd viscosity in 2D active materials. In this talk I will present a novel microscopic Hamiltonian theory for odd viscosity, valid also in 3D. Our theory give rise to intriguing 3D effects such as generalization of Bernoulli's principle, propagation of bulk waves, and a few types of unidirectional surface waves. We further predict that odd viscosity should emerge in actomyosin gels and bacterial suspensions.

Quincke Oscillation of Colloids at Planar Electrodes* ZHENGYAN ZHANG (Presenter), YONG DOU, KYLE BISHOP, Columbia Univ — Dielectric particles immersed in a weakly conducting liquid are known to exhibit spontaneous rotational motion under uniform DC electric fields above a critical magnitude. So-called Quincke rotation near a planar substrate leads to particle translation and provides a useful experimental model for studying the collective dynamics of active colloids. Here, we show that individual Quincke rollers at planar electrodes can also exhibit oscillatory dynamics, whereby particles move back and forth about a stationary location. The transition from steady rolling to oscillatory motion occurs at a critical field three times larger than that required for rolling. In contrast to previous reports of oscillatory Quincke dynamics based on inertial effects, our observations of micron-scale particles are characterized by low Reynolds numbers (Re \(\sim\) 0.01) and therefore negligible inertia. We propose a plausible explanation for Quincke oscillations using the leaky-dielectric model and accounting for electric (and hydrodynamic) interactions of the particle with the conductive substrate.

*We gratefully acknowledge funding from the CBES(Center for Bio-Inspired Energy Science) and Department of Energy.

Capturing the local entropy production of an active Brownian particles system by compression* BUMING GUO (Presenter), Center for Soft Matter Research, New York University, STEFANO MARTINIANI, Department of Chemical Engineering and Materials Science, University of Minnesota, PAUL M CHAIKIN, Center for Soft Matter Research, New York University, DOV LEVINE, Department of Physics, Technion - IIT — The entropy production of a stationary process is known to be the Kullback-Leibler divergence (KLD), or relative entropy, between the probability of observing a trajectory with time running forward and its time reversal, which quantitatively characterizes the time-reversal asymmetry and features the nonequilibrium nature of the system. Here we use a compression based Ziv-Merhav method and other techniques to estimate KLD and time reversal symmetry to define a natural spatial decomposition of entropy production by applying the algorithms on discrete time series of state evolution in local block regions. As an example, we will discuss how local entropy production is captured with this method in a phase-separated system of active Brownian particles.

*National Science Foundation Physics of Living Systems Grant No. 1504867
9:12AM R25.00007: Superdiffusion and hydrodynamic phase separation in a uniaxial active suspension* LOKRSHI DADHICHI (Presenter), TIFR Centre for Interdisciplinary Sciences, K VIJAY KUMAR, TIFR-ICTS, J K BHATTACHARJEE, Indian Association for the Cultivation of Science, SRIRAM RAMASWAMY, Physical Science, Indian Institute of Science — We examine, analytically and to some extent numerically, the dynamics of the concentration field in an active suspension with permanent uniaxial anisotropy. We show that in the homogeneous phase the advection of fluctuations in the concentration, by the active flow they themselves generate, leads to a superdiffusive dynamic exponent $z = d/2$ for dimension $d < 4$. We uncover a novel flow-induced contribution to active-particle currents that can lead to a negative effective diffusivity on a cone of directions, and hence to a purely hydrodynamic mechanism for phase separation. We suggest experimental tests of our predictions.

9:24AM R25.00008: Chemistry-Induced Mobility in Catalytic Chemical Reactions HUAN WANG (Presenter), MYEONGGON PARK, TSVI TLUSTY, STEVE GRANICK, Institute for Basic Science — With a standard pulse-field gradient nuclear magnetic resonance based diffusion ordered spectroscopy (DOSY), we measure chemical-shift specific molecular diffusivity simultaneously with reaction kinetics in situ as reaction progresses. In simple exothermic, catalysed chemical reactions, we observe unexpected solvent enhanced diffusion, both in water and in organic solvents, to be tightly correlated with molecular catalytic cycles. Scaling analysis suggests the critical role of hydrodynamic coupling at nanoscale among “force-dipole-like” chemical reaction centers. The observation of chemistry-induced mobility challenges the simple “passive” picture of chemical reaction, suggesting rich energy dissipation pathways that eventually lead to collective consequences, for example, a counterintuitive antichemotaxis flux, revealed from a gradient microfluidic chip measurement.
9:36AM R25.00009: Spontaneous locomotion of nano-catalysed BZ droplets  
D JAYA PRASANNA KUMAR, KABEER JASUJA, PRATYUSH DAYAL (Presenter), Indian Inst of Tech Gandhinagar
— The motion in living systems by chemo-mechanical transduction has inspired the scientists to design and develop self-moving biomimetic systems. Here, we harness self-oscillating Belousov-Zhabotinsky (BZ) reaction, synergized by graphene-based catalytic mats to demonstrate the spontaneous motion of the BZ reaction droplet in oil-surfactant medium. Specifically, we synthesize graphene-based catalytic mats by decorating Ru nanoparticles (NP) on graphene nanosheets, thereby creating 0D-2D heterostructures; subsequently, use these mats to catalyze BZ reaction within a droplet. Our results demonstrate spontaneous locomotion of BZ droplets due to Marangoni flow facilitated by the interaction between BZ reaction intermediates and the surfactant in the surrounding oil. We further show that the velocity of droplet motion depends upon the conductivity of the catalytic mats. In particular, we observe highest droplet velocities when RuNP decorated graphene sheets are used to catalyze the BZ reaction. In addition, we witnessed some interesting behaviours when multiple BZ droplets interact within the oil-surfactant medium. Our findings can be used to design self-moving synthetic systems to control their behavior through the use of 0D-2D hybrid nanomaterials.

*DST-SERB (EMR/2016/007778) and IITGn

NGUYEN T NGUYEN (Presenter), SPENCER SMITH, Mt Holyoke Coll
— A general feature of active matter systems is that they consume energy on the small scale and coherent flows emerge on the large scale. Whether the units comprising these systems are bacteria, birds, or the microtubules of active nematics, coherence arises due to local interactions. In a now classic model, the Vicsek model, coherence, as measured by an order parameter, undergoes a phase transition with the changing importance of local interactions. We revisit this result from the perspective of mixing and fluid advection. In particular, we use a measure of dynamic disorder, the topological entropy, which captures the complexity of how the trajectories of these active agents wind about one another. We are able to calculate this mixing measure, and probe the thermodynamic limit of larger ensembles of agents, thanks to a new algorithm, which combines ideas from low dimensional topology and computational geometry. We will show some interesting results in how this disorder parameter behaves as we change the importance of local interactions.
10:00AM R25.00011: Anomalous topological active matter*   KAZUKI SONE (Presenter), YUTO ASHIDA, Department of Applied Physics, Univ of Tokyo — Systems with topologically nontrivial band structures, which are at the center of the modern condensed matter physics, exhibit unidirectional modes that propagate along the edge of a sample and are immune to disorder. Here, we show that the topological edge modes can ubiquitously emerge in active matter, the collection of self-propelled particles, under influences of spatially periodic structures [1]. Topological edge modes have been found in some active systems by constructing the counterparts of quantum Hall effect. However, to realize the effective external magnetic field, they introduce intricate structures, which can be the bottleneck for an experimental realization. We conclude that, without those intricate structures, it is hard to construct an active-matter counterpart of quantum Hall effect. Instead, by constructing the analogy with quantum anomalous Hall effect, our theoretical proposal eliminates the bottleneck for realizing topological active matter and broadens its applicability. We also discuss its relevance to ongoing experiments in biological systems.

10:12AM R25.00012: Homotopy analysis method for Non-Markovian processes in active matter   LEONARDO APAZA PILCO (Presenter), MARIO SANDOVAL-ESPINOZA, Physics, Metropolitan Autonomous University — We solve the Fokker-Planck (FP) equation for active non-Markovian and quasi-Markovian processes using the homotopy analysis method, and provide analytical expressions for classic mean values as a series in time. For non-Markovian processes we show that the solution is equivalent to a Dyson series in the Fokker-Planck operator. As an example, the active particles case with color noise in an arbitrary potential is solved. Our analytical results were compared to Brownian dynamics simulations showing a good agreement.

10:24AM R25.00013: Computational study of autonomous mechanical oscillations in a colloidal network crosslinked via clock proteins*   LAUREN MELCHER (Presenter), Rochester Institute of Technology, ELISABETH RENNERT, University of Chicago, JENNIFER L ROSS, Syracuse University, MICHAEL RUST, University of Chicago, RAE M ROBERTSON-ANDERSON, University of San Diego, MOUMITA DAS, Rochester Institute of Technology — We investigate a colloidal network as a model system that can dynamically switch between crosslinked and unlinked states when connected via crosslinkers made of clock proteins such as the bacterial circadian oscillator proteins KaiABC. We study this system using Brownian Dynamics simulations and obtain collective properties, such as the degree of order in the system, size of connected clusters, and the mechanical rigidity of the system as a function of time for different volume fractions of colloids, interaction strengths, and crosslinking kinetics. Using experimental parameters for polystyrene spheres and biotinylated KaiABC crosslinkers, we predict the behavior of real systems. Our results can provide insights into the design of self-sustaining soft materials that can autonomously transition between solid-like and fluid-like states, and how the properties of such materials can be tuned.

*This work was funded by a W.M. Keck Foundation Research Grant.
**10:36AM R25.00014: Scalar activity induced phase separation and liquid–solid transition in a Lennard-Jones system**  
* CHANDAN DASGUPTA (Presenter), S SIVA NASARAYYA CHARI, PRABAL K MAITI, Indian Institute of Science - Dept of Physics — Molecular dynamics simulations are used to investigate the effects of scalar activity in a three-dimensional system of Lennard-Jones particles at state points spanning from the gas to the liquid regime. Scalar activity is introduced by increasing the temperature of half of the particles (labeled 'hot') while keeping the temperature of the other half (labeled 'cold') constant at a low value. The ratio of the temperatures of the two subsystems is considered to be a measure of scalar activity. We observe that the two species tend to phase separate at sufficiently high temperature ratio. The degree of phase separation is quantified by a suitably defined order parameter and the entropy production in the process of phase separation is determined by employing the two-phase thermodynamics (2PT) method. We observe that the degree of phase separation and the entropy production increase with the density of the system. The mean number of clusters and the mean size of the largest cluster are determined as functions of the density and the temperature ratio. A calculation of bond orientation order parameters reveals that the largest cluster develops solid-like order consisting of both FCC and HCP packings.

**Session R26 DBIO DPOLY GSNP: Physics of Genome Organization: From DNA to Chromatin: I**  
403 - Alexandre Morozov, Rutgers University, New Brunswick - Tag(s): Focus

**8:00AM R26.00001: Strategies transcription factors use to gain access to nucleosomal DNA**  
* [Invited] MICHAEL POIRIER (Presenter), Ohio State Univ - Columbus — The physical organization of all eukaryotic genomes is evolutionarily conserved. Histone protein octamers repeatedly wrap genomic DNA into nucleosomes to form long chromatin fibers. Nucleosomes and chromatin function to control accessibility of transcription factors to their DNA target sites, while transcription factors target DNA sites to active transcription by “opening up” chromatin. However, the dynamic interplay between transcription factor binding and nucleosome/chromatin DNA compaction is poorly understood at the mechanistic level. I will discuss proposed strategies for how transcription factors bind to their sites within compact chromatin, and the differences between activating and pioneering transcription factors. I will then present our recent single molecule studies on how nucleosomes have profoundly different impacts on the DNA binding and dissociation dynamics of these two types of transcription factors. Our finds provide a potential way to define the functional differences between activating and pioneering transcription factors.

*This work was funded by NIH grants: GM121966, GM121858 and GM131626.
8:36AM R26.00002: Theory and modeling of active nucleosome repositioning* ZHONGLING JIANG (Presenter), BIN ZHANG, Massachusetts Institute of Technology MIT — Nucleosome positioning controls the accessible regions of chromatin and plays essential roles in DNA-templated processes. Its establishment in vivo is significantly influenced by ATP driven remodeling enzymes and transcription, which involves remodeler recruitment. On one hand, the non-equilibrium nature of remodelers has hindered the development of a unified theoretical framework for nucleosome positioning. On the other hand, explicit models are lacking in explaining the impact of transcription levels on nucleosome positioning since the complicated transcription process. For remodeling enzymes, we use a perturbation theory to show that the effect of these enzymes can be well approximated by effective equilibrium models with rescaled temperatures and interactions. Our theory provides an intuitive understanding for the impact of remodelers. By combining remodelers and RNAP II, we developed a transcription model, which illustrates opposite trends of nucleosome positioning patterns changing with transcription levels in yeasts and higher animals. This explanation qualitatively reproduces the experimental nucleosome positioning patterns.

8:48AM R26.00003: Centromeres and Telomeres as Rheological Probes of the Human Nucleus* ALEXIS CLAVIJO (Presenter), STEVEN IONOV, ALEXANDRA ZIDOVSKA, Physics, New York Univ NYU — The nucleus of eukaryotic cells stores genetic information in chromatin, the functional form of DNA in cells. Chromatin loci have been observed to exhibit anomalous motion that is often ascribed to the viscoelastic nature of the chromatin, transient interactions of DNA-associated proteins and/or physical obstructions [1,2]. However, a direct link between motion of a chromatin locus and the rheology of its local environment is missing. In this work, we investigate dynamics of specific genomic loci, centromeres and telomeres, the centers and ends of the linear interphase chromosomes, respectively, in the context of their local rheological environment. Using simultaneous two-color spinning disc confocal microscopy combined with recently developed machine-learning-assisted tracking algorithms [3], we monitor the motion of telomeres and centromeres in live human cells and extract the rheological properties of their surrounding environment, mapping the chromatin rheology across the cell nucleus.

9:00AM R26.00004: Knot dynamics of a DNA strand pushed inside a nanochannel  JAN ROTHÖRL (Presenter), PETER VIRNAU, Institute for Physics, Johannes Gutenberg University, ANIKET BHATTACHARYA, Univ of Central Florida — We investigate knot formation for a model DNA polymer pushed inside a square nanochannel whose width is much shorter compared to the contour length of the chain using Brownian dynamics simulation. We characterize different kind of knots formed, and monitor their evolution as the DNA is pushed inside the channel towards a steady state distribution. We repeat the calculations for several chain persistence lengths to understand how knots affect the DNA dynamics inside a nanochannel.

9:12AM R26.00005: Error-speed correlations in biopolymer synthesis  SIMONE PIGOLOTTI (Presenter), DAVIDE CHIUCHIU, Okinawa Institute of Science and Technology, YUHAI TU, BM T.J. Watson Research Center — Synthesis of biopolymers such as DNA, RNA, and proteins are biophysical processes aided by enzymes. Performance of these enzymes is usually characterized in terms of their average error rate and speed. However, because of thermal fluctuations in these single-molecule processes, both error and speed are inherently stochastic quantities. We study fluctuations of error and speed in biopolymer synthesis and show that they are in general correlated. This means that, under equal conditions, polymers that are synthesized faster due to a fluctuation tend to have either better or worse errors than the average. The error-correction mechanism implemented by the enzyme determines which of the two cases holds. For example, discrimination in the forward reaction rates tends to grant smaller errors to polymers with faster synthesis. The opposite occurs for discrimination in monomer rejection rates. Our results provide an experimentally feasible way to identify error-correction mechanisms by measuring the error-speed correlations.

9:24AM R26.00006: Noninvasive Measurement of Interphase Chromatin Rheology In Vivo*  IRAJ ESHGHI (Presenter), JONAH EATON, ALEXANDRA ZIDOVSKA, New York Univ NYU — Material properties of the genome are critical for its proper function and organization inside the cell nucleus. Chromatin, the functional form of DNA in cells, consists of DNA and associated proteins, forming long linear fibers in the interphase nucleus of eukaryotic cells. Traditionally, rheology of cellular components has been studied by tracking microparticles injected inside the cell [1]. Recently, we developed an injection-free noninvasive approach to study chromatin rheology using nuclear organelles as native probes [2]. Here, we show an alternative noninvasive experimental strategy using intrinsic dynamics to measure chromatin rheology across a large range of timescales, and elucidate the viscoelastic nature of chromatin in live cells. The measured rheology is captured by a surprisingly simple model whose few parameters have clear physical interpretations for this complex active material.

*This work was supported by the National Institutes of Health Grant R00-GM104152, the National Science Foundation (NSF) Grants CAREER PHY-1554880 and CMMI-1762506, New York University (NYU) MRSEC NSF Grant DMR-1420073 and NYU Whitehead Fellowship for Junior Faculty in Biomedical and Biological Sciences (to AZ).
Variability in gene expression ensures that cells with the same genotype always exhibit different phenotypes. Transcription bursting, or the random interruptions in the production of messenger RNA molecules, is one probable cause of this ubiquitous variability. Yet, the molecular mechanisms behind the bursting behavior remain unclear. Recent studies suggest that DNA supercoiling, which occurs during transcription, might be directly related to the bursting behavior. Stimulated by these observations, we developed a stochastic mechano-chemical model of supercoiling-induced transcriptional bursting. Using thermodynamically consistent coupling between mechanical and chemical processes, dynamic properties of transcription are explicitly evaluated. Theoretical analysis shows that the transcription bursting is observed when both supercoiling and the mechanical stress-release due to an enzyme gyrase are present in the system. A comparison with experimental data on bacteria allowed us to evaluate the energetic cost of supercoiling during transcription. We find that a relatively weak mechano-chemical coupling allows transcription to be regulated most effectively.

*Welch Foundation (C-1559), NSF (CHE-1664218), Center for Theoretical Biological Physics sponsored by NSF (PHY-1427654)

Chromosomal regions are known to adopt stable, heritable states which result in bistable gene expression without changes to the underlying DNA sequence. Such epigenetic control is a consequence of covalent modifications of histones. We introduced a (0+1)-dimensional kinetic model, wherein modified nucleosomes recruit enzymes that similarly modify neighbouring nucleosomes, to investigate the stability and heritability of the states. To make the model analytically tractable, we used the Doi-Peliti formalism, a second quantized description of the underlying master equation of a stochastic process such as the epigenetic problem at hand, that makes it amenable to attack via path integral methods such as semi-classical approximations, perturbation theory and renormalization group. Our model exhibits bistability, and using minimum action methods we can compute escape paths and probabilities between the two stable states. We are now coupling the model with a gene switch to quantify the developmental landscape of cell differentiation.

*This work has been supported by the Lester Wolfe Fellowship.
10:00AM R26.00009: Pulling a DNA through a Double-Nanopore system: A Brownian Dynamics Study  
PETER SMUCZ (Presenter), SWARNADEEP SETH, ANIKET BHATTACHARYA, Univ of Central Florida — We study translocation of a model DNA polymer captured in a double nanopore (DNP) system using Brownian dynamics (BD). We consider two different configurations as reported in recent experimental studies. In the first case, the direction of translocation is parallel to the vector connecting the two pores (X. Liu et al., Small 2019, 1901704). In the second case, the direction of translocation is perpendicular to the vector connecting the two pores (S. Pud et al., Nano Lett. 2016, 16, 8021-8028). In the former case we demonstrate that in the absence of a time dependent feedback mechanism, the velocity of the segment in between the pores is not constant, which hinders the mapping of the data from the time domain into genomic length. In the second case, we investigate parameters for optimal translocation of the chain through the DNP system. We consider limiting cases, where the distance between the pores is much shorter than the contour length of the chain, and show that one can use scaling results for single nanopore translocation to interpret results for the DNP translocation.

10:12AM R26.00010: Loop extrusion in chromatin: A question of time!*  
AJOY MAJI (Presenter), Physics, Indian Institute of Technology Bombay, RANJITH PADINHATEERI, Biosciences and Bioengineering, Indian Institute of Technology Bombay, MITHUN KUMAR MITRA, Physics, Indian Institute of Technology Bombay — One important question in the context of the 3D organization of chromosomes is the mechanism of formation of large loops between distant base pairs. Recent experiments suggest that the formation of loops might be mediated by Loop Extrusion Factors like cohesin. Experiments of cohesin have shown that cohesins walk diffusively on the DNA and nucleosomes act as obstacles to the diffusion, lowering the permeability and hence lowering the effective diffusion constant. An estimation of the times required to form the loops of typical sizes seen in Hi-C experiments using these low effective diffusion constants leads to times that are unphysically large. The puzzle then is the following, how does a cohesin molecule diffusing on the DNA backbone achieve speeds necessary to form the large loops seen in experiments? We propose a simple physical answer to this puzzle and show how a naive obstacle view of nucleosomes can be misleading.

**10:24AM R26.00011: Structural and Dynamical Signatures of Local DNA Damage in Live Cells**

JONAH EATON (Presenter), ALEXANDRA ZIDOVSKA, New York Univ NYU — The dynamic organization of chromatin inside the cell nucleus plays a key role in gene regulation and maintaining genome integrity. While the static folded state of the genome has been studied before, the dynamical signatures of processes such as transcription or DNA repair are unknown. We investigate the interphase chromatin dynamics in human cells in response to local damage, DNA double strand breaks (DSBs), by monitoring the DSB dynamics and the compaction of the surrounding chromatin in live cells. We find DSBs to possess a unique chromatin compaction profile, while being more mobile when located in the nuclear interior as opposed to the periphery. We show that DSB motion is subdiffusive, ATP-dependent, and exhibits unique dynamical signatures compared to undamaged chromatin. We find that DSB mobility follows a universal relationship based on the local environment suggesting that the repair processes are robust and likely deterministic. Such knowledge may help in detection of DNA damage in live cells and aid our biophysical understanding of genome integrity in health and disease [Eaton & Zidovska, Biophys. J., 2019].

**10:36AM R26.00012: Extracting the degree of order in the bacterial chromosome using statistical physics**

JORIS MESSELINK (Presenter), Arnold Sommerfeld Center for Theoretical Physics, Ludwig Maximilian University of Munich, JACQUELINE JANSSEN, Max Planck Institute for the Physics of Complex Systems, Dresden, MURIEL VAN TEESELING, MARTIN THANBICHLER, Faculty of Biology, Philipps University Marburg, CHASE BROEDERSZ, Arnold Sommerfeld Center for Theoretical Physics, Ludwig Maximilian University of Munich — Elucidating the three-dimensional spatial organization of the bacterial chromosome is essential to understand how genomic processes are spatially regulated inside the cell. Recent Hi-C chromosome conformation capture experiments provide contact frequency maps of the chromosome. These experiments reveal structural organization beyond that of an amorphous polymer. However, despite such experimental advances, the degree of spatial organization of the bacterial chromosome remains unclear. To investigate this, we develop a maximum entropy approach to extract the three-dimensional structure of the bacterial chromosome from such data. Using this approach, we obtain a coarse-grained model for the full distribution of chromosome configurations for the bacterium *C. crescentus*. We validate the predictive power of our model by experiments on the localization of chromosomal loci in the cell. Our model reveals novel features of spatial chromosome organization on various length scales. Our approach is not organism-specific, and opens up a new way of analyzing spatial chromosome organization.

R26.00013: Direct Quantification of Gene Regulation by Transcription-Factor Binding at an Endogenous Gene Locus  
JINGYAO WANG, School of Life Sciences and Biotechnology, Shanghai Jiao Tong University, YIJING DONG, HUIHAN BAO, XINTAO YAO, School of Physics and Astronomy, Shanghai Jiao Tong University, ANNA MARIE SOKAC, School of Molecular & Cellular Biology, University of Illinois at Urbana-Champaign, IDO GOLDING, Department of Physics, University of Illinois at Urbana-Champaign, HENG XU (Presenter), School of Physics and Astronomy, Shanghai Jiao Tong University — Gene activity is controlled by the binding of transcription factors (TFs) to the regulatory sequence of the gene, yet a direct in situ mapping from TF binding to mRNA production of a single gene remains elusive, due to the difficulty of capturing individual TF binding events of a specific gene from the ocean of TF signal in cell nucleus. Here we combine single-molecule fluorescent imaging of protein, mRNA, and gene loci to detect and quantify distinct binding configurations of multiple TFs and epigenetically modified histones, as well as the resulting nascent mRNAs at endogenous hunchback (hb) gene loci in early Drosophila embryos. Using stochastic theoretical analysis, we show that TF binding follows nonequilibrium multi-state kinetics, breaking the law of mass action. hb transcription activation is a multi-step process initiated by transient binding of the Bicoid transcription factor. Unlike TF binding at hb, the histone signal is deprived at active gene loci, indicating that nucleosome unwinding is necessary for gene activation. Our method provides a general framework to decipher the dynamics of complex gene regulatory networks in situ.

Session R27 FIAP: Thermal and Ballistic Transport in Semiconductors

8:00AM R27.00001: Non-degenerate heavy electrons and Planckian limit to scattering in doped strontium titanate*  
CLEMENT COLLIGNON (Presenter), BENOIT FAUQUE, JEIP, College de France, KAMRAN BEHNIA, LPEM, ESPCI — The metallicity of lightly doped SrTiO$_3$ is strange. The combination of the effective mass extracted from quantum oscillations and the amplitude of room-temperature mobility implies a mean-free-path (mfp) below the Mott Ioffe Regel (MIR) limit and a scattering time shorter than the Planckian time ($\tau_P$=h/2πkB$T$). Here, we present a study of electric resistivity and thermoelectric power above room temperature pointing to a possible exit out of this maze. According to our data, resistivity is metallic and does not saturate up to 900 K. In the non-degenerate regime, the Seebeck coefficient is set by the ratio of the de Broglie wavelength, $\lambda_{dB}$, to the interelectron distance, $n^{-1/3}$. We demonstrate that the temperature dependence of the shrinking $\lambda_{dB}$ (before its saturation to a length twice the lattice parameter) points to a continuous change in the effective mass of charge carriers. Combining the latter with mobility keeps the mfp above the MIR limit and the scattering time longer than $\tau_P$. Our results imply the existence of a hitherto unknown case of non-degenerate metallicity driven by temperature-induced mass amplification.

Energetics of solid-state metathesis reactions in nanostructured thermoelectric systems*  

XIA HUA (Presenter), JEFF W DOAK, CHRISTOPHER MARK WOLVERTON, Northwestern University — Thermoelectric systems with large compositions of AB (e.g. SnTe) and much smaller compositions of A′B′ (e.g. CdS, ZnS) are promising candidates since the second-phase nanostructures scatter phonons, reducing lattice thermal conductivity and increasing ZT. In this work, we use high-throughput density functional theory (DFT) calculations to evaluate the metathesis reactions (AB+A′B′↔A′B+AB′) of 1638 quaternary phase systems (A,A')(B,B′) in order to understand the behaviors and predict potential nanostructured thermoelectrics. We include systems most relevant for rocksalt-based thermoelectrics: group II, IIb, and IV cations, and group VI anions. In addition, we include group III cations and group V anions as possible secondary phases. We find that the metathesis reactions exhibit well-defined trends, which can be explained within the context of hard-soft acid-base theory (HSAB). Deviations from these trends are examined in more detail and finite temperature effects are investigated for select systems.

The thermoshape voltage induced by quantum shape effects  

ALTUG SISMAN, Uppsala University, ALHUN AYDIN (Presenter), Istanbul Tech Univ, JONAS FRANSSON, Uppsala University — We propose here a new effect for the conversion of heat energy into electricity with nanostructures. We recently used size-invariant shape transformation to completely separate quantum size and shape effects from each other, which allows one to focus on purely quantum shape effects. In this work, we first present the existence of the quantum shape effects on thermoelectric transport properties of GaAs nanostructures at ballistic regime. Then we consider a junction composed of the same material having exactly the same geometric sizes, but distinct shapes. We show that an electric voltage is induced under a temperature gradient in such a junction because of the quantum shape effects on Seebeck coefficients. This cross effect is called the thermoshape effect. Our calculations based on Landauer formalism predict that the thermoshape voltage is persistent and in the order of mV/K for non-degenerate GaAs semiconductors. Our study explicitly suggests how important the effect of overall geometry is in nanoscale thermoelectric materials, and can be utilized even if all sizes are the same. A thermoshape junction not only represents a viable setup for the macroscopic manifestation of quantum shape effects, but also constitutes their first possible device application.
Observation of anomalous Shapiro steps in ballistic Josephson junctions of InAs nanowires

KENTO UEDA (Presenter), Univ of Tokyo, SADASHIGE MATSUO, RIKEN, HIROSHI KAMATA, YUUSUKE TAKESHIKE, YOSUKE SATO, SHOJI BABA, Univ of Tokyo, LARS SAMUELSON, Lund University, KAN LI, Peking University, SOREN JEPPESEN, Lund University, HONGQI XU, Peking University, SEIGO TARUCHA, RIKEN — Advances in semiconductor technology provide the high electric controllability and long mean free path in various kinds of nanostructure. Especially proximity-induced superconductivity in semiconductor nanowire (NW)-superconductor junctions provides intriguing platforms to study exotic superconducting phenomena occurring in the ballistic transport regime.

For example, the quantized conductance due to Majorana Fermions (MFs) [1], and high-efficient Cooper pair splitting [2] have been observed in a superconducting junction of a single NW, and double NW, respectively.

Here we report on observation of anomalous Shapiro steps measured in Josephson junctions (JJ) of InAs NWs. The Shapiro steps appear on not only integer multiples of hf/2e but also the half-integer multiples. We attribute these anomalous steps to the skewed current-phase relation (CPR) expected in the ballistic JJ. Our results contribute to establish the relationship between the CPR and Shapiro step anomalies, which is also important for study of MFs.

Ballistic transport in black phosphorus transistors*

XUEFEI LI (Presenter), Huazhong University of Science & Technology — As a strong candidate for future electronics, atomically thin black phosphorus (BP) has attracted great attention in recent years due to its tunable bandgap and high mobility. Here we show that the transport properties of BP device under high electric field can be improved greatly by the interface engineering of high-quality HfLaO dielectrics and transport orientation. By designing the device channels along the lower effective mass armchair direction, a record high drive current up to 1.2 mA/μm at 300 K and 1.6 mA/μm at 20 K can be achieved in a 100 nm back-gated BP transistor, surpassing any two-dimensional semiconductor transistors reported to date. The highest hole saturation velocity of $1.5 \times 10^7$ cm/s is also achieved at room temperature. Ballistic transport shows a record high 36% and 79% ballistic efficiency at room temperature and 20 K, respectively, which are also further verified by theoretical simulations.

9:00AM R27.00006: Quantum Technologies using Ge and GeSn on Si. YILMAZ GUL (Presenter), STUART NICHOLAS HOLMES, London Center for Nanotechnology, MAKSYM MYRONOV, Physics, University of Warwick, MICHAEL PEPPER, London Center for Nanotechnology — Large scale fabrication using Complementary Metal Oxide Semiconductor compatible technology of semiconductor nanostructures that operate on the principles of quantum transport is an exciting possibility now due to the development of ultra-high mobility hole gases in epitaxial germanium grown on standard silicon substrates. We present here a ballistic transport study of patterned surface gates on strained Ge quantum wells with SiGe barriers, which confirms the quantum characteristics of the Ge heavy hole valence band structure in 1-dimension. We also present transport properties of light holes in GeSn quantum well structures grown on standard Si (001) substrate. Furthermore we present the current and future measurements taking place using Ge, including spin focusing and majorana fermion studies using superconducting junctions on Ge layers. The experimental results shown here suggests a new area of experimentation in quasi 1D systems, particularly direct measurement of the charge, with implications for possible schemes of topological quantum information processing.

9:12AM R27.00007: Thermal transistor and thermometer based on coupled quantum dot and point contact*. JING YANG ( Presenter), CYRIL ELOUARD, University of Rochester, JANINE SPLETTSTOESSER, Chalmers University of Technology, BJÖRN SOTHMANN, Universität Duisburg-Essen and CENIDE, RAFAEL SÁNCHEZ, Universidad Autónoma de Madrid, ANDREW N JORDAN, University of Rochester — We propose a three-terminal setup consisting of a Coulomb coupled quantum dot quantum point contact. The source and drain reservoirs are connected to the QPC while the base reservoir is tunnel coupled to the Coulomb blockade quantum dot, which can contain at most one electron. We show that the setup can work as a nanoscale thermal transistor to control the electric or heat current flow in the quantum point contact. Alternatively, by detecting the electric current in the quantum point contact, the setup can also act as the nanoscale thermometer. We calculate the sensitivity and power gain for the transistor and the sensitivity for the thermometer respectively. We derive the operating condition maximizing their respective sensitivities. We show that the resolution in previous experiments on temperature sensing can be further improved if it is tuned to the optimal regime we derived here.

9:24AM R27.00008: Hopping conduction characterization in amorphous semiconductors and cross-linked metal nanoparticles*  BRIANNA WESTERN (Presenter), MICHAEL HARCROW, ATHANASIOS J SYLLAIOS, VINCENT LOPES, CHRISTOPHER LITTLER, University of North Texas, ZHI-GANG YU, RAY GUNAWIDJAJA, Washington State Univ — In amorphous semiconductors, e.g. a-Si, conduction occurs via charge carrier hopping between localized states. The key figures of merit in characterization, particularly in microbolometer applications, include the temperature dependence of conductivity, summarized by the temperature coefficient of resistance (TCR), and electrical noise, which are controlled in the hopping regime by the hopping conduction parameters. For next-generation bolometer material, cross-linked metal nanoparticles (CLMPs) conduction occurs via electron hopping between adjacent nanoparticles, and the conductivity exhibits Arrhenius temperature-dependent behavior. In these systems, TCR and noise are theorized to be controlled by nanoparticle diameter and separation distance between adjacent nanoparticles, respectively. Diameter and separation distance in CLMPs are independent of each other, with the separation distance being controlled by organic ligands bonded to the nanoparticle surface. This work examines the effect of different organic ligands on electrical conductivity and TCR in CLMPs.

Characterization, Modeling, and Optimization of Cross-Linked Metal Particles for Microbolometers

9:36AM R27.00009: Non-equilibrium nature of non-linear optical response: Application to the bulk photo voltaic effect  TAMOGHNA BARIK (Presenter), JAY SAU, University of Maryland, College Park — The bulk photo-voltaic effect (BPVE) is an example of non-linear optical response that leads to a DC current in non-centrosymmetric materials which is relevant to photo-voltaic applications. We theoretically study this effect in the presence of electron-phonon interactions. Using the response function formalism, we show that the non-linear optical response, in general, contains correlator of three operators which are not ordered in time. This out of time-ordered correlator (OTOC) for an interacting system cannot be calculated using equilibrium field theory. Using a semiclassical approach instead, we show that BPVE can be attributed to the dipole moment of generated electron hole pairs. We confirm the validity of semiclassical result for the non-linear DC response from a quantum master equation approach. From this formalism we also find that the electron-phonon coupling strength has a strong implicit effect on the scaling dependence of the non-linear DC response on the optical field. Most interestingly, the semiclassical treatment shows that the non-linear DC response for spatially inhomogeneous excitation profiles is strongly non-local and must involve the aforementioned OTOC that cannot be computed by equilibrium field theory.

9:48AM R27.00010: Measurement of Hall conductivity near the metal insulator transition by torque magnetometry*  
SAMUEL MUMFORD (Presenter), TIFFANY PAUL, Physics, Stanford University, SEUNG HWAN LEE, AMIR YACOBY, Physics, Harvard University, AHARON KAPITULNIK, Physics, Stanford University — We study Hall conductivity near the disorder-induced metal-insulator transition and present the first measurements of Hall conductivity utilizing a torque magnetometry method. A Corbino disk exhibits a magnetic dipole moment proportional to Hall conductivity when voltage is applied across a test material. This magnetic dipole moment can be measured through torque magnetometry. The symmetry of this contactless technique allows us to measure the Hall conductivity of insulating materials and materials near the metal-insulator transition such as sputtered indium tin oxide. We have measured the Hall conductivity of indium tin oxide with a ratio of transverse to longitudinal resistivity of 1E-4 and can now measure Hall conductivity independently of longitudinal resistance.

10:00AM R27.00011: Kinetic Inductance in Ballistic Transport Jashan Singhal¹ and Debdeep Jena¹,²,³  
¹ School of Electrical and Computer Engineering, Cornell University ² Department of Materials Science and Engineering, Cornell University ³ Kavli Institute at Cornell for Nanoscale Science, Cornell  
JASHAN SINGHAL (Presenter), DEBDEEP JENA, School of Electrical and Computer Engineering, Cornell University — Electron transport in nanoscale semiconductors approaches the ballistic limit. Without scattering, the kinetic inductance (KI) of carriers becomes considerably large [1,2]. What are the consequences in devices and circuits? We investigate the generalized kinetic inductance in a d-dimensional conductor with various band-structures (e.g. parabolic and conical) in the ballistic limit. The KI per unit length is evaluated as a function of carrier density and temperature at low bias voltages. The KI is found to very weakly depend on V, and strongly on the electron density. An increase in KI at low density is expected because more velocity is needed to maintain the same current. The ballistic model predicts that even without considering phonon scattering, the KI decreases at high temperature. Because of the Fermionic nature of electrons, their collective excitation exhibits a Newtonian inertia, which decreases with an increase in temperature. The quantum mechanical ballistic KI is compared to the standard ‘classical’ inductance, and its importance is classified for various carrier densities, and dimensions.

10:12AM R27.00012: Novel computational approach for electron-transport from first-principles*  
ALEX GANOSE (Presenter), JUNSOO PARK, ANUBHAV JAIN, Lawrence Berkeley National Laboratory — Accurate calculation of transport properties has so far proved challenging due to the difficulty of computing carrier relaxation times. Methods which explicitly include electron-phonon interactions, such as Electron-Phonon Wannier (EPW), yield high-quality predictions but are incredibly computationally expensive and therefore limited to systems with few electrons. Conversely, using the constant relaxation time approximation (CRTA), predictions are obtained quickly but can be unreliable.

We have developed a new framework for calculating the electronic transport properties of solid-state materials from first-principles. With performance close to that of EPW at a fraction of the computational cost, the technique is both accurate and amenable to high-throughput calculations. We demonstrate the speed and performance of the package by screening the Materials Project database for novel thermoelectric materials.

*We acknowledge support from the US Department of Energy, Office of Basic Energy Sciences, Early Career Research Program (ECRP). 10:24AM R27.00013: A model of dephasing in shift current processes*  
BENJAMIN FREGOSO (Presenter), Kent State Univ - Kent — The shift current is a second order nonlinear effect in the optical field thought to be the dominant transport mechanism in many ferroelectric materials and to carry information about the topology of the Bloch wave functions. The shift current requires quantum coherence in the solid. We construct a simple model of electrons coupled to a chain of one-dimensional ions lacking inversion symmetry. We analyze the thermalization of electrons within the model at high and low excitations frequencies (close to the band edge). The model allows the study of decoherence in shift current process beyond the classical transport regime.

*NERSC-DOE DE-AC02-05CH11231
8:00AM R28.00001: Following a Theoretical Roadmap to Low Nucleation Barriers for CO₂

**Nucleation in Polyol** [Invited] JULIA A KORNFIELD (Presenter), Caltech — The quest for insulation with thermal conductivity as low as stagnant air motivates production of ultra-low density foams with cells as small as 1μm across, requiring the controlled nucleation and growth of \(10^{10}\) bubbles/(cm³ mother liquid). In relation to polyurethane foam, we seek high nucleation density guided by predictions from density functional theory (DFT) with the string method for the activation barriers. Predicted composition profiles across the interface suggest that cyclopentane (C5), a physical blowing agent, promotes CO2/polyol nucleation in multiple ways: C5 increases the density of the CO₂-rich nucleus, and C5 preferentially concentrates at the interface---both tend to reduce the interfacial tension. To test theoretical predictions, we validated the thermodynamic properties of binary (CO₂/polyol) and ternary (CO₂/C5/polyol) systems. Experimental results for binary systems quantify the reduction of interfacial tension near the critical point and accord with predictions. In ternary systems, theory directed our attention to a range of composition and pressure in which three-phase coexistence may occur and preliminary results support the theoretical predictions. Then we investigated nucleation kinetics using a high-pressure microfluidic apparatus. Initial results obtained using optical microscopy will be presented, laying the foundation for future scattering measurements to quantify the number and size of incipient bubbles. This work was conducted in collaboration with Dow, including T Fitzgibbons, WJ Zhou, HK Chao, J Griffith, B Winniford, S Horsch and V Ginzburg; E DiMaio at Uni Naples and A Ylitalo, ZG Wang and RC Flagan at Caltech.

*This research is funded by Dow.

8:36AM R28.00002: Polymer Foams for Building Insulation (STYROFOAM and beyond) [Invited]

STEPHANE COSTEUX (Presenter), Safety & Construction, DuPont — Thermoplastic foams have been used in buildings for over 75 years, since the initial introduction of STYROFOAM™ extruded polystyrene foam. Although significant progress has been made to improve the product performance, durability and sustainability, the process itself has remained relatively unchanged, and the levers used to control foam structure – and thus performance - still rely on empiricism. An examination of mechanisms involved in the foaming process of thermoplastic polymers points to the difficulty of predicting cell nucleation density, as well as the quantitative influence of cells interactions during expansion and stabilization. These limitations are particularly apparent now that the foam community has turned its attention to nanocellular foams, which are expected to demonstrate superior properties but are very difficult produce by known commercial processes.

[ STYROFOAM™ is a trademark of DuPont Inc. ]
9:12AM R28.00003: Polyurethane Application Innovation: Translating Chemistry to Materials to Solve Real-World Problems [Invited]  WILLIAM KOONCE (Presenter), Dow Chemical — Polyurethane materials have grown rapidly in recent years and now touch most facets of modern life from comfortable sleep to energy efficiency and transportation among others. Polyurethane chemistry provides high versatility in application processes with conversion from low viscosity liquids to polymeric solids in seconds. This processing versatility enables generation of varied foam structures, filling of complex geometries, and coating of diverse substrates. Beyond processing, polyurethane polymers can be designed to deliver a range of structures and resulting properties from hard to soft, viscoelastic to elastic, hydrophobic to hydrophilic. Examples of using these versatile processing and material properties to solve real world problems will be shared.

9:48AM R28.00004: Modeling Nucleation in Polymeric Foams using Self-Consistent Field Theory* [Invited]  RUSSELL B THOMPSON (Presenter), University of Waterloo — Self-consistent field theory is a method in statistical mechanics that is effective for the study of inhomogeneous polymer structures, typically block copolymer self-assembly. Self-consistent field theory can also be used to understand some aspects of nucleation in polymer foaming, especially for nano-cellular foams. An introduction to this approach, including its advantages and disadvantages, will be given. Implications for the validity of classical nucleation theory and nucleation barriers from this perspective will be discussed, as will some new predictions related to heterogeneous nucleation.

10:24AM R28.00005: Fluid dynamics of bubbly drinks [Invited]  ROBERTO ZENIT (Presenter), School of Engineering, Brown University — Most people find bubbly drinks to be attractive and refreshing. With the excuse of trying to answer why, we explore the physics involved in this particular kind of two-phase, mass-transfer-driven flows. Discussion and analysis of the processes of bubble formation, ascension, accumulation and bursting are presented. Links to other relevant flow phenomena are presented in each case.

Thursday, March 5, 2020 8:00 AM - 10:24 AM

Session R29 DSOFT DBIO GSNP DPOLY: Active Matter and Liquid Crystals in Biological Systems II  501 - Kimberly Weirich, University of Chicago - Tag(s): Focus
8:00AM R29.00001: Defect Ordering and Patterning in Active Nematics*  
SURAJ SHANKAR  
(Presenter), Physics, Harvard University, M CRISTINA MARCHETTI, Physics, University of California, Santa Barbara — Active nematics combine liquid crystalline orientational order with internal active driving to generate novel dynamical states involving complex spatio-temporal flows along with spontaneous defect pair creation and proliferation. Topological defects acquire self-propulsion due to activity and play a prominent role in driving large scale flows in two-dimensional active nematics. By focusing on defects as the relevant excitations, we develop a hydrodynamic theory of active defects incorporating both defect motility and active torques that align defect orientations. Our model predicts a defect ordered polar flock at high activity and uncovers the underlying physical mechanism for defect ordering. Extending our framework to include spatially inhomogeneous activity, we show how activity gradients act as "electric fields" that can sort defects based on their topological charge. Our continuum model hence offers a useful and versatile approach to quantify the patterning of defects and flow in active nematics by the spatial control of activity.

*This work was supported by the NSF grants DMR-1609208, at KITP under PHY-1748958, and at the Aspen Center for Physics under PHY-1607611.

8:12AM R29.00002: Ordering and Correlations of Active Nematic Defects in 2D Flat Space  
JYOTHISHRAJ NAMBISAN  
(Presenter), Georgia Institute of Technology, DANIEL PEARCE, University of Geneva, PERRY W ELLIS, Harvard University, LUCA GIOMI, Leiden University, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — Topological defects are regions in an ordered material where the characteristic order is undefined. These defects are of significant interest in understanding the dynamics of active nematics, which are intrinsically out of equilibrium. One of the aims of our work is to address the orientation of defects in curved geometries. However, in this talk, I will discuss our results in flat space. We first explain how we prepare and image the system and how we identify defects using image analysis techniques. We focus on their orientation calculated directly from the divergence of the nematic tensor order parameter. We then use the defect positions and orientations to define relevant order parameters – polar and nematic order for the +1/2 defects, and a 3-fold bond angle order for the -1/2 defects. These quantities give us insights on the average orientational ordering of our system of defects. We then proceed to look at orientational correlations, and present insights into the configurations adopted by the defects as a function of the inter-defect spacing. Remarkably, we find that the local orientational order persists irrespective of the defect density.

8:24AM R29.00003: Defect order in active nematics  
ZHITAO CHEN  
(Presenter), MARK J BOWICK, M CRISTINA MARCHETTI, University of California, Santa Barbara — Using a recently derived model of active defects as quasi-particles, some of us have reported emergent states where +1/2 defects in active nematics organize in structures with large scale polar order. While ordered states of +1/2 defects have been obtained in both experiments and simulations of active nematic hydrodynamics, both polar and nematic alignment of the +1/2 defects have been seen depending on whether active flows are dissipated by friction with a substrate or by viscous stresses. In this talk, we will discuss the interplay between elastic and active torques, active flows and frictional dissipation in controlling defect patterns in these active liquid crystals.
8:36AM R29.00004: Dynamical Behavior of Defects in Circularly Patterned Active Nematics
ALI MOZAFFARI (Presenter), RUI ZHANG, University of Chicago, ANDREY SOKOLOV, ALEXEY SNEZHKO, Argonne National Laboratory, JUAN DE PABLO, University of Chicago — Active nematics represent a new class of non-equilibrium systems that combine orientational ordering with active stresses applied to elongated particles. Continuum simulations of the active nematic are employed to explain how the interplay of activity-fueled energy injection to the system and frictional damping forces impact the dynamics of topologically imposed self-propelling +1/2 defects. We show that by patterning the activity by imposing active stresses in circular domains near the center of confinement, it is possible to regulate the motion of defects. A phase diagram of the dynamical response of defects based on activity strength and hydrodynamic friction is developed, revealing a wealth of new phenomena. Our results disclose that defects synchronize their dynamics to minimize the elastic distortion energy while being driven out of equilibrium by active stresses. A phase diagram is presented that displays a rich dynamical behavior, including immobile defects, steady rotation, bouncing defects, cruising defects, and a synchronized dancing state.

8:48AM R29.00005: Photo-Patterning DNA Structures with Topological Defects and Arbitrary Patterns through Multiple Length Scales CHENHUI PENG (Presenter), JINGHUA JIANG, NETRA DHAKAL, Physics and Materials Science, The University of Memphis — DNA is the building block for all living organisms, hence controlling supramolecular self-assembly of DNA structures is important not only for better understanding its biological properties, but also sheds light to designing new functional materials for biological engineering and material science applications. However, it is still challenging to control the DNA molecular self-assembly structures in the predesigned manner across multiple length scales. In this work, we demonstrate that the orientational order of DNA molecules can be precisely controlled by using photo-patterning technique. This technique imprints various spatially varying patterns into a layer of liquid crystalline polymer which will be further used to control the DNA structures. It is demonstrated that DNA orientations can be patterned with two dimensional lattice of topological defects and arbitrary patterns through length scale from micrometers to millimeters. The resulting programmable and predesigned DNA self-assembly structures will open opportunities in advanced materials and devices for optical and biological applications.
9:00AM R29.00006: Cells as liquid crystals, and what happens when they can't align [Invited]
KIRSTEN ENDRESEN, MINSU KIM, FRANCESCA SERRA (Presenter), Johns Hopkins University — The organization of cells in tissues is crucial in determining their properties and functionalities. From the embryonic organization to mature tissues, cells are often arranged in well-determined patterns, which control the mechanical properties of the tissue and the ability to sense the environment. Many cell types have a characteristic anisotropic shape, and show an intrinsic ability to align with their neighbors. This behavior is analog to nematic liquid crystals (LCs). One special feature of LCs is the presence of topological defects, regions where the nematic order is lost and where stresses are concentrated in small regions. Monolayers of cells show alignment defects analog to LC topological defects. There is increasing evidence that such defects have a biological role, and their importance has been discussed in processes such as cell apoptosis, formation of 3D protrusions, growth of tumors stroma and cell migrations from tumors.
To better understand the role of these disordered regions in tissues, we induce topological defects in cell monolayers and study the cells behavior. Our goal is to connect biological properties of cells to the LC properties of the monolayers that the cells can form. We use topography to investigate the behavior of cells near induced topological defects, each characterized by their topological charge. Using shallow patterned grooves, we can impose defects with various charges without totally constraining the cells, and we study the cells’ behavior. Our data show a very different behavior of fibroblasts 3T6 and epithelial cells EpH-4 near topological defects with azimuthal or hyperbolic orientation of cells (+1 and -1 topological charge respectively), both in the ability to align and in the distribution of cell density within the monolayers. Finally, the behavior of cells near defects can provide a unique way to determine the size of the defect core.

9:36AM R29.00007: Quantifying orientational interactions among defects in active nematics*
SUPAVIT POKAWANVIT (Presenter), ZHIHONG YOU, M CRISTINA MARCHETTI, MARK J BOWICK, University of California, Santa Barbara — In passive two-dimensional systems, from superfluid films to nematic layers, topological defects play a key role in controlling continuous order-disorder transitions. Inspired by this, some of us have recently derived an effective description of the dynamics of topological defects in 2D active nematics as quasiparticles, where the unbound defects are modeled as a gas of self-propelled (+1/2) and passive (-1/2) particles with Coulomb interactions and aligning torques. We have now tested this model against defect trajectories obtained from numerical simulations of 2D active nematic hydrodynamics. Specifically, we demonstrate that the polar +1/2 defects interact via torques that tend to align the defect polarization with the elastic force they experience from other defects, as in previously studied models of flocking.

9:48AM R29.00008: Effect of active enzyme diffusion on mesoscale particles

BAHAR ROUHVAND (Presenter), Univ of Mass - Amherst, JENNIFER L ROSS, Physics, University of Syracuse —

Most of the phenomena in a living matter occur far from equilibrium and, therefore, cannot be treated within the framework of classical equilibrium thermodynamics. The elements of active matter, self-propelled particles, can be used to power active baths that can be rectified to recover work from noisy, non-equilibrium systems. Prior work has used bacteria or colloidal active matter to serve as active baths that can turn rotors or be rectified. However, the large size of bacteria creates a lower limit on the size of a material powered by a bacterial active bath. Cell biological studies have implied that metabolism enzymes serve to mix the viscous and complex fluid of the cytoplasm. Using these ideas our prior expertise in studying enzymes, we will focus on how enzyme baths can power the fluctuation spectrum of nano particles, and their effect on the diffusivity and fluctuations of larger particles such as passive proteins, quantum dots, and colloidal particles. Activity of passive elements will be analyzed through single particle tracking and differential dynamic microscopy.

10:00AM R29.00009: Collective trapping of flocking particles by asymmetric obstacles*

JUAN ARAGONES (Presenter), RAUL MARTINEZ, Univ Autonoma de Madrid, FRANCISCO ALARCON, Departamento de ingenieria fisica, Universidad de Guanajuato, CHANTAL VALERIANI, Departamento de Estructura de la Materia, Fisica Termica y Electronica, Universidad Complutense de Madrid — Anisotropic obstacles not only are capable to induce ratchet effects on suspensions of run-and-tumbling particles, but also affect the collective behaviour of active aligning particles, such as Vicsek particles [1, 2]. In this talk, I will show that flocking particles which follow the Vicsek model aligning rules experience a collective trapping in the presence of a wall of funnels made of chevrons, concentrating at the opposite side of a wall of funnels than run-and-tumbling particles. We study the dynamics of this collective self-trapping behaviour and identify two regimes, one static and other dynamical in which particles are effectively trapped by constantly escaping and getting into the channels. Exploiting these two regimes, we engineer a system showing two perpendicular flows of Vicsek particles.

*The project that gave rise to these results received the support of a fellowship from "la Caixa" Foundation (ID 100010434). The fellowship code is LCF/BQ/LI18/11630021.
10:12AM R29.00010: Polar flocking of active clusters  PAUL DOMMERSNES (Presenter), JON OTTO FOSSUM, Department of Physics, Norwegian University of Science and Technology — Biological active matter, such as populations of cells and animals, often change between different flocking regimes. One example is shoaling, milling and schooling transitions in fish. Synthetic active matter consist of self-propelled inanimate units and can emulate the flocking behavior of biological active matter. Here we report on a system of electro-propelled rolling granular beads with tuneable interactions. Many active matter regimes is realized in the same experiment as a function of the electric field: including active crystals and clusters with long range polar order, a stripe phase of clusters, and polar liquid flocks. Remarkably, the crystal to liquid transition occurs at a different velocity threshold than the local to global polar order transition. The stripe phase is reminiscent of those seen in quasi two-dimensional matter with competing interactions. The experimental system offers a physical model for flocking transitions in biological active matter, and can also open new routes for controlling self-assembly in soft matter technologies.

R29.00011: Flocking and clustering of self-propelled disks with active reorientation  TING ZHENG (Presenter), School of Physics, Southeast University, LU CHEN, Beijing Computational Science Res Ctr, ZHANCHUN TU, Beijing Normal University, XIANG CHENG, University of Minnesota, XINLIANG XU, Beijing Computational Science Res Ctr — In this talk we present a numerical investigation of self-propelled disks that integrates a behavior of active reorientation in analogy to collision avoidance in animal herds. The results of our simulations show rich phase dynamics including a flocking state, and a clustering state as a result of the mobility-induced phase separation. With a systematic exploration, our study reveals the unexpected link between the two collective behaviors. This study illustrated the importance of active reorientation on the emergent behaviors of self-propelled particles relevant to many natural and engineered active systems.

Session R30 DSOFT DPOLY GSNP DBIO: Visualizing Forces in Soft Materials via Photoelastic and Other Optical Techniques 502 - Karen Daniels, North Carolina State University - Tag(s): Focus
8:00AM R30.00001: Stress and velocity fluctuations in photoelastic granular avalanches*
NATHALIE VRIEND (Presenter), BP Institute, Univ of Cambridge, AMALIA THOMAS, DAMTP, Univ. of Cambridge, KAREN DANIELS, Department of Physics, NCSU — We study granular avalanches using a custom-built narrow chute where we release 2D photoelastic disks down an incline. Using high-speed imagery, we are able to obtain position and velocity data from particle tracking, and the full stress tensor, including normal and shear stress components, from the photoelastic response of interacting particles. Even though the avalanche is steady-state in time and space, minute fluctuations in velocity and forces away from the mean directly influence the rheology and fluidity.

In this study, we analyze the correlation between velocity fluctuations and stress fluctuations in both the quasi-steady layer (close to the rough base) and the flowing layer (near the free surface). We correlate the fluctuations with direct measurements of the measured non-local properties within this photoelastic avalanche.

8:12AM R30.00002: Photoelastic Analysis of Cohesive Granular Aggregates CARTER PATTERSON (Presenter), Haverford College, JONATHAN KOLLMER, Universität Duisburg-Essen, THEODORE ANTHONY BRZINSKI, Haverford College — Photoelasticimetry facilitates the non-invasive measurement of individual contact forces in granular materials. This gives us greater insight into the spatially heterogeneous structure of force transmission characteristic of amorphous granular solids. To our knowledge, photoelasticimetry has been used exclusively to measure contact force networks in aggregates of repulsive particles. We present photoelasticimetric force measurements of systems of particles which exhibit attractive interparticle forces, and contrast the structure of force networks in these systems with the networks in purely repulsive aggregates.
8:24AM R30.00003: Optical characterization of underwater contact mechanics  MENGYUE SUN (Presenter), SUKHMANJOT KAUR, Univ of Akron — For survival in extreme environments, organisms have evolved adhesive mechanisms and materials. While chemistry of underwater bio-adhesion is a source of valuable insight, the mechanics by which surfaces expel water and come in contact underlies critical understanding of natural solutions and evaluating biomimetic analogs. Hydrophobicity of an adhesive surface has been shown to be crucial in removing water from a hydrophilic substrate, but the resulting contact is typically heterogeneous, with patches of unevacuated water. Here, we present a simple, FTIR-based imaging technique to spatially resolve and quantify thickness of nanoscopic puddles formed between two solids in contact under water. The technique is validated by comparing measured air gap thickness of a glass lens in contact with glass prism with Hertzian contact theory, and then applied to characterize the drainage and formation of patches of water as a soft PDMS lens approaches a glass surface at varying speeds. The work paves the way for better characterization of interfaces in contact under water and can find application in adhesive development, biological study and tribology.

8:36AM R30.00004: Worms in Jell-O: Using photoelastic stress analysis to measure burrowing forces* [Invited]  KELLY DORGAN (Presenter), Dauphin Island Sea Lab — Muddy marine sediments are elastic materials through which worms and other animals extend burrows by fracture. Gelatin has similar fracture properties to muds, and worms burrow readily through this transparent analog. Polarized light shows that the water-filled burrow has an elongated, tongue-depressor-shaped crack. Photoelastic stress analysis was used to measure forces applied by worms burrowing in gelatin. These results, combined with modeling, show that stress intensity factors at the crack tip reach the fracture toughness, validating the method of burrow extension by fracture. Additionally, these measured forces and understanding of the mechanics of burrowing allowed for quantification of the energetic cost of burrowing, which is much lower than previously thought. Stress visualization in gelatin has also been used to test instruments to measure fracture toughness and stiffness of marine sediments. These properties govern burrowing behaviors and may be important metrics to quantify the ecosystem engineering impacts of animals living in sediments.

9:12AM R30.00005: Exploiting photoelasticity to characterize dynamics of polymer networks  CAROLINE SZCZEPANSKI (Presenter), Michigan State Univ, KELSEY-ANN NATASHA LESLIE, ROBERT DOANE-SOLOMON, SRI SHTI ARORA, MICHELLE R DRISCOLL, Northwestern University — The development of internal stresses within polymer networks is a major factor to consider when utilizing this class of soft materials, particularly when compared to their linear analogues. As an example, internal stresses that develop during network polymerizations often lead to macroscopic failures such as delamination or cracking when networks are constrained at one or multiple interfaces. To better understand and mitigate stress behavior, macroscopic mechanical characterization techniques (e.g. tensile testing, rheometry) have typically been employed. However, these methods provide little to no insight as to the dynamics of stress evolution on a local level, nor how internal stresses evolve in response to environmental changes. In this work, we exploit the photoelastic behavior of polymer networks to characterize internal stresses that develop during swelling and subsequent rupture of hydrogels. Compared to the majority of studies into mechanics of hydrogels, which typically characterize materials in one of two separate states (dry or swollen), this approach enables a non-invasive, real-time assessment of internal stress development during swelling. We discuss how this approach can better inform soft materials developed for dynamic environments.

9:24AM R30.00006: The local mechanics of macroscopic heterogeneous photoelastic polymer networks  JOHANNES N.M. BOOTS (Presenter), JORIK SCHAAP, JOSHUA DIJKSMAN, JASPER VAN DER GUCHT, THOMAS KODGER, Wageningen University — Stress localization and fracture within networks are common observations but predicting failure relies on a complex interplay between each connected component or beam. Simulations on model networks have shown intriguing connections between connectivity and stress. But do these results translate into physical experiments? To explore this, we produce macroscopic (~cm), heterogeneous (removing beams or varying beam thickness), 2D networks by using a 3D printed mold that is cast first with a silicone rubber, and then with a highly responsive photoelastic resin. Upon straining these networks to failure, each beam experiences a local stress resulting in a proportional photoelastic signal which is captured with a camera while measuring the bulk force with a capacitive load cell. This signal is compared to a previously measured force-intensity calibration curve from a single beam. Concomitantly, a second camera captures brightfield images, used to calculate the local strain. This local stress/stRAIN information in programmable heterogenous networks is used as input for spring network simulations. We will present the comparisons between simulations/experiments and explore the underlying mechanics of a polymer network in both the linear and non-linear regime just before network failure.
9:36AM R30.00007: Direct force measurement of microscopic droplets pulled along soft surfaces*  HAMZA KHATTAK (Presenter), KARI DALNOKI-VERESS, McMaster Univ — Recently, there has been growing interest in understanding the interactions of liquid droplets with soft materials. In these systems, forces exerted by a droplet can deform the material it contacts. This property leads to a plethora of unique physical phenomena with applications in fields ranging from water collection to surface sensing. We explore droplet dynamics on soft materials using a micropipette-based technique to simultaneously image, and measure the forces on, a microscopic droplet dragged along a soft interface. By changing the thickness of the soft material, we can control the compliance independent of surface chemistry. We show that material stiffness is a key parameter in droplet dynamics.

9:48AM R30.00008: Experimental Studies on Slow Impacts and Interaction with Regolith Covered Surfaces in Low Gravity* [Invited]  JONATHAN KOLLMER (Presenter), Experimental Astrophysics, Universität Duisburg-Essen — Splashes from slow impacts into granular materials play an important role in the sculpting of asteroid surfaces and for the structures formed in wind blown sands. This talk I will give an overview of some recent experiments that explore ejecta generation and material redistribution from slow impacts into a granular bed under realistic space conditions. Most prominently an experiment which shows that ejecta created by slow impacts will stay close to the impact site under conditions realistic for a small asteroid, which has implications for observed size sorting effects. However this experiment also found that ejecta will not always be created directly at the impact site. By using photoelastic materials it was possible to identify that subsurface buckling introduced by the impact is responsible for this effect. Also, using similar techniques, it is possible investiage the ejecta creation process when mechanically interacting with planetary surfaces, e.g. landing or sampling, with the goal to identify an interaction design that will minimize ejecta creation.

10:24AM R30.00009: Optical spatio-temporal control of active matter systems in 2-D.*
NESRIN SENBIL (Presenter), Brandeis Univ, LINNEA LEMMA, ZVONIMIR DOGIC, University of California Santa Barbara, SETH FRADEN, Brandeis Univ — Active matter systems consist of self-driven units which convert chemical energy into mechanical energy and organize themselves into various patterns. Their pattern and flow properties exhibit non-equilibrium properties. In our experiments, we investigate the pattern formation of microtubule, kinesin motor kinesin motor proteins in 2-D fluid/fluid interfaces. The kinesin motor proteins are engineered in a way that light induces reversible linkage between them. Thus, under the exposure to the light (blue light centered at wavelength 460nm) the end groups of kinesin motor proteins bind and create the sliding motion between the microtubule bundles. Due to topological constraints, bundles create + ½ (motile) and - ½ (non-motile) defects. Using various light patterns, we confine the sample both in space and time. Illuminated regions exhibit strong bundling where the flow patterns and speed of the + ½ defects depend on the power and the design of the light pattern. Our goal is to control the defect velocity and their direction to guide them towards a certain destination.

10:36AM R30.00010: Dynamical Inference of Forces Using Three-dimensional Tomographic Imaging of Dusty Plasmas* WENTAO YU (Presenter), GUGA GOGIA, JOSHUA MENDEZ, BRADY WU, JUSTIN BURTON, Physics, Emory University — Charged, micron-sized particles can be suspended in a in a low-pressure plasma through a balance of gravitational and electrostatic forces. Known as a dusty plasma, the particles are also subject to a screened, Coulomb repulsion, in addition to a number of kinetic and hydrodynamic drag forces from the ambient environment, leading to a rich array of nonequilibrium collective behavior. Using a new, high-speed, three-dimensional imaging technique based on laser-sheet tomography, we are able to track the dynamics of up to 50 individual particles over tens of seconds. In small systems with 2-3 particles, normal-mode decomposition provides a quantitative estimate of the equilibrium charge of the particles, the Debye length in the plasma, and the local electric field. For larger systems with many particles, the data also allows us compute the average pairwise forces between particles as a function of separation. The method is robust to noise in the data, and can be applied to other many-body systems with complex interactions.

Session R31 DSOFT: Membranes, Micelles, and Vesicles 503 - Joseph Zasadzinski, University of Minnesota
8:00AM R31.00001: A super-swelled lamellar lipid system*  JACOB RUEBEN (Presenter), DYLAN STEER, CECILIA LEAL, University of Illinois at Urbana-Champaign — Lipid bilayers are an integral structure found in myriad biological systems. Sometimes lipid bilayers stack to make a lamellar phase, in which bilayers are separated by water layers with thicknesses determined by intermolecular interactions such as undulation repulsion, attractive van der Waals forces, and in the case of charged lipids, double layer forces. Water layers in charged lipid systems have demonstrated swelling abilities up to 30 nm, but soft (low bending rigidity) bilayers usually lose periodicity approaching these values due to higher undulation force effects [1]. Here we report a simple lipid system of low-bending-rigidity lipid doped with small amounts of charged lipid that forms a previously undocumented super-swelled lamellar phase with layer spacings upwards of 80 nm at low dilution. These results differ from previous studies into similar systems, and defy currently held theories of maximum lamellar spacings for soft membranes. The formulated lipid systems were characterized with confocal fluorescence microscopy, cryogenic TEM, and ultra-small angle X-ray scattering.

8:12AM R31.00002: Characterization of phospholipid monolayer viscoelasticity using microbubble acoustic radiation force*  AWANEESH UPADHYAY (Presenter), University of Colorado, Boulder, OUTI SUPPONEN, Mechanical Engineering, McGill University, FRANCESCO GUIDI, Information Engineering, University of Florence, HENDRIK VOS, Biomedical Engineering Thorax Center, Erasmus MC Rotterdam, PERO TORTOLI, Information Engineering, University of Florence, MARK BORDEN, University of Colorado, Boulder — Lipid monolayers (LM) stabilize the gas/water interface of the lung, ear and eye, and serve as model membrane for understanding the properties of bilayer leaflets. However, the nature of viscoelasticity of gel-phase LM for dilatational deformations remains poorly characterized. Microbubbles offer a novel experimental platform to study LM viscoelasticity, and their behavior is directly relevant to medical ultrasonics applications. The acoustic radiation force acting on a microbubble (MB) is maximal at the resonance frequency, which depends on its size and the LM shell viscoelastic properties. Here, we demonstrate a method using multi-gate spectral Doppler with an open source ultrasound scanner to measure the acoustic radiation force displacements of individual resonant MBs as we scan a frequency range between 3 and 7 MHz. The LM shell viscoelastic properties are determined by fitting the measured displacements to a modified Rayleigh-Plesset equation with Sarkar shell terms. Our results show the effects of lipid composition and temperature. These results provide mechanistic insights into LM dilatational viscoelasticity and illustrate rational design principles to engineer MBs for ultrasound imaging and therapy.

*M.B. acknowledges the funding provided by NIH grant R01CA195051.
8:24AM R31.00003: Tuning the microstructure of phospholipid monolayers using substrate curvature*  JOSEPH BARAKAT (Presenter), TODD M SQUIRES, University of California, Santa Barbara — Two-dimensional monolayers and bilayers of phospholipids exhibit a heterogeneous microstructure, which is essential for fluidity, mechanical stability, and spatial localization of proteins, cholesterol, and signaling molecules. There is a growing body of evidence that lipid morphology is influenced by the curvature of the underlying template. Although this geometric dependence remains poorly understood, it becomes extremely relevant to the study of monolayers (e.g., in lung alveoli and microemulsions) and bilayers (in cells, organelles, and vesicles) with radii of curvature on the order of 10-100 microns. In this work, I will discuss how continuum-level theory can predict the effect of curvature on the phase behavior of lipid monolayers, using planar and spherical geometries as model templates. First, I will demonstrate that curvature decreases the expected radius of condensed domains due to the attenuation of dipolar repulsions. Second, I will show that curvature stabilizes circular domains (“droplets”) from elliptic distortions into elongated structures (“stripes”). The transition between these states is determined by the substrate curvature and condensed-phase area fraction, which parametrize the phase space of lipid morphologies on curved templates.

*NIH NHLBI R01-HL135065

8:36AM R31.00004: Molecular dynamics study on encapsulation of ibuprofen and indomethacin in Triton X-100 micelles  HRACHYA ISHKHANYAN (Presenter), Department of Physics, King's College London, DAVE BARLOW, Institute of Pharmaceutical Science, King's College London, CHRISTIAN D. LORENZ, Department of Physics, King's College London — Surfactants are widely used in biological applications including the extraction of proteins from cell membranes, the enhancement of the permeability of cell membranes\(^1\) and the encapsulation of poorly soluble drug molecules\(^2\). In this study, drug encapsulation capabilities of a non-ionic surfactant Triton X-100 were studied using molecular dynamics (MD) simulations. An all-atomic simulation has been performed in an aqueous solution of pre-assembled surfactants and drug molecules using the CHARMM force-field. The micelle becomes saturated with ibuprofen molecules after approximately around 50% of them are encapsulated within 50ns. Whereas the micelle does not get saturated with indomethacin until approximately 70% of the available molecules are encapsulated. Furthermore, the simulation shows that in the presence of drug molecules the semi-spherical micelle becomes increasingly rod-like in shape. More analysis shows that the volume as well as the surface area of the micelle expand significantly in the presence of indomethacin, and are fairly the same in the presence of ibuprofen.

8:48AM R31.00005: Faceted Shapes of Cooled Emulsion Droplets of CTAB and Hexadecane*
ABDULLAH HASHIM (Presenter), SUBAS DHAKAL, Department of Physics, Le Moyne College — Recent experiments [Denkov et al., Nature 528 (2015) 392] have shown that the emulsion droplets resulting from the spontaneous self-assembly of cetyltrimethylammonium bromide (CTAB) surfactants with alkanes of similar carbon chain length such as Hexadecane in water “self-shape” into regular polyhedral, platelets, and rods on cooling. To understand the mechanism of the faceting of those emulsion droplets, we performed the coarse-grained (CG) molecular dynamics simulation of aqueous solutions of CTAB and Hexadecane using the Martini force field in GROMACS. In 1 (CTAB): 1(Hexadecane) solutions, we find that the average droplet size scales as $c^{0.4}$ with the concentration of Hexadecane (C). A variety of polyhedral shapes of the emulsion droplets observed at low temperatures in simulations will be compared with those of the experiments. The mechanism for faceting of the droplets will be discussed.

9:00AM R31.00006: Pore Formation: How Cubic Lipid-siRNA Constructs Escape the Endosome*
LINING ZHENG (Presenter), CECILIA LEAL, University of Illinois at Urbana-Champaign — Small interfering RNA (siRNA) silences gene expression and has shown great potential in medical applications. However, intracellular delivery of siRNA remains a great challenge. Lipid nanoparticles have been one of the most successful siRNA carriers to date, but their delivery efficiency is limited due to low endosomal release. We have shown that cubic structured lipid nanoparticles (cubosomes) loaded with siRNA - cuboplexes, show greater siRNA knockdown compared to traditional lamellar structured liposomes. In this work, we aim to elucidate the reason behind this difference in delivery efficiency. We will show confocal microscopy (CF), flow cytometry and live cell imaging data demonstrating higher cellular uptake of cubosomes compared to liposomes. CF, fluorescent based fusion assays, cryogenic transmission electron microscopy and dynamic light scattering measurements indicate that compared to liposomes, cubosomes are more prone to fuse and form aggregates with endosomes, which implies a stronger pore forming capability that leads to siRNA escape. These results support our suggestion that cubosomes can lower the free energy required to promote endosome pore formation and establish a topologically active delivery mechanism.

*This work is supported by the NIH (1DP2EB024377-01).
Osmotic Shrinking of Vesicles Embedded in Hydrogels  NATASHA RIGBY (Presenter), MARGARITA STAYKOVA, Durham University — Lipid vesicles can be dispersed in various gel matrices as an encapsulation technology and as a model system for cells supported by an extracellular matrix.

By using confocal fluorescence microscopy on Giant Unilamellar Vesicles (GUVs) embedded in an agarose hydrogel matrix, we can observe changes in the liposome shape under hyperosmotic shocks.

Compared to free floating vesicles, gel-supported vesicles show irregular shapes during shrinkage. The results from our simple model system are reminiscent of plant cell plasmolysis.

We propose that the observed membrane shapes are caused by a non-specific adhesion between the membrane lipids and the agarose gel matrix. By varying the membrane-gel contact (chemical or physical), the strength of the gel and the osmotic shock, we want to explore the analogy between our system and biological systems, and use the effects to create functional hydrogels.

Mechanically mediated interactions between solid domains in composite vesicles*  HAO WU (Presenter), MARIA SANTORE, GREGORY GRASON, Univ of Mass - Amherst — We explore the structure and interactions of fluid/solid composite vesicles using continuum models compared with experimental studies of phase-separated two-component vesicles. In contrast to well-known fluid-fluid phase-separated domain structure, we show that shear rigidity of solid phospholipid domains coexisting with a fluid phase produces qualitatively new collective behaviors in composite vesicles. Beyond simply an enhanced bending stiffness, shear rigidity of the solid domains tends to expel Gaussian curvature into the fluid membrane phase, an effect which generically competes with the global spherical topology of the vesicle. We show that fluid membrane elasticity leads to bending-mediated interactions between solid domains, controlled by their size and the vesicle area-to-volume ratio. For sufficiently tensed vesicles we find that fluid phase bending induces a depletion-like attraction between solid domains of sufficiently large size, driven by tendency to consolidate elastic high-bending “hinges” that flank the solid domains at high pressure. This result suggests a qualitatively new picture of large solid domains as “2D colloids” dispersed in a fluid background, whose effective interactions are tunable through global vesicle properties.

*DOE BES, Award No. DE-SC0017870
Biomimetic Lung Surfactant Nanodrops for Acoustic Droplet Vaporization

ACLE N THOMAS, MARK BORDEN (Presenter), University of Colorado, Boulder — Acoustic droplet vaporization (ADV) involves the liquid-to-gas phase conversion of a superheated emulsion droplet by ultrasound to form an echogenic bubble. This technology may be useful for medical ultrasound, as nanodroplets small enough to leak through endothelial fenestrations may be converted to echogenic microbubbles for extravascular ultrasound imaging of inflamed and angiogenic vasculature. Additionally, droplets may be transformed to acoustically pulsating microbubbles to enhance ultrasound-guided drug delivery. However, surfactant coverage on the droplet often fails to stabilize the expanding interface during ADV, resulting in transitory microbubbles with limited utility. Here we show that interfacial melting and spreading by lung surfactant during surface dilation can be harnessed to increase the echogenicity and stability of post-ADV microbubbles. Lung surfactant, whose composition in the mammalian lung has been honed over millions of years of evolution, has thus proven to be a superior coating material for ADV droplets, and its biomimicry will be an important step toward clinical translation of ADV in ultrasound imaging and therapy.

Microsecond Coarse-Grained MD Simulations of Beta-Amyloid Fibrils Binding to Phase Separated Lipid Raft Domains Reveal Diverse Membrane-bounded Conformations and Binding Kinetics of Protein Depending on the Fibril size and Lipid Domain Structure

KWAN CHENG (Presenter), Physics, Trinity University, SARA CHENG, Physics, UT Austin, YIYI CAO, Physics, Trinity University, M ROUZBEHANI, Neuroscience, Trinity University, RONALD J DAVENPORT-DENDY, A URBY, S SPURLOCK, Physics, Trinity University — An early event associated with several protein aggregation diseases is the binding of amyloidogenic fibrils to cell membranes. At present, the binding conformation and kinetics of these fibrils on structurally heterogeneous and dynamic cholesterol-enriched raft domains remain elusive. We have constructed 4 coarse-grained (CG) beta-amyloid fibrils, ranging from dimer to pentamer, and 5 phase-separated CG lipid rafts, containing phospholipid and cholesterol or tail- or headgroup modified cholesterol. Using CG-MD simulations, the binding conformation, kinetics and interaction energetics of each fibril from solution to the rafts were studied. Within 20 μs, all fibrils bound to the raft surface and formed stable fibril/raft complexes at the liquid-ordered and -disordered phase boundary. The dimer fibrils bound to the raft exclusively via its hydrophobic C-terminal (C-state). Other than the C-state, the larger fibrils bound to the rafts via the hydrophilic N-terminal (N-state) and termini (T-state) with weaker binding energies. Interestingly, a transmembrane inserted state (I-state) of a trimer fibril was found for the raft containing tailgroup modified cholesterol. Our study indicates diverse conformations, kinetics and energetics of fibril/raft interactions in cells.

An implicit lipid model to simulate reaction-diffusion of proteins binding to membrane surface  

YIBEN FU (Presenter), Johns Hopkins University — Localization of proteins to a membrane surface is an essential step in a broad range of biological processes such as signaling, virion formation, and clathrin-mediated endocytosis. The strength and specificity of proteins binding to a membrane depend on the lipid composition. Single-particle reaction-diffusion method is a powerful tool for capturing lipid-specific binding to membrane by treating lipids explicitly as individual diffusable binding sites. However, modeling lipid particles is computationally expensive. Here we present an algorithm for reversible binding of proteins to continuum surfaces with implicit lipids, providing dramatic speed-ups to many body simulations. The kinetics show excellent agreement between our method and the full explicit lipid model. Crucially, we demonstrate our method’s application to membranes of arbitrary curvature and topology, modeled via a subdivision limit surface. We also utilize this method to describe experimental data of membrane binding and the feedback from the curvature generation. Our method will enable efficient cell-scale simulations involving proteins localizing to realistic membrane models, which is a critical step for predictive modeling and quantification of \textit{in vitro} and \textit{in vivo} dynamics.

Relationship among Phase Behavior, Micellar Structure and Thin Film Drainage in Aqueous Surfactant Solutions  

SHANG GAO (Presenter), Chemical and Biomolecular Engineering, University of California, Los Angeles, CHRSTIAN OCHOA, VIVEK SHARMA, Chemical Engineering, University of Illinois at Chicago, SAMANVAYA SRIVASTAVA, Chemical and Biomolecular Engineering, University of California, Los Angeles — Sodium naphthenates (NaNs) are petrochemical anionic surfactants that stabilize petroleum emulsions and foams and pose significant environmental challenges when released into water bodies. Relatively little is known about the phase behavior and self-assembly (including micelle formation) as well as thin film drainage kinetics of aqueous NaN self-assemblies, impeding the development of strategies for NaN sequestration and petroleum foams and emulsions destabilization.

In this presentation, we will discuss experimental methodologies to elucidate surfactant phase behavior and self-assembly microstructure through a combination of small-angle X-ray scattering and cryoelectron microscopy. First, we will explicate the influence of surfactant and salt concentrations on micellar micromorphology of aqueous solutions of sodium dodecyl sulfate (SDS), a model, well-researched system. These trends will be compared with nanoscopic topography of draining SDS foam films, highlighting the striking similarity between intermicellar separations in bulk solutions and stratification step sizes in thin films. Next, phase behavior and microstructure of aqueous NaN self assemblies will be discussed, again highlighting the role of intermicellar correlations in dictating drainage of thin liquid films.
Alkylbenzene sulfonates are one of the most important synthetic surfactant families, considering their wide applicability, cost-effectiveness, and overall consumption levels. Nevertheless, their low salt tolerance (especially divalent ion contents) prevented wider applications such as enhanced oil recovery in high salinity reservoirs. Here, using experiments and atomistic molecular dynamics simulations, we demonstrated that the high salinity colloidal stability of alkylbenzene sulfonates can be dramatically increased by mixing with zwitterionic co-surfactants in oil-swollen micelles. By mixing with co-surfactants we had two important observations: (1) The polydispersity of surfactant mixture oil-swollen micelles were largely decreased due to the less rigid oil/water interfaces with mixed surfactants, which formed fewer but larger uniform micelles. (2) Strong dehydration of sulfonates due to the shielding from protruding more extended zwitterionic co-surfactants at the oil/water interfaces. Both observed molecular assembly characteristics triggered by the co-surfactants effectively reduced the total exposure of sulfonates to the water phase which may form divalent ion bridging and large aggregates, thus increasing the high salinity colloidal stability.

Session R32 DPOLY DSOFT DCP DMP: Molecular and Polymer Glass Structure

8:00AM R32.00001: On the Allowable or Forbidden Nature of Vapor-Deposited Glasses*
MATHIEU BAUCHY (Presenter), University of California, Los Angeles — Vapor deposition can yield glasses that are more stable than those obtained by the traditional melt-quenching route. However, it remains unclear whether vapor-deposited glasses are "allowable" or "forbidden," that is, if they are equivalent to glasses formed by cooling extremely slowly a liquid or if they differ in nature from melt-quenched glasses. Here, based on reactive molecular dynamics simulation (MD) of silica glasses, we show that, under certain conditions, vapor-deposited glasses can indeed be more stable than melt-quenched glasses. Importantly, we demonstrate that the allowable or forbidden nature of vapor-deposited glasses depends on the temperature of the substrate and, in turn, is found to be encoded in their medium-range order structure.

8:12AM R32.00002: Stable polystyrene glass films through PVD and UV radiation  JUNJIE YIN (Presenter), ADAM RAEGEN, JAMES A FORREST, University of Waterloo — Stable glasses have proved to be an extraordinary type of material with enhanced density and exceptional kinetic stability compared to normal glasses. So far stable glasses prepared through physical vapor deposition (PVD) have been generally limited to organic small molecules such as indomethacin. We have recently employed PVD to make stable oligomeric glasses. In this study, we extend our capacity to make high molecular weight polystyrene stable glass by using oligomeric stable glass as a starting point. We do this by crosslinking the stable oligomeric glasses by dehydrogenation reaction under ultraviolet (UV) radiation. Depending on the degree of crosslinking, the resulting stable glass can have significantly higher molecular weight and kinetic stability. The sample molecular weight distribution is characterized by MALDI (matrix-assisted laser desorption/ionization), and the stable glass properties are characterized by ellipsometry.

8:24AM R32.00003: Physical vapor deposition of a polyamorphic system  BENJAMIN KASTING (Presenter), MADELEINE BEASLEY, MEGAN TRACY, MARK EDIGER, University of Wisconsin - Madison — In a few recently investigated systems, physical vapor deposition (PVD) has been shown to produce glasses that transform into liquids with properties that differ from the liquid produced by melting the crystal. Here we use PVD to investigate triphenyl phosphite (TPP), a known polyamorphic system where the second amorphous state (glacial phase) can be obtained by annealing the ordinary liquid (liquid 1) for hours slightly above its glass transition temperature (205 K). The properties of PVD glasses of TPP and the liquids formed from these glasses are studied by alternating current nanocalorimetry and interdigitated electrode dielectric spectroscopy. Deposition between 0.75 and 0.95 T_g results in glasses with very high kinetic stability. Independent of substrate temperature, the liquid that results from transforming the deposited glasses displays the properties of liquid 1, the ordinary liquid. Interestingly, films deposited above T_g also grow as liquid 1 even at temperatures previously used to transform liquid 1 into the glacial phase. The PVD mechanism allows the bulk of the film to inherit the structure at the free surface. These results suggest the preferred surface structure of TPP is similar to the structure of liquid 1, irrespective of deposition temperature.

8:36AM R32.00004: Physical properties of ultrastable computer-generated glasses  [Invited] LUDOVIC BERTHIER (Presenter), University of Montpellier — Computer simulations give unique insights into the microscopic behavior of amorphous materials. It became recently possible to generate ultrastable glass configurations using a simple Monte Carlo algorithm for a broad variety of model glass-formers. In this talk, we show that this discovery has allowed a deeper understanding of the rheological, thermodynamic and thermal properties of amorphous solids. We discuss in particular recent work regarding the brittle yielding of glassy materials, the Kauzmann transition, and low-temperature excitations of amorphous solids.
9:12AM R32.00005: Effects of internal degrees of freedom on simulated vapor deposited glass films
ALEX MOORE (Presenter), PATRICK WALSH, ZAHRA FAKHRAAI, ROBERT RIGGLEMAN, University of Pennsylvania — Recently, amorphous films of small molecules formed via physical vapor deposition (PVD) have been shown to exhibit remarkable thermodynamic and kinetic properties, equivalent to those that have been aged on the order of hundreds of years. Previous results suggest that the stability differences observed in these PVD glasses are the result of enhanced mobility near the free surface, such that molecules are allowed to sample a greater number of configurations before being trapped by subsequent deposited layers. However, much remains to be learned about the effects of properties like molecular shape and rotational freedom on the stability and morphology of these PVD amorphous packings. By using molecular dynamics simulations to mimic the PVD process of coarse-grained small molecules, we can make fine-tuned changes to these properties and then closely observe changes in films, both during and after the deposition process. Notably, we can then potentially make a connection between changes in internal degrees of freedom and the corresponding molecular entropy and changes in PVD film properties. Thus far, we suggest that molecules exhibiting greater entropy in their supercooled liquid state create more stable PVD glass films.

9:24AM R32.00006: Anisotropy of extremely monodisperse polymer stable glass thin films
ADAM RAEGEN (Presenter), JUNJIE YIN, QI ZHOU, JAMES A FORREST, Physics and Astronomy, University of Waterloo — In the twelve years since their introduction, ultrastable molecular glasses have become a topic of great interest. Thin films prepared by vapour deposition at substrate temperatures slightly below T_g can exhibit increased densities and stabilities similar to those expected for isotropic glassy films aged hundreds or thousands of years. However, these ultrastable glasses may not truly present the same state as aged glasses. In many ultrastable glasses, the samples display anisotropy, unless steps are taken to make films only in a narrow range of production parameters such as substrate temperature and deposition rate. Simulations have suggested (Lin et. al. J. Chem. Phys. 140, 204504 (2014)) that evaporated oligomeric samples may provide a way to avoid this anisotropy and produce truly isotropic stable glass. In this case, the length of oligomeric samples can greatly influence anisotropy. Using our recently demonstrated technique for making polymer stable glasses, we present an experimental study of extremely monodisperse, ultrastable polymeric/oligomeric thin films. We use spectroscopic ellipsometry to measure birefringence caused by anisotropy in such samples as a function of the stability (fictive temperature) and the oligomeric size.
9:36AM R32.00007: Stability dependence of local elastic inhomogeneities of amorphous solids*  ALIREZA SHAKERPOOR (Presenter), ELIJAH FLENNER, GRZEGORZ SZAMEL, Colorado State University — There is a rich history of studies that suggest the vibrational and thermal anomalies in amorphous solids are linked to the local fluctuations in the elastic matrix of the amorphous medium. More recently numerical and experimental studies have shown a correlation between the vibrational properties and the stability of the medium. In this work, we studied the interplay between the stability and the fluctuations in the local elastic constants for a wide range of stabilities. We found that the variance of the local elastic constants becomes smaller with increasing stability. We also investigated the spatial correlations of the local elastic constants and determined that these constants have only very short range correlations.

NSF CHE-1800282

9:48AM R32.00008: Strong elasticity anisotropy in molecular glasses*  ZUYUAN WANG (Presenter), YU CANG, GEORGE FYTAS, Max Planck Institute for Polymer Research, CAMILLE BISHOP, MARK EDIGER, Department of Chemistry, University of Wisconsin-Madison — Although glass is often considered isotropic, anisotropic glasses can be prepared by physical vapor deposition of rod-shaped organic molecules. Those glasses feature tunable molecular orientations and anisotropic properties that are beneficial for applications such as organic semiconductors. While the deposition-condition-dependent molecular orientation and the associated optical birefringence of molecular glasses have been investigated, little is known about their mechanical anisotropy, which, however, is needed for understanding their strength upon mechanical loading in packaging and application. In this work, we use micro-Brillouin light spectroscopy to determine the elastic stiffness tensors of three glass films of itraconazole vapor-deposited at substrate temperatures \((T_{\text{sub}})\) of 330, 315, and 290 K, respectively. The five independent elastic constants in each tensor demonstrate the strong influence of the molecular orientation on the elastic anisotropy. The in- and out-of-plane Young’s moduli of the high \(T_{\text{sub}}\) sample, which features a vertical molecular orientation, exhibit a record high anisotropy ratio of 2.1 among molecular systems.

*ERC AdG SmartPhon (#694977), University of Wisconsin MRSEC.
10:00AM R32.00009: High Stability of Ultrathin Vapor Deposited Molecular Glasses  *  YI JIN (Presenter), YUE ZHANG, SARAH WOLF, AIXI ZHANG, SHIVAJEE GOVIND, CONNOR N WOODS, SUBARNA SAMANTA, Department of Chemistry, University of Pennsylvania, MIKHAIL ZHERNENKOV, GUILLAUME FREYCHET, National Synchrotron Light Source II, Brookhaven National Laboratory, ZAHRA FAKHRAAI, Department of Chemistry, University of Pennsylvania — Previous studies demonstrate that a mobility gradient exists within organic glass films, where molecules at or close to the free surface are more mobile than those in the bulk. The stability of glasses formed via vapor deposition relies on the equilibration of as-deposited molecules at the surface. An ultrathin stable glass (SG) film (~50 nm) has a higher proportion of molecules affected by the free surface dynamics, therefore likely has enhanced stability compared to a bulk SG (>200 nm). Here, we show that ultrathin SG films of TPD (N,N'-diphenyl-N,N'-bis(3-methylphenyl)-1,1'-biphenyl-4,4'-diamine) have higher stability, indicated by a higher density increase and a lower fictive temperature than bulk SG films of TPD. Surprisingly, at optimal deposition conditions, density increases higher than the limiting super-cooled liquid states are achieved. Anisotropy indicated by synchrotron scattering measurements suggest a possibility that there exists an amorphous as-deposited state of the molecule, volumetrically denser than its supercooled liquid counterpart, that is more isotropic than bulk SG. The potential origins of this phenomenon will be discussed in this presentation.

NSF-MRSEC DMR-1720530

10:12AM R32.00010: Over what length-scale can the substrate perturb the structure of a vapor-deposited organic glass?  *  KUSHAL BAGCHI (Presenter), University of Wisconsin - Madison, CHUTING DENG, University of Chicago, CAMILLE BISHOP, YUHUI LI, University of Wisconsin - Madison, NICHOLAS JACKSON, University of Chicago, MICHAEL TONEY, SLAC National Accelerator Laboratory, LIAN YU, University of Wisconsin - Madison, JUAN DE PABLO, University of Chicago, MARK EDIGER, University of Wisconsin - Madison — Ultrathin (<30 nm) vapor-deposited layers are often utilized in OLED (organic light emitting diodes) devices. However, the vast majority of structural studies of vapor-deposited glasses have focused on films that are 100 nm or thicker. As a result these studies have not been sensitive to glass structure at the buried interface, which is of significance for OLED performance. Here we study, with grazing incidence x-ray scattering, the structure of vapor-deposited glasses of molecular glass former DSA-Ph as a function of film thickness. We span a thickness range of 10-600 nm. For films deposited on a Si/SiO₂ substrate at ~ 0.8 Tg, we estimate that the region near the buried interface with qualitatively different packing is less than 4 nm. A coarse-grained Lennard-Jones model of DSA-Ph qualitatively reproduces the short interfacial length-scale observed experimentally, implying our results are broadly applicable to molecular glasses that form continuous films on deposition.

Molecular Orientation Depth Profiles from Resonant Soft X-ray Reflectivity

JACOB THELEN (Presenter) National Institute of Standards and Technology, KUSHAL BAGCHI, CAMILLE BISHOP, Chemistry, University of Wisconsin - Madison, SUBHRANGSU MUKHERJEE, ELIOT H GANN, R. JOSEPH KLINE, National Institute of Standards and Technology, MARK EDIGER, Chemistry, University of Wisconsin - Madison, DEAN DELONGCHAMP, National Institute of Standards and Technology — Orientation within amorphous molecular glass films can impart unique optoelectronic properties that provide enhanced performance in devices such as organic light emitting diodes (OLEDs). Bulk molecular orientation in vapor-deposited glass films can be tuned through processing conditions; however, little is known about the molecular orientation at the film surface or at the buried interface(s), where anisotropic optoelectronic properties can have a large impact on device performance. We use vapor-deposited films of tris(4-carbazoyl-9-ylphenyl)amine (TCTA) as a model system to develop soft X-ray techniques to extract molecular orientation from organic thin films. Variable incident-angle near edge X-ray absorption fine structure (NEXAFS) spectroscopy is used to probe the average molecular orientation within the top few nanometers of the TCTA films, as well as to determine the energy-dependence of orientation sensitivity for TCTA. Informed by the NEXAFS spectra, polarized resonant soft X-ray reflectivity (pRSoXR) measurements are performed at selected X-ray energies to probe molecular orientation through the depth of the film. Using the combined NEXAFS and pRSoXR data, we demonstrate a methodology to extract molecular orientation depth profiles with (sub)nanometer-level resolution.

Molecular dynamics simulation for investigation of Boson peak in a polymer system

AKIRA KOYAMA (Presenter), Department of General Education, National Institute of Technology, Toyota College, KOJI FUKAO, Department of Physical Sciences, Ritsumeikan University, TAKASHI YAMAMOTO, Graduate School of Science and Engineering, Yamaguchi University — We performed a molecular dynamics simulation to investigate Boson peak (BP) in a united atom polyethylene system. We computed vibrational density of states (DOS), dynamic structure factor (DSF) and wave-vector-dependent dynamic susceptibility (WDS) in a wide range of the angular frequency $\omega$ and the wave vector $q$. The BP was successfully observed in the profiles of DOS and DSF at the temperatures near and below the glass transition point. We determined the peak position of the BP ($\omega_{BP}/2\pi=0.25$ THz) from the fitting results of DOS; the peak position does not change with changing temperature. The BP was also recognized as an isolated peak on the 3D graph of DSF; the peak position along the $q$ axis ($q_{BP}$) on the line of $\omega=\omega_{BP}$ shifts toward high $q$ with decreasing temperature $T$, where $q_{BP} \sim T^{-0.5}$.

Using a simple harmonic oscillation model, we estimated the number of monomers $n_{BP}$ giving rise to the BP; $n_{BP}=3.2$. In the 3D graph of the real part of WDS, 2 distinct steps intersect on the line of $\omega=\omega_{BP}$; and in that of the imaginary part, a ridge laying diagonally from high $q$ and $\omega$ region to low $q$ and $\omega$ region terminates on the same line. From these results, we conclude that the BP in this simulation originates from the localized oscillation of the monomer groups consisting of 3.2 monomers.
10:48AM R32.00013: The effect of molecular architecture on the physical properties of supercooled liquids studied by MD simulations. Density scaling and its relation to the equation of state

KAJETAN KOPERWAS (Presenter), GRZYBOWSKI ANDRZEJ, MARIAN PALUCH, Institute of Physics, University of Silesia in Katowice — Theoretical concepts in condensed matter physics are typically verified and also developed by exploiting computer simulations mostly in simple models. However, the simplicity of the simple-liquids makes that predictions based on the mentioned model systems are often at odds with measurement results obtained for real materials. One of the examples is an intriguing problem within the density scaling idea (which has attracted attention in recent decades due to its hallmarks of universality), i.e., the fact that difference between density scaling exponent and exponent of the equation of state is observed for real materials, whereas it has not been reported for the model system. Given this problem into account, we project new model systems, which in contrast to the simple-liquids exhibit structural anisotropy, and we examine the effect of molecular anisotropy on the dynamic and thermodynamic properties of the material. We identify the applicable range of intermolecular interactions for a given physical process, and then we explain the reason for observed differences between the behavior of the model and real systems [J.Chem.Phys.150,014501(2019)].

Session R33 DPOLY DSOFT DBIO: Chirality in Polymers and Soft Matter: From Molecular to Hierarchical Scales

505 - Gerd Schroeder-Turk, Murdoch Univ - Tag(s): Focus
Spontaneous Appearance of Chiral Structures from Lyotropic Liquid Crystals in Confinement

MOHAN SRINIVASARAO (Presenter), Georgia Inst of Tech, KARTHIK NAYANI, Chemical and Biomolecular Engineering, Cornell University, RUI CHANG, Georgia Inst of Tech, JINXIN FU, Materials Science and Engineering, Georgia Institute of Technology, JUNG O PARK, Georgia Inst of Tech — Optical activity, a consequence of reflection-symmetry breaking, since the time of its discovery by Biot in the early 1800s, has captivated the imagination of scientists. Since Pasteur's time, the appearance of macroscopic chirality during crystallization from both chiral and achiral molecules has frequently been observed. Crystallization apart, optical activity resulting from achiral units has been observed in liquid crystals, and polymeric materials, without a molecular chiral center.

In this talk, I intend to discuss the appearance of chiral structures from a class of liquid crystals, the so-called lyotropic liquid crystals. In particular, in recent years there has been significant research conducted on a class materials known as Lyotropic Chromonic Liquid Crystals (LCLCs). LCLCs consist of many dyes, drugs, nucleic acids, antibiotics, carcinogens and anti-cancer agents. I will explore the spontaneous emergence of chiral structures from achiral lyotropic chromonic liquid crystals as well as polymeric lyotropic systems, when confined to cylindrical capillaries with various boundary conditions, as well as in capillaries with rectangular and square cross-sections.

Threading the Spindle: A Geometric Study of Chiral Liquid Crystal Polymer Microparticles

HELEN ANSELL (Presenter), DAE SEOK KIM, RANDALL D KAMIEN, ELENI KATIFORI, University of Pennsylvania, TERESA LOPEZ-LEON, ESPCI Paris — Polymeric particles are strong candidates for designing artificial materials capable of emulating the complex twisting-based functionality observed in biological systems. In this study we investigate the swelling behavior of chiral twisted spindle-shaped polymer microparticles, which are formed due to the anisotropic contraction of spherical bipolar polymer liquid crystalline microparticles during deswelling. We observe a relationship between the aspect ratio of the spindle shape and the corresponding twist angle of the polymer at the surface. We find that there are two regions in the deswelling process: shrinking without twisting followed by shrinking due to twisting. We propose a geometric model to interpret these two behaviors as well as describing the observed spiral patterns on the surface.

8:48AM R33.00003: Chiral nematic liquid crystals in cylinders: Layering transition and conservation of layer structure* JONGHEE EUN, SUNG-JO KIM, JOONWOO JEONG (Presenter), Physics, Ulsan Natl Inst of Sci & Tech — Chiral nematic lyotropic chromonic liquid crystals (LCLCs) confined in a cylindrical cavity exhibit layering transition and intriguing topological defects. With a planar degenerate anchoring at the cavity wall, the chiral LCLCs have the double-twist (DT) director configuration. To our interest, as we increase the chiral dopant concentration, the degree of twist in the DT configuration increases discontinuously. This "step-like" layering transition occurs because there exist local minima in the elastic free energy landscape; depending on the dopant concentration, one of the minima becomes the ground state. Consequently, meta-stable domains with different twist angles can coexist with dislocation-like defects between them. Lastly, we learn that the meta-stable domains are topologically protected because of the layer number conservation.

9:00AM R33.00004: Truth about the origin of twist - a circular argument* ELISABETTA MATSUMOTO (Presenter), Georgia Inst of Tech, ALIREZA DASTAN, DOUG J CLEAVER, Materials and Engineering Research Institute, Sheffield Hallam University — We examine emergent twist by applying both simulation and molecular theory to chromonic amphiphiles. Specifically, we study intrinsically achiral particles: amphiphilic discotics in a solvent of spheres. While these systems exhibit a veritable zoo of hierarchical, chiral self-assembled structures, we restrict ourselves here to a set of parameterizations that lead to twisted bilayer structures. Here, we return to the elephant in the room – what causes and controls the supramolecular twist that develops in these systems? In considering this, we demonstrate that, while chirality is manifested at several levels in the twisted bilayers formed by amphiphilic chromonics, it originates from spontaneously-chiral preferred packing at a molecular level.

While this structural chirality sets the underlying template for the twist, stresses from the growth dynamics yield topological defects. There is surprisingly little sensitivity to molecular-level properties (unless they render the bilayer unstable with respect to an alternative aggregate). Thus, the emergence of a supramolecular pitch in these systems is demonstrated to be a many-body but molecular-scale process, founded on the stabilization of a packing-optimising chiral complex.

9:12AM R33.00005: Thermoresponsive Colloidal Chains Collapse to Form Helices*  BIPUL BISWAS, KP FAYIS, SURESH BHAT, Polym Sci Engg, Natl Chem Lab, GURUSWAMY KUMARASWAMY (Presenter), Indian Inst of Tech-Bombay — Colloids linked to form linear chains represent model systems for polymers. Chains are prepared using fluorescent micron sized colloidal polystyrene beads that are coated with 100 nm thermoresponsive PNIPAM microgels. Microgel-coated PS beads are lined up in an AC electric field and are crosslinked through amine groups in the microgels, to form thermoresponsive colloidal chains. Here, we demonstrate that these chains exhibit thermally-induced reversible transitions. Interestingly, we show that chains characterized by intermediate flexibility spontaneously organize into helices on heating. In contrast, stiffer chains exhibit a modest decrease in size, without a qualitative change in shape. More flexible chains exhibit a dramatic decrease in size but do not form an ordered helical structure. Thus, in chains where there is no directional specificity to the interactions between monomeric beads, we obtain helical structures when chains with intermediate flexibility collapse. Our work suggests that a purely mechanical instability for semiflexible filaments can drive helix formation, without the need to invoke any directional interactions.

*DST (Chemical Engineering)

9:24AM R33.00006: Skyrmion formation and organization on a shell*  VIVIANA PALACIO-BETANCUR (Presenter), University of Chicago, GUILLAUME DUREY, Laboratoire Gulliver, ESPCI Paris, ALEXANDER COHEN, University of Chicago, MONIROSADAT SADATI, Chemical Engineering, University of South Carolina, TERESA LÓPEZ LEÓN, Laboratoire Gulliver, ESPCI Paris, JUAN P. HERNANDEZ-ORTIZ, Departamento de Materiales y Minerales, Universidad Nacional de Colombia, Sede Medellin, JUAN DE PABLO, University of Chicago — Blue phases (BPs) arise spontaneously in chiral liquid crystals (ChLCs) as the result of minimizing the global free energy, by forming networks of defects with specific cubic symmetry. Confining cuboidal phases to a channel smaller than the molecular pitch results in frustrating the full development of a BP cell, creating skyrmions that pack with hexagonal order. Beyond confinement in a channel, here, we consider the effect of curvature by confining a ChLC in spherical shells. The equilibrium configurations are obtained following a theoretically-informed Monte Carlo relaxation and a Ginzburg-Landau relaxation of the free energy functional, described within the Landau-de Gennes formalism, and solved numerically through finite element discretization. By considering homeotropic and planar anchoring, we stabilize half and full skyrmions. When stabilized in a shell, the hexagonal packing becomes imperfect, to accommodate for the closed surface, resulting in the creation of 5-7 pairs of skyrmions on the surface of the shell. The control over the formation and packing of the skyrmions offers opportunities for pattern design and engineering 2D ordered nanoparticle assemblies.

9:36AM R33.00007: Peculiar Phase Morphologies from Twisting of Self-Assembled Ribbons in Chiral Block Copolymers KAI-CHIEH YANG (Presenter), RONG-MING HO, Natl Tsing Hua Univ — The chirality effects on BCP self-assembly gives rise to the formation of helical phase (H*) from the self-assembly of polylactide-based chiral block copolymers (BCPs*) with achiral segment-rich fraction. The formation of the helical cylinder is attributed to the packing of helical chains with which twisted cylinder microdomain can be formed from twisting and shifting. By contrast, twisted ribbon with a bilayer-like lamellar texture can be formed in self-assembled polylactide-based BCPs* with chiral segment-rich fraction from twisting and bending. Those twisted ribbons can be further developed to give peculiar phase morphologies in bulk through scrolling, giving a roll cake and concentric lamellar textures. We speculate that those helical and twisted textures are built from the chiral interface of chiral and achiral segments as proposed by the tilted chiral lipid bilayer (TCLB) theory and also the mesochiral assembly of the helical chains predicted by the orientational self-consistent field theory (oSCFT). With the homochiral evolution from helical conformation to hierarchical superstructure via inter-chain chiral interactions, it is appealing to control the handedness of the forming morphologies from BCPs*.

9:48AM R33.00008: Folding of chiral colloidal membranes* [Invited] PRERNA SHARMA (Presenter), LACHIT SAIKIA, AYANTIKA KHANRA, Indian Institute of Science - Dept of Physics, ZVONIMIR DOGIC, Physics, University of California Santa Barbara — Rod-like viruses self-assemble into one rod-length thick liquid-like monolayers in presence of depletion attraction induced by non-adsorbing polymers. The global constraint of 2-D geometry of these colloidal membranes is incompatible with local chiral interactions of the rods. Consequently, competition between these opposing tendencies leads to a variety of polymorphic transitions. We illustrate this through phenomena that cause flat colloidal membranes to transform into 3-D structures. Crystallization of colloidal membranes proceeds through the usual nucleation and growth pathway. However, the growing crystalline domains spontaneously wrinkle to satisfy local chiral interactions and on completion of the growth lead to macroscopic buckling of the membrane. In contrast, fluid colloidal membranes can be folded by simply doping them with shorter rods of same chirality. These uniformly mixed bi-disperse membranes become unstable and deform into saddle shapes. The origin of this instability lies in enhancement of Gaussian modulus of the monolayer membranes due to doping. At high doping ratio, membranes fold into higher order structures of increasing complexity. These include unduloids, tri-unduloids, unduloid-enneper surfaces as well as system spanning plumber's nightmare-like phases. Taken together, these results show how chirality may have similar implications for conventional lipid bilayers which are rich in chiral molecules like cholesterol.

*This work is supported by DST-SERB.
Self-assembly of chiral networks in achiral block copolymer systems using coarse-grained simulations*  

NATALIE BUCHANAN, KRYSLA BROWKA, LIANNA KETCHAM, HILLARY LE, POORNIMA PADMANABHAN (Presenter), Rochester Institute of Technology — Ordered network materials, such as the double gyroid, are comprised of two interwoven networks embedded in a matrix and can be formed via the self-assembly of block copolymers. By selecting the interaction parameters that promote elongated conformations, an alternating gyroid morphology can be formed, thereby breaking network symmetry and resulting in a structurally chiral morphology. In this talk, we investigate the self-assembly of model achiral block copolymers into alternating gyroid morphologies using coarse-grained molecular simulation. We show that effective chirality can further be tuned by co-assembling with a suitable species to grow one network and shrink the other. Insights into stability are obtained by measuring polymer end-to-end distances and network topology.

Amino Acids as RNA-Folding Chaperones: Single Molecule Experiments Reveal Chiral Sensitivity  

DAVID NICHOLSON (Presenter), DAVID JOHN NESBITT, University of Colorado, Boulder — Early RNA-based life may have relied on amino acids to promote correct folding in RNA molecules, i.e. to act as RNA-folding chaperones. Chiral specificity in this interaction could have driven evolutionary mechanisms to favor a single chirality of amino acid, which may explain the origin of amino acid homochirality. To probe how chirality determines an amino acid’s influence on RNA folding dynamics, we have performed single molecule spectroscopy on a ubiquitous RNA tertiary motif, the tetraloop-tetraloop receptor (TL-TLR). Our kinetic measurements show that TL-TLR folding is sensitive to many amino acids, but only one amino acid, arginine, is observed to have a chirally-specific effect. The kinetic and thermodynamic features of this chiral interaction are presented, and with the help of all-atom molecular dynamics simulations, we propose a mechanistic interpretation of these results based on nonspecific arginine-RNA interactions.
The interplay between polymer–solvent interaction and interactions that impose secondary structures determines polymer chain conformation in dilute solution. Polypeptoids–poly(N-substituted glycines) can form helical secondary structures primarily driven by steric interactions from chiral, bulky side chains, while a racemic mixture of the same side chains results in unstructured coil chains. Small-angle neutron scattering (SANS) reveals that the helical polypeptoids are locally stiffer but overall flexible. However, the radii of gyration ($R_g$) of both helical and coil polypeptoids do not increase with improved solvent quality ($A_2$), and the chain expansion deviates from the universal swelling of polymer chains in dilute solution. Potential effects from solvents disrupting the steric interactions of chiral side chains are excluded by comparing to another chemically analogous coil polypeptoid devoid of side chain chirality. The results indicate that chain conformation change of these polypeptoids cannot be simply captured by excluded volume interactions, nor the steric interactions imposing the helical secondary structure. It is likely that the specific interactions between polypeptoid segments dominate the chain shape as opposed to polypeptoid–solvent interactions.

Session R34 DPOLY DSOFT: Processing-Dependent Nanoscale Structures in Polymers and Predictive Methods 506 - Michael Hore, Case Western Reserve University - Tag(s): Focus
8:00AM R34.00001: Solvent-Non-Solvent Rapid Injection for the Preparation of Hierarchically Ordered Hydrogels  ROBERT HICKEY (Presenter), Pennsylvania State University — Non-solvent-induced phase separation is a non-equilibrium method used heavily in industry for fabricating separation membranes. The resulting microstructure forms when a homopolymer initially in a good solvent is immersed into a poor solvent, inducing polymer phase separation and forming a microporous membrane consisting of polymer-rich and non-solvent-rich regions. We recently showed that non-solvent-induced phase separation methods will produce hierarchically ordered physically crosslinked hydrogels when amphiphilic triblock copolymers are used instead of homopolymers. In our system, when triblock copolymers comprising of a hydrophobic-hydrophilic-hydrophobic chain sequence initially in a common solvent will rapidly self-assemble at the nano and microscale when injected into water. We have developed a universal and quantitative method for producing physically crosslinked hydrogels exhibiting tunable mechanical properties superior to typical physically crosslinked triblock copolymer hydrogels, and interesting structural color properties. At a fundamental level, the rapid injection process described here encompasses two self-assembly processes (microphase and macrophase separation), further increasing the tunable parameters for controlling material structure and property.

8:12AM R34.00002: WITHDRAWN ABSTRACT  —

8:24AM R34.00003: Understanding and controlling metal oxide growth within block copolymers  NETA SHOMRAT, INBAL WEISBORD (Presenter), ROTEM AZOULAY, BARUN BARICK, ASSAF SIMON, TAMAR SEGAL-PERETZ, Technion - Israel Institute of Technology — In recent years, sequential infiltration synthesis (SIS) has emerged as a novel technique for growth of inorganic materials within block copolymers (BCP) and templating inorganic nanostructures from BCP due to SIS high growth rate and selectivity within polar BCP domains. However, to utilize SIS in a variety of BCP and in multiple length scales, there is high need for a full description of SIS mechanism.

Here we investigate the principles that govern SIS growth in homopolymers and block copolymers using cominnation of in situ growth characterization, 3D TEM tomography, and quantum mechanical calculations. We probe the diffusion and growth within the polymers and show its relationship to the polymer chemistry, precursor chemistry, and SIS process parameters. From this data, SIS model was constructed that enabled us to fabricate new BCP-templated nanostructures, including porous particles, heterostructure nanorod array and multi-layer membranes.
Process-directed self-assembly: Do we understand the collective short-time dynamics in multicomponent polymer melts?

MARCUS MUELLER (Presenter), University of Gottingen — Process-directed self-assembly refers to processes that reproducibly trap the kinetics of structure formation that ensues after a sudden change (“quench”) of the thermodynamic state into a desired, (meta)stable target state. This strategy benefits from specific advantages of copolymer systems, such as the rather comprehensive knowledge of equilibrium properties and the timescale separation between the quench of thermodynamic state variables, the spontaneous relaxation of the system towards the “nearest” metastable state, and the thermally activated escape from the metastable target state. Typically the relaxation from the unstable state occurs on a time scale that is comparable to the single-chain relaxation time. This short-time kinetics of structure evolution templates the morphology at later stages but poses challenges for a theoretical description. Examining simple, prototypical examples, we highlight the role of internal modes and indicate how dynamic SCFT can be generalized to include the consequences of the subdiffusive single-chain dynamics for the collective kinetics on times comparable to the Rouse-relaxation time.

Financial support has been provided by the Deutsche Forschungsgemeinschaft (DFG) und grant Mu1674/16.

Nonsolvent Induced Phase Separation in Polymer Droplets

DOUGLAS TREE (Presenter), RAMI ALHASAN, DAKOTA BANKS, TANNER WILCOXSON, Brigham Young Univ - Provo — Nonsolvent induced phase separation (NIPS) occurs when a polymer solution is brought into contact with a miscible nonsolvent, leading to the precipitation of a polymer-rich phase. Because of its simplicity, NIPS processes are widely used to generate a variety of microstructures in polymer materials such as membranes and micro/nanoparticles. Despite its prevalence, predicting and controlling the microstructure generated by NIPS remains a difficult challenge, owing to the complex interactions between the diffusive transport, hydrodynamics and phase-separation kinetics in the process. In our approach, we use simulations of a phase-field model of a polymer solution to examine the effect of mass transfer, hydrodynamics and geometry on the formation of microstructure. In particular, we study the NIPS process in polymer droplets, where we examine the effect of droplet size, shape, and composition on the resulting microstructure. We also examine the impact of finite solvent/nonsolvent miscibility on the kinetics and microstructure of the phase separation.

*We acknowledge funding from the Board of Trustees at Brigham Young University as well as computational resources from the Brigham Young University Office of Research Computing.
9:00AM R34.00006: Arrested mobility and thermal fluctuation effects on the mass transfer induced phase separation of ternary polymer solutions*  JAN ULRIC GARCIA (Presenter), University of California, Santa Barbara, DOUGLAS TREE, Brigham Young University, TATSUHIRO IWAMA, Asahi Kasei Corporation, KRIS T DELANEY, GLENN H FREDRICKSON, University of California, Santa Barbara — Many polymer membranes are made by immersion of a polymer solution film in a nonsolvent bath: the mass transfer exchange between the nonsolvent from the bath and the solvent in the film induces phase separation of the film into a polymer-rich phase that becomes the membrane matrix and a polymer-poor phase that becomes the membrane pores. Microstructure formation of these membranes is still not fully understood due to the nature of the physical processes involved: the mass transfer induced phase separation, the coarsening of domains, and the vitrification of the polymer-rich phase that arrests membrane microstructure. In this work, we use phase-field models of the ternary polymer-nonsolvent-solvent system to solve the coupled convection-diffusion and momentum equations that describe membrane formation. We model the glass transition using contrasts in the viscosity and mobility of the polymer-rich and polymer-poor phases. We report how glassy dynamics, and the inclusion of thermal fluctuations, contribute to microstructure formation.

*We acknowledge support from the Center for Scientific Computing from the CNSI, MRL: an NSF MRSEC (DMR-1720256) and NSF CNS-1725797. We also thank Asahi Kasei Corp for support.

9:12AM R34.00007: Precision polymer nanoparticles* [Invited]  RACHEL O’REILLY (Presenter), Chemistry, University of Birmingham — Polymerization-induced self-assembly (PISA) is a versatile method to prepare nanoparticles of various morphology. Traditionally, nanoparticles are prepared via self-assembly of pre-formed polymers in H2O. Rigorous optimization is often required in these systems, involving iterative cycles of polymer synthesis, self-assembly, and evaluation of the self-assembled morphologies. PISA offers an elegant solution to the tedious procedures of conventional self-assembly by forming the particles in situ as the polymerization progresses. PISA involves chain-extension of a hydrophilic macroinitiator (or macro-chain-transfer agent) with monomers that are miscible with water, but form a hydrophobic, immiscible polymer, driving self-assembly. PISA can be conducted at high solids contents under a wide variety of reaction conditions (i.e., low or high temperature, variable solvent mixtures, or in the presence of drugs or biomacromolecules). However, monomers which can be utilized in PISA are often difficult to identify from their chemical structures alone, and experiments are often necessary to determine their usefulness in PISA. We have been developing synthetic methods and developing predictive tools to expand the scope of PISA and also show its application in the design of functional materials.

*ERC (grant number 615142) is thanked for funding.
**9:48AM R34.00008: Molecular Modeling of Poly(methylmethacrylate-block-acrylonitrile) as Precursors of Porous Carbon Fibers**

XI RYAN HAO (Presenter), JOEL M. SERRANO, TIANYU LIU, ASSAD ULLAH KHAN, BRANDON BOTSET, BENJAMIN J. STOVALL, ZHEN XU, DONG GUO, KE CAO, GUOLIANG LIU, SHENGFENG CHENG, Virginia Tech — Porous carbon fibers (PCFs) based on block copolymers exhibit well-controlled hierarchical porous structures and high specific interfacial areas, which lead to excellent electrochemical properties. Understanding the conformation and morphology of polymer precursors before conversion is crucial for designing and optimizing PCFs. To expedite materials discovery, we perform molecular dynamic simulations for a series of poly(methylmethacrylate-block-acrylonitrile) (PMMA-b-PAN) with various block molecular weights and develop a model to characterize the morphology and compute the interfacial area of PMMA-b-PAN melts. We build both laminar and disordered phase of PMMA-b-PAN melts with an atomistic model of the polymer. For the disordered melts, our results show that the interfacial area is maximized when the volume fraction of either block is close to 50%, consistent with experimental results. The stability of the laminar phase is probed by performing thermal annealing on the systems and the conversion to a disordered phase is realized by introducing extra attractions between PAN blocks, which mimic the cross-linking reactions of PAN blocks in experiments. Our models pave the way of optimizing PCFs by designing PMMA-b-PAN precursors in silico.

**10:00AM R34.00009: Phase diagram for diblock copolymer melts from Langevin field-theoretic simulations**

TOM BEARDSLEY (Presenter), MARK W MATSEN, University of Waterloo — Field-theoretic simulations (FTS) provide fluctuation corrections to self-consistent field theory (SCFT) by simulating its field-theoretic Hamiltonian rather than applying the saddle-point approximation. Here, we apply Langevin FTS (L-FTS) to AB diblock copolymer melts, where the composition field fluctuates via Langevin dynamics but the saddle-point approximation is still applied to the pressure field that enforces incompressibility. The method is demonstrated to be one or two orders of magnitude faster than previous Monte Carlo simulations (MC-FTS), permitting the rapid formation of spontaneously ordered configurations and the accurate determination of their order-disorder transitions. The results are used to construct a phase diagram for diblock copolymer melts of high invariant polymerization index, N = 10^4.

Entanglements in block copolymers self-assembled into lamellae morphology

NICOLAS GARCIA (Presenter), Institut Laue-Langevin, 71 Avenue des Martyrs, 38042 Grenoble, France, JEAN-LOUIS BARRAT, Université Grenoble Alpes, Liphy, CNRS, France — Understand the viscoelastic behavior of polymers is of fundamental interest but also is relevant to consider their technological applications. It is well-known that the mechanical properties of polymers depend fundamentally on the molecular chain weight. The main effect of increasing weight is the arise of entanglements.

Entanglements in homopolymer systems have been studied through simulations and experiments and supported by theories. However, little is known about those topological constraints on multi-component systems, like the block copolymers (BCPs).

In this work, we investigate the viscoelastic properties of BCPs when segregating in a lamellar morphology. We found the entanglements are not distributed homogeneously in the space but instead follow the underlying pattern of the segregated domains. Moreover, the interface separating nearby domains induces a surface effect, decreasing the number of entanglement. On the other hand, in the center of the lamellae domain, the monomer density slightly increases due to the impact of the attractive potential, whose main consequence is an increment of the number of entanglements. Both results are locals, compete with each other, and depend on the segregation regime, being more extended in space in the regime of strong segregation.

Systematic construction of the dynamic density functional theory for inhomogeneous polymer systems

SRITEJA MANTHA (Presenter), FRIEDERIKE SCHMID, Johannes-Gutenberg Univ — Time scales predicted by the dynamic density functional theory (DDFT) for an inhomogeneous polymer system are far from accurate. One of the main reasons for this is, approximate local and non-local schemes employed to compute the mobility coefficient, $\Lambda_{\alpha\beta}(r,r')$. In the DDFT calculations, $\Lambda_{\alpha\beta}(r,r')$, relates the thermodynamic driving force due to the monomer $\beta$ at $r'$ to the current of the monomer $\alpha$ at $r$. In this talk, we will put forward a physically motivated approach to compute the $\Lambda_{\alpha\beta}(r,r')$ with the objective to improve the DDFT predictions. We compute the $\Lambda_{\alpha\beta}(r,r')$ from the relaxation time of the single chain dynamic structure factor. We find that the $\Lambda_{\alpha\beta}(r,r')$ obtained from such an approach captures both the global dynamics and the effective local rearrangements of the chain at relevant length scales. Using this scheme, we conduct DDFT calculations to study two related problems. One is the formation of the lamellar morphology in a symmetric diblock copolymer system starting from a homogeneously dispersed state, and the other is the relaxation of the lamellar morphology into a homogeneously dispersed state. We show that the DDFT predictions for the above problems are in reasonably good agreement with the corresponding fine-grained simulations.

10:36AM R34.00012: Spectrally-Accurate Linear-Scaling Self Consistent Field Theory and Applications*  DANIEL VIGIL (Presenter), CARLOS J GARCIA-CERVERA, KRIS T DELANEY, GLENN H FREDICKSON, University of California, Santa Barbara — We present a new algorithm for numerical polymer self-consistent field theory (SCFT) that has spectral accuracy in the contour dimension while maintaining near-linear computational cost scaling with number of contour sample points, which no other reported algorithm achieves. The new algorithm is enabled by using a coherent states (CS) model of the polymer field theory, which replaces the chain propagator objects from auxiliary field (AF) models with fields that generate chain statistics. We also show that the newly reported algorithm is compatible with a variety of AF algorithms, but can replace their propagator algorithms with our linear-scaling spectrally accurate algorithm. Applications enabled by this new algorithm are presented.

10:48AM R34.00013: Open-source SCFT on graphics processing units  GUO KANG CHEONG (Presenter), ANSHUL CHAWLA, DAVID CLARK MORSE, KEVIN D DORFMAN, University of Minnesota — Self-consistent field theory provides an effective framework for materials discovery, allowing one to target particular morphologies by rapid examination of their phase space. We present a GPU-accelerated self-consistent field solver parallel to the open-source Polymer Self-Consistent Field (PSCF) codebase. The codebase is built from the ground up to utilize highly efficient GPU-acceleration yet remains backwards-compatible with PSCF. Our testing shows up to 60x acceleration in computing time for the largest problems. Improvement in open-source tools enables new opportunities by the community to pursue various problems of interest such as the inverse design of the bulk phases. Increasingly, speed becomes vital in such problems especially in an era of data and machine learning where the manipulation of large data sets is key to the understanding of fundamental polymer physics.
**8:00AM R35.00001: How to Define Electric Potential in a Polarized Polymer Electrolyte Why is it Important?** [Invited] NITASH BALSARA (Presenter), University of California, Berkeley — Polymer electrolytes comprise mobile ionic species, usually both cations and anions, but are electronic insulators. The definition of electric potential is not trivial as the case of the metallic current collectors wherein the presence of excess electronic charge can readily be sensed by a voltmeter. Newman's concentrated theory is built on potential measured using an electrode that undergoes a reversible electrochemical reaction. We apply this theory to polymer electrolytes that are examined under a constant direct current (dc). The concentration gradients in the electrolyte can be calculated without invoking the potential. For practical applications, however, it is important to know if the potential drop necessary to drive the current is within the range afforded by the chosen electrodes. We have worked through these relationship for homopolymer electrolytes. We are currently working on establishing these relationships in block copolymer electrolytes. We hope to present these results at the meeting.

**8:36AM R35.00002: The impact of chemical modification on charge injection at metal/polyolefin interfaces** YIYUAN WANG (Presenter), Departments of Materials and Physics, and the Thomas Young Centre for Theory and Simulation of Materials, Imperial College London, Exhibition Road, London SW7 2AZ, UK, MIKAEL UNGE, ABB Corporate Research, 72178 Västerås, Sweden, SARI J. LAIHONEN, Power Grid Research, 72178 Västerås, Sweden, ARASH A MOSTOFI, Departments of Materials and Physics, and the Thomas Young Centre for Theory and Simulation of Materials, Imperial College London, Exhibition Road, London SW7 2AZ, UK — The process of charge injection at metal/polymer interfaces is crucial to many areas of research and technology, such as organic light emitting and harvesting devices, high-voltage capacitors and cables. In this work, we study charge injection at metal/polymer interfaces for two polymers commonly used in high-voltage applications, namely polyethylene (PE) and polypropylene (PP). Using first-principles electronic structure methods, we compute charge injection barriers at model aluminium/PE and aluminium/PP interfaces. We show that the introduction of polar chemical groups (e.g., -COOH, -CH2Cl, and -CHO) in the polymer chains at the interface can tune the intrinsic charge injection barrier significantly. We take into account of thermal disorder by averaging over a large ensemble of interface structures obtained from first-principles molecular dynamics trajectories. Our results suggest the possibility of rational design of metal/polymer interfaces via localised chemical modification.
Field-theoretic study of salt-induced order and disorder in a polarizable diblock copolymer

DOUGLAS GRZETIC (Presenter), KRIS T DELANEY, GLENN H FREDRICKSON, University of California, Santa Barbara — We study a salt-doped polarizable symmetric diblock copolymer using a recently-developed field theory that self-consistently embeds dielectric response, ion solvation and van der Waals (vdW) attractions via the attachment of classical Drude oscillators and/or fixed dipoles to the constituent fluid elements. This field theory can be directly simulated via the complex Langevin sampling technique, requiring no approximations beyond the phenomenology of the underlying coarse-grained model. We measure the shift in the order-disorder transition with salt-loading in our simulations and observe rich non-monotonic behavior in which ion solvation competes with dilution and charge screening effects to determine whether the ordered or disordered phase is stabilized. At low salt concentrations, the salt behaves as a selective solvent, localizing into the high-dielectric domains and stabilizing the ordered phase. At high salt concentrations, however, the salt localization vanishes due to charge screening effects, and the salt behaves as a nonselective solvent that screens vdW attractions and stabilizes the disordered phase. Our results raise questions regarding the conditions under which it is appropriate to ignore the screening effect of the ion cloud in theories of salt-doped polymers.

Nanostructure and Local Dynamic Effects on Ionic Conductivity of Polymer-Grafted Nanoparticles in Ionic Liquids*

SIQI LIU (Presenter), Stevens Inst of Tech, MADHUSUDAN TYAGI, Neutron-Condensed Matter Science Group, National Institute of Standards and Technology, PINAR AKCORA, Stevens Inst of Tech — In this talk, I will present our recent results about structures and dynamics of poly(methyl methacrylate) (PMMA)-grafted iron oxide nanoparticles in (1-hexyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide) (HMIM-TFSI) / solvent mixtures. The dynamics of HMIM$^+$ cation is measured with QENS experiments and conductivity of grafted particles in HMIM-TFSI is obtained from impedance spectroscopy. Higher diffusivity and conductivity were achieved when grafted particles are dispersed in HMIM-TFSI/acetonitrile mixture than in methanol. These results reveal that acetonitrile solvates HMIM-TFSI and better dispersion of grafted particles leads to better mixing between PMMA and TFSI$^-$ anions. The ion-dipole interactions between TFSI$^-$ and PMMA self-dissociate HMIM-TFSI, thereby increase the number of free cation carriers. The dynamic measurements combined with conductivity results suggest that grafted particles dispersion and conductivity increases with the solvation and with the interactions between high graft density PMMA and TFSI$^-$. Particles form strings in methanol and yield lower conductivity. In conclusion, both solvation and solubility of grafted particles in ionic liquid/solvent mixtures determine the mobility of ions in well-defined particle dispersions.

9:12AM R35.00005: Capacitance of films containing polymerized ionic liquids

RAJEEV KUMAR (Presenter), VERA BOCHAROVA, JYOTI P MAHALIK, Oak Ridge National Laboratory, Oak Ridge, TN 37831, KEVIN SILMORE, Chemical Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139 — Electrode-polymer interfaces, which encompass adsorbed layers of polymers, dictate many of the properties of thin films such as capacitance, electric field experienced by polymers and charge transport. To develop an understanding of electric field-induced transformations of electrode-polymer interfaces, we have studied electrified interfaces of an imidazolium based polymerized ionic liquid (PolyIL) using combinations of broadband dielectric spectroscopy (BDS), specular neutron reflectivity and simulations based on the Rayleigh dissipation function formalism. We demonstrated that the Rayleigh dissipation function formalism provides key insights into charge storage, which include information about capacitance of interface, thicknesses of absorbed and diffuse layers. Overall, the camel-shaped dependence of the capacitance on applied voltage was obtained which originated from responses of absorbed layer to applied voltages. Furthermore, the diffuse layer contribution to the capacitance should decrease with applied voltage \( V \) as \( V^{-1/2} \), which is a direct consequence of local incompressibility/crowded nature of the PolyIL melts.

9:24AM R35.00006: Comparing Stockmayer Fluid Simulation and Experiment: Ion Solvation with Permanent Dipoles

CAMERON SHOCK (Presenter), ISSEI NAKAMURA, Michigan Technological Univ, AMALIE FRISCHKNECHT, MARK STEVENS, Sandia National Laboratories — The solvation of ions in polymer membranes has been studied over many decades. Nevertheless, understanding of the solvation mechanism involves various computational challenges. This is primarily because molecular simulations for ion solvation that can simultaneously consider both atomic and molecular length scales are still significantly limited, even in cases of non-polymeric solvents. In this study, we developed a coarse-grained Stockmayer fluid simulation to address this issue, treating solvent molecules as soft-core spheres with permanent dipole moments. In this talk, we validate our model concept by considering monovalent and divalent ions dissolved in various non-polymeric solvents, such as water and methanol. Despite model simplicity, the results of our simulations show striking agreement when compared with experimental data for the free energy and enthalpy of ion solvation. We will also discuss that the primary contribution to the solvation energy arises mainly from the first and possibly second solvation shells near the ions.

Enhancing the Dielectric Breakdown Strength of Solid-State Polymer Capacitors by Chain End Manipulations

MANINDERJEET SINGH, WENJIE WU, Univ of Houston, MEI DONG, DAVID TRAN, KAREN L WOOLEY, Texas A&M University, NIHAR PRADHAN, Jackson State University, DHARMARAJ RAGHAVAN, Howard University, ALAMGIR KARIM (Presenter), Univ of Houston

— The need for high power density, flexible and light weight energy storage devices requires the use of polymer film-based dielectric capacitors. Theoretically, it has been shown that chain ends contribute adversely to electrical breakdown, resulting in low energy density in polymer capacitors. In this work, we enhanced the energy density of polymer capacitor by using well-ordered high molecular weight block copolymer (BCP), in which the chain ends are segregated to narrow zones. Cyclic homopolymers (no chain ends) and linear homopolymers having chemistry-controlled chain ends also show enhanced breakdown strength, resulting in higher energy density as compared to the linear counterparts. These novel insights into manipulating chain end distribution such as in BCPs and with molecular topology to increase the energy density of polymers will be helpful for fulfilling next-generation energy demands.

The authors would like to acknowledge NSF HBCU-UP EiR NSF DMR # 1900692 and NSF DMR# 1905960 grants for funding this research.

Dendrimer Approach toward High Permittivity Polymer Dielectrics for Electrical Energy Storage

BEIBEI CHEN (Presenter), SAMANTHA DAYMON, Univ of Southern Mississippi, OLUWAPELUMI KAREEM, MCKENNA REDDING, Tulane University, BRIAN OLSON, Univ of Southern Mississippi, MOHAMED K. HASSAN, Qatar University, SCOTT M GRAYSON, Tulane University, SERGEI NAZARENKO, Univ of Southern Mississippi

— Polymers which display high dielectric permittivity (DP) and low dissipation factor (DF) are important in the area of energy storage using film capacitors. Unfortunately, most polymers, even polar, exhibit fairly low DP, 2-4. It has been shown in this study that well dried films prepared from second generation dendrimer (D2) (T_g ~ 50°C) synthesized using 2,2-bis(hydroxymethyl)propionic acid monomer (bis-MPA) demonstrate at room temperature a fairly high DP = 10.5 and low DF = 0.014 in the kHz range of frequencies. The dipole relaxation mechanism, which contributes to this unusual dielectric response was found to be linked to numerous hydroxyl groups situated in the periphery of dendrimer molecules. WAXS and computer molecular dynamics (MD) simulation all indicated that these highly mobile hydroxyl groups in bis-MPA D2 glassy films exhibit a very high level of dipole-dipole (OH-OH) correlation mediated by H-bonding. In fact, terminal hydroxyls readily form H-bonded ‘chain-like’ clusters of different lengths which can range from single H-bond associations to clusters containing tens of hydroxyls. This behavior explains why D2 exhibits a high dielectric constant.

This work was supported by National Science Foundation.
High κ polymers of intrinsic microporosity: A new class of high-temperature and low-loss dielectrics for microelectronic applications

**LEI ZHU (Presenter), ZHONGBO ZHANG, MAN HIN KWOK, Case Western Reserve University** — High performance polymer dielectrics is a key component for power and printable electronics. In this work, organo-soluble polymers of intrinsic microporosity (PIMs) are reported for the first time to show desirable dielectric properties with high permittivity (or κ), high temperature capability, and low dielectric loss. Due to the polar sulfonyl side groups and rigid contorted polymer backbone, sulfonylated PIM (SO2-PIM) exhibited an optimized balance between relatively high κ and low dielectric loss in a broad temperature window (up to 200 °C). For examples, its discharged energy density reached as high as 17 J cm⁻³ with κ = 6.0. The discharge efficiencies were 94% at 150 °C/300 MV m⁻¹ and 88% at 200 °C/200 MV m⁻¹. Furthermore, its application as high-κ gate dielectrics in field effect transistors (FETs) is demonstrated. With the bilayer SO2-PIM/SiO2 gate dielectric, the InSe FETs exhibited a significantly improved electron mobility in the range of 200-400 cm² V⁻¹ s⁻¹, much higher than 40 cm² V⁻¹ s⁻¹ for the bare SiO2-gated InSe FET. This study indicates that highly dipolar PIMs with rigid polymer backbone and large free volume are promising as high performance, next generation polymer dielectrics.

Phase equilibria in P(TrFE-VDF): conformation and chirality

**BING ZHANG (Presenter), WENCHANG LU, Department of Physics, North Carolina State University, YANG LIU, WENHAN XU, AZIGULI HAIBIBU, ZHUBING HAN, QING WANG, Department of Materials Science and Engineering, The Pennsylvania State University, JERRY BERNHOLC, Department of Physics, North Carolina State University** — Ferro- and piezo-electric materials near a phase boundary usually possess enhanced dielectric or piezoelectric properties. We have discovered a morphotropic phase boundary (MPB) in P(VDF-TrFE) polymers [1], the first for any organic material. We show that the MPB forms due to intrachain rather than interchain conformation competition between the planar all-trans and 3/1-helical conformations in single P(VDF-TrFE) chains [2]. Our ab-initio calculations reveal low energy barrier electric dipole moment rotations between the nearly energetically degenerate chain conformations, which result in the piezoelectric enhancement near MPB. In particular, chirality plays a crucial role in the formation of a helical conformation and the relative stability of chain conformations strongly depends on the spatial arrangement of chirality centers. Our results explain the experimental data and the near degeneracy of multiple phases in the P(VDF-TrFE) material. They also provide a guideline for designing new polymers with MPB from a molecular point of view.

10:24AM R35.00011: Ionic and Local Electric Polarization Effects in Polymers [Invited]
GEORGE FLOUDAS (Presenter), Dept. of Physics, University of Ioannina & MPIP — The fundamental role of electric polarization in polymer physics is discussed via two examples. The first discusses purely ionic polarization effects in single ion conductors that are based on polymerized ionic liquids (PILs) (collaboration with the group of Ulli Scherf, Wuppertal). We employ a series of PILs with a polythiophene backbone bearing imidazolium salts with butyl, hexyl, octyl, and decyl side groups and several counteranions. PILs bearing the polythiophene backbone are unique as they can simultaneously conduct electronic charge and ions at nanometer length scales. Dielectric spectroscopy measurements performed as a function of temperature and pressure revealed that ionic conductivity is controlled by the balance between ion diffusion and ion complexation. The former is favored by the small ion size, the presence of ion channels and the decoupling from the backbone dynamics. On the other hand, ion complexation is controlled by ion size, the dielectric constant and charge delocalization. We propose a stick and jump model for ion motion in PILs.

The second example explores the local electric polarization effects in polymer blends (collaboration with M. Kappl, H.-J. Butt, Mainz). The design of multi-component materials for nanotechnology requires knowledge of the local composition. Hence, it is essential to develop techniques that can probe the local composition at the nanoscale. Local dielectric spectroscopy (LDS) is based on the electrostatic interaction between a conductive atomic force microscopy (AFM) probe in close proximity with the sample supported by a flat conductive substrate. Here, LDS is employed to analyze the dynamic heterogeneity in miscible blends as a function of film thickness. In thin films, phase segregation occurs and the kinetics of phase demixing was studied using as a probe the change in local composition. These results open new possibilities for studying interdiffusion and adhesion at polymer-polymer interfaces.

Thursday, March 5, 2020 8:00 AM - 11:00 AM

Session R36 DBIO: Physics of Organelles 601/603 - Elena Koslover, University of California, San Diego - Tag(s): Invited

8:00AM R36.00001: Is the endoplasmic reticulum an obstacle to intracellular diffusion? [Invited]  GREG HUBER (Presenter), Chan Zuckerberg Biohub — Intracellular spaces are tightly packed and the biggest potential obstacle in the crowded interior of a eukaryotic cell is the endoplasmic reticulum (ER), whose total membrane area can be 20-30 times that of the cell’s plasma membrane. Much of this area is in parallel sheets, however the sheet-like ER has also been found to be riddled with spiral dislocations, known as ‘Terasaki ramps’, in the vicinity of which the sheets’ doubled bilayer membranes can be approximately modeled by helicoids. We analyze diffusion on a surface with locally helicoidal topological dislocations, and use the results to argue that the Terasaki ramps facilitate an efficient transport of water-soluble molecules both within the lumen of the endoplasmic reticulum, and in the adjacent cytoplasmic space. (This is joint work with Michael Wilkinson.)
The interior of eukaryotic cells is highly compartmentalized by a variety of organelle structures. A particularly prominent organelle is the endoplasmic reticulum (ER) that feeds virtually all secretory processes of a cell (amongst other duties). Large portions of the ER are organized as a vast dynamic network of membrane tubules that are connected by three-way junctions. Dispersed on this network are numerous membrane domains, so-called ER exit sites (ERES), at which nascent proteins leave the ER via transport vesicles to get transported along the cell's secretory pathway.

Using time-resolved imaging, we have analyzed the dynamics of ER junctions and of ERES domains as well as the self-organization of ERES on the ER network. As a result, we observed that both, ER junctions and ERES, show a marked subdiffusion with signatures of an anti-persistent fractional Brownian motion and a strong dependence on the cytoskeleton's integrity: ER junctions move like monomer units of (semi)flexible polymers with the overall dynamics of the ER network being governed by fractons due to the network's self-similar geometry. Moreover, active cytoskeleton-associated processes endow the subdiffusion of ER junctions with a distinct nonequilibrium character. In contrast, ERES rather are mobile domains that perform a quasi-one-dimensional random walk on the shivering ER backbone. Moreover, ERES show a self-organization that is reminiscent of two-dimensional droplet formation where coarsening is hindered by geometric and topological constraints imposed by ER junctions. In line with this view, a substantial coarsening of ERES to fewer but larger domains is observed upon lifting the hindrance via an RNAi-induced reduction of ER junctions.

9:12AM R36.00003: Fundamental limits to organelle biogenesis control in *Saccharomyces cerevisiae* [Invited]  KIANDOKHT PANJTAN AMIRI, ASA KALISH, SHANKAR MUKHERJI (Presenter), Washington University, St. Louis — Among the most important processes in the self-assembly of the eukaryotic cell is the synthesis of its organelles, specialized biochemical compartments that house processes crucial to cellular physiology. Two critical properties closely linked with organelle function are their copy numbers and sizes. Numerous molecular factors that regulate the numbers and sizes of a diverse array of organelles, including the Golgi, mitochondria, peroxisomes and lipid droplets among others, have been identified. However, our understanding of the quantitative principles governing organelle number and size control remains incomplete. Here, we combine experimental data from the single-celled eukaryote *Saccharomyces cerevisiae* and mathematical theory to show that cells tolerate substantial fluctuations in organelle number while robustly controlling fluctuations in organelle sizes. In particular, our framework suggests that organelle size increases in random bursts from a limited pool of building blocks, which in turn imposes an asymmetry in optimal organelle number and size control. Burst like growth is a potentially general mechanism by which the cell efficiently assembles subcellular structures from its finite resources.

9:48AM R36.00004: Decoding the variance in intracellular organization of the undifferentiated hiPS cell [Invited]  MATHEUS VIANA (Presenter), SUSANNE RAFELSKI, Allen Institute for Cell Science — The Allen Institute for Cell Science is developing a state space of structural signatures of the undifferentiated human induced pluripotent stem cell (hiPSC) to understand how cells organize and transition between states (cellular morphogenesis). To do this we take advantage of the ~35 endogenous fluorescently tagged hiPSC lines in the Allen Cell Collection (www.allencell.org), each expressing a monoallelic EGFP-tagged protein representing a particular organelle. We develop image-based assays and segmentations for quantitative analyses, taking advantage of thousands of replicate high-resolution 3D images for each structure. We are investigating biological sources of cellular variation in a high-dimensional space that represents integrated intracellular organization. We applied the Allen Cell Structure Segmenter to images of lamin B1-tagged cells to extract nuclear shapes, which we then fit using spherical harmonics. We performed principal component analysis on the fitting coefficients and we found the first five components explain 85% of the total variance. Each of these components was mapped into a mode corresponding to a distinct biological source of variation. The first mode represented nuclear volume, which increases throughout interphase at timescales of hours. The second mode represented how flat (vs. round) a nucleus appeared in the apical-basal axis (Z-direction), which was linked to changes in colony cell packing dynamics consistent with a timescale of several days for cell packing within colonies. The remaining modes represented how elongated a nucleus appeared in the XY plane and how tilted the nucleus appeared along the major and minor axis. We found these modes to be caused by interactions with neighboring cells occurring at timescales of minutes. We are now applying these analyses to develop biophysical models of nuclear shape. Our framework will be extended to cell shape and key intracellular structures in an integrative fashion.
10:24AM R36.00005: Modelling membrane-bound cellular organelles with non-equilibrium dynamics [Invited]  PIERRE SENS (Presenter), Insitut Curie / CNRS, JEAN-PATRICK VREL, Institut Curie, QUENTIN VAGNE, MPI-CBG — Membrane-bound cellular organelles perform many essential functions, among which the sorting and biochemical maturation of cellular components. Organelles along the secretory and endocytic pathways are strongly out-of-equilibrium structures, which display large stochastic fluctuations of composition and shape resulting from inter-organelle exchange and enzymatic reactions. Understanding how the different molecular mechanisms controlling these processes are orchestrated to yield robust fluxes of matter and to direct particular components to particular locations within the cell is an outstanding problem of great interest for cell biologist, but also for physicists.

In this talk, I will discuss a conceptual model of organelle biogenesis and maintenance that include vesicular exchange (budding, transport, and fusion) and biochemical maturation, i.e. the change of identity of an organelle over time (early to late endosomes, cis to trans Golgi cisternae...). I will show how the non-equilibrium steady-state of an organelle or a network of organelles may be varied in a controlled manner by modifying a limited number of coarse-grained parameters (essentially, the budding, fusion and maturation rates) and discuss the relevance of these results for the structure of the Golgi apparatus.

Session R37 GPC: Predictability of the Climate System 605 - William Collins,
Lawrence Berkeley National Laboratory - Tag(s): Invited, Undergrad Friendly

8:00AM R37.00001: Data Assimilation and Uncertainty Quantification in the Geosciences*
[Invited]  JUAN RESTREPO (Presenter), Mathematics, Oregon State University — Data assimilation is the name commonly given to the estimation process that generates moments of probability density functions of time dependent processes modeled by physics, and observations. The inherent uncertainties of model and data are taken into account using a Bayesian framework. Data assimilation is presently used in applications as diverse as weather forecasting and spacecraft navigation. I will appeal to familiar statistical physics to present the general methodology. I will briefly describe a couple of computational implementations of the method summarize some of the key research challenges that arise in their application. I will also describe some novel applications of the methodology, potentially useful in tracking targets, hurricanes, and ongoing research in the application of stochastic parametrization and machine learning for the purpose of dimension reduction.

8:36AM R37.00002: Climate Change and Climate Variability: A Unified Framework* [Invited]
MICHAEL GHIL (Presenter), Ecole Normale Supérieure, Paris and University of California, Los Angeles —
The “death of stationarity” poses a substantial challenge to climate predictability and to the climate sciences in general. This challenge is addressed herein by formulating the problems of change in the climate's intrinsic variability within the framework of the theory of nonautonomous and random dynamical systems (NDS and RDS) with time-dependent forcing. A key role in this theory is played by the pullback attractors (PBAs) that replace the strange attractors of the more familiar theory of autonomous dynamical systems, in which there is no explicit time dependence of either forcing or coefficients.
The concepts and methods of the NDS and RDS approach will be introduced and will be illustrated using a stochastically perturbed version of the Lorenz (1963) convection model. This illustration will be followed by applications to models of the wind-driven ocean circulation and the El Niño–Southern Oscillation (ENSO). One finds that two local PBAs, a quiescent and a chaotic one, coexist within the wind-driven ocean model's decadally modulated global PBA, whereas a critical transition between two types of chaotic behavior occurs in the seasonally forced ENSO model.
Implications for the climate sciences in the era of anthropogenic change will be discussed.

9:12AM R37.00003: Quantifying uncertainty in climate predictability using perturbed physics ensembles and climate model emulation [Invited] KATHERINE DAGON (Presenter), National Center for Atmospheric Research, BENJAMIN SANDERSON, ROSIE FISHER, CERFACS, DAVID LAWRENCE, National Center for Atmospheric Research — Climate models are essential tools for understanding and predicting Earth system processes and feedbacks, but uncertainties in their future projections remain challenging to characterize. Improvements in physical process realism and the representation of human influence arguably make models more comparable to reality, but also increase the degrees of freedom in model configuration leading to parametric and structural uncertainties in projections. Perturbed physics ensembles sample the uncertainty space through different choices of parameter settings. Climate model emulators can be a computationally efficient method of producing large ensembles of climate model output, in order to study different sources of uncertainty. In this work we use a machine learning algorithm to build an emulator for the land surface component of a climate model. Using a perturbed physics ensemble of model simulations, we train the emulator to predict model output given a set of parameter values as input. We optimize parameter values by comparing emulated model output with observations across multiple relevant metrics, including global carbon and water flux benchmarks. We also account for structural and observational uncertainty through a novel Bayesian calibration approach. By sampling the resulting posterior distributions and running future climate simulations, we can then estimate the contribution of land model parameter uncertainty in future projections of climate change.
9:48AM R37.00004: Earth System Modeling 2.0: Toward Data-Informed Climate Models With Quantified Uncertainties* [Invited] TAPIO SCHNEIDER (Presenter), Caltech — While climate change is certain, precisely how climate will change is less clear. But breakthroughs in the accuracy of climate projections and in the quantification of their uncertainties are now within reach, thanks to advances in the computational and data sciences and in the availability of Earth observations from space and from the ground. To achieve a leap in accuracy of climate projections, we are developing a new Earth system modeling platform. It will fuse an Earth system model (ESM) with global observations and targeted local high-resolution simulations of clouds and other elements of the Earth system. The ESM is being developed by the Climate Modeling Alliance (CliMA), which encompasses Caltech, MIT, and the Naval Postgraduate School. CliMA will capitalize on advances in data assimilation and machine learning to develop an ESM that automatically learns from diverse data sources, be they observations from space or data generated computationally in high-resolution simulations. It will also engineer the ESM from the outset to be performant on emerging computing architectures, including heterogeneous architectures that combine traditional CPUs with hardware accelerators such as graphical processing units (GPUs). This talk will cover key new concepts in the ESM, including turbulence, convection, and cloud parameterizations and fast and efficient algorithms for assimilating data and quantifying uncertainties.

Bayesian Inference for Climate prediction — Bayesian Inference in the geosciences is called data assimilation. It studies how to best combine information from complex numerical models with information from observations of the system at hand, given limited computational resources. This requires knowledge of the physics, numerical modeling including computer architecture, quantification of deficiencies in the numerical models, characteristics of observation errors, and Bayesian inference for very high dimensional highly nonlinear systems.

An important characteristic of the climate system is that the different Earth system components (e.g. atmosphere, ocean, land surface and icecaps) have vastly different internal time scales. The main work horse for weather prediction, a (variational) smoother in which observations over a time window of 6-12 hours are used to find the best starting point for predictions, is problematic because the optimal time window length is substantially different for the different components. Even after 20 years of intensive research no satisfying smoother solution has been found. This suggests to use a filter solution without an assimilation window, but the main workhorse there, the Ensemble Kalman Filter, suffers from too small ensemble sizes to accommodate the large number of observations (even when so-called localization is applied).

Another issue is that with its many feedbacks the climate system is highly nonlinear, while the standard methods for weather predictions are only optimal for linear, and perhaps weakly nonlinear systems. Furthermore, system updates are typically too abrupt and need to be added incrementally during the prediction.

We will discuss potential solutions based on existing techniques, and alternative ideas based on so-called particle flows. The latter are fully nonlinear while combining the strong points of smoothers and filters mentioned above, and have the potential to make substantial strides forwards towards better climate prediction.

Thursday, March 5, 2020 8:00 AM - 11:00 AM

Session R38 DQI: DQI Invited Session: Quantum State Preparation and Measurement (SPAM) in Semiconductor Qubits — Exchange-only triple-quantum-dot spin qubits are a promising approach to scalable quantum information processing. In such systems, state preparation is generally performed by biasing the device to exchange electrons with a cold electron reservoir, while measurement is realized by spin-to-charge conversion and detection with a nearby electrometer. In this talk I will discuss implementation of these techniques in isotopically-enriched Si/SiGe triple dots using a direct dot-sensor electrometer with a cryogenic HEMT amplifier. I will examine the non-idealities in these operations, and explain how those factors can be hidden or revealed by choice of metric, showing data which exhibits SPAM infidelity in the low parts-per-thousand level. Further, I’ll detail a budget for what performance is expected, given properties of the device and instrumentation.
9:12AM R38.00003: Quantum non-demolition measurement of an electron spin qubit*
[Invited] JUN YONEDA (Presenter), CEMS, RIKEN — While single-shot spin detection of electron spin qubits in semiconductor quantum dots is now a laboratory routine, the need for quantum error correction in a large-scale system demands a quantum non-demolition (QND) implementation. The QND spin readout imposes minimal disturbance to the probed spin polarization and can therefore be repeated to extinguish measurement errors. Furthermore, it also works as a high-fidelity state preparation device. However, its realization is challenging as it involves exquisite exposure of the system to the external readout circuitry while maintaining the qubit coherence and integrity. In this talk, we show that an electron spin qubit in quantum dots can be measured in a highly non-demolition manner by probing a neighboring electron spin qubit Ising-coupled to the qubit spin. The high QND fidelity enables enhancement of the measurement fidelity of a single electron spin state by repeating the readout process several dozens of times. We describe the analysis method based on statistical inference, which is crucial to achieve the optimal performance in the presence of the qubit relaxation. We will further discuss how such QND measurements can improve the fidelity of measurement-based state preparation in addition to the measurement fidelity.

8:00AM R39.00001: Frustrated magnets and fermions with Neural Network Quantum States* [Invited] KENNY JING CHOO (Presenter), Univ of Zurich, ANTONIO MEZZACAPO, IBM T.J. Watson Research Center, TITUS NEUPERT, Univ of Zurich, GIUSEPPE CARLEO, Flatiron Institute — Neural-Network quantum states (NQS) have been recently proposed as a method to solve challenging interacting quantum problems. During this talk, I will discuss the application of NQS to two problems. First, we use a deep convolutional network to find the ground state of the frustrated J1-J2 model on the square lattice. While early representations of many-body quantum states in terms of neural networks are usually based on shallow architectures such as the restricted Boltzmann machine, the benefits of deeper architectures are emerging in the latest research. Here, we show that these deep convolutional NQS can achieve results that are competitive with other state of the art variational methods developed in the past decade. Second, we present an extension of NQS to model interacting fermionic problems. Borrowing techniques from quantum simulation, we directly map fermionic degrees of freedom to spin ones, and then use NQS to perform electronic structure calculations. On small test molecules, we achieve energies below chemical accuracy, and frequently improves upon coupled cluster methods.

8:36AM R39.00002: Learning the Ground State Wavefunction of Periodic Systems Using Recurrent Neural Networks* CHRISTOPHER ROTH (Presenter), ALLAN MACDONALD, University of Texas at Austin — Modeling quantum many-body systems is enormously challenging due to the exponential scaling of Hilbert dimension with system size. Finding an Ansatz that efficiently compresses the wavefunction is key to simulating large systems. Here, we present an approach for simulating periodic quantum systems using long short term memory networks (LSTMs), whose recurrent structure is able to efficiently capture invariance to discrete translations in the bulk. We perform Variational Monte Carlo using an autoregressive Ansatz, where the probability amplitude associated with an electron having a particular quantum number is conditioned on the quantum numbers of the electrons behind it. These amplitudes and phases are iteratively generated by an LSTM, which is trained to minimize the energy using stochastic gradient descent. We show that such a formulation can be used to find the ground state of the 1D Hubbard and J1-J2 Heisenberg models for several hundred electrons. Furthermore, we can learn about the bulk by "growing" the sample; iteratively training the solution on progressively larger systems until the edge effects become negligible. We argue that such a scheme can be generalized more naturally to higher dimensions than Density Matrix Renormalization Group.

**8:48AM R39.00003: Calculating Renyi Entropies with Neural Autoregressive Quantum States**
ZHAOYOU WANG (Presenter), EMILY J DAVIS, Stanford Univ — Entanglement entropy is an essential metric for characterizing quantum many-body systems, but its numerical evaluation for neural network representations of quantum states has so far been inefficient and only demonstrated for the restricted Boltzmann machine architecture. We estimate generalized Renyi entropies $S_n$ of an autoregressive neural quantum state using quantum Monte Carlo methods. A naive “direct sampling” approach performs well for small Renyi order $n$ but fails for larger orders when benchmarked on a 1D Heisenberg model. We therefore propose an improved “conditional sampling” method exploiting the autoregressive structure of the network ansatz, which outperforms direct sampling in both 1D and 2D Heisenberg models. Conditional sampling facilities calculations of high-order Renyi entropies up to at least $n > 30$, which allows for a polynomial approximation of the von Neumann entropy as well as extraction of the largest eigenvalue of the reduced density matrix, and thus the single copy entanglement. By demonstrating good convergence even up to high Renyi order, our methods elucidate the potential of neural network quantum states in quantum Monte Carlo studies of entanglement entropy for many-body systems.

**9:00AM R39.00004: Probabilistic Simulation of Quantum Circuits with the Transformer**
JUAN CARRASQUILLA, Vector Institute, DI LUO (Presenter), University of Illinois at Urbana-Champaign, FELIPE PEREZ, Layer6 AI, BRYAN CLARK, University of Illinois at Urbana-Champaign, ASHLEY MILSTED, Perimeter Institute for Theoretical Physics, MAKSIMS VOLKOVS, Layer6 AI, MARIO AOLITA, Universidade Federal do Rio de Janeiro — In this work, we present an exact probabilistic formulation of quantum dynamics through positive value-operator measurements (POVM). In this formulation, unitary dynamics and quantum channels are represented by quasi-stochastic matrices acting on true probability distributions which specify the quantum state univocally. The probability distribution representation of the quantum state opens up the possibility of bridging the state-of-the-art techniques from machine learning into the simulation of quantum mechanics. Using the POVM formalism, we have developed a practical algorithm for the probabilistic simulation of quantum circuits with the Transformer, a powerful ansatz responsible for the most recent breakthroughs in the natural language processing research. The method is applied to state preparation of GHZ state and Linear Graph state up to 60 qubits, as well as variational quantum circuit preparation of the ground state of the Transverse Field Ising Model.

9:12AM R39.00005: Variational optimization in the AI era [Invited] BRYAN CLARK (Presenter), DMITRII KOCHKOV, DI LUO, University of Illinois at Urbana-Champaign — The variational method has been a cornerstone approach to tackling the quantum many-body problem since the beginnings of quantum mechanics. Throughout this history, wave-functions have grown in number of parameters and generality. The eventual conclusion to this arc is to consider the variational space of all computer programs. Using tools and inspiration from AI, we have developed an approach to represent this class (computational graph states); a novel way to optimize tens of thousands of parameters within this space (supervised wave-function optimization); and multiple novel variational ansatz (neural net backflow, etc). We will describe these advancements and our effort to push forward, in the age of AI, the variational approach to the quantum many body problem.

9:48AM R39.00006: Deep neural network solution of the electronic Schrödinger equation JAN HERMANN (Presenter), ZENO SCHÄTZLE, FRANK NOE, Free University of Berlin — The electronic Schrödinger equation describes fundamental properties of molecules and materials, but cannot be solved exactly for larger systems than a hydrogen atom. Quantum Monte Carlo is an apt approach for high-quality approximations, because its accuracy is limited in principle only by the flexibility of the used wave-function ansatz, but traditional trial wave functions are too rigid to take full advantage of this potential. Here, we greatly increase the flexibility of existing ansatzes by incorporating deep neural networks, which are known as superb universal function approximators. Our architecture, dubbed PauliNet, is built around the Hartree–Fock solution as a baseline, includes analytical cusp conditions, and uses the Jastrow-factor and backflow constructions as entry points for graph-convolutional neural networks, which ensure the exact permutational antisymmetry. We demonstrate that PauliNet outperforms comparable state-of-the-art trial wave functions on atoms, small molecules, and a strongly correlated model system. Our approach opens a new path towards highly accurate and systematically improvable electronic structure methods with explicit access to the corresponding wave function and hence a variety of electronic properties.
10:00AM R39.00007: Ab-Initio Solution of the Many-Electron Schrödinger Equation with Deep Neural Networks  JAMES SPENCER (Presenter), DAVID PFAU, ALEX MATTHEWS, DeepMind, W MATTHEW C FOULKES, Physics, Imperial College London — Calculating analytic solutions to the Schrödinger equation is impossible except in a small number of special cases. Approximate solutions typically impose a fixed functional form on the wavefunction. Neural networks have shown impressive power as accurate practical function approximators\(^1\) and have been recently used in bosonic\(^2\) and lattice systems\(^3\). We show that deep neural networks can learn the ground state wavefunction of chemical systems given only the positions and charges of the nuclei using a combination of variational Monte Carlo (VMC) and optimisation methods from machine learning\(^4\). The neural network Ansatz, FermiNet, is compact yet flexible and gives more accurate energies than conventional Ansätze. We obtain ground state energies, ionisation potentials and electron affinities to within chemical accuracy on a variety of atoms and small molecules and outperform VMC using conventional Slater-Jastrow wavefunctions.

DP and JS contributed equally to this work.

10:12AM R39.00008: Towards neural network quantum states with nonabelian symmetries*  TOM VIEIJRA (Presenter), CORNEEL CASERT, JANNES NYS, Department of Physics and Astronomy, Ghent University, WESLEY DE NEVE, Center for Biotech Data Science, Ghent University Global Campus, JUTHO HAEGERMAN, JAN RYCKEBUSCH, FRANK VERSTRAETE, Department of Physics and Astronomy, Ghent University — Although artificial neural networks have recently been proven to provide a promising new framework for constructing quantum many-body wave functions, the parameterization of a quantum wavefunction with nonabelian symmetries in terms of a Boltzmann machine inherently leads to biased results due to the basis dependence. We demonstrate that this problem can be overcome by sampling in the basis of irreducible representations instead of spins, for which the corresponding ansatz respects the nonabelian symmetries of the system. We will show that this representation is connected to symmetric tensor network states.

We apply our methodology to find the ground states of the one-dimensional antiferromagnetic Heisenberg (AFH) model with spin-half and spin-1 degrees of freedom. The proposed ansatz can target excited states, which is illustrated by calculating the energy gap of the AFH model.

Implementing non-abelian symmetries in variational quantum states is an important step towards solving frustrated quantum systems. We demonstrate recent results using our ansatz on the frustrated J1-J2 model.

10:24AM R39.00009: Designing neural networks for stationary states in open quantum many-body systems*  NOBUYUKI YOSHIOKA (Presenter), RYUSUKE HAMAZAKI, Department of Physics, University of Tokyo — We propose a new variational scheme based on the neural-network quantum states to simulate the stationary states of open quantum many-body systems [1]. Using the high expressive power of the variational ansatz described by the restricted Boltzmann machines [2], which we dub as the neural stationary state ansatz, we compute the stationary states of quantum dynamics obeying the homogeneous Markovian quantum master equations. The mapping of the stationary-state search problem into finding a zero-energy ground state of an appropriate Hermitian operator allows us to apply the conventional variational Monte Carlo method for the optimization. Our method is shown to simulate various spin systems efficiently, i.e., the transverse-field Ising models in both one and two dimensions and the XYZ model in one dimension.

10:36AM R39.00010: Deep Learning-Enhanced Variational Monte Carlo Method for Quantum Many-Body Physics  LI YANG (Presenter), Google Research, ZHAOQI LENG, Princeton University, LI LI, Google Research, ANKIT PATEL, Rice University, WENJUN HU, University of Tennessee, HAN PU, Rice University — Artificial neural networks have been successfully incorporated into variational Monte Carlo method (VMC) to study quantum many-body systems. However, there have been few systematic studies of exploring quantum many-body physics using deep neural networks (DNNs), despite of the tremendous success enjoyed by DNNs in many other areas in recent years. One main challenge of implementing DNN in VMC is the inefficiency of optimizing such networks with large number of parameters. We introduce an importance sampling gradient optimization (ISGO) algorithm (arXiv:1905.10730), which significantly improves the computational speed of training DNN in VMC. We design an efficient convolutional DNN architecture to compute the ground state of a one-dimensional (1D) SU(N) spin chain. Our numerical results of the ground-state energies with up to 16 layers of DNN show excellent agreement with the Bethe-Ansatz exact solution. Furthermore, we also calculate the loop correlation function using the wave function obtained. Our work demonstrates the feasibility and advantages of applying DNNs to numerical quantum many-body calculations.

Session R40 DCOMP DAMOP DCMP: Precision many-body physics VI: Novel methods and algorithms  705 - Olga Goulko, Boise State University - Tag(s): Focus
8:00AM R40.00001: DMRG Approach to Optimizing Two-Dimensional Tensor Networks
[Invited] KATHARINE HYATT (Presenter), MILES STOUDENMIRE, Simons Foundation — Tensor network algorithms have been remarkably successful solving a variety of problems in quantum many-body physics. However, algorithms to optimize two-dimensional tensor networks known as PEPS lack many of the aspects that make the seminal density matrix renormalization group (DMRG) algorithm so powerful for optimizing one-dimensional tensor networks known as matrix product states. We implement a framework for optimizing two-dimensional PEPS tensor networks which includes all of steps that make DMRG so successful for optimizing one-dimension tensor networks. We present results for several 2D spin models and discuss possible extensions and applications.

8:36AM R40.00002: Diagrammatic Monte Carlo for the Hubbard Model: Recent developments* [Invited] MICHEL FERRERO (Presenter), FEDOR SIMKOVIC, Ecole Polytechnique, RICCARDO ROSSI, CCQ, Flatiron Institute — In this talk, I will present recent developments of the diagrammatic Monte Carlo method applied to the Hubbard model. Diagrammatic Monte Carlo methods are based on the construction of a perturbation series for physical observables. They face two main challenges: The first challenge is the accurate stochastic computation of the series coefficients that suffers from the fermionic sign problem. The second difficulty is the resummation of the series whose success depends on the structure of the physical observable expressed in the complex plane of the expansion parameter, e.g. the onsite repulsion U in the Hubbard model. I will discuss how these two issues can be addressed and, in particular, how the freedom to choose the non-interacting starting point of the theory can be used to construct more efficient perturbation series. I will illustrate these developments with calculations performed in different regimes of the Hubbard model.

*We acknowledge support from the Simons Foundation within the Many-Electron Collaboration program.

9:12AM R40.00003: Differentiable Programming Tensor Networks HAI-JUN LIAO (Presenter), JIN-GUO LIU, LEI WANG, TAO XIANG, Institute of Physics, The Chinese Academy of Sciences — Differentiable programming is a fresh programming paradigm which composes parameterized algorithmic components and trains them using automatic differentiation (AD). We present theory and practice of programming tensor network algorithms in a fully differentiable way. By formulating the tensor network algorithm as a computation graph, one can compute higher order derivatives of the program accurately and efficiently using AD. We present essential techniques to differentiate through the tensor networks contractions, including stable AD for tensor decomposition and efficient backpropagation through fixed point iterations. As a demonstration, we compute the specific heat of the Ising model directly by taking the second order derivative of the free energy obtained in the tensor renormalization group calculation. Next, we perform gradient based variational optimization of infinite projected entangled pair states for quantum antiferromagnetic Heisenberg model and obtain start-of-the-art variational energy and magnetization with moderate efforts. Differentiable programming removes laborious human efforts in deriving and implementing analytical gradients for tensor network programs, which opens the door to more innovations in tensor network algorithms and applications.
Simulating open quantum many-body systems using matrix product state purifications* YIKANG ZHANG (Presenter), XIN ZHANG, THOMAS BARTHEL, Duke University — Although we usually try to isolate quantum systems in the lab as effectively as possible, some degree of external noise and interaction with the environment is inevitable. This generally leads to decoherence, dissipation, and can alter the critical behavior in many-body systems. One can also try to engineer the environment coupling to achieve new physical phenomena. We consider Markovian systems, evolving according to Lindblad master equations. We introduce a new algorithm based on matrix product state purifications to simulate open many-body systems. This resolves a fundamental problem in simulations using matrix product density operators (MPDO) which generally lose positivity in truncations, leading to nonphysical states. We test and demonstrate our algorithm for spin chains and fermionic systems, comparing to exact diagonalization, analytical solutions, and MPDO simulations.

Compressing Infinite Matrix Product Operators with an Application To Twisted Bilayer Graphene* DANIEL PARKER (Presenter), XIANGYU CAO, TOMOHIRO SOEJIMA, MICHAEL ZALETEL, University of California, Berkeley — We present a new method for compressing matrix product operators (MPOs) which represent sums of local terms, such as Hamiltonians. Just as with area law states, such local operators may be fully specified with a small amount of information per site. Standard matrix product state (MPS) tools are ill-suited to this case, due to extensive Schmidt values that coexist with intensive ones, and Jordan blocks in the transfer matrix. We ameliorate these issues by introducing an "almost Schmidt decomposition" that respects locality. Our method is "ε-close" to the accuracy of MPS-based methods for finite MPOs, and extends seamlessly to the thermodynamic limit, where MPS techniques are inapplicable. As an application, we compress the Hamiltonian for a model of twisted bilayer graphene --- whose naive bond dimension is tens of thousands --- down to a size where its ground state may be computed.

This talk is based on arXiv: 1909.06341.

We present a quantum electronic embedding method derived from the exact factorization approach to calculate static properties of a many-electron system. The method is exact in principle but the practical power lies in utilizing input from a low-level calculation on the entire system in a high-level method computed on a small fragment, as in other embedding methods. Here, the exact factorization approach defines an embedding Hamiltonian on the fragment. Various Hubbard models demonstrate that remarkably accurate ground-state energies are obtained over the full range of weak to strongly correlated systems.

10:00AM R40.00007: Putting modern many-body methods to the test: the two-dimensional Hubbard model at weak coupling

THOMAS SCHAEFER (Presenter), CPHT, École Polytechnique, NILS WENTZELL, Center for Computational Quantum Physics (CCQ), Flatiron Institute, FEDOR SIMKOVIC, CPHT, École Polytechnique, YUAN-YAO HE, Center for Computational Quantum Physics (CCQ), Flatiron Institute, CORNELIA HILLE, Institute for Theoretical Physics, Universität Tübingen, CHRISTIAN ECKHARDT, Institute of Solid State Physics, TU Wien, BEHNAM ARZHANG, Department of Physics and Physical Oceanography, Memorial University of Newfoundland, VIKTOR HARKOV, Institute of Theoretical Physics, Universität Hamburg, FRANÇOIS-MARIE LE RÉGENT, ALFRED KIRSCH, CPHT, École Polytechnique, YAN WANG, Département de Physique and Centre de Recherche en Physique du Solide, Université de Sherbrooke, AARAM J. KIM, EVGENY KOZIK, Department of Physics, King's College London, EVGENY STEPanOV, Institute of Theoretical Physics, Universität Hamburg, ANNA KAUCH, Institute of Solid State Physics, TU Wien, SABINE ANDERGASSEN, Institute for Theoretical Physics, Universität Tübingen, JAMES LEBlANC, Department of Physics and Physical Oceanography, Memorial University of Newfoundland, SHIWEI ZHANG, Center for Computational Quantum Physics (CCQ), Flatiron Institute, ANDRE-MARIE TREMBLAY, Département de Physique and Centre de Recherche en Physique du Solide, Université de Sherbrooke, MICHEL FERRERO, CPHT, École Polytechnique, OLIVIER PARCOLLET, ANTOINE GEORGES, Center for Computational Quantum Physics (CCQ), Flatiron Institute — We provide a detailed synopsis and comparison of a comprehensive set of state-of-the-art many-body techniques for the weak-coupling regime of the two-dimensional half-filled Hubbard model on a square lattice. We put each of these methods to the test, for both one- and two-particle observables, in relation to the salient physical crossovers of this model: upon cooling from the high-temperature incoherent regime, coherent quasiparticles are formed below $T_{QP}$. At lower $T$, magnetic correlations stemming from the antiferromagnetically ordered phase at $T=0$ are gradually enhanced, resulting in the opening of an electronic (pseudo-)gap at $T^{*}$. By covering the range of modern many-body techniques available today, from numerically exact benchmark methods (determinantal and diagrammatic QMC [CDet]), over (dynamical) mean field theory (RPA, DMFT) and its cluster (DCA) and vertex based extensions (DΓA, TRILEX, DF, DB) to well-known approximations like parquet approximation (PA), the two-particle-self-consistent approach (TPSC) and the functional renormalization group (fRG), the realm of their applicability is put into perspective and a reference and agenda for future improvements is provided.

*Erwin-Schrödinger Fellowship J 4266 - "SuMo" (FWF), Grant No. 319286 "QMAC" (ERC), The Simons Foundation
10:12AM R40.00008: A time-dependent tunneling approach to RIXS and other core-hole spectroscopies* ADRIAN FEIGUIN (Presenter), KRISSIA ZAWADZKI, Northeastern University, ALBERTO NOCERA, Stewart Blusson Quantum Matter Institute, University of British Columbia — We introduce a numerical approach to calculate the Resonant Inelastic X-Ray Scattering (RIXS) in strongly correlated systems. Since accounting for intermediate processes involved in RIXS requires the knowledge of all eigenstates of the Hamiltonian, these computations have remained very challenging. We recast the calculation as a tunneling problem that can be readily solved by means of the time-dependent DMRG method and does not require a full knowledge of the excitations. This powerful formulation overcomes all the hurdles imposed by other techniques that rely on explicitly obtaining dynamical spectral functions. Results for the Hubbard model are achieved with minimal effort on large systems using a fraction of the states -- and simulation time-- required by the dynamical DMRG formulation. These ideas can be readily applied without modification away from equilibrium.

10:24AM R40.00009: A time and momentum resolved tunneling spectroscopy approach to non-equilibrium phenomena in correlated systems* KRISSIA ZAWADZKI (Presenter), ADRIAN FEIGUIN, Northeastern University — We introduce a numerical method to calculate the spectral density of correlated systems using a tunneling approach efficiently implemented through the time-dependent Density Matrix Renormalization-Group (tDMRG). By using an extended probe, which is basically a copy of the system of interest, we are able to extract the time-resolved spectrum with the momentum information of the excitations. We illustrate our ideas by calculating the time-resolved spectrum of a Mott-insulating extended Hubbard chain after a sudden quench. Our results demonstrate that the system realizes a non-thermal state that contains an admixture of spin and charge density excitations, with corresponding signatures recognizable as in-gap subbands. In particular, we identify a band of excitons and one of stable anti-bound states at high energies that gains enhanced visibility after the pump. We do not appreciate noticeable relaxation within the time-scales considered, which is attributed to the lack of decay channels due to spin-charge separation.

*KZ is supported by a Faculty of the Future fellowship of the Schlumberger Foundation. AEF acknowledges the U.S. Department of Energy, Office of Basic Energy Sciences for support under grant No. DE-SC0014407.
The effect of electron-phonon coupling on Dirac fermions raises interesting questions concerning charge-density wave (CDW) formation in a semi-metal, which have recently been explored on a honeycomb lattice \[1,2\]. Here, we use the unbiased determinant Quantum Monte Carlo (DQMC) method to study the Holstein model on a half-filled staggered-flux square lattice, and compare with the results on the honeycomb lattice. Our work analyzes a range of phonon frequencies, \(0.1 \leq \omega \leq 2.0\). We find that interactions give rise to charge-density wave order but only above a finite coupling strength \(\lambda_{\text{crit}}\). The transition temperature is evaluated and presented in a \(T_c - \lambda\) phase diagram. An accompanying mean-field theory (MFT) calculation also reveals the existence of quantum phase transition, although at a smaller critical coupling strength than found in DQMC.

The effect of disorder on the phase diagrams of hard-core lattice bosons with cavity-mediated long-range and nearest-neighbor interactions

We use quantum Monte Carlo simulations with the worm algorithm to study the phase diagram of a two-dimensional Bose-Hubbard model with cavity-mediated long-range interactions and uncorrelated disorder in the hard-core limit. Our study shows the system is in a supersolid phase at weak disorder and a disordered solid phase at stronger disorder. Due to long-range interactions, a large region of metastable states exists in both clean and disordered systems. By comparing the phase diagrams for both clean and disordered systems, we find that disorder suppresses metastable states and superfluidity. We compare these results with the phase diagram of the extended Bose-Hubbard model with nearest-neighbor interactions. Here, the supersolid phase does not exist even at weak disorder. We identify two kinds of glassy phases: a Bose glass phase and a disordered solid phase. The glassy phases intervene between the density-wave and superfluid phases as the Griffiths phase of the Bose-Hubbard model. The disordered solid phase intervenes between the density-wave and Bose glass phases since both have a finite structure factor.
8:00AM R41.00001: Magnetic textures with particle properties beyond skyrmions: chiral bobbers, globules, and hopfions [Invited]  NIKOLAI S. KISELEV (Presenter), Institute for Advanced Simulation, Forschungszentrum Julich GmbH — Magnetic crystals with competing interactions allow the existence of localized magnetic textures possessing a lot of similarities to ordinary particles meaning that they can move and interact with each other: attract, repel, or mutually annihilate. In my presentation, I discuss a wide variety of different types of such textures existing in magnetic crystals.

First, I will discuss the chiral magnets where the competition between the Heisenberg exchange and the Dzyaloshinsky-Moriya interactions leads to the emergence of magnetic skyrmions (Sk). Recently we have shown that besides ordinary Sk [1], the micromagnetic functional for chiral magnets admits an infinite number of solutions with different topological charges, energies, static, and dynamical properties [2].

We have shown theoretically [3] and experimentally [4] that in 3D crystals of isotropic chiral magnets besides Sk tubes (SkTs) penetrating through the whole sample, there are also other types of solutions, so-called hybrid solitons (HSs) [3]. HSs are topologically trivial objects, which can be thought of as a SkT with one end – chiral bobber [3,4] or two ends – magnetic globule [5], where the ends are magnetic singularities – Bloch points.

In the final part, I will discuss true 3D to topological magnetic solitons or magnetic hopfions [6,7]. The magnetic hopfions can be thought of as SkTs with closed ends. Such closed tubes, in general, have the shape of complex mathematical knots. I present the micromagnetic functional [8] and magnetic interactions allowing the stability of these objects and discuss the static and dynamic properties of these objects.

**8:36AM R41.00002: Magnetic structures in 1D spin chains with long-range RKKY and Dzyaloshinskii-Moriya interactions**  
EDSON VERNEK (Presenter), OSCAR AVALOS-OVANDO, SERGIO E ULLOA, Physics and Astronomy, Ohio University — Magnetic order in 1D magnetic chains has gained considerable interest in recent years. Absent in one dimensional systems with only short-range interaction (SRI), magnetic order is still possible if long-range interaction (LRI) is present, without violating the celebrated Mermin-Wagner theorem. Indeed, interesting quantum phase transitions have been investigated in a Heisenberg chain with LRI [1]. We investigate the role of spin-orbit effects by considering spin-1/2 chains in the presence of both RKKY and Dzyaloshinskii-Moriya (DM) LRIs. Our results show an interestingly rich phase diagram in which the system transitions from collinear to transverse magnetic correlated order as the ratio between RKKY and DM coupling strength changes. We analyze the new ground states and explore their possible physical implementation in different systems.

**8:48AM R41.00003: Magnetic field induced spin liquids and quantum phase transitions in spin orbit coupled quantum magnets.**  
MINSEONG LEE (Presenter), VIVIEN ZAPF, Los Alamos National Laboratory, HAIDONG ZHOU, Physics and Astronomy, University of Tennessee — When an external magnetic field suppressed the magnetic ordering in spin-orbit coupled system, a new magnetic phase is often observed. For example, controversial theoretical and experimental results propose spin liquid behavior above in-plane 7 T where antiferromagnetic order is suppressed in a-RuCl3. Theoretical studies also show that out-of-plane magnetic field can induce spin liquid phase in this system as well. In this work, we present the analysis of inelastic neutron scattering data of a-RuCl3 and extracted g-factor and the $\Gamma/J$ using linear spin wave theory. In addition, we present the out-of-plane pulsed field data of a-RuCl3 to study a new phases predicted by theoretical studies by drawing the full field vs temperature phase diagram. We also explore the how the magnetic field breaks the orbital assisted spin dimerized phase in one dimensional spin chains, and new magnetic phases are induced to discuss the role of the orbital degrees of freedom in rescale the Hund coupling and on-site interorbital Coulomb interactions in spin-orbit coupled systems.
9:00AM R41.00004: Exchange Coupling Torque in Ferrimagnetic Bi-layer Systems at the Angular Momentum Compensation Temperature*  
ROBIN BLÄSING (Presenter), TIANPING MA, Max Planck Institute of Microstructure Physics, SEE-HUN YANG, CHIRAG GARG, IBM Almaden Res Ctr, STUART PARKIN, Max Planck Institute of Microstructure Physics — Within the last decade, the efficiency of current-induced motion of magnetic domain walls (DWs) has been enhanced tremendously by utilizing the exchange coupling torque (ECT) in synthetic antiferromagnets. In this talk we show that this mechanism also applies to ferrimagnetic layers consisting of a transition metal layer and a rare earth metal layer which couple antiferromagnetically. The motion is most efficient when the angular momenta of both layers compensate each other and the ECT is maximized. Additionally, we demonstrate that at angular momentum compensation a magnetic field, which is applied along the effective Dzyaloshinskii-Moriya interaction field, has no influence on the DW velocity. By changing the temperature of a Co/Gd ferrimagnetic bi-layer, we can to tune the ratio of angular momenta of Co and Gd and identify the angular momentum compensation temperature $T_A$. Since the device temperature is significantly increased by the current pulses, taking into account Joule heating is of major importance. The presented findings can be used for the development of novel storage devices and improving their efficiency.

9:12AM R41.00005: Spontaneous rotation of ferrimagnetism driven by antiferromagnetic spin canting*  
ANURADHA VIBHAKAR (Presenter), University of Oxford, DMITRY KHALYAVIN, PASCAL MANUEL, ISIS facility, Rutherford Appleton Laboratory, ALEXEI BELIK, National Institute for Materials Science, ROGER JOHNSON, University College London — Spin-reorientation phase transitions that involve the rotation of a crystal's magnetisation have been well characterised in distorted perovskite oxides such as the orthoferrites. In these systems spin reorientation occurs due to competing rare earth and transition metal anisotropies coupled via $f - d$ exchange. Here, we demonstrate an alternative paradigm for spin reorientation in distorted perovskites. We show that the $R_2CuMnMn_4O_{12}$ ($R = Y$ or Dy) triple A-site columnar ordered quadruple perovskites have three ordered magnetic phases and up to two spin reorientation phase transitions. Unlike the spin reorientation phenomena in other distorted perovskites, these transitions are independent of rare earth magnetism, but are instead driven by an instability towards AFM spin canting originating in frustrated Heisenberg exchange interactions, and the competition between Dzyaloshinskii-Moriya and single-ion anisotropies.

9:24AM R41.00006: Using structural phase transitions to enhance the coercivity of ferromagnetic films  
RYAN NEED (Presenter), Materials Science and Engineering, University of Florida, JOSHUA P LAUZIER, LOGAN SUTTON, Physics, Colorado State University, BRIAN JAMES KIRBY, National Institute of Standards and Technology, JOSE DE LA VENTA, Physics, Colorado State University — Heat-assisted magnetic recording (HAMR) is a promising magnetic information storage technology that uses a heating step to lower the coercivity of the recording media and decrease the energy of each writing operation. However, HAMR currently requires temperature increases of several hundred Kelvin, which can cause heat spreading and limit recording rates. Here, we describe a mechanism for tuning the coercivity of ferromagnetic films over small temperature ranges by coupling them to a layer that undergoes a structural phase transition. The method is demonstrated in Ni/FeRh bilayers where Ni layers were deposited either above or below the FeRh metamagnetic transition at 370 K. When the Ni layer is grown at high temperatures, the 1% FeRh lattice expansion alters the Ni’s crystallographic texture and leads to a 500% increase in coercivity upon cooling through the FeRh’s metamagnetic transition. Analysis suggests this effect is due to domain wall pinning across grain boundaries with different orientations and strain states. Our work highlights a means to increase the thermal coercivity response of ferromagnetic materials through structural coupling to underlying films, which could enable simplified heatsink designs and expand the selection of materials compatible with HAMR.

9:36AM R41.00007: Parity-Time Symmetric Spintronics and Spin Cavitronics*  
YUNSHAN CAO, HUANHUAN YANG, CHEN WANG, TIANLIN YU (Presenter), PENG YAN, University of Electronic Science and Technology of China — Non-Hermitian Hamiltonian obeying parity-time (PT) symmetry can exhibit real spectra and a spontaneous symmetry breaking accompanied by a real-to-complex spectral phase transition at the ‘exceptional point (EP)’. Here, we predict that a ferromagnet with gain (loss) is equivalent to an antiferromagnet with an equal amount of loss (gain), and show a ferromagnet to antiferromagnet phase transition in PT-symmetric magnetic bilayers when the balanced gain-loss parameter exceeds a critical value. We then generate the idea to a spin cavitronic device that allows the strong coupling between photons and magnons. We demonstrate a “Z”-shape transmission spectrum in the exact PT phase. The spectrum evolves to a step function when the polariton touches the third-order exceptional point. The estimated magnetic sensitivity can approach $10^{-15}$ T Hz$^{-1/2}$ around the third-order EP. Our work paves the way for investigating the parity-time symmetry in spintronics and spin cavitronics, and for designing ultrasensitive magnetometers.

9:48AM R41.00008: Ultrafast Control of Charge Density and Spin Density waves in Chromium   LOUIS PONET (Presenter), Istituto Italiano di Tecnologia, OLEG GOROBTSOV, ANDREJ SINGER, Cornell University, SERGEY ARTYUKHIN, Istituto Italiano di Tecnologia — Experimental advances in ultrafast physics have allowed to monitor structural and electronic processes and even phase transitions on their natural timescales. Here we model recent experiments on ultrafast control of spin density wave phase in elemental Chromium with a sequence of optical pulses. The strain wave and CDW, induced by the spin density modulation via exchange striction, are monitored using x-ray diffraction. Results show order parameter oscillations and a partial melting of the SDW in response to optical pulses. Interestingly, depending on the exact delay between two sequential optical pulses, one can increase or decrease the oscillation amplitude, allowing for optimal control. We use Landau theory and heat transfer equations to describe the dynamics of the interacting charge and spin density waves. All details of the experiment are replicated to a high degree by the model.

10:00AM R41.00009: Realizing corner states in artificial crystals based on topological spin textures*   PENG YAN (Presenter), ZHIXIONG LI, YUNSHAN CAO, University of Electronic Science and Technology of China, XIANG RONG WANG, Physics, The Hong Kong University of Science and Technology — The recent discovery of higher-order topological insulators (HOTIs) has significantly extended our understanding of topological phases of matter. Here, we predict that second-order corner states can emerge in the dipolar-coupled dynamics of topological spin textures in two-dimensional artificial crystals. Taking a breathing honeycomb lattice of magnetic vortices as an example, we derive the full phase diagram of collective vortex gyrations and identify three types of corner states that have not been discovered before. We show that the topological "zero-energy" corner modes are protected by a generalized chiral symmetry in the sexpartite lattice, leading to particular robustness against disorder and defects, although the conventional chiral symmetry of bipartite lattices is absent. We propose the use of the quantized Z_6 Berry phase to characterize the nontrivial topology. Full micromagnetic simulations confirm the theoretical predictions with good agreement. Our findings open up a promising route for realizing higher-order topologically protected corner states in magnetic systems and finally achieving topological spintronic memory and computing.

10:12AM R41.00010: 3D Topological solitons in chiral magnets  ROBERT VOINESCU (Presenter), IVAN I SMALYUKH, JUNG-SHEN TAI, University of Colorado, Boulder — Three dimensional knotted solitons are continuous field configurations classified by a Hopf topological invariant. These quasi-particles are known to arise in many laboratory systems and more exotic settings ranging from theories in particle physics to cosmology. By exploiting the external magnetic field and crystalline anisotropy couplings in a micromagnetic hamiltonian we numerically model a new class of 3D topological solitons embedded in a helical background. We determine the parameter region of stability afforded by the non-trivial twisting and windings present in our particle-like excitation. Furthermore, we analyze individual topological solitons and an ensemble of such in the bulk with multiparticle simulations to determine their interaction and self-assembly properties. Finally, we discuss how such topological excitations may find uses in racetrack magnetic memory devices and spintronics applications.

10:24AM R41.00011: Unprecedented Electronic Structure, Magnetism, and Anisotropy in Rare Earth Intermetallics  DURGA PAUDYAL (Presenter), RENU CHOUDHARY, Ames Lab, RALPH SKOMSKI, University of Nebraska — We investigate magnetic rare earth intermetallics with quantum properties. Many quantum features of rare earth intermetallics are consistent with the past research, but some of the findings are seemingly contradictory. The disagreement is not caused by numerical errors or accidental mistakes but reflects how the many-electron nature of the rare-earth 4f electrons is interpreted by crystal-field and local spin density approximation with onsite electron correlation and spin orbit coupling theories [Das et. al, PRB 100, 024419 (2019)]. The two-sublattice crystal-field theory describes a broad variety of physical properties exhibited by rare earth transition metals, such as the temperature dependence of magnetization and anisotropy, but it is not a first-principles approach. By contrast, our first-principles approach yields a substantial orbital-moment quenching, which violates Hund's rules and is contradictory to conventional knowledge accumulated over decades of rare-earth research. Rationalizing the orbital-moment quenching in terms of the dependence of the 4f charge distribution on the magnetization angle, we argue that medium- and long-run future research will be necessary to reconcile experiment, sublattice models, and first-principle calculations in rare earth intermetallics.
10:36AM R41.00012: Nanoscale Spatial Dependence of Photoinduced Structural Phase Transition in FeRh*  YOUNGJUN AHN (Presenter), Department of Materials Science and Engineering, University of Wisconsin - Madison, MATHEW J. CHERUKARA, Center for Nanoscale Materials, Argonne National Laboratory, ZHONGHOU CAI, DONALD A WALKO, Advanced Photon Source, Argonne National Laboratory, MICHAEL BARTLEIN, TAO ZHOU, Center for Nanoscale Materials, Argonne National Laboratory, JAN-ULRICH THIELE, Seagate Technology, ERIC FULLERTON, Center for Magnetic Recording Research, University of California at San Diego, MARTIN HOLT, Center for Nanoscale Materials, Argonne National Laboratory, PAUL G. EVANS, Department of Materials Science and Engineering, University of Wisconsin - Madison, HAIDAN WEN, Advanced Photon Source, Argonne National Laboratory — Simultaneous temporal and spatial characterization of materials with high resolution provides multidimensional data essential for a deeper understanding of nanoscale heterogeneities that arise from complex interactions during solid-solid phase transitions. Time-resolved hard x-ray microscopy has unique capabilities to provide a direct structural probe. Here, using newly developed x-ray diffraction microscopy with unprecedented 100 ps and 30 nm resolution at the Advanced Photon Source, we have observed the nanoscale dependence of the structural relaxation dynamics following ultrafast laser excitation of an FeRh thin film. The spatial dependence is linked to variations in spatially inhomogeneous strain, resulting in different thresholds for driving the antiferromagnetic-ferromagnetic phase transition. In addition, we have found the spatially different degree of the broadening of transition in temperature near nano-island regions. The observed relationship between lattice parameter and transition threshold gives new insight on the photoinduced phase transition at the nanoscale and has important implications in heat-assisted magnetic recording.

10:48AM R41.00013: Electric-field control of the interlayer exchange coupling*  SHEHRIN SAYED (Presenter), CHENG-HSIANG HSU, NIKLAS ROSCHEWSKY, EECS, University of California, Berkeley, SEE-HUN YANG, IBM Research, Almaden, SAYEEF SALAHUDDIN, EECS, University of California, Berkeley — Magnetization switching with electric-field is of great current interest to achieve high density and low energy non-volatile memory devices. We propose a new mechanism for electric-field controlled magnetization switching, assisted solely by the interlayer exchange coupling (IEC) between the fixed and the free magnets. Using non-equilibrium Green's function (NEGF) method, we show that the resonant tunneling mechanism can tune the IEC with an electric-field, which in turn can switch the free magnet to have either a parallel or antiparallel configuration with respect to the fixed magnet, depending on the sign of the IEC. Such bi-directional switching can be achieved with the same voltage polarity but different magnitudes. Due to the 'conservative' nature of the exerted torque by IEC, the switching threshold is decoupled from the speed, while the conventional spin-torque devices exhibit a trade-off due to the 'non-conservative' nature of the exerted torque.

8:00AM R42.00001: Manipulation of magnetic coupling and magnon transport in magnetic insulator-ferromagnetic metal hybrid structures [Invited]  YABIN FAN (Presenter), Massachusetts Institute of Technology MIT, PATRICK QUARTERMAN, National Institute of Standards and Technology, JOSEPH FINLEY, Massachusetts Institute of Technology MIT, ALEXANDER GRUTTER, National Institute of Standards and Technology, LUQIAO LIU, Massachusetts Institute of Technology MIT — Magnetic insulators and ferromagnetic metals are widely used in spintronic structures for the generation of magnon spin current, control of magnetization states, and for detecting magnon spins. Most of the previous spintronic structures are based primarily on either magnetic insulators or ferromagnetic metals, and the heterostructures that integrate both have not been fully explored while they may exhibit new magnetic coupling and magnon transport properties. Here, we introduce a Pt/yttrium iron garnet (YIG)/permalloy(Py) hybrid structure grown on Si substrate, where YIG is a ferrimagnetic insulator and Py is a ferromagnetic metal. Surprisingly, the YIG and the Py layers show antiferromagnetic coupling when external field is small, and the two layers align to the same direction only when in-plane field is large enough, as evidenced by both vibrating-sample magnetometry and polarized neutron reflectometry measurements. More importantly, the parallel and antiparallel magnetization configurations in this YIG/Py structure could be utilized to control magnon spin current in spin-pumping and spin Seebeck experiments. With easy access to grow by magnetron sputtering, fully controllable magnetization configuration, and efficient control of magnon spin current, the Pt/YIG/Py hybrid structure could potentially find applications in spin logic devices that are fabricated on a Si chip.
8:36AM R42.00002: Xe-PFIB microstructuring of Yttrium Iron Garnet films for quantum magnonic applications  DMYTRO BOZHKO (Presenter), Department of Physics, University of Colorado at Colorado Springs, PAUL BAITY, SERGEY DANILIN, RAIR MACEDO, VALENTINO SEFERAI, UMBERTO NASTI, ALESSANDRO CASABURI, James Watt School of Engineering, University of Glasgow, WILLIAM SMITH, STEPHEN MCVITIE, School of Physics and Astronomy, University of Glasgow, ROBERT HADFIELD, MARTIN WEIDES, James Watt School of Engineering, University of Glasgow — Recently, the growing interest in quantum magnonics triggered intensive investigation of magnetic materials in the quantum limit. One of the main challenges in this area is to achieve long magnon lifetimes at cryogenic temperatures. Among all currently known magnetic materials, single-crystal Yttrium Iron Garnet (YIG, Y₃Fe₅O₁₂) possesses the lowest damping due to low spin-orbit coupling. Thin YIG films are, however, grown on GGG (Gd₃Ga₅O₁₂) substrates, which induce high magnetic damping at low temperatures [1]. Here we report on using Xenon Plasma Focused Ion Beam (Xe-PFIB) technique to prepare high-quality microstructured YIG films detached from GGG substrates. This technique allows production of relatively large (50 x 50 x 20 µm³) structures in a reasonable time of a few hours. The magnetic properties of these samples were evaluated using broadband ferromagnetic resonance spectroscopy in a wide temperature range (down to 80mK). Additional investigations were done by means of wavevector-resolved Brillouin light scattering spectroscopy. Through these techniques, we evaluate the effects of Xe-PFIB structuring on the magnetic damping. We believe that our findings will pave the way to efficient implementation of YIG elements into hybrid quantum circuits.

8:48AM R42.00003: Py-Cu Graded-Index Magnonic Waveguides*  KRISTEN REPA (Presenter), CELIA MERCOVICH, CASEY MILLER, Rochester Institute of Technology — Spin waves (magnons) have many optical analogies, including the law of reflection, which allows total internal reflection (akin to a fiber optic cable). For this reason, we’re working to create a magnonic waveguide made from Py-Cu multilayered films. We grow films via sputter deposition with a 10 nm core of Py₀.₈Cu₀.₂ that is symmetrically bound by 10 nm of Cu and 10 nm of Py₀.₆Cu₀.₄. Py-Cu alloys are attractive for this study because we can easily tune magnetic properties by changing the Cu content of each layer (Tₐ decreases as Cu content increases). We measure samples using ferromagnetic resonance (FMR) with frequencies from 3-20 GHz and fit results to the Kittel equation. We extract values for the Gilbert damping parameter and inhomogeneous broadening, which informs us of how magnons propagate through each multilayer film. Ideally, if we reverse the magnetic layers, instead of seeing total internal reflection, we should observe a complete spin absorber.

Non-linear spin torque, pumping and cooling in superconductor/ferromagnet systems

RISTO OJAJÄRVI (Presenter), Department of Physics and Nanoscience Center, University of Jyväskylä, JUUSO MANNINEN, Department of Applied Physics, Low Temperature Laboratory, Aalto University, PAULI VIRTANEN, TERO T HEIKKILÄ, Department of Physics and Nanoscience Center, University of Jyväskylä — We study the effects of the coupling between magnetization dynamics and the electronic degrees of freedom in a heterostructure of a metallic nanomagnet with dynamic magnetization coupled with a superconductor containing a steady spin-splitting field. We predict how this system exhibits a non-linear spin torque, which can be driven either with a temperature difference or a voltage across the interface. We generalize this notion to arbitrary magnetization precession by deriving a Keldysh action for the interface, describing the coupled charge, heat and spin transport in the presence of a precessing magnetization. We characterize the effect of superconductivity on the precession damping and the anti-damping torques. We also predict the full non-linear characteristic of the Onsager counterparts of the torque, showing up via pumped charge and heat currents. For the latter, we predict a spin-pumping cooling effect, where the magnetization dynamics can cool either the nanomagnet or the superconductor.

Acoustic Ferromagnetic Resonance Assisted Spin-Torque Switching of Perpendicular MTJs

WALID AL MISBA (Presenter), MD MAHADI RAJIB, DHRITIMAN BHATTACHARYA, JAYASIMHA ATULASIMHA, Virginia Commonwealth Univ — Resonant Surface Acoustic Wave (SAW) assisted Spin Transfer Torque (STT) can drive the magnetization of a perpendicular magnetic tunnel junction (p-MTJ) and write bits with an order of magnitude lower energy dissipation compared to the conventional STT current approach [1]. Simulations show that such acoustically driven ferromagnetic resonance (FMR) results in the magnetization precessing in a cone with large deflections relative to the perpendicular direction. The larger the precession angle, the lower the STT current required for switching the magnetization. While our prior simulations [1] of such magnetization dynamics were based on macro-spin assumptions, here we will perform micromagnetic simulations to study incoherent switching in the presence of room temperature thermal noise as well as incorporate realistic effects such as material inhomogeneity, grains, surface roughness and lithographic imperfections. The ramification of such incoherency in magnetization dynamics on the switching error will be discussed. Preliminary experimental work will also be presented.

9:24AM R42.00006: Transport and Magnetic Properties of Amorphous Fe:Dy Oxide Films.
SARA BEY (Presenter), OLIVIA DENTON, TATIANA ALLEN, Univ of Tennessee, Chattanooga, KRISHNA KOIRALA, University of Tennessee, WILLIAM ROES, Tennessee Valley Association, GERD DUSCHER, RAMKI KALYANARAMAN, University of Tennessee — Novel amorphous FeDy-Oxide thin films, deposited by e-beam evaporation, show room-temperature magnetism, as well as high electrical conductivity, carrier mobility, and optical transparency that is very promising for a multitude of applications. We have systematically studied transport, optical and magnetic properties of a large set of films deposited on Quartz and SiO2/Si substrates at different oxygen partial pressures [10-6,10-8,10-9 Torr]. Atomic ratios of Fe to Dy in the films (confirmed by EDS) varied from 0.3 to 6, but all samples had resistivity less than 2.5E-03 Ohm*cm. Optical bandgap of as prepared films was 2.4±0.1 eV. The films showed high ordinary Hall mobility (~10 cm2/V-s) which is among the highest for amorphous oxides, as well as anomalous Hall mobility (~102 cm2/V-s). At low temperatures there was two step magnetization that suggests coexistence of two magnetic phases below H=0.08 T and ferromagnetic phase at higher fields. Select films were taken through cyclic annealing (300-700K) which, after 3 cycles, resulted in still amorphous, thermally stable homogeneous FeDyO material. These results will motivate further investigation into the fundamental mechanisms responsible for these properties and how they might be tuned for integration in devices.

9:36AM R42.00007: Nonlinear Optical Imaging of Current Induced Spin Switching in Antiferromagnetic Materials* JOONGWON LEE (Presenter), YONGJIAN TANG, ANTONIO B MEI, OKAN KOKSAL, DARRELL SCHLOM, DANIEL RALPH, FARHAN RANA, Cornell University — Electrical switching of the Neel order in Antiferromagnetic (AF) materials via spin transfer (STT) has attracted considerable attention [1,2]. Experiments have shown that AF switching is non-uniform, influenced by magneto-elastic coupling, and the efficacy of STT in inducing AF switching has also been questioned [3]. In this paper, we show that scanning optical second harmonic generation (SHG) can be used to image and identify magnetic domains in inversion symmetric AF materials. Using this technique, we image magnetic domains in nanometer thick epitaxial AF layers. We show that the SHG technique can image even when AF materials are covered with metallic spin Hall layers such as Pt. We use scanning SHG to study electrical switching in NiO/Pt devices. Our results show that AF switching is non-uniform across our 100 sq-micron devices. We observe regions that show AF switching in agreement with the STT predictions and regions where magnetoelastic effects seem to dominate, and we also see regions which exhibit no evidence of switching. The contributions of various effects will be discussed. [1] Phys. Rev. Lett. 120, 207204 (2018). [2] Scientific Reports 8, 14167 (2018). [3] arXiv:1907.00314 (2019).

AURELIEN MANCHON (Presenter), Physics Department, Aix-Marseille University, SUMIT GHOSH, ADEL ABBOUT, GUILHEM MANCHON, AHEMD HAJIR, ABDULKARIM HARIRI, King Abdullah Univ of Sci & Tech (KAUST) — Magnetic materials lacking inversion symmetry constitute a unique platform for the exploration and control of magnetism [1]. In these systems, typically multilayers of transition metal ferromagnets and heavy metals (W, Pt, Bi$_2$Se$_3$ etc.), interfacial spin-orbit coupling promotes a wealth of physical phenomena, among which the emergence of magnetic skyrmions – topological magnetic textures –, spin-orbit torques– an efficient means to electrically control magnetization dynamics –, as well as chiral magnetic damping – energy dissipation that depends on the texture chirality. While most of the initial theoretical progress has been achieved using minimal models (e.g., the Rashba two-dimensional gas), we have recently developed a multiorbital tight-binding model of such heterostructures that enables us to model these various phenomena on equal footing and in a transparent manner [2,3]. Based on the results of this model, I will address various aspects of the interplay between spin transport and magnetism mediated by spin-orbit coupling. I will first discuss the orbital nature of interfacial spin-orbit coupling in multilayers and examine how it facilitates the onset of chiral magnetic textures. I will then present the physics of spin-orbit torques, and inspect their relation to chiral magnetic properties such as Dzyaloshinskii-Moriya interaction and chiral magnetic damping. Finally, I will discuss the current-driven dynamics of magnetic skyrmions and propose various strategies to enhance their mobility, exploiting topological spin currents flowing through the texture [4].

Magnetotransport properties of granular oxide-segregated CoPtCr films for applications in future magnetic memory technology*  

MORGAN WILLIAMSON, MAXIM TSOI (Presenter), University of Texas at Austin, PIN-WEI HUANG, GANPING A JU, CHENG CW WANG, Fremont Research Center, Seagate Technology — Magnetotransport properties of granular oxide-segregated CoPtCr films were studied on both macroscopic and microscopic length scales by performing bulk and point-contact magnetoresistance measurements, respectively. Such a perpendicular magnetic medium is used in state-of-the-art hard disc drives and if combined with magnetoresistive phenomena (for read/write operations) may lead to a novel concept for magnetic recording with high areal density. While the bulk measurements on the films showed only small variations in dc resistance as a function of applied magnetic field (magnetoresistance of less than 0.02 %), the point-contact measurements revealed giant-magnetoresistance-like changes in resistance with up to 50,000 % ratios. The observed magnetoresistive effect could be attributed to a tunnel magnetoresistance between CoPtCr grains with different coercivity. The tunneling picture of electronic transport in our granular medium was confirmed by the observation of tunneling-like current-voltage characteristics and bias dependence of magnetoresistance; both the point-contact resistance and magnetoresistance were found to decrease with the applied dc bias.

The spontaneous electrical and spin Hall effect in a collinear antiferromagnet*  

GEN YIN (Presenter), Department of Electrical and Computer Engineering, University of California, Los Angeles, JIE-XIANG YU, Department of Physics, University of Florida, ROGER LAKE, Department of Electrical and Computer Engineering, University of California, Riverside, JIADONG ZANG, Department of Physics and Astronomy, University of New Hampshire, KANG L. WANG, Department of Electrical and Computer Engineering, University of California, Los Angeles — In collinear antiferromagnets, since the combined operation of time reversal and a half-unit-cell translation is symmetric for the magnetic lattice, a spontaneous Hall effect is usually absent. Here, we show that in a collinear antiferromagnet, MnTe, the non-magnetic atomic structure breaks such symmetry, therefore allows a spontaneous Hall effect, which is known as planar Hall effect. Such spontaneous Hall effect does not result from the intrinsic Berry curvature. Instead, it comes from the extrinsic scattering centers with either positive or negative polarized spins along the easy axis of the Neel vector. This behavior is intriguing since it is by now the most convenient method to read-out (and potentially to write) the information encoded in antiferromagnets for high-speed device applications. Such zero-field planar Hall effect has already been observed in experiments. Our calculation shows that the spontaneous Hall effect and spin Hall effect can be up to 30%, suggesting a vast space to improve the performance for device applications.

8:00AM R43.00001: Creating Novel Magnetic Compounds with Complementary Experimental and Computational Methods* [Invited] BALAMURUGAN BALASUBRAMANIAN, DAVID SELLMYER (Presenter), Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska — New materials discovery has governed the development of science and technology for decades. In particular, the search for new magnetic compounds is important to satisfy ever-increasing demand for magnets with a wide range of applications including spintronics, data storage, hybrid vehicles, and wind turbines. This requires efficient computational and experimental approaches for high throughput and efficiency [1]. When increasingly powerful computational techniques are combined with special fabrication methods far from equilibrium, the search also can uncover new metastable magnetic compounds [2-6]. This talk will focus on the development of novel magnetic compounds with high magnetocrystalline anisotropy, magnetization, and Curie temperature by combining experiments, an adaptive genetic algorithm search, and electronic-structure calculations. Magnetism of novel compounds such as Fe$_{3+x}$Co$_{3-x}$Ti$_2$, Co$_3$N, Fe$_2$CoC, and Co$_3$Si will be discussed in terms of intrinsic atomic-scale and extrinsic nanoscale effects. This research is done in collaboration with D.J. Sellmyer, C.Z. Wang, K.M. Ho, X. Xu, and J. R. Chelikowsky.

8:36AM R43.00002: A high throughput workflow for magnetic ferroelectrics from first-principles

STEPHANIE MACK (Presenter), University of California, Berkeley, TESS E SMIDT, SINÉAD GRIFFIN, JEFFREY B NEATON, Lawrence Berkeley National Laboratory — Multiferroics, which combine ferroelectricity and magnetism, are of great interest for a variety of electronics applications. Although discovery of new multiferroics based on chemically manipulating known structural motifs has yielded new candidates, there are still relatively few known multiferroics with highly tunable electric and magnetic orders at room temperature. Using symmetry constraints based on Landau theory of phase transitions, and on the identification of both a polar and nonpolar reference structure, and first-principles density functional theory calculations using the Materials Project database, we develop a high throughput workflow to predict the ground state magnetic ordering and spontaneous polarization of new multiferroic candidate materials. Comparison to known multiferroics will be discussed, and we will classify the most promising candidate materials to aid future synthesis efforts. This work is supported by the Department of Energy through the Materials Project FWP at Berkeley Lab. Computational resources provided by NERSC.

8:48AM R43.00003: Generating a database of predicted ground-state magnetic orderings of inorganic crystalline materials suitable for high-throughput screening applications

MATTHEW HORTON (Presenter), KRISTIN PERSSON, Lawrence Berkeley National Laboratory — Bridging the gap from toy model to synthesizable material and ultimately to working device is of crucial importance when investigating exotic magnetic phenomena. Since 2011, The Materials Project has offered an open-access database of inorganic crystalline materials and their associated properties as calculated by Density Functional Theory. However, to date, the magnetic ordering of these materials has not been explored in a systematic way.

We have developed a workflow suitable for high-throughput use, benchmarked to experiment, to predict the ground-state magnetic ordering for ferromagnetic, antiferromagnetic and ferrimagnetic materials with collinear spin even in the case of multiple magnetic sub-lattices and complex orderings[1]. This workflow has been applied to create a large database of predicted ground states for transition metal oxides which can be searched across a variety of axes including magnetic lattice type.

We share an example of screening this database for discovery of new materials for magnetocaloric applications.

TANUSRI SAHA-DASGUPTA (Presenter), ANITA HALDER, S N Bose Natl Ctr Basic Sci, AISHWARYO GHOSH, Presidency University — In the present study, we use a combination of computational tools; machine learning technique for screening of stable candidates, evolutionary algorithm for crystal structure determination, and first-principles calculations for characterization of electronic and magnetic states, to make predictions on a set of new magnetic double-perovskites of composition $A_2BB'O_6$. Out of 412 scanned candidates composition with 3$d$ and 4$d$ or 5$d$ transition metals at B and B' sites, 33 compounds are found to form in stable double-perovskite structure, 25 of which are further considered for characterization of their crystal structure and properties. This exercise provides 21 new double-perovskites of varying magnetic and electronic properties, which range from ferromagnetic half-metals to ferri- and antiferro-magnetic insulators to ferromagnetic metals and rare example of antiferromagnetic metals. Our computational study is expected to help in discovering new magnetic double perovskites.

*The authors acknowledge funding from Department of Science and Technology, India.
Defects and impurities play an important role in determining the properties of materials and must be carefully considered as part of materials design and synthesis. This applies to semiconductors and materials used for energy generation and storage. Defects can act as electron donors or acceptors, implying that their concentrations can be tuned by introducing oppositely charged species. These dopants must be carefully chosen to avoid undesirable side effects, such as autocompensation or, in the case of ionic conductors, high mobile carrier binding energies.

We discuss how first-principles calculations can address these considerations for two promising solid-state hydrogen electrolyte materials. The alkaline-earth zirconates (AeZrO$_3$; Ae = Sr, Ca, Ba) are solid-state hydrogen conductors in which protons move interstitially. Oxygen vacancies, which act as donors, act as precursors to proton incorporation. To maximize oxygen vacancy concentrations, acceptor dopants are introduced. We identify the alkali metal dopants that are most ideal for incorporating oxygen vacancies, while avoiding harmful compensation effects.\(^1\) The alkaline-earth hydrides (AeH$_2$) conduct hydrogen via a vacancy-mediated mechanism. Optimizing the vacancy concentration again requires the introduction of acceptor dopants, and alkali metal dopants are most effective to this end. We estimate an increase in ionic conductivity by roughly two orders of magnitude in the case of BaH$_2$ doped with potassium.\(^2\) We discuss implications of our results for studies of other novel hydrogen-conducting materials and, in general, how to use defect engineering to optimize material performance.

9:48AM R43.00006: Atomistic Kinematics of Carbon Diffusion and Clustering in BCC Fe with Point Defects*  
TIEN QUANG NGUYEN (Presenter), Institute for NanoScience Design, Osaka University, 
KAZUNORI SATO, Division of Materials and Manufacturing Science, Graduate School of Engineering, Osaka University, 
YOJI SHIBUTANI, Division of Mechanical Engineering, Graduate School of Engineering, Osaka University — Carbon diffusion and clustering in iron are important phenomena as they closely link to processes of production of steels such as cementite formation, phase transition, and so on. Here, we studied these phenomena using multi-scale approach. First, the stability of carbon and its interaction with point defect were examined via total energy optimization using our own newly developed Fe-C potential. Then, the diffusion mechanisms for carbon interstitials were analyzed. By using kinetic Monte Carlo (kMC) simulations, diffusion coefficients of carbon depending on temperature were estimated to clarify the influence of vacancy on the diffusion and clustering processes. We found that in perfect lattice, carbon atoms tend to form stable C-C pairs, while the presence of vacancies leads to the formation of larger vacancy-carbon (VC_n) clusters with VC_2 as the most stable structure. In addition, due to the presence of vacancies, the diffusion paths of carbon are strongly modified. The kMC simulations show that diffusion coefficient is decreased as vacancy content increases. Therefore, it is suggested that vacancies may play an important role in the clustering process of carbon.

10:00AM R43.00007: First-principles Study of Large Seebeck Coefficients in Fe-doped Si-Ge Alloys*  
RYO YAMADA ( Presenter), Division of Materials and Manufacturing Science, Osaka University, 
AKIRA MASAGO, Center for spintronics research network (CSRN), Osaka University, 
TETSUYA FUKUSHIMA, Institute for Solid State Physics, University of Tokyo, 
HIKARI SHINYA, Research Institute of Electrical Communication, Tohoku University, 
TIEN QUANG NGUYEN, Institute for NanoScience Design, Osaka University, 
KAZUNORI SATO, Division of Materials and Manufacturing Science, Osaka University — Si-Ge alloys are one of the cheapest nontoxic thermoelectric materials utilized at high temperatures, but their dimensionless figure of merit, $ZT$, is relatively small. To improve their low $ZT$ values, there are some attempts to modify an electronic band structure by doping Fe, and it has been reported that a high $ZT$ value, $ZT>1.88$ (at $T=873K$), as well as a large Seebeck coefficient, $|S|>517\mu V/K$ (at $T=673K$), were produced in the nanostructured Si$_{0.55}$Ge$_{0.35}$P$_{0.10}$Fe$_{0.01}$ sample [1]. It is believed that they originate from a strong peak at the edge of the conduction band generated by the Fe-doping (a so-called impurity state). However, an occurrence of the impurity state in the Fe-doped Si-Ge system has not been confirmed yet. In this work, therefore, the impurity state in the Fe-doped Si-Ge alloys is calculated from an electronic band structure calculation, and the reported large Seebeck coefficient is reproduced with the use of the linear response theory. Using a special quasi-random structure with a hybrid functional (HSE06), the impurity state was successfully produced, and computed Seebeck coefficients showed good agreement with the experimental data.

10:12AM R43.00008: Assessing Aqueous Stability of Nonequilibrium Nickel Chromium Oxides from First Principles*  KATHLEEN MULLIN (Presenter), MICHAEL WATERS, JAMES RONDINELLI, Northwestern University — Ni-Cr alloys are used in high temperature applications where corrosion resistance is critical to performance. It has generally been thought that this corrosion resistance comes from a passive film made of NiO with the rock salt crystal structure and Cr$_2$O$_3$ with the corundum crystal structure. Recently, however, new data shows that valence-precise compositions and bulk equilibrium structures do not necessarily form in the ultrathin limit[1]. Specifically, Ni-Cr alloys form nonequilibrium phases through a solute capture process, whereby Ni-Cr oxide in the rock salt structure with unexpectedly large solubility of Cr on the Ni lattice occurs (and likewise for Ni in the corundum lattice). In order to better understand the formation of this nonequilibrium oxide, we use ab-initio Density Function Theory calculations to parameterize a cluster expansion model of the Ni-Cr-O system as a function of Cr and Ni content. Next, we use energies of formation derived from the cluster-expansion for use in electrochemical Pourbaix diagrams to understand the impact of the nonequilibrium compositions on the stability of the oxide in aqueous environments.

10:24AM R43.00009: Influence of cation site disorder in ZnGeN$_2$ on electronic properties  JACOB CORDELL (Presenter), NREL/Colorado School of Mines, JIE PAN, National Renewable Energy Laboratory, CELESTE MELAMED, NREL/Colorado School of Mines, GARRITT TUCKER, Mechanical Engineering, Colorado School of Mines, ADELE TAMBOLI, STEPHAN LANY, National Renewable Energy Laboratory — Cation disorder-dependent II-IV-V$_2$ materials show promise for tuning band gaps with lattice parameters matched to their analogue III-V semiconductors for use in energy-relevant devices such as LEDs and PV. Disorder-synthesis-property relationships for these materials are not well understood, but new computational techniques can provide information complementary to experimental investigations and reveal the underlying physics of these materials. Using a combination of first principles, cluster expansion, and Monte Carlo methods, we investigated cation disorder in ZnGeN$_2$ and its effect on electronic structure as a function of effective temperature. We identify an order-disorder transition at an effective temperature of 2500K (achievable using nonequilibrium synthesis), where the local environment of nitrogen changes from exclusively 2:2 Zn:Ge coordination to the inclusion of higher energy motifs. Since ordering is a complex effect with implications on multiple length scales, metrics for assessing ordering based on cation site occupancy are compared for disordered structures at effective temperatures above this transition. This study provides insight into the synthesis-property relationship for ZnGeN$_2$ and provides a point of comparison with other ternary semiconductor systems.
Perfect short-range ordered alloy with line-compound-like properties in the ZnSnN$_2$:ZnO system*  

**STEPHAN LANY** (Presenter), **JIE PAN**, National Renewable Energy Laboratory, **JACOB CORDELL**, **GARRITT TUCKER**, Colorado School of Mines, **ANDRIY ZAKUTAYEV**, **ADELE TAMBOLI**, National Renewable Energy Laboratory — Inorganic crystalline materials are either line compounds or solid solutions, and computational materials discovery has so far focused primarily on the former. We here present a new condensed-matter phase which is a disordered solid solution but offers many ordered line-compound features. The emergent physical phenomena are rooted in the perfect short-range order. We model the dual-sublattice mixed semiconductor alloy (ZnSnN$_2$)$_{1-x}$(ZnO)$_{2x}$ using first-principles calculations, Monte-Carlo simulations with a model Hamiltonian, and an extension of the regular solution model by incorporating short-range order. We demonstrate that this unique solid solution, occurring at a “magic” composition, can provide an electronically pristine character without disorder-induced charge localization and, therefore, a superior carrier transport similar to ordered phases. Interestingly, this phase shows singularities that are absent in the conventional solid-solution models, such as the regular solution and band-gap bowing model. Thermodynamically, this alloy phase has a sharply reduced enthalpy at its composition (like a line compound), but it still requires the entropy from long-range disorder to be stabilized at experimentally accessible temperatures.

The design of disordered three-dimensional auxetic networks*  

**MENG SHEN** (Presenter), **MARCOS REYES-MARTINEZ**, **EDWIN P CHAN**, **CHRISTOPHER SOLES**, **NIST**, **NIDHI PASHINE**, **SIDNEY ROBERT NAGEL**, **HEINRICH M. JAEGER**, **JUAN DE PABLO**, University of Chicago — Auxetic materials are characterized by a negative Poisson's ratio. They have attracted a lot of attention from both the scientific and engineering communities because of a variety of potential applications, such as impact mitigation, indentation resistance and biocompatibility. The design of auxetic materials is usually realized in lattice-based periodic structures in an Edisonian way. Disordered networks have the potential for the design of tunable isotropic auxetic metamaterials. However, the design of disordered three-dimensional auxetic networks has been challenging due to lack of a universal design principle. Here we propose computational strategies for the systematic design of disordered three-dimensional auxetic networks. Our designs are validated by experimental measurement of 3D-printed networks. This work builds a powerful computational framework to manipulate the auxetic properties.

Session R44 DCOMP DMP: Electrons, Phonons, Electron Phonon Scattering, and Phononics IV  

704 - Ludger Wirtz, University of Luxembourg Limpertsberg - Tag(s): Focus
8:00AM R44.00001: Phonon anharmonicity and structural transitions – neutron scattering and first-principles simulations* [Invited] OLIVIER DELAIRE (Presenter), Duke University — Using a combination of inelastic neutron/x-ray scattering and first-principles simulations, we investigate anharmonic effects on phonons across phase transitions. This presentation will focus on transitions potentially associated with soft mode condensation. In particular, we will highlight results on phonons in SnS and SnSe across the high-temperature Pnma-Cmcm transition, in VO2 across the rutile-M1 transition, and NbNiTe2 across its subtle structural orthorhombic-monoclinic transition at 373K. The effects of phonon anharmonicity on thermal transport and thermodynamics will be discussed.

*Funding from the US DOE, Basic Energy Sciences, Materials Sciences and Engineering Division.

8:36AM R44.00002: Ab initio study of electron and hole transport in a naphthalene crystal including polaron effects BENJAMIN CHANG (Presenter), JIN-JIAN ZHOU, NIEN-EN LEE, MARCO BERNARDI, Department of Applied Physics and Materials Science, California Institute of Technology — Organic semiconductors have broad applications in electronics, but their transport properties are notoriously difficult to predict due to their complex structure, strong electron-phonon (e-ph) interactions and localized charge carriers (polarons). We recently showed [1] calculations of the hole mobility in naphthalene, assuming band-like transport and using lowest-order ab initio e-ph interactions within the Boltzmann equation approach. Although our calculations provided hole mobilities in agreement with experiment, several open questions remain, such as improving the accuracy of the method and extending it to charge transport in the polaron regime. In this work, we employ our recently developed finite-temperature cumulant-expansion method [2] to compute the electron spectral functions, and from them the mobility, in a naphthalene crystal. Our method can correctly include strong e-ph interactions and polaron effects. We will discuss the carrier spectral functions and mobilities as a function of temperature in naphthalene, comparing the results with experiments and lowest-order theory. The applicability of our method to a range of organic crystals will be discussed.

Towards ultrafast control of dielectric response through nonlinear lattice excitation

GURU KHALSA (Presenter), NICOLE A BENEDEK, JEFFREY A. MOSES, Cornell University — The development of intense laser sources in the infrared has created an opportunity for unprecedented ultrafast selective control of crystal structure. Striking changes in material properties have been achieved by the optical nonlinear phononics effect - where large amplitude infrared (IR) phonons drive Raman active phonons through nonlinear lattice coupling. [Rep. Prog. Phys. 79, 064503 (2016)] Excitation of IR phonons with light is conventionally described by coupling of the infrared electric field to a linear dipole induced by the IR phonon. When IR phonons are excited to large amplitude, when multiple optical phonons are displaced simultaneously, or when multiple laser sources are used concurrently, the conventional linear description of the crystal's dipole may be insufficient.

Using theory and first-principles calculations, we explore the implications of the nonlinear dipole moment to optical experiments. When considered in concert with nonlinear lattice coupling, we find sizable polarization dependent dielectric changes can span a broad frequency range, including frequencies far above the IR resonance. In addition to changes in the optical response, the nonlinear dipole moment provides an additional strategy for ultrafast structural control.

Theoretical Study of Pressure-Induced Superconductivity in Palladium Chalcogenides

OLIVIER GINGRAS, FELIX ANTOINE GOUDREAULT, MICHEL COTE (Presenter), Universite de Montreal — The pressure-induced superconductivity observed in palladium chalcogenides is not fully understood. Although insulating at ambient conditions, increasing isotropic pressure in PdSe$_2$ and PdS$_2$ leads to metallic phases, followed by structural transitions. These materials eventually become superconductors at higher pressure. In PdSe$_2$, the critical temperature is directly correlated with the bonding strength of Se-Se dumbbells, suggesting phonon mediated superconductivity[1]. However, the opposite is observed in PdS$_2$[2]. In order to understand the pairing mechanism in these emerging superconducting materials, we investigate the different transition temperatures using first-principles density functional theory and test the phonon mediated pairing hypothesis by calculating the superconducting dome.

*NSERC Grants No. RGPIN-2016-06666, Calcul Québec, Calcul Canada.
9:12AM R44.00005: Renormalization of magnetic interactions due to thermal disorder from first principles  MATTHEW HEINE (Presenter), Department of Physics, Boston College, OLLE HELLMAN, Department of Physics, Chemistry and Biology (IFM), Linkoping University, DAVID BROIDO, Department of Physics, Boston College — In magnetic materials, temperature dependent magnetic properties can be investigated using a Heisenberg Hamiltonian. In such a picture, raising T increases disorder in local magnetic moment orientations, the interaction of which are governed by a constant exchange parameter, J. In a more complete picture, however, such increase in moment disorder may affect the strength of the moment interactions, thereby renormalizing J as a function of T, J(T). Moreover, raising T also increases lattice disorder, which may also renormalize the interaction J(T) via spin-lattice coupling thus affecting physical quantities such as M(T) and phonon frequencies. In this study, we extend the Temperature Dependent Effective Potential (TDEP) framework to calculate such renormalized J(T) from first principles. Density Functional Theory (DFT) is employed using constrained noncollinear magnetic moments. We calculate J(T), M(T) and phonons for the test case of bcc Fe and find good agreement with experiment. We also find the lattice disorder to significantly renormalize J in the vicinity of the Curie Temperature.

9:24AM R44.00006: Emergence of Superconductivity Around Polar Quantum Critical Point in Doped Ferroelectrics*  JIAJI MA (Presenter), New York University Shanghai, RUIHAN YANG, Donald Bren School of Information and Computer Science, University of California Irvine, HANGHUI CHEN, New York University Shanghai — We combine first-principles calculations and Eliashberg equation to demonstrate that with itinerant electrons inducing a polar-to-centrosymmetric quantum critical point (pQCP) in doped ferroelectrics, softened zone-center polar phonon modes strongly couple to itinerant electrons, which enhances electron-phonon coupling around pQCP. By considering a prototypical ferroelectric material BaTiO3, we find that around its pQCP, electron-phonon coupling is increased to about 0.5, sufficiently large to induce phonon-mediated superconductivity with an optimal transition temperature of about 1 K. However, different from superconducting dome associated with other structural quantum critical points, around pQCP the superconducting transition temperature of doped BaTiO3 is enhanced much more substantially in the polar phase than in the cubic phase.

9:36AM R44.00007: Electron-phonon interactions and photoemission kink in cuprates: A GW perturbation theory study* ZHENGLU LI (Presenter), MENG WU, YANG-HAO CHAN, STEVEN LOUIE, Lawrence Berkeley National Laboratory and University of California at Berkeley — The nexus of electron-phonon (e-ph) and many-electron interactions plays an important role in shaping the electron spectral function. We present first-principles calculations of the observed photoemission kink in cuprates using our recently developed method for e-ph coupling, the GW perturbation theory (GWPT) [1]. In this approach, the e-ph coupling is calculated using linear-response theory within the ab initio GW method, combined with Wannier interpolation technique. We find that self-energy effects significantly renormalize the e-ph interactions in the cuprates, giving rise to dramatic changes in the strength of the photoemission kink as compared with results from standard density-functional perturbation theory.

*This work was supported by the Theory of Materials Program and by the Center for Computational Study of Excited-State Phenomena in Energy Materials (C2SEPEM) at the Lawrence Berkeley National Laboratory funded by the U.S. Department of Energy, Office of Basic Energy Sciences under Contract No. DE-AC02-05CH11231, and by the National Science Foundation. Computational resources have been provided by NERSC and XSEDE.

9:48AM R44.00008: First-principles study of vibrational properties of lithium niobate MONA ASADI NAMIN (Presenter), STEVEN LEWIS, University of Georgia — We present first-principles calculations of the well-known non-linear optical material LiNbO₃. Starting from the ground state properties, e.g. band structure of the stoichiometric system, we use density functional perturbation theory to find the vibrational modes. Since LiNbO₃ is a polar ferroelectric material that involves long range interactions, we use the Ewald summation to add the coulombic interaction to the dynamical matrix formalism. The transverse and longitudinal modes are in good agreement with the other ab-initio calculations, as well as the spectroscopic measurements. In addition, we calculate the relative stability of various intrinsic and extrinsic defects in this material and study their effect on the electronic, optical, and vibrational properties of this system. Achieving desirable defect properties is essential for improving the photorefractive response of LiNbO₃.

10:00AM R44.00009: BaTiO₃ as electric field controllable reservoir of phonon angular momentum* KEVIN MOSENI (Presenter), SINISA COH, Materials Science and Engineering, University of California, Riverside — We studied the angular momentum of phonons (PAM) in BaTiO₃ from first principles. We find that the PAM is four times larger in directions perpendicular to polarization than parallel. Furthermore, PAM is strongly non-linear as a function of BaTiO₃ tetragonality. We assign these observations to specific interatomic force constants in the material. Finally, we suggest experiments using BaTiO₃ as an electric field controllable phonon angular momentum reservoir.

*This work was supported by grant NSF DMR-1848074.
10:12AM R44.00010: Lattice Dynamics and Electron Transport in α-Ga$_2$O$_3$  ANKIT SHARMA
(Presenter), Electrical Engineering, University at Buffalo, MAHITOSH BISWAS, ELAHEH AHMADI, EECS, University of Michigan, UTTAM SINGISETTI, Electrical Engineering, University at Buffalo — Ga$_2$O$_3$ is an important wide bandgap material with applications ranging from power to RF electronics. It occurs in 5 polymorphs α, β, γ, δ and ε. β-Ga$_2$O$_3$ is extensively studied as it is thermodynamically a more stable phase & availability of bulk crystals. However, α-Ga$_2$O$_3$ has higher bandgap than β-phase, so better performance is expected for power applications. Although few reports exist on α-Ga$_2$O$_3$, it has not gained much traction as it is thermodynamically semi-stable making its synthesis challenging until recently where single crystalline α-Ga$_2$O$_3$ thin films were successfully grown. This opens a wide array of fields in device synthesis using α-phase (R3-c) which has a structure like corundum and thus can be potentially alloyed with materials like Cr$_2$O$_3$ and Fe$_2$O$_3$, with possibilities for magnetoelectric applications. We will present a detailed study of the lattice dynamics, electronic structure and low field electron transport properties in α-Ga$_2$O$_3$. Calculated Raman spectra is compared with experiments. The electron-phonon matrixelements are calculated under the DFT, DFPT and Wannier function formalism. We will also analyze the effects of temperature and doping on the mobility using the Boltzmann transport eqn. Emphasis will be laid on identifying the dominant scattering mechanism.

10:24AM R44.00011: Superconductivity of Liquids*  HUIYING LIU, YING YUAN, DONGHAO LIU, XIN-ZHENG LI, JUNREN SHI (Presenter), Peking Univ —
We develop a non-perturbative approach for calculating the superconducting transition temperatures ($T_c$'s) of liquids. The electron-electron scattering amplitude induced by electron-phonon coupling (EPC), from which an effective pairing interaction can be inferred, is related to the fluctuation of the $T$-matrix of electron scattering induced by ions. By applying the relation, EPC parameters can be extracted from a path-integral molecular dynamics simulation. For determining $T_c$, the linearized Eliashberg equations are re-established non-perturbatively. We apply the approach to estimate $T_c$'s of metallic hydrogen liquids. It indicates that metallic hydrogen liquids in the pressure regime from 0.5 to 1.5 TPa have $T_c$'s well above their melting temperatures, therefore are superconducting liquids.

*This work is supported by National Basic Research Program of China (973 Program) Grant No. 2015CB921101, 2016YFA0300900, and National Natural Science Foundation of China Grant No. 11325416, 11774003.
Coupling many-body-perturbation-theory calculations of electron-electron and electron-phonon coupling

HAN YANG (Presenter), Department of Chemistry, University of Chicago, MARCO GOVONI, Materials Science Division and Center for Molecular Engineering, Argonne National Laboratory, GIULIA GALLI, Pritzker School of Molecular Engineering, University of Chicago — Recently a method [1] was proposed to couple the calculations of $G_0W_0$ quasiparticle energies and electron-phonon scattering in molecules and nanostructures by using the spectral decomposition of dielectric matrices [2]. Here we generalize this approach to solids. Our implementation in the WEST [3] code (www.west-code.org) does not require summation over conduction bands or any self-consistent density-functional-perturbation-theory calculations. We validate our framework by computing phonon frequencies and electron-phonon lifetimes of several semiconductors and insulators, and we discuss the accuracy and efficiency of the method relative to existing techniques.

*This work was supported by the Midwest Integrated Center for Computational Materials (MICCoM), as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division through Argonne National Laboratory, under contract number DE-AC02-06CH11357.

Thursday, March 5, 2020 8:00 AM - 10:36 AM

Session R45 DCOMP GSNP: Computational Methods for Statistical Mechanics: Advances and Applications I 706 - Markus Eisenbach, Oak Ridge National Lab - Tag(s): Focus
Self-avoiding walks are simply defined as walks on a lattice that avoid themselves, and provide the simplest model of a polymer that captures universal features such as the Flory exponent $\nu$ which characterises the size of a polymer. In recent years, high precision Monte Carlo simulations of self-avoiding walks with many millions of steps have been realised through the use of a radically efficient implementation of the pivot algorithm via a hierarchical data structure. This data structure allows for global updates of the system to be performed in the same CPU time as local updates.

I will describe the key geometric intuition behind this implementation, and outline its application to the calculation of various quantities for self-avoiding walks, such as the critical exponents $\nu = 0.58759700(40)$ [1] and $\gamma = 1.15695300(95)$ [2] for three-dimensional walks, and the study of logarithmic corrections for four-dimensional walks [3].

Finally, I will discuss some recent extensions of the method to dense polymer systems and to continuum models of polymers, and will speculate on possible future applications of fast global Monte Carlo moves to other models in statistical physics.

**8:36AM R45.00002: Smart random walks for accelerated Monte Carlo simulations**

YING WAI LI (Presenter), Los Alamos National Laboratory, ALFRED C.K. FARRIS, Emory University, MARKUS EISENBACH, Oak Ridge National Lab — Monte Carlo simulations are robust methods to study statistical physics. However, the unpredictable convergence time and the ease of being trapped in local minima have plagued the efficiency of both traditional and modern Monte Carlo algorithms. We propose strategies to mitigate these problems. We highlight two recent algorithmic developments: the histogram-free multicanonical method for obtaining the density of states for physical systems [1], and a global update scheme that adjusts the sampling weights across the phase space simultaneously. Combining these two methods, we have observed speedups ranging from 1-3 orders of magnitude compared to existing flat-histogram methods such as Wang-Landau sampling and multicanonical sampling, depending on the problem of interest. These methods are implemented and publicly available in an open-source Monte Carlo software suite, the Oak-ridge Wang-Landau (OWL) code [2].

*We acknowledge the support of the U.S. Department of Energy through the Los Alamos National Laboratory (LANL)'s Laboratory-Directed Research and Development (LDRD) Program for this work.

**8:48AM R45.00003: Replica-Exchange Wang-Landau Simulations of Lattice Peptide Aggregation**

MATTHEW WILSON (Presenter), GUANGJIE SHI, University of Georgia, THOMAS WUEST, Scientific IT Services, ETH Zurich, DAVID P LANDAU, University of Georgia, FRIEDERIKE SCHMID, Institute of Physics, Johannes Gutenberg University — The computational study of interacting biomolecules is a challenging endeavor due to the large range of time and length scales associated with the relevant physical transitions. In order to analyze the general, qualitative statistical physics of such systems as they transition from dissolved to aggregated crystalline states, we use the H0P lattice protein model\(^1,2\) simulated on simple cubic and face centered cubic lattices. Utilizing the parallel Replica-Exchange Wang-Landau\(^3\) Monte Carlo algorithm, the energy states and density of states are calculated for multiple interacting H0P peptides. Thermodynamic quantities are studied for short (< 20 residues) model peptides at a range of concentrations and temperatures as structures such as disordered oligomers, amyloid fibrils, and aggregates are formed. Additional structural observables such as the cluster size distribution are calculated in a post-simulation production run, and used to further elucidate the physical behavior during transitions.

9:00AM R45.00004: A Combinatorial Perspective on Ising Model Hysteresis  YULING GUAN (Presenter), ANG LI, STEPHAN WOLFGANG HAAS, SATISH KUMAR THITTAMARANAHALLI, SVEN KOENIG, Univ of Southern California — In this work, we apply combinatorial methods used extensively in Artificial Intelligence (AI) to understand Ising model hysteresis. Our approach is based on efficiently generating the top K solutions of the Ising model and its generalization in AI, called the Weighted Constraint Satisfaction Problem (WCSP). We discuss how the WCSP model with a memory effect can be used to study hysteresis combinatorially; and in this context, we also discuss how the memory effect is related to an effective temperature parameter. Turning to more complex variants of the Ising model, we show that the introduction of long-range dipole interactions leads to variations of the hysteresis curves and the introduction of three-spin interactions leads to the emergence of meta-stable plateau states. We also show how to apply the Discrete Fourier Transform for the analysis of such phase transitions in the Ising model induced by three-spin interactions.

9:12AM R45.00005: Steering a solute between coexisting solvation states: calculation of free energy differences in the adaptive resolution method* MAZIAR HEIDARI, ROBINSON CORTES HUERTO (Presenter), Max Planck Inst, RAFFAELLO POTESTIO, Physics Department, University of Trento, KURT KREMER, Max Planck Inst — In the adaptive resolution method, it is possible to represent molecules with atomistic resolution in a simulation subregion and as ideal gas particles in a large reservoir. To enforce a uniform density profile across the simulation box, an external potential is applied and identified with the system's excess chemical potential. Indeed, atomistic and ideal gas images coexist at a constant temperature, volume, and chemical potential. In this context, we present a method to calculate solvation free energies (SFEs) [1]. The idea is to steer the solute between coexisting solvation states, represented by incorporating solvent and ideal gas at a constant chemical potential. At finite pulling speeds, the applied work gives SFEs via non-equilibrium relations, whereas at infinitely slow pulling, the calculation is equivalent to a thermodynamic integration. Results for small molecules well agree with literature data and pave the way to systematic studies of arbitrarily large and complex molecules.

ALFRED FARRIS (Presenter), Oxford College of Emory University, DANIEL T SEATON, Open Learning, Massachusetts Institute of Technology, DAVID P LANDAU, University of Georgia — Using Wang-Landau sampling [1], we compare and contrast folding behavior in coarse-grained models for Crambin -- a 46 amino acid protein. We investigate Crambin in the context of the hydrophobic polar (HP) lattice model [2] and the semi-flexible H0P lattice model [3] -- an extension to the HP model in which an additional monomer type and an interaction accounting for chain-stiffness are included. We also examine folding behavior in the analogous continuum models, with potentials designed specifically to mimic the lattice models. Through analysis of thermodynamic and structural behavior, we paint a clear picture of the folding process in all cases, and gain an understanding of the effects of certain interactions on the folding process, as well as how lattice constraints impact the folding process. As the complexity of the model interactions increases, the two major transitions observed in nature -- the coil-globule collapse and the folding transition, split into multi-step processes, wherein the level of model coarse-graining has a significant impact on the details of the folding.

9:36AM R45.00007: The self-consistent multi scale simulation of complex fluids*  
HIDEKI KOBAYASHI (Presenter), Department of Chemistry, University of Cambridge, PAUL ROHRBACH, Department of Applied Mathematics and Theoretical Physics, University of Cambridge, ROBERT SCHEICHL, Institute for Applied Mathematics and Interdisciplinary Center for Scientific Computing (IWR), University of Heidelberg, NIGEL B. WILDING, School of Physics, University of Bristol, ROBERT L JACK, Department of Applied Mathematics and Theoretical Physics, University of Cambridge — We present a method that uses self-consistent simulation of coarse grained and fine-grained models, in order to analyse properties of physical systems. The method uses the coarse-grained model to obtain a first estimate of the quantity of interest, before computing a correction by analysing properties of the fine system.

We illustrate the method by applying it to the Asakura-Oosawa (AO) model of colloid-polymer mixtures. We show that the liquid-vapour critical point in that system is affected by three-body interactions which are neglected in the corresponding coarse-grained model. We analyse the size of this effect and the nature of the three-body and higher interactions. Additionally, we apply our methodology to the binary hard-sphere mixture to demonstrate the existence of the liquid-vapour critical point.

9:48AM R45.00008: Equilibrium density calculation of generalized Muttalib-Borodin ensembles. SWAPNIL YADAV (Presenter), KAZI ALAM, KHANDKER A MUTTALIB, University of Florida, DONG WANG, Mathematics, National University of Singapore — The Muttalib-Borodin (MB) random matrix ensemble, which has an additional interaction, was introduced as a solvable toy model for quasi one-dimensional (1D) disordered conductors. We generalize the MB random matrix ensemble with a disorder dependent parameter $\gamma$ which characterizes the strength of the additional interaction term. This generalization can be considered as a simple toy model which captures the essential features of a quasi 1D to 3D generalization of disordered conductors and we call it the $\gamma$-ensembles. Our results suggest that the $\gamma$-ensembles can be mapped on to an MB ensemble by replacing the single particle confining potential with a $\gamma$-dependent effective confining potential. We numerically solve the Riemann-Hilbert (RH) problem associated with the equilibrium density of $\gamma$-ensembles for a range of $\gamma$ between 0 and 1. We also study some interesting limits of the parameters of the $\gamma$-ensembles, where the equilibrium density for a generalized form of the $\beta$-ensembles can be explored.

10:00AM R45.00009: Enhanced sampling of cylindrical microphase separation via shell-averaged bond-orientational order parameter* MIN YOUNG HA (Presenter), BUMJOON SEO, WON BO LEE, Seoul Natl Univ — The formation of a hexagonal phase from the disordered phase is one of the typical order-disorder transitions (ODT) observed in asymmetric diblock copolymer systems. In order to drive this transition in a particle-based simulation, we introduce a shell-based bond-orientational order parameter that selectively responds to the mesoscopic order of the hexagonal cylinder phase. From metadynamics simulations in a bond-free particle model system, the characteristic pathway involved with the underlying free energy surface is deduced for the disordered-to-hexagonal transition. It is shown consecutively that the transition pathway and the metastable state are reproduced in dissipative particle dynamics simulations for the corresponding transition in bulk asymmetric block copolymer melt system. These agreements suggest that efficient strategies for enhanced sampling with particle-based simulations of block copolymer systems can be devised using coarse-grained pictures of the mesoscopic order.

Probing predictions due to the nonlocal interface Hamiltonian: Monte Carlo simulations of interfacial fluctuations in Ising films*  
LIJUN PANG (Presenter), Georgia Gwinnett College, DAVID P LANDAU, University of Georgia, KURT BINDER, Johannes Gutenberg University Mainz — Extensive Monte Carlo simulations have been performed on an Ising ferromagnet under conditions that would lead to complete wetting in a semi-infinite system. We studied an $L \times L \times D$ slab geometry with oppositely directed surface fields so that a single interface is formed and can undergo a localization-delocalization transition. Under the chosen conditions the interface position is, on average, in the middle of the slab, and its fluctuations allow a sensitive test of predictions that the effective interactions between the interface and the confining surfaces are nonlocal. The decay of distance dependent correlation functions are measured within the surface, in the middle of the slab, and between middle and the surface for slabs of varying thickness $D$. From Fourier transforms of these correlation functions a non-linear correlation length is extracted, and its behavior is found to confirm theoretical predictions for $D>6$ lattice spacings.

Integer lattice gases, Molecular Dynamics Lattice Gas and an alternative derivation of the lattice Boltzmann method  
ALEXANDER WAGNER (Presenter), NOAH SEEKINS, REZA PARSA, ALEKSANDRA PACHALIEVA, North Dakota State Univ — We report on recent progress in two related areas:

1) that lattice Boltzmann methods can be derived rigorously from Molecular Dynamics simulations through a coarse graining approach (MDLG) that maps Molecular Dynamics onto an integer lattice gas. This gives insights into the surprisingly large correct fluctuations for non-ideal gases and fluids as well as the physical meaning of over-relaxation in lattice Boltzmann.

2) the efficient implementation of integer lattice gases that can be considerably more efficient than the equivalent lattice Boltzmann implementation.
R45.00012: Machine-learning approach to real-space renormalization of the 2D Potts model

*CHAK MING CHAN (Presenter), LIANG TIAN, LEI-HAN TANG, Hong Kong Baptist Univ — The ordering transition of the q-state Potts model on a square lattice changes from continuous to first-order at q=4. This changeover has been analyzed in real-space renormalization group (RSRG) studies[1] but a clear physical picture is lacking. We have previously conjectured that the weak first order transition at q>4 is related to the four-color theorem in graph theory[2]. Here we implement a recently proposed deep-learning scheme that maps configurations at successive scales to each other[3]. Parameters of the mapping are learned by maximizing mutual information. We take into account symmetry properties of the model and analyze the resulting RG flow to extract critical exponents and other properties. The emergence of "mosaic domains" which represent dilution of the original Potts model under the RG transformation will be discussed[4].

Session R46 GMAG DMP: Triangular Lattice II

8:00AM R46.00001: Characterizing the Spin-½ Heisenberg model on the triangular lattice through the Dynamical Spin Structure

TA TANG (Presenter), THOMAS DEVEREAUX, Stanford Univ, BRIAN MORITZ, SLAC, YI-FAN JIANG, Stanford Univ — The ground state phase of the spin-1/2 Heisenberg model on the triangular lattice with nearest-neighbor exchange $J_1$ can be frustrated by the next nearest neighbor coupling $J_2$ and turns into a stripe phase for large $J_2$. While both small and large values of $J_2/J_1$ lead to magnetically ordered phases, a spin liquid phase with short correlation length can be established at intermediate values. However, the nature of this spin liquid phase remains under debate, with finite size DMRG calculations suggesting a gapped $Z_2$ spin liquid phase, but also showing possible gapless spinon excitations. Here, we use exact diagonalization on a series of finite-size clusters to analyze the character of the ground state and lowest-lying the excited states of the model for various values of $J_2$. We further characterize the evolution of the model as a function of $J_2$ by analyzing the dynamical spin structure factor $S(q,w)$ to provide key information on the changes of the underlying magnetic structure.
Generalized SU(3) Spin Wave Theory on Effective S=1 Triangular Lattice Magnet FeI₂

HAO ZHANG (Presenter), SHANG-SHUN ZHANG, Department of Physics and Astronomy, University of Tennessee, XIAOJIAN BAI, ZHILING DUN, School of Physics, Georgia Institute of Technology, MATTHEW STONE, ALEXANDER KOLESNIKOV, FENG YE, Neutron Scattering Division, Oak Ridge National Laboratory, MARTIN MOURIGAL, School of Physics, Georgia Institute of Technology, CRISTIAN BATISTA, Department of Physics and Astronomy, University of Tennessee — Magnetic and quadrupolar excitations can coexist in magnetically ordered S=1 spin systems because the local Hilbert space has dimension three. By using a generalized SU(3) spin wave theory (GSWT), we uncover the hybridized nature of the low-energy modes revealed by inelastic neutron scattering (INS) measurements of the effective S=1 triangular antiferromagnet FeI₂. Band crossing between dipolar and quadrupolar modes enables a large hybridization between them that is induced by symmetric exchange anisotropy. Because of this hybridization, modes with dominant quadrupolar character can be observed with INS. These modes can also be obtained from a generalized Landau-Lifshitz dynamics of SU(3) spins (3 dipolar + 5 quadrupolar components), which turns out to be the adequate dynamics for describing the low-temperature dynamical properties of FeI₂.

Magnetic Excitations of the Frustrated Triangular Ising Magnet FeI₂*

XIAOJIAN BAI (Presenter), School of Physics, Georgia Institute of Technology, SHANG-SHUN ZHANG, Department of Physics and Astronomy, University of Tennessee, Knoxville, ZHILING DUN, School of Physics, Georgia Institute of Technology, HAO ZHANG, Department of Physics and Astronomy, University of Tennessee, Knoxville, WILLIAM ADAM PHELAN, Department of Chemistry, Johns Hopkins University, HAIDONG ZHOU, Department of Physics and Astronomy, University of Tennessee, Knoxville, MATTHEW STONE, ALEXANDER KOLESNIKOV, FENG YE, Neutron Scattering Division, Oak Ridge National Laboratory, CRISTIAN BATISTA, Department of Physics and Astronomy, University of Tennessee, Knoxville, MARTIN MOURIGAL, School of Physics, Georgia Institute of Technology — We present a detailed investigation of the spin dynamics in single-crystals of the layered spin-one triangular-lattice compound FeI₂. Previous thermo-magnetic measurements revealed a strong Ising single-ion anisotropy for the Fe²⁺ ions in FeI₂ and a magnetically long-range ordered state below 9.3K, which can be understood from the competition between nearest neighbor ferromagnetic interactions and a complex set of further-neighbor interactions. Early neutron scattering, far-infrared and ESR measurements, revealed the emergence of a two-magnon bound state (TMBS) as the lowest energy mode from this ordered state. The TMBS carries an apparent g-factor that is doubled compared to that of single magnon excitations, which can be explained by a change of 2 units in spin angular momentum, at odds with the dipole selection rule. We revisit the spin excitations of FeI₂ using modern neutron-scattering instrumentation and map out the magnetic structure, diffuse scattering and low-energy magnetic excitation spectrum. We extract a model Hamiltonian for FeI₂ and elucidate a novel hybridization mechanism that quantitatively explains current and previous spectroscopic experiments on this enigmatic compound.

8:36AM R46.00004: Anisotropic-exchange magnets: triangular lattice and all* [Invited]
ALEXANDER CHERNYSHEV (Presenter), University of California, Irvine — I will describe our efforts to understand the phase diagram of a model that combines paradigmatic geometrical frustration of spins on a triangular lattice with strong spin-orbit-induced interactions. This model is relevant to a growing family of rare-earth-based magnets and other related materials and our work sets up a consistent interpretation of the current and future experiments in them. I will also attempt to review our recent incursion to the honeycomb-lattice territory and attempts to shed light on the properties of the Kitaev materials such as α-RuCl₃.

*Funded by the DoE, Award No. DE-FG02-04ER46174

9:12AM R46.00005: Interplay between magnetic structures, domain physics, and transport properties in a family of triangular layered materials  
CHUNXIAO LIU (Presenter), University of California, Santa Barbara, LEON BALENTS, Kavli Institute for Theoretical Physics — The triangular layered magnet PdCrO₂ has attracted interest due to the interplay between its antiferromagnetic order and high in-plane conductivity, widely believed to be the key to understanding an unconventional anomalous Hall effect (AHE) in the material. More recent experiments reveal that the domain physics in the material may also play an important role on its electronic transport. Motivated by these experimental findings, we study the interplay between magnetic structures, domain physics, and transport properties of a layered triangular lattice with alternating layers of hopping electrons and localized spins. We analyze the possible magnetic orders of the most general symmetry allowed spin Hamiltonian at nearest neighbor level. Assuming appropriate intralayer exchange parameters and treating the interlayer exchange perturbatively, we show that threefold rotation symmetry breaking domains can emerge, in accordance with the experiments. We further show that, under certain conditions the Kondo lattice Hamiltonian possesses a particular symmetry that forbids contribution from the electron band topology to the Hall conductance. Finally we study various other effects including magnetic breakdown and spin-orbit coupling and comment on their contribution to the unconventional AHE.
9:24AM R46.00006: Triangular antiferromagnet NiGa2S4: a low-dimensional analog of the pyrochlores*  
HAOYU WANG (Presenter), OLEG TCHERNYSHYOV, Johns Hopkins University — NiGa2S4 is a frustrated magnet on a triangular lattice with a strong antiferromagnetic third-neighbor exchange J3 and a weak ferromagnet first-neighbor exchange J1. Although the system has been studied for more than a decade [1], its behavior, particularly the lack of long-range order, remains enigmatic. Exotic scenarios have been proposed for its explanation, including the formation of a quadrupolar spin order that cannot be seen by the usual probes like neutrons [2]. We propose a different scenario based on a simple observation: the 4-sublattice structure resulting from a strong J3 makes the system similar to a pyrochlore antiferromagnet. The geometrical frustration of the pyrochlore antiferromagnet can be relieved by a lattice distortion [3]. A similar tendency may exist in NiGa2S4. The spin-Peierls phase transition may be preempted by structural disorder involving random strains.

*Supported by the Institute for Quantum Matter under DOE EFRC grant DE-SC0019331

9:36AM R46.00007: Complex magnetic behavior of the Co2+ triangular (saw-tooth) 1D chains in CsCo2(MoO4)2(OH)*  
DUMINDA SANJEEWA (Presenter), VASILE O GARLEA, JIE XING, ATHENA S. SEFAT, Oak Ridge National Lab — Low-dimensional magnetic materials have drawn continued attention in condensed-matter physics for their electronic and magnetic anisotropic properties. In particular, the oxyanion-based systems, with transition-metal (M) oxide sublattices that are magnetically isolated by closed-shell nonmagnetic oxyanions (SiO4−4, PO3−4, AsO3−4), show great potential for diverse magnetic phenomena. We synthesize CsCo2(MoO4)2(OH) single crystals, find the crystal structure, and characterize thermodynamic properties. CsCo2(MoO4)2(OH) belongs to a rare class of compounds named delta-chain (or sawtooth) type structure, with corner-sharing isosceles triangles whose vertices consist of one Co(1) and two Co(2) atoms. The magnetic susceptibility result reveals long-range ordering below 5 K with a strong anisotropy. The isothermal magnetization data shown a stepwise magnetization when the magnetic field is along the Co-O-Co (saw-tooth chain) direction, with two metamagnetic transitions at 0.3 kOe and 40 kOe. The magnetic structure consists of ferrimagnetic chains which are antiferromagnetically coupled with each other, seen in neutron diffraction.

*Work at ORNL was supported by U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES), Materials Science and Engineering Division.
**9:48AM R46.00008: Synthesis and Characterization of Rare-Earth Based Triangular Antiferromagnet Borates**  MATTHEW ENNIS (Presenter), RABINDRANATH BAG, SACHITH DISSANAYAKE, ZHENZHONG SHI, Department of Physics, Duke University, ALEXANDER KOLESNIKOV, Neutron Scattering Division, Oak Ridge National Lab, JOSE RODRIGUEZ-RIVERA, HUI WU, CRAIG BROWN, Center for Neutron Research, National Institute of Standards and Technology, DAVID E GRAF, National High Magnetic Field Laboratory and Department of Physics, Florida State University, SARA HARAVIFARD, Department of Physics and Department of Mechanical Engineering & Materials Science, Duke University — Recently, triangular antiferromagnetic materials have attracted attention because competing interactions on the lattice can give rise to exotic phenomena, such as Quantum Spin Liquids. We have initiated systematic efforts to synthesize single crystal samples of a family of rare-earth based triangular antiferromagnet borates. We have used x-ray diffraction as well as thermal and magnetic measurements to characterize these compounds. Additionally we have carried out neutron scattering experiments to probe the static and dynamic properties of these systems. In this talk, we will present the results of our experimental efforts.

**10:00AM R46.00009: Magnetic short-range correlations and Kosterlitz-Thouless transitions in TmMgGaO4**  MARCUS DAUM (Presenter), ZHILING DUN, Georgia Inst of Tech, HAIDONG ZHOU, University of Tennesse, Knoxville, MARTIN MOURIGAL, Georgia Inst of Tech — Transverse Ising model on a triangular lattice is known to host two Kosterlitz-Thouless (KT) transitions at low temperatures. Triangular lattice antiferromagnet TmMgGaO4 is a promising candidate to realize such physics due to the interplay between geometric frustration, spin orbit coupling, and crystal electric fields. In TmMgGaO4 short-range magnetic correlations are observed over a broad temperature range. However, the nature of this short-range magnetic order is under debate. Recent numerical work has predicted a Kosterlitz-Thouless transition at 4 K, which however lacks any experimental evidence thus far. Using AC susceptibility and neutron scattering measurements, we unveil this transition and discuss its implications in understanding the rich physics of TmMgGaO4.

*The work at Georgia Tech was sponsored by the National Science Foundation under NSF-DMR-1750186*
10:12AM R46.00010: Studying the Dynamic Magnetic Properties of the Triangular Antiferromagnet YbZnGaO4 in Applied Field  WILLIAM STEINHARDT (Presenter), SACHITH DISSANAYAKE, ZHENZHONG SHI, Department of Physics, Duke University, NICHOLAS BUTCH, Center for Neutron Research, National Institute of Standards and Technology, DAVID E GRAF, National High Magnetic Field Lab, Florida State University, ANDREY PODLESNYAK, YAOHUA LIU, Neutron Scattering Division, Oak Ridge National Laboratory, YANG ZHAO, GUANGYONG XU, JEFFREY LYNN, Center for Neutron Research, National Institute of Standards and Technology, CASEY MARJERRISON, Department of Physics, Duke University, SARA HARAVIFARD, Department of Physics, Department of Mechanical Engineering & Materials Science, Duke University — In the last few years Yb-based triangular antiferromagnets emerged as promising quantum spin liquid candidates, and subsequently their ground states have been the subject of ardent debates. Though many experimental and theoretical studies have been devoted to investigating the magnetic properties of these systems at very low temperatures, and exploring a range of possible explanations for the observed spin liquid-like phenomena, a definitive description remains elusive mainly due to thermal fluctuations and chemical disorder. In this talk we discuss neutron scattering experiments in applied magnetic field to probe features of the “partially magnetized” state in YbZnGaO4, which generated great excitement in YbMgGaO4 as a possible signature in support of spinon Fermi surface hypothesis [1].

10:24AM R46.00011: A quantitative study of short-range correlations in triangular Ising antiferromagnet TmMgGaO4 via magnetic pair distribution function analysis  RAJU BARAL (Presenter), BENJAMIN FRANDSEN, Department of Physics and Astronomy, Brigham Young University, HENRY EDWARD FISCHER, Institut Laue-Langevin, QING HUANG, HAIDONG ZHOU, Department of Physics & Astronomy, University of Tennessee, MARCUS DAUM, ZHILING DUN, MARTIN MOURIGAL, School of Physics, Georgia Institute of Technology — Interacting Ising spins decorating a triangular lattice are expected to show rich magnetic behavior, including a possible Kosterlitz-Thouless (KT) transition at low temperature. Recently, TmMgGaO4 has been found to exhibit a perfect triangular lattice of Ising-like Tm$^{3+}$ magnetic moments, providing a promising platform for investigating potential KT physics in a solid-state magnetic system. Initial studies have revealed significant diffuse magnetic scattering at low temperature, indicating the presence of short-range magnetic correlations that may hold the key to understanding the magnetic ground state of this system. Here, we utilize the magnetic pair distribution function (mPDF) technique to probe these correlations in real space via Fourier transformation of the diffuse scattering pattern. We present a magnetic model that reproduces the observed mPDF pattern with quantitative accuracy and discuss the significance of these results in the context of existing work on TmMgGaO4.
10:36AM R46.00012: Chiral correlation in triangular lattice Hubbard model*  BIN-BIN CHEN
(Presenter), Ludwig Maximilian University of Munich, WEI LI, Department of Physics, Beihang University, ANDREAS WEICHSELBAUM, Brookhaven National Laboratory — The fermionic triangular lattice Hubbard (TLH) model constitutes a playground for intriguing emergent quantum phenomena and novel exotic states in strongly correlated system. In a recent paper [1], by using mixed real- and momentum-space basis in iDMRG, a chiral spin liquid is found for intermediate onsite Coulomb interaction U between the small-U metallic phase and large-U three-sublattice magnetic phase, against the conclusion in ref. [2].
In this talk, I will focus on finite-size DMRG simulations of the TLH for system sizes that go clearly beyond [2] while also exploiting SU(2) spin symmetry. Comprehensive characterizations, including entanglement entropy, spin correlation, and chiral correlation, are carried out to distinguish the phase boundary between the above three phases. By tuning the on-site Coulomb interaction U to intermediate values, we observe for significantly large systems strong indications in favor of a chiral spin liquid. Specifically, for U10, we observe a plateau in the static chiral correlations vs. distance, and the estimated spontaneous chiral order parameter shows good agreement with ref. [1].

*This work is supported by the DFG WE4819/3-1, and DOE DE-SC0012704.

10:48AM R46.00013: Topological frustration: Quantum statistics of vortices from a dual theory of the XY ferromagnet*  SAYAK DASGUPTA (Presenter), Johns Hopkins University, SHU ZHANG, University of California, Los Angeles, IBRAHIMA BAH, OLEG TCHERNYSHYOV, Johns Hopkins University — The familiar concept of geometrical frustration can be extended to frustration induced by the topology of spin textures. For instance, in a magnetic vortex the spins on the periphery rotate in the easy plane, leaving the spins at the vortex core frustrated. To reduce the exchange energy, the core spins come out of the easy plane and point along the hard axis. There is a degeneracy resulting from the associated $\mathbb{Z}_2$ symmetry (polarization) which has well-known important consequences for the dynamics of a vortex. Here we show that topological frustration at the vortex core may induce a nontrivial quantum statistics of vortices. We extend the well-known mapping between the easy-plane ferromagnet and electrostatics in $d = 2$ spatial dimensions, introduced by Kosterlitz [1], to dynamical and quantum phenomena in a $d = 2+1$ spacetime. Ferromagnetic vortices behave like quantum particles with an electric charge equal to the vortex number and a magnetic flux equal to the transverse spin of the vortex core. Vortices with half-integer core spin exhibit fermionic statistics.

*Supported by the Institute for Quantum Matter under DOE EFRC grant DE-SC0019331.

Thursday, March 5, 2020 8:00 AM - 11:00 AM
8:00AM R47.00001: Chemical control of magnetism in $S = 1$ quantum materials: new twists on a seemingly old theme*  

[Invited] JAMIE MANSON (Presenter), JACQUELINE VILLA, DANIELLE Y. VILLA, ISABEL CALDERON-LIN, ZACHARY MANSON, NATHAN GRINALDS, ASHLEY SARGENT, Eastern Washington University, WILLIAM BLACKMORE, SAM CURLEY, PAUL GODDARD, Physics, University of Warwick, JOHN SINGLETON, NMFL, Los Alamos National Lab, MATTHEW STONE, Quantum Condensed Matter Div, Oak Ridge National Lab, ROGER JOHNSON, Physics, University of Oxford, VASILE O GARLEA, Quantum Condensed Matter Div, Oak Ridge National Lab, PASCAL MANUEL, ISIS, STFC RAL, CRAIG BROWN, NIST Center for Neutron Research, NIST — We aim to control the spatial exchange and single-ion anisotropies ($D$) in bespoke $S = 1$ Ni(II) quantum magnets. Early work led to $[\text{Ni(HF}_2\text{)(pyz)}_2\text{SbF}_6]$ which contains Ni-FHF-Ni chains ($J_{\text{FHF}}$) cross-linked by Ni-pyz-Ni segments ($J_{\text{pyz}}$) to form a tetragonal network [1]. The material undergoes $XY$-AFM order below $T_N = 12.2$ K with collinear Ni(II) moments confined to the $[\text{Ni(pyz)}_2]^{2+}$ plane. High-field $M(H)$ and inelastic neutron scattering (INS) revealed $D = J_{\text{FHF}} \gg J_{\text{pyz}}$. In the related square lattices [2,3], $\text{NiX}_2\text{(pyz)}_2$ ($X = F, Cl, Br, I$, NCS), the electronegativity of $X$ dictates the Ni(II) spin direction with $XY$-and Ising-like ground-states observed for $X = F, Cl$ and $X = Br, I$, NCS, respectively. We used INS to determine $J_{\text{pyz}}$ and $J_{\perp}$. Chemical substitution of pyz for pyrimidine (pym) affords unusual topologies and enhanced magnetic interactions along Ni-pym-Ni relative to Ni-pyz-Ni. Thus, we synthesized two new Q1D chains: staggered $[\text{Ni(pym)(H}_2\text{O)}_4\text{]SO}_4\bullet2\text{H}_2\text{O}$ and chiral $[\text{Ni(pym)}(\text{H}_2\text{O)}_4\text{]SiF}_6\bullet\text{H}_2\text{O}$, each showing multiple field-induced phase transitions below 5 K. Lastly, we will describe a unique 3D chiral Ni(II) framework that may display spin-liquid behavior at low temperatures. Time permitting, the structural and magnetic properties of these materials will be discussed.

*NSF DMR-1703003 (EWU), DMR-1157490 (MagLab), DoE, State of FL, ERC, EPSRC

We report on a new molecule-based magnet NiI2(3,5-lutidine)4 characterized using x-ray diffraction, electron-spin resonance, magnetometry, inelastic neutron scattering and muon-spin relaxation. The system is a near-ideal realization of the $S = 1$ Haldane chain with intrachain exchange $J = 17.5$ K, energy gaps of 5.3 K and 7.7 K split by easy-axis anisotropy $D = -1.2$ K, and with no sign of magnetic order down to 20 mK. The value $D/J = -0.07$ implies one of the most isotropic Haldane systems yet discovered, while the ratio $\Delta/J = 0.40(1)$ (where $\Delta$ is the average gap size) is close to the ideal theoretical value, suggesting a very high degree of magnetic isolation of the chains. The Haldane gap is closed by orientation-dependent critical fields 5.3 T and 4.3 T, which are readily accessible experimentally. The fully polarized state occurs above 46.0 T. The results are explicable within the so-called fermion model, which is in contrast to other reported easy-axis Haldane systems. The flexible nature of this molecule-based material readily permits tuning via applied pressure and introduction of disorder along the exchange pathway.

8:48AM R47.00003: Magnetic ground-state of two new highly one-dimensional ferromagnetic chain compounds $M$(NCS)$_2$(thiourea)$_2$; $M = \text{Co, Ni}$.\* SAM CURLEY (Presenter), ROBERT C WILLIAMS, PAUL GODDARD, Department of Physics, University of Warwick, REBECCA SCATENA, STEPHEN BLUNDELL, Department of Physics, University of Oxford, PIERO MACCHI, Department of Chemistry and Biochemistry, University of Bern, THOMAS HICKEN, TOM LANCASTER, Centre for Materials Physics, Durham University, FAN XIAO, Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institute, JAMES C ECKERT, Department of Physics, Harvey Mudd College, VIVIEN ZAPF, Los Alamos National Laboratory, National High Magnetic Field Laboratory, JACQUELINE VILLA, JAMIE MANSON, Department of Chemistry and Biochemistry, Eastern Washington University — Low-dimensional magnetic materials have garnered much attention from theorists and experimentalists alike for many years. Chains of low-spin, ferromagnetically (FM) or antiferromagnetically (AFM) coupled magnetic-ions can both harbour exotic magnetic ground-states: such as the gapped Haldane ground state in Heisenberg AFM chains, or the field-induced quantum paramagnetic state in Ising-like FM chains. In terms of physically realizing such systems, co-ordination chemistry has had great success in promoting crystal architectures that can lead to quasi-1D behaviours. Altering the bridging or non-bridging ligand species can modify both the Heisenberg exchange ($J$) and single-ion anisotropy ($D$). It is the interplay of these two parameters that ultimately determines the magnetic ground-state. To this end, we have recently synthesised two new, highly one-dimensional and isostructural molecule-based magnets; $M$(NCS)$_2$(thiourea)$_2$ [thiourea = $\text{CH}_4\text{N}_2\text{S}$, $M$ is Co ($S = 3/2$) or Ni ($S=1$)]. We employ a combination of magnetometry, heat capacity and muon spin-rotation in addition to theoretical charge density analysis, in an attempt to resolve the magnetic ground-state of both materials.

9:00AM R47.00004: Cluster-Based Haldane States in Spin Cluster Chains TAKANORI SUGIMOTO (Presenter), KATSUHIRO MORITA, TAKAMI TOHYAMA, Tokyo Univ of Science, Katsushika — The $S=1$ Haldane state has attracted much attention due to its topological characters. This state emerges not only in the $S=1$ spin chain, but also in an $S=1/2$ two-leg spin ladder with a ferromagnetic rung interaction. Additionally, our recent study on low-temperature magnetism in a naturally occurring mineral Fedotovite, has shown the Haldane state consisting of cluster-based $S=1$ spins, in collaboration with experimental groups. In this compound, edge-shared tetrahedral spin clusters which include six spins in a cluster, are linked by a nearest-neighbor antiferromagnetic inter-cluster interaction in one dimension. The low-energy state in a cluster is a triplet and the inter-cluster interaction is perturbative as compared with the intra-cluster excitation energy, so that we can explain the low-temperature physics in an effective $S=1$ spin model obtained by projection into cluster's triplet states. Furthermore, we extend the cluster-based Haldane state to spin-cluster systems which have odd-number $S=1/2$ spins in a cluster, and find cluster-based Haldane state with breaking time-reversal symmetry. Thus, we will present several varieties of cluster-based Haldane states obtained in possible spin lattices.
A Novel Strongly Spin-Orbit Coupled Quantum Dimer Magnet: Yb$_2$Si$_2$O$_7$*

GAVIN HESTER, HARIKRISHNAN S NAIR, TIMOTHY REEDER, DANIELLE R YAHNE, TIMOTHY DELAZZER, Colorado State University, LÉO BERGES, DJAMEL ZIAT, Physics, Université de Sherbrooke, JAMES NEILSON, Colorado State University, ADAM ACZEL, GABRIELE SALA, Oak Ridge National Laboratory, JEFFREY A QUILLIAM, Physics, Université de Sherbrooke, KATE ROSS (Presenter), Colorado State University — The quantum dimer magnet (QDM) is the canonical example of 'quantum magnetism'. This state consists of entangled nearest-neighbor spin dimers and often exhibits a field-induced 'triplon' Bose-Einstein condensate (BEC) phase. I will discuss a new QDM in the strongly spin-orbit coupled, distorted honeycomb-lattice material Yb$_2$Si$_2$O$_7$. Single crystal neutron scattering, specific heat, and ultrasound velocity measurements reveal a gapped singlet zero field ground state with sharp, dispersive excitations. We find a field-induced magnetically ordered phase reminiscent of a BEC phase, with exceptionally low critical fields of $H_{c1} \sim 0.4$ T and $H_{c2} \sim 1.4$ T. Using inelastic neutron scattering we observe a Goldstone mode that persists throughout the entire field-induced magnetically ordered phase, suggestive of the spontaneous breaking of U(1) symmetry expected for a triplon BEC. However, in contrast to other well-known cases of this phase, the high-field ($H > 1.2$T) part of the phase diagram in Yb$_2$Si$_2$O$_7$ is interrupted by an unusual regime signaled by a change in the field dependence of the ultrasound velocity and net magnetization, as well as the disappearance of a sharp anomaly in the specific heat. These measurements raise the question of how anisotropy in strongly spin-orbit coupled materials modifies the field induced phases of QDMs.

Dimensionality of the BEC state in structurally healed Sr-doped BaCuSi$_2$O$_6$

DAGMAR WEICKERT (Presenter), MARCELO JAIME, Los Alamos Natl Lab, PASCAL PUPHAL, Paul-Scherrer-Institute, SHUSAKU IMAOJO, YOSHIMITSU KOHAMA, Tokyo University, JOOSEP LINK, RAIVO STERN, NICBP, Tallinn — In the last 20 years, more than a dozen quantum paramagnets have been identified to show properties consistent with the formalism of Bose-Einstein condensation (BEC) when a magnetic field is used to induce XY-type AFM order at cryogenic temperatures. Among them, BaCuSi$_2$O$_6$ orders between critical fields $H_{c1} = 23.5$T and $H_{c2} = 49$T, below $T_{c,max} = 4$K. However, BaCuSi$_2$O$_6$ additionally undergoes a structural phase transition at 90K into a monoclinic lattice at lower temperature causing a spatial modulation of the spin gap along the c-axis. This spin gap modulation is suspected to be the reason for a dimensional crossover in the magnetic excitations spectrum observed in the critical exponent of the phase transition close to $H_{c1}$. We discuss experimental results on newly synthesized single crystals BaCuSi$_2$O$_6$ doped with 10% Sr, structurally healed, which do not exhibit a phase transition at 90K and allow the investigation of the BEC close to $H_{c1}$ in the absence of spin gap modulation. We establish the $H-T$ phase diagram based on magnetization, magnetic torque, specific heat and magnetocaloric effect (MCE) measurements in DC and pulsed magnetic fields that address the dimensionality of excitations in the BEC critical exponents.
10:00AM R47.00007: Unconventional critical behavior in the quasi-one-dimensional $S = 1$ chain NiTe$_2$O$_5$  JUN HAN LEE, Ulsan Natl Inst of Sci & Tech, MARIE KRATOCHVÍLOVÁ, Seoul National University, HUIBO CAO, Oak Ridge National Laboratory, ZAHRA-SADAT YAMANI, Canadian Neutron Beam Centre, JUNGSOO KIM, University of Florida, JE-GUEN PARK, Seoul National University, GREGORY RANDALL STEWART, University of Florida, YOON SEOK OH (Presenter), Ulsan Natl Inst of Sci & Tech — The physical quantities develop with critical behavior near the (quantum) critical regime of correlated systems, such as superfluid density of two dimensional superconductor, surface critical behavior in topological phase, Higgs mode in quantum antiferromagnet, quantum criticality in multiferroics, quantum phase transition in two-dimensional electron system, etc. Despite the variety of complex interactions and correlations, the critical behavior only depends on global properties such as the spatial dimension, the symmetry of the order parameter, and the range of interaction. Recently we found a new quasi-one-dimensional chain compound NiTe$_2$O$_5$, in which spin-1 of Ni$^{2+}$ ions form a one-dimensional chain structure through NiO$_6$ octahedra’s edge-sharing. Although it undergoes a long-range antiferromagnetic (AFM) order with an archetypical anisotropic AFM anomaly at $T_N = 30.5$ K, the AFM order parameter develops with intriguing unconventional critical exponents. In this talk, we present magnetic properties and structure of NiTe$_2$O$_5$ and discuss its unconventional critical behavior.

10:12AM R47.00008: Magnetic phase diagram and anisotropy in the one-dimensional quantum spin system Rb$_2$Cu$_2$Mo$_3$O$_{12}$  SHOHEI HAYASHIDA (Presenter), DOMINIC BLOSSER, KIRILL POVAROV, ZEWU YAN, SEVERIAN GVASALIYA, ETH Zurich, ALEXEY PONOMARYOV, SERGEI ZVYAGIN, Helmholtz-Zentrum Dresden-Rossendorf, ANDREY ZHELUDEV, ETH Zurich — We report low temperature thermodynamic, magnetic and electron spin resonance (ESR) measurements on single crystal samples of a quantum spin chain material Rb$_2$Cu$_2$Mo$_3$O$_{12}$. In heat capacity measurement, phase transitions to magnetically ordered state are clearly observed, and the entire phase diagram is mapped out in detail. It is found that the criticalities of the transitions at lower and upper fields are dominated by three-dimensional order and one-dimensionality, respectively. The measured phase boundaries and ESR data prove that anisotropy heavily influences the magnetic state of Rb$_2$Cu$_2$Mo$_3$O$_{12}$ [1].

10:24AM R47.00009: Comparison of spin dynamics in green and black dioptase: from classical chains to quantum fluctuations*  ANDREY PODLESNYAK (Presenter), Oak Ridge National Lab, STANISLAV NIKITIN, Max Planck Institute for Chemical Physics of Solids, D-01187 Dresden, Germany., OLEKSANDR PROKHNENKO, Helmholtz-Zentrum Berlin für Materialien und Energie, D-14109 Berlin, Germany, ALEXANDER KOLESNIKOV, Oak Ridge National Lab, TIMOTHY PRISK, National Institute of Standards and Technology, LAWRENCE (LARRY) M. ANOVITZ, Oak Ridge National Lab — The magnetic excitations of a gem crystal green dioptase Cu$_6$[Si$_6$O$_{18}$]·6H$_2$O and fully dehydrated black dioptase Cu$_6$Si$_6$O$_{18}$ have been studied by inelastic neutron scattering. The intrachain $J_c$ and interchain $J_{ab}$ interactions as well as the anisotropy of the $J_c$ have been determined. The observed spectrum of green dioptase contains two sharp magnetic modes and a prominent spin gap that is consistent with the ordered ground state of Cu moments coupled antiferromagnetically in spiral chains along the c axis and ferromagnetically in ab planes on the hexagonal cell. We found that dehydration has a dual effect on the magnetic interactions: it significantly increases the intrachain exchange interaction $J_c$, and simultaneously decouples the chains by suppressing $J_{ab}$. The spin dynamics of green dioptase are dominated by conventional magnon excitations, whereas the continuum of excitations observed in black dioptase indicates the presence of fractionalized spinons. We suggest that black dioptase behaves like a nearly ideal $S=1/2$ antiferromagnetic Heisenberg spiral chain with enhanced quantum fluctuations and weak spinon confinement $J_{ab}/J_c$~0.02.

10:36AM R47.00010: Using muons to probe magnetic phases in quantum disordered systems through muon-induced distortions*  BENJAMIN HUDDART (Presenter), TOM LANCASTER, Durham University, FRANCIS L. PRATT, STFC — In muon-spin spectroscopy ($\mu^+\text{SR}$) experiments, concerns are often raised about the influence of the implanted muon on its local environment. In this talk, we will present examples where the distortions induced by the muon provide sensitivity to the magnetic state of the system. Transverse-field $\mu^+\text{SR}$ spectra for the strong-rung molecular spin ladder system (Hpip)$_2$CuBr$_4$ exhibit characteristic behaviour in each of the regions of the phase diagram [1]. Analysis of the muon stopping sites in this compound, obtained from density functional theory calculations, suggests that the magnetic field shift at the muon site in the quantum disordered phase results from a local muon-induced antiferromagnetic state. We propose that a similar mechanism enables the detection of field-induced transitions in the quantum spin liquids (QSLs) $\kappa$-(BEDT-TTF)$_2$Cu$_2$(CN)$_3$ and $\kappa$-(BEDT-TTF)$_2$Ag$_2$(CN)$_3$. In these cases, the field distributions seen by the muon correspond to those expected from adjacent ordered phases in the 2D triangular lattice QSL phase diagram.

We study the phases and phase transitions of a spin-1 chain with next-nearest neighbor (NNN) interaction $J_2$ and uniaxial single-ion anisotropy $D$ by density-matrix renormalization group method. We reconfirm the topological first-order transition of the $J_1$-$J_2$ chain by the bond reversal method [Q. Luo, et al., Phys. Rev. B 100, 121111(R) (2019)], and we show accurately that the transition occurs at $J_{2,t} = 0.7607(2)$. When considering a negative $D$, there is a spontaneously dimerized phase so as to avoiding the direct transition between the Neel phase and the NNN-Neel phase. The Neel--Dimer transition is of Gaussian type with central charge $c = 1$, while the NNN-Neel--Dimer transition belongs to the 2D Ising universality class. For the positive $D$ case, there is a gapless chiral phase with a broken parity symmetry. It separates the NNN-Haldane phase and the large-$D$ phase before the direct transition between the two. We also determine the topological critical points between the Haldane phase and the large-$D$ phase by the level spectroscopy technique supplemented by the Richardson method. The critical point is obtained with spectacular accuracy, $D_c = 0.96847256(2)$, for the frustration-free case.
8:00AM R48.00001: Chirality polarization and spectral bulk-boundary correspondence

AKITO DAIDO (Presenter), YOUICHI YANASE, Kyoto Univ — Surface physics dominated by bulk properties is attracting much attention. For example, bulk-boundary correspondence predicts topological boundary states. Another important context is the electric polarization: Surface charge is the bulk property modulo a quantum [1]. This relation is analogous to BBC, in the sense that physics apparently sensitive to the surface details is the bulk property. It is an interesting question whether this "BBC" can be generalized to the other physical quantities.

Recently, Tamura et al. proposed by numerics that surface accumulation of odd-frequency Cooper pairs is the bulk property [2]. This relation is named spectral bulk-boundary correspondence (SBBC). However, formal proof for SBBC has been lacking.

In this work, we prove SBBC based on the analogy with electric polarization: SBBC can be regarded as polarization of chiralities.

8:12AM R48.00002: Exciton-induced Charge Fluctuations in One-dimensional Quasi-periodic “Metallic” Chains: A Possible Embodiment of Room Temperature Superconductivity

PAUL GRANT (Presenter), W2AGZ Technologies — It is well known that a purely periodic chain of odd-electron atoms, nominally expected to exhibit metallic behavior, is unstable to charge/spin spatial displacement which lowers its ground state energy by gapping its multi-degenerate Fermi surface, in this case consisting of nesting parallel sheets. It is largely for these reasons that superconductivity is not observed in highly one-dimensional metals -- it is simply energetically more favorable for CDW/SDW gaps to form, rather than a BCS state, at least one mediated by electron-phonon coupling. In this talk, we explore the hypothetical electronic properties of a nominally "metallic" quasi-periodic chain using both an analytical approach and computationally with density functional theory, searching for configurations which yield "gap-lets" sufficiently small to permit the formation of BCS pairs as the new energetically favored ground state. The particular embodiment we examine is a string of aluminum atoms with interatomic spacing determined by a Fibonacci sequence. We propose a path to attempt synthesis of such a structure for experimental examination, and perhaps leading to an entirely new class of higher temperature superconductors.

A New Superfast Method for Combinatorial Search of High-Temperature Hydride Superconductors under Extreme Pressures  TIANRAN CHEN (Presenter), TANER YILDIRIM, National Institute of Standards and Technology — Due to the low atomic mass and high electron-phonon coupling strength of hydrogen, hydride compounds under extreme pressures are most promising in the search for high-Tc superconductors. First-principles based computational search has become extremely important not only predicting new materials but also guiding high-pressure experimental measurements. However, the calculation of electron-phonon coupling and the corresponding Tc for a given system is usually computationally very expensive, limiting the application of computational search to a few numbers of candidate systems. In this work, we have developed a super-efficient and fast method for searching high-Tc hydride superconductors. We introduce new "metrics" that are strongly correlated to strong electron-phonon coupling and Tc but it is much faster to calculate them. Using our new method, we have searched more than 50,000 binary hydride superconductors and predicted many new high-Tc systems, one of which may even break the current record. Our work will not only greatly accelerate the discovery of new hydride superconductors but also give a detailed understanding of important factors that yield superconductivity near room temperature at high pressures.

Emergent unconventional superconductivity in doped valence bond solid insulators  ZIXIANG LI (Presenter), DUNGHAI LEE, University of California, Berkeley — In this talk, I will discuss the unconventional superconductivity and non-Fermi liquid behavior in the doped valence bond solid insulators. Through sign-problem-free Quantum Monte Carlo simulation, we investigate the superconductor emergent from the doped valence bond solid insulators, which shares many properties with the superconductivity in doped resonance valence bond phases. Close to the valence bond solid quantum critical point, we observe the Non-Fermi liquid properties from the transport behavior. Our study sheds new light on Cooper pairing in the presence of strong Coulomb interaction. Moreover, this result might point to a new direction for searching high-Tc superconducting materials.
Possible counterintuitive enhancement of superconductivity in ladder-type cuprates by longitudinal compression

KAZUHIKO KUROKI (Presenter), HIKARU SAKAMOTO, Department of Physics, Osaka University — We explore how the electron hoppings of the ladder type cuprates are affected when uniaxial compression or tension is applied to the lattice in the leg or rung directions, and investigate its consequences to superconductivity. For simplicity, we consider the two-leg ladder cuprate without the chains, that is, SrCu$_2$O$_3$, although this material is known to be difficult to dope carriers. By constructing a model based on first principles calculation, we surprisingly find that the ratio $t_r/t_l$, where $t_r$ ($t_l$) is the nearest neighbor hopping in the rung (leg) direction, is enhanced when the lattice is compressed in the leg direction or stretched in the rung direction. This counterintuitive manner of the hopping variation can be attributed to the on-site hybridization between Cu $d_{x^2-y^2}$ and Cu 4$s$ orbitals, which arises due to the low symmetry of the lattice. We apply the fluctuation exchange approximation to the model and study how superconductivity is affected under uniaxial deformation. Due to the above mentioned variation of the hoppings, we find that the superconducting transition temperature is enhanced when the lattice is compressed in the leg direction, opposed to an intuitive expectation. The effect is expected to be strong especially in the electron-doped regime.

Ground state phase diagram of the doped Hubbard model on a two-leg ladder

CHENG PENG (Presenter), YI-FAN JIANG, SIMES, SLAC National Accelerator Laboratory and Stanford University, YUVAL GANNOT, Stanford University, CHAO-MING JIAN, University of California, Santa Barbara, STEVEN KIVELSON, Stanford University, HONG-CHEN JIANG, SIMES, SLAC National Accelerator Laboratory and Stanford University — We have revisited the problem of the two-leg Hubbard ladder using DMRG methods but keeping larger number of states than in previous studies so as to obtain definitive results on the long-distance behavior of relevant ground-state correlation functions. In light of recent evidence that relatively small changes in the ratio of next nearest height for nearest neighbor hopping matrix, $t'/t$, can cause transitions between distinct ground-state phases, we have studied the model for a range of $t'/t$, electron density per site, $n$, and for several "intermediate" values of $U/t$. We find for a broad range of $t'/t$ the ground-state exhibits quasi-long-range singlet superconducting order. For $t'/t$ negative and large enough, two additional phases are found: One is characterized by commensurate charge-density-wave long-range order and a single gapless spin mode. Unexpectedly, for a relatively narrow range of negative $t'/t$, there exists an exotic intermediate phase with gapless charge and spin excitations, but one less gapless mode than for the non-interacting system.

Finding the breakdown of the linear Holstein model using determinant quantum Monte Carlo*  STEVEN JOHNSTON (Presenter), PHILIP DEE, University of Tennessee, Knoxville, JENNIFER COULTER, Harvard — A large-scale effort is underway to determine when vertex corrections are required to the Migdal approximation for electron-phonon (e-ph) coupled systems. Most often, the underlying model for these studies is the simple Holstein Hamiltonian, which captures e-ph interactions as an on-site coupling of electrons to the linear displacement of the phonon field operators. When these displacements are large, however, introducing nonlinear corrections to the e-ph interaction can significantly alter measured correlations. Using determinant quantum Monte Carlo, we compared pairing and charge density wave correlations obtained with and without second-order nonlinear corrections. We find signs of disagreement between the linear and nonlinear models for relatively small values of the dimensionless e-ph coupling λ, and importantly, these discrepancies often occur in the same parameter regions where Migdal's theorem breaks down. Our results suggest that questions of the validity of Migdal's theorem go hand in hand with questions of the validity of the linear Holstein model.

The superconducting $T_c$ and the metal-insulator transition in the Hubbard-Holstein model  TAE-HO PARK (Presenter), HAN-YONG CHOI, Sungkyunkwan Univ — We present that the maximum superconducting $T_c$ is on the phase boundary between metallic and insulating states of the normal state in the Hubbard-Holstein model. It is a prototype model including the local Coulomb interaction $U$ and the electron-phonon coupling $g$. We performed the dynamical mean field theory (DMFT) calculations employing the numerical renormalization group (NRG) technique and identified the normal state phase diagram for the metal-insulator transition. Interestingly, local maximum $T_c$ occurs along the lower critical phase boundary $g_{c1}$ of the 1st order metal-insulator transition in the normal state where the quantum fluctuation becomes maximum. Implications of this finding will be discussed in comparison with the quantum critical superconductivity. In addition, we obtained the electron-phonon coupling spectra $\alpha^2 F(\omega)$ and examined whether the maximum $T_c$ calculated from the Eliashberg theory lies on the $g_{c1}$. 
9:36AM R48.00009: Pairing correlations in the cuprates: a numerical study of the three-band Hubbard model*  
PEIZHI MAI (Presenter), Oak Ridge National Lab, STEVEN JOHNSTON, Department of Physics and Astronomy, University of Tennessee knoxville, THOMAS MAIER, Oak Ridge National Lab — We study the three-band Hubbard model for the copper oxide plane of the high-temperature superconducting cuprates using exact diagonalization, determinant quantum Monte Carlo, and dynamical cluster approximation (DCA) with an emphasis on pairing correlations. Using these methods, we provide a comprehensive view of pairing in the model. Specifically, we compute the pair-field susceptibility for these methods and study its dependence on temperature, doping, interaction strength, and charge-transfer gap. Using DCA, we also solve the Bethe-Salpeter equation for two-particle Green's function to identify the dominant pairing correlations and its orbital composition, and to determine the transition temperature to the superconducting state.

*This work was supported by the Scientific Discovery through Advanced Computing (SciDAC) program funded by U.S. Department of Energy, Office of Science, Advanced Scientific Computing Research and Basic Energy Sciences, Division of Materials Sciences and Engineering.

9:48AM R48.00010: Explaining the Anomalous Isotope Shift in Cuprate High Temperature Superconductivity  
DENNIS NEWNS (Presenter), GLENN MARTYNA, Pimpernel SSIT, NY, SOUMYA KANTI GANGULY, Physics, Indian Institute of Science — The pairing mechanism of cuprate High Temperature Superconductors is still controversial. A vibrational component to the pairing mechanism is suggested by the anomalous Isotope Shift (IS), which is of order the BCS value at dopings well below the maximum Tc, but is very low at dopings close to the maximum Tc. Here, based on the Fluctuating Bond Model [1] (FBM), we re-examine the IS issue focusing on the oxygen soft mode associated in the FBM with the pseudogap - knowing that a soft mode plus a van Hove singularity in the electronic density of states is one mechanism capable of leading to the cuprate-type anomalous IS [2]. A quantum mechanical treatment of the FBM model in Born-Oppenheimer approximation shows soft excitations of a few meV. Solving the Eliashberg equation we evaluate the IS, and will present the results.

10:00AM R48.00011: Tendency of nematicity in the extremely underdoped t-J model*

YIHSUAN LIU (Presenter), Institute of Physics, Academia Sinica, Nankang, Taiwan, WEI-LIN TU, Institute for Solid State Physics, The University of Tokyo, Kashiwa, Japan, TING-KUO LEE, Department of Physics, National Sun Yat-sen University, Kaohsiung, Taiwan — Underdoped cuprates exhibiting electronic nematicity have been reported by various measurements such as scanning tunneling microscopy (STM) [1, 2] and resistivity [3]. These results indicate that nematicity already exists in very lightly doped thin film, which motivates us to study the extremely underdoped t-J model and Heisenberg model via variational Monte Carlo (VMC) method and renormalization mean-field theory (RMFT). In the previous VMC study of the Heisenberg model, various groups have confirmed that the uniform RVB+AFM trial wave function has the lowest energy [4], which is very close to the best numerical estimation of the exact ground state energy. However, we found that various C4 broken states are almost degenerate with the uniform solution. Also, we will study the lightly doped cases with one hole only.

*The authors are grateful for the support of Taiwan Ministry of Science and Technology Grant MOST 108-2112-M-110-015

10:12AM R48.00012: Nematic superconductivity in twisted bilayer graphene*

DMITRY CHICHINADZE (Presenter), LAURA CLASSEN, ANDREY CHUBUKOV, University of Minnesota — Twisted bilayer graphene (TBG) shows insulating and superconducting phases in connection with an exceptional flattening of its lowest-lying energy bands. In the hole-doped case with the highest critical temperature the superconducting state is nematic, i.e. the threefold lattice rotation symmetry is broken inside the superconducting phase. We analyze superconductivity near Van Hove (VH) filling in TBG within an itinerant approach. In particular, we present a mechanism for nematic superconductivity, which originates in the interplay of two superconducting orders with similar critical temperatures. We argue that TBG can be properly described by patch models with six VH points for electron and twelve for hole doping reflecting the electron-hole asymmetry. We obtain the pairing interactions being dependent on twist-induced non-local interactions. For hole-doping, two channels with almost equal coupling constants are attractive. We show that the ground state is a nematic phase of coexistence. We find two possible mixed states, one is time-reversal symmetric, the other breaks time-reversal in addition to the lattice rotation symmetry.

*The work was supported by U.S. DOE, Office of Science, Basic Energy Sciences, under Award No. DE-SC0014402.
Magnetic and superconducting correlation in monolayer and twisted bilayer graphene

TIANXING MA (Presenter), Beijing Normal Univ — Using exact quantum Monte Carlo method, we identify the phase diagram of the half filled, the lightly doped and heavily doped graphene. At half filling, the system is driven to a Mott insulator with antiferromagnetic long range order by increasing interaction, and a transition from a $d+i d$ pairing to a $p+i p$ pairing is revealed, depends on the next-nearest hoping and the electronic fillings. We also examine the recent novel electronic states seen in magic-angle graphene superlattices. We reveal that an antiferromagnetically ordered Mott insulator emerges beyond a critical $U_c$ at half filling, and with a small doping, the pairing with $d+i d$ symmetry dominates over other pairings at low temperature. The effective $d+i d$ pairing interaction strongly increase as the on-site Coulomb interaction increases, indicating that the superconductivity is driven by electron-electron correlation. Our non-biased numerical results demonstrate that the twisted bilayer graphene share the similar superconducting mechanism of high temperature superconductors, which is a new and idea platform for further investigating the strongly correlated phenomena.

Superconductivity in the doped quantum spin liquid on the triangular lattice

HONG-CHEN JIANG (Presenter), SLAC - Natl Accelerator Lab — Broad interest in quantum spin liquid (QSL) phases was triggered by the notion that they can be viewed as insulating phases with preexisting electron-pairs, such that upon light doping they might automatically yield high temperature superconductivity. Yet despite intense efforts, definitive evidence showing that doping QSLs leads to superconductivity has been lacking. We address the problem of a lightly doped QSL through a large-scale density-matrix renormalization group study of the $t$-$J$ model on the triangular lattice with a small but non-zero concentration of doped holes. We provide direct evidences that doping QSL can naturally give rise to superconductivity. The ground state is consistent with a Luther-Emery liquid with power-law superconducting and charge-density-wave correlations but short-range spin-spin correlations. Specifically, the superconducting correlations are the dominant correlations on both four-leg and six-leg cylinders, indicating that long-range superconductivity would emerge in doping QSL in two dimensions.

This work was supported by the Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract DE-AC02-76SF00515.
10:48AM R48.00015: Supoerconductiviy in the doped chiral spin liquid on triangular lattice*

YI-FAN JIANG (Presenter), HONG-CHEN JIANG, SLAC and Stanford Univ — Theory proposes that doping chiral spin liquid (CSL) can give rise to topological superconductivity. Yet it has been extensively studied in the past, definitive evidences showing this has been lacking. We address this problem by studying the t-J model supplemented by spin chiral interaction (with coupling $J^\chi$) on the triangular lattice using density-matrix renormalization group. It has been established that the ground state of the system at half-filling is a CSL when $0.32 \leq J^\chi / J \leq 0.56$, or equivalently $\nu=1/2$ bosonic fractional quantum Hall state. Interestingly, we find that the ground state of the system upon light doping the CSL is consistent with a Luther-Emery liquid, which is characterized by quasi-long-range superconducting and charge-density-wave correlations but with a finite spin gap and one gapless charge mode. Furthermore, we show that the superconducting correlations are the dominant correlations and its pair symmetry is consistent with d+id-wave.

Session R49 DCMP: Superconducting Proximity Effect and Josephson Junctions IV Mile High Ballroom 1B - Thomas Bullard, UES, Inc.

8:00AM R49.00001: Search for Majorana bound states in niobium-Bi2Se3-niobium arrays and junctions* XIANGYU SONG (Presenter), YANG BAI, GUANG YUE, JAMES N ECKSTEIN, DALE J VAN HARLINGEN, ALEXEY BEZRYADIN, University of Illinois at Urbana-Champaign — Under the right conditions, Majorana bound states (MBS) are believed to live in lateral Josephson junctions formed by depositing s-wave superconductors onto the surface of topological insulator thin films, e.g., Bi2Se3.

We have fabricated and measured lateral superconductor-topological insulator-superconductor (S-TI-S) single junctions, square arrays, transmon geometries, and other geometries to look for the signatures of MBS.

Our experiments include Fraunhofer patterns on such patterns, which show some signature kinks at fields less then flux quantum, lifted nodes, and missing critical current maxima. We will discuss extensive measurement performed on niobium-Bi2Se3 hybrid structures in microwave resonators, which include kinetic inductance vs. magnetic field and the quality factor vs. magnetic field measurements. The possibility of making a transmon qubit with a topological insulator film will be discussed.

*The work is supported by NSF-DMR 1836710 grant and by Army Research Office under agreement W911NF1910067.
8:12AM R49.00002: Growth and Characterization of (Bi\textsubscript{x}Sb\textsubscript{1-x})\textsubscript{2}Te\textsubscript{3}/MgB\textsubscript{2} heterojunctions
LONG CHENG (Presenter), LIN LI, University of Waterloo, HUI ZHANG, XIAODONG MA, Hefei National Laboratory for Physical Sciences at the Microscale (HFNL), University of Science and Technology of China, GEORGE NICHOLS, PETER SPRENGER, DELER LANGENBERG, DAVID CORY, GUOXING MIAO, University of Waterloo — Topological insulator-superconductor heterostructure, which was predicted to be an ideal system to search Majorana Fermions, has been extensively studied in recent years. Zero bias conductance peak (ZBCP) in such system was reported as a signature of Majorana bound states by several groups. Here we report the growth of epitaxial (Bi\textsubscript{x}Sb\textsubscript{1-x})\textsubscript{2}Te\textsubscript{3} (BST) thin film on MgB\textsubscript{2} and study the vertical Josephson junction based on BST/MgB\textsubscript{2}. The interface of BST/MgB\textsubscript{2} was found to be chemically reactive. Substrate temperature has to be lowered than typical growth temperature of BST to inactivate the reaction. In addition, a 2.5nm thin Nb layer inserted in between BST and MgB\textsubscript{2} can significantly improve the interface quality with little reduction to the pairing gap. Finally, 50nm Nb thin film was deposited on top to form the Nb/BST/MgB\textsubscript{2} and Nb/BST/Nb/MgB\textsubscript{2} junction. The former one shows tunneling behavior due to the formation of insulating layer at the interface of BST/MgB\textsubscript{2}, while the latter one behaves more like a Josephson junction. ZBCPs were observed in both the junctions, which survive even above 4.2K, much higher than previously reported. Our study provides a new design for searching Majorana Fermions which may exist at a higher temperature than before.

8:24AM R49.00003: Shapiro steps as a thermal probe in superconducting nanobridges*
CONNOR SHELLY (Presenter), PATRICK SEE, IVAN RUNGGER, JONATHAN WILLIAMS, National Physical Laboratory — We present measurements of microwave-induced Shapiro steps in a superconducting nanobridge weak link in the dissipative branch of a hysteretic current-voltage characteristic. Typically the hot-spot Joule heating in nanobridges is suggested to extend many micrometers beyond the nanobridge itself and into the superconducting electrodes heating the system above the critical temperature. We demonstrate that the Shapiro steps can be used to infer a reduced critical current and an associated local temperature. The observation of the Shapiro steps in the dissipative branch of the IVC show that a finite Josephson coupling exists in the dissipative state, and although the nanobridge is heated, our thermal model shows that the temperature remains always below the critical temperature. This work provides evidence that Josephson behaviour can remain in thermally-hysteretic nanobridges and allows extension of the temperature range that nanobridge devices (e.g., SFQ circuits, nanoSQUIDs) can be operated in.

*This work is funded as part of a feasibility study funded by Innovate UK: Project number 102677. Co-funding by the UK NMS Programme.
8:36AM R49.00004: Towards Perfect Andreev Reflection in Graphene-NbSe$_2$ planar Josephson Junctions  ADAM KRISTOPHER WILLIAMS (Presenter), MITALI BANERJEE, CORY DEAN, Physics, Columbia University — Several theoretical proposals suggest that combining 2D superconductors with 2D semiconductors could provide a rich platform to study novel quantum phases such as Majorana zero modes — fractional quasiparticles localized at boundaries of topological superconductors. However, interfacing these two phenomena with high interfacial transparency remains a longstanding challenge. The rapidly growing catalogue of 2D Van der Waals materials provides a platform for making atomically clean interfaces between materials with a variety of properties. In this talk I will present newly developed techniques to assemble NbSe$_2$-graphene Josephson junctions such that we simultaneously improve the junction transparency while also maintaining high mobility in the graphene channel. Transparent graphene-NbSe$_2$ contacts as a platform to explore planar topological Josephson junctions will be discussed.

8:48AM R49.00005: Tunneling spectroscopy of c-axis epitaxial cuprate junctions*  DOUGLAS NATELSON (Presenter), PANPAN ZHOU, Physics and Astronomy, Rice University, LIYANG CHEN, Applied Physics Graduate Program, Rice University, ILYA SOCHNIKOV, Department of Physics, University of Connecticut, TSZ CHUN WU, MATTHEW FOSTER, Physics and Astronomy, Rice University, ANTHONY TRAVIS BOLLINGER, XI HE, IVAN BOZOVIC, Brookhaven National Laboratory — Tunnel junctions are valuable tools for electronic spectroscopy, with epitaxial structures minimizing extrinsic effects of disorder. We report tunneling spectroscopy measurements, over a broad temperature and bias range, in c-axis La$_{2-x}$Sr$_x$CuO$_4$/La$_2$CuO$_4$/La$_{2-x}$Sr$_x$CuO$_4$ heterostructures grown via atomic layer-by-layer molecular beam epitaxy. Above $T_c$ of the LSCO layers, these structures show the pseudogap, while below $T_c$, the devices show superconductor/insulator/superconductor (SIS) response. Down to 20 mK there is no Josephson critical supercurrent $I_c$, indicating strongly incoherent transport. Tunneling spectra show greatly suppressed coherence peaks. The $T=0$ zero-bias conductance remains at approximately 20-30% that of the normal-state, implying a substantial population of unpaired carriers. As temperature is raised, the superconducting gap fills in rather than closing at $T_c$. The spectra show an inelastic tunneling feature at $\sim 0.08$ eV, suppressed as $T$ exceeds $T_c$. We discuss how these properties are inconsistent with standard $d$-wave tunneling expectations, despite the structural perfection of the epitaxial stack.

9:00AM R49.00006: Scanning Tunneling Spectroscopy Study of the Superconducting Proximity Effect in (110)-oriented Manganite/Cuprate and Nickelate/Cuprate Thin Films* 
RAINNI CHEN (Presenter), CHAO C ZHANG, CHRIS GRANSTROM, JOHN Y.T. WEI, Univ of Toronto — An anomalously long-ranged (~ 30 nm) superconducting proximity effect was previously reported in thin-film heterostructures of ferromagnetic La_{2/3}Ca_{1/3}MnO_3 (LCMO) and superconducting YBa_2Cu_3O_{7-δ} (YBCO), and attributed to the induction of spin-triplet pairing [1,2]. However, there remains debate over the existence of this long-ranged proximity effect, since scanning tunneling spectroscopy (STS) on c-axis LCMO/YBCO bilayers has failed to observe any direct and microscopic evidence of this effect [3]. In this work, we extend prior STS studies to (110)-oriented films, the orientation most likely to produce d-wave Andreev resonances that show up as zero-bias conductance peaks (ZBCP). We observe these ZBCPs ubiquitously on our unilayer YBCO films, but do not observe them on our bilayer LCMO/YBCO films down to an LCMO overlayer thickness of ~ 5 nm. The ZBCPs also do not appear on (110)-oriented LaNiO_3/YBCO bilayers, measured as a non-magnetic control. Our results are inconsistent with proximity-induced spin-triplet superconductivity in LCMO/YBCO structures.

*This work was supported by NSERC, CFI, OIT, and CIFAR.

9:12AM R49.00007: Absence of proximity induced superconductivity in Bi/Bi2212 heterostructure*  
ASISH KUNDU (Presenter), ILYA DROZDOV, ZEBIN WU, GENDA GU, TONICA VALLA, Condensed Matter Physics and Material Science, Brookhaven National Laboratory, Upton, NY, United States — Mixing of topological states with superconductivity could result in topological superconductivity, where the elusive Majorana fermions could be applied in fault-tolerant quantum computing. Recent study\(^{(1)}\) suggests that topological superconductivity might be possible to realize in a Bi /Bi\(_2\)Sr\(_2\)CaCu\(_2\)O\(_{8+δ}\) (Bi2212) heterostructure by inducing a pairing in the Rashba-spin–orbit-coupled states of Bi by proximity effect. Here, we present an angle-resolved photoemission spectroscopy study of ultrathin Bi films grown in-situ on Bi2212 that show the absence of proximity effect. We find that the electron transfer from the film to the substrate and the resulting severe underdoping of Bi2212 interface is a likely origin for the absence of proximity effect. We also propose a possible way of preventing a total loss of proximity effect in this system.

The proximity effect in disordered and quasiperiodic systems

GAUTAM RAI (Presenter), STEPHAN WOLFGANG HAAS, Univ of Southern California, ANURADHA JAGANNATHAN, Laboratoire de physique des solides, Université Paris-Sud — We investigate the superconducting proximity effect in one-dimensional hybrid rings with a superconducting and a normal part. We consider two cases: when the normal part is a) a weakly disordered crystal and b) quasiperiodic. We carry out self-consistent calculations using a real space mean field Bogoliubov-de Gennes type approach within the tight binding framework. For the disordered case we find that the decay of the superconducting order parameter into the normal region reflects the the band center anomaly—a cusp like deformation in the density of states around E=0 known to exist for weak disorder. The order parameter decay when the normal chain has a Fibonacci hopping sequence will be discussed as well, along with the key features that differentiate the proximity effect in the two cases.

Proximitized Josephson junctions in highly-doped InAs nanowires robust to optical illumination*

LILY YANG (Presenter), STEPHAN STEINHAUER, KTH Royal Inst of Tech, ELIA STRAMBINI, NEST-Pisa, Istituto Nanoscienze, THOMAS LETTNER, LUCAS SCHWEICKERT, MARIJN VERSTEEGH, KTH Royal Inst of Tech, FRANCESCO GIAZOTTO, VALENTINA ZANNIER, LUCIA SORBA, NEST-Pisa, Istituto Nanoscienze, DMITRY SOLENOV, Physics, Saint Louis University — We have studied the effects of optical-frequency light on proximitized InAs/Al Josephson junctions based on highly n-doped InAs nanowires at varying incident photon flux and at three different photon wavelengths. The experimentally obtained IV curves were modeled using a shunted junction model which takes scattering at the contact interfaces into account. The Josephson junctions were found to be surprisingly robust, interacting with the incident radiation only through heating, whereas above the critical current our devices showed non-thermal effects resulting from photon exposure. Our work provides guidelines for the co-integration of Josephson junctions alongside quantum photonic circuits and lays the foundation for future work on nanowire-based hybrid photon detectors.

*The fabrication and measurement at KTH are co-funded by Vinnova and Marie Curie Actions FP7-PEOPLE-2011-COFUND (GROWTH 291795), and the growth activity at NEST is cofunded by H2020-FETOPEN-2018-2020 (AndQC).
9:48AM R49.00010: Quantum phenomena in Unconventional 1D Josephson Arrays*  WENSEN LU (Presenter), KONSTANTIN KALASHNIKOV, PLAMEN KAMENOV, THOMAS J DINAPOLI, MICHAEL GERSHENSON, Rutgers University, New Brunswick — The largely unexplored regime of low transparency Josephson junction chains with low charging energy $E_C$ has attracted theoretical interest since it offers a platform to realize many-body effects in superconducting circuits [1] and quantum phase slip devices [2]. In this work we study the current-voltage characteristics (IVc) of Josephson junction with Josephson energy $E_J \sim E_C \sim 0.01-1K$ and temperature range 0.03-1K. We observed the suppression of switching current $I_{SW}$ and finite zero-biased-resistance $R_0$ for different $E_J/E_C$ and $E_J/T$ ratios due to thermally activated phase slips and macroscopic quantum phase tunneling. We will discuss the behavior of $I_{SW}$ and $R_0$ at different temperature and environmental impedance, and propose potential experimental conditions to observe many-body physics such as localization effects [1] and Bloch oscillations [2] as analogues to condensed matter systems.

10:00AM R49.00011: Proximity effects of niobium nano-hydrides on state of the art superconducting radio frequency Nb cavity*  ZUHAWN SUNG (Presenter), ALEXANDER ROMANENKO, ANNA GRASSELLINO, Fermilab — Nb hydrides are responsible for performance degradation at high accelerating field regime in a superconducting radio frequency cavity for the linear particle accelerator, known as high field Q slope (HFQS). Normal conductive Nb hydride precipitates at the cavity operation temperature , ~2K, and leads to breakdown of surface superconductivity due to proximity effect under RF magnetic field, from which significant power dissipation occurs on the cavity surface. In this study, precipitation of nano-meter scale Nb hydrides on a SRF Nb cavity surface is first directly observed using cryogenic atomic force microscopy, and statistical morphological features of Nb hydrides are compared with HFQS behaviors of state of the art SRF Nb cavities that have shown high accelerating gradient close to the theoretical limit, 50MV/m. Additionally, RF magnetic field enhancement due to Nb hydride topological properties are discussed.

10:12AM R49.00012: Low Temperature Annealing and the Generation of Superconductivity in Nickel-Bismuth Bilayers* MATTHEW VAUGHAN, NATHAN SATCHELL, MANNAN ALI, Univ of Leeds, CHRISTY KINANE, GAVIN STENNING, SEAN LANGRIDGE, ISIS Neutron and Muon Source, Rutherford-Appleton Laboratory, GAVIN BURNELL (Presenter), Univ of Leeds — Unconventional superconductivity has been suggested to be present at Ni/Bi interfaces in thin-film bilayers. We report a study of the structural, magnetic and superconducting properties of sputtered Bi/Ni bilayers. As-grown, our films do not display a superconducting transition. However, when stored at room temperature, after about 14 days our bilayers do develop a superconducting transition up to 3.8 K.

We perform structural characterization with X-ray diffraction and spin polarized neutron reflectometry, and measure magnetisation and low temperature electron transport for samples annealed at 70°C. We show that the onset of superconductivity in our samples is coincident with the formation of ordered NiBi$_3$ intermetallic alloy, known to be an s-wave superconductor. We find that the annealing process has a rather low activation energy of (0.86±0.06) eV. Gentle heating as typical for cleanroom processing will result in NiBi$_3$ formation which poses a challenge for studying distinct Bi/Ni interface behaviour.

10:24AM R49.00013: Superconducting Phase Slip Oscillations on Demand* IRIS DORN (Presenter), ARMEN GULIAN, Chapman Univ — Remarkable properties of phase slip centers (PSCs) have direct analog with weakly coupled superconductors (Josephson contacts, SNS-junctions, ScS systems, etc.). In typical 1-D wire models of these types, PSC oscillations arise in the geometric wire centers or, if more than one PSC, symmetrically to this center location. We add weak spots in the model, which shift the position of the PSCs away from the symmetric location in a degree dependent on the imperfection's character, by taking into account enhanced phonon feedback onto the Cooper-pair/normal metal system of the wire which generates these phonons. The inclusion of this effect into the time-dependent Ginzburg-Landau (TDGL) system of equations requires an additional function and corresponding equation in the TDGL system. Interestingly, the system finds there is a competition between the induced weak points and symmetry-induced locations. Thus using our approach the PSCs can be generated on demand and provides the opportunity to initiate PSCs at the required time and required place in the wire without changing its biasing properties with high accuracy theoretical modeling.

8:00AM R50.00001: Spin Hall magnetoresistance studies of differently strained ultrathin SrMnO$_3$ films
ARIJIT DAS (Presenter), ADAM J WATSON, ESWARA PHANINDRA VALLABHANENI, TAMALIKA BANERJEE, Univ of Groningen — The ability to tune magnetic ordering in a nominally antiferromagnetic insulator, making use of the co-dependence of the charge, spin and orbital degrees of freedom in transition metal oxides, opens a vast playing field in the area of antiferromagnetic spintronics. We use Spin Hall magnetoresistance (SMR) as a probe of the magnetic ordering in thin films of SrMnO$_3$ (SMO) when grown on two different substrates – SrTiO$_3$ (STO) and LaAlO$_3$ (LAO) - that changes the induced strain from tensile to compressive respectively. An in-plane magnetic field dependent angular measurement of the transverse resistivity of Pt Hall bars patterned on SMO films were studied for both cases. The compressively strained SMO film on LAO shows a 180° phase shift relative to the tensile strained SMO film on STO, suggesting a change in the magnetic ordering from antiferromagnetic to ferromagnetic. This is brought about by the presence of oxygen vacancies promoted by the underlying tensile strain in SMO on STO. This work shows the unique possibility of tailoring the magnetic properties in complex oxides with strain and the ability of interface spin-transport probes as SMR to fingerprint them, establishing their suitability for magnon transport studies.

8:12AM R50.00002: Orbital wave in the Raman scattering cross section of LaMnO$_3$*
PUREVDORJ MUNKHBAATAR (Presenter), Institute of Photonics and Information Technology, Jeonbuk National University, MYUNG-WHUN KIM, Department of Physics, Jeonbuk National University — We calculated the polarization-dependent Raman scattering cross-section spectra of LaMnO$_3$ below the A-type magnetic ordering temperature. Two strong peaks appear around the MnO$_6$ octahedra stretching phonon frequency. One mode shows Ag symmetry, while the other mode shows Bg symmetry. We found that the Ag symmetry peak is a Jahn-Teller phonon coupled to the orbital wave and the Bg symmetry peak is an orbital wave mode coupled to a Q2 phonon mode via the Jahn-Teller electron-phonon coupling.

*This research was supported by the National Research Foundation of Korea (Grants No. 2016R1D1A1B03934648 and No. 2016K2A9A1A09914398); by the National Research Foundation of Mongolia (Grant No. SSA 017/2016).
The Jahn-Teller (JT) distortion occurs in a single valance system where a structural distortion is needed to lift the orbital degeneracy. In the mixed valance system La$_{1-x}$Sr$_x$MnO$_3$ (LSMO), the JT transition remains robust and sharp. It is not clear if the distribution of Mn$^{3+}$ in Mn$^{4+}$ matrix plays an important role. On cooling, LSMO undergoes the cooperative JT transition to order orbitals, spin ordering transition, and the charge ordering transition[1]. Pair distribution function analysis of neutron powder diffraction data has previously been done to discuss the role of polarons in the transition[2,3]. With single-crystal neutron diffuse scattering (NDS), we have observed patterns that show an interesting evolution as it is cooled through three transitions. Weak rod-shaped NDS features along L with even H+K above $T_{JT}$ get enhanced as the temperature is cooled below $T_{JT}$, suggesting coherent scattering is developed above $T_{JT}$. The NDS features disappear below the charge ordering transition temperature $T_{CO}$, associated with the formation of superlattices. Potential models to interpret the observations will be discussed.

**Visualization of Site- and Bond-Centered Charge Order in a Half-Doped Manganite**

ISMAIL EL BAGGARI (Presenter), Physics, Cornell University, DAVID J. BAEK, Electrical and Computer Engineering, Cornell University, MICHAEL J. ZACHMAN, Applied and Engineering Physics, Cornell University, DI LU, Physics, Stanford University, YASUYUKI HIKITA, Applied Physics, Stanford University, ELIZABETH NOWADNICK, Materials Science and Engineering, University of California Merced, HAROLD HWANG, Applied Physics, Stanford University, LENA KOURKOUTIS, Applied and Engineering Physics, Cornell University — Charge order instabilities, the ordering of electrons and spins into periodic structures, occur in many classes of correlated quantum matter. Within a superlattice, charge-ordered states may have distinct electronic patterns and symmetries, however, distinguishing between them is challenging. In half-doped manganites, for instance, both site-centered (stripe) and bond-centered (bi-stripe) orders have been proposed. Using cryogenic scanning transmission electron microscopy, we map the charge-ordered structure in a Nd1/2Sr1/2MnO3 thin film by measuring picoscale periodic lattice distortions. We find two distinct ground states coexisting over tens of nanometers. The first is consistent with site-centered order. The second represents bi-stripes which remarkably are not purely bond-centered. The bi-stripes are intermediate between bond- and site-centered order and break inversion symmetry.

8:48AM R50.00005: Probing Orbital Order in Magnetite with Resonant Elastic X-Ray Scattering*
NELSON HUA (Presenter), University of California, San Diego, JIANHENG LI, University of California, Davis, STJEPAN B HRKAC, ANATOLY SHABALIN, University of California, San Diego, ANDI BARBOUR, WEN HU, CLAUDIO MAZZOLI, STUART B WILKINS, Brookhaven National Laboratory, ROOPALI KUKREJA, University of California, Davis, ERIC FULLERTON, OLEG SHPYRKO, University of California, San Diego — The underlying mechanism driving the metal-insulator transition in magnetite and the presence of charge order in the low-temperature insulating state remain unresolved since Verwey first discovered this transition back in 1939. Standard X-ray diffraction studies are difficult to perform due to twinned domains, and the various studies investigating the bond lengths between Fe+2 and Fe+3 at the octahedral sites have shown at most a charge disproportionality. However, the presence of a Bragg forbidden (001/2) superlattice peak, which is only observable in the insulating state at resonant energies, is a hidden door into magnetite's charge and orbital states. We have used coherent soft x-rays at the Fe L-edge resonant energy to probe the orbital order at the octahedral Fe sites. An unexpected diffuse scattering ring about the (001/2) superlattice peak that exists in both the insulating and metallic phases was discovered simultaneously. By following the shape and intensity of this diffuse scattering ring in reciprocal space, we can map out the degree of correlated disorder of the Fe ions in both the metallic and insulating phases.

9:00AM R50.00006: Metal-insulator transition with ferromagnetic background in the two-orbital model for manganites*
CENGIZ SEN (Presenter), Physics Department, Lamar University, ELBIO DAGOTTO, Physics Department, University of Tennessee — The complex spin, electron and phonon dynamics of manganese oxides continues to attract attention. In this talk, we present results of unbiased Monte Carlo simulations with fermionic exact diagonalization of the two-orbital model with Jahn-Teller phonons at filling x=1/3 on lattice sizes up to 15x15. We identify a region in the finite-temperature phase diagram with a metal-insulator transition upon increasing electron-phonon coupling. In the metal the spin background is ferromagnetic (FM) with uniform charge order, whereas the insulator shows diagonal stripes while retaining the FM background. We report resistivity and magnetization measurements alongside with spin and charge structure factors.

*The authors acknowledge support from the Advanced Computing Facility (ACF) at the National Institute of Computational Sciences (NICS).
9:12AM R50.00007: Gyrotropic birefringence via electromagnon resonance in multiferroic manganite

MAKIKO OGINO (Presenter), Applied physics, Univ of Tokyo, YOSHIO KANEKO, YOSHINORI TOKURA, Center for Emergent Matter Science (CEMS), RIKEN, YOUTAROU TAKAHASHI, Applied physics, Univ of Tokyo — The magnetoelectric (ME) coupling has been exemplified in the certain classes of crystalline solids including multiferroics and topological insulators. Since the ME coupling modifies the Maxwell’s equations, such ME materials give rise to the exotic electromagnetic phenomena. In particular, the light-matter interaction can induce the unconventional gyrotropy, which is called gyrotropic birefringence (GB), whereas its observation remains highly limited. We focus on the electrically active spin excitation i.e. electromagnon, inherent to the multiferroics, which potentially exhibits the enhanced optical ME effect. Here we report the first observation of GB on multiferroic manganite with spin-induced ferroelectricity by use of the time-domain terahertz polarimetry. The enhanced optical rotation arising from the GB was found on the electromagnon resonance. It is demonstrated that the GB is scaled by the bilinear coupling of ferroic order parameters $P \cdot M$ ($P$: Electric polarization, $M$: magnetization) in the magnetic field dependence. In addition, the quantitative spectral analysis reveals that the electromagnon and antiferromagnetic resonance cooperatively produce the enhanced GB, indicating the important role of inter-mode coupling for the enhanced dynamical ME effect.

9:24AM R50.00008: Torsional mode as order parameter in H-ErMnO$_3$: mode screening, Fröhlich resonance, bipolarons

NÉSTOR MASSA (Presenter), CONICET- Univ. Nac. La Plata, Argentina, AURELIEN CANIZARÈS, LEIRE DEL CAMPO, CNRS-CEMHTI, Orléans, France, KARSTEN HOLLDACK, HZB, BESSY II, Berlin, Germany, VINH TA PHUOC, GREMAN, Univ. François-Rabelais,Tours, France, PAULA KAYSER, CSEC-UE, Edinburgh, UK, JOSE ANTONIO ALONSO, ICMM-CSIC, Madrid, Spain — While far infrared absorption, normal reflectivity, and emission spectra of hexagonal ErMnO$_3$ give a quantitative picture of phonon softening and merging on heating, the torsional mode at ~306 cm$^{-1}$ (300 K), associated to the negative thermal expansion and a $c$ axis hybridization of O-2p with Er$^{3+}$ levels, displays at lock-in Tc~830 K a distinctive infrared line shape anomaly and reststrahlen screening within the context of a ferroelectric instability inferred for a Mott-Hubbard insulator. Since the longitudinal optical (LO) mode macroscopic field screening implies phonon dynamic coupling to charge fluctuations in an electron correlated insulating polar environment we used the above the gap $\lambda_{exc}$= 355 nm Raman line to turn on the Fröhlich mechanism at macroscopic field frequencies at which the interaction between carriers and the Coulomb long range, responsible of the TO-LO split, takes place. We found a new Raman activated band that has its contour red shifted overlapping the infrared reflectivity minimum. It implies a univocal visualization of a huge electron-lattice interaction concomitant with finding small polaron correlations for which that phonon mediates in the formation of high temperature H-ErMnO$_3$ mid-infrared bipolarons below the metal-insulator transition at ~1600 K.
9:36AM R50.00009: Doping evolution of the electronic structure in RENiO$_3$* JIARUI LI (Presenter), Massachusetts Institute of Technology MIT, ROBERT GREEN, University of Saskatchewan, ZHIHAI ZHU, GRACE H ZHANG, DA ZHOU, MIN GU KANG, Massachusetts Institute of Technology MIT, JERZY T. SADOWSKI, Brookhaven National Laboratory, RONNY SUTARTO, FEIZHOU HE, Canadian Lightsource, ZHEN ZHANG, YIFEI SUN, SHRIRAM RAMANATHAN, Purdue University, RICCARDO COMIN, Massachusetts Institute of Technology MIT — Rare earth nickelates (RENiO$_3$) exhibit metal-insulator transitions accompanied by the appearance of charge and spin order, at times concurrently. The understanding of the evolving ground state in these materials is hindered by the existence of multiple competing orders which are further coupled to various kinds of local perturbations (strain, defects, disorder). Very recently, control of carrier doping by means of oxygen stoichiometry has been achieved in RENiO$_3$, presenting an opportunity to study the broader electronic phase diagram of these systems. In this talk, I will present our recent soft X-ray spectroscopy, resonant scattering, and photoemission microscopy experiments on both pristine and electron doped RENiO$_3$. Our results reveal the doping evolution of the electronic structure in RENiO$_3$.

*This material is based upon work supported by the National Science Foundation under Grant No. 1751739

9:48AM R50.00010: Local metallic properties of LaNiO$_3$ detected using β-detected NMR VICTORIA KARNER (Presenter), ARIS CHATZICHRISTOS, DAVID L CORTIE, MARTIN H DEHN, OLEKSANDR FOYEVTSOV, KATERYNA FOYEVTSOVA, DEREK FUJIMOTO, ROBERT F KIEFL, University of British Columbia, PHILIP C. P. LEVY, RUOHONG LI, TRIUMF, RYAN M. L. MCFADDEN, University of British Columbia, GEORGE MORRIS, DAVID PEARSON, MONIKA K STACHURA, TRIUMF, JOHN TICKNOR, University of British Columbia, GEORG CHRISTIANI, GENNADY LOGVENOV, FRIEDERIKE WROBEL, BERNHARD KEIMER, Max Planck Institute for Solid State Research, JUNJIE ZHANG, JOHN MITCHELL, Argonne National Laboratory, W ANDREW MACFARLANE, University of British Columbia — The rare earth nickelates (RNiO$_3$) are a prototypical example of a metal-insulator transition in strongly correlated materials; LaNiO$_3$ is the only RNiO$_3$ that remains metallic. Here, we will compare measurements on a single crystal and a thin film of LaNiO$_3$ using β-detected NMR. Analogous to μSR, β-NMR is a sensitive local probe of the electronic and magnetic properties of materials through the coupling between the $^8$Li nuclear spin and the electromagnetic properties of the host material and; therefore, provides a unique, local perspective. We find clear evidence of metallic behaviour and no static magnetism. However, the detailed account of the data appears inconsistent with the commonly considered distorted perovskite structure[1].

10:00AM R50.00011: Electron- and Hole-Doping Effects on the Metal-Insulator Transition in “113” Nickelates [RNiO$_3$, $R = \text{Pr, Nd, (La,Y)}$] Prepared at High Oxygen Pressure*  
GREGORIO PONTI, ZACHARY P. KUKLINSKI, QUINN D. B. TIMMERS, JOHN MARKERT (Presenter), Department of Physics, University of Texas at Austin — We report x-ray diffraction, electrical resistivity, and other data on bulk polycrystalline materials prepared under high oxygen pressure (150–200 bar) at high temperature ($T \approx 1000^\circ$C). These conditions stabilize the nearly simple-perovskite “113” structure, RNiO$_3$. For the orthorhombic parent compounds with the largest rare-earth ions that exhibit a metal-insulator transition, $R = \text{Pr and Nd}$, we dope with divalent Sr and Ba (hole doping) and tetravalent Ce and Th (electron doping). Results for Nd$_{1-x}$A$_x$NiO$_3$ ($A = \text{Sr, Ce, Th}$) have been reported previously$^1$: for example, for Ce$^{4+}$, the net effect on the metal-insulator transition, $\partial T_{\text{MI}}/\partial x \approx -220$ K, was corrected for size effects to obtain a bare electron-doping effect, $\partial T_{\text{MI}}/\partial x_{\text{elec}} \approx -1100$ K. Remarkably in our study, we find that, for Pr$_{1-x}$Ce$_x$NiO$_3$, the shift in the metal-insulator transition temperature with concentration $x$ is positive, with a net $\partial T_{\text{MI}}/\partial x \approx +225$ K. Also, we find hysteresis in the metallic resistivity of rhombohedral La$_{1-x}$Ce$_x$NiO$_3$, perhaps a signature of low-$T$ pseudogap monoclinic short-range order.$^2$

10:12AM R50.00012: Large magnetic excitation gap in antiferromagnetic YNiO$_3$ detected by NMR*  
LUKAS KOROSEC (Presenter), ETH Zurich and University of Geneva, DARIUSZ GAWRYLUK, MARISA MEDARDE, Paul Scherrer Institute, TONI SHIROKA, HANS RUDOLF OTT, JOEL MESOT, ETH Zurich and Paul Scherrer Institute — The rare-earth nickelate perovskites (RENiO$_3$) are an archetypal family of strongly correlated electron materials. Their antiferromagnetic state with four nickel atoms per period remains poorly studied, even though it has been predicted to be a type-II multiferroic with large polarization. Currently, there is no agreement on the magnetic structure and low-energy spin model for bulk RENiO$_3$. We present $^{17}$O nuclear-spin–lattice relaxation measurements demonstrating the presence of a large gap of 30 meV in the magnetic excitation spectrum of YNiO$_3$.

NMR relaxation data on quadrupolar nuclei (spin > 1/2) such as $^{17}$O in a polycrystalline or powdered antiferromagnet often seem to contain an unphysical jump in the temperature-dependence of the apparent relaxation rate within the antiferromagnetic state. This jump occurs when the effects of the magnetic order and the electric quadrupole moment on the NMR spectrum become similar in magnitude. We have found a new theoretical expression, which allows us to determine the correct value of the relaxation time $T_1$ for quadrupolar nuclei in antiferromagnetic powders, thus getting rid of this unphysical discontinuity.

10:24AM R50.00013: Impact of low-temperature stripe freezing in \( \text{La}_{1.67}\text{Sr}_{0.33}\text{NiO}_4 \) *JOHN TRANQUADA (Presenter), Brookhaven National Laboratory, ADRIAN MERRITT, DMITRY REZNIK, University of Colorado at Boulder, VASILE O GARLEA, Oak Ridge National Laboratory, GENDA GU, Brookhaven National Laboratory — \( \text{La}_{1.67}\text{Sr}_{0.33}\text{NiO}_4 \) develops charge stripe order below 240 K and spin stripe order below 190 K. We have reconsidered a wide variety of experimental studies that indicate changes in the stripe correlations below \( \sim 50 \) K [1]. From new neutron diffraction measurements of a significant set of stripe-order peaks, we make the case that the charge stripes, which can be centered on either Ni or O sites, become predominantly Ni-centered at low temperature. This is a prerequisite for the one-dimensional spin fluctuations on charge stripes that are observed at low temperature.

10:36AM R50.00014: Many-body physics of single and double spin-flip excitations in NiO

ABHISHEK NAG (Presenter), HANNAH ROBARTS, Diamond Light Source Ltd, F WENZEL, Institute for theoretical physics, JIEMIN LI, Diamond Light Source Ltd, H. ELNAGGAR, Debye Institute for Nanomaterials Science, RU-PAN WANG, Institute for theoretical physics, A C WALTERS, MIRIAN GARCIA-FERNANDEZ, Diamond Light Source Ltd, F. M. F. DE GROOT, Debye Institute for Nanomaterials Science, MAURITS HAVERKORT, Institute for theoretical physics, KEJIN ZHOU, Diamond Light Source Ltd — Understanding many-body physics of elementary excitations has advanced our control over material properties. Here, we study spin-flip excitations in NiO using Ni L3-edge RIXS and present a strikingly different resonant energy behaviour between single and double spin-flip excitations. Comparing our results with single-site full-multiplet ligand field theory calculations we find that the spectral weight of the double-magnon excitations originates primarily from the double spin-flip transition of the quadrupolar RIXS process within a single magnetic site. Quadrupolar spin-flip processes are among the least studied excitations, despite being important for multiferroic or spin-nematic materials due to their difficult detection. We identify intermediate state multiplets and intra-atomic core-valence exchange interactions as the key many-body factors determining the fate of such excitations.
How the electronic structure of correlated oxides evolves with electron and hole doping is a fundamental question of importance for applications. We have studied structural and electronic properties of high-quality MBE-grown doped NiO thin films using a variety of experimental and theoretical methods. We find that both K- and In-doped films at concentrations below 10% exhibit good X-ray diffraction spectra. However, extended X-ray absorption fine structure (XAFS) spectra indicate broadening of the K-O bond length distribution, and an increased bond length, much larger than obtained using theoretical methods. Ab-initio molecular dynamics suggests the XAFS feature is due to K-O\textsubscript{\textit{v}}-K defect structures in the thin film. Spectroscopic ellipsometry shows a smooth but asymmetric evolution of a decreasing optical gap for hole (K) and electron (In) doping, consistent with the behavior of a charge transfer insulator. Analysis shows that the decrease of the optical gap is due to the emergence of an absorption peak below (in energy) the optical gap of un-doped NiO. Calculations using Dynamical Mean Free Theory are in good agreement with the measurements and show the emergence of occupied states just above the valence band edge, and with an asymmetry between hole and electron doping.
8:00AM R51.00001: Spin-momentum Locking in an Array of Defect Lines in Gated Bilayer Graphene
RAUL GUERRERO, Donostia International Physics Center (DIPC), Paseo Manuel Lardizabal 4, 20018 Donostia-San Sebastián, Spain, MARTA PELC, Centro de Física de Materiales, CFM-MPC CSIC-UPV/EHU, Paseo Manuel Lardizabal 5, 20018 Donostia-San Sebastián, Spain, LEONOR CHICO, Instituto de Ciencia de Materiales de Madrid (ICMM), Consejo Superior de Investigaciones Científicas (CSIC), C/ Sor Juana Inés de la Cruz 3, 28049 Madrid, Spain, WLODZIMIERZ JASKOLSKY, Institute of Physics, Faculty of Physics, Astronomy and Informatics, Nicolaus Copernicus University, Grudziadzka 5, 87-100 Torun, Poland, ANDRES AYUELA (Presenter), Centro de Física de Materiales, CFM-MPC CSIC-UPV/EHU, Paseo Manuel Lardizabal 5, 20018 Donostia-San Sebastián, Spain — Graphene can have defect lines with pentagons and octagons (8-55) that induce localized states [1]. This domain wall in gated bilayer graphene produces a change between AB to BA stacking and presents topological states in the gap [2-4]. In this work using density functional theory calculations, we investigate an array of these defect lines in bilayer graphene. We found that the band structure shows a magnetic phase in which the spin is locked to the momentum, as in topological insulators. We also follow the topological states that appear even without a gate because of the array of defect lines. We lastly study the differences in spin bands and identified topological states when engineering by doping and/or electric field. All these results are summing to the new interesting data of the correlated behavior of electrons with the stacking in two-dimensional materials [5].

8:12AM R51.00002: Effect of correlation on nearly flat bands in twisted bilayer graphene*
MANCHEON HAN (Presenter), YOUNG WOO CHOI, HYOUNG JOON CHOI, Department of Physics, Yonsei University, Seoul 03722, Korea — Recently, correlated insulating phases were observed experimentally in twisted bilayer graphene (TBG) at different doping concentrations. To study possible mechanisms for insulating phases, we investigate electronic and magnetic properties in TBG by performing dynamical mean-field theory calculations based on a minimal tight-binding Hamiltonian. We study variation in the spectral function of the nearly flat bands for a range of local interaction parameters, electron filling, and temperature. We compare our results with experimental reports and discuss the possibility of Mott insulating phase in this system.

*This work was supported by NRF of Korea (Grant No. 2011-0018306), KISTI supercomputing center (Project No. KSC-2018-CRE-0097), and the Graduate School of Yonsei University Research Scholarship Grants in 2018.
8:24AM R51.00003: Visualization of the flat electronic band in twisted bilayer graphene near the magic angle twist  IQBAL UTAMA (Presenter), University of California, Berkeley, ROLAND KOCH, Advanced Light Source, Lawrence Berkeley National Laboratory, KYUNGHOO LEE, University of California, Berkeley, NICOLAS LECOMTE, Department of Physics, University of Seoul, HONGYUAN LI, SIHAN ZHAO, LILI JIANG, JIA Yi ZHU, University of California, Berkeley, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, PAUL ASHBY, ALEXANDER WEBER-BARGIONI, Molecular Foundry, Lawrence Berkeley National Laboratory, ALEX ZETTL, University of California, Berkeley, CHRIS JOZWIAK, Advanced Light Source, Lawrence Berkeley National Laboratory, JEIL JUNG, Department of Physics, University of Seoul, ELI ROTENBERG, AARON BOSTWICK, Advanced Light Source, Lawrence Berkeley National Laboratory, FENG WANG, University of California, Berkeley — Bilayer graphene was theorized to host a moiré miniband with flat dispersion if the layers are stacked at specific twist angles known as the “magic angles”. Recently, such twisted bilayer graphene (tBLG) with the first magic angle twist was reported to exhibit correlated insulating state and superconductivity, where the presence of the flat miniband in the system is thought to be essential for the emergence of these ordered phases in the transport measurements. Tunneling spectroscopy and electronic compressibility measurements in tBLG have revealed a van Hove singularity that is consistent with the presence of the flat miniband. However, a direct observation of the flat dispersion in the momentum-space of such moiré miniband in tBLG is still elusive. Here, we report the visualization of the flat moiré miniband by using angle-resolved photoemission spectroscopy with nanoscale resolution (nanoARPES). The high spatial resolution in nanoARPES enabled the measurement of the local electronic structure of the tBLG. We clearly demonstrate the existence of the flat moiré band near the charge neutrality for tBLG close to the magic angle at room temperature.

8:36AM R51.00004: Low Temperature Insulating State in hBN-Encapsulated Multilayer Graphene  NICHOLAS MAZZUCCA (Presenter), MARC W BOCKRATH, CHUN NING LAU, Ohio State Univ - Columbus, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science — Bilayer graphene is susceptible to strong electron-electron interactions at charge neutrality, leading to the possibility for spontaneous symmetry breaking and the associated opening of a gap at low temperatures, even in the absence of any external fields [1]. Recent experiments confirm this possibility for Bernal stacked graphene layers of thickness up to 8 layers [2-4], but this physics is only observed via transport in suspended devices of the highest quality. Here, we present evidence for the opening of a gap at low temperatures in multilayer graphene systems which are encapsulated in hBN. The dielectric environment of hBN not only alleviates the requirement for suspension, but also poses constraints on the nature of the interactions. Our results provide new insights into the insulating state of multilayer graphene systems, and help to facilitate their fabrication for potential applications.

8:48AM R51.00005: Signature of Viscous Electron Flow in Graphene Using a Scanning Probe Microscope  MICHAEL ZIRPOLI (Presenter), SAGAR BHANDARI, Slippery Rock Univ — Graphene is a single layer of carbon atoms held together in a hexagonal crystalline structure. Graphene has shown great promise in electronics and photonics because of its two-dimensional properties. These properties reduce the scattering of electrons that are seen in metals, and thus graphene has the ability to be much more conductive than commonly used conductors such as copper. In graphene, at certain range of temperature and electron density, electrons begin interacting with each other in such a way that they start acting together as a viscous fluid. The purpose of this paper is to model the viscous flow of electrons in graphene and analyze the fluid behavior. The model of an incompressible fluid using the Navier-Stokes equations will be created to examine this behavior. The goal is to construct the best geometry and determine suitable boundary conditions for the walls and circular obstacle. The walls act as the edge of the graphene strip, and the circular obstacle acts as the tip perturbation of a scanning probe microscope. The objective is to obtain a suitable geometry showing signature of viscous electron flow.

9:00AM R51.00006: Engineering of the electronic properties of an epitaxial graphene on an SiC(0001) substrate by manganese adatoms  JINWOONG HWANG (Presenter), JIEUN LEE, MINHEE KANG, Physics, Pusan National University, BYEONG-GYU PARK, Pohang Accelerator Laboratory, JONATHAN DENLINGER, SUNG-KWAN MO, Lawrence Berkeley National Laboratory, CHOONGYU HWANG, Physics, Pusan National University — The application of graphene in electronic devices requires an energy band gap with its remarkable properties. By using angle-resolved photoemission spectroscopy, we show that it is possible to decouple the graphene from substrate by manganese (Mn) intercalation concomitant with energy band gap opening. Upon introducing Mn adatoms, we observe a charge neutrality of the graphene band with energy band gap at the Dirac energy up to ~ 0.4 eV. In addition, the Mn-intercalated graphene shows fully screened energy-momentum dispersion as Mn 3d states play a role of a metallic background on graphene. These observations provides a viable route towards the engineering of the electronic properties of graphene.

9:12AM R51.00007: Lévy flights and Hydrodynamic Superdiffusion on the Dirac Cone of Graphene*  EGOR KISELEV (Presenter), JOERG SCHMALIAN, Institute for Condensed Matter Theory, Karlsruhe Institute of Technology — It is shown that hydrodynamic collision processes in graphene at the neutrality point can be described in terms of a Fokker-Planck equation with a fractional derivative. This is a consequence of the fact that the phase space dynamics of electrons is governed by Lévy flights: rare large-angle scattering events interrupting the small-angle scattering. Lévy flights give rise to superdiffusive dynamics of collective excitations. Implications for transport and relaxation processes will be discussed.

*We thank the European Commission’s Horizon 2020 RISE program Hydrotronics (Grant Agreement 873028) for support.
9:24AM R51.00008: Scanning tunneling microscopy and electronic transport of gold-decorated graphene devices*  JAKE RIFFLE (Presenter), CAITLYN MEDITZ, SHAWNA HOLLEN, Univ of New Hampshire — Past studies on graphene show that scattering from disorder can give rise to weak Anderson localization, but a disorder-driven quantum metal-insulator transition has not been observed. Using a low temperature scanning tunneling microscope (STM) on graphene field effect transistors, we present simultaneous STM and electronic transport measurements of graphene devices decorated with gold adatoms. These data show quasiparticle scattering off of gold adatoms on graphene on SiO2/Si. We study the microscopic scattering mechanisms, including the effects of charge puddles versus point-like disorder, and correlate these mechanisms with macroscopic electronic transport. These experiments are the first steps toward understanding the phase space near disorder-tuned metal-insulator quantum phase transitions in 2D materials.

*This work supported by NSF DMR #1709029

9:36AM R51.00009: Atomic Engineering of Monolayer Graphene: Inducing Kekulé Bond Order by Adatom Deposition*  AMY QU (Presenter), PASCAL NIGGE, CHRISTOPHER GUTIERREZ, JISUN KIM, University of British Columbia, STEFAN LINK, Max Planck Institute for Solid State Research, GIORGIO LEVY, MATTEO MICHIARDI, MICHAEL SCHNEIDER, SERGEY ZHDANOVICH, University of British Columbia, ULRICH STARKE, Max Planck Institute for Solid State Research, DOUGLAS ANDREW BONN, SARAH A BURKE, ANDREA DAMASCELLI, University of British Columbia — The Kekulé distortion (KD) periodically modifies the carbon-carbon bonds in graphene, resulting in a √3×√3 R30° superstructure and symmetry breaking between three previously equivalent hexagonal plaquettes. Previous scanning tunnelling microscopy (STM) experiments have shown that such a distortion induced by vacancies in the graphene substrate can produce charge density modulations corresponding to the superstructure [1]. Here, we induce a KD phase in monolayer graphene by low-flux deposition of a small number of lithium adatoms. Using angle-resolved photoemission spectroscopy (ARPES), we observe backfolding of the Dirac cones to Γ, as well as a gap opening (2Δ = 0.22 ± 0.02 eV) at the Dirac point. Low-energy electron diffraction (LEED) measurements also show the appearance of peaks corresponding to the new periodicity. Finally, we discuss the real-space behaviour of the adatoms by comparing STM data with predictions by a Monte Carlo toy model.

9:48AM R51.00010: Scanning Tunneling Spectroscopy of Coupled Graphene Quantum Dots

DANIEL WALKUP (Presenter), FERESHTE GHAHARI KERMANI, National Institute of Standards and Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Materials Science, NIKOLAI ZHITENEV, JOSEPH STROSCIO, National Institute of Standards and Technology — In backgated graphene devices with hexagonal boron nitride (hBN) substrates, impurities in the hBN can be locally charged by applying a voltage pulse to the tip of a scanning tunneling microscope. These charges create a writeable, tunable potential landscape for the graphene charge carriers, which we use to create isolated or coupled quantum dots in graphene. Under a strong perpendicular magnetic field, the free carriers condense into Landau levels (LLs). In a single dot, the LLs form a concentric pattern of alternating compressible and incompressible strips at the Fermi energy. The incompressible strips act as tunnel barriers creating a confined, concentric quantum dot system. When two or more such dots are placed next to each other, their charges interact. Addition of carriers to the dots manifests itself as peaks in the tunneling dI/dV, which can be tracked through the space of tip position, sample bias, and backgate voltage. Here, we explore the interaction between the dots revealed in the avoided crossings of their two sets of peaks to examine an intricate interplay of Coulomb interaction and tunnel coupling in this novel confined electron system.

10:00AM R51.00011: Frictional drag between graphene and LaAlO3/SrTiO3 heterostructures*

QING GUO (Presenter), JIANAN LI, JEN-FENG HSU, Univ of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin–Madison, PATRICK IRVIN, Univ of Pittsburgh, BRIAN R D'URSO, Physics, Montana State University, JEREMY LEVY, Univ of Pittsburgh — Vertical stacking of heterostructures that combine layered materials offer new ways of combining interesting properties of dissimilar electronic materials. Over the past few years we have been integrating graphene with complex-oxide heterostructures, specifically, the LaAlO3/SrTiO3 system. Furthermore, conducting nanostructures can be written under graphene, producing interesting interactions between the two systems. Here we report Coulomb drag measurements between single-layer graphene and a conductive LaAlO3/SrTiO3 interface. Fabry-Perot oscillations are observed in both graphene and drag signal in graphene, which indicate the local doping in graphene by conductive atomic force microscope(c-AFM) lithography. While the drag resistance is greatly enhanced in SrTiO3 in the superconducting region, the drag in graphene remain unchanged. We also observed key differences between longitudinal drag and hall drag in both graphene and SrTiO3.

10:12AM R51.00012: Visualizing broken symmetry states in the zeroth Landau level of the graphene quantum Hall system  SUNGMIN KIM (Presenter), DANIEL WALKUP, Physical Measurement Laboratory, National Institute of Standards and Technology, JOHANNES SCHWENK, Laboratory of Nanostructure at Surfaces, Ecole Polytechnique Federale de Lausanne, YIHANG ZENG, Department of Physics, Columbia University, FERESHTE GHAHARI KERMANI, Department of Physics and Astronomy, George Mason University, SON LE, Physical Measurement Laboratory, National Institute of Standards and Technology, JULIAN BERWANGER, Institute of Experimental and Applied Physics, University of Regensburg, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, FRANZ J GIESSIBL, Institute of Experimental and Applied Physics, University of Regensburg, NIKOLAI ZHITENEV, Physical Measurement Laboratory, National Institute of Standards and Technology, CORY DEAN, Department of Physics, Columbia University, JOSEPH STROSCIO, Physical Measurement Laboratory, National Institute of Standards and Technology — In graphene, the combination of electron spin and two equivalent sublattice atoms results in a four-fold degeneracy of Landau levels. A number of competing quantum Hall isospin states inside the four-fold degenerate zeroth landau level of graphene have been suggested based on macroscopic transport measurements. Here we observe the broken symmetry states of the zeroth Landau level in graphene with Kelvin Probe Force Microscopy (KPFM) by using a millikelvin scanning probe microscope coupled with qPlus sensor. The field dependence of the energy difference between isospin states is suggestive of transitions between isospin configurations at certain magnetic field values. In addition, we show how the quantum Hall edge channels of zeroth Landau level spatially develop and disperse at the edge of Hall bar.

10:24AM R51.00013: Imaging ballistic and hydrodynamic electron flow in the Corbino geometry  CHANDAN KUMAR (Presenter), Department of Condensed matter Physics, Weizmann Institute of Science, Rehovot 76100, Israel, JOHN BIRKBECK, DAVID PERELLO, School of Physics & Astronomy, University of Manchester, Manchester M139PL, United Kingdom, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science,1-1 Namiki, Tsukuba, 305-0044, Japan, ANDRE GEIM, School of Physics & Astronomy, University of Manchester, Manchester M139PL, United Kingdom, SHAHAL ILANI, JOSEPH SULPIZIO, Department of Condensed matter Physics, Weizmann Institute of Science, Rehovot 76100, Israel — Hydrodynamic flow is predicted to exhibit unique voltage patterns which are distinct from both the Ohmic and ballistic regimes. A flow geometry to best highlight these patterns is the Corbino disc, in which the current is driven from a circular central contact into an outer ring. In this geometry there are no walls, and so the electrons can only transfer momentum to either impurities or to other electrons. In the hydrodynamic regime in which the flow is dominated by such electron-electron scattering, momentum is conserved, leading to an expulsion of the electric field across the bulk of the disc and hence a constant electrostatic potential. In this situation, the device resistance may even be lower than in the fully ballistic regime, where the potential drops inversely with the radius. We present our initial results on imaging electron flow in high-mobility graphene Corbino discs using a nanotube single electron transistor. We image the voltage drop of the flowing electrons from the inner to outer contact, with the aim of distinguishing these unique spatial signatures of ballistic and hydrodynamic flow.
10:36AM R51.00014: Correlation-Driven Kekule’ Dimerization and Semimetal-Insulator Transition in Strongly Isotropically Strained Graphene* ERIO TOSATTI (Presenter), SANDRO SORELLA, International School for Advanced Studies, KAZUHIRO SEKI, TOMONORI SHIRAKAWA, SHOHEI MIYAKOSHI, SEIIJI YUNOKI, RIKEN — Freestanding graphene will spontaneously distort and become insulating under a large isotropic tensile strain. We calculate the ground state enthalpy (not just energy) of strongly strained graphene by an off-lattice quantum Monte Carlo correlated approach of great accuracy and variational flexibility, removing the limitations of earlier density-functional or rigid lattice approaches. Beginning with undistorted semimetallic graphene at low strain, we find [1] that multideterminant Heitler-London correlations stabilize between 8.5% and 15% tensile strain an insulating Kekule’ dimerized state. Closer to a crystallized resonating-valence bond than to a Peierls state, Kekule’ dimerization of graphene prevails over the competing antiferromagnetic insulating state favored by density-functional calculations which we conduct in parallel. The insulator gap grows from zero at onset to over 1 eV before mechanical failure near 15% strain, and is topological in nature, implying under certain conditions 1D metallic interface states lying in the bulk energy gap. [1] S. Sorella, et al., PRL 121, 066402 (2018).

10:48AM R51.00015: Enhancement of Ultrafast Photoluminescence from Deformed Graphene KUNG-HSUAN LIN (Presenter), EN-XIANG CHEN, HAO-YU CHENG, Academia Sinica, WEILIANG CHEN, National Taiwan University, MONIKA KATARIA, National Central University, YU-MING CHANG, YANG-FANG CHEN, National Taiwan University, WEI-BIN SU, Academia Sinica — We studied the correlation between the ultrafast photoluminescence and the morphology of graphene, and observed enhancement of the ultrafast photoluminescence from the deformed graphene. In comparison to the planar graphene, the enhancement factor of ultrafast photoluminescence could be up to several times at the highly curved region. We found that the intensity of photoluminescence from the uniaxially rippled graphene depends on the polarization of excitation light. Furthermore, Raman spectroscopy was used to measure the strain distribution. Pump-probe measurements were conducted to reveal the carrier dynamics. From the experimental results, two mechanisms were confirmed to mainly account for the enhancement of ultrafast photoluminescence from the deformed graphene. One is the deformation-induced strain increases the absorption of graphene. The other is the prolonged carrier relaxation time in the curved graphene.

Session R52 DCMP: Thin Film nucleation, growth, and morphology Mile
High Ballroom 1E - Daniel Dougherty, North Carolina State University
8:00AM R52.00001: Introducing open boundary conditions in modeling nonperiodic materials and interfaces  JAMES CHARLES (Presenter), SABRE KAIS, TILLMANN KUBIS, Purdue Univ — Simulations are essential to accelerate the discovery of new materials. We introduce the first method of open boundary conditions in material and interface modeling. The new method, which we named ROBIN (recursive open boundary and interfaces) allows for discretizing millions of atoms in real space, thereby avoiding any symmetry or order of the atom distribution. The computational costs are limited to solving quantum properties in a focus area. It is verified in detail that the impact of the infinite environment on that area is included exactly. Calculations of graphene with the same amount of 1) periodic (currently available methods) and 2) randomly distributed silicon atoms shows that assuming periodicity elevates a small perturbation into a strong impact on the material property prediction. Graphene was confirmed to produce a band gap with periodic substitution of 3% carbon with silicon in agreement with published periodic boundary condition calculations. Instead, 3% randomly distributed silicon in graphene only shifts the energy spectrum. The predicted shift agrees quantitatively with published experimental data. Periodic boundary conditions can be applied on truly periodic systems only. Other systems should apply an open boundary method.

8:12AM R52.00002: Morphology and Mechanical Response of a Compressed Cylindrical Shells*  HUNG-CHIEH FAN CHIANG (Presenter), HSIN-HUEI LI, TZAY-MING HONG, Physical Society of Taiwan — Uniaxially compressed cylindrical shells are common in our daily life, such as rolled-up sleeves and retreated package of drinking straws. The deformations are complex and unpredictable, but often contain arrays of diamond. Is there any other modes of pattern? How does the cylinder respond mechanically when these modes transit? To clarify these problems, we perform both experiments and Molecularly Dynamics simulation. A rod is inserted inside and coaxial to the cylindrical shell in both approaches to avoid folding. It turns out that there are five more different patterns, besides the famous Yoshimura diamonds. These six modes of deformation are respectively spiral, ladder, diamond, wrinkle, ridge, and sagging. Phase diagram is drawn in a 3D plot with the spacing between shell and rod, compression strain and compression rate as axes. Material properties are incorporated to render these three parameters dimensionless. Two main features that worth noting are that different modes are allowed to mix and mode transitions are always accompanied by the absorption or release of latent heat. Simulation reveals that plasticity may disrupt and cause nonuniformity of the pattern.

8:24AM R52.00003: Up against a wall: interfacial free energies at curved surfaces*  SETH MARTIN (Presenter), BRIAN LAIRD, Univ of Kansas — Interfacial free energies drive diverse physical phenomena, from wetting and capillarity to dendrite growth in crystal systems. While the interfacial free energy, $\gamma$, is largely controlled by the microscopic interactions between different phases, the geometry of the interface also plays a role in tuning the interfacial free energy. Although several analytic theories that try to include these geometric effects on $\gamma$ have been proposed, experimental and simulation studies of curvature dependence of $\gamma$ are few. Here we present simulation results for the 2-dimensional hard-disk fluid model at curved, hard, structureless walls and use the simulation results to test the limits of currently available analytical theories for interfacial free energy, including Morphometric Thermodynamics.

*Funding was provided by the NSF, grant #1465226.

8:36AM R52.00004: Two-step Unconventional Protocol for Epitaxial Growth in One Dimension with Hindered Reactions*  JULIÁN A. SÁNCHEZ (Presenter), DIEGO LUIS GONZÁLEZ, Physics, Universidad del Valle, A.A. 25360, Cali, Colombia, THEODORE EINSTEIN, Physics, University of Maryland, College Park — We study the effect of hindered aggregation and/or nucleation on the island formation process in a two-step (rather than the conventional one-step) growth protocol. In the proposed model, the attachment of monomers to islands and/or other monomers is hindered by additional energy barriers which decrease the hopping rate of monomers to occupied sites. For zero and weak barriers, the attachment is limited by diffusion while for strong barriers it is limited by reaction. We describe the time evolution of the system in terms of the monomer and island densities, $N_1$ and $N$. We also calculate the gap length, capture zone, and island-size distributions. For all sets of barriers considered, we compare the results from this analytical model with those from kinetic Monte Carlo simulations. The behavior of the system depends on the ratio of the nucleation barrier to the aggregation barrier. The two-step growth protocol gives more control and understanding of the island formation mechanism by intrinsically separating the nucleation and aggregation processes into different times regimes. We discuss experimental implications

8:48AM R52.00005: Foamability of oil mixtures  
HOAI-PHUONG TRAN (Presenter), LAURENCE TALINI, FRANÇOIS LEQUEUX, ESPCI Paris — In the absence of stabilization mechanism of films of pure liquids, foams do not form in pure liquids. Froth formation is observed in liquid mixtures, among which, oil mixtures, and that effect is well documented in the literature. The higher film lifetimes has however not been understood in non-volatile liquids and in the absence of surface-active molecules. We have experimentally studied the foaming of binary mixtures of liquids, and found the foam lifetime depends not only on the nature of the liquids but also on the proportions of the two liquids. We suggest a stabilizing mechanism of thin films of liquid mixtures based on non-linear variations of the mixture's surface tension with its composition, analogous to Gibbs’ elasticity defined for surfactant solutions. We show that the variations of foam lifetime with mixture composition is quantitatively described by the model. Finally, we define an effective disjoining pressure for thin films that can be fully computed from the variations of the surface tension of any liquid mixture which surface tension does not vary linearly with composition.

9:00AM R52.00006: Coupled Sublattice Melting and Charge-Order Transition in Two Dimensions*  
TYLER SMITH (Presenter), Department of Physics and Astronomy, University of Tennessee, Knoxville, FANGFEI MING, State Key Laboratory of Optoelectronic Materials and Technologies, School of Electronics and Information Technology, Sun Yat-sen University, D.G. TRABADA, CESAR GONZALEZ, DIEGO SOLER-POLO, FERNANDO FLORES, JOSÉ ORTEGA, Departamento de Física Teórica de la Materia Condensada and Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, HANNO H WEITERING, Department of Physics and Astronomy, University of Tennessee, Knoxville — Two-dimensional melting is one of the most fascinating and poorly understood phase transitions in nature. Theoretical investigations often point to a two-step melting scenario involving unbinding of topological defects at two distinct temperatures. Here we report on a novel melting transition of a charge-ordered K-Sn alloy monolayer on a silicon substrate. Melting starts with short-range positional fluctuations in the K sublattice while maintaining long-range order, followed by longer-range K diffusion over small domains, and ultimately resulting in a molten sublattice. Concomitantly, the charge-order of the Sn host lattice collapses in a multi-step process with both displacive and order-disorder transition characteristics. Our combined experimental and theoretical analysis provides a rare insight into the atomistic processes of a multi-step melting transition of a two-dimensional materials system.

*NSF DMR 1410265
9:12 AM R52.00007: Quantification of multiple crystallite orientations in complex thin film materials

JONATHAN OGLE (Presenter), DANIEL POWELL, ERIC AMERLING, University of Utah, DETLEF-M. SMILGIES, Cornell High Energy Synchrotron Source, Cornell University, LUISA WHITTAKER-BROOKS, University of Utah — As thin films and interfaces have become more intricate, the morphological and structural information also grows in complexity. An increasing amount of studies have focused on understanding correlations between crystallite orientation and electronic structure. Crystallite orientation within thin films is studied using grazing incidence wide-angle X-ray scattering (GIWAXS) patterns, where the Miller indices of a crystal structure are related to the scattering reflections. GIWAXS can be used to elucidate crystallite orientations within a thin film by comparing the azimuthal distribution of specific Miller indices. However, as thin film technologies advance, there is a growing need to quantify the orientational distribution of similar thin films or also for multiple orientations within a single thin film in a comparative manner. Herein, we present a new method for quantifying the orientational distribution of crystallites, dubbed the Mosaicity Factor (MF). The efficacy of this method will first be studied using a model system consisting of Gaussian distributions. We will highlight the strengths and capabilities of MF when characterizing multiple Gaussian shapes and overcoming signal noise. Case studies will be used to show the range of applications available and the strengths of MF.

9:24 AM R52.00008: The role of He and H on the structural evolution of He- and H-irradiated 6H-SiC

NABIL DAGHBOUJ (Presenter), Department of Control Engineering, Faculty of Electrical Engineering, Czech Technical University in Prague, BINGSHENG LI, state key laboratory, university of science and technology china, MAURO CALLISTI, materials science and metallurgy, University of cambridge, HUSEYIN SENER SEN, Department of Control Engineering, Faculty of Electrical Engineering, Czech Technical University in Prague, MIROSLAV KARLIK, Department of materials, Faculty of Nuclear sciences and Physical engineering, JIE LIN, XIN OU, state key laboratory of Functionnal materials for informatics, Shanghai Institute of microsystem and information technology, TOMAS POLCAR, Department of Control Engineering, Faculty of Electrical Engineering, Czech Technical University in Prague — The behavior of irradiated H and He ions in the 6H-SiC lattice was rather different. H irradiated with low fluence at RT, blisters were formed after annealing at 1100°C, while at high irradiation fluence no blister cavities were observed due to the formation of an amorphous layer. At an irradiation temperature of 450 and 900°C, amorphization of 6H-SiC did not occur and hydrogen-containing microcracks grew laterally below the surface. Thus blisters appeared on the surface of the samples irradiated at 900°C even without annealing. For He irradiation, regardless of the fluence and irradiation temperature, blisters did not form. The presented results are well supported by density functional theory calculations. The coalescence between two small bubbles is an exothermic process when the H₂-bubbles contain an unpaired hydrogen and endothermic process when the H₂-bubbles contain paired H atoms, but it is energetically cheap. On the other hand, activation of the coalescence of He bubbles is endothermic and energetically very expensive.

Epitaxial growth of cubic WC$_y$(001) thin films

PEIJIAO FANG (Presenter), BAIWEI WANG, Rensselaer Polytechnic Institute, CHRISTOPHER MULLIGAN, Benét Laboratories, THOMAS MURRAY, SUNY Polytechnic Institute, SANJAY V. KHARE, University of Toledo, DANIEL GALL, Rensselaer Polytechnic Institute — Tungsten carbide films were sputter-deposited onto MgO(001) substrates at 400 °C in 5 mTorr Ar-CH$_4$ gas mixtures as a function of the CH$_4$ fraction $f_{CH_4} = 0.4$ - 6%. High resolution transmission electron microscopy (TEM) and x-ray diffraction ω-2θ scans, ω-rocking curves, and reciprocal space maps on $d = 10$ nm thick layers indicate epitaxial growth of rock-salt WC$_y$ with a cube-on-cube epitaxial relationship: (001)$_{WC}$ || (001)$_{MgO}$ and [100]$_{WC}$ || [100]$_{MgO}$. The measured out-of-plane coherence length matches the film thickness for $d = 10$ nm but remains nearly unaffected by a 60-fold increase in layer thickness to $d = 600$ nm. This suggests a critical thickness for epitaxial breakdown of ~ 10 nm, associated with the nucleation of misoriented grains as also observed by TEM. The relaxed lattice constant increases monotonically from 0.419 to 0.425 nm with increasing $f_{CH_4}$. Comparing these measured lattice parameters with first-principle predictions indicates a C-to-W ratio $y = 0.47$ - 0.68. However, composition measurements using energy-dispersive x-ray spectroscopy and Rutherford backscattering spectrometry yield measured C-to-W ratios of 0.57-1.25, suggesting that a considerable fraction (18 – 46 %) of C does not incorporate in the cubic phase but likely forms amorphous carbon.

InAs(111) Homoepitaxy with Molecular Beam Epitaxy

KEVIN VALLEJO (Presenter), TRENT ALAN GARRETT, KEVIN SAYTHAVY, KATHRYN SAUTTER, Micron School of Materials Science and Engineering, Boise State University, BAOLAI LIANG, California NanoSystems Institute, UCLA, PAUL J SIMMONDS, Micron School of Materials Science and Engineering, Boise State University — In this study we have mapped the growth parameters for optimal homoepitaxy of InAs on InAs(111)A substrates using molecular beam epitaxy. Increasing the substrate temperature reveals a transition from 2D flat island growth to step-flow. The optimized parameters we established (substrate temperature = 500° C, growth rate = 0.12ML/s and V/III ratio = 48) produce an atomically flat surface, free of 3D imperfections. We study material quality using photoluminescence and have established a relationship between InAs(111)A surface smoothness and light emission intensity. This work paves the way for integrating the 6.1 Å family of materials with the desirable properties of semiconductors with a (111) orientation. In addition, we will present preliminary results demonstrating the self-assembly of InGaAs quantum dots on these smooth InAs(111) surfaces, strongly indicating new paths towards ultra-low bandgap tunable light emitters for infrared optoelectronics.

*We acknowledge the support of the College of Engineering at Boise State University.
**10:00AM R52.00011: Droplet spreading on a surface exhibiting solid-liquid interface premelting**  
YANG YANG, Physics, East China Normal University, BRIAN LAIRD (Presenter), Chemistry, University of Kansas — We study, using molecular-dynamics simulation, the spreading kinetics and equilibrium shape of liquid Pb droplets on an Al(111) substrate. The Al-Pb solid-liquid interface (SLI) was found previously to exhibit interfacial premelting at temperatures below the Al melting point [1]. We examine here how premelting affects the spreading and compare with both hydrodynamic (viscosity dominated) and kinetic (interfacial friction dominated) spreading mechanisms. For premelted surfaces, kinetic spreading is observed at intermediate times, in contrast to low temperatures near the Pb melting point where the surface is faceted and the hydrodynamic mechanism dominates. We conclude that the presence of the premelting layer has a significant effect on the thermodynamics of the Al(111)/Pb SLI and that the induced surface disorder gives rise to a kinetic spreading mechanism. We also observe that the structure of the droplet contact line with the premelted surface resembles that seen in reactive wetting.

**10:12AM R52.00012: Visualization of Nanorod Assembly and Dynamics on Liquid Surfaces**  
SATYAM SRIVASTAVA (Presenter), ZACHARY FINK, PAUL Y KIM, ALEXANDER E RIBBE, DAVID HOAGLAND, THOMAS RUSSELL, Univ of Mass - Amherst — The two-dimensional phase behavior of rod-like particles was studied by dispersing silica-coated gold nanorods on a liquid surface. Nanorods with aspect ratio ranging from 3 to 6 were synthesized, coated with silica, functionalized with polyethylene glycol (PEG), and then dispersed in ionic liquid 1-ethyl 3-methylimidazolium ethyl sulfate ([EMIM][EtSO4]). The dispersed rods, driven to the surface by the low surface energy of PEG, were observed directly on the surface of an ionic liquid droplet by scanning electron microscopy. Rod diffusion coefficients were calculated in dilute systems by tracking position and orientation of single nanorods. In concentrated systems, the nanorod packing was studied using an in-situ liquid cell to control volume and surface area of the droplet. The 2D packing was characterized by pair correlation function, translational order parameter, orientational order parameter, and Voronoi tessellation. Order parameters were calculated as a function of areal density and nanorod aspect ratio. An increase in local orientational order was observed at higher areal densities but a liquid crystalline phase was not observed due to low aspect ratio.

*NSF DMR-1807255.*
10:24AM R52.00013: Effects of short-range repulsive barriers on island nucleation  
SAMEER HAMADNA (Presenter), INDIRAS KHATRI, JACQUES AMAR, Univ of Toledo — A variety of effects such as strain and surfactants can lead to attachment barriers in thin-film growth. While several studies of the effects of attachment barriers on submonolayer growth have been carried out, the emphasis has been on rate-equations which do not take into account island geometry or coalescence and are primarily applicable to point-islands. Here we present the results of kinetic Monte Carlo simulations for the case of extended 2D islands with critical island-size $i = 1$ which were carried out to determine the dependence of the exponent $\chi$ (describing the dependence of the peak island density on deposition rate) on barrier strength and ratio $R = D/F$ of the monomer hopping rate $D$ to deposition rate $F$. In particular, we have studied two different cases, one with a barrier to island nucleation and attachment as well as the case with an island attachment barrier but no nucleation barrier. Our results indicate that in both cases - and in contrast to the case of no barrier for which $\chi$ is equal to $1/3$ - the asymptotic (large $R$) value of $\chi$ increases continuously with barrier strength, reaching a value close to $1/2$ in the limit of a very strong barrier and very large $R$. The effects of attachment barriers on island morphology and coalescence will also be discussed.

10:36AM R52.00014: X-ray Photon Correlation Spectroscopy Studies of Ion Beam Nanopatterning Kinetics and Dynamics  
PECO MYINT (Presenter), Division of Materials Science and Engineering, Boston University, XIAOZHI ZHANG, Department of Physics and Materials Science Program, University of Vermont, DENISE ERB, Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf e.V., ANDREI FLUERASU, LUTZ WIEGART, YUGANG ZHANG, National Synchrotron Light Source II, STEFAN FACSKO, Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf e.V., RANDALL HEADRICK, Department of Physics and Materials Science Program, University of Vermont, KARL F LUDWIG, Department of Physics & Division of Materials Science and Engineering, Boston University — Solid surfaces can be ultra-smoothened or patterned on the nanoscale by irradiating with a broad beam of energetic ions. Different nanopatterns can be achieved by varying target-ion combination, the energy of ions, ions’ incident angle or the temperature of the solid target. There are several theories that seek to explain nanopatterning processes, but a definitive fundamental understanding has not been reached. In this study, the surface sensitive X-ray technique of Grazing-Incidence Small-Angle X-ray Scattering (GISAXS) is used to do real-time investigations of nano-pattern formation on Silicon and Germanium due to $\text{Ar}^+$ and $\text{Kr}^+$ bombardment. The coherent X-ray beam that is utilized in these GISAXS experiments enables us to study not only the kinetics, but also the fluctuations around the average kinetics, i.e. the dynamics of the nanopatterning process. The X-ray Photon Correlation Spectroscopy (XPCS) two-time correlation function shows a novel behavior in the early stage, with memory stretching back to the beginning of the bombardment. During the late stage, the stationary intensity auto-correlations are computed to determine the correlation times as a function of length-scale.

**10:48AM R52.00015: Recent Applications of Voronoi Tessellation and Analysis of Their Size Distributions with the Generalized Wigner Surmise**  
**THEODORE EINSTEIN (Presenter)**, University of Maryland, College Park — While Voronoi tessellation has long been applied in spatial studies, analysis of their cell-size distribution using the single-adjustable-parameter generalized Wigner surmise, \( P_\beta(s) = a s^\beta \exp(-b s^2) \), has only been done in the last decade. Here we discuss some intriguing examples: Mitko et al. (2019) consider the evolution of morphology during growth of island films of low-e dielectric films via vapor deposition polymerization. Löbl et al. (2019) probe infilling Al-droplet-etched nanoholes in an AlGaAs surface. In both cases, estimates of the critical nucleus size were extracted from the value of the exponent \( \beta \) determined from a fit to \( P_\beta(s) \). We discuss the results and their implications. In other tantalizing examples, the Voronoi cell-size was not [yet] analyzed using \( P_\beta(s) \). Brookes (2017) uses Voronoi analysis of cells on the outer layer of eye-banked corneas to assess their viability before transplanting. Konishi et al. (2017) studied the growth-rate dependence of the spatial distribution of self-assembled 2D quantum dots on InAs-GaAs. They also consider the influence of modest array size.

**8:00AM R53.00001: Optical Second-Harmonic Interference in Two-Dimensional Heterostructures**  
**WONTAEK KIM, SUNMIN RYU (Presenter)**, Pohang Univ of Sci & Tech — Atom-thick two-dimensional (2D) transition metal dichalcogenides (TMDs) with strong excitonic transitions in the NIR and visible range are excellent media for optical second-harmonic generation (SHG). SHG is not only a powerful structural method owing to its sensitivity to crystallographic symmetry, but also a coherent probe because of its instantaneous but non-dissipative response. In this talk, I will present our recent findings on SHG interference occurring in 2D TMD heterostructures. All 2D crystal samples were prepared by mechanical exfoliation and studied with a polarized SHG micro-spectroscopy setup powered by a tunable femtosecond Ti-sapphire laser. Polarization-resolved SHG polar plots of MoS\(_2\) homo-bilayers exhibited a six-petal pattern with six angular nodes like those of MoS\(_2\) monolayers. Remarkably, the SHG behavior of MoS\(_2\)/WS\(_2\) was much different from that of MoS\(_2\) bilayers in that the former lacked angular nodes. This anomalous angular background became larger for more staggered hetero-bilayers but decreased for increased fundamental wavelength. All the results were nicely explained by an SHG interference model considering material-dependent phase delay in their nonlinear response, which was corroborated with phase-resolved interferometric SHG measurements.
8:12AM R53.00002: Interlayer Exciton in atomically reconstructed MoSe2/WSe2 van der Waals Heterostructure  HSUN JEN CHUANG (Presenter), United States Naval Research Laboratory, AUBREY T. HANBICKI, United States Naval Research Laboratory/ Laboratory for Physical Sciences, MATTHEW ROSENBERGER, United States Naval Research Laboratory, VLADIMIR P. OLESHKO, National Institute of Standards and Technology, KATHLEEN M MCCREARY, SAUJAN V SIVARAM, IGOR MAZIN, BEREND THOMAS JONKER, United States Naval Research Laboratory — Interlayer exciton (ILE) can be created by artificially stacking MoSe2 onto WSe2 to form a heterostructure with type II band alignment. With hBN encapsulation and a relative rotational angle close to 60 degrees, well pronounced ILE emission is observed at room temperature and further splits into two distinct peaks (ILE1 and ILE2) at low temp. Furthermore, we demonstrate that the ILE emission peaks have opposite circular polarizations when excited by circularly polarized light. Ab initio calculations provide an explanation of this unique and potentially useful property and indicate that it is a result of the indirect character of both transitions. We further investigate the atomic structure arrangement of MoSe2/WSe2 by TEM and reveal that the heterostructure indeed reconstructs under a small twist angle (≤ 1°) between the TMDs. With a small twist angle, periodic domains form with commensurate stacking within the domain. On the other hand, a rigid moiré structure is also observed by TEM when a larger twist angle (≥ 3°) is applied. These results may provide fundamental insights into the mechanical and optical behavior of this exciting class of semiconductor heterostructure.

8:24AM R53.00003: Nonradiative energy transfer enhances Raman intensity in layered heterostructure  MEDHA DANDU (Presenter), Electrical Communication Engineering, Indian Institute of Science, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, AJAY SOOD, Physics, Indian Institute of Science, KAUSIK MAJUMDAR, Electrical Communication Engineering, Indian Institute of Science — Since the discovery of Graphene enhanced Raman scattering, layered materials and their heterostructures are emerging as promising candidates for realizing Raman enhancement on flat surfaces. While most of the Raman enhancement studies on these materials are based on charge transfer interaction, here, we experimentally demonstrate for the first time, a strong enhancement of Raman intensity through nonradiative energy transfer (NRET) in a layered heterostructure. We achieve a ten-fold Raman enhancement of a monolayer transition metal dichalcogenide (1L-TMD, such as 1L-MoS2 and 1L-WS2) stacked on a multilayer SnSe2. Spectral resonance, extreme spatial proximity and in-plane orientation of dipoles result in strong dipole-dipole coupling that enables NRET driven Raman enhancement even when a barrier layer like hBN is introduced between 1L-TMD and SnSe2. We corroborate the evidence for NRET driven Raman enhancement by decoupling it from other effects and demonstrating its tunability through modulation of spectral overlap between 1L-TMD and SnSe2 by varying the sample temperature. Observation of such non-local, uniform Raman enhancement over a wide junction area opens new ways to engineer sensing mechanisms using NRET in tandem with other existing enhancement techniques.
8:36AM R53.00004: Circular emission under linear excitation from interlayer excitons in WSe$_2$/MoSe$_2$ heterobilayer* XIN LU (Presenter), WEIJIE LI, SUDIPTA DUBEY, AJIT SRIVASTAVA, Emory University — We report circularly polarized emission from interlayer excitons in WSe$_2$/MoSe$_2$ heterobilayer under linear excitation at zero magnetic field. The magnitude and sign of the degree of circular polarization (DCP) varies spatially over the sample. The DCP is independent of excitation energy when incident laser is linearly polarized, however, can be modulated by circular pumping or magnetic field. This is in stark contrast with WSe$_2$ and MoSe$_2$ intralayer excitons where circular emission only occurs with an applied magnetic field or under circular pumping. The observation of circularly polarized emission, in absence of magnetic field and circular pumping, implies an effective time-reversal symmetry (TRS) breaking in the WSe$_2$/MoSe$_2$ heterobilayer. As different cool downs result in very similar spatial patterns of DCP, we rule out spontaneous TRS breaking in the sample. Due to the momentum space-indirect nature of interlayer excitons, there is a finite center-of mass momentum in the recombining exciton state. This, together with the ubiquitous inhomogeneous strain in exfoliated samples can explain our observations.

*NSF EFRI NewLAW grant #EFMA-1741691

8:48AM R53.00005: Dipole-dipole interactions between localized interlayer excitons in WSe$_2$/MoSe$_2$ heterobilayer* WEIJIE LI (Presenter), XIN LU, SUDIPTA DUBEY, LUKA MATEJ DEVENICA, AJIT SRIVASTAVA, Emory University — We explored localized interlayer excitons in WSe$_2$/MoSe$_2$ heterobilayer by low temperature (~ 4K) photoluminescence spectroscopy. With type-II band alignment, the localized interlayer exciton compromises of an electron from MoSe$_2$ and a hole from WSe$_2$, forming an out-of-plane electric dipole moment. We thus tuned its energy by hundreds of its linewidth via an external electric field. In addition to the field-tuneability, the permanent dipoles have repulsive dipolar interaction scaled as $\sim 1/r_{ex}^3$ where $r_{ex}$ is the interexcitonic distance. Here we observed a peak blueshifted from the localized interlayer exciton peak by $\sim 2$ meV with increasing incident power. The blue peak is assigned to be the biexciton peak due to the same synchronized jittering as the exciton and its superlinear power dependence. The similar $g$ factor and gate dependence of biexciton and exciton imply that the second excitation has negligible impact on the exciton wavefunction. The polarization of the biexciton and exciton under finite magnetic field is consistent with the spin-valley singlet nature of the dipolar molecule states. With the singlet configuration and dipolar interaction $\sim 2$ meV, the confinement length of the localized interlayer exciton is calculated to be $\sim 5$ nm.

*NSF EFRI NewLAW grant # EFMA-1741691.
9:00AM R53.00006: Confinement of long-lived interlayer excitons in WSe$_2$/WS$_2$ heterobilayers*  ALEJANDRO MONTBLANCH, DHIREN KARA, IOANNIS PARADEISANOS, CAROLA PURSER (Presenter), GANG WANG, Univ of Cambridge, PAWEL LATAWIEC, MARKO LONCAR, Harvard University, SEFAATTIN TONGAY, Arizona State University, ANDREA FERRARI, METE ATATURE, Univ of Cambridge — Recently, there has been an increased focus on controllable quantum gases with long-range anisotropic interactions to simulate condensed matter problems that have so far remained intractable. Interlayer excitons (IX) in transition metal dichalcogenides (TMDs), which have a permanent electric dipole moment, have emerged as an alternative pathway to realising quantum simulations in the solid state. Here, we create ultra-long-lived IX and demonstrate they can be trapped - an important prerequisite for future investigations. We do this by depositing a heterostructure of monolayer WSe$_2$ and WS$_2$ on a pre-patterned substrate. We observe lifetimes of IX approaching 200 μs at cryogenic temperatures, an order of magnitude longer than any previous IX and three orders for any TMD IX. Power-dependent PL evidences IX-IX interactions and the ability to confine single IX at pre-defined locations. The potential to create arbitrary trapping profiles for long-lived dipolar particles evidences the capability of TMDs to provide a unique avenue for probing exotic states of matter in degenerate gases and artificial lattices.

9:12AM R53.00007: Mechanically tunable nonlinear optics from a van der Waals interface in twisted hexagonal boron nitride heterostructures*  NATHAN FINNEY (Presenter), KAIYUAN YAO, Mechanical Engineering, Columbia University, SAMUEL MOORE, Physics, Columbia University, FANG LIU, Chemistry, Columbia University, JENNY ARDELEAN, XINYI XU, Mechanical Engineering, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, XIAOYANG ZHU, Chemistry, Columbia University, DMITRI BASOV, CORY DEAN, Physics, Columbia University, P. JAMES SCHUCK, JAMES C HONE, Mechanical Engineering, Columbia University — In the bulk limit, the second harmonic generation (SHG) response from hexagonal boron nitride (BN) includes electric quadrupole and dipole contributions. Both the total layer number and layer parity play a critical role in determining the overall nonlinear optical response. Here we investigate micromechanical devices consisting of a rotatable crystal of bulk BN placed on top of another crystal of BN, where the relative rotational alignment of the two crystal lattices can be dynamically tuned via an atomic force microscope (AFM) in contact mode. We find significant angle dependence of the unpolarized SHG response where the SHG signal is strongly suppressed or enhanced depending on the stacking order (AA’ or AA, respectively) at the homojunction between the top and bottom BN. At intermediate rotation angles of the top BN crystal between 0 and 60 degrees, we observe continuous modulation of both the SHG intensity and polarization. The non-symmetry-selective third harmonic generation (THG) signal remains unchanged over all rotation angles, suggesting that the observed modulation in nonlinear optical response is induced by mechanically tuning the symmetry at the van der Waals interface between the crystals.

9:24AM R53.00008: Interlayer Exciton Fine Structure in MoSe$_2$/WSe$_2$ Heterostructure

SHENGNAN MIAO (Presenter), TIANMENG WANG, ZHIPENG LI, Rensselaer Polytechnic Institute, ZHENGGUANG LU, Natl High Magnetic Field Lab, SUFEI SHI, Rensselaer Polytechnic Institute — The realization of the valleytronics based on transitional metal dichalcogenides (TMDCs) is hindered by the short lifetime of the exciton. Recently, it is predicted that the long-lived interlayer exciton in aligned TMDC hetero-bilayer possesses fine structures with distinctive valley polarization selection rules, which can be utilized to lift this limitation. However, the revealing of the details of the interlayer exciton is hindered by the sample quality. Further, the Moiré effect due to small twist angle also complicates the spectroscopy signature of the interlayer exciton. In this work, we present a comprehensive study of the interlayer excitons through gate-dependent, magnetic-field dependent spectroscopy study. The valley polarization is investigated through photoexcitation spectroscopy (PLE) study, and the high valley polarization of interlayer exciton is also explored. Our work paves the way for future exploration and understanding of the fascinating interlayer excitonic physics and Moiré physics in TMDC heterostructures.

9:36AM R53.00009: Evidence of Purely Electronic Lattice at Interface of TMD/Bi$_2$Se$_3$ 2D Heterostructures Induced by Strong Interlayer Coupling*

ZACHARIAH HENNIGHAUSEN (Presenter), CHRISTOPHER LANE, IOANA G BUDA, VINEET K MATHUR, ARUN BANSIL, SWASTIK KAR, Physics, Northeastern University — Vertically-stacked 2D heterostructures are more than a sum of the individual layers, but a product of the interlayer coupling and twist angle. New properties emerge from interlayer orbital interactions and charge redistribution, further modulated by the interlayer atomic registry and moiré superlattice. This talk shows experimental and theoretical indications of a real-space, non-atomic lattice formed by significant charge redistribution in vertically stacked Bi$_2$Se$_3$/Transition Metal Dichalcogenide (TMD) 2D heterostructures. High-energy (200keV) selected area electron diffraction (SAED) patterns correspond excellently with simulations from the moiré superlattices, suggesting substantial charge redistribution at sites of high interlayer atomic registry. Density functional theory (DFT) predicts concentrated charge pools reside in the interlayer region, located at sites of high nearest-neighbor atomic registry, suggesting the non-atomic lattices are standalone, reside in the interlayer region, and are purely electronic.

9:48AM R53.00010: Investigation of interfacial charge transfer in hybrid system of Graphene-MoS$_2$ * SAJEDEH POURIANEJAD (Presenter), Joint School of Nanoscience and Nanoengineering, University of North Carolina at Greensboro, FREDERICK ARYEETEY, Joint School of Nanoscience and Nanoengineering, North Carolina A&T State University, OLUBUNMI AYODELE, Joint School of Nanoscience and Nanoengineering, University of North Carolina at Greensboro, SHYAM ARAVAMUDHAN, Joint School of Nanoscience and Nanoengineering, North Carolina A&T State University, TETYANA IGNATOVA, Joint School of Nanoscience and Nanoengineering, University of North Carolina at Greensboro — Heterostructures of two dimensional layered materials have exciting optical properties that encourage scientists to further study of their photodetector applications. Interactions and, in particular, charge transfer between the constituting layers plays a critical role in the electronic and optical properties. Heterostructure of a few layers of graphene/MoS$_2$ has been demonstrated as a promising candidate for diverse unique optoelectronic devices owing to the high transparency of graphene, the tunability of its Fermi level and, the magnificent optical properties of MoS$_2$. Here, the magnitude and the direction (i.e. electron or hole) of the charge transfer was investigated in a graphene/MoS$_2$ heterostructure. Confocal Raman microscopy and photoluminescence were used to study doping and strain configuration. The surface morphologies of MoS$_2$ and graphene were investigated by scanning electron microscopy. To correlate work function difference to charge-related phenomena, KPFM and EFM were carried out. We speculate that the tunable Fermi level in graphene allows excellent work-function match with MoS$_2$, resulting in low contact resistance.

*Samples were provided by The Pennsylvania State University 2DCC-MIP supported by NSF DMR-1539916. To JSNN, a member SENI C NSF ECCS-1542174).

10:00AM R53.00011: Trion light emission in type-I WSe$_2$/MoTe$_2$ van der Waals heterostructures HYEMIN BAE, SUK HYUN KIM (Presenter), Seoul Natl Univ, SEUNGMIN LEE, Yonsei Univ, OURI KARNI, AIDAN O’BEIRNE, ELYSE BARRÉ, Stanford Univ, SANGWAN SIM, Hanyang University, TONY F HEINZ, Stanford Univ, HYUNYONG CHOI, Seoul Natl Univ — Two-dimensional (2D) transition metal dichalcogenides (TMDs) are attractive materials to investigate the light-induced many-body excitons. The reduced Coulomb screening leads to a large exciton binding energy, and stacking two or more dissimilar TMDs provides easy way to build van der Waals (vdW) heterostructures. With this features TMDs enables us to study a variety body of excitons such as neutral exciton, charged excitons, type-II interlayer excitons, moiré excitons, and localized excitons. Here we perform photoluminescence (PL), reflection contrast (RC) and photoluminescence excitation (PLE) to investigate vdW type-I heterostructures. We report the spectroscopic identification in type-I heterostructure of trions, a quasiparticle composed of two electrons and a hole. In the heterostructure spectra, we observe a significant enhancement of the MoTe$_2$ A trion PL emission under the excitation in resonance with the WSe$_2$ trion resonances. The enhancement is interpreted as a transfer effect arising from trions initially created in either layer. We suggest that the trions generated in WSe$_2$ have a great influence on the MoTe$_2$ trion emission. Our results show possibilities for fundamental studies of many-body interactions in 2D TMDs heterostructures.
The bright side of defects in MoS$_2$ and WS$_2$ and a generalizable chemical treatment protocol for defect passivation

HOPE BRETSCHER (Presenter), ZHAOJUN LI, JAMES XIAO, Department of Physics, University of Cambridge, DIANA QIU, Department of Mechanical Engineering and Materials Science, Yale University, SIVAN REFAELY-ABRAMSON, Department of Materials and Interfaces, Weizmann Institute of Science, JACK ALEXANDER-WEBBER, Department of Engineering, University of Cambridge, ARELO TANOH, Department of Physics, University of Cambridge, YE FAN, Department of Engineering, University of Cambridge, GERAUD DELPORT, Department of Physics, University of Cambridge, CYAN WILLIAMS, SILVIA VIGNOLINI, Department of Chemistry, University of Cambridge, SAM STRANKS, Department of Physics, University of Cambridge, STEPHAN HOFMANN, Department of Engineering, University of Cambridge, STEVEN LOUIE, JEFFREY NEATON, Department of Physics, University of California, Berkeley, AKSHAY RAO, Department of Physics, University of Cambridge

Defects in transition metal dichalcogenides, such as MoS$_2$ and WS$_2$, are frequently considered responsible for quenching photoluminescence (PL) and lowering mobility, limiting many of the proposed applications. However, while many chemical treatments have been proposed to passivate defects, primarily assumed to be sulfur vacancies, the mechanism of this passivation is poorly understood. In this work, we illustrate how TFSI superacid treatment reveals an optical subgap state associated with sulfur vacancies. At room temperature, this subgap state contributes to enhanced quantum yields and lengthened emission lifetimes, compared to untreated samples, rather than quenching PL. Building on this understanding, we propose a generalizable treatment protocol to passivate defects in monolayer MoS$_2$ and WS$_2$, increasing photoluminescence and maintaining mobilities. This protocol opens up a route for solution-based, post-processing of samples, which could not only passivate defects, but also simultaneously tune properties and functionalize materials.

Probing the nonlinear response of strongly coupled plasmon-WSe$_2$ system

CHENTAO LI (Presenter), XIN LU, AJIT SRIVASTAVA, HAYK HARUTYUNYAN, Emory University

Plasmonic nanostructures have been previously shown to facilitate strong light-matter interactions in a wide variety of systems. With the recent progress in our understanding of 2D transition metal dichalcogenides (TMDs), studies on plasmon-exciton coupling in these systems have increasingly attracted considerable attention, demonstrating evidence of strong light-matter coupling in scattering spectra. However, more convincing evidences of strong coupling are still needed, including probing in nonlinear optical interactions, to give a direct access for studying near-field properties of the coupled system.

In this work, gold nanorods and WSe$_2$ flakes (TMD material) are successfully assembled to investigate the strong light-matter interaction. Rabi splitting and anti-crossing phenomena in dark-field spectra is utilized as signatures of strong-coupled candidates. Interestingly, simulation based on the classical oscillator model predicts that second harmonic generation (SHG) will show a pronounced spectral splitting in this regime, which can be further verified by SHG experiments with a femtosecond pulsed laser. Thus, we suggest that probing in the nonlinear regime may give a clearer evidence of strong coupling that could not be observed in linear measurements.

Homogeneous Broadening of Excitons in Bilayer MoSe$_2$* KEVIN SAMPSON (Presenter), Department of Physics, University of Texas at Austin, SOPHIA HELMRICH, Department of Optics and Atomic Physics, Technische Universität Berlin, CARTER YOUNG, Department of Physics, University of Texas at Austin, NINA OWSCHIMIKOW, Department of Optics and Atomic Physics, Technische Universität Berlin, JACOB EMBLEY, KAI HAO, Department of Physics, University of Texas at Austin, ULRIKE WOGGON, Department of Optics and Atomic Physics, Technische Universität Berlin, XIAOQIN (ELAINE) LI, Department of Physics, University of Texas at Austin — In transition metal dichalcogenides (TMDs), the electronic band structure shifts dramatically when the thickness of a sample is reduced from bilayer to monolayer, producing a concurrent change in their optical properties. Exciton resonances form at the K points on the Brillouin zone boundary in both the monolayers and bilayers, however, we find that their quantum dynamics differ drastically. We perform two-dimensional electronic coherent spectroscopy (2DECS) on a MoSe$_2$ monolayer and bilayer to investigate the quantum decoherence (homogeneous linewidth) of various exciton resonances. We first identify the A-exciton and trion resonances in the monolayer. The bilayer A-exciton is shifted to lower energy, consistent with previous studies. Despite the presence of an inhomogeneous broadening, we were able to extract the homogeneous linewidth using 2DECS. Most notably, the homogeneous linewidth of the bilayer exciton exceeds that of the monolayer exciton and trion significantly. Because the band structure of a MoSe$_2$ bilayer evolves to an indirect bandgap, we expect that scattering with additional interlayer phonon modes would lead to additional dephasing, consistent with the increased homogeneous linewidths observed.

*We gratefully acknowledge funding from NSF DMR-1808042.

Electron relaxation and motion at coplanar 1T'/2H MoTe$_2$ homojunction imaged by time-resolved photoemission electron microscopy AIQIN HU (Presenter), XIAOLONG XU, WEI LIU, State Key Laboratory for Mesoscopic Physics, Frontiers Science Center for Nano-optoelectronics, Collaborative Innovation Center of Quantum Matter, School of Physics, Peking U, QUAN SUN, Research Institute for Electronic Science, Hokkaido University, QIHUANG GONG, YU YE, GUOWEI LU, State Key Laboratory for Mesoscopic Physics, Frontiers Science Center for Nano-optoelectronics, Collaborative Innovation Center of Quantum Matter, School of Physics, Peking U — One critical aspect of optoelectronic devices, such as transistors, diodes, and solar cells, is the internal motion of electrons through the interface between semiconductor and electrode. High spatial and temporal resolution imaging the movement of these electrons would provide unprecedented insight into this critical phenomenon. Here, employing the femtosecond time-resolved photoemission electron microscopy with an energy analyzer, we demonstrate imaging of carrier dynamics in space and time after photoexcitation at 1T'/2H MoTe$_2$ coplanar homojunction, a seamlessly contacted metal/semiconductor interface. The energy-resolved photoelectron images revealed a highly non-equilibrium distribution of photocarriers in space and energy. Combining the time-resolved images, we visualize the motion of electrons from metallic 1T'-MoTe$_2$ to semiconducting 2H-MoTe$_2$ within about 1 picosecond. And the carriers lifetime and transfer rate can be obtained from the modified rate equations set for the homojunction. Our findings provide a new insight for the in-plane semiconductor-metal heterostructure, and it will aid the development of future high-performance devices based on 2D materials.
8:00AM R54.00001: Self-duality of the integer quantum Hall to insulator transition: a composite fermion description*  
PRASHANT KUMAR (Presenter), KEVIN S HUANG, Stanford Univ, YONG-BAEK KIM, Physics, University of Toronto, SRINIVAS RAGHU, Stanford Univ — The integer quantum Hall to insulator transition (IQHIT) is a paradigmatic quantum critical point. Key aspects of this transition, however, remain mysterious, due to the simultaneous effects of quenched disorder and strong interactions. We study this transition using a composite fermion (CF) representation, which incorporates some of the effects of interactions. As we describe, the transition also marks a IQHIT of CFs: this suggests that the transition may exhibit self-duality. We show the explicit equivalence of the electron and CF Lagrangians at the critical point via the corresponding non-linear sigma models, revealing the self-dual nature of the transition. We show analytically that the resistivity tensor at the critical point is $\rho_{xx} = \rho_{xy} = e^2/h$, which are consistent with the expectations of self-duality, and in rough agreement with experiments.

8:12AM R54.00002: Superuniversality of topological quantum phase transitions*  
ALEXANDER TYNER (Presenter), PALLAB GOSWAMI, Northwestern University — Since two topologically distinct phases cannot be adiabatically deformed into each other, they must be separated by a sharp phase transition. Therefore, our understanding of global phase diagrams of topological quantum materials remains incomplete without addressing the nature of topological quantum critical points. We will show that irrespective of underlying symmetry classes, the universal behaviors of several topological phase transitions at different spatial dimensions are controlled by massless Dirac fermion fixed points. Based on this idea of superuniversality, we will address the scaling properties of topological quantum critical points for different Altland-Zirnbauer symmetry classes.

*NSF DMR-1720319
8:24AM R54.00003: Identification of Topological Phase Transitions in Kitaev Quantum Spin Liquids
ARA GO, Center for Theoretical Physics of Complex Systems, Institute for Basic Science, KYUSUNG HWANG, Department of Physics, Korea Institute for Advanced Science, BEOM HYUN KIM, Department of Computational Sciences, Korea Institute for Advanced Science, JI HEON SEONG (Presenter), EUN-GOOK MOON, Department of Physics, Korea Advanced Institute of Science and Technology — We investigate physical quantities of a spin model and argue that magnetic field angle dependence and resonant inelastic X-ray scattering may probe topological phase transitions in Kitaev quantum spin liquids (KQSLs). By using exact-diagonalization, spin-wave theory, and parton mean field analysis, characteristic signatures of topological phase transitions in KQSLs are obtained in a spin model with the Kitaev, Heisenberg, and off-diagonal symmetric terms. Especially, we find qualitative differences between KQSLs and zig-zag ordered phases. We also apply our results to a candidate system α-RuCl3 and provide smoking-gun experiments.

8:36AM R54.00004: Probing Topological Phase Transition Using Rotational Second-Harmonic Generation in (Bi\textsubscript{1-x}Sb\textsubscript{x})\textsubscript{2}Se\textsubscript{3} KUN ZHAO (Presenter), SILU HUANG, JISUN KIM, MATTHEW T CURTIS, JOEL E TAYLOR, Department of Physics & Astronomy, Louisiana State University, LOUIS H HABER, Department of Chemistry, Louisiana State University, RONGYING JIN, E WARD PLUMMER, Department of Physics & Astronomy, Louisiana State University — Topological phase transitions have attracted significant attention recently. (Bi\textsubscript{1-x}Sb\textsubscript{x})\textsubscript{2}Se\textsubscript{3} demonstrates a metal-insulator transition as well as a topological phase transition from a topological insulator to a normal insulator driven by isoelectronic substitution. Although this topological phase transition has been studied both theoretically and experimentally for thin films and single crystals, very conflicting results have been reported and the critical transition point is still under debate. The symmetric study of surface electronic symmetry has never been conducted. Rotational second-harmonic generation (RSHG) is a powerful and non-invasive nonlinear optical technique for probing the electronic symmetry originating from broken symmetry at the surface. In this talk, we symmetrically characterize the surface electronic symmetry and the topological phase transition using high-quality (Bi\textsubscript{1-x}Sb\textsubscript{x})\textsubscript{2}Se\textsubscript{3} single crystals. From the RSHG patterns, we confirm the Bi\textsubscript{2}Se\textsubscript{3} surface shows a C\textsubscript{3v} symmetry and the Sb\textsubscript{2}Se\textsubscript{3} surface shows a C\textsubscript{2v} symmetry. By analyzing the evolution of RSHG patterns with substitution concentration, the critical transition point is further derived. The interplay between the topological phase transition and the metal-insulator transition is also discussed.
8:48AM R54.00005: Topological Phase Transitions in a Hybridized Three-Dimensional Topological Insulator*  SU KONG CHONG (Presenter), Department of Physics & Astronomy, University of Utah, LIZHE LIU, FENG LIU, TAYLOR D. SPARKS, Department of Materials Science and Engineering, University of Utah, VIKRAM V. DESHPANDE, Department of Physics & Astronomy, University of Utah — As the three-dimensional (3D) topological insulator (TI) approaches its 2D thickness limit, quantum tunneling between top and bottom surfaces turns their gapless Dirac band into a gapped state at the Dirac points. Analytical formulation suggests that the hybridization gap scales exponentially with a decrease in number of layers while the system oscillates between topologically trivial and non-trivial insulators. This work explores the transport properties of a 3D TI in the inter-surface hybridization regime. By experimentally probing the hybridization gap as a function of TI thickness using three different methods, namely thermal activation, differential conductance, and quantum capacitance, we map the crossover from 3D TI to 2D insulating state. We detect gap-closing features in the moderate hybridization regime with a perpendicular electric field, suggesting topological phase transitions in the regime. In certain parameter spaces of the non-trivial insulator, we observe quantization of the longitudinal conductance at $2e^2/h$ indicating the quantum spin Hall state.

9:00AM R54.00006: Quasi-periodic dynamical phase transitions in multi-band topological insulators  NICHOLAS SEDLMAYR (Presenter), Institute of Physics, Maria Curie-Sklodowska University — Dynamical phase transitions are non-equilibrium phenomena where non-analyticities occur in dynamically evolving correlation functions, in analogy with the non-analyticities in the derivatives of the free energy for a standard phase transition. Topological phase transitions separate phases of equivalent symmetry but different topology. The ways in which these two phenomena can be connected has recently become a topic of great interest. Here we will report on dynamical phase transitions in many-band one dimensional topological insulators which demonstrate curious quasi-periodic, rather than periodic, dynamical phase transitions. Furthermore we will consider the role of the topologically protected edge states in the dynamics and connections with fidelity susceptibility and dynamical entanglement entropy.

9:12AM R54.00007: Topological multicriticality of spin-orbit coupled electrons in one dimension*  MARIANA MALARD (Presenter), DAVID BRANDAO, PAULO E. DE BRITO, University of Brasilia, HENRIK JOHANNESSEN, University of Gothenburg — A central tenet in the theory of quantum phase transitions (QPTs) is that a nonanalyticity in the ground state energy in the thermodynamic limit implies a QPT. Here we report on a finding that challenges this assertion. As a case study we take the phase diagram of a one-dimensional band insulator with spin-orbit coupled electrons with trivial and topological gapped phases separated by intersecting critical surfaces. The intersections define multicritical lines across which the ground state energy becomes nonanalytical, but with no phase transition taking place. We propose a simple picture for how multicriticality gives rise to this unexpected phenomenon.

*This work was supported by the Swedish Research Council through Grant No. 621-2014-5972.
9:24AM R54.00008: Construction of second-order topological phases protected by chiral symmetry  RYO OKUGAWA (Presenter), WPI-AIMR, Tohoku University, SHIN HAYASHI, TAKESHI NAKANISHI, MathAM-OIL, National Institute of Advanced Industrial Science and Technology — We investigate topological phase transitions of a model to construct two-dimensional second-order topological insulators protected by chiral symmetry. By the theory of the topological phase transitions, we propose second-order topological semimetallic and insulating phases with flat hinge bands in chiral-symmetric three-dimensional systems. We also demonstrate the various second-order topological phases by constructing a two-dimensional lattice model from the Su-Schrieffer-Heeger models and by stacking the lattice models.

9:36AM R54.00009: Piezoelectricity and Topological Quantum Phase Transitions in Two-Dimensional Spin-Orbit Coupled Crystals with Time-Reversal Symmetry*  JIABIN YU (Presenter), CHAO-XING LIU, Pennsylvania State University — Topological quantum phase transitions can be reflected by the sudden jump of certain physical response functions, e.g., the transition between quantum spin Hall state and normal insulator state featured by the jump of the two-terminal conductance. In this work, we demonstrate that the piezoelectric response can also change discontinuously across a topological quantum phase transition in two-dimensional time-reversal invariant systems with spin-orbit coupling. We study all gap closing cases for all 7 plane groups that allow non-vanishing piezoelectric tensor and find that any gap closing with 1 fine-tuning parameter between two gapped states changes either the Z2 invariant (characterizing the quantum spin Hall phase) or the "locally" stable valley Chern number (characterizing the valley Hall phase). The jump of the piezoelectric response is found to exist for all these transitions, and we propose the HgTe/CdTe quantum well and BaMnSb2 as two potential experimental platforms.

Vortex and Surface Phase Transitions in Superconducting Higher-order Topological Insulators

SAYED ALI AKBAR GHORASHI (Presenter), William & Mary, TAYLOR L HUGHES, University of Illinois at Urbana-Champaign, ENRICO ROSSI, William & Mary — Topological insulators (TIs) having intrinsic or proximity-coupled s-wave superconductivity host Majorana zero modes (MZMs) at the ends of vortex lines. The MZMs survive up to a critical doping of the TI at which there is a vortex phase transition that eliminates the MZMs. In this work, we show that the phenomenology in higher-order topological insulators (HOTIs) can be qualitatively distinct. In particular, we find two distinct features.(i) We find that vortices placed on the gapped (side) surfaces of the HOTI, exhibit a pair of phase transitions as a function of doping. The first transition is a surface phase transition after which MZMs appear. The second transition is the well-known vortex phase transition. We find that the surface transition appears because of the competition between the superconducting gap and the local T-breaking gap on the surface.(ii) We present numerical evidence that shows strong variation of the critical doping for the vortex phase transition as the center of the vortex is moved toward or away from the hinges of the sample. We believe our work provides new phenomenology that can help identify HOTIs, as well as illustrating a promising platform for the realization of MZMs.

Topological invariants and edge modes at quantum criticality

RUBEN VERRESEN (Presenter), Harvard University, RYAN THORNGREN, Harvard CMSA, NICK G. JONES, University of Bristol, FRANK POLLMANN, Technical University of Munich, ASHVIN VISHWANATH, Harvard University — It is sometimes presumed that a finite correlation length is essential to stabilizing topological phenomena. This applies even to well-studied topological semi-metals, where one appeals to gapped degrees of freedom (in momentum-space). In this talk, I will show that this common wisdom is not justified: topological invariants and edge modes can survive at phase transitions. This leads to the novel notion of symmetry-enriched quantum criticality, examples of which are hiding in plain sight.

Landau-forbidden quantum phase transitions between bosonic Z2 symmetry-protected topological phases in 2+1D

MAXIME DUPONT, University of California, Berkeley, SNIR GAZIT, Hebrew University of Jerusalem, THOMAS SCAFFIDI (Presenter), University of Toronto — We perform a Quantum Monte Carlo study of quantum phase transitions between different classes of Z2 bosonic symmetry-protected topological (SPT) phases in 2+1D. This is made possible by an advantageous choice of basis which takes care of the sign problem that one might naively expect. Depending on the classes of SPTs considered, we find a variety of unusual intermediate symmetry-broken phases, as well as evidence for a quantum critical direct transition.
**8:00AM R55.00001:** Characterization for higher-order symmetry-protected topological phases by quantized Berry phases

HIROMU ARAKI (Presenter), YASUHIRO HATSUGAI, TOMONARI MIZOGUCHI, Department of Physics, University of Tsukuba — We propose the $Z_Q$ Berry phase as a topological invariant for higher-order symmetry-protected topological (HOSPT) phases for two- and three-dimensional systems. It is topologically stable for electron-electron interactions assuming the gap remains open. The integer $Q$ is determined by the rotational symmetry the system has. As a concrete example, we show that the Berry phase is quantized in $Z_4$ and characterizes the HOSPT phase of the extended Benalcazar-Bernevig-Hughes (BBH) model, which contains the next-nearest neighbor hopping and the intersite Coulomb interactions. In addition, we introduce the $Z_4$ Berry phase for the spin-model-analog of the BBH model. Furthermore, we demonstrate the Berry phase is quantized in $Z_4$ for the three-dimensional version of the BBH model. We also confirm the bulk-corner correspondence between the $Z_Q$ Berry phase and the corner states in the HOSPT phases.

**8:12AM R55.00002:** Evolution of planar topological phases in topocircuits

JUNKAI DONG (Presenter), Cornell University, VLADIMIR JURICIC, NORDITA, BITAN ROY, Lehigh University — Liberation of topological phases from the realm of electronic materials has been recently initiated by their realizations in highly tunable metamaterials, such as phononic and photonic systems, as well as in electric circuits. These classical systems facilitate engineering of various seemingly complex phases of matter, and unveil their topological or geometric properties. We here present a systematic evolution of two-dimensional topological insulators, starting from the analog of quantum anomalous and spin Hall insulators, supporting one-dimensional edge states in electric circuits, also known as topocircuits. Subsequently, we construct rotational symmetry breaking higher-order topological insulators (HOTIs), supporting pointlike corner modes protected by an antiunitary symmetry. The systemic reduction in localization of the topological boundary modes from the edge to the corners is detected from site and orbital selective measurement of the impedance. We also present a simple circuit model for three-dimensional HOTI.

**8:24AM R55.00003:** Magnetotransport in a second-order topological insulator

BENJAMIN LEVITAN (Presenter), TAMI PEREG-BARNEA, McGill University — The most salient feature distinguishing topological insulators from ordinary band insulators is their bulk-boundary correspondence: the topologically-nontrival nature of a bulk sample is signalled by the presence of protected gap-crossing electronic states, localized to the boundary of the sample. Higher-order topological insulators exhibit a somewhat more subtle bulk-boundary correspondence. They still possess protected gap-crossing states, but these are localized to a particular submanifold of the boundary. In the case of a three-dimensional, second-order topological insulator (SOTI), the protected states are localized to the one-dimensional "hinges" of a rectangular nanowire.

We theoretically examine the effects of an applied magnetic field in a model of an SOTI, considering the case where the field couples to the orbital electronic motion. Based on numerical calculations, we predict a clear magnetotransport signature reflecting the interplay between Landau level physics and the hinge modes of the SOTI.
8:36AM R55.00004: Many-Body Invariants for Topological Insulators: Multipole, Chern, and Hinge States  BYUNGMIN KANG (Presenter), School of Physics, Korea Institute for Advanced Study, GIL YOUNG CHO, Department of Physics, Pohang University of Science and Technology (POSTECH) — We propose many-body invariants for the broad classes of topological insulators including Chern insulators, chiral hinge insulators, and multipole insulators. Unlike band indices which only work for non-interacting band insulators, our invariants can detect non-trivial topology of quantum many-body wave functions hence applicable to fully interacting quantum systems. To this end, we design several unitaries whose expectation values on many-body ground states serve as the invariants. We show that the unitaries detect the coefficients of the topological field theory, which are the defining characteristics of topological insulators. This allows us to develop a new way of evaluating Chern numbers, and also the many-body invariant for chiral hinge insulator. Furthermore, we will also show that boundary observables such as the edge-localized polarizations and the corner charge can be measured purely by the many-body unitaries when endowed with appropriate background geometry.

8:48AM R55.00005: Gapless hinge states from adiabatic pumping of axion coupling  THOMAS OLSEN, Department of Physics, Technical University of Denmark, TOMAS RAUCH, Friedrich-Schiller-University, Jena, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University, IVO SOUZA (Presenter), Centro de Física de Materiales, Universidad del País Vasco — We demonstrate that gapless chiral hinge states naturally emerge in insulating crystals undergoing a slow cyclic evolution that changes the Chern-Simons axion coupling θ by 2π. This happens when the surface (not just the bulk) returns to its initial state at the end of the cycle, in which case it must pass through a metallic state to dispose of the excess quantum of surface anomalous Hall conductivity pumped from the bulk. If two adjacent surfaces become metallic at different points along the cycle, there is an interval where they are in topologically distinct insulating states, with gapless chiral modes propagating along the connecting hinge. We illustrate these ideas for a 3D tight-binding model consisting of coupled Haldane-model layers. The surface topology is determined in a slab geometry using two different markers, surface anomalous Hall conductivity and surface polarization, and we find that both correctly predict the appearance of gapless hinge states in a rod geometry.

9:00AM R55.00006: Transport signature of helical hinge states of quasi-one-dimensional topological insulators*  YANFENG ZHOU (Presenter), FAN ZHANG, Department of Physics, The University of Texas at Dallas — Higher-order topological insulators exhibit protected corner or hinge states generalizing the bulk-boundary correspondence. The quasi-one-dimensional materials Bi₄Br₄ and Bi₄I₄ have been predicted to be prototypical examples of such topological matter with helical hinge states along the atomic chain direction. We examine the electronic behavior of their helical hinge states and predict unique signatures in transport experiment. We further show how these signatures depend on the applied electric and magnetic fields.

*This theoretical work at UTD is supported by Army Research Office under Grant No. W911NF-18-1-0416 and Natural Science Foundation under Grant No. DMR-1921581 through the DMREF program.
9:12AM R55.00007: Flux Response of Higher-Order Topological Insulators  FRANK SCHINDLER (Presenter), STEPAN TSIRKIN, TITUS NEUPERT, Univ of Zurich, ANDREI BERNEVIG, BENJAMIN WIEDER, Princeton University — One of the highlights of the past few years of topological condensed matter physics has been the discovery of new forms of 3D topological crystalline insulators that are characterized by gapped bulks and surfaces and gapless hinges. Incipient experimental signatures of the gapless hinge states of these “higher-order” topological insulators (HOTIs) have been observed in bismuth, MoTe$_2$, and WTe$_2$. However, these signatures have also attracted other explanations. Therefore, it is of intense interest to establish additional indicators of higher-order topology beyond anomalous hinge states. In this work, we use threaded π-flux to probe HOTIs with and without time-reversal symmetry. We establish a general framework that captures the 0D and 1D bound states, charge, and spin that accumulate on the flux cores and tubes. Our framework captures all previous results, such as the fractional charges bound to flux cores in Chern insulators. However, we also discover new examples. Specifically, we demonstrate that π-flux tubes in inversion- and time-reversal-symmetric HOTIs bind Kramers pairs of end states, which represent observable signatures of the anomalous “half” quantum spin Hall effect present on the surfaces of weak topological insulators and HOTIs.

9:24AM R55.00008: Disordered intrinsic higher-order topological insulators  JAHAN CLAES (Presenter), TAYLOR L HUGHES, University of Illinois at Urbana-Champaign — Higher order topological insulators are a novel phase of matter in which topologically protected modes appear at corners or hinges rather than surfaces. Unlike conventional topological insulators, higher-order topological insulators can be protected by either a bulk gap or a Wannier gap. Here, we study disordered models of higher-order topological insulators whose topological modes are protected by internal symmetries and a Wannier gap. Like conventional topological insulators, we find that the topological modes are stable against weak disorder. However, we also find that increasing disorder leads to a transition to a trivial state without the mobility gap closing, in striking contrast to the case of conventional disordered topological insulators, in which topological transitions only occur at mobility gap closings. Instead, the topological transition occurs during a real-space Wannier gap closing.

9:36AM R55.00009: Higher Order Topological Insulators in Amorphous Solids  ADHIP AGARWALA (Presenter), ICTS, VLADIMIR JURICIC, NORDITA, BITAN ROY, Lehigh University — We identify the possibility of realizing higher order topological (HOT) phases in noncrystalline or amorphous materials. Specifically, starting from two and three dimensional crystalline HOT insulators, accommodating topological corner states, we gradually enhance structural randomness in the system. Within a parameter regime, as long as amorphousness is confined by outer crystalline boundary, the system continues to host corner states, realizing an amorphous HOT insulator. However, as structural disorder percolates to the edges, corner states start to dissolve into amorphous bulk, and ultimately the system becomes a trivial insulator (devoid of corner modes), when amorphousness plagues the entire system. These outcomes are further substantiated from the scaling of the quadrupolar (octupolar) moment in two (three) dimensions with the scrambling radius. Therefore, HOT phases can be realized in amorphous solids, when wrapped by a thin crystalline layer.
9:48AM R55.00010: Pfaffian formalism for higher-order topological insulators  HEQIU LI (Presenter), KAI SUN, Univ of Michigan - Ann Arbor — We generalize the Pfaffian formalism, which has been playing an important role in the study of time-reversal invariant topological insulators (TIs), to 3D chiral higher-order topological insulators (HOTIs) protected by the product of four-fold rotational symmetry $C_4$ and the time-reversal symmetry $T$. This Pfaffian description reveals a deep and fundamental link between TIs and HOTIs, and allows important conclusions about TIs to be generalized to HOTIs. As examples, we demonstrate in the Letter how to generalize Fu-Kane's parity criterion for TIs to HOTIs, and also present a general method to efficiently compute the $Z_2$ index of 3D chiral HOTIs without a global gauge.

10:00AM R55.00011: Identifying Higher Order Topology and Fractional Corner Charge Using Entanglement Spectra*  PENGHAO ZHU (Presenter), Department of Physics and Institute for Condensed Matter Theory, University of Illinois at Urbana-Champaign, KIERAN LOEHR, Department of physics, Cornell University, TAYLOR HUGHES, Department of Physics and Institute for Condensed Matter Theory, University of Illinois at Urbana-Champaign — We study the entanglement spectrum (ES) of two-dimensional Cn-symmetric second-order topological insulators (TIs). We show that some characteristic higher order topological, e.g., the filling anomaly and its associated fractional corner charge, can be determined from the ES of atomic and fragile TIs. By constructing the relationship between the configuration of Wannier orbitals and the number of protected in-gap states in the ES for different symmetric cuts in real space, we express the fractional corner charge in terms of the number of protected in-gap states of the ES. We show that our formula is robust in the presence of electron-electron interactions as long as the interactions preserve rotation symmetry and charge-conservation symmetry. Moreover, we discuss the possible signatures higher order topology in the many-body ES. Our methods allow the identification of some classes of higher order topology without requiring the of nested Wilson loops or nested entanglement spectra.

Session R56 DCMP: Cerium-Based Heavy Fermion Metals  Mile High Ballroom 2C - James Allen, University of Michigan
**8:00AM R56.00001: Interplay of CEF effects and RKKY interaction in Ce- and Yb-based heavy-fermion compounds**

GERTRUD ZWICKNAGL (Presenter), Institut f. Mathemat. Physik, Techn. Univ. Braunschweig, VILEN ZEVIN, The Racah Institute of Physics, The Hebrew University of Jerusalem — We calculate the influence of Crystalline Electric Field (CEF) effects on the indirect Ruderman-Kittel-Kasuya-Yoshida (RKKY) exchange interaction between local 4f moments in Ce- and Yb-compounds. Starting from a periodic Anderson model and neglecting spin-orbit effects among the conduction states, we show that the anisotropy of the CEF ground state manifests itself in the anisotropy of the effective exchange coupling constant $J(R, R')$ between two moments at sites $R$ and $R'$ while the interaction between two Kramers doublets is isotropic in pseudo-spin space. We evaluate the exchange constant for various models of the conduction states in tetragonal Ce- and Yb-122 compounds. The influence of spin-orbit interaction among the conduction electrons is discussed.

*Partially supported by the joint French-German ANR-DFG grant Fermi-NESt.

**8:12AM R56.00002: Crystal-field excitations and magnetic fluctuations of heavy-fermion metal CeB$_6$**

MAI YE (Presenter), Department of Physics and Astronomy, Rutgers University-New Brunswick, HSXANG-HSI KUNG, Department of Physics and Astronomy, University of British Columbia, PRISCILA ROSA, ERIC BAUER, Los Alamos National Laboratory, ZACHARY FISK, Department of Physics and Astronomy, University of California-Irvine, GIRSH BLUMBERG, Department of Physics and Astronomy, Rutgers University-New Brunswick — CeB$_6$ enters an antiferro-quadrupolar (AFQ) phase below $T_{AFQ}=3.2K$, in which the $T_{2g}$-symmetry quadrupoles order at a finite wave vector [Rep. Prog. Phys. 79, 066502 (2016)]. With its cubic lattice structure and 4f$^1$ Ce$^{3+}$ electronic configuration, this compound is considered a prototypical example of heavy-fermion metal with quadrupolar ordering. We study the crystal-field (CF) excitations and magnetic fluctuations at Ce$^{3+}$ sites by Raman scattering [Phys. Rev. Materials 3, 065003 (2019)]. The spectral linewidth of the CF transitions increases on cooling below 80K, at which the electric resistivity shows its maximum. This coincidence points to the relationship between the broadening of linewidth and Kondo physics. For quasi-elastic fluctuations, the temperature dependence of the static Raman susceptibility in the magnetic channel is consistent with the previously-reported magnetic susceptibility data. Such behavior implies that above $T_{AFQ}$, the tendency towards AFQ ordering induces ferromagnetic correlations which manifest as long-wavelength magnetic fluctuations.

Large Fermi surface expansion through anisotropic mixing of conduction and f electrons in the semimetallic Kondo lattice CeBi

PENG LI, ZHONGZHENG WU, FAN WU, CHUNYU GUO, Zhejiang Univ; YI LIU, University of Science and Technology of China; HAIJIANG LIU, Swiss Light Source, ZHE SUN, University of Science and Technology of China, MING SHI, Swiss Light Source, FANNY RODOLAKIS, JESSICA L MCCHESENY, Advanced Photon Source, CHAO CAO, Hangzhou Normal University, HUIQIU YUAN, FRANK STEGLICH, YANG LIU (Presenter), Zhejiang Univ — Using angle-resolved photoemission spectroscopy (ARPES) and resonant ARPES, we report evidence of strong anisotropic conduction-f electron mixing (c-f mixing) in CeBi by observing a largely expanded Ce-5d pocket at low temperature, with no change in the Bi-6p bands. The anisotropic Fermi surface (FS) expansion is accompanied by a pronounced spectral weight transfer from the local 4f$^{0}$ peak of Ce (corresponding to Ce$^{3+}$) to the itinerant conduction bands near the Fermi level. Careful analysis suggests that the observed large FS change (with a volume expansion of the electron pocket up to 40%) can most naturally be explained by a small valence change (~ 1%) of Ce, which coexists with a very weak Kondo screening. Our work therefore provides evidence for a FS change driven by real charge fluctuations deep in the Kondo limit, which is highly dependent on the orbital character and momentum and is made possible by the low carrier density.

Vanishing Hall number at a quantum critical point

NIKOLA MAKSIMOVIC (Presenter), TAYLOR COOKMEYER, IAN HAYES, EHUD ALTMAN, JAMES ANALYTIS, University of California, Berkeley — Certain types of quantum critical points, phase transitions at zero-temperature, have long been thought to underlie unconventional superconductivity in a variety of systems. We study the effect of particle-hole dilution in the unconventional superconductor CeCoIn$_5$, and discover an unusual critical point that connects two distinct Fermi liquids with different Fermi surface volumes without any apparent symmetry breaking. The signature of this transition is pronounced in the Hall number, which nearly vanishes at the phase boundary between the two Fermi liquids and exhibits a strong dependence on the applied magnetic field. The experiment provides evidence for a type of quantum critical point that fractionalizes conventional metallic quasiparticles into gapless spin excitations and gapped charge carrying excitations. Calculations are presented which suggest that the experimentally measured Hall resistivity in this material reflects the motion of charged particles in the fractionalized Fermi fluid.

*This work was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, Energy Frontier Research Center.
8:48AM R56.00005: Quantum Critical Strange Metal and Fermi Surface Reconstruction in a large-$N$ Kondo Lattice Model  AAVISHKAR PATEL, TAYLOR COOKMEYER, ERIK ALDAPE (Presenter), EHUD ALTMAN, University of California, Berkeley — Quantum critical points in heavy Fermion materials, involving a change of the Fermi surface volume, have presented a long standing puzzle. One way to describe such a transition within a Kondo lattice model is through condensation of a slave Boson. However, this approach leads to a weakly coupled critical point, which fails to describe non-Fermi liquid behavior, such as the ubiquitously observed $T$-linear resistivity at criticality. We present a modified large-$N$ Kondo lattice model, which also describes a transition from a small Fermi surface to a heavy Fermi liquid with a large Fermi surface, but gives rise to $T$-linear resistivity at the critical point. In the large-$N$ limit we also compute the behavior of the Hall transport properties across the transition and compare the results to recent experiments with CeCoIn$_5$. We show under what conditions a strong enhancement of the Hall coefficient, seen in the experiment, is expected.

9:00AM R56.00006: Spectroscopic evidence for pre-formed heavy electron pairs and novel pairing mechanism in CeCoIn$_5$ (Part 1/2)*  KESHAV SHRESTHA (Presenter), National High Magnetic Field Laboratory, SHENGZHI ZHANG, Florida State University, LAURA GREENE, National High Magnetic Field Laboratory, JOE D THOMPSON, Los Alamos National Laboratory, YOU LAI, Florida State University, RYAN BAUMBACH, National High Magnetic Field Laboratory, KALYAN SASMAL, M BRIAN MAPLE, University of California, San Diego, WAN KYU PARK, National High Magnetic Field Laboratory — The heavy-fermion compound CeCoIn$_5$ shows unconventional superconductivity ($T_c=2.3$ K) with $d_{x^2-y^2}$-wave pairing symmetry[1]. Despite evidence for pseudogap in the normal state[2], their spectroscopic nature remains to be unraveled. Here, we present results from planar tunneling spectroscopy measurements on CeCoIn$_5$ along [001], [100], and [110] directions. While the nodal junction exhibits only a zero-bias conductance peak, the non-nodal junctions show sharp double peaks corresponding to the superconducting gap. Interestingly, they evolve continuously crossing the $T_c$, merging into a single broad peak at $T_p=5$K. From quantitative analyses of the conductance spectra, we have found that the gap persistent in the normal state originates from the formation of heavy electron pairs that condense into a coherent state below $T_c$. We will discuss the implications of our findings in the context of other measurement results in the literature along with the underlying pairing mechanism.

*Supported by NSF/DMR-1704712(FSU), DOE, Office of BES, & Division of MSE(LANL), NSF/DMR-1810310(UC-San Diego), and NSF/DMR-1644779 & the State of Florida (NHMFL).
The glue that binds heavy electrons into pairs in CeCoIn$_5$ ($T_c=2.3$K) is not known unambiguously yet. The origin of the neutron resonance peak[1] is still controversial[2] despite the original interpretation as evidence for the spin fluctuation mechanism. Also, the hump-dip feature expected in tunneling conductance is missing in scanning tunneling spectroscopy measurements[3]. Here, we present results from planar tunneling spectroscopy on CeCoIn$_5$, revealing the pairing gap opens at $T_p \sim 5$K. Interestingly, under a magnetic field, the pairing gap turns into a field-induced gap-like feature (FIG). The FIG increases linearly with the field and is observed only below $T_p$. This concomitance of the FIG with the pairing along with its linear field dependence strongly suggests that it is intimately tied to the underlying pairing mechanism. We will discuss these findings in the context of the composite pairing mechanism based on the cooperative two-channel Kondo effect[4].

*Supported by NSF/DMR-1704712(FSU), DOE, Office of BES&Division of MSE(LANL), NSF/DMR-1810310(UC-San Diego) & NSF/DMR-1644779 & the State of Florida(NHMFL).
Resonances in thermal conductivity of superconducting CeCoIn$_5$ in rotating magnetic field

DUK YOUNG KIM, SKKU, South Korea, Institute of Basic Science, SHIZENG LIN, ERIC BAUER, FILIP RONNING, ROMAN MOVSHOVICH (Presenter), Los Alamos Natl Lab — We performed thermal conductivity measurements of d-wave superconducting CeCoIn$_5$ in magnetic field up to 12 Tesla rotating in the a-b plane of this tetragonal compound, in a dilution refrigerator. The heat current $J$ was applied along the [100] direction, antinodal of the superconducting order parameter. In similar previous measurements we observed sharp field-magnitude independent resonances in thermal conductivity for field direction $\Theta = \pm 33^\circ$ away from the direction of the heat current $J$ applied along [110], the direction of the nodes. For heat current $J || [100]$ we observe the resonances at $\Theta = \pm 12^\circ$, complimentary to previous $33^\circ$ resonances, also independent of the magnitude of the magnetic field. The field direction with respect to the crystallographic direction, not the direction of the heat current, is therefore of importance. Our model calculation of the density of state in the normal CeCoIn$_5$ in magnetic field show sharp resonances as function of the field orientation. This suggests that the sharp resonances in thermal conductivity in superconducting CeCoIn$_5$ should be attributed to normal parts of the Fermi surface, which were suggested to exist in magnetic field.

Thermal expansion of heavy-fermion CeRhIn$_5$ under pressure

SOONBEOM SEO (Presenter), SEAN THOMAS, FILIP RONNING, ERIC BAUER, JOE D THOMPSON, PRISCILA ROSA, Los Alamos National Laboratory — Antiferromagnetic CeRhIn$_5$ is a prototypical heavy-fermion compound. With applied pressure, the antiferromagnetic ordering of CeRhIn$_5$ disappears and an unconventional superconducting state emerges. Crystalline electric field (CEF) effects are known to be important in the determination of the ground state of heavy-fermion materials. However, CEF effects in CeRhIn$_5$ have not been studied under pressure because of the limiting volume and background of pressure cells. Here we probe the CEF scheme of CeRhIn$_5$ via thermal expansion measurements under pressure using the strain gauge method at high temperature and optical fiber sensors at low temperature. We report the temperature dependence of the linear thermal-expansion coefficient of CeRhIn$_5$ under pressure. Our results allow us to determine CEF splitting energies from the ground state to the excited state and observe the evolution of the phase transitions under pressure. We will discuss the pressure dependence of CEF effects in CeRhIn$_5$ in comparison with other 115 compounds.

9:48AM R56.00010: Ferromagnetic quantum critical point in heavy fermion compound CeRh₆Ge₄
BIN SHEN, YONGJUN ZHANG, MICHAEL SMIDMAN, Zhejiang Univ, MICHAEL NICKLAS, ROBERT BORTH, MPI-CPfS, AN WANG, HANOH LEE, FRANK STEGLICH, HUIQIU YUAN (Presenter), Zhejiang Univ — Due to the low energy scales, the ground state of heavy fermion compounds can be readily tuned by parameters such as pressure, magnetic fields or doping. There have been numerous studies into antiferromagnetic quantum criticality and unconventional superconductivity, which have been revealed a possible role for spin fluctuations in the superconducting pairing [1, 2]. However, ferromagnetism in heavy fermion systems has been less investigated and there is still short of evidence for the presence of ferromagnetic quantum critical point in a pure system [3]. Here we report various measurements of the ferromagnetic compound CeRh₆Ge₄ under pressure, which provide clear evidence for the existence of a ferromagnetic critical point, at which strange metal behavior is also observed [4].

10:00AM R56.00011: Theoretical investigation of mixed valence compound CeRh₃ by means of 3d-4f resonant inelastic X-ray scattering
NORIMASA SASABE (Presenter), Japan Synch Rad Inst (JSRI) — Ce intermetallics, which are typical strongly correlated system, show the various phenomena, Kondo effects, magnetic ordering and so on. This variety is caused to the 4f electron behavior of Ce atoms, and the electron state needs to be investigated for the understanding of the phenomena.

X-ray core-level spectroscopy is an efficient technique to investigate the electronic state of strongly correlated systems. Recent years, experimental techniques have been rapidly developing and, especially, the progress in experimental resolution has enabled us to observe fine spectral features, which were not formerly observed. These advantages will enable us to observe spectral fine features related with the electron state related to Kondo effects and/or magnetic ordering of the Ce intermetallics.

In this study, the spectral calculation for 3d-4f resonant inelastic X-ray scattering (RIXS) of CeRh₃ is shown, and the character of the final state for 3d-4f RIXS is clarified by paying attention to the incident X-ray energy and polarization. This calculation is performed with an impurity Anderson model considering full multiplet effects in addition to a realistic band effect based on a local density approximation calculation.
10:12AM R56.00012: Low temperature characterization of single crystalline Ce$_2$Ni$_2$In

JANNIS MAIWALD (Presenter), MEIGAN ARONSON, University of British Columbia — Materials with the $R_2T_2X$ ($R$ = Ce,Yb; $T$=transition metal; $X$=main group element) stoichiometry span an extensive (~40) class of compounds. The underlying interactions of these tetragonal systems leads typically to dimerization of the 4f magnetic moments associated with the $R$ ions. These materials feature a broad range of physics, ranging from valence fluctuations, non-Fermi liquid behavior and heavy fermion ground states. Most recently fractional excitations have been observed in inelastic neutron scattering experiments performed on Yb$_2$Pt$_2$Pb. In this talk we will introduce Ce$_2$Ni$_2$In, as a new single crystalline addition to the 221 family of materials. We will discuss its synthesis, general characterization, measurements of the specific heat as well as directional dependent measurements of the magnetic susceptibility and electrical transport from room temperature down to 50 mK.

10:24AM R56.00013: Frist Principles Study of the Fermi Surface Topology of CeCu$_2$Si$_2$*

ROXANNE TUTCHTON (Presenter), Los Alamos National Laboratory, QIMIAO SI, Department of Physics and Astronomy, Rice University, JIAN-XIN ZHU, Los Alamos National Laboratory — Since the discovery of heavy-fermion superconductivity in CeCu$_2$Si$_2$, the material has attracted interest in the nature of superconducting pairing. So, it is essential to better understand the electronic Fermi surface topology and its role in strong antiferromagnetic fluctuations. We have performed electronic ground state calculations on CeCu$_2$Si$_2$ using the Gutzwiller approximation. This method captures the quasiparticle band renormalization from the strong onsite Coulomb repulsion. We have performed an analysis of the electronic structure and the Fermi surface topology by varying the interaction strength and taking into account the crystal-field splitting. Using the de Haas van Alphen effect, the extremal Fermi surface cross-sectional areas were calculated to quantify the quasiparticle mass renormalization in the energy bands. Our results confirm two Fermi surface sheets corresponding to the heavy and light quasiparticles, which is in agreement with the renormalized band method. We also discuss the connection of the Fermi surface topology to hot-spots in the magnetic susceptibility form factor measured by neutron scattering.

Quantum Criticality from Sequential Destruction of SU(4) Spin-Orbital-coupled Kondo Effect

SILKE BUEHLER-PASCHEN (Presenter), Vienna University of Technology, CHIA-CHUAN LIU, ANG CAI, Rice Univ, EMILIAN NICA, Arizona State University, RONG YU, Renmin University of China, KEVIN INGERSENT, University of Florida, QIMIAO SI, Rice Univ — Quantum criticality and the beyond-Landau physics of Kondo destruction [1,2] have recently been studied in systems with multipolar degrees of freedom. The compound Ce$_3$Pd$_{20}$Si$_6$ shows evidence of two consecutive Fermi surface collapsing quantum critical points (QCPs) as it is tuned from a paramagnetic to an antiferroquadrupolar and then to an antiferromagnetic state [3]. A theory was advanced [3] for a sequential destruction of spin-orbital-coupled Kondo entanglement in an SU(4) Bose-Fermi Kondo model, an effective model for a multipolar Kondo lattice. Here we report an analytical renormalization group calculation of the model with Ising anisotropy, using a Coulomb-gas representation. We show that a generic trajectory in the parameter space contains two QCPs associated with the destruction of the orbital and spin Kondo effects, respectively. Our work establishes a firm theoretical ground for the sequential Kondo destruction.

X-ray and neutron-diffraction studies of the CeOs$_4$Sb$_{12}$ valence transition at low temperatures and high magnetic fields

JOHN SINGLETON (Presenter), National High Magnetic Field Laboratory, Los Alamos National Laboratory, KATHRIN GOETZE, MATTHEW PEARCE, Physics, Warwick University, ZAHIRUL ISLAM, Advanced Photon Source, Argonne National Laboratory, ULRICH WELP, Argonne National Laboratory, PAUL GODDARD, Physics, Warwick University, ROGER JOHNSON, University College London, PASCAL MANUEL, ISIS Neutron Source, M BRIAN MAPLE, UCSD, PEI-CHUN HO, Physics, Fresno State University — CeOs$_4$Sb$_{12}$ exhibits a very unusual field- and temperature-driven valence transition that is accompanied by a drastic change in Fermi-surface topology. It is also a candidate heavy-fermion topological semimetal and sports a field-induced quantum-critical point at about 20 T. Single crystal x-ray diffraction in pulsed magnetic fields of up to 30 T using a unique instrumental combination at the Advanced Photon Source permitted a study of the change in unit-cell volume as the field swept through the valence transition. In addition, neutron-diffraction measurements probed the analogous structural changes as a function of temperature in zero magnetic field. Both measurements shed light on the unique “wedge-shaped” phase boundary that marks the valence transition in CeOs$_4$Sb$_{12}$.
8:00AM R57.00001: Epitaxial growth of stanene and antimonene on noble metal and oxidized metal surfaces  AIDI ZHAO (Presenter), School of physical science and technology, Shanghaitech University — Group-IV and group-V monoelement two-dimensional (2D) materials like stanene, antimonene or bismuthene has been theoretically proposed to be quantum spin Hall (QSH) insulator with large energy gaps for room-temperature use. However, to experimentally fabricate such ultra-thin materials with topologically nontrivial properties remains challenging. It requires accurate control over substrate-interface structures at the atomic level. We successfully grown an ultraflat stanene layer with an in-plane s-p band inversion together with a large spin-orbit-coupling-induced topological gap (~ 0.3 eV), which represents a first group-IV ultraflat graphene-like material displaying topological features in experiment. Such an in-plane s-p band inversion results in a nontrivial σ-orbital-derived QSH phase described by the Bernevig-Hughes-Zhang model and this QSH phase is more environmentally stable comparing to those π-orbital-derived QSH phases. We also successfully synthesized an antimonene film on Ag(111) surface showing an extraordinarily large tensile strain and bilayer stanene on an oxidized Cu(110) surface with large anisotropic strain.

8:12AM R57.00002: Effects of short-range order and interfacial interactions on the electronic structure of two-dimensional antimony-arsenic alloys*  QI AN (Presenter), School of Materials Science and Engineering, University of Science and Technology Beijing, MATTHIEU FORTIN-DESCHÊNES, Department of Engineering Physics, École Polytechnique de Montréal, GUANGHUA YU, School of Materials Science and Engineering, University of Science and Technology Beijing, OUSSAMA MOUTANABBIR, Department of Engineering Physics, École Polytechnique de Montréal, HONG GUO, Department of Physics, McGill University — The growth of two-dimensional (2D) antimony-arsenic alloys has been recently demonstrated using solid-source molecular beam epitaxy and this provides an additional degree of freedom to tailor their basic properties. With this perspective, we propose and conduct a comprehensive first principles investigation on this 2D group-V antimony arsenide (2D As$_x$Sb$_y$), in both free-standing form as well as on common substrates of Ge(111), Si(111), bilayer graphene and bilayer hexagonal boron nitride (h-BN). Structural and electronic properties of the 2D As$_x$Sb$_y$ are evaluated for different compositions, different types of atomic arrangements for each composition, different lattice matched interfacial configurations of the composite heterostructures for the four substrates. These systematic studies provide property benchmarks for this new class of group-V 2D materials and reveal microscopic origins of the interfacial interactions, orbital hybridization, charge transfer and the resulting electronic structures of the 2D alloy.

*This work is supported by the Natural Sciences and Engineering Research Council of Canada (NSERC) and the Natural Science Foundation of China (Grant No. 51571017 and 51871018).
LaBr, a layered magnetic material that is weakly bound by van der Waals interactions, is an ambient pressure electride and, using first-principles electronic structure calculations, we show that monolayer LaBr is potentially exfoliable, stable, retains the magnetic ordering of bulk LaBr and could also be an electride at ambient pressure.

Furthermore, in monolayer LaBr, we show that the two interstitial sites occupied by electrons have a strong tendency to bind with, e.g., hydrogen and we propose several new structures with composition of La, H and Br. We have calculated the composition phase diagram of LaBr with hydrogen, finding LaBr to be a potential promising candidate material for high-density hydrogen storage, and monolayer La$_2$HBr$_2$ to be a potential promising candidate 2D multiferroic material.

8:48AM R57.00005: Quasiparticle band structure of bulk and few-layer transition-metal dichalcogenides*  
HAN-GYU KIM (Presenter), HYOUNG JOON CHOI, Department of Physics, Yonsei University, Seoul 03722, Korea — We studied the work function, ionization energy, and electron affinity of bulk and few-layer transition-metal dichalcogenides (TMDs) in 2H phase using the density functional theory (DFT) and the GW approximation. We obtained DFT band energies of few-layer TMDs with respect to the vacuum level. For the vacuum level of bulk TMDs, we considered a sufficiently thick slab system which has a similar band gap with bulk. We introduced the GW approximation to obtain the quasiparticle energy shift of valence band maximum and conduction band minimum and estimated the work function, band gap, ionization energy, and electron affinity as functions of the number of layers. We compare our quasiparticle band energies of TMDs with available experimental reports.

*This work is supported by the NRF of Korea (Grant No.2011-0018306). Computational resources have been provided by KISTI Supercomputing Center (Project No. KSC-2018-CRE-0097).

9:00AM R57.00006: Single-particle spectral function formulated and calculated by variational Monte Carlo method*  
MAXIME CHARLEBOIS (Presenter), CCQ, Flatiron Institute, MASATOSHI IMADA, Science and Engineering, Waseda University — A method to calculate the one-body Green’s function for ground states of correlated electron materials is formulated by extending the variational Monte Carlo method. We benchmark against the exact diagonalization (ED) for the one- and two-dimensional Hubbard models of 16 site lattices, which proves high accuracy of the method. The application of the method to larger-sized Hubbard model on the square lattice correctly reproduces the Mott insulating behavior at half filling and gap structures of \( d \)-wave superconducting state in the hole doped Hubbard model, evidencing a wide applicability to strongly correlated electron systems.

*This work was supported by Fonds de recherche du Québec - Nature et technologies (FRQNT) and by a Grant-in-Aid for Scientific Research (No. 16H06345) from Ministry of Education, Culture, Sports, Science and Technology, Japan.
I present two 2D material systems where their crystallinities are paradoxically improved by defects during growth. First, I demonstrate that a new class of defect complex, interlayer Frenkel pairs, enhances the orientational epitaxy of transition metal dichalcogenides on hexagonal boron nitride, leading to experiments that achieve 95% consistency in orientational order by strongly suppressing inversion domains [1,2]. I will show how the stability of the defect complex originates from its electronic structure at the density functional theory level and discuss our recent extension to accelerated GW-level computations for defects. Second, I discuss our recent joint theory and experimental work on a 2D metal-semiconductor heterostructure hosting air-stable, crystalline 2D metals. Enabled by graphene defects in an initial graphene/SiC system, p-block metal atoms such as Ga, In, and Sn intercalate under graphene and bond covalently to the SiC beneath, forming lattice-matched 2D metals, as demonstrated by their calculated phase stabilities [3,4]. Based on first-principles calculations assisted by Wannier functions, I explain the presence of superconductivity in spite of the metals' free-electron-like electronic structure.

*Funding for this work was provided by the 2D Crystal Consortium National Science Foundation (NSF) Materials Innovation Platform under cooperative agreement DMR-1539916.
Structural and optical properties of bulk and monolayer GeSe: A Quantum Monte Carlo Study*  
HYEONDEOK SHIN (Presenter), Argonne Natl Lab, JARON KROGEL, PAUL KENT, Oak Ridge Natl Lab, ANOUAR BENALI, OLLE HEINONEN, Argonne Natl Lab — We have performed quantum Monte Carlo simulations of the monochalcogenide GeSe to study its structural and optical properties. 2D GeSe has received a great deal of attention due to its wide range of applications in industrial devices, such as photodetector, gas sensor, and anode material. Density functional theory (DFT) studies show that the monolayer has smaller lattice parameters than the bulk system, with small band gap energy (1~2 eV). However, DFT cannot conclusive determine if the monolayer has a direct or indirect band gap because of very small differences (~0.02 eV) between direct and indirect gaps. Moreover, the geometry for GeSe is not clear within DFT scheme because the DFT lattice parameters and atomic coordinates vary strongly with the particular exchange-correlation functional used. Using fixed-node diffusion Monte Carlo (DMC), we reproduce accurate lattice parameters and band gaps compared to the experimental values for bulk GeSe. For the monolayer, we find that the DMC optimal lattice parameters for the monolayer are close to the bulk ones, and DFT significantly underestimates its lattice parameters. Finally, we compute accurate DMC band gap energies at the optimal geometry for the monolayer.

Tailoring of interlayer hopping integral at K valley in transition metal dichalcogenides*  
WEI-TING HSU (Presenter), JIAMIN QUAN, Department of Physics, The University of Texas at Austin, PENG-JEN CHEN, Institute of Atomic and Molecular Sciences, Academia Sinica, XIAOQIN (ELAINE) LI, Department of Physics, The University of Texas at Austin, JUNG-FU LIN, Jackson School of Geosciences, The University of Texas at Austin, CHIH-KANG SHIH, Department of Physics, The University of Texas at Austin — Interlayer electronic coupling plays a critical role in developing novel electronic metamaterials such as unconventional superconductivity in graphene and moiré excitons in transition metal dichalcogenides (TMDs), in which the potential landscape is determined by the interlayer hopping integral. In addition to the well-known effects of stacking configuration, a largely unexplored factor is the van der Waals (vdW) gap, which impacts the hopping integral exponentially. Here, by measuring the direct optical transitions, we quantitatively determine the interlayer hopping integral of K valley as ~40 meV in Bernal-stacked MoS$_2$. The vdW-gap dependence was further investigated by tuning the temperature and hydrostatic pressure. We observed a 2.4-fold enhancement at a reduced vdW gap of ~7%. The experimental results were compared with the density functional theory. Our work has shed light on designing the TMD-based moiré heterostructures in the future.

*This research was supported by the Welch Foundation (F-1672), the US Airforce (FA2386-18-1-4097), and the US National Science Foundation (DMR-1808751 and the MRSEC program DMR-1720595).
10:12AM R57.00010: The relationship between activation energy and band gap in a disordered 2D insulator  YANJUN HE (Presenter), BRIAN SKINNER, Ohio State Univ - Columbus — We study how the activation energy for conductivity is related to the band gap in a 2D band insulator that experiences a disorder potential created by charged impurities. This problem can be mapped to a problem of classical percolation, since the conductivity is limited by the rate at which electrons are activated from the chemical potential to a percolating energy contour in real space (the classical mobility edge). When impurities are sparse, we find that the activation energy is the same as in the disorder-free case, even though there is significant band bending. On the other hand, when the Coulomb disorder is strong enough to induce large, closely-spaced electron puddles, the activation energy reflects the Coulomb charging energy of large puddles, and has a critical dependence on the band gap that is characteristic of 2D percolation.

10:24AM R57.00011: The temperature dependence of the band structures in mono-layer, few-layer and bulk black phosphorus  SHENYANG HUANG (Presenter), FANJIE WANG, Fudan Univ, GUOWEI ZHANG, Northwestern Polytechnical University, CHAOYU SONG, YUCHEN LEI, QIAOXIA XING, CHONG WANG, Fudan Univ — Black phosphorus (BP), an emerging two-dimensional material, has attracted abundant research interests. However, the study of temperature dependence of the bandgap in few-layer BP is still lacking. Here we systematically investigated the temperature dependence of the electronic structures in mono-layer, few-layer and bulk BP. We found that the temperature dependence of the electronic structure has strong layer and transition-index dependence, which is closely related to the temperature dependent interlayer interaction. Surprisingly, the band gaps of monolayer and bulk BP showed opposite temperature effect. Such diverse behavior sheds light on the importance of van der Waals coupling in defining the electronic structures of 2D materials.

10:36AM R57.00012: Effective Hamiltonian for Extrinsic Spin-Orbit Coupling in 2D Materials  SEYED MOHAMMAD FARZANEH (Presenter), Electrical and Computer Engineering, New York University, Brooklyn, NY 11201, SHALOO RAKHEJA, Holonyak Micro and Nanotechnology Laboratory, University of Illinois at Urbana-Champaign, Urbana, IL 61801 — Inversion symmetry of a two-dimensional (2D) electron system can be broken by a perpendicular external electric field which lifts the spin degeneracy while it preserves the time-reversal symmetry. The resulting spin splitting, known as the Bychkov-Rashba (BR) spin-orbit coupling, can be used for spin manipulation solely using electric fields without an external magnetic field. However, the main limitation of the phenomenological BR Hamiltonian is that it is inapplicable to two-dimensional (2D) monolayer materials in which the crystal structure is different than that of conventional zinc-blende and wurtzite semiconductors. In this work, we use the theory of invariants to derive the effective Hamiltonian for 2D materials, such as phosphorene and transition metal dichalcogenides, without resorting to any phenomenological prefactor as that in the BR model. Owing to their vertical and lateral scalability and high electron mobility, 2D materials provide an excellent platform to realize semiconducting spintronics devices. We determine the bands that contribute to the extrinsic spin-orbit coupling of conduction electrons and calculate the prefactors in terms of k.p parameters.

Metal-dependent interfacial properties in pthalocyanine-MoS$_2$ heterostructures*  
TEODOR STANEV (Presenter), SAMUEL H AMSTERDAM, QUNFEI ZHOU, Northwestern University, PIERRE DARANCET, Argonne National Lab, MARK C HERSAM, TOBIN MARKS, NATHANIEL PATRICK STERN, Northwestern University — Mixed-dimensional heterostructures made by combining 2D materials with other systems of different dimensionality can exhibit unique interfacial effects and modify the properties of the individual constituent layers. Organic molecules are an attractive building block for these structures due to their synthetically tunable properties and ease of processing. Here we discuss interfacial charge transfer in metallophthalocyanine (MPc) – MoS$_2$ heterojunctions. These interfaces show heterojunction-specific optical absorption transitions, strong Raman enhancement, and defect emission quenching in the MoS$_2$, all of which depend the identity of the single metal (M) atom at the MPc core. Temperature dependent optical and electrical characterization were carried out to characterize and to understand the interfacial interactions. The metal core dependence provides a ‘knob’ for controlling opto-electronic properties of both the interface and the underlying layer, highlighting the complex and tunable nature of 0D/2D van Der Waals interfaces.

8:00AM R58.00001: Ultrafast Spin Dynamics with TDDFT* [Invited]  PETER ELLIOTT (Presenter), Max Born Institute Berlin, Berlin, Germany — Laser-induced ultrafast spin dynamics can manipulate the magnetic moment of materials on femtosecond timescales, several orders of magnitude faster than traditional methods.

In the past few years, we have applied real-time time dependent density functional theory to study the induced spin dynamics and provide an overdue ab-initio perspective to this problem. We observed two main mechanisms for ultrafast change in local magnetic moments: 1) spin-orbit driven spin-flips[1] leading to ultrafast demagnetization and 2) optical inter-sublattice spin transfer OISTR[2].

OISTR was first predicted in Heusler compounds[2], but appears for a wide range of materials, including anti-ferromagnetic systems where it can be used to switch the material to a transient ferromagnetic state[3].

The signature of OISTR has been seen experimentally for several materials including Heusler compounds, Co/Cu interfaces[4], Ni/Pt multilayers, CoPt, and FeNi.

In this talk I will review our findings so far and hope to convince you that ultrafast spin dynamics has been a real success story for TDDFT.

In collaboration with: Peter Elliott (Max Born Institute Berlin, Berlin, Germany), J.K. Dewhurst (Max Planck Inst of Microstructure Physics), Eberhard K Gross (ritz Haber Center for Molecular Dynamics, The Hebrew University of Jerusalem), Sangeeta Sharma (Max Born Institute Berlin, Berlin, Germany)

**8:36AM R58.00002: A real-time TDDFT study of CDW phase under femtosecond optical pulse in monolayer 2H-NbSe2**

TOWFIQ AHMED (Presenter), JIAN-XIN ZHU, Los Alamos Natl Lab —

Abstract: Intense, transient electromagnetic (EM) fields have recently emerged as an exciting alternative for driving quantum materials into new phases by selectively coupling to specific degrees of freedom, making it possible to create transient and metastable states that do not exist in equilibrium. First principles study of such driven quantum phases are now possible, thanks to the velocity-gauge implementation of real-time time-dependent density functional theory (RT-TDDFT). Ultra-fast/femtosecond laser pump and probe can reveal important information in 2D transition metal dichalcogenides many of which exhibit short time-scale complex interplay between quantum phases such as CDW, valley polarization and superconductivity. In this study, we performed RT-TDDFT calculations to study how the higher-harmonic generation (HHG) behaves in CDW and non-CDW phases of monolayer NbSe2 under different laser field intensities. We simulated frequency dependent current spectra to identify the HHG modes in NbSe2 under intense laser field.

**8:48AM R58.00003: Emergence of band gaps, mass enhancement and Jahn-Teller distortions in AFM and PM 3d Oxides from polymorphous DFT**

ALEX ZUNGER (Presenter), University of Colorado, Boulder, JULIEN VARIGNON, CRISMAT, Normandie — A central feature in understanding the properties of 3d Oxides is their magnetic structure. While local moments are present both in the AFM and PM phases, the latter has traditionally been simplistically modeled as non-magnetic (NM) structure in which each atom was thought to have zero moment, (while the real condition is only that the total PM cell will have zero moment). This NM approximation underlying the N-DFT approach (N= Naive) has led to the opinion that DFT misses the Mott gap in PM insulators, effective mass enhancement effect, bond disproportionation and Jahn-Teller distortions. These discrepancies suggested in the literature invoking explicitly dynamically correlated approaches. We explored the alternative option of staying within (single determinant) DFT but getting rid of N-DFT. Instead of using a minimal unit cells, we use a supercell where the total moment is constrained to be zero but local moments and displacements that lower the total energy are allowed. This generalization creates finite band gaps in AFM and PM phases of ABO3 perovskites (except PM metals SrVO3 and CaVO3 ), disproportionation (in SmNiO3 and YNiO3), mass enhancement (in SrVO3 and doped SrTiO3) and explains the observed trends in JT distortions throughout the series.

9:00AM R58.00004: Characterizing Single-Molecule Magnets using Density Functional Theory
HENRY FITZHUGH (Presenter), JAMES FURNESS, JIANWEI SUN, Tulane Univ — Single-molecule magnets are valued as prospective components in devices for information processing and storage. Computational modeling can aid in understanding and optimizing their magnetic properties. Many single-molecule magnets are too large for analysis using high-level wavefunction theories, making density functional theory (DFT) an attractive choice.

The magnetic properties of single-molecule magnets depend on a strong exchange interaction between orbitals and the spatial localization of spin orbitals, properties that have been challenging for conventional exchange-correlation functionals. It is therefore crucial to understand the relative effectiveness of DFT methods. Here we apply functionals at the meta-GGA, and local hybrid levels in conjunction with broken symmetry methods to single-molecule magnet systems with exchange-coupled metallic cores. We determine effective coupling parameters and other magnetic properties, and investigate the practical utility of the functionals.

9:12AM R58.00005: Exchange-correlation magnetic fields in spin-density-functional theory
EDWARD A PLUHAR (Presenter), CARSTEN A. ULLRICH, Physics and Astronomy, Univ of Missouri - Columbia — In spin-density-functional theory for noncollinear magnetic materials, the Kohn-Sham system features exchange-correlation (xc) scalar potentials and magnetic fields. The significance of the xc magnetic fields is not very well explored; in particular, they can give rise to local torques on the magnetization, which are absent in standard local and semilocal approximations. We obtain exact benchmark solutions for two electrons on four-site extended Hubbard lattices over a wide range of interaction strengths, and compare exact xc potentials and magnetic fields with approximations obtained from orbital-dependent xc functionals. The xc magnetic fields turn out to play an increasingly important role as systems become more and more correlated and the electrons begin to localize; the effects of the xc torques, however, remain relatively minor. The approximate xc functionals perform overall quite well, but tend to favor symmetry-broken solutions for strong interactions.

9:24AM R58.00006: A benchmark of predicting magnetic structures using a combination of the cluster multipole expansion and LSDA* MARIE-THERESE HUEBSCH (Presenter), Graduate School of Frontier Sciences, University of Tokyo, TAKUYA NOMOTO, Department of Applied Physics, University of Tokyo, MICHI-TO SUZUKI, Institute for Materials Research, Tohoku University, RYOTARO ARITA, Department of Applied Physics, University of Tokyo — The cluster multipole (CMP) expansion for magnetic structures [1] provides a scheme to systematically generate candidate magnetic structures specifically including noncollinear magnetic configurations adapted to the crystal symmetry of a given material. A comparison with the experimental data collected on MAGNDATA [2] shows that the most stable magnetic configurations in nature are a linear combination of only few CMPs. Furthermore, a high-throughput generalized local spin-density approximation (LSDA) calculation, in which each candidate magnetic structure was considered as an initial guess, was performed using VASP [3]. We benchmark the predictive power of CMP+LSDA by testing whether CMP administers an appropriate list of candidate magnetic structures and LSDA reproduces the experimental magnetic configurations.

9:36AM R58.00007: TDDFT for spin waves in two-dimensional systems: orbital-based approximations* MATTHEW ANDERSON (Presenter), CARSTEN A. ULLRICH, Univ of Missouri - Columbia — The collective dynamics of electrons with Dirac-like dispersions, such as in doped graphene, is not well described by the usual semilocal approximations of (TD)DFT, which are based on the traditional electron gas. Instead, we use orbital-based approximations, most notably the Singwi-Tosi-Land-Sjolander (STLS) approach, generalized to systems with noncollinear spin. We calculate spin-wave dispersions in magnetized two-dimensional systems of itinerant electrons.

The effect of removal of self-interaction error on the magnetic exchange couplings

PO-HAO CHANG (Presenter), PRAKASH MISHRA, RAJENDRA ZOPE, TUNNA BARUAH, University of Texas, El Paso — Spin coupling within and between molecules has played an important role in the design and development of molecular magnets, spintronics, and memory devices. Accurate theoretical determination of magnetic properties in molecular complexes has therefore become crucial. The Green's function (GF)-based approach, often used in solid-state physics, for computing exchange coupling can potentially offer additional insights into local pathway in exchange spin coupling. We implement this approach into the UTEP-NRLMOL and FLOSIC codes and apply it, along with Noodleman's spin-projected (SP) broken-symmetry approach, to study the exchange coupling in a set of molecules. In particular, we use Fermi-Lowdin self-interaction method to investigate the role of self-interaction error in predicting exchange-coupling with three (LSDA, PBE, and SCAN) non-empirical density functional approximations that correspond to the first three rungs of Perdew-Schmidt ladder of functionals.

Self-interaction-corrected electronic structure of Fe-based single-ion magnetic molecule

ANRI KARANOVICH (Presenter), Virginia Tech, YOH YAMAMOTO, University of Texas at El Paso, KAI TREPTE, KOBLAR JACKSON, Central Michigan University, RAJENDRA R ZOPE, TUNNA BARUAH, University of Texas at El Paso, KYUNGWHA PARK, Virginia Tech — Density-functional theory (DFT) has been successful in predicting properties of various systems ranging from molecules to solids. However, self-interactions of electrons that do not cancel out in local and semi-local approximate exchange-correlation functionals, impede accurate prediction of properties. Recently, an effective way to perform self-interaction correction (SIC) has been proposed using localized Fermi-Lowdin orbitals (FLO) by introducing a Fermi orbital descriptor for each occupied orbital. We apply this method to a Fe-based single-ion magnetic molecule with large magnetic anisotropy barrier, using FLOSIC code, in order to study electronic and magnetic properties. We discuss calculated projected density of states as well as an energy gap between the highest-occupied molecular orbital (HOMO) and the lowest-unoccupied molecular orbital (LUMO) for the ground-state spin configuration. We further compare our SIC-calculated result to DFT calculations without SIC and DFT+U calculations.

10:12AM R58.00010: Fermi-Lowdin orbital self-interaction correction on magnetic properties of Cu(II)-acetate monohydrate*  PRAKASH MISHRA (Presenter), Computational Science Program, University of Texas at El Paso, YOH YAMAMOTO, RAJENDRA ZOPE, TUNNA BARUAH, University of Texas, El Paso — We study the magnetic properties of copper acetate monohydrate [Cu(CH3COO)2(H2O)]2 using the Fermi-Lowdin orbital based self-interaction corrected (FLOSIC) density functional method. Most common density functional approximations that often accurately predict equilibrium properties have a self-interaction error that tends to unphysically lower the energies of fractionally occupied state which leads to deviation from piecewise linear behavior of total energy between two integer occupations. This leads to delocalization of the orbitals which is more apparent in d-electron systems resulting in incorrect electron densities. We find that removing self-interaction error using FLOSIC improves the magnetic coupling constant resulting in better agreement with experiment. The performance of self-interaction corrected density functional approximations on the magnetic properties is studied. The effect of self-interaction correction on the orbitals, density and the zero field splitting parameters will be presented and discussed.

8:00AM R59.00001: Fermi surface instability in the antiferromagnetic Dirac material Ca1- xNaₓMnBi₂ LEONARDO DEGIORGI (Presenter), MATTEO CORASANITI, RUN YANG, ETH Zurich — The quasi-two-dimensional bismuth layer-like AMnBi₂ (A= alkaline as well as rare earth atom) lately advanced as an arena for the investigation of low-energy quasiparticle excitations in topological materials. The A= Sr or Ca compositions have attracted special attention because of the coexistence of the anisotropic Dirac cones with antiferromagnetic order. In a broader context, the title compound also provides an opportunity to study low-dimensional magnetism and its putative relationship to the electronic properties. This work describes novel results of reflectivity measurements from the far-infrared up to the ultraviolet that probe the optical response as a function of temperature. This gives access to the optical conductivity which captures the relevant energy scales shaping the electronic structure. We discover [1] a reshuffling of spectral weight, defined as the integral of the real part of the optical conductivity, for energy scales up to 0.2 eV. This occurs at the onset of the spin reorientation transition which also manifests as an anomaly in the dc transport data of the title compound. This may reveal the inclination towards a Fermi surface instability in topological materials.

8:12AM R59.00002: Evidence for Strong Electron-Phonon Coupling in Weyl Semimetals

GAVIN OSTERHOUDT (Presenter), Boston College, CHRISTINA GARCIA, Harvard University, VINCENT PLISSON, Boston College, JENNIFER COULTER, Harvard University, JOHANNES GOOTH, Max Planck Institute for Chemical Physics of Solid, BING SHEN, NI NI, Univ of California Los Angeles, CLAUDIA FELSER, Max Planck Institute, PRINEHA NARANG, Harvard University, KENNETH BURCH, Boston College

— Since the experimental discovery of topological semimetals (TSM) there has been a flurry of activity focused on identifying signatures of topological transport. However, many of the transport properties display behavior that is dominated by non-topological interactions with the phonon system. A deeper understanding of these TSMs therefore requires investigation of the coupling between the topological electronic system and the non-topological vibrational system. In this presentation we discuss our recent temperature dependent Raman measurements on multiple TSMs which reveal unusual temperature dependence of the linewidths. These linewidths indicate strong electron-phonon coupling in these materials, and furthermore, they show a preponderance of optical phonon decay into electron-hole pairs which seems to be a relatively general feature in TSMs.

8:24AM R59.00003: Second Order Nonlinear Responses in Chiral Weyl Semimetal CoSi

ELIZABETH DRUEKE (Presenter), RACHEL OWEN, MATTHEW W DAY, Univ of Michigan - Ann Arbor, SHANGJIE TIAN, CHANGE LI, HECHANG LEI, Renmin University of China, STEVEN THOMAS CUNDIFF, LIUYAN ZHAO, Univ of Michigan - Ann Arbor — The origin of the nonlinear responses in Weyl semimetals has become an increasingly contentious issue in recent years, with some of these effects being attributed to topology and others to symmetry. Part of this contention comes from the fact that the Weyl nodes are required by mirror symmetries in non-chiral Weyl semimetals to appear at exactly the same energy in the band structure, making it impossible to probe a single cone. Recently, chiral Weyl semimetals – with no mirror symmetries – have been observed with paired Weyl cones at significantly different energies (>100meV), allowing for cone discrimination based on choice of laser wavelength. Here, we present our study of the second order nonlinear responses in one such chiral Weyl semimetal, CoSi. In particular, we look at variation of the second harmonic generation (SHG) at multiple crystalline facets of CoSi, and the spatial inhomogeneity and temporal dynamics of its induced SHG. Further, we compare the SHG response strength to a variety of second order nonlinear crystals. Finally, we examine the spontaneous photocurrent response in CoSi.

Magnetic-Field Dependence of Chirality-Resolved Optical Phonon in Weyl semimetal

KUNYAN ZHANG (Presenter), Pennsylvania State University, AMBER MCCREARY, National Institute of Standards and Technology, FEI HAN, MINGDA LI, Massachusetts Institute of Technology, ANGELA HIGHT WALKER, National Institute of Standards and Technology, SHENGXI HUANG, Pennsylvania State University — Weyl semimetal (WSM), the solid-state realization of chiral Weyl fermions, exhibits chiral zeroth Landau levels in the magnetic field contributing to novel transport and optical properties. While electronic transport has been a focus of studies, the optical response of WSM is relatively under-explored, yet it can also reflect the topological nature of WSM. For example, the chirality of the Weyl fermions can be determined by measuring the photocurrent using circularly polarized mid-infrared light. In this work, we study the chirality-resolved optical phonons in type-I WSM TaP under magnetic field, using Raman spectroscopy with excitations of both linear and circularly polarized lasers. Under magnetic field, the $B_{1}^{1}$ mode prohibited at zero field for 633 nm excitation can be evidently observed for linear polarization. With circularly polarized excitation, the measured phonon modes break the classical Raman tensor theory, and the symmetry-prohibited modes can be observed. Moreover, the phonon mode intensity exhibits non-reciprocity with polarizations of incident and scattered light ($\sigma+/\sigma+$ and $\sigma+/\sigma-$). Our observation is closely related to the chiral Landau levels and shows the capability of Raman spectroscopy in studying the magnetic field response of WSMs.

Unique Optical Responses of Weyl Semimetals

KENNETH BURCH (Presenter), Boston College — The isolation of electrons of different chirality in Weyl semimetals led to predictions of novel transport phenomena. Amongst these are the nonlinear responses and chiral anomaly. Here I will discuss our recent results on a range of Weyl semimetals. First I will focus on their nonlinear responses. Next, I will cover how Raman reveals surprisingly large electron-phonon coupling, that is relevant to their high mobility and potential for chiral transport.

Weyl Semimetals in Nanophotonics and Quantum Optoelectronics

CHRISTINA GARCIA (Presenter), PRINEHA NARANG, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Weyl semimetals obtain their topological classification from the breaking of inversion or time-reversal symmetry. Consequently, they hold the potential for large optical nonlinearities and nonreciprocal behavior, making Weyl semimetals a very interesting materials class for optoelectronic and photonic applications. In this talk, we discuss our first principles calculations of optoelectronic properties of Weyl semimetals for integration with nanophotonic and plasmonic architectures. We discuss the coupling of atom-like emitters to cavities made from Weyl semimetals, designed with the idea of minimizing the loss penalty of conventional metals, as well as the use of Weyl semimetals for nonreciprocal thermal radiation control, which could avoid the applied magnetic field required in previous nanophotonic device designs. Finally, as an outlook, we will present a general computational approach to develop low-loss, highly nonlinear Dirac and Weyl semimetal materials for photonic information science.

10:00AM R59.00007: Large longitudinal circular photogalvanic effect in a chiral Weyl semimetal  ZHUOLIANG NI (Presenter), Department of Physics & Astronomy, University of Pennsylvania, KEFENG WANG, Department of Physics, University of Maryland, College Park, BING XU, Department of Physics, University of Fribourg, XINGYUE HAN, Department of Physics & Astronomy, University of Pennsylvania, KAUSTUV MANNA, Max Planck Institute for Chemical Physics of Solids, JOHNPIERRE PAGLIONE, Department of Physics, University of Maryland, College Park, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, LIANG WU, Department of Physics & Astronomy, University of Pennsylvania — Breaking all of the mirror symmetries in a chiral Weyl semimetal lifts the energy degeneracy of two Weyl points with opposite Chern numbers. One of the consequences is the large or even quantized circular photogalvanic effect (CPGE), which originates from one of the Weyl points by keeping the other node Pauli-blocked. Here, we report a large photocurrent generated by circularly polarized light in a chiral Weyl semimetal. Symmetry analysis shows that the photocurrent is consistent with the longitude CPGE in bulk. The second-order conductivity spectrum of CPGE in near-infrared and mid-infrared regions is then obtained and the condition of quantization is examined.

10:12AM R59.00008: Polarized Transient Reflectance Spectroscopy of Type II Weyl Semimetal NbIrTe$_4^*$  SAMUEL LINSER (Presenter), GIRIRAJ JNAWALI, SEYYEDESADAF POURNIA, IRAJ ABBASIAN SHOJAEI, HOWARD E JACKSON, LEIGH M SMITH, Department of Physics, University of Cincinnati, CONGCONG LE, FU-CHUN ZHANG, Kavli Institute of Theoretical Sciences, University of the Chinese Academy of Sciences, BRENDEN ORTIZ, STEPHEN WILSON, Materials Engineering, University of California, Santa Barbara — Weyl semimetals have attracted intense interest for exhibiting chiral Fermion states. Strong nonlinear effects such as 2$^\text{nd}$ harmonic generation and DC photocurrents via circular photogalvanic effect are seen. Less understood is the dynamic response of said chiral carriers. We present polarized transient reflectance of single nanoflakes of NbIrTe$_4$, employing ultrafast (140 fs) NIR pump and MIR probe pulses. We use a photo-elastic modulator to produce a ~50 kHz oscillation of the circular probe polarization from left to right handedness. DFT calculations predict the presence of 8 pairs of Weyl nodes with opposite chirality in the BZ of NbIrTe$_4$. We observe a typical transient response composed of a rapid (~500 fs) decay followed by a slow (~1 ns) relaxation. A sign change in the transient response is observed at ~0.5 eV, suggestive of a band-to-band transition between a band below the Fermi energy and near the Weyl nodes to some higher-lying state.

10:24AM R59.00009: Angle and Polarization-Resolved Resonant Raman Spectroscopy of the Type-II Weyl Semimetal NbIrTe₄

* IRAJ ABBASIAN SHOJAEI (Presenter), GIRIRAJ JNAWALI, SEYYEDESADAF POURNIA, SAMUEL LINSER, HOWARD JACKSON, LEIGH SMITH, Univ of Cincinnati, CONGCONG LE, FU-CHUN ZHANG, Kavli Institute of Theoretical Sciences, University of the Chinese Academy of Sciences, BRENDEN ORTIZ, STEPHEN WILSON, Materials Engineering, University of California, Santa Barbara — We perform polarized Raman spectroscopy measurements of single nanoflakes exfoliated from a single crystal of the layered ternary compound NbIrTe₄. By varying the angle between the polarization direction of incident light and the crystalline “a” axis, spectra indicate strongly anisotropic Raman peaks which are consistent with the broken inversion symmetry of the crystal, which is an essential enabling condition for a type II Weyl semimetal. We have used both 633 nm and 514 nm laser excitation with incoming and backscattered rays parallel to the c-axis normal to the flake with the “a” and “b” axes in the plane of the nanoflake. The comparison of these spectra shows an enhancement of Raman peaks and also changes in rotational symmetry for 633 nm excitation. This suggest a possible unresolved resonance with a state at lower energies. Density Functional Theory (DFT) calculations of this crystal (space group Pmn2₁) show close correspondence with both the frequency and symmetries of the modes detected in our measurement.

*We acknowledge the financial support of the NSF through grants DMR 1507844, DMR 1531373, DMR 1505549 and ECCS 1509706, and NSF of China through grant 11674278.

10:36AM R59.00010: Investigating the Energy Dependent Photogalvanic Effect in the Type-II Weyl Semimetal NbIrTe₄

* SEYYEDESADAF POURNIA (Presenter), GIRIRAJ JNAWALI, IRAJ ABBASIAN SHOJAEI, SAMUEL LINSER, HOWARD JACKSON, LEIGH M SMITH, Univ of Cincinnati, CONGCONG LE, Kavli Institute of Theoretical Sciences, FU-CHUN ZHANG, University of Hong Kong, STEPHEN WILSON, BRENDEN ORTIZ, University of California, Santa Barbara — We explore the photogalvanic effect in NbIrTe₄, a type II Weyl semimetal. NbIrTe₄ exhibits 8 pairs of Weyl nodes which are monopoles of Berry curvature with opposite ±1 chiralities. We measured the photoresponse for a full rotation of a quarter wave plate for energies ranging from 0.3 to 1 eV. The Photothermoelectric (PT), and Circular (CPGE) and Linear (LPGE) Photogalvanic responses were extracted by fitting the angular dependence of the signal. The PT response shows an onset at an energy at 0.3 eV, consistent with DFT calculations. The LPGE response is relatively constant over this energy range, while the CPGE response shows a strong increase at low energies as the excitation approaches the Weyl nodes at the Fermi energy. Surprisingly, a strong peak in the CPGE response is also seen in the range 0.5 to 0.7 eV. This suggests that the CPGE response may be enhanced by a transition between bands near the Weyl point and a higher lying state.

*We acknowledge the support of NSF grants DMR 1507844, 1531373, 1505549 and ECCS 1509706, and the NSF of China through grant 11674278.
Investigation of optical properties of 3D Dirac materials

FRANCOIS JOINT (Presenter), GREGORY S JENKINS, University of Maryland, College Park, ROBERT J. CAVA, Chemistry, Princeton University, DMITRI BASOV, Physics, Columbia University, HOWARD DREW, University of Maryland, College Park — 3D Dirac semimetals are newly discovered topological materials that are characterized by Weyl nodes with double degeneracy in the bulk. The electronic bands are protected from gapping by crystal symmetries and touch at special points in the BZ zone. A Dirac semimetal band structure has been observed in with ARPES but the study of their electric-optical properties has yet to be further developed. Here, we present spectral measurements on the 3D Dirac semimetal. Using FITR technics in reflectivity configuration, we have observed the electromagnetic response of the 3D Dirac material from the FIR up to the NIR frequency range in different electrical field polarization configuration. Our measurements reveal the presence of unusual collective excitations near the screened plasma frequency. We attribute these excitations as arising from the extra-term in the action of the electromagnetic field that originates from the chiral shift between the Weyl nodes. We will also present the optical response in an applied magnetic field.

Session R60 DMP: Topological Superconductivity with 1D Modes

Mile High Ballroom 4A - Enrico Rossi, William & Mary College - Tag(s): Focus
8:00AM R60.00001: Interference effects in quanum Hall - superconductor hybrid devices

[Invited] GLEB FINKELSTEIN (Presenter), ANDREW SEREDINSKI, LINGFEI ZHAO, ETHAN ARNAULT, ANNE M DRAELOS, ALEXEY BONDAREV, TREVYN LARSON, MING-TSO WEI, Duke University, HENGMING LI, Physics, Appalachian State University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, NIMS, Japan, FRANCOIS AMET, Physics, Appalachian State University, HAROLD U BARANGER, Duke University — I plan to discuss our group's two recent results: realization of the quantum Hall-based SQUID in side-gated samples; and observation of the chiral Andreev edge states – hybrid electron/hole single particle modes running along the superconductor - quantum Hall interfaces.

1) We have developed graphene Josephson junctions with self-aligned side gates, which enable full control over the electrostatic potential near the sample edges. The gates allow us to tune the local electron density in a wide range, in particular inducing counterpropagating quantum Hall edge states along either side gate. The close spacing between these states allows them to efficiently couple through Andreev reflections and carry supercurrent. When both side gates are applied, superconducting channels are created on both sides of the junction, thereby realizing a gate-tunable quantum Hall-based SQUID.

2) We observe direct signatures of chiral Andreev edge states (CAES) – single particle modes running along the superconductor - quantum Hall interfaces. Semi-classically, the CAES can be interpreted as a result of multiple Andreev reflections of a single electron/hole skipping along the interface. Experimentally, we observe fluctuations of the signal propagating along the superconducting contact and interpret them in terms of interference between the CAES.

We study a tight-binding model of a graphene nanoribbon in the integer quantum Hall state with one edge coupled to an s-wave superconductor. Along the superconducting edge at high field, we find two gapless electron-hole hybrid modes related by particle-hole symmetry. These modes have nearly equal electron and hole content and propagate more slowly than the corresponding pure vacuum-quantum Hall edge modes. The momentum difference between these modes leads to accumulation of a relative phase between them. This phase is tunable via gate voltage, magnetic field, or applied bias. We show that such phase variation gives rise to oscillations of the longitudinal resistance between electron-like and hole-like transport similar to those measured recently by Zhao et al. [1]. Armchair and zigzag nanoribbons lead to similar results because the valley degeneracy is broken by the superconductor.

8:48AM R60.00003: Hybrid quantum circuits in vertical magnetic fields  KAVEH DELFANAZARI (Presenter), Engineering Department & Cavendish Laboratory, University of Cambridge, UK, LLORENS SERRA, IFISC (UIB-CSIC) and Physics Department, University of the Balearic Islands, Spain, PENGCHENG MA, Cavendish Laboratory, University of Cambridge, UK, IAN FARRER, Department of Electronic and Electrical Engineering, University of Sheffield, UK, DAVID A RITCHIE, Cavendish Laboratory, University of Cambridge, UK, HANNAH J JOYCE, Engineering Department, University of Cambridge, UK, MICHAEL JOSEPH KELLY, Engineering Department & Cavendish Laboratory, University of Cambridge, UK, CHARLES G SMITH, Cavendish Laboratory, University of Cambridge, UK — Topological superconductors, that host Majorana zero modes and parafermions, can also be realized at the interface of superconductivity and the quantum Hall states in hybrid superconductor-semiconductor devices. Here, we present (i) two types of artificially engineered hybrid Josephson circuits fabrication methods, and (ii) sub-Kelvin temperature-dependent transport measurements at low and high magnetic fields $B$. We experimentally demonstrate that the 2D Josephson junctions and field-effect transistors under vertical magnetic fields show (i) an unusual magnetoconductance oscillations together with asymmetric $dI/dV$ curves at $B < 100$ mT, (ii) Superconducting correlation on quantum Hall states at $B$ up to 6 T, respectively. Our experimental results are qualitatively explained by a model considering the trivial and topological phase transitions in hybrid 2D Josephson junctions in vertical fields.

Topological superconductors (TS) represent a phase of matter whose properties are insensitive to local perturbations. This robustness renders TS suitable for application in quantum computing. The past decade has witnessed substantial progress towards a quantum bit using Majorana modes, the well-known non-Abelian modes in TS. However, because Majoranas lack a universal logic gate set, Majorana quantum bits are computationally limited. This important drawback can be overcome by parafermions, a novel set of non-Abelian modes whose array supports universal topological quantum computation. A primary route to synthesize parafermions involves inducing superconductivity in fractional quantum Hall (FQH) edge. Here we use high-quality van der Waals devices coupled to a narrow NbN which remains superconducting in the magnetic fields required for robust FQH. We find crossed Andreev reflection (CAR) across the narrow NbN that separates two counterpropagating FQH edges. Control experiments show that CAR vanishes with increasing temperature, excitation and magnetic field as expected from the theory. These results lay the groundwork for experimental parafermion research in condensed matter.

9:24AM R60.00006: Chiral Majorana Mode in Topological Superconducting Element Hcp Thallium
MOTOAKI HIRAYAMA (Presenter), RIKEN, TAKUYA NOMOTO, RYOTARO ARITA, University of Tokyo — The chiral Majorana fermion is an exotic particle that is its own antiparticle. It can arise in a one-dimensional edge of topological materials, and especially that in a topological superconductor can be exploited in non-Abelian quantum computation. While the chiral Majorana mode (CMM) remains elusive, a promising situation is realized when superconductivity coexists with a topologically non-trivial surface state. Here, we perform the fully non-empirical calculation for the CMM considering superconductivity and surface relaxation and show that hexagonal close-packed thallium (Tl) has an ideal electronic state that harbors the CMM [1]. The $k_z = 0$ plane corresponds to the TCI with mirror Chern number $|N_M| = 2$. One of the Dirac points on the (01-10) surface is located almost at the Fermi level. Tl is a textbook-like s-wave superconductor and the gap function has no significant wave-number dependence. Only one of the two Dirac points is relevant for the gap opening due to the superconducting transition, and the CMM appears at the hinge under the Zeeman field. Our calculation indicates that Tl will provide a new platform of the Majorana fermion and quantum computation.

9:36AM R60.00007: Spontaneous thermal Hall conductance in superconductors with broken time-reversal symmetry*
FIRAT YILMAZ (Presenter), SUNGKIT YIP, Academia Sinica — The thermal Hall conductivities (THCs), $\kappa_{ij}$s have extensively been studied in recent condensed matter experiments. THC can spontaneously become non-zero for a time-reversal symmetry (TRS) broken system, and have a contribution from topologically protected edge states. In this talk, we focus on an additional bulk effect, the impurity pair breaking mechanism (IPM) in superconductors (SCs). Previously, the THCs were calculated for the chiral p-wave [1-2] SCs for point impurities. Motivated by d-wave TRS broken SCs; URu$_2$Si$_2$, SrPtAs including Sr$_2$RuO$_4$ which is recently suggested to be also possibly, we calculate THCs at finite temperatures and for finite size impurities using the non-equilibrium quasiclassical Green's functions.

We find that the IPM is dominant in $\kappa_{yx}$ at finite temperatures when compared to the topological contribution except at very low temperatures. There are two experimental signatures of IPM: 1. a non-monotonic temperature dependence, 2. sign change as a function of temperature depending on the scattering process.

Microwave spectroscopy of semiconductor-nanowire-based superconducting qubits with Majorana bound states  RAMON AGUADO (Presenter), JESUS AVILA, CSIC - Madrid, ELSA PRADA, IFIMAC, UAM, Madrid, PABLO SAN-JOSE, CSIC - Madrid — Recent experimental efforts have focused on replacing the weak link in the Josephson Junction (JJ) of a superconducting qubit by electrostatically-gateable technologies compatible with high magnetic fields. Such alternatives are crucial in order to reach a regime relevant for readout of topological qubits based on Majorana bound states (MBS). We here focus on a system where a semiconducting nanowire forming the JJ is driven to a topological superconductor phase with MBS which coherently interact with the superconducting qubit degrees of freedom. Our fully microscopic theoretical description of this nanowire-based superconducting qubit allows to unveil new physics. This includes the magnetic field dependence of the qubit frequency, which follows the gap closing and the emergence of MBS in the topological phase. In this phase, the periodicity of the qubit spectrum with respect to $n_g$ can be either that of Cooper pairs $2e$ or single electrons $e$, depending on microscopic parameters such as the degree of Majorana energy splitting or the ratio of Josephson to charging energy $E_J/E_C$. Overall, the corresponding microwave spectroscopy presents nontrivial features, including a full mapping of zero energy crossings and fermionic parity switches in the nanowire owing to Majorana oscillations.

Decays of Majorana or Andreev Oscillations Induced by Steplike Spin-Orbit Coupling*  ZHAN CAO (Presenter), Southern University of Science and Technology, HAO ZHANG, Tsinghua University, HAI-FENG L'U, University of Electronic Science and Technology of China, WAN-XIU HE, Lanzhou University, HAIZHOU LU, Southern University of Science and Technology, XINCHENG XIE, Peking University — The Majorana zero mode in the semiconductor-superconductor nanowire is one of the promising candidates for topological quantum computing. Recently, in islands of nanowires, subgap-state energies have been experimentally observed to oscillate as a function of the magnetic field, showing a signature of overlapped Majorana bound states. However, the oscillation amplitude either dies away after an overshoot or decays, sharply opposite to the theoretically predicted enhanced oscillations for Majorana bound states. We reveal that a steplike distribution of spin-orbit coupling in realistic devices can induce the decaying Majorana oscillations, resulting from the coupling-induced energy repulsion between the quasiparticle spectra on the two sides of the step. This steplike spin-orbit coupling can also lead to decaying oscillations in the spectrum of the Andreev bound states. For Coulomb-blockade peaks mediated by the Majorana bound states, the peak spacings have been predicted to correlate with peak heights by a $\pi/2$ phase shift, which was ambiguous in recent experiments and may be explained by the steplike spin-orbit coupling. Our work will inspire more works to reexamine effects of the nonuniform spin-orbit coupling in experimental devices.

**10:12AM R60.00010: Nonlocal conductance in three-terminal hybrid Al/InSb nanowire devices**  
SEBASTIAN HEEDT (Presenter), Microsoft Quantum Lab Delft, FRANCESCO BORSOI, QuTech, Delft University of Technology, MARINA QUINTERO PEREZ, ALEXANDRA FURSINA, Microsoft Quantum Lab Delft, NICK VAN LOO, QuTech, Delft University of Technology, GHADA BADAWY, SASA GAZIBEGOVIC, Eindhoven University of Technology, KEVIN VAN HOOGDALEM, Microsoft Quantum Lab Delft, ERIK BAKKERS, Eindhoven University of Technology, LEO P KOUWENHOVEN, Microsoft Quantum Lab Delft — Majorana zero-energy modes (MZMs) emerge at the edges of a one-dimensional topological segment. Signatures of these modes are correlated zero-bias peaks (ZBPs) in the local conductance that emerge simultaneously at both edges. The energy gap that separates them from the continuum - the bulk topological gap - can be identified in the nonlocal conductance, which is insensitive to local Andreev levels or transmission resonances. Thus, it is a vital tool to distinguish nontopological zero-energy modes and MZMs. Here, we have realized hybrid three-terminal devices based on InSb nanowires. The proximity-induced superconductivity is achieved via selective shadow-wall deposition of Al thin films. We demonstrate a hard induced gap using voltage-bias spectroscopy and study the appearance of zero-bias peaks in the local conductance. Harnessing the three-terminal geometry, we investigate the evolution of the nonlocal conductance in a magnetic field before the transition to the normal state.

**10:24AM R60.00011: Engineering Majorana Bound States with Periodic Structures**  
BENJAMIN WOODS (Presenter), TUDOR DAN STANESCU, West Virginia Univ — Majorana bound states within semiconductor-superconductor heterostructures are a promising platform for future topological quantum computation. Here we theoretically explore the effects of periodic potentials and periodic structures on the emergence and properties of topological superconductivity and Majorana bound states within 1D and quasi-1D systems. Three key findings suggest that periodic structures may possess some advantages over homogeneous systems in supporting topological superconductivity. The three findings to be discussed are (1) an increased region of parameter space in which the topological phase and Majorana bound states are realized, (2) an increasing topological gap as one moves to higher energy mini-bands, and (3) an increased robustness against disorder compared to homogeneous systems. We also explore several physical systems in which the periodic potential/structure can be engineered and discuss their outlook.

**10:36AM R60.00012: Topological Josephson effect in gate-tunable qubit devices**  
ANDREY ANTIPOV (Presenter), CAMERON KING, KEWEI LI, JOHN GAMBLE, BELA BAUER, GEORG WINKLER, ROMAN LUTCHYN, Microsoft Corp — Gate-tunable superconducting qubits that host Majorana zero modes realize an intermediate step to topologically protected qubits by storing the quantum state in topological degrees of freedom. In this talk I will present numerical simulations of such devices that combine superconducting proximity effect, orbital effects, electrostatic environment and realistic geometry. I will show the phase diagram and the key properties of these topological Josephson junctions, in particular the Josephson energy and Majorana coupling energy. Based on these I identify regimes of the surrounding electrostatic environment most favorable for realizing qubits and relate this to observable experimental features.
8:00AM R61.00001: Heisenberg-Kitaev physics in magnetic fields [Invited] MATTHIAS VOJTA (Presenter), LUKAS JANSSEN, Physics, Technische Universitaet Dresden — Kitaev's bond-anisotropic spin model on the honeycomb lattice describes an exactly solvable quantum spin liquid with emergent gauge fields and fractionalized excitations. By now, a number of honeycomb-lattice magnets have been proposed to host sizeable Kitaev interactions, driven by strong spin-orbit coupling, among them Na$_2$IrO$_3$, α-Li$_2$IrO$_3$, and α-RuCl$_3$. Given the strong spin anisotropies, their response to applied magnetic fields is particularly rich. In this talk, I will describe the behavior of the relevant Heisenberg-Kitaev models and their extensions in applied field, with focus on field-induced exotic phases and their experimental signatures. I will also discuss phases of the hyperhoneycomb-lattice extended Kitaev models relevant for β-Li$_2$IrO$_3$ and a mapping connecting them to their two-dimensional counterparts.

8:36AM R61.00002: Emergence of a field-driven U(1) spin liquid in spin-1 Kitaev systems SIMON TREBST (Presenter), CIARAN HICKEY, Univ Cologne, PANAGIOTIS PETER STAVROPOULOS, University of Toronto, CHRISTOPH BERKE, Univ Cologne, HAE-YOUNG KEE, University of Toronto — Recent proposals for spin-1 Kitaev materials, such as Na$_3$Ni$_2$SbO$_6$, have shown that these compounds naturally realize antiferromagnetic (AFM) Kitaev couplings. Interest in such AFM Kitaev systems has recently sparked by the observation of a transition to a gapless U(1) spin liquid at intermediate field strengths in the AFM spin-1/2 Kitaev model. However, all known spin-1/2 Kitaev materials exhibit ferromagnetic bond-directional exchanges. Here we discuss the physics of the spin-1 Kitaev model in a magnetic field and show, by extensive numerical analysis, that for AFM couplings it exhibits an extended gapless U(1) quantum spin liquid at intermediate field strengths. The close analogy to its spin-1/2 counterpart suggests that this gapless spin liquid exhibits a spinon Fermi surface.

8:48AM R61.00003: Ground-state phase diagram of the Kitaev-Γ model on a honeycomb lattice TAKAFUMI SUZUKI (Presenter), SEI-ICHIRO SUGA, Univ of Hyogo — We investigate the ground-state phase diagram of the Kitaev-Γ model on a honeycomb lattice by utilizing several numerical methods, such as the numerical exact-diagonalization method and the density-matrix-renormalization-group method. In this study, we focus on the effect of the anisotropic interaction; we connect the isolated dimer limit and the spin-chain limit by changing the coupling constants. From the numerical results, we find that there are three kinds of phases, namely the Tomonaga-Luttinger (TL) liquid phase and two kinds of magnetic ordered states, in the spin-chain limit. When the Γ interaction is positive and the Kitaev interaction is negative, the TL liquid is stable against the interchain couplings, which implies that the TL liquid survives up to the vicinity of the isotropic point or shows a crossover behavior. The dimer phases also survive in the vicinity of the isotopic limit. We expect that many states are competing around the isotropic point.
Large off-diagonal exchange coupling driven magnetic anisotropy and spin liquid states in the C$_3$-symmetric iridate K$_2$IrO$_3$* 

RAJYAVARDHAN RAY (Presenter), RAVI YADAV, SATOSHI NISHIMOTO, MANUEL RICHTER, JEROEN VAN DEN BRINK, IFW - Dresden — Honeycomb lattice spin-orbit insulators are promising candidates for realization of quantum spin liquid states. The iridate oxide K$_2$IrO$_3$ is an end member of the recently synthesized iridate family K$_x$Ir$_y$O$_2$, and features a C$_3$ point-group symmetry at the Ir sites. Using ab-initio techniques, we investigate the magnetic couplings in the proposed structural model for K$_2$IrO$_3$. We find that the higher point-group symmetry leads to strong magnetic anisotropy driven by the unusually large off-diagonal exchange couplings (Γ’s) as opposed to other spin liquid candidates considered so far. High magnetic frustration and large quantum fluctuations imply lack of magnetic ordering consistent with the experiments. Exact diagonalization calculations for the fully anisotropic K−J−Γ Hamiltonian reveal a rich phase diagram with competing magnetic as well as spin liquid states. Our study points out the importance of the Γ’s in stabilizing a spin liquid state and highlights an alternative route to stabilize spin liquid states for ferromagnetic K.

Chemical tuning between triangular and honeycomb structures in a 5d spin-orbit Mott insulator* 

ROGER JOHNSON (Presenter), Department of Physics and Astronomy, University College London, INEKE BROEDERS, University of Oxford, KAVITA MEHLAWAT, Department of Physical Sciences, ISER, YING LI, Institut fur Theoretische Physik, Goethe-Universitat Frankfurt, YOGESH SINGH, Department of Physical Sciences, ISER, ROSE VALENTI, Institut fur Theoretische Physik, Goethe-Universitat Frankfurt, RADU COLDEA, University of Oxford — We report structural studies of the spin-orbit Mott insulator family K$_x$I$_y$O$_2$, with triangular layers of edge-sharing IrO$_6$ octahedra bonded by potassium ions. The potassium content acts as a chemical tuning parameter to control the amount of charge in the Ir-O layers. Unlike the isostructural families with Ir replaced by Co or Rh (y = 1), which are metallic over a range of potassium compositions x, we instead find insulating behaviour with charge neutrality achieved via iridium vacancies, which order in a honeycomb supercell above a critical composition x$_c$. By performing density functional theory calculations we attribute the observed behaviour to a subtle interplay of crystal-field environment, local electronic correlations and strong spin-orbit interaction at the Ir 4+ sites, making this structural family a candidate to display Kitaev magnetism in the experimentally unexplored regime that interpolates between triangular and honeycomb structures.

9:24AM R61.00006: Raman Scattering Investigation of a New Candidate for a Quantum Spin Liquid, the Magnetic Insulator, $\text{Ba}_3\text{Ir}_4\text{O}_{10}$*  
AARON SOKOLIK (Presenter), NICK PELLATZ, GANG CAO, DMITRY REZNICK, University of Colorado, Boulder —  
The insulator $\text{Ba}_3\text{Ir}_4\text{O}_{10}$ is a new candidate for a frustrated quantum spin liquid, which was reported to have a stabilized quantum spin liquid state down to 0.2 K. The frustration parameter of around 3800 is extremely high. The spin liquid is also extraordinarily sensitive to changes in the lattice parameters as shown with the effects from strontium doping. The replacement of approximately 2% of barium with strontium readily lifts the frustration parameter and this doped material has long-range order from an antiferromagnetic transition at 130 K. Raman spectroscopy results show that both materials are also strongly anisotropic. We will present a comparison of the results of Raman scattering experiments on Sr-doped and undoped samples of $\text{Ba}_3\text{Ir}_4\text{O}_{10}$.

9:36AM R61.00007: Ab-Initio insight into non-local charge fluctuations in optical conductivity for $\alpha$-$\text{RuCl}_3$ through a Wannier basis: Highlighting the role of chemistry in correlated electron systems  
CASEY EICHSTAEDT (Presenter), University of Tennessee, Knoxville, TOM BERLIJN, Oak Ridge National Laboratory, KEN BURCH, Boston College, ADOLFO GERMAN EGUILUZ, University of Tennessee, Knoxville — $\alpha$-$\text{RuCl}_3$ is one of the top contenders for hosting a quantum spin liquid as its exact ground state by possibly being a real material realization of Kitaev's anisotropic spin model. While there is still no consensus for the magnetic ground state, there is plenty of rich physics in the electronic excitations (i.e optical conductivity). We simulate the optical excitations of $\alpha$-$\text{RuCl}_3$, by invoking a parameter-free treatment of the Random Phase Approximation (RPA) to exact Time Dependent Density Functional Theory (TD-DFT) implemented using a Wannier basis. The calculated optical peak for $\alpha$-$\text{RuCl}_3$ (peak at ~1eV) is in very good agreement in location and absolute units with experiment. There are two key findings using this implementation. The first is the origin of the insulating gap in the ground state appears to be due to the interplay between relativity (spin-orbit coupling) and correlation (Hubbard U). The second finding is the surprising result that to converge the optical peak in the calculation, there are sizable Ru-Ru electron-hole pairs of Wannier d-like orbitals spanning beyond neighboring sites. This is determined due to the strong covalency built into the underlying solid state electronic structure of the underlying $\alpha$-$\text{RuCl}_3$, in particular the hexagonal arrangement of Ru atoms.
**9:48AM R61.00008:** New magnetic order revealed in α-RuCl$_3$ at intermediate magnetic fields using neutron diffraction  
CHRISTIAN BALZ (Presenter), ISIS Neutron and Muon Source, LUKAS JANSSEN, TU Dresden, PAULA LAMPEN-KELLEY, University of Tennessee, ARNAB BANERJEE, YAOHUA LIU, JIAQIANG YAN, Oak Ridge National Laboratory, DAVID MANDRUS, University of Tennessee, MATTHIAS VOJTA, TU Dresden, STEPHEN E NAGLER, Oak Ridge National Laboratory — It is well-known that an external magnetic field can induce a transition in α-RuCl$_3$ from a magnetically ordered state to a disordered state that may be related to the Kitaev quantum spin liquid. The overall temperature - magnetic field phase diagram of α-RuCl$_3$ is currently under intense scrutiny, and presently there is no universal agreement on the number of field induced phase transitions between the zero-field state and the high field polarized paramagnet. Single crystals with minimal stacking faults show a transition near $T_N = 7$ K at $B = 0$ T to a low temperature ordered phase that has a zigzag AFM structure in a single honeycomb layer, with a 3-fold periodicity perpendicular to the planes. For fields applied in the honeycomb plane perpendicular to a Ru-Ru bond there is evidence from magnetization, AC susceptibility, thermal transport [1], and magnetocaloric effect [2] data for an intermediate-field phase with a different magnetic order that precedes the disordered phase. Here we discuss neutron diffraction data that clarifies the magnetic structure in this phase. The intermediate ordered phase puts additional constraints on the minimal model magnetic Hamiltonian for α-RuCl$_3$.

**10:00AM R61.00009:** Phononic Structure of Kitaev Quantum Spin Liquid Candidate Material alpha-RuCl$_3$  
TOM BERLIJN (Presenter), ARNAB BANERJEE, YONGQIANG CHENG, Oak Ridge National Lab, SAI MU, UC Santa Barbara — While many studies have focused on the magnetic excitations in alpha-RuCl$_3$, its vibrational excitation spectrum has remained relatively unexplored. However, understanding phonons in RuCl$_3$ is important for example to analyze the controversial observation of the half-integer thermal quantum Hall effect. We investigate the phononic structure of alpha-RuCl$_3$ via Density Functional Theory calculations and Inelastic Neutron Scattering experiments.
10:12AM R61.00010: X-ray scattering studies of elementary excitations of $\alpha$-RuCl$_3$  BLAIR LEBERT (Presenter), SUBIN KIM, Physics, University of Toronto, VALENTINA BISOGNI, IGNACE JARRIGE, ANDI BARBOUR, NSLS-II, Brookhaven National Laboratory, AHMET ALATAS, AYMAN SAID, APS, Argonne National Laboratory, YOUNG-JUNE KIM, Physics, University of Toronto — We investigated the Kitaev quantum spin liquid candidate $\alpha$-RuCl$_3$ using resonant inelastic x-ray scattering (RIXS) and inelastic x-ray scattering (IXS). Our room temperature M$_3$-edge RIXS results revealed a spin-orbit exciton from which we extracted values for the spin-orbit coupling constant and trigonal distortion field energy which support the $j_{\text{eff}} = 1/2$ nature of $\alpha$-RuCl$_3$ [1]. I will discuss the potential of M$_3$-edge RIXS to study 4d transition metal systems and perspectives on low temperature measurements on $\alpha$-RuCl$_3$. Finally, I will present our IXS measurements of the dispersion of acoustic phonons in $\alpha$-RuCl$_3$ measured at 5 K.

10:24AM R61.00011: Raman scattering response in the Kitaev magnet beta-Li$_2$IrO$_3$ and its evolution in the magnetic field*  MENGQUN LI (Presenter), University of Minnesota, IOANNIS ROUSOCHATZAKIS, Loughborough University, NATALIA PERKINS, University of Minnesota — Raman scattering has been proven to be a powerful dynamical probe to study magnetic excitations in various frustrated magnets. Here we analyze theoretically the one- and two-magnon Raman scattering intensity in the Kitaev magnet beta-Li$_2$IrO$_3$ and its evolution in the magnetic field. Our analysis shows that the response is very sensitive to the polarization of light and the direction of the external magnetic field, reflecting a peculiar spin dynamics of this compound which arises due to the competition between anisotropic exchange interactions and applied magnetic field.

*We acknowledge the support of the US Department of Energy, Office of Science, Basic Energy Sciences under Award No. DE-SC0018056.
10:36AM R61.00012: Giant linearly-polarized photogalvanic effect and second harmonic generation in zero-plateau quantum anomalous Hall systems*  LI YANG (Presenter), RUIXIANG FEI, WENSHEN SONG, Physics, Washington University in St. Louis — Combining quantum perturbation theory and first-principles simulation, we predict giant nonlinear optical responses (NLOs) in even septuple layers of MnBi\textsubscript{2}Te\textsubscript{4} family materials (MBTs), which are the zero-plateau quantum anomalous Hall systems (QAHs). The interlayer antiferromagnetic order breaks the inversion symmetry, and the amplitudes of injection current and second harmonic generation can be about one order of magnitude larger than those of the ferroelectrics, such as LiNbO\textsubscript{3} and BiFeO\textsubscript{3}. Moreover, unlike the injection current in ferroelectrics, we find that the injection photocurrent only emerges under a linearly polarized light in MBTs. Our analysis indicates that these giant linearly-polarized second-order NLOs are resulted from the parity-time symmetry, three-fold rotation symmetry, and large spin-orbit coupling. These enhanced NLOs are valuable for characterizing subtle magnetic orders in QAHs and shed light on photo-detecting and photovoltaic applications based on emerging magnetic topological materials.

*This work is supported by the National Science Foundation CAREER DMR-1455346 and EFRI2DARE-1542815, and the Air Force Office of Scientific Research grant FA9550-17-1-0304. The computational resources are provided by the Stampede of TACC through XSEDE.

10:48AM R61.00013: Berry Curvature Engineering by Gating Two-Dimensional Antiferromagnets  SHIQIAO DU (Presenter), Tsinghua University — Recent advances in tuning electronic, magnetic, and topological properties of two-dimensional (2D) magnets have opened a new frontier in the study of quantum physics and promised exciting possibilities for future quantum technologies. In this study, we find that the dual gate technology can well tune the electronic and topological properties of antiferromagnetic (AFM) even septuple-layer (SL) MnBi\textsubscript{2}Te\textsubscript{4} thin films. Under an out-of-plane electric field that breaks PT symmetry, the Berry curvature of the thin film could be engineered efficiently, resulting in a huge change of anomalous Hall (AH) signal. Beyond the critical electric field, the double-SL MnBi\textsubscript{2}Te\textsubscript{4} thin film becomes a Chern insulator with a high Chern number of 3. We further demonstrate that such 2D material can be used as an AFM switch via electric-field control of the AH signal. These discoveries inspire the design of low-power memory prototype for future AFM spintronic applications.

Session R62 DMP: Thermal Transport in Nanostructures I  Mile High Ballroom 4C
- Charles Harris, Sandia National Laboratories - Tag(s): Focus
**8:00AM R62.00001: Advanced Josephson junctions circuits and nanoscale devices: The phase-coherence in heat transport** [Invited] FRANCESCO GIAZOTTO (Presenter), CNR Scuola Normale Superiore — The emerging field of *phase-coherent caloritronics* (from the Latin word *calor*, heat) [1] is based on the possibility of controlling heat currents by using the phase difference of the superconducting order parameter. The goal is to design and implement thermal devices that can control energy transfer with a degree of accuracy approaching that reached for charge transport by contemporary electronic components. This can be done by making use of the macroscopic quantum coherence intrinsic to superconducting condensates, which manifests itself through the Josephson effect and the proximity effect. Here, I will initially report the first experimental realization of a heat interferometer. We investigate heat exchange between two normal metal electrodes kept at different temperatures and tunnel-coupled to each other through a thermal device in the form of a DC-SQUID. Heat transport in the system is found to be phase dependent, in agreement with the original prediction. After this initial demonstration, we have extended the concept of heat interferometry to various other devices, implementing the first quantum `diffractor` for thermal fluxes, realizing the first balanced Josephson heat modulator, and the first tunable 0-π thermal Josephson junction. Finally, I will conclude by showing the realization of the first phase-tunable Josephson thermal router. Thanks to the Josephson effect, this latter structure allows to regulate the thermal gradient between the output electrodes until reaching its inversion, and represents an important step towards the realization of caloritronic logic components, and quantum thermal machines.

*The European Union Seventh Framework Programme (FP7/2007-2013)/ERC Grant No. 615187 - COMANCHE, and Horizon 2020 and Innovation Programme under grant agreement No. 800923-SUPERTED are acknowledged for partial financial support.

---

**8:36AM R62.00002: Topological Quantum Thermocouple** CHARLES STAFFORD, MARCO ANTONIO JIMENEZ VALENCIA (Presenter), Univ of Arizona — The flows of charge and heat in an open quantum system coupled to three macroscopic electron reservoirs are studied. It is shown that even without particle-hole asymmetry in the electronic structure, thermoelectric effects can be induced topologically by the Aharonov-Bohm effect. The Peltier effect is calculated, and the conditions of maximum cooling power are determined. The Carnot bound on the refrigeration coefficient is verified, and in so doing, a generalized relationship between the Peltier and Seebeck effects in multi-terminal quantum devices is derived. An apparent thermodynamic paradox involving persistent Peltier cooling in equilibrium is resolved by a rigorous treatment of heat flow at the quantum level.

*This work was supported by the U.S. Department of Energy (DOE), Office of Science, under Award No. DE-SC0006699.*
8:48AM R62.00003: Noise emitted by a temperature biased tunnel junction* SAMUEL LAROCQUE, EDOUARD PINSOLLE (Presenter), CHRISTIAN LUPIEN, BERTRAND M REULET, Université de Sherbrooke — Caloritronic in small systems has been of high interest in recent years since new ways to manipulate electronic heat currents at the nanoscale have been developed. The ability to make mesoscopic systems with well controlled temperature enables the study of quantum heat transport and out of equilibrium quantum thermodynamic, which is of fundamental interest. A tunnel barrier between two metallic electrodes forms the basic unit in the study of non-equilibrium physics and fluctuations. This system has been put to great use in the understanding of electronic transport whether at equilibrium where fluctuations are used as thermometer or in the presence of voltage bias where information on charge carrier can be accessed. In this talk we present calculations and measurements of the electrical noise in a metallic tunnel junction in presence of a thermal and voltage gradient, pushing farther our understanding of its non-equilibrium properties.

9:00AM R62.00004: Thermal Conductivity of Small Angle Twisted Bilayer Graphene* CHENYANG LI, ROGER LAKE (Presenter), University of California, Riverside — The effect of misorientation on the in-plane thermal conductivity of twisted BLG (TBG) is still poorly understood. The one experimental study found that interlayer misorientation could reduce the in-plane thermal conductivity by 50%. A recent theoretical study of TBG with the three smallest commensurate unit cells, 21.8°, 32.2°, and 13.2°, found that the thermal conductivity decreased approximately linearly as the commensurate lattice constant increased. What happens at smaller misorientation angles of 10° or less is still an open question. For this range of rotation angles, we perform large-scale, non-equilibrium molecular dynamics calculations of the thermal conductivity of TBG for twist angles down to 1.89°. The picture that emerges from this study is that the misorientation reduces the shear elastic constant C44 which increases the wrinkling of the TBG. The increased out-of-plane wrinkling then reduces the thermal conductivity.

Heterostructures of two-dimensional materials (2D) are a promising platform for the observation of phonon interface transport and coherent-phonon effects. Layer thickness and orientation can be tuned during heterostructure fabrication which provides a variety of ways to control the thermal-transport properties of the system. Using the 3ω method, we measure the interfacial thermal resistance between two common 2D materials, hexagonal boron nitride (hBN) and graphene (Gr), to be significantly lower than previously reported Raman thermometry values. The uncertainty of our measurement is limited by the uncertainty in the literature value for the bulk thermal conductivity of hBN. We aim to provide a precise measurement of the cross plane thermal resistance of hBN flakes from the bulk-like down to the ballistic phonon transport regime and demonstrate that a variety of geometries of 3ω wires including a semicircle with 750μm diameter, measure the same cross plane thermal resistance of a 70nm thick SiO₂ film with a standard deviation of 4.7 m² K GW⁻¹.

*Measurements supported by US DOE Basic Energy Sciences #DE-FG02-03ER46028. Growth of hBN by K.W. and T.T. is supported by the Elemental Strategy Initiative conducted by the MEXT Japan A3 Foresight by JSPS and the CREST (JPMJCR15F3) JST.
Engineering ultrahigh thermal anisotropy in 2D van der Waals films

SHI EN KIM (Presenter), Pritzker School of Molecular Engineering, University of Chicago, JOONKI SUH, School of Materials Science and Engineering, Ulsan National Institute of Science and Technology, AKASH RAI, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, FAUZIA MUJID, Department of Chemistry, University of Chicago, CHIBEOM PARK, James Franck Institute, University of Chicago, ARIANA RAY, DAVID ANTHONY MULLER, School of Applied and Engineering Physics, Cornell University, DAVID CAHILL, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, JIWOONG PARK, Pritzker School of Molecular Engineering, University of Chicago — Thermally anisotropic materials, whose thermal conductivity differs depending on the direction of heat conduction, are technologically important for heat management and fundamentally intriguing in terms of their mechanism of heat transport. Previous studies have achieved thermal anisotropy through anisotropic bonding, fabricating heterostructures, and introducing low dimensional defects, giving rise to anisotropic ratios of 1-2 orders of magnitude. Herein we report an ultrahigh thermal anisotropy (~1000 at room temperature) in large-area thin films with tunable thicknesses made by stacking transition metal dichalcogenide (MoS\textsubscript{2} or WS\textsubscript{2}) monolayers. We measure an ultralow cross-plane thermal conductivity comparable to that of air, which can be attributed to interlayer rotation and the lack of lattice order. In the in-plane direction, a high thermal conductivity close to that of the single crystal counterpart is maintained due to the long-range lattice order and grain connectivity in the polycrystalline monolayers. The overall thermal anisotropy ratio in our films is higher than that of any man-made or natural material, demonstrating interlayer structure as a new degree of freedom for engineering thermal anisotropy in matter.

Phonon Localization in Ultrathin Silicon Membranes with Surface Nanostructures

QUENTIN MOORE (Presenter), SANGHAMITRA NEOGI, University of Colorado, Boulder — Surface nanostructures have been shown to introduce new vibrational modes that locally couple with phonon modes of the base and impact in-plane phonon propagation. Nanoscopic surface imperfections have been experimentally and theoretically demonstrated to decrease the thermal conductivity (TC) of silicon (Si) membranes. However, the tunability of the coupling or hybridization mechanisms due to unique surface geometries, and the extent of their impact on phonon properties are not fully understood. Using direct non-equilibrium molecular dynamics (MD), we investigate the effect of periodic “nanofins” on the thermal properties of ultrathin Si membranes. Our study exhibits that these structures engender a distinct in-plane anisotropy in the TC of the membrane, and create unique localized temperature and phonon-induced strain profiles, in accordance with the surface structure periodicity. Further investigation, using lattice dynamics with the quasi-harmonic approximation, reveals a significant reduction in mode diffusivity, indicating phonon localization, approaching behavior similar to highly disordered solids, e.g., amorphous Si. These results further establish surface nanoengineering as a viable approach to meter and direct heat flow in future microelectronic/quantum technologies.
Surface phonon mode remarkably limits heat conduction in a silicon ultra-thin film*  

MICHIMASA MORITA (Presenter), TAKUMA SHIGA, Mechanical Engineering, Univ of Tokyo — Decrease of silicon channel thickness is efficient to suppress short channel effects, which is beneficial for further miniaturizing of MOS transistor. However, this causes larger reduction thermal conductivity, resulting in temperature rise of the channel region. Therefore, accurate analysis of heat conduction in thin film is needed for heat dissipation control. The Sondheimer model, which has been widely used, is known to be valid for reproducing heat conduction in the range of 50-100 nm thickness. However, since the Sondheimer model uses the bulk phonon property, the applicability of the model to ultra-thin film with several nanometers is doubtful. Here, in order to validate the model, we performed the anharmonic lattice dynamics explicitly considering atomic structure of the film to rigorously calculate thermal conductivity and phonon transport properties of the ultra-thin silicon film. Consequently we found that the Sondheimer model cannot reproduce spectral phonon transport properties of ultra-thin film because it ignores the change of phonon dispersion and presence of surface phonon. We will discuss this discrepancy in terms of surface phonon scattering to suggest the way to resolve this.

*JST PRESTO (JPMJPR1715).

Numerical study on the transition from coherent to incoherent phonon transport in a superlattice*  

TATSUKI ICHIKAWA (Presenter), TAKUMA SHIGA, Mechanical Engineering, Univ. of Tokyo — Superlattice has been widely investigated due to its capability of modulating phonon dispersion and suppressing transport. However, increases of superlattice periodicity and temperature cause phonon decoherence and then suppress the reduction of lattice thermal conductivity [1], which is well known as the issue for developing heat conduction control by superlattice. Here a criterion for which phonon coherence is preserved needed to be identified. Ref. [2] derived the phonon coherence condition with respect to wavelength and temperature as $\lambda \geq (\hbar v/ kBT)$ with speed of sound ($v$), however, we addressed this issue from different viewpoint, namely, the uncertainty associated with energy and momentum conservations; it should be satisfied that not only the multiplication of phonon frequency $\omega$ and relaxation time $\tau$ is large enough ($\omega \tau \gg 1$) but also fluctuation of momentum $\delta(hk/2\pi)$ is sufficiently smaller than reciprocal lattice vector $G(=2\pi/a)$ ($\delta(hk/2\pi) \ll hG/2\pi$), where $a$ denotes periodicity. These discussions finally result in the relationship $T \leq (hvg/kBa)$, where $vg$ denotes group velocity. By using molecular dynamics simulations, we will report the verification of this formula.

*PRESTO (JPMJPR1715).
10:12AM R62.00010: Nonequilibrium phonon distribution in current-driven nanostructures
GUANXIONG CHEN (Presenter), RYAN M FREEMAN, ANDREI ZHOLUD, SERGEI URAZHDIN, Department of Physics, Emory University — Electric energy of current flowing in materials or devices is dissipated mostly as Joule heat. However, in nanoscale systems, the generated phonons can escape before they thermalize, which can result in the breakdown of the Joule heating approximation.
We demonstrate a strongly non-equilibrium phonon distribution in current-driven metallic microwires, which cannot be described in terms of heat [1]. Our main observation is a linear dependence of resistance on current at cryogenic temperatures, qualitatively inconsistent with the effects of Joule heating, as confirmed by the simulations of heat flow. As the temperature is increased, the zero-current singularity becomes smoothed out, but the linear dependence remains apparent at sufficiently large currents even near ambient temperatures. A kinetic model based on the quasi-ballistic escape approximation for the nonequilibrium phonons generated by electron scattering reproduces our main observations. The demonstrated effects are important for optimizing thermal management in electronic and thermoelectric nanodevices, and for the analysis of current-induced thermal effects at nanoscale.

10:24AM R62.00011: New regimes of nanoscale thermal transport from nanostructured heat sources on diamond probed using coherent EUV beams
BRENDAN MCBENNETT (Presenter), JOSHUA KNOBLOCH, BEGOÑA ABAD, TRAVIS D FRAZER, STROBE and JILA, University of Colorado and NIST, ALBERT BEARDO, LLUC SENDRA, JUAN CAMACHO, JAVIER BAFALUY, Departament de Física, Universitat Autònoma de Barcelona, WEILUN CHAO, Center for X-Ray Optics, Lawrence Berkeley National Laboratory, ROGER WIRTH FALCONE, Department of Physics, University of California, Berkeley, JORGE HERNÁNDEZ-CHARPAK, HENRY KAPTEYN, STROBE and JILA, University of Colorado and NIST, XAVIER ALVAREZ, Departament de Física, Universitat Autònoma de Barcelona, MARGARET MURNANE, STROBE and JILA, University of Colorado and NIST — Nanostructured materials make it possible to engineer properties that are unattainable using conventional bulk materials, with applications in next-generation energy efficient devices. However, macroscopic, diffusive transport models break down at length scales comparable to a material's dominant phonon mean free path. Moreover, there are few, if any, characterization techniques that can probe functional nanosystems. Here we use short wavelength (~30nm), ultrafast pulse (~10fs) extreme ultraviolet (EUV) beams to nondestructively probe nanoscale thermal transport in diamond. We first impulsively heat nickel nano-gratings fabricated on the diamond sample with an infrared pump laser and then extract thermal conductivity by monitoring surface relaxation with a time-delayed EUV probe. Diamond is an ideal candidate for validating emergent transport behaviors because its long phonon mean free path causes non-diffusive effects to appear at larger length scales. We compare our results to an advanced hydrodynamic transport model to isolate the contribution of viscous resistivity directly underneath the nanoheaters to thermal transport. Finally, we gain insight into non-diffusive cooling processes by examining the individual diffracted orders in the scattered EUV probe beam.
10:36AM R62.00012: Nanoelectronic thermometry and refrigeration for sub-millikelvin temperatures

JONATHAN PRANCE (Presenter), SAMULI AUTTI, Physics, Lancaster University, KESTUTIS GRIGORAS, VTT Technical Research Centre of Finland, ANTHONY GUÉNAULT, Physics, Lancaster University, DAVID GUNNARSSON, VTT Technical Research Centre of Finland, RICHARD HALEY, ALEXANDER JONES, YURI PASHKIN, Physics, Lancaster University, MIKA PRUNNILA, LEIF ROSCHIER, VTT Technical Research Centre of Finland, DMITRY ZMEEV, Physics, Lancaster University — It has recently been shown that magnetic refrigeration can be deployed on-chip to cool nanoelectronic devices below the base temperature of a dilution refrigerator [1, 2, 3]. This technique has the potential to unlock microkelvin electron temperatures in nanoscale structures and devices. However, there are still significant challenges in thermometry and thermal isolation to be overcome. In this talk, we present our recent work to lower the operating temperature of Coulomb blockade thermometers to ≈300µK, and to improve the base electron temperature reachable by demagnetisation refrigeration of on-chip copper.

Session R63 DMP DCMP FIAP: Defects: Structure and Strain 2 Mile High

Ballroom 4D - Rachel Goldman, Univ of Michigan - Ann Arbor
8:00AM R63.00001: Dynamic Dark-Field X-ray Microscopy to Probe Mesoscale Defects and their Dynamics* [Invited] LEORA DRESSELHAUS-COOPER (Presenter), Lawrence Livermore Natl Lab — Many problems in semiconductor physics require a detailed understanding of material defects at the mesoscale (e.g. dislocations, stacking faults, twins, etc.). While techniques exist to probe material defects, they are mainly limited to surface measurements or rastered scans that cannot measure the dynamics of irreversible processes. Dark-field X-ray microscopy (DFXM) can now directly image defects in single- and poly-crystals, spatially resolving the lattice strain and inclination with high sensitivity (ε~10^{-5}) and resolution across hundreds of micrometers. I extend DFXM to study structural dynamics, resolving how material defects show how crystals respond disturbances in their surroundings. I will show real-time movies that visualize how long-range dislocation patterns evolve in both temperature and time and will extend this to high-intensity X-ray radiation damage to demonstrate dynamic DFXM's capabilities. These results present important opportunities for semiconductor physics, as they can now address important problems at the mesoscale. Results from these findings can directly connect to dislocation models that have previously relied on multi-scale modeling and indirect measurements for refinement.

8:36AM R63.00002: High-throughput identification of point defects in SiC JOEL DAVIDSSON (Presenter), VIKTOR IVADY, RICKARD ARMIENTO, IGOR ABRIKOSOV, Linkoping University — Qubits and single photon emitters are examples of point defects applications. Before a point defect can be utilized in these applications, an important step is to identify and understand both the defect type and different configurations. A promising way to identify a defect is to combine experimental data with ab initio calculations which include zero-phonon lines and hyperfine coupling parameters. In earlier work, we made a convergence study for divacancies in 4H-SiC. Due to the size of the supercell and the number of calculations needed, we restrict us to the PBE exchange functional. Based on our understanding of the convergence of these calculations, we made an automatic workflow that can calculate zero-phonon lines for many different defects. Each defect is calculated for a range of different configurations, charges, spins, and possible excitations. Currently, we are running these calculations in a high-throughput manner and producing a database for an array of different defects. We present the results from the workflow for various vacancy configurations in 4H-SiC. Our preliminary results suggest that with this choice of methodology, useful data are obtained at a feasible computational cost for a large number of defect types and configurations available in SiC.
8:48AM R63.00003: Theoretical Investigations of the Hyperfine Coupling in Group IV-Vacancy Centers in Diamond Using Hybrid Density Functional Theory*  
RODRICK KUATE DEFO (Presenter), EFTHIMIOS KAXIRAS, Harvard University, STEVEN RICHARDSON, Howard University, Harvard University — Recently, single-photon emitters comprised of Group IV (Si, Ge, Sn, and Pb)-vacancy centers in diamond have attracted considerable interest in the literature because of their potential applications in quantum information processing and quantum metrology. Because some of these Group IV-vacancy color centers are paramagnetic, their electronic properties can be experimentally characterized using electron paramagnetic resonance (EPR) which is a direct measure of the hyperfine interaction at a microscopic level. It has been demonstrated that an understanding of the core spin polarization is essential to providing accurate hyperfine tensors in a number of point defects in diamond, including the NV(-) center.\(^1,^2\) In this work we use density-functional theory (DFT) with the HSE06 exchange functional to compute the hyperfine tensors of several paramagnetic Group IV-vacancy centers in diamond and we compare our results with other experimental and theoretical results where available.

9:00AM R63.00004: Theory on spectral diffusion and electrically driven interferometry of qubits*  
PÉTER UDVARHELYI, GERGO THIERING, VIKTOR IVADY, ADAM GALI (Presenter), Wigner Research Center for Physics — Scalable spin-to-photon interfaces require quantum emitters with strong optical-transition dipole moment and low coupling to phonons and stray electric fields. Here, we show that inversion symmetry is not a prerequisite criterion for a spectrally stable quantum emitter. We find that identical electron density in ground and excited states can eliminate the coupling to the stray electric fields. We demonstrate this effect on silicon-vacancy qubit in silicon carbide by first principles methods (SiC)\(^1,^2\). Our study opens an additional rationale in seeking promising materials towards the realization of robust spin-to-photon interfaces. Furthermore, we show by density functional theory that low-symmetry of defects can provide coherent optical and spin subsystems that can be harnessed to achieve electrically driven interferometry of SiC divacancy qubits\(^3\).

9:12AM R63.00005: Progress for high photon collection of color centers in quantum materials  
TONY ZHOU, PRESTON ZHOU (Presenter), GABRIEL SILVERMAN, KELECHI UKAH, LING XIE, AMIR YACOBY, Harvard University — Color centers in materials have attracted enormous amount of attention due to their interesting quantum properties for quantum computation, quantum optics\cite{1}, and quantum sensing applications\cite{2}. The most notable research has been focused on NV centers, SiV centers in diamond, divacancy in silicon carbide, and etc. There is also an increasing focus on defects, exciton physics in 2D materials. These collections of point-like entities share common optical technique in studies. Thus, efficient collection of each associated photons serves as the ultimate bottle neck in all applications. In this work, we present an effective approach to tackle this fundamental limit and use NV center as an example for its application\cite{3,4}.

9:24AM R63.00006: Modeling the Electronic Structure of Phosphorus Donor Clusters in Quantum Devices*  
QUINN CAMPBELL (Presenter), PETER A SCHULTZ, MITCHELL I BRICKSON, NOAH T JACOBSON, Sandia National Laboratories, LEON N MAURER, Google, EZRA BUSSMANN, SHASHANK MISRA, ANDREW BACZEWSKI, Sandia National Laboratories — Modeling the electronic structure of phosphorus donor clusters is essential for understanding and predicting the behavior of quantum devices fabricated using atomic precision advanced manufacturing (APAM) techniques. Scanning Tunneling Microscope (STM) lithography is one such technique for creating nanoelectronic devices by placing activated shallow dopants in silicon with atomic precision. To model these devices, we first use kinetic Monte Carlo parameterized from first principles calculations to predict the geometry of phosphorus donor clusters. From these geometries, we predict device performance by applying multivalley effective mass theory, developing a formalism for using a basis of anisotropic atomic orbitals for the envelope functions. We then compare the predicted electronic structure of these donor clusters to experimentally realized devices, reporting on observables such as charging energy and tunnel coupling.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA-0003525.
9:36AM R63.00007: Electron paramagnetic resonance study of sodium guests in silicon clathrates, a cage-like crystalline silicon allotrope*  WILLIAM SCHENKEN (Presenter), Department of Physics, Colorado School of Mines, YINAN LIU, Department of Chemical and Biological Engineering, Colorado School of Mines, LAKSHMI KRISHNA, Department of Physics, Colorado School of Mines, AHMAD AFIF ABDUL MAJID, CAROLYN KOH, Department of Chemical and Biological Engineering, Colorado School of Mines, P CRAIG TAYLOR, REUBEN T COLLINS, Department of Physics, Colorado School of Mines — Si clathrates are cage-like crystalline Si allotropes with potentially exciting properties. They are synthesized in the presence of alkali guest atoms, e.g. Na, which occupy interstitial sites in the cages. However, Na guests degenerately dope the crystal. Realizing the potential of these materials requires fundamental understanding of guest properties in the host crystal structure. We present an EPR study of Na guests in Type II Si clathrate powders with ≤1 at. % Na. At low temperature, the spectrum shows four lines from the hyperfine interaction of the Na valence electron with the $^{23}$Na nucleus ($I=3/2$). We attribute a line to Si dangling bonds in a highly disordered phase surrounding each grain, and identify doublets around the four hyperfine lines as arising from interactions with a $^{29}$Si nucleus ($I=1/2$) in the surrounding cage. We estimate about half of the electronic wavefunction on the Si sub-lattice extends past the confining cage. Additional structure is observed halfway between the strong hyperfine lines, which we attribute to interactions of two $^{23}$Na nuclei ($I=3$) in adjacent cages. A relatively broad line is attributed to clustered sodium. The relative intensities show the Na distribution is inhomogeneous.

9:48AM R63.00008: Quadrupolar interactions between acceptor pairs in p-doped semiconductors  ADAM DURST (Presenter), GENESIS YANG-MEJIA, Hofstra University, RAVINDRA NAUTAM BHATT, Princeton University — We consider the interaction between acceptor pairs in doped semiconductors in the limit of large inter-acceptor separation relevant for low doping densities. Modeling individual acceptors via the spherical model of Baldereschi and Lipari, we calculate matrix elements of the quadrupole tensor between the four degenerate ground states and show that the acceptor has a nonzero quadrupole moment. As a result, the dominant contribution to the large-separation acceptor-acceptor interaction comes from direct (charge-density) terms rather than exchange terms. The quadrupole is the leading nonzero moment, so the electric quadrupole-quadrupole interaction dominates for large separation. We calculate the matrix elements of the quadrupole-quadrupole interaction Hamiltonian in a product-state basis and diagonalize, obtaining a closed-form expression for the energy spectrum. All dependence on material parameters enters via an overall prefactor, resulting in surprisingly simple and universal results. This simplicity can be traced to the nontrivial vanishing of a particular Wigner 6-j symbol. Results are relevant to the control of two-qubit interactions in quantum computing implementations based on acceptor spins, as well as the thermodynamic properties of insulating p-type semiconductors.
10:00AM R63.00009: Nanoscale NV-detected Electron Spin Resonance at 115 GHz and 4.2 Tesla*  
BENJAMIN FORTMAN (Presenter), Dept. of Chemistry, Univ. of Southern California, JUNIOR PENA, SUSUMU TAKAHASHI, Dept. of Physics & Astronomy, Univ. of Southern California — The nitrogen-vacancy (NV) center is a promising candidate for single-spin electron spin resonance (ESR). NV-detected ESR enables ESR analysis for paramagnetic spins with sensitivity of a single spin. We have recently shown that the spectral resolution of NV-detected ESR is improved by carefully adjusting microwave (MW) pulse duration and intensity [1]. Pulsed ESR spectroscopy at high magnetic fields offers higher spectral resolution and greater spin polarization than measurements at lower magnetic fields. However, the shift to high fields requires a high frequency MW source whose output power is often much lower than that of a low frequency MW source. This results in incomplete population inversion due to limited excitation bandwidths and spin relaxation. Within this talk we present our development and application of adiabatic pulses at 115 GHz to overcome this challenge. We utilize these pulses to control the spin states of single NV centers and to perform ESR using a single NV center at a field of 4.2 Tesla [2].

10:12AM R63.00010: Defects in 4H-SiC Studied by Electrically Detected Magnetic Resonance and Electrically Detected Electron Nuclear Resonance*  
RYAN WASKIEWICZ (Presenter), BRIAN MANNING, DUANE MCCRARY, PATRICK LENAHAN, Pennsylvania State University — We utilize electrically detected magnetic resonance (EDMR) and electrically detected electron nuclear double resonance (EDENDOR) to observe defects responsible for recombination in fully processed 4H-SiC bipolar junction transistors (BJTs). The EDMR response in these devices is detected via spin dependent recombination (SDR) within the space charge region of the forward biased emitter-base junction with the collector grounded. (We link the observed response to silicon vacancies in the 4H-SiC.) We demonstrate the application of EDENDOR on these devices. To the best of our knowledge, this is the first demonstration of EDENDOR on a fully processed device. The EDENDOR measurements combines the power of EDMR with a nuclear magnetic resonance (NMR) excitation, allowing for the identification of magnetic nuclei near the observed defects. Our EDENDOR measurements indicate the presence of $^{14}$N nuclei near the silicon vacancies that are measured with EDMR. This work brings the unparalleled analytical power of ENDOR to applications with functional nanoscale devices.

10:24AM R63.00011: Hybrid spintronics as a novel platform for quantum sensing. ARTUR LOZOVOI (Presenter), HARISHANKAR JAYAKUMAR, DAMON DAW, CARLOS MERILES, The City College of New York — Defects in semiconductors are emerging as a robust solid-state platform for quantum sensing and quantum information processing. These applications demand efficient readout of the defect spin state with high fidelity. We propose a novel spin readout technique based on a non-local hybrid spin-to-charge conversion that takes advantage of drift and diffusion of the charge carriers in semiconductors in the presence of electric field. In this approach, spin-dependent generation of charge carriers from the target defects with superior spin properties is coupled to emitters with high quantum efficiency, optical cycling frequency and favorable photoionization properties. We implement this technique in type IIa diamonds and demonstrate that it provides higher sensitivity compared to the conventional spin readout techniques. We note that the proposed approach is universal in its nature and can be applied to spin-active impurities in other semiconductor materials. In addition to that, we use this technique to characterize charge dynamics and capture cross-sections of optically active and dark defects in diamond.

10:36AM R63.00012: High-density defect ensembles in SiC for superradiance and magnetometry* PETER BRERETON (Presenter), SETH RITTENHOUSE, JOSEPH WIEDEMANN, JEFFREY R VANHOY, US Naval Academy, JOHNN ABRAHAM, Johns Hopkins APL — The silicon vacancy in SiC has recently become of great interest as a platform for quantum sensing and quantum information processing. In particular, recent theoretical work has shown that the spin 3/2 multiplet of a single silicon vacancy in 4H-SiC can achieve magnetic field sensitivities sufficient to detect single nuclear spins [1]. However, there has been less work done in the high-density, radiatively coupled regime in SiC. Superradiant coupling between atoms [2] and nitrogen vacancies in diamond [3] has been demonstrated experimentally and has been proposed as a route toward ultra-sensitive quantum sensing in the solid state. We explore the details of the superradiant transition in the 4H-SiC silicon vacancy and show possible routes toward engineering suitable defect ensembles.

Session R64 DMP DCOMP: Chiral and Polar Structures in Thin Film Oxides Mile High Ballroom 4E - Kaveh Ahadi, NC State University - Tag(s): Focus
**8:00AM R64.00001: Electric-field control of emergent chirality in PbTiO$_3$/SrTiO$_3$ superlattices** [Invited] MARGARET MCCARTER (Presenter), SUJIT DAS, University of California, Berkeley, CHRISTOPH KLEWE, Advanced Light Source, ELIZABETH P DONOWAY, University of California, Berkeley, PADRAIC SHAFER, Advanced Light Source, GERRIT VAN DER LAAN, Diamond Light Source, LANE WYATT MARTIN, RAMAMOORTHY RAMESH, University of California, Berkeley — Novel chiral phases in ferroelectric materials—the polar analogs of magnetic vortices and skyrmions—can be stabilized in superlattices of PbTiO$_3$ and SrTiO$_3$. These chiral structures emerge in low-dimensional ferroelectrics, where the competition among gradient, electrostatic, and elastic energies favors non-uniform polarization configurations. Such phases can lead to new functional properties such as negative capacitance as well as unique interactions with polarized light. The characterization of these new phases and their three-dimensional chiral structure remains a challenge due to limitations of conventional electron microscopy and X-ray diffraction techniques.

In this talk, I will discuss how resonant soft X-ray diffraction (RSXD) can be used to study chirality in the emergent polarization textures (polar vortices and skyrmions) that form in PbTiO$_3$/SrTiO$_3$ superlattices. RSXD provides an element-specific probe with which to study the chiral configuration of orbitals in these materials. I will show that circular dichroism in RSXD originates from chiral arrays of electric quadrupoles, which are intrinsically related to the electric polarization. The presence of circular dichroism points to the formation of helical spirals of electric polarization, akin to Bloch domain walls in magnetic materials. Furthermore, circular dichroism can be observed in second harmonic generation. By performing electric-field dependent second harmonic generation circular dichroism experiments, we can demonstrate a coupling between the electric field and the handedness of chiral polar vortices.

**Negative capacitance in polar skyrmions**

SUJIT DAS (Presenter), University of California, Berkeley, ZIJIAN HONG, VLADIMIR A STOICA, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, Pennsylvania 16802, USA, MAURO A. P. GONÇALVES, Materials Research and Technology Department, Luxembourg Institute of Science and Technology (LIST), 5 avenue des Hauts-Fourneaux, L-4362 Esch/Alzette, Luxemburg, ERIC PARSONNET, SAHAR SAREMI, MARGARET MCCARTER, ARMANDO REYNOSO, DEREK MEYERS, VISHAL RAVI, University of California, Berkeley, HUA ZHOU, ZHAN ZHANG, HAIDAN WEN, Advanced Photon Source, Argonne National Laboratory, Argonne, IL, USA, FERNANDO GÓMEZ-ORTIZ, PABLO GARCIA-FERNANDEZ, Universidad de Cantabria, JEFFREY BOKOR, University of California, Berkeley, JORGE INIGUEZ, Materials Research and Technology Department, Luxembourg Institute of Science and Technology (LIST), 5 avenue des Hauts-Fourneaux, L-4362 Esch/Alzette, Luxemburg, JOHN WILLIAM FREELAND, Advanced Photon Source, Argonne National Laboratory, Argonne, IL, USA, JAVIER JUNQUERA, Universidad de Cantabria, LONG Q. CHEN, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, Pennsylvania 16802, USA, SAYEEF SALAUDDIN, LANE WYATT MARTIN, RAMAMOORTHY RAMESH, University of California, Berkeley — Topological solitons such as magnetic skyrmions have drawn enormous attention as stable quasi-particle-like objects. The recent discovery of polar vortices and skyrmions in ferroelectric oxide superlattices, exhibiting exotic physical phenomena, has opened up new vistas to explore topology, emergent phenomena, and approaches for manipulating such features with electric fields [1,2]. Here, using macroscopic dielectric measurements, phase-field simulations, and second-principles calculations, we demonstrate that polar skyrmions in (PbTiO$_3$)$_n$/(SrTiO$_3$)$_n$ superlattices are distinguished by a sheath of negative permittivity at the periphery of each skyrmion which enables a strong enhancement of the effective dielectric permittivity as compared to the individual SrTiO$_3$ and PbTiO$_3$ layers. Electric-field-dependent X-ray scattering measurements, phase-field simulations, and second-principles calculations are used to determine the relative fraction of skyrmions and quantify the local dielectric susceptibilities. A large, electric-field tunable negative permittivity provides a fundamental framework to enable novel low-power electronics.

9:00AM R64.00004: Polar Domains in Strained SrTiO$_3$ Films  
SALVA SALMANI-REZAIE  
(Presenter), KAVEH AHADI, SUSANNE STEMMER, University of California, Santa Barbara — We report on the microscopic mechanisms of how the incipient ferroelectric SrTiO$_3$ transforms into a ferroelectric by epitaxial strain. These films have recently been shown to have enhanced superconducting transition temperatures when doped, pointing to a relationship between superconductivity and ferroelectricity order parameters. Here, using high-angle annual dark-field scanning transmission electron microscopy, we detect local polar regions at room-temperature in compressively strained and unstrained SrTiO$_3$ films, respectively. Our image analysis uses the average deviation of the Ti column from the cubic position as the polar order parameter. We find that unstrained SrTiO$_3$ stays paraelectric while compressively strained films show short-range cooperative displacements within nano polar regions at room temperature. The observation of polar regions may explain optical second harmonic generation (SHG) studies, showing a residual SHG signal at room temperature in strained SrTiO$_3$. Oxygen annealing suppresses the formation of polar regions, highlighting the importance of free carriers for the stability of the polar regions.

9:12AM R64.00005: Strain-Induced Ferroelectricity in Freestanding SrTiO$_3$ Membranes  
RUIJUAN XU (Presenter), Department of Applied Physics, Stanford University, JIAWEI HUANG, School of Science, Westlake University, ED BARNARD, The Molecular Foundry, Lawrence Berkeley National Laboratory, SEUNG SAE HONG, Department of Applied Physics, Stanford University, ED WONG, The Molecular Foundry, Lawrence Berkeley National Laboratory, VARUN HARBOLA, Department of Physics, Stanford University, PRASTUTI SINGH, Department of Applied Physics, Stanford University, BAI YANG WANG, Department of Physics, Stanford University, SHI LIU, School of Science, Westlake University, HAROLD HWANG, Department of Applied Physics, Stanford University — SrTiO$_3$ is known to exhibit quantum paraelectricity in which quantum fluctuations suppress ferroelectric ordering at low temperature. Despite the intrinsic paraelectric nature of SrTiO$_3$, epitaxial strain applied via the lattice mismatch in thin-film heterostructures can significantly enhance the ferroelectric transition temperature $T_c$. Here we utilize freestanding crystalline membranes to extend the lattice control of ferroelectric ordering in SrTiO$_3$. By dissolving a water-soluble buffer layer, we release SrTiO$_3$ films from substrates, and transfer the resulting freestanding membranes onto flexible substrates that can be dynamically stretched into various strain states. Using second harmonic generation microscopy, we probe the ferroelectric phase transition as a function of strain wherein we observe $T_c$ is significantly enhanced by strain. Upon applying 1.5% uniaxial strain, we observe robust room-temperature ferroelectricity with the notable feature of 180° ferroelectric domains using piezoresponse force microscopy. First-principle calculations and molecular dynamics simulations further reveal the structural nature at each given strain state and the order-disorder character of phase transition in strained SrTiO$_3$ membranes.
Manipulation of superdomains in Pb(Zr_{0.2}Ti_{0.8})O_3 epitaxial films grown on SrTiO_3 (110) substrates

YI-CHUN CHEN (Presenter), Department of Physics, National Cheng Kung Univ., HENG-JUI LIU, Department of Materials Science and Engineering, National Chung Hsing Univ., YUCHEN LIU, MENG-XUN XIE, YU-HUAI LI, SHENG-ZHU HO, Department of Physics, National Cheng Kung Univ., YI-CHIA CHOU, Department of Electrophysics, National Chiao Tung Univ., YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung Univ., JAN-CHI YANG, Department of Physics, National Cheng Kung Univ. — Various interesting physical properties arising from manipulating strain energy terms in epitaxial films have attracted great attention. For tetragonal Pb(Zr_{0.2}Ti_{0.8})O_3 (PZT) films, the large piezoelectric response mainly originates from the switching of 90-degree c/a domains due to the strain-relief-induced reorientation. In this study, we found a superdomain structure existing the epitaxial PZT films when grown on the (110)-oriented SrTiO_3 (STO). The in-plane strain from STO breaks the uniaxial symmetry of the tetragonal PZT film, and with suitable adjusting the strain energy, superdomains can be formed in long-range areas. We used X-ray diffraction, transmission electron microscopy, and piezoresponse force microscopy (PFM) to investigate the distortion of crystal and domain structures. The PFM images show periodic nanodomains with size about 50-80 nm in the superdomain region and indicate the coexistence of at least two distortions of the crystal. The superdomains can be effectively induced or erased by external fields. Based on systematical investigations, the mechanism to create superdomains by electric fields is concluded relating to the surface energy. This study provides basic understanding and control of this unique superdomain structure.

Low-temperature synthesis of BaTiO_3 thin film by molecular beam epitaxy

YEONGJAE SHIN (Presenter), JUAN JIANG, YICHEN JIA, FREDERICK J WALKER, CHARLES H AHN, Yale University — The perovskite oxide BaTiO_3 is a lead-free material with high performance ferroelectric/piezoelectric properties. Integrating BaTiO_3 with existing semiconductor technology requires the synthesis of high-quality BaTiO_3 in the thin-film form at low temperatures to decrease the thermal budget during device fabrication. We describe our synthesis of BaTiO_3 thin films by molecular beam epitaxy at various temperatures and find that coherently strained BaTiO_3 can be grown at a temperature as low as 280 °C. The growth mechanism and strain state of these films are characterized as a function of temperature using x-ray diffraction and in-situ reflection high-energy electron diffraction. Our results pave the way toward large-scale integration of BaTiO_3 with semiconductor technology.
Monoclinic Phase and Interphase Boundaries in Perovskite Ferroelectrics  
TYLER LIEBSCH (Presenter), VLADIMIR SOBOLEV, South Dakota School of Mines and Technology — The temperature intervals of phase coexistence, including the recent experimentally observed monoclinic phase, in ferroelectric BaTiO$_3$ have been investigated using the Landau-Ginzburg-Devonshire phenomenological approach. Comparison of the thermodynamic potential for all phases in BaTiO$_3$ showed that the monoclinic phase is metastable near the tetragonal-orthorhombic phase transition, in the absence of an electric field. The structure and width of the interphase boundaries separating domains of coexisting phases near the phase transitions have been analyzed. The temperature dependence of polarization distributions, width, and energy density of the interphase boundary separating the tetragonal and monoclinic phases as well as the orthorhombic and monoclinic phases were found. The obtained results for interphase boundaries were compared to previous experimental and theoretical results for the domain walls existing within the above-mentioned phases.

Surface Proximity Effect, Imprint Memory of Ferroelectric Twins, and Tweed in the Paraelectric Phase of BaTiO$_3$*  
NICHOLAS BARRETT (Presenter), CLAIRE MATHIEU, CHRISTOPHE LUBIN, SPEC, CEA, CNRS, Université Paris-Saclay, PASCALE GEMEINER, BRAHIM DKHIL, SPMS, Centrale Supélec, Université Paris Saclay, EKHAARD SALJE, Department of Earth Sciences, University of Cambridge — For post-CMOS electronics applications using ferroic materials, the surface can play a crucial role. Non-invasive techniques are required to study the chemistry and electronic structure underlying their unique electrical properties. The sensitivity of photoemission (PEEM) electron microscopy to local surface potential, chemistry and electronic structure makes it a useful tool for probing the ferroic surfaces. We present a PEEM study of the evolution of the domain structure in BaTiO$_3$(001) through the phase transition. At room temperature, in- and out-of-plane polarized domains are present with ferroelectric and ferroelastic domain walls. Adsorbate screening results in inversion of the electrostatic surface potential contrast. Domain-related structure above the Curie temperature ($T_C$) is observable. Ferroelectric memory persist up to 550 K. The domain-like structures above $T_C$ may be related to a combination of atomic relaxation, adsorbates and oxygen vacancies. Finally, we present some first results of PEEM imaging of domain wall creep at the surface of BaTiO$_3$ around $T_C$.

10:12AM R64.00010: Coherent Acoustic Phonons and Ultrafast Carrier Dynamics in BaTiO3-BiFeO3 Films and Nanorods* RATHSARA R HERATH MUDIYANSELAGE (Presenter), BRENDEN A MAGILL, GITI KHODAPARAST, Virginia Tech, CHRISTOPHER J STANTON, Univ. of Florida, JADE HOLLEMAN, STEPHEN A MCGILL, NHMFL, Florida, MIN-GYU KANG, Penn State, HAN-BYUL KANG, Virginia Tech, SHASHANK PRIYA, Penn State — BiFeO3 has become a popular multiferroic material as an alternative to PZT since it is lead free. The addition of about 25% BaTiO3 in solid solution has been shown to substantially improve the coupling between electric, magnetic, optical, and structural orders parameters and offers the possibility of developing high speed multifunctional devices. We performed two-color (400 nm pump, 800 nm probe) time resolved transient reflectivity measurements of (1-x) BaTiO3-(x) BiFeO3, with x = 0.725 and BaTiO3-BiFeO3 nanorods. Our results show ultrafast carrier dynamics in BaTiO3-BiFeO3, which we interpret as diffusion of the photoexcited carriers away from the surface with an ambipolar diffusion constant that is below 1-2 cm²/s. The differential reflectivity also showed evidence of coherent acoustic phonons (CP) in both the films and nanorod samples at lower temperatures (100 K). The ability to generate strain via ultrafast optics can offer the intriguing possibility of dynamically manipulating and controlling electric and magnetic fields.

10:24AM R64.00011: Understanding the ferroelectric switching in freestanding BiFeO3 films QIWU SHI (Presenter), Department of Materials Science and Engineering, University of California, Berkeley; Sichuan University, YEN-LIN HUANG, HONGRUI ZHANG, XIAOXI HUANG, SUJIT DAS, RAMESH RAMAMOORTHY, Department of Materials Science and Engineering, University of California, Berkeley — The goal to achieve the low-voltage switching in BiFeO3 could be significant for reducing the energy consumption for the electric field control of magnetism, and promoting the prospect of ultra-low power ferroelectric memories. Although several strategies have been proposed, such as size scaling, strain engineering or achieving high-quality of crystals, the value of switching voltage has been still limited. In this work, we design the freestanding BiFeO3 films for elucidating the ferroelectricity without the “clamping effect” from substrate. Due to the release of the imposed strain from substrate, the lattice distortion and a reduced c/a value are observed. And the ferroelectric domain pattern of BiFeO3 shows a highly-order to disorder transition after freestanding. This inhomogeneous domain structure might be induced by the release of the clamping effect from the substrate and could be one of the reasons for the reduced switching voltage in the freestanding BiFeO3. It indicates that the freestanding methodology may pave a new pathway toward the next-generation low-power ferroelectric memory.
**10:36AM R64.00012: Manipulation of spin and the effective spin-orbit coupling in complex oxides**

WEICHUAN HUANG (Presenter), SUJIT DAS, University of California, Berkeley, USA, RUCHIRA CHATTERJEE, KATHERINE INZANI, EVAN SHERIDAN, SINÉAD GRIFFIN, Lawrence Berkeley National Laboratory, USA, VALENTIN V. LAGUTA, Czech Academy of Sciences, Prague, Czech Republic, YEN-LIN HUANG, Lawrence Berkeley National Laboratory, USA, HONGRUI ZHANG, RAMAMOORTHY RAMESH, University of California, Berkeley, USA — Electric field manipulation of spins and control of spin-orbital coupling have stimulated an intense interest due to their promise for new functionalities and power efficient device concepts. We are particularly interested in the manipulation of spin state (high spin to low spin) as well as their directionality, for example in a \(d^5\) state Fe\(^{3+}\) ion. Using Fe-doped PbTiO\(_3\) (Fe-PTO) as a model system, we present a systematic study of the thickness, temperature and electric field-dependent spin manipulations and spin-orbit coupling (SOC) effect in dilute magnetic ferroelectrics. Using laser MBE, we synthesized a series of Fe-PTO thin films with thickness range from 15 nm to 200 nm on various substrates in order to access systematically strained states in the Fe-PTO layer. Electron spin resonance from the Fe-site demonstrates a strong \(g\)-factor anisotropy from the normal to in-plane direction of the films. Moreover, we observed that the \(g\)-factor anisotropy systematically changes under tensile strain. These results demonstrate the manipulation of spins as well as effective SOC by subtle aspects of lattice strain/electric field.

**10:48AM R64.00013: Octahedral rotations in Ruddlesden-Popper layered perovskites under pressure from first principles**

SRIRAM POYYAPAKKAM RAMKUMAR (Presenter), ELIZABETH NOWADNICK, Materials Science and Engineering, University of California, Merced — Octahedral rotations are ubiquitous in perovskite oxides and couple closely to their electronic and magnetic properties. Applying pressure to bulk perovskites tunes the octahedral rotation amplitudes, and in some cases changes the octahedral rotation pattern. While the pressure response of octahedral rotations in ABO\(_3\) perovskites has been well studied, the impact of pressure on layered perovskites such as the n=2 Ruddlesden-Popper (RP) phase A\(_3\)B\(_2\)O\(_7\) is much less explored. Here, we use density functional theory calculations to investigate the pressure response of several A\(_3\)B\(_2\)O\(_7\) layered perovskites. We find that these RPs have a distinct pressure response compared to ABO\(_3\) materials. In particular, while the pressure response of ABO\(_3\) perovskites often can be classified according to the charge state of the A- and B-site cations, we find that each of the A\(_3^{2+}\)B\(_2^{4+}\)O\(_7\) RPs that we study exhibits a different response to pressure. Using a Landau expansion, we show how the interplay between different energetic contributions in RPs leads to this diverse set of responses to pressure. Our results offer insight into how to tune the structure and hence properties such as ferroelectricity in layered perovskites.

8:00AM R65.00001: Large Tunability of Band Edges and Band Gaps in Colloidal Nanoplatelets

QUNFEI ZHOU (Presenter), Materials Research Science and Engineering Center, Northwestern University, YEONGSU CHO, Department of Chemistry, University of Chicago, SHENYUAN YANG, Institute of Semiconductors, Chinese Academy of Sciences, EMILY WEISS, Materials Research Science and Engineering Center, Northwestern University, TIMOTHY BERKELBACH, Department of Chemistry, Columbia University, PIERRE DARANCET, Center for Nanoscale Materials, Argonne National Laboratory — Colloidal semiconductor nanoplatelets (NPLs) are quasi-two-dimensional nanostructures, that exhibit outstanding physical and chemical properties for optoelectronic applications. Using first-principles density functional theory calculations, we demonstrate large tunability of NPLs band edge energies over a range of 5 eV through surface passivation by common organic molecules, and how this could be leveraged in controlling the functionality in mixed-dimensional heterojunctions and photocatalysis[1]. Meanwhile, ligands induce up to 300 meV band gap shifts, in addition to the shifts by quantum confinement dictated by the number of atomic layers in thickness. We developed simple quantitative theory describing the independent tunability of band edge and band gap shifts in terms of ligand-induced surface dipole, and strain, respectively, which can be used for controlled modification of photochemistry and optoelectronic properties for NPLs.

*Funded by NSF through Northwestern MRSEC grant DMR-1720139. Use of the Center for Nanoscale Materials, an Office of Science user facility, was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.
8:12AM R65.00002: Suppression of Impurity Phase in Cesium Halide Perovskites by using Pressure  
LANANH NGUYEN (Presenter), DUONG MINH NGUYEN, YOUNGJONG KANG, Hanyang Univ, LIN WANG, HPSTAR, JAEYONG KIM, Hanyang Univ — Cesium halide perovskites, Cs$_4$PbBr$_6$ are new promising candidates for the applications of wide band gap semiconductors. However, the unavoidable appearance of CsPbBr$_3$, during the growth of the host crystal significantly hinders the optical and electrical properties of the materials. We report the suppression of the CsPbBr$_3$ phase by applying pressure in an order of giga-pascal scale. The results of XRD revealed that the CsPbBr$_3$ phase disappeared at 2.6 GPa. No PL and band edge peak of CsPbBr$_3$ was observed at 3.0 GPa, which demonstrates the disappearance of the fluorescence from the UV irradiated sample. With further pressure, the XRD data showed a reversible phase transition from rhombohedral to monoclinic of Cs$_4$PbBr$_6$ at 2.6 GPa. The main peaks were stable under pressure up to 20.0 GPa. After releasing the pressure, a very small intensity of PL peak, the band edge, and XRD peaks for CsPbBr$_3$ phase were observed. The Cs$_4$PbBr$_6$ phase was recovered at ambient conditions. It is speculated that CsPbBr$_3$ crystals are sensitive to pressure with the distortion of [PbBr$_6$]$^{4-}$ network at moderately low pressure (<3.0 GPa), while Cs$_4$PbBr$_6$ crystals are much stable at high pressure (up to 20.0 GPa) due to the isolated octahedral PbBr$_6$$^{4-}$ ions interspersed Cs$^+$ cations.

8:24AM R65.00003: A Machine Learning Approach to the Analysis of X-ray Diffraction Patterns From Multilayered Thin Film Diffusion Couples*  
ALEXEI KANANENKA (Presenter), MATTHEW FORBES DECAMP, KARL UNRUH, Physics and Astronomy, Univ of Delaware — A machine learning approach based on Neural Network and Gaussian Process Regression algorithms has been developed to extract structural information from the x-ray diffraction (XRD) patterns of multilayered Au/Pt diffusion couples. These algorithms have been trained on a subset of about 100,000 simulated XRD patterns computed at various stages of diffusional mixing in multilayers containing a fixed number of bilayers but a fluctuating number of atomic planes in each (unreacted) Au and Pt layer. When used to analyze the simulated diffraction patterns, this approach has been successful in reconstructing the known composition profile and the number of unreacted Au and Pt planes in each layer.

*This material is based upon work supported by the National Science Foundation under Grant No. DMR140076.
First principles study of hBN-AlN short-period superlattice heterostructures*  CATALIN SPATARU (Presenter), MARY H. CRAWFORD, ANDREW A. ALLERMAN, Sandia National Laboratories — We present a theoretical study [1] of the structural, electronic, and optical properties of hBN-AlN superlattice (SL) heterostructures using a first-principles approach based on standard and hybrid density functional theory. We consider a short-period (L < 10 nm) SL and find that its properties depend strongly on the AlN layer thickness L_{AlN}. For L_{AlN} less than ~1nm, AlN stabilizes into the hexagonal phase and the SL displays insulating behavior with type II interface band alignment and optical gaps as small as 5.2 eV. The wurtzite phase is formed for thicker AlN layers. In these cases, built-in electric fields lead to the formation of polarization compensating charges as well as two-dimensional conductive behavior for electronic transport along interfaces. We also find defect-like states localized at interfaces which are optically active in the visible range. [1] C.D. Spataru, M.H. Crawford and A.A. Allerman, Appl. Phys. Lett. 114, 011903, (2019).

Hydrogen passivation effect on the sealing problem of edge growth in h-BN*  WENJING ZHAO (Presenter), JUNYI ZHU, Physics, The Chinese University of HongKong — Edge kinetics in two dimensional structure has been the key to understand the growth. In this talk, we'll illustrate the intrinsic difficulty to fill out the last few atoms to the edge of hexagonal BN and define such a difficulty as a sealing problem. The physical origin is due to the accumulation of local strain energy of the reconstruction near edges. Specifically, the local distortion becomes severe when more atoms are imperfectly placed to fill the gap on the edge. To solve the sealing problem and reduce the energy barrier to form a perfect edge, it's possible to passivate the dangling bonds of the edge atoms to reduce the edge reconstruction by hydrogen. This new finding and growth strategy may largely enhance the crystal quality and growth rate.

*This work is supported by Hong Kong RGC/GRF under the project number of 14307219 and 14319416.
**9:00AM R65.00006: Epitaxial growth of atomically-sharp GeSn/Ge/GeSn tensile strained (≥1.5 %) quantum well on Si**  SIMONE ASSALI (Presenter), ANIS ATTIAOUI, PATRICK DEL VECCHIO, SAMIK MUKHERJEE, AASHISH KUMAR, OUSSAMA MOUTANABBIR, Ecole Polytechnique de Montreal — In a full-group IV integrated semiconductor platform for tensile-strained Ge the direct-band gap can be obtained when the Ge is grown on a lattice-mismatched Ge$_{0.87}$Sn$_{0.13}$ substrate. The main challenge is to increase the incorporation of Sn in Ge above the ~1at.% equilibrium composition. Major developments were recently achieved in the epitaxial growth of random GeSn alloys with composition above 16at.%. A biaxial tensile strain in a Ge layer up to ~1.5% was demonstrated when growing on a Ge$_{0.88}$Sn$_{0.12}$ substrate. However, despite the large amount of tensile strain in Ge, no information are available on the abruptness of the Ge-GeSn interface and on the possibility of the subsequent GeSn growth on top.

Here, we discuss the epitaxial growth of a tensile-strained GeSn/Ge/GeSn heterostructure(s-Ge) with sharp interfaces and in-plane biaxial strain above 1.5% grown on lattice-mismatched Ge$_{0.86}$Sn$_{0.14}$. The sharpness of the Ge/GeSn heterostructure interfaces will be addressed using TEM-EELS and atom probe tomography(APT) measurements. A defect-free s-Ge layer thickness in the 13-1.2nm range is achieved and its pseudomorphic nature will be discussed using STEM and XRD. The s-Ge QW platform is a new versatile platform to investigate LH spin-based qubits and high hole mobility electronics.

**9:12AM R65.00007: Field emission characteristics of solid-state, GaN-based vacuum nanoelectronic devices**  KESHAB R SAPKOTA (Presenter), ALBERT A TALIN, FRANCOIS LEONARD, Sandia National Laboratories, BARBARA A KAZANOWSKA, KEVIN S JONES, Engineering, University of Florida, BRENDON P GUNNING, GEORGE T WANG, Sandia National Laboratories — Vacuum nanoelectronics have notable advantages over conventional solid state devices. Vacuum channel devices are inherently robust in harsh environments and allow high frequency and power operation due to ballistic electron conduction. By shrinking the vacuum channel to nanoscale size well below the electron mean free path in air, these devices should be operable in air while maintaining the advantages of vacuum transport. Here we propose GaN as a superior materials platform compared to silicon or metals for solid-state, nanogap field emission devices based on its lower electron affinity, higher chemical stability, and high breakdown voltage. These novel GaN nanogap field emission device exhibit low turn-on voltage, high field emission current, and excellent on-off ratio. We will present experimental and modeling results on the field emission characteristics of these devices at various gap sizes and operating pressures.

*Sandia National Laboratories is managed and operated by NTESS under DOE NNSA contract DE-NA0003525*
9:24AM R65.00008: Classification of Critical Points in Energy Bands Based on Topology, Scaling and Symmetry  
NOAH YUAN (Presenter), LIANG FU, Massachusetts Institute of Technology  
MIT — A critical point of the energy dispersion is the momentum where electron velocity vanishes. At the corresponding energy, the density of states (DOS) exhibits non-analyticity such as divergence. Critical points can be first classified as ordinary and high-order ones, and the ordinary critical points have been studied thoroughly by Leon van Hove, whose DOS is particle-hole symmetric and logarithmically divergent. In this work, we describe and classify high-order critical points based on topology, scaling and symmetry. We show that high-order critical points can have power-law divergent DOS with particle-hole asymmetry, and can be realized at generic or symmetric momenta by tuning a few parameters such as twist angle, strain, pressure and/or external fields.

9:36AM R65.00009: Super-geometric electron focusing on the hexagonal Fermi surface of PdCoO$_2$  
MAJA BACHMANN (Presenter), AARON SHARPE, ARTHUR W BARNARD, Physics, Stanford University, CARSTEN PUTZKE, École Polytechnique Fédéral de Lausanne, MARKUS KOENIG, SEUNGHYUN KHIM, Max Planck Institut for Chemical Physics of Solids, DAVID GOLDHABER-GORDON, Physics, Stanford University, ANDREW MACKENZIE, Max Planck Institut for Chemical Physics of Solids, PHILIP MOLL, École Polytechnique Fédéral de Lausanne — The ultrapure delafossite metal PdCoO$_2$ exhibits a strikingly long mean free path of $\sim 20$ µm at temperatures below 20K. Owing to its peculiar Fermi surface, resembling a nearly perfect hexagon, the electron’s ballistic trajectories are mainly restricted into three directions, rendering PdCoO$_2$ an ideal material to investigate unusual anisotropic ballistic effects. We fabricate ballistic structures for transverse electron focusing from as-grown single crystals using focused ion beam machining, and demonstrate magnetic focusing up to 35 µm. Compared to typically studied materials with circular Fermi surfaces, the transverse focusing amplitude is strongly enhanced due to the large parallel sections of the hexagonal Fermi surface. We demonstrate this focusing enhancement experimentally, and corroborate it by transport simulations.
XUEDONG BAI (Presenter), Chinese Academy of Sciences, Institute of Physics — In-situ transmission electron microscopy (TEM) method is powerful in a way that it can directly correlate the atomic-scale structure with physical and chemical properties. Here, we will report on the construction and applications of the in-situ TEM setup including mechanical, electrical and optical holders, which were built by STM technique. So the manipulation and physical measurement have been realized inside TEM, where the real-time imaging of electrically and/or mechanically driven structural evolution at atomic scale has been carried out by the homemade in-situ TEM setup.

Exploring the lattice degree of freedom of metal oxides in transition between different structural phases may provide a route to the new properties in oxide materials. Here we report on the electrically driven oxygen vacancy ordering in CeO$_2$ films, and the experimental finding of strain-inhibited structural transition from perovskite to brownmillerite during the oxygen vacancy electromigration in epitaxial LaCoO$_3$ thin films, as well as the mechanically induced ferroelectric vortices transformation in PbTiO$_3$/SrTiO$_3$ superlattice will be included. This is a fundamental research for the future nanoelectronics such as memories and also the valuable insight into lattice-charge interactions at nanoscale.

Thursday, March 5, 2020 8:00 AM - 11:00 AM

Session R66 DCMP: Exploring the Relation Between Electron Nematicity and Superconductivity in Strongly Correlated Electronic Systems

Four Seasons 1 - Daniel Arovas, University of California, San Diego - Tag(s): Invited
Strain sensitivity and other experimental consequences of nematic-mediated superconductivity* [Invited] SAMUEL LEDERER (Presenter), Cornell University, EREZ BERG, Weizmann Institute of Science, EUN-AH KIM, Cornell University — In many unconventional superconductors, nematic quantum fluctuations are strongest where the critical temperature is highest, inviting the conjecture that nematicity plays an important role in the pairing mechanism. Recently, strontium-doped barium nickel oxide has been identified as a tunable nematic system that provides an ideal testing ground for this proposition. We therefore propose several sharp empirical tests, supported by quantitative calculations in a simple model of this material. The most stringent predictions concern experiments under uniaxial strain, which has recently emerged as a powerful tuning parameter in the study of correlated materials. Since uniaxial strain so precisely targets nematic fluctuations, such experiments may provide compelling evidence for nematic-mediated pairing in this and other materials, analogous to the isotope effect in conventional superconductors.

*SL was supported in part by a Bethe/KIC fellowship at Cornell. Theoretical studies by SL and E-AK were supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering under Award de-sc0018946.

Sixfold enhancement of superconductivity in a tunable electronic nematic system* [Invited] JOHNPIERRE PAGLIONE (Presenter), University of Maryland, College Park — The electronic nematic phase - in which electronic degrees of freedom lower the crystal rotational symmetry - is commonly observed in high-temperature superconductors. However, understanding the role of nematicity and nematic fluctuations in Cooper pairing is often made more complicated by the coexistence of other orders, particularly long-range magnetic order. Here we report the enhancement of superconductivity in a model electronic nematic system that is not magnetic, and show that the enhancement is directly born out of strong nematic fluctuations associated with a quantum phase transition. We present measurements of the resistance as a function of strain in Ba$_{1-x}$Sr$_x$Ni$_2$As$_2$ to show that strontium substitution promotes an electronically-driven nematic order in this system. In addition, the complete suppression of that order to absolute zero temperature leads to an enhancement of the pairing strength, as evidenced by a sixfold increase in the superconducting transition temperature. The direct relation between enhanced pairing and nematic fluctuations in this model system, as well as the interplay with a unidirectional charge density wave order comparable to that found in the cuprates, offers a means to investigate the role of nematicity in boosting superconductivity.

Historically, the antiferromagnetic insulator state of CuO$_2$ is transformed by hole-doping onto the oxygen sites, into an exotic quantum fluid that is usually referred to as the pseudogap (PG) phase. Its defining characteristic is a strong suppression of the electronic density-of-states for energies $E<D$, where $D$ is the pseudogap energy scale. Within the pseudogap phase, complex broken-symmetry phases have been detected by a very wide variety of techniques. First, there is the finite-Q charge-density-wave (CDW) state that is locally commensurate and unidirectional, with $4a_0$ periodicity and a $d$-symmetry form factor. Second, is the finite-Q pair-density-wave (PDW) state which is detected with superconducting-tip STM as having a $4a_0$ periodicity in the magnitude of Josephson currents and an $8a_0$ periodicity in its energy-gap modulations. Third, there is the nematic (NE) state which breaks rotational symmetry at $Q=0$.

Simultaneous measurements of the PDW and CDW phenomenology now reveal strong evidence that they are facets a single, fundamental, density wave (DW) state that breaks translational symmetry. More surprisingly, several characteristics of the NE state appear closely related to those of this DW state. For example, by simultaneously imaging the doping and energy dependence of the DW and NE states, we find that the maximum spectral intensity of these quite distinct forms of symmetry breaking always occurs at the same energy, and that this is always the pseudogap energy for hole-density $p<0.19$. We discuss how this perplexingly linked phenomenology of two highly distinct broken-symmetry states may be understood as the natural consequence of a vestigial nematic state within the pseudogap phase of Bi$_2$Sr$_2$CaCu$_2$O$_8$.

Strain-tuning nematic order and signatures of nematic quantum criticality* [Invited] IAN FISHER (Presenter), Department of Applied Physics and Geballe Laboratory for Advanced Materials, Stanford University — Quantum criticality associated with electronic nematic order has been suggested as a possible avenue for a range of exotic electronic effects, from non-Fermi liquid behavior to superconductivity. In order to study the behavior of metals proximate to such a quantum critical point, it is useful to establish effective tuning parameters that can drive the critical temperature of an electronic nematic phase to zero. I will describe how both symmetric and orthogonal antisymmetric strains can play this role, and demonstrate these effects in an archetypal Fe-based superconductor. For compositions progressively closer to the putative nematic quantum critical point, these tuning parameters become increasingly more effective, the precise variation of which provides evidence for a wide range of composition and temperature over which quantum critical fluctuations play a key role in shaping the properties of this family of materials. Additional evidence can be found in the temperature and doping dependence of the nematic susceptibility, which, by applying large magnetic fields, can be measured in the absence of superconductivity down to low temperatures. Further insights can be obtained by consideration of other model material systems, in particular materials that undergo ferroquadrupolar order of local 4f atomic orbitals.

Divergent nematic susceptibility near the pseudogap critical point in Bi-cuprate superconductors* [Invited] TAKASADA SHIBAUCHI (Presenter), Univ of Tokyo-Kashiwanoha — In strongly correlated materials, superconductivity is often found near a magnetic quantum critical point (QCP) where a magnetic phase vanishes in the zero-temperature limit. Moreover, the maximum of superconducting transition temperature $T_c$ frequently locates near the magnetic QCP, suggesting that the proliferation of critical spin fluctuations emanating from the QCP plays an important role in Cooper pairing. In cuprate superconductors, however, the superconducting dome is usually separated from the antiferromagnetic phase and $T_c$ attains its maximum value near the verge of enigmatic pseudogap state that appears below doping-dependent temperature $T^*$. Thus a clue to the pairing mechanism resides in the pseudogap and associated anomalous transport properties. Recent experiments suggested a phase transition at $T^*$ but the key question is what kind of fluctuations are associated with the pseudogap. Here we report elastoresistance measurements of nematic susceptibility in $(\text{Bi,Pb})_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$, which is sensitive to an electronic order with twofold in-plane anisotropy. The nematic susceptibility shows an anomaly at $T^*$ evidencing a phase transition with broken rotational symmetry. Near the pseudogap end point, nematic susceptibility becomes singular and divergent. This signifies the presence of a nematic QCP, which has emerging links to the high-$T_c$ superconductivity and strange metallic behaviours in cuprates.

Session R67 DCMP DCOMP: Predictive Discoveries of Novel Two-Dimensional (2D) Materials Through Complementary High-Throughput Approaches Four Seasons 2-3 - Ismaila Dabo, Pennsylvania State University - Tag(s): Invited
We performed extensive density-functional theory calculations of the geometries, band structures, and Z2 topological invariants of 2D honeycomb materials. Using a recently developed artificial-intelligence approach (SISSO, Ref. 1) we identify the actuators ('material's genes') that govern the topological transition. We also draw a 'map of materials properties' which identifies the regions of metals, trivial insulators, and topological insulators. The latter region contains several million newly predicted topologically nontrivial alloyed materials.

*This work was partially funded by the NOMAD (Novel Materials Discovery) Center of excellence: https://nomad-coe.eu .
We have performed an extensive high-throughput screening of known inorganic materials, to identify those that could be exfoliated into novel two-dimensional monolayers [1]. The screening protocol first identifies bulk materials that appear layered according to a simple and robust chemical definition of bonding, determining then for all of these the binding energies of the respective monolayers, their electronic state (metallic vs insulating), magnetic configuration (ferro-, ferri- or antiferromagnetic), and phonon dispersions (to evaluate mechanically stability). Such protocol identifies a portfolio of close to 2,000 inorganic materials that appear either easily or potentially exfoliable. With further data ingestion, this initial portfolio has recently almost doubled, providing an extensive pool to investigate promising properties. First focus has been on the determination of the effective masses and mobilities (from the full solution of the Boltzmann transport equation) for electronic applications; of topological invariants; of superconductivity and charge-density waves; and of photocatalytic parameters for water splitting. Thanks to the use of the AiiDA (http://aiida.net) materials' informatics platform, all the high-throughput calculations can be performed and streamlined in fully searchable and reproducible ways, they are stored in a database with the full provenance tree of all parent and children calculations, and can be shared with the community at large in the form of raw or curated data via the Materials Cloud (http://www.materialscloud.org) dissemination portal.

*Support from the Swiss National Science Foundation through the Ambizione career program and the MARVEL National Centre for Competence in Research is greatly acknowledged.
SHENGBAI ZHANG (Presenter), Rensselaer Polytechnic Institute — Recent years have witnessed an amazing expansion in the family of 2D materials, which has led to many exotic physical properties distinctly different from their bulk counterparts. An example is the traditional II-VI compound semiconductors in their monolayer limit [1], for which the experiments have been catching up rapidly. Besides the monolayer honeycomb (MLHC) $h$BN-like structure, a double layer honeycomb (DLHC) structure was also predicted to be stable over a large portion of ordinary semiconductors [2]. It is becoming clear that when the thickness of a solid is below certain critical value, irrespective of its commonly-observed bulk form, a universal van der Waals stacking may happen, leading to unexpected physical properties. Taking GaAs, a well-known covalent semiconductor, as an example, non-trivial topological properties emerge as a result of the stacking of DLHCs [2], as well as the formation of an excitonic insulator (EI) where the excitonic binding energy magically becomes larger than its band gap [3]. In strongly-correlated 2D systems such as MX$_2$ where M = Ni, Co and X = Cl, Br, on the other hand, half excitonic insulator can also form where one spin channel is an ordinary semiconductor while the other spin channel is an EI, leading to Bose-Einstein condensation [4].

*Work in the US was supported by the US DOE Grant No. DE-SC0002623. The supercomputer time sponsored by NERSC under DOE contract No. DE-AC02-05CH11231 and the CCI at RPI are also acknowledged.
CLAUDIA DRAXL (Presenter), Physics Department, Humboldt University Berlin — 2D materials exhibit peculiar optoelectronic properties [1] that can be further tuned by stacking, functionalization, or creating interfaces [2-4]. Analysis based on many-body approaches provide us insight into their intriguing features. Making use of this information and the large data pool of the NOMAD Repository [5], we apply data-analytics tools to create a pool of fingerprints and find descriptors for particular properties. A novel approach, based on these fingerprints, will be demonstrated to unravel hidden similarities between materials.

10:24AM R67.00005: Epitaxial tellurene, phosphorene and MoTe$_2$ derivatives: from theoretical prediction to experimental observations* [Invited] MAOHAI XIE (Presenter), Physics Department, The University of Hong Kong — The family of 2D materials has been expanding continuously showing the diverse structural, symmetrical and electronic properties. Presently, there are two major categories of 2D materials experimentally obtainable: one is by exfoliation from bulk crystals (e.g., graphene) and the other is by epitaxial growth (e.g., silicene), and the latter is more versatile capable of synthesizing materials that would otherwise be not present naturally. In this presentation, some of our synergistic research efforts between theory, modeling, and experiments in the discoveries and further characterizations of a few members of the 2D materials family will be given. These include layered tellurium [1,2], metal-phosphorene network consisted of blue-phosphorene units linked by Au atoms [3,4], and a variational hexagonal phase of molybdenum telluride [5]. Each of these are achieved by molecular-beam epitaxy and their structural and electronic properties are characterized by scanning transmission electron microscopy, scanning tunneling microscopy and scanning tunneling spectroscopy. These materials show potentials of various applications.

*The works are financially supported by a Collaborative Research Fund (No. C7036-17W), a General Research Fund (No. 17304318), and a NSFC/RGC joint research grant (No. N_HKU732/17) from the Research Grant Council, Hong Kong Special Administrative Region, China.

Session R68 DQI: Control and Calibration Tools for Scalable Quantum Computing Four Seasons 4 - Robin Blume-Kohout, Sandia National Laboratories - Tag(s): Focus
Estimation of statistical significance in the quantum supremacy experiment with the Sycamore processor  

PING YEH (Presenter), ADAM ZALCMAN, SERGIO BOIXO, Google, Inc. — Google’s quantum supremacy experiment is based on sampling of output bitstrings of random quantum circuits [1]. To demonstrate quantum supremacy, it is critical to establish that the hardware fidelity at sampling time is not degraded to zero due to errors and the sampled bitstrings correspond to the expected noisy distribution. In addition, since the run time of classical approximate simulations is proportional to fidelity, it is important to verify that the fidelity is above a threshold at which classical simulation is estimated to be hard. In this talk, I will describe the methodologies for the statistical analyses and show that the bitstring distributions are extremely unlikely to be explained by noise alone and the fidelity is significantly above the threshold.

How OpenSuperQ is planning to fully calibrate and characterize a 100 qubit superconducting QPU over the weekend*

SHAI MACHNES (Presenter), NICOLAS WITTWER, FEDERICO ROY, Univ des Saarlandes, ANURAG SAHA ROY, Citizen scientist, KEVIN PACK, FRANK WILHELM, Univ des Saarlandes — The current methodology of designing control pulses for superconducting circuits often results in an absurd situation: simplified analytic models which do not predict gate fidelities to high accuracy, and calibrated pulse shapes which achieve good fidelities, but do not correspond to the model. For large number of qubits the QPU calibration is long and difficult, and determining a detailed error budget is nearly impossible.

To rectify the situation, we have implemented a novel procedure of Combined Calibration and Characterization (C3): An interative combination of open-loop pulse optimization, model-free tune-up and iterative model fitting and refinement, utilizing a high-performance TensorFlow simulator. It allows for a rapid, and largely automated bring-up process of QPUs. The result is a high-fidelity model, comensurate high-fidelity gates and a detailed error budget.

The above components are then utilized to implement machine-learning capabilities such as adversarial system characterization and automated experiment design, to further accelerate the process of gaining insight into the behaviour of our systems.

C3 software will be made available as an open-source project.

*Project OpenSuperQ (820363) EU Flagship Quantum Technologies, IARPA LogiQ grant W911NF-16-1-0114
As the era of NISQ is dawning, calibration and characterization of QPUs is becoming an increasingly complex task due to the growing amount of qubits and high fidelity requirements. To tackle this problem, we developed a machine learning driven approach for Combined Calibration and Characterization procedure, C^3. This talk focuses on the gate calibration task, where optimization algorithms are used to find the best pulse parameter values in a multidimensional space.

We present a strategy which is capable of optimizing dozens of parameters, optimizing both an entangling gate and the single qubit gates of the two qubits involved, and to do so significantly faster than previously possible.

To succeed in this endeavor we engaged in an in-depth study of the multitudes of gradient-free algorithms available. The result is a unique portfolio of algorithms, for fast initial convergence and high fidelities.

Finally, we present experimental results by several labs that applied the above methodology. We show how our method takes entire gate sets all the way from 0.85 fidelities to state-of-the-art fidelities, using our open-source software.

*Project OpenSuperQ (820363) of the EU Flagship Quantum Technologies. IARPA through the LogiQ grant No. W911NF-16-1-0114.
8:36AM R68.00004: Automatic Calibration and Characterization of Quantum Devices - Experimental Results on NISQ QPUs and Quantum Memory devices* SHAI MACHNES, NICOLAS WITTLLER (Presenter), FEDERICO ROY, Univ des Saarlandes, ANURAG SAHA ROY, Citizen scientist, KEVIN PACK, FRANK WILHELM, Univ des Saarlandes — The practical application of optimal control techniques, especially in superconducting settings, requires extensive calibration to reach high fidelities. By controlling both experiment and a high performance numerical simulation, the C3 procedure provides a framework to systematically design and apply even intricate open loop optimal control pulses.

We demonstrate the characterization and tune-up of a quantum computing device with a few qubit, as well as a quantum memory device composed of a transmon with a 3D microwave cavity. The memory experiment presents different challenges, as the control protocol involves high-power sideband transitions, leading to system dynamics that are incompatible with simple models for qubit-cavity interactions.

In both cases, we numerically simulate the measurement of gate sequences and, by comparing the results to experimental data, improve the model of the experiment, including both simple parameters such as qubit frequencies, as well as non-trivial aspects such as line responses and bandwidth limitations of the electronic equipment that distort and imposes constraints on control signals.

*Project OpenSuperQ (820363) of the EU Flagship Quantum Technologies. IARPA through the LogiQ grant No. W911NF-16-1-0114

8:48AM R68.00005: Active Learning of Hamiltonians ARKOPAL DUTT (Presenter), Massachusetts Institute of Technology, EDWIN PEDNAULT, CHAI WU, SARAH SHELDON, LEV S BISHOP, JOHN SMOLIN, IBM Thomas J. Watson Research Center, ISAAC CHUANG, Massachusetts Institute of Technology — Querying a quantum system produces measurement outcomes which originate from the Hamiltonian dynamics of the system and its environment. Learning a Hamiltonian from a class that best fits these observations is the Hamiltonian tomography problem. Prior work has focused on estimation and offline optimal experiment design. Here, we consider an active learner that is given an initial set of training examples and the ability to interactively query the quantum system to generate new training data. The goal is to then minimize the training data required for Hamiltonian learning. To this end, we present an efficient active learning algorithm based on Fisher information and assess its performance on recalibrating superconducting qubit systems based on the cross-resonance (CR) gate. The CR Hamiltonian has up to nine parameters and admits queries involving input state, measurement operator and interaction time. Practical challenges include exponential growth of number of parameters with number of qubits, and modeling different noise sources such as readout, and imperfect pulse shapes. We show that we can achieve a constant 30% reduction in queries compared to a uniformly random approach. We also describe a regime where we achieve Heisenberg limited convergence rate during learning.
9:00AM R68.00006: Optimizing Quantum Gate Frequencies for Google's Quantum Processors  PAUL KLIMOV (Presenter), JULIAN KELLY, KEVIN SATZINGER, ZIJUN CHEN, HARTMUT NEVEN, JOHN M MARTINIS, Google AI Quantum — A crucial component of operating a quantum processor is mitigating computational errors from energy-relaxation, dephasing, leakage, and control imperfections. In superconducting qubits, these sources of error can arise from control-electronics noise, control-pulse distortions, and the parasitic coupling of qubits to other qubits, two-level system defects, spurious microwave modes, and the control and readout circuitry. In frequency-tunable qubit architectures, it is possible to mitigate these sources of error by choreographing qubit gate frequencies over the course of quantum algorithms. This choreography maps to constructing and optimizing a high-dimensional, high-constraint, non-convex, and time-dependent objective over a search space that significantly exceeds the Hilbert-space dimension of the processor. In this talk, I will introduce the frequency optimization problem and the Snake optimizer that we developed to solve it for Google’s flagship quantum processors [1].

9:12AM R68.00007: Quantum Orchestration Platform Integrated hardware and software for design and execution of complex quantum control protocols  YONATAN COHEN (Presenter), ITAMAR SIVAN, NISSIM OFEK, LIOR ELLA, NIV DRUCKER, TAL SHANI, ORI WEBER, HANAN GRINBERG, MICHAEL GREENBAUM, Quantum Machines — The incredible progress in designing quantum systems, engineering their environment, and controlling them effectively, has led to significant improvements in coherence times, gate fidelities and the ability to integrate more qubits into a single quantum processor. While development of quantum processors remains the number one challenge, many bottlenecks exist in the classical control hardware layer as well as the software layer, where optimizations can play a critical role for near term quantum computing. Some examples include (1) feedback for error correction and repeat until success protocols, (2) complex calibrations, and (3) hybrid quantum classical algorithms. Here we present a new platform for designing quantum control protocols, executing them on a wide range of quantum hardware, and optimizing performance. The platform, called Quantum Orchestration Platform incorporates a unique FPGA architecture and integrates classical hardware and software in a novel way that allows for combining the most cutting-edge real-time control capabilities with an intuitive programming environment and programing language. We show examples and present results of several protocols, including multiqubit feedback and complex control flow.
9:24AM R68.00008: Quantum Orchestration Platform Integrated hardware and software for design and execution of complex quantum control protocols  ITAMAR SIVAN (Presenter), YONATAN COHEN, NISSIM OFEK, TAL SHANI, ORI WEBER, LIOR ELLA, MICHAEL GREENBAUM, HANAN GRINBERG, NIV DRUCKER, Quantum Machines — Quantum computing holds a great promise for immense computational power. In last years, it was suggested that noisy intermediate-scale quantum (NISQ) processors may already demonstrate an advantage over classical hardware for particular computational tasks which may be of commercial use. Nonetheless, significant additional technological progress, at every layer of the quantum computer, is required in order to advance from NISQ processors to ones capable of running fault-tolerant-quantum-computation (FTCC). In particular, for FTCC, multi-qubit real-time feedback capabilities have to be developed far beyond those we know today. Here we present the recently developed Quantum Orchestration Platform (QOP) allowing for general multi-qubit protocols to be run. The QOP is a scalable system designed to support hybrid quantum-classical algorithms with the outlook to FTCC, and is optimized for driving multiple qubits simultaneously as well as performing complex readout schemes and branching based on readout results with ultra-low latency feedback. In this talk, we will show examples for quantum-error-correction protocols and demonstrate how they are programmed and run with the QOP.

9:36AM R68.00009: High-Fidelity, Scalable Quantum-Classical Control Interface using Photonics*  JACKY CHAN (Presenter), APURVA S. GOWDA, PETER T. S. DEVORE, BRANDON W. BUCKLEY, JONATHAN L DUBOIS, JASON CHOU, Lawrence Livermore Natl Lab — Quantum computing (QC) has been hailed as the next big leap for the digital age; however, state-of-the-art QC devices have yet to surpass classical computers. One bottleneck is in the number of quantum operations that can be done within a qubit lifetime, also known as the "circuit depth". The circuit depth on current hardware is limited to 10-100 operations due to uncontrolled coupling to the classical environment, infidelities in the qubit operations and the gate operation time. Effective control signal generation is essential to extending the circuit depth by improving classical control over the quantum system. To address this need, we propose an RF-photonic implementation of a QC control interface, via high-fidelity, scalable quantum drive signal generation and fiber optic transport of this signal to the qubit. By increasing the signal dynamic range and bandwidth, the time per quantum gate operation can be reduced, thus widening the circuit depth bottleneck. Additionally, replacing RF cabling with optical fiber reduces waste heat and thermalization issues, improving scalability to larger qubit systems. We show experimental results from a single-channel system and discuss its extension to a multi-channel system via simulations.

*Prepared by LLNL under Contract DE-AC52-07NA27344.
9:48AM R68.00010: Automatic single qubit characterization with QubiC*  
YILUN XU  
(Presenter), GANG HUANG, Lawrence Berkeley National Laboratory, RAVI KAUSHIK NAIK, BRADLEY MITCHELL, Physics, University of California, Berkeley, DAVID SANTIAGO, Lawrence Berkeley National Laboratory, IRFAN SIDDIQI, Physics, University of California, Berkeley — Initial setup a physical qubit is a complex procedure which involve multiple instruments and multiple experiments and optimization. After the initial setup, they still need to be carefully calibrated routinely because the qubit is sensitive to the environment and the qubit itself can have slow drift so as to impact the gate fidelity.

The Qubit Control system (QubiC) combines the high-speed pulse generation, data acquisition, parallel processing, and deterministic high-throughput data exchange together through the FPGA. Based on this feature, we propose a single qubit characterization and gate optimization protocol which automatically find and tune the qubit. The automatic calibration executes a full suite of serialized and recursive tasks from initial device bring-up to qubit setup to gate optimization in few hours.

*This work was supported by the U.S. Department of Energy, Office of Science, Office of High Energy Physics, under Contract DEAC02-05CH11231.

10:00AM R68.00011: Optimal Control of Superconducting Qubits*  
MAX WERNINGHAUS  
(Presenter), DANIEL EGGER, IBM Research - Zurich, FEDERICO ROY, SHAI MACHINES, FRANK WILHELM, Saarland University, STEFAN FILIPP, IBM Research - Zurich — Fast and accurate two-qubit gates are a key requirement to perform complex algorithms on current quantum computers. Ideally, the duration of the gate should be much shorter than the coherence time of the system. However, shorter gates can result in unwanted loss of states from the computational subspace.

Optimal control theory aims to design fast control pulses suppressing such side effects of the driving field. Even with an accurately calibrated system model, control pulses require a tune-up to accommodate for parameter-drifts and model-inaccuracies. Here we present our work on optimal control algorithms, using a closed loop approach with direct experimental feedback to design complex pulses. This approach avoids errors from an inaccurate initial system model and uses information gained during the pulse optimization to update the model. We improve the interplay of control instruments and multidimensional optimization algorithms to speed up the tune-up of feedback-loops, reducing evaluation times from several minutes to a few seconds. With these measures, we achieve a reduction of gate errors by more than a factor of five for short pulses.

*we acknowledge the support of the European Commission Marie Curie ETN “QuSCo” (GA N°765267)
The promise of quantum computers is that certain computational tasks might be executed exponentially faster on a quantum processor than on a classical processor. A fundamental challenge is to build a high-fidelity processor capable of running quantum algorithms in an exponentially large computational space. Here we report the use of a processor with programmable superconducting qubits to create quantum states on 53 qubits.

We create ergodic dynamics by applying a sequence that alternates between a randomly chosen single-qubit gates and an entangling two-qubit gate. Measuring the output of these quantum circuits amounts to sampling from the underlying probability distribution and produces a set of bitstrings. We verify that the quantum processor is working properly using a method called cross-entropy benchmarking, which compares how often each bitstring is observed experimentally with its corresponding ideal probability computed via simulation on a classical computer. We discuss the computational complexity of the sampling problem and show how the results of computation in a $10^{16}$ dimensional Hilbert space can be verified. Furthermore, we demonstrate how our processor is programmable by showing how various algorithms can be implemented.

10:48AM R68.00013: Calibration of flux crosstalk in flux qubit based quantum annealers with persistent current readout devices*

XI DAI (Presenter), ANTONIO JAVIER MARTINEZ, DANIEL M TENNANT, DENIS MELANSON, ALI YURTALAN, SALIL BEDKIHAL, YONGCHAO TANG, University of Waterloo, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, RABINDRA DAS, DAVID K KIM, JONILYN YODER, STEVEN WEBER, ANDREW JAMES KERMAN, MIT Lincoln Laboratory, SERGEY NOVIKOV, STEVEN M DISSELER, JAMES I BASHAM, JEFFREY GROVER, Northrop Grumman, EVGENY MOZGUNOV, DANIEL A LIDAR, University of Southern California, ADRIAN LUPASCU, University of Waterloo — Quantum annealing with superconducting flux qubits requires reliable control of externally applied magnetic fluxes. We present results on the calibration of flux crosstalk in a device consisting of two flux qubits coupled by a chain of seven couplers. The device has 27 superconducting loops and 27 bias lines. The method relies on the use of flux detectors formed of RF-SQUID terminated waveguide resonators, attached to each qubit and coupler. An iterative version of the method is demonstrated, which is more tolerant to errors arising from persistent currents in the complete circuits. The ability to perform reliable crosstalk calibration and compensation allows maintaining high coherence qubit designs and eliminates overhead in designs that are robust against crosstalk. We discuss future extensions of this work, relevant for large scale annealing control.

8:00AM R70.00001: Predicting γ'-Phase Stability in Co-Based Superalloys*  
HAYDEN SCOTT OLIVER (Presenter), CHANDRAMOULI NYSHADHAM, BRAYDEN BEKKER, GUS HART, Brigham Young Univ - Provo — The discovery of a cobalt-based γ/γ'-forming superalloy in 2006 inspired our computational investigation of the Co-Al-W system. We use the Moment Tensor Potentials (MTP) active-learning framework to predict the total energy, forces, and stresses for nearly 300,000 derivative superstructures in the Co-Al-W system. We report several new structures on the convex hull with the ordered L1_2-Co_3(Al, W) crystal structure, which may correspond to the experimentally discovered γ' phase. Small additions of tantalum, titanium, and vanadium lower the formation enthalpy of the L1_2 structure, which could act as γ' stabilizers at high temperature. While the total cost of the MTP analysis is about 1/1000th the cost of a similar result using DFT, the difference between calculated and predicted results is less than 3 meV/atom. MTP can be used for high-throughput phase stability analysis for many kinds of materials, such as high-temperature superalloys, multi-principle element alloys, high-Tc magnetic materials, superhard materials, and electrochemical materials.

8:12AM R70.00002: Elastic properties of the Ni-containing metallic glasses.*  
OLEKSIY SVITELSKI (Presenter), DANIELLE DUGGINS, DAVID S LEE, Gordon College, Wenham MA, ALEXEY SUSLOV, National High Magnetic Field Laboratory, Tallahassee FL — Several different acoustic techniques can be used to determine the elastic constants of a material. We use resonant ultrasound spectroscopy (RUS) and acoustic pulse-echo (APE) to investigate the elastic properties of Ni_{71.5}Cr_{5.6}Nb_{3.4}P_{16.5}B_{3}, a bulk metallic glass alloy (Ni-BMG). The sample was made by a counter-gravity suction casting technique. Modeling of the measured spectrum of acoustic resonances for the sample in its cylindrical geometry was done with finite element analysis (FEA). FEA gives a longitudinal modulus (C11) of 300 GPa, and a Youngs modulus (C44) of 50 GPa (+/-5%). We compare these values with literature values for other Ni-bearing bulk metallic glass alloys.

Undercooling of gold nanodroplets levitated in a quadrupole ion trap in high vacuum

Joyce Coppock (Presenter), Quinn Waxter, José Hannan, Samuel Klueter, University of Maryland, College Park, Hope Reynolds, Montgomery Blair High School, Maryland, Gregory Schare, Columbia University, New York, Bruce E Kane, Laboratory for Physical Sciences, 8050 Greenmead Dr., College Park, MD 20740 — A nanoparticle levitated in vacuum has minimal thermal contact with its surroundings and can be heated efficiently with a laser beam. Precise control of the temperature of a levitated particle could facilitate thermodynamic measurements of materials with very high melting points. To establish such a measurement technique using a well-characterized material, we levitate a charged 200 nm gold nanoparticle in an AC quadrupole electric field trap in a vacuum chamber and use a 532 nm laser to illuminate and heat it. Accurate measurements of the mass of the particle are used to deduce the internal temperature of the particle from the rate of mass erosion. We have observed undercooling of gold particles, a phenomenon in which a melted droplet remains liquid when cooled below the usual freezing temperature. In our preliminary measurements, particles have remained liquid to temperatures around 190 K below the freezing point and have persisted in this state in excess of two minutes without refreezing. We will discuss progress toward the precise control of the temperature of a gold nanoparticle and prospects for the measurement of other materials.

Thermodynamic theory of crystal plasticity – formulation and application to fcc copper

Charles Lieou (Presenter), Los Alamos National Laboratory, Curt A Bronkhorst, University of Wisconsin-Madison — We present a thermodynamic description of crystal plasticity. Our formulation is based on the thermodynamic dislocation theory (TDT) of Langer et al., which asserts the fundamental importance of an effective temperature that describes the state of configurational disorder and therefore the dislocation density of the crystalline material. We extend the TDT description from isotropic plasticity to crystal plasticity with many slip systems. Finite-element simulations show favourable comparison with experiments on polycrystal fcc copper under uniaxial compression. The thermodynamic theory of crystal plasticity thus provides a thermodynamically consistent and physically rigorous description of dislocation motion in crystals. We also discuss new insights about the interaction of dislocations belonging to different slip systems.
8:48AM R70.00005: Ab initio studies of TiPd-M (M= Os, Ru, Co) high temperature shape memory alloys*
RAMOGHLO DIALE (Presenter), Materials Modelling Centre, Private Bad x1106, Polokwane, South Africa, University of Limpopo, ROSINAH MODIBA, Future Production: Manufacturing, PO Box 395, Pretoria, 0001, South Africa, CSIR, PHUTI NGOEPE, HASANI CHAUKE, Materials Modelling Centre, Private Bad x1106, Polokwane, South Africa, University of Limpopo — The TiPd alloy has a potential for high temperature shape memory applications due to its martensitic transformation capability from B2 to B19 at 823 K. Previous studies indicated that B2 TiPd is unstable displaying a negative C at room temperature. In order to improve its properties, the effects of partial substitution of Pd with either Os, Ru or Co were investigated using density functional theory. The calculations are carried out within PBE-GGA for the exchange correlation functional. It was found that the heats of formation decrease with an increase in Os and Ru concentration and increases with Co addition. The ductility of TiPd-M (M= Os, Ru and Co) is predicted using Pugh’s ratio, Poisson’s ratio and Cauchy pressure. It was found that the structures showed positive C above 18.75 at. % Os, 20 at. % Ru and 31 at. % Co, displaying condition of stability. The calculated moduli confirm that alloying with Os effectively increases hardness and ductility better compared to Ru and Co. Partial substitution of Pd with Os and Ru was found more effective as a strengthening elements and may enhance the martensitic transformation temperature of B2 TiPd alloy.

9:00AM R70.00006: First-Principles Study on the Role of Doped In in Fe–Pd–In Systems
YASUTOMI TATETSU (Presenter), University Center for Liberal Arts Education, Meio University, KENSHI MATSUMOTO, RYOTA SATO, TOSHIHARU TERANISHI, Institute for Chemical Research, Kyoto University — Electronic states, for example, atomic positions, orbital hybridization, etc. determine crystal structures and these physical properties. The most stable crystal structure of binary Fe–Pd systems is known as a \( L_1^2 \)-type crystal structure[1, 2]. However, according to our latest experimental studies, a new Mille-feuille-like Fe–Pd structure is synthesized by adding a small amount of In, implying that In is the key to stabilizing the new system.
We performed first-principles calculations for the In-doped FePd\(_3\) systems in order to understand the role of In in terms of its stability. There are two symmetrically different sites for Pd in the new system, which are labeled e and g, and In prefers the e site. This result is consistent with our recent experiments. From our analysis, we find that the distance between Fe, Pd, and In is the key factor in stabilizing the new system.
9:12AM R70.00007: Molecular Dynamics (MD) Potential Development for Carbides

TYLER MCGILVRY-JAMES (Presenter), MUZTOBA RABBANI, Department of Physics, Astronomy, and Materials Science, Missouri State University, NIRMAL BAISHNAB, Department of Physics and Astronomy, University of Missouri, PUJA ADHIKARI, SARO SAN, Department of Physics and Astronomy, University of Missouri-Kansas City, ANDREW IAN DUFF, Daresbury Laboratory, Science and Technology Facilities Council, WAI-YIM CHING, Department of Physics and Astronomy, University of Missouri-Kansas City, RIDWAN SAKIDJA, Department of Physics, Astronomy, and Materials Science, Missouri State University — We utilized the reference-free (RF) MEAMfit code to generate many-body potentials of Embedded Atom Method (EAM) and Modified Embedded Atom Method (MEAM) for a variety of MC (M = Transition Metals, C = Carbon) systems with an emphasis on the M23C6 and MC carbide phases. These phases are the key ingredients to strengthen the Ni-based Superalloys at the grain boundary. By sampling of the results of energy, stress and force data from the DFT calculations, a set of transferable potentials can be produced and be utilized to model the mechanical properties of these carbides.

*Funding from DOE (NETL) Grant No. FE0031554 (Crosscutting Research Program) is gratefully acknowledged.

9:24AM R70.00008: Developing the Modified Embedded Interatomic Potential for Atomistic Simulations in Ni-Ti-Hf System

MEGHNATH JAISHI (Presenter), GARRITT TUCKER, AARON P. STEBNER, Mechanical Engineering, Colorado School of Mines — The NiTiHf alloy, owing to its superior mechanical behavior over the parent alloy NiTi (nitinol) has received a considerable attention in recent years as a promising alternative for shape memory and super-elastic applications. The substantial mechanical strength, and wide variability in martensitic transformation temperature of NiTiHf shape memory alloy have enabled its applications in numerous sectors ranging from bio-medical to aviation industries. However, the lack of atomic level understanding during its micro-structural engineering is inhibiting its further applicabilities. To unlock the atomic level information for an efficient shape memory application requires an interatomic potential to perform the atomistic simulations with a high predictive accuracy. Herein, we discuss the development of an optimized interatomic potential for NiTiHf system within the framework of modified embedded atom method (MEAM).
9:36AM R70.00009: Accelerating the computational design of multi-principle element alloys*  DUANE D JOHNSON (Presenter), RAHUL SINGH, PRASHANT SINGH, AAYUSH SHARMA, Ames Lab, GANESH BALASUBRAMANIAN, Lehigh University, PA — We present a metaheuristic hybrid Cuckoo-Search (CS) algorithm that overcomes NP-hard global optimization and produces ultrafast solutions for large-dimensional combinatorial problems, using Levy flights (global) and Monte Carlo (local) searches, which avoids local-minima traps that stagnate solutions. The hybrid-CS removes a roadblock to computational materials design of arbitrary MPEAs by enabling \`on-the-fly\' construction of optimized Super-Cell Random Approximates (SCRAPS) with extraordinary reduction in solution times, scaling linear with cell size and exhibiting strong scaling for parallel solution. For example, a 4-element, 128-atom cell [10^{73}+ space] in 45s or 5-element, 500-atom cell [10^{415}+ space] in 270s. For a 4-component 128-atom model, we find a factor of 12,600+ reduction in parallel [400+ in serial] execution over current limited strategies. SCRAPS has specified point and pair probabilities with proper Gaussian distributions. We present several example applications using electronic-structure-based energetics and phonons.

*Supported by the U.S. DOE, Office of Science, Basic Energy Sciences, Materials Science & Engineering Division. Work was performed at Ames Laboratory, which is operated by Iowa State University for the U.S. DOE under contract #DE-AC02-07CH11358.

9:48AM R70.00010: Ab initio typical medium theory of substitutional disorder*  ANDREAS OESTLIN (Presenter), Augsburg University, YI ZHANG, avli Institute for Theoretical Sciences, Beijing 100190, China, HANNA TERLETSKA, Middle Tennessee State University, VOICU POPESCU, Sophie-Scholl-Gymnasium Oberhausen, 46145 Oberhausen, Germany, KRZYSZTOF BYCZUK, Institute of Theoretical Physics, Faculty of Physics, University of Warsaw, Poland, LEVENTE VITOS, Uppsala University, SE-75121 Uppsala, Sweden, MARK JARRELL, Louisiana State University, Baton Rouge, Louisiana 70803, DIETER VOLLHARDT, Augsburg University, FLORIAN BEIUUSEANU, Faculty of Science, University of Oradea, RO-410087 Oradea, Romania, LIVIU CHIONCEL, Augsburg University — By merging single-site typical medium theory with density functional theory we introduce a self-consistent framework for electronic structure calculations of materials with substitutional disorder which takes into account Anderson localization. The scheme and details of the implementation are presented and applied to the hypothetical alloy Li_{1-c}Be_{c}, and the results are compared with those obtained with the coherent potential approximation. Furthermore we demonstrate that Anderson localization suppresses long-range magnetic order for a very low concentration of (i) carbon impurities substituting oxygen in MgO_{1-c}C, and (ii) manganese impurities substituting magnesium in Mg_{1-c}Mn_{c}O for the low-spin magnetic configuration.

*U.S. Department of Energy, Award Number DE-SC0017861 DFG, (German Research Foundation) - Projectnumber 107745057 - TRR 80/F6
10:00AM R70.00011: Prediction of Stability, Short-range Order, and Phase Selection in Multi-Principal-Element-Alloys*  PRASHANT SINGH (Presenter), ANDREY V. SMIRNOV, Ames Lab, PRATIK K RAY, Indian Institute of Technology Ropar, India, MATTHEW J KRAMER, Ames Lab, SEZER PICAK, Texas A&M University, College Station, TX, YURIY I. CHUMLYAKOV, Tomask State University, RAYMUNDO ARROYAVE, Texas A&M University, College Station, TX, K.G. PRADEEP, Indian Institute of Technology, Madras, India, IBRAHIM KARAMAN, Texas A&M University, College Station, TX, DUANE D JOHNSON, Ames Lab — We present the capabilities of KKR-CPA-based stability and short-range order (SRO) prediction in multi-component solid-solution alloys for general lattices. The refractory-based Al$_x$TiZrHf and Cantor-type FeMnCoCr are chosen to showcase the powerful predictive capabilities and insights found from our electronic-structure-based thermodynamic linear-response method. For Al$_x$TiZrHf (x=1) we discovered a vacancy-mediated mechanism for phase selection driven by vacancy-atom SRO. Our X-ray diffraction data finds a variant of gamma-brass with 4 vacancies per cell (not 2, as in typical brasses), which was indicated by the calculated SRO. For fcc FeMnCoCr, we monitor energy, stacking fault energy, and SRO and find quantitative agreement with single-crystal data.

*Supported by the U.S. DOE, Office of Science, Basic Energy Sciences, Materials Science & Engineering Division. Work was performed at Ames Laboratory, which is operated by Iowa State University for the U.S. DOE under contract #DE-AC02-07CH11358. We also acknowledge the NSF grant no. 1729350 (DMREF).

10:12AM R70.00012: Synthesis of nanocrystalline Mg-based alloy powders by mechanical alloying and their microstructural characterization  CELAL KURSUN (Presenter), DAN J. THOMA, JOHN H. PEREPEZKO, Materials Science and Engineering, University of Wisconsin - Madison — Nanocrystalline Mg$_{65}$Ni$_{25}$Y$_{5}$M$_{5}$ (M= Si, B, Ag) alloys have been produced by mechanical alloying from mixtures of pure crystalline Mg, Ni, Y and M powders using a Spex Industries Mill Model 8000 in order to characterize the influence of Si, B and Ag on the microstructure of Mg-Ni-Y alloy system. Microstructural evolution, thermal behavior and morphological changes of the mechanically alloyed powders at different stages of milling have been investigated using a variety of analytical techniques including x-ray diffraction (XRD), scanning electron microscopy (SEM), energy dispersive spectrometry (EDX), differential scanning calorimetry (DSC) and transmission electron microscopy (TEM). The present results revealed that the crystallite size of Mg$_{65}$Ni$_{25}$Y$_{5}$M$_{5}$ (M= Si, B, Ag) powders decreased with increasing milling time and it was determined in the range of 18–30 nm by TEM observation. After 65 h of milling, different intermetallic phases such as Mg$_{24}$Y$_{5}$, MgB$_{2}$, Mg$_{2}$Ni and Mg$_{2}$Ni$_{3}$Si were obtained. According to SEM images, particle size of the powders decreased during mechanical alloying and their shape and distribution became uniform. The compositional homogeneity of the Mg$_{65}$Ni$_{25}$Y$_{5}$M$_{5}$ (M= Si, B, Ag) alloys after mechanical alloying were confirmed by EDX analyses.
**10:24AM R70.00013: Ab initio investigation of Pb-based solder replacements**  
MICHAEL WOODCOX (Presenter), Physics, Binghamton University, JOSHUA YOUNG, Chemical and Materials Engineering, New Jersey Institute of Technology, MANUEL SMEU, Physics, Binghamton University — Alloys have been the focus of a large amount of research across different disciplines due to the ability to manipulate inherent properties of different materials. Due to the tunable nature of these materials, industrial needs can be more readily met with materials that are designed towards a specific purpose, as opposed to bulk materials that may not fit a unique need. One specific area that can be satisfied through the alloy process is the removal of industrial components that are harmful to humans, or their environment, with alloys that are equally effective. In this work, we have used density functional theory (DFT) and *Ab Initio* Molecular Dynamics (AIMD) to model materials at temperatures below and above their melting points. From these simulations, we are able to calculate the temperature dependence of the mechanical properties of materials which increases the quantitative understanding of the physical nature of ductility and how these properties can be captured on short time scales using first principles techniques.

---

**10:36AM R70.00014: The Temperature Evolution of Dislocation Dynamics in Aluminum**

LEORA DRESSELHAUS-COOPER (Presenter), Lawrence Livermore Natl Lab, PHIL COOK, BOKU, CAN YILDIRIM, CEA Grenoble, HUGH SIMONS, DTU, CARSTEN DETLEFS, ESRF, HENNING FRIIS FRIIS POULSEN, DTU, JON HENRY EGGERT, Lawrence Livermore Natl Lab — A material’s response to its surroundings depends on both its native properties and the imperfections (defects) in its structure. While techniques exist to probe material defects, they are mainly limited to surface measurements or rastered scans that cannot measure the dynamics of irreversible processes. Dark-field X-ray microscopy can now directly image defects in single- and poly-crystals, resolving the lattice tilt and inclination with high sensitivity over long length-scales. I extend this novel technique to time-resolved studies that measure real-time movies to visualize how dislocations evolve at thermal equilibrium. These movies resolve the creep dynamics of dislocations in high-purity single-crystal aluminum, directly measuring their mobility and interactions by measuring the strain with $10^{-5}$ resolution over hundreds of micrometers. Our results directly measure the dislocation velocity as a function of temperature, covering the final 6% of temperatures for $T < T_{\text{melt}}$. These findings have important implications for dislocation models that have relied on multi-scale modeling and indirect measurements.

11:15AM S01.00001: Exploring synthetic quantum matter in superconducting circuits [Invited]
RUICHAO MA (Presenter), Purdue University — Superconducting circuits have emerged as a competitive platform for quantum computation, satisfying the challenges of controllability, long coherence and strong interactions. Here we apply this toolbox to the exploration of strongly correlated quantum materials made of microwave photons. I will present our recent results on a new approach for preparing photonic many-body phases, where engineered dissipation is used as a resource to protect the fragile quantum states against intrinsic losses [1]. We build a strongly interacting Bose-Hubbard lattice and realize a dissipatively stabilized Mott insulator of photons. The dynamics of thermalization towards the Mott phase is probed using lattice-site- and time-resolved microscopy. In a separate experiment, we create Chern insulator lattices for microwave photons and observe topologically protected edge states [2]. I will discuss future directions to stabilize strongly correlated photonic states, study many-body dynamics in driven-dissipative settings, and engineer topological lattices to explore strongly interacting topological phases and realize robust encoding and transport of quantum information.

11:51AM S01.00002: Listening to Bulk Crystalline Vibrations with Superconducting Qubits*
VIJAY JAIN (Presenter), TAEKWAN YOON, CHAN U LEI, YIWEN CHU, LUIGI FRUNZIO, PETER T RAKICH, ROBERT SCHOELKOPF, Yale University — Superconducting circuits are a versatile platform for quantum computing owing to their scalability and reconfigurability, integration with high quality microwave resonators, and demonstrated ease in interfacing with hybrid quantum platforms. Recent work has demonstrated strong coupling to long-lived phonons of bulk acoustic waves (BAWs) of pristine crystalline substrates [1]. Despite achieving single-phonon control, a superconducting qubit piezoelectrically coupled to BAWs had a significantly reduced lifetime (T₁ = 7 us) compared to a naked transmon qubit (T₁ = 40 us), suggesting that uncontrolled coupling to BAW modes may be complicit in the qubit’s decoherence.

Here, we use the lifetime of a superconducting qubit to measure the local density of acoustic states in sapphire as a proxy for electro-mechanical decoherence. Varying the crystalline geometry can be used to systematically modify the qubit’s lifetime in order to ascertain how the coupling geometry leads to a mechanical Purcell effect. Our work offers insights into the design of compact quantum memories based on BAW resonators.

*We acknowledge support from US Dept of Energy Grant Nr. DE-SC0019406 and the Max Planck Research Award from the Alexander von Humboldt Foundation.
12:03PM S01.00003: Strong coupling of two individually controlled atoms via a nanophotonic cavity*  
PALOMA L OCOLA (Presenter), POLNUP SAMUTPRAPHOOT, TAMARA DORDEVIC, Harvard University, HANNES BERNIEN, University of Chicago, CRYSTAL SENKO, University of Waterloo, VLADAN VULETIC, Massachusetts Institute of Technology, MIKHAIL LUKIN, Harvard University — We demonstrate photon-mediated interactions between two individually trapped atoms coupled to a nanophotonic cavity. Specifically, we observe collective enhancement when the atoms are resonant with the cavity, and level repulsion when the cavity is coupled to the atoms in the dispersive regime. Our approach makes use of individual control over the internal states of the atoms, their position with respect to the cavity mode, as well as the light shifts to tune atomic transitions individually, allowing us to directly observe the anti-crossing of the bright and dark two-atom states. These observations open the door for realizing quantum networks and studying quantum many-body physics based on atom arrays coupled to nanophotonic devices.

*This work was supported by the Center for Ultracold Atoms, the National Science Foundation, AFOSR MURI, Vannevar Bush Faculty Fellowship, and ARL CDQI.

12:15PM S01.00004: Generating multipartite entangled states with Cavity Rydberg Polaritons*  
HADISEH ALAEIAN (Presenter), TILMAN PFAU, University of Stuttgart — Polaritons are superpositions of matter and photon states, whose effective masses are from the photonic part and their interactions originate from their matter part. While the small mass of the photons allows for observing quantum effects at higher temperatures, even up to the room temperature, the interaction allows creating collective many-body effects. In this work, I introduce a new type of quasi-particles called cavity-Rydberg polariton, with large interaction inherited from their strongly-interacting Rydberg constituents. In particular, I will show how this dipole-dipole interaction can be utilized to induce large non-linearity between discrete modes of an optical cavity. A property that can be further utilized to generate bipartite and tripartite entangled photons.

*IQST Young Investigator Award and Baden-Württemberg Foundation
12:27PM S01.00005: Parity switching in a semiconductor-based transmon qubit*  DEIVIDAS SABONIS (Presenter), OSCAR ERLANDSSON, ANDERS KRINGHØJ, Univ of Copenhagen, BERNARD VAN HECK, THORVALD LARSEN, TORSTEN KARZIG, DMITRY I. PIKULIN, PETER KROGSTRUP, KARL PETERSSON, Microsoft, CHARLES MARCUS, Univ of Copenhagen — Unpaired quasiparticles can adversely affect the performance of superconducting devices, including qubits based on Majorana zero modes. We study charge parity switching in a superconductor-semiconductor nanowire-based transmon device that shows Little-Parks oscillations of its frequency as a function of magnetic field. In the recovery regime, where a single flux quantum threads the cross-section of the wire transport measurements recently revealed signatures compatible with Majorana zero modes [1].

We read out the charge parity by dispersive monitoring of a readout resonator to which the transmon qubit is coupled. At zero magnetic field, we measure parity switching times in the range of 10-100 ms. As the magnetic field is increased toward the first closing of the superconducting gap, the switching time is decreased and is consistent with the superconducting gap reduction. In the recovery regime where the gap is re-opened, the switching time is reduced below the sensitivity of our measurement, putting a bound on the minimum observable Majorana hybridization energy in a full-shell nanowire system.

Suppression of charge dispersion by resonant tunneling in a single-channel transmon qubit

ANDERS KRINGHØJ (Presenter), Microsoft Quantum Lab Copenhagen and Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Universitetsparken 5, 2100 Copenhagen, Denmark, BERNARD VAN HECK, Microsoft Quantum Lab Delft, Delft University of Technology, 2600 GA Delft, The Netherlands, THORVALD LARSEN, OSCAR ERLANDSSON, DEIVIDAS SABONIS, Microsoft Quantum Lab Copenhagen and Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Universitetsparken 5, 2100 Copenhagen, Denmark, PETER KROGSTRUP, Microsoft Quantum Materials Lab and Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Kanalvej 7, 2800 Kongens Lyngby, Denmark, LUCAS CASPARIS, KARL PETERSSON, CHARLES MARCUS, Microsoft Quantum Lab Copenhagen and Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Universitetsparken 5, 2100 Copenhagen, Denmark — Motivated by the importance of understanding the underlying charge physics in superconducting qubits, we investigate the charge dispersion of a gate-controlled nanowire-based transmon. When approaching the pinch-off regime of the nanowire junction, we observe resonant behavior of the plasma frequency, which we attribute to the formation of a quantum dot in the junction. By measuring the charge dispersion while crossing a resonance, we observe that it is suppressed far below the range expected for a conventional transmon at comparable values of the Josephson and charging energies. The enhanced suppression can be explained and quantitatively modeled by the presence, at resonance, of a single transport channel with near-unity transmission. Our results establish an experimental validation of the theory of Coulomb oscillations in Josephson junctions in a previously unexplored regime. In addition, these results show that charge dispersion can be suppressed without the necessity of large $E_J/E_C$ ratios, potentially allowing a very large qubit anharmonicity.

This work was supported by Microsoft and the Danish National Research Foundation.

Efficient microwave measurement of superconducting optomechanical circuits

GABRIEL PETERSON (Presenter), University of Colorado, Boulder, SHLOMI KOTLER, FLORENT LECOCQ, KATARINA CICAK, X. Y. JIN, RAYMOND W SIMMONDS, JOSE AUMENTADO, JOHN TEUFEL, National Institute of Standards and Technology — Optomechanical interactions between electromagnetic modes and mechanical resonators have proven to be a valuable testbed for measurement and control of linear quantum systems. In this context, the light is considered as a meter that probes and influences the quantum state of the mechanical object. Reaching quantum limits of measurement and control therefore requires both that the optomechanical coupling overwhelms any decoherence and that the light is measured with sufficiently high efficiency. In microwave optomechanical systems, the first requirement has been demonstrated, but the second remains an experimental challenge, with state-of-art continuous linear measurements of microwave fields struggling to exceed 50% efficiency. Here I report recent progress to increase microwave measurement efficiencies to enable new regimes of ponderomotive squeezing and displacement sensing beyond the standard quantum limit.
1:03PM S01.00008: A Scalable Nanophotonic Platform for Rare Earth Ions* SUBHOJIT DUTTA (Presenter), University of Maryland, College Park, ELIZABETH GOLDSCHMIDT, Physics, University of Illinois, SABYASACHI BARIK, UDAY SAHA, EDO WAKS, University of Maryland, College Park — Rare earth ion ensembles doped in single crystals are a promising platform with widespread applications in optical signal processing, lasing and quantum information processing. The ability to engineer nanoscale patterns surrounding these ions would enable strong light matters interaction and open possibilities for a new generation of photonic devices. We present a new nanophotonic platform with Thulium ions doped in single crystal Lithium niobate thin films on insulator, that supports scalable top down fabrication. The ions in the thin film retain bulk like optical properties. We show spectral hole burning in a nanophotonic waveguide with powers upto 2 orders of magnitude lower than previously reported bulk waveguides. Such a platform paves way for on chip lasers and efficient ensemble quantum memories. The high electro-optic coefficient of lithium niobate coupled with densely patterned electrodes promises large stark tuning which may be useful for ensemble quantum memory protocols like CRIB. Lastly strong light matter interaction can lead to Purcell enhancement and the ability to isolate single ions as a long lived qubit.

*National Science Foundation (Award No. EFMA1741651)

1:15PM S01.00009: Spin-photon interfaces based on tin-vacancy centers in diamond MATTHEW TRUSHEIM (Presenter), Harvard University, LORENZO DE SANTIS, KEVIN CHEN, Massachusetts Institute of Technology, CHRISTOPHER CICCARINO, Harvard University, DIRK R. ENGLUND, Massachusetts Institute of Technology, PRINEHA NARANG, Harvard University — Color centers in diamond are quantum systems that can combine long-lived spin degrees of freedom with coherent optical transitions for applications in quantum networks and information processing. The tin-vacancy (SnV) center in diamond in particular combines the characteristic inversion symmetry of the Group IV-vacancy complexes with a large spin-orbit splitting of its ground-state orbitals, enabling the demonstration of long spin coherence times at accessible temperatures. Several challenges remain in the application and understanding of these centers, including a complete theoretical description of the electronic structure, universal spin control, and the engineering of efficient light-matter interaction. Here we discuss theoretical and experimental work towards coherent spin-photon interfaces based on SnV centers at liquid-helium temperatures.
1:27PM S01.00010: Investigating Microwave Raman Transitions Beyond the Rotating Wave Approximation in the Electronic Ground State of the Nitrogen-Vacancy Center  FLORIAN BÖHM (Presenter), NIKO NIKOLAY, SASCHA NEINERT, BERND SONTHEIMER, OLIVER BENSON, Humboldt University of Berlin — Up to now, spin manipulation experiments with the NV center were mostly limited to applying subsequent monochromatic microwave pulses, manipulating only single electronic transitions at a time. In our work we explore the possibility of applying multitone microwave pulses, allowing a full simultaneous control of all three electronic ground states of the NV center. This here presented spin manipulation scheme opens up new measurement possibilities, which could be used to increase the NV center's magnetic field sensitivity.

We will present the implementation of a spin-forbidden coherent population swapping between the $m_s = -1$ and $m_s = +1$ states, without undergoing the spin allowed transition into the $m_s = 0$ state via microwave Raman transitions and compare our experimental results with theoretical calculations. These Raman transitions are operated in a regime exceeding the rotating wave approximation (RWA). This has hardly been investigated as the RWA is traditionally applied in the single atom community. Due to the short coherence times, a low detuning has to be chosen, which in turn causes fast Raman transitions and a breakdown of the RWA. An indication for this is an experimentally observed beating signal which we want to utilize for faster and more robust population swapping.

1:39PM S01.00011: Solid-state defect based quantum modules  MICHAEL HANKS (Presenter), National Institute of Informatics (NII), MICHAEL TRUPKE, Vienna Center for Quantum Science and Technology, Universität Wien, WILLIAM MUNRO, NTT Basic Research Laboratories & NTT Research Center for Theoretical Quantum Physics, NTT Corporation, KAE NEMOTO, National Institute of Informatics (NII) — The development of technology required for quantum modules is likely to form the basis of any large-scale quantum information processing device. The question of the appropriate physical implementation of such technology remains, however, unsettled. In this presentation, we compare and contrast a number of different solid-state defects – including the nitrogen-, silicon-, and germanium-vacancy centers in diamond, as well as a variety of defects in silicon carbide – according to their suitability for quantum modules based on strong coupling to optical cavities. The primary aspects forming the basis of this comparison are Hilbert space size and connectivity, optical transition contrast and branching ratios, decay lifetimes, and the capability for robust information storage across multiple failed probabilistic optical operations. Our results show several promising candidates.

Thursday, March 5, 2020 11:15 AM - 2:03 PM

Session S02 GSCCM: Dynamic Compression II: Experiments 105 - Camille Chauvin
11:15AM S02.00001: Complex loading experiments to study multiphase strength in Cerium
BRIAN JENSEN (Presenter), M9 Shock and Detonation Physics, Los Alamos National Laboratory —
Understanding the mechanical properties of materials at extreme conditions is relevant to a wide range of dynamic phenomena related to geophysics and planetary science, general solid and fluid flow behavior, and applications for ballistics and armor development, for example. Efforts in recent years have used multiple-shock and release loading to examine material strength in metals including single crystal and polycrystalline aluminum. Despite these efforts, data that describes strength effects following a shock-induced, solid-solid phase transition is lacking. In this work, complex loading experiments were analyzed to examine the strength of cerium shocked to stress states that span the low-pressure phase transition up toward the melt boundary. The experimental results and data analysis will be presented along with a discussion on their implications and future work.

EMMA MCBRIDE (Presenter), SLAC - Natl Accelerator Lab —
Although vital, the direct measurement of temperature at extreme conditions, in particular in the warm dense matter regime is challenging. We combine a cryogenic jet with a chirped short pulse laser to generated a laser-driven shock-wave with a setup for performing high-resolution inelastic X-ray scattering measurement at the Linac Coherent Light Source (LCLS) to directly measure the evolution of temperature of laser-compressed argon. We use the principle of detailed balance to determine temperature directly, from the bulk sample probed by the X-ray beam. In addition, we measure the sample density using X-ray diffraction, and estimate the sound speed at extreme conditions from a direct measurement of the dispersion curve. The techniques described are applicable across a wide range of fields of plasma and warm dense matter science.

11:39AM S02.00003: Toward predictive pulsed power loss estimates to ensure dynamic materials properties experiment success*
ANDREW PORWITZKY (Presenter), BRIAN HUTSEL, Sandia National Laboratories — Successful execution of dynamic materials properties experiments on large scale pulsed power machines can involve over-taxing the pulsed power driver. Under some circumstances, electrical loses can alter the isentropic compression path of the sample material at high pressure, resulting in shock formation or a failure to reach the desired peak pressure. Loss models based on space charge limited ion emission, enhanced by electron flow current, are beginning to demonstrate potential for predictive modeling of materials experiments. We present the state of this effort and some of the challenges inherent in the use of the ion loss model.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.
**11:51AM S02.00004: Electrical Conductivity of Tin Under Shock Conditions**  
RYAN CRUM (Presenter), MINTA C AKIN, DAVID BRANTLEY, RICKY CHAU, Lawrence Livermore Natl Lab — Electrical conductivity of materials under extreme conditions may provide the necessary information to obtain bulk temperatures, the location of phase boundaries, and pertinent knowledge for ongoing electromagnetic responses for planetary interiors. We introduce a means to study the electrical conductivity of metals, in this study tin, with an easily accessed melt boundary between 45 and 70 GPa on the principal Hugoniot. A plate impact methodology is implemented to drive the tin sample to high pressure and temperature states while the electrical resistivity and conductivity of the sample are recorded. We observe a stark jump in the electrical resistivity and conductivity associated with the melt boundary, further constraining the tin melt boundary. Through the Wiedemann-Franz law, we will address implications of whether the law holds and what the predicted temperature and thermal conductivity are under shock conditions.

*Work was performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344.

**12:03PM S02.00005: Shock Driven Dynamics on the Benchtop: Generation and Characterization with Imaging and Spectroscopy**  
DMITRO MARTYNOWYCH (Presenter), JET LEM, KEITH ADAM NELSON, Massachusetts Institute of Technology MIT — We have developed a benchtop platform to generate shockwaves in materials and monitor the ensuing material response and chemistry. A thin layer (20-100 µm) of material is pressed between two glass plates, confining it to a planar geometry. A nanosecond laser pulse is focused into a circular “ring” pattern of 180 µm radius, launching a shock wave that propagates within the plane of the sample and focuses toward the circle’s center. Using a high-speed multi-frame camera, we have been able to record up to sixteen images of a single shock event with time intervals as short as 5 ns. Employing a host of spectroscopic techniques, we can further interrogate the structural and chemical nature of the shocked sample. This single-shot method of imaging and characterizing shocked samples has allowed us to investigate a variety of chemical and physical phenomena including cavitation, structural phase transitions, and chemical reactivity/decomposition.
Determining an orientation relationship for the diffusionless hcp-bcc phase transition in Mg under dynamic loading

MATTHEW BEASON (Presenter), BRIAN JENSEN, Los Alamos National Laboratory — For years, crystallographers have sought to decompose phase transitions into a series of dilations, shears, or contractions based on fundamental symmetries between the parent and product phases. Burger’s mechanism describes the bcc-hcp phase transition through two steps: a strain in the [001]_{bcc} direction followed by an internal shear of the (110)_{bcc} planes along the [1-10]_{bcc} direction displacing every alternate plane and resulting in the hcp structure. While such mechanisms may describe certain transitions under static conditions and provide a framework for theoretical studies, it is not clear that such an orderly process is relevant for a shock driven transformation. This presentation reports on experiments performed at the Dynamic Compression Sector (DCS) on the hcp-bcc phase transition of Mg. By performing in situ X-ray diffraction (XRD) on shock loaded Mg we have captured the orientation of the bcc phase at the shock state, allowing an orientation relationship to be established with the initial hcp lattice. This represents an important first step in ongoing efforts to develop a transition mechanism for the hcp-bcc phase transition under dynamic loading.

Cellular Structures Imaged in the Detonation Front of Pure Liquid Nitromethane

ERIN NISSEN (Presenter), MITHUN BHOWMICK, DANA D DLOTT, University of Illinois at Urbana-Champaign — We developed a tabletop compression microscope, which uses laser driven flyer plates to generate 4-ns duration planar shocks in tiny cuvettes filled with the high explosive nitromethane. When the flyer velocity is 4.0 km/s, a detonation forms at a pressure of 19 GPa and a velocity of 6.25 µm/ns. We implemented a high-speed high-resolution camera in combination with photon Doppler velocimetry to watch how the reaction zone develops on the nanoscale. We captured, for the first time in pure liquid nitromethane, micron-scale structures, known as cellular structures in the detonation front. These cells are caused by a superdetonation, a shock traveling in a precompressed medium, that forms behind the shock front after a short delay. The superdetonation will collide with the original shock front and reflect transverse waves into the reacting material behind it. These waves bounce between the backwards traveling shock from the superdetonation and the shock front creating a complex reactive flow with a convoluted shock front. Applying the size of the cells measured in the front to known theory allows us to measure the reaction zone length.

*We acknowledge support from the DOE NNSA SSGF under cooperative Agreement No. DE-NA002135 and Army Research Office under W911NF-19-2-0037.
12:39PM S02.00008: Molecular Influence in Microparticle Impact Response of Elastomers
DAVID VEYSSET (Presenter), YUCHEN SUN, YOU-CHI MASON WU, STEVEN E KOOI, TIMOTHY M. SWAGER, KEITH ADAM NELSON, Massachusetts Institute of Technology MIT, ALEX J. HSIEH, Army Research Laboratory — Segmented elastomers have gained attention for their performance against high-velocity impacts through tailored segmental dynamics. The influence of molecular moieties has also been reported to be important on the dynamic behavior of polymers. In this work, we present impact measurements of laser-launched supersonic micro-particle impacts on polyurea and polyurethane elastomers. In a laser-induced projectile impact test (LIPIT), we accelerate solid microparticles to supersonic velocities up to 1 km/s through a laser-ablation process. The impact events are observed in situ using an ultra-high-speed multi-frame camera that can record up to 16 images with time resolution of each frame as short as 5 ns. We study the high-strain rate deformation response of elastomers to unravel the relation between microstructure and high-rate properties. In particular, we are interested in the influence of the nature and the extent of hydrogen bonding and the role of intermolecular interaction in the dynamic response of these polymers. We demonstrate that LIPIT is capable of quantifying the variation in dynamic stiffening observed among these elastomers upon impact at strain rate $\sim 10^8 \text{ s}^{-1}$.

12:51PM S02.00009: Hot Spot and Reaction Temperature of Insensitive High Explosives using Time-Resolved Optical Pyrometry
MEYSAM AKHTAR (Presenter), DANA D DLOTT, University of Illinois at Urbana-Champaign — The capability of time-resolved optical pyrometry of our dynamic shock microscope system enables us to explore the evolution of the hot spot and combustion temperatures of shocked insensitive high explosives with nanosecond time resolution. Primarily, we analyze plastic-bonded explosive (PBX) formulations of triaminotrinitrobenzene (TATB), 1,1-diamino-2,2-dinitroethene (FOX-7), and 2,6-Diamino-3,5-Dinitropyrazine-1-Oxide (LLM-105). These explosives are particularly interesting because they are powerful but insensitive to accidental initiation. These three insensitive explosives have a yellow color, which causes a significant absorption in the blue region of the visible spectrum. This deviation from thermal radiation complicates the pyrometry experiment and should be accounted for in the determination of the temperature.

The experiments used short-duration (4 ns) shocks using laser-launched flyer plates with velocities of 1-4.5 km/s. The dynamic shock microscope system has, in addition to the optical pyrometer, a high-speed Photon Doppler Velocimeter (PDV), high-speed imaging cameras. We have developed methods to mass-produce tiny well-characterized PBX charges in arrays with hundreds of charges. The tiny charges were 80% explosive and 20% binder.
1:03PM S02.00010: High-speed X-ray Phase Contrast Imaging Analysis of Microscale Shock Response of a Mock Additively Manufactured Energetic Material*  KARLA WAGNER (Presenter), ANDREW BODDORFF, AMIRREZA KEYHANI, GREGORY B. KENNEDY, Georgia Inst of Tech, DIDIER MONTAIGNE, Eglin Air Force Research Lab, MIN ZHOU, NARESH N THADHANI, Georgia Inst of Tech — X-ray phase contrast imaging (XPCI) is used to probe the interior of a mock additively manufactured energetic material (AMEM) under dynamic loading and determine the equation of state (EOS). AMEMs have a range of structural characteristics with a hierarchy of length scales and process-inherent heterogeneities. Many of these features are difficult to precisely control or avoid and it is important to understand how they affect the dynamic response of the AMEM. To this effect, XPCI is a technique that grants insight into micro- and meso-scale processes during a shock event. We use XPCI results to analyze the shock response of a mock AMEM loaded in different directions at several impact conditions. By tracking displacement of the shock front and features behind it, we can determine shock velocity and particle velocity. PDV was also used to measure the free surface velocity of the specimens and from that the particle velocities, which correlate well with those obtained from XPCI. The shock and particle velocity EOS is found to approximately follow \( U_s = 1.63U_p + 2619 \) with \( R^2 = 0.8 \). The experiments presented were performed at the DCS in the APS at Argonne National Lab, in collaboration with Brian Jensen at Los Alamos National Lab.

*This project is funded by DTRA grant HDTRA-18-1-004.

1:15PM S02.00011: Quantitative Assessment of the Interior Deformation of an Additively Manufactured Energetic Material Simulant under Shock Loading*  AMIRREZA KEYHANI, KARLA WAGNER, ANDREW BODDORFF, NARESH N THADHANI (Presenter), MIN ZHOU, Georgia Inst of Tech — The performance of energetic materials subjected to dynamic loading depends on the morphology of their microstructures. The geometric flexibility and versatility offered by additive manufacturing open new pathways to control the performance of these materials and functionally tailor them for given applications. Additively manufactured energetic materials (AMEM) have a wide range of microstructures with a hierarchy of length scales and heterogeneities which are difficult to control or avoid. To understand how they affect the response of such materials under shock loading, X-ray phase contrast imaging (XPCI) is used to probe the interior and quantify the deformation fields in the impacted samples. Two to four XPCI images were captured revealing the shock front and deformation. DIC analysis was then used to provide the first-ever assessment of the average strain fields inside the material under shock loading. The results show that the average axial strain in the samples depends on the intensity of shock loading and reaches as high as \( \sim 0.23 \) for impact velocities up to 1.5 m/k. The experiments presented were performed at the DCS in the APS at Argonne National Lab, in collaboration with Brian Jensen at Los Alamos National Laboratory.

*This project is funded by DTRA grant HDTRA-18-1-004.
1:27PM S02.00012: Inferring 3D Behavior of Dynamically Compressed Granular Materials from X-ray Tomography and Dynamic Radiography Measurements* ADYOTA GUPTA, KALIAT T RAMESH, RYAN HURLEY (Presenter), Johns Hopkins University — Dynamically compressed granular materials have primarily been studied using macroscopic measurements (e.g., VISAR, PDV). However, simulations and x-ray imaging measurements have revealed the rich, heterogeneous behavior occurring at the microscale during dynamic compression of granular materials: force chains, non-planar shock fronts, porosity-dependent shock velocities.

I will present the results of recent shock compression experiments performed on granular materials composed of spherical and angular particles at the Dynamic Compression Sector (DCS) of the Advanced Photon Source (APS). We integrate: (1) sample characterization with x-ray computed tomography (XRCT), (2) dynamic x-ray phase contrast imaging (XPCI) performed in situ, (3) an x-ray phase contrast or absorption image generation algorithm, and (4) an optimization algorithm to combining XRCT and XPCI to infer the time-evolution 3D particle positions. We are using this approach to understand the energy budget local heterogeneity, shock-front planarity, and porosity and inter-particle contact-network dependence of shock events.

*We acknowledge support from the Johns Hopkins University's Whiting School of Engineering and the Army Research Laboratory Cooperative Agreement Number 911NF-12-2-0022.

1:39PM S02.00013: Deviation from classical laws in shock-driven gas mixtures at moderate Mach numbers.* PETER VOROBIEFF (Presenter), HUMBERTO SILVA, CALEB WHITE, PATRICK J WAYNE, University of New Mexico — We conducted a series of experiments where planar shocks propagated through mixtures of helium and sulfur hexafluoride. Even at modest Mach numbers, the bulk temperatures and pressures measured in the shocked mixture deviated significantly from the predictions of both Dalton's and Amagat’s laws. As early as in the 1960s, it was already known that the behavior of gas mixtures in the immediate vicinity of a shock front was highly non-classical, however, our measurements show that the observed non-classical behaviors may persist far beyond the temporal and spatial scales associated with the shock passage. Simple molecular physics considerations can help explain some of the observed discrepancy. Numerical simulation of the experiments helps elucidate the observed disagreement between observations and models.

*This work was funded by NNSA grant DE-NA-0002913. We also acknowledge support from Sandia National Laboratories.
Laser-driven shock compression is a common method to study the equations of states (EOS) of materials under extreme conditions. The shock etalon method is an effective method to extract the shocked dynamic parameters of transparent materials. However, the sample surface reflection should be eliminated when using this method, which results in more time and efforts on the sample preparation. Here, we proposed a modified shock etalon method to measure the shocked dynamic parameters of transparent materials. The proposed method utilizes the \( p \)-polarized chirped probe pulse under the Brewster incident angle to eliminate the sample surface reflection, thus no extra efforts on the sample preparation are needed and can adapt the simplest solid transparent thin film samples. Simulation results show that the proposed method is feasible, accurate and robust on the shocked dynamics metrology for solid transparent materials. At last, the shock compression experiment with the proposed method is carried out on a polycarbonate thin film and the shocked dynamic parameters are obtained successfully, such as the shock velocity, the particle velocity and the shocked refractive index.

Session S07 DQI: Quantum Computing with Defects 102 - Viatcheslav Dobrovitski, Delft University of Technology
Towards fault-tolerant quantum error correction with spins in diamond

MOHAMED ABOBEIH (Presenter), JOE RANDALL, QuTech and Kavli Institute of Nanoscience Delft, Delft University of Technology, YANG WANG, QuTech, Delft University of Technology, SJOERD LOENEN, CONOR BRADLEY, QuTech and Kavli Institute of Nanoscience Delft, Delft University of Technology, BARBARA MARIA TERHAL, QuTech, Delft University of Technology, TIM HUGO TAMINIAU, QuTech and Kavli Institute of Nanoscience Delft, Delft University of Technology — Quantum error correction (QEC) is essential for reliable large-scale quantum information processing. Pioneering experiments have demonstrated QEC codes that could only correct specific types of errors using various physical platforms [1,2]. However, an experimental demonstration of a fault-tolerant QEC code that can correct any type of single-qubit error remains an open challenge. Here, I will present our progress towards the implementation of a fault-tolerant QEC code using a solid-state spin register in diamond. Recently, we have demonstrated that such a register can hold up to 10 qubits with high-fidelity universal control, coherence times up to one minute, and genuine multipartite entanglement [3]. Building upon these promising results, I will show how we can use non-destructive repeated parity measurements to encode a logical state in multiple C13 nuclear-spin qubits in diamond. These parity measurements might be further used to detect and correct arbitrary single-qubit errors on the logically encoded state, and are therefore an important step towards fault-tolerant quantum information processing.

Hardware-Efficient Quantum Error Correction with NV Center

MO CHEN (Presenter), DAVID LAYDEN, PAOLA CAPPELLARO, Massachusetts Institute of Technology MIT — The near-term intermediate-scale quantum (NISQ) era dawns with the demonstration of `quantum supremacy'. In the NISQ era, it is under debate if quantum error correction (QEC) is required. Although QEC is essential towards scalable universal quantum computation, it imposes a prohibitively high overhead for NISQ devices. To reduce the overhead, a hardware-efficient QEC approach has recently been employed and enjoyed experimental success [1]. Applying the same philosophy to our system—a quantum register consisting of one NV electronic spin and neighboring nuclear spins, we have carefully characterized the system and recently identified its dominant decoherence source [2]. Moving forward, we developed a hardware-efficient QEC code for such noise, which requires exponentially less overhead [3], and we are progressing in experiments towards one logical qubit consisting of two physical qubits.

Detection and control of large systems of nuclear-spin qubits in diamond

JOE RANDALL (Presenter), MOHAMED ABOBEIH, CONOR BRADLEY, FLORIS VAN DER GRONDEN, MAARTEN J DEGEN, HANS BARTLING, TIM HUGO TAMINIAU, Delft University of Technology — Nuclear spins in diamond are promising for their use as qubits in quantum computers and quantum networks, and for simulating many-body physics phenomena. Recently, we demonstrated the 3D imaging of a system of 27-nuclear-spin qubits using a nitrogen vacancy (NV) center in diamond [1], and a universally connected 10-qubit register formed of 9 nuclear spins combined with the NV center electron spin [2].

Building on these recent results, I will present new methods that allow us to extend control over more nuclear spin qubits. By combining precise knowledge of the nuclear spin environment with dynamic nuclear polarization techniques and selective readout protocols, we can prepare and measure individual nuclear spin qubits within a large interacting cluster. As well as extending the number of qubits available for quantum information applications, these techniques open the door to the quantum simulation of complex many-body physics phenomena using nuclear spins in diamond.

Hidden Silicon-Vacancy Centers in Diamond

CHRISTOPHER SMALLWOOD (Presenter), Physics and Astronomy, San Jose State University, RONALD ULBRICHT, Max Planck Institute for Polymer Research, MATTHEW W DAY, Physics, University of Michigan, TIM SCHRODER, Engineering and Computer Science, Massachusetts Institute of Technology, KELSEY M BATES, Physics, University of Michigan, TRAVIS AUTRY, JILA, University of Colorado and NIST, GEOFFREY DIEDERICH, Physics and Astronomy, University of Denver, EDWARD S BIELEJEC, Sandia National Laboratories, MARK SIEMENS, Physics and Astronomy, University of Denver, STEVEN THOMAS CUNDIFF, Physics, University of Michigan — Color centers in diamond—in particular, negatively charged silicon-vacancy (SiV\textsuperscript{−}) centers—have generated excitement recently as potential hardware elements in quantum networks and devices. The attention is due in part to the protective influence of diamond’s wide bandgap and weak magnetic susceptibility, and in part to the technology available for manipulating and detecting light at these photon energies. In spite of this, open questions remain concerning the optical properties of SiV\textsuperscript{−} centers and related defects, and there exist significant opportunities for elucidating these properties using nonlinear optical spectroscopy. Here we report measurements on a high-density sample of negatively charged SiV\textsuperscript{−} centers in diamond through the use of collinear optical multidimensional coherent spectroscopy (MDCS). Using the technique, we have uncovered a hidden population of centers that not typically observed in photoluminescence, and which exhibit a high degree of spectral inhomogeneity and longer-than-expected single-particle electronic $T_2$ dephasing times. The phenomenon is likely caused by strain, indicating opportunities for controllably mediating electronic coherence in color-center-based quantum devices.
Second-order Nonlinear Frequency Conversion and Integrated Color Centers in Silicon Carbide Nanophotonics

MELISSA GUIDRY (Presenter), DANIIL LUKIN, CONSTANTIN DORY, KIYOUL YANG, Stanford Univ, PRAFUL VASIREDDY, MAMDOUH NASR, EMILIO NANNI, SLAC National Accelerator Laboratory, Stanford University, JELENA VUCKOVIC, Stanford Univ — 4H-Silicon carbide photonics offer the unique prospect of monolithic generation and frequency conversion of quantum light on-chip, as the material hosts color centers with favorable spin coherence properties and has a strong second-order optical nonlinearity. We integrate single color centers into thin-film nanophotonic devices and demonstrate efficient second-harmonic generation using a doubly resonant microring resonator scheme, which may be modified for quantum frequency conversion to the telecommunications band. We introduce color centers into thin films via electron irradiation and study the optical stability of single defects.

National Science Foundation under grant number NSF/EFRI-1741660

Controlling the Silicon Vacancy in Silicon Carbide via Electric and Magnetic Fields

DANIIL LUKIN (Presenter), MELISSA GUIDRY, SHUO SUN, CONSTANTIN DORY, JELENA VUCKOVIC, Stanford Univ — The Silicon Vacancy in Silicon Carbide is an optically-active, spin-3/2 defect with a long spin coherence and potential for integration into large-scale nanophotonic circuits due to its narrow, stable optical transitions and small inhomogenous broadening. We demonstrate the optical transitions of the Silicon Vacancy are widely tunable via electric fields, which may enable multi-emitter scalability. We perform magnetic-field spectroscopy on single defects, and discuss the cavity-assisted spin-initialization protocols enabled by its fine structure.

U.S. Department of Energy, Office of Science, under Award DE-SC0019174

Computational identification of defect qubits in transition metal dichalcogenide WSe₂

JENG-YUAN TSAI (Presenter), JINBO PAN, QIMIN YAN, Physics, Temple University — Nitrogen-vacancy (NV) center in diamond serves as a leading solid-state qubit system due to its fidelity of manipulation at room temperature, while the search for novel solid-state systems with NV-like defects is highly desirable for the future development of solid-state quantum technologies. Two-dimensional solid-state systems are superior platforms to implement controlled manipulation of qubits. Our computational studies focus on point defects in WSe₂ as one of the well-known compounds in the family of transition metal dichalcogenides (TMDs). First-principle calculations based on density functional theory are adopted to study the formation energetics and electronic properties of point defects including intrinsic defects such as V₆ and Se antisite (W₆Se), and extrinsic defects such as V₆-N₆Se, V₆-P₆Se, and V₆-As₆Se. Our calculations show that both intrinsic and extrinsic defects can exhibit high magnetic moments and triplet ground states, which offer a set of defect candidates as qubits in this 2D TMD system. In addition, optical transition paths between ground and excited states will be discussed, which provide potential optical signatures for experimental verification.
12:39PM S07.00008: Probing the Coherent Spin Dynamics of Divacancies in Silicon Carbide with Spin Correlated Low-Field Magnetoresistance*  

STEPHEN MCMILLAN (Presenter), MICHAEL FLATTÉ, Univ of Iowa — Silicon carbide has attracted attention in the quantum information community due to remarkably long room temperature spin coherence times [1] and the potential for integration with the photonics and communications sectors due to divacancy energies in the near-infrared regime [2]. Isolated neutral divacancies are realizable and addressable via optically detected magnetic resonance [3]. The long coherence times of these individual deep centers suggest that they are ideal candidates for single spin sensing and quantum memory applications. We describe an approach we predict will allow exploration of the coherent spin dynamics of these divacancies through low-field magnetoresistance by addressing an individual divacancy with a spin-polarized scanning tunneling microscope (SP-STM) [4]. Measurement of the spin coherence time should be feasible and signatures of the local hyperfine interactions and single-spin exchange interactions should be resolvable.

*We acknowledge support from DOE BES through Grant No. DE-SC0016379.

12:51PM S07.00009: Site-controlled generation of tin-vacancy centers in diamond via shallow ion implantation and subsequent diamond growth*  

ALISON E RUGAR (Presenter), HAIYU LU, CONSTANTIN DORY, SHUO SUN, PATRICK J MCQUADE, ZHIXUN SHEN, NICHOLAS A MELOSH, JELENA VUCKOVIC, Stanford University — Color centers in diamond have garnered much interest in recent years as potential solid-state spin qubits. Paramount to implementing these color centers in scalable photonic systems is the development of techniques to generate high-quality, site-controlled emitters. This challenge is amplified for color centers with larger group-IV impurity atoms, which have emerged as otherwise promising emitters due to predictions of long spin coherence times without a dilution refrigerator. In the case of the tin-vacancy (SnV-) center, conventional site-controlled color center generation methods either damage the diamond surface or yield bulk spectra with unexplained features. In this talk we present a novel method to generate site-controlled SnV- centers with clean, consistent bulk spectra. We shallowly implant Sn ions and subsequently grow a layer of diamond via chemical vapor deposition. This method is compatible with nanophotonic device fabrication and can be extended to other color centers.

1:03PM S07.00010: Integrated Photonic Circuit for Generation and Isolation of Single Photons from Quantum Dot Ensembles  COREY MCDONALD (Presenter), TRAVIS AUTRY, RICHARD MIRIN, KEVIN SILVERMAN, National Institute of Standards and Technology Boulder — Practical quantum photonic technology must be scalable, highly isolated from noise, low loss, and have high stability of optical elements. These needs have motivated the development of photonic integrated circuits (PICs) for quantum optical devices. While significant progress has been made in silicon PICs, generating single photons depends on heralded, probabilistic processes such as spontaneous down-conversion. III-V quantum dots (QDs) have demonstrated deterministic, high-purity, single-photon and entangled-pair emission, including electrically-pumped QDs, providing a path towards source integration. We have previously demonstrated tungsten silicide waveguide-integrated superconducting single-photon detectors with low dark counts (~1 count per 1000 s) on a III-V PIC with waveguide-coupled LEDs. These detectors may allow in-situ measurement of on-chip single-photon sources. We will demonstrate on-chip generation of single photons from a QD ensemble, using ring resonators to isolate the emission of single dots. These circuits may be tuned thermally, and cascaded ring resonators may have sufficiently high Q-factors to isolate single transitions. On-chip detectors may be used to quantify single-photon purity using an integrated Hanbury-Brown and Twiss interferometer.

1:15PM S07.00011: Ab-initio and crystal-field calculations of defect properties of Er$^{3+}$ in yttria*  CUNEYT SAHIN (Presenter), University of Iowa, TIAN ZHONG, University of Chicago, MICHAEL FLATTÉ, University of Iowa — Wide band-gap oxides with rare-earth impurities exhibit narrow transitions with long coherence times and high quantum efficiency due to partially filled f orbitals. This allows the fabrication and usage of these materials in highly efficient optical amplifiers, high power lasers, data, and quantum information processing. We study electronic, structural, and spin properties of trivalent erbium impurities in yttria. First, we perform ab-initio calculations of the structural properties using the generalized gradient approximation and the pseudopotential method. We also calculate the electronic band structure and the density of states of the bulk and doped yttria. Then we proceed to compute the formation energies of erbium impurities. We also compute level splittings and g-tensors using a crystal field Hamiltonian. We show that the g-tensor is highly anisotropic, with a large component in one direction. The presence of an abundant isotope with a non-zero nuclear spin and anisotropic g-tensor suggest that an experimental control of the spin dynamics of this system is possible through the Zeeman and hyperfine interaction.

Quantum networks will require scalable quantum information processing architectures for fast data rates and reliable communication. Recently, the first memory-enhanced quantum repeater that beats direct photon transmission between two communication nodes was realized[1]. However, achieving the range and speed demanded by proposed quantum applications on the quantum internet requires quantum repeater nodes with many multiplexed memory qubits[2]. In particular, it is necessary to optically excite and measure multiple quantum memories fast and efficiently. In this talk, we will discuss recent experimental progress on multiplexed repeaters based on color centers in diamond, with a particular focus on the efficient fluorescence collection towards high-speed entanglement distribution.

1:39PM S07.00013: Atomic-scale control of tunneling in few-donor quantum dots  XIQIAO WANG (Presenter), University of Maryland, College Park, RANJIT KASHID, JONATHAN WYRICK, PRADEEP NAMBOODIRI, ALBERT RIGOSI, National Institute of Standards and Technology, FAN FEI, University of Maryland, College Park, RICHARD SILVER, National Institute of Standards and Technology — Donor-based quantum devices in silicon are a promising candidate for spin-based solid-state quantum computing and analog quantum simulation. Carefully designing the tunneling strength in tunnel-coupled quantum dots is critical to high fidelity performance of spin initialization, readout, spin-exchange operations. This presentation covers our results in atomic-scale control and characterization of tunneling in STM-patterned devices in the few-donor quantum dots regime. We present resonant tunneling spectroscopy analysis of the tunnel junctions in few-donor single-electron transistors and double-dot devices where the tunnel gaps are defined at the atomic-scale. We characterize the tunneling rates between few-donor quantum dots and atomically aligned single electron charge sensors and report their impact on spin-selective tunneling for spin initialization and readout in few-donor quantum dots.
1:51PM S07.00014: Seeking superconductivity with new, two-dimensional dopants super-saturated in silicon  KE TANG (Presenter), HYUN SOO KIM, ARUNA N RAMANAYAKA, National Institute of Standards and Technology, MICHAEL E HOENK, SHOULEH NIKZAD, APRIL JEWELL, Jet Propulsion Laboratory, JOSHUA POMEROY, National Institute of Standards and Technology — Realizing superconducting Josephson junctions within group-IV semiconductors would herald a new era of solid-state quantum computing. For some acceptors, super-saturated doping has been demonstrated to superconduct, e.g. boron-doped silicon having a \(T_c\) of 0.6 K [1]. Here we explore the possibility of superconductivity in similar material systems using both n-type (antimony) and p-type (aluminum) delta-doped layers. Low-temperature molecular beam epitaxy (MBE) has been used to embed atomically thin (2D) layers of antimony and aluminum atoms with dopant densities on the order of \((10^{13} - 10^{14})\text{ cm}^{-2}\). Mesa-etched Hall bar devices are fabricated on these delta layers and magnetotransport measurements at 4 K will be presented to study the material properties, such as carrier concentration and mobility. Temperature dependent measurements below 500 mK will be carried out in a dry dilution refrigerator to test for superconductivity. Comparisons between different dopant systems will also be presented.

2:03PM S07.00015: EPR spectroscopy of Er:CaWO\(_4\) at millikelvin temperatures*  MILOS RANCIC (Presenter), MARIANNE LE DANTEC, PATRICE BERTET, DENIS VION, CEA-Saclay, THIERRY CHANELIÈRE, Néel Institute, Grenoble Alpes University, PHILIPPE GOLDNER, Chimie ParisTech, SYLVAIN BERTAINA, PHANO, Institut Matériaux Microélectronique Nanosciences de Provence — Rare-earth-ions are interesting physical systems because they have long lived states and record coherence times, due the screening of the 4f valence shell by the 5s and 5p filled shells. Rare-earths with an odd number of electrons are also paramagnetic, with an electron-spin transition at GHz frequencies in magnetic fields less than 1 Tesla. For such transitions, coherence times around 50-100 us have been measured at temperatures as low as 1.4K [1]. Here we present results from our recent Electron-Paramagnetic-Resonance (EPR) studies of 0.005% Er:CaWO\(_4\). These measurements were recorded in a novel regime for this material: sub-Kelvin temperature down to 10mK, using a superconducting micro-resonator fabricated directly on the material surface and using a superconducting parametric amplifier for the microwave signals [2], [3]. We observe the longest recorded Hahn-echo decay for an electronic spin transition in an Erbium doped material, up to 1 ms.

Thursday, March 5, 2020 11:15 AM - 2:15 PM
11:15AM S08.00001: Asymmetric Sensing Dot for Scaleable Baseband Readout of Spin Qubits  
EUGEN KAMMERLOHER (Presenter), MATTHIAS KÜNNE, INGA SEIDLER, JARA-Institute for Quantum Information, RWTH Aachen University, D-52074 Aachen, Germany, ARNE LUDWIG, ANDREAS WIECK, Lehrstuhl für angewandte Festkörperphysik, Ruhr-Universität Bochum, D-44801 Bochum, Germany, LARS SCHREIBER, HENDRIK BLUHM, JARA-Institute for Quantum Information, RWTH Aachen University, D-52074 Aachen, Germany — High fidelity scalable readout is one of the key requirements for quantum computers with more than just a few qubits. Charge sensing dots are in this regard the most sensitive sensors for spin qubit readout. The most widespread readout technique is based on RF reflectometry, satisfying the requirement of high fidelity, but requires bulky, power-hungry components and is not well scalable. A more scalable alternative is to use transistors in close proximity to the qubit [1,2].

For best performance a high output swing of the sensor is desirable. We present experimental results in GaAs of an asymmetric sensing dot (ASD), improving the sensor response by a factor of 15 compared to conventional charge sensing dots. We perform charge sensing using a current biased ASD and observe a 2.36 mV swing in response to a (1,1)→(2,0) transition in a nearby double dot.

The improved voltage swing is due to a device design with a strongly decoupled drain reservoir from the sensor dot, mitigating negative feedback effects.

11:27AM S08.00002: A Reservoir Computing Approach to Quantum State Measurement*  
GERASIMOS ANGELATOS (Presenter), HAKAN TURECI, SAEED KHAN, Princeton University — Quantum state measurement is an essential step in the probe or operation of any quantum system, and its optimization has accordingly been the focus of considerable ongoing research. Increases in the speed and fidelity of continuous measurements directly contribute to quantum information processing applications and the fundamental study of quantum systems. In this work, we propose a hardware-based reservoir computing system for quantum state measurement and discuss its performance when compared to conventional approaches. We theoretically analyze the readout of a superconducting circuit via direct coupling to a minimal reservoir computer and demonstrate how such a system provides a low latency approach to state measurement.

11:39 AM S08.00003: Neural Network assisted Superconducting Qubit Readout*  

BENJAMIN LIENHARD (Presenter), ANTTI VEPSALAINEN, Massachusetts Institute of Technology MIT, LUKE GOVIA, Raytheon BBN Technologies, YANJIE QIU, Massachusetts Institute of Technology MIT, DIEGO RISTÈ, MATTHEW WARE, Raytheon BBN Technologies, DAVID K KIM, MIT Lincoln Laboratory, RONI WINIK, Massachusetts Institute of Technology MIT, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, JONILYN YODER, MIT Lincoln Laboratory, GUILHEM RIBEILL, THOMAS A OHKI, HARI K KROVI, Raytheon BBN Technologies, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, Massachusetts Institute of Technology MIT, WILLIAM OLIVER, MIT Lincoln Laboratory, Massachusetts Institute of Technology — A significant error source in contemporary quantum processors is qubit-state readout. For a single qubit connected to a unique readout line, a linear matched filter is sufficient for high-fidelity readout. However, it is more resource efficient to frequency-multiplex multiple qubits on the same readout line. In this case, the single-qubit matched filters are no longer optimal. Rather, readout discrimination becomes a computationally intensive, multi-state classification problem. Here, we present a new approach to the readout problem based on neural networks. We discuss different types of neural network architectures and their readout discrimination performance compared to current readout methods when applied to experimental single and multi-qubit readout data.

11:51 AM S08.00004: Single-Qubit Optimal Quantum Readout via Neural Networks  

WEI TANG (Presenter), Computer Science, Princeton University, ZHAOQI LENG, Physics, Princeton University, ANDREW HOUCK, Electrical Engineering, Princeton University, MARGARET MARTONOSI, Computer Science, Princeton University — High fidelity readout is an essential part of quantum computing. Conventional approaches for superconducting circuit readout rely on linear models. We explore the benefits of employing alternative classification schemes based on neural networks. We discuss different types of neural network architectures and their readout discrimination performance compared to current readout methods when applied to experimental single and multi-qubit readout data.

12:03 PM S08.00005: Dispersive readout for Majorana qubits  

THOMAS SMITH (Presenter), STEPHEN D BARTLETT, ARNE GRIMSMO, Univ of Sydney — We analyze the use of dispersive readout for qubits encoded in topological superconducting nanowires. Two models are considered: the Majorana transmon qubit and the Majorana box qubit. We model the interaction with each qubit and a readout resonator, and calculate the size of the qubit state-dependent dispersive shift of the resonator. We show that dispersive readout of Majorana qubits is protected against measurement-induced bit flips. Furthermore, we find that Majorana transmon qubits are well-suited to dispersive readout, producing dispersive shifts comparable to that of conventional superconducting transmons. Majorana box qubits produce more modest, but still potentially viable, dispersive shifts.
12:15PM S08.00006: Tracking non-Markovian quantum dynamics of a superconducting qubit with a recurrent neural network filter*  NOAH STEVENSON (Presenter), GERWIN KOOLSTRA, BRADLEY MITCHELL, AKEL HASHIM, Univ of California - Berkeley, SHIVA BARZILI, JUSTIN DRESSEL, Chapman Univ, IRFAN SIDDIQI, Univ of California - Berkeley — Precise quantum control of superconducting qubits necessitates determining the time-dependent Hamiltonian of control pulses with high fidelity. While continuous state tracking has proved effective for determining qubit time-evolution in regimes with Markovian dynamics, fast control pulses used for native quantum gates and entanglement generation can result in non-Markovian transient dynamics. We use quantum state tracking with continuous weak measurement to experimentally investigate non-Markovianity in a transmon superconducting qubit coupled to a readout resonator. By weakly measuring the qubit state during a Rabi oscillation sequence on a timescale comparable to the cavity decay rate, we isolate dynamics that are difficult to describe with single-qubit trajectory theory. We train a recurrent neural network to reconstruct the quantum trajectories, motivated by such a network's demonstrated ability to learn long-time correlations in sequential data, and estimate parameters of the stochastic master equation.

*This research was supported by the LPS HiPS program under ARO grant W911NF1810178.

12:27PM S08.00007: High-fidelity quantum state estimation via autoencoder tomography*  SHIVA LOTFALLAHZADEH BARZILI (Presenter), Chapman Univ, NOAH STEVENSON, BRADLEY MITCHELL, Univ of California – Berkeley, RAZIEH MOHSENINIA, Univ of Southern California, IRFAN SIDDIQI, Univ of California – Berkeley, JUSTIN DRESSEL, Chapman Univ —

We investigate the use of supervised machine learning, in the form of a denoising autoencoder, to simultaneously remove experimental noise while encoding one- and two-qubit quantum state estimates into a minimum number of nodes within the latent layer of a neural network. We decode these latent representations into positive density matrices and compare them to similar estimates obtained via linear inversion and maximum likelihood estimation. Using a superconducting multiqubit chip we experimentally verify that the neural network estimates the quantum state with greater fidelity than either traditional method. Furthermore, we show that the network can be trained using only product states and still achieve high fidelity for entangled states. This simplification of the training overhead permits the network to aid experimental calibration, such as the diagnosis of multi-qubit crosstalk.

*This research was supported by the LPS HiPS program under ARO grant W911NF1810178.
12:39PM S08.00008: Characterization and tomography of a hidden qubit*  MAREK PECHAL, MARC GANZHORN, MAX WERNINGHAUS, DANIEL EGGER, GIAN SALIS, STEFAN FILIPP (Presenter), IBM Research - Zurich — In circuit-based quantum computing it is typically assumed that the available gate set consists of single qubit gates acting on each individual qubit as well as an entangling gate between pairs of qubits. In some physical architectures, not all qubits may be addressable, but some may be hidden and only connected to another control qubit. In this case, no single qubit operations can be applied to the hidden qubit and its state cannot be measured directly, but entangling gates with the control qubit can be carried out. Tomography of the combined two-qubit system is still possible on the combined two-qubit system whenever an iSWAP-type interaction in combination with a controlled-phase gate and single qubit operations on the control qubit is available. In our experiment we use transmon-type superconducting qubits along with parametric tunable-coupler gates to realize both types of two-qubit interactions. We further discuss the tune-up process required to completely characterize the gate set used for tomography and we evaluate the resulting fidelities.

*This project has received funding from the EU H2020 under the Grant Agreement No. 828826.

12:51PM S08.00009: Quantum Rifling: Protecting a Qubit from Measurement Back-action DANIEL B SZOMBATI, ALEJANDRO GOMEZ FRIEIRO (Presenter), Univ of Queensland, CLEMENS MUELLER, IBM Research Zürich, TYLER JONES, MARKUS JERGER, ARKADY FEDOROV, Univ of Queensland — Quantum mechanics postulates that measuring the qubit's wave function results in its collapse, with the recorded discrete outcome designating the particular eigenstate the qubit collapsed into. We show this picture breaks down when the qubit is strongly driven during measurement. More specifically, for a fast evolving qubit the measurement returns the time-averaged expectation value of the measurement operator, erasing information about the initial state of the qubit, while completely suppressing the measurement back-action. We call this regime `quantum rifling', as the fast spinning of the Bloch vector protects it from deflection into either of its two eigenstates. We study this phenomenon with two superconducting qubits coupled to the same probe field and demonstrate that quantum rifling allows us to measure either one of the two qubits on demand while protecting the state of the other from measurement back-action. Our results allow for the implementation of selective read out multiplexing of several qubits, contributing to efficient scaling up of quantum processors for future quantum technologies.
Over the past decade tremendous progress has been made on spin qubits based on electron spins in silicon quantum dots. As with any qubit implementation, a critical requirement is the ability to read out the qubit rapidly, with high fidelity, and in a scalable manner. Much attention has been focused on improving single-electron transistors embedded in radio-frequency reflectometry circuits as charge detectors to detect, in combination with a spin-to-charge conversion scheme, electron spin states. While these are the most sensitive detectors to date, they come with additional resources that take up valuable space near the quantum dots (gate electrodes, electron reservoirs), which makes scaling up to two-dimensional spin qubit arrays difficult. More efficiently, read-out can be performed utilizing gates that are already in place for defining quantum dots by connecting those gates to a resonant circuit. This promising method of gate-based sensing has been developed for quantum dots with off-chip resonators, and only very recently achieved the sensitivity necessary for single-shot read-out of spins in silicon [1]. In this talk, I will describe the use of an on-chip superconducting microwave resonator to improve the sensitivity, aided by its high quality factor and impedance. Using Pauli Spin Blockade as the spin-to-charge conversion scheme, we demonstrate the gate-based read-out of a two-electron spin state in a single shot with an average fidelity of 98% in only 6 microseconds [2]. Furthermore, our latest work towards long-distance spin-spin coupling will be presented.

1:39PM S08.00011: Improving Multilevel Qudit Readout Fidelity During Relaxation Events via Hidden Markov Models

LUIS MARTINEZ (Presenter), YANIV J. ROSEN, JONATHAN L. DUBOIS, Lawrence Livermore National Laboratory — Quantum state determination with high fidelity is a requirement for quantum computation. However, qubit relaxation imposes a limiting constraint on readout fidelity. Longer readout measurement times increase the distinguishability between the qudit states, however state decay during a long readout pulse can obfuscate the measurement and result in misclassification of qudit state. To overcome this constraint, we demonstrate high-fidelity multi-state readout by detecting qubit relaxation with Hidden Markov Models on LLNL’s Quantum Design and Integration Testbed (QuDIT). The ability of Hidden Markov Models to account for relaxation and thermal excitation processes allows for longer readout times, extraction of transition probabilities, and higher readout fidelity.

1:51PM S08.00012: Continuous Indirect detection of stabilizers for quantum error correction

YI-HSIANG CHEN (Presenter), TODD BRUN, Univ of Southern California — Measuring high-weight operators is an important problem in quantum computation. The conventional procedure to measure a high-weight operator involves multiple pairwise unitary operations, which may require a large number of quantum gates. We provide an alternative method to passively detect the value of an operator. This approach involves joint interactions between the system and continuously-monitored ancillary qubits. The continuous measurement outcomes of the monitor qubits reveal information about the values of the stabilizer generators. This information can be retrieved using an estimator, which is driven by the measurement outcomes. We also show that there is a more efficient way to read out the outcomes directly from the time average of the signals. The interaction Hamiltonian can use only two-local operators, based on techniques similar to perturbative gadgets. We apply this indirect detection scheme to the four-qubit Bacon-Shor code, where the two stabilizers are indirectly monitored using four ancillary qubits. Since it is an error-detecting code, we show that non-Markovian errors, e.g., the Hamiltonian 1/f noise, can be suppressed by the indirect detection. This detection scheme could be implemented in near-term experimental systems and operate in real time.

2:03PM S08.00013: Diagnosing Errors in Quantum Gates Using Continuous Measurements

JOHN STEINMETZ (Presenter), ANDREW N JORDAN, University of Rochester — We use continuous weak measurements to track a quantum gate operation as it develops in time, which allows us to identify the full time-dependent dynamics of any systematic errors. We account for measurement backaction such that it has no bearing on the error estimate. This diagnostic method is tested on imperfect single- and two-qubit gates, and is shown to accurately extract known time-dependent error pulses. This offers significant advantages over traditional quantum process tomography, as it provides the ability to identify the origin and nature of any deviations from the desired evolution, which can give insight into how to modify the gate pulse.

*We acknowledge funding from the US Army Research Office.
11:15AM S09.00001: Observing a Topological Transition in Weak-Measurement-Induced Geometric Phases*  
YUNZHAO WANG (Presenter), Department of Physics, Washington University in St. Louis, KYRYLO SNIZHKO, The Weizmann Institute of Science, ALESSANDRO ROMITO, Lancaster University, YUVAL GEFEN, The Weizmann Institute of Science, KATER MURCH, Department of Physics, Washington University in St. Louis — Quantum measurements induce backaction on quantum states resulting in measurement induced dynamics. A sequence of weak measurements can consequently realize a cyclic motion for the qubit state in Hilbert space and thus induce a geometric phase. As the measurement strength is varied between weak and strong regimes, we expect a topological transition corresponding to a change in the Chern number of the surface tracked by the qubit's cyclic motion. To experimentally measure this transition, we employ quantum non-demolition measurement of a superconducting transmon circuit in the strong dispersive regime. This transition is revealed as a quantized jump in the averaged geometric phase when tuning the strength for the measurement sequence, giving new insights into how weak measurements are a powerful tool for quantum control.

11:27AM S09.00002: Microscopic magnetometry of neurons using a superconducting flux qubit*  
HIRAKU TOIDA (Presenter), KOJI SAKAI, IMRAN MAHBOOB, TETSUHIKO F. TESHIMA, KOUSUKE KAKUYANAGI, SHIRO SAITO, NTT Basic Research Labs — We have developed a microscopic magnetometer based on a superconducting flux qubit [1]. Using it, we have successfully obtained a magnetization signal from neurons. The neurons were cultured on parylene-C film in iron-rich medium to increase the number of spins in the cell. The film also worked as an insulator between the neurons and the flux qubit. The magnetization signal increased as a function of the inverse temperature and the Zeeman magnetic field. Considering that the control experiment without neurons showed no significant magnetization signal, this result strongly suggests that the signal originates from the spins in neurons. In the case of spins in neurons, because the spins distribute inhomogeneously in the cell, the contribution to the magnetization signal from the spins distant from the chip surface plays an important role, unlike the case of solid state spins [1]. To improve sensitivity to such widely distributed organic spins, a capacitively shunted flux qubit with a large loop size is developed and its design parameters are discussed [2]. [1] H. Toida et. al., Commun. Phys. 2, 33 (2019). [2] D. Marcos et. al., Phys. Rev. Lett. 105, 210501 (2010).

**11:39AM S09.00003: High contrast dual-mode optical and hyperpolarized $^{13}$C magnetic resonance imaging in diamond particles**  
XUDONG LV (Presenter), University of California, Berkeley, JEFFREY H WALTON, Nuclear Magnetic Resonance Facility, UC Davis, EMANUEL DRUGA, FEI WANG, ALESSANDRA AGUILAR, TOMMY MCKNELLY, RAFFI NAZARYAN, LAN WU, University of California, Berkeley, OLGA SHENDEROVA, Adamas Nanotechnologies, DANIEL VIGNERON, Department of Radiology and Biomedical Imaging, UCSF, CARLOS MERILES, Department of Physics, City College of New York, JEFFREY A REIMER, ALEXANDER PINES, ASHOK AJJOY, University of California, Berkeley — Multichannel imaging - the ability to acquire images of an object through more than one imaging mode simultaneously - has opened exciting new avenues in several areas from astronomy to biomedicine. Visible optics and magnetic resonance imaging (MRI) offer complementary advantages of resolution, speed and depth of penetration, and as such would be attractive in combination. In this work, we integrate optical and MR imaging in diamond particles endowed with a high density of quantum defects, Nitrogen Vacancy (NV) centers. Under optical excitation, NV centers fluoresce brightly in the visible, as well as electron spin polarize, allowing the hyperpolarization of lattice $^{13}$C nuclei. Leveraging the ability of optical and MR imaging to simultaneously probe Fourier-reciprocal domains (real and k-space), we elucidate a hybrid sub-sampling protocol in both conjugate spaces to vastly accelerate dual-image acquisition, while concurrently reducing the net optical power, by two orders of magnitude in sparse-imaging scenarios. In addition, we demonstrate background-free imaging in optical and MR domains respectively. This work portends new avenues for quantum-enhanced dual-mode imaging platforms and opens possibilities for new therapeutic avenues including in low-field MRI-guided endoscopy.

**11:51AM S09.00004: Expanding the possibility of quantum metrology with a mixture of superpositions of macroscopically distinct states**  
MAMIKO TATSUTA (Presenter), Univ of Tokyo, YUICHIRO MATSUZAKI, National Institute of Advanced Industrial Science and Technology, AKIRA SHIMIZU, Univ of Tokyo — A quantum sensor can beat the best sensitivity of a classical sensor, which is called the standard quantum limit (SQL), by the factor which scales with the square root of the system size. Sensitivity with such an enhancement is called the Heisenberg scaling. Although some specific examples that achieve the scaling have been studied, there is no general criteria about what kind of quantum states have the potential to achieve it. Here we prove that every state identified as a generalized cat state (GCS), i.e., superposition of macroscopically distinct states characterized by quantum coherence, can achieve it if used as a field sensor [1]. Importantly, even a mixture of exponentially large number of states can be identified as a GCS. We also show that GCSs beat the SQL in scaling despite the presence of dephasing which degrades the sensitivity. As a concrete example, we propose a protocol to generate a mixed GCS at finite temperature with donor spins in silicon. Its sensitivity is about 20 times better than that of a separable state even though it has an exponentially low purity.

**12:03PM S09.00005: Weak Measurements of a Superconducting Qubit Reconcile Incompatible Observables**

JONATHAN MONROE (Presenter), TAEHO LEE, Washington University, St. Louis, NICOLE YUNGER HALPERN, Harvard University, KATER MURCH, Washington University, St. Louis — Traditional uncertainty relations dictate a minimal amount of noise in incompatible projective quantum measurements. The noise comes from the observables' not sharing an eigenbasis. However, not all measurements are projective. In particular, weak measurements are minimally invasive tools for obtaining partial state information without projection. Weak measurements obey an entropic uncertainty relation based on generalized measurement operators [Yunger Halpern et al. Commun. Phys. 2, 92 (2019)]. We experimentally test the entropic uncertainty relation with strong and weak measurements of a superconducting transmon qubit. We find that a weak measurement can reconcile the incompatibility of two strong measurements via the weak measurement's backaction.

*This work was supported by NSF grants PHY-1607156 and PHY-1752844.

**12:15PM S09.00006: Control-enhanced quantum parameter estimation through reinforcement learning**

HAN XU (Presenter), XIN WANG, City Univ of Hong Kong — Measurement and estimation of parameters are indispensable for science and engineering. One of the main goals in parameter estimation is to find systematic schemes achieving high precision. Schemes for quantum parameter estimation could focus on optimizing the probe, its interaction with the system and measurements. Recently, schemes that add controls during the evolution are realized for significantly improving the precision. However, the identification of the control-enhanced scheme is usually computationally demanding, because the controls depend on the parameter value and need to be re-optimized after each update of the estimation. Here we show an efficient way to identify the controls through reinforcement learning that can improve the precision for both single-parameter estimation and multi-parameter estimation. Reinforcement learning also shows great generalizability, namely the neural network trained under a particular value of the parameter can work for different values within a broad range. These results suggest that reinforcement learning can be an efficient alternative to conventional optimal quantum control methods.

*This work is supported by the Research Grants Council of the Hong Kong SAR (Grant Nos. CityU 21300116, CityU 11303617, CityU 11304018).

**12:27PM S09.00007: Optimal protocols for simultaneous measurement of multiple analytic functions with quantum sensor networks**

JACOB BRINGEWATT (Presenter), PRADEEP NIROULA, PRZEMYSLAW BIENIAS, University of Maryland, College Park, ALEXEY V GORSHKOV, National Institute of Standards and Technology — We expand on previous work for measuring analytic functions of input parameters of quantum sensor networks with qubit sensors. We consider the optimal bound with respect to different figures of merit for simultaneous measurement of multiple such analytic functions and propose protocols to achieve these bounds and thus Heisenberg scaling in the mean square error. We discuss conditions on the analytic functions where the possible speed-up over classical or sequential protocols is greatest and consider potential applications.
12:39PM S09.00008: Optimal control for quantum detectors  PARAJ TITUM (Presenter), KEVIN SCHULTZ, GREGORY QUIROZ, DAVID CLADER, Applied Phys Lab/JHU — Quantum systems are promising candidates for sensing of weak signals as they can provide unrivaled performance when estimating parameters of external fields. However, when trying to detect weak signals that are hidden by background noise, the signal to noise ratio is a more relevant metric than raw sensitivity. We identify, under modest assumptions about the statistical properties of the signal and noise, the optimal control to detect an external signal in the presence of background noise using a quantum sensor. We show this by considering the time-dependent control using the filter function formalism, and we use this formalism to derive the optimal protocol that maximizes the signal-to-noise ratio for the quantum detector. Interestingly, this optimal solution is the simple and well-known spin-locking control scheme. We further show, using numerical techniques, that this result is robust even when lifting some of our assumptions. These results show how that an optimal detection scheme can be easily implemented in near-term quantum sensors without the need for complicated pulse shaping.

12:51PM S09.00009: Optimal Control and Glassiness in Quantum Sensing  CHRISTOPHER TIMMS (Presenter), MICHAEL KOLODRUBETZ, University of Texas at Dallas — The extreme responsiveness of qubits to their external environment has proven to be very useful for the purpose of quantum sensing. While this is valuable for sensing small target fields, this also makes the qubits very susceptible to disruption by external noise. We simulate the use of quantum optimal control to control the qubits for sensing protocols. Our work extends the pioneering results of Poggiali et al [PRX 8, 021059 (2018)] by allowing the use of non-pi pulses. We show that this added complexity translates into both improved sensitivity and qualitative modifications of the control landscape. In particular, we explore the connection of the rough control landscape to that of a (classical) spin glass and comment on possible applications of this connection to improving quantum sensing more broadly.

1:03PM S09.00010: Statistical Certification of Majorana fermions  ABU ASHIK MD. IRFAN (Presenter), Indiana Univ - Bloomington, KARL MAYER, NIST, GERARDO ORTIZ, Indiana Univ - Bloomington, EMANUEL H KNILL, NIST — Physicists conjectured the existence of Majorana zero-energy modes in various condensed matter setups. Several experimental groups have even reported evidence of their existence by means that do not reflect or exploit its non-Abelian braiding statistics, a prerequisite for topological computation. What constitutes conclusive evidence for Majorana fermion detection? We present a quantum self-testing protocol that uses minimal assumptions and establishes strong conditions for Majorana fermion detection. We propose a contextuality witness $W$ which consists of putative Majorana fermion parity operators. The resulting Bell-like inequality $<W> \leq 3$ can be violated only if the system exhibits quantum contextuality. We further show that observing the ideal measurement statistics, leading to $<W>=5$, implies anticommutativity of the implemented Majorana fermion parity operators, a necessary prerequisite for the non-Abelian braiding statistics of Majoranas. Our protocol is robust to experimental errors. We obtain lower bounds on the fidelities of the state and measurement operators using both analytical calculations and a Semi Definite Programming approach. We also propose a protocol that certifies the gates which are implemented by the braiding of Majorana modes.
1:15PM S09.00011: Demonstration and Application of Long-lived state in a four-spin system hyperpolarized at room temperature*  KOICHIRO MIYANISHI (Presenter), NAOKI ICHIJO, MAKOTO MOTOYAMA, AKINORI KAGAWA, Graduate school of Engineering Science, Osaka Univ, MAKOTO NEGORO, Quantum Information and Quantum Biology Division, Institute for Open and Transdisciplinary Research Initiatives, Osaka Univ, MAKOTO MOTOYAMA, AKINORI KAGAWA, Graduate school of Engineering Science, Osaka Univ — A solution with hyperpolarized nuclear spins encoded into a long-lived state has been utilized for sensing chemical phenomena in vivo and in vitro. In a conventional way, nuclear spins are hyperpolarized at very low temperatures, and it needs a large-scale setup with a cryogenic instrument. In this work, we demonstrate the encoding of a four-nuclear-spin system hyperpolarized at room temperature into a long-lived state in a solution. Both room temperature hyperpolarization and quantum encoded sensor are a hot topic in quantum sensing. Experiments are performed for the aromatic protons in p-chlorobenzoic acid. The lifetime of spin polarization was increased 2.4 times by the quantum encoding. We apply the solution with the long-lived state as a sensor in ligand--receptor binding experiments.

1:27PM S09.00012: Diamond quantum DC magnetometer with efficient digital signal processing*  YUTA MASUYAMA (Presenter), Natl Inst for Quantum & Radiological Science & Tech (QST), TAKAYUKI IWASAKI, MUTSUO HATANO, Tokyo Institute of Technology, TAKESHI OHSHIMA, Natl Inst for Quantum & Radiological Science & Tech (QST) — Nitrogen-vacancy (NV) centers in diamond are promising solid-state quantum sensors. The sensor can potentially monitor the real-time magnetic field at room-temperature toward the brain-machine interface. One of the biggest challenges is to implement a highly sensitive sensor in a compact system. The sensor based on a digital signal processing with the Fourier transform has an advantage of its simpler system than an analog type, but it is hard to monitor the real-time magnetic field because the method needs many computational resources.

Here, we demonstrate an alternative method of digital signal processing with less computational resources than the Fourier transform. The method uses a digital filter that effectively becomes a sinc filter utilizing the orthogonality of trigonometric functions by multiplication of the acquired data by a trigonometric function. The computational time of the method to compute the signal from n points of data is O(n), whereas the time with Fourier transform is O(n log n). We confirm our method with a large detection volume of the ensemble NV centers. Consequently, we obtained a DC magnetic field sensitivity of 2.4 nT/√Hz.

Magnetic Measurement of SPIONs using NVs in Diamond

MAZIAR SALEH ZIABARI (Presenter), PAULI KEHAYIAS, JACOB D HENSHAW, TZU-MING LU, CHARLES HARRIS, EDWARD S BIELEJEC, DALE L HUBER, Sandia National Laboratories, VICTOR ACOSTA, University of New Mexico, MICHAEL P LILLY, ANDREW M MOUNCE, Sandia National Laboratories — Superparamagnetic iron oxide nanoparticles (SPIONs) have numerous biological, magnetic, and chemical applications. Their nontoxicity and functionalizability supports medical applications as temporally and spatially controlled nanovectors for drug delivery, markers for enhanced MRI sensitivity, and for externally controlled hyperthermia in tumors. While bulk magnetic properties of SPIONs have been the subject of numerous studies, the magnetic properties of single SPIONs aren't well understood. Nitrogen vacancy defects in diamond are particularly suitable for characterizing isolated nanoparticles due to their extreme sensitivity to local magnetic fields. We characterize the magnetic properties of SPIONs of varying size and density, deposited on the surface of NV implanted diamond.

This work was funded by the Sandia National Laboratory LDRD program and at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science. Sandia National Laboratories is a multi-mission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International, Inc., for the DOE's National Nuclear Security Administration under contract DE-NA0003525.

Imaging nanoscale volumes of single spins with shallow nitrogen-vacancy quantum spin sensors in diamond

ZHIRAN ZHANG (Presenter), University of California, Santa Barbara, DOLEV BLUVSTEIN, Havard University, NICOLAS RYAN WILLIAMS, ANIA JAYICH, University of California, Santa Barbara — The single shallow nitrogen-vacancy (NV) center, as an atomic-sized quantum sensor, can be incorporated with scanning probe microscopy with the potential of imaging single molecule structure with atomic-scale resolution. Here we present NV-based imaging of electron spins patterned on the nanoscale structure, where we employ DNA origami, a powerful molecular self-assembly platform, to enable bottom-up patterning of single spin-containing molecules. Such molecular structures can serve as two-dimensional calibration ‘spin’ rulers for the development of NV nanometrology. Specifically, we demonstrate the synthesis of the Gd chelate labeled DNA origami structures and present images of these structures acquired with NV center T1 imaging. Lastly, we discuss the outlook for our imaging technique to image spin-labelled molecules at the single spin level.

We gratefully acknowledge support from DARPA DRINQS program (agreement D18AC00014).
2:03PM S09.00015: Time-resolved diamond magnetic microscopy of superparamagnetic nanoparticles*  NATE RISTOFF (Presenter), University of New Mexico, ABDELGHANI LARAOUI, University of Nebraska - Lincoln, ILJA FESCENKO, JOSHUA DAMRON, NAZANIN MOSAVIAN, JANIS SMITS, University of New Mexico, ANDREY JARMOLA, ODMR Technologies Inc., PAULI KEHAYIAS, Sandia National Laboratory, MAZIAR SALEHIZABARI, University of New Mexico, ANDREW M MOUNCE, DALE L HUBER, Sandia National Laboratory, VICTOR ACOSTA, University of New Mexico — Magnetic nanoparticles have many biomedical applications including hyperthermia for cancer therapy, magnetic resonance imaging, and magnetic relaxation imaging. These applications require that the magnetic nanoparticles have uniform magnetic properties, size and morphology. We report progress on a nitrogen vacancy (NV) center widefield magnetic microscope which measures the Neel relaxation and hysteresis curve of many single magnetic nanoparticles. In addition, we report on progress to correlate these relaxation measurements to particles size via scanning electron microscope (SEM).

Session S15 DFD GSNP: Granular, Porous Media, & Multiphase Flows II
210/212 - Nathan Keim, California Polytechnic State University

11:15AM S15.00001: Nonlinear acoustic resonance and wave-induced softening in dense granular matter through flow heterogeneities  CHARLES LIEOU, Los Alamos National Laboratory, JEROME LAURENT, Institut Langevin, PAUL A JOHNSON (Presenter), Los Alamos National Laboratory, XIAOPING JIA, Institut Langevin — We report a series of experiments on the softening and compaction of a dense granular pack through traveling acoustic pressure and shear waves. Softening is manifested by a reduction the traveling-wave speed, as the amplitude of the disturbance increases beyond some threshold. We explain these seemingly contradictory observations using a theoretical model, based on shear transformation zones (STZs), that directly attributes these observations to dynamical heterogeneities and slipping contacts in the granular pack. Softening is accounted for by the increase of the fraction of STZs or slipping contacts as a function of increasing strain amplitude, while compaction is explained by an Ising-like correlation between STZs in the subyield regime. In so doing, we demonstrate the fundamental connection between nonaffine granular rearrangements, mesoscopic glassy dynamics, jamming and unjamming, and matter-wave interactions.
11:51AM S15.00002: Scaling and dynamics of impacts into cornstarch and water suspensions*  MARC BRASSARD (Presenter), NEIL CAUSLEY, The Naval Postgraduate School, JOSHUA DIJKSMAN, Wageningen University & Research, ABE CLARK, The Naval Postgraduate School — Impacts into dense suspensions, which consist of micron-scale particles suspended in a Newtonian fluid, undergo a dramatic solidification when subjected to sudden impact. Recent work has shown that the forces during the initial moments of impact are too large to be described by discontinuous shear thickening (DST), which is a steady-state description. Other descriptions, such as the added mass model proposed by Waitukaitis and Jaeger, capture some aspects of the dynamics well but fail to predict certain features. Here, we show results from experimental impacts into dense suspensions consisting of cornstarch particles and water. We vary the size, speed, mass, and shape of the projectile as well as the density of the suspension. We quantify the forces as a function of time using high-speed imaging and other sensors. We use scaling analysis to probe the underlying physical mechanisms and compare our results to existing descriptions.

*Funded by the Office of Naval Research, Grant No. N0001419WX01519 (program manager Roshdy Barsoum) and by the Office of Naval Research Global, Grant No. VSP 19-7-001.

12:03PM S15.00003: Peak Force Scaling During Impacts into Wet and Dry Granular Materials*  NEIL CAUSLEY (Presenter), NASSER F KRIZOU, MARC BRASSARD, The Naval Postgraduate School, JOSHUA DIJKSMAN, Wageningen University & Research, ABE CLARK, The Naval Postgraduate School — Impacts into granular materials, both wet and dry, are common in engineering and nature, but a fundamental description of the forces during impact is still lacking. Certain drag laws (e.g., Poncelet laws) and other rheological descriptions (e.g., inertial rheology for dry grains or discontinuous shear thickening for suspensions) are often successful in describing certain aspects of the forces, but these descriptions typically fail to capture the largest forces during the initial moments of impact. Here, we use experiments and simulations to study early time dynamics of impacts into wet and dry granular materials. We show that the magnitude and time scales of the peak forces obey power law scaling that is similar across the different types of materials we study, and we use dimensional analysis to isolate the relevant physical mechanisms. We find that existing models do not predict many of the scaling laws we observe, suggesting the need for new models to describe this process.

*Funded by the Office of Naval Research Grant No. N0001419WX01519 (program manager Roshdy Barsoum). Additionally, we acknowledge VSP 19-7-001 visitor grant from the Office of Naval Research Global.
12:15PM S15.00004: Proper Spatial Average Operators in a Heterogeneous Porous Medium
EHSAN TAGHIZADEH (Presenter), BRIAN DAVID WOOD, Oregon State Univ — In this work, we explore a wide range of kernel functions commonly used in Bayesian statistics to evaluate their functionality in attenuating geometrical fluctuations arising from sudden change in the porosity in a heterogeneous porous medium. Boxcar; single-, double-, and triple-convoluted boxcar; Epanechnikov; Tricube; Gaussian; Cosine; Logistic; Sigmoid; and Silverman are among weighting functions we examined for the cases where (1) a periodic homogeneous medium, (2) a quasi-periodic heterogeneous medium with a gradual porosity change, (3) a quasi-periodic heterogeneous material with a discontinuous jump in porosity, and (4) a disordered heterogeneous porous medium with a discontinuous jump in the porosity exist. We use an extended porous material's diffusion model developed based on volume averaging method recently reported by Battiato et al 2019 [1]. The model retains the zero- and first-order terms in the closure problem and neglects the second-order Taylor series. Results are promising in a sense that mollified version of some of those weighting functions can improve divergence of Taylor series approximation of the average flux of mass through the porous material.

12:27PM S15.00005: Fluid Flow with Suspended Soft Particles in Porous Media* SHUAIJUN LI (Presenter), JING FAN, The City College of New York — Transport of soft particles with flow in porous media is ubiquitous in many natural and engineering processes. For example, preformed-particle-gel (PPG) treatment is a common technique in enhanced oil recovery. While the measurable properties in this process are at the microscale, such as gel size, properties, and the macroscopic permeability directly correlates with the overall recovery efficiency. Therefore, it is desirable to find the quantitative relation between the macroscopic permeability and the relevant microscopic properties. However, this remains an unsolved problem. In this work, we study transport of mono-dispersed suspended soft particles in porous media. We start from analyzing a soft particle transport through a single pore throat and find the correlation between injection pressure and the properties of the soft particle. Based on this result, we then expand the analysis to macroscale. we find a quantitative relation between the macroscopic permeability and pore-scale properties in the presence of pore blockage. The work significantly improves our understanding on transport of soft particles in porous media and directly benefits the relevant industrial applications.

Granular packings with sliding, rolling and twisting friction*  ANDREW SANTOS (Presenter), ISHAN SRIVASTAVA, DAN STEFAN BOLINTINEANU, JEREMY LECHMAN, GARY GREST, Sandia National Laboratories, LEO SILBERT, Central New Mexico Community College — Intuition tells us that a rolling or spinning sphere will eventually stop due to the presence of friction. The resistance to rolling and spinning/twisting that stops one sphere also changes the microstructure of a granular packing of frictional spheres. Isostatic constraint counting allows packings of 3d spheres to span an average number of contacts per sphere between 6 to 2, depending on the types of frictional constraints. We perform discrete element modeling simulations to construct sphere packings implementing a range of frictional constraints under a stress-controlled protocol. The simulated granular packings are tested against the isostatic conjecture and are compared to experimental values. Stable packings are achievable at low volume fractions and average coordination numbers, circa 0.52 and 2.6 respectively, when the particles experience high resistance to sliding, rolling and twisting.

Elastogranular Buckling of a Slender Ring*  DAVID SCHUNTER, JR. (Presenter), DOUGLAS HOLMES, Boston Univ — Thin flexible-walled structures provide utilitarian geometries in a variety of biological and engineering contexts. Whether describing the origins of certain vascular disorders, the mechanics of thin membranes, or in constructing domed architectures, understanding how these thin objects respond due to external forcing is crucial. Previous work has focused on thin structures deforming within media that, in general, have both compositional and mechanical homogeneity. In comparison, much less is known about the behavior of slender structures embedded in active or driven matter, such as a vibrating granular monolayer. By placing a thin elastic ring within a horizontally driven 2D granular bed, we investigate the phase space of buckling morphologies that arises under gradual compression of this coupled system. Varying the compression rate U, we see a crossover between two distinct regimes, with ring buckling geometries reflecting the degree of granular force homogeneity. These results will bring new insight into how flexible structures deform & pack within complex media, and will be relevant for geometric approaches to cell mechanics, the design of soft robots, the modeling of animal movements, and developing responsive, directable medical devices.

1:03PM S15.00008: Using time-dependent random resistor networks to capture the dynamics of flow in disordered porous media  AHMAD ZAREEI (Presenter), Harvard University, SHIMA PARSA, Rochester Institute of Technology, DAVID A WEITZ, ARIEL AMIR, Harvard University — The heterogeneous microstructure of a disordered porous medium determines the pore-level flow. Any changes to the micro-structure in a porous medium, such as solute retention during polymer flow (effectively "clogging" some pores in the network), affects the pore-level flow and alters the bulk behavior. In order to better understand the effect of microstructure on flow behavior, we study a model based on a disordered network of tubes, mathematically equivalent to a random resistor network. We show that this approximate model captures the observed velocity distribution in experiments on glass beadpack. We model the dynamics of structural changes during polymer retention, and show that the (dynamic) resistor network produces flow velocity distributions and bulk properties consistent with the experiments.

Session S16 DQI: Multi-mode and 3D-cavity Circuit QED Systems II  201 -

Yvonne Gao, Yale University

11:15AM S16.00001: Mediating interactions between superconducting microwave cavities with three-wave mixing, part 1*  STIJN DE GRAAF (Presenter), BENJAMIN CHAPMAN, YAXING ZHANG, SHANTANU O MUNDHADA, AKSHAY KOOTTANDAVIDA, NICHOLAS FRATTINI, LUKE BURKHART, ALEXANDER P READ, LUIGI FRUNZIO, STEVEN GIRVIN, MICHEL H. DEVORET, ROBERT SCHOELKOPF, Yale University — Engineering tunable bilinear couplings between microwave cavities provides a way to manipulate and entangle long-lived quantum states. Two-cavity gates, such as the beam splitter and exponential SWAP (eSWAP), have been successfully demonstrated using a driven transmon coupled to both cavities. However, the fidelity of these gates is limited by unwanted 4th order processes such as the AC Stark effect. By replacing the transmon's Josephson junction with a superconducting nonlinear asymmetric inductive element (SNAIL), we produce a bilinear interaction via its 3rd order nonlinearity while minimizing 4th order effects. This is expected to offer high fidelity two-cavity gates using all-RF control. I will discuss experimental design considerations and the theory behind the coupled-cavity device.

11:27AM S16.00002: Mediating interactions between superconducting microwave cavities with three-wave mixing, part 2* BENJAMIN CHAPMAN (Presenter), STIJN DE GRAAF, YAXING ZHANG, SHANTANU O MUNDHADA, AKSHAY KOOTTANDAVIDA, NICHOLAS FRATTINI, LUKE BURKHART, ALEXANDER P READ, LUIGI FRUNZIO, STEVEN GIRVIN, MICHEL H. DEVORET, ROBERT SCHOELKOPF, Yale University — Quantum memories formed from three-dimensional superconducting microwave cavities provide the coherence and large Hilbert spaces needed for quantum error correction. To date, coupling between these memories has been primarily facilitated by transmons. There, four-wave mixing allows for the creation of beam-splitter, single-mode, and two-mode-squeezing interactions, from which gates can be built. Although this approach has proven to be flexible and robust, the engineered couplings are accompanied by unwanted Kerr and Stark effects, which can limit the fidelity of cavity-cavity gates. Here, we design the nonlinear coupling element to be an RF-driven three-wave mixer. The desired bilinear interactions may then be engineered while suppressing spurious fourth-order processes. In this talk, we present preliminary measurements of two microwave cavities coupled by such a three-wave mixing element.

11:39AM S16.00003: Superconducting radio frequency cavities with seconds of photon lifetime in quantum regime ALEXANDER ROMANENKO (Presenter), ROMAN PILIPENKO, DANIIL FROLOV, SILVIA ZORZETTI, MOHAMED AWIDA, SAM POSEN, ERIC T HOLLAND, SERGEY A BELOMESTNYKH, ANNA GRASSELLINO, Fermilab — Superconducting radio frequency (SRF) cavities developed for accelerators are the highest quality factor (Q) man-made oscillators with record Q > 4e11, whereas Q~3e10 is a routine operation. Adopted for quantum regime, SRF cavities offer a route for multifold increase in photon lifetimes for applications in quantum computing and fundamental physics searches such as dark photons and axions. Initial demonstrations showed that the quantum regime lifetimes of tens of milliseconds can be achieved for SRF cavities "as-is", limited by the two-level-system (TLS) dissipation [1,2].

In this contribution we present the recent advancements [2] in the quantum regime performance of SRF cavities enabled by applying combined materials science investigations and vacuum heat treatments. We demonstrate the mitigation of the TLS dissipation and achievement of the 0.5 seconds of photon lifetime for 5 GHz and 2 seconds for 1.3 GHz cavities. Such cavities are currently being employed for several QIS type and fundamental physics applications such as dark photon searches, which we will summarize briefly as well.

11:51AM S16.00004: Exploiting tunable, ultrastrong nonlinearies of the cavity Cooper-pair transistor system for generating microwave quantum states*  WILLIAM BRAASCH, MILES BLENCOWE (Presenter), OSCAR D. FRIEDMAN, Dartmouth Coll, ANDREW D. ARMOUR, Physics and Astronomy, University of Nottingham, BENJAMIN BROCK, ALEXANDER J RIMBERG, Dartmouth Coll — The cavity Cooper-pair transistor (cCPT) device enables the engineering of a wide range of nonlinear, effective cavity oscillator interactions through the tunability of both its gate voltage and flux biases. Such nonlinearities can be strong even under low average photon number drives on the cavity. We utilize the recently developed Wigner current vector field (Wigner current) construct to give a geometrical analysis of the formation and possible stabilization of quantum microwave oscillator states in the presence of dissipation and noise for the cCPT.

12:03PM S16.00005: Passive Error Correction with Grid States in a Non-Reciprocal Superconducting Circuit  MARTIN RYMARZ (Presenter), STEFANO BOSCO, JARA Institute for Quantum Information, RWTH Aachen University, Germany, ALESSANDRO CIANI, QuTech, Delft University of Technology, The Netherlands, DAVID PETER DIVINCENZO, JARA Institute for Quantum Information, RWTH Aachen University, Germany — Non-reciprocal circuit elements play an essential role for the practical realization of a solid-state quantum computer, independent of the chosen implementation. For that matter, non-reciprocal circuit elements often constitute the interface between the classical and quantum description of an electrical network. In electrical network theory, the gyrator proposed by Tellegen [1] in 1948 is considered to be the most fundamental non-reciprocal circuit element. The miniaturization of the actual device allows for the description of the gyrator within the lumped element model. Besides the incorporation of the gyrator into the theory of circuit quantum electrodynamics [2], we propose a non-reciprocal superconducting circuit comprising a gyrator, whose effective dynamics is described by the Hofstadter Hamiltonian [3]. Thus, the eigenstates of the system constitute grid states, which can be used for passive error correction in terms of the continuous variable code proposed in 2001 by Gottesman, Kitaev and Preskill [4].

12:15PM S16.00006: Cat-qubit operations preserving error structure*  JONATHAN GROSS (Presenter), Institut Quantique, Universite de Sherbrooke, SHRUTI PURI, Yale Quantum Institute, Yale University, ALEXANDRE BLAIS, Institut Quantique, Universite de Sherbrooke — A universal quantum computer will require error correction to perform in a fault-tolerant way, imposing substantial engineering challenges. Fortunately, many devices are subject to errors with structure that can be exploited to ease the burden of fault tolerance. Stabilized cat qubits in superconducting circuits push this principle to the extreme, with recent work identifying dramatic reduction of fault-tolerance requirements on this platform. Essential to this reduction is the ability to perform operations on the qubits that preserve the error structure, made possible by the infinite-dimensional Hilbert space in which the cats live. We present additional operations fulfilling this requirement and discuss their potential for near- and long-term applications.

*This work was undertaken thanks in part to funding from NSERC and the Canada First Research Excellence Fund. Shruti Puri also acknowledges support from ARO W911NF-18-1-0212 and NSF DMR-1609326.

12:27PM S16.00007: Multiplexed readout of four qubits in 3D cQED architecture using broadband JPA [Invited]  R VIJAY (Presenter), TIFR — Vijay has led the development of broadband quantum amplifiers, key to measurement in multiplexed systems.

1:03PM S16.00008: Waveguide Bandgap Engineering with an Array of Superconducting Qubits  JAN BREHMH (Presenter), ALEXANDER STEHLI, Karlsruhe Institute of Technology, ALEXANDER N. PODDUBNY, Ioffe Physical Technical Institute, TIM WOLZ, HANNES ROTZINGER, ALEXEY V. USTINOVO, Karlsruhe Institute of Technology — The interaction of qubits with free space instead of a cavity gives rise to several effects, which could play an important role for the implementation of a quantum computer. One of the most intriguing features is that in one-dimensional free space the interaction between qubits is of infinite range and can be tuned by varying the qubit separation [1]. In this work, we experimentally study an array of eight superconducting transmon qubits with local frequency control, which are all coupled to the mode continuum of a superconducting waveguide. The spacing between adjacent qubits is substantially smaller than the wavelength corresponding to their excitation frequency, eliminating almost completely the coherent exchange type interaction between qubits. By consecutively tuning the qubits to a common resonance frequency we observe the formation of super- and subradiant states as well as the emergence of a bandgap. Making use of the anharmonic level structure of the transmon qubit we study the nonlinear saturation of the collective modes with increasing photon number and electromagnetically induce a transparency window in the bandgap region of the ensemble.

1:15PM S16.00009: Quantum impurity simulation in a photonic crystal with superconducting circuits*  
ANDREI VRAJITOAREA (Presenter), Princeton University, RON BELYANSKY, REX LUNDGREN, University of Maryland, SETH P WHITSITT, ALEXEY V GORSHKOV, JQI-NIST, ANDREW HOUCK, Princeton University — Superconducting circuits have emerged as a rich platform for emulating synthetic materials composed of artificial atoms and photonic lattices. Here, we apply this toolbox for exploring the physics of a quantum impurity coupled to a photonic crystal. In previous experiments, strongly coupling a transmon qubit to the band structure of a stepped impedance waveguide filter has led to the first observation of atom-photon dressed bound states. In this work, we push the coupling strength even further to go beyond the single-photon limit. Our platform consists of a photonic crystal implemented as a linear array of 26 coupled microwave resonators, and a fluxonium qubit galvanically coupled to one resonator site. Tuning the coupling strength, we can reach a regime where counterrotating terms become relevant and multiphoton bound states participate in the single-photon scattering dynamics. Additionally, by probing the transmission response for each discrete bath mode subject to a qubit drive, we can extract the spin-bath susceptibilities that capture the many-body correlations between the impurity and the harmonic degrees of freedom in the crystal.

1:27PM S16.00010: High coherence bosonic modes in long Josephson junction chains  
NITISH JITENDRAKUMAR MEHTA (Presenter), ROMAN KUZMIN, NICHOLAS GRABON, VLADIMIR MANUCHARYAN, University of Maryland, College Park — Owing to high coherence and easy fabrication, 3-D Superconducting microwave cavities coupled to ancilla qubits are an attractive platform for the storage and manipulation of continuous variable quantum information. Recent experiments have demonstrated high fidelity QND readout, arbitrary control and remote entanglement of photonic states in these cavities[1]. Despite the progress, large size of the 3-D cavities poses a significant hurdle in scaling up the architecture. Here we present a way to get around the problem by using standing wave modes in 6mm long transmission line made out of two parallel chains of Josephson junctions[2]. Remarkably, we measure energy relaxation times exceeding 1ms in a setup with more than 20,000 junctions in one device.

Experimental Realization of the bosonic Kitaev-Majorana model  

JIMMY SHIH-CHUN HUNG, J. BUSNAINA, M.V. MOGHADDAM, CHUNG WAI SANDBO CHANG, ANANTHAPADMANABHA VADIRAJ, C.M. WILSON (Presenter), Institute for Quantum Computing, University of Waterloo — Superconducting quantum circuits (SQC) are a natural platform for quantum simulations of a wide variety of important lattice models, spanning condensed matter to high-energy physics. The varied toolbox of SQC allow the simulation of a variety of phenomena, including topological effects. Recently, McDonald et al proposed one such topological model that they dubbed the bosonic Kitaev-Majorana model. The model is a bosonic analog of the well-known fermionic Kitaev-Majorana model that has garnered great interest recently. Both models consist of a 1D chain connected by a hopping term but also subject to a pairing potential for the resident excitations. While the bosonic model does not reproduce all of the features of the original, it still exhibits a number of interesting topological features, such as chiral transport. Here we implement the bosonic Kitaev-Majorana model using a multimode superconducting parametric cavity. The nodes of the lattice are mapped to frequency modes of the cavity. The complex hopping terms are created by parametric pumping at mode-difference frequencies, while the pairing potential is induced by pumping at mode-sum frequencies. We present results for simulations on small lattices and discuss possibilities for scaling up the lattice size.

Driven quantum nonlinear resonators: new exact solution techniques and generalized photon blockade  

DAVID ROBERTS (Presenter), AASHISH CLERK, University of Chicago — Interacting driven-dissipative quantum resonators are at the forefront of research in quantum optics and quantum computing with superconducting circuits. We develop a new theoretical approach that allows one to non-perturbatively find the steady states of such systems. Our approach uncovers surprising phenomena in systems with an unusual three-photon coherent drive. This includes a new kind of generalized photon blockade effect, where interference causes a sharp cut-off in the system’s photon-number distribution despite without requiring extremely strong nonlinearity. This is distinct from standard photon blockade (which requires a strong nonlinearity), or the so-called “unconventional photon blockade” (which does not completely suppress high photon number states). We also describe a new kind of quantum bistability in these systems, which we can understand as a kind of interference between pairs of holomorphic functions in phase space. The effects we describe are well within the reach of current experiments in circuit QED, and could be harnessed for a variety of applications in quantum information processing.
 Encoding qubits in Bloch states of superconducting devices

THOMAS STACE (Presenter), Univ of Queensland, ARNE GRIMSMO, University of Sydney, CLEMENS MUELLER, ETH Zurich, JARED H. COLE, RMIT, DAT THANH LE, Univ of Queensland — We describe two related superconducting circuits, the transmon [1] and the dualmon [2] in terms of Bloch states that reflect periodic symmetries in their Hamiltonians. We use these two systems to illustrate a new scheme for encoding a qubit into superconducting qubits, using states in the lowest Bloch band. We discuss how these states are likely to be extremely robust against relaxation and noise, and suggest possible gates for controlling the state of such systems.

*This work was funded by the Australian Research Council Centre of Excellence in Engineered Quantum Systems CE170100009
11:51AM S17.00002: Logical Cooling for Noise Reduction in Analogue Quantum Simulation*
SUSAN M. CLARK (Presenter), CRAIG W. HOGLE, JAIMIE S. STEPHENS, KEVIN YOUNG, ROBIN
BLUME-KOHOUT, DANIEL L STICK, PETER MAUNZ, Sandia National Laboratories — Analogue
quantum simulation is arguably the most promising near-term application of quantum
computing. However, analogue simulators are susceptible to noise, and it is not known if realistic
noise destroys their computational power. Here, we report our progress using a technique to
remove errors in the computational basis of the system, without resorting to a full error
correcting scheme, to both measure and increase an analogue quantum simulator's robustness
to noise.

12:03PM S17.00003: Characterizing the Propagation of Gate Errors in Experimental
Quantum Algorithms*  GABRIEL SAMACH (Presenter), MORTEN KJAERGAARD, AMY GREENE,
Massachusetts Institute of Technology, MOLLIE SCHWARTZ, MIT Lincoln Laboratory, ANDREAS
BENGTTSSON, Chalmers Institute of Technology, MICHAEL O'KEEFFE, MIT Lincoln Laboratory, CHRIS
MCNALLY, YOUNGKYU SUNG, Massachusetts Institute of Technology, PHILIP KRANTZ, Chalmers
Institute of Technology, JOCHEN BRAUMUELLER, RONI WINIK, Massachusetts Institute of Technology,
DAVID K KIM, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, JONILYN YODER, DANNA
ROSENBERG, KEVIN OBENLAND, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, SIMON
GUSTAVSSON, WILLIAM OLIVER, Massachusetts Institute of Technology — Universal quantum
computation requires a complete gate-set of single-qubit operations and a two-qubit entangling
gate. As research progresses towards useful applications of NISQ-era quantum processors,
infidelities in these operations limit the depth of algorithms accessible on near-term devices.
While Clifford Randomized Benchmarking provides a rough metric for the fidelity of operations in
a random quantum algorithm, this metric can fail to capture the buildup of coherent error in
algorithms with significant internal symmetry, such as Trotterization. In this talk, we present
recent measurements characterizing the propagation of gate errors in a Trotterized quantum
algorithm performed using >99.9% fidelity single-qubit and 99.7% fidelity controlled-phase (CZ)
gates between flux-tunable transmon qubits. We consider the role played by coherent and
incoherent gate errors in deep quantum circuits, and we look at how their propagation depends
on the choice of gate compilation.

12:15PM S17.00004: Time-Dependent Simulation of Superconducting Quantum Circuits in the Presence of Non-Markovian Noise*  
SAM ALTERMAN (Presenter), ANDREW JAMES KERMAN, MIT Lincoln Laboratory — Understanding the practical impact of realistic noise on the performance of superconducting quantum circuits is vital to evaluating their prospects for potential applications and system architectures. This understanding is particularly limited at present for the more complex circuits involved in quantum annealing and reversible logic, which are subject to both damping and non-Markovian 1/f flux noise. In this presentation, we discuss a quantum trajectory-based dynamics simulation method for such circuits, and present progress towards its use in evaluating residual power dissipation in reversible logic circuits.

*This research is funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) under Air Force Contract No. FA8721-05-C-0002. The views and conclusions contained herein are those of the authors and should not be interpreted as necessarily representing the official policies or endorsements, either expressed or implied, of ODNI, IARPA, or the U.S. Government.

12:27PM S17.00005: Low Rank Density Matrix Evolution for Noisy Quantum Circuits  
YI-TING CHEN (Presenter), COLLIN FARQUHAR, ROBERT PARRISH, QC Ware Corp — Quantum circuit simulators validate the accuracy of quantum computing hardware and facilitate the invention of quantum algorithms and the deployment of quantum solutions on real world problems. In this work, we present an algorithm for simulating noisy quantum circuits based on the fact that the effective dimensionality of a density matrix is low when the noise level is reasonable small. Under certain conditions on the noise level and circuit depth, we proof that the numerical rank of a density matrix grows only linearly with the number of qubits. This allow us to track the evolution of a compressed representation of a density matrix with exponentially less computational resource. We implement this algorithm in an in-house simulator, Quasar, showing that the low rank algorithm speeds up simulations more than two orders of magnitude against the standard full density matrix method, with a trade-off of small amount of error. We benchmark the performance of the algorithm with different noise channels, noise strength and circuit types. Finally, we implement instances of Grover's search algorithm, showing that the low rank evolution benefits not only random circuit simulations, but also structured quantum algorithms.

ROBIN HARPER, Univ of Sydney, WENJUN YU, Tsinghua University, STEVEN FLAMMIA (Presenter), Univ of Sydney — To achieve a scalable estimation of quantum noise we need to learn efficient and complete representations of that noise. We can do this by using descriptions that have clear and relevant physical assumptions baked in. Here I will present work on a scalable and complete protocol to learn a Pauli channel which only has $s$ non-negligible Pauli error rates. So long as the number of error rates scales polynomially with the number of qubits, then this is an efficient protocol and requires only $O(n \times s)$ experiments, linear in the number of qubits. The classical computational effort is also efficient in $n$. Learning these error rates is directly relevant to improving quantum error correction and we have already implemented this to efficiently learn all the errors on a 14-qubit quantum device.
**12:51PM S17.00007: Random Circuit Metrics for Performance Assessment and Model Testing** LUKE GOVIA (Presenter), GUILHEM RIBEILL, MATTHEW WARE, HARI K KROVI, Raytheon BBN Technologies — Random circuit metrics, such as cross-entropy benchmarking, have recently emerged as a powerful set of tools to assess the performance of quantum processors. A natural question is to what extent these techniques can be used to learn noise characteristics of the processor. Here, we present results on extensions of random circuit metrics to testing error models. We demonstrate for small processors built from superconducting qubits that analysis of random circuit distributions is a viable method to compare candidate error models for device operation. Such models feed directly into the debugging cycle, and can be used to guide future operation towards optimal performance, or in the design of future devices.

**1:03PM S17.00008: Benchmarking tools for NISQ systems** DAVID MCKAY (Presenter), LEV S BISHOP, ANTONIO D CORCOLES, PETAR JURCEVIC, ABHINAV KANDALA, JIN-SUNG KIM, ISAAC LAUER, SETH MERKEL, ZLATKO MINEV, NEEREJA SUNDARESAN, SRIKANTH SRINIVASAN, MAIKA TAKITA, XUAN WEI, SARAH SHELDON, JAY M GAMBETTA, IBM TJ Watson Research Center — As the field marches towards quantum advantage with near-term quantum processors, it becomes imperative to characterize, verify, and validate performance. An outstanding scientific challenge in the community is a scalable set of metrics or experiments which can shed light on the usability of a device for near-term algorithms. Moreover, it becomes critical to explore techniques to extend the computational reach of noisy systems, be it through understanding underlying non-idealities, or more efficient circuit compilation. In this talk I will review the work we are doing at IBM to benchmark NISQ devices and I will discuss our recent results on quantum volume, large-scale entanglement and randomized benchmarking.

*This work was supported by the Army Research Office under contract W911NF-14-1-0124*
**1:15PM S17.00009: Model Refinement of Noisy Quantum Circuits Using Experimental Characterization**

MEGAN LILLY (Presenter), Bredesen Center for Interdisciplinary Research and Graduate Education, University of Tennessee, Knoxville, TRAVIS HUMBLE, Quantum Computing Institute, Oak Ridge National Laboratory — Current quantum processing units represent noisy intermediate scale quantum systems that tend to be poorly characterized. Accurate modeling of these devices can provide insight into the underlying noise as well as methods for mitigating errors. We present a test-driven methodology for quantifying QPU performance and characterizing NISQ behavior that offers an alternative to costly experimental characterizations using standard tomographic methods. We demonstrate modeling of noisy gate operations by fitting experimental characterization circuits using a series of bootstrapped numerical methods. We generate parameterized gate models that are composed easily to model noisy quantum circuits. We demonstrate the effectiveness of this modeling method for applications of GHZ state preparation and the Bernstein-Vazirani algorithm using a family of superconducting transmon QPUs. We quantify the accuracy of the generated models using the total variation distance between experimental observations and numerically simulated results. Our results show that model refinement from test-driven experimental characterization offers an accessible methodology for approximating performance of NISQ devices.

*This work was supported by the Department of Energy Office of Science Early Career Research Program.

**1:27PM S17.00010: Modeling leakage in superconducting quantum computers**

FILIP WUDARSKI (Presenter), NASA Ames Research Center — Current quantum computing architectures are fragile and prone to various imperfections that limit computational capabilities. In order to better understand behavior of quantum hardware, we need to develop a theoretical framework that captures possibile sources of device errors.

Recent development in noise description allow us to characterize within statistical accuracy net effects of numerous unknown contributions. The most commonly used method for this is based on randomized Pauli channels (PC) approach, that can reflect circuit's fidelity.

In this talk, we discuss a potential extension to PC technique, that can in principle take into account leakage to non-computation basis. The method is based on Weyl matrices. We show the effect of projecting leakage subspace into a qubit space, and compare the method with PC. Finally, we briefly explain possibility of expanding this model to larger dimensions.

Benchmarking noise with Quantum alternating operator ansatz (QAOA) circuits with a symmetry

ZHUIHUI WANG (Presenter), MICHAEL STREIF, Quantum AI Lab, USRA; NASA Ames Research Center, ELEANOR RIEFFEL, Quantum AI Lab, NASA Ames Research Center — QAOA as a quantum heuristic algorithm has attracted a lot of interest with its simple iterative structure. We propose adapting a symmetry-preserving QAOA circuit for benchmarking noise. Consider the system consisting of a number of subsets of qubits, we design the QAOA such that it preserves certain quantity of the subsets (e.g., a constant Hamming weight). When errors are present, the evolution will quickly escape from the preserved subspace. We study how this escaping rate scales with the iteration of the circuit and system size. Our analysis shows for a wide range of local noise channels the escaping rate can be exactly obtained with only the knowledge of the error model, thanks to the non-increasing reverse causal cone with QAOA level with respect to noise. We show that the analysis is stable against inhomogeneity in the subsystem, hence our scheme is feasible for benchmarking local noises in realistic situations.

Entanglement in superconducting qubits and quantum foundations

ARI MIZEL (Presenter), Lab for Physical Sciences — Leggett has proposed an experimental program to probe the limits of quantum mechanics using superconducting qubits. With this in mind, we consider the number of particles entangled in certain superconducting qubit states. Implications for quantum foundations are discussed.

Progress towards high-fidelity CZ gates in a tunable coupling architecture

CHRIS QUINTANA (Presenter), KEVIN SATZINGER, ANDRE PETUKHOV, ZIJUN CHEN, XIAO MI, YU CHEN, Google LLC — We describe progress towards implementing high-fidelity CZ gates in the Sycamore tunable coupling architecture.

11:15AM S18.00001: Beyond Backprop: Different Approaches to Credit Assignment in Neural Nets [Invited]  IRINA RISH (Presenter), Computer Science and Operations Research (Département d'informatique et recherche opérationnelle), Université de Montréal / Mila - Quebec AI Institute —

Backpropagation algorithm (backprop) has been the workhorse of neural net learning for several decades, and its practical effectiveness is demonstrated by recent successes of deep learning in a wide range of applications. This approach uses chain rule differentiation to compute gradients in state-of-the-art learning algorithms such as stochastic gradient descent (SGD) and its variations. However, backprop has several drawbacks as well, including the vanishing and exploding gradients issue, inability to handle non-differentiable nonlinearities and to parallelize weight-updates across layers, and biological implausibility. These limitations continue to motivate exploration of alternative training algorithms, including several recently proposed auxiliary-variable methods which break the complex nested objective function into local subproblems. However, those techniques are mainly offline (batch), which limits their applicability to extremely large datasets, as well as to online, continual or reinforcement learning. The main contribution of our work is a novel online (stochastic/mini-batch) alternating minimization (AM) approach for training deep neural networks, together with the first theoretical convergence guarantees for AM in stochastic settings and promising empirical results on a variety of architectures and datasets.

12:27PM S18.00003: David Schwab Invited Talk [Invited] —

1:03PM S18.00004: Surya Ganguli Invited Talk [Invited] —

Despite tremendous success of Stochastic Gradient Descent (SGD) algorithm in deep learning, little is known about how SGD finds generalizable solutions in the high-dimensional weight space. By analyzing the SGD-based learning dynamics and the loss function landscape near solutions found by SGD, we discover a counter-intuitive relation between the weight fluctuation and the loss landscape – the flatter the landscape the smaller the weight variance. To explain this inverse variance-flatness relation, we develop a random landscape theory of SGD, which shows that noise strength (effective temperature) in SGD depends inversely on the landscape flatness and thus SGD serves effectively as a self-tuned (landscape-dependent) annealing mechanism to find the generalizable solutions at the flat minima of the loss landscape. Application of these new insights for preventing catastrophic forgetting will also be discussed.

Thursday, March 5, 2020 11:15 AM - 2:15 PM

Session S19 GMAG: New Opportunities in Spin Sensing, Manipulation and Resonance without Time-Varying Magnetic Fields 207 - Michael Flatté, Univ of Iowa - Tag(s): Invited
ALEXANDRE BOURASSA (Presenter), University of Chicago — The neutral divacancy (VV0) in silicon carbide (SiC) combines the advantages of a long lived spin system [1] and a near-infrared spin-photon interface [2] in a material compatible with state-of-the-art CMOS type fabrication techniques. Here, we use this scalable material to demonstrate a flexible quantum platform built by integrating and isolating single divacancies in a p-i-n diode structure.

This simple integration allows us to reduce electrical noise by engineering the defect's environment using charge depletion. This technique effectively eliminates spectral diffusion leading to optical linewidth narrowing approaching the transform limit. Broadly, this method could be generalized to produce ideal quantum emitters in various electrically “noisy” host materials. Additionally, field confinement in the junction enables wide tuning of the optical lines by almost a terahertz. Since this field is applied along the symmetry axis, the orbital splitting and associated mixing can be minimized. Finally, using electric fields and optical excitation, we show a method for deterministic charge state control of the divacancy.

Overall, we present a narrow, widely tunable and stable spin based single photon source ideal for communication networks and long-distance entanglement. These results demonstrate the power in combining highly coherent quantum spin system with scalable classical electronics.

PATRICK LENAHAN (Presenter), Pennsylvania State University — We have investigated changes in current dominated by spin dependent recombination and spin dependent variable range hopping [1-3] in a variety of systems resulting from the application of relatively small magnetic fields. We compare the current changes resulting from the small magnetic fields to current changes induced by electrically detected magnetic resonance. Magnetic fields of order one mT can yield significant current changes in silicon and silicon carbide based metal oxide semiconductor (MOS) field effect transistors (MOSFETs), bipolar junction diodes and transistors, pin diodes, MOS gated diodes, amorphous silicon nitride, amorphous silicon dioxide and amorphous carbon thin films. These near zero magnetic field induced changes are easily observable at room temperature. The near zero magnetic field response is invariably a strong function of bias applied to the device structures; both the overall amplitude of the response and the “shape” of the response can be strongly influenced by the biasing conditions. In some cases one may also apply a time dependent biasing waveform to explore the kinetics of charge capture events. In this presentation I will discuss the potentially rich source of information about electronic transport which these electron spin based measurements can provide.

Magnetoresistance Measurements as an Alternative to Magnetic Resonance Methods for Studying Paramagnetic Defects* [Invited] NICHOLAS HARMON (Presenter), Univ of Evansville — Magnetic resonance methods such as electronic paramagnetic resonance and other companion methods like electrically detected magnetic resonance have been popular for studying unpaired spins in a wide array of materials. In some situations resonance methods are not feasible — for instance when a system of interest is beneath conductive layers as in three-dimensional integrated circuits.

Recently an alternative approach to probing paramagnetic spins was devised which does not require any electromagnetic resonant field but instead magnetoresistance is measured near zero field [1]. The magnetoresistance arises from correlations between spin pairs that involve either a carrier recombining at a trap or hopping through a trap [2]. This magnetoresistance method can be used in electronic devices to great advantage by probing paramagnetic defect environments such as hyperfine and spin-orbit couplings. A theoretical description of the magnetoresistance effect utilizes a multi-spin stochastic Liouville equation [3] which provides agreement with recombination currents in MOSFETs. For high-nuclear spin defects, the theory predicts new resonances in the magnetoresistance that provide precise determination of hyperfine constants. These results offer a new means of analysis which does not rely on a resonator and are potentially applicable to systems inaccessible to conventional resonance methods.

HUIYAO CHEN (Presenter), Cornell University — Here we report on diamond mechanical resonator device engineering and its application to the acoustic control of NV center quantum states. We fabricate high quality diamond bulk acoustic resonators with gigahertz modes and integrated NV centers. Driving the resonator creates direct coupling of phonons to NV center electron spin and orbital states. At room temperature, we observe both single and double quantum spin transitions driven by phonons. Through improved device engineering, we demonstrate efficient acoustic control of NV center spin states using a semi-confocal high over-tone resonator. At cryogenic temperature, we probe the orbital states of a single NV center using photoluminescence excitation (PLE) spectroscopy. We show that the effects of phonon driving are spectroscopically revealed as Autler-Townes splitting and the occurrence of Raman sidebands. Lastly, we discuss how mechanical driving can be leveraged for decoherence protection based on phonon-dressed NV electronic states.

Nonlinear planar Hall effect* [Invited]  GIOVANNI VIGNALE (Presenter), Department of Physics and Astronomy, Univ of Missouri - Columbia, PAN HE, DAPENG ZHU, SHUYUAN SHI, HYUNSOO YANG, Department of Electrical and Computer Engineering and NUSNNI, National University of Singapore, STEVEN S -L ZHANG, Department of Physics, Case Western University, OLLE HEINONEN, Materials Science Division, Argonne National Laboratory — An intriguing property of a three-dimensional (3D) topological insulator is the existence of surface states with spin-momentum locking, which offers a new frontier of exploration in spintronics. Here, we report the observation of a new type of Hall effect in a 3D topological insulator Bi$_2$Se$_3$ film. The Hall resistance scales linearly with both the applied electric and magnetic fields and exhibits a $\pi/2$ angle offset with respect to its longitudinal counterpart, in contrast to the usual angle offset of $\pi/4$ between the linear planar Hall effect and the anisotropic magnetoresistance. This novel nonlinear planar Hall effect originates from the conversion of a nonlinear transverse spin current to a charge current due to the concerted actions of spin-momentum locking and time-reversal symmetry breaking, which also exists in a wide class of non-centrosymmetric materials with a large span of magnitudes. This provides a new way to characterize and utilize the nonlinear spin-to-charge conversion in a variety of topological quantum materials.

Session S20 DBIO: Single-Molecule Techniques and Enzymes 301 - Helmut Strey, Stony Brook University
**11:15AM S20.00001: Multi-scanning of single DNA Molecules in a Dual Nanopore Device**

XU LIU, PHILIP ZIMNY, Ontera, YUNING ZHANG, McGill University, ANKIT RANA, ROLAND NAGEL, Ontera, WALTER W REISNER (Presenter), McGill University, WILLAM DUNBAR, Ontera — Single-molecule techniques can access to biomolecular information that is otherwise masked by ensemble averaging, and that can lead to new research discoveries or clinically applications. Solid-state nanopores offer a compact and electrical single-molecule sensing approach. However, single reads of molecules taken with solid-state nanopores generally do not possess sufficient quality for applications that otherwise require alignment of multiple reads of molecules from heterogeneous samples. Here we present a single-molecule manipulation and sensing approach based on a dual nanopore device that can linearize DNA and improve read quality by enabling repeated scanning at reduced speeds of the same molecule. A DNA molecule is first co-captured by the two pores with unbalanced voltage forces applied at the pores (tug-of-war state), and then repeatedly scanned back-and-forth by automated voltage control logic. The method enables detection of sequence-specific protein tags that are used for triggering the motion control during dual current sensing. We have achieved up to 100’s of scans, and analysis of multiple scans from a single molecule demonstrates a reproducible binding pattern, or molecular barcode, with tag spacings corresponding to expected sequence positions of the tags.

**11:27AM S20.00002: Computational design and interpretation of single-RNA translation experiments.**

* LUIS AGUILERA (Presenter), WILLIAM RAYMOND, KENNETH LYON, TATSUYA MORISAKI, TIMOTHY J. STASEVICH, BRIAN MUNSKY, Colorado State University — Recent advances in time-lapse fluorescence microscopy allow live-cell quantification of ribosome kinetics at single-molecule resolution. Here, we integrate single-molecule experimental data and stochastic models to investigate canonical and non-canonical translation processes. In a first study, we developed a new fluorescent tag system that allowed us to observe, for the first time, ribosomal frameshifting at single-molecule resolution. Our results corroborate that frameshifting is a bursty process, where the RNA stochastically switch between non-frameshifting and frameshifting state (Lyon, K., et al., 2019. Molecular Cell). In a second study, we developed novel stochastic models to estimate biophysical parameters, such as ribosomal elongation and initiation rates. Our methods were used to simulate single-molecule experiments under multiple imaging conditions and for thousands of human genes, and we evaluate which experiments provide accurate estimates of elongation kinetics. With this, we present an interpretation for the well-established experimental procedures, including Correlation Spectroscopy, ribosome Run-Off Assays, and FRAP (Aguilera, L., et al., 2019, Plos Comp Biology).

11:39AM S20.00003: Single-Molecule Sensitivity in Mass Spectrometry Using Nanoscale Ion Sources*  NICHOLAS DRACHMAN (Presenter), MATHILDE LEPOITEVIN, BENJAMIN N WIENER, DEREK STEIN, Brown University — Electrospray ionization has revolutionized the analysis of biomolecules by softly transforming molecules in solution into gas-phase ions, which can be analyzed by mass-spectrometry. Due to the chaotic process by which the electrosprayed droplets break down into ever-smaller droplets, eventually yielding singly charged ions via ion evaporation, only a small fraction of the sample molecules makes it to the mass analyzer. We have shown that a nanoscale ion source allows ions to evaporate directly off of the meniscus, bypassing the wasteful droplet evaporation process. The small area of the liquid-vacuum interface also prevents significant evaporative heat loss, enabling the use of volatile solvents like water. This technique has been shown to work with simple salt solutions as well as aqueous solutions of biomolecules such as amino acids, nucleic acids, and small peptides. Adoption of these nanopore ion sources could drastically improve the sensitivity of mass spectrometry experiments and open the door to a wide range of potential applications, including single-molecule protein sequencing and single cell proteomic studies.

11:51AM S20.00004: Brownian motion alone may not be sufficient to supply ribosomes with tRNA during translation elongation  AKSHAY J MAHESHWARI (Presenter), Bioengineering, Stanford University, EMMA DEL CARMEN GONZALEZ GONZALEZ, ALP M SUNOL, Chemical Engineering, Stanford University, DREW ENDY, Bioengineering, Stanford University, ROSEANNA ZIA, Chemical Engineering, Stanford University — The construction of artificial cells holds significant promise for biotechnology and medicine. However, substantial work remains to make such cells modelable. In particular, the set of functions necessary for life remains elusive, most acutely demonstrated by the existence of genes of unknown function that are essential for life1.

We hypothesize that some of the functions that remain unknown pertain to the physics of how molecules organize to produce cellular functions. To test our hypothesis we introduce translation elongation in E. coli as a model system. Due to its central role in protein production, elongation is likely to have undergone tremendous selective pressure to operate at the limits of physics. We construct a colloidal model of elongation and demonstrate that variable local volume densities around ribosomes at different growth rates may lead to competing trade-offs in tRNA transport and reaction. We then use lower-bounding simulations to show that tRNA transport via Brownian motion alone may be insufficient to recover experimentally determined elongation rates. Overall, we predict that currently unknown mechanisms for speeding up tRNA transport or biasing its spatial organization are implicated in translation elongation.

12:03PM S20.00005: Enhanced diffusion and enzyme dissociation at high substrate concentration  AH-YOUNG JEE (Presenter), Institute for Basic Science, KUO CHEN, Beijing National Research Center for Molecular Sciences, TSVI TLUSTY, Institute for Basic Science, JIANG ZHAO, Beijing National Research Center for Molecular Sciences, STEVE GRANICK, Institute for Basic Science — The concept that catalytic enzymes can act as molecular machines transducing chemical activity into motion has conceptual and experimental support, but much of the claimed support comes from experimental conditions where the substrate concentration exceeds $k_M$ (the Michaelis-Menten constant), meaning that it exceeds concentrations that are biologically relevant. Moreover, many of the enzymes studied experimentally to date are oligomeric. Urease, a hexamer of subunits, has been considered to be the gold standard demonstrating enhanced diffusion. Here we show that urease and certain other oligomeric enzymes of high catalytic activity above $k_M$ dissociate into their smaller subunit fragments that diffuse more rapidly, thus providing a simple physical mechanism of enhanced diffusion in this regime of concentrations. Data for urease are presented in the main text and the conclusion is validated for hexokinase and acetylcholinesterase with data presented in supplementary information. For substrate concentration regimes below $k_M$ at which these enzymes do not dissociate, we validate that enzymatic catalysis does lead to the enhanced diffusion phenomenon.

12:15PM S20.00006: Stochastic Simulation to Visualize Gene Expression and Error Correction in Living Cells* KEVIN Y CHEN, Chemistry, University of Cambridge UK, DANIEL M ZUCKERMAN, Biomedical Engineering, Oregon Health & Science Univ., PHIL NELSON (Presenter), Physics and Astronomy, Univ of Pennsylvania — Stochastic simulation can make the molecular processes of cellular control more vivid than the traditional differential-equation approach by generating typical system histories, instead of just statistical measures such as the mean and variance of a population. Simple simulations are now easy for students to construct from scratch, that is, without recourse to black-box packages. In some cases, their results can also be compared directly to single-molecule experimental data. After introducing the stochastic simulation algorithm, we give two case studies, involving gene expression and error correction, respectively. For error correction, several proofreading models are compared to find the minimal components necessary for sufficient accuracy in translation. Animations of the stochastic error correction models provide insight into the proofreading mechanisms. [Ref: KYC, DMZ, PCN, "The Biophysicist" in press.]

12:27PM S20.00007: Single-pair measurements of nonradiative energy transfer efficiency between quantum dots and organic dyes reveals orientational variation  NOOSHIN SHATERY NEJAD (Presenter), CANDICE M. ETSON, Physics, Wesleyan University — Förster resonance energy transfer (FRET) is a technique that can be used to measure the nanoscale distances and to report on biomolecular dynamics at the single-molecule level. Organic dyes FRET pairs are commonly used in biophysical studies, but this approach suffers from the fact that the organic dyes have short bleaching lifetimes. Quantum dots have longer lifetimes, which makes them ideal for use as FRET donors in longer experiments. However, the energy transfer between quantum dots and organic dye molecule acceptors has not formerly been characterized at the single-molecule level. Therefore, we used TIRF microscopy to observe surface immobilized FRET pairs separated by known lengths of duplex DNA. We used two methods to construct these assemblies. In both cases, we observed broad distributions of FRET efficiencies and little correlation between duplex length and the average FRET efficiency. However, when we probe multiple donor-acceptor distances for a particular quantum dot, we observe the expected decrease in FRET efficiency with increasing duplex length. We attribute these contradictory observations to variations in the orientation factor for each single quantum dot, based on its inherent dipole moment and the location at which the DNA molecule is coupled to its surface.

12:39PM S20.00008: Bayesian nonparametrics allow for super resolution microscopy without photo-switching  IOANNIS SGOURALIS (Presenter), Arizona State University — Super resolution microscopy permits direct observation of biomolecules. However, due to noise, distinguish single molecules demands specialized analysis models that facilitate the interpretation of the acquired images. In such models, the positions of the molecules are represented by random variables and conventionally the total number of random variables in a model is kept fixed and finite. However, prevailing uncertainty in the number of individual molecules contributing photons to the images, makes existing approaches inappropriate as they rely on pre-specification of the number of unknown parameters. Switching of the fluorophores between bright and dark states, induced by experimental means (STORM, PALM, PAINT), ensures that each time at most one fluorophore is visible leading to a convenient solution. Nevertheless, photo-switching requires specialized fluorophores and long experiments necessary to collect photons from multiple switching events. In the talk, I will walk through recent modeling advances and highlight how Bayesian nonparametrics can be used to achieve super resolved localization of single molecules without photo-switching and so allowing for super resolution microscopy with less specialized fluorophores and significantly shorter experiments.
12:51PM S20.00009: Intensity Distribution of a Dilute Solution of Point Emitters under Gaussian Detection*  HELMUT STREY (Presenter), Stony Brook University — In single-molecule techniques, one often employs a Gaussian illumination profile to measure fluorescence intensities from a dilute solution of molecules. Typically such measurements are performed by single-photon detection and result in a sequence of single-photon arrival times. Here we develop a general framework for calculating the intensity distribution of a dilute solution of Point emitters under Gaussian Detection. We will show that the resulting Intensity distributions dramatically change character at low emitter concentrations when considering different dimensionalities of Gaussian Detection. In particular the one- and two-dimensional solutions are strongly structured, exhibiting discontinuities in their derivative at integer multiples of the brightness. This makes these distributions strong candidates for applications that distinguish and measure concentrations of mixtures of emitters of different brightnesses. Finally, we will discuss a maximum likelihood method to determine concentration and brightness from a sequence of single-photon arrival times.

1:03PM S20.00010: Reliable Imaging of Dynamic Structures in Live-Cell Super-Resolution  OWEN ANDREWS (Presenter), IBRAHIM CISSE, Massachusetts Institute of Technology MIT — Super-resolution imaging by single-molecule localization is a powerful tool for visualizing structures inside of cells that are smaller than the diffraction limit. However, imaging in living matter poses a challenge because structures can be mobile and dynamic, yet single-molecule localization microscopy can require a long time to generate images. In this talk, I will present a metric for assessing image reliability, based on robust estimation of the density of detected molecules. This simple metric quantitatively defines the tradeoff between spatial and temporal resolutions, and their relationships to acceptable levels of noise in density estimation. I will discuss how this implies variations in resolution across a data set, and present a tool for visually assessing data quality.
1:15PM S20.00011: Controlled sliding of DNA knots in solid-state nanopores*  RAJESH SHARMA (Presenter), Center for Advanced 2D Materials, National University of Singapore, ISHITA AGRAWAL, Department of Biomedical Engineering, National University of Singapore, LIANG DAI, Department of Physics, City University of Hong Kong, PATRICK DOYLE, Department of Chemical Engineering, Massachusetts Institute of Technology, SLAVEN GARAJ, Center for Advanced 2D Materials, National University of Singapore — Knots in DNA are useful for investigating the static and dynamic physics of biopolymers in solutions. Recently, we showed nanopores that probe the equilibrium structures of DNA knots in solutions. With unprecedented statistics, our distributions of sizes of equilibrium DNA knots and their positions provide important insights relevant from biological, physical, and technological perspectives. Although nanopores enable statistically significant single molecule investigation, these distributions get biased due to sliding of knots through nanopores, adversely affecting the conclusions. Using our experiments and parametrized simulations, we demonstrate complete control over sliding of knots in nanopores over a molarity range of 1M-3M. We show that controlling the experimental parameters enabled the detection of equilibrium knots in both linear and circular DNA molecules. These results open up an exciting opportunity for statistically significant biophysical investigation of knots in single biomolecules, generating unprecedented insights useful from both scientific and technological perspectives.

1:27PM S20.00012: Optimal Control and Reinforcement Learning of Regulation and Enzyme Activities*  SAMUEL BRITTON (Presenter), MARK ALBER, University of California, Riverside, JENNIFER HURLEY, MEAGHAN JANKOWSKI, Department of Biological Sciences, Rensselaer Polytechnic Institute, JEREMY ZUCKER, Biological Sciences Division, Pacific Northwest National Laboratory, SCOTT BAKER, Environmental Molecular Sciences Laboratory, Pacific Northwest National Laboratory, TINA KELLIHER, JAY DUNLAP, Geisel School of Medicine at Dartmouth, Department of Molecular and Systems Biology, WILLIAM CANNON, Research Computing Group, Pacific Northwest National Laboratory — Experimental measurement or computational inference/prediction of the enzyme regulation needed in a metabolic pathway is hard problem. Consequently, regulation is known only for well-studied reactions of central metabolism in various model organisms. In this study, we use statistical thermodynamics and metabolic control theory as a theoretical framework to calculate enzyme regulation policies for controlling metabolite concentrations to be consistent with experimental values. A reinforcement learning approach is utilized to learn optimal regulation policies that match physiological levels of metabolites while maximizing the entropy production rate and minimizing the heat loss. The learning takes a minimal amount of time, and efficient regulation schemes were learned that either agree with theoretical calculations or result in a higher cell fitness using heat loss as a metric. We demonstrate the process on four pathways in the central metabolism of Neurospora crassa (gluconeogenesis, glycolysis-TCA, Pentose Phosphate-TCA, and cell wall synthesis) that each require different regulation schemes.

*DOE SCGSR, NIH
1:39PM S20.00013: Binding Energies of Fn Cas12a  PETE RIGAS (Presenter), Cornell University — In recent years, CRISPR proteins have attracted much attention due to their use as a DNA binding platform, in which the protein undergoes steps of PAM attachment, crRNA-DNA inspection, and reconfiguration. Thermodynamically, we can model determinants of binding energies for different sites of the genome with a partition function that reflects energetic costs associated with base pair mismatches. From suitably chosen weights that assign higher energetic contributions to base pair mismatches among the first 6 positions of a DNA sequence, appropriate transition probabilities for a random walk $X$ will be defined so as to coincide with base pair mismatches. As $X$ approaches the position of binding, we stipulate that none of the transition probabilities of $X$ from all positions before $N$ vanish. Furthermore, with such a probabilistic approach, we will analyze the energy landscape of Fn Cas12a, leading to a more comprehensive understanding of how the binding energy of a sequence is dependent on individual base pairs. More broadly, this work will also study gRNA and DNA sequences that are conducive to binding in Fn Cas12a.

Thursday, March 5, 2020 11:15 AM - 2:03 PM

Session S21 GERA: Energy-related Thermal Phenomena 302

11:15AM S21.00001: Towards high power density, high efficiency thermophotovoltaic energy conversion system in the near field  ROHITH MITTAPALLY (Presenter), LINXIAO ZHU, ANTHONY FIORINO, Univ of Michigan - Ann Arbor, DAKOTAH THOMPSON, Univ of Wisconsin Madison, EDGAR MEYHOFER, PRAMOD REDDY, Univ of Michigan - Ann Arbor — Solid-state energy conversion holds promise for efficient extraction of electricity from different heat sources like solar and industrial waste heat. In particular, thermophotovoltaic (TPV) system involves a hot emitter radiating photons that excite electron hole pairs in a photovoltaic (PV) cell. Most TPV architectures in the far-field demonstrate very low power densities. Several theoretical proposals have shown that dramatic enhancement in power density can be achieved by reducing the gap to tens of nanometers where evanescent waves start contributing to power transfer. However, such demonstrations have been elusive due to the challenge of maintaining nano separations between a hot emitter (~1000 K) and a cold cell (~300 K). Here, we will first describe how high resolution calorimetry and custom-built nano-positioning platform have made possible, the first demonstration of ~40 fold increase in the power output, compared to far field, when the gap between the PV cell and thermal emitter at 650 K is reduced from ~10 µm to 60 nm. Further, we will describe ongoing efforts to achieve increases in both power output and efficiencies by engineering emitters that can reach high temperatures.
11:27AM S21.00002: Highly Efficient Solar Steam Generation by Glassy Carbon Foam Coated with Two-Dimensional Metal Chalcogenides*  
ZEESHAN TAHIR (Presenter), SUNGDO KIM, FARMAN ULLAH, Department of Physics, Univ of Ulsan, JOON I JANG, Department of Physics, Sogang University, YONG SOO KIM, Department of Physics, Univ of Ulsan — Steam generation by ecofriendly solar energy has immense potential in terms of low-cost power generation, desalination, sanitization and wastewater treatment. Herein, highly efficient steam generation in a bilayer solar steam generator (BSSG) is demonstrated which is comprised of a large-area SnSe-SnSe$_2$ layer deposited on glassy carbon foam (CF). Both CF and SnSe-SnSe$_2$ possess high photothermal conversion capabilities and low thermal conductivities. The combined bilayer system cumulatively converts input solar light into heat through phonon-assisted transitions in the indirect-bandgap SnSe-SnSe$_2$ layer, together with trapping of sunlight via multiple scattering due to the porous morphology of the CF. This synergistic effect leads to efficient broadband solar absorption. Moreover, the low out-of-plane thermal conductivities of SnSe-SnSe$_2$ and CF confine the generated heat at the evaporation surface, resulting in a significant reduction of heat losses. Additionally, the hydrophilic nature of the acid-treated CF offers effective water transport via capillary action, required for efficient solar steam generation in a floating form. A high evaporation rate (1.28 kgm$^{-2}$h$^{-1}$) and efficiency (84.1%) are acquired under one sun irradiation.

*National Research Foundation of Korea (NRF)

11:39AM S21.00003: Highly Efficient TiO$_2$ Nanorods@CF based Solar Steam Generator*  
SUNGDO KIM (Presenter), ZEESHAN TAHIR, ANH NGUYEN, JONGWOO PARK, YONG SOO KIM, Department of Physics, Univ of Ulsan — Harvesting solar energy via steam generation is an efficient way for brine and sewage water treatment. Directly bulk water heating with natural light yields low evaporation rates, owing to immense heat losses and its high heat capacity of water. Herein, we report styrofoam supported solar steam generator (SSG) comprised of glassy carbon foam (CF) covered with TiO$_2$ nanorods (TNRs). It shows a record high evaporation rate of 3.14 kgm$^{-2}$h$^{-1}$ under one sun irradiation. Such a high evaporation rate is mainly attributed to the synergetic effect of significant heat localization and reduction in enthalpy. Employing a low thermal conductivity, styrofoam naturally isolates the bulk water yielding an enhanced localization of heat. Concurrently, rapid water transport to SSG is ensured via a 2D air-laid paper as a wicking material. Moreover, the water molecules adsorbed in the form of clusters to the edges and tips of TNRs are more likely evaporate as clusters and thereby effectively reducing the enthalpy. Besides, the SSG offers broadband solar absorption displaying excellent photothermal conversion capability. Finally the facile method, low cost and longevity make our SSG a good candidate for application on a large scale.

11:51AM S21.00004: Continuum Model of Underground Thermal Energy Storage Applied to Efficiency Optimization  ANDERS CARLSSON (Presenter), Washington University, St. Louis — A major obstacle to extensive deployment of renewable energy sources is their seasonal intermittency. Borehole thermal energy storage (BTES) is an inexpensive technology that can mitigate this intermittency. Hot water is pumped from the center to the edge of an array of boreholes to heat it in the summer, and heat is discharged in winter by reversing the process. Mathematical modeling is key to efficiency improvement. I develop an approach to modeling BTES that is simpler than existing approaches that use either embedded symmetrized borehole temperature fields or explicit simulation of the full 3d geometry. This approach focuses on the average radial flow of water, and develops coupled 1d reaction-diffusion equations for the water and soil temperatures. These are supplemented by a time-dependent heat-transfer coefficient. With two adjustable parameters, the model fits four-year temperature data at 10-minute intervals from the Drake Landing Solar Community closely. I use the model to explore possible modifications to the charging and discharging strategies. A strategy in which heated water is discharged at variable distances can increase the efficiency by over 20% in some cases.

12:03PM S21.00005: Rattling-Induced Ultralow Lattice Thermal Conductivity in Simple Systems  RINKLE JUNEJA (Presenter), ABHISHEK SINGH, Indian Institute of Science — Rattling motion is one of the significant phenomena for achieving notable reduction in the thermal conductivity in complex crystal systems. To carry forward the advantages of rattling to simple crystal systems, we explored it in simpler cubic compounds AgIn$_5$S$_8$ and CuIn$_5$S$_8$. The weak and anisotropic bonding of Ag and Cu with the neighboring In and S causes the rattling motion, which result in very shallow anharmonic potential well for the rattlers Ag and Cu. The phonon spectra of these compounds have multiple avoided crossing of optical and acoustic modes, which are a signature of rattling motion. This leads to ultralow thermal conductivity. Even though Ag atoms contribute to the valence band states, the rattler modes of Ag do not scatter carriers significantly, leaving the electronic transport virtually unaffected. A combination of favorable thermal and electronic transport results in unprecedented figure of merit of 2.2 in p-doped AgIn$_5$S$_8$ at 1000 K. The proposed idea of having rattlers in simpler systems can be extended to a wider class of materials, which would accelerate the development of thermoelectric modules for waste energy harvesting.

12:15PM S21.00006: On photon thermal Hall effect and persistent heat current in radiative heat transfer*  CHENG GUO (Presenter), YU GUO, SHANHUI FAN, Stanford Univ — We study the photon thermal Hall effect and the persistent heat current in radiative heat transfer. We show that the photon thermal Hall effect is not a uniquely nonreciprocal effect; it can arise in some reciprocal systems with broken mirror symmetry. This is in contrast with the persistent heat current, which is a uniquely non-reciprocal effect that can not exist in any reciprocal system. Nevertheless, for a specific class of systems with C4 rotational symmetry, we note that the photon thermal Hall effect is uniquely nonreciprocal, and moreover there is a direct connection between the persistent heat current and the photon thermal Hall effect. In the near-equilibrium regime, the magnitude of the photon thermal Hall effect is proportional to the temperature derivative of the persistent heat current in such systems. Therefore, the persistent heat current as predicted for the equilibrium situation can be probed by the photon thermal Hall effect away from equilibrium.

*This work is supported by a MURI grant from the U. S. Army Research Office (Grant No. W911NF-19-1-0279), and by the Department of Energy Photonics at Thermodynamic Limits Energy Frontier Research Center under Grant de-sc0019140.

12:27PM S21.00007: Self-sustaining Thermophotonic Circuits  BO ZHAO (Presenter), SIDDHARTH BUDDHIRAJU, PARTHIBAN SANTHANAM, KAIFENG CHEN, SHANHUI FAN, Stanford Univ — Photons represent one of the most important heat carriers. The ability to convert photon heat flow to electricity is therefore of substantial importance for renewable energy applications. However, photon-based systems that convert heat to electricity, including thermophotovoltaic systems where photons are generated from passive thermal emitters, have long been limited by low power density. This limitation persists even with near-field enhancement techniques. Thermophotonic systems, which utilize active photon emitters such as light-emitting diodes, have the potential to significantly further enhance the power density. However, this potential has not been realized in practice, due in part to the fundamental difficulty in thermodynamics of designing a self-sustaining circuit that enables steady-state power generation. Here, we overcome such difficulty by introducing a configuration where the light-emitting diodes are connected in series, and thus multiple photons can be generated from a single injected electron. As a result, we propose a self-sustaining thermophotonic circuit where the steady-state power density can exceed thermophotovoltaic systems by many orders of magnitude. This work points to possibilities for constructing heat engines with light as the working medium.
12:39PM S21.00008: Demonstration of thermal energy conversion though radiating optical rectennas for night harvesting applications  
AMINA BELKADI (Presenter), GARRET MODDEL, University of Colorado, Boulder — Night harvesting, where heat is harvested from the temperature difference between Earth and deep space, promises clean energy when sunlight is not available. The low efficiency of available thermal-to-electrical energy conversion technologies has been the largest barrier in the commercial pursuit of this technology. We present a new approach using radiating optical rectennas – femtosecond-fast metal-insulator-metal (MIM) diodes and micron-scale antennas – to overcome the limitations of low efficiency for low temperature differences (<100 °C). We experimentally demonstrate the basic principle of thermal-to-electrical energy conversion using a Ni-NiO-Al₂O₃-Cr-Au MIM diode-based optical rectenna, with a transmission line compensation structure to enhance the coupling efficiency between antenna and diode at terahertz frequencies. For a temperature gradient of 80° C, the device generates an open circuit voltage of 300 mV, corresponding to a power of at least 93 mW/m². Under practical operating conditions, this technology has the potential to exceed similar technologies exploiting radiative cooling.

12:51PM S21.00009: Relaxor-ferroelectrics: An efficient material for waste-heat harvesting*
AMRIT SHARMA (Presenter), MAKHES K BEHERA, SANGRAM K PRADHAN, CARL E BONNER, MESSAOUID BAHOURA, Norfolk State Univ — The need for efficient energy utilization is driving research to harvest waste-heat, which is ubiquitous, abundant, and free. Thermal energy harvesting for low power electronic devices using ferroelectric materials is one of the emerging areas of research because they possess spontaneous polarization and exhibit excellent pyroelectric coefficients. These materials are unique as they only sense time-dependent temperature change to generate electric power. We have grown lead-free BaZr₀.₂Ti₀.₈O₃ (BZT)/Ba₀.₇Ca₀.₃TiO₃ (BCT) multilayer heterostructures on SrRuO₃ (SRO) buffered SrTiO₃ (STO) single crystal substrates by optimized pulsed laser deposition (PLD) technique. We have developed a device with a capacitive structure of 200 nm thick BZT/BCT multilayer heterostructures sandwiched between platinum top and SRO bottom electrodes. The device demonstrates excellent pyroelectric current of ~600 nA in response to temperature fluctuation of 11 K using a laser diode of wavelength 850 nm with a repetition rate of 0.1 Hz and power 150 mW. Our findings suggest that the relaxor-ferroelectric thin film may be competitive with thermoelectric materials for low-grade thermal harvesting.

Inorganic Multilayer Emitter for Passive Daytime Radiative Cooling

DONGWOO CHAE (Presenter), PIL-HOON JUNG, SOOMIN SON, YUTING LIU, HEON LEE, Department of Materials Science and Engineering, Korea university — Passive radiative cooling has been actively researched to compromise problems of active cooling. Passive radiative cooling refers to the cooling of a surface using optical properties without the supply of electricity from the external. In this study, Ag/Al₂O₃/Si₃N₄/SiO₂ multilayer structure was suggested and optimized by Particle Swarm Optimization (PSO). The multilayer was fabricated by E-beam evaporation and PECVD. Fabricated multilayer also has excellent radiative cooling properties with just three IR emissive layers of Al₂O₃, Si₃N₄, and SiO₂. In addition, since Al₂O₃, Si₃N₄, and SiO₂ is generally used as passivation layer, it has higher durability compared to polymer-based radiative cooler. The cooling temperature of the multilayer was measured using self-customized external cooling temperature measurement system. The cooling performance was calculated based on the optical properties of the multilayer using self-developed MATLAB tool. In Seoul which is mid-latitude and have relatively humid climate, the multilayer had cooling temperature of around 8°C during the daytime. And the calculated net cooling power and cooling temperature of the multilayer resonator was 66.0W/m² and 7.64°C respectively at T = 300K.

Low-temperature heat conduction in the Metal-Organic Framework Perovskite [C(NH₂)₃]Ni(HCOO)₃

DHARMENDRA SHUKLA (Presenter), Physics, Univ of Miami, THOMAS M. CARLINO, AMY M. SCOTT, Chemistry, Univ Miami, JOSHUA COHN, Physics, Univ of Miami — We report thermal conductivity (κ) measurements on single crystals of the metal-organic framework perovskite compound [C(NH₂)₃]Ni(HCOO)₃ in the temperature range 5K≤T≤300K. Measurements with heat flow along different crystallographic directions and under applied electric field will be presented and compared to κ measurements on the closely related compounds [C(NH₂)₃]X(HCOO)₃ (X=Zn, Cu).Thermal hysteresis, observed in the range 80K≤T≤300K, will also be discussed.

This material is based upon work supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Material Sciences and Engineering, under grant No. DE-SC0008607, and by the Univ. Miami CAS Convergence grant.
Passive radiative cooling (PRC) of objects involves radiative heat loss into the cold outer space through the long wavelength infrared (LWIR) atmospheric transmission window. Due to its passive operation and net cooling effect, it is a promising alternative or complement to electrical cooling.\textsuperscript{1-2} For efficient PRC of objects, an unimpeded view of the sky is ideal. However, the view of the sky is often limited - for instance, the walls of buildings have $>50\%$ of their field of view subtended by the earth, while low-lying roofs are overshadowed by taller buildings. Moreover, objects on earth become heat sources under sunlight. Therefore, buildings with hot terrestrial objects in view experience reduced cooling or even heating.

We show that by using common materials with selective LWIR emittances, walls and roofs can radiatively cool to considerably lower temperatures than achievable by using traditional broadband emitters like paints. Cooling enhancements (theoretical and demonstrated) achieved by such materials opens opportunities for the appropriate selection and design of materials for building envelopes.

Neutron studies of the structure and dynamics of barocaloric Ammonium Sulfate*
HELEN WALKER (Presenter), Rutherford Appleton Lab, BERNET MEIJER, GUANQUN CAI, SHURONG YUAN, School of Physics and Astronomy, Queen Mary University of London, FRANZ DEMMEL, HELEN PLAYFORD, Rutherford Appleton Lab, ANTHONY PHILLIPS, School of Physics and Astronomy, Queen Mary University of London — Conventional vapour-compression refrigeration relies on refrigerants that contribute both to global warming and ozone depletion. Barocaloric materials, in which a large isothermal entropy change is associated with a pressure-induced phase transition, offer an eco-friendly alternative.

Recently a giant barocaloric effect has been demonstrated near the ferrielectric phase transition of ammonium sulfate [1], which is cheaply and widely available. The transition is associated with a symmetry change from Pnma to Pna2₁ at ~224 K at ambient pressure, while small changes in hydrostatic pressure drive giant inverse barocaloric effects near the ferrielectric phase transition.

The phase transition in (NH₄)₂SO₄ has been extensively studied, including crystallographic, Raman, reflectivity, NMR and infrared investigations, yet its exact nature is surprisingly still a matter of debate. We will present our neutron scattering experiments (total scattering, INS and QENS) probing the structure and dynamics of this material, which aim to identify the characteristics responsible for its exceptional barocaloric behaviour; and hence create a roadmap to develop new barocaloric materials and optimise their properties.

A new source of thermal power
MILLICENT GIKUNDA (Presenter), PAUL MTHIBADO, Univ of Arkansas-Fayetteville — Due to an increasing need to produce self-charging, portable, implantable and wireless electronics with extended lifespans, development of energy harvesting systems is becoming increasingly important. Much emphasis has been placed on scavenging for vibrational energy as an alternative power source. A recent notable breakthrough is the discovery that when relaxed, sheets of freestanding graphene exhibit a rippled morphology, in which adjacent regions alternate between concave and convex curvature. These ripples form due to self-compression.

Here, I will discuss modelling ripple curvature inversion dynamic of freestanding graphene using Langevin's equation and fluctuation - induced current from freestanding graphene. I model one ripple as a Brownian particle in a double well potential with a minimum energy which corresponds to a ripple with concave and convex curvature. The particle is in contact with a thermal bath which is represented by an external white noise source. Interactions with the other ripples which occurs on longer time scales and keep the ripple out of equilibrium are mimicked by an Ornstein-Uhlenbeck colored noise.
11:15AM S22.00001: Adaptive robot morphology and behavioral control policy through responsive composite materials [Invited] REBECCA KRAMER-BOTTIGLIO (Presenter), Yale University — Robots generally excel at specific tasks in structured environments, but lack the versatility and adaptability required to interact with the real world. In this talk, I will introduce several soft robot platforms that can adapt both their shape and behavior to accommodate different tasks or environments. While actuation alone may temporarily change a robot’s shape, I will show that the ability to change resting shape is an advantage of soft robots, and that shape control can offset computationally-expensive tasks such as gait changes and obstacle avoidance. The focus will be on the responsive composites that enable these functional capabilities, including variable stiffness materials for move-and-hold shapeshifting applications, switchable stretchability materials for adaptive trajectories of volumetrically-expanding actuators, and stretchable circuitry for material-embedded computation.

11:51AM S22.00002: Robots and animals transition from less to more favorable modes to traverse obstacles RATAN SADANAND OTHAYOTH MULLANKANDY (Presenter), GEORGE THOMS, CHEN LI, Johns Hopkins University — Legged robots still struggle to robustly traverse obstacles in complex terrain using physical interaction, which animals do at ease. Recent studies revealed that cockroaches use body-beam interaction to traverse grass-like beam obstacles, probabilistically transitioning between locomotor modes. To understand what governs the direction of locomotor transitions between modes, we developed and studied a robophysical model traversing beams of variable stiffness. We discovered that, when viewed on a potential energy landscape resulting from body-beam interaction, different locomotor modes (system state trajectories) were attracted to different local minima basins. Regardless of beam stiffness, the system was always more likely to transition from less to more favorable modes (i.e., from lower to higher energy local minima) on the landscape, as long as kinetic energy fluctuation from oscillatory self-propulsion is sufficient to overcome the potential energy barrier in between. We made similar observations in cockroaches, despite their active behaviors. These physical principles are surprisingly similar to microscopic systems (e.g., protein-folding transitions on a free energy landscape). Our study is a step in establishing energy landscapes for locomotor transitions in complex terrain.
12:03PM S22.00003: Active adjustments help cockroaches traverse obstacles by lowering potential energy barrier  YAQING WANG (Presenter), RATAN SADANAND OTHAYOTH MULLANKANDY, CHEN LI, Johns Hopkins University — Robots predominantly navigate complex environments by using geometric models to avoid physical contact with obstacles. By contrast, animals easily traverse obstacles by using physical interaction controlled by active feedback. Our previous study revealed that cockroaches made active adjustments to traverse grass-like beam obstacles. As the animal pushed against the beams, its body pitched up. Then, the animal often quickly rolled into the gap between beams to traverse. In this process, the animal's head often flexed repeatedly, and one hind leg pushed against the ground while the other retracted. Here, we used physics modeling and robot experiments to understand the function of such active adjustments. We calculated system potential energy (resulting from gravity and beam elastic bending) as a function of head flexion. When the animal was in contact with the beams, head flexion lowered its potential energy barrier to transition from pitch to roll mode (by nearly half for the observed head flexion of 20°). We hypothesize that the animal uses proprioception (internal position and force sensing) to detect changes in beam resistive forces, which reflect the reducing transition barrier. We are developing a robotic physical model instrumented with force sensors to test this hypothesis.

12:15PM S22.00004: A template model reveals self-righting mechanism of a winged robot QIHAN XUAN (Presenter), CHEN LI, Johns Hopkins University — Animals and robots must self-right after flipping-over on the ground. Winged insects like many cockroaches push wings against the ground while flailing legs to generate lateral perturbation to self-right. Our previous study of a cockroach-inspired robot revealed the importance of good coordination (measured by phase) between wing pushing and leg flailing. Here, we elucidate the mechanism of phase dependence by developing a template model, validated against multi-body dynamics simulation. The model consists of a point mass body rotating in the sagittal plane, two massless wings, and a flailing leg with a point mass at its end. With modest wing opening and leg flailing, the model struggled to self-right, and successful righting relied on good coordination of the wings and leg. We used the model to calculate the potential energy barrier the body must overcome, mechanical energy input by the wings and leg, and energy dissipation due to collision and friction. With good phases, mechanical energy accumulation exceeded potential energy barrier; with bad phases, it did not do so. We used the template model to predict an optimal coordination strategy to increase self-righting probability. Our study highlighted the importance of appendage coordination in strenuous locomotor transitions.
12:27PM S22.00005: Testing the effect of scaling on microrobot locomotion performance
KAUSHIK JAYARAM (Presenter), University of Colorado, Boulder, ROBERT WOOD, Harvard University — The effects of scaling on locomotion performance has fascinated biologists, physicists and engineers alike. In particular, roboticists have exploited dynamic scaling to build systems at sizes varying from a tens of centimeters to several meters. Thanks to recent advances in manufacturing, insect-scale robotics is currently an exciting research direction and holds the promise of tremendous impact in areas of search-and-rescue and high-value asset inspection. However, most robots at this scale have simplified morphology and can only demonstrate basic mobility. Here, we present the newly designed HAMR-Jr, a 22.5mm, 320mg quadrupedal microrobot. With eight independently actuated degrees of freedom, HAMR-Jr is, to our knowledge, the most mechanically dexterous legged robot at its scale and is capable of high-speed locomotion (13.91 bodylengths/s) at a variety of stride frequency (1-200Hz) using multiple gaits. We achieved this using a design and fabrication process that is flexible, allowing us to exploit and implement the physics of scaling with minimum changes to our workflow. We further characterized HAMR-Jr’s open-loop locomotion and compared it with the larger scale HAMR-VI microrobot to demonstrate the effectiveness of scaling laws in predicting running performance.

12:39PM S22.00006: Tail control decreases jamming of a mechanics-dominated legged robot on rough terrain  DANIEL SOTO (Presenter), DANIEL I GOLDMAN, Georgia Inst of Tech — To develop robot locomotion principles which leverage mechanics to simplify control, we study a minimally aware quadrupedal RHex-type robot (~3kg, 20 cm long) walking on a rough terrain composed of blocks with Gaussian height distribution with mean and variance approximately leg length and one-quarter leg length respectively. This terrain resulted in failure modes due to limb jamming in protruding regions of the terrain. Performance was insensitive to gait symmetries (phasing and duty factor of limbs). To reduce jamming probability while maintaining the focus on minimal control and mechanics, we added a motor driven 10 cm long tail whose pitch and yaw actuation was uncoupled to limb dynamics. We experimented with a variety of open loop behaviors such as tapping, pulsing, and maintaining a constant angle with the body. We also developed a closed loop tapping scheme that triggered on IMU measured pitch and roll of the robot. Jamming probability could be reduced to near zero for open and closed loop schemes. The appropriate tail behaviors helped maintain either high or low “robot temperature” (variance of instantaneous velocity) relative to tail-less robot temperature.
12:51PM S22.00007: Modulation of robot orientation by exploiting leg-obstacle collisions through successive choices of gait* FEIFEI QIAN (Presenter), YONGXIN GUO, ANMOL KATHAIL, DANIEL KODITSCHEK, University of Pennsylvania — An environment can provide different affordances for locomotion based on a locomotor’s actions. Our study aims to explore how multi-legged robots can use various gaits to exploit the affordance of obstacle collisions to negotiate complex environments in different ways.

To allow assessment of obstacle affordances, we represent physical obstacles as a horizontal-plane disturbance field. For a given physical environment, the disturbance field is fixed. However, when a (structured) disturbance field couples with (periodic) locomotor gaits, there emerge stable fixed-point heading directions with substantial basins of attraction.

In this study, we show that the basins around these fixed-point headings depend sensitively on the locomotor gaits. We investigate the transit between these basins as a quadrupedal robot explores its 3-dimensional gait space (each dimension represents the relative phase difference between one pair of legs), and show that these gait-dependent basins allow the robot to take advantage of the repeated leg-obstacle collisions to robustly achieve desired sequences of headings without active steering.

1:03PM S22.00008: A systematic approach to creating terrain-capable hybrid soft/hard myriapod robots YASEMIN OZKAN-AYDIN, ENES AYDIN, BAXI CHONG, DANIEL I GOLDMAN (Presenter), Georgia Inst of Tech — Multi-legged animals such as centipedes move effectively in diverse terrain. Their flexible body and limbs allow them to adapt their shape to the environment and traverse obstacles. To examine how the variation in body/limb forms of legged animals affects the mechanics of terrestrial locomotion, we built a multi-legged hybrid (soft/rigid) robot that has 8 segments (9 cm/segment), each with two out of phase legs. Back elements and limbs are driven by servo motors. We systematically tested the gait patterns with different leg contacts and body undulation provided by geometric mechanics on various environments including flat ground, obstacle course, stair climbing, and unstructured natural terrain. On flat ground, the robot with completely rigid parts moved in the same way as theoretically predicted gaits. As the complexity of the environment increases, adding flexibility into the robot body parts (legs, body joints, etc.) improved the locomotion performance by either reducing the effects of environmental disturbances or increasing stability.
1:15PM S22.00009: Basilisk Lizard Bipedal Locomotion on Sand, Mud, and Water: An Insight to Future Morphing Amphibious Robots  
HOSAIN BAGHERI (Presenter), MARCUS GAMBATESE, Arizona State Univ, DAVID LENTINK, Stanford University, HAMIDREZA MARVI, Arizona State Univ — With the astonishing development in robotics, one area that still remains an open challenge is their physical interaction with the outside world, beyond that of factory floors. In order for robotic devices to integrate and conquer obstacles introduced by the surrounding world, they will need to be able to traverse on and through diverse and alternating mediums and terrains. To address this desire of adaptive multi-modal locomotion, we look to the basilisk lizard as a form of inspiration and means of understanding how it can effectively run and transition from land to water, and vice versa. By shedding light on both active (i.e. gait, body dynamics) and passive (i.e. tail swing, toe fringes) mechanisms used by the animal, more competent robotic systems can be developed for the interaction and exploration of both terrestrial and aquatic environments. Notably, passive mechanisms do not require input power, sensing, or controls for operation. Through conducting animal experiments in both terrestrial and aquatic environments (and the transition between the two), the hierarchical physics of animal interaction with complex environments can be extracted and channeled towards the development of a bio-inspired amphibious robot for planetary exploration and search-and-rescue applications.

1:27PM S22.00010: Hierarchical control in sea star inspired locomotion*  
SINA HEYDARI (Presenter), Aerospace and Mechanical Engineering, University of Southern California, THEODORA PO, MATTHEW MCHENRY, Ecology and Evolutionary Biology, University of California, Irvine, EVA KANSO, Aerospace and Mechanical Engineering, University of Southern California — There is a growing effort to understand decentralized control mechanisms, particularly in application to robotic systems with distributed sensors and actuators. Sea stars, being equipped with hundreds of tube feet, are an ideal model system for studying decentralized sensing and actuation. The activity of the tube feet is orchestrated by a nerve net that is distributed throughout the body; there is no central brain. We developed mathematical models of the biomechanics of the tube feet and the sea star body. We then formulated hierarchical control laws that capture salient features of the sea star nervous system. Namely, at the component level, the individual tube feet follow a state-dependent feedback controller. At the system level, a directionality command is communicated to all tube feet. We studied the locomotion gaits afforded by this control model. We find that these minimally-coupled tube feet coordinate to generate robust forward locomotion on different terrains. Our model also predicts different gait transitions consistent with our experiments performed on Protoreaster nodosus. These findings offer a new paradigm for walking using soft actuators, with potential applications to autonomous robotic systems.

*Supported by Office of Naval Research (ONR) grant N00014-17-1-2062.
1:39PM S22.00011: Hopping with Elastic Restitution Is More Difficult Than It Seems  TAYLOR MCLAUGHLIN, MARION ANDERSON (Presenter), SHAI REVZEN, Univ of Michigan - Ann Arbor — Bouncing rubber balls and hopping on pogo sticks might suggest that building a robot that hops with a significant fraction of elastic energy restitution would be straightforward. Using spring steel legs with 99% restitution individually, we built a three-legged hopper. The hopper achieved a minute 11.2% restitution when using the springs in series with the actuators. We present five generations of three-legged hoppers: four have actuators in series with springs. Three different types of ground contact were tested. Our best design so far uses actuators in parallel with the springs, and achieves 49+/−5% restitution. This work will be of use to those interested in using elastic energy storage in legged locomotion.

1:51PM S22.00012: Recovery of Behaviors of Robots without Dynamics  GEORGE COUNCIL (Presenter), SHAI REVZEN, Univ of Michigan - Ann Arbor — For robots to function without humans on hand to fix them, they must be able to compensate for malfunctions that inhibit their ability to move all actuators.

The conventional choice would be to model the damaged robot, either by anticipating damage types and their effects on a known model, or by performing system identification on the damaged device. However, anticipating failure is fragile, and data-driven system ID of dynamics is expensive in time and robot wear-and-tear.

We instead suggest a method that leverages data from examples of successful motion to produce "behavior specifications" as constraints on outputs and states. By collecting time-series data from (nearly arbitrary) observation functions on a working robot, we defined a behavior as a list of differential constraints. The constraints, along with intrinsic constraints of physics, classify trajectories into those that yield a desired behavior, and those that do not.

For systems with many degrees-of-freedom, there are typically entire sub-manifolds of curves that meet the constraints. Assuming that the damaged robot retains enough control freedom to re-enforce our constraints, we can design an input that restores a desired behavior.

We demonstrate our method on a crawler in simulation, and on a dynamic hexapod in hardware.

2:03PM S22.00013: Modeling of the Primary Animal Gaits by Coupled Identical Raleigh-Van der Pol Oscillators  MASOUD ASADI-ZEYDABADI (Presenter), MOZHDEH SAFFARI-PARIZI, RANDALL TAGG, University of Colorado, Denver — Mathematical models based on coupled oscillators successfully describe animal gaits. The dynamics of individual oscillators (internal dynamics) in the network is nonlinear and must be at least two-dimensional to have a Hopf bifurcation. One example of this type of dynamics is a network of Rayleigh - Van der Pol oscillators which is used to produce primary gaits such as walk, trot, pace and bound. When these oscillators couple together, they produce patterns of relative phases that correspond to the different animal gaits. The patterns emerge through bifurcations as parameters describing the coupling are varied. At least eight cells are required to model the quadruped gaits.

Thursday, March 5, 2020 11:15 AM - 2:15 PM
11:15AM S23.00001: Protein condensates as aging Maxwell fluids [Invited] LOUISE JAWERTH (Presenter), for the Physics of Complex Systems, Max Planck Institute — Liquid-like protein condensates (LLPCs) are intracellular compartments that segregate material without the use of a membrane. The liquid-like behavior of the condensates is a defining characteristic and the viscosity, surface tension and other material properties determine how segregated species diffuse into and within condensates; they, thus, critically impact the biological function of the condensates. It has become increasingly clear that some LLPCs do not have time-independent material properties, but can, instead, transition to more solid, gel-like materials. Here, we present our efforts to quantify these new materials as they age in vitro. We measure the visco-elastic material properties of several proteins, (PGL-3, FUS and DDX4), by means of a combination of active and passive microrheology. At early times, we find that the droplets behave much like simple liquids but gradually become more elastic. Surprisingly, the changing mechanical properties can all be scaled onto a single master curve using one characteristic time scale which grows as the sample ages. This and other features we observe bear a striking resemblance to the behaviors observed in materials with glass-like aging. We consider protein condensates as soft glassy materials with age dependent material properties that we call Maxwell glasses. To gain insight into the molecular origins of this behavior, we present electron microscopy images of the condensates at different ages. Furthermore, we demonstrate how salt concentration tunes the characteristics of the aging process. Lastly, we speculate on possible molecular origins that might lead to the glass-like arrest we observe and how such arrest could be used for modulation of cellular biochemistry.

11:51AM S23.00002: Surface Fluctuations and Coalescence of Nucleolar Droplets in the Human Cell Nucleus* CHRISTINA M. CARAGINE (Presenter), SHANNON C HALEY, ALEXANDRA ZIDOVSKA, Physics, New York Univ NYU — The nucleolus is a membraneless organelle embedded in chromatin solution inside the cell nucleus. By analyzing the surface dynamics and fusion kinetics of nucleoli in live human cells, we find that the nucleolar surface exhibits subtle, but measurable, shape fluctuations and the radius of the neck connecting two fusing nucleoli grows as r(t)~t^{1/2} [1]. This is consistent with liquid droplets with low surface tension ~10^{-6} Nm^{-1} coalescing in a fluid of higher viscosity ~10^{3} Pa s, i.e. chromatin solution. We find the neck velocity, dr/dt, is comparable to the velocity of chromatin solution [2]. Surprisingly, nucleolar coalescence occurs in an active fluid, yet can be described by coalescence theory for passive liquid droplets, suggesting the measured quantities might be effective quantities. Our study presents a noninvasive approach, using natural probes to investigate material properties of the cell as well as to understand the physical interactions between nucleoli and chromatin solution [1,3].

12:03PM S23.00003: Phase separation in the nucleus is limited by chromatin mechanics* 

YAOJUN ZHANG (Presenter), DANIEL LEE, Princeton University, YIGAL MEIR, Physics, Ben-Gurion University, CLIFF BRANGWYNNE, NED WINGREEN, Princeton University — Liquid-liquid phase separation is a fundamental mechanism underlying biological organization. While conventional theory predicts that a single phase-separated condensate would be energetically favored, both natural and synthetic condensates in cells typically appear as multiple dispersed droplets with suppressed growth dynamics. Here, we combine coarse-grained molecular dynamics simulations and theory of liquid-liquid phase separation to show that mechanical interactions with chromatin can constrain the size of droplets in the nucleus. The "gel-like" chromatin suppresses both droplet coalescence and ripening dynamics, resulting in a reduced scaling exponent for mean droplet radius versus time. Our work highlights the impact of the local mechanical environment on biomolecular condensate formation and growth, and further elucidates the role of mechanics in fundamental biological processes taking place in the cell nucleus.

12:15PM S23.00004: Subdiffusive Dynamics of Optogenetic Droplets Report on Local Chromatin Mechanics* 

DANIEL LEE (Presenter), Lewis-Sigler Institute for Integrative Genomics, Princeton University, SHUNSUKE SHIMOBAYASHI, YI-CHE CHANG, AMY R STROM, Department of Chemical and Biological Engineering, Princeton University, NED WINGREEN, Department of Molecular Biology; Lewis-Sigler Institute for Integrative Genomics, Princeton University, CLIFF BRANGWYNNE, Department of Chemical and Biological Engineering, Princeton University; Howard Hughes Medical Institute — DNA is organized into chromatin, a complex material which stores information and controls gene expression. Liquid-liquid phase separation is believed to be a principal mechanism governing its organization. Previous work with optogenetically activatable droplets demonstrated that liquid condensates displace chromatin. Here, we show that droplet growth dynamics are directly inhibited by chromatin. Generally, droplet radii follow a power law scaling with time, such that $R \sim t^\beta$. We observe an anomalously slow coarsening exponent during interphase but recover dynamics more consistent with classical theory when chromatin is condensed during mitosis. We show that this slowed growth is due to subdiffusion of individual condensates, a clear signature of elastic behavior in the nucleus. We further apply this framework to elucidate local mesoscopic mechanics of the nucleus in various biologically relevant contexts. Thus, our work demonstrates the use of engineered intracellular condensates as “probes” of local mesoscale nuclear organization.

Converting Stochastic Assembly into an Assembly Line: Non-Equilibrium Droplet Dynamics Assists Ribosome Formation  
TYLER HARMON (Presenter), FRANK JULICHER, Max Planck Institute for the Physics of Complex Systems — The nucleolus is a large liquid-like membraneless organelle responsible for the majority of the processing of ribosomal components and the assembly of ribosomes, which involves hundreds of proteins. It has been suggested that one of the primary functions of the nucleolus is to concentrate these proteins with the ribosomal RNA (rRNA), thereby significantly enhancing the binding rates and enzyme reaction speed for ribosome assembly and post-translational modifications.

Here we expand on this idea by considering the non-equilibrium effects that arise from having a constant rRNA flow outward from the center of a nucleolus and an inward flow of ribosomal protein (rProtein) from the nucleoplasm. We show numerically and analytically that the binding of specific rProteins to rRNA can be localized within a well-defined radial shell inside the nucleolus instead of being homogeneously distributed. By giving the different rProteins different physical properties, the different rProteins can be confined to bind to the rRNA at different radial distances from the transcription centers within the nucleolus. Thus, as rRNA molecules diffuse outward through the nucleolus, the rProteins can be added in sequential order like an assembly line.

Reentrant Liquid Condensation of Ribonucleoprotein–RNA Complexes  
MURALIKRISHNA RAJU (Presenter), RABIA LAGHMACH, DAVIT POTOYAN, Iowa State University — Intracellular Ribonucleoprotein (RNP) granules are membrane-less liquid condensates that dynamically form, dissolve, and mature into a gel-like state in response to a changing cellular environment. RNP condensation is largely governed by attractive inter-chain interactions mediated by low-complexity domains. Using an archetypal disordered RNP, fused in sarcoma (FUS), here we employ atomistic simulations to study how RNA, a primary component of RNP granules, can modulate the phase behavior of RNPs by controlling both droplet assembly and dissolution. Electrostatic interactions are found to be the primary driving force behind condensate formation. Monotonically increasing RNA concentration initially leads to droplet assembly via complex coacervation and subsequently triggers an RNP charge inversion, which promotes disassembly. We construct phase diagrams based on Droplet density and Shannon entropy calculations, wherein three distinct regimes can be identified based on RNA and peptide concentrations. Increasing salt concentration is found to inhibit the formation of liquid condensates and narrow the coexistence region. The internal organization and dynamics of the condensates are investigated as a function of RNA/peptide concentrations, RNA chain length and salt concentration.
12:51PM S23.00007: Size selection of phase-separated liquid droplets in strain-stiffening elastic networks*  SHENG MAO (Presenter), MIKKO HAATAJA, ANDREJ KOSMRLJ, Princeton University — Membraneless organelles are formed via phase separation inside cells, but it remains unclear how cytoskeleton affects this process. Recent experiments showed the size of separated droplets is controlled by the stiffness of the surrounding elastic network. This is in contrast to phase separation of liquid mixtures, which continue to coarsen indefinitely (Ostwald ripening). Motivated by these observations, we developed a model to investigate the coupling between the separating liquid mixture and the elastic network. We find that the elastic energy of distorted network effectively modifies the nucleation barrier and the critical nucleus size for the separating mixture. For a neo-Hookean elastic network we find that the coarsening proceeds indefinitely. On the other hand, for networks with sufficiently strong strain-stiffening considered in experiments we find that the elastic energy arrests the coarsening once droplets reach certain size. Furthermore, finite element simulations indicate that the interactions between droplets via the distorted elastic network are rather short-ranged, which explains why observed droplets in experiments achieve a uniform size.

1:03PM S23.00008: A hydrodynamic instability drives TPX2 protein droplet formation on microtubules and leads to branching microtubule nucleation*  SAGAR SETRU (Presenter), BERNARDO GOUVEIA, RAYMUNDO ALFARO-ACO, MATTHEW R KING, HOWARD A STONE, JOSHUA SHAEVITZ, SABINE PETRY, Princeton University — Microtubules are protein polymers with a variety of roles in biological cells. During cell division, many microtubules are generated by branching from the surface of preexisting microtubules. Recent work in vitro and ex vivo shows that the protein TPX2 drives the nucleation of branched microtubules by bringing augmin and the gamma-tubulin ring complex (gTuRC) to microtubules. It has also been shown that TPX2's ability to condense into a liquid phase is important for branching. Using atomic force microscopy, fluorescence imaging, electron microscopy, and hydrodynamic theory, we show that the dynamics of liquid TPX2 are crucial for nucleating branched microtubules. Initially, TPX2 coats the surface of microtubules in seconds, producing a cylindrical, liquid tube around the microtubule with an even thickness of 13-17 nm. Then, this layer loses stability due to surface tension, producing discrete droplets regularly spaced by 140-250 nm via a Rayleigh-Plateau mechanism. These droplets bind augmin and gTuRC to the microtubule surface, thus localizing where branches can form. Together, our work explains how the liquid phase of TPX2 leads to branching microtubule nucleation.

Motif Sequences and Intracellular Phase Separation

BENJAMIN WEINER (Presenter), Princeton University, YIGAL MEIR, Ben-Gurion University, NED WINGREEN, Princeton University — Intrinsically Disordered Proteins (IDPs) lack a unique folded structure, and yet perform diverse and important functions inside cells. Recent work suggests that some IDPs promote the formation of membrane-less organelles via phase separation, helping cells spatially organize their biomolecules. Classical theories of phase separation focus on homopolymers, but IDPs have evolved particular sequences of interacting motifs. How does an IDP’s motif sequence determine its physical properties? We propose a statistical physics model of IDPs to elucidate the relationship between motif sequence, the phase boundary, and the partitioning of proteins between phases.

We find that motif sequences strongly influence the physical properties of model IDPs. Intuitively, each sequence has its own preference for inter- versus intra-protein bonds, which favor a condensed versus a dilute phase, respectively. As a result, the concentration of IDPs required for phase separation depends strongly on the motif sequence. Our work demonstrates the emergence of spatial order from conformational disorder, a process which may play a key role in intracellular organization.

Coupling signaling cascades to membrane criticality

TAYLOR SCHAFFNER (Presenter), BENJAMIN B MACHTA, Yale University — Cellular biology has long understood spatial organization to be a crucial feature for determining function. Recent evidence suggests that thermodynamic phase separation may explain a range of structures in Eukaryotic cells. In particular, proximity to a liquid-liquid critical point may underlie membrane domains that are often termed lipid rafts. Such domains have been implicated in the functioning of many signaling cascades by localizing components to particular domains. Addition of ligand may lead to the formation of signaling platforms, and perturbations to membrane criticality often modify signaling outcomes. In order to create a theory that explains the interplay between signaling cascades and membrane criticality, here we present a model and Monte-Carlo simulation framework for proteins coupled to their surrounding lipid membrane using a 2D Ising model. We have additionally developed schematic diagrams that predict the effects of domain size on the outcome of various simple signaling cascade motifs. Our model naturally explains how changes in domain size arising from perturbations to membrane criticality can lead to changes in the rates of interaction amongst signaling components, eventually leading to altered signaling outcomes.

Wetting of Critical Membranes by Protein Droplets

MASON ROUCHES (Presenter), Molecular Biophysics and Biochemistry, Yale University, SARAH VEATCH, Biophysics, University of Michigan, BENJAMIN B MACHTA, Physics, Yale University — Phase-separated liquid-droplets of protein and RNA have recently been found as ubiquitous structures in cells – coordinating reactions, organizing cellular machinery, and protecting sensitive biomolecules. In two dimensions, the plasma membrane is organized by heterogeneities in lipid composition, with membrane domains posited to be a consequence of proximity to a miscibility critical point. These structures are linked by components that interact with both 2D and 3D phases such as lipidated proteins that partition into specific membrane phases. This leads protein droplets to localize to particular membrane domains, as seen in the post-synaptic structure, the immunologic synapse, and components of cell adhesion. Here, we consider the underlying thermodynamics of this interaction, constructing a minimal Landau theory describing the wetting of protein droplets to a near-critical membrane. The resulting phase diagram shows non-standard wetting behavior, where surface criticality greatly enhances a prewetting-like regime where bulk and surface phase separate together. We buttress these theoretical predictions with simulations of nearly critical Ising surfaces coupled to coacervating lattice polymers and link existing experimental observations to this phase diagram.

*NSF DMR-1905621

Probing the Dynamics of Optically Induced Protein Droplets with Single-Walled Carbon Nanotubes

HUGH HIGINBOTHAM (Presenter), SEBASTIAN COUPE, YOON JUNG, NIKTA FAKHRI, Massachusetts Institute of Technology MIT — Eukaryotic cells exhibit high levels of internal spatial organization, including a wide variety of membrane-less compartments. Protein-protein and protein-RNA interactions have been implicated as the primary factors responsible for these membrane-less structures, but how they are maintained and utilized by the cell is still poorly understood. Many proteins essential to the formation of these structures feature long intrinsically disordered regions (IDRs) that interact with each other and can induce demixing, as seen in many recent in vitro studies. However, quantitative characterization of these structures in vivo remains challenging due to the complexity of intracellular environments. Here, we use single-walled carbon nanotubes (SWNTs), which fluoresce in the near infrared and are photostable, to probe the local environment of optically induced protein droplets in vivo. The dynamics of SWNTs can reveal internal organization within these droplets and the influence of the intracellular environment on their mechanical properties.
Measuring protein concentrations in biomolecular condensates via quantitative phase microscopy

PATRICK MCCALL (Presenter), Max Planck Institute of Molecular Cell Biology and Genetics; Max Planck Institute for the Physics of Complex Systems; Center for Systems Biology Dresden, KYOOGHYUN KIM, Biotechnology Center, Technische Universität Dresden; Max Planck Institute for the Science of Light, JIE WANG, Max Planck Institute of Molecular Cell Biology and Genetics, ANATOL W. FRITSCH, Max Planck Institute of Molecular Cell Biology and Genetics; Max Planck Institute for the Physics of Complex Systems; Center for Systems Biology Dresden, ANDREY POZNYAKOVSKIY, Max Planck Institute of Molecular Cell Biology and Genetics, BENEDICT DIEDERICH, Leibniz Institute of Photonic Technology, MORITZ KREYSING, Max Planck Institute of Molecular Cell Biology and Genetics; Center for Systems Biology Dresden, RAINER HEINTZMANN, Leibniz Institute of Photonic Technology; Institute of Physical Chemistry and Abbe Center of Photonics, Friedrich-Schiller-University Jena, JOCHEN GUCK, Biotechnology Center, Technische Universität Dresden; Max Planck Institute for the Science of Light, SIMON ALBERTI, Max Planck Institute of Molecular Cell Biology and Genetics; Biotechnology Center, Technische Universität Dresden, JAN BRUGUÉS, Max Planck Institute of Molecular Cell Biology and Genetics; Max Planck Institute for the Physics of Complex Systems; Center for Systems Biology Dresden, ANTHONY HYMAN, Max Planck Institute of Molecular Cell Biology and Genetics — Many compartments in eukaryotic cells are protein-rich biomolecular condensates formed via phase separation from the cyto- or nucleoplasm. Although knowledge of condensate composition is essential for a full description of condensate properties and potential functions, measurements of composition pose a number of technical challenges. To address these, we use quantitative phase microscopy and optical diffraction tomography to measure the refractive index of model condensates, from which the protein concentration may be inferred. Here, model condensates are formed by phase separation of purified protein constructs derived from the primarily disordered RNA-binding domain (RBD) of TAF15. Surprisingly, we find that phase separation of TAF15(RBD) is attenuated only weakly by salt (0.05-3 M KCl) or temperature (10-50 °C), suggesting that Coulombic and entropic interactions, respectively, play only minor roles in controlling the phase equilibria. Interestingly, we also find that partition coefficients determined by fluorescence microscopy dramatically underestimate protein concentrations in condensates. A simple model including inner filter and excited-state saturation effects suggests that the discrepancy stems primarily from reduced fluorescence quantum yields in condensates.

Thursday, March 5, 2020 11:15 AM - 2:15 PM

Session S24 GSNP DSOFT DBIO: Glassy Dynamics: From Simple Models to Biological Tissues | 401 - Amy Graves, Swarthmore Coll
11:15AM S24.00001: Solving the equilibrium dynamics of particle systems in infinite dimensions* ALESSANDRO MANACORDA (Presenter), FRANCESCO ZAMPONI, Laboratoire de Physique de l'Ecole Normale Supérieure, ENS, Université PSL, CNRS, Sorbonne Université, Université de Paris, F-75005 Paris, France, GRÉGORY SCHEHR, LPTMS, CNRS, Univ. Paris-Sud, Université Paris-Saclay, 91405 Orsay, France — In the last years, a general framework to study the dynamics of particle systems in infinite dimensions has been developed. This theory can be applied to a wide class of physical cases both in and out of equilibrium, including the physics of glasses, colloids and active matter. On the other hand, even for the equilibrium - simplest - case, an analytical solution of the dynamical equations is out of reach. I will show how a numerical solution can be found, leading to the emergence of a dynamical transition in the case of short-ranged repulsive potentials. The numerical analysis for long times matches the predictions obtained by thermodynamical arguments at equilibrium, and provides new observations such as the behavior in time of the memory kernel and the critical scaling of the diffusivity when approaching the dynamically arrested phase. The consistency of the results at equilibrium is the first step to obtain new insights into non-equilibrium physical phenomena, which will represent the future direction of the research.

11:27AM S24.00002: Investigating Hydrogen Glass Dynamics in Amorphous Germanium and Amorphous Silicon-Germanium Alloys* BRENDA KNAUBER (Presenter), School of Physics and Astronomy, University of Minnesota, MOHAMMAD ALI ESLAMISARAY, Department of Mechanical Engineering, University of Minnesota, JAMES KAKALIOS, School of Physics and Astronomy, University of Minnesota — A hydrogen glass model has successfully accounted for stretched exponential relaxation (SER) of the conductivity and non-Gaussian $1/f$ noise in hydrogenated amorphous silicon (a-Si:H) thin films, in agreement with hydrogen diffusion studies. We have recently reported non-Gaussian $1/f$ noise in hydrogenated amorphous germanium (a-Ge:H) consistent with hierarchically constrained kinetics, reflected in log-normal noise power distributions, strong correlations between noise power octave bins and scaling of the second spectra. The similarities in the $1/f$ noise of a-Ge:H and a-Si:H motivated our study of current relaxation in a-Ge:H. However, unlike the a-Si:H SER decay of the conductivity, in a-Ge:H we find a time-dependent increase of the conductivity at constant temperature. For a-Ge:H, the stretched exponential power-law exponent and time constant are similar to that observed in a-Si:H, but only for temperatures above 390K. A set of hydrogenated amorphous silicon-germanium alloys are studied to investigate the transition in the noise statistics and conductivity relaxation as the alloy fraction changes.

11:39AM S24.00003: Towards a Unifying Scaling Theory of Rigidity Transitions*

FARSHID JAFARPOUR (Presenter), SEAN RIDOUT, ANDREA JO-WEI LIU, University of Pennsylvania — A large class of models describing various athermal disordered systems such as granular materials, living tissues, and polymer networks exhibit transitions from fluid or floppy states to rigid states. In some cases, the transition marks the boundary between the underconstrained region of parameter space to the overconstrained region, while in other cases, the transition takes place entirely in the underconstrained region as strain is varied. We study a spring-network model that exhibits both types of transitions and provide a unifying perspective based on a scaling ansatz for the rigidity transition in this model.

*This material is based upon work supported by the National Science Foundation under Grant No. NSF-DMR-1506625 and Simons Investigator Award 327939.

11:51AM S24.00004: Soft glassy dynamics and rheology: A damped soft-sphere model*

AMRUTHESH THIRUMALAIswamy (Presenter), ROBERT RIGGLEMAN, JOHN CROCKER, CBE, University of Pennsylvania — The mechanical response of a diverse family of seemingly disparate materials, like foams, cells, and emulsions, exhibiting a similar response to applied deformation, has largely defied explanation. One example being their rheology, where the complex modulus shows a weak power-law dependence on frequency, that we recently postulated could be a direct manifestation of the fractal energy landscape of these materials. In this work, we extend our previous study by performing bubble dynamics simulations with damped, non-inertial bubbles evolving similar to ripening observed in foams. We study the coarsening system in the dynamic scaling state, and the resulting physical and dynamic properties over a range of damping effects. As shown before, the under-damped system gives rise to spatially correlated dynamics with avalanches while traversing fractal paths in 3N-dimensional configuration space through super-diffusive motion. Further, we investigate the statistical nature of avalanches in time and their disappearance in the over-damped limit, and the corresponding changes in the rheology of the system. Lastly, we study the aging of the system after strong perturbations and look for signatures of self-organization in the dynamical steady state.

*NSF DMR-1609525
12:03PM S24.00005: Crystallization Instability in Glass-Forming Mixtures*  PADDY ROYALL (Presenter), Physics, University of Bristol, TROND INGEBRIGSTEN, JEPPE C DYRE, THOMAS SCHRODER, Department of Science and Environment, Roskilde University — Understanding the mechanisms by which crystal nuclei form is crucial for many phenomena such as gaining control over crystallization in glass-forming materials or accurately modeling rheological behavior of magma flows. The microscopic nature of such nuclei makes understanding hard in experiments, while computer simulations are hampered by short timescales and small system sizes. Here we use GPU simulations to reveal a general nucleation mechanism in mixtures. We find that the supercooled liquid of a prized model glass former is inherently unstable to crystallization, i.e., that nucleation is unavoidable on the structural relaxation timescale, for sufficient system sizes. This is due to compositional fluctuations leading to regions composed of one species which rapidly crystallize. This mechanism provides a minimum rate of nucleation in mixtures in general, and we show that it pertains to the metallic glass former copper zirconium.

12:15PM S24.00006: Cells on spheres: glassy dynamics of vertex models in curved space  DANIEL SUSSMAN (Presenter), Emory University — The analogy between cellular monolayers and aggregates on the one hand and jammed solids or colloidal glasses on the other has provided a powerful framework for probing questions of rigidity, motilitiy, and collective excitations in dense biological tissues. However, simple coarse-grained theoretical models of these systems — such as vertex or Voronoi models of confluent cells — have both an unusual zero-temperature rigidity transition and highly anomalous glassy dynamics. The underlying reasons for these atypical behaviors are poorly understood. Here we begin to discriminate between theoretical explanations by numerically studying cellular models embedded on the surface of a sphere. By introducing constant Gaussian curvature we lift the large degenerate space of zero-energy modes that contributes to the unusual jamming transition of vertex-like models, and explore how this changes the finite-temperature glassy dynamics.
12:27PM S24.00007: Anticipating Challenges of Propensity Measurements in Colloidal Systems*  CORDELL DONOFRIO (Presenter), ERIC WEEKS, Emory University — In order to study dynamics near the glass transition we simulate the Kob-Andersen binary glassformer in a series of isoconfigurational ensembles. This follows the work of Widmer-Cooper et al, (2004), where they used such an ensemble to define the propensity of each particle as the average motion of the particle, where the averaging is done across the ensemble. We seek to understand how sensitive the measurement of propensity is to the polydispersity of the particles. One could imagine attempting to measure propensity experimentally using a colloidal glass system, but these particles would have some distribution of size and there would always be the possibility for error when attempting to create an isoconfigurational copy of the system. We introduce polydispersity by splitting the population of each of the binary components into its own binary where half are increased in size and the other half are decreased in size by the same percentage. Experimental errors are then simulated by exchanging large and small variants each time a isoconfigurational copy is created. We find that the propensity signal is strengthened when polydispersity is increased, but decreased as more and more errors are introduced.

*NSF (DMR-1609763)

12:39PM S24.00008: Glassy behavior and memory effects in the elastic response of a disordered protein*  IAN L MORGAN, University of California, Santa Barbara, RAM AVINERY, ROY BECK, Tel Aviv University, OMAR SALEH (Presenter), University of California, Santa Barbara — We investigate the dynamic mechanical properties of an intrinsically-disordered protein derived from neurofilament tail domains. We use a single-molecule stretching technique, magnetic tweezers, to force a disordered polyprotein out of equilibrium, and observe the relaxation of its end-to-end extension. The relaxation is logarithmic and slow, enduring for minutes to hours. We explain our results in terms of a phenomenological model, originally developed for bulk glassy systems, that assumes relaxation is caused by the sum of many independent structural transitions with widely varying rates. Such a model makes sense for macroscopic systems but is surprising to observe in a single molecule. Yet, the model quantitatively accounts for both the force-dependence of the logarithmic relaxation, and our observation of a non-monotonic (Kovacs) relaxation when subjecting the protein to a multi-step force protocol. The Kovacs memory effect is an unambiguous signature that many independent and parallel structural transitions are contributing to the overall dynamic mechanical properties of the IDP. This is fundamentally different from previous examples of glassy behavior in folded proteins which rely on a heterogeneous population of conformations.

**12:51PM S24.00009: Crystallization properties of amorphous and supercooled liquid antimony**  
RICCARDO MAZZARELLO (Presenter), IDER RONNEBERGER, Institute for Theoretical Solid State Physics and JARA, RWTH - Aachen, YUHAN CHEN, WEI ZHANG, Center for Advancing Materials Performance from the Nanoscale, Xi'an Jiaotong University, Xi'an, China — Chalcogenide phase change materials are highly important for technological applications in data storage and neuro-inspired computing devices, which exploit the ability of these materials to undergo fast and reversible transitions between crystalline and amorphous states with pronounced electrical contrast. Antimony alloys form an important family of phase-change materials. Recent work has shown that even pure antimony can be employed in phase-change devices, in spite of its high proneness to crystallization. In this talk, we investigate the structural and crystallization properties of amorphous and supercooled liquid models of pure and alloyed antimony by ab initio molecular dynamics. We study the effects of quenching rate and finite size on the crystallization speed and elucidate how the dopants affect the short-range order and the crystallization kinetics.

**1:03PM S24.00010: Jammed solids held together with pins: The effect of pin geometry on structure and mechanical response**  
AMY GRAVES (Presenter), LIAM PACKER, BRIAN JENIKE, ARI LILOIA, Swarthmore College, SEAN RIDOUT, University of Pennsylvania — Currently, much is known about the theory and broad applicability of the jamming transition. Here, we address unanswered questions on the geometrical role that a scaffolding of fixed particles, or "pins", plays in structure and dynamical response of jammed, soft bi- or polydisperse particles. Our 2d system consists of particles and tiny pins which harmonically repel overlaps, fixed in various geometrical arrangements: square, triangular, or honeycomb lattices, or distributed randomly. While at low pin densities the jamming threshold, $\varphi_j$, decreases linearly with pin density, independently of pin geometry; at higher densities it reflects lattice-specific constraints on particle packing, and $\varphi_j$ may even increase with pin density. The distribution of bond angles may be anisotropic, and contact force distribution reflect the presence of pins. Changes in the linear elastic response can be seen in bulk and shear moduli, their scaling with pressure near jamming, and a Zener ratio indicating that pin geometry might break the mechanical isotropy of the jammed state.

1:15PM S24.00011: Boundary and Interface Modes in Periodically Triangulated Origami
JAMES MCINERNEY (Presenter), School of Physics, Georgia Inst of Tech, BRYAN G CHEN, Physics, University of Massachusetts, LOUIS THERAN, School of Mathematics and Statistics, University of St. Andrews, CHRISTIAN SANTANGELO, Physics, Syracuse University, ZEB ROCKLIN, School of Physics, Georgia Inst of Tech — Origami is an important system for architectured materials because its mechanical response is controlled by the geometry of its crease pattern. While researchers are typically interested in the uniform deformations that arise from rigid folding, the role of boundaries and interfaces are important in design applications. Here, we investigate the linear modes of triangulated origami, for which the number of constraints matches the number of degrees of freedom, i.e. mechanical criticality. Such mechanically critical systems have zero modes on their boundaries which can be robustly moved from one side to the other, known as topological polarization. However, Chen et al. (2016) found triangulated origami does not admit such topological polarization. We first explain how this arises via a vertex duality in triangulated origami which prevents any net topological polarization. We then explore triangulated origami as an element of a recently identified symmetry class which can admit new types of modes at interfaces that depend on the geometry of the joined crease patterns.

1:27PM S24.00012: High Throughput Mechanical Quantification of Glassy Thin Films using Additively Manufactured Elastomeric Lattices  
RICHARD ARTHUR VAIA (Presenter), Materials and Manufacturing Directorate, Air Force Research Laboratory, ANESIA AUGUSTE, UES, Inc, ALLEN SCHANTZ, ANDREW GILLMAN, Materials and Manufacturing Directorate, Air Force Research Laboratory, ANDREW C TIBBITS, UES, Inc, PHILIP BUSKOHL, Materials and Manufacturing Directorate, Air Force Research Laboratory — Understanding the improved toughness, stiffness, and fracture resistance achieved with nanoscale thin films are crucial to numerous technologies, ranging from soft robotics to medicine, energy storage, and smart separation membranes. However, the development of structure-composition-processing-performance relationships are hinder by the lack of techniques that rapidly quantify the plasticity and failure mechanisms of these thin films, especially in relevant environments. In this work, we will discuss a high throughput concept to measure the elastic moduli, plasticity and failure strain of thin polymer films. Building from the copper grid technique developed by Lauterwasser and Kramer, we design an additively manufacture compliant elastomeric lattices to replace the traditionally rigid grid. The geometry of the lattice with differing Poisson's ratios transduces macroscopic, uniform, in-plane deformation into a wide range of local deformation fields at each lattice cell. By placing a thin polystyrene film on top of the lattice structure, each cell acts as a unique deformation stage, allowing simultaneous mapping of the yield and fracture envelope. Combining this with optical techniques and image processing, enables statistically robust analysis of various parameters in parallel.
1:39PM S24.00013: Classical E&M with a twist: A geometric Hall effect without magnetic field* NICHOLAS SCHADE (Presenter), DAVID I SCHUSTER, SIDNEY ROBERT NAGEL, University of Chicago — The classical Hall effect, the traditional means of determining charge-carrier sign and density in a conductor, requires a magnetic field to produce transverse voltages across a current-carrying wire. We demonstrate a fundamentally novel use of geometry to create transverse potentials along curved paths without any magnetic field. These potentials also reflect the charge-carrier sign and density, and they arise because a transverse electric field must accelerate the current radially in order to follow the curve. We demonstrate this effect experimentally in curved graphene wires where the transverse voltages are as large as millivolts. The potentials are consistent with the doping and change polarity as we switch the carrier sign. In straight wires, we measure transverse voltage fluctuations with random polarity demonstrating that the current follows a complex, tortuous path. This geometrically-induced potential offers a sensitive characterization of inhomogeneous current flow in thin films.

1:51PM S24.00014: Rigidity Transitions in Flexible Polymer Networks* JUSTIN LITTLE (Presenter), ROBJIN F BRUINSMA, University of California, Los Angeles — Granular media composed of hard paritcles undergo a rigidity transition with increasing volume fraction. We show that networks of flexible polymers in good solvent described by the Edward's Hamiltonian undergo first-order rigidity transitions as the excluded volume interaction is increased. At the transition point, the network acquires a finite shear modulus, and the density of the network becomes anisotropic. This transition is dominated by the eigenvalue spectrum of the Laplacian matrix of the network.

*We thank the NSF-DMR under Grant 1836404 for funding.

2:03PM S24.00015: Biological Regulatory Networks are Minimally Frustrated* SHUBHAM TRIPATHI (Presenter), PhD Program in Systems, Synthetic, and Physical Biology, Rice University, DAVID A KESSLER, Department of Physics, Bar-Ilan University, HERBERT LEVINE, Department of Physics, Northeastern University — How do biological regulatory networks differ from random networks? Multiple studies have attempted to answer this question by looking for topological features of biological networks that are absent in random networks, yielding few functional insights. Here, using a Boolean modeling framework to compare the dynamical behavior of five real biological networks to that of random networks with similar topological features, we show that biological networks possess sets of stable states that are minimally frustrated. These states exhibit gene expression patterns characteristic of canonical cell types and possess large basins of attraction due to which most cells end up in one the canonical types. The number of commonly observed cell types is thus restricted to the number of gene expression patterns in these minimally frustrated states. Random networks, with topological features similar to biological networks but with varying levels of hierarchy, do not possess such minimally frustrated stable states. Our analysis thus provides crucial insights into the design principles of biological regulatory networks.

Session S25 GSNP: Shell Buckling

11:15AM S25.00001: TBD [Invited]  OUSMANE KODIO (Presenter), Massachusetts Institute of Technology — tbd

11:51AM S25.00002: Postbuckling analysis of hyperelastic thick tube*  YU ZHOU (Presenter), YUZHEN CHEN, LIHUA JIN, University of California, Los Angeles — In recent years, mechanical instabilities of soft materials have been substantially investigated and utilized. Though tube structures are widely used and instabilities of thin-walled tubes are well studied, postbuckling behavior of hyperelastic thick tubes is elusive. It is well known that exact solutions of postbuckling are hard to obtain, especially for structures under three-dimensional finite deformation. In this presentation, we conduct buckling and postbuckling analysis for hyperelastic thick tubes undergoing finite deformation. We will briefly introduce the asymptotic expansion method for buckling and weakly postbuckling of elastic bodies and apply this theory to thick tubes. Our analytical results are validated by finite element simulations. As a result, a long tube prefers the Euler buckling mode, while a short tube prefers the barreling mode. Depending on the geometry, three kinds of postbuckling paths, including increasing force, snap-through and snap-back, are discovered. We summarize our results in two phase diagrams of buckling and postbuckling with respect to geometric parameters, which provide guidelines for utilization of tube structures.

*We acknowledge startup fund from Henry Samueli School of Engineering and Applied Science at UCLA and Hellman fellowship.

12:03PM S25.00003: Buckling in thin thermalized ribbons under longitudinal compression
PAUL HANAKATA (Presenter), ABIGAIL PLUMMER, SURAJ SHANKAR, DAVID ROBERT NELSON, Harvard University — Introducing kirigami cuts to thin sheets, ranging from macro to nanoscale, can allow for sensitive control of mechanical properties such as stretchability. The out-of-plane buckling due to in-plane compression can be a key feature in preventing failure upon stretching. While thin plate theory can predict critical buckling for thin frames and nanoribbons at very low temperatures, a unifying framework to describe the effects of thermal fluctuations on the buckling presents subtle problems. In analogy with understanding semi-flexible polymers with long persistence lengths, we address under what conditions a thin thermalized nanoribbon behaves like a classical plate and how its thermal modes compete with the buckling modes. We develop a mean field approach to understand how the critical buckling changes due to thermal fluctuations both above and below the buckling transition. We simulate thin graphene nanoribbons under axial compression using molecular dynamics simulations to test our predictions.
Poking and buckling of pressurized spherical shells  
AREFEH ABBASI, DONG YAN, MATTEO PEZZULLA, PEDRO REIS (Presenter), Ecole Polytechnique Federale de Lausanne — Imperfection sensitivity in shell buckling makes it difficult to predict the critical buckling conditions of shells with realistic distributions of defects. Recently, a non-destructive technique has been proposed and successfully applied to cylindrical shells [1,2], to access their landscape of stability using a probing force. It is still debatable whether this technique can also be used for spherical shells. Here, we combine precision experiments, finite element simulations and shell theory to explore the ability of a poking technique to determine the critical buckling pressure of a spherical shell containing a dimple-like defect. We find that the critical point can indeed be probed when the force is applied at the defect. However, when the poking is done further away from the defect, this becomes invisible to the probing and the shell buckles prior to the cue provided by the poking. Specifically, we quantify a threshold angle for the location of the probing force, beyond which poking no longer seems to be applicable as a non-destructive testing technique. The basis of our analysis is the localized nature of the deformation of shells under point-load indentation.

Multi-component assembly of microcompartments*  
SIYU LI (Presenter), YAOHUA LI, TAYLOR NICHOLS, NOLAN KENNEDY, DANIELLE TULLMAN-ERCEK, MONICA OLVERA DE LA CRUZ, Northwestern University — Many bacteria generate bacterial microcompartments (BMC) in their metabolic processes. These particles are protein-based shells that encapsulate enzymes spontaneously. Using all-atom and coarse-grained molecular dynamics, we study the mechanical properties of protein subunits and the assembly process. We find that the hexamers (PduA) are associated mainly due to the hydrogen bonding, the strength of which exactly corresponds to the region that BMC successfully formed. In addition, we observe cylinder and “samosa” shaped shells coexistent in solution when reducing the pentamer (PduN)-hexamer interaction. We calculate the free energy for each morphology thermodynamically and find that the cargo-hexamer attraction in cylinder/samosa compensates the energy loss of missing pentamers. We also discuss other thermodynamic parameters that can be used to control the shell morphology, which provides a prediction for future experiments.

*We thank DOE support of the grant DE-FG02-08ER46539 from the Department of Energy Basic Energy Science Office and the Sherman Fairchild Foundation.
12:39PM S25.00006: Shallowness effect on buckling of spherical shells  KANGHYUN KI (Presenter), JEONGRAK LEE, ANNA LEE, Pohang University of Science and Technology — We study the buckling of clamped spherical caps under uniform pressure. Since the 1960s, several theoretical and computational studies have addressed the non-monotonic relationship between the shallowness of the shells and its critical buckling pressure. However, there is a lack of precise experiments to corroborate these predictions. Using a recently developed technique, we fabricate polymeric spherical shells containing a precise geometric defect. We vary the shallowness of our shells by precisely changing the location of the clamped boundary conditions and measure the critical buckling pressure. Finite element simulations are conducted to analyze the buckling behavior of our shallow shells, in excellent agreement with the experiments. We find that the critical buckling pressure and the shallowness parameter have a decaying sinusoidal relationship, hence, the buckling strength of shallow shells can be larger or smaller than that of complete spherical shells. Moreover, this sinusoidal form is systematically characterized which is affected by a geometric defect.

12:51PM S25.00007: Circumferential Buckling of the Confined D-cone* LUCIA STEIN-MONTALVO (Presenter), KANANI ALMEIDA, DOUGLAS HOLMES, Boston Univ — Thin structures deform in dramatic ways to avoid stretching, and this strongly depends on how they are constrained. We observe that in-plane confinement forces the classical packed d-cone to deviate from its characteristic form. Instead of forming a cone with a single region of high stretching, thin, flexible plates wrinkle circumferentially in response to radial and packing-type confinement together. Geometry sets the limiting maximum wavenumber, but dynamic changes in morphology occur even as confinement increases quasi-statically. In a primarily experimental study, we investigate the role of confinement on shape selection, curvature distribution, stretching localization, and the resultant force as waves develop sequentially.

*We gratefully acknowledge financial support from NSF through CMMI-1824882.
1:03PM S25.00008: Investigating imperfection-sensitivity in shell buckling using a toy model

RAINER GROH (Presenter), ALBERTO PIRRERA, Univ of Bristol — Shell buckling is known for its extreme sensitivity to initial imperfections. It is generally understood that this sensitivity is caused by an unstable (subcritical) bifurcation, i.e. geometric imperfections rapidly erode the buckling load of the perfect shell. It is less commonly appreciated that subcriticality also creates a strong proclivity for spatially localised buckling modes. The ability of localisations to appear anywhere across the domain (spatial multiplicity) leads to a large set of possible trajectories to instability, with each trajectory affine to a particular imperfection signature. Using a toy model of a link system on a softening elastic foundation, we show that the spatial multiplicity of localisations leads to a large spread in buckling loads, even for indistinguishable random imperfections of the same amplitude. By imposing a dominant imperfection, the strong sensitivity to random imperfections is ameliorated, and the ability to control the trajectory to buckling via dominant imperfections or elastic tailoring, creates interesting possibilities for designing imperfection-insensitive shells.

1:15PM S25.00009: Newton’s method for experimental path-following of nonlinear structures

JIAJIA SHEN, RAINER GROH, ROBIN M NEVILLE, MARK SCHENK, ALBERTO PIRRERA (Presenter), Univ of Bristol — Traditional experimental testing of nonlinear structures has not evolved beyond the fundamental techniques of force control (dead loading) and displacement control (rigid loading). These two experimental paradigms face the same issues that computational solvers faced before numerical path-following; namely, limit points in the force-displacement response cannot be traversed by sole force or displacement control. To extend the capabilities of nonlinear testing methods, we have implemented an experimental analogue to numerical path-following. In addition to controlling the displacement at the primary load-introduction points, extra actuators and sensors are attached to control the overall shape of the structure. By perturbing the structure at these control points, and recording the resulting changes in reaction force, an “experimental tangent stiffness” matrix is computed, which is then used in a feedback control system based on Newton’s method. Using an experiment on a shallow arch, we demonstrate the capability of the test setup to path-follow stable and unstable equilibria and traverse limit points.

*R.M.J.G. is funded by the Royal Academy of Engineering [RF\201718\17178]. J.S. and A.P. are funded by the UK Engineering and Physical Sciences Research Council [EP/M013170/1].
EMMANUEL VIROT (Presenter), Harvard University, ANAIS ABRAMIAN, Institut Jean Le Rond d’Alembert, EMILIO LOZANO, TOBIAS SCHNEIDER, EPFL, SHMUEL RUBINSTEIN, Harvard University — What is the critical load required to crush a soda can or a space rocket shell? Surprisingly, there is no good way to estimate it, because of the high defect-sensitivity of the buckling instability.

Here we measure the response of (imperfect) soda cans to lateral poking and identify a generic stability landscape, which fully characterizes the stability of real imperfect shells in the case where one single defect dominates.

By using this new paradigm, we are able to accurately and non-destructively predict the buckling load of real imperfect shell structures, thereby promising drastic reductions of the costs of structural engineering experimental tests.

We will discuss the success rate of the method and the perspectives offered by such an approach.

NICHOLAS CUCCIA (Presenter), EMMANUEL VIROT, MICHAEL PHILLIP BRENNER, SHMUEL RUBINSTEIN, Harvard University — Materials under cyclic loading experience changes in their physical properties, commonly exhibiting structural fatigue, damage and eventually failure. There exists much interest in how a material ‘remembers’ the damage done to it, and few methods exist to, without irreversibly deforming the material, quantitatively describe this ‘memory’. Here, we explore the effects of cyclic loading on the stability of cylindrical shells with many small unknown defects (empty soda-cans). Using a custom-built multi-axial tester, we repeatedly load and unload our cans and generate stability landscapes by measuring the can’s response to non-destructive lateral poking at various axial loads. Here, we will show that cyclic loading changes the can’s reaction to poking, which can be visualized through the evolution of the can’s stability landscape.

We will also show how the initial defect structure of our shells can inform their overall fatigue and can be understood via topological features of our shell’s stability landscape.

*This research is supported by Harvard's Materials Research Science and Engineering Center (MRSEC) and the National Science Foundation (NSF) under Award Number DMR-1420570.
We study the bulging behavior of thin cylindrical balloons with various aspect ratios under internal pressure loading. Although the localized bulging of long circular tubes has been extensively studied experimentally and analytically, there is a lack of investigation on the deformation of short and moderate-length tubes. For non-cylindrical balloons, a recent simulation study on the inflation of spheroidal shells reported the boundary aspect ratio that determines the occurrence of localized bulging. We first experimentally investigate the bulging behavior of hyperelastic tubes under internal pressure by systematically varying the aspect ratio. We also explore the effect of prestretch both on the critical bulging pressure and the instability. Then, we compare our experimental results with analytical solutions. Furthermore, we combine multiple tube segments to achieve complex deformation. Our results can be used to understand inflatable biological structures and design soft pneumatic actuators.

Thursday, March 5, 2020 11:15 AM - 2:15 PM

Session S26 DBIO DPOLY GSNP: Physics of Genome Organization: From DNA to Chromatin: II 403 - Alexandre Morozov, Rutgers University, New Brunswick - Tag(s): Focus
11:15AM S26.00001: On the Border of Order: Chromosomal Organization in Space and Time*

[Invited] YAOJUN ZHANG, Princeton University, NIMISH KHANNA, Molecular Biology, University of California, San Diego, JOSEPH LUCAS, Physics, University of California, San Diego, CORNELIS MURRE, Molecular Biology, University of California, San Diego, OLGA DUDKO (Presenter), Physics, University of California, San Diego — Many biological processes, from antibody production to tissue differentiation, share a common fundamental step — establishing a physical contact between distant genomic segments. How do remote segments find each other on a remarkably short timescale despite being strung out over millions of base pairs along the DNA? What is the mechanism of the high degree of orchestration of remote genomic interactions? We address these questions in the context of adaptive immunity – the system that enables the individual to respond to a great variety of pathogens through a diverse repertoire of antibodies. Experimental data from live-cell imaging in B-lymphocytes reveal the signatures of anomalous diffusion that help us identify the dominant mechanism of genomic motion. Comparison of experimental and simulated data, along with insights from polymer physics, suggest that an interphase chromosome behaves as a network of cross-linked chains characteristic of a gel phase, yet it is poised near the sol phase, a solution of independent chains. Chromosome organization near the phase boundary provides the genome with a tradeoff between stability and responsiveness and orchestrates the timing of genomic interactions.

SWARNADEEP SETH (Presenter), ANIKET BHATTACHARYA, Univ of Central Florida — In an experimental “Tug-of-War” (X. Liu et al., Small 2019, 1901704), a DNA segment co-captured in both the pores in a Double-Nanopore system is subject to two equal and opposite biases at two pore locations for better control and repeated measurements of the same segment. We simulate a model system in three dimensions and use Brownian dynamics to reveal the details of the single file translocation. Specifically, we study the consequence of increased persistence length of the segment in between the pores due to the tug-of-war forces. We characterize the diffusive motion of the chain either for exact “Tug-of-War” with zero bias, or subject to a small net bias, and provide error estimates of the length translocated through the Double- nanopore from the velocity measurements. Furthermore, we compare the velocities of the individual monomers with the average velocity of the entire chain and explore measures to reduce the fluctuation in velocity along the chain.
12:03PM S26.00003: Studies of nucleosome-decorated DNA structures and deformations using a new analytical model*  
SEYED AHMAD SABOK-SAYR (Presenter), WILMA K OLSON, Rutgers University, New Brunswick — The two meters of DNA found in almost every human cell must be folded by many orders of magnitude to fit in the nucleus. The first step in this compaction involves the coiling of ~150 base pairs of DNA around a core of eight positively charged histone proteins. Understanding the biological processing of DNA requires knowledge of how the nucleosomes are arranged in space. We introduce a new analytical treatment of nucleosome-decorated DNA which is made up of three essential parts: nucleosomal DNA; protein-free stretches of DNA; and the intervening connectors. Every connector provides a physically smooth DNA pathway between a protein-bound and/or a protein-free segment. We have used this approach to study the energetically preferred configurations of torsionally relaxed, 360-base pair DNA rings with two evenly-spaced nucleosomes as well as rings of the same size with a single nucleosome subject to deformation in structure and/or variation in DNA wrapping. We have identified conditions where the closed DNA chain switches from one global configuration state to another. We are also using this model to study more complicated structures, such as the Simian virus 40 minichromosome, an assembly of ~20 nucleosomes on ~5200 base pairs of DNA supercoiling.

12:15PM S26.00004: Long-lived memory and dynamics of liquefied chromatin  
EDWARD BANIGAN (Presenter), Massachusetts Institute of Technology MIT, HOUDA BELAGHZAL, TYLER BORRMAN, JOB DEKKER, University of Massachusetts Medical School, LEONID MIRNY, Massachusetts Institute of Technology MIT — Chromatin is organized into spatially segregated compartments, referred to as (active) euchromatin and (inactive) heterochromatin. Compartments are thought to be formed by phase separation, which may be facilitated by the underlying linear polymer structure of the genome. However, recent “liquid Hi-C” experiments in which chromosomes are fragmented into tiny segments reveal an hours-long spatial memory that does not rely on large-scale polymer connectivity. To understand the physical mechanisms and dynamics of this memory, we analyze Hi-C genome contact maps and perform polymer molecular dynamics simulations. In a heteropolymer simulation model, we find that strong interactions between inactive chromatin segments can lead to slow melting of inactive compartments, as in experiments. Surprisingly, in Hi-C maps, we find that contacts between segments separated by small genomic distances are maintained despite the fragmentation of the genome. Our model can only reproduce this counterintuitive behavior when such contacts are maintained by another cell nuclear structure, such as the lamina. Thus, while phase separation may globally compartmentalize chromatin, it is insufficient to dictate short-distance contacts, which instead may be maintained by specific, long-lived interactions.
12:27PM S26.00005: The Dynamic Archaeal Chromatin “Slinky” [Invited] SAMUEL BOWERMAN (Presenter), University of Colorado Boulder — Eukaryotic organisms package genomes that are significantly larger and more complex than genomes that are typically found in prokaryotes. The fundamental unit of compaction is the nucleosome, which is formed by histone heteromers – two H2A-H2B dimers flanking an H3-H4 tetramer – forming an octamer that binds approximately 147 bp of DNA. While histones were originally thought to only be present in eukaryotes, a plethora of histone sequences have been identified in a wide range of archaea, one of the prokaryotic domains of life. Our lab recently determined the structure of histone-based archaeal chromatin that showed striking similarities to eukaryotic nucleosomes, but crystal lattice packing and biochemical experiments suggested that archaea may form repeated stacking interactions, potentially forming long “Slinky-like” extended chromatin arrangements. Here, we utilize molecular dynamics simulations, cryoEM, and analytical ultracentrifugation to study the inherent dynamics of these putative chromatin slinkies. Formation of “Slinky stacking” interactions are observed to reduce system dynamics, and perturbing this interaction through stack-hindering mutations yields more flexible constructs and increases solution accessibility. The openness of the Slinky is also sensitive to the salt environment. We utilize these data to explore how inherent dynamics of archaeal Slinky chromatin may regulate transcription.

1:03PM S26.00006: 5-methyl-cytosine binding proteins loop DNA under nanoconfinement* MING LIU (Presenter), North Carolina State University, DAVID C. WILLIAMS, Department of Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, HONG WANG, ROBERT RIEHN, North Carolina State University — Methyl-binding domain proteins are a family of proteins that possess a domain to selectively bind 5-methyl cytosine in an CpG context. Members of the family interact with other proteins to modulate DNA packing. Stretching of DNA-protein complexes in nanofluidic channels with a cross-section of a few persistence lengths allows us to probe the degree of packing by such proteins. Here we demonstrate compaction by MeCP2 while MBD2 does not affect DNA configuration. By using atomic force microscopy (AFM), we determined that the likely mechanism for compaction by MeCP2 is the formation of bridges between distant DNA stretches and the formation of loops. We discuss the potential of both proteins for epigenetic mapping.

*We acknowledge funding from the NSF (DBI1353897) and the NIH (GM107559, GM123246)
1:15PM S26.00007: Nuclear chromatin patterns: modeling dynamics of intra-chromatin interactions and its impact on structure organization  RABIA LAGHMACH (Presenter), Iowa State University, MICHELE DI PIERRO, Center for Theoretical Biological Physics, Rice University, DAVIT POTOYAN, Iowa State University — The description of chromatin organization and its dynamics, at a large scale, are functionally important factors in the genome regulation function. Growing evidence suggests that chromatin within the nucleus has a liquid-like behavior mediated by phase separation into micro-droplets with distinct transcriptional states. The formation and spatial arrangement of chromatin droplets within the nucleus depending on their transcriptional states either active (euchromatin) or inactive (constitutive and facultative heterochromatin) genes are important features of the nuclear architecture. Understating mechanisms that control the dynamics and spatiotemporal regulation of droplets formation is a possible way to elucidate the relationship between nuclear architecture and gene regulation. Here, we introduce a mesoscale liquid model of nucleus (MELON) that incorporates dynamic of interactions between A-B-C chromatin compartments of the nucleus, as well as the affinity between constitutive heterochromatin and Lamina at the nuclear envelope and nucleus deformation. Using MELON framework, we show that phase separation together with surface tension effects and nuclear shape deformation is sufficient for recapitulating large-scale morphology and dynamics of chromatin along the life cycle of cells.

1:27PM S26.00008: Long-distance group dynamics of RNA polymerases via DNA supercoiling  SANGJIN KIM (Presenter), University of Illinois at Urbana-Champaign — Genes are often transcribed by multiple RNA polymerases (RNAPs) at densities that can vary widely across genes and environmental conditions. Here, we provide in vitro and in vivo evidence for a built-in mechanism by which co-transcribing RNAPs display either collaborative or antagonistic dynamics over long distances (>2 kb) through transcription-induced DNA supercoiling. In Escherichia coli, when the promoter is active, co-transcribing RNAPs translocate faster than a single RNAP, but their average speed is not altered by large variations in promoter strength and thus RNAP density. Environmentally induced promoter repression reduces the elongation efficiency of already-loaded RNAPs, causing premature termination and quick synthesis arrest of no-longer-needed proteins. This negative effect appears independent of RNAP convoy formation and is abrogated by topoisomerase I activity. Antagonistic dynamics can also occur between RNAPs from divergently transcribed gene pairs. Implications for genome organization and evolution will be discussed. Our findings may be broadly applicable given that transcription on topologically constrained DNA is the norm across organisms.
1:39PM S26.00009: Interplay of chromatin self-adhesion and lengthwise compaction on interchromosomal organization* SUMITABHA BRAHMACHARI (Presenter), VINICIUS CONTESSOTO, MICHELE DI PIERRO, JOSE N ONUCHIC, Rice Univ — Chromosome folding is driven by an interplay between two major forces: self-adhesion between specific chromatin segments and lengthwise compaction, which is in line with experimental observations of structure and dynamics of cellular chromosomes. We use a coarse-grained polymer model for chromosomes where centromeres and telomeres are treated as polymer blocks featuring respective self-adhesion, and simulate multiple chromosomes in a confined volume. We find that our scheme of lengthwise compaction drives the formation of chromosome territories, whereas, self-adhesive centromeres and telomeres tend to form localized clusters. We highlight the interplay between self-adhesion and lengthwise compaction, based on their relative strengths, that addresses a fundamental aspect of genome organization in the eukaryotic nuclei.

1:51PM S26.00010: A minimal model for correlated chromatin dynamics* KUANG LIU (Presenter), ALISON PATTESON, Syracuse University, EDWARD BANIGAN, MIT, JENNIFER SCHWARZ, Syracuse University — The multiscale spatial structure of chromatin spans several decades from the nanometer scale to the micron scale. In addition to its nontrivial spatial structure, chromatin also exhibits nontrivial dynamics. For instance, correlated motion of chromatin on the length scale of microns over the time scale of tens of seconds has been observed. Correlations are diminished in the absence of ATP, suggesting that motor/enzymatic activity promotes chromatin collective dynamics. Therefore, we construct a minimal polymeric model to study the spatiotemporal properties of chromatin by simulating a Rouse chain with excluded volume interactions confined within a rigid, spherical shell that represents the lamina. We characterize the spatiotemporal properties of the chain in the presence of motor activity, crosslinking, and binding to the shell. These components model an active chromatin network with lamin-binding domains. We find correlated motion under several conditions, without the need for long-range forces. Notably, when chromatin is bound to the lamina, crosslinking and motor activity are required for strong correlations in chromatin motion. We also study the effects of a deformable lamina shell in order to study the coupling of correlated chromatin motion to nuclear shape.

*NSF-DMR-1832002
Due to the intrinsic twist of DNA, eukaryotic replication generates DNA supercoiling as the replisome unravels parental DNA. If not resolved, this supercoiling may intertwine chromatin fibers and result in significant topological challenges during chromosome replication. Since the replisome alone is incapable of driving its substrates out of torsional equilibrium, the generated supercoiling partitions ahead of or behind the replication fork to maintain a balance of torque. By making direct torque measurements, we demonstrated that a single chromatin fiber (as would be located ahead of a replisome) is torsionally soft, while a braided chromatin fiber (as would be located behind the replisome) is relatively stiff. These results imply that supercoiling on chromatin substrates is preferentially directed in front of the replication fork. We further showed that topoisomerase II relaxation displays a strong preference for a single chromatin fiber over a braided fiber, suggesting a synergistic coordination—the mechanical properties of chromatin inherently suppress intertwining during replication elongation by driving DNA supercoiling ahead of the fork, where it is more efficiently removed by topoisomerase II. This work highlights the fundamental role of physical principles in the cell.

Session S27 FIAP: Thermodynamic and Transport Properties 404 - Elena Cimpoiasu, US Naval Academy

11:15AM S27.00001: Charge Scattering Mechanisms in shallow InAs quantum wells*  ELENA CIMPOIASU, MATTHEW J. FOX (Presenter), US Naval Academy, SHAWN MACK, JOSEPH A. CHRISTODOULIDES, BRIAN R BENNETT, Naval Research Laboratory — We studied the charge scattering mechanisms present in In_{0.2}Al_{0.8}Sb/InAs/Al_{0.8}Ga_{0.2}Sb wells placed in close proximity to the surface of the heterostructures, at depths from 7 nm to 15 nm. The heterostructures were either unintentionally-doped, doped from below the channel or from above the channel. Measurements of sheet and Hall resistances were performed at T = 2K in variable magnetic field and under illumination with wavelengths of 400 nm up to 1300 nm. The charge density dependencies of the Hall mobility and quantum scattering time were used to infer the dominant mechanisms. We found that the transport quality of the sample is dominated by bottom interface roughness, and that reducing the asymmetry of the potential well results in improved charge transport as the scattering of interface roughness is reduced. This is, however, detrimental to the strength of spin-orbit coupling and to spin-based applications of these materials

*This work was supported by the Office of Naval Research.
Transport properties of exfoliated GaTe thin flakes

WENKAI ZHENG (Presenter), Natl High Magnetic Field Lab, JUSTIN FELDER, Chemistry, University of Texas at Dallas, ZACHARY BRYCE GORAUM, Physics, Florida State University, GREGORY MCCANDLESS, JULIA CHAN, Chemistry, University of Texas at Dallas, LUIS BALICAS — Metal mono-chalcogenide(MMCs), such as GaS, GaSe, InSe, and GaTe, have recently attracted much attention due in part to the evolution of their direct bandgap as a function of the number of layers. Although intrinsic MMC is nonmagnetic, a recent first principle calculation [1] predicts a Stoner-type magnetic instability that leads to the formation of a half-metallic and hence ferromagnetic ground state, which would make these materials interesting for spin transport or applications in spintronics. Here we discuss the temperature-dependent response of Field-Effect Transistors fabricated from GaTe single-crystals grown via a flux method, and measured through two and four-terminal configurations. We will also discuss the evolution of the Hall effect as a function of the temperature.

Electronic Properties of Bismuth Iodide (Bi$_4$I$_4$) Thin Films

YULU LIU (Presenter), Ohio State Univ - Columbus, RUOYU CHEN, ASM, SHENG LI, XIAOYUAN LIU, University of Texas, Dallas, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science (NIMS), BING LV, FAN ZHANG, University of Texas, Dallas, CHUN NING LAU, Ohio State Univ - Columbus — Due to the gapless conductive surface states which are protected against perturbations, topological insulator materials have attracted much attention in this field. Bi$_4$I$_4$ is a quasi-one-dimensional van der Waals material, and its beta phase has been revealed by angle-resolved photoemission spectroscopy to be a topological insulator, thus offering a new platform for exploring topological phases. To date, all prior works on Bi$_4$I$_4$ are based on the bulk material. Here we report transport measurements of thin Bi$_4$I$_4$ films that are mechanically exfoliated Bi$_4$I$_4$ from bulk crystals. Devices in both alpha and beta phases are characterized. Their gate-tunable resistance demonstrates surface-dominated transport, which is further supported by the observation of weak antilocalization in magnetic fields. Moreover, the temperature behavior in b-Bi$_4$I$_4$ suggests that the inelastic scattering process at low temperature is dominated by the electron-electron interaction.
Amorphous silica (silicon dioxide) is one of the strongest glass formers known, and silicate glasses are by far the most widely produced for applications. Liquid-quenched silica shows tunneling two-level system density, as probed by low-temperature specific heat and internal friction, in the so-called universal glassy range observed for nearly all amorphous materials. We present low-temperature (down to 300 mK) specific heat and mechanical loss measurements on silica thin films grown at temperatures from 60 to 800 °C by e-beam evaporation. Results indicate that silica grown near room temperature shows TLS density, extracted from cryogenic specific heat, above the universal range. The mechanical loss, though high, is still within the universal range, and falls to the level of bulk silica as the growth temperature is increased to 800 °C. This is consistent with the observed increase in atomic density of approximately 10% as the growth temperature is raised 60 to 800 °C. These results are compared to previous work on amorphous silicon and tantala, with attention drawn to the somewhat unusual relative change of the sound velocity with temperature and how this changes systematically with growth temperature for the silica films.

*Supported by NSF Grants DGE 1752814 and DMR 1809498.

Amorphous silicon shows anomalous properties at low temperatures due to two-level systems, which affect both mechanical and electromagnetic oscillators. However, it is unclear whether the two-level systems responsible for these effects are the same. We performed mechanical and dielectric loss measurements of amorphous silicon films grown by electron beam deposition. Samples grown at 425 °C show a large reduction of mechanical loss and a mild reduction of dielectric loss compared to those grown at room temperature. Results indicate mechanical loss is related to mass density, while dielectric loss is to dangling bond density. Moreover, mechanical loss results show lower loss per unit volume for thicker films, while dielectric loss results show lower loss per unit volume for thinner films, suggesting an underlying structural and differential origin for both types of energy dissipation processes. Additionally, specific heat measurements show that the density of two-level systems extends far above the well-known glassy range, indicating that some interactions play a crucial role in creating the universal values of mechanical losses at low temperatures.

*We thank NSF DMR-1508828 and 1809498, Office of Naval Research, and Lawrence Livermore National Laboratory support.
**12:15PM S27.00006: Electrical Transport in Chemically Exfoliated Li$_x$CoO$_2$ in 2D Nanoflake**

**Form**  
KYLE CROWLEY (Presenter), KEVIN PACHUTA, SANTOSH KUMAR RADHA, Case Western Reserve University, HALYNA VOLKOVA, Centre des matériaux, MINES ParisTech, ALP SEHIRLIOGLU, WALTER LAMBRECHT, Case Western Reserve University, MARIE-HELENE BERGER, Centre des matériaux, MINES ParisTech, XUAN GAO, Case Western Reserve University — Layered oxides possess various novel electronic and magnetic phases, many of which remain either unexplained or continually debated. Li$_x$CoO$_2$ is one such material; one of the most commonly used cathode materials in rechargeable batteries, this oxide exhibits a rich landscape of properties, with many aspects still not fully understood. Li$_x$CoO$_2$ contains electrostatically stabilized layers, making it difficult to study in its few-layer, single-crystal form. Herein, a two-step process is utilized to chemically delithiate Li$_x$CoO$_2$ in the range 0.3<x<0.8. Li$_x$CoO$_2$ is then chemically exfoliated, producing nanoflakes 5-100nm thick. Electrical characterization of these individual nanoflakes reveals an insulating behavior upon contact formation, and suppression of metallic tendencies in the low-lithium range (x<0.75), likely due to termination effects of the surface lithium plane. Additionally, an anomaly in the temperature dependent resistance is observed in flakes of specific lithium content, indicating that this fabrication method is suitable for studying charge ordering phenomena in Li$_x$CoO$_2$. This technique offers potential for exploring Li$_x$CoO$_2$ in its two dimensional form, which has not been reported for single crystals to date.

**12:27PM S27.00007: Diamagnetic Susceptibility, Disorder, and Linear Magnetoresistance in Ag$_{2-\delta}$Te**

**Ian Leahy** (Presenter), PETER SIEGFRIED, University of Colorado, Boulder, HAROLD SCHNYDERS, Department of Physics, Grand Valley State University, MINHYEA LEE, University of Colorado, Boulder — The origin of linear magnetoresistance in Ag$_{2-\delta}$Te has historically sparked debate between several intrinsic and extrinsic mechanisms. We investigate the magnetotransport properties of the narrow-gap semiconductors Ag$_{2-\delta}$Te as a function of silver deficiency in order to quantify the role of disorder on their observed linear magnetoresistance. Built on our earlier work [1], we study the temperature and field dependence of the Hall angle and the diamagnetic susceptibility in order to develop a framework to quantify the disorder parameters, namely disorder potential $V_0$ and the characteristic lengths $\xi$, as a function of silver deficiency. These quantities will be compared as silver deficiency is varied. We will discuss the implication of our results in terms of generalized conditions for emergence of linear magnetoresistance.

12:39PM S27.00008: Quantum Transport in Epitaxial Ultra Wide Bandgap Aluminum Gallium Oxide Tunnel Heterostructures*  
NICHOLAS TANEN (Presenter), CELESTA CHANG, VLADIMIR PROTASENKO, JONATHAN MCCANDLESS, DAVID ANTHONY MULLER, HUILI XING, DEBDEEP JENA, Cornell University — In this work, we studied the epitaxial growth of the wide-band gap, monoclinic beta-Ga$_2$O$_3$ (~4.4-4.9 eV) and (Al$_x$Ga$_{1-x}$)$_2$O$_3$ (~4.4-9.0 eV, Al% = 0-100) using molecular beam epitaxy on (010) beta-Ga$_2$O$_3$ substrates. We will discuss the optimum growth conditions for both materials and how the formation of Ga interstitial-divacancy complexes in unoptimized growths of (Al$_x$Ga$_{1-x}$)$_2$O$_3$ can lead to the formation of unwanted phases of Ga$_2$O$_3$ in our heterostructures. Additionally, tunnel barrier structures made with an (Al$_x$Ga$_{1-x}$)$_2$O$_3$ layer sandwiched between two n+ Ga$_2$O$_3$ layer are studied to explore tunneling behavior in this material system. The current-voltage characteristics are measured for a varying Al composition and the (Al$_x$Ga$_{1-x}$)$_2$O$_3$ barrier thickness. Using the Wentzel–Kramers–Brillouin approximation and Non-equilibrium Green's Function formalism, the current-voltage characteristics of these tunnel barrier devices are simulated and compared to experimental data. The above study helps identify the conduction band offset $\Delta E_c$ a critical unknown in this material family directly from transport. The $\Delta E_c$ thus found between beta-(Al$_x$Ga$_{1-x}$)$_2$O$_3$ and beta-Ga$_2$O$_3$ is compared to those extracted from XPS, capacitance-voltage measurements, and also by DFT.

12:51PM S27.00009: Lateral charge carrier transport properties of B-10 enriched hexagonal boron nitride epilayers*  
SAMUEL GRENADIER (Presenter), AVISEK MAITY, JING LI, JINGYU LIN, HONGXING JIANG, Texas Tech Univ — Hexagonal boron nitride (h-BN) has emerged as a promising candidate for many technologically significant applications due to its unique physical properties. However, h-BN is one of the least studied members of the III-nitride materials system and many important fundamental properties including room temperature carrier mobility, lifetime and surface recombination velocity remain unexplored. We report Time-of-Flight (TOF) probed room temperature lateral carrier drift mobilities ($\mu$) and lifetimes ($\tau$) for both electrons and holes in highly resistive, wide bandgap h-BN epilayers. Photoconductive type detectors were fabricated from freestanding B-10 enriched h-BN material. We obtained values of $\mu_e$ ~ 34 cm$^2$/Vs for electrons and $\mu_h$ ~ 36 cm$^2$/Vs for holes and carrier lifetimes on the order of 10 $\mu$s. Surface recombination velocity (S) was then calculated by combining the $\mu$ from TOF with the ratio of S to $\mu$ (S/$\mu$) extracted directly from the bias voltage dependence of photocurrent. These results represent a valuable contribution to the understanding of the electrical transport properties of h-BN.

1:03PM S27.00010: Physical properties at the 157K-phase transition in Pr$_4$Ni$_3$O$_{10}$

SHANGXIONG HUANGFU (Presenter), Univ of Zurich, DARIUSZ GAWRYLUK, PSI, XIAOFU ZHANG, Univ of Zurich, EKATERINA POMJAKUSHINA, PSI, ANDREAS J SCHILLING, Univ of Zurich — As a member of the Ruddlesden–Popper Ln$_4$Ni$_3$O$_{10}$ series rare earth nickelates, the Pr$_4$Ni$_3$O$_{10}$ is constituted by three Ni-O layers piled up to a quasi-two-dimensional perovskite-like structure[i], and shows mixed Ni valent states of +2 and +3. A phase transition at ~ 157 K has already been observed in previous studies, which was interpreted as a charge-density wave (CDW) transition[ii][iii]. We have grown single crystals of Pr$_4$Ni$_3$O$_{10}$ in high oxygen pressure, and report on the physical properties around that phase transition, such as heat capacity, magnetization and electron transport. We observe a distinct anisotropy between in-plane and out-of-plane properties both in zero-field and in magneto-resistance. In addition, the magnetic susceptibility obeys a Curie-weiss law, with different Curie constants for the high temperature and the low temperature phases. We discuss a possible scenario in which a change of the d orbitals of the Ni ions at the Fermi level explains the changes in all these measured quantities at the phase transition.

1:15PM S27.00011: Charge transport mechanism near crystal edge of layered halide perovskites*

XIJJUN LIAN (Presenter), Florida State Univ, ENZHENG SHI, LETIAN DOU, Purdue University, HANWEI GAO, Florida State Univ — Halide perovskites show superior optical and electrical properties, which make this group of materials promising for highly efficient optoelectronic applications. Researchers have reported that there existed below-bandgap energy states at the edges of the layered perovskites and the presence of these lower energy states resulted in highly improved solar cell efficiency. In our work, the photophysics investigation near crystal edge unveiled the local charge transport mechanism and energy flow in layered halide perovskites, which will provide vital guidance for designing and engineering highly efficient optoelectronics based on this group of materials.

1:27PM S27.00012: Dynamic disorder in BaTiS₃*  RAPHAEL HERMANN (Presenter), MICHAEL E MANLEY, BARRY WINN, Oak Ridge National Laboratory, KATHARINE L. PAGE, The University of Tennessee, AHMET ALATAS, Argonne National Laboratory, JAERYUN MOON, AUSTIN MINNICH, California Institute of Technology, JAYAKANTH RAVICHANDRAN, University of Southern California, Los Angeles — BaTiS₃ exhibits a hexagonal perovskite structure comprised of columns of sulphur coordinated Ti linked by barium making it a quasi-1D structure. Neutron pair distribution function measurements reveal that the Ti atomic displacement parameters increase with decreasing temperature. This observation suggest proximity to a ferroelectric type phase transition or, alternatively, dynamic disorder persisting in the ground state. A combination of phonon spectroscopy by inelastic x-ray scattering and inelastic neutron scattering supports the dynamic disorder scenario which extends into the quantum regime with Ti occupying a double-well potential. This unique dynamics have a profound consequence on the thermal conductivity and suggest a novel mechanism for thermal transport design.

1:39PM S27.00013: A High Throughput DFT Study of Half Heusler Solid Solution Mixtures ANDREW LEE (Presenter), SHASHWAT ANAND, Northwestern University, LOGAN WARD, Argonne National Laboratory, CHRISTOPHER MARK WOLVERTON, Northwestern University — Half heuslers exhibit properties well-suited for thermoelectrics. The best performing half heusler thermoelectrics such as TiNiSn, NbFeSb, and ZrCoBi-based systems are solid-solution alloys with disorder scattering which reduces thermal conductivity. However, only a handful of such alloy systems have been reported. Furthermore, these systems are studied with mixing on just one of the three sub-lattices at a time. Hence, a comprehensive study of solubility in mixed alloy systems can guide future choices of half heusler thermoelectrics. Here, we use DFT to calculate mixing energies and relative stabilities of around 1000 binary solid solutions using restrictions of isovalent substitution and single sublattice mixing. Half of these have mixing energies suitable for forming single phase alloys, when |E_mix| < 0.05 eV/atom (kBT @ 600K). We then extend our search to higher component mixtures and the unexplored concept of multi-sublattice mixing. Continuing with DFT is too slow given the combinatorically expanding composition space, so we develop a machine learning model to help classify mixing behavior. With trends identified from the model and DFT, we hope to better guide future experiments toward improved half heusler thermoelectrics.
**1:51PM S27.00014: Low temperature thermopower in CoSbS**  
QIANHENG DU (Presenter), State Univ of NY - Stony Brook, MILINDA ABEYKOON, YU LIU, Brookhaven National Laboratory, GABRIEL KOTLIAR, Rutgers University, CEDOMIR PETROVIC, Brookhaven National Laboratory — Thermopower of FeSb2 reaches colossal values of up to -45 mV/K, however, the physical mechanism is not well understood. In order to make progress and enable predictive materials design, it is important to discover new materials with high thermoelectric parameters and with tunable physical properties. Recently, it was shown that CoSbS could be a high-temperature thermoelectric material due to several positive factors that work simultaneously to enhance its thermoelectric performance. We report giant thermopower $S = 2.5$ mV/K in CoSbS single crystals [1], a material that shows strong high-temperature thermoelectric performance when doped with Ni or Se. Changes of low temperature thermopower induced by magnetic field point to mechanism of electronic diffusion of carriers in the heavy valence band. Intrinsic magnetic susceptibility is consistent with the Kondo-Insulator-like accumulation of electronic states around the gap edges. This suggests that giant thermopower stems from temperature-dependent renormalization of the noninteracting bands and buildup of the electronic correlations on cooling.

**S27.00015: Large magnetothermopower and anomalous Nernst effect in HfTe$_5$**  
JUNFENG HU (Presenter), BeiHang University, MARCO CAPUTO, Paul Scherrer Institute, EDUARDO BONINI GUEDES, EPFL, SA TU, BeiHang University, EDOARDO MARTINO, ARNAUD MAGREZ, HELMUTH BERGER, J. HUGO DIL, EPFL, HAIMING YU, BeiHang University, JEAN-PHILIPPE ANSERMET, EPFL — Topological quantum materials have stimulated a growing attention because they reveal novel aspects of condensed matter physics and point to new opportunities in materials science, in particular for thermoelectrics. Here, we experimentally study thermoelectric effects in HfTe$_5$, which was predicted to be at the boundary between strong and weak topological insulators. The magnetic field dependence of HfTe$_5$ thermoelectric properties attests to the anomalous character of this material, supported by our angle-resolved photoemission spectroscopy (ARPES) measurements. A possible topologically non-trivial band structure is proposed to account for our observations. Our results constitute a highly constraining set of data for any model of transport based on HfTe$_5$ band structure. Furthermore, the extraordinary thermoelectric properties suggest a new paradigm for the development of thermoelectric applications based on layered transition-metal chalcogenides.

The theoretical limits of electron tomography have long been defined by the Crowther criterion, which relates 3D resolution to the number of projections acquired, and the dose fractionation theorem, which dictates total dose requirement across projections. However, these relations are invalid for aberration-corrected scanning transmission electron microscopy (STEM) where high convergence angles limit the ability to reconstruct objects larger than the depth-of-focus (c.a. 5 nm). We show overcoming the limitations of aberration-corrected STEM tomography requires collecting information beyond a traditional tilt series by acquiring a through-focal stack at every tilt. Here, information is no longer mapped to a plane in Fourier (k) space, but becomes a volumetric toroid.

Here we present a theoretical foundation for aberration-corrected electron tomography by establishing analytic descriptions for resolution, sampling, object size, and dose—with direct analogy to the Crowther criterion. The 3D structure of a contrast transfer function (CTF) for through focal tomography where every specimen tilt measures a toroid with petal-shaped cross-section. A remarkable feature of the 3D CTF is the overlapped regions that permit complete information collection—unachievable with conventional tomography. This breaks expected Crowther relationships and the maximum reconstructable object size is unlimited up to spatial frequency $k_c$. At resolutions beyond $2/k_c$, Crowther-like tradeoffs define the maximum object size (D) allowed for given 3D resolution (d).

When the tilt angle spacing becomes smaller than twice the convergence angle (2α) a continuum of information is measured and object size is unbounded at midband resolution. This occurs under typical instrument operation (> 25 mrad) and sampling (< 2° tilt). We show atomic resolution (1Å) 3D imaging is allowed across extended objects (> 20 nm) using currently available microscopes and modest specimen tilting (< 3°).
Phonons can be excited by fast electrons in two fundamentally different ways: by dipole scattering, which is similar to exciting the sample by infrared light, and by impact scattering, which bears a closer resemblance to neutron scattering. Dipole scattering occurs only in polar materials, and is characterized by small scattering angles (~0.1 mrad) and interaction distances of tens of nanometers. Impact scattering involves a direct interaction between the fast electron and an atomic nucleus, and leads to large scattering angles. Selecting the impact scattering (with an aperture in the diffraction plane) allows the vibrational signal to be imaged in materials such as h-BN with atomic resolution (0.2 nm).

The angular (momentum) distribution of vibrational scattering of fast electrons has also been explored. Attainable spatial resolution is then inversely related to the angular resolution. Optical and acoustic branches of vibrational scattering have been mapped in several materials while maintain a spatial resolution of a few nm. A change in the acoustic phonon signal has been observed at a single lattice defect in SiC, making it likely that the influence of lattice defects on thermal transport will be properly elucidated at last.

Dipole scattering provides another exciting experimental possibility: probing the sample from a small distance, by “aloof spectroscopy”. This approach limits the maximum energy that can be transferred to the sample with significant probability as 1/b, where b is the distance of the focused electron beam from the sample. In this way, vibrational properties of biological and other “fragile” materials can be probed without significant radiation damage, presently with about 5 meV energy resolution. This promises to revolutionize analysis in the electron microscope.
Heterogeneous nucleation at solid-liquid interfaces underlies a number of technologically important processes, from catalyst synthesis to fabrication of thin films, but remains poorly understood due to the dearth of techniques for quantifying nucleation energetics. In this talk, I will discuss development of a liquid cell transmission electron microscopy (LC-TEM) method for quantifying important parameters of heterogeneous nucleation, including supersaturation ratio and interfacial energy, and our efforts to utilize this approach to visualize nanoscale variations in nucleation kinetics at a solid-liquid interface. We quantify the supersaturation ratio of solute with numerical simulations of the electron beam induced chemistry during LC-TEM experiments, which enables fitting nucleation data using classical nucleation theory. Multiparticle tracking analysis applied to LC-TEM movies of nanoparticle nucleation reveals local variations in nucleation kinetics and preferential nucleation sites with nanometer scale spatial resolution. With this approach, we have demonstrated that heterogeneous nucleation of silver nanocrystals at a planar, uniform silicon nitride-water interface occurs preferentially in discrete nanoscale domains of the interface. Characterization of the solid-liquid interface with atomic force microscopy and covalent nanoparticle labeling revealed domains of surface functional groups on the interface acted as preferential nucleation sites. These results challenge previously held beliefs about nucleation on uniform interfaces, showing that nanoscale variations in surface chemistry can propagate nanoscale variations in nucleation kinetics.

*This work has been funded by ORAU (Award 17061851) and ACS PRF (61111-DNI10).
Nanocrystals often readily change structure and morphology during growth, self-assembly and applications when interacting with their environments. It imposes challenges as well as opens opportunities for the understanding and engineering of these nanostructures for practical applications. Due to the nanometer length scale and the dynamic nature of these transformations, in situ transmission electron microscopy (TEM) has become an indispensable technique for the investigation of these processes. Recently, the significant technical advances in in situ TEM have revealed many dynamic phenomena of nanocrystals with high spatial and temporal resolution that were previously unreachable. In this talk, I will show a few examples about the structural transformations of nanocrystals during growth and self-assembly in solution. Special attention has been made to the transient states, which may draw the system outside thermodynamic equilibrium. An understanding of the nanoscale dynamics and the intermediate states aid the future design of novel materials and devices.

*The project was funded by U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DE-AC02-05-CH11231 within the in situ TEM program (KC22ZH). The Intersection of Cryo, Laser Ablation, and Nanoscale Electron Imaging for Intact Battery Characterization

KATHERINE JUNGJOHANN (Presenter), Sandia National Laboratories — Characterization of intact batteries is challenging due to the great diversity of the component materials. For example, lithium anode batteries contain a stack consisting of a metal current collector, the lithium metal anode, a polymer separator saturated with lithium salts in an aprotic electrolyte, a transition metal oxide cathode, and another metal current collector. These components are generally stacked within a spring-loaded coin cell for electrochemical performance testing of the cell for repeated charge and discharge cycling. General characterization techniques require the disassembly of the stainless-steel coin cell, with analysis of each of the components individually. Here, we present a method for retaining the internal structure of the coin cell by cryogenic plunge freezing of the entire stack, followed by in-situ, athermal, ultrashort-pulse laser ablation to access the internal components in cross-section, followed by standard characterization using scanning electron microscopy and energy dispersive x-ray spectroscopy. This provides the complete structural and compositional analysis of the intact battery stack with nanometer resolution, where we have determined several failure modes of lithium metal anodes for use as rechargeable batteries.

Session S29 DSOFT DBIO GSNP DPOLY: Active Matter and Liquid Crystals in Biological Systems III

NOAH MITCHELL (Presenter), KITP, UC Santa Barbara, DILLON CISLO, University of California, Santa Barbara, SURAJ SHANKAR, Harvard, ZVONIMIR DOGIC, University of California, Santa Barbara, BORIS I SHRAIMAN, KITP, UC Santa Barbara, SEBASTIAN STREICHAN, University of California, Santa Barbara — A common theme in biology is the assembly of cells into tubes, which in turn develop into specific shapes for specific functions. In a large class of organs including the gut, a simple tube transforms into a coil of compartments. This process is particularly striking in the Drosophila melanogaster midgut -- a tube that folds and then coils into a helical configuration in only two hours. Using a combination of light-sheet microscopy, genetics, and computer vision techniques, we extract the full 3D dynamics of this organ with subcellular resolution. We present a quantitative account of the dynamics of folding and coiling of the midgut that links cellular motion and deformation to the macroscopic shape change of the organ.
