11:27AM S29.00002: Dynamical self-consistent field-theory for active nematic liquid crystals: Nematic order and spatio-temporal structure in surface colonies of rod-like bacteria  DRAKE LEE (Presenter), ROBERT WICKHAM, Univ of Guelph — We present a dynamical self-consistent field theory for interacting, self-propelled rods that we use to study fascinating time-dependent, inhomogeneous structures observed in surface colonies of twitching *Pseudomonas aeruginosa* bacteria. We apply an extremal principle to an exact dynamical functional integral derived from the microscopic, many-body dynamics of self-propelled rods moving in two-dimensions. This reduces the problem to that of a single self-propelled rod moving in response to self-consistent, mean-force and torque fields. We address the thorny problem of calculating rod-rod interactions in this mean-field approximation. For uniform systems in two-dimensions, we observe that a continuous isotropic-nematic phase transition occurs at a critical rod concentration. The value of the critical concentration is independent of the magnitude of the self-propulsive force. We discuss our preliminary simulations of inhomogeneous, dynamical structures formed in motile bacteria surface colonies.

11:39AM S29.00003: Growth and dynamics of active nematic droplets of *Myxococcus xanthus* bacteria  CASSIDY YANG (Presenter), JOSHUA SHAEVITZ, Princeton University — *Myxococcus xanthus* is a rod-shaped soil bacterium that exhibits various forms of emergent collective phenomena using only short-range interactions. When starved, they collectively bead from surfaces to form 3D droplet-like aggregates known as fruiting bodies that are comprised of hundreds of thousands of cells and are crucial for sporulation and survival. The combination of active cellular motility and local nematic interactions generates increased pressures that drive the dewetting process. Unlike passive fluids that form axisymmetric spherical cap-shaped droplets, we find that these aggregates break symmetry and are often elongated in shape with non-uniform contact angles. We characterize the growth and dynamics of these active nematic droplets and make progress towards understanding the role of motility in the formation of stable fruiting bodies through tracking sparsely labelled cells.
11:51AM S29.00004: Solid-liquid transitions of deformable active particles*  
BENJAMIN LOEWE (Presenter), Department of Physics, University of California, Santa Barbara, MICHAEL CHIANG, DAVIDE MARENUZZO, School of Physics and Astronomy, University of Edinburgh, M CRISTINA MARCHETTI, Department of Physics, University of California, Santa Barbara — Experiments have established that confluent epithelial tissues exhibit solid-liquid transitions. Although epithelial tissues usually form a cell monolayer, there are situations in which that monolayer structure breaks, such as in cell extrusion and pseudo-stratified epithelia. To describe such situations, we have developed a multi-phase field model where cells are characterized by multiple scalar fields, and interact through steric repulsion. By reducing their deformability, these cells go from being highly-deformable with no overlap to almost-circular with high overlap, which can be thought of as a way to incorporate layering between cells. Using this model we have examined the interplay of cell deformability and cell motility in controlling the solid-liquid transition of ordered lattices. We find that by reducing cell deformability the melting transition changes from continuous to discontinuous: at finite overlap the system develops an intermittent region, alternating between crystalized and liquid states. Finally, by studying the formation of defect pairs in the intermittent region, we find that they correlate with spatial fluctuations of the cell-overlap, suggesting that cell extrusion is correlated with structural defects.

12:03PM S29.00005: Uncovering the dynamic precursors to motor-driven contraction of active gels*  [Invited]  
JOSÉ ALVARADO (Presenter), University of Texas at Austin — Cells and tissues have the remarkable ability to actively generate the forces required to change their shape. This active mechanical behavior is largely mediated by the actin cytoskeleton, a crosslinked network of actin filaments that is contracted by myosin motors. Experiments and active gel theories have established that the length scale over which gel contraction occurs is governed by a balance between molecular motor activity and crosslink density. By contrast, the dynamics that govern the contractile activity of the cytoskeleton remain poorly understood. Here we investigate the microscopic dynamics of reconstituted actin–myosin networks using real-space video microscopy and Fourier-space dynamic light scattering. Light scattering reveals different regimes of microscopic dynamics. We uncover two dynamical precursors that precede macroscopic gel contraction. One is characterized by a progressive acceleration of stress-induced rearrangements, while the other consists of sudden, heterogeneous rearrangements. Our findings suggest a qualitative analogy between self-driven rupture and collapse of active gels and the delayed rupture of passive gels observed in earlier studies of colloidal gels under external loads.

12:39PM S29.00006: Microscopic simulations of a 3D active nematic composed of semiflexible polymers* MATTHEW PETERSON (Presenter), MICHAEL HAGAN, APARNA BASKARAN, Brandeis University — The field of active matter studies materials whose constituent particles can consume energy at the particle scale to produce motion. An active nematic has the additional constraint that these particles have nematic symmetry. Unlike a passive nematic, an active nematic can exhibit spontaneous creation and annihilation of topological defects. Recent work on 3D active nematics shows notable differences in the structure and dynamics of these defects compared to 2D systems—for example, defects tend to form as neutrally charged disclination loops. Here, we will use particle-based simulations to better understand the dynamical properties of dry active nematics in 3D, both in bulk and under confinement.

12:51PM S29.00007: The structure and dynamics of microtubule bundles mediated by motor proteins BEZIA LEMMA (Presenter), Physics, Harvard, LINNEA LEMMA, Physics, Brandeis, SEBASTIAN FUERTHAUER, MICHAEL JOHN SHELLEY, Flatiron Institute, ZVONIMIR DOGIC, Physics, UC Santa Barbara, DANIEL NEEDLEMAN, Harvard — Mixtures of polar microtubule (MT) filaments and force-generating motor proteins self-organize by cross-linking and sliding MTs into dense networks of polar and apolar bundles. We can measure the geometric structure of these MT-based bundles using small-angle x-ray scattering and determine the polar structure of these materials by taking advantage of their chiral crystal lattice which produces constructive interference of second harmonic signal between polar-aligned MTs. A transition in the bundles' structure to a compressed square lattice corresponds to a change in the microtubules extensile sliding dynamics. These results are useful in understanding the dynamics of filamentous active materials. The quantified geometric packing of microtubule bundles can be incorporated into a framework of highly cross-linked active gel theories.

1:03PM S29.00008: Microscopic to mesoscopic: what can modular molecular motors teach us about the nature of active stress? STEVEN REDFORD (Presenter), University of Chicago, PAUL RUIJGROK, Stanford University, JONATHAN COLEN, University of Chicago, SASHA ZEMSKY, Stanford University, VINCENZO VITELLI, University of Chicago, ZEV BRYANT, Stanford University, AARON DINNER, MARGARET GARDEL, University of Chicago — Coarse-grained hydrodynamic theories have proven invaluable to our understanding of active nematic liquid crystals. In general, these treatments succeed despite coarse graining out the microscopic details of the material, because they account for certain mesoscopic consequences of microscopic change. For example, changing the elastic constants in the nematic governing equations can account for microscopic differences in mesogen length and rigidity. However, no such treatment accounts for the microscopic nature of the stress itself. Here, we step towards rectifying this discrepancy by experimentally tuning the properties of stress-generating myosin motors in an actin based active liquid crystal. Within this system, we can begin to understand how systematically varying the microscopic properties of these motors affects the resultant active flow.
1:15PM S29.00009: 2D Patterns of Active Stress ascribe 3D Deformations of Driven Actomyosin Networks  VIKRANT YADAV (Presenter), Department of Biomedical Engineering, Yale University, TAEYOON KIM, Weldon School of Biomedical Engineering, Purdue University, ENRIQUE DE LA CRUZ, Department of Molecular Biophysics and Biochemistry, Yale University, MICHAEL MURRELL, Department of Biomedical Engineering, Yale University — During morphogenesis 2D active stresses in actomyosin networks can lead to 3D deformation of epithelial sheets. Though there is consensus on role of stress, how in-plane activity morphs epithelial sheets out of plane is not clearly understood. To understand this relation, we design an invitro actomyosin network with tunable mechanical stiffness and activity. The active stresses can be locally programmed into the 2D actomyosin sheets by photoactivation of myosin motors. We demonstrate that an interplay between mechanics of sheet and activity leads to controlled 3D deformations. We show that the extent of 3D deformation of network is proportional to activity, but varies non-monotonically with stiffness. By controlling the shape and duration of activation protocol, we can create 3D deformations of various shapes with positive, negative, or zero gaussian curvature. Through experiments and agent-based simulations we show that local inhomogeneities in stiffness of actomyosin sheet are responsible for activity-driven out of plane deformations. These results open an arena for designing bio-inspired smart active materials with programmable deformations.

1:27PM S29.00010: Confinement effects on the phase behavior of collagen-like semiflexible polymers* RUSSELL SPENCER (Presenter), BAE-YEUN HA, University of Waterloo — Semiflexible polymers often self-assemble into aligned structures with emergent mechanical and optical properties. These properties depend on the particular molecular arrangement they form. Indeed, the main structural component of bone, skin and corneas is collagen, but their mechanical and optical properties are vastly different because of the way these molecules are arranged. In this talk, we discuss the phase behavior of collagen-like semi-flexible polymers in the presence or absence of confinement, focusing on isotropic, nematic and cholesteric phases. Using self-consistent field theory, we first investigate phase boundaries and locate regions where each arrangement is stable or metastable. We then consider confinement effects by introducing planar walls. Our results suggest that the presence of planar walls reduces allowed alignment directions to being parallel with the wall, allowing the ordering direction to be uniquely set by the geometry of the experimental setup. We discuss how they can be used to tailor materials.

1:39PM S29.00011: Shape study of Spindle-like microtubule tactoids using experiment and computation
SUMON SAHU (Presenter), Syracuse University, LENA HERBST, RYAN QUINN, UMass Amherst, JENNIFER L ROSS, Syracuse University — Mitotic spindles during metaphase are a fundamentally important puzzle of biophysics at the base of the question of how a cell divides its genetic material. Mitotic spindle self-assembly is inherently non-equilibrium with a vast parameter space. Factors that play a role as a system include microtubules, molecular motors, crosslinkers, and associated proteins, whose working principles are not yet clear. Recently, we reconstituted a minimal model system for creating microtubule-based spindle-like assemblies using microtubules and the plant-derived crosslinker, MAP65. Here we have extended our work to determine the important requirements for tactoid formation by exploring different crowders or viscosity agents to show that they do not play a significant role determining the formation or shape of the tactoids. Also, using a computational approach we have shown that similar steady state tactoids can evolve from growing filaments that follow a damped Langevin equation and Hookean type crosslinkers. We explored the phase space of this organization by varying initial conditions like filament number, orientation, and length as well as crosslinker number, binding dynamics. Using these two directions we are uncovering the principles behind spindle organization using tactoid as a model.

1:51PM S29.00012: Shear-induced gelation of self-yielding active networks*
DAVID GAGNON (Presenter), CLAUDIA DESSI, Georgetown University, ZVONIMIR DOGIC, University of California Santa Barbara, DANIEL BLAIR, Georgetown University — The activity of molecular motors reconfigures biopolymer networks and modifies their mechanical properties. Designing these active gels with tunable properties analogous to the cytoskeleton is a key prerequisite for creating biomimetic systems to study cellular behavior such as division and motility. Active gels form ephemeral networks with long-range but temporary active mechanical contacts. In this talk, I will describe how microscopic dynamics modify the macroscopic mechanical properties of extensile microtubule networks. Rheological measurements reveal a non-monotonic dependence on the applied shear rate. A simple phenomenological model, which describes the network as a collection of fluid-like and solid-like elements, quantitatively explains the shear-rate-dependent viscosity in terms of locally-measured activity-induced flows. Fast, active elements remodel the network and therefore do not transmit elastic stresses, while slow, temporarily crosslinked elements behave elastically until they break and reform under shear.

Session S30 DSOFT GSNP: Origin of Rigidity and Yielding 502 - Sriram
Ramaswamy, Indian Institute of Science - Tag(s): Focus
11:15AM S30.00001: A statistical mechanical theory for the origin of rigidity in crystalline solids [Invited]  
SURAJIT SENGUPTA (Presenter), Hyderabad campus, Tata Institute of Fundamental Research (TIFR) — It is known that if local atomic rearrangements leading to exchange of neighbours are allowed, no crystalline solid can be rigid in the thermodynamic limit. The usual rigid, elastic, response to shape changes, a defining character of a crystalline solid, arises because the time needed for such rearrangements diverge as the magnitude of deformation approaches zero. Starting from these general considerations, we had shown that crystal rigidity arises as a consequence of a first order phase transition in an expanded parameter space [1]. The solid is subjected to not only elastic deformation but also to a fictitious external field, which penalises rearrangements, with the understanding that properties of real crystals are recovered by first taking the thermodynamic limit and then letting this field go to zero. Within this picture, we obtain a first order phase transition between a rigid crystal, N, and a crystal, M, where atoms rearrange to eliminate internal stress for any given deformation while maintaining crystalline order. The N-M phase boundary, in the thermodynamic limit, passes through the origin, where both field and deformation is zero. This picture gives us a fundamentally new viewpoint on the phenomenon of yielding, i.e. the loss of rigidity of a crystal when deformed beyond a limit, viz. the yield point. The phenomenon of yielding is now simply the nucleation of bubbles of the thermodynamically stable M phase within the metastable, rigid N crystal. An outcome of this theory is that the yield point is always a weak function of the rate of deformation and vanishes in the true quasistatic limit. The analytic form derived by us for the yield point as a function of the rate of deformation is able to explain experimental data over 15 orders of magnitudes in time [2]. We also discuss several details of yielding in Lennard Jones solids in 2 and 3 dimensions. 

11:51AM S30.00002: Critical Scaling of Avalanches with Strain Rate in Athermal, Disordered Solids*  
MARK ROBBINS (Presenter), Johns Hopkins University, JOEL CLEMMER, Sandia National Laboratory, KENNETH SALERNO, Army Research Laboratory — Molecular dynamics simulations are used to study critical behavior in slowly sheared disordered solids that are modeled as a bidisperse Lennard-Jones glass. The mean flow stress rises as strain rate to the power 1/β. Finite-size scaling is used to determine β and the exponent ν describing the divergence of the correlation length. The system length L varies from 55 to 1753 particle diameters in d=2 and 20 to 163 in d=3. Fluctuations in the stress and kinetic energy per particle scale as L^{-d/2}, implying that the largest avalanche scales as L^α with α < d/2. Temporal correlations are used to measure the dynamical exponent z relating the duration of an avalanche to its linear dimension. In contrast to lattice models, we find z>1, as required by causality. New scaling laws are derived for exponents describing the power law decay of the noise power spectrum with frequency and tested using finite-size scaling.

12:03PM S30.00003: Bauschinger effect in model glasses* SYLVAIN PATINET, ARMAND BARBOT, ISMAIL EL KORDE, MATTHIAS LERBINGER, DAMIEN VANDEMBROUCQ (Presenter), PMMH, ESPCI Paris, ANAÎL LEMAÎTRE, Laboratoire Navier, IFSTTAR — Once a material has experienced a significant plastic deformation, it it generally exhibits a softer stress response under reverse loading than under reloading in the original direction. The origin of this so-called Bauschinger effect, observable in various classes of materials remains poorly understood. We present here recent results obtained on two-dimensional model glasses at atomistic and mesoscopic scales. Using a numerical method developed in [1] we perform measurements of the local plastic thresholds in the steady state flow of a 2D model glasses under athermal quasi-static (AQS) deformation. Our results show evidence for the development of a forward-reverse asymmetry of the distribution of the residual strengths that can be directly connected with the Bauschinger effect [2].

12:15PM S30.00004: Shear banding transition in granular materials under uniform and boundary shear* YIQIU ZHAO (Presenter), Department of Physics & Center for Nonlinear and Complex Systems, Duke University, Durham, North Carolina 27708, USA, JONATHAN BARES, Laboratoire de Mécanique et Génie Civil, Université de Montpellier, CNRS, Montpellier, 34090, France, HU ZHENG, Department of Geotechnical Engineering, College of Civil Engineering, Tongji University, Shanghai, 200092, China, JOSHUA SOCOLAR, Department of Physics & Center for Nonlinear and Complex Systems, Duke University, Durham, North Carolina 27708, USA —

We experimentally study shear band formation in a 2D granular material subjected to quasistatic shear using Couette apparatus with a base consisting of 21 rotating concentric rings. The rings can independently be controlled to interpolate between uniform shear and boundary shear in a layer of photo-elastic disks resting on them. Previous uniform shear experiments using this setup [PhysRevLett.123.158001] showed that a steady localized shear band forms at sufficiently large strains for packing fractions \( \varphi > 0.78 \). In the present work, we study how this transition is affected by the specific choice of the relative velocities of the rings. For \( \varphi < 0.78 \), the flow roughly follows the basal velocity profile. For \( \varphi > 0.78 \), we find that the steady flow profile is insensitive to the basal velocity profile, though the times needed to reach the steady flow regime are different. For \( \varphi \sim 0.78 \), a localized shear band forms and dissolves irregularly in association with the formation and yielding of a strong force network.

* Work supported by NSF grant DMR-1809762.
12:27PM S30.00005: Strain localization and shear band formation during tensile tests of disordered floating granular monolayers*   HONGYI XIAO (Presenter), ROBERT IVANCIC, GE ZHANG, ROBERT RIGGLEMAN, ANDREA JO-WEI LIU, DOUGLAS DURIAN, University of Pennsylvania — Understanding and predicting strain localization and shear band formation during deformation of amorphous solids is an ongoing challenge. In this study, quasi-static tensile experiments were performed using a model disordered solid consisting of a monolayer of polydisperse granular spheres with capillary attractions floating on an air-oil interface. Under tensile deformation, the strain in the monolayer gradually localizes into an inclined shear band, upon which failure occurs. The ductility of the monolayer can be tuned by using different particle sizes compared to the capillary length, which sets the interaction range. Using machine learning methods, we developed a scalar field, softness, that relates the local structure around particles and particle-level dynamics. We found that softness tends to increase around particles that have rearranged. Furthermore, planes that develop into shear bands tend to have higher than average softness prior to deformation and become even softer as the shear band forms. These results reveal the relation between structure and dynamics that leads to strain localization, which could potentially apply to a broad range of amorphous solids.

12:39PM S30.00006: Yielding and mechanical failure in (amorphous) solids [Invited]   JUERGEN HORBACH (Presenter), Institute for Theoretical Physics: Soft Matter, University of Duesseldorf, Germany — Recently, a Monte Carlo simulation study [1] has shown that yielding in crystalline solids is associated with an underlying quasi-static first-order phase transition. As a consequence, in the limit of a deformation with sufficiently low strain rate, the rigid response of a crystal due to a shape change of its boundaries corresponds to a metastable state that transforms to a stable state where internal stresses are eliminated, maintaining the crystalline order. A nucleation theory based on these findings predicts the yield point as a function of strain rate and shows agreement with data from experiment and molecular dynamics (MD) simulations over 15 orders of magnitude [2]. In the case of amorphous solids (glasses), a MD simulation study, using an athermal quasi-static (aqs) deformation protocol [3], have found a sharp stress drop in the stress-strain relation that marks the transition from an elastic response of the glass to plastic flow. In Ref. [3], this stress drop has been interpreted as a non-equilibrium first-order transition, leading to the occurrence of shear localization, i.e. shear banding, after the drop. Using MD simulations of a glassforming binary Lennard-Jones (LJ) mixture under shear, we study the conditions for the occurrence of shear bands at finite temperatures [4] and discuss the response of the LJ glass to an external shear in the limit of zero strain rate. We argue that there is no quasi-static first-order transition as in the case of crystalline solids.

1:15PM S30.00007: Unjamming and reentrant jamming of dense systems in the extreme active limit* DESHPREET BEDI (Presenter), Brandeis University, PINAKI CHAUDHURI, The Institute of Mathematical Sciences, CHANDAN DASGUPTA, Indian Institute of Science, BULBUL CHAKRABORTY, Brandeis University — Simulations of dense, athermal assemblies of self-propelled soft particles with infinite persistence time display intriguing mechanical properties as a function of the strength of the active propulsion force and the packing fraction of the system. Applying active propulsion to an initial, passively-jammed state results in unjamming and subsequent flow of the system. We find that there is a threshold force above which the system remains fluid indefinitely but below which the system experiences reentrant jamming, and that this threshold force increases as the density of the system is increased. Interestingly, we find that the average coordination numbers of both fluid and re-jammed states under active propulsion are larger than those of the passively-jammed states for a given packing fraction.

We analyze various network properties over time series of such systems to illuminate the structural differences between packings formed with passive and active constituents, as well as understand the underlying mechanisms of reentrant jamming in this extreme active limit. We also investigate the effect of the magnitude of the active force on jamming behavior.

1:27PM S30.00008: States of self-stress in disordered solids SHANG ZHANG (Presenter), LEYOU ZHANG, Univ of Michigan - Ann Arbor, VISHWAS VASISHT, IIT Palakkad, India, EMANUELA DEL GADO, Georgetown University, XIAOMING MAO, Univ of Michigan - Ann Arbor — We investigate the interplay between the mechanical responses of disordered solids and their states of self-stress (SSSs), which are equilibrium stress distributions in a mechanical network with force balanced on any component. SSSs are determined by the geometry of the network (they span the null space of the network's equilibrium matrix) and govern load-bearing abilities of this network. On the other hand the mechanical load changes the geometry and feedback to the SSSs. By presenting our results on SSSs in disordered solids generated by molecular dynamics simulations as well as jamming protocols, we explore the relation between SSSs in a disordered solid and the memory of how the mechanical network is prepared, as well as how they yield under stress.
1:39PM S30.00009: Local order and structural rearrangement in two-dimensional jammed systems under oscillatory shear  ERIN TEICH (Presenter), LARRY GALLOWAY, PAULO ARRATIA, DANIELLE BASSETT, University of Pennsylvania — Amorphous, jammed systems are abundant in nature and utilized often in man-made materials. The way in which their disordered structure evolves under the application of shear stress is an area of active investigation with consequences in contexts ranging from earth science to cancer research. Identifying local structural characteristics that influence macroscopic dynamics in these materials remains an ongoing challenge, and previous work has indicated generally that particles with ordered local environments are less likely to dynamically rearrange under shear. Here, we expand on this preliminary conclusion, and quantify it concretely in a two-dimensional colloidal jammed system subject to oscillatory shear. We analyze local crystallinity and identify crystal grains in these systems. We track structural correlations over time, and find that crystalline particles that are more interior within grains are less likely to rearrange. Moreover, propensity to rearrange occurs in a hierarchy according to the degree to which particles are “protected” within the grains. In addition, structural correlations qualitatively change at strain amplitudes above yield, where elasticity and viscosity become comparable, implying a transition in structural memory in the system.

1:51PM S30.00010: Yielding and transient shear banding in soft jammed solids  VISHWAS VASISHT (Presenter), Physics, IIT Palakkad, EMANUELA DEL GADO, Georgetown University — We have designed 3D numerical simulations of a soft spheres model, with size polydispersity and in athermal conditions, to study the transient shear banding that occurs during yielding of jammed soft solids. We have analyzed the effects of different types of drag coefficients used in the simulations and compare the results obtained using Lees-Edwards periodic boundary conditions with the case in which the same model solid is confined between two walls. While load curves and velocity profiles obtained in different conditions displays some differences, the presence of a stress-overshoot and a related transient banding phenomenon are a robust feature for overdamped systems and large enough samples. We use this computational approach to investigate the microscopic origin of the flow inhomogeneities and the role played by the confinement.
2:03PM S30.00011: Strain dependent hysteresis in nanoparticle aggregate dispersions visualized to explain origin of the Payne Effect and Spectral Hole Burning in cross-linked filled rubber*  
ZACH GAULT (Presenter), ZSOLT TERDIK, PETER JAMES LU, JOERG WERNER, DAVID A WEITZ, Harvard University — Filled rubbers are composite materials containing two interpenetrating phases: crosslinked elastomers, and a ‘filler’ consisting of nanoparticle particle aggregates. The nanoparticle aggregates form a system-spanning subnetwork that reinforces the elastomer network and introduces a new energy loss mechanism at low strains of only 1-5%. This loss mechanism, known as the Payne Effect, is one of the mechanical hallmarks of filled rubbers and is a major contributor to rolling friction in tires. We create a transparent model system to study the strain dependent hysteresis of nanoparticle aggregates. With this system we can directly observe microstructural changes of filler particle aggregates during \textit{in situ} shear deformation. We complement these observations with bulk rheological tests, including spectral hole burning, to gain new insight into the microscopic structural changes that occur during cyclic deformation.

Session S31 DSOFT DBIO GSNP: Emergent Collective Dynamics in Biology: from Microbes to Organs I  
503 - Miguel Ruiz Garcia, University of Pennsylvania - Tag(s): Focus

11:15AM S31.00001: Dynamics and self-organization of active surfaces [Invited]  
FRANK JULICHER (Presenter), Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — Biological cells are active systems and exhibit complex dynamic behaviours such as cell division, cell polarity establishment and cell locomotion. Such dynamic processes emerge from the collective interplay of many molecular components far from thermodynamic equilibrium. Active molecular processes such as the force generation of molecular motors along filaments of the cytoskeleton transduce chemical free energy to generate movements and mechanical work. The cell cortex, a thin film of active material assembled below the cell membrane, plays a key role in cellular symmetry breaking processes such as cell polarity establishment and cell division. I will present a minimal model of the mechano-chemical self-organization of the cell cortex that is based on a hydrodynamic theory of curved active surfaces and that can capture the emergence of shapes. Active stresses on this surface are regulated by a diffusing molecular species. We show that coupling of the active surface to a passive bulk fluid enables spontaneous polarization and the formation of a contractile ring on the surface via mechano-chemical instabilities. We discuss the role of external fields in guiding such pattern formation. Our work reveals that key features of cellular symmetry breaking and cell division can emerge in a minimal model via general dynamic instabilities. Self-organised active surfaces provide minimal models for the generation of shape and the emergence of dynamic patterns in basic cellular processes.
**11:51AM S31.00002: Microtubule Motility on Fixed and Diffusive Motor Proteins**

FERESHTEH MEMARIAN (Presenter), University of California, Merced, JOSEPH LOPES, Physics, Brandeis University, LINDA S. HIRST, University of California, Merced — Motor proteins transporting cargo by walking on microtubules (MTs). MTs are part of the cytoskeleton and are important in cell division, giving shape to the cell membrane. Here we investigate motor-based transportation and behavior of MTs. In a MT gliding assay, motor proteins adhere to the glass while MTs glide on them. MT behavior in gliding assay experiments with high MT concentration is compared with behavior on diffusing motor proteins and at similar concentration. An interesting twist on the standard gliding assay is to attach the motors to a lipid bilayer and let them diffuse on the membrane. Using fluorescence recovery after photobleaching (FRAP), we measured motor diffusion constants. We demonstrate the MT “snuggling” effect, i.e. they spontaneously align locally while gliding on the membrane-bound motor proteins. When MTs encounter each other for gliding assays, they simply cross over in the absence of a crowding agent. Furthermore, we observe that MTs exhibit collective motion, much like bird flocking, with diffusing kinesins, which is not replicable with fixed kinesins.

*We acknowledge the National Science Foundation grant DMR-1808926, NSF-CREST: NSF-HRD-1547848. The data was collected, in part, with a confocal microscope acquired through the NSF MRI Award DMR-1625733*

**12:03PM S31.00003: Modeling of the collective motion of microtubules with mobile kinesin motors**

MADHUVANTHI ATHANI (Presenter), FERESHTEH MEMARIAN, LINDA S. HIRST, DANIEL BELLER, University of California, Merced — The microtubule gliding assay, an in-vitro technique commonly used to study motility of motor proteins, also provides an opportunity to study the collective motion of microtubules as an active fluid. Computational modeling of this system usually studies the microtubule positions assuming a spatially uniform distribution of the motor proteins, which models the experiments where the positions of motors are fixed. We explore a modified setup where kinesin motors are mobile. We use Brownian Dynamics simulations to model the collective motions of microtubules with explicit consideration of the concentration of the motors. We investigate spontaneous dynamical spatial variation in microtubule density that is introduced by allowing diffusion and transport of the motors. We also address how the mobile kinesin motors change the phase diagram as a function of kinesin and microtubule densities.

*We acknowledge support from National Science Foundation NSF grant DMR-1808926, NSF-CREST: Center for Cellular and Bio-molecular Machines at UC Merced (NSF-HRD-1547848). The data in this work was collected, in part, with a confocal microscope acquired through the National Science Foundation MRI Award Number DMR-1625733.*
12:15PM S31.00004: Multi-functional crystalline frameworks self-assembled from amphiphilic DNA nanostructures.  RYAN BRADY, University of Cambridge, NICHOLAS BROOKS, Imperial College London, PIETRO CICUTA, University of Cambridge, LORENZO DI MICHELE (Presenter), Imperial College London — Several emerging technologies require the production of porous frameworks with a precisely controlled nanoscale morphology and stimuli-responsiveness. Due to the binding selectivity of nucleic acids, their facile synthesis and functionalization, DNA nanotechnology has emerged as a prime route for the production of programmable nanoscale materials. Nonetheless, the reliable preparation of crystalline, highly porous and functional 3D DNA frameworks remains elusive.

I will discuss a novel class of amphiphilic DNA building blocks dubbed “C-stars” that combine Watson-Crick base pairing and hydrophobic forces to self-assemble into 3D single crystals [1-3]. The lattice parameter of C-star crystals can be tuned over several nanometers, resulting in programmable pore size [2]. The robustness and versatility of our approach enables the modification of the amphiphilic building blocks with responsive motifs, which can be triggered to induce, among other effects, the isothermal melting of the network [2] and the reversible entrapment and release of protein cargoes [2], making C-stars an ideal platform for the design of smart nanomedical devices.

12:27PM S31.00005: Controlled membrane remodeling by DNA origami nanorods:
Experiments targeting the design principles for membrane-based materials*  SARAH ZURAW (Presenter), ANTHONY DUPRAT DINSMORE, Univ of Mass - Amherst, MAHSA SIAVASHPOURI, Physics, Brandeis Univ, ZVONIMIR DOGIC, Physics, UC Santa Barbara, THOMAS GERLING, HENDRIK DIETZ, Physics, Technical University of Munich — Membrane remodeling facilitated by the self-assembly of proteins on the membrane is essential for cellular function. Inspired by this system, we use DNA origami nanorods to illuminate the role of particle shape and adhesion on membrane reconfiguration. We combine giant unilamellar vesicles with oppositely charged nanorods and observe them with optical and electron microscopy. The binding affinity of the nanorods to the membrane is tunable via lipid composition, which reveals three primary behaviors. For weak particle binding vesicles adhere to one another and form a stable gel. At intermediate binding strengths the gel forms but is subsequently destroyed by avid binding of the nanorods. At higher binding strengths the vesicles rupture without forming a gel. Cryo transmission electron microscopy reveals in-plane ordering of rods on the membrane. These responses are robust and repeatable providing a physical understanding of the dependence on shape, binding affinity and concentration in membrane remodeling. The design principles derived from these experiments will lead to bio-inspired membrane materials that are stimuli-responsive and reconfigurable.

12:39PM S31.00006: A coarse-grained model for lipid bilayer formation, fusion, and its hydrodynamics* YUAN-NAN YOUNG (Presenter), New Jersey Inst of Tech, SZU-PEI FU, ROLF RYHAM, Mathematics, Fordham University — In this paper a theoretical model for long-range, hydrophobic attraction between amphiphilic particles is developed to quantify the macroscopic assembly and mechanics of a lipid bilayer membrane in solvents. The non-local interactions between amphiphilic particles are obtained from the first domain variation of a hydrophobicity functional, giving rise to forces and torques (between particles) that dictate the motion of both particles and the surrounding solvent. The functional minimizer (that accounts for hydrophobicity at molecular-aqueous interfaces) is a solution to a boundary value problem of the screened Laplace equation. We reformulate the boundary value problem as a second-kind integral equation. Solving a mobility problem in Stokes flow is incorporated to obtain corresponding rigid body motion. The simulated fluid-particle systems exhibit a variety of multiscale behaviors over both time and length: Over short time scales, the numerical results show self-assembly for model lipid particles. For large system simulations, the particles form realistic configurations like micelles and bilayers. Over long time scales, the bilayer shapes emerging from the simulation appear to minimize a form of bending energy.

12:51PM S31.00007: Phase separation and domain registry in giant multilamellar vesicles prepared with biologically-relevant lipid compositions.* DYLAN STEER (Presenter), CECILIA LEAL, University of Illinois at Urbana-Champaign — Lipids are amphiphiles that commonly form bilayer sheets in the form of vesicles when exposed to excess water. Most commonly lipids have been studied in the context of the plasma membrane and other unilamellar vesicles containing a single bilayer. However, several key biological systems such as the myelin sheath, tubular myelin, or pulmonary lipid-based membranes are known to rely on correlated stacks of lipid bilayers into onion-like multi-lamellar vesicles. Lateral ordering of lipids is well-understood mostly in single-bilayer systems. Most often, the macroscopic distribution of phases is only well-characterized for giant unilamellar vesicles. Here we report on the macroscopic arrangement of phase-separated domains in multilamellar forms with biologically-relevant compositions. We will show how the registration of individual domains results in large changes in macroscopic vesicle structure and properties. Confocal fluorescence microscopy allows direct visualization of phase separation, supported by SAXS and spectrometry studies of lipid ordering.

1:03PM S31.00008: Clustering dynamics of collectively migrating malignant lymphocytes
FARNAZ GOLNARAGHI (Presenter), DAVID A. QUINT, Department of Physics, University of California, Merced, NIR SCHACHNA GOV, Department of Chemical and Biological Physics, Weizmann Institute of Science, AJAY GOPINATHAN, Department of Physics, University of California, Merced — Multi-cellular aggregates such as cell clusters and tissues exhibit collective migration with complex emergent behaviors that are very different from the behavior of the constituent single cells. We focus on the migration of clusters of malignant lymphocytes, responsible for the metastases of lymphomas. Previous work has shown that, in chemokine gradients, these clusters show a number of novel collective phases including rotations that enhance their chemotactic efficiency. Here we study the attachment and detachment dynamics that ultimately guides the formation of the clusters, which is similar to the gas-liquid transition of passive (thermal equilibrium) systems. We aim to quantify cell cluster shape dynamics and chemotactic efficiency as a function of cellular parameters such as, cell-cell adhesion and alignment, contact inhibition and chemotactic response. In particular, we show that cell-cell adhesion and alignment are important regulators of cell cluster size and shape, which in turn affects their chemotactic efficiency. Our systematic approach will allow us to identify regions of parameter space that may shed light on candidate strategies for suppressing metastatic potential.

1:15PM S31.00009: Imaging the emergence of bacterial turbulence using light-powered E. coli
YI PENG (Presenter), Chinese Academy of Sciences, Institute of Physics, ZHENGYANG LIU, XIANG CHENG, Department of Chemical Engineering and Materials Science, University of Minnesota — The collective motion of bacteria leads to intermittent jets and swarming vortices, a fluid pattern often referred as bacterial turbulence. We investigate the emergence of the collective motion of Escherichia coli suspensions and explore the kinetic pathway towards bacterial turbulence. We map the phase diagram of bacterial flows as functions of bacterial concentration, bacterial swimming speed and the number fraction of active bacteria. A simple model based on two-body hydrodynamic interaction quantitatively predicts the phase boundary of the 3D phase diagram. Furthermore, we trigger bacterial turbulence by using genetically engineered light-powered E. coli, whose swimming speeds vary with light intensity. The kinetics show one step near the phase boundary and two steps with an intermediate state far above the phase boundary. The transition rate increases as the system moves deep inside the turbulent phase. Our research reveals the microscopic origin of bacterial turbulence and provides new insights into nonequilibrium phase transitions in active matter.

1:27PM S31.00010: Activity-induced phase transitions in confined bacterial suspensions

DIPANJAN GHOSH (Presenter), ZHENGYANG LIU, XIANG CHENG, University of Minnesota — Active matter exhibits fascinating emergent ordered structures absent in passive equilibrium systems and, therefore, has been extensively studied as a model to explore nonequilibrium phase transitions. Here, we study the emergence of collective order in confined suspensions of genetically engineered *Escherichia coli*, whose propulsion speed can be controlled via intensity of light. The suspensions, when placed in a Hele-Shaw cell having a gap thickness of 10 microns, show various ordered phases unseen in their three-dimensional counterparts. Using a bright-field microscope, we image the positions and orientations of individual bacterium through different phase transitions. We identify a transition from a disordered phase to a nematic phase characterized by a long-range orientational order and the formation of lanes. The dependence of transition dynamics on the concentration and swimming speed of bacteria is explored. Moreover, we examine the rise of bacterial polar ordering within the nematic phase. Our study provides an experimental benchmark for understanding the role of complex interplays between hydrodynamic and steric interactions responsible for the emergence of ordered phases in confined active systems.

1:39PM S31.00011: Comparing sperm collective swimming with flocking transition

ALLAN ODUOR, North Carolina A&T State Univ, YISHAK BILILIGN, Duke University, DANIEL SUSSMAN, Syracuse University, SOON HON CHEONG, SUSAN S SUAREZ, Cornell University, M. LISA MANNING, Syracuse University, CHIH-KUAN TUNG (Presenter), North Carolina A&T State Univ — In viscoelastic fluid, bovine sperm are able to interact and align with their neighbors to swim in clusters. The formation of the polar liquid phase, or large flocks of sperm, however, did not solely depend on the number density and the alignment mediated by the fluid, but was strongly influenced by the initial conditions. If a pulse of flow was used to create an aligned initial condition, hundreds of sperm were able to form a flock swimming in the same direction. This suggests that the transition is first-order, with strong hysteresis. Analyzing these flocks, we found the decay of the orientation correlation function to be linear on a log-log plot. From our finite flock sizes, there was no indication that the correlation function decayed to a non-zero value, as suggested theoretically for the polar liquid phase. Further, the effective exponents of the correlation function were found to vary for the same flock at different time points, which made us wonder about some of the premises of continuum theoretical models. From tracking individually swimming sperm, we found that the rotational noise is an exponential decay, while the speed follows a Gamma distribution. Neither is commonly used in theoretical models.

1:51PM S31.00012: Correlations in suspensions of microswimmers  ALEXANDER MOROZOV  
(Presenter), Univ of Edinburgh — Recent years witnessed a significant interest in physical properties of self-propelled particles that can extract energy from the environment and convert it into directed motion. One of the most striking consequences of this ability is the appearance of collective motion in self-propelled particles suspended in a fluid observed in recent experiments and simulations: at low densities particles move around in an uncorrelated fashion, while at higher densities they organise into jets and vortices comprising many individual swimmers.

Here, we present a novel kinetic theory that predicts the existence of strong correlations even below the transition to collective motion. We calculate the velocity-velocity correlation functions and the effective diffusivity of passive tracers, and reveal their non-trivial density and velocity dependence. The theory is in quantitative agreement with our recent Lattice-Boltzmann simulations (J. Stenhammar et al., Phys. Rev. Lett. 119, 028005 (2017), D. Bardfalvy et al., Soft Matter 15, 7747 (2019)), and captures the asymmetry between pusher and puller swimmers below the transition to collective motion. We discuss the consequences of these correlations for the nature of the transition to collective motion.

2:03PM S31.00013: Collective migration of bacteria in disordered media  TAPOMOY BHATTACHARJEE (Presenter), DANIEL AMCHIN, FELIX S KRATZ, JENNA A OTT, SUJIT DATTA, Princeton University — While bacterial motility is well-studied on flat surfaces or in unconfined liquid media, most bacteria are found in disordered porous media, such as biological gels and tissues, soils, sediments, and subsurface formations. Understanding how porous confinement alters bacterial motility is therefore critical to modeling the progression of infections, applying beneficial bacteria for drug delivery, and bioremediation. We recently discovered that isolated cells of *E. coli* move through disordered media via intermittent hopping and trapping, reminiscent of thermally-activated transport. Here, we use direct visualization and 3D bioprinting to investigate how this behavior manifests in multicellular communities in porous media. We find that cellular chemotaxis drives collective migration—and that this process depends sensitively on pore-scale confinement, colony density, and differential metabolism of nutrients. Our results thus expand the current understanding of collective migration, which focuses on populations in homogeneous environments, to the case of bacteria in disordered porous media.

11:15AM S32.00001: A Novel Technique for the Characterization of Freestanding Ultrathin Film Mechanics*  
LUKE GALUSKA (Presenter), SONG ZHANG, School of Polymer Science and Engineering, Univ of Southern Mississippi, ERIC MUCKLEY, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, DAKOTA EHLENBERG, School of Polymer Science and Engineering, Univ of Southern Mississippi, ILIA IVANOV, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, XIAODAN GU, School of Polymer Science and Engineering, Univ of Southern Mississippi — The contribution of nanoconfinement to ultrathin film mechanics has challenged the field for many years. Our previous work utilized a pseudo-free-standing tensile test which relies on water as a support and has successfully been employed throughout many systems. However, the effect of water on the mechanics of nanoconfined films is unclear. Here, we developed a novel truly free-standing (in air) tensile platform to study sub-100 nm thick films. Tensile characterization of stiff glassy polymer such as polystyrene and soft semicrystalline poly(3-hexylthiophene-2,5-diyl) films has been achieved at sub-80 nm thicknesses. We report negligible differences between the moduli obtained from on water and in air measurements, leading us to conclude that water plays an insignificant role despite other factors such as confinement, which is evident in the reduced modulus of PS with decreasing thickness. Our current work is to utilize this newly developed free-standing tensile platform to provide in-situ characterization of ultrathin film deformation mechanics across multiple size scales.

*NSF Award # DGE – 1449999

11:27AM S32.00002: Chains entanglements and flow within the mobile surface layers of glassy polymers*  
BAIO ZUO (Presenter), ZHIWEI HAO, XINPING WANG, Department of Chemistry, Zhejiang Sci-Tech University, RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — The existence of a mobile surface layer of several nanometers thick has been established as critical to dynamical deviations in nanostructured polymers. Several questions arise, such as i) How are segments in this region entangled? and ii) How do polymers in this region flow especially when polymer size is larger than thickness of the surface layer? Herein, we design a creep experiment to investigate rheology in this layer. In this experiment, a micro-droplet was placed atop polymer surfaces to induce a nanometer deformation, called a wetting ridge, by the vertical component of surface tension of the droplet. The time evolution of the height of the wetting ridge, reflecting polymer relaxation at different length scales, was monitored. Results show that segments in the very thin surface layer are readily entangled. The terminal relaxation time was scaled by molecular weight ($M_w$) with a power law of 1.5. We proposed a 2D entanglement and limited flow to explain the phenomena. Within the surface layer, segments were entangled in direction parallel to the surface, but free of entanglements in film thickness direction. Flow of polymer in surface layer was constrained by the glassy underlying bulk, resulting in lower $M_w$ dependence.

**11:39AM S32.00003: Entanglement Effect on Mechanical Properties of Ultrathin Glassy Polymer Films**

CYNTHIA BUKOWSKI (Presenter), ALFRED J CROSBY, Univ of Mass - Amherst —

Entanglement density is known to influence the large strain and failure responses of glassy polymer films. For ultrathin films, recent extension measurements show that failure strength decreases severely as film thickness decreases below the average size of an unconfined chain. The hypothesized cause for this effect is the loss of interchain entanglements as polymers statistically interact with themselves more than neighbors when confined. To provide more insight into how entanglements control the failure mechanisms of glassy polymers, especially in ultrathin films, we introduce polymer chains shorter than the entanglement molecular weight to control the entanglement density by effectively swelling the entanglement network. Specifically, we blend short (10.5 kDa or 61.8 kDa) and long (151.5 kDa) polystyrene chains and measure the changes in mechanical properties using The Uniaxial Tensile Tester for UltraThin films (TUTTUT). For 100 nm films, we observe a decrease in yield stress and work to failure with increasing diluent concentration that is diluent length dependent. These results establish the framework of how entanglement density affects mechanical properties of ultrathin polymer films.

**11:51AM S32.00004: Effect of Confinement on Modulus and Fracture of Thin Conjugated Polymer Films For Organic Electronics**

XIAODAN GU (Presenter), Univ of Southern Mississippi, DONGSHAN ZHOU, Nanjing University, SIMON RONDEAU-GAGNÉ, University of Windsor —

In this talk, I will discuss our research on understanding the glass transition phenomena and thin-film mechanical property for those rigid conjugated polymers. This class polymers are electronically active and find great potential in future solution-processed electronics. Since those polymers are predominantly used in thin-film devices (e.g. <100nm), thus confinement effect plays a key role in those thin films. I will discuss our research journey using a thin-film tensile tester to study those novel class of polymers down to 20nm supported on the water surface. Specifically, we found the confinement effect plays a critical role in the modulus and fracture behavior of polymeric materials. I will also discuss the effect of the backbone rigidity on the thin film mechanical property studied by neutron scattering.

12:27PM S32.00005: Mechanical Relaxations of Free-standing Polymer Films*  
HAILIN YUAN (Presenter), OPHELIA TSUI, Hong Kong University of Science and Technology — Young’s modulus of free-standing polystyrene films with thicknesses, \( h \), from 48 nm to 100 μm was studied as a function of temperature and relaxation time. For the \( h \leq 115 \) nm or \( h \geq \sim 3.5 \) mm films, data could be fit to a single Kohlrausch-Williams-Watts (KWW) function, with the former showing relaxation times shorter than the bulk (denoted \( t_s \)) and the latter similar to the bulk (\( t_{\text{bulk}} \)). For the films with thicknesses in between, data could be described by a double KWW function with relaxation times of \( t_s \) and \( t_{\text{bulk}} \), respectively. We found that \( t_s \) is similar to the fast relaxation time observed in previous optical anisotropy relaxation experiment. However, the apparent thickness found here of the film portion where fast relaxations take place is \( \sim 100 \) times larger. Our result shows that mechanical relaxations are much more susceptible to perturbations by the free surface than molecular relaxations are. Confinement effects may have far bigger impact on the properties of polymers than previously contemplated.

*We acknowledge supports of the Research Grant Council of Hong Kong through the Projects 16303418 and 16301919.

12:39PM S32.00006: Effects of Nanoparticles Motion on a Bound Layer in Strongly Attractive Polymer Nanocomposites  
HAMED EMAMY (Presenter), Columbia Univ, FRANCIS STARR, Physics Department, Wesleyan University, SANAT KUMAR, Columbia Univ — The attractive interactions between polymers and nanoparticles (NPs) in polymer composites can lead to the formation of a "bound" layer around the nanoparticle (NP) with very slow dynamics. Previous simulations show that this bound layer has a significantly larger relaxation time compared to polymer matrix. However, these studies have been done for a NP that is fixed at its initial position and does not move during simulation (infinitely massive NP). Here, we perform molecular dynamics simulations for polymer composites, where the NP can move in the polymer matrix. We explore the degree to which the NP diffusion affects nanocomposite dynamics. To explain the effects of NP diffusion, we study the dynamical properties of polymer composites, e.g., scattering function, relaxation time. We find that the motion of the NP reduces the bound layer relaxation time significantly. We show that the bound layer diffuses with NPs, and that results in shorter relaxation time. We also study the effects of NP motion on the glass transition temperature.
Annealing a polymer system at temperatures above its $T_g$ can induce the growth of an irreversibly adsorbed layer at the polymer-substrate interface which can impact the system's bulk properties. Several efforts have been made to explore the implications of irreversibly adsorbed layer growth in thin films, however consideration has not yet been given to polymer nanocomposites, whose high processing temperatures and significant interfacial area may especially favor irreversible adsorption. Herein, we describe the local effects of irreversible adsorption in polystyrene-silica nanocomposites. By combining direct, local techniques such as fluorescence spectroscopy and TEM imaging, we elucidate the relationship between irreversibly adsorbed layer thickness and the corresponding local $T_g$ perturbances, as well as how these parameters evolve with annealing time. The insights provided by this characterization of local interfacial dynamics may inform future endeavors towards the engineering of new and improved polymer nanocomposite materials.

*This material is based upon work supported by the NSF GRFP under Grant No. DCE-1656466. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the NSF.*

How the conformations and dynamics of surface bound chains influence neighboring chains are fundamental to adhesion and reinforcement mechanisms in polymer films and nanocomposites. Efforts to investigate adsorbed chains in melt films rely on solvent washing conditions to expose such near-surface chains. However, we find that the adsorbed layer thickness remaining from this protocol is entirely determined by the solvent washing conditions used, with only the time in solution needed to reach this final adsorbed amount affected by prior treatment of the melt film. These observations are consistent with surface diffusion and exchange measurements of adsorbed chains in solution demonstrating that surface bound chains are highly mobile, even for the case of strong adsorption. By directly comparing solution grown adsorbed layers with those formed by solvent washing melt films, we leverage the wealth of information on polymer adsorption in solution developed over several decades to inform us about polymer conformations in the melt. We investigate how these different populations of surface bound chains alter local glass transition properties of neighboring homopolymer chains, and compare them to end-tethered grafted chains.
**1:15PM S32.00009: Property enhancements and dynamic gradients in P2VP-silica nanocomposites**  
TONG WEI (Presenter), JOHN TORKELSON, Northwestern University — A fluorescence technique is used to probe the glass transition temperature ($T_g$) associated with α-relaxation dynamics at different locations in poly(2-vinylpyridine) (P2VP)-silica nanocomposites. The interfacial layer $T_g$ ($T_{g,\text{inter}}$) is determined using pyrene dye molecule covalently labeled to filler surface. The average matrix $T_g$ ($T_{g,\text{matrix}}$) is determined using evenly dispersed, free pyrene dye in the polymer matrix. For the first time, we decouple the interfacial dynamics from the rest of polymer matrix in nanocomposites. In 2.1 kg/mol P2VP nanocomposites containing 0.5 vol% nanoparticle, $T_{g,\text{inter}}$ is 21 °C higher than in neat P2VP $T_g$, indicating that the α-relaxation dynamics are significantly slowed down due to H-bonding between P2VP and silanol groups on the filler surface. The $T_{g,\text{matrix}}$ is only 3 °C higher than neat P2VP due to the low fraction of interfacial regimes at low filler loading. Both $T_{g,\text{inter}}$ and $T_{g,\text{matrix}}$ increase with increasing filler loading. At same filler dispersion and filler loading, 110 kg/mol P2VP nanocomposites exhibit a much reduced $T_g$ enhancement relative to 2.1 kg/mol P2VP nanocomposites. We hypothesize that 2.1 kg/mol P2VP chains can orderly pack and align at the filler surface, leading to higher H-bonding density and stronger $T_g$ enhancement.

**1:27PM S32.00010: Polymer conformations and dynamics in polymer nanoparticle composite with high nanoparticle loading**  
EMILY LIN (Presenter), ROBERT RIGGLEMAN, University of Pennsylvania — Polymer nanoparticle composites (PNC) with high loadings of nanoparticles (>50%) are an interesting class of material for a wide range of applications. Recent experiments have shown that these highly loaded PNC exhibit simultaneously improved strength and stiffness without compromising, sometimes even improving, the toughness compared to neat systems. These PNCs also show a large increase in the polymer glass transition temperature and viscosity, suggesting a slowdown in both segmental and chain-scale dynamics due to confinement. The goal of this work is to understand how confining polymers to the cavities of a random close packed nanoparticle solid affects polymer conformations and dynamics from the segmental to the chain scale. We performed molecular dynamics simulation of both entangled and unentangled coarse-grained polymer equilibrated in the voids of a nanoparticle packing. We varied the polymer fill fraction and compared the dynamics of the polymer in PNC to the pure polymer system, finding that the changes in the dynamics depend on the number of nanoparticles in contact with a polymer. Finally, we deformed the PNC uniaxially to track rearrangement behavior of nanoparticles and polymer segments to provide a molecular view of the toughening mechanism in these materials.
1:39PM S32.00011: Direct probing of the fracture behavior for pseudo-free-standing polymeric ultra-thin films*  SONG ZHANG (Presenter), Polymer Science and Engineering, Univ of Southern Mississippi, MASATO KOIZUMI, LIHUAN JIN, MECHANICAL AND AEROSPACE ENGINEERING, California State University, Los Angeles, XIAODAN GU, Polymer Science and Engineering, Univ of Southern Mississippi — The understanding of fracture mechanics of free-standing ultra-thin polymeric films is crucial for modern technology that heavily relies on thin films, including the semiconductor industry and coating. Past decades have witnessed improved understanding of several physical properties of the ultra-thin film, however, their fracture behavior is rarely explored due to limited testing methods on hard-to-handle samples. In this work, we reported a new testing methodology that not only can directly measure the fracture energy of ultra-thin films floated on the water, but also visualize the local stress field during the deformation through the wrinkling pattern of the film. Using polystyrene as a model system, we demonstrated for the first time the existence of a critical molecular weight/thickness, below which the fracture energy increases consistently, and above which levels up. Later, this method was applied to other polymeric thin films for further demonstration of its broad applicability to both stiff and soft materials.

1:51PM S32.00012: Glassy, Conjugated Polymer Nanoparticles Formed by a Semiflexible Polymer: A Molecular Dynamic Study*  SUPUN SAMINDRA KAMKANAM MOHOTTALALAGE (Presenter), Department of Chemistry, Clemson University, Clemson, SC, United States, 29634, GARY GREST, Sandia National Laboratories, Albuquerque, NM, United States, 87123, DVORA PERAHIA, Department of Chemistry/Department of Physics, Clemson University, Clemson, SC, United States, 29634 — Conjugated polymers confined into nano dimensions form long-lived luminescent particles (polydots), with potential as bio markers, where the chain dynamics and conformation determine the photophysics in the confined state. Here we probe the structure and dynamics of semiflexible polymers MEH-PPV confined to their nano dimension, using fully atomistic molecular dynamics (MD) simulations as the temperature is varied. We find that the polymer swells below $T_g$ and $R_g$ increases linearly with temperature. A transition takes place at 605-610 K. This transition is attributed to transformation of glass-like particle to a more dynamic state. The auto correlation function of the backbones of the confined chains, were calculated and analyzed in terms of KWW stretched exponentials, yielding correlation times of $\sim$3.5 ms. This semiflexible polymer remains in its confined state over a broad temperature range. In comparison with polydots formed by rigid polymers, backbone flexibility results in a tighter packing and formation of internal correlations of the side chains.

2:03PM S32.00013: On the stability of initiators for surface-initiated controlled radical polymerization  CHRISTIAN PESTER (Presenter), Pennsylvania State University — The covalent attachment of polymers has emerged as a powerful strategy for the preparation of multifunctional surfaces. Patterned, surface-grafted polymer brushes provide spatial control over a variety of physical properties and allow for fabrication of ‘intelligent’ substrates which selectively adapt to their environment. However, the route towards such patterned polymer brush surfaces often remains challenging, creating a demand for more efficient and less complicated fabrication strategies. Here, we describe recent advances in our group in reduction photolithography to produce topographically and chemically pattern polymer brushes by using light-mediated controlled radical polymerization. We highlight recent work on expanding our technique towards photoinduced electron/energy transfer (PET) reversible addition–fragmentation chain transfer (RAFT) polymerization. We present findings regarding the long-term stability of the surface-grafted initiating sites and discuss reproducibility of SI-PET-RAFT and other polymerization techniques.

11:15AM S33.00001: Bubble Nucleation in Polymer-CO₂ Mixtures* [Invited] ZHEN-GANG WANG (Presenter), Division of Chemistry and Chemical Engineering, California Institute of Technology — Bubble nucleation is a critical first step in the foaming process, but its theoretical understanding is still rather incomplete. While the classical nucleation theory (CNT) offers a qualitative picture of the process, more advanced theories are needed to better describe molecular details. Here, we combine the string method with the state-of-the-art density functional theory (DFT) to investigate bubble nucleation in CO₂-supersaturated polymers. Nucleation in our study is initiated by saturating the polymer liquid with high pressure CO₂ gas and subsequently reducing the pressure to ambient condition. The string method is used to find the minimum free energy path on the free energy landscape that connects the metastable CO₂-supersaturated state with a well-developed bubble. The nucleation pathway, i.e., the evolution of the density profiles in the formation of the nuclei, as well as the nucleation barrier, are obtained as a function of the temperature and the initial pressure. We present an incipient-phase analysis which allows identification of phases that can form from the metastable CO₂-supersaturated parent phase. As result of an underlying metastable transition from an incipient CO₂-rich-vapor phase to an incipient CO₂-rich-liquid phase, there can be two kinds of nucleating bubbles, a liquid-like bubble and a vapor-like bubble, which can differ substantially in their nucleation barrier. We apply our theory to three common polymers: polystyrene, polymethylmethacrylate, and a commercial polyol. We also examine the effects of adding a third volatile component to the polymer-CO₂ mixture.

*The Dow Chemical Company is acknowledged for funding.
11:51AM S33.00002: Equilibrium coexistence between polyol, CO2, and a physical blowing agent at elevated pressures*  
HUlkUAN CHAO (Presenter), Dow Chemical Company Foundation, ANDREW YLITALO, JULIE KORNFIELD, California Institute of Technology, VALERIY GINZBURG, WEIJUN ZHOU, THOMAS FITZGIBBONS, Dow Chemical Company Foundation, ZHEN-GANG WANG, California Institute of Technology — Rigid polyurethane (PU) foams are widely used as thermal and acoustic insulation materials. The insulation properties depend critically on the size and distribution of cells from nucleation and growth of small-molecule bubbles during foaming. To achieve desired cell structures, the foaming recipe needs to be formulated. Besides reactants (polyols, isocyanates and water), the recipe typically contains physical blowing agents (PBAs) to increase the nucleation rate of bubbles. However, due to complex chemical and physical reactions, how PBAs affect the bubble formation are not understood. As a fist step to approach the issue, we develop a liquid-state theory of a ternary foaming system (PBA, CO2 and polyols) and study the phase behaviors of the system at manufacture-relevant conditions. Our results show a transition in the system from a liquid-vapor into a liquid-liquid coexistence via an intermediate triple-phase coexistence with increasing amount of PBA. When the polyol-rich phase in the coexistence is destabilized (e.g. upon rapid decompression), we find the incipient phase that metastably coexists with the polyol-rich phase changes its nature from a vapor-like to a liquid-like PBA/CO2-rich phase with increasing weight fraction PAB in the polyol-rich phase.

12:03PM S33.00003: Microfluidic Approach to Study Bubble Nucleation in Polymeric Foams for the Development of DFT-based Models  
ANDREW YLITALO (Presenter), HUIKUAN CHAO, Caltech, THOMAS FITZGIBBONS, VALERIY GINZBURG, WEIJUN ZHOU, Dow Chemical, ZHEN-GANG WANG, JULIE KORNFIELD, Caltech — Bubble nucleation sets the structural foundation of a foam, yet remains poorly understood. Single-component classical nucleation theory predicts erroneous nucleation barriers, particularly when applied to foaming of multicomponent liquids used to produce lightweight, functional materials. Multicomponent theories are limited by lack of (1) thermodynamic and (2) nucleation rate data for validation. For the first, we used gravimetry-axisymmetric drop shape analysis (G-ADSA) in the Di Maio lab (U Naples) to measure equilibrium compositions and interfacial tension of polymer-CO2 mixtures up to 8MPa, which validated PC-SAFT and DFT models from the Wang group (Caltech) that enable string method calculations of the nucleation barrier. For the second, we developed a microfluidic hydrodynamic-focusing apparatus that linearly decreases pressure from 10MPa to as low as 0.1MPa within 100ms while observing bubble nucleation and growth. The instrument, designed for use with optical microscopy, X-ray scattering, thermography and FTIR, will be described. This approach to validating multicomponent theories of bubble nucleation can be extended to study complex effects of additives on foaming and enable design of foam composition and processing conditions to achieve desired material properties.
12:15PM S33.00004: An Off-Lattice Sanchez-Lacombe Related Equation of State Extensible to Polymeric Foams*  

HASSAN ALAM (Presenter), Physics and Astronomy, University of Waterloo, CHUL B. PARK, Mechanical & Industrial Engineering, University of Toronto, RUSSELL B THOMPSON, Physics and Astronomy, University of Waterloo — We have extended an off-lattice model of the Sanchez-Lacombe equation of state for pure polymeric systems by including internal degrees of freedom to polymer chains. The extension allows us to predict glass transition temperatures of pure polymeric systems at different pressures. To find unknown parameters of the model only two experimental values are required, namely, the glass transition temperature of the pure polymer at atmospheric pressure and the change in isobaric heat capacity of the pure polymer across the glass transition. The model is also successful in predicting the behavior of isobaric heat capacities of polymer melts as a function of temperature. The model shows that the Gibbs-DiMarzio criterion for the glass transition is invalid for the Sanchez-Lacombe equation of state. Thus, we proposed a new criterion for glass transition temperature calculations. Predictions of the model are compared with a lattice-based version of the Sanchez-Lacombe equation of state for several pure polymeric systems. The proposed model can be extended to multi-component polymeric systems and thus to retrograde vitrification in polymeric foams.

12:27PM S33.00005: Experimental Test of the Border-Crossing Model of Diffusive Coarsening in Wet Foams*  

DOUGLAS DURIAN (Presenter), ANTHONY CHIECO, University of Pennsylvania — For dry foams, the transport of gas from small high-pressure bubbles to large low-pressure bubbles is dominated by diffusion across the thin soap films separating neighboring bubbles. For wetter foams, the film areas become smaller as the Plateau borders and vertices inflate with liquid. So-called \"border-blocking\" models can explain some features of wet-foam coarsening based on the presumption that the inflated borders totally block the gas flux; however, this approximation dramatically fails in the wet/unjamming limit where the bubbles become close-packed spheres. Recently we accounted for the ever-present border-crossing flux by a new length scale defined by the average gradient of gas concentration inside the borders that is proportional to the geometric average of film and border thicknesses. We also showed how the well-known $dA/dt=K(n−6)$ von Neumann law is modified by the appearance of terms that depend on bubble size and bubble shape as well as the concentration gradient length scale. Here we extend this theory and describe on-going experiments to test it by measurement of area changes for six-sided bubbles, which would neither grow nor shrink if perfectly dry. Indeed we find six-sided bubbles that change area with time, and we find that they do so in good accord with our prediction based on their size and shape and degree of wetness.

*NASA Grant 80NSSC19K0599
1:03PM S33.00006: Experimentally Testing a Generalized Coarsening Model for Quasi-Two-Dimensional Wet Foams* ANTHONY CHIECO (Presenter), DOUGLAS DURIAN, University of Pennsylvania — In dry foams, a bubble's area grows or shrinks according only to its number of sides, \( \frac{dA}{dt} = K_0(n-6) \). While exact for a purely two dimensional foam with no liquid content this von Neumann law is increasingly violated for wetter quasi-2d foams. These latter foams have Plateau borders that are inflated with liquid and extend into the z-plane. Accounting for the size of the Plateau borders and gas that diffuses through both the Plateau Borders and thin films separating two bubbles, we modify von Neumann's law to a no-fit general coarsening equation where bubble size and shape now matter. To test this experimentally, we measure the growth rate of individual bubbles in quasi-2d foams of variable wetness confined between parallel plates. Interestingly, some 6-sided bubbles grow and others shrink - in direct violation of the usual von Neumann law but in agreement with our generalized version. We will show the coarsening of 6-sided bubbles and other violations of von Neumann's law for n-sided bubbles are driven predominantly by the bubble shape which is a key ingredient in our model.

*We would like to thank NASA Grant 80NSSC19K0599 for funding this research.

1:15PM S33.00007: Intelligent Design of Cellular Solids for Impact Mitigation MARCOS REYES-MARTINEZ (Presenter), National Institute of Standards and Technology, MENG SHEN, University of Chicago, EDWIN P CHAN, CHRISTOPHER SOLES, National Institute of Standards and Technology, NIDHI PASHINE, SIDNEY ROBERT NAGEL, HEINRICHA M. JAEGER, JUAN DE PABLO, University of Chicago — Disordered networks, comprised of random arrangements of bonds and nodes, offer degrees of mechanical tunability not accessible to periodic systems. These networks have emerged as the basis of a new class of metamaterials allowing for precise control over density (\( \rho \)), bulk (\( K \)), shear (\( \mu \)) modulus, and Poisson's ratio (\( \nu \)). Here, we demonstrate bond pruning and global node position optimization as effective routes for designing cellular materials with isotropic auxetic properties, and for independently controlling \( \mu \) and \( K \). We show how bond pruning controls \( \rho \), \( \mu \) and \( K \). Node position optimization allows for the tunability of \( \nu \) from \(-0.3\) to \(-0.5\), control over two orders of magnitude of \( K \) with almost no change to \( \mu \) and minimal change in foam density. We use multi-resin 3D-printing to extract the 2D and 3D disordered networks out of the simulation box and systematically study how the tunability of elastic constants affect their dynamic deformation behavior. We explore how node bending stiffness can affect global elastic properties and quantify how it affects the range of elastic tunability. This study demonstrates the power of top-down design of disordered network metamaterials and how such level of tunability can affect the next generation of materials for impact mitigation.

1:27PM S33.00008: Heat transfer of low-density styrenic foam ANSON WONG (Presenter), MARK RICKARD, Safety & Construction, DuPont — The heat transfer characteristics of extruded styrenic foams with various carbonaceous additives were reported. The effects of cellular morphology and type of additives on the thermal conductivity of the foams were analyzed with a predictive model. The total thermal conductivity as well as hemispherical reflectance and transmittance were measured. Comparison between the theoretical and experimental results was made to assess the performance of the predictive model.
Human Comfort and the Physics of Foams

KAORU AOU (Presenter), WENBO XU, LAURA DIETSCHE, DOUGLAS BRUNE, MANOJ THOTA, Dow Chemical Co — Human Comfort and the Physics of Foams is a current topic in the bedding and furniture industry. Polyurethane (PU) foams are thermally insulating, cushioning materials. Flexible open cell PU foams are used in padding materials for furnitures and bed mattresses, where insulation can be useful, but depending on the local climate, insulation can lead to localized heating that can lead to discomfort. In order to maintain comfort, two factors are needed: (1) preventing overheating, and (2) good cushioning (absence of pressure points). Thermal comfort simulation was conducted using the ASHRAE Human Comfort model, coupled with a multiphysics model taking into account natural convection of air, thermal conduction and mass (water vapor) diffusion phenomena. It is demonstrated that effective diffusivity of water vapor through foam is the critical parameter that determines whether the human body is able to regulate its skin temperature. Pressure relief measurements and simulations were also conducted, using an indenter held at a constant temperature of 23 and 34 °C. The relative insensitivity of the contact pressure to indenter temperature is reported.

*Authors thank support from The Dow Chemical Company for the research.

Foam formation in microfluidic EDGE devices: tuning the bubble size

BOXIN DENG, KARIN SCHROËN, JOLET DE RUITER (Presenter), Agrotechnology and Food Sciences, Wageningen University — The stability and flow properties of foams crucially depend on the bubble size and its distribution. Microfluidic devices are capable of producing extremely monodisperse yet small foam bubbles at low energetic cost. Upscaling towards an array of parallelized pores allows to increase the throughput of the device, but increases complexity of bubble formation due to possible pore-pore and bubble-bubble interactions. We use so-called partitioned-EDGE microfluidic chips with which we can produce bubbles in an array of rectangular pores. Pore height is minimized to (sub)micron size in order to produce bubbles down to 20 micron in diameter. The size of a single bubble formed at a pore is independent of pressure for the lower range of applied gas pressures (spontaneous formation mechanism), followed by bubble size increase (blow-up) at higher gas pressures. Here we discuss the final bubble size obtained for high gas flow rate through an array of parallel pores, which induces additional bubble-bubble interactions that can be modified by shear flow rate and stabilizer (protein) concentration. Surprisingly, monodisperse foams with a coefficient of variation around 10% can be produced, irrespective of these additional complexities.
2:03PM S33.00011: Phoamtonic designs yield sizeable 3D photonic band gaps*  MICHAEL ANDREAS KLATT (Presenter), PAUL J STEINHARDT, SALVATORE TORQUATO, Princeton University — We show that it is possible to construct foam-based heterostructures with complete photonic band gaps. Three-dimensional foams are promising candidates for the self-organization of large photonic networks with combinations of physical characteristics that may be useful for applications. The largest band gap found is based on 3D Weaire-Phelan foam, a structure that was originally introduced as a solution to the Kelvin problem of finding the 3D tessellation comprised of equal-volume cells that has the least surface area. The photonic band gap has a maximal size of 16.9% (at a volume fraction of 21.6% for a dielectric contrast of 13) and a high degree of isotropy, properties that are advantageous in designing photonic waveguides and circuits. We also present results for two other foam-based heterostructures based on Kelvin and C15 foams that have somewhat smaller but still significant band gaps.

Session S34 DPOLY FIAP DMP: Organic Electronics I: Microstructure and Mechanical Property 506 - Stephanie Lee, Stevens Inst of Tech - Tag(s): Focus

11:15AM S34.00001: Advances in Non-Fullerene Organic Photovoltaics* [Invited]  SAMSON JENEKHE (Presenter), University of Washington — Recent progress in molecular engineering of organic small-molecule and polymer semiconductors and in engineering of the blend active layer morphology has pushed the state-of-the-art organic photovoltaic (OPV) device efficiency above 15%, narrowing the gap with theoretical values. In this talk I will discuss our work in both of the main classes of OPV devices: (i) all-polymer solar cells (all-PSCs) composed of both donor and acceptor polymers; and (ii) blends of a small-molecule non-fullerene acceptor (NFA) with a donor polymer. We have found that binary blends of new random copolymer acceptors with a known donor polymer can spontaneously self-organize into optimal bulk heterojunction morphologies without the use of any solution processing additives; thereby, enabling highly efficient all-PSCs with low energy loss and near unity internal quantum efficiency. Another example is our finding of the different roles of charge transport, blend morphology, and blend photophysics in dictating the photovoltaic properties of NFA/polymer blends, highlighting the importance of fused-ring NFAs in suppressing geminate and bimolecular recombination and enabling improved photocurrent and fill factor.

*Work supported by the National Science Foundation (NSF) and the Office of Naval Research (ONR).
11:51AM S34.00002: Revealing the Microstructure of the Active Layer of Ternary Organic Solar Cells using Energy-Filtered TEM  ISMAIL ALPEREN AYHAN (Presenter), ENRIQUE D GOMEZ, Chemical Engineering, The Pennsylvania State University — Fullerene-free ternary organic solar cells have emerged as a promising class of devices with higher efficiencies when compared with solar cells that encompass binary active layers. Compared with traditional fullerene acceptors, non-fullerene acceptors have stronger absorption in the visible and near-infrared, which helps to generate high photocurrent for solar cells. Nevertheless, controlling phase separation and domain size in the photoactive layer morphology is crucial to enable efficient charge separation, transport and collection. Here, we demonstrate high-efficiency devices by combining the organic semiconductors with complementary light absorption, using PTB7-Th as donor, and IDIC, COi8DFIC, Eh-IDTBR, and O-IDTBR as acceptors. The combination of Grazing-Incidence Wide-Angle X-ray Scattering (GIWAXS), Energy-Filtered Transmission Electron Microscopy (EFTEM), Resonant Soft X-ray Scattering (RSoXS) reveals the impact of crystallization on the mesoscale morphology. We show that ternary systems composed of compatible nonfullerene acceptors exhibit fibril-like nanostructures in the active layer, leading to devices with efficiencies in excess of 10%. The morphology suggests that compatibility between two of the three components is important for maximizing performance in devices.

12:03PM S34.00003: Solution Processed Organic and Inorganic Transistors – Application in Inverter Circuits*  JOHN BARRON (Presenter), ALEC PICKETT, JAMES GLASER, SUCHISMITA GUHA, Department of Physics and Astronomy, University of Missouri, Columbia, MO, USA — In the fabrication of organic field-effect transistors (FETs), the usage of high κ dielectrics lowers the operating voltage and enhances device performance. Polymer ferroelectrics open the path not just for high κ values but allow processing of the films via electrical poling. Poled ferroelectric dielectrics in p-type organic FETs is seen to improve carrier mobility and reduce parasitic current when compared to unpoled devices using the same dielectric. Furthermore, n-type inorganic FETs using solution processed ZnO have shown improved performance when the semiconductor layer is subjected to a UV-ozone treatment. FETs were fabricated using the ferroelectric polymer poly(vinylidene fluoride-trifluoroethylene) (PVDF-TrFE) as the dielectric insulator and the electron donor-acceptor polymer diketopyrrolopyrrole-dithienylthieno[3,2-b]thiophene (DPP-DTT) for the semiconductor layer, with devices showing mobilities as high as 0.4 cm²/Vs when electrical poling was utilized. ZnO thin film FETs were fabricated with SiO₂ as the dielectric layer, yielding carrier mobilities on the order of 10⁻² cm²/Vs. Both p- and n-type FETs were used in a voltage inverter circuit, showing promising characteristic gain.

*This work was supported by National Science Foundation under Grant No. ECCS-1707588
12:15PM S34.00004: Electric field-induced second harmonic generation imaging of organic thin-film devices* PAYAL BHATTACHARYA (Presenter), Physics and Astronomy, University of Missouri-Columbia, OKSANA OSTROVERKHOVA, Physics, Oregon State University, PING YU, SUCHISMITA GUHA, Physics and Astronomy, University of Missouri-Columbia — The application of an electric field is an effective mechanism for breaking the symmetry in otherwise symmetric molecular systems. Electric-field induced second harmonic generation (EFISHG) provides a tool for investigating chromophore orientation in nonlinear optical (NLO) materials and understanding transport at the semiconductor-dielectric interface in thin film transistors. A microscopic imaging platform in the reflection geometry has been developed for measuring second harmonic generation (SHG) and EFISHG signals from organic thin-film devices. The polymer poly(vinylidene fluoride) (PVDF), with its low glass transition temperature, provides a medium for orienting embedded NLO molecules under the application of external fields. Malonitrile based NLO chromophores were mixed with PVDF to form thin films. An in-plane electric field upwards of $6 \times 10^5$ V/m yields a strong EFISHG signal. The SHG signal is seen to increase with the magnitude of the applied in-plane field and decreases upon the application of a vertical electric field. We further apply this technique to small molecule based organic transistors, where the application of a source-drain potential breaks the symmetry and allows the investigation of carrier transport using an EFISHG signal.

*NSF under Grant No. ECCS-1707588

12:27PM S34.00005: Structure of vapor-deposited glasses within a few nanometers of organic-organic interfaces is bulk-like MARIE FIORI (Presenter), KUSHAL BAGCHI, University of Wisconsin - Madison, MICHAEL TONEY, SLAC National Accelerator Laboratory, MARK EDIGER, University of Wisconsin - Madison — Vapor-deposited (PVD) glasses are used in OLED devices as <50 nm layers, each deposited onto the layer below it. The bulk structure of a >100 nm PVD glass depends on the temperature at which it was deposited; it is unaffected by the substrate. The distance over which the substrate perturbs the structure of a PVD glass is unknown. In this work, we prepare PVD films made of 60 alternating 10 nm layers of organic semiconductors, DSA-Ph and Alq3, creating 60 interfaces. The large number of organic-organic interfaces allows us to access the X-ray scattering of the structure near the organic substrate. GIWAXS of films with 60 interfaces is virtually identical to the sum of the scattering of thick films of the pure components, indicating that the organic substrate perturbs the glass structure for <2 nm. When deposited at or below 0.8 °Tg, we find that the DSA-Ph molecules at organic interfaces lie parallel to the substrate. We expect that this is true for all PVD glassy films of rigid, flat molecules like DSA-Ph, ensuring good π-π orbital overlap at the organic-organic interface, allowing for efficient charge transport across the interface and into the semiconductor layer.
12:39PM S34.00006: Polymer light-emitting diodes with an emitting layer based on a nano-confined semiconducting polymer blend  ANIELEN RIBEIRO, KATHARINA LANDFESTER, PAUL BLOM, JASPER MICHELS (Presenter), Max Planck Inst — Blending a visible light-emitting organic semiconductor with an insulator alleviates the trap-limited nature of the electron current. Solution-processed organic light emitting diodes (OLEDs) comprising such a blend as emissive layer exhibit a two-fold increase in luminous efficiency with only 10% semiconductor. This low content of semiconductor can only be achieved with polymeric emitters. Hence, polymer-LEDs are considerably more cost-effective than devices based on small molecular emitters. However, due to the reduced translational entropy, polymers typically exhibit a low miscibility. In principle, macro-phase separation can be avoided if the molecular weight is kept low, which is however disadvantageous due to low charge carrier mobilities. An alternative strategy is to impose a nano-confinement. We prepare aqueous nanodispersions of poly(p-phenylenevinylene)-based emitters, blended with polystyrene. Macro-phase separation is fully suppressed, as confirmed by scanning force microscopy. Despite the fact that fabricating OLEDs from aqueous nanoparticle dispersions poses considerable risks of strong field inhomogeneity and high leakage currents, we succeed in fabricating such devices highly reproducibly and at efficiencies similar to the non-particle based reference devices.

12:51PM S34.00007: Sub-Turn-on Exciton Quenching Modulated by Spontaneous Orientation Polarization in Organic Light-Emitting Devices* JOHN BANGSUND (Presenter), JACK R VAN SAMBEEK, RUSSELL J HOLMES, University of Minnesota — Many common materials used in organic light-emitting devices (OLEDs) show preferred molecular orientation in thin films. In molecules with a permanent dipole moment, this can lead to spontaneous orientation polarization (SOP) of the film and can generate a large interface charge. This polarization charge is compensated in a device by the accumulation of charge carriers, typically holes, in the adjacent layer. While it has been speculated that these accumulated charges can quench excitons and accelerate degradation, no direct demonstration of these effects has been made. Here, we show that electron transport layers exhibiting SOP induce substantial exciton quenching prior to device turn-on, reducing the peak external quantum efficiency by ~20% relative to layers without SOP. In addition, we find that the accumulated charges accelerate degradation of emitter photoluminescence efficiency under optical pumping. We further show that SOP can be eliminated by substrate heating during deposition, thereby improving device efficiency and stability. These findings confirm that SOP is an important material parameter that must be considered when optimizing efficiency and lifetime of OLEDs.

Influence of Acceptor Type and Polymer Molecular Weight on the Mechanical and Photovoltaic Properties of Polymer Solar Cells [Invited]  BUMJOON KIM  
(Presenter), KAIST — The mechanical robustness of polymer solar cells (PSCs) is of great importance to ensure the long-term stability and enable their use as power-generators in flexible and stretchable electronics. Here, we present a comparative study of the mechanical properties of small-molecule acceptor (SMA)-based, polymer acceptors (PA)-based, and fullerene-based PSCs. We chose ITIC, P(NDI2OD-T2), and PCBM as three representative acceptor materials and blended them with the same polymer donor. To understand the difference between the mechanical properties of SMA-based and PA-based PSCs, we control the number-average molecular weight ($M_n$) of P(NDI2OD-T2) from 15 to 163 kg mol$^{-1}$ in all-PSCs. The high $M_n$ PA-based-PSCs exhibited a high strain at fracture of 31.1%, which is 9- and 28-fold higher than those of SMA-PSCs and PCBM-PSCs, respectively. The superior mechanical robustness of all-PSCs is attributed to using a PA above the critical molecular weight ($M_c$), which produces tie molecules and polymer entanglements that dissipate substantial mechanical strain energy with large plastic deformation. The connectivity between the crystalline domains generated by PA tie chains leads to high charge mobilities and photovoltaics performances of all-PSCs. Also, this feature explains very high donor:acceptor composition tolerance of all-PSCs in the photovoltaic and mechanical performances. Therefore, our work highlights the importance of incorporating high $M_n$ PAs above the $M_c$ for producing the PSCs with excellent mechanical robustness and device performance.

Mechanically-durable high performance OPVs using semi-interpenetrating networks*  ZHIQI HU, CHANGXU SUN, JOSHUA JACKSON, TANGUY TERLIER, RAFAEL VERDUZCO  
(Presenter), Rice Univ — Organic photovoltaic (OPVs) devices offer a number of unique advantages over conventional single crystal silicon solar cells, including simple and low-cost fabrication and reduced weight. However, OPV devices exhibit poor durability to mechanical deformations. Here, we study the use of an elastic semi-interpenetrating network to improve the mechanical durability of the active layer of OPV devices based on the high-performance PBDBT-2F:ITIC donor:acceptor blend. The elastic interpenetrating network is synthesized *in situ* after solution deposition of the donor:acceptor blend along with reactive thiol-ene small molecules. We systematically investigate the effects of strain on the network-stabilized active layer structure and show that network-stabilized devices outperform pristine devices above a critical bending strain and number of bending deformations. The elastic interpenetrating network suppresses crack formation and improves durability to high-curvature and repeated bending deformations. This work describes a general route to high performance flexible devices and detailed design parameters that influence performance.

*We acknowledge support from National Science Foundation under Grant No. CMMI-1352099 and Welch Foundation under Grant No. C-1888.
1:51PM S34.00010: Mechanically-Robust and High-Performance Thin Film Transistors with Regioregular-block-Regiorandom Poly(3-hexylthiophene) Copolymers  HYEONJUNG PARK (Presenter), BOO SOO MA, JIN-SEONG KIM, YOUNGKOWON KIM, KAIST, HYEONG JUN KIM, University of Massachusetts, Amherst, DONGUK KIM, HONGSEOK YUN, JUNGHUN HAN, KAIST, FELIX SUNJOO KIM, Chung-Ang University (CAU), TAEK-SOO KIM, BUMJOON KIM, KAIST — We develop mechanically-robust and high-performance organic thin film transistors (OTFTs) based on poly(3-hexylthiophene) (P3HT) regioblock copolymers (block-P3HTs). These block-P3HTs consist of regioregular (rre) and regiorandom (rra) P3HTs, where the crystalline rre block allows efficient charge transport while the amorphous rra block provides mechanical robustness and inter-domain connection. A series of block-P3HTs, having different molecular weight (M_n) of rra blocks with fixed M_n of rre blocks, are prepared and they all exhibit high hole mobility due to the formation of well-developed edge-on crystallites. In addition, mechanical robustness of block-P3HT thin films is remarkably enhanced with the longer rra block, finally leading to 30.2% of elongation at break, which is 100 times higher than rre P3HT homopolymer. In particular, the noticeable enhancement of both elongation at break and toughness is observed between the M_n of rra block, 8 and 20 kg mol\(^{-1}\), indicating that the critical molecular weight of rra P3HT plays an important role in mechanical response of the block-P3HT thin films. This study provides good strategies for high-performance soft electronics to improve the mechanical properties of electroactive materials without disruption of optoelectrical properties.

2:03PM S34.00011: Multiscale-ordered, highly stretchable polymer semiconductor through nanoconfinement  JIE XU (Presenter), Nanoscience and Technology Division, Argonne National Lab — Semiconducting polymers have been developed as a key component to enable skin-like wearable electronics, but their electrical performance must be improved while maintaining good mechanical stretchability. To substantially improve their charge carrier mobility under strain, we reported a novel and genetic approach that combines advanced solution processing with nanoconfinement effect to achieve multi-scale ordering and high stretchability in conjugated polymers. Here, the increased polymer chain dynamics under nanoconfinement significantly reduces the modulus of the conjugated polymer and largely delays the onset of crack formation under strain. As a result, our fabricated semiconducting film can be stretched up to 100% strain without affecting mobility. By using solution shearing with a patterned microtrench coating blade, macroscale alignment of conjugated-polymer nanostructures was achieved along the charge transport direction. In conjunction, the nanoscale spatial confinement aligns chain conformation and promotes short-range π–π ordering, substantially reducing the energetic barrier for charge carrier transport. As a result, the mobilities of stretchable conjugated-polymer films have been enhanced up to threefold and maintained under a strain up to 100%.

Session S35 DPOLY: Electrostatic Complexation of Proteins and Protein Mimics  507 - Samanvaya Srivastava, University of California, Los Angeles - Tag(s): Focus
The Effect of Protein Surface Charge Distribution on Protein-Polymer Complexation*

Sieun Kim, Hrsh Sureka (Presenter), Massachusetts Institute of Technology MIT, Basak Kayitmazer, Bogazici University, Bradley Olsen, Massachusetts Institute of Technology MIT — Charge patches on protein surfaces have been known to play a significant role in the coacervation and complexation of proteins with one another and with polymers; however, quantifying this patchiness has remained elusive. We present a methodology for quantifying the charge patchiness of protein surfaces and measure how the patchiness of a panel of proteins—engineered to have the same charge, but different charge distributions—affects complexation with a variety of polyelectrolytes. The panel complexed most strongly with the strong polycation used, poly(1-methyl-4-vinylpyridinium iodide), with the proteins with the largest patches complexing over a broader range of polymer-protein ratios than those with smaller patches. Only weaker complexation was seen with the other polyelectrolytes screened, which may have been driven by the weak net negative charge of the mutants. However, the mutant with the largest patches was found to form soluble complexes with both of the weak polyanions tested, hyaluronic acid and poly(acrylic acid). A cutoff between 0.25 and 0.3 in the patchiness parameter was predictive for whether the mutants would complex with any of the polymers tested (particularly qP4VP).

Influence of charge heterogeneity and charge regulation in complexation between proteins and weak polyelectrolytes.

Rituparna Samanta (Presenter), Venkatraghavan Ganesan, University of Texas at Austin — We discuss the complexation of weakly dissociating proteins in the presence of oppositely charged polyelectrolytes using coarse-grained molecular simulations. We have used single chain in mean field simulation method with constant pH ensemble in a semi-grand canonical framework to include the charge dissociation effects. Through results (adsorption and bridging) pertaining to one and two proteins and several polyelectrolytes, we compare the influence of charge regulation and charge heterogeneities on proteins. Our results demonstrate that the charge regulation exerts bridging by polymers higher than that due to charge patches. We discuss the influence of different parameters such as polyelectrolyte concentration, number of charge patches, pH etc.
11:39AM S35.00003: Coacervate gel composites: Phase behavior and topologically frustrated dynamical hierarchy*  DI JIA (Presenter), MURUGAPPAN MUTHUKUMAR, Univ of Mass - Amherst — We report the discovery of a novel coacervate gel composite state and experimental results on the phase behavior and dynamics of this state. This state is qualitatively different from the traditional coacervate liquid states composed of oppositely charged macromolecules formed via liquid-liquid phase separation. The cross-linking of one of the components of our system induces a new dynamical state for the oppositely charged guest polymer. In this state, the guest molecule is topologically frustrated exhibiting a hierarchy of internal chain dynamics, and is non-diffusive, although the water content in the coacervate gel is very high. In addition, we find rich phase behaviors as a function of cross-linking of one component, charge stoichiometry, pH, and salt concentration. An interlude of an coacervate-emulsion phase prior to the gel formation and its response to cross-linking at different experimental control variables will be presented.

*Support from NSF DMR-1504265 is gratefully acknowledged.

11:51AM S35.00004: SAXS Investigations of Structure and Phase Behavior of Polyelectrolyte–Nanoparticle Assemblies  ADVAIT HOLKAR (Presenter), JESSE TOLEDO, SAMANVAYA SRIVASTAVA, University of California, Los Angeles — Aqueous mixtures of oppositely charged polyelectrolytes (PE) and nanoparticles (NP) self-assemble into dense complexes. This self-assembly forms the basis of diverse phenomena ranging from flocculant action in water treatment, where the PE-NP flocs phase separate and sediment, to DNA compaction around histone proteins into chromatin. Factors such as the PE length, architecture and concentrations; NP charge, morphology and concentrations; and solution conditions (pH and ionic strength) play key roles in directing these PE-NP assemblies. In this presentation, we will delineate fundamental investigations into the phase behavior and structure of polycation-silica NP assemblies using small angle X-ray scattering, turbidimetry and thermogravimetric analysis with systematic variation of PE sizes and flexibility, NP sizes, and a wide range of concentrations of both components. Trends in interparticle spacings and correlations as well as fractal dimensions of assemblies with varying PE and NP concentrations will be discussed, presenting a comprehensive narrative of the hierarchical structure of PE-NP self-assemblies. Near-contact compaction of NPs in the PE-NP assemblies above a critical ratio of PE and NP concentrations will be highlighted.
12:03PM S35.00005: Stabilizing Membraneless Polyelectrolyte Complex Coacervates Towards Inherent Coalescence  
AMAN AGRAWAL (Presenter), ALAMGIR KARIM, Chemical and Biomolecular Engineering, University of Houston — Although recent interests in polyelectrolyte coacervates have shown their advanced applications such as microscale bioreactors with enhanced transcription rates, these applications are, however, usually limited to spatially isolated coacervate droplets or those with lipid or polymer membrane because of membraneless droplets’ instability towards coalescence. In this experimental work, we systematically explored the role of the droplet size distribution (~1-10 μm), negative to positive monomer ratio, and salt concentrations in governing the zeta potential and the long-term stability of droplets. We worked with a well-studied coacervate system: PDDA - ATP. Near-uniform size droplets were formed using a PDMS based microfluidic flow-focusing system in the laminar flow (Re<2100). As has been shown earlier, droplets with narrow size distribution had higher stability and coalesced slowly, over a period of several days, as compared to polydisperse droplets which were stable only for minutes to hours before coalescing. This work has an important consequence as this analysis allows us to understand the stability of various phase-separated liquid systems formed in vivo which finds applications ranging from protein storage to neurodegenerative diseases.

12:15PM S35.00006: Protein Purification by Complex Coacervation  
RACHEL KAPELNER (Presenter), ALLIE OBERMEYER, Columbia University — Proteins are an important class of biomolecules with applications across many industries, including as therapeutics and biocatalysts. Their use in some industries, such as the food and pharmaceutical industries, require a high degree of protein purity for their products. Therefore, a highly selective, yet high throughput and low-cost purification method is of great interest to purify proteins from cell lysate. Complex coacervation, the liquid-liquid phase separation of oppositely charged polyelectrolytes, shows promise as a protein purification technique. Previous work in the field, however, has only addressed separating a protein of interest from a relatively simple mixture. In this work, we demonstrate the utility of complex coacervation as a platform to purify proteins from cell lysate. Using a spectroscopic method, we designed a high throughput approach to screen protein purity and recovery from cell lysate. We were then able to assess how protein and polymer design properties and solution conditions impact protein purity and recovery from cell lysate.
12:27PM S35.00007: Effects of therapeutic chemical modifications on polyelectrolyte properties of oligonucleotides  
JEFFREY VIEREGG (Presenter), ALEXANDER E. MARRAS, MATTHEW TIRRELL, University of Chicago — Polyelectrolyte complex micelles (PCMs), core-shell nanoparticles formed by complexation of polyelectrolytes and polyelectrolyte - hydrophilic neutral block copolymers, are an interesting laboratory for studying polyelectrolyte physics. They also provide an attractive solution to the longstanding problem of delivering therapeutic nucleic acids into cells, as nucleic acids are highly charged anions and are efficiently complexed by cationic polyelectrolytes. We recently published a set of structure-property data that provides rules for constructing DNA oligonucleotide PCMs with well-controlled morphology and low polydispersity and have found that they are applicable to several other polyelectrolytes, suggesting the possibility of developing general principles for PCM self-assembly. DNA oligonucleotides are accessible and chemically stable but are not bioactive, motivating investigation of how chemical modifications affect oligonucleotides' polyelectrolyte properties. Surprisingly, we find that even single atom changes (e.g. DNA to RNA, or phosphate to phosphorothioate) can have large effects on the properties of the resulting PCMs. I will discuss these, and their interpretation, which highlight the need to include chemical information in models of polyelectrolyte complexation.

12:39PM S35.00008: From Monomer Sequence to Self-Assembly in Polyelectrolyte Coacervation*  
GARY MIN CHIANG ONG, University of Illinois at Urbana-Champaign, TYLER LYITTLE, Chemistry, University of Wisconsin Madison, CHARLES SING (Presenter), University of Illinois at Urbana-Champaign — Oppositely-charged polyelectrolytes can undergo an associative phase separation known as complex coacervation, forming dense polymer phases that maximize favorable electrostatic interactions. This interaction motif can be harnessed to drive polymer assembly, via the incorporation of opposite charges on pairs of block copolymers. We present a recent theory developed to describe the equilibrium phase behavior of complex coacervation, capable of predicting both the correlated molecular structure of the bulk coacervate phase as well as matching experimental phase diagrams. We incorporate this model into a self-consistent field theory (SCFT) of polyelectrolyte self-assembly to predict phase diagrams, revealing a correspondence between salt concentration in charge-driven assembly and temperature in solvophobicity-driven assembly. We also show the limits of blockiness, mapping out the transition between micro-phase separated and macro-phase separated polymers as a function of the monomer sequence on a polyelectrolyte.

*We acknowledge funding from NSF CAREER Award DMR-1654158.
12:51PM S35.00009: Sequence-Controlled Complex Coacervation of Random Polyelectrolytes
ARTEM RUMYANTSEV, NICHOLAS JACKSON, BOYUAN YU, JEFFREY M TING, WEI CHEN, MATTHEW TIRRELL, JUAN DE PABLO (Presenter), University of Chicago — The primary sequence of monomers along a backbone of heteropolymers impacts their physical properties. Random heteropolymers with the sequences following a first-order Markov process arise from statistical copolymerization of different monomers. In this work, we study complex coacervation of oppositely charged, random polyelectrolytes, i.e., polyanions and polycations containing statistically distributed charged and uncharged units. It is shown that increasing blockiness of charged monomers in the primary structure of the random polyelectrolytes favors the formation of dense coacervates. Charge blockiness also improves coacervate salt resistance and increases the width of the two-phase solution region. This effect is due to the enhanced cooperativity of Coulomb interactions between oppositely charged monomers within the coacervate. Our findings demonstrate that the solution phase behavior can be controlled through the design of the Markov monomer sequences, which are governed by the kinetics of statistical copolymerization.

1:03PM S35.00010: Concentration and separation of proteins using polyion condensates*
SASKIA LINDHOUD (Presenter), Nanobiophysics, University of Twente — When oppositely charged macromolecules are mixed in aqueous systems at the right conditions, i.e., ionic strength, mixing ratio, pH, etc., solutions phase separate in a condensed phase which is rich in macromolecules and a dilute phase. The so formed polyion condensate can be liquid-like or solid-like. In both cases proteins can be captured in the condensate phase. This protein partitioning strongly depends on the ratio between the oppositely charged macroions. The cellular fluids contain liquid-like domains with similar properties to polyion condensates. This is not surprising since these cellular structures consist of intrinsically disordered proteins (IDPs) which are zwitterionic in nature, these readily phase separate in vitro, or contain RNA, which is negatively charged, and IDPs with high amount of basic residues. These cellular condensates are expected to selectively partition other biomacromolecules. Cellular condensates are very complex multi-component systems, which can be mimicked using simple polyion condensates, consisting of synthetic oppositely charged polyelectrolytes. In this talk I will discuss two features of these polyion condensates which can be linked to the cellular condensates. First of all their ability to concentrate proteins and second that the partitioning of proteins can be very selective. This selectivity can be used to separate two types of proteins. Both these features are also important for extraction processes in chemical engineering. This talk will therefore conclude by discussing the possibility to use these condensates as tunable extraction media for biorefinery applications.

1:39PM S35.00011: Complex coacervation of polymerized ionic liquids in non-aqueous solvents
MINJUNG LEE (Presenter), RYAN HAYWARD, Univ of Mass - Amherst — The formation of polyelectrolyte complex coacervates within solutions of two oppositely charged polymers is a topic of great recent interest. Studies to date have focused almost exclusively on polyelectrolyte mixtures in water or aqueous solvent mixtures. In this study, polymerized ionic liquids (PILs) were used to investigate the effects of solvent on complex coacervation in non-aqueous solvents. We constructed phase diagrams of PIL mixtures in non-aqueous solvents via experiments using UV-Vis and quantitative $^{19}$F-NMR spectroscopy, and found a substantial difference between two solvent systems in terms of the salt resistance, i.e., the concentration of added salt where complex coacervates are destroyed. Through these studies we seek to provide insight into the role of dielectric constant and solvent/polymer interactions on complex coacervation.

*This research was supported by the National Science Foundation Division of Materials Research (NSF DMR-157384)

1:51PM S35.00012: Computational Investigation of Sequence-Controlled Complex Coacervation in Statistical Copolymers
BOUAN YU (Presenter), NICHOLAS JACKSON, ARTEM RUMYANSEV, JUAN DE PABLO, Pritzker School of Molecular Engineering, University of Chicago — Control of the monomer sequence of polymeric materials provides a pathway for the design of materials that mimic biomacromolecular complexity. In practice, this control can be achieved by tuning the reaction kinetics of random polymerization of different monomers, where the primary sequence distribution follows a first-order Markov chain. In this work, classical Gibbs ensemble and molecular dynamics simulations are used to explore the phase diagrams of polyelectrolyte coacervates with distinct monomer sequences controlled by a simple model for statistical copolymerization. Our results are summarized in phase diagrams that are in line with our previous theoretical findings and experimental observations including the fact that high charge “blockiness” within the sequence results in denser coacervates. Simulations also explore the important role of salt ion specificity as manifested by excluded volume interactions, and how these effects influence complex coacervate thermodynamics. The results presented in this work provide a deeper understanding of how chemical sequence can be used to control complex coacervation.

Session S36 DCOMP: Ultrafast Dynamics of Coupled Electrons and Atomic Motions: Experiments and Precise Simulations
Andre Schleife, University of Illinois at Urbana-Champaign - Tag(s): Invited
11:15AM S36.00001: Terahertz frequency switching in topological Weyl semimetals [Invited]
AARON LINDENBERG (Presenter), Stanford Univ — I will describe femtosecond-resolution crystallographic measurements probing dynamic switching responses driven by terahertz light pulses in topological Weyl semimetals, focusing on the 2D transition metal dichalcogenide WTe$_2$. We describe a new mechanism for driving large amplitude interlayer shear oscillations with ~1% strain amplitudes, leading to a topologically distinct metastable phase. We further show that such shear strain serves as an ultrafast, energy-efficient means to induce more robust, well-separated Weyl points or to annihilate all Weyl points of opposite chirality. I will also discuss new efforts investigating other means for manipulating the topological phase diagram and interlayer stacking of this material through the application of pure electric fields and through doping/intercalation as probed by both optical and transport measurements. This work defines new possibilities for ultrafast manipulation of the topological properties of solids and for the development of new types of topological optoelectronic devices.

11:51AM S36.00002: Observables of real-time lattice dynamics in time-dependent density functional theory [Invited] HANNES HUEBENER (Presenter), Max Planck Institute for the Structure and Dynamics of Matter — I will discuss real-time simulations of lattice vibrations in solids and their signatures in spectroscopy. In particular signatures of electron-phonon coupling in optical and electron spectroscopies have long been used to investigate materials. With the increasing interest in controlling and manipulating materials properties in a non-equilibrium state, such signatures become relevant also in time-resolved measurements. I will discuss how real-time time-dependent density functional calculations can be used to understand spectral features of electron-phonon coupling of driven electronic structure in solids. A useful interpretative tool that emerges from such a treatment is the picture of a dressed electronic structure, which allows to discuss effects in driven systems without referring to perturbation theory.

12:27PM S36.00003: Toward Precise Ab Initio Simulations of the Ultrafast Dynamics of Electrons and Phonons [Invited] MARCO BERNARDI (Presenter), Caltech — Recent progress in combining density functional theory and related ab initio methods with kinetic equations are enabling spectacular advances in computing carrier dynamics in materials from first principles. We will first review this framework and early ab initio calculations of electron scattering rates and carrier thermalization, and then discuss recent developments. The talk will focus on a numerical approach to evolve in time the coupled Boltzmann transport equations (BTEs) of electrons and phonons, using ab initio electron-phonon and phonon-phonon interactions together with a parallel algorithm to explicitly time step the BTEs. Our approach can simulate the electron and phonon dynamics up to hundreds of picoseconds (with a femtosecond time resolution), and the accuracy of the interactions used in the calculations can be validated by computing transport properties. We show example calculations on graphene and semiconductors, for which we compute carrier cooling rates, mode-resolved phonon dynamics, transient absorption, and time-resolved structural snapshots and diffuse X-ray scattering. We will show how this approach can be extended to include excitons, by discussing calculations of exciton-phonon interactions and real-time exciton dynamics. We will outline code development efforts, open problems and future directions.
1:03PM S36.00004: Recent advances in light induced superconductivity [Invited] ANDREA CAVALLERI (Presenter), Max Planck Inst Structure & Dynamics of Matter — I will discuss how coherent electromagnetic radiation at infrared and TeraHertz frequencies can be used to drive collective excitations in solids and especially experiments in which superconducting correlations can be induced at temperatures higher than the thermodynamic transition temperature. I will discuss results in cuprates, doped fullerenes and recent work in organic salts. By comparing these examples a clearer microscopic picture is emerging for driven unconventional superconductivity.

1:39PM S36.00005: Time-dependent potential energy surfaces from the exact factorization: A predictive first-principles approach to ultra-fast non-adiabatic dynamics [Invited] EBERHARD K GROSS (Presenter), Fritz Haber Center, Institute of Chemistry, The Hebrew University of Jerusalem — Some of the most fascinating phenomena in physics and chemistry, such as the process of vision, as well as exciton dynamics in photovoltaic systems involve the coupled motion of electrons and nuclei beyond the adiabatic approximation, i.e. processes not captured by the dynamics on a single Born-Oppenheimer surface. To go beyond the adiabatic approximation is notoriously difficult as one has to start from the full Hamiltonian of interacting electrons and nuclei. We deduce an exact factorization [1] of the full electron-nuclear wave function into a purely nuclear part and a many-electron wave function which parametrically depends on the nuclear configuration and which has the meaning of a conditional probability amplitude. The equations of motion of these two wave functions provide an ideal starting point to develop efficient algorithms for the study non-adiabatic phenomena. The successful prediction of ultrafast laser-induced isomerization processes [2], the description of decoherence [3], calculations of the molecular Berry phase without invoking the Born-Oppenheimer approximation [4] and accurate predictions of vibrational spectroscopy [5], especially dichroism, will demonstrate the power of this new approach. To tackle non-adiabatic phenomena in solids, such as laser-induced phase transitions, the equations of motion of the exact factorization are “density-functionalized” [6], leading to a coupled set of Kohn-Sham equations for electrons and phonons [7].

11:15AM S37.00001: Atomically thin van der Waals magnets: a career in flatland [Invited]
EFREN NAVARRO-MORATALLA (Presenter), Univ de Valencia — Layered magnetic materials are at the origin of modern magnetism and among the very first compounds to be explored at cryogenic temperatures. The phenomenon of magnetic ordering in layers has tantalized condensed matter physicists ever since the theory put forward by Mermin and Wagner demonstrating that long-range ordering in low dimensions is forbidden in an isotropic spin lattice. In order to confirm this hypothesis, many experiments have been performed in the aforementioned layered crystals as an approximation of a two-dimensional (2D) spin lattice. However, interlayer coupling in bulk systems is not negligible and an approach for the study of true 2D magnetism had been for a long time. With the avenue the 2D materials a genuine approach to correlated states in low-dimensions has been unlocked. In this talk I will narrate the launch of my independent research carrier, which has been intimately tied to our discovery of the first free-standing 2D ferromagnet made out of a single layer of a ferromagnetic insulator: chromium triiodide. I will try to stimulate for risk taking and multidisciplinarity in condensed matter physics careers and provide insight into timely research opportunities.

11:51AM S37.00002: Electrocatalysis from two-dimensional materials: an ERC project [Invited]
DAMIEN VOIRY (Presenter), University of Montpellier — Electrochemical reactions can afford hydrogen gas (H2) and small organic molecules from water and CO2, respectively and therefore offers promise for the production of fuels. Owing to their reduced dimensionality, two-dimensional (2D) materials have emerged as interesting platforms for studying electrocatalysis. In addition, their properties can largely be tuned by changing their elemental composition, their thickness and their atomic structure.
In 2018, our activity received support from the European Research Council (ERC) for exploring the influence of the defects, the crystal structure and the electronic properties on the catalytic performance towards the reduction of CO2. By developing engineering strategies, our group aims at investigating the electrocatalytic properties of 2D materials including transition metal dichalcogenides and quasi-2D transition metals. To do so, we have recently reported the fabrication of electrochemical microcells using microfabrication techniques. This device architecture allows testing individual nanosheets in order to precisely quantify the activity from the edges and the basal planes. In my talk, I will illustrate how the ERC grant was pivotal in developing my research activities in Europe.

References:
12:27PM S37.00003: Obtaining an ERC Starting Grant* [Invited]  TOMA SUSI (Presenter), Univ of Vienna — The European Research Council (ERC) is the continent's pre-eminent source of competitive funding to support investigator-driven frontier research across all fields. The ERC was designed by researchers and its funding decisions are made by disciplinary peers solely on the basis of scientific excellence. This 'bottom-up' approach allows the scientists themselves to identify new opportunities in any field of research, rather than being led by priorities set by politicians. Grants are awarded through open competition to projects headed by starting and established researchers who are working or moving to work in Europe.

In 2014, I discovered that the scattering of energetic electrons can cause silicon impurities to move through the graphene lattice, revealing a potential for atomically precise manipulation using the focused electron probe. To develop this into a practical technique, improvements in the description of beam-induced displacements, advances in heteroatom implantation, and a concerted effort towards the automation of manipulations were required in a multidisciplinary effort combining computational and experimental work in a custom-modified scanning transmission electron microscope electron microscope.

In this talk, I will describe my journey from designing a high-risk, high-reward frontier research project to writing a successful proposal and presenting it to my peers in a grant interview. After successfully receiving the grant and completing the grant negotiations, I started my project in October 2017. The generous support of 1.5 million euros over five years from an ERC Starting Grant allowed me to start my own research group devoted to this topic, and gave ample visibility within my university. This and the fact the grant is tied to my person and transferrable to another institution directly contributed to the tenure track position I received at the University of Vienna in 2019.

*Toma Susi is supported by the European Research Council (ERC) Grant 756277-ATMEN.

1:03PM S37.00004: PHYSICS FOR SOCIETY: GRAND CHALLENGES IN THE HORIZON 2050 [Invited] CARLOS HIDALGO (Presenter), European Physical Society — The talk will provide an overview of the EPS action designed to address the social dimension of science and the grand challenges in Physics that will bring radical change to developed societies and to provide basic understanding of nature on the Horizon 2050.

Although the quest for knowledge in itself is not necessarily susceptible to ethical evaluation, science abandons its ethical neutrality when it addresses the way in which knowledge is generated and when one considers the impact of its technological applications on individuals and society. Some consequences of being science (as a whole) a non-ethically neutral actor in Society will be addressed.

This action, developed within the framework of the EPS Forum Physics and Society, should reach a broad audience that is willing to explore a future shaped by science. A target audience is young people looking for perspectives in physics.
FRANCESCO DI STASIO (Presenter), Istituto Italiano di Tecnologia — Colloidal semiconductor nanocrystals (commonly referred to as Quantum Dots) are one of the earliest examples of Nanomaterials as their initial discovery dates back to 1986. Nevertheless, they still attract considerable attention thanks to their versatile chemical synthesis, desirable properties for optoelectronics and rich photophysics. Since 2013, my research effort has been dedicated to the development of optoelectronic devices based on colloidal semiconductor nanocrystals. Nanocrystals based II-VI semiconductors have served as a model system for understanding the strong correlation between chemical synthesis and physical properties, as well as the development of technological applications such as solar cells, lasers and light-emitting diodes (LEDs). Such knowledge is employed nowadays for the development of the newly discovered lead-based perovskites (general formula: APbX3, where A = Cs or an organic moiety and X = Cl, Br or I).

In this talk, I will present some recent results on NC light-emitting diodes (LEDs) based on PbS and perovskite nanocrystals, operating both in the visible and in the infrared spectral range. The efficiency of NC-LEDs has now reach important milestones thanks to interdisciplinary collaboration between physicists, chemists and material scientists. Yet, LEDs based on ensemble of nanocrystals (i.e. nanocrystal films) show good performance in terms of efficiency and luminance but their applicability is still limited to standard consumer electronics products such as displays and illumination.

The future challenge is to exploit colloidal semiconductor nanocrystals for single-photon generation under electrical excitation, thus leading to a novel class of non-classical light sources. In this playground, the ERC has provided me support through a starting grant. In the last part of my talk I will describe how “connecting the dots” between different research fields has led me to a successful grant application.

Thursday, March 5, 2020 11:15 AM - 2:03 PM

Session S38 DQI: Optimal Quantum Control 607 - Matthew Grace, Sandia National Laboratories - Tag(s): Focus
11:15AM S38.00001: Variational quantum control for single- and two-qubit transmon gates*  
ANDRES RUIZ CHAMORRO, ERIK TORRONTEGUI, JUAN JOSE GARCIA-RIPOLL (Presenter), Instituto de Fisica Fundamental — Transmon are among the most successful qubits in the superconducting world, enabling the largest gate-based quantum computations to-date. In this talk I will present a new set of techniques to design single-qubit and two-qubit gates for transmon qubits, which can be used to tune qubit frequencies, implement direct or cavity mediated CZ interactions [1], and √SWAP gates with tuneable couplers. The technique is based on variational estimates of the transmon qubit state dynamics, and provides semi-analytical controls that can be further tuned to develop more robust protocols. With minor efforts, methods provide various orders of magnitude improvement in fidelity over earlier techniques based on fast-quasi-adiabatic passages or conventional square or segmented pulses, as used in current experiments.

*This material is based upon work supported by the Air Force Office of Scientific Research under award number FA2386-18-1-4019. This work has been supported by funding from project PGC2018-094792-B-I00 (MCIU/AEI/FEDER, UE) and CAM/FEDER Project No. S2018/TCS-4342 (QUITEMAD-CM).

11:27AM S38.00002: Universal gates for protected superconducting qubits using optimal control*  
BRIAN BAKER (Presenter), Northwestern University, MOHAMED ABDELHAFEZ, University of Chicago, ANDRAS GYENIS, PRANAV MUNDADA, ANDREW HOUCK, Princeton University, DAVID I SCHUSTER, University of Chicago, JENS KOCH, Northwestern University — In this talk I will discuss the use of quantum optimal control theory to realize quantum gates for two protected superconducting circuits: the heavy-fluxonium qubit and the 0-π qubit. Utilizing automatic differentiation facilitates the simultaneous inclusion of multiple optimization targets, allowing one to obtain high-fidelity gates with realistic pulse shapes. For both qubits, disjoint support of low-lying wave functions prevents direct population transfer between the computational-basis states. Instead, optimal control favors dynamics involving higher-lying levels, effectively lifting the protection for a fraction of the gate duration. For the 0-π qubit, offset-charge dependence of matrix elements among higher levels poses an additional challenge for gate protocols. To mitigate this issue, we randomize the offset charge during the optimization process, steering the system towards pulse shapes insensitive to charge variations. Closed-system fidelities obtained are 99% or higher, and show slight reductions in open-system simulations.

*We gratefully acknowledge support from the Army Research Office through Grant Nos. W911NF-15-1-0421 and W911NF-19-1-0016.
11:39AM S38.00003: Uncomputability and complexity of quantum control  DENYS BONDAR
(Presenter), Tulane Univ, ALEXANDER N PECHEN, Steklov Mathematical Institute of Russian Academy of Sciences — In laboratory and numerical experiments, physical quantities are known with a finite precision and described by rational numbers. Based on this, we deduce that quantum control problems both for open and closed systems are in general not algorithmically solvable, i.e., there exists no algorithm that can decide whether dynamics of an arbitrary quantum system can be manipulated by accessible external interactions (coherent and dissipative) such that a chosen target reaches a desired value. This conclusion holds even for the relaxed requirement of the target only approximately attaining the desired value. These findings does not preclude an algorithmic solvability for a particular class of quantum control problems. To arrive at these results, we develop a technique based on establishing the equivalence between quantum control problems and Diophantine equations, which are polynomial equations with integer coefficients and integer unknowns. In addition to proving uncomputability, this technique allows to construct quantum control problems belonging to different complexity classes. In particular, an example of the control problem involving a two-mode coherent field is shown to be NP-hard, contradicting a widely held believe that two-body problems are easy.

11:51AM S38.00004: Robust control for tight SWAP cold atom sensors  MICHAEL HUSH
(Presenter), VIKTOR PUCINCIC, PER LIEBERMANN, ANDRE CARVALHO, HARRY SLATYER, RAJIB CHAKRAVORTY, HARRISON BALL, MICHAEL BIERCUK, Q-CTRL — Cold atom sensors currently provide state-of-the-art performance under lab conditions. Deploying these in tight-SWAP conditions, however, presents a variety of challenges arising from laser instabilities, such as power, frequency, and phase fluctuations. We demonstrate that robust control techniques - related to dynamic decoupling and dynamically-corrected composite pulses - can significantly improve the sensitivity of cold atom sensors in tight SWAP conditions, achieving performance commensurate with state-of-the-art lab conditions. We derive these robust control pulses using a custom numerical-optimization package, producing control solutions robust to specific coloured noise spectrums, and with relevant experimental constraints including bandwidth limitations. Our robust protocol is benchmarked against standard atom interferometry protocols, showing comparable sensitivity under ideal conditions, and over an order or magnitude improvement in a simulated field-deployed environment including realistic laser fluctuations.
Optimizing quantum circuits subject to cross coupling

PER LIEBERMANN (Presenter), HARRISON BALL, HARRY SLATYER, Q-CTRL, MACHIEL S BLOK, VINAY RAMASESH, University of California, Berkeley, ANDRÉ CARVALHO, VIKTOR PUCINCIC, RAJIB CHAKRAVORTY, MICHAEL HUSH, MICHAEL BIERCUK, Q-CTRL — We present a new optimization technique which creates time-optimized circuits capable of combating unwanted crosstalk in transmon circuits. The low anharmonicity of transmons allows for the performance of quantum computations with either qubits or qutrits realized using the three lowest energy levels of the device. Unfortunately when employed in circuits residual ZZ-type couplings can lead to error sources which degrade algorithmic performance. We demonstrate the optimization of complex Unitaries on up to five qutrits using SU(2) and SU(3) operations. Based on a custom GPU-compatible optimization toolkit, high-fidelity and robust circuits are generated by optimizing both applied SU(N) operations and their timing in the circuit. We further demonstrate the ability to find robust solutions optimized to account for additional time-varying noise processes. We compare numeric with analytic results and GPU-optimization speeds with CPU-limited methods. Overall this approach forms a new kind of optimized circuit compilation which trades-off algorithmic execution time for improved overall error performance in a deterministic fashion.

High fidelity unitary evolution using constrained control fields.

THALES FIGUEIREDO ROQUE (Presenter), Max Planck Inst for Sci Light, AASHISH CLERK, University of Chicago, HUGO RIBEIRO, Max Planck Inst for Sci Light — The problem of coherent errors, where the quantum unitary evolution is corrupted by populating spurious states (leakage error) or accumulates the wrong phase (phase error), is generic to a variety of situations. This type of errors often arise because it is a difficult task to find control fields that would generate with high accuracy a desired unitary evolution. The task becomes even more complex when taking into account experimental constraints: unavailable control fields, bandwidth limitations, amplitude limitations, etc. Here we attack a class of problems where suitable controls are known in an idealized scenario, but unwanted perturbative interactions disrupt the desired unitary evolution. We show how a recently-proposed Magnus expansion based algorithm for quantum control [1] can be modified to find control fields that both suppress coherent errors and are compatible with experimental constraints. In this talk, we focus on presenting the general method and revisit the problem of single qubit gates in a transmon qubit.

Quantum optimal control in a ZZ-free qubit architecture

ROSS SHILLITO (Presenter), Institut quantique and Département de Physique, Université de Sherbrooke, RONI WINIK, Research Laboratory of Electronics, Massachusetts Institute of Technology, CATHERINE LEROUX, AGUSTIN DI PAOLO, Institut quantique and Département de Physique, Université de Sherbrooke, JOCHEN BRAUMUELLER, MORTEN KJAERGAARD, ANTTI VEPSALAINEN, Research Laboratory of Electronics, Massachusetts Institute of Technology, DAVID K KIM, JONILYN YODER, MIT Lincoln Laboratory, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, WILLIAM OLIVER, MIT Lincoln Laboratory, ALEXANDRE BLAIS, Institut quantique and Département de Physique, Université de Sherbrooke — Quantum optimal control is a powerful technique for improving the performance of quantum gates. Numerical methods, such as GRAPE, have been demonstrated to reduce infidelity of single- and two-qubit gates by several orders of magnitude. In this talk, we demonstrate the application of quantum optimal control in a newly proposed architecture in which the ZZ-interaction is inherently suppressed. We explore the parameter regimes of this system to optimize the performance of a cross-resonance gate on this architecture.

A comparative study for reinforcement learning and traditional algorithms on state transfer problem

XIAOMING ZHANG (Presenter), XIN WANG, City Univ of Hong Kong — While reinforcement learning (RL) has been widely used in quantum control problems, it remains unclear whether RL is the most suitable algorithm when the control has specific constraints. We perform a comparative study on the efficacy of three RL algorithms: tabular Q-learning, deep Q-learning and policy gradient, as well as stochastic gradient descent and Krotov algorithms, in the problem of quantum state preparation. Overall, the deep Q-learning and policy gradient algorithms outperform others when the problem is discretized, e.g. allowing discrete values of control and when the problem scales up. Moreover, the reinforcement learning algorithms can also adaptively reduce the complexity of the control sequences. Our work provides insights into the suitability of reinforcement learning in quantum control problems.

12:51PM S38.00009: A geometric approach to dynamically corrected gates* [Invited]  EDWIN BARNES (Presenter), Virginia Tech — Future technologies such as quantum computing, sensing and communication demand the ability to control microscopic quantum systems with unprecedented accuracy. This task is particularly daunting due to unwanted and unavoidable interactions with noisy environments that destroy quantum information through decoherence. I will present recent progress in understanding and modeling the effects of noise on the dynamics of a qubit and show how this can be used to develop new ways to slow down decoherence. I will then describe a new general theory for dynamically combatting decoherence by driving qubits in such a way that noise effects destructively interfere and cancel out. This theory exploits a rich geometrical structure hidden within the time-dependent Schrödinger equation.

*We acknowledge support from the U.S. Army Research Office (Grant No. W911NF-17-0287) and from the U.S. Office of Naval Research (Grant No. N00014-17-1-2971).

1:27PM S38.00010: Application of Pontryagin's Minimum Principle to Grover's Quantum Search Problem  CHUNGWEI LIN (Presenter), Mitsubishi Electric Research Lab — Grover's algorithm is one of the most famous algorithms which explicitly demonstrates how the quantum nature can be utilized to accelerate the searching process. In this work, Grover's quantum search problem is mapped to a time-optimal control problem. Resorting to Pontryagin's Minimum Principle we find that the time-optimal solution has the bang-singular-bang structure. This structure can be derived naturally, without integrating the differential equations, using the geometric control technique where Hamiltonians in the Schrödinger's equation are represented as vector fields. In view of optimal control, Grover's algorithm uses the bang-bang protocol to approximate the optimal protocol with a minimized number of bang-to-bang switchings to reduce the query complexity. Our work provides a concrete example how Pontryagin's Minimum Principle is connected to quantum computation, and offers insight into how a quantum algorithm can be designed.
1:39PM S38.00011: Variational quantum gate optimization on superconducting qubit system*  HEYA KENTARO (Presenter), Research Center for Advanced Science and Technology, The University of Tokyo, YASUNARI SUZUKI, NTT Secure Platform Laboratories, NTT Corporation, YUTAKA TAKEDA, AKHIL PRATAPS SINGH, Research Center for Advanced Science and Technology, The University of Tokyo, SHINGO KONO, KOH-ICHI NITTOH, KOICHI KUSUYAMA, Center for Emergent Matter Science, RIKEN, SHUHEI TAMATE, YUTAKA TABUCHI, Research Center for Advanced Science and Technology, The University of Tokyo, KEISUKE FUJII, Graduate School of Engineering Science, Osaka University, YASUNOBU NAKAMURA, Research Center for Advanced Science and Technology, The University of Tokyo — Hybrid quantum-classical (HQC) algorithms aim at realizing the quantum advantage in shallow depth quantum circuits with an aid of classical computation. Recently, HQC algorithms have been extensively studied with the expectation that they may solve practical problems in the near future. However, the quantum gate fidelities directly limit the sizes of executable problems in quantum computers without quantum error correction. While HQC algorithms require fewer quantum gates, the state-of-the-art gate fidelities are still insufficient to deal with practical problems. In this presentation, we propose a gate optimization method, where high-fidelity multi-qubit gates are generated by optimizing parametrized quantum circuits consisting of tunable high-fidelity single-qubit gates and fixed multi-qubit gates with limited controllability. We call the method variational quantum gate optimization (VQGO) and demonstrate it on a superconducting qubit system.

1:51PM S38.00012: Using Algebra to Dissect Quantum Optical Evolution for Quantum Control*  RILEY E MARTELL, Washington University in Saint Louis, JEAN-FRANCOIS VAN HUELE (Presenter), TY BEUS, MANUEL BERRONDO, Brigham Young Univ - Provo — Quantum control is the ability to affect quantum systems through judicious selection of dynamical parameters and their time dependence. Wei-Norman factorization [Wei and Norman, Proc. Amer. Math.Soc.15, 327 (1964)] is a powerful method to parametrize the quantum mechanical evolution operator before applying it to specific states. We first illustrate this method on the dynamics of optomechanical oscillators. We then extend the method to the pseudo-dynamics associated with the squeeze operator and characterize its action on a variety of optical states. This leads to improved insight into quantum control at a level accessible to undergraduates.

Session S39 DCOMP GDS DMP: Machine learning for quantum matter IV  703 - Linda Hung, Toyota Research Institute - Tag(s): Focus
11:15AM S39.00001: Self-learning projective quantum Monte Carlo simulations guided by restricted Boltzmann machines [invited] SEBASTIANO PILATI, University of Camerino, ESTELLE INACK (Presenter), Perimeter Inst for Theo Phys, PIERBIAGIO PIERI, University of Camerino — Projective quantum Monte Carlo (QMC) simulations have been successfully used to simulate various relevant quantum many-body systems. They are systematically implemented in a two-step approach, in which a variational ansatz inspired by theory is first optimized using traditional variational optimization techniques. Later, the optimized ansatz is used as a guiding wave function in projective QMC simulations. In this work, we present a novel method that uses unsupervised machine learning techniques to combine the two steps above. It adaptively trains the guiding wave function (represented by a restricted Boltzmann machine) within QMC simulations, thus avoiding the need for separate variational optimization. On the one hand, this approach greatly increases the efficiency and accuracy of projective QMC simulations. On the other hand, it provides a new way to develop ground-state ansatzes, complementary to the common variational optimization schemes. We present extensive benchmarks that demonstrate the efficiency of our self-learning method.

11:51AM S39.00002: Self-learning Hybrid Monte Carlo method for first-principles molecular simulations YUKI NAGAI (Presenter), MASAHIKO OKUMURA, Japan Atomic Energy Agency, KEITA KOBAYASHI, RIST, MOTOYUKI SHIGA, Japan Atomic Energy Agency — We propose a novel approach called Self-Learning Hybrid Monte Carlo (SLHMC) which is a general method to make use of machine learning potentials to accelerate the statistical sampling of first-principles density-functional-theory (DFT) simulations. The trajectories are generated on an approximate machine learning (ML) potential energy surface. The trajectories are then accepted or rejected by the Metropolis algorithm based on DFT energies. In this way the statistical ensemble is sampled exactly at the DFT level for a given thermodynamic condition. Meanwhile the ML potential is improved on the fly by training to enhance the sampling, whereby the training data set, which is sampled from the exact ensemble, is created automatically.

12:03PM S39.00003: On-the-fly machine learning algorithm for accelerating Monte Carlo sampling: Application to the stochastic analytical continuation* HONGKEE YOON (Presenter), MYUNG JOON HAN, Korea Adv Inst of Sci & Tech — We present a new Monte Carlo method whose sampling is assisted by modern machine learning (ML) technique. In order to improve the MC sampling efficiency in high dimensional problems, we suggest ML generative model as being a part of MC sampler. We apply this ML+MC method to a long-standing numerical problem in quantum many-body physics, namely, analytic continuation. In our scheme, ML sampler naturally satisfies physical constraints such as detailed balance because it is combined with the conventional Markov chain MC procedure. Furthermore, massive data sets generated by MC procedure provides the on-the-fly ‘learnings’ for ML sampler. Remarkable improvement has been achieved in terms of both convergence speed and the quality of continuation result. The same approach can be applicable to various other problems for which MC algorithm has been used.

12:15PM S39.00004: Automatic Differentiable Monte Carlo: Theory  SHIXIN ZHANG
(Presenter), ZHOU-QUAN WAN, HONG YAO, Tsinghua University — Differentiable programming emerges as the new programming paradigm empowering the rapid development of deep learning as it has been shown equally powerful in computational physics. Here we propose a general theory framework with detach function techniques enabling infinite order automatic differentiation on Monte Carlo expectations with unnormalized probability distributions. By introducing automatic differentiable Monte Carlo (ADMC), we can leverage state-of-the-art machine learning framework and toolbox to traditional Monte Carlo approaches in statistics and physics by simply implementing relevant Monte Carlo algorithms on computation graphs.

12:27PM S39.00005: Automatic Differentiable Monte Carlo: Applications  ZHOUQUAN WAN
(Presenter), SHIXIN ZHANG, HONG YAO, Tsinghua University — Differentiable programming emerges as the new programming paradigm empowering the rapid development of deep learning as it has been shown equally powerful in computational physics. By introducing automatic differentiable Monte Carlo (ADMC), we can leverage state-of-the-art machine learning frameworks and techniques to traditional Monte Carlo approaches in statistics and physics by simply implementing relevant Monte Carlo algorithms on computation graphs. We show the power of ADMC by three specific applications from physics and statistics: 1. Locate the critical temperature for 2D Ising model; 2. Compute Fisher matrix with automatic differentiation setup; 3. End-to-end, easy-to-implement, automatic differentiable variational Monte Carlo on 2D Heisenberg model with general neural network wavefunction anstaz. We further discuss about other potential possibilities that ADMC bring us in the innovations and breakthroughs of Monte Carlo methods.

12:39PM S39.00006: Optimal Real-Space Renormalization-Group Transformations with Artificial Neural Networks*  JUI-HUI CHUNG, YING-JER KAO (Presenter), Natl Taiwan Univ — We introduce a general method for optimizing real-space renormalization-group transformations to study the critical properties of a classical system. The scheme is based on minimizing the Kullback-Leibler divergence between the distribution of the system and the normalizing factor of the transformation parametrized by a restricted Boltzmann machine. We compute the thermal critical exponent of the two-dimensional Ising model using the trained optimal projector and obtain a very accurate exponent $\gamma_t=1.0001(11)$ after the first step of the transformation.

12:51PM S39.00007: Machine-learning-accelerated predictions of optical properties of condensed systems based on many-body perturbation theory*  SIJIA DONG (Presenter), MARCO GOVONI, Materials Science Division, Argonne National Laboratory, GIULIA GALLI, University of Chicago — Accurate and efficient predictions of absorption spectra of molecules and solids are essential for the understanding and rational design of broad classes of materials, including photo-absorbers in solar and photo-electrochemical cells and defective insulators and semiconductors hosting optically addressable spin-defects. We present an approach to improve the efficiency of first principles calculations of absorption spectra of complex materials at finite temperature, based on the solution of the Bethe-Salpeter equation (BSE) [1]. We use machine learning techniques to predict the spectra of snapshots extracted from ab initio molecular dynamics simulations, and we use data generated by explicitly solving the BSE for a small subset of snapshots. We present results for nanoclusters, solids, liquids, including water, and semiconductor-water interfaces.

*The work was supported by Advanced Materials for Energy-Water Systems (AMEWS) Center, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences (DOE-BES), and Midwest Integrated Center for Computational Materials (MICCoM) as part of the Computational Materials Science Program funded by DOE-BES.

1:03PM S39.00008: Machine Learned Spectral Functions for the Quantum Impurity Problem  ERICA STURM (Presenter), Brookhaven National Laboratory, MATTHEW R CARBONE, Department of Chemistry, Columbia University, DEYU LU, ANDREAS WEICHSELBAUM, ROBERT KONIK, Brookhaven National Laboratory — Machine learning techniques can greatly reduce simulation times by providing highly accurate approximations, thus circumventing the need for more expensive models. This work leverages a feed-forward neural network (NN) to predict the spectral functions of the single impurity Anderson model (SIAM) as a function of five physical parameters including the Coulomb interaction U, hybridization constant Γ, impurity energy ε_d, magnetic field B, and temperature T. The NN was trained on ~670,000 unique SIAM system spectral functions generated by Wilson’s Numerical Renormalization Group (NRG). The NN predicts the spectral function with a mean absolute difference of less than 3% compared to the ground truth. The ability to efficiently predict a spectral function for the quantum impurity problem can improve the computation time for dynamical mean field theory and related methods that investigate strong correlation in condensed matter systems.

1:15PM S39.00009: Finding New Mixing Strategies for Self Consistent Field Procedures Using Reinforcement Learning*  
DANIEL ABARBANEL (Presenter), HONG GUO, McGill Univ — Density mixing is a technique to improve the convergence for self-consistent field (SCF) procedures, and is used extensively to calculate electronic structure and transport properties in the context of density functional theory (DFT). Typically, a single mixing method will be chosen for the whole of a SCF calculation, but recent research suggests that alternating the mixing strategy between subsequent SCF iterations can improve the time of convergence. There are many untested SCF mixing methods beyond those already discovered that can be constructed using combinations of established methods. We present a new method to discover mixing strategies by applying a reinforcement learning algorithm (RLA). The state space of the RLA consists of SCF parameters such as the density, potential and convergence error. The action space of the RLA consists of previously developed mixing methods including simple mixing, Broyden mixing and Pulay mixing, with the crucial point being that the RLA is able to alter the mixing strategy in situ.

1:27PM S39.00010: Machine learning spin dynamics in the double-exchange systems  
PUHAN ZHANG (Presenter), PREETHA SAHA, GIA-WEI CHERN, Univ of Virginia — The double-exchange (DE) mechanism plays an important role in our understanding of the colossal magnetoresistance phenomenon. It describes itinerant electrons interacting with local magnetic moments through the Hund's rule coupling. Although extensive effort has been devoted to studying the equilibrium properties of the DE models, dynamical phenomena in these systems remain much less explored, partly due to the expensive computational cost of their microscopic simulations. For example, in Landau-Lifshitz dynamics (LLD) simulations of the DE systems, the electron tight-binding Hamiltonian has to be solved at every time-step in order to obtain the torque acting on the local spins. Here we propose a machine learning (ML) technique that can solve the dynamics of the DE model in linear time complexity. Our approach is similar to the ML-based force prediction in quantum molecular dynamics. In our method, a deep-learning neural network trained by dataset from small system simulations is used to directly predict the effective local exchange force. We will also present our ML-enabled large-scale LLD simulation of phase separation phenomena in DE systems.

1:39PM S39.00011: Machine learning of high-throughput DFT electron densities  
LINDA HUNG (Presenter), DANIEL SCHWEIGERT, ARJUN BHARGAVA, CHIRRANJEEVI GOPAL, Toyota Research Institute — Kohn-Sham density functional theory (DFT) provides a good balance between accuracy and efficiency, and its utility has given rise to high-throughput DFT databases including the Materials Project and the Open Quantum Materials Database. In this talk, we demonstrate how electron density datasets from these databases can be used to train machine learning models that complement and enhance the capabilities of DFT. We quantify the accuracy of neural networks that predict electron densities, and also report the trends observed in electronic structure-property relationships.
1:51PM S39.00012: Machine learning as a solution to the electronic structure problem
BEATRIZ GONZALEZ DEL RIO (Presenter), RAMAMURTHY RAMPRASAD, School of Materials Science and Engineering, Georgia Institute of Technology — An essential component of materials research is the use of simulations based on density functional theory (DFT), which imposes severe limitations on the size of the system under study. A promising development in recent years is the use of machine learning (ML) methodologies to train surrogate models with DFT data to predict quantum-accurate results for larger systems. Many successful ML models have been created to predict higher-level DFT results such as the total potential energy and atomic forces, and initial steps have been taken to create deep-learning based ML methodologies that can predict fundamental DFT outputs such as the charge density, wave functions and corresponding energy levels [1]. Here, we explore the applicability of this latter methodology using convolutional and recurrent neural networks to learn and predict the electronic charge density and the density of states of carbon, for a large variety of allotropes spanning from metallic to insulating behavior. Further improvements to the speed, accuracy and versatility of this DFT-emulation methodology will also be presented.

2:03PM S39.00013: Machine learning spectral indicators of topology
NINA ANDREJEVIC (Presenter), Massachusetts Institute of Technology, JOVANA ANDREJEVIC, CHRISTOPHER RYCROFT, Harvard University, MINGDA LI, Massachusetts Institute of Technology — Topological materials discovery has emerged as an important frontier in condensed matter physics due to the exceptional properties arising from nontrivial band topology. Recent theoretical methods based on local and global symmetry indicators have been used to identify several thousand candidate topological materials, yet experimental determination of materials’ topological character often poses significant technical challenges. X-ray absorption spectroscopy (XAS) is a widely-used characterization technique of materials’ local geometric and electronic structure, as it is sensitive to the symmetry and local chemical environment of constituent atoms; thus, it is a potentially useful encoding of topological character. Here, we study the effectiveness of XAS as a predictor of topology using machine learning methods to disentangle key structural information from the complex spectral features. We discuss the utility of experimental spectra to inform materials’ topology and compare the predictive power of individual absorbing elements.

11:15AM S40.00001: Direct measurement of ion mobility by electrophoretic NMR and implications for correlated migration in liquid electrolytes [Invited]  
MONIKA SCHÖNHOFF (Presenter), FLORIAN SCHMIDT, MARC BRINKKÖTTER, MARK PHILLIP ROSENWINKEL, PINCHAS NÜRNBERG, University of Muenster — In studies of ion transport in electrolytes, multinuclear (1H, 7Li, 19F) electrophoretic NMR (eNMR) allows to directly measure electrophoretic mobilities, extracting them from the ion drift velocity in an electric field. For example, in Li salt-in-Ionic Liquid systems a negative mobility of Li⁺ may occur, implying a drift direction opposite to the expectation for a cation. This was attributed to a vehicular transport of Li in net negatively charged Li-anion clusters. Their stoichiometry can be deduced from the effective charge. Employing compositional variations, such as using asymmetric anions or high Li salt concentrations, a transition from a vehicular to a structural transport mechanism of Li⁺ can be achieved. In further liquid electrolytes, containing organic additives or in glyme-based solvate ionic liquids, a drift of uncharged molecules in the electric field can be identified by 1H eNMR. Thus, conclusions on their correlated transport, due to coordination to Li⁺ are possible, shedding light on the mechanisms governing Li transport. In summary, electrophoretic NMR elucidates transport mechanisms on a molecular level, and provides unique information; in particular, where correlated motion of different ion species is involved.

11:51AM S40.00002: Modulation of ion transference number by dynamic hydrogen bond network  
VERA BOCHAROVA (Presenter), Oak Ridge National Lab, ZANETA WOJNAROWSKA, University of Silesia in Katowice, Poland, ANDREW ERWIN, Georgia Tech, NISHANI JAYAKODY, STEVEN GREENBAUM, Hunter College of The City University of New York, IVAN POPOV, Oak Ridge National Lab, CATALIN GAINARU, Technische Universität Dortmund, Germany, SHIWANG CHENG, Michigan State University — Ionic liquids (IL) are important materials with potential to be used in various technologies because of their non-toxicity, non-flammability, and high ionic conductivity. Although high conductivity in ionic liquids can be achieved, their relatively low transference number remains a problem. Ionic materials with high transference number are required to design high power batteries. In the present talk, we demonstrate that addition of small nanoparticles capable of formation of hydrogen bonds can reduce electrostatic interaction between ions in IL which improves ion dissociation. Furthermore, with increase in concentration of nanoparticle a clear evidence of network formation has been obtained from rheology. By studying various aspects of diffusion, conductivity, and dynamics in the network at ambient and elevated pressure, we found that formation of the network promotes decoupling between ion conductivity and structural relaxation and controls ion diffusion trough hydrogen bond network. Our studies provide fundamental insights into decoupling phenomena which is a major mechanism of conductivity in solid ion conductors. Furthermore, introduction of additional interaction into IL seems to be a promising direction to control diffusion of the ions.
12:03PM S40.00003: Ionic Association, Solvation and Gelation in Super-Concentrated Electrolytes*  MICHAEL MCELDREW (Presenter), Massachusetts Institute of Technology MIT, SHENG BI, ZACHARY GOODWIN, ALEXEI A. KORNYSHEV, Chemistry, Imperial College London, MARTIN BAZANT, Massachusetts Institute of Technology MIT — In super-concentrated electrolytes, ion-ion association can become extensive and complex. When the extent of ion association reaches a certain threshold, infinite percolating ionic gel networks can be formed spontaneously. We developed a thermodynamic model of reversible ionic association and gelation in super-concentrated electrolytes accounting for the competition between ion solvation and ion association. Our model is able to predict the populations of ionic clusters of different sizes as a function of salt concentration, as well as capture the onset of ionic gelation. We benchmark our model against molecular dynamics simulations of aqueous LiTFSI electrolyte for a large range of salt concentrations. We find that the ionic association and gelation observed in the molecular simulations are captured nearly quantitatively by our theory. The extent of ionic association and gelation greatly affects both the fraction of “free” ions in solution that can carry ionic current, as well as the viscosity of the mixture. Thus, knowledge of what governs these phenomena is essential in understanding the transport properties of super concentrated electrolytes.

*We acknowledge the Amar G. Bose Research Grant and Imperial College-MIT seed fund grant.

12:15PM S40.00004: Unsupervised learning of ion dynamics in electrolytes using graph dynamical networks*  TIAN XIE (Presenter), ARTHUR FRANCE-LANORD, YANMING WANG, YANG SHAO-HORN, JEFFREY C GROSSMAN, Massachusetts Institute of Technology MIT — Understanding the dynamical processes that govern the performance of functional materials is essential for the design of next generation materials to tackle global energy and environmental challenges. Many of these processes involve the dynamics of individual atoms, ions, or small molecules in condensed phases, which are difficult to understand due to the complexity of local environments. Here we present graph dynamical networks [1], an unsupervised learning approach for atomic scale dynamics in arbitrary phases and environments from molecular dynamics simulations. We apply the methodology to ion dynamics in polymer electrolytes, and show how important features related to ion-ion correlations can be automatically captured. With the large amounts of molecular dynamics data generated every day in nearly every aspect of materials design, this approach provides a broadly applicable, automated tool to understand atomic scale dynamics in material systems.

**12:27PM S40.00005: Ion clustering in electrolytes: impact on correlated transport and voltage stability**  
ERIC FADEL (Presenter), Materials Science And Engineering, Massachusetts Institute of Technology MIT, NICOLA MOLINARI, School of Engineering and Applied Sciences, Harvard University, ARTHUR FRANCE-LANORD, Materials Science And Engineering, Massachusetts Institute of Technology MIT, BORIS KOZINSKY, School of Engineering and Applied Sciences, Harvard University, JEFFREY C GROSSMAN, Materials Science And Engineering, Massachusetts Institute of Technology MIT — The study of ionic transport is an important tool for the optimization of the performance of Lithium ion batteries. The diffusion of Lithium ions across the electrolyte system often exhibits complex correlated motion, which remain relatively poorly understood. Building on previous studies showing the existence of cluster motion in different electrolytes (solid polymers, ionic salts ...) we study the fundamentals of the clustering behavior, to provide insights into cluster formation. In particular, we develop algorithms to describe conditions for clustering to appear, the nature and composition of these clusters, the distribution in size, composition and diffusion coefficient of clusters during transport. We also investigate the lifetime of cluster and relate it to the transport properties of the electrolyte, particularly with regard to the recently reported negative transference number in a variety of systems. This study is also linked back to our work on the voltage stability of organic electrolytes, that shows how the stability of anions in these systems is weakened by the presence of the solvent, and increased by the presence of cations. Therefore, clustering behavior would impact not only the diffusion properties but also the voltage window of the electrolyte.

**12:39PM S40.00006: Molecular Dynamics Simulations of FcMIM-based Ionic Liquids**  
QING GUO (Presenter), Michigan Technological Univ, KAHCHUN LAU, California State University, Northridge, RAVINDRA PANDEY, Michigan Technological Univ — Room temperature ionic liquids (RTILs) are salts in liquid state below 100 °C, and have attracted great attention as electrolytes candidates in battery systems due to properties such as low vapor pressure, high ionic-conductivity, and large operation temperature window, etc. In this talk, we will present the results of Molecular Dynamics simulations identifying the structural characteristics of the ferrocene-imidazolium-based ionic liquids and their aqueous solutions. We will also provide atomistic view of the system to facilitate fundamental understanding at molecular level which is critical for improvement in the electrolyte properties for battery systems.

*Financial support from Alfred P Sloan Foundation is acknowledged.*
Adaptive dimensionality reduction for accelerated calculations of ionic conductivity in correlated electrolytes

NICOLA MOLINARI, YU XIE, IAN LEIFER (Presenter), BORIS KOZINSKY, Harvard University — Molecular dynamics (MD) computation of the ionic conductivity of correlated electrolytes does not allow for the use of the familiar mean square displacement, instead requiring to collect statistics on the total ionic flux fluctuations, which leads to the need of much longer trajectories to obtain converged results. We propose a way to systematically reduce the noise in the conductivity and diffusivity calculations from MD in regimes of moderate correlation (Haven ration 0.5-2). For systems with a time-independent correlation structure, we use spectral decomposition of the short-time position covariance matrix to learn the optimal set of diffusion eigenmodes and perform the analysis of the full MD trajectory in that basis. The proposed method allows to significantly decrease the uncertainty of conductivity estimates.

Asymmetric composition of ionic cluster and correlated transference number in water-in-salt electrolytes

ZHOU YU (Presenter), LEI CHENG, Argonne Natl Lab — The recent research breakthrough on “water-in-salt” electrolytes opens up exciting new avenues for expanding the electrochemical window of aqueous electrolytes. Subsequent work from the electrolyte community found the solvation environment of ions in the “water-in-salt” systems dictates ion mobility. In this work, the crosslinked heterogeneous ion and water domains were captured by molecular dynamics (MD) simulations and small-angle X-ray scattering techniques. The asymmetric composition of ionic clusters composed of more TFSI\(^-\) ion than Li\(^+\) ion was first observed in the water-in-salt electrolyte. The decay of the Li-TFSI association correlation function is faster than that of the residence correlation function for the large percolated ionic clusters with asymmetric composition, which implies that the Li\(^+\) ion can hop through the TFSI\(^-\) ions in the ionic cluster. Furthermore, a reasonably high correlated transference number (i.e., ~0.32) can be maintained even in 20 m electrolytes due to a weak negative correlation between the motion of cations and anions featuring heterogeneous ionic regions.

*This research was supported by the Joint Center for Energy Storage Research (JCESR), a U. S. Department of Energy, Energy Innovation Hub.
1:15PM S40.00009: Ion-ion correlations from aggregation and the Nernst-Einstein equation*

ARTHUR FRANCE-LANORD (Presenter), JEFFREY C GROSSMAN, Massachusetts Institute of Technology

MIT — We present a new approximation [1] to ionic conductivity well suited to dynamical atomic-scale simulations, based on the Nernst-Einstein equation. Ionic aggregates constitute the elementary charge carriers, and are considered as non-interacting species. This approach conveniently captures a dominant effect of ion-ion correlations on conductivity, namely short range interactions in the form of clustering. In addition to providing better estimates to the conductivity at a lower computational cost than exact approaches, this new method allows to understand the physical mechanisms driving ion conduction in concentrated electrolytes. As an example, we consider Li⁺ conduction in poly(ethylene oxide), a standard solid-state polymer electrolyte. Using our newly developed approach, we are able to reproduce recent experimental results reporting negative cation transference numbers at high salt concentrations, and to confirm that this effect can be caused by a large population of negatively charged clusters involving cations.

*This project is supported by the Toyota Research Institute (TRI), and used computational ressources of NERSC.

1:27PM S40.00010: Transport anomalies in electrolytes emerging from strong ionic correlation

NICOLA MOLINARI (Presenter), Harvard University, JONATHAN PRADANA MAILOA, Robert Bosch LLC, BORIS KOZINSKY, Harvard University — Electrolytes control battery recharge time and efficiency, anode/cathode stability, and ultimately safety, consequently electrolyte optimization is crucial for the design of modern energy storage device. Electrolytes containing ionic liquids (ILs) possess superior chemical stability, however, poor transport properties are hindering their applicability. These systems possess high degrees of ion-ion correlation, therefore posing a non-trivial yet crucial and interesting challenge to understanding their transport properties.

Here we present molecular dynamics analysis of transport properties in IL-based electrolytes. First, we show that intra- and inter-species correlation can lead to anomalously low and even negative Li transference numbers. Second, we computationally quantify the recently measured negative Li transference number in IL-based electrolytes, and extend this surprising result to a vast range of different chemistries, suggesting a universal behavior of this class of electrolytes. Additionally, we show that lithium-containing clusters carry a negative charge. Third, we leverage our microscopic understanding to suggest and test modifications to increase the cation transference number.
1:39PM S40.00011: Exploring the ion solvation environments in solid-state polymer electrolytes at different concentrations through free-energy sampling.  
SIDDHARTH SUNDARARARAMAN (Presenter), DAVID PRENDERGAST, Lawrence Berkeley National Laboratory — A major obstacle to improving the performance of Li ion solid state polymer electrolyte batteries is that the exact mechanism of ion conduction in such systems is not well understood. A deeper understanding of solvation from atomistic simulations would prove to be a great stride towards overcoming this challenge. Unfortunately, systematic differences were observed in local forces predicted by various classical force fields in literature and ab-initio results for the system of interest (PEO/LiTFSI). Hence, parameters in the GAFF potential were modified to predict various structural features like bond length, angles and dihedrals in closer agreement with ab-initio estimates, resulting in significant improvements in the local interactions between atoms. These accurate classical force fields were then applied to the study of ion solvation cages and transport in these electrolytes at different ion concentrations. Accelerated molecular dynamics and free-energy sampling techniques were employed to explore the distribution of solvation cages within these electrolytes, their variation with concentration and hopping between them as a possible mechanism of transport. These insights will go a long way towards understanding the mechanism of ion solvation and conduction.

1:51PM S40.00012: Ion Correlation and Collective Dynamics in Organic Electrolytes and Ionic Liquid Mixtures: From Dilute Solutions to the Ionic Liquid Limit  
CHANG YUN SON (Presenter), Chemistry, Pohang University of Science and Technology, JESSE G. MCDANIEL, Chemistry, Georgia Tech — Quantifying ion association and collective dynamical processes in electrolytes is essential for fundamental property interpretation and optimization for electrochemical applications. The extent of ion correlation depends on both the ion concentration and dielectric strength of the solvent; ions may be largely uncorrelated in sufficiently high-dielectric solvents at low concentration, but properties of concentrated electrolytes are dictated by correlated and collective ion processes. In this work, we utilize molecular dynamics simulations to characterize ion association and collective ion dynamics in electrolytes composed of binary mixtures of BMIM$^+$BF$_4^-$ and various organic solvents, water, and LiTFSI salt. We illustrate different physical regimes of characteristically distinct ion correlations for the systematic range of electrolyte concentrations and solvent dielectric strengths. Electronic polarization and solvent dielectric controls the extent of ion pairng and clustering, changing the dominant ion correlation mechanism characterized by quantifying the fractional self and distinct contributions to the net ionic conductivity. The analysis also shed light on understanding the negative transference number observed in ionic liquid mixtures and concentrated polymer electrolytes.

Thursday, March 5, 2020 11:15 AM - 2:15 PM

Session S41 GMAG DMP DCOMP: Emergent magnetism in correlated electron systems II  
707 - Bruce Gaulin, McMaster University
11:15AM S41.00001: Scanned-probe study of spin pumping from Y$_3$Fe$_5$O$_{12}$ into two-dimensional materials using ferromagnetic resonance force microscopy  GUANZHONG WU (Presenter), DONGYING WANG, Department of Physics, The Ohio State University, RYAN MUZZIO, Department of Physics, Carnegie Mellon University, YANG CHENG, GUIXIN CAO, Department of Physics, The Ohio State University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, CHUN NING LAU, FENGYUAN YANG, Department of Physics, The Ohio State University, SIMRANJEET SINGH, JYOTI KATOCH, Department of Physics, Carnegie Mellon University, MARC BOCKRATH, P CHRIS HAMMEL, Department of Physics, The Ohio State University — Driving a ferromagnet to resonance will generate spin current normal to the interface with an adjacent normal metal due to spin pumping. Spin angular momentum dissipation in normal metal will lead to increasing damping in the ferromagnet. This phenomenon is less understood in the case of the ferromagnet/two-dimensional materials interface. Graphene, the best-known two-dimensional material, has a spin diffusion length of order of 1um, making it a poor spin sink. However, there are reports of detectable spin pumping from Y$_3$Fe$_5$O$_{12}$ (YIG) into CVD grown graphene that is attributed to large Rashba-Edelstein effect at the YIG/Graphene interface. Here we report a study of spin pumping in YIG/graphene heterostructures using local, force detected ferromagnetic resonance (FMR). This technique can detect FMR in an area of a few microns and, therefore, enables study of exfoliated two-dimensional materials, which have better crystal quality than CVD grown materials. We discuss spin pumping in pristine graphene as well as graphene/transition metal dichalcogenide bilayers studied using scanned ferromagnetic resonance force microscopy. We will also discuss the surprising discovery of a magnetic uniaxial anisotropy induced in a thin YIG film by the transition metal dichalcogenide overlayer.

11:27AM S41.00002: Localized gap states in oxides and their anti-doping*  OLEKSANDR MALYI (Presenter), ALEX ZUNGER, University of Colorado, Boulder — In standard unreactive doping, adding charge carrier to a compound results in a shift of the Fermi level towards the conduction band for electron doping and towards the valence band for hole doping. We point out a curious case of anti-doping where p-type (n-type) doping results in band gap opening, moving the previously occupied (unoccupied) bands to the principal conduction (valence) band and reducing conductivity. We find that this is a generic behavior for a class of materials and find inverse-design principles for detecting such materials. For instance, early transition metal oxides where the sum of composition-weighed formal oxidation states is positive (e.g., TiO$_{2-x}$, CeO$_{2-x}$, Ba$_2$Ti$_6$O$_{13}$ and Ba$_4$Ti$_{12}$O$_{27}$) tend to form in the band gap an intermediate trapped electron band localized on reduced cation orbitals. Upon p-type doping of such materials, hole annihilates a trapped electron on just one cation; consequently, electronically equivalent cation sublattices in the undoped compound become electronically distinct after doping, i.e., symmetry breaking. We give specific theoretical predictions for target compounds where hole and electron anti-doping might be observed experimentally for the first time.

*This work is supported by NSF-DMR-EPM.
11:39AM S41.00003: Charge disorder induced magnetic order  JINNING HOU (Presenter), Tsung-Dao Lee Institute, YUTING TAN, Natl High Magnetic Field Lab, WEI KU, Tsung-Dao Lee Institute — We propose a scenario of inducing magnetic order via charge disorder in systems with coexisting local moment and itinerant degrees of freedom. By disrupting quantum magnetic fluctuation originated by the itinerant carriers, the long-range magnetic order of the local moment can emerge. We demonstrate this mechanism using realistic spin-model for the undoped FeSe as an example and demonstrate the appearance of anti-ferromagnetic order with enough disruption. This mechanism provides a possible resolution to the observation in many strongly correlated materials, for example the ruthenates [1] in which clean non-magnetic samples turns magnetic with introduction of small number of impurities during synthesis.

11:51AM S41.00004: Magnetic avalanches induced by magnetic sweep rate in a cluster glass  SHALINEE CHIKARA (Presenter), CMS, National High Magnetic Field Laboratory, GIA-WEI CHERN, Department of Physics, University of Virginia, NEIL HARRISON, JOHN SINGLETON, NHMFL, Los Alamos National Laboratory, LEONARDO CIVALE, Quantum Material Group, Los Alamos National Laboratory, JOHN MITCHELL, Materials Science Division, Argonne National Laboratory, VIVIEN ZAPF, NHMFL, Los Alamos National Laboratory — We study magnetic avalanches in La$_{1-x}$Sr$_x$CoO$_3$ and show that we can induce these avalanches for certain magnetic field sweep rates. La$_{1-x}$Sr$_x$CoO$_3$ with 0.1 ≤ x ≤ 0.15 are magnetic cluster glasses consisting of magnetic Co clusters seeded by Sr dopant atoms, surrounded by non-magnetic Co ions. For certain ranges of magnetic field sweep rates, large and random steps are observed in the magnetization, consistent with near-system-size magnetic avalanches. Beyond this range, magnetic field sweep rates produce smooth curves of magnetization vs magnetic field. We develop a model effectively showing that the magnetic interactions between the clusters are controlled by the magnetic field sweep rate.
**12:03PM S41.00005: The Role of Charge Doping in High Entropy Perovskite Oxides**

ALESSANDRO MAZZA (Presenter), YOGESH SHARMA, ELIZABETH SKOROPATA, WENRUI ZHANG, Materials Science and Technology Division, Oak Ridge National Lab, THOMAS HEITMANN, University of Missouri Research Reactor, TIMOTHY R CHARLTON, Neutron Sciences Division, Oak Ridge National Lab, JOHN WILLIAM FREELAND, Argonne National Lab, THOMAS ZAC WARD, Materials Science and Technology Division, Oak Ridge National Lab — Disorder is an important aspect of correlated quantum systems. As examples, it can be used to manipulate superconductivity, magnetic ordering, and enable scaling of non-fermi liquid responses. While synthesis of new quantum materials is generally focused on creating perfect crystals comprised of only a few elemental building blocks, we will present our recent efforts to create high quality single crystals with a high degree of configurational elemental disorder on sublattice sites. Complex crystal structures comprising two or more sublattices, such as those in the perovskite family, are particularly promising. This is due to the nearest neighbor cations on one configurationally disordered sublattice being tied together by an intermediate common and uniform anion sublattice. We will present our recent stabilization of single crystal epitaxial films of the ABO$_3$ perovskite, La(Cr$_{0.2}$Mn$_{0.2}$Fe$_{0.2}$Co$_{0.2}$Ni$_{0.2}$)O$_3$. Hole doping the A site with Sr is shown to give access to unexpected functional responses, as demonstrated by transport, magnetometry, x-ray spectroscopy, and neutron studies.

**12:15PM S41.00006: Classification of materials with phonon angular momentum and microscopic origin of angular momentum**

SINISA COH (Presenter), University of California, Riverside — We group materials into five symmetry classes and determine in which of these classes will phonons generically carry angular momentum. In some classes of materials, phonons acquire angular momentum via the forces induced by relative displacements of atoms out of their equilibrium positions. However, for other materials, such as ferromagnetic iron, phonon angular momentum arises from the forces induced by relative velocities of atoms. These latter effects are driven by the spin-orbit interaction.

*This work was supported by grant NSF DMR-1848074.
12:27PM S41.00007: The Role of Oxygen Vacancies in the Magnetic and Electronic Structure of La$_{0.7}$Sr$_{0.3}$MnO$_3$ * ZACHARY ROMESTAN (Presenter), Department of Physics and Astronomy, West Virginia University, A. C. GARCIA-CASTRO, School of Physics, Universidad Industrial de Santander, XU HE, Physique Théorique des Matériaux, Université de Liège, MIKEL HOLCOMB, ALDO H ROMERO, Department of Physics and Astronomy, West Virginia University — Perovskite manganites host a variety of phenomena such as (anti)ferromagnetism, charge and orbital order, metal-insulator transitions, and colossal magnetoresistance that are highly sensitive to charge carrier density and crystal structure. As with cation substitution, oxygen vacancies can provide control over these parameters through electronic doping and steric effects. In our investigation, we consider the role of oxygen vacancies on the magnetic, electronic, and structural properties of La$_{0.7}$Sr$_{0.3}$MnO$_3$-$\delta$ within the DFT+U formalism. In order to isolate the effects of the vacancies, we utilize the Virtual Crystal Approximation to treat the La/Sr content. We report the cases when $\delta = 0.125$, 0.25, and 0.5. For each system, we consider all symmetry inequivalent vacancy sites. We optimize each structure to determine the energetically favorable vacancy sites and magnetic ordering. For the low energy structures, we determine the vacancy formation energy, electronic structure, magnetic structure, magnetic exchange coupling parameters, and conductivity. From the results, we correlate the calculated properties with the effects of the vacancies on the orbital character.

12:39PM S41.00008: Insulating antiferromagnetism in VTe DAVID PARKER (Presenter), LIURUKARA D SANJEEWA, XIAOPING WANG, VALENTINO COOPER, YAOHUA LIU, ATHENA S. SEFAT, Oak Ridge National Lab — We report a comprehensive theoretical and experimental study on the vanadium monotelluride VTe, which crystallizes in the NiAs hexagonal structure. First principles calculations reveal a complex hierarchy of magnetic interactions and energy scales, with the ground state theoretically determined as an \((1/2,0,1)\) antiferromagnetic ordering with insulating character and a band gap of 0.5 eV. These interactions vary significantly from a nearest-neighbor or extended Heisenberg-like model, suggesting a similarity to the parent state of the iron-based superconductors and the possibility of superconductivity if appropriately doped. Experimental synthesis and characterization efforts find a substantially off-stoichiometric orthorhombic structure (a defect NiAs structure) with composition V$_{0.85}$Te, and an apparent Neel point of some 45 K. Our first principles calculations find the stoichiometric phase VTe to have a negative Vanadium defect formation energy, thus explaining the formation of the off-stoichiometric phase.
12:51PM S41.00009: On-chip terahertz characterization of the antiferromagnet CaFe$_2$O$_4$*

DANIEL HELIGMAN (Presenter), RACHEL RESNICK, Ohio State Univ - Columbus, LUNYONG ZHANG, Laboratory for Pohang Emergent Materials and Max Plank POSTECH Center for Complex Phase Materials, Pohang University of Science and Technology, Pohang 790-784, Korea, JAE WOOK KIM, Physics and Astronomy, Rutgers University, SANG-WOOK CHEONG, Rutgers University, Physics and Astronomy, and Laboratory for Pohang Emergent Materials and Max Plank POSTECH Center for Complex Phase Materials, Pohang University of Science, ROLANDO VALDES AGUILAR, Ohio State Univ - Columbus — We report on the magnetic excitations of the antiferromagnet CaFe$_2$O$_4$ as measured with time-domain terahertz spectroscopy via an on-chip device. This material has been previously measured with a free-space terahertz apparatus, showing a magnon excitation at ~725 GHz below the material's Neel temperature of 200 K. We have observed a possible first-order phase transition between 60 K and 120 K, indicating the coexistence of two different magnetic phases. For this experiment the material was measured with a device that generates a terahertz pulse confined to a transmission line. We report on the results of this experiment.

*Funding for this research was provided by the Center for Emergent Materials: an NSF MRSEC under award number DMR-1420451

1:03PM S41.00010: Ferrimagnetism in High Entropy Transition Metal Spinel Oxides*

GRAHAM JOHNSTONE (Presenter), ALANNAH HALLAS, University of British Columbia — High entropy oxides (HEOs) have a crystal structure comprised of chemically ordered oxygen anions and an equimolar proportion of five metal cations randomly distributed over their sublattice. The imposition of large disorder allows configurational entropy to overcome the enthalpy of formation and stabilize a new high entropy phase. HEOs have potential applications ranging from ferroic multifunctionality to reversible energy storage. Studies of the magnetic properties of HEOs to date have been limited to (MgCoNiCuZn)$_{0.2}$O, which has a rock-salt structure. This material undergoes a long-range antiferromagnetic ordering transition at $T_N$=113K despite intense disorder and a 40% magnetic dilution. Here, we present the discovery of three 3$d$-transition metal based ferrimagnetic spinel type HEOs. The high entropy phase is confirmed by Rietveld refinement of powder x-ray diffraction data and elemental microprobe analysis. Magnetic susceptibility measurements of these HEOs suggest that all three transition into ferrimagnetic ordered states between $T$=300K and 400K, followed by a spin reorientation around 100K. In this talk we will present a robust characterization of their magnetic and electronic ground states via heat capacity and resistivity measurements.

*SBQMI
**1:15PM S41.00011: Giant Electric Field Modulation of Magnetism in Ferrimagnetic Heusler Heterostructures**  QILONG SUN (Presenter), SOHEE KWON, NICHOLAS KIOUSSIS, California State University, Northridge — The demand for high efficient magnetoelectric random access memory (MeRAM) requires the search of novel materials and magnetic tunnel junction stacks with voltage-controlled magnetic anisotropy (VCMA) efficiency greater than the 1000 fJ/(Vm) challenge. In this talk, we will present predictions of *ab initio* electronic structure calculations of the VCMA of Ir/Mn$_3$Ga/MgO heterostructures, in which the ultrathin ferrimagnetic Mn$_3$Ga has the tetragonal DO$_{22}$ structure. We find that the Mn$_{\text{II}}$-Mn$_{\text{II}}$ (Mn$_{\text{I}}$-Ga-) terminated interfaces exhibit large out-of-plane (in-plane) magnetic anisotropy (MA). More importantly, the calculations reveal colossal PMA and VCMA efficiency of about one order of magnitude higher than the values reported today. We demonstrate that both the MA and VCMA depend critically on the heavy metal thickness. We also predict a sign reversal of the VCMA efficiency from the Mn$_{\text{II}}$-Mn$_{\text{II}}$ to the Mn$_{\text{I}}$-Ga-terminated interface. Our results show that the dominant contribution to both the PMA and VCMA arises from the strong spin-orbit-coupling of Ir and the E-field induced shift of the Ir $d$-derived orbitals. These findings provide useful guiding rules in the design of more energy-efficient ferrimagnetic-based MeRAM devices.

**1:27PM S41.00012: Hybrid Purification and Sampling Approach for Thermal Quantum Systems**  JING CHEN (Presenter), MILES STOUDENMIRE, Simons Foundation — We propose an algorithm combining two methods for studying finite-temperature quantum systems with tensor networks. One approach is the ancilla method, which gives high-precision results but scales poorly at low temperatures. The other is the minimally entangled typical thermal state (METTS) sampling algorithm which scales better than the ancilla method at low temperatures and can be parallelized, but requires many samples to converge. Our proposed hybrid of these two purifies physical sites in a small central spatial region with partner ancilla sites, sampling the remaining sites by the METTS. Observables measured within the purified cluster have much lower sample variance than in the METTS approach, while sampling the sites outside the cluster reduces their entanglement and the computational cost of the algorithm. The sampling steps of the algorithm remain straightforwardly parallelizable. The hybrid approach also solves an important technical issue with METTS that makes it difficult to benefit from quantum number conservation. By studying $S=1$ Heisenberg ladder systems, we find the hybrid method converges more quickly than both the ancilla and METTS algorithms at intermediate temperatures and for systems with higher entanglement.

Fermi surface investigation of intermetallic La$_2$Pt$_3$Ge$_5$*  

ELIZABETH GREEN (Presenter), National High Magnetic Field Laboratory, JOHANNES KLOTZ, KATHRIN GOETZE, HLD (HZDR) / TU Dresden, TOBIAS FOERSTER, MARC UHLARZ, HLD (HZDR), ALIX MCCOLLAM, HFML-Nijmegen, JENNIFER NEU, THEO SIEGRIST, National High Magnetic Field Laboratory, TINO GOTTSCHALL, HLD (HZDR), JOACHIM WOSNITZA, HLD (HZDR) / TU Dresden, KEFENG WANG, CEDOMIR PETROVIC, Brookhaven National Laboratory — Rare-earth intermetallic compounds, specifically those in the R$_2$T$_3$X$_5$ family (where R is rare-earth, T is transition metal, and X is p-block element), have garnered interest due to their novel electronic and magnetic properties. Though they have been a topic of research for decades, detailed Fermi surface studies have been lacking. To fill this void, we performed de Haas-van Alphen effect measurements on La$_2$Pt$_3$Ge$_5$, which was reported to have the highest critical temperature in the R$_2$T$_3$X$_5$ family, $T_c \sim 8.1$ K [1], though the presence of superconductivity is a topic of debate [2]. Our results from a high-quality sample evidence several small pockets in the Fermi surface. Electronic band structure calculations and the implications of our results will be discussed.

High-field resonant torsion magnetometry as a probe of magnetic phases in honeycomb lattice Na$_2$IrO$_3$*  

CHRISTOPHER POCS (Presenter), IAN LEAHY, PETER SIEGFRIED, GANG CAO, Physics, University of Colorado, Boulder, ARKADY SHEKHTER, DC Facility, National High Magnetic Field Laboratory, ROSS MCDONALD, NHMFL-PFF, Los Alamos National Laboratory, MINHYEA LEE, Physics, University of Colorado, Boulder — We probe magnetoanisotropy of the quasi-2d honeycomb antiferromagnet Na$_2$IrO$_3$ via resonant torsion magnetometry in pulsed fields up to 65T. In recent years, this material has received much experimental and theoretical attention as a candidate for realizing Kitaev spin-liquid physics. At low temperatures, Na$_2$IrO$_3$ has a robust zigzag AFM ground state and unambiguous signatures of any field-induced transition out of this state have remained elusive so far. Our analysis of the magnetoanisotropy reveals unusual field and angular dependence at high field and a possible signature of a field-driven transition to a quantum disordered state, providing strong evidence for a potential quantum spin liquid phase at high field. We will discuss how resonant torsion magnetometry can extract detailed thermodynamic information and show how it is used to map the entire magnetic free energy in real space from data at only a handful of low symmetry angles. These results are compared to the case of related Heisenberg Kitaev material RuCl$_3$.

2:03PM S41.00015: Quasi-2D magnon identification in antiferromagnetic FePS$_3$ via magneto-Raman spectroscopy  
JEFFREY SIMPSON (Presenter), Towson Univ, AMBER MCCREARY, THUC MAI, ROBERT MCMICHAEL, JASON E DOUGLAS, NICHOLAS BUTCH, CINDI DENNIS, ANGELA HIGHT WALKER, NIST, ROLANDO VALDES AGUILAR, Ohio State Univ — The recent discovery that van der Waals-bonded magnetic materials retain long range magnetic ordering down to a single layer stimulates a thorough magneto-Raman study of one such material, FePS$_3$, a large spin ($S = 2$) Mott insulator where the Fe atoms form a honeycomb lattice. Bulk FePS$_3$ was shown to be a quasi-2D Ising antiferromagnet, with additional features in the Raman spectra emerging below the Neel temperature ($T_N \approx 120$ K). Using temperature and magnetic field dependent Raman spectroscopy as an optical probe of magnetic structure, we demonstrate that one of these Raman-active modes below $T_N$ is a magnon with a frequency of $\approx 3.7$ THz (122 cm$^{-1}$). Contrary to previous work, which interpreted this feature as a phonon, our Raman data shows the expected frequency shifting and splitting of the magnon as a function of temperature and magnetic field, respectively, were we find the $g$-factor $= 2$. In addition, the symmetry behavior of the magnon is studied by polarization-dependent Raman spectroscopy and explained using the magnetic point group of FePS$_3$. Temperature dependence of the Raman-active phonons will also be discussed.

Session S42 GMAG: Spin-Orbit Torques  
Thursday, March 5, 2020 11:15 AM - 2:03 PM

11:15AM S42.00001: Partitioning the spin-orbit torque in heavy metal/ferromagnet heterostructures*  
FEI XUE (Presenter), University of Maryland & National Institute of Standards and Technology, PAUL HANEY, National Institute of Standards and Technology — In heterostructures composed of heavy metals and ferromagnets, the spin-orbit torque is the result of reduced symmetry and the presence of spin-orbit coupling. In order to optimize the spin-orbit torque efficiency, we provide a general scheme to identify the contributions to the intrinsic spin-orbit torque due to the wave-function change induced by an external electric field in the steady state. Using a toy model of a bilayer system with atomic p-orbitals, we find both spin current from spin Hall effect and Berry curvature-like pseudo-magnetic field contribute to the torque. We next apply our analysis to first-principles calculation of spin-orbit torque in multilayer Pt/Co and 1T'-WTe2/Co systems. The additional in-plane symmetry breaking in 1T'-WTe2 allows for an unconventional out-of-plane torque. We find that the atomic orbital current can be transferred to spin current at the interface heavy metal layer, which is the dominant spin current contribution to the torque. The contributions identified by our partitioning scheme in the ferromagnet/heavy metal heterostructure could shed light on how to improve the spin-orbit torque switch efficiency.

11:27AM S42.00002: Bulk versus Interface Contributions to the Spin-Orbit Torque in Ferromagnetic Heterostructures*  FARZAD MAHFOUZI (Presenter), NICHOLAS KIOUSSIS, California State University, Northridge — We present an ab initio-based theoretical framework which elucidates the origin of the bulk versus interface contributions to the spin-orbit torque (SOT) in Heavy-Metal(HM)/Ferromagnet(FM) heterostructures. We find that (i) the Field-Like (FL) SOT is dominated by the interface component and (ii) both components contribute to the Damping-Like (DL) SOT on equal footing. We demonstrate that the FL-SOT can be expressed in terms of the non-equilibrium spin-resolved orbital moment accumulation. The calculations reveal that the experimentally reported oxygen-induced sign-reversal of the FL-SOT in Pt/Co bilayers is due to the significant reduction of the majority-spin orbital moment accumulation on the interfacial HM atoms.

*The work is supported by NSF ERC-Translational Applications of Nanoscale Multiferroic Systems (TANMS)- Grant No. 1160504.

11:39AM S42.00003: Spin-orbit torque generated by amorphous Fe\textsubscript{x}Si\textsubscript{1-x}  CHENG-HSIANG HSU (Presenter), Electrical Engineering and Computer Science, University of California, Berkeley, JULIE E KAREL, Materials Science and Engineering, Monash University, NIKLAS ROSCHEWSKY, DINAH SIMONE BOUMA, Physics, University of California, Berkeley, SCOTT BENNETT, ALEXANDER NGUYEN, Materials Science and Engineering, Monash University, SURAJ S CHEEMA, Materials Science and Engineering, University of California, Berkeley, SHEHRIN SAYED, Electrical Engineering and Computer Science, University of California, Berkeley, FRANCES HELLMAN, Physics, University of California, Berkeley, SAYEEF SALAHUDDIN, Electrical Engineering and Computer Science, University of California, Berkeley — Despite the tremendous amount of work that has gone into spin-orbit torque and spin current generation in heavy metals, questions on the origin of the underlying physics still remain, often stemming from the challenge in differentiating between spin currents that are generated from the bandstructure of the heavy metal, and other sources, such as inversion symmetry breaking at the interface and or scattering. Here we report observation of spin-orbit torque under room temperature in fully amorphous non-magnetic Fe(x)Si(1-x)/cobalt bilayer via spin-torque ferromagnetic resonance and harmonic Hall measurements. Both techniques provide a consistent spin Hall angle of about 3%. According to the conventional theory of the spin Hall effect, a spin current in an amorphous material is not expected to have any contribution from the bandstructure. Despite this fact, our observation of a reasonably strong spin-orbit torque paves a new avenue for understanding the underlying physics of spin-orbit interaction.
11:51AM S42.00004: Transverse and parallel spin-torque ferromagnetic resonance for improved measurements of spin-orbit torques  SABA KARIMEDDINY (Presenter), JOSEPH MITTELSTAEDT, ROBERT BUHRMAN, DANIEL RALPH, Cornell University — We present a method to quantify the contribution of the spin-pumping/inverse-spin-Hall-effect (SP-ISHE) voltage to spin-torque ferromagnetic resonance (ST-FMR) measurements of spin-orbit torques. In this approach the resonant homodyne voltages transverse to and parallel to the applied microwave current are measured simultaneously. We leverage the fact that spin-pumping only contributes as a symmetric Lorentzian to derive consistency conditions which allow the SP-ISHE to be separated from the rectification signals associated with the spin-orbit torque. The method does not require knowledge of parameters such as the effective spin mixing conductance and spin diffusion lengths of heavy metals. Our findings show that for some material combinations SP-ISHE can alter the ST-FMR signal significantly, and the relative sign of rectification and SP-ISHE is unambiguously determined.

12:03PM S42.00005: Interfacial contributions to spin-orbit torque and magnetoresistance in ferromagnet/heavy-metal bilayers*  KIRILL BELASHCHENKO (Presenter), ALEXEY KOVALEV, Department of Physics and Astronomy, University of Nebraska - Lincoln, MARK VAN SCHILFGAARDE, Department of Physics, King's College London — The thickness dependence of spin-orbit torque and magnetoresistance in ferromagnet/heavy-metal bilayers is studied [1] using the first-principles non-equilibrium Green’s function formalism combined with the Anderson disorder model. A systematic expansion in orthogonal vector spherical harmonics is used for the angular dependence of the torque. The damping-like torque in Co/Pt and Co/Au bilayers can be described as a sum of the spin-Hall contribution, which increases with thickness in agreement with the spin-diffusion model, and a comparable interfacial contribution. The magnetoconductance in the plane perpendicular to the current in Co/Pt bilayers is of the order of a conductance quantum per interfacial atom, exceeding the prediction of the spin-Hall model by more than an order of magnitude. This suggests that the "spin-Hall magnetoresistance," similarly to the damping-like torque, has a large interfacial contribution unrelated to the spin-Hall effect.

*This work was supported by NSF through DMR-1609776 (K.B.) and Nebraska MRSEC DMR-1420645 (K.B. and A.K.), DOE grant DE-SC0014189 (A.K.), and EPSRC CCP9 Flagship Project EP/M011631/1 (M.v.S.).
**Field-free spin-orbit torque switching of Cr-induced perpendicular magnetization**  

TSAO-CHI CHUANG (Presenter), Department of Physics, National Taiwan University, CHI-FENG PAI, Department of Materials Science and Engineering, National Taiwan University, SSU YEN HUANG, Department of Physics, National Taiwan University — Current-induced spin-orbit torque (SOT) switching in a heterostructure with perpendicular magnetic anisotropy (PMA) has attracted great attention, as a new writing method for spintronic devices. However, this highly attractive switching scheme is often accompanied by an unfavorable external magnetic field. In this work, we show that the 3d Cr, without any heavy metals and the MgO layer, can induce strong interfacial PMA and deliver deterministic SOT switching. Most importantly, we demonstrate field-free SOT switching in 3d Cr without any complex schemes, including asymmetrical layers, pattern structure, and additional ferromagnetic or antiferromagnetic layers. We show that the underlying cause for the deterministic field-free switching lies in the slanted columnar microstructure for the otherwise uniform thin films. The direction of oblique columnar structure dictates the up and down orientations of the PMA layer, resulting in polarity-controlled field-free SOT switching [1]. Our results uncover the significant role of 3d materials and shed light on field-free SOT magnetization switching.
Current-induced spin-orbit torques have attracted a considerable amount of attention in recent years. The typical structure for studying the spin-orbit torque is a ferromagnetic metal/ nonmagnetic material bilayer. Most research has focused on the spin-orbit torque generated externally by the nonmagnetic material, overlooking the possibility that the ferromagnetic metal can generate spin-orbit torque on itself. We recently discovered that a ferromagnetic metal can in fact generate equal and opposite spin-orbit torques at its surfaces, which is termed as the anomalous spin-orbit torque, due to its analogy to the anomalous spin Hall effect. The strong anomalous spin-orbit torque may challenge our current understanding of spin-orbit torque in bilayer/multilayer systems. It also provides new opportunities that ferromagnet itself can be a source of spin-orbit torques.

Spin-orbit driven spin depolarization in the ferromagnetic Weyl semimetal Co$_3$Sn$_2$S$_2$* SANDEEP HOWLADER (Presenter), Department of Physical Sciences, IISER Mohali, SURABHI SAHA, Department of Physics, Indian Institute of Science, RITESH KUMAR, Department of Physical Sciences, IISER Mohali, VIPIN NAGPAL, SATYABRATA PATNAIK, School of Physical Sciences, Jawaharlal Nehru University, TANMOY DAS, Department of Physics, Indian Institute of Science, GOUTAM SHEET, Department of Physical Sciences, IISER Mohali — Co$_3$Sn$_2$S$_2$ has recently emerged as a ferromagnetic Weyl semimetal. Previous experiments and theoretical investigations of the band structure have provided an indication of the possibility of half-metallicity in this compound. However, our spectroscopic investigations have shown that a spin-polarized super-current flows through a Nb/Co$_3$Sn$_2$S$_2$ point contact with a large Andreev reflection indicating a huge deviation from half-metallic character. In fact, we have observed a 50% spin polarization at the Fermi level. Theoretical calculation of the electronic density of states with inclusion of spin-orbit coupling showed that this deviation stems from a spin depolarizing effect near the Fermi energy. Additionally, the calculations revealed a particle-hole asymmetry that explains our experimental observation of asymmetric Andreev reflection spectra.

*SERB EMR/2016/003998

Spin Orbit Torque in Graphene/Co Heterosystem KENAN SONG (Presenter), AURELIEN MANCHON, UDO SCHWINGENSCHLOGL, King Abdullah Univ of Sci & Tech (KAUST) — The spin-orbit torque (SOT) technique has opened new horizons for the development of innovative magnetic devices beyond memories and data storage. When graphene is attached to the surface of Co (001), the inversion symmetry is broken, which results in the onset of a built-in perpendicular electric field. As a result, in the presence of the large spin-orbit coupling of Co, Rashba effect emerges at the interface. Therefore, a spin density driven by a net current can be achieved at the interface, bringing SOT into such a heterostructure. With density functional theory, we show that Co atoms at the interface exhibit spin-momentum locking, which is in line with the experiments. Around the Fermi level, the graphene Dirac cones couple with the Co 3d states around the K and K' points, resulting in a spin texture odd in momentum k. This special spin texture promotes current-driven SOT. We then project the band structure obtained by first principles onto Wannier orbitals to get the tight-binding Hamiltonian. Non-equilibrium properties then are calculated using the Kubo formula. Our results show that the SOT can be used to electrically control the magnetization of the Co layer and to realize fast electronic device.
1:27PM S42.00010: Time-evolution of spin-orbit torque and magnetization in Rashba ferromagnet from multiscale time-dependent-quantum-transport/classical-micromagnetics formalism UTKARSH BAJPAI (Presenter), BRANISLAV NIKOLIC, Univ of Delaware — Spin-orbit torque originates in a ferromagnetic material when the nonequilibrium electronic spin density emerging due to spin-orbit coupling is noncollinear to the local magnetization. In this work, we investigate the time-evolution of spin-orbit torque in a Rashba ferromagnet using a recently developed quantum-classical hybrid framework where quantum electrons described by time-dependent nonequilibrium Green functions (TDNEGF) are self consistently coupled to local magnetization dynamics described by classical-micromagnetics using the Landau-Lifshitz-Gilbert (LLG) equation. It has been previously shown that such a self-consistent TDNEGF+LLG framework microscopically generates a spatially inhomogeneous and time-dependent dynamical Gilbert damping [1] through a memory kernel, contrary to conventional micromagnetics where a static Gilbert damping parameter is introduced phenomenologically. Here, we explore the influence of Rashba spin-orbit coupling on the resulting time-dependent spin-orbit torque, magnetization dynamics and dynamical Gilbert damping parameter in our TDNEGF+LLG framework which is further compared to the Gilbert damping parameter and magnetization dynamics evaluated using the scattering matrix theory.

1:39PM S42.00011: Theoretical study of spin torque and domain wall motion on ferromagnetic Kagome lattice SEHOON KIM (Presenter), KENTARO NOMURA, Institute for Materials Research, Tohoku University — We theoretically study spin torque and domain wall motion induced electrically in a ferromagnetic Kagome lattice, which has spin-orbit coupling. For details, we suppose the exchange interaction with an inhomogeneous magnetic texture of uniaxial magnetic anisotropy and the spin-dependent second-nearest neighbor hopping acting as the spin-orbit coupling. Because of the chiral edge conduction, electric charges are accumulated around the domain wall. We calculate the spin polarization of localized charges as a response of the electric field by the Kubo formula. As a result, the spins of localized charges are polarized and exert spin torque on the domain wall. Firstly, we discuss the spin torque and domain wall motion in two-dimensional limits of the ferromagnetic Kagome lattice. [1] Second, we extend the 2D model to thin films of Kagome-lattice shandite, [2] which are more realistic. All of the two models cause non-adiabatic spin-transfer torque on the domain wall reducing the intrinsic threshold current. These results and discussions suggest a good comparison between ideal models and realistic models in terms of spin torques in topological materials.

Current-induced unidirectional magnetoresistance in FeRh/Pt bilayers

JULIE SHIM (Presenter), Physics, University of Illinois at Urbana-Champaign, HILAL SAGLAM, Materials Science Division, Argonne National Laboratory, KISUNG KANG, Materials Science and Engineering, University of Illinois at Urbana-Champaign, JUNSEOK OH, Physics, University of Illinois at Urbana-Champaign, YI LI, Materials Science Division, Argonne National Laboratory, WEI ZHANG, Physics, Oakland University, MATTHEW GILBERT, Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, ANDRE SCHLEIFE, AXEL HOFFMANN, Materials Science and Engineering, University of Illinois at Urbana-Champaign, JOSEPH SKLENAR, Physics and Astronomy, Wayne State University, NADYA MASON, Physics, University of Illinois at Urbana-Champaign — Antiferromagnetic (AFM) spin-orbit torque oscillators are important due to potential applications ranging from magnetic random-access memory to THz emitters. However, AFM spin-torque oscillators operate in the THz-range, and direct observation of THz magnetization dynamics is difficult. Previously, in ferromagnetic spin-torque oscillators, current-induced unidirectional magnetoresistance (UMR) signals accompanied the emission of microwave radiation at the ferromagnetic resonance frequency [1,2], which implies that observations of UMR may provide indirect evidence of AFM-resonance. Here we present transport results on magnetron sputtered AFM FeRh/Pt films, fabricated into nanowire geometries. A current-induced UMR is observed, in addition to anisotropic magnetoresistance effects. These findings suggest a route toward designing AFM spin-orbit torque oscillators.

Thursday, March 5, 2020 11:15 AM - 1:51 PM

Session S43 DCOMP DMP: Computational Design and Discovery of Novel Materials IV: 2D and Layered Materials - Kai-Ming Ho, Iowa State University - Tag(s): Focus
11:15AM S43.00001: Computational Discovery at the Interface of Chemistry and Materials: 1D Carbon Nanothreads and 2D Polar Metals* [Invited] VINCENT CRESPI (Presenter), YUANXI WANG, BO CHEN, TAO WANG, NADIRE NAYIR, BOYANG ZHENG, ADRI C.T. VAN DUIN, Pennsylvania State University, ROALD HOFFMANN, Cornell — The total number of equilibrium crystal structures composed from subsets of the periodic table is likely bounded fairly strictly by phase separation of multi-component mixtures. In contrast, the design space afforded by metastable structures is essentially unbounded: the key challenge here is to craft kinetic constraints that access structures with compelling properties. One strategy to this end deploys the immense design power of synthetic organic chemistry within a solid-state context to produce carbon nanothreads of diverse compositions and properties as ordered lattices comprising uniquely one-dimensional sp³ or mixed sp²/sp³ macromolecules at the ultimate juncture between crystalline rigidity and molecular control. These systems exhibit unique behaviors as the thinnest possible objects whose rigidity is maintained by covalent bonds. In two dimensions, kinetic control in service of unique structure can also be obtained by crafting similarly unique synthesis "containers", for example the gallery between silicon carbide and epitaxial graphene, which can host a broad family of epitaxial, air-stable, crystalline two-dimensional polar metals with record-breaking optical nonlinearities, excellent surface-enhanced Raman performance, and intriguing prospects for the integration of metals into quantum heterostructures. In both cases, predictive computational theory can provide strong guiding principles.

11:51AM S43.00002: Robust Half-Metallicity and Perfect Spin Filtering in 2D oxide layer* ARQUM HASHMI (Presenter), Center for Computational Sciences, University of Tsukuba, Japan, KENTA NAKANISHI, Graduate School of Pure and Applied Sciences, University of Tsukuba, Japan, MUHAMMAD UMAR FAROOQ, Department of Physics, Southern University of Science and Technology, Shenzhen, China, TOMOYA ONO, Department of Electrical and Electronic Engineering, Kobe University, Japan — We use first-principles calculations to demonstrate the transition metal oxide monolayer (ML) of Cr₂O₃ as an ideal candidate for next-generation spintronics applications. Cr₂O₃ ML has a honeycomb-kagome lattice that possesses the kagome band characteristics, where the Dirac and strongly correlated fermions coexist around the Fermi level. Furthermore, the classical Heisenberg Hamiltonian shows strong FM interactions between Cr spins, and the Cr³⁺ ions are in a low-spin state leading to a spin S = 3/2. Cr₂O₃ ML possesses a robust half-metallic behavior with a large spin gap of ~ 3.9 eV and a high T_c = 190 K. We also find that Cr₂O₃ ML displays an intrinsic Ising ferromagnetism with a giant PMAE of ~ 0.9 meV. More importantly, NEGF calculations reveal that the Cr₂O₃ ML exhibits an excellent spin filtering effect.

*This research was partially supported by MEXT as a social and scientific priority issue (Creation of new functional devices and high-performance materials to support next generation industries) to be tackled by using post-K computer, JSPS KAKENHI Grant No. 19K15381, and JSPS Core-to-Core program (Controlled Interfacing of 2D materials for Integrated Device Technology).
**12:03PM S43.00003: Giant polarization charge density at ScN/GaN interfaces**

NICHOLAS ADAMSKI (Presenter), Department of Electrical and Computer Engineering, University of California, Santa Barbara, CYRUS DREYER, Department of Physics and Astronomy, Stony Brook University, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara —

GaN is a wurtzite semiconductor that exhibits a large spontaneous polarization, while ScN is a semiconducting nitride that takes the nonpolar rocksalt crystal structure. Due to small lattice mismatch between ScN and GaN, it is possible to create a polar-nonpolar interface between the two materials.

Using density functional theory and the Berry-phase method, we examine the formal polarization of rocksalt ScN along the [111] direction, finding a polarization discontinuity of -1.358 Cm$^{-2}$. We confirm this finding with explicit ScN/GaN supercell calculations. The polarization discontinuity causes a high-density electron gas to form on the N-polar GaN/ScN interface, and a hole gas to form on the Ga-polar interface, with carrier concentrations up to $8.5 \times 10^{14}$ cm$^{-2}$. The large polarization difference and low lattice mismatch make ScN a promising material for integration with III-nitride electronic and optoelectronic devices.

**12:15PM S43.00004: Quasi-Binary Transition Metal Dichalcogenide Alloys: Thermodynamic Stability Prediction, Scalable Synthesis and Application**

ZAHRA HEMMAT, The University of Illinois at Chicago, JOHN CAVIN (Presenter), Washington University, St. Louis, ALIREZA AHMADIPARIDARI, ALEXANDER RUCKEL, The University of Illinois at Chicago, SUNG BEOM CHO, Korea Institute of Ceramic Engineering and Technology, ROBERT KLIE, The University of Illinois at Chicago, ROHAN MISHRA, Washington University, St. Louis, AMIN SALEHI-KHOJIN, The University of Illinois at Chicago —

Quasibinary alloying in transition metal dichalcogenides (TMDCs) has been successfully used to improve applications including optoelectronics and catalysis. However, the vast compositional space of possible TMDC alloys remains largely unexplored. To guide the synthesis of such alloys, we present ab-initio calculations of equilibrium phase diagrams for 25 TMDC alloys: $M_{1-x}M'_{x}X_{2}$ and $MX_{2(1-x)}X'_{2x}$ ($M,M' = V, Nb, Ta, Mo, W; X,X' = S, Se$). We verify the predictions made by these phase diagrams by synthesizing a subset of 12 alloys using scalable chemical vapor transport. We demonstrate the ability to exfoliate these alloys into few-layers. One of these alloys, Nb$_{1-x}$Ta$_{x}$S$_{2}$, is shown to have outstanding thermal stability, exceptional CO$_{2}$ reduction activity with near zero overpotential, and excellent energy efficiency in a Li-air battery. Our work highlights the large number of TMDC alloys accessible to a scalable synthesis-process. By expanding beyond group VI TMDC alloys, this study lays the groundwork for studying how alloying in group V TMDCs affects novel properties such as superconductivity, magnetism, and topological properties.

12:27PM S43.00005: First-principles prediction of optomechanically controlling phase transition of IV-VI semiconductors  
JIAN ZHOU (Presenter), Xi’an Jiaotong Univ — Diffusional phase-change materials, such as Ge-Sb-Te alloys, are used in rewritable nonvolatile memory devices (PC-RAM). This order-disorder transition contains a large latent heat and requires breaking of chemical bonds. It is thus highly desired to develop new phase change materials with diffusionless and order-to-order transitions to accelerate the read/write kinetics, reduce energy dissipation, and eliminate fatigue. Two-dimensional materials are considered as potential phase change materials. For example, one famous 2D material example is transition metal dichalcogenide monolayer which exists in 2H and 1T' structures. However, it always requires mechanical, electrical, or electrochemical contacts and patterning to trigger phase transition. Non-contacting optical readout/write with focused laser would be preferable in many circumstances, especially for low-dimensional materials which are easily optically accessible. Here, we computationally illustrate an optomechanical strategy, which uses a linearly polarized laser pulse with selected frequency. We will give a few examples of such ultrafast diffusionless martensitic phase transition in various materials. With no or only a few chemical bonds breaking, the phase transition would occur very fast and requires low energy input.

12:39PM S43.00006: Predicting synthesizable multi-functional edge reconstructions in two-dimensional transition metal dichalcogenides*  
GUOXIANG HU (Presenter), ANH PHAM, VICTOR FUNG, XIAHAN SANG, RAYMOND UNOCIC, PANCHAPAKESAN GANESH, Center for Nanophase Materials and Sciences, Oak Ridge National Laboratory — Two dimensional transition metal dichalcogenides have attracted great interest due to their exceptional properties, especially at the edges. Recently, more complex edge reconstructions were discovered experimentally. This poses intriguing questions: what is the whole family of synthesizable reconstructed edges and what are they good for? Here, we develop a high-throughput *ab initio* based computational approach to shed light on this. Using MoS$_2$ as a model, we screened hundreds of edge configurations, leading to predictions of new reconstructions with record thermodynamic stability in addition to the discovered ones. We find that the reconstructed edges can be optimized as catalysts for a wide range of reactions and suited for applications in information storage, spintronics, and topologically protected dissipationless transport from their exhibited wide distribution of work function, half-metallicity, magnetic variations, and intriguing topologically protected edge-states.$^{1,2}$ *Our work reveals the existence of a wide family of synthesizable, reconstructed edges, thereby opening a new field of intrinsic edge engineering of 2D materials as multifunctional materials.*

Hybrid assemblies of two-dimensional octagonal monolayers of C and BN*  

PRASHANT VIJAY GAIKWAD (Presenter), ANJALI KSHIRSAGAR, Univ of Pune — In the dominating regime of hexagonal family, 2D octagonal monolayers (o-MLs) have emerged recently. High coordination cluster assembly route [J. Phys.: Condens. Matter 29, 335501 (2017)] is employed to form o-MLs of C and BN and their hybrid assemblies. The o-MLs are dynamically and thermally stable. Most of the MLs reveal charge transfer among atoms and asymmetric sp$^2$ hybridization. Hybrid assemblies can be tuned from metallic to insulating (4.13 eV). Stacking of zigzag buckled o-MLs forms stable body centered tetragonal bulk phase of C and BN. Dynamically stable nanotubes (NT), obtained by cutting chunk, with diameter 3.6 Å and 3.57 Å for o-C and o-BN respectively, can also be realized as vertically stacked o-rings and can be contrasted with the rolling of hexagonal ML. We thus report a CNT with a size smaller than the reported theoretical limit and synthesized experimentally till now.

Present work has established octagonal ring as a basic unit to form 1D, 2D and 3D materials of groups IV, III-V and II-VI. Studies of their properties, possible constraints, mechanism for stabilization, bonding and hybridization are fascinating and can unlock unusual facts for many applications.

Theoretical studies on excitonic and half-metallic properties in 2D chalcogenides  

XIAOLONG ZOU (Presenter), NANNAN LUO, SHUQING ZHANG, Tsinghua University — In this talk, I will present theoretical investigation on two classes of chalcogenides with interesting properties, i.e., the saddle-point excitons and half-metallicity. First, monolayer b- and γ-phase group-IV monochalcogenides (MX, M = Ge or Sn; X = S or Se) are shown to possess saddle-point and camel's back like band structure, respectively. While saddle-point exciton in b-MX leads to its strong adsorption, render them promising for solar cell applications with power conversion efficiencies as large as 1.11%,[1] a high-temperature exciton gas to electron-hole liquid transition can be achieved in γ-MX. Second, a class of CoGa$_2$X$_4$ (X= S, Se or Te) monolayer with triangular lattice exhibits intrinsic in-plane half-metallic ferromagnetism. The half-metal gaps are large enough (about 0.5 eV) to make them stable against the spin flip under weak external disturbances. We have systematically investigated the underlying origin of the ferromagnetism and predicted their high transition temperature $T_C$.[2]

1:15PM S43.00009: New 2D massless Dirac fermion systems and quantum spin Hall insulators based on sp–sp\(^2\) carbon sheets  MINWOO PARK (Presenter), Physics, Konkuk University, YOUNGKUK KIM, Physics, Sungkyunkwan University, HOONKYUNG LEE, Physics, Konkuk University — Graphene was identified as a quantum spin Hall (QSH) insulator when considering spin-orbit coupling (SOC), which opens a band gap at the Dirac points. This discovery has initiated new research efforts to study the QSH effect on its application for quantum computing and spintronics. Nevertheless, the SOC strength of graphene is too small (~40 µeV) to induce the topological insulator phase in an experimentally achievable temperature regime. Here, we design two-dimensional sp–sp\(^2\) hybrid carbon sheets to discover new Dirac systems, hosting the QSH phase. We find that 21 out of 31 new carbon sheets are identified as Dirac fermion systems without SOC, distinct from graphene in the number, shape, occurring Dirac cones. Furthermore, we find 19 out of the 21 new Dirac fermion systems become QSH insulators with a sizable SOC gap. It is enhanced up to an order of meV, allowing for the QSH effect at experimentally accessible temperatures. Besides, based on the 26 Dirac fermion systems, we find a correlation between the number of Dirac points without SOC and the resultant QSH phase. We hope our findings contribute to new prospects for the design of topological materials with desired properties.

1:27PM S43.00010: A first principle study on the role of Li intercalation in the structural transition from a few-layer black to blue phosphorene*  MD RAJIB KHAN MUSA (Presenter), MING YU, Physics and Astronomy, University of Louisville — A systematic study on the role of Li intercalation played in the structure transition from a few-layer black to blue phosphorene has been carried out from first principle calculations based on the density functional theory. It is found that, depending on Li concentration and configuration intercalated on black phosphorene surface, the structure of the black phosphorous is either maintained its A17 symmetry, transferred to blue phosphorene with A7 symmetry, or distorted to form zigzag chains. Specifically, it was found that within a certain Li configurations intercalated on black phosphorene, Li atoms could play as ‘catalysts’ to drive the specific P atoms moving along specific directions, resulting bond breaking and forming, and subsequently, transforming a few-layer black to a few-layer blue phosphorene. This study opened a new pathway that, at a certain high rate Li intercalation, a feasible transition pathway from black to blue phosphorene. The role of the Li intercalation induced phase transition will be further studied and discussed, which will guide us to identify the specific conditions for such structural transformation.

1:39PM S43.00011: The role of Configurational entropy in real time mass sensing.* Sudeep Adhikari (Presenter), Kevin Stuart David Beach, Univ of Mississippi — We present a theoretical framework for determining the mass deposited on a mechanical resonator subject to a flux of incoming particles of a single species. We consider the specific example of a vibrating nanostring and infer the history of mass deposition events from the frequency shifts in real time using a numerical optimization algorithm that correctly compensates for the configurational entropy. Our approach is tested against simulated data and is shown to perform well. We extend this model for a two particle system and try to comment on its applicability over a multi-particle deposition.

S43.00012: A Computational Study of Layered Sulfides for CO2 Reduction Photocatalysts*

Hao Yu (Presenter), Department of Physics, Southern University of Science and Technology, Elizabeth A Peterson, Jeffrey B Neaton, Department of Physics, University of California, Berkeley — The CO2 reduction reaction (CO2RR) is central to artificial photosynthesis, a means of using excess CO2 in atmosphere to generate solar fuels. While advances have been made in improving efficiency and selectivity of known catalysts for CO2RR, new materials are needed to realize scalable platforms for solar fuels generation. The high valence bands seen in low-band gap layered sulfides show promise for meeting the high redox potentials required for CO2RR, and motivate a focused high-throughput search with first-principles density functional theory (DFT). Our calculations, using van der Waals (vdW) dispersion corrections, lead to nearly a dozen photocatalyst candidates, many which are not identified by prior studies. Refining Materials Project crystal structures with vdW corrections, we find excellent agreement with experimental lattice parameters for our candidate photocatalysts. For the identified materials, we perform HSE06 band edge calculations. The alignment of the band edges with CO2RR potentials and implications for experiments on the newly identified layered sulfide compounds are discussed.

Stabilized Penta-silicene: An Elemental Ferroelectric Material with High Curie Temperature

YAGUANG GUO (Presenter), QIAN WANG, Peking Univ — The compatibility of Si semiconductor technology with current electronic devices has led to continuing search for new Si-based materials with novel properties. The recent synthesis of penta-Si nanoribbons is a new addition to this family. However, penta-silicene, a two dimensional (2D) sheet composed of only Si pentagons, was found to be unstable in penta-graphene-like configuration. Using first-principles calculations and a thorough analysis of its imaginary frequencies, we show that penta-silicene can be made dynamically stable by tilting the Si dimers to reduce the Coulomb repulsion between them. The consequence of this tilting leads to an interesting discovery: the stabilized penta-silicene breaks the centrosymmetry, resulting in intrinsic ferroelectricity with a high Curie temperature of 1190 K. This realizes the spontaneous electrical polarization in a pure 2D Si system, which has the potential to work as a future non-volatile phase change material.

Session S44 DCOMP DMP: Electrons, Phonons, Electron Phonon Scattering, and Phononics V

704 - Xiulin Ruan, Purdue University - Tag(s): Focus
11:15AM S44.00001: Characterization of Thermal Effects in Wide Bandgap Semiconductor Materials and Devices* [Invited] SAMUEL GRAHAM (Presenter), Georgia Inst of Tech — Wide bandgap electronics made from nitrides (e.g., Gallium Nitride (GaN)) and oxides (e.g., Gallium Oxide (Ga$_2$O$_3$)) are currently under development due to their potential to create some of the most advanced RF and power electronic devices in the world. However, the thermal response of these devices under applied electric fields can create large power densities (RF and power electronics) that must be understood. For many of these devices, the electrothermal response plays a strong role in both the acceptable operation or long-term failure and reliability of the devices. Thus, tools that can help elucidate these responses and provide a method to help design better devices is of critical need for this field.

In this talk we will discuss advancements in thermal characterization techniques that have allowed new insights into electrothermal behavior in GaN and Ga$_2$O$_3$ materials and devices. Specifically, a focus on the role of device architecture and material processing will be addressed. For GaN and Ga$_2$O$_3$ RF and power electronics, the role of thermal interfaces in the heat dissipation of both lateral and vertical device architectures will be discussed. We will cover aspects of semiconductor-semiconductor as well as metal-semiconductor interfaces and their roles in device thermal management. A highlight will be the use of plasma activated bonding to provide ultralow thermal resistance interfaces that allow for heterogenous integration of nitrides and oxides with high thermal conductivity substrates. Finally, we will discuss the implications of these effects on device behavior through experiments and modeling.

11:51AM S44.00002: Direct solution to the space-time dependent Peierls-Boltzmann transport equation using an eigendecomposition method CHENGYUN HUA (Presenter), Oak Ridge National Lab — Nonlocal thermal transport is generally described by the Peierls-Boltzmann transport equation (PBE). However, solving the PBE for a general space-time dependent problem remains a challenging task due to the high dimensionality of the integro-differential equation. In this work, we present a direct solution to the space-time dependent PBE with a linearized collision matrix using an eigendecomposition method. Furthermore, we show that there exists a generalized Fourier type relation that links heat flux to the local temperature, and this constitutive relation is valid from ballistic to diffusive regimes. Combining this approach with ab initio calculations of phonon properties, we demonstrate that the derived solution gives a more accurate description of thermal transport in crystals that exhibit weak anharmonicity than the commonly-used single-mode relaxation time approximation and thus will lead to an improved understanding of phonon transport in solids.
12:03PM S44.00003: Calculation of mode Gruneisen parameters made simple  ANGELO BONGIORNO (Presenter), CUNY College of Staten Island — Gruneisen parameters measure the degree of anharmonicity of a material. These parameters can be used to calculate the coefficient of thermal expansion, as well as the thermal conductivity of a material. The existing method to calculate mode Gruneisen parameters relies on the (quasi-)harmonic approximation, and the numerical differentiation of phonon frequencies computed at different volumes (through the use of energy schemes based on either classical force fields or a first principles approach). Here we present a new method to calculate mode Gruneisen parameters. This method involves two steps. First, the calculation of the harmonic frequencies at only the equilibrium volume of a material. Second, for each normal mode, a few self-consistent field calculations are needed to calculate the corresponding mode Gruneisen parameter. In this talk, we discuss the conceptual basis of the new method, its technical implementation and validation, its advantages and disadvantages, and selected applications. In particular, our method in combination with a density functional theory approach is used to calculate mode Gruneisen parameters and the coefficient of thermal expansion of silicon and aluminum.

12:15PM S44.00004: Density functional perturbation theory for lattice dynamics with fully relativistic ultrasoft pseudopotentials: the magnetic case  ANDREA URRU (Presenter), ANDREA DAL CORSO, International School for Advanced Studies — We discuss the extension of density functional perturbation theory for lattice dynamics with fully relativistic ultrasoft pseudopotentials to magnetic materials [1]. We avoid the computation of the response at -q by using explicitly the time-reversal operator, which is applied to the Sternheimer linear system and to its self-consistent solutions, an approach that has been introduced for the calculation of magnons [2]. We validate our implementation by comparison with the frozen phonon method in fcc Ni and in a monatomic ferromagnetic Pt wire, and present an application to MnBi. We are working to extend the technique to the computation of the phonon dispersions of magnetic polar insulators.

Photothermal imaging as a new tool for the investigation of the temperature-dependent properties of the medium in nanoscale  MARYAM ZAHEDIAN (Presenter), BOGDAN DRAGNEA, Chemistry, Indiana University Bloomington — Photothermal imaging is a powerful technique to detect small light-absorbing nanoparticles down to 1.4 nm with a high spatial resolution (1). The signal magnitude is proportional to the absorption cross-section of the nanoparticle as well as properties of the medium. Finite thermal diffusivity of the medium causes a phase delay in the response of the heat dissipation. The phase delay at each point integrated over the resolution disk is identified as the photothermal signal phase that depends on the material property (2). In this study, first, we demonstrate that the photothermal phase is capable of monitoring the local medium modifications, with high sensitivity. Second, we determine that, with the aid of simulation, information about the temperature-dependent properties of the medium, such as heat conductivity is attainable in nanoscale.

Thermal Transport in Phosphorene  GUANGZHAO QIN (Presenter), Department of Mechanical Engineering, University of South Carolina, ZHENZHEN QIN, Zhengzhou Univ — Phosphorene, a novel elemental 2D semiconductor, possesses fascinating chemical and physical properties which are distinctively different from other 2D materials. The rapidly growing applications of phosphorene in nano/optoelectronics and thermoelectrics call for comprehensive studies of the thermal transport properties. In this talk, based on the theoretical and experimental progresses, the thermal transport properties of single-layer phosphorene, multilayer phosphorene (nanofilms), and bulk black phosphorus are summarized to give a general view of the overall thermal conductivity trend from single-layer to bulk form. The mechanism underlying the discrepancy in the reported thermal conductivity of phosphorene is discussed by reviewing the effect of different functionals and cutoff distances on the thermal transport evaluations. This review then provides fundamental insight into the thermal transport in phosphorene by reviewing the role of resonant bonding in driving giant phonon anharmonicity and long-range interactions. In addition, the extrinsic thermal conductivity of phosphorene is reviewed by discussing the effects of strain and substrate, together with phosphorene based heterostructures and nanoribbons.
**12:51PM S44.00007: Thermoelectric properties of half-Heusler TaFeSb from first-principles electron-phonon scattering calculations**

NATALYA FEDOROVA (Presenter), ANDREA CEPELLOTTI, BORIS KOZINSKY, Harvard University — We investigate thermoelectrics transport properties of half-Heusler TaFeSb within the Boltzmann transport formalism, using first principles calculations of the electronic relaxation times. Our goal is to explore the microscopic origin of exceptionally high ZT values (up to 1.52 at 973 K) recently reported from the experimental measurements of transport properties of TaFeSb-based compounds. In particular, we focus on the effects arising from the electron-phonon interaction. For that we calculate corresponding scattering rates using Wannier-Fourier interpolation of electron-phonon matrix elements as well as the recently developed electron-phonon averaged (EPA) approximation. We discuss the likely mechanisms of high ZT in TaFeSb-based systems and possible ways to further improve thermoelectric properties of half-Heusler compounds.

*This work is supported by Swiss National Science Foundation (grant number P2EZP2_178532)*

**1:03PM S44.00008: Thermal phonons with micron-scale mean free paths in ultra-drawn polyethylene**

TAEYONG KIM (Presenter), Division of Engineering and Applied Science, California Institute of Technology, STAVROS X. DRAKOPOULOS, IGNACIO MARTIN-FABIANI, Department of Materials, Loughborough University, ANDREW ROBBINS, Division of Engineering and Applied Science, California Institute of Technology, SARAH RONCA, Department of Materials, Loughborough University, AUSTIN MINNICH, Division of Engineering and Applied Science, California Institute of Technology — Heat conduction in highly oriented polymers is of fundamental and practical interest. It is well-known that the thermal conductivity of certain polymers such as polyethylene (PE) increases by orders of magnitude with drawing, but the microscopic properties of phonons responsible for heat conduction have remained difficult to access experimentally. Here, we report the observation of thermal phonons with micron-scale mean free paths (MFPs) in ultradrawn polyethylene using transient grating spectroscopy. The MFPs are comparable to those in covalent single crystals such as Si despite the imperfect nature of the sample’s microstructure. Further, the sample exhibits a decrease in thermal conductivity with increasing temperature above 200 K, indicating that anharmonic scattering is dominant over reflections from domains between crystallites. Our work provides new insights into the microscopic origin of high uniaxial thermal conductivity of ultradrawn polymers.

**1:15PM S44.00009: Accelerated Screening of Electron-Phonon Transport in 2D Materials**

JENNIFER COULTER (Presenter), BORIS KOZINSKY, Harvard University — Numerous experimental and theoretical studies have identified promising 2D materials for thermoelectric applications. These materials can exhibit an advantageous combination of electrical and thermal properties, sometimes resulting in large thermoelectric figure-of-merit values. Using an in-house method to perform accelerated screening of transport properties through first-principles electron-phonon calculations, we consider thermoelectric effects in a broader set of 2D materials. From these calculations, we consider how specific electronic and vibrational properties relate to thermoelectric potential, and identify the best candidate materials for use in application. Additionally, we consider the practical importance of substrate effects on the electron-phonon interaction and transport properties of these materials.
1:27PM S44.00010: Simulations of thermoelectric coefficients using DFT bandstructures and energy dependent scattering rates* PATRIZIO GRAZIOSI (Presenter), CHATHURANGI KUMARASINGHE, NEOPHYTOS NEOPHYTOU, School of Engineering, University of Warwick — Performance prediction for thermoelectric (TE) materials requires extracting DFT bandstructures and computation of TE coefficients using Boltzmann transport equation (BTE). The constant relaxation time approximation is commonly employed due to complexities in accurately computing scattering rates.
In this work, we describe the construction of an advanced simulator, which couples generic bandstructures (e.g. from DFT) with BTE, utilizing the full numerical energy/momentum/valley dependences of all states in the extraction of the relaxation times. The method provides more predictive capabilities and accuracy, but also considers all scattering mechanisms (acoustic, non polar optic and polar phonons, ionized impurities) independently, as well as intra- and inter-band transitions.
We show that according to the scattering physics under consideration, the performance ranking between different materials and their doping and temperature dependence varies significantly compared to constant relaxation time consideration.

*This work is funded by the Marie Sklodowska-Curie Actions (Grant agreement No. 788465) and from the European Research Council (ERC) under the European Union's Horizon 2020 Research and Innovation Programme (Grant Agreement No. 678763).

1:39PM S44.00011: Zero-Point renormalization of the band structure within Quasiparticle Self-consistent GW SAVIO LARICCHIA (Presenter), NICOLA BONINI, MARK VAN SCHILFGAARDE, Department of Physics, King's College London — The reliability of Density Functional Theory (DFT) for the electron-phonon coupling in many materials, including even simple sp-bonded compounds, has been questioned in recent years. Hybrid functionals and quasiparticle GW corrections suggest that nonlocal exchange-correlation enhances the electron-phonon interaction as a consequence of an improved description of the electronic screening. This has highlighted the need to move beyond local exchange-correlation functionals within DFT, but complete field-theoretic investigations are still missing in literature. In this talk I will introduce the development of a field-theoretic methodology which is able to predict on an equal footing electronic quasiparticles and phonons as well as their interaction. Such an approach has been implemented within the Quasiparticle Self-consistent GW (QSGW) formalism which describes well the electronic properties for a wide range of materials, including many where standard DFT fails. The reliability of a such field-theoretic methodology will be discussed with applications ranging from the renormalization of the optical gap of nonpolar semiconductors to the renormalization of the Fermi surface of correlated materials such as FeSe.
Quantum coherent coupling between a zone-center phonon and two acoustic phonons was observed in two GaAs/AlAs superlattices (8 nm/8 nm and 5.4 nm/5.4 nm) at ambient temperature. Using degenerate coherent phonon spectroscopy, a multi-cycle oscillation feature appears in the time-resolved phonon amplitudes of both samples, as a result of the coherent energy exchange between a driving phonon mode near first Brillouin zone center and two target acoustic phonon modes. This feature resembles the photon resonant parametric down/up-conversion processes, as well as the reversible coherent energy exchange between the optical field and a mechanical oscillator, suggesting quantum coherent coupling between the driving and target phonon modes. In the 8nm/8nm superlattice, the coupling strength increases nonlinearly at high pump fluences, which may eventually reach an extreme state where all three phonon modes share the same coherent state, as predicted by Orbach in the 1960’s.

Session S45 DCOMP GSNP: Computational Methods for Statistical Mechanics: Advances and Applications II
Coupled Molecular Dynamics and Spin Dynamics display very attractive features that allow to get new insights of the intriguing interplay between structure and magnetism in Fe-based alloys. Each atom is treated as a moving particle, eventually charged, supporting a classical spin. Coordinate dependent on both magnetic exchange and magnetic anisotropic functions ensure minimal coupling between the spin and the lattice degrees of freedom to translate the well known magneto-elastic behavior of magnetic materials. These functions need well crafted magnetic and mechanical Hamiltonian parametrized on \textit{ab-initio} calculations to recover the size dependence of the energy barriers and characteristic time scales of the magnetization relaxation of condensed phases. The equations of motion (eoms) come naturally from the Nambu dynamics that formulates covariant Poisson brackets for classical fields that encode the constrained structure of the topological space of spins. To solve these coupled eoms in practical simulations, numerical integration algorithms based on decomposition methods have to be considered, that preserve the structure of the flow of canonical variables in such an extended phase space. Consequences of such schemes will be discussed in details from the point of view of the known invariant quantities. To mimic experimental conditions, various statistical ensembles have to be generated to monitor the physical properties by varying external temperature for instance, as a stochastic connection. One consequence is that the positions, momenta and spins of all the atoms become, in return, varying quantities evolving through stochastic instead of deterministic differential equations of motion. The challenge to compute these quantities in parallel and examples provided by the SPIN package in the open source LAMMPS code are discussed.

Quantum-accurate multiscale modeling of ramp compressions and magneto-elastic phase transitions in iron* JULIEN TRANCHIDA (Presenter), ATTILA CANGI, MITCHELL WOOD, AIDAN THOMPSON, MICHAEL PAUL DESJARLAIS, Sandia National Laboratories — Magnetic spin fluctuations have a significant impact on the thermodynamic properties of magnetic metals. Accurately predicting magneto-structural phase transitions in compressed iron hence requires accounting for those effects.

We achieved this by constructing a magneto-elastic Hamiltonian. Following the Spectral Neighbor Analysis Potential approach, a machine-learning interatomic potential for iron was trained on ab initio calculations performed on the pressure and temperature range of interest. This potential was combined to a magnetic Hamiltonian accounting for transverse and longitudinal spin fluctuations.

Leveraging the numerical capability combining lattice and magnetic degrees of freedom that was recently implemented in LAMMPS, large scale spin-lattice simulations of ramp compressions and phase transitions in iron are performed based on the developed Hamiltonian.

*Sandia National Laboratories is managed and operated by NTESS under DOE NNSA contract DE-NA0003525.

Absolute entropy calculation from liquid state correlation functions* MICHAEL WIDOM (Presenter), Carnegie Mellon Univ, MICHAEL GAO, National Energy Technology Lab —

Because entropy is a function of thermodynamic state it can be determined without need for thermodynamic integration. Concepts from information theory relate the entropy of a liquid metal to its correlation functions, which can be accurately determined from ab-initio molecular dynamics. This relationship is equivalent to the "S2" method that has previously been applied to model liquids. We demonstrate the accuracy of the approach by calculating the absolute entropy of liquid aluminum entirely from first principles, and demonstrate excellent agreement with experimental data.

*This work was supported by the Department of Energy under grant DE-SC0014506.
12:15PM S45.00004: Absolute free energies from ab-initio calculation: application to phase stability of liquid metal alloys*  YANG HUANG (Presenter), Carnegie Mellon Univ, MICHAEL GAO, National Energy Technology Lab, MICHAEL WIDOM, Carnegie Mellon Univ — Absolute liquid state entropies calculated using the "S2" method can be combined with ab-initio enthalpies to predict absolute Gibbs free energies. We apply this method to model the phase behavior of the liquid alkali metal alloy Li-Na, which is known to phase separate, compared with Na-K, which exhibits a eutectic. Our ab-initio simulations employ hybrid Monte Carlo/molecular dynamics to accelerate sampling of the ensemble and provide accurate pair correlation functions for the entropy calculation. Both alloys exhibit effective unlike-atom repulsion, but the weaker repulsion of Na-K allows an entropically stabilized eutectic, while the stronger repulsion of Li-Na overwhelms the entropy below a high temperature critical point which we approximately locate.

*This work was supported by the Department of Energy under grant DE-SC0014506.

12:27PM S45.00005: Investigation of Fe by means of atomistic spin dynamics coupled with ab initio molecular dynamics simulations  DAVIDE GAMBINIO (Presenter), BJORN ALLING, Linkoping University — Ab initio molecular dynamics (AIMD) is a mature approach for the investigation of nonmagnetic materials. Magnetism in condensed matter, however, introduces a further challenge for the theoretical community. A recently developed method that allows to take advantage of the accuracy of AIMD and couples the magnetic and vibrational degrees of freedom is the atomistic spin dynamics - ab initio molecular dynamics (ASD-AIMD) method [1]. In this approach, the atomic and magnetic dynamics are run in parallel while communicating with each other. The applicability of the method has been shown in the study of CrN, a semiconducting system with well localized magnetic moments. Here, we employ ASD-AIMD simulations to investigate Fe near its Curie temperature. Being Fe a ferromagnetic metal, temperature induces fluctuations not only on the transversal magnetic degrees of freedom, but also on the longitudinal ones, which are often considered irrelevant for a system like bcc Fe. In our simulations we include this type of excitations through a mean-field entropic term, and we compare results in absence of this effect. This work is a pre-step in the calculation of free energy differences in magnetic systems with ab initio accuracy.

Spin dynamics simulations on Surface for a nanoscale Heisenberg antiferromagnet  
ZHUOFEI HOU (Presenter), University of Georgia — Monte Carlo and spin dynamics techniques with fourth-order Suzuki-Trotter decompositions of the exponential operator have been used to perform large-scale simulations of the dynamic behavior of a nanoscale, classical, Heisenberg antiferromagnet on a simple-cubic lattice at a temperature below the Néel temperature 1. A classical isotropic Heisenberg model with an antiferromagnetic nearest-neighbor exchange interaction was studied. A simple-cubic lattice with free boundary conditions was used. The assumption of q-space spin-wave reflections with broken momentum conservation due to free-surface confinements was developed and used to explain multiple excitation peaks for wave vectors within the first Brillouin zone appear in the spin-wave spectra of the transverse component of dynamic structure factor in the nanoscale classical Heisenberg antiferromagnet. In this study, we applied the same simulation techniques to the nanoscale classical Heisenberg antiferromagnet we studied before for studying spin dynamic behavior on the surfaces of a nanoscale antiferromagnet.

Effective diffusion in rough potential energy landscapes*  
THOMAS GRAY (Presenter), Univ of Cambridge — Diffusion in spatially rough, confining, one-dimensional energy landscapes is treated using Zwanzig's proposed formalism, which is based upon the Smoluchowski Equation. Disagreement between its predictions and the results of numerical simulations is observed. We use the configurational partition function to amend Zwanzig's formalism, and resolve the disagreement. The analogous over-damped Langevin Equation is proposed, and a numerical simulation scheme offering potentially significant reductions in computational time is derived. The case of random roughness is treated. We then extend the above into higher dimensions and calculate effective diffusion coefficients for motion in non-confining, rough, multi-dimensional potential energy landscapes. This leads us to propose an expression for the mean first-passage time from one potential minimum to any one of the immediately adjacent potential minima. As before, simulation schemes offering significant improvements upon those derived from the unmodified Langevin Equation are obtained. Good agreement between our theory's predictions and both numerical simulation schemes - unmodified and modified - is observed.

1:03PM S45.00008: Stefan–Maxwell diffusivities extracted from molecular dynamics simulations via Onsager’s regression hypothesis*  
CHARLES MONROE, MAXIM ZYSKIN (Presenter), University of Oxford — We report on our development of a method to measure macroscopic diffusion coefficients in silico by analysing molecular-dynamics (MD) data. Application of Onsager’s regression hypothesis to the macroscopic constitutive laws for multicomponent Stefan–Maxwell mass transport allows application of Casimir’s fluctuation theory, which shows how the decay rates of certain autocorrelation functions relate to macroscopic mutual diffusivities. The autocorrelation functions are then determined numerically, using periodic MD simulations in the Gibbs ensemble. As an illustrative example, we compute the diffusivities for a ternary Lennard–Jones gas mixture, a case where the diffusivities measured by MD can be compared to diffusivities determined analytically by the Chapman–Enskog kinetic theory. The ultimate application of this method will be to quantify component activities and transport properties in liquids, with the ultimate aim of studying electrochemical transport properties in electrolytic solutions.

1:15PM S45.00009: Machine Learning the Effective Hamiltonian in High Entropy Alloys with Large DFT Datasets*  
XIANGLIN LIU (Presenter), JIAXIN ZHANG, Oak Ridge National Lab, YANG WANG, CARNEGIE MELLON UNIVERSITY, MARKUS EISENBACH, Oak Ridge National Lab — The development of machine learning sheds new light on the Monte Carlo simulation of complex alloys. One major challenge, however, is that machine learning models are generally data-hungry, while the data from density functional theory (DFT) are computationally expensive. To solve this problem, we use the atomic local energy as the target variable, and harness the power of the linear-scaling DFT method to obtain large DFT data sets. This method is used to calculate the energy data of a range of MoNbTaW refractory high entropy alloys, with machine learning techniques including kernel ridge regression, Gaussian process, and artificial neural network applied to construct the effective Hamiltonian. The results demonstrate that machine learning model built on the configurational space, which naturally incorporates non-linear and multi-site interactions, can efficiently and accurately predict the DFT energy.

1:27PM S45.00010: Quantifying the disassembly of viral capsids from a multiscale molecular simulation approach*
HORACIO ANDRES VARGAS GUZMAN (Presenter), Soft Matter Theory Department, Institute Josef Stefan, CHRISTOPHER COOPER, Department of Mechanical Engineering, Technical University Federico Santa Maria, ADOLFO POMA, Institute of Fundamental Technological Research, Polish Academy of Sciences — Molecular simulation of large biological systems, such as viral capsids, remains a challenging task in soft matter research. On one hand, coarse-grained (CG) models attempt to make feasible the description of the entire viral capsids. On the other hand, novel development of molecular dynamics (MD) simulation approaches, like enhance sampling which attempt to overcome the time scales required in biophysics. Those methods have a potential for delivering molecular structures and properties of biological systems. Nonetheless, exploring the process on how a capsid disassembles by all-atom MD simulations has been rarely attempted. Here, we propose a methodology to analyze the disassembly process of viral capsids quantitatively. In particular, we look at the effect of pH and charge of the genetic material inside the capsid, and compute the free energy of a disassembly trajectory by combining CG simulations to a Poisson-Boltzmann solver. We employ such multiscale approach on the triatoma virus as a test case, and find that even though an alkaline environment enhances the stability of the capsid, the resulting deprotonation of the internal solvent generates an electrostatic repulsion that triggers disassembly.

1:39PM S45.00011: Exploring the Potential of Parallel-Biasing in Flat Histogram Methods*
SHANGHUI HUANG (Presenter), JONATHAN K. WHITMER, University of Notre Dame — Metadynamics, a member of the "flat histogram" class of advanced sampling algorithms, has been widely used in molecular simulations to drive exploration of states that are separated by high free energy barriers and promote the sampling of full free energy landscapes. A recently proposed variant, parallel bias metadynamics (PBMetaD) promises to aid in exploration of free energy landscape along multiple important collective variables by exchanging the n-dimensional free energy landscape required by standard methods for n one-dimensional marginal free energy landscapes. In this study, we systematically examine how parallel biasing affects convergence of free energy landscapes along each variable relative to standard methods, and the effectiveness of the parallel biasing strategy for addressing common bottlenecks in the use of advanced sampling to calculate free energies.

*NSF DMR-1751988
1:51PM S45.00012: Superfluidity and dimensional cross-over in Quasi-1D systems* PER BOLLMARK (Presenter), ADRIAN KANTIAN, Uppsala Univ — 1D systems cannot attain long-range order (LRO) but have a wide range of other benefits. One method to cure the missing LRO is to construct an infinite array of weakly coupled 1D systems.

We consider a 3D array of one-dimensional repulsive bosons. If the bosons are hard-core they can model the electron-pairs in e.g. a quasi-1D USC such as the Bechgaard and Fabre salts. Static Mean-Field (SMF) combined with Density Matrix Renormalization Group (DMRG) reduces the full 3D model to a self-consistently treated 1D one, enabling calculation of ground and thermal equilibrium states. This approach is motivated by the low cost of such an implementation and further allows the simulation of real-time/frequency dynamics.

This model exhibits a phase transition from a 3D superfluid (SF) to a 1D Mott insulator (MI) that forms the basis of the more complex behavior in the USCs. Interestingly, the order parameters indicating the different phases suggest a mix between first- and second-order transitions.

11:15AM S46.00001: Kondo effect in a spinon metal [Invited] ANDREJ ZORKO (Presenter), MATJAZ GOMILSEK, ROK ZITKO, MARTIN KLanjSEK, MATEJ PREGELJ, Jozef Stefan Institute, QINGMING ZHANG, School of Physical Science and Technology, Lanzhou University — The Kondo screening of localized impurities possessing magnetic moments is traditionally associated with exchange scattering of conduction electrons. This nontrivial display of many-body physics is common to ordinary metals and was recently found also in various more complex conducting systems, such as quantum dots, graphene, and topological insulators. Moreover, the Kondo effect was theoretically predicted for certain electric insulators in which emergent fractional magnetic excitations can effectively take over the role of itinerant electrons in screening the impurities’ magnetic moments [1-4].

Indeed, our experimental study of the kagome lattice antiferromagnet Zn-brochantite, ZnCu$_3$(OH)$_6$SO$_4$, with a spin-liquid ground state has finally confirmed these theoretical predictions [5]. Although in this material the charge degrees of freedom are frozen, an effect conceptually identical to the traditional Kondo effect takes place. This is possible because the magnetic spinon excitations of Zn-brochantite behave like quasi-free fermions with a Fermi surface and thus, regarding their interactions with localized impurities, closely resemble itinerant electrons in a metal. The observed Kondo response is, however, to a certain degree modified from the ordinary case, which is attributed to spinon-spinon interactions. The discovered spinon-based Kondo effect thus provides a prominent platform for characterizing enigmatic spin-liquid states through impurities acting as in situ local probes of the host magnetic state.

11:51AM S46.00002: Dynamics of jammed spin liquid on the kagome bilayer SHENG ZHANG (Presenter), PREETHA SAHA, DEPEI ZHANG, SEUNGHUN LEE, GIA-WEI CHERN, Univ of Virginia — The Heisenberg antiferromagnet on the kagome bilayer is one of the canonical frustrated spin systems. It also provides a basic model for the compound SCGO that triggered the interest in highly frustrated magnets. The source of the seemingly glassy behavior observed in SCGO at temperatures below $T_g \approx 3.5 \rightarrow 7$ K remains unclear even after decades of intensive study. In particular, previous works [1], including our own [2], seem to indicate that dilution alone does not engender a spin glass in its classical spin-liquid ground state. Instead, it is suggested that the glassy behavior likely originates from the interplay between disorder and the coplanarity tendency due to quantum fluctuations-[1,3]. In this work, we study the dynamical properties of an effective Hamiltonian that incorporates the collinear/coplanar tendency through a biquadratic spin interaction. We report unusual relaxation dynamics and the dynamical structure factor of the effective model and discuss their experimental implications.
12:03PM S46.00003: Electron-nuclear hyperfine coupling in quantum kagome antiferromagnets from first-principles calculation and a reflection of the defect effect*

SHUNHONG ZHANG (Presenter), ICQD, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, YI ZHOU, Institute of Physics, Chinese Academy of Science, FENG LIU, Department of Materials Science and Engineering, University of Utah, ZHENG LIU, Institute for Advanced Study, Tsinghua University — The discovery of ideal spin-1/2 kagome antiferromagnets Herbertsmithite and Zn-doped Barlowite represents a breakthrough in the quest for quantum spin liquids (QSLs), and nuclear magnetic resonance (NMR) spectroscopy plays a prominent role in revealing the quantum paramagnetism in these compounds. However, interpretation of NMR data that is often masked by defects can be controversial. Here, we show that the most significant interaction strength for NMR, i.e. the hyperfine coupling (HFC) strength, can be reasonably reproduced by first-principles calculations for these proposed QSLs. Applying this method to a supercell containing Cu-Zn defects enables us to map out the variation and distribution of HFC at different nuclear sites. This predictive power is expected to bridge the missing link in the analysis of the low-temperature NMR data.

12:15PM S46.00004: Thermal conductivity of the quantum spin liquid candidate herbertsmithite

PATRICK BOURGEOIS-HOPE (Presenter), PIERRE LEFLOÎC, NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, Universite de Sherbrooke, PHILIPPE MENDELS, Universite Paris-Sud, MATIAS VELAZQUEZ, Universite de Bordeaux — Hosting a $S = 1/2$ system on a kagome lattice, herbertsmithite (ZnCu$_3$(OH)$_6$Cl$_2$) is a leading candidate in the search for quantum spin liquids. Despite the absence of magnetic ordering down to very low temperature and several probes detecting a significant density of low-energy states, a debate persists on whether this material has gapless spinon excitations. Our thermal conductivity measurements down to 60 mK show no signs of the $T$-linear contribution to heat conduction that is expected from mobile spinons. Instead, our results suggest that the low-energy spin excitations in herbertsmithite are either localized or gapped.
12:27PM S46.00005: Diverse $S=1/2$ distorted kagome Hamiltonians in titanium fluorides
HARALD JESCHKE (Presenter), Okayama University, HIROKI NAKANO, TORU SAKAI, University of Hyogo
— We determine the connection between highly frustrated kagome based Hamiltonians and a recently synthesized family of materials containing Ti$^{3+}$ $S = 1/2$ ions [1]. With the help of a combination of all electron density functional theory and numerical diagonalization techniques, we establish the Heisenberg Hamiltonians for the distorted kagome antiferromagnets Rb$_2$NaTi$_3$F$_{12}$, Cs$_2$NaTi$_3$F$_{12}$, and Cs$_2$KTi$_3$F$_{12}$. We determine magnetization curves in excellent agreement with experimental observations. Our calculations successfully clarify the relationship between the experimental observations and the magnetization-plateau behavior at 1/3 height of the saturation and predict characteristic behaviors under fields that are higher than the experimentally measured region. We demonstrate that the studied Ti(III) family of materials interpolates between the kagome strip and kagome lattice. Further members of this family of materials are also considered.

12:39PM S46.00006: The origin of trimerized phase in $S=1$ kagome magnet Na$_2$Ti$_3$Cl$_8$*
ARPITA PAUL (Presenter), University of Minnesota, CHIA-MIN CHUNG, Ludwig-Maximilians-Universitat Munchen, HITESH CHANGLANI, Florida State University, TURAN BIROL, University of Minnesota — The kagome magnet Na$_2$Ti$_3$Cl$_8$ with $S=1$ spins undergoes a structural transition involving trimerization or breathing distortion of the underlying kagome lattice as the temperature lowers. We investigate the magnetic ground state of this compound by constructing a model spin Hamiltonian based on first-principles density functional theory and analyzing it using exact diagonalization and density matrix renormalization group methods. Along with the nearest neighbor Heisenberg and biquadratic exchanges, we propose a new exchange term fourth order in spins - ring exchange that does not originate from spin-orbit coupling and involves simultaneous hopping of electrons from one site to its two neighboring sites. The parameters that our first principles calculations give for the high temperature crystal structure place this compound to the ferroquadrapolar region of the phase diagram predicted by exact diagonalization and density matrix renormalization group calculations. We thus suggest that a spin - lattice coupling favors the trimerized phase over the quadrapolar phase, even though density functional theory alone does not predict a lattice instability.

*NSF DMREF Grant No. DMR-1629260 and Minnesota Supercomputing Institute
12:51PM S46.00007: Dynamical properties of site-diluted Heisenberg antiferromagnetic on the kagome bilayer  PREETHA SAHA (Presenter), DEPEI ZHANG, SEUNG-HUN LEE, GIA-WEI CHERN, Univ of Virginia — We present spin dynamical simulations of the site-diluted Heisenberg antiferromagnet with nearest neighbor interactions on a quasi-2D kagome bilayer. This geometrically frustrated lattice consists of two kagome layers connected by a triangular-lattice layer. We combine Monte Carlo method with precessional spin dynamics simulations to compute the dynamical structure factor of the classical spin liquid and study the thermal and dilution effects. The low frequency and long wavelength dynamics of the classical spin liquid in kagome bilayer is dominated by spin diffusion [1]. In the presence of spin vacancies, the dynamical properties of the diluted system can be understood within the two population picture [2,3]. The spin diffusion of the “correlated” spin clusters gives rise to an exponentially decaying autocorrelation function. On the other hand, the diffusive dynamics of the quasi-free “orphan” spins leads to a distinctive long time power-law tail in the autocorrelation function. We discuss the implications of our work for the glassy behaviors observed in the frustrated magnet SrCr$_{9p}$Ga$_{12-9p}$O$_{19}$ (SCGO).

1:03PM S46.00008: Search for simplex solid and spin liquid phases in highly frustrated S=1 antiferromagnets* [Invited] HITESH CHANGLANI (Presenter), Physics, Florida State University — Quantum spin liquids are enigmatic phases of matter characterized by the absence of symmetry breaking and conventional quasiparticles. The search for their realisation in actual magnetic materials has targeted, but is not limited to, materials involving the geometrically frustrated triangular, kagome and pyrochlore geometries with low spins. Indeed, while there have been significant efforts to synthesize quantum spin liquid materials in spin-1/2 systems in two dimensions, fewer efforts have been devoted to three dimensions and higher spins. In this talk, we show that both these criteria may be too restrictive. We thus expand our search to spin-1 frustrated antiferromagnets which are abundant in nature but where few theories or results exist to understand their general properties and behavior. Motivated by recent realizations of S=1 kagome and pyrochlore geometries, we address the question of their quantum many-body ground state. For kagome, a spin liquid state known as the Hexagonal Singlet State, motivated by the Affleck Kennedy Lieb Tasaki state in one dimension, is found to be competitive in energy. However, for the pure Heisenberg model it loses out to a symmetry broken trimerized (simplex solid) ground state, a conclusion we derive from density matrix renormalization group calculations. We show that this finding is relevant to the recently synthesized S=1 kagome material Na$_2$Ti$_3$Cl$_8$ which shows a large trimerized distortion in its low temperature phase. For the S=1 pyrochlore case, our search bears fruit - we find a nearly idealized Heisenberg model in NaCaNi$_2$F$_7$. Our results show strong evidence for a quantum spin liquid phase based on both its static and dynamical properties.

1:39PM S46.00009: Magnetoresistance Study of Kagome Artificial Spin Ice with Fibonacci Distortions*  JUSTIN WOODS (Presenter), BARRY W FARMER, Univ of Kentucky, YONG-LEI WANG, Nanjing University, WAI-KWONG KWOK, Material Sciences, Argonne National Laboratory, LANCE ERIC DE LONG, Univ of Kentucky — Nanofabrication techniques allow magnetic thin films to be lithographically patterned into arrays of interacting macro-spins designed to exhibit emergent physical properties. We study the effects of continuous symmetry breaking on the magnetoresistive behavior of frustrated Kagome (alt. honeycomb) ASI whose periodic lattice is aperiodically distorted by repeated application of a substitution algorithm: A Fibonacci sequence of binary digits is mapped into short (d1) and long (d2) primitive lattice translations, which alters the magnetic moments and angular coordination of the three-fold Kagome vertices. Kagome arrays with variable distortions are patterned in series to permit simultaneous longitudinal and transverse magnetoresistances measurements in external magnetic fields. The direction and magnitude of applied field was varied to produce distinct, interesting differences in the magnetoresistance response of the distorted Kagome arrays, compared to the undistorted arrays.

S46.00010: Tuning the Two-step Melting of Magnetic Order in Dipolar Kagome Ice by Quantum Fluctuations  YAO WANG (Presenter), STEPHAN HUMENIUK, YUAN WAN, Institute of Physics, Chinese Academy of Sciences — Complex magnetic orders in frustrated magnets may exhibit rich melting processes when the magnet is heated toward the paramagnetic phase. In this talk, we show that one may tune such melting processes by quantum fluctuations. We consider a kagome lattice dipolar Ising model subject to transverse field and focus on the thermal transitions out of its magnetic ground state, which features a root 3 by root 3 magnetic unit cell. Our quantum Monte Carlo (QMC) simulation suggests that, at weak transverse field, the root 3 by root 3 order melts by way of an intermediate, magnetically charge ordered phase where the lattice translation symmetry is restored whilst the time reversal symmetry remains broken[1]. By contrast, at moderate transverse field, QMC simulation suggests the root 3 by root 3 order melts through a floating Kosterlitz-Thouless (KT) phase. The two distinct melting processes are likely separated by a multicritical point identified in Ref.[2].

Non-coplanar magnetic order and topological magnons in tripod kagome antiferromagnet $\text{Yb}_3\text{Mg}_2\text{Sb}_3\text{O}_{14}$*  
ZHILING DUN (Presenter), Georgia Inst of Tech, OWEN BENTON, Riken center for Emergent Matter Science, XIAOJIAN BAI, Georgia Inst of Tech, NICHOLAS BUTCH, NIST center for neutron research, HAIDONG ZHOU, University of Tennessee, MARTIN MOURIGAL, Georgia Inst of Tech — Kagome antiferromagnet is one of the most studied models for geometrical frustration which is expected to be a topological magnon insulator in the presence of Dzyaloshinskii–Moriya interactions. The recent discovered tripod kagome materials provide us a platform to explore such ideas with strongly spin-orbit coupled rare earth ions. Using elastic neutron scattering measurements, we show that one of the tripod kagome compounds, $\text{Yb}_3\text{Mg}_2\text{Sb}_3\text{O}_{14}$, orders into a strongly non-coplanar magnetic ground state below 0.88 K which calls for large antisymmetric exchanges. Inelastic neutron scattering experiment on polycrystalline samples reveals both dispersive and flat magnon bands which can be fitted by an anisotropic exchange Hamiltonian derived from a symmetry analysis. Along with numerical calculations, our results unveil $\text{Yb}_3\text{Mg}_2\text{Sb}_3\text{O}_{14}$ as a candidate to host topological non-trivial magnon bands.

Topological Insulator/Magnetic Insulating Oxide: A Platform for Efficient Spin Current Transport* [Invited]

PENG LI (Presenter), Auburn University, STEVEN S-L ZHANG, Case Western Reserve University, LAUREN RIDDIFORD, Stanford University, TIMOTHY PILLSBURY, Penn State University, JINJUN DING, Colorado State University, JAMES KALLY, Penn State University, ALEXANDER GRUTTER, National Institute of Standards and Technology, GAURAB RIMAL, University of Wyoming, CHONG BI, Stanford University, GYORGY CSABA, Pazmany Peter Catholic University, J SAMUEL JIANG, JUNJIA DING, Argonne National Laboratory, WEI ZHANG, Oakland University, JINKE TANG, University of Wyoming, WEIGANG WANG, University of Arizona, OLLE HEINONEN, VALENTYN NOVOSAD, Argonne National Laboratory, AXEL HOFFMANN, University of Illinois at Urbana-Champaign, NITIN SAMARTH, Penn State University, YURI SUZUKI, Stanford University, MINGZHONG WU, Colorado State University — Topological insulators (TIs) hold great promise for spintronic devices due to their large charge-to-spin conversion efficiency. It has been demonstrated that a TI can induce a spin-orbit torque to switch the magnetization of a magnetic metal. However, it is unclear if this is due to the topological surface state (TSS) because the electrons from the magnetic metal can suppress TSS. Here we discuss experiments that identified bona fide surface state-induced spin-orbit torques in topological insulator/magnetic oxide bilayers. In Bi$_2$Se$_3$/BaFe$_{12}$O$_{19}$, a large spin-orbit torque from Bi$_2$Se$_3$ switched the magnetization of BaFe$_{12}$O$_{19}$. When the magnetization was switched by a magnetic field, a current in Bi$_2$Se$_3$ can reduce the switching field by about 4000 Oe. The switching efficiency at 3 K is 300 times higher than at room temperature. When BaFe$_{12}$O$_{19}$ is replaced with Mg(Al,Fe)$_2$O$_4$, efficient spin pumping in the bulk-dominated regime was found at room temperature. These results highlight the promise of topological insulator/ferromagnetic insulating oxide bilayers as a platform for studying topological surface states in the context of spin-to-charge interconversion.

**11:51AM S47.00002: Nonlinear Hall effect in topological insulator-ferromagnet heterostructures**

YANG WANG (Presenter), YONG WANG, TAO WANG, YU-SHENG OU, YI JI, MATTHEW F DOTY, BRANISLAV NIKOLIC, STEPHANIE ANN LAW, JOHN Q XIAO, University of Delaware — Topological insulators (TIs) are a new class of materials which have insulating bulk bands and gapless helical surface states. The unique spin-momentum locking property leads to large charge-to-spin conversion efficiency which can be used to manipulate the magnetization in an adjacent ferromagnetic layer via spin-orbit torques (SOTs). However, more rich phenomena can happen in topological insulator/ferromagnet bilayers. Here, we report current-nonlinear Hall effect in Bi$_2$Se$_3$/CoFeB heterostructures measured by second harmonic Hall voltage method, which is commonly used to extract SOTs in TI/FM bilayers. By field dependence analysis and magneto-optical Kerr effect spin-orbit torque measurement, the origin of the second harmonic Hall voltage is mainly attributed to asymmetric magnon scattering mechanism. We further show that the second harmonic Hall resistance might be linked to quantum interference effect in TIs.

**12:03PM S47.00003: Nonlinear planar Hall effect**

PAN HE, Department of Electrical and Computer Engineering, National University of Singapore, SHULEI ZHANG (Presenter), Materials Science Division, Argonne National Lab, DAPENG ZHU, SHUYUAN SHI, Department of Electrical and Computer Engineering, National University of Singapore, OLLE HEINONEN, Materials Science Division, Argonne National Lab, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri, HYUNSOO YANG, Department of Electrical and Computer Engineering, National University of Singapore — An intriguing property of a three-dimensional topological insulator (TI) is the existence of surface states with spin-momentum locking. We report the discovery of a new type of Hall effect in a TI Bi$_2$Se$_3$ film [1]. The Hall resistance scales linearly with both the applied electric and magnetic fields and exhibits a $\pi/2$ angle offset with respect to its longitudinal counterpart, in contrast to the usual angle offset of $\pi/4$ between the linear planar Hall and anisotropic magnetoresistance. This novel nonlinear planar Hall effect originates from the conversion of a nonlinear transverse spin current to a charge current due to the concerted actions of spin-momentum locking and time-reversal symmetry-breaking, which also exists in other non-centrosymmetric materials [e.g., WTe$_2$ and the 2DEG on the SrTiO$_3$(001) surface] with a large span of magnitude.

12:15PM S47.00004: Nonlinear Hall signatures of ferroelectric switching in atomically thin WTe$_2$

BENJAMIN T. ZHOU (Presenter), CHENG-PING ZHANG, XUEJIAN GAO, Hong Kong University of Science and Technology, KAIFEI KANG, KIN FAI MAK, School of Applied and Engineering Physics, Cornell University, KAM TUEN LAW, Hong Kong University of Science and Technology — Recent experiments have observed nonlinear Hall effects (NLHEs) in atomically thin WTe$_2$, an ultrathin ferroelectric material which may enable miniaturizing ferroelectric memories. However, signatures of ferroelectricity in NLHEs have remained elusive. In this work, we demonstrate that the direction and magnitude of nonlinear Hall currents can be highly sensitive to the ferroelectric polarization in WTe$_2$. In particular, there exists a wide experimental regime in which different polarization states are associated with opposite Hall current directions. We point out that such strong NLHE signatures of ferroelectricity originate from polarity-dependent Berry curvature dipoles, which arises from the broken mirror symmetry under strong out-of-plane displacement fields near polarity-switching points. Our work establishes the polarity-dependent NLHE as a novel scheme for fast and nondestructive reading in WTe$_2$-based ferroelectric memory devices.

12:27PM S47.00005: Magnetization control of ferromagnetic materials based on topological insulator Sb$_2$Te$_3$ sputtered thin films

SOFIA FERREIRA TEIXEIRA (Presenter), Department of Physics and Astronomy - University of Porto, IFIMUP, ALEXANDER VANSTONE, Blackett Laboratory, Physics Department, Imperial College London, ANA L. PIRES, Department of Physics and Astronomy - University of Porto, IFIMUP, WILL R BRanford, Blackett Laboratory, Physics Department, Imperial College London, JOÃO P. ARAÚJO, Department of Physics and Astronomy - University of Porto, IFIMUP, LESLEY COHEN, Blackett Laboratory, Physics Department, Imperial College London, ANDRÉ M. PEREIRA, Department of Physics and Astronomy - University of Porto, IFIMUP — Topological Insulators (TI) are a recent category of materials. 3D TIs host a protected metallic state on their surface while having an insulating bulk. The state appears in the form of a spin-textured Dirac cone. Due to these properties, several applications are foreseen. However, a better fundamental understanding of the relationship between the TI surface and bulk states is required.

In this paper, the structural and electrical properties of a uniform nanocrystalline Sb$_2$Te$_3$ thin film fabricated by ion beam sputtering will be reported. We show that the thin film bulk conduction is dominated by Variable Range Hopping. However, the presence of the weak antilocalization cusps on the magnetoresistance at low temperatures and low magnetic fields is also analyzed and found to be consistent with the existence of a TI surface state, having a phase coherence length of ~60 nm and a single 2D channel open at 2 K. Following these properties, the preliminary results of ferromagnetic resonance spin current generation and magnetization control of Sb$_2$Te$_3$ - Py thin films bilayers will be discussed, including our estimate of the spin Hall angle. As these bilayers were made using a scalable inexpensive method, the results offer promising opportunities for future applications in spintronics.
Persistence of spin memory in the insulating state of the crystalline phase-change material SnSb$_2$Te$_4$ revealed by magnetotransport measurements

NICHOLAS BREZNAY (Presenter), Harvey Mudd College, JOHANNES REINDL, HANNO VOLKER, MATTHIAS WUTTIG, RWTH Aachen University — Understanding the driving mechanisms for quantum materials, whether strongly correlated, strongly disordered, or characterized by nontrivial band topology, often derives from precise studies of electronic lifetimes. Sufficiently long electronic spin and phase-coherence lifetimes result in weak localization or (in the presence of strong spin-orbit coupling) antilocalization, effects that can be used to spectroscopically probe complex materials. Here we identify a distinct, complementary phenomenon that can also be used to probe electronic lifetimes in strongly disordered materials [1]. We find an unexpected spin sensitive hopping conductivity in the phase change material SnSb$_2$Te$_4$ that can be tuned with disorder. An isotropic magnetoconductance arises from disruption of spin correlations that inhibit hopping transport, the recently described ‘spin memory’ effect [2], whose occurrence signals that the spin plays a previously overlooked role in the disorder-driven transition between weak and strong localization in spin-orbital materials. [1] J. Reindl, H. Volker, N. Breznay, M. Wuttig, npj Quantum Materials (2019). [2] O. Agam, I. Aleinder, B. Spivak PRB 89, 100201(R) (2014).

Observation of magnetoresistance effects in a heterostructure of Bi$_2$Se$_3$ and a ferromagnet with perpendicular magnetic anisotropy*

JUNSEOK OH (Presenter), University of Illinois at Urbana-Champaign, VINCENT HUMBERT, Unité Mixte de Physique CNRS/Thales, JOSEPH SKLENAR, Wayne State University, BORA BASA, MATTHEW GILBERT, NADYA MASON, University of Illinois at Urbana-Champaign — Topological insulators (TIs) have insulating bulk states and topologically protected gapless boundary states that exhibit spin momentum locking and prohibited backscattering. Such unusual properties of topological surface states (SSs) in three dimensional TIs make the material much favorable for spintronic applications. However, the properties of these SSs can be largely modified in the presence of ferromagnetism in out-of-plane direction which breaks the time reversal symmetry. We report magnetoresistance (MR) signals in a heterostructure of 3D TI Bi$_2$Se$_3$ and Co/Pt multilayer with perpendicular magnetic anisotropy. In particular, the abrupt switching between the high and low MR states was observed for temperature lower than 1K and for field along in-plane and out-of-plane directions. This MR is incompatible with the magnetization behavior of the ferromagnetic layer and thus attributed to the magnetic ordering in the TI. Our observations indicate the possible existence of proximity magnetized SSs in Bi$_2$Se$_3$ with out-of-plane spin component.

1:03PM S47.00008: Bi-linear magnetoresistance in surface states of topological insulator: the role of Rashba-Edelstein effect and relaxation processes  ANNA DYRDAL (Presenter), JOZEF BARNAS, Faculty of Physics, Adam Mickiewicz University in Poznan, ALBERT FERT, Unite Mixte de Physique, CNRS, Thales, Univ. Paris-Sud — Magnetoresistance effects scaling linearly with both external electric and magnetic fields are currently of great interest. These phenomena may be observed even in a uniform layer of material with strong spin-orbit coupling (SOC). A recent theoretical description of this bi-linear magnetoresistance (BMR) assumes a hexagonal warping of the band structure, which enables electron backscattering [1]. However, the experimental data on the topological insulator α-Sn(001) (a material without hexagonal symmetry) indicate that BMR can also exist in materials without hexagonal warping. Thus, one may expect another mechanisms contributing to the BMR in systems with isotropic energy spectra.

We will present our recent study on BMR of surface electronic states in TIs and in 2D Rashba gas [2]. The mechanism is based on the interplay of current-induced spin polarization and scattering processes due to peculiar spin-orbit defects. Additionally, we will discuss the role of the particle-hole asymmetry term and compare our approach with other theoretical descriptions and available experimental data.

1:15PM S47.00009: Nonreciprocal second harmonic generation in CuB$_2$O$_4$  SHINGO TOYODA (Presenter), RIKEN CEMS, MANFRED FIEBIG, ETH Zurich and RIKEN CEMS, TAKA-HISA ARIMA, YOSHINORI TOKURA, RIKEN CEMS and University of Tokyo, NAOKI OGAWA, RIKEN CEMS and JST-PRESTO — In a matter with broken time-reversal and space-inversion symmetries, optical responses can differ for the photons propagating in the opposite directions. The so-called nonreciprocal optical effect has been observed ranging from GHz to X-ray. Especially, CuB$_2$O$_4$ is known to show huge nonreciprocal effects for the linear optical response, such as absorption, luminescence and refraction. In this study, we have investigated nonreciprocity of second harmonic generation. It is demonstrated that such gigantic nonreciprocal effects can show up for not only linear optical responses but also for nonlinear optical responses.

CuB$_2$O$_4$ shows nonreciprocal absorption at 1.405 eV, which corresponds to the intratomic transition of Cu$^{2+}$ hole [1]. In addition, it has been reported that the large second harmonic signal appears at this transition [2]. Therefore, we expect nonreciprocal second harmonic generation at this photon energy. By carefully tuning the amplitude and phase of electric-dipole and magnetic-dipole transitions, we realize very large nonreciprocal signal reaching 97 %. The temperature dependence and magnetic-field dependence will also be discussed in the presentation.

**S47.00010: Magnetic torque of holmium antimonide topological semimetal**

NARAYAN POUDEL (Presenter), Idaho National Laboratory, M. MOFAZZEL HOSEN, University of Central Florida, DARIUSZ KACZOROWSKI, Institute of Low Temperature and Structure Research, Polish Academy of Sciences, MADHAB NEUPANE, University of Central Florida, KRZYSZTOF GOFRYK, Idaho National Laboratory — The family of compounds AX, where A = Lanthanides or Actinides and X = pnictides, have drawn a great scientific interest recently due to their unusual magneto-transport properties and potential non-trivial nature of the topological ground state. HoSb in one of the candidates of this family that shows antiferromagnetic transition at 5.7 K. Our recent magneto-transport and ARPES studies indicate the presence of the Rashba-type surface-states and non-trivial semimetallic characteristics in this material. In non-trivial magnetic semimetals it is important to understand the interplay between topology and magnetism. In HoSb, however, this behavior is still not well-understood. In order to account for this issue, we have initiated detailed studies of magnetic torque of HoSb along the three crystallographic directions, and in the antiferromagnetic and paramagnetic phases. We show that in this cubic system the torque exhibits large magnetic anisotropy in antiferromagnetic phase and an angle dependence indicates the presence of complex magnetic structure below the Neel temperature. We will discuss implications of these studies in the context of the presence of non-trivial topological state in this material.

**S47.00011: Large Spin-to-Charge Conversion Induced by Hybrid Rashba- and Surface-State in Topological Insulator Heterostructures**

RUI SUN (Presenter), Chinese Academy of Sciences, Institute of Physics, SHIJIA YANG, North Carolina State University, Department of Physics, YANG XU, Chinese Academy of Sciences, Institute of Physics, ERIC VETTER, DALI SUN, North Carolina State University, Department of Physics, LI NA, LEI SU, YAN LI, YANG LI, ZIZHAO GONG, ZONGKAI XIE, QEEMAT GUL, WEI HE, XIANGQUN ZHANG, ZHAO HUA CHENG, Chinese Academy of Sciences, Institute of Physics — Efficient spin-to-charge conversion at room temperature is of great value in spintronics applications. Recently, Topological insulators (TIs) have emerged as some of the most efficient spin-to-charge converters because of their correlated spin-momentum locking at helical Dirac surface states. While endeavors have been made to pursue large “charge-to-spin” conversions in novel TI materials using spin-torque-transfer geometries, the reciprocal process “spinto-charge” conversion, characterized by the inverse Edelstein effect length ($\lambda_{IEE}$) in the prototypical TI material (Bi$_2$Se$_3$), remains moderate. Here, we demonstrate that, by incorporating a “second” spin-splitting band, namely, a Rashba interface formed by inserting a bismuth interlayer between the ferromagnet and the Bi$_2$Se$_3$ (i.e., ferromagnet/Bi/Bi$_2$Se$_3$ heterostructure), $\lambda_{IEE}$ shows a pronounced increase (up to 280 pm) compared with that in pure TIs. We found that $\lambda_{IEE}$ alters as a function of bismuth interlayer thickness, suggesting a new degree of freedom to manipulate $\lambda_{IEE}$ by engineering the interplay of Rashba and Dirac surface states. Our finding launches a new route for designing TI- and Rashba-type quantum materials for next-generation spintronic applications.
Charge-density modulations are inevitably accompanied by a distortion of the crystalline lattice. Electronic or phononic origins of charge order are therefore difficult to distinguish. Here we propose a mechanism which traces the charge-density wave formation in underdoped cuprates to the incipient softening of a bond-buckling phonon. The momentum dependence of its coupling to the electrons in the copper oxygen planes favourably selects the incommensurate and axial ordering wavevector. But, it requires strong electronic correlations via their cuprate specific renormalization of the weight and the dispersion of quasiparticles to enable a unique enhancement of the charge susceptibility near the $B_{1g}$-phonon selected wavevector. The frequency of the $B_{1g}$ phonon softens by a few percent, and a lattice instability with concomitant finite range charge-density wave correlations will form locally, if nucleated by materials’ defects or dopant disorder.

Superconducting order in the doped Holstein model* 

The Holstein model (HM) is a tight-binding Hamiltonian which describes the interaction between electrons and local phonon modes on a lattice. Although charge density wave (CDW) order dominates at half-filling, the electron-phonon interaction is known to give rise to superconducting (SC) order away from half-filling. We use Quantum Monte Carlo simulations to explore the onset of SC order in doped systems through measurements of the s-wave pair susceptibility. We provide estimates for the critical temperature of the SC transition, obtained through a scaling analysis, for various values of the electron-phonon coupling $\lambda$ and phonon frequency $\omega$. We complement our calculation of the pair susceptibility with measurements of the electron kinetic energy and nearest-neighbor charge correlator.

*This work was supported by the Department of Energy, grant DE-SC0014671.
The interplay between electron-electron correlations and disorder has been a central theme of condensed matter physics over the last several decades, with the possibility that interactions might cause delocalization of an Anderson insulator into a metallic state, and the disrupting effects of randomness on magnetic order and the Mott phase both being central themes of investigation. Here we extend this physics to explore electron-phonon interactions and show, via exact quantum Monte Carlo simulations, that the suppression of the charge density wave correlations in the half-filled Holstein model by disorder can stabilize a superconducting phase. We discuss the relationship of our work to studies of the disorder quenching of the charge ordered phase in ZrTe$_3$ through Se doping, and the interplay with the observed superconductivity in that material, reproducing the qualitative features of the phase diagram in the temperature-disorder strength plane.

11:51AM 548.00004: Charge ordering due to topological reconstruction of the Fermi surface*  DANKO RADIĆ (Presenter), Department of Physics, University of Zagreb, Faculty of Science, ANATOLY M. KADIGROBOV, Theoretische Physik III, Ruhr-Universitaet Bochum, ALEKSA BJELIŠ, Department of Physics, University of Zagreb, Faculty of Science — Numerous experiments in recent years indicate presence of charge ordering such as charge density wave (CDW) in layered 2D materials among which we single out HiTC cuprates in pseudogap regime and intercalated graphite. External magnetic field leads to the stabilization of long-ranged CDW. We show that topological reconstruction of the Fermi surface (FS), appearing as a consequence of spontaneously created CDW of such wave vector to bring closed electron pockets to touching, lowers the total energy of electron condensate. Opening the gap Δ at the touching points transforms the chain of closed electron pockets into a continuous open FS. Such CDW appears as rather peculiar quantum phase transition, with nonstandard dependence of condensate energy on Δ for coupling constant of responsible interaction exceeding the critical value [PRB 97 235439]. It appears in the regime opposite to the standard CDW mechanism related to the FS nesting. Introducing external magnetic field, and taking into account magnetic breakdown, even more strengthens the spontaneous FS reconstruction because open FS does not undergo the energy-increasing Landau quantization [PRB 100 115108]. Reconstruction in two directions changes sign of the Hall constant.

12:03PM 548.00005: Enhanced electron-phonon coupling for charge-density-wave formation in La$_{1.8-x}$Eu$_{0.2}$Sr$_x$CuO$_4$  YINGYING PENG, Peking Univ, ALI HUSAIN, MATTEO MITRANO, XIAOLAN SUN, THORMAS JOHNSON, ALEXANDER ZAKRZEWSKI, GREG MACDOUGALL, University of Illinois at Urbana-Champaign, ANDI BARBOUR, IGNACE JARRIGE, VALENTINA BISOGNI, Brookhaven National Laboratory, PETER ABBAMONTE (Presenter), University of Illinois at Urbana-Champaign — Charge density waves (CDW) are prevalent in all copper-oxide superconductors and their connection to high-temperature superconductivity is hotly debated. A key issue is that, although widely studied, that the microscopic origin of CDW is still unclear. For conventional CDWs in metals, electron-phonon coupling (EPC) plays an important role for the CDW formation. Resonant inelastic X-ray scattering (RIXS) has recently become an effective tool to directly determine the momentum dependence of the electron-phonon coupling strength. Here we present the first RIXS study of the CDW and Cu-O bond-stretching phonons in La$_{1.8-x}$Eu$_{0.2}$Sr$_x$CuO$_4$ compounds. By varying the sample doping and temperature, we show that the EPC is surprisingly enhanced around the CDW wave vector. Our results support a picture in which lattice excitations play a central role in the formation of the CDW, and furthermore exhibit a feedback effect in which the CDW enhances the EPC.
Observation of two types of charge-density-wave orders in superconducting La$_{2-x}$Sr$_x$CuO$_4$*  

JIAJIA WEN (Presenter), HAI HUANG, SANG JUN LEE, SLAC - Natl Accelerator Lab, HOYOUNG JANG, PAL-XFEL, Pohang Accelerator Laboratory, JASON KNIGHT, SLAC - Natl Accelerator Lab, YOUNG SANG LEE, Stanford University, MASAKI FUJITA, K. M. SUZUKI, SHUN ASANO, Tohoku University, STEVEN KIVELSON, Stanford University, CHI-CHANG KAO, JUN-SIK LEE, SLAC - Natl Accelerator Lab — Density wave orders, including charge- and spin-density-wave (CDW/SDW), have been widely observed in cuprate superconductors. However, to fully elucidate the relationship between the density wave orders and high temperature superconductivity (SC) has been challenging. Here we use resonant soft X-ray scattering to study the CDW order in superconducting La$_{2-x}$Sr$_x$CuO$_4$ (LSCO) over a broad doping range. We discover two types of CDW orders in LSCO, namely CDW stripe order and CDW short-range order (SRO). They exhibit distinct interactions with SC that are not simply competitive. While the CDW-SRO is suppressed by SC, it is partially transformed into the CDW stripe order which keeps growing with developing SDW stripe order below the superconducting $T_c$. Our findings suggest that the stripe orders and SC are inhomogeneously distributed in the superconducting CuO$_2$ planes, and point to the emergence of a heterogeneous low temperature state as a result of the intricate interplay between CDW, SDW, and SC in LSCO.

Observation of an extended charge density wave boundary beyond the LTT phase in optimally doped LBCO  

SANG JUN LEE (Presenter), SLAC - Natl Accelerator Lab, SANGJUN LEE, University of Illinois Urbana Champaign, HAI HUANG, SLAC - Natl Accelerator Lab, YOUNG-IL JOE, WILLIAM B DORIESE, NIST, JASON KNIGHT, DONGHUI LU, SLAC - Natl Accelerator Lab, JOEL N ULLOM, PAUL SZYPRYT, DANIEL SWETZ, NIST, PETER MICHAEL ABBAMONTE, University of Illinois Urbana Champaign, JUN-SIK LEE, SLAC - Natl Accelerator Lab — Charge density wave (CDW) correlation in cuprates has been deemed a key ingredient to understand high-Tc superconductivity (SC). Since CDW is intertwined with other phases in a complicated way, determining the phase diagram of CDW is of critical importance. Here we focus on an archetypal La-based cuprate La$_{2-x}$Ba$_x$CuO$_4$ (LBCO) that has shown an interesting CDW behavior. The onset of CDW appears correlated with the low-temperature tetragonal (LTT) phase transition in the underdoped region whereas there is a big discrepancy above x=1/8. Particularly at the optimal doping of x=0.155, CDW was reported to occur at more than 20 K below the LTT transition. This contrasting behavior has not been well understood. Here, we present a resonant soft X-ray scattering (RSXS) study of CDW in optimally-doped LBCO, where we utilized a novel TES spectrometer with unprecedented sensitivity. Surprisingly, we detected short-ranged CDW up to T ~ 115 K, which is much higher than not just the previously reported CDW onset temperature but also the LTT transition temperature. We also observed behavior that suggests a positive correlation between CDW and SC, which are thought to be in general competing with each other. In this presentation, we will further discuss the implications of these new findings.
12:39PM S48.00008: Doping dependence study of CDW and its excitations via high
resolution RIXS*

HAIYU LU (Presenter), MATTHIAS HEPTING, MAKOTO HASHIMOTO, SU-DI CHEN, SLAC National Accelerator Laboratory, SHIGEYUKI ISHIDA, YOSHIYUKI YOSHIDA, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, ABHISHEK NAG, MIRIAN GARCIA-FERNANDEZ, Diamond Light Source, RICCARDO ARPAIA, Chalmers University of Technology, GIACOMO GHIRINGHELLI, LUCIO BRAICOVICH, Politecnico di Milano, BRIAN MORITZ, EDWIN HUANG, SLAC National Accelerator Laboratory, KURT KUMMER, NICHOLAS B BROOKES, European Synchrotron Radiation Facility, KEJIN ZHOU, Diamond Light Source, ZHIXUN SHEN, THOMAS DEVEREAUX, WEISHENG LEE, SLAC National Accelerator Laboratory — Although it is now well established a charge
order (CO) is ubiquitous high-temperature superconducting cuprates, its doping dependence, interplay with superconductivity, and more importantly, its relevance to the putative quantum critical fluctuation inside the superconducting dome remain an active area of research. To gain further insights, it is necessary to conduct a comprehensive doping and temperature
dependence study. High energy resolution momentum-resolved resonant inelastic soft x-ray scattering (RIXS) experiments at the Cu L3-edge has been performed on the high-temperature superconductor Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$ with 8 different doping concentration throughout the phase
diagram, including antiferromagnetic, underdoped, optimally doped, and overdoped regime, at the superconducting critical temperature Tc and well below the Tc. Doping and temperature
dependence of the CDW, the associated phonon softening, and excitations will be discussed.

Sciences, Materials Sciences and Engineering Division, under contract DE-AC02-76SF00515

12:51PM S48.00009: Resonant x-ray scattering studies of nematicity and charge order in the
La-based superconducting cuprates

TIMOTHY BOYLE (Presenter), MORGAN WALKER, ZITONG ZHAO, WILLIAM MOORE, EDUARDO H DA SILVA NETO, University of California, Davis, ALEJANDRO RUIZ, ALEX FRANO, University of California, San Diego, SANTIAGO BLANCO-CANOSA, Donostia International Physics Center, ZHAO W LI, HANJIE GUO, ALEXANDER KOMAREK, Max Planck Institute, CHRISTIAN SCHÜSSLER-LANGEHEINE, ENRICO SCHIERLE, Helmholtz-Zentrum Berlin, RONNY SUTARTO, FEIZHOU HE, Canadian Light Source, FABIO BOSCHINI, University of British Columbia — Charge-density waves (CDWs) are ubiquitous in the cuprates, however it is often difficult to distinguish between their different patterns and rotational symmetries. Additional phases, such as superconductivity and nematicity, further enrich the interplay between the low temperature phases in the cuprates and rotational symmetry. In particular, the La-based materials show an orthorhombic (LTO) to tetragonal (LTT) phase transition, with the LTT stabilizing stripes within the CuO$_2$ planes. Recent resonant inelastic x-ray scattering (RIXS) experiments also indicate the presence of high-temperature CDW correlations in these materials. In this study we use resonant x-ray scattering (RXS) to probe the energy and temperature dependent CDW correlations. We interpret our results in terms of the effects of uniaxial strain to the CDW correlations to uncover the nature of their interplay with nematic order.
**1:03PM S48.00010: X-ray scattering study of the role of charge-order in enhancing the superconducting transition**

MAXIME LEROUX (Presenter), LNCMI-Toulouse, CNRS, ZAHIRUL ISLAM, APS synchrotron, Argonne National Laboratory, VIVEK MISHRA, Oak Ridge National laboratory, JACOB RUFF, CHESS synchrotron, Cornell University, JOHN TRANQUADA, Brookhaven National Laboratory, MATTHEW SMYLIE, Hofstra University, PRASHANTA NIRAULA, ASGHAR KAYANI, Western Michigan University, GENDA GU, Brookhaven National Laboratory, WAI-KWONG KWOK, ULRICH WELP, Argonne National Laboratory — We combined proton irradiation (PI) and x-ray scattering to controllably tune and probe the competition between superconductivity (SC) and spatially modulated orders (e.g. charge order, CO). In particular, in La$_{2-x}$Ba$_x$CuO$_4$ (LBCO) complementary magnetization, tunnel diode oscillator, and resistivity measurements discovered that, despite being a d-wave superconductor, disorder induced by PI increases the superconducting critical temperature ($T_c$) by up to 50 % (4 K to 6 K) near $x = 1/8$ doping. X-ray scattering revealed that this $T_c$ increase coincides with a substantial suppression in CO strength and correlation length, providing clear evidence of strong competition between CO and bulk SC in LBCO. Insight from scattering and TDO suggest this competition originates from the cancellation of the interlayer Josephson coupling between CuO$_2$ planes.

**1:15PM S48.00011: Time-resolved resonant soft x-ray scattering study on charge density wave in YBCO**

HOYOUNG JANG (Presenter), MINSEOK KIM, INTAE EOM, PAL-XFEL, Pohang Accelerator Laboratory, MASAKI FUJITA, IMR, Tohoku University, JUN-SIK LEE, SSRL, SLAC National Accelerator Laboratory — Charge order / charge density wave (CO/CDW) have been observed in the most of cuprate superconductor families by x-ray scattering and they are considered as ubiquitous features in cuprate superconductors. To understand their properties and relation to superconductivity, the CDW have been investigated as a function of temperature, external magnetic field, doping, and other conditions.

In this study, we have investigated the temporal dynamics of the CDW in YBa$_2$Cu$_3$O$_{6+x}$ single crystal using time-resolved resonant soft x-ray scattering (tr-RSXS) at the newly developed RSXS endstation of the PAL-XFEL. Using infrared optical pump, CDW correlation changes within a few picosecond time window. Detailed results, i.e. temperature and fluence dependence, will be discussed in the presentation.

*Supported by National Research Foundation (Korea), Grant-in-Aid for Scientific Research (Japan), and Department of Energy (USA)
1:27PM S48.00012: Search for charge density wave order in (Y_{1-x}Pr_x) Ba_2Cu_3O_7* KALYAN SASMAL (Presenter), ALEJANDRO RUIZ, BRANDON GUNN, Department of Physics, University of California, San Diego, JUN-SIK LEE, SSRL, SLAC National Accelerator Laboratory, JESSICA L MCCCHESNEY, FANNY RODOLAKIS, Advanced Photon Source, Argonne National Laboratory, ALEX FRANO, M BRIAN MAPLE, Department of Physics, University of California, San Diego — High-\( T_c \) superconductivity in cuprates occurs in proximity to competing low-temperature density-wave-order states. Superconductivity appears when spin order of the parent compound is destroyed and for underdoped compounds it competes with charge density wave (CDW) order. Resonant elastic soft x-ray scattering (RSXS) combines x-ray scattering with x-ray spectroscopy, making it possible to probe a variety of exotic spin, charge, orbital and structural ordering phenomena. We report on the growth and characterization of single crystals of Y_{1-x}Pr_xBa_2Cu_3O_7 cuprate superconductors with \( 0 < x < 1.0 \) by means of XRD, magnetic susceptibility, and electrical resistivity measurements, as well as RSXS measurements performed to probe the relationship between CDW order, the pseudogap, and high \( T_c \) superconductivity in this unexplored system.

*Research supported by US DOE: DE-FG02-04ER46105, NSF: DMR 1810310

1:39PM S48.00013: Visualizing charge ordering in a charge-transfer insulating cuprate* ILIJA ZELJKOVIC (Presenter), HE ZHAO, ZHENG REN, BRYAN RACHMILOWITZ, Boston College, JOHN SCHNEELOCH, University of Virginia, RUIDAN ZHONG, Princeton University, GENDA GU, Brookhaven National Lab, ZIQIANG WANG, Boston College — Although numerous symmetry-broken electronic states have been detected in metallic and superconducting cuprates at relative high carrier doping, there still exists little information about the “parent” state of cuprates after the first few charge carriers are introduced. The bottleneck in large part lies in the difficulty of synthesizing and characterizing bulk cuprates in the very lightly doped insulating regime at low temperatures. We demonstrate that by annealing the surface of optimally-doped superconducting Bi_2Sr_2CaCu_2O_{8+x} (\( T_c \sim 91 \) K) in ultra-high vacuum, we can reduce the oxygen dopant density near the surface and extend the hole doping range to achieve the previously inaccessible charge-transfer insulating state at low temperature (Zhao et al., Nat. Mater. 18, 103 (2019)). At this low doping, we discover a unidirectional charge-stripe order with a commensurate 4\( a_0 \) period, the same as the charge ordering wave vector previously seen across the pseudogap phase and the superconducting dome. Our work provides strong evidence that charge ordering in cuprates is unlikely to be related to the pseudogap phase.

*We gratefully acknowledge the support from the NSF Grant No. 1654041, the Army Research Office Grant No. W911NF-17-1-0399 and the DARPA Grant No. N66001-17-1-4051.
The effect of magnetic field on the charge density wave in La$_{2-x}$Sr$_x$CuO$_4$ near the critical end point

MENGZE ZHU (Presenter), ALEXANDER PETSCH, Univ of Bristol, OLEH IVASHKO, Deutsches Elektronen Synchrotron DESY, ELIZABETH BLACKBURN, Lund University, LAUREN CANE, Univ of Bristol, MARTIN VON ZIMMERMANN, Deutsches Elektronen Synchrotron DESY, STEPHEN HAYDEN, Univ of Bristol — The interplay between superconductivity and other competing tendencies has been intensely investigated in high temperature cuprate superconductors. In underdoped La- based cuprates, the charge and spin orders appear to be intertwined to form stripes with the incommensurability $\delta_{\text{charge}} = 2\delta_{\text{spin}}$ [1]. In contrast, in YBa$_2$Cu$_3$O$_{6+x}$ (YBCO), charge density waves (CDW) and spin density waves (SDW) emerge at different doping indicating that they might compete with each other. These competing tendencies can be tuned by a magnetic field. In YBCO, a magnetic field can give rise to a ferro-type long-range CDW in-phase along the $c$ direction, distinct from the short-range anti-phase CDW at zero field [2,3]. Here, we study the effects of a magnetic field on the CDW of La$_{2-x}$Sr$_x$CuO$_4$ ($x = 0.132$), a composition close to the end point of the SDW where no SDW is observed at zero field. We find that the magnetic field induces a CDW such that its intensity grows linearly with field. A similar increase in the SDW intensity is observed for the SDW suggesting that the SDW and CDW modulations are strongly coupled as required for example in stripe theories.

Thursday, March 5, 2020 11:15 AM - 2:15 PM

Session S49 DCMP: Electronic Structure of Superconductors
(photoemission, etc.) Mile High Ballroom 1B - Anton Vorontsov, Montana State University, Bozeman

11:15AM S49.00001: ARPES Study on the Electronic Structure of Ferromagnet Rb$_{0.93}$Co$_{1.87}$Se$_2$ JIANWEI HUANG (Presenter), HAN WU, Department of Physics and Astronomy, Rice University, ZHICAI WANG, HONGSHENG PANG, School of the Gifted Young, University of Science and Technology of China, SUNG-KWAN MO, Advanced Light Source, Lawrence Berkeley National Lab, ALEXANDER F KEMPER, Department of Physics, North Carolina State University, ROBERT J BIRGENEAU, MENG WANG, Department of Physics, University of California, Berkeley, MING YI, Department of Physics and Astronomy, Rice University — As an isostructural analogue of AFe$_2$Se$_2$ (A=K,Rb,Cs) iron-based superconductors, ACo$_2$Se$_2$ (A=K,Rb,Cs) exhibits distinct magnetic ground states without manifestation of superconductivity. Specifically, in Rb$_{0.93}$Co$_{1.87}$Se$_2$, a ferromagnetic transition occurs at 83K. Here we use angle-resolved photoemission spectroscopy to study the electronic structure of Rb$_{0.93}$Co$_{1.87}$Se$_2$ across the ferromagnetic transition. Clear spin-splitting of bands of different orbitals are observed across the transition. Detailed comparison with first-principle calculations both in the normal state and the magnetic state will be presented. The contribution of different orbitals to the ordered moment as well as the nature of the ferromagnetism in Rb$_{0.93}$Co$_{1.87}$Se$_2$ will be discussed.
11:27AM S49.00002: ARPES studies of model cuprate high-temperature superconductor*

SUDHEER ANAND SREEDHAR (Presenter), Physics, University of California, Davis, ZACHARY ANDERSON, YANG TANG, MARTIN GREVEN, Physics and Astronomy, University of Minnesota, ROBERT J BIRGENEAU, Physics, University of California, Berkeley, MING YI, Physics and Astronomy, Rice University, INNA VISHIK, Physics, University of California, Davis — HgBa$_2$CuO$_{4+d}$ (Hg1201) is a model single-layer cuprate which has uniquely elucidated the cuprate phase diagram via transport, scattering, and optics studies, but it has received relatively little ARPES study owing to the difficulty in cleaving and achieving good photoemission cross-section. We will discuss recent progress in identifying three energy scales of interactions near the node and evaluating their evolution with doping, temperature, and momentum. We will also discuss recent progress in identifying experimental conditions which optimize antinodal spectra.

*SAS and IV supported by Air Force Office of Scientific Research grant #FA9550-18-1-0156.

11:39AM S49.00003: Further evidence of concurrent mass enhancement and superconductivity in a topological state*

NADER ZAKI (Presenter), GENDA GU, PETER JOHNSON, Brookhaven National Laboratory — Previously$^{1,2}$, we reported on the concurrent onset of mass enhancement at the Dirac point below the superconducting transition in FeSe$_x$Te$_{1-x}$. In this talk, we will review these results and provide more evidence of this phenomenon using low energy laser-based ARPES measurements. Given the increased interest in this system, due in part to the co-existence of superconductivity and non-trivial topology, our results show that this system is even more complicated than perhaps previously presumed and may require re-interpretation of recent experimental reports.

$^1$2019 APS March Meeting (talk: K05.00009)
$^2$arXiv:1907.11602 [cond-mat.supr-con]

*The work carried out at Brookhaven was supported in part by the U.S. DOE under Contract No. DE- SC0012704 and in part by the Center of Computational Design of Functional Strongly Correlated Materials and Theoretical Spectroscopy.
11:51AM S49.00004: Evolution of Electronic Spectral Weight in the Hubbard ladder
MASANORI KOHNO (Presenter), Natl Inst for Materials Sci — Although the number of electronic bands is usually considered invariant in a conventional band picture, the electronic states can generally emerge, grow, and disappear as the electron density changes in strongly correlated systems. Here, the evolution of the electronic states as a function of the electron density is illustrated in the Hubbard ladder in the strong Coulomb repulsion and strong intra-rung hopping regime using the non-Abelian dynamical density-matrix renormalization group method and perturbation theory. An emergent mode in the low-electron density regime grows with the electron density and plays a significant role in the dimer Mott physics at quarter filling, whereas an originally non-interacting band at zero electron density loses the spectral weight and disappears in the Mott transition at half filling, which leads to the spin excitation of the Mott insulator. The emergence and disappearance of electronic states, which have almost been overlooked in conventional band theory and Fermi liquid theory, are particularly important in understanding of the physics around the Mott transition.

12:03PM S49.00005: Non-local correlation effect in iron-based superconductors* KARIM ZANTOUT (Presenter), Goethe University Frankfurt, STEFFEN BACKES, Centre de Physique Theorique, Institut Polytechnique de Paris, ROSER VALENTI, Goethe University Frankfurt — While experimental studies of many iron-based superconductors observe momentum-dependent effects like the so-called blue/red shift that describes opposite energetic shifts of electron- and hole-parabolas with respect to bandstructure calculations, DMFT by construction is not able to capture such features. We therefore present a momentum-dependent and dynamical many-body method, the Two-Particle Self-Consistent (TPSC) approach, and apply it to an ab-initio-derived multi-orbital Hubbard model.
Multi-orbital TPSC assumes the irreducible interaction vertex to be an orbital-dependent constant, which is self-consistently determined from local spin and charge sum rules. Those are immediate representatives of the Pauli principle. We disentangle the contribution of non-local correlations in LiFeAs and show that in the local approximation, i.e. after momentum-averaging the self-energy, one recovers dynamical-mean field theory (DMFT) results. The comparison of our results to experimental data shows that non-local correlations in LiFeAs are decisive to describe the spectral function, Fermi surface and scattering rates.

*We thank the German ResearchFoundation (Deutsche Forschungsgemeinschaft) for financial support.
**12:15 PM S49.00006: Electronic structure and superconductivity in unconventional cuprates**

*KUN JIANG (Presenter), Boston College, CONGCONG LE, FU-CHUN ZHANG, Kavli Institute of Theoretical Sciences, University of Chinese Academy of Sciences, ZIQIANG WANG, Boston College, JIANGPING HU, Institute of Physics, Chinese Academy of Sciences — We study the recently discovered 73K high-$T_c$ superconductor $\text{Ba}_2\text{CuO}_{3+\delta}$ at $\delta \approx 0.2$ grown under high pressure. Neutron experiments find that the polycrystal exhibits a structure similar to $\text{La}_2\text{CuO}_4$, but with dramatically different lattice parameters due to the CuO$_6$ octahedron compression. The octahedron compression leads to an \{\em inverted\} Cu $3d\ e_g$ complex with the $d_{x^2-y^2}$ orbital sitting below the $d_{3z^2-r^2}$ orbital and an electronic structure highly unusual compared to the conventional cuprates. We conjecture that the material realizes a new path of in-plane positional oxygen doping, where the doped oxygens create matrices of compressed $\text{Ba}_2\text{CuO}_4$ embedded in $\text{Ba}_2\text{CuO}_3$. Constructing a strongly correlated two-orbital model at hole doping $x = 2\delta$ of the Cu $d^9$ state, we show that the multi-orbital exchange interactions lead to an antiphase $d$-wave superconducting state, i.e. a nodal $d_{\pm}$ pairing state. These findings suggest that the class of unconventional cuprates with liberated orbitals as doped two-band Mott insulators can be a direction for realizing high-$T_c$ superconductivity.

*The work is supported by the U.S. Department of Energy, Basic Energy Sciences Grant No. DE-FG02-99ER45747.

**12:27 PM S49.00007: Photoemission studies of BSCCO-2212 across the phase diagram with in-situ control of doping**

*ILYA DROZDOV (Presenter), GENDA GU, TONICA VALLA, Brookhaven National Laboratory — I will present angle-resolved photoemission studies of $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ enabled by oxide MBE [1]. Single crystals were cleaved and annealed in ultra-high vacuum or in ozone (O$_3$) to reduce or increase the doping level. Photoemission studies have been carried out on a wide range of dopings spanning the superconducting dome and covering the previously inaccessible, metallic, non-superconducting phase on the overdoped side (OD0K). This allowed us to study the evolution of the Fermi surface with doping [2], the reconstruction of the Fermi surface due to the superstructure modulation [3], and the renormalization of the electronic spectrum concomitant with the onset of superconductivity [4]. In this talk, I will focus on the sample preparation aspects and cover the first two results.

*US DOE, BES, contract no. DE-SC0012704.
Disappearance of Superconductivity Due to Vanishing Coupling in the Overdoped Cuprate Superconductors

TONICA VALLA (Presenter), ILYA DROZDOV, GENDA GU
Condensed Matter Physics and Materials Science, Brookhaven National Laboratory — In high-temperature cuprate superconductors, superconductivity is accompanied by a "plethora of orders" and phenomena that may compete, or cooperate with superconductivity, but which certainly complicate our understanding of origins of superconductivity. While prominent in the underdoped regime, these orders weaken or completely vanish with overdoping. Here, we approach the superconducting phase from the more conventional highly overdoped side. We present angle-resolved photoemission studies of Bi$_2$Sr$_2$CaCu$_2$O$_{8+δ}$ single crystals cleaved and annealed in ozone to increase the doping all the way to the non-superconducting phase. We show that the mass renormalization in the antinodal region of the Fermi surface, associated with the structure in the quasiparticle self-energy, that possibly reflects the pairing interaction, monotonically weakens with increasing doping and completely disappears precisely where superconductivity disapears. This is the evidence that in the overdoped regime, superconductivity is determined by the coupling strength. A strong doping dependence and an abrupt disapearance above $T_c$ eliminate the conventional phononic mechanism of the observed mass renormalization.

*This work was supported by the US DOE, Office of Basic Energy Sciences, contract no. DE-SC0012704.

ARPES on Unusual Superconducting Properties of Single-Layer FeSe/SrTiO$_3$ Films

YU XU (Presenter), QINGYAN WANG, HONGTAO RONG, DINGSONG WU, Chinese Academy of Sciences, Institute of Physics, YONG HU, University of Science and Technology of China, XINXUAN GUO, LIN ZHAO, GUODONG LIU, Chinese Academy of Sciences, Institute of Physics, ZUYAN XU, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences , Beijing 100190 , China, XINGJIANG ZHOU, Chinese Academy of Sciences, Institute of Physics — Single-layer FeSe films grown on SrTiO$_3$ substrates have attracted much attention because of their record high superconducting critical temperature and distinct electronic structure. Here we report MBE growth of very high-quality single-layer FeSe/STO films, and systematic investigations of their electronic structure and superconducting properties by high-resolution angle-resolved photoemission spectroscopy measurements. Two ellipse-like electron pockets are clearly resolved at one Brillouin zone corner and obvious band splitting is observed. The anisotropic superconducting gap along the Fermi surface is measured with high precision. In particular, we observe very strong superconductivity-induced band back-bending that extends to rather high binding energy. The implications of these observation on superconductivity mechanism of the single-layer FeSe/SrTiO$_3$ films will be discussed.
1:03PM S49.00010: Angle-resolved photoemission spectroscopy of in-situ grown cuprate heterostructures by molecular beam epitaxy  ZHUOYU CHEN (Presenter), YUNTIAN LI, YONG ZHONG, SLAVKO REBEC, TAO JIA, Stanford University, MAKOTO HASHIMOTO, DONGHUI LU, ROBERT G MOORE, SLAC National Accelerator Laboratory, ZHIXUN SHEN, Stanford University — The molecular beam epitaxy (MBE) system in-situ connected to the beam-line angle-resolved photoemission spectroscopy (ARPES) in Stanford Synchrotron Radiation Lightsource (SSRL) enables rational design of complex material systems and direct electronic structure measurements. The in-situ connected scanning tunneling microscopy (STM) further enables electronic property mapping in the spatial dimensions. Particularly, cuprate films and heterostructures grown atomic-layer-by-layer are of great interest to be explored. In this talk, we will present the newest results about ARPES on cuprate heterostructures.

1:15PM S49.00011: Improved Understanding of Gap Dynamics from Time- and Angle-Resolved Photoemission Spectroscopy of a Nonequilibrium Superconductor*  TIANRUI XU, DANIEL EILBOTT (Presenter), Physics, University of California, Berkeley, CLAUDIA FATUZZO, Materials Science Division, Lawrence Berkeley National Laboratory, TAKAHIRO MORIMOTO, Applied Physics, University of Tokyo, JOEL MOORE, ALESSANDRA LANZARA, Physics, University of California, Berkeley — Time- and angle-resolved photoemission spectroscopy (tr-ARPES) has shown to be a useful tool in studying non-equilibrium states of matter. However, the absence of time-translation invariance presents a challenge to understanding the underlying dynamics of the system from the measurements in a straightforward manner. In equilibrium, ARPES intensity is understood to be \( I(k, \omega) \propto f(\omega) A(k, \omega) \) with broadening, where \( f(\omega) \) is the Fermi-Dirac distribution, and \( A(k, \omega) \) is the electronic spectral function. Here we study how one should interpret \( I(k, \omega, t) \), now as a function of time \( t \). We focus our study on tr-ARPES measurements of a non-equilibrium superconducting system where the superconducting gap changes with time. With a focus on situations where the standard quasi-static analysis method fails, we present a possible better way to obtain superconducting gap dynamics.

1:27PM S49.00012: Gap opening in monolayer FeSe/TiO$_2$(100) at low doping  CHENHUI YAN (Presenter), Pritzker School of Molecular Engineering, University of Chicago, BRENDAN D. FAETH, Department of Physics, Laboratory of Atomic and Solid State Physics, Cornell University, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University, SHUOLONG YANG, Pritzker School of Molecular Engineering, University of Chicago, KYLE M. SHEN, Department of Physics, Laboratory of Atomic and Solid State Physics, Cornell University — Monolayer FeSe grown on SrTiO$_3$(001) has been established to host a high-temperature superconducting state, with the gap-opening temperature between 60 and 70 K. On the other hand, it was shown that monolayer FeSe exhibits an insulating gap when the electron doping level is below 0.09 electron per iron atom. This insulating gap is temperature independent, in contrast to the gap-opening phenomenology in superconducting monolayer FeSe. Here we grow monolayer FeSe on rutile TiO$_2$(100), and show that the gap opens below 40 K with an electron doping of 0.08 electron per iron atom. This doping level is lower than the previously reported doping threshold for superconductivity. We will discuss the origin of this gap.

1:39PM S49.00013: Strong particle-hole asymmetry in a 200 Kelvin superconductor*  SOHAM GHOSH (Presenter), YUNDI QUAN, WARREN E PICKETT, University of California, Davis — The superconducting state of metals have long provided a classic example of particle-hole symmetry at low energy. We present fermionic self-energy results based on first-principles theory for the electron-phonon coupling in H$_3$S which illustrates strong particle-hole asymmetry in the dynamics arising from the underlying sharp structure in the fermionic density of states. We evaluate the momentum-resolved and zone-averaged spectral densities and interacting thermal distribution function, all of which clearly illustrate strong particle-hole asymmetry. The results allow us to study the infrared conductivity and to note that the strength and position of extrema are affected by electron-phonon coupling.

*The project was supported by NSF Grant No. DMR 1607139.
1:51PM S49.00014: Band structure motif and bosonic excitations in the fluctuating superconductivity of overdoped cuprates* YU HE (Presenter), Physics, University of California at Berkeley, SU-DI CHEN, Applied Physics, Stanford University, MAKOTO HASHIMOTO, SSRL, SLAC National Laboratory, SHAN WU, XIANG CHEN, YU SONG, Physics, University of California at Berkeley, HIROSHI EISAKI, AIST, Japan, ZHIXUN SHEN, Applied Physics, Stanford University, ROBERT J BIRGENEAU, Physics, University of California at Berkeley — Superconducting fluctuation is one of the central discussions in the physics of high-Tc superconductivity, especially when the system is optimally doped. Recent years have seen a renewed interest in this topic regarding overdoped cuprates, where the expectation is to seek a resolution closer to various BCS premises. However, a series of transport and optical experiments reveal substantial departure from the conventional wisdom.

We combine angle-resolved photoemission spectroscopy (ARPES) with inelastic neutron scattering (INS), and aim to provide a holistic view on this issue on overdoped single crystal Bi-2212. In particular, we discuss the role of the van Hove point on the electronic structure and the partial flat band around it [1]. The relation between electronic structure and the underlying magnetic excitation will also be discussed in the context of d-wave pairing and pair-breaking [2].

*Miller Institute for Basic Research in Science
Department of Energy, Office of Science, Basic Energy Sciences

2:03PM S49.00015: Interface-enhanced superconductivity of single layer FeSe grown on non-TiO2 based oxides* YUAN-HE SONG (Presenter), XIA LOU, XIAOYANG CHEN, RAN TAO, TIANLUN YU, RUI PENG, HAICHAO XU, State Key Laboratory of Surface Physics, Department of Physics, and Advanced Materials Laboratory, Fudan Univ, HAO RU, YI-HUA WANG, Department of Physics and State Key Laboratory of Surface Physics, Fudan Univ, ZHENG CHEN, YAN-WU XIE, Department of Physics, Zhejiang Univ, QINGHUA ZHANG, LIN GU, XUETAO ZHU, JIANDONG GUO, Institute of Physics, Chinese Academy of Sciences, DONGLAI FENG, State Key Laboratory of Surface Physics, Department of Physics, and Advanced Materials Laboratory, Fudan Univ — The single layer FeSe film on SrTiO3 indicates that interfaces can play a significant role in high-temperature superconductivity. Here we report a new FeSe-based interface, single layer FeSe grown on non-TiO2 based oxides by molecular beam epitaxy (MBE) method, was successfully obtained. The structure of the interface was determined by high resolution transmission electron microscopy (HRTEM). The angle-resolved photoemission spectroscopy (ARPES) shows that it is superconducting with a large gap, while the ex-situ mutual inductance measurements indicate it has a high onset temperature for diamagnetism. This heterostructure can provide a new platform for understanding the interface-enhanced superconductivity.

Unraveling the Mott-Peierls intrigue in Vanadium dioxide

ADRIANO AMARICCI (Presenter), MICHELE FABRIZIO, SISSA, FRANCESCO GRANDI, Department of Physics, Erlangen University — Vanadium dioxide is one of the most studied strongly correlated materials. The nature of the rutile metal to monoclinic insulator transition in this system triggered a longstanding debate about which comes first, the Mott localisation or the Peierls distortion. Here, we show that the electronic correlations and the lattice vibrations conspire to stabilise the monoclinic insulator, and so they must be treated on equal footing. We design a minimal model for VO2 that includes all the important physical ingredients: the electronic correlations, the multi-orbital character, and the two components antiferrodistortive mode that condenses in the monoclinic insulator. We solve this model by dynamical mean-field theory within the adiabatic Born-Oppenheimer (BO) approximation. Consistently with the first-order character of the metal-insulator transition, the BO potential has a rich landscape describing the distorted and undistorted phases, and which translates into an equally rich thermodynamics that we uncover by the Monte Carlo method. Remarkably, we find that a distorted metal phase intrudes between the low-temperature distorted insulator and high-temperature undistorted metal, which sheds new light on the debated experimental evidence of a monoclinic metallic phase.

Correlation induced emergent charge order in metallic vanadium dioxide thin films

CHRISTOPHER SINGH, LOUIS F. J. PIPER, Binghamton University, HANJONG PAIK, DARRELL SCHLOM, Cornell University, WEI-CHENG LEE (Presenter), Binghamton University — Understanding the metal-insulator transition in vanadium dioxide is complicated by symmetry breaking structural transitions accompanying correlated electronic transitions. Resolving this problem though is at the heart of many scientific and technological advancements. To that end, we develop a cross-phase, symmetry-consistent approach to treat structural distortions and electronic correlations in epitaxial VO2 films from first principles. By adopting a uniform Bravais symmetry across several epitaxial growth configurations, we demonstrate the exquisite sensitivity of correlation physics to apical bond lengths in the presence of lattice symmetry breaking, and discover emergent charge order preceding the dimerized insulating phase even in the metallic rutile phase. We discuss the deep physical implications for the phase diagram of VO2, and argue for the unparalleled significance of correlation physics and sample quality in light of this result.

*This material is based upon work supported by the Air Force Office of Scientific Research under award number FA9550-18-1-0024.
11:39AM S50.00003: Probing the Mott transition in \(V_2O_3\) with Pair Distribution Function Analysis

ETHAN FLETCHER (Presenter), BENJAMIN FRANDSEN, Department of Physics and Astronomy, Brigham Young University, KENTARO HIGASHI, HIROSHI KAGEYAMA, Department of Energy and Hydrocarbon Chemistry, Kyoto University — \(V_2O_3\) is a popular system for studying Mott insulators, which are materials that are driven into an insulating state by strong electron correlations. Despite decades of research, a complete understanding of the metal-insulator transition in \(V_2O_3\) has not been conclusively established. Here, we present comprehensive atomic and magnetic pair distribution function (PDF) analyses of \(V_2O_3\) using both x-ray and neutron total scattering measurements, shedding new light on the mechanism of the transition from the point of view of short-range structural and magnetic correlations on both sides of the transition. The results allow us to thoroughly examine the transition from the metallic state to the insulating state with complementary sensitivity provided by the x-rays (sensitive to the vanadium displacements) and neutrons (sensitive to the oxygen displacements and magnetic correlations). We discuss the implications of these results in the context of other recent experimental and theoretical studies of \(V_2O_3\).

11:51AM S50.00004: Nanosecond fluctuators in \(V_2O_3\) film within the metal-insulator-transition

LIYANG CHEN (Presenter), PANPAN ZHOU, Rice Univ, YOAV KALCHEIM, IVAN SCHULLER, University of California, San Diego, DOUGLAS NATELSON, Rice Univ — Vanadium sesquioxide (\(V_2O_3\)) is an archetypal Mott insulator, and exhibits a first-order transition at 160 K between a low temperature monoclinic, antiferromagnetic insulator and a high temperature, rhombohedral, paramagnetic, metallic phase. Resistive noise as measured through electronic transport can be used as a probe of the fluctuating dynamics of the two-phase domain structure. We measure noise spectra at both low frequencies (up to 300 kHz) and radio frequencies (between 200 MHz and 1 GHz). At low current densities the noise power is quadratic in bias current, as expected for resistive fluctuations probed nonperturbatively by the current. The low frequency noise generally resembles flicker-type \(1/f^\alpha\) noise, often taking on the form of Lorentzian noise dominated by a small number of fluctuators as the insulating phase is approached. The presence of radio frequency noise power that is quadratic in the bias current allow identification of domain fluctuations with lifetimes below 1 ns, comparable to timescales seen in non-equilibrium pump-probe studies of the transition.

Low-temperature metallic phase in V$_2$O$_3$ films due to structural confinement

YOAV KALCHEIM (Presenter), COLINE ADDA, NAREG GHAZIKHANIAN, HENRY NAVARRO, PAVEL SALEV, JAVIER DEL VALLE, IVAN SCHULLER, Department of Physics, University of California San Diego — We show that high purity V$_2$O$_3$ films grown on certain substrates exhibit a suppressed metal insulator transition (MIT) and in some cases even a reentrant metallic phase at low temperature. This occurs only in films which have the c-axis in the out-of-plane direction. For this lattice orientation the MIT entails a structural expansion which is entirely in the film plane. As the MIT progresses, some expansion into the low temperature monoclinic phase occurs but in-plane confinement prohibits a full expansion of the lattice. Instead, a coexisting metallic phase is stabilized down to the lowest temperatures measured. This low temperature metallic phase exhibits structural and electrical properties which are distinct from the high temperature metallic phase.

*Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award No. DE-SC0019273.

Controlled growth of VO$_2$ Nanowires by direct conversion of V$_2$O$_5$ solution film

GAVIN BLAIR, ABIN JOSHY, ANDREW STEELY, JIANG WEI (Presenter), Tulane Univ — Vanadium dioxide is known to exhibit fascinating properties due to its phase transition from insulating to metallic phase at 340 K. Effectively growing single-crystal VO$_2$ nanowires has been difficult to realize in a controlled, repeatable way. Through the use of a chemical vapor deposition using solutions of V$_2$O$_5$, we realized a consistent growth of single crystals with their size ranging from nanowires to microbeams. A comprehensive understanding of the growth mechanism has also been obtained. With combined probing techniques, including an Enhanced Darkfield Optical Microscopy, Atomic Force Microscopy, and Raman Microspectroscopy, we captured the dynamics of growth, along with the stoichiometry and crystal structure for nanocrystals at different growth stages. We revealed that the growth starts with the vaporization of V$_2$O$_5$, followed by dense seed nucleation on the substrate, and then the growing of large crystals as a result of consuming neighboring seeds.

The new method of VO$_2$ nanowires growth based on V$_2$O$_5$ film provides a simpler and more economical solution for their application in industry.

Observation of the voltage-triggered insulator to metal transition in a VO$_2$ thin film as a function of temperature.* 

ALYSON SPITZIG (Presenter), XUGUANG WANG, MICHAEL ARUMAINAYAGAM, DILEK YILDIZ, JASON HOFFMAN, JENNIFER E. HOFFMAN, Harvard University — VO$_2$ undergoes an insulator to metal transition with a resistivity change up to five orders of magnitude upon heating through 340 K. The transition has also been observed via current-voltage (IV) measurements as a sharp jump in the current when sweeping the applied voltage. We have previously used the tip of an atomic force microscope (AFM) to map the local current response of voltage-biased polycrystalline VO$_2$ thin films[1]. We have fit the IV curve immediately preceding the transition to the temperature-dependent Poole-Frenkel conduction mechanism and calculated the local temperature of the film. While these measurements were nominally performed at room temperature, we calculated an increased local temperature of 335 K immediately preceding the transition, confirming the role of Joule heating in our voltage-biased, tip-sample geometry. Here, we extend these measurements to a wider temperature range to further understand the effects of Joule heating on the voltage-triggered insulator to metal transition in VO$_2$ thin films. ([1] Spitzig et al. arXiv:1903.03062v1)

Selective phonon-mode excitation revealed by tracing the pathway of photo-induced structural-phase-transition in single-crystal VO$_2$* 

JUNJIE LI (Presenter), WEI WANG, LIJUN WU, Brookhaven National Laboratory, OLIVIER DELAIRE, Duke University, JING TAO, YIMEI ZHU, Brookhaven National Laboratory — The Metal-Insulator (M-I) transition in VO$_2$ that is associated with a monoclinic-rutile (M-R) structure phase transition has been extensively studied due to the potential application of its fast electrical/optical switch properties. It remains a big challenge to reveal the transition pathway to fully understand the underlying mechanism. In this study, we use MeV ultrafast electron diffraction to monitor the structure evolution in single-crystal VO$_2$ under femtosecond laser excitation. The M-R phase transition was observed at a high sample temperature (T = 314 K) under a specific pump fluence of 16 mJ/cm$^2$. Crystallographic structural analysis reveals that the atomic motions have a two-step dynamics. During the first a few ps, both stretching and rotation A$_g$ phonon modes are involved in the collective vanadium motions. Then only rotation A$_g$ phonon mode is continuously excited in the following hundreds of ps. Moreover, such the M-R phase transition cannot be observed at a much lower sample base temperature (T = 77 K), indicating a certain role of thermal fluctuation in this photo-induced phenomenon.

12:51PM S50.00009: Probing the insulator-to-metal transition in VO$_2$ using non-contact atomic force microscopy*  
MICHAEL ARUMAINAYAGAM (Presenter), ALYSON SPITZIG, XUGUANG WANG, LARISSA LITTLE, DILEK YILDIZ, JASON HOFFMAN, JENNIFER E. HOFFMAN, Harvard University — Vanadium dioxide (VO$_2$) undergoes an insulator-to-metal transition (IMT) when heated above a critical temperature of 340 K. The role of Joule heating and applied electric field in inducing this transition is an active area of research. In this study, the IMT of VO$_2$ thin films grown using oxygen plasma molecular beam epitaxy are examined using non-contact atomic force microscopy (AFM) in ultrahigh vacuum. By measuring the dissipated power through a qPlus AFM tuning fork, the competing effects of Joule heating and applied electric field are assessed. With this non-invasive and highly sensitive technique, we can measure the IMT as a function of tip-sample distance and bias voltage.

1:03PM S50.00010: Resistive switching and filament formation in VO$_2$ vertical devices*  
MINHAN LEE (Presenter), Materials Science and Engineering, University of California-San Diego, SHAOBO CHENG, Department of Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, JAVIER DEL VALLE, Center for Advanced Nanoscience, Department of Physics, University of California-San Diego, YIMEI ZHU, Department of Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, IVAN SCHULLER, Center for Advanced Nanoscience, Department of Physics, University of California-San Diego — Vanadium oxides exhibit electrically-triggered, volatile, resistive switching and provide a promising opportunity to mimic spiking neurons for neuromorphic computing. The control of the physical properties of these oxides is an important requirement to develop oxide electronics for future technology. However, a detailed understanding of the non-volatile filamentary formation in these Mott materials is still lacking. In this work, we investigated the mechanisms behind volatile and non-volatile resistive switching in electrically-driven VO$_2$ vertical devices. By using electrical transport measurement and in-situ transmission electron microscopy, the metal-insulator transition properties of the conductive filament and its nanoscale lattice structure are studied. Our works address the important issues in resistive switching based neuromorphic technologies.

*Work supported by the Quantum Materials for Energy-Efficient Neuromorphic Computing (Q-MEEN-C) Energy Frontier Research Center (EFRC), funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award DE-SC0019273.
The acoustoelectric (AE) effect, which manifests itself as the generation of a DC current by a propagating acoustic wave, may convey crucial information on the interdependence between the structural and electronic properties of strongly correlated oxides. We observed that acoustic waves may be coupled not only to an electronic but also to a magnonic state of these materials. In this work, we studied the AE effect in non-magnetic (VO$_2$, V$_2$O$_3$) and ferromagnetic La$_{0.7}$Sr$_{0.3}$MnO$_3$ wires grown on top of piezoelectric LiNbO$_3$ substrates. It was observed that the resistance change across a metal-insulator transition results in a significant enhancement of the AE current in the vanadates wires. Additionally, we show that the sign of the AE current differs for excitations produced by bulk and surface acoustic waves. Importantly, it was observed that the AE current in the La$_{0.7}$Sr$_{0.3}$MnO$_3$ wire can be significantly tuned by applying an external magnetic field. Our work provides a new platform for surface acoustic wave devices based on Mott transitions.

This research was supported by the Office of Basic Energy Science, U.S. Department of Energy, BES-DMS funded by the Department of Energy's Office of Basic Energy Science, DMR under grant DE FG02 87ER-45332.

VO$_2$ displays a first-order metal-insulator phase transition near 340 K. Accompanying this electronic transition is a structural transition. The connection between these two transitions is unclear, with electronically-driven and structurally-driven models providing conflicting results. Electron doping with molybdenum enhances metallicity and reduces the structural transition temperature; between 17% and 19% Mo, we find that the long-range structural transition is suppressed entirely while the electronic transitions remain similar. Diffuse x-ray scattering measurements were performed on a single crystal of the V$_{0.81}$Mo$_{0.19}$O$_2$. In the low-temperature insulating phase, sharp rods are observed, indicating two-dimensional ordering of atomic displacements. The slight oscillation of these rods about the [110] direction in reciprocal space can be explained by weak, inherently frustrated coupling between the ordered planes. Such fragile embedded order is predicted by an Ising-like ferrodistortive model proposed by Lovorn and Sarker. 3D-ΔPDF analysis of the diffuse scattering and structural simulations provide a clear picture of the local order in this system.

1:39PM S50.00013: Nonequilibrium-induced quantum fluctuations in resistive phase transition  JONG E HAN (Presenter), State Univ of NY - Buffalo — We investigate the quantum mechanical origin of resistive phase transitions in solids driven by a constant electric field in the vicinity of a metal-insulator transition. The mean-field theory [1] showed that the self-consistent Landau-Zener mechanism reproduced main experimental features, and we show that it is equivalent to the empirical resistor network theories based on electronic scenarios applicable to systems like VO$_2$. Despite the qualitative agreement, reliable quantitative predictions for the switching electric-field has remained elusive. Theoretical estimates based on the Landau-Zener mechanism are typically orders of magnitude larger than experimentally observed threshold electric-fields of kV/cm for the insulator-to-metal transition in transition metal oxides and chalcogenides. We investigate the similarities between the resistive switching and the charge-density-wave (CDW) system. Motivated by the CDW theories, we construct a Lagrangian for the gap parameter and investigate the role of the quantum fluctuations to the gap parameter as a quantum variable. We discuss how quantum corrections affect the nonequilibrium resistive transition.

1:51PM S50.00014: Emergent properties in films of transition metal oxides*  D. LAHNEMAN (Presenter), P. MCARDLE, H. JIANG, M. M. QAZILBASH, Department of Physics, College of William & Mary, T. SLUSAR, H.-T. KIM, Metal-Insulator-Transition Laboratory, Electronics and Telecommunications Research Institute (ETRI), A. BISWAS, Department of Physics, University of Florida, F. KEILMANN, Fakultät für Physik & Center for NanoScience (CeNS), Ludwig-Maximilians-Universität — Transition metal oxides exhibit diverse emergent phenomena such as strongly correlated Mott insulating states, magnetic and structural phase transitions, and metal-insulator transitions. Many of these emergent states occur at nanometer length scales which cannot be accessed with traditional infrared focusing methods due to the Abbe diffraction limit. However, scattering-type scanning near-field infrared microscopy (S-SNIM) can circumvent the Abbe diffraction limit and probe optical properties with spatial resolution of tens of nanometers. We have coupled table-top plasma light sources developed in-house to a commercial S-SNIM apparatus from Neaspec GmbH to demonstrate broadband infrared nano-spectroscopy. This is used to study the novel nanoscale properties of ultrathin vanadium dioxide (VO$_2$) film on rutile titanium dioxide (TiO$_2$) substrate. Due to strain from the substrate, the metal-insulator transition in the VO$_2$ film occurs at a temperature of 305 K which is much lower than in bulk VO$_2$. We also study the surface metallic layer induced by vacuum-annealing of insulating strontium titanate (SrTiO$_3$) crystals and extract the dynamical properties of the free charge carriers.

Session S51 DCMP: Graphene: Electron interactions Mile High Ballroom 1D - George Kioseoglou, Univ of Crete
11:15AM S51.00001: Fabry–Pérot Quantum Hall Interferometry in Graphene  YUVAL RONEN
(Presenter), THOMAS WERKMEISTER, Harvard University, DANIAL HAEI NAJAFABADI, University of Massachusetts Lowell, ANDREW PIERCE, BOBAE JOHNSON, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, AMIR YACOBY, PHILIP KIM, Harvard University — The fractional quantum Hall effect (FQHE) manifests when a large magnetic field is applied to a 2-dimensional electron gas with strong electron-electron interactions. The excitations of this highly correlated phase are expected to possess anyonic exchange statistics. Inspired by experiments in GaAs heterostructures that have attempted to demonstrate anyonic exchange statistics via quantum Hall interferometry, we explore the possibility of determining quasiparticle charge and statistics by measuring quantum Hall interferometers in graphene heterostructures. We utilize hBN-encapsulated monolayer graphene with top and bottom graphite gates to electrostatically define interferometers in the FQHE regime. We demonstrate that two quantum point contacts (QPC), which individually act as beam splitters for quantum Hall edge states, cascaded in series forms a Fabry–Pérot interferometer. We will discuss development toward realizing Aharanov-Bohm dominated interference.

11:27AM S51.00002: Optical conductivity of graphene with second-nearest neighbors coupling*  ENRIQUE MUNOZ (Presenter), Physics, Pontifical Catholic University of Chile, HORACIO FALOMIR, Physics, Universidad Nacional de La Plata, MARCELO LOEWE, Physics, Pontifical Catholic University of Chile, RENATO ZAMORA, Centro de Investigacion y Desarrollo de Ciencias Aeroespaciales (CIDCA), Fuerza Aerea de Chile — Optical transparency experiments show that optical conductivity depends on the fine structure constant, as it can be fully explained within the effective theory of two-dimensional relativistic Dirac fermions. In this work, we investigate how this property is affected by second-nearest-neighbors coupling t'. Within a field theoretical representation in the continuum approximation arising from an underlying tight-binding atomistic model, we obtain the dependence of the optical conductivity on frequency, temperature and finite chemical potential. We investigated the model in the Keldysh contour representation at zero temperature[1], as well as in Matsubara space for finite temperature and chemical potential[2]. Our results reproduce the universal and experimentally verified value at zero frequency and, more importantly, they reveal that a small but still measurable shift in the conductance minimum at finite temperatures arises as a function of the second-nearest neighbors hopping t’, thus providing the possibility to directly measure this parameter in transport experiments.

The equilibration dynamics of spin-polarized quantum Hall edges at graphene p-n junction

ARUP KUMAR PAUL (Presenter), MANAS SAHU, CHANDAN KUMAR, Indian Institute of Science - Dept of Physics, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Namiki 1-1, Ibaraki 305-0044, Japan., ANINDYA DAS, Indian Institute of Science - Dept of Physics — The understanding of equilibration dynamics of quantum Hall (QH) edges is essential to realize an electron interferometer, which has the potential to exhibit fractional statistics and quantum entanglement. Recently, graphene pn junction with spin-valley polarized QH edges showed an ideal platform for an electron interferometer. However, the interplay of different scattering mechanisms in equilibration of polarized QH edges at the graphene pn junction remain elusive. In this report, we have carried out the conductance together with shot noise measurements for symmetry broken QH edges co-propagating along a pn junction. The pn junction was realized in a dual graphite gated hexagonal boron nitride (hBN) encapsulated graphene device. Earlier studies with unpolarized QH edges showed incoherent processes as the dominant scattering mechanism for mode mixing. However, Our results reveal that the mode mixing dynamics of the polarized QH edges are much more intricate depending on the spin sequence of QH edges. A complete crossover from incoherent to fully coherent scattering regime was observed by tuning the number of participating polarized QH edges at the pn junction, which will pave the way to design the electron quantum optics experiments based on polarized QH edges of graphene.

Light-induced anomalous Hall effect in graphene*

JAMES MCIVER (Presenter), BENEDIKT SCHULTE, FALK-ULRICH STEIN, TORU MATSUYAMA, GREGOR JOTZU, GUIDO MEIER, ANDREA CAVALieri, Max Planck Inst Structure & Dynamics of Matter — In this talk I will discuss our recent observation of an anomalous Hall effect in monolayer graphene driven by a femtosecond pulse of circularly polarized light [1]. This was achieved using an ultrafast device architecture based on photoconductive switches. The dependence of the Hall effect on a gate potential used to tune the Fermi level reveals multiple features that reflect a Floquet-engineered topological band structure [2], similar to the band structure originally proposed by Haldane [3]. This includes an approximately 60 meV wide conductance plateau centered at the charge neutrality point, where a gap of equal magnitude is predicted to open. We find that when the Fermi level lies within this plateau, the non-equilibrium anomalous Hall conductance saturates around 1.8±0.4 e^2/h.

12:03PM S51.00005: Landau Levels in Bilayer Graphene under Pressure*  BRET GREEN
(Presenter), JORGE OSVALDO SOFO, Pennsylvania State University — Bilayer graphene in a magnetic field hosts various ordered phases near neutrality, built from 8 low-energy Landau levels labeled by orbital n=0,1, valley ξ=+,− and spin σ=↑,↓. Phase energies depend strongly on interactions and the variables magnetic field, interlayer bias, and pressure. We find the ground state as function of these variables using a Hartree-Fock treatment including the effects of metallic gates, layer separation, layer thickness. Gates screen long-range interactions, separation weakens intervalley interactions, and thickness weakens the Coulomb blockade between layers; these effects distort the phase diagram but do not change its topology. We find that pressure strengthens the noninteracting scale relative to the Coulomb energy, which drives phase transitions to occur at lower fields. This stabilizes two orbitally polarized states not yet predicted or observed, adding to previously-identified valley-, spin-, and partially polarized states.

12:15PM S51.00006: Ballistic to hydrodynamic crossover in twisted bilayer graphene
ISABELLE PHINNEY (Presenter), DENIS BANDURIN, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — At elevated temperatures, electron-electron (e-e) collisions dominate transport in high-mobility graphene, causing the flow of charge carriers to resemble that of classical fluids or gases and allowing for a hydrodynamic description [1][2]. However, experimental conditions are typically such that the onset of fluidity and truly hydrodynamic phenomena occur in a regime where electron-phonon scattering becomes significant. Twisted bilayer graphene (TBG), which has already seen success as a host for the study of strongly interacting electron systems [3], can provide an exceptional alternative platform to study hydrodynamic electron flow due to reduced Fermi velocity and thus a higher e-e scattering rate. Here we show that, at liquid helium temperatures, such devices exhibit micrometer-scale ballistic transport, probed using transverse magnetic focusing. At higher temperatures, we observe the development of a negative potential in the vicinity of the current injecting contact, which can be attributed to the onset of hydrodynamic electron behavior.

12:27PM S51.00007: Hydrodynamic electron flow in a graphene-based device with engineered edge conditions*  
RUPINI KAMAT (Presenter), ARTHUR W BARNARD, JOE FINNEY, Stanford Univ, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, MARC KASTNER, DAVID GOLDHABER-GORDON, Stanford Univ — Hydrodynamic electron flow is expected to emerge in the regime where electron-electron interactions dominate over all other interactions. In this regime, electrons should flow like a viscous fluid. Evidence of such behavior in graphene has been found experimentally in the form of superballistic flow through constrictions [1] and negative local resistance measurements [2]. Hydrodynamic electron transport may strongly depend on boundary conditions, which can range from no-slip (all tangential momentum is dissipated at the boundary) to no-stress (the boundary exerts no force on the fluid). To isolate the impact of boundary conditions on hydrodynamic electron flow, we have fabricated a graphene device in a pipe geometry with the first half of the pipe having smooth edges and the second half having jagged edges. Through a combination of simulations and transport measurements with this device, we tune between the two extreme boundary conditions and identify the impact of edge geometry on the flow profile of a viscous electron fluid.

12:39PM S51.00008: Hydrodynamic and Ballistic AC transport in two-dimensional Fermi Liquids  
MANICHANDRA MORAMPUDI, GITANSH KATARIA, DESHDEEP SAHDEV (Presenter), Quazar Technologies Pvt. Ltd, RAVISHANKAR SUNDARARAMAN, Materials Science and Engineering, RENSSELAER POLYTECHNIC INSTITUTE — Electron transport in clean two-dimensional systems with weak electron-phonon (e-ph) coupling can transition from an Ohmic to a ballistic or a hydrodynamic regime. The ballistic regime occurs when electron-electron (e-e) scattering is weak whereas the hydrodynamic regime arises when this scattering is strong. Despite this difference, we find that vortices and a negative nonlocal resistance believed to be quintessentially hydrodynamic are equally characteristic of the ballistic regime. These non-Ohmic regimes cannot be distinguished in DC transport without changing experimental conditions. Further, as our kinetic calculations show, the hydrodynamic regime in DC transport is highly fragile and is wiped out by even sparse disorder and e-ph scattering. We show that microwave-frequency AC sources by contrast readily excite hydrodynamic modes with current vortices that are robust to disorder and e-ph scattering. Current reversals in the non-Ohmic regimes occur via repeated vortex generation and mergers through reconnections (movie : vimeo.com/261891439). Crucially, AC sources give rise to strong spatiotemporal correlations across the entire device that unambiguously distinguish all regimes.
12:51PM S51.00009: Dynamic response functions of graphene with short-range interactions*  MEGHA AGARWAL (Presenter), EUGENE MISHCHENKO, OLEG STARYKH, University of Utah — We consider a short-range interaction between electrons in graphene and determine their dynamic response functions, such as a longitudinal and a transverse electric conductivity and a polarization function. The calculations are performed to all orders in the interaction by taking into account the self-energy renormalization of the electron velocity and using a ladder approximation to account for the vertex corrections, ensuring that the Ward identity (charge conservation law) is satisfied. We discuss whether a collective mode can exist in this system corresponding to the propagation of electric polarization of correlated electron-hole pairs.

1:03PM S51.00010: Detecting Hall viscosity in the absence of inversion or time reversal symmetries  MUHAMMAD IMRAN (Presenter), University of Florida — The Hall viscosity is experimentally observed in graphene. The Hall viscosity is characterized by the induced voltage with its polarity opposite to the Hall voltage. A formula is derived for the induced voltage entering from the Hall viscosity for the prototype models of bilayer graphene in the absence of time reversal symmetry and the semiconductor heterostructures with strong spin orbit coupling. The fault tolerant Hall viscosity is predicted to be observed in the non-local resistance measurement.

1:15PM S51.00011: Reciprocal and non-reciprocal energy and momentum drag between 1D and 2D conductors  LAUREL ANDERSON (Presenter), AUSTIN K CHENG, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, PHILIP KIM, Harvard University — Double-layer drag experiments are an exceptionally sensitive tool for studying interactions in low-dimensional systems, since the drag response depends on long-range Coulomb interactions rather than particle exchange. Graphene in particular has exhibited unusual drag effects near charge neutrality that have been attributed to competing energy and momentum transfer between the layers. We have performed measurements of 1D-2D drag resistance between a single carbon nanotube (CNT) and monolayer graphene separated by a few-layer boron nitride flake. At high temperatures, the drag response is symmetric under interchange of the drive and drag layers, and resembles momentum transfer from drive to drag layer. This layer reciprocity is broken near the charge neutrality point of graphene at lower temperatures, which can be attributed to energy transfer or thermoelectric effects. Intriguingly, the high-temperature drag response decays with distance from the CNT slower than expected from the Ohmic diffusive current distribution. This suggests additional electron interactions coming into play near charge neutrality in the graphene layer.
1:27PM S51.00012: Cavity quantum electrodynamics with cyclotron resonance transitions in graphene  
YASHIKA KAPOOR (Presenter), JORDAN RUSSELL, ELLIE IRENE HUNT, REBECCA LIM, ERIK HENRIKSEN, Washington University, St. Louis — Cyclotron resonance transitions between highly-degenerate Landau levels are good candidates to achieve the ultrastrong coupling regime in cavity QED, as shown recently for GaAs quantum wells [1]. Graphene provides a similarly ideal platform, with the additional advantage of a strongly anharmonic Landau level spectrum so that a two-level system may be readily explored. We have recently demonstrated graphene cyclotron transitions with quality factor Q~500 at a field of 8 T. Incorporated into cavities with either thin metal or dielectric mirrors, we estimate that cooperativities C~100 and reduced coupling strengths \( \eta \sim g/\omega \sim 0.2 \) can be reached using graphene in an infrared cavity. We will present initial results of measurements on such graphene cavity QED devices and outline prospects for reaching higher coupling strengths.  

1:39PM S51.00013: Cyclotron Resonance in Dual-Gated Bilayer Graphene  
JORDAN RUSSELL (Presenter), JESSE BALGLEY, YASHIKA KAPOOR, Washington University, St. Louis, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ERIK HENRIKSEN, Washington University, St. Louis — We report observations of cyclotron resonance in boron nitride-encapsulated, dual-gated bilayer graphene by way of transmission infrared magnetospectroscopy. The inter-Landau level transitions \(-2 \rightarrow 1\) and \(1 \rightarrow 2\) are studied at a fixed magnetic field of 13 T as a function of the Landau level filling factor, \( \nu \), and the layer symmetry-breaking perpendicular electric displacement field, \( D \). Varying \( D \) at \( \nu = 4 \) yields a direct and high-resolution measurement of the optical bandgap in bilayer graphene at low energies. For increasing \( D \) at \( \nu = 0 \) we observe a varying number of transitions as the K and K' valleys diverge, while a sharp change in the CR energies signals the transition to a layer polarized state at finite \( D \). A detailed description of the data requires consideration of band parameters beyond the lowest order inter- and intra-layer hopping terms. Measurements at \( D = 0 \) reveal a pronounced electron-hole asymmetry and many-body interaction effects as \( \nu \) is varied.  

1:51PM S51.00014: Dynamic gauge field and quantum pumping in graphene nanoelectromechanical resonators*  
RUI PU (Presenter), DU XU, State Univ of NY - Stony Brook —  
Quantum pumping generates charge or valley current through periodic variation in its internal parameters. Graphene, with its large electron mobility and strong coupling between electronic properties and mechanical strain, is a promising candidate for the experimental realization of quantum pumping. Here we study the case of graphene nanoelectromechanical resonator suspended over a gate electrode as a quantum charge pump. The deformation of graphene sheet from electrostatic potential induces a cyclic modulation of carrier density as well as an effective dynamic gauge potential. By explicit breaking of spatial inversion symmetry, we observed a finite charge pumping current near the mechanical resonance frequency. We also explore the possibility of generating valley current in graphene nanoelectromechanical resonators.  

*This work is funded by NSF award DMR-1808491
11:15AM S52.00001: Symmetry breaking of in-plane anisotropic magnetoresistance with temperature in La-doped Sr$_2$IrO$_4$ film* MINGRUI LIU (Presenter), HONGXIA XUE, JIANCHAO MENG, Beijing Normal Univ, RUIPENG BAI, Chinese Academy of Sciences, WEIMIN JIANG, ZHE ZHANG, JINGZHOU LING, LIN HE, RUIFEN DOU, CHANGMIN XIONG, JIACAI NIE, Beijing Normal Univ — Electron-doped Sr$_2$IrO$_4$ has been the subject of recent attention because of its similarities with hole-doped La$_2$CuO$_4$. However, direct evidence of its superconductivity has not yet been observed, which has led to various unresolved issues related to this material. In this study, a 14-nm thick La-doped Sr$_2$IrO$_4$ film was grown on a (001) SrTiO$_3$ substrate. We found that the fourfold component of the in-plane anisotropic magnetoresistance disappears and is replaced by a twofold symmetry as the temperature increases. Variable-temperature x-ray diffraction and spatially resolved optical second-harmonic generation experiments eliminate the possibility of crystal structural distortion. The temperature dependence of direct current magnetization measurements indicates that a change in the spin structure may account for the symmetry breaking, similar to the nematic ordering of iron-based and other superconductors. These provide a perspective on these materials that helps elucidate the nature of magnetic interactions and explores the expected superconductivity of iridates.

11:27AM S52.00002: Rock-salt type superconductor/ferromagnet heteroepitaxial junction: LaO/EuO* KENICHI KAMINAGA (Presenter), DAICHI OKA, HIROFUMI OKA, TOMOTERU FUKUMURA, Tohoku University — We report the first synthesis of rock-salt type superconductor/ferromagnet heteroepitaxial junctions using ferromagnetic semiconductor EuO [1]. As the superconducting layer, we deposited LaO with the maximum $T_c$ of 5.2 K onto EuO. The small lattice mismatch made it possible to synthesize a high-quality heteroepitaxial junction with an atomically sharp interface that realizes the ideal magnetic proximity effect. The magnetization of LaO/EuO heteroepitaxial junctions was governed by the ferromagnetic EuO layer. The saturation magnetization of 7 $\mu_B$/Eu atom at 5 K was equivalent to that of EuO thin film. Owing to the sharp interface and the strong magnetization, superconductivity in 21 nm thick LaO layer was fully suppressed by only 6 nm thick EuO layer. This system can be used for a new heteroepitaxial platform of superconducting spintronics devices. [1] K. Kaminaga et al., Chem. Lett. 48, 1244 (2019).

11:39AM S52.00003: Growth and electronic structure of LTO/STO heterostructure: Multimodal studies*   HAWOONG HONG (Presenter), FRIEDERIKE WROBEL, XI YAN, ANAND BHATTACHARYA, DILLON FONG, Argonne Natl Lab — LTO/STO interfaces have interesting features including 2-DEG, superconductivity and magnetism. These systems may realize complex-oxide based electronic devices. LTO is supposed to be insulators. However, PLD produced films, under compressional stress, behave like metal. It also undergoes transition to a Mott insulator below -145° C. Advanced photon source has beamlines suited for complex oxide studies. Sector-33 oxide-MBE allows operando studies of x-ray diffraction and RHEED measurements during the growth of oxide films. One can also transfer the sample in a UHV vacuum suitcase to soft-xray ARPES station at the beamline 29. Soft-xray ARPES provides significant enhancement in the penetration depth and one can study the interfaces in addition to the surfaces of samples. Deposition by alternating lanthanum and titanium did not produced pure phase of LaTiO3. Interestingly, the 6 unit cell sample from alternating deposition showed 2-DEG features in ARPES. LaTiO3 films could be successfully produced through codeposition of lanthanum and titanium. However, x-ray diffraction measurements showed the films from codeposition easily became rough after the growth.

*Work at the Advanced Photon Source was supported by the DOE, under Contract No. DE-AC02-06CH11357.

11:51AM S52.00004: Coherent lattice motion in freestanding perovskite films probed by ultrafast electron diffraction*   YIFAN SU (Presenter), ALFRED ZONG, ANSHUL KOGAR, Massachusetts Institute of Technology, DI LU, SEUNG SAE HONG, HAROLD HWANG, Stanford University, NUH GEDIK, Massachusetts Institute of Technology — Advances in femtosecond lasers make it possible to coherently generate specific phonon modes in crystals. These coherent lattice vibrations enable one to pinpoint specific atomic motion on the picometer scale, and this knowledge, in turn, helps one to realize ultrafast control of material property by laser pulses. In this experiment, we performed ultrafast electron diffraction on a 20-nm freestanding film of La_{0.67}Ca_{0.33}MnO_{3}. Following photoexcitation, we observed a 0.15 THz acoustic phonon extracted from Bragg peak intensity, position and width. By tracing the coherent oscillations in these three channels for more than 20 Bragg peaks, we are able to reconstruct in real space the unconventional atomic trajectory following the arrival of the laser pulse.

*Gordon and Betty Moore Foundation; U.S. Department of Energy
12:03PM S52.00005: Stoichiometry-Dependence of Electronic Properties in LaVO$_3$ Thin Films

BIWEN ZHANG (Presenter), JADE HOLLEMAN, Physics, Florida State University, YAN XIN, STEPHEN A MCGILL, National High Magnetic Field Laboratory, CHRISTIANNE BEEKMAN, Physics, Florida State University — LaVO$_3$ (LVO) has been proposed as a promising material for photovoltaics because its strongly correlated 3d electrons can facilitate creation of multiple electron-hole pairs per incoming photon, which would lead to increased device efficiency. Our group grows thin films of LVO on SrTiO$_3$ substrates using pulsed laser deposition. We control the La:V ratio of the films from ~60:40 to ~40:60 by adjusting laser fluences. We find that while V-rich films show behaviors that are similar to bulk LVO, films that are La-rich show remarkable differences in optical measurements, and more rich temperature dependent transport behaviors, which indicates the presence of electronic phase separation. This study allows us to better understand the complex physical properties of strongly correlated insulators paving the way for their use as absorbers in high performance photovoltaics.

*A portion of this work was performed at the National High Magnetic Field Laboratory, which is supported by National Science Foundation Cooperative Agreements No. DMR-1157490 and No. DMR-1644779, and the State of Florida. S.M. acknowledges support under grant NSF DMR-1229217.

12:15PM S52.00006: Oxygen vacancy induced electronic phenomena of KTaO$_3$

SHASHANK KUMAR OJHA (Presenter), SANAT KUMAR GOGOI, MANISH JAIN, SRIMANTA MIDDEY, Indian Institute of Science — Emergent two-dimensional electron gas (2-DEG) at complex oxide interfaces has been a subject of huge interest over the last fifteen years. The discovery of 2-DEG at the interface between LaAlO$_3$ and SrTiO$_3$ has lead to a massive search for other 2-DEG systems. Various mechanisms viz. polar catastrophe, cationic intermixing and oxygen vacancy have been proposed to explain the origin of interfacial conduction. Since more than one mechanism can be operative simultaneously, well-defined understanding remains a challenge. In this work, we report on sole effect of oxygen vacancy on electronic structure modification of a prototypical perovskite KTaO$_3$ by deliberately creating oxygen vacancies in a pristine single-crystalline sample. Oxygen deficiency turns KTaO$_3$ into a metal which shows many interesting quantum transport phenomena such as Shubnikov-de Haas oscillations, anomalous Hall effect. Ab-initio calculations find the existence of vacancy induced local magnetic moments on Ta around vacancy and the skew scattering of conduction electrons by these local moments lead to the observation of anomalous Hall effect.
12:27PM S52.00007: Effect of Growth Conditions on the Formation of a 2-Dimensional Electron Gas at Antiferromagnetic LaCrO3 /SrTiO3 Interfaces*  ATHBY AL-TAWHID (Presenter), North Carolina State University — The realization of a high mobility two-dimensional conducting interface between a polar anti-ferromagnet, LaCrO3 (LCO) and non-polar SrTiO3 (STO) has important implications for the interfacial coupling of electronic and magnetic degrees of freedom. To realize such an interface, we examine the effect of growth conditions and post growth treatment on the structural and electronic properties of the polar/non-polar(LCO/STO) interfaces. Growth at high temperatures and low oxygen partial pressure followed by post growth annealing in Oxygen results in a 2-dimensional electron gas(2-deg) at the interface. The dimensionality of the conducting layer is confirmed by electric and magneto transport measurements. Growth at a lower temperature or higher partial oxygen pressure leads to an insulating interface. High-resolution synchrotron X-ray-based structural determination of the atomic-scale structures of both metallic and insulating LCO/STO interfaces shows structural differences between the two cases attributed to competing mechanisms present to alleviate the interfacial polar discontinuity.

12:39PM S52.00008: Interfacial mechanical coupling at the interface of Pb$_{0.2}$Zr$_{0.8}$TiO$_3$/LaNiO$_3$/SrTiO$_3$ heterostructures  CLAUDIA LAU (Presenter), CRISTINA VISANI, STEPHEN ALBRIGHT, Yale University, ZHAN ZHANG, Argonne National Lab, ANKIT DISA, Max Planck Institute for the Structure and Dynamics of Matter, DIVINE KUMAH, North Carolina State University, CHARLES H AHN, FREDERICK J WALKER, Yale University — The coupling of ferroelectric polarization to thin films of the conducting oxide LaNiO$_3$ results in large changes of conductivity at an epitaxial ferroelectric-LaNiO$_3$ interface. The observed changes in conductivity are larger than what is expected from band theory, implying the importance of electronic and structural correlations. To characterize the structural changes at the interface, specially designed capacitor structures are fabricated from thin films of PbZr$_{0.2}$Ti$_{0.8}$O$_3$ deposited on epitaxial LaNiO$_3$. The device geometry is optimized for in operando synchrotron x-ray diffraction measurements of crystal truncation rods in order to identify the atomic-scale structural changes responsible for the changes in conductivity. These structural changes include rotations of the LaNiO$_3$ oxygen octahedra, which are characterized via measurement of half-order Bragg peaks. The octahedral rotations exhibit a hysteresis loop as the applied voltage is swept through the coercive field of the ferroelectric and are correlated with the conductivity of the channel, with larger rotations leading to reduced conductivity.
Zero-Bias Anomalies Observed in the Tunneling Spectra of Sr$_3$(Ru$_{0.84}$Mn$_{0.16}$)$_2$O$_7$° YIFAN YANG (Presenter), Louisiana State University, Baton Rouge, MINGMING FU, QIANG ZOU, Center for Nanophase Materials Sciences Oak Ridge National Laboratory Oak Ridge, TN 37831, USA, RONGYING JIN, Louisiana State University, Baton Rouge, ZHENG GAI, Center for Nanophase Materials Sciences Oak Ridge National Laboratory Oak Ridge, TN 37831, USA, JIANDI ZHANG, E WARD PLUMMER, Louisiana State University, Baton Rouge — The partial substitution of Mn for Ru in the bilayer ruthenate Sr$_3$(Ru$_{1-x}$Mn$_x$)$_2$O$_7$ stabilizes long-range antiferromagnetic (AFM) ordering with the highest transition temperature $T_N = 82$ K for $x = 0.16$ [1]. Here, we report the observation of a well-defined symmetric zero-bias anomaly (ZBA) at 5.2 K in the scanning tunneling spectroscopy (STS) of $x = 0.16$. The temperature dependence of the ZBA shows thermal broadening and does not correlate with the bulk AFM transition. Consistent with this observation, there is no change in the ZBA with the application of a magnetic field (9T). This is in contrast to the case for $x = 0$, in which the ZBA is asymmetric about zero bias and magnetic field dependent which gradually vanished at 11T [2]. The more symmetric and narrower ZBA in $x = 0.16$ could originate from the distinct surface properties [3]. We will discuss the relationship between doping (disorder), the surface properties, and ZBA.

Tuning the electronic properties of the 4d transition metal oxide LaRhO$_3$° JUAN JIANG (Presenter), TAEKYUN LEE, SANGJAE LEE, SOHRAB ISMAIL-BEIGI, FREDERICK J WALKER, CHARLES H AHN, Yale University — Perovskite transition metal oxides exhibit various novel properties due to strong correlations among their d electrons. These correlation effects are well known in the 3d transition metal oxides, such as LaCoO$_3$, where multiple spin states can be observed. Electronic correlations are expected to change as the transition metal is changed from a 3d element to a 4d element in the same column of the periodic table, for example changing from Co to Rh. To explore these changes, we grow epitaxial La$_{1-x}$Sr$_x$RhO$_3$ thin films with Sr concentrations as large as 50% using molecular beam epitaxy. Hall measurements show a sign change from hole-like conduction for low doping to electron-like conduction for a large doping level of $x=0.3$. Systematic changes in electronic structure as a function of doping are predicted by theory and may provide a basis for understanding electronic correlations in transition metal oxides.

1:15PM S52.00011: Engineering Coercivity of SrRuO$_3$ thin film by SrTiO$_3$ capping layer  

EUN KYO KO (Presenter), Center for Correlated Electron Systems (CCES), Institute for Basic Science (IBS), JUNSIK MUN, Department of Materials Science and Engineering and Research Institute of Advanced Materials, Seoul National University, HAN-GYEOL LEE, JINKWON KIM, Center for Correlated Electron Systems (CCES), Institute for Basic Science (IBS), MIYOUNG KIM, Department of Materials Science and Engineering and Research Institute of Advanced Materials, Seoul National University, LINGFEI WANG, TAE WON NOH, Center for Correlated Electron Systems (CCES), Institute for Basic Science (IBS) — Oxide heterostructures have a high potential for spintronics applications due to their well-defined heterointerfaces and vast functionalities. Understanding and utilizing the advantages of oxide spintronics requires effective control of magnetism, such as engineering coercivity ($H_C$). SrRuO$_3$ (SRO) is an itinerant ferromagnet with high tunable electron-electron correlation and spin-orbit coupling. It could be a good candidate for exploring spintronics applications due to the recently discovered exotic topological properties. [1, 2]

Here, we reported our recent result on controlling $H_C$ of SRO ultrathin film by a SrTiO$_3$ (STO) capping layer. The film was deposited by pulsed laser deposition. By controlling the thickness and growth oxygen partial pressure of STO capping layer, we can tune the $H_C$ of SRO films by an amplitude over 100%. Such an effective modulation of $H_C$ is highly related to the oxygen vacancies transferred from STO capping layer to SRO film.

1:27PM S52.00012: Effects of Tungsten Doping on Magnetic and Material Properties of VO$_2$/Ni Bilayers  

LOGAN SUTTON (Presenter), JOSE DE LA VENTA, JOSHUA P LAUZIER, Colorado State University — Magnetic hybrid materials show increasing promise as candidates for magnetic storage and magnetic sensors under a wide range of operating environments. Strain coupled materials are a type of magnetic hybrid materials that show a strong potential for precise control over magnetic properties. Vanadium oxides are a class of compounds which have structural phase transitions (SPTs) at various temperatures, making them ideal candidates in the fabrication of hybrid materials of this nature. Previous work has shown sputtered vanadium oxide/ferromagnetic bilayers have large changes in magnetization and coercivity at the vanadium oxide transition temperature. In this study, a sol-gel synthesis technique was used to fabricate W-doped VO$_2$/Ni bilayers. Doping with W allows for the VO$_2$ transition temperature to be lowered in an easily controlled manner, making it more viable for various applications. The effects of this doping technique on the material and magnetic properties of the VO$_2$ layers are investigated. We find a stabilization of the rutile phase of VO$_2$, and formation of V$_2$WO$_6$. VO$_2$/Ni bilayers show a sharp decrease in the coercivity and increase in the magnetic moment at the VO$_2$ SPT. W doping decreases the temperature of these magnetic effects and also decreases their magnitude.
**1:39PM S52.00013: Pulsed-laser epitaxy of metallic delafossite PdCrO₂**  
JONG MOK OK  
(Presenter), MATTHEW BRAHLEK, Materials Science and Technology Division, Oak Ridge National Lab, WOO SEOK CHOI, Department of Physics, Sungkyunkwan University, KEVIN ROCCAPRIORE, MATTHEW F CHISHOLM, Center for Nanophase Materials Sciences, Oak Ridge National Lab, GAURAB RIMAL, Department of Physics and Astronomy, Rutgers University, SOYEUN KIM, CHANGHEE SOHN, Department of Physics, Ulsan National Institute of Science and Technology, ELIZABETH SKOROPATA, Materials Science and Technology Division, Oak Ridge National Lab, SEONGSHIK OH, Department of Physics, Sungkyunkwan University, HO NYUNG LEE, Materials Science and Technology Division, Oak Ridge National Lab — Within the metallic ABO₂ delafossites, the natural heterostructuring among the A-layers, that are highly-conductive and 2-dimensional, with the triangular and localized nature on the BO₂ is a basic platform for many interesting phenomena. Thin film growth of these materials can enable both tuning basic properties as well as giving new insight into the novel phenomena found in this class of materials, yet this has proven extremely challenging. Here, we report the epitaxial growth of the metallic delafossite PdCrO₂ by pulsed laser deposition (PLD) across many different substrates and epitaxial buffer layers and growth conditions. This work has revealed the fundamental role PLD-growth conditions, epitaxial strain, and chemical and structural character of the substrate play in stabilizing the growth of PdCrO₂. It is found that a low-strain delafossite buffer layer is required to stabilize PdCrO₂. The resulting films are commensurately strained, show very narrow rocking curve widths as low as ~0.1°, and show an antiferromagnetic transition at 40 K that persists down to as thin as 3.6 nm. This works provides key insight for the growth of the boarder class of metallic delafossites and will enable tuning the basic properties of these interesting materials.

**1:51PM S52.00014: Growth of metallic delafossite PdCoO₂ by molecular beam epitaxy**  
MATTHEW BRAHLEK (Presenter), Oak Ridge National Lab, GAURAB RIMAL, Physics, Rutgers University, JONG MOK OK, DEBANGSHU MUKHERJEE, ALESSANDRO MAZZA, LU QIYANG, HO NYUNG LEE, THOMAS ZAC WARD, RAYMOND UNOCIC, GYULA ERES, Oak Ridge National Lab, SEONGSHIK OH, Physics, Rutgers University — The ABO₂ delafossite oxides are a unique class of oxides with layered A–BO₂–A–BO₂ structure with inplane trigonal coordination. Here, we report successful growth of the metallic delafossite PdCoO₂ by molecular beam epitaxy (MBE) [1]. The key challenge is controlling the oxidation of Pd in the MBE environment where phase segregation is driven by the reduction of PdCoO₂ to cobalt oxide and metallic palladium. This is overcome by combining low-temperature atomic layer-by-layer MBE growth in the presence of reactive atomic oxygen with a postgrowth high-temperature anneal. Thickness dependence (5-265 nm) reveals that in the thin regime (<75 nm), the resistivity scales inversely with thickness, likely dominated by surface scattering; for thicker films, the resistivity approaches the values reported for the best bulk crystals at room temperature, but the low-temperature resistivity is limited by structural twins. This work shows that the combination of MBE growth and a postgrowth anneal provides a route to creating high-quality films in this interesting family of layered, triangular oxides.

Molecular Modeling of the Adsorption-Induced Expansion of Graphene Oxide Frameworks

吸附材料如活性炭（AC）具有潜在的气体存储或分离能力。ACs经常被建模为狭缝形孔：平行的石墨烯状薄片，具有非常高的比表面积。在几乎所有的吸附分析中，吸附剂被假定结构上是惰性的。已知，在液体吸附时，吸附剂会发生结构变形。最近，门控开启转换在金属有机框架（MOF）中被观察到在亚临界气体吸附过程中。这种变形起源于固体-液体相互作用，并取决于吸附剂-吸附质相互作用的性质，有时会收缩或膨胀。最近，苯硼烷酸（DBA）石墨烯氧化物框架（GOF）的d间距的单调增加（大约为4%）在超临界吸附各种气体时被观察到。我们基于第一性原理模型的分子动力学模拟的结果表明，一个随机取向的共价连接DBA链的模型与实验观察结果一致。

Session S53 DMP: Synthesis and Characterizations of Large Scale 2D Materials I Mile High Ballroom 1F - Ismail El Baggari, Cornell University - Tag(s): Focus

In order to build these atomically thin circuits, we developed a series of chemistry-based approaches that are scalable and precise. They include wafer-scale synthesis of three atom thick semiconductors and heterojunctions (Nature, 2015; Science 2018), a wafer-scale patterning method for one-atom-thick lateral heterojunctions (Nature, 2012), and most recently, atomically thin films and devices that are vertically stacked to form more complicated circuitry (Nature, 2017). Once realized, these atomically thin circuits will be foldable and actutable, which will further increase the device density and functionality.
11:51 AM S53.00002: Chirality transfer through multistep reaction processes towards the synthesis of enantiopure chiral graphene nanoribbons*  MOHAMMED SABRI G. MOHAMMED (Presenter), NESTOR MERINO-DÍEZ, Donostia International Physics Center, JESÚS CASTRO-ESTEBAN, University of Santiago de Compostela, LUCIANO COLAZZO, ALEJANDRO BERDONCES, JAMES LAWERENCE, Donostia International Physics Center, JOSÉ IGNACIO PASCUAL, CIC nanogune, DIEGO PEÑA, University of Santiago de Compostela, DIMAS GARCÍA DE OTEYZA, Donostia International Physics Center — Besides its interest for potential optoelectronic devices, molecular chirality is of utmost importance in biology and medicine. Consequently relevant is the selective synthesis of enantiopure molecular compounds, which has been hardly addressed in the growing field of “on-surface synthesis”. In this frame, 2,2'-dibromo-9,9'-bianthracene reactants are known to form chiral graphene nanoribbons (GNR) on coinage metal substrates through a complex multi-step reaction including an initial radical step growth polymerization by Ullmann coupling and following cyclodehydrogenation steps. In this work we show how, starting from enantiopure reactants deposited onto Au(111), their chirality is sequentially transferred to the polymers and finally to the GNRs with an excellent level of selectivity. Unambiguous evidence of this effect is obtained by high-resolution scanning tunneling microscopy images.

*The project leading to this contribution has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (grant agreement No 635919), from the Spanish Ministry of Economy, Industry and Competitiveness (MINECO, Grant No. MAT2016-78293-C6).

12:03 PM S53.00003: Narrow optical transition linewidth of MoS2 monolayers grown by chemical vapor deposition: impact of dielectric disorder  SHIVANGI SHREE, CNRS/INSA, ANTONY GEORGE, Friedrich Schiller University Jena, TIBOR LEHNERT, Ulm University, CHRISTOF NEUMANN, Friedrich Schiller University Jena, MERYEM BENELAJLA, CEDRIC ROBERT, XAVIER MARIE, CNRS/INSA, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS Tsukuba, UTE KAISER, Ulm University, ANDREY TURCHANIN, Friedrich Schiller University Jena, BERNHARD URBASZEK (Presenter), CNRS/INSA — Chemical vapor deposition (CVD) allows growing transition metal dichalcogenides (TMDs) over large surface areas on inexpensive substrates, but optical transition linewidth of as-grown monolayers (MLs) is usually tens of meV. We correlate the structural quality of CVD grown MoS2 MLs on SiO2/Si wafers studied by high-resolution transmission electron microscopy (HRTEM) with the optical quality revealed in optical emission and absorption from cryogenic to ambient temperatures. With HRTEM we determine a defect concentration of the order of $10^{13}$/cm$^2$ for our samples, comparable to standard exfoliated flakes from bulk crystals. To have access to the intrinsic optical quality of the CVD grown MLs, we remove the MLs from the SiO2 growth substrate and encapsulate them in hBN flakes with low defect density. In encapsulated MLs we show optical transition linewidth of 5 meV at low temperature T=4 K for the free excitons in emission and absorption. This is comparable to the best ML samples obtained by mechanical exfoliation of bulk material. The CVD grown MoS2 ML shows strong photoluminescence that is dominated by neutral excitons and not by defects even at cryogenic temperatures. We study the valley Zeeman effect in magnetic fields up to 9T accessible thanks to the narrow emission linewidth.
12:15PM S53.00004: Grain rotation and growth in binary hexagonal two-dimensional materials  
BRENDON WATERS (Presenter), ZHI FENG HUANG, Wayne State Univ — Generally polycrystalline structures are formed during large-scale fabrication of 2D materials, with individual crystalline domains separated by grain boundaries. During growth, these grain boundaries move and evolve as neighboring grains interact. We study this dynamic process via Phase Field Crystal (PFC) modeling for 2D hexagonal materials. By tracking the motion of circular grains misoriented with respect to the surrounding crystalline matrix, we analyze the angle dependence of grain boundary dynamics and their implications for grain growth. In particular, due to the continuity of lattice planes across the boundary the grain is expected to rotate towards a larger misorientation angle, as governed by the Cahn-Taylor mechanism for the coupled normal-tangential motion of the boundary. For binary 2D materials like hBN our PFC study indicates a dynamic property beyond this geometrically-controlled effect, particularly for grain misorientations close to 30 degree which show abnormally fast rotation and strong normal-tangential coupling. This behavior can be associated with the change of angle dependence of grain boundary energy in binary materials with lattice inversion symmetry breaking.

12:27PM S53.00005: Van der Waals Epitaxy of the Transition Metal Dichalcogenide WTe₂*  
KEVIN HAUSER (Presenter), CHRISTIAN MATT, JASON HOFFMAN, RUIZHE KANG, Harvard University, JOHAN CHANG, Physics Department, University of Zurich, JENNIFER E. HOFFMAN, Harvard University — Thin film transition metal dichalcogenides (TMD) are strong candidates for future technological application, which require controlled means of ultra-high purity synthesis, as provided by molecular beam epitaxy (MBE). So far, MBE-synthesized TMD monolayers have been limited to islands with lateral sizes on the order of tens of nanometers due to the large difference of surface diffusivity of the transition metals and chalcogen species. Here, we adopt a van der Waals epitaxy method [1], based on the metal-organic precursor W(CO)₆, with the goal to develop a growth recipe for WTe₂ monolayer films. Employing surface-sensitive measurement techniques, we characterized the as-grown films and observed WTeₓ-based, one-dimensional nanostructures at the step edges and two-dimensional islands on the substrate terraces. From these results, we investigate the growth dynamics of WTe₂ few-layer thin films.

12:39PM S53.00006: Synthesis and characterization of large-area single-crystal sheets of borophene on various metal surfaces* RONGTING WU (Presenter), Department of Chemistry and Energy Sciences Institute, Yale University, ADRIAN GOZAR, Energy Sciences Institute, Yale University, IVAN BOZOVIC, Department of Chemistry and Energy Science Institute, Yale University; Bookhaven National Laboratory — Borophene, an atomically thin covalently bonded boron sheet, has attracted great attention as a novel quantum material because of its structural tunability and potential utilization in next-generation electronics. Here, we report the synthesis of borophene on various single-crystal substrates and nanometer-scale thick crystallized metal films on sapphire. With real-time feedback from low-energy electron microscopy and diffraction, we have developed a process of enlarging monocrystal borophene domains, by repeated submersion of boron into substrates at high temperature, resurfacing and re-crystallization at low temperature. We demonstrate the synthesis of borophene as faceted micrometer-size monocrystal islands or as full-monolayer sheets. The process is scalable to wafer size; moreover, metallic buffers could be sacrificed, and sapphire substrate reused. Our work opens the door for new experiments and applications.

12:51PM S53.00007: In situ photo-chemical conversion of layered transition metal ditellurides* FLORENCE NUGERA (Presenter), TEPIE MENG, TARIQ AFANEH, NALAKA A KAPURUGE, Physics Department, University of South Florida, YAN XIN, National High Magnetic Field Laboratory, HUMBERTO GUTIERREZ, Physics Department, University of South Florida — WTe$_2$ and MoTe$_2$ are good candidates for spintronics, thermoelectric and piezoelectric applications. In general, the 1T` phase of these 2D materials displays metallic behavior, making them interesting candidates for in-plane interconnects when combined with 2D semiconductors. In this study, we synthesize large-area WTe$_2$ and MoTe$_2$ films using a simple CVD process. Raman spectroscopy and TEM were used to study the crystal quality as well as phase and chemical composition. Subsequently, the as-grown films were chemically modified using an *in situ* laser-assisted method recently developed in our group. The entire process takes place within a home-made mini-chamber with an optical quartz window, were the samples are exposed to a laser beam in the presence of a controlled environment rich in a different chalcogen atom (sulfur in this case). For an optimized set of parameters (e.g. exposure time and laser power), the tellurium atoms are replaced by sulfur atoms and the chemical exchange process is monitored in real time via Raman spectroscopy. The site-selective replacement of the chalcogen atoms generate metal-semiconductor heterojunctions. FET-like devices where fabricated to study the electrical response of these junctions.

*HRG acknowledge support from NSF grant DMR-1557434
Controllable Growth and Electronic Structures of 2D Transition Metal Dichalcogenides Thin Films*  

YI ZHANG (Presenter), Nanjing Univ — The 2D transition metal dichalcogenides (TMDCs) have attracted extensive interest due to their remarkable properties. Using molecular beam epitaxial (MBE) method, we achieved the controllable growth of atomically thin TMDCs MoSe$_2$ and WSe$_2$ films. Combining with the in-situ angle-resolved photoemission spectroscopic (ARPES) measurements, we directly characterized the electronic structures of them and studied the evolution of their electronic structures in 2D limit [1-2]. Moreover, we achieved band structuring engineering in epitaxial TMDCs Mo$_x$W$_{1-x}$Se$_2$ alloy monolayers with controllable stoichiometric ratio x. We also realized the growth of meta-stable 1T'-WSe$_2$ monolayer, and studied its thermo-driven structure phase transition to stable 2H-WSe$_2$ [3]. Our findings not only help understanding of TMDC materials but also enrich the family of epitaxial 2D materials toward a fully MBE grown epitaxial heterostructures for light emission and photon-voltage devices.

Scaling-up atomically thin coplanar semiconductor-metal circuitry via phase engineered chemical assembly  

YU YE (Presenter), Peking Univ — Phase engineered growth of 2H-MoTe$_2$ was understood by a solid-to-solid phase transformation mechanism, enabling the controlled growth of chip-size single-crystalline 2H-MoTe$_2$. Based on that, we report on the large-scale, spatially controlled chemical assembly of the integrated 2H MoTe$_2$ field-effect transistors with coplanar metallic 1T' MoTe$_2$ contacts via phase engineered approaches.
**1:27PM S53.00010: MOCVD Growth of High Quality Large Area WS\textsubscript{2} Films**  
WILLIAM CAMPBELL (Presenter), Univ of Bath, RAVI SUNDARAM, Oxford Instruments, SIMON J BENDING, Univ of Bath — Tungsten disulphide (WS\textsubscript{2}) is of particular interest in optoelectronics because of the band gap transition from indirect to direct as the crystal thickness is reduced from bulk to a single layer [1]. To achieve large area coverage suitable for industrial applications, growth methods such as chemical vapour deposition (CVD) need to be developed. Current powder-based CVD approaches [2] produce crystalline flakes that are useful for fundamental studies but cannot produce continuous wafer scale films [3]. In this work, we produce continuous and uniform thin films of WS\textsubscript{2} via MOCVD techniques at scales up to 200mm wafer sizes.

Our films are deposited at 600C using a tungsten hexachloride precursor gas and a hydrogen sulphide sulphur source. Raman spectroscopy and photoluminescence (PL) measurements demonstrate high quality as-grown WS\textsubscript{2} thin films on sapphire substrates. We further show how a post-growth annealing step in H\textsubscript{2}S quenches sulphur vacancy sites in the WS\textsubscript{2} and dramatically increases the PL intensity.

**1:39PM S53.00011: Enabling Direct Write Mask Free Fabrication of Low Dimensional Nanoscale Architectures on Different Substrates using Aqueous Inks and CVD synthesis**  
IRMA KULJANISHVILI (Presenter), DHEYAA ALAMERI, DEVON KARBACH, RUI DONG, Saint Louis University, YUZI LIU, RALU DIVAN, Center for Nanoscale Materials, Argonne — Low dimensional materials such as nanowires and 2D films, when assembled in vertical or lateral arrangements, often lead to the largely enhanced properties, and new functionalities. While the preparation of layered architectures usually involves multi-step fabrication processes it also relies on mask assisted lithographic techniques. Here we present methodology for controlled selective preparation of 1D and 2D nanostructures of MoS\textsubscript{2}, WS\textsubscript{2} and ZnO in the variety of geometric assemblies by employing parallel direct write patterning (DWP) of aqueous ink precursors on substrates at predefined locations. In a two-step process (1st patterning and 2nd growth) our unconventional fabrication approach enables simple and flexible production of hetero-structures and other architectures based on “mix and match” principle in precisely controlled fashion. Location specific synthesis of materials provides access to as-grown interfaces and rapid testing of materials’ quality, crystallinity and chemical composition which was confirmed by various characterization methods (Raman Spectroscopy, PL, AFM, XRD etc). Acknowledgement. Use of the Center for Nanoscale Materials was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, Contract No. DE-AC02 06CH11357
**S53.0012: Formation and self-assembly of graphene nanoribbons and nanosheets in metals**

LOURDES SALAMANCA-RIBA (Presenter), XIAOXIAO GE, CHRISTOPHER KLINGSHIRN, MADELINE MORALES, ODED RABIN, MANFRED WUTTIG, University of Maryland, College Park, DANIEL COLE, CHRISTOPHER SHUMEYKO, Aberdeen Proving Ground, MD, U.S. Army Research Laboratory, SHENJIA ZHANG, Indianapolis, IN, General Cable — Composites consisting of carbon nanostructures, such as graphene and carbon nanotubes, and metals are desirable for power transmission lines, interconnects and heat transfer applications due to the combination of excellent charge carrier mobility, thermal conductivity and mechanical strength of the carbon nanostructures and the high density of electrons in the metal. Metal/nanocarbon composites made by chemical vapor deposition, friction stir, ball milling, and plasma spraying have yielded materials with enhanced hardness and tensile strength but their electrical and thermal conductivities usually deteriorate. We use an electrocharging assisted process which consists of the application of a high DC current to a mixture of liquid metal and carbon particles to form crystalline graphitic nanoribbons in the liquid metal. The solid composites have shown 5% higher electrical conductivity and enhanced local stiffness, measured by nanoindentation, compared to the pure Al alloys. Molecular dynamic simulations of nanoindentation tests into the nanocarbon metal composite show how the graphene nanoribbons impede dislocation motion and increase hardness. Conductive AFM shows an increase in the local conductivity from these samples compared to the parent aluminum alloy.

**S53.0013: Growth of 10 × 10 cm² single-crystal hexagonal boron nitride monolayer on the symmetry broken substrate**

LI WANG (Presenter), XUEDONG BAI, Institute of Physics, Chinese Academy of Sciences, DAPENG YU, Shenzhen Key Laboratory of Quantum Science and Engineering, and Department of Physics, South University of Science and Technology, ENGE WANG, KAIHUI LIU, School of Physics, Peking University — The ability to grow high-quality large single crystals of essential 2D materials, is at the heart for the industrial applications of 2D devices. Atom-layered hexagonal boron nitride (hBN), with its excellent stability, flat surface and large bandgap, has been reported to be the best 2D insulator. However, the size of single-crystal 2D hBN is still typically less than the wafer scale, mainly due to the extreme difficulties in its single-crystal growth: the three-fold symmetry of hBN lattice leading to antiparallel domains resulting in twin boundaries on most substrates. Here, we report the first epitaxial growth of a 10 × 10 cm² single-crystal hBN monolayer on a low symmetry Cu(110) “vicinal surface” obtained by annealing an industrial Cu foil. Our experimental and theoretical work indicate that epitaxial growth is made by Cu<211> step-zigzag hBN edge coupling that serves to break the equivalence of antiparallel hBN domains, enabling unidirectional domains alignment of > 99%. The findings in this work can significantly boost the applications of 2D devices, and also pave the way for the epitaxial growth of broad non-centrosymmetric 2D materials, such as various transition metal dichalcogenides, into large-sized single crystals.

11:15AM S54.00001: Quantized energy pumping in quasi-periodically driven Nitrogen Vacancy Centres*  ANUSHYA CHANDRAN (Presenter), Boston Univ, IVAR MARTIN, Argonne National Laboratory, PHILIP CROWLEY, Boston Univ — A spin strongly driven by two incommensurate tones can exhibit a topological class of dynamics in which it (i) pumps energy from one drive to the other at a quantized average rate, in precise relationship with the quantum Hall effect, and (ii) exhibits an oscillatory response to a perturbation to the phases of the drives. We show these remarkable signatures to be realized in experiments in Nitrogen Vacancy centres. We further provide an experimental demonstration of half-integer quantization of various responses at the transition between the topological and trivial classes of dynamics.

11:27AM S54.00002: Z2 topological quench dynamics  POK-MAN CHIU (Presenter), PO-YAO CHANG, Natl Tsing Hua Univ — In this talk, we present a quench setup for a realization of a Z2 topological quench dynamics in 3+1 dimensions. We show the Z2 feature can be identified from the flow of Berry phase. In addition, the entanglement spectra in both real and frequency space reveal the topological features. Finally, we discuss some possible realizations of our model.

11:39AM S54.00003: Photoinduced interfacial chiral modes in threefold topological semimetal*  SEIKH ISLAM (Presenter), ALEXANDER ZYUZIN, Aalto University — We investigate the chiral electronic modes at the interface between two regions of a threefold topological semimetal, which is illuminated by left and right handed elliptically polarized waves. The radiation effects on the band structure of semimetal is analyzed by using Floquet theory. Two distinct solutions of the interface modes are found with the chirality depending on the phase of the irradiation. We also consider the anomalous Hall response which is attributed to the interband contribution between dispersionless flat band and conic bands.

11:51AM S54.00004: Space-time group symmetry and response functions Congjun Wu
University of California, San Diego — Congjun Wu (Presenter), University of California, San Diego —
Recently, space-time group was proposed to describe the dynamic crystalline symmetries of a large class of dynamic systems beyond the Floquet system (Xu and Wu, Phys. Rev. Lett. 120, 096401 (2018)), including laser-driven solid crystals, dynamic photonic crystals, and optical lattices. We further study its consequences on physical observables on the response functions by applying the group theory representation analysis. This work will provide useful guidance for studying physical properties in time-dependent systems.

12:03PM S54.00005: Electrons in Narrow-Band Moire Graphene: Electric and Magnetic Two-Dimensional Bloch Oscillations  
Zhiyu Dong, Ali Fahimnia, Leonid Levitov (Presenter), Massachusetts Institute of Technology — Bloch oscillating electrons, moving in a two-dimensional crystal under a DC electric field, are described, in a quasiclassical picture, by trajectories that wind quasiperiodically around the 2D Brillouin zone. The oscillations feature two or more discrete frequencies that depend on the field, but not on individual particle velocities, producing narrow lines in ensemble-averaged noise power spectrum. An externally applied magnetic field alters the dynamics, creating new types of Bloch oscillations that do not exist in one-dimensional solids. The conventional “electric” oscillations persist at weak B fields; above a critical B value a different dynamics sets in that combines Bloch oscillations and Larmor drift. In this “magnetic” regime particle trajectories are extended in position space and confined in momentum space, with a complex chaotic behavior arising at the transition.

12:15PM S54.00006: Energy filtered leads for quantized transport in Floquet systems* 
Netanel Lindner (Presenter), Technion - Israel Institute of Technology, Mads Kruse, Mark Rudner, Niels Bohr Institute —
In equilibrium, robust electronic edge or surface modes play key roles in the fascinating quantized responses exhibited by topological materials. Topological bands and edges states can be induced dynamically even in trivial materials, using a time-periodic drive. In contrast to their equilibrium counterparts, the dynamically induced Floquet topological insulators do not exhibit quantized transport when probed using conventional measurements, such as the differential conductance. This lack of quantization arises due to photon assisted tunneling from the system to the leads and vice versa. We show that quantization of the differential conductance can be restored by connecting the system and the leads via an energy filter. We discuss the utility of this approach for achieving quantization of other responses in topological Floquet systems.

Photoinduced Topological Phase Transition and Optical Conductivity of Black Phosphorene

YOUSUNG KANG (Presenter), KYUNGSUN MOON, Yonsei University

We theoretically study the photoinduced topological phase transition of black phosphorene induced by laser light with moderate-intensity, which can satisfy the experimentally realistic requirement to preserve the quality of the sample. By deriving the effective Floquet Hamiltonian in terms of pseudo-spin S=1/2 degrees of freedom, we calculate the Chern number and the optical conductivity of the system with varying laser frequency. As one can expect from the photon-assisted transport, the longitudinal optical conductivity has a threshold frequency at $\Omega=\Delta/h$ with $\Delta$ being the band gap of black phosphorene. Unlike the longitudinal optical conductivity, the optical Hall conductivity sharply increases when $h\Omega$ goes beyond one half of the band gap $\Delta/2$. We also show that the Chern number changes from trivial to non-trivial one upon increasing frequency beyond $h\Omega=\Delta/2$.

Enhancement of High Harmonics Generation by Floquet Engineering

ABHISHEK KUMAR (Presenter), YANTAO LI, BABAK H SERADJEH, Indiana Univ - Bloomington

High harmonic generation (HHG) in gaseous systems and solids is well studied. Since periodically driven systems can produce harmonic response, it is important to study the influence of external driving on the HHG power spectrum. We formulate a theory of high-harmonic current using Floquet theory of periodically driven systems. As an application of our theory, we study HHG in the Su-Schrieffer-Heeger (SSH) model with and without periodic drive. We find that there is a significant enhancement in higher harmonics when the system is driven. Moreover, this enhancement peaks for an optimal harmonic at a value that increases when the intensity of the laser is reduced. This means HHG can be generated even at lower pulse intensities in a Floquet system. We obtain analytical expressions for HHG power spectrum in the high-frequency approximation for driven SSH model. Further, we study the effects of laser polarization and occupation of Floquet bands on HHG in two dimensional systems. We also investigate the consequences of spatiotemporal symmetries and Floquet topology for HHG in Floquet systems.

12:51PM S54.00009: Correlation-Enhanced Quantized Charge Pumping* JACOB MARKS
(Presenter), Physics Department, Stanford University, MICHAEL SCHÜLER, Stanford Institute for Materials and Energy Science (SIMES), Stanford University, JAN BUDICH, Technical University Dresden, THOMAS DEVEREAUX, Photon Sciences, Stanford Linear Accelerator (SLAC) — We investigate charge pumping in the vicinity of order-obstructed topological phases. To explore this, we study a prototypical Su-Schreiffer-Heefer model with non-local interaction that gives rise to orbital charge density wave order, and characterize the impact of this order on the model's topological properties. In the ordered phase, where the many-body topological invariant loses quantization, we find that not only is quantized charge pumping possible, it is assisted by the collective nature of the orbital charge density wave order.

*Supported by the U.S. Department of Energy (DOE), Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, under contract DE-AC02-76SF00515.

1:03PM S54.00010: Stability of dynamical quantum phase transitions in quenched topological insulators: From multi-band to disordered systems CHRISTIAN MENDL (Presenter), TU Munich, JAN BUDICH, Physics, TU Dresden — Dynamical quantum phase transitions (DQPTs) represent a counterpart in non-equilibrium quantum time evolution of thermal phase transitions at equilibrium, where real time becomes analogous to a control parameter such as temperature. In quenched quantum systems, recently the occurrence of DQPTs has been demonstrated to be intimately connected to changes of topological properties. Here, we contribute to broadening the systematic understanding of this relation between topology and DQPTs to multi-orbital and disordered systems. Specifically, we provide a detailed ergodicity analysis to derive criteria for DQPTs in all spatial dimensions, and construct basic counter-examples to the occurrence of DQPTs in multi-band topological insulator models. As a numerical case study illustrating our results, we report on microscopic simulations of the quench dynamics in the Harper-Hofstadter model. Furthermore, going gradually from multi-band to disordered systems, we approach random disorder by increasing the (super) unit cell within which random perturbations are switched on adiabatically. This leads to an intriguing order of limits problem which we address by extensive numerical calculations on quenched one-dimensional topological insulators and superconductors with disorder. (arXiv:1909.01402)

1:15PM S54.00011: Observation of long excitation lifetime in photoexcited Sb-doped Bi$_2$Se$_3$ nanoplatelets* ADAM GROSS (Presenter), YASEN HOU, ANTONIO ROSSI, DONG YU, INNA VISHIK, University of California, Davis — Bi$_2$Se$_3$ is a three-dimensional topological insulator (TI), characterized by a bulk band gap of approximately 0.3 eV and a Dirac-like protected surface state. The material is usually n-type due to selenium vacancies, and chemical substitution, such as Sb-doping, is typically needed to bring the chemical potential into the bulk band gap. We will present ultrafast transient reflectivity measurements on Bi$_2$Se$_3$ and Bi$_{2-x}$Sb$_x$Se$_3$ nanoplatelets which reveal starkly different carrier decay dynamics in n-type vs. insulating samples. This will be discussed in the context of optoelectronic applications of TIs, including as a material for exciton condensation.

*NSF DMR-1838532-0
1:27PM S54.00012: Time-domain anyon interferometry in Kitaev honeycomb spin liquids and beyond  KAI KLOCKE (Presenter), Physics, Caltech, DAVID AASEN, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, ROGER MONG, Physics, University of Pittsburgh, EUGENE DEMLER, Physics, Harvard University, JASON F. ALICEA, Physics, Caltech — Motivated by recent evidence of a non-Abelian spin liquid in α-RuCl₃, we introduce a new experimental method for probing the edge and quasiparticle content of such a phase. Our scheme exploits a pair of ancillary quantum spins that communicate via judicious time-dependent tunneling of energy into and out of the spin liquid's gapless chiral Majorana edge state. We show that the ancillary-spin dynamics not only probes the Majorana edge modes, but in suitable geometries allows one to detect individual non-Abelian anyons and emergent fermions via a time-domain counterpart of anyon interferometry developed in the quantum-Hall context. The tools that we develop are expected to be widely applicable to topological phases both in solid-state and cold-atoms settings.

1:39PM S54.00013: Electron localization in two-dimensional topological and non-topological bands* AKSHAY KRISHNA, Princeton University, MATTEO IPPOLITI, Stanford University, RAVINDRA NAUTAM BHATT (Presenter), Princeton University — Many-body localization (MBL) is a well-established phase present in disordered one-dimensional spin models with short-range interaction. However, the stability of MBL in higher dimensions, in the presence of long range interaction and under the effect of a topologically non-trivial single-particle band structure, is still an area of ongoing research. We demonstrate a method to construct nearly flat subbands with arbitrary Chern numbers, using a weak periodic potential in the lowest Landau level. This two-dimensional system is a novel platform for the detailed study of the interplay between disorder, interaction and topology in a continuum model. Using exact diagonalization, we investigate the localization properties of single-particle eigenstates, as well as the tendency to many-body localize in the presence of interaction, both in the quasi 1-D and 2-D limits. Our results are based on an analysis of both the many-body eigenvalue spacings and the time evolution of an initial charge imbalance [1], [2].

Session S55 DCMP: Topology in Magnetic Systems Mile High Ballroom 2B
11:15AM S55.00001: Infinite Matrix Product States for Spin-Liquid Wavefunctions  GABRIEL PETRICA (Presenter), University of Illinois at Urbana-Champaign, BO-XIAO ZHENG, GARNET CHAN, California Institute of Technology, BRYAN CLARK, University of Illinois at Urbana-Champaign — Quantum spin liquids are disordered ground states of interacting spin systems. As such they cannot be characterized by a local order parameter. Instead, entanglement measures, such as the entanglement spectrum and entanglement entropy, can be used to detect the presence of topological order. We present here a highly parallelizable, efficient method to obtain an infinite matrix product state for Gutzwiller projected mean-field wave-functions, a common variational class of wavefunctions used to study quantum spin liquids. We then extract the entanglement spectrum from the iMPS using it to understand the topological properties of these states.

11:27AM S55.00002: Spinon Fermi surface in the Kitaev model induced by staggered magnetic field  JING-YUN ZHANG (Presenter), HONG YAO, Institute for Advanced Study, Tsinghua University — Kitaev model on the honeycomb lattice is an exactly solvable model of realizing quantum spin liquids which exhibits two distinct spin liquids in the parameter space: a gapped phase 'A' carries $\mathbb{Z}_2$ topological order and a gapless phase 'B' carries gapless fermions and gapped vortices. For the B phase, applying a uniform magnetic field would induce a gapped spin liquid phase with non-Abelian anyons. In this talk, we will discuss the effect of a staggered external magnetic field in the B phase. We show that the original gapless Dirac cone spectra of fermions can be immediately turned into a finite spinon Fermi surface by a weak staggered field. Our analytical perturbative results are further supported by numerical computations.
11:39AM S55.00003: A New Synthetic Quantum Spin Liquid Candidate CCO111*  XIAORAN LIU, SOBHIT SINGH, Physics and Astronomy, Rutgers University, TOMOYA ASABA, Physics, University of Michigan, JESS H BREWER, TRIUMF, QINGHUA ZHANG, CAS, Beijing National Laboratory for Condensed-Matter Physics and Institute of Physics, JOHN WILLIAM FREELAND, Advanced Photon Source, Argonne National Lab, SRIMANTA MIDDEY, Department of Physics, Indian Institute of Science, MIKHAIL KAREEV, Physics and Astronomy, Rutgers University, DIPANKAR DAS SARMA, Department of Physics, Indian Institute of Science, PADRAIC SHAFER, ELKE ARENHOLZ, Advanced Light Source, LBNL, LU LI, Physics, University of Michigan, DAVID VANDERBILT, JAK CHAKHALIAN (Presenter), Physics and Astronomy, Rutgers University — Quantum spin liquid is a new state of quantum strongly correlated topological matter characterized by the presence of a Mott gap, topological order and fictionalized spectrum of spin excitations. Despite the tremendous progress in bulk synthesis of potential QSL candidates the `smoking-gun' compound remains elusive. Here, we present a new synthetic candidate QSL material successfully templated from (111)-oriented CoCr$_2$O$_4$ by pulsed laser deposition. Remarkably, as the thickness is reduced to four Kagome-triangular atomic planes, the magnetic ground state suddenly switches from a spiral order to the quantum paramagnetic regime with no sign of long-range spin ordering down to 30 mK and 9T. At the same time, the frustration factor rises by almost three orders of magnitude indicating the first realization of a quantum spin liquid state on the new artificial lattice. Our findings open the opportunities of achieving novel ultra-quantum states of matter in a broad class of synthetic materials.

11:51AM S55.00004: Dynamics of chiral spin liquids in the Kitaev-Yao-Kivelson model  BOHAI LI (Presenter), JING-YUN ZHANG, HONG YAO, Institute for Advanced Study, Tsinghua University — Chiral spin liquid (CSL) is a type of quantum spin liquids which spontaneously break time reversal symmetry (TRS). For the exactly solvable Kitaev-Yao-Kivelson (KYK) model on the star lattice, the ground state is a CSL phase with either Abelian or non-Abelian anyons, depending on the parameters of the KYK model. We perform a theoretical study of the dynamical structure factor in both Abelian and non-Abelian phases of this model. Our result shows direct signatures of the Majorana fermions, vortex excitations, zero-energy modes of vortex excitations in the non-Abelian phase.
**12:03PM S55.00005: Z₂ topological quantum spin liquids with only two-body Ising interactions and transverse fields**  
KAI-HSIN WU (Presenter), CLAUDIO CHAMON, ANDERS W SANDVIK, Physics, Boston University — In the recent study[1], the authors proposed a generalization of the transverse-field Ising model which can realize the $Z₂$ gauge theory with only simple two-body interaction. The deconfined phase in the $Z₂$ gauge model is the topologically ordered phase that is protected against any local perturbation. The model is also interesting in the sense that it can be implemented in the D-Wave Chimera-lattice structure. Here, we study the model using exact diagonalization and stochastic series expansion quantum Monte Carlo. We present our simulation results of the transition between the confined phase and deconfined phase that support the theoretical prediction.

**12:15PM S55.00006: Numerical evidence of a chiral spin liquid in the spin-1/2 honeycomb XY model**  
YIXUAN HUANG (Presenter), Physics, Univ of Houston, XIAOYU DONG, DONNA SHENG, Physics and Astronomy, California state university, Northridge, CHIN-SEN TING, Physics, Univ of Houston — The frustrated XY model on the honeycomb lattice has received lots of attentions because of the potential chiral spin liquid (CSL) in the intermediate region. Using density matrix renormalization group method on the cylinder system, we study the spin-1/2 XY model with first-neighbor (J₁) and second-neighbor (J₂) interactions, and in the presence of a chiral term. We obtain a quantum phase transition and a non-magnetic phase with finite scalar chiral order when we turn on a small chiral interaction. Further analysis of the entanglement spectrum is consistent with the Kalmeyer-Laughlin CSL in this region.

**12:27PM S55.00007: Toward Kitaev's Sixteenfold Way in a Honeycomb Lattice Model**  
SHANGSHUN ZHANG, CRISTIAN BATISTA, University of Tennessee, Knoxville, GABOR HALASZ (Presenter), Oak Ridge National Lab — Kitaev's sixteenfold way is a classification of exotic topological orders in which $Z₂$ gauge theory is coupled to Majorana fermions of Chern number C. The 16 distinct topological orders within this class, depending on C mod 16, possess a rich variety of Abelian and non-Abelian anyons. We realize more than half of Kitaev's sixteenfold way, corresponding to Chern numbers 0, ±1, ±2, ±3, ±4, and ±8, in an exactly solvable generalization of the Kitaev honeycomb model. For each topological order, we explicitly identify the anyonic excitations and confirm their topological properties. In doing so, we observe that the interplay between lattice symmetry and anyon permutation symmetry may lead to a "weak supersymmetry" in the anyon spectrum. The topological orders in our honeycomb lattice model could be directly relevant for honeycomb Kitaev materials, such as $\alpha$-RuCl₃, and would be distinguishable by their specific quantized values of the thermal Hall conductivity.
12:39PM S55.00008: Finding the Generalized Gibbs Ensemble in the Real Space Entanglement Spectra of (2+1)-dimensional Chiral Topological Systems  MARK ARILDSEN (Presenter), ANDREAS W LUDWIG, University of California, Santa Barbara — The numerical calculation of entanglement spectra (ES) has become a useful way to diagnose topological properties of interesting many-body ground states. For (2+1)D quantum Hall states a correspondence between the low-lying levels of the ES across a given bipartition and of the physical spectrum of the edge states along the same cut was observed in Ref. [1]. When the ES of a chiral topological state is computed at a (finite) real space entanglement cut, however, we posit that additional physics should be visible in the splitting of the degeneracies of the low-lying energy levels arising from the presence of higher-order conserved quantities (irrelevant in the renormalization group sense) in the generalized Gibbs ensemble (GGE) associated to the theory on the edge. We analyzed the real space ES obtained in several previous numerical studies of (2+1)D chiral spin liquids with edges hosting (1+1)D conformal field theories possessing SU(2)-level-1 and SU(2)-level-2 symmetry. We fitted the splittings in these ES with sets of (irrelevant) conserved quantities and find that for the most part, we confirm their correspondence with the GGE picture outlined above.

12:51PM S55.00009: Exchange Bias and Quantum Anomalous Hall Effect in the MnBi$_2$Te$_4$-CrI$_3$ Heterostructure  HUIXIA FU (Presenter), Department of Condensed Matter Physics, Weizmann Institute of Science, CHAO-XING LIU, Department of Physics, the Pennsylvania State University, BINGHAI YAN, Department of Condensed Matter Physics, Weizmann Institute of Science — The layered antiferromagnetic MnBi$_2$Te$_4$ films have been proposed to be an intrinsic quantum anomalous Hall (QAH) insulator with a large gap. To realize this proposal, it is crucial to open a magnetic gap of surface states. However, recent experiments have observed gapless surface states, indicating the absence of out-of-plane surface magnetism, and thus the quantized Hall resistance can only be achieved at the magnetic field above 6 T. In this work, we propose to induce out-of-plane surface magnetism of MnBi$_2$Te$_4$ films via the magnetic proximity with magnetic insulator CrI$_3$. Our calculations have revealed a strong exchange bias ~40 meV, originating from the long Cr-eg orbital tails that hybridize strongly with Te p-orbitals. By stabilizing surface magnetism, the QAH effect can be realized in the MnBi$_2$Te$_4$/CrI$_3$ heterostructure. Our calculations also demonstrate the high Chern number QAH state can be achieved by controlling external electric gates. Thus, the MnBi$_2$Te$_4$/CrI$_3$ heterostructure provides a promising platform to realize the electrically tunable zero-field QAH effect.
1:03PM S55.00010: ARPES studies on antiferromagnetic topological insulators MnBi$_{2n}$Te$_{3n+1}$

YONG HU (Presenter), University of Science and Technology of China, C.-F. CHEN, ShanghaiTech University, GANG Xu, Huazhong University of Science and Technology, XIANHUI CHEN, JUNFENG HE, University of Science and Technology of China — The intrinsic magnetic topological insulators are believed to be an ideal platform for the study of various topological quantum phenomena, including the quantum anomalous Hall effect and topological magnetoelectric effect. Recently, a van der Waals layered structure, MnBi$_2$Te$_4$, was proposed to be the first intrinsic antiferromagnetic topological insulator. Furthermore, the related MnBi$_{2n}$Te$_{3n+1}$ (n=2,3) heterostructures are considered to be new magnetic topological insulators with weak interlayer magnetic coupling. In this talk, we report angle-resolved photoemission spectroscopy (ARPES) studies on a series of the heterostructures MnBi$_{2n}$Te$_{3n+1}$ (n=1,2,3). Our results reveal that the intrinsic magnetic topological insulators MnBi$_{2n}$Te$_{3n+1}$ host a rich platform to realize various novel topological states.

1:15PM S55.00011: Surface state single Dirac cone in magnetic material Gd$_x$Sb$_{2-x}$Te$_3$.*

FIROZA KABIR (Presenter), M. MOFAZZEL HOSEN, Univ of Central Florida, XIAxin DING, Idaho national lab, GYANENDRA DHAKAL, KLAUSS DIMITRI, CHRISTOPHER SIMS, SABIN REGMI, WILLIAM NEFF, Univ of Central Florida, JIAN-XIN ZHU, Los Alamos National Lab, ARJUN K PATHAK, Ames lab, KRZYSZTOF GOFRYK, Idaho national lab, MADHAB NEUPANE, Univ of Central Florida — Three-dimensional topological insulators (TI) have emerged as novel states in condensed matter physics. The surface states of a 3D TI are composed of odd number of massless Dirac cones in a Brillouin zone. The existence of these Dirac cones on the surface is characterized by the $Z_2$ topological invariant. Strongly spin-orbit coupled material Sb$_2$Te$_3$ and most of its doped materials belong to the $Z_2$ topological-insulator class. Using a combination of first-principles calculations, magneto transport properties and angle resolved photoemission spectroscopy (ARPES), we directly show that Gd$_x$Sb$_{2-x}$Te$_3$ is a large spin-orbit-induced indirect bulk bandgap magnetic material whose surface is characterized by a single topological spin-Dirac cone. We demonstrate that the dynamics of spin Dirac fermions of Sb$_2$Te$_3$ can be controlled through Gd doping, making this magnetic material classes potentially suitable for topological device applications.

*This project is supported by the Center for Thermal Energy Transport under Irradiation, an Energy Frontier Research Center funded by the U.S. DOE, Office of Basic Energy Sciences.
1:27PM S55.00012: Photon energy and polarization dependent electronic structure of Cr doped Bi2Se3 thin films  
TURGUT YILMAZ (Presenter), GENDA GU, ELIO VESCOVO, KONSTANTINE KAZNATCHEEV, Brookhaven National Laboratory, BORIS SINKOVIC, Physics, University of Connecticut — Here, we reported a comparison study of photon energy and photon polarization dependent electronic structure of Cr-doped and pristine Bi2Se3 to reveal the topological phase in transition metal doped topological insulators. Circular dichroism and photon energy dependent angle resolved photoemission experiment strongly confirm that the Cr doped samples have topologically non-trivial band structure. The surface electronic structure measurements with linear and circular polarized light show signature of the hybridization of the surface states and the impurity bands. Our observation not only provide further spectroscopic information about topological materials but also promotes additional experimental pathways to control the spin-orbital texture in topological materials.

1:39PM S55.00013: Electronic structure of topological insulator Bi2Se3 thin films on thulium iron garnet heterostructures  
SHENG-WEN HUANG (Presenter), Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, KENG-YUNG LIN, Graduate Institute of Applied Physics and Department of Physics, National Taiwan University, Taipei, Taiwan, CHUN-CHIA CHEN, MENGXIN GUO, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, CHAO-KAI CHENG, Graduate Institute of Applied Physics and Department of Physics, National Taiwan University, Taipei, Taiwan, CHENG-MAW CHENG, National Synchrotron Radiation Research Center, Hsinchu, Taiwan, MINGHWEI HONG, Graduate Institute of Applied Physics and Department of Physics, National Taiwan University, Taipei, Taiwan, JUEINAI KWO, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan — Breaking time-reversal symmetry (TRS) in topological insulator (TI) leads to exotic phenomena such as quantum anomalous Hall effect (QAHE). The novel phenomena originated from a gap opening at the Dirac surface state by exchange interaction with magnetic elements. Magnetically doped TI was first reported to exhibit such an exchange gap, but the observation temperature of QAHE was less than 2 K. Another way to break TRS is through interfacial magnetic proximity effect (MPE) in TI/ferromagnetic insulator bilayer with a strong ferromagnetism and uniform interfacial magnetization. In this work, TI films Bi2Se3 were grown by molecular beam epitaxy on ferromagnetic thulium iron garnet (TmIG) with perpendicular magnetic anisotropy and high $T_C$ above 500K. The band structures of 2-6 quintuple layer (QL) Bi2Se3/TmIG bilayers were investigated by angle-resolved photoemission spectroscopy. Comparative study in 2-6 QL Bi2Se3/sapphire was also performed. The energy gap opening at the surface state of Bi2Se3/TmIG is larger than that of Bi2Se3/sapphire by about 20 meV. The larger surface state gap of Bi2Se3/TmIG could be induced by MPE, on top of hybridization of top and bottom surfaces. Our study demonstrates the opportunity of probing interfacial band of TI-based heterostructures.
Path to building quantum spin liquids and topological qubits within existing quantum hardware*  ZHICHENG YANG (Presenter), University of Maryland, College Park, DMITRY GREEN, ResearchPULSE LLC, CLAUDIO CHAMON, Boston University — We address a central problem in the creation and manipulation of quantum states: how to build topological quantum spin liquids with physically accessible interactions. Theorists have been studying models of quantum spin liquids that rely on “multi-spin” interactions since the 1970s, and, more recently, have realized that these models can be used for quantum computing. However, nature does not provide such interactions in real materials. We construct a lattice gauge model where the required, fully quantum, multi-spin interactions can in fact be emulated exactly in any system with only two-body Ising interactions plus a uniform transverse field. The latter systems do exist, and we provide an explicit embedding of our model into one such system, the commercially available D-Wave machine. Therefore, our solution is an alternative path to building a workable topological quantum computer within existing hardware. Our bottom-up construction is generalizable to other gauge-like theories, including those with fractonic topological order such as the X-cube model. Taken as a whole, our approach is a blueprint to emulate topologically ordered quantum spin liquids in programmable quantum machines.

Optical Evidence of an Enhanced Electronic Effective Mass in the Anomalous Pb_{1-x}Tl_{x}Te Superconductor  LEONARDO DEGIORGI, MANUEL CHINOTTI (Presenter), ANIRBAN PAL, ETH Zurich — The narrow band-gap semiconductor PbTe exhibits a number of striking properties upon thallium (Tl)-doping, including the onset of superconductivity at temperatures T_c which are substantially higher than for materials with equivalent charge carrier concentration. Here, we provide a thorough optical investigation of Pb_{1-x}Tl_{x}Te over a very broad spectral range and contrast its normal-state, complete excitation spectrum with the optical response of the non-superconducting analog Na-doped PbTe [1]. We capture the relevant energy scales shaping their electronic structure and uncover the formation of an impurity band upon doping with Tl, which evolves into a resonant state for large doping. This implies a large density of states and an enhancement of the optical effective mass m*/m_e of the itinerant charge carriers, which is stronger for Tl- than for Na-doping. Since the enhancement of m*/m_e particularly occurs upon crossing a critical concentration x_c in Tl-doped PbTe for which T_c≠ 0, we advance its relevance for the onset of superconductivity.

Weyl-Kondo semimetal: controlling the nodes via magnetic field

SARAH GREFE (Presenter), HSIN-HUA LAI, Physics and Astronomy, Rice University, SILKE BUEHLER-PASCHEN, Institute of Solid State Physics, Vienna University of Technology, QIMIAO SI, Physics and Astronomy, Rice University — In the effort to study topological metals in strongly-correlated settings, a Weyl-Kondo semimetal (WKSM) has been concurrently discovered in theoretical\(^1\) and experimental\(^2,3\) studies. This time-reversal-invariant state appears in a non-centrosymmetric Kondo lattice model. The theoretical and experimental signatures of the WKSM phase, include correlations-enhanced specific heat \(C=\Gamma T^3\) and a giant topological Hall response from the Kondo-driven Weyl nodes being pinned near the Fermi energy. Recently, high magnetic field experiments revealed a two-stage quantum phase transition, including a topological transition from the WKSM to a Kondo insulator.\(^4\) To connect with these experiments, we studied an Anderson lattice model with terms that break both time reversal and inversion symmetries.\(^5\) Tuning these terms controls the position and number of Weyl nodes in the Brillouin zone, and several topologically distinct phases emerge in this model.

11:39 AM S56.00003: Quasiparticles as Detector of Topological Quantum Phase Transitions*

SOURAV MANNA (Presenter), NAGARA SRINIVASA PRASANNA SRIVATSA, theoretical condensed matter physics, Max Planck Institute for the Physics of Complex Systems, JULIA WILDEBOER, Department of Physics, Arizona State University, ANNE E. B. NIELSEN, theoretical condensed matter physics, Max Planck Institute for the Physics of Complex Systems — Phases and phase transitions provide an important framework to understand the physics of strongly correlated quantum many-body systems. Topologically ordered phases of matter are particularly challenging in this context, because they are characterized by long-range entanglement and go beyond the Landau-Ginzburg theory. A few tools have been developed to study topological phase transitions, but the needed computations are generally demanding, they typically require the system to have particular boundary conditions, and they often provide only partial information. There is hence a high demand for developing further probes. Here, we propose to use the study of quasiparticle properties to detect phase transitions. Topologically ordered states support anyonic quasiparticles with special braiding properties and fractional charge. Being able to generate a given type of anyons in a system is a direct method to detect the topology, and the approach is independent from the choice of boundary conditions. We provide three examples, and for all of them we find that it is sufficient to study the anyon charge to detect the phase transition point. This makes the method numerically cheap.

11:51 AM S56.00004: Higher-form symmetry perspective on fracton phases*

MARVIN QI (Presenter), LEO RADZIHOVSKY, MICHAEL A HERMELE, University of Colorado, Boulder — Higher form symmetry provides a framework to understand some aspects of topologically ordered phases. Motivated by this, we study the role that higher form symmetry plays in the context of fracton phases. We introduce the notion of a non-faithful higher form symmetry and describe how fractons can arise via condensation of objects charged under such a symmetry. Finally we describe how such a non-faithful higher form symmetry can arise as a quotient of an ordinary higher-form symmetry via gauging certain subgroups.

*This research is supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award number DE-SC0014415 prior to September 2019, and by the Department of Defense through the National Defense Science and Engineering Graduate Fellowship (NDSEG) program beginning September 2019.
12:03PM S56.00005: Local and Non-local correlation effects in topological quantum phase transitions  LORENZO CRIPPA (Presenter), ADRIANO AMARICCI, SISSA, GIORGIO SANGIOVANNI, Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, University of Würzburg, MASSIMO CAPONE, SISSA — The fate of quantum phase transition among different topological states in presence of strong interaction is of primary interest in condensed matter. We study the effects of electronic interactions at the local and non-local level in a paradigmatic model for topological insulator in two dimensions. In the non-interacting regime topological transitions occurs via the continuous closing the energy gap. Using Dynamical Mean-Field Theory and various cluster extensions (Cluster-DMFT, Variational Cluster Approximation, etc.), we show how short-range correlation effects are responsible for the breakdown of the continuous topological transition in favour of a first-order one. The discontinuous transition occurs without the celebrated closing of the energy gap, yet without the breaking of the symmetries which protect the topological state.

12:15PM S56.00006: Anomalous localization at the boundary of an interacting topological insulator  ITAMAR KIMCHI (Presenter), University of Colorado, Boulder, YANG-ZHI CHOU, University of Maryland, RAHUL NANDKISHORE, LEO RADZIHOVSKY, University of Colorado, Boulder — The boundary of a topological insulator (TI) hosts an anomaly restricting its possible phases: e.g. 3D strong and weak TIs maintain surface conductivity at any disorder if symmetry is preserved on-average, at least when electron interactions on the surface are weak. However the interplay of strong interactions and disorder with the boundary anomaly has not been well studied theoretically. Here we present our results on this combination, for the edge of a 2D TI and the surface of a 3D weak TI, showing how it can lead to an "Anomalous Many Body Localized" (AMBL) phase that preserves the anomaly. We discuss its anomaly manifestation, predictions for experimental observations, and theoretical consequences for understanding 3D TIs and anomaly restrictions.
12:27PM S56.00007: Interaction effects on centrosymmetric Bogoliubov Fermi surfaces
HANBIT OH (Presenter), EUN-GOOK MOON, Department of physics, Korea Adv Inst of Sci & Tech —
Exotic quantum phases including topological insulators/semi-metals and non-Fermi liquids may be realized by quantum states with total angular momentum j=3/2 as manifested in HgTe and pyrochlore iridates. Recently, an exotic superconducting state with a finite density of zero energy Bogoliubov quasiparticles, Bogoliubov Fermi-surface, was also proposed in a centrosymmetric j=3/2 system with a Z2 topological invariant. We consider interaction effects of the Bogoliubov Fermi surfaces by using standard renormalization group and mean-field theory and discuss the implication of inversion symmetry breaking. Possible applications of our theory to iron based superconductors and heavy fermion systems including FeSe are also discussed.

12:39PM S56.00008: Twisted dualities and the 2d Majorana checkerboard
MARCUS BINTZ (Presenter), University of California, Berkeley — Large ensembles of bound Majorana modes can form their own strongly-interacting phases of matter. For example, a square lattice of Majoranas coupled purely by four-fermion plaquette terms may be the effective description for the vortex lattice on the surface of certain 3d topological insulators. This talk leverages recently formulated exact dualities to derive novel representations of such a 2d Majorana checkerboard. Some connections to quantum cellular automata (QCA) and subsystem symmetry protected topological order (SSPT) are also discussed.

12:51PM S56.00009: Universal SPT invariants using swap operators*
SHRIYA PAI (Presenter), MICHAEL A HERMELE, University of Colorado, Boulder — We will describe many-body topological invariants/order parameters for SPT phases that involve acting with symmetry operators and a swap operator. To do so, we use the universal notion of distinguishing between different phases of matter: phases are equivalence classes defined in the thermodynamic limit by (i) adiabatic continuity, and (ii) adding trivial degrees of freedom. In the process, we will also formulate gauge-invariant versions of these order parameters. Since our arguments for the universality of such many-body invariants do not depend on the spatial dimension we are working in, this discussion can help serve as a basis for generalizations to higher spatial dimensions. We will also show how to picture the invariant by putting the system on a spacetime manifold and by thinking in terms of TQFT partition functions.

Exceptional-torus in strongly correlated nodal-line semimetals with many-body chiral symmetry

KAZUHIRO KIMURA (Presenter), TSUNEYA YOSHIDA, NORIO KAWAKAMI, Physical Society of Japan — Recent studies have revealed a new type of topological phase described by a non-Hermitian (NH) Hamiltonian. In equilibrium systems, if we describe the energy spectrum of quasiparticles having the complex self-energy in terms of effective Hamiltonian, NH physics naturally shows up because of the life time effects from self-energy. The most important point is the emergence of gapless defective points (DPs), which lead to an open Fermi surface, such as Fermi arcs in the bulk energy spectrum.

In previous studies, it is pointed out that the effect of symmetry leads to the symmetry protected NH band touching, such as the symmetry-protected exceptional torus (SPETs). A typical example is a parity-time reversal (PT) symmetric nodal-line semimetal (NLSM).

In this study, we demonstrate how the SPETs can emerge in strongly correlated systems. We analyze correlated NLSM on a diamond lattice model with a sublattice dependent on-site Hubbard interaction by using the dynamical mean-field theory. First, we reveal the emergence of a SPET unique to NH physics with many-body chiral symmetry, which forms the 3D open Fermi surface locked on the Fermi level. We further elucidate that the static susceptibility for a sublattice with weak interaction is enhanced by the emergence of SPETs.

Realizing the Majorana Quasiparticle fermionic dynamics in (1+1) dimensional Topological Quantum Materials*

SUSHANT KUMAR BEHERA (Presenter), PRITAM DEB, Department of Physics, Tezpur University — A Majorana fermion and its dynamics are determined by the Majorana equation having equal values of spinor and conjugate field, thereby making topological quantum material a technological reality [Phys. Rev. Lett.] 121, 067701, 2018]. It is interesting to study the dynamics of Majorana fermions in presence of external perturbations in (1+1) dimensions, a scalar potential by approaching for the first time implementing the methods of supersymmetric quantum mechanics [Phys. Rev. Lett.] 106, 060503, 2011; Rev. Mod. Phys.] 80, 1083, 2008]. Moreover, the dynamics of two competing effects (i.e. strain and magnetic field) is worth to focus in monolayer quantum material with the aim to explore its impact in various phenomena of quantum field theory, such as induced charge density, magnetic catalysis, symmetry breaking, dynamical mass generation, and magnetization. The combined effect of real and pseudomagnetic fields produces an induced valley polarization creating new platforms to design quantum computers and valleytronics devices.

1:27PM S56.00012: Crystal-to-Fracton Tensor Gauge Theory Dualities*  ZHENGZHENG ZHAI (Presenter), MICHAEL PRETKO, LEO RADZIHOVSKY, University of Colorado, Boulder — We discuss the duality between elasticity of two-dimensional crystals and fracton tensor gauge theories, developed by two of the authors [1,2,3]. This duality leads to numerous predictions for the phases and phase transitions in fracton systems, such as the existence of gauge theory counterparts to the (commensurate) crystal, supersolid, hexatic, and isotropic fluid phases of elasticity theory, that will be discussed. The classical finite temperature limit, provides a complementary description of the KTHNY theory of 2D melting, formulated in terms of a higher derivative vector sine-Gordon model. Broader implications of this duality, such as the quantum melting transitions and quantum phase diagrams, symmetry enriched fracton order, and connection to the interacting topological crystalline insulators, will be discussed.

1:39PM S56.00013: Interactions in nodal-line semimetals with quadratic band touching*  GEO JOSE (Presenter), BRUNO UCHOA, Univ of Oklahoma — We address the problem of Coloumb interactions in 3D nodal-line semimetals with quadratic band touching using perturbative Wilsonian renormalization group approach. At one loop order, we find that the non-interacting fixed point is unstable and flows to an interacting fixed point. We compute corrections to the dynamical exponent, the screening charge and find corrections to other experimentally measurable quantities such as the specific heat, compressibility, etc. We also consider the emergence of other competing instabilities in the charge sector from short-range interactions.

*We acknowledge the Carl. T. Bush fellowship at the University of Oklahoma.
TIBOR RAKOVSZKY, PABLO SALA DE TORRES-SOLANOT (Presenter), TU Munich, RUBEN VERRESEN, Department of Physics, Harvard university, MICHAEL KNAP, FRANK POLLMANN, TU Munich — Certain disorder-free Hamiltonians can be non-ergodic due to a strong fragmentation of the Hilbert space into disconnected sectors. We show how to characterize such systems by introducing the notion of 'statistically localized integrals of motion' (SLIOM), whose eigenvalues label the connected components of the Hilbert space. SLIOMs are not spatially localized in the operator sense, but appear localized to sub-extensive regions when their expectation value is taken in typical states with a finite density of particles. We will illustrate this general concept on several Hamiltonians, both with and without dipole conservation. For the former we uncover additional SLIOMs due to dipole moment conservation on finite regions of the chain. Moreover, we explain that there exist perturbations which destroy these integrals of motion in the bulk of the system, while keeping them on the boundary. This results in statistically localized strong zero modes, leading to infinitely long-lived edge magnetizations along with a thermalizing bulk. We also show that these edge modes can lead to the appearance of topological string order in a certain subset of highly excited eigenstates, and conclude providing experimental realizations of these models using existing experimental platforms.

WENJIE XI (Presenter), Department of Physics, Southern University of Science and Technology, ZHIHAO ZHANG, School of Mathematical Sciences, University of Science and Technology of China, ZHENGCHENG GU, Department of Physics, The Chinese University of Hong Kong, WEIQIANG CHEN, Department of Physics, Southern University of Science and Technology — Topological phases in non-Hermitian systems became a fascinating subject recently. In this paper, we attempt to classify topological phases in 1D non-Hermitian systems. We begin with the non-Hermitian generalization of Su-Schrieffer-Heeger(SSH) model and discuss its many body topological Berry phase, which is well defined for any quasi hermitian systems(non-Hermitian systems that have real energy spectrum). We then demonstrate that the classifications of topological phases for quasi hermitian systems are exactly the same as their hermitian counterparts. Moreover, we find that unitarity actually can emerge for fixed point partition function describing topological phases in 1D non-Hermitian systems with local interactions. Thus we conjecture that for 1D non-Hermitian system, the classification of topological phases are exactly the same as Hermitian systems.

11:15AM S57.00001: Visualizing and Manipulating Bilayer Graphene Quantum Dot States*

ZHEHAO GE (Presenter), FREDERIC JOUCKEN, EBERTH A QUEZADA, Department of Physics, University of California, Santa Cruz, DIEGO RABELO DA COSTA, Department of Physics, Federal University of Ceará, JOHN DAVENPORT, Department of Physics, University of California, Santa Cruz, BIRAN GIRALDO, NOBUHIKO KOBAYASHI, Department of Electrical and Computer Engineering, University of California, Santa Cruz, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, TONY LOW, Department of Electrical & Computer Engineering, University of Minnesota, JAIRO VELASCO JR., Department of Physics, University of California, Santa Cruz — Quantum confinement enables the control of a material's electronic, spin, and optical properties. A common platform to realize quantum confinement is a quantum dot (QD), which can be achieved through various methods such as electrostatic, self-assembly, and etching. Electrostatically defined monolayer and bilayer graphene QDs are unique compared to lateral semiconductor QDs because the quasi particles in the former possess chirality. As a result, upon normal incidence on a potential barrier monolayer graphene (MLG) features a 100% transmission (Klein tunneling) and bilayer graphene (BLG) features a 100% reflection (anti-Klein tunneling). Recently, several scanning tunneling spectroscopy (STS) studies have been performed on exposed electrostatically defined MLG QDs and have revealed chiral bound states with a tunable Berry phase. However, to date, no STS studies have directly probed the quasi-bound states in BLG QDs. Here we present our latest experimental progress on directly probing and manipulating the quasi-bound states in exposed BLG QDs with a scanning tunneling microscope (STM).

11:27AM S57.00002: Graphene quantum dot bolometers for high frequency EPR of single molecule magnets

LUKE ST. MARIE (Presenter), A EL FATIMY, Georgetown University, JAKUB HRUBY, IVAN NEMEC, CEITEC, JAMES HUNT, Georgetown University, RACHAEL MYERS-WARD, DAVID KURT GASKILL, Naval Research Laboratory, MATTIAS KRUSKOPF, YANFEI YANG, RANDOLPH ELMQUIST, NIST, RAPHAEL MARX, JORIS VAN SLAGEREN, University of Stuttgart, PETR NEUGEBAUER, CEITEC, PAOLA BARBARA, Georgetown University — Graphene's properties, including broadband absorption and a small heat capacity, make it an ideal material for hot-electron bolometers. By nanostructuring graphene to open a quantum confinement gap, we have fabricated bolometers with extremely high responsivity. We use these graphene quantum bolometers to perform EPR spectroscopy of single molecule magnets (SMMs). We take advantage of the bolometers' extreme sensitivity to conduct these measurements on thin layers of SMMs deposited by sublimation, allowing for the observation of substrate effects not detectable when measuring bulk samples of SMMs using standard techniques.
Manipulation of quantum geometrical properties in Weyl semimetal

JUN XIAO (Presenter), Stanford Univ, YING WANG, University of California Berkeley, HUA WANG, Texas A&M University, SRI CHAITANYA DAS PEMMARAJU, SLAC, SIQI WANG, University of California Berkeley, PHILIPP KARL MUSCHER, EDBERT JARVIS SIE, CLARA M NYBY, THOMAS DEVEREAUX, Stanford Univ, XIAOFENG QIAN, Texas A&M University, XIANG ZHANG, University of California Berkeley, AARON LINDENBERG, Stanford Univ — Quantum materials with novel phases of matter are the key building blocks of energy efficient quantum electronics and powerful quantum computation. Exploiting control of those materials is fascinating to achieve new functionalities and information algorithm in future quantum devices. Quantum nanomaterials like layered materials, has revealed many exotic properties such as extremely large magnetoresistance (MR)\(^1\), type-II Weyl electron transport and diverging Berry curvature\(^2\). On the other hand, the nature of layered materials leads to ultra large tunability of physical properties via external stimuli. Here we report the manipulation of quantum geometrical properties in layered Weyl semimetal devices. With such control and various characterization means, we observed substantial modulation in optical and electrical responses from the device. The observations indicate such changes are closely associated with the variation of topological and geometrical property. Our findings highlight the potential for the realization of topological quantum devices based on layered quantum materials.

Quantum transport of a two-dimensional hole gas in a diamond/h-BN heterostructure

YOSUKE SASAMA (Presenter), KATSUYOSHI KOMATSU, SATOSHI MORIYAMA, MASATAKA IMURA, TOKUYUKI TERAJI, SHIORI SUGIURA, TAICHI TERASHIMA, SHINYA UJI, KENJI WATANABE, TAKASHI TANIGUCHI, TAKASHI UCHIHASHI, YAMAGUCHI TAKAHIDE, National Institute for Materials Science — Diamond attracts increasing attention as a next-generation semiconducting material because of its fascinating properties such as a wide-band gap, high thermal conductivity, high breakdown electric field, and high mobility. In this study, we fabricated a p-type diamond field-effect transistor (FET) using a diamond/hexagonal boron nitride (h-BN) heterostructure. A single-crystalline h-BN was cleaved by the scotch tape method and laminated on a hydrogen-terminated diamond surface. The laminated h-BN flake was used as a gate dielectric. The excellent insulating properties of h-BN enabled the mobilities of holes accumulating at the diamond surface to be higher than 300 cm\(^2\)V\(^{-1}\)s\(^{-1}\) at room temperature for hole densities above 5\times10^{12} cm\(^{-2}\). The high mobility allowed to observe Shubnikov–de Haas oscillations in both the longitudinal and Hall resistivities. The oscillations provided valuable information on the hole transport at the diamond surface, such as the cyclotron effective mass, quantum lifetime, and two dimensionality. The high-quality two-dimensional hole gas demonstrated in this study will lead to new studies of quantum transport in diamond and development of high-performance diamond electric devices. (Y. Sasama et al., APL mater. 6 111105 (2018), arXiv:1907.13500)
12:03PM S57.00005: Electrostatically gated quantum dots in van der Waals materials*
JUSTIN BODDISON-CHOUINARD (Presenter), Univ of Ottawa, ALEXANDER M BOGAN, National Research Council Canada, PAWEL HAWRYLAK, Univ of Ottawa, SERGEI STUDENIKIN, LOUIS GAUDREAU, ANDREW STANISLAW SACHRAJDA, National Research Council Canada, ADINA A LUICAN-MAYER, Univ of Ottawa — Quantum confinement of electrons into quantum dots has been thoroughly explored in materials such as silicon or gallium arsenide showing interesting physical phenomena as well as promise for use in quantum technologies. With rapid advancement in the fabrication of van der Waals heterostructures and their devices, quantum confinement provides a route for harnessing the properties of 2D materials towards building novel quantum computing platforms. Working towards that goal, in this talk we present the design and fabrication of electrostatically gated quantum structures based on monolayer and few atomic layers of molybdenum disulfide (MoS$_2$) and bilayer graphene. Furthermore, we show and discuss our preliminary electron transport results aimed at probing the confined electron states in these structures.

*The authors acknowledge funding from the National Sciences and Engineering Research Council (NSERC) Discovery Grant RGPIN-2016-06717. We also acknowledge the support of the Natural Sciences and Engineering Research Council of Canada (NSERC) through Strategic Project STPGP-521420.

12:15PM S57.00006: Transport Properties in Interacting Graphene Quantum Dots*
FILIPÉ MATUSALEM (Presenter), ALEXANDRE R ROCHA, Univ Estadual Paulista-UNESP — Chemically derived graphene quantum dots (QD) hold great promise for applications in electronics, optoelectronics, and bioelectronics. Using a gate electrode, it is possible to control the number of electrons contained in the dot as well as the current flow when electrodes are attached. Experimentally, the fabrication of atomically precise graphene QDs consisting of low-bandgap armchair graphene nanoribbon (AGNR) segments were recently reported [1]. In this work, we apply a combination of dynamic mean field theory [2] and a molecular-based non-equilibrium Green's function technique coupled to DFT [3,4] to tackle the problem of interacting electrons in graphene quantum dots in AGNR including a gate electrode. We observe conductance peaks associated with the localized states related to the graphene QDs presented in the AGNR in a realistic parameters range giving us precise gap tunability. Such device can be used to design a graphene-based single electron transistor.

As transistors continue to scale down in size, physical limitations from nanoscale field-effect operation begin to cause undesirable effects that are detrimental to the further advancement of computing. We explore an alternative to conventional field-effect transistor operation by using dynamic strain engineering on 2D van der Waals materials to induce electronic/structural phase transitions. Strain has been widely popularized in industry in its static form to enhance silicon mobility, but using strain to dynamically control materials properties has been more challenging for 3D bonded systems due to substrate limitations and defect formation. Systems involving 2D materials are freed from substrate constraints and have high elastic limits, but have not been heavily explored for dynamic strain engineering due to the difficulty in transferring strain into a material that is weakly bonded out-of-plane. In this talk, we focus on challenges in achieving dynamically controllable strain in 2D-bonded materials and how these challenges can be overcome in a scalable on-chip device. We introduce one implementation of such a device using both static thin film stress capping layers and ferroelectric oxide gate-dielectrics. Here, MoTe$_2$ can be reversibly switched with electric-field induced strain between the 1T'-MoTe$_2$ (semimetallic) phase and a semiconducting MoTe$_2$ phase in a three-terminal field effect transistor geometry.

Using strain, we achieve large non-volatile changes in channel conductivity ($G_{on}/G_{off}$~$10^7$ vs. $G_{on}/G_{off}$~0.04 in control devices) at room temperature. Using this implementation as a starting point, other phase transitions in 2D materials may be explored using this ‘straintronic’ device concept, which may enable low-power, high-speed, non-volatile, gate-controllability over a wide variety of exotic states of matter.

1:03PM S57.00008: Imaging Strain-Induced Quantum Emitters* ASHLEY CAVANAGH (Presenter), DYLAN RENAUD, MARKO LONCAR, ROBERT MOORE WESTERVELT, John A. Paulson School of Engineering and Applied Sciences, Harvard University —
Color centers in diamond produce long lived quantum emitters [1]. An alternative approach to creating quantum emitters, as suggested by [2], involves using an array of silica nanopillars to induce strain in a two dimensional Van der Waals material, creating quantum dot-like quantum emitters at each point of strain. This approach is appealing because the locations of the quantum emitters can be controlled and their properties are tunable. Our goal is to electrically characterize these strain-induced quantum emitters using the scanning probe microscope (SPM) technique described in [3]. The cooled SPM tip will be used as a moveable gate to spatially resolve rings of conductance around each point of strain due to the Coulomb-blockade and provide information about the number of electrons at each point.

1:15PM S57.00009: Spin-orbit torques in heterostructures of 2D van der Waals magnets* VISHAKHA GUPTA (Presenter), GREGORY M STIEHL, THOW MIN CHAM, JOSEPH MITTELSTAEDT, ARNAB BOSE, KAIFEI KANG, SHENGWEI JIANG, KIN FAI MAK, JIE SHAN, ROBERT BUHRMAN, DANIEL RALPH, Cornell University — The discovery of intrinsic magnetism in 2D materials has opened an exciting new platform for spintronics, allowing fundamental studies of efficient mechanisms for electrically controlling magnetic materials. Here we explore spin-orbit torques in heterostructures of ultrathin single-crystal magnetic insulators and large spin-orbit coupling (SOC) materials: heavy metals and topological insulators. We report current induced switching in insulating ferromagnet \(\text{Cr}_2\text{Ge}_2\text{Te}_6\) at current densities as low as \(10^6 \text{ Acm}^{-2}\) from spin-orbit torques generated in heterostructures with Pt and Ta. We will discuss methods for quantifying the efficiency of these torques using both optical and electrical-transport techniques.

*DOE (DE-SC0017671)
Fabrication of Hall Micromagnetometers for Probing Two-Dimensional Magnets

SEAN NELSON (Presenter), MARC BOCKRATH, JOSHUA GOLDBERGER, DANIEL WEBER, Ohio State Univ - Columbus — Two-dimensional (2D) magnetic materials have emerged as a promising area for both new physics and potential spintronics applications. Recent work has shown the ballistic Hall micromagnetometry using graphene Hall bars can be used to detect the magnetization of atomically thin 2D magnetic materials. We will discuss our approach to the fabrication of such devices on top of 2D magnetic layers. The magnetic layers are first exfoliated onto a clean Si/SiO2 chip. A Hall bar is fabricated using a standard dry transfer technique, layer stacking, and electron beam lithography. The Hall bar is placed so that it half covers the magnetic layer. As in reference 1, the region covering the magnetic material is actively compared to the region not covering the magnetic material, which acts as a control. We perform low temperature magnetoconductance measurements, and the latest results will be discussed.

Effect of Potential Fluctuation on Ferroelectric-Gated Bilayer Graphene*

HANYING CHEN (Presenter), ZHIYONG XIAO, YIFEI HAO, University of Nebraska - Lincoln, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science - Japan, XIA HONG, University of Nebraska - Lincoln — We investigated the effect of a ferroelectric gate on the transport properties of bilayer graphene (BLG). BLG flakes were mechanically exfoliated on epitaxial 300 nm Ba0.6Sr0.4TiO3 (BSTO) thin films grown on Nb-doped SrTiO3 substrates. Selected flakes were fabricated into field-effect transistor devices. At 2 K, the BLG devices exhibit field-effect mobility up to µFE ~ 3,000 cm²/Vs and quantum Hall effect, from which we deduced a dielectric constant of 113 for BSTO. The devices exhibit resistance hysteresis induced by nonvolatile polarization switching at high gate voltage. The temperature dependence of BLG at the charge-neutral point can be well described by thermally activated behavior at high temperature, which evolves to nearest-neighbor hopping below 80 K. We extracted activation energy of ~20 meV and hopping energy of ~0.3 meV. The result indicates that the epitaxial BSTO films yield less potential fluctuation compared with conventional SiO2 substrate. We will also discuss the effects of remote interfacial optical phonon scattering and capping with a top h-BN layer on these ferroelectric-gated BLG devices.

*This work was primarily supported by the U.S. Department of Energy, BES, under Award No. DE-SC0016153.
1:51PM S57.00012: Improved Adhesion of Two-Dimensional Materials to Ferroelectrics from Poling

CARLA WATSON (Presenter), TASNEEM KHAN, TARA PENA, STEPHEN M WU, University of Rochester — Ferroelectric materials can control mechanical strain in coupled 2D materials to induce phase transitions with applied electric field [1]. 2D flake-to-ferroelectric adhesion is crucial to device performance since it affects the efficiency of strain transfer. We discuss a framework to enhance 2D-ferroelectric adhesion through repeated ferroelectric poling. We explore this using exfoliated MoTe$_2$ thin flakes on structurally mixed-phase rhombohedral (R)/tetragonal (T) BiFeO$_3$ (BFO) ferroelectric thin films grown with a metallic La$_{0.7}$Sr$_{0.3}$MnO$_3$ (LSMO) bottom counterelectrode for switching. Flakes with less adhesion are less conformal to the underlying R/T-BFO stripe domains due to a competition between strain energy and adhesive force. We quantify adhesion by measuring substrate conformality before and after local out-of-plane electric-field poling with a conductive AFM probe. Local poling causes both ferroelectric switching and structural transformation between R and T phases of BFO, which contribute to enhanced substrate conformality as well as a route to on-demand nanoscale strain engineering.

*This material is based upon work supported by the National Science Foundation Graduate Research Fellowship Program under Grant No. DGE-1939268.

2:03PM S57.00013: Control of transport properties of hybrid molybdenum disulfide (MoS$_2$) – ferroelectric devices via domain engineering

ALEXEY LIPATOV (Presenter), University of Nebraska - Lincoln, TAO LI, Xi’an Jiaotong University, NATALIIA S. VOROBEVA, ALEXANDER SINITSKII, ALEXEI GRUVERMAN, University of Nebraska - Lincoln — We demonstrate a concept of programmable ferroelectric devices comprised of two-dimensional (2D) and ferroelectric (FE) materials, which enables precise modulation of the in-plane conductivity of a 2D channel material through nanoengineering of FE domains with out-of-plane polarization. The functionality of these new devices has been demonstrated using field-effect transistors (FETs) fabricated with monolayer molybdenum disulfide (MoS$_2$) channels on the Pb(Zr,Ti)O$_3$ substrates. Using piezoresponse force microscopy, we show that local switching of FE polarization by a conductive probe can be used to tune the conductivity of the MoS$_2$ channel. Specifically, patterning of the nanoscale domains with downward polarization creates conductive paths in a resistive MoS$_2$ channel so that the conductivity of an FET is determined by the number and length of the paths connecting source and drain electrodes. In addition to the device programmability, we demonstrate the device ON/OFF cyclic endurance by successive writing and erasing of conductive paths in a MoS$_2$ channel. These findings may inspire the development of advanced energy-efficient programmable synaptic devices based on combination of 2D and FE materials.
11:15AM S58.00001: Theory and implementation of nonlinear X-ray spectroscopies: application to time-resolved diffraction, X-ray chirality and transient grating experiments

[Invited] JEREMY ROUXEL (Presenter), SHAUL MUKAMEL, University of California, Irvine — Thanks to the progresses of X-ray light sources, ultrafast non-linear X-ray experiments are now feasible. We discuss how such spectroscopies can be theoretically described in terms of the minimal coupling Hamiltonian, allowing a unified description of diffraction-detected and resonant techniques. Coherent X-ray sources can access new material quantities such as transition charge densities thanks to their atomic resolution. We present how X-ray experiments can make use of their element selectivity to probe matter chirality with additional structural information. Finally, we present hybrid visible pump - X-ray probe transient grating measurements conducted on Bi4Ge3O12 (BGO). This 3rd order technique allows to probe excited carrier dynamics and propagation at unprecedented time and length scale.

11:51AM S58.00002: Quantum control of high-energy harmonic generation by pulse shaping

GUAN GUI (Presenter), ROBERT M KARL, JEREMY THURSTON, PETER JOHNSEN, CHARLES BEVIS, IONA BINNIE, HENRY KAPTEYN, MARGARET MURNANE, CHEN-TING LIAO, JILA, University of Colorado Boulder — High harmonic generation (HHG) is the most extreme high-order nonlinear optical process, which can be selectively enhanced at lower photon energies around ~40eV by using temporally shaped laser pulses [1]. Here we demonstrate the ability for enhancing the HHG flux and spectrum at higher photon energies around ~100eV, relevant for imaging and magnetic spectroscopies. By changing the spectral phase of the 800nm driving laser pulses using a genetic algorithm, we can enhance the total HHG flux, or selectively enhance individual HHG orders, or spectrally shift the HHG peaks. These control capabilities can be explained by intra-atomic phase matching on attosecond timescales [2]. Here the phase of the driving laser is optimized so that HHG bursts from each half cycle of the laser pulse interfere coherently, leading to enhancement or suppression in HHG spectrum. This demonstrates that we can extend these quantum control capabilities to higher photon energies, to design and tailor HHG sources for applications in ultrafast spectroscopy, resonant magnetic scattering, and hyperspectral imaging.

HANS JAKOB WOERNER (Presenter), ETH Zurich — Attosecond spectroscopy has the potential to address fundamental questions in chemical sciences. A promising approach is offered by the element- and site-sensitivity of X-ray spectroscopy. We have recently demonstrated the potential of table-top X-ray absorption spectroscopy with a water-window high-harmonic source, observing the temporal evolution of unoccupied molecular orbitals and molecular shape resonances during chemical reactions [1]. Compressing the mid-infrared driving pulses to less than 2 optical cycles, we have demonstrated the extension of this light source to fully cover the oxygen K-edge [2]. Using the same technique, we have also demonstrated the generation of isolated attosecond pulses, which have established a new record of the shortest light pulses ever measured (43 attoseconds) [3].

Since the vast majority of chemical processes takes place in the liquid phase, the extension of attosecond spectroscopy to liquids is desirable. I will discuss the first observation of extreme-ultraviolet high-harmomic generation from liquids, achieved through the application of ultrathin (0.6-2 μm) flat microjets [4]. I will also present the extension of attosecond time-resolved spectroscopy from molecules [5] to liquids [6]. The time delays between photoemission from gaseous and liquid water range from 50-70 attoseconds and are shown to mainly originate from the solvation of water molecules, with liquid-phase electron scattering playing a minor role. These developments set the stage for attosecond time-resolved studies of molecular systems of chemical complexity.

Fundamental understanding of photo-induced charge generation and charge transfer in organic semiconductors is of crucial importance for understanding the functionality of organic optoelectronics. Transient X-ray absorption spectroscopy (Tr-XAS) offers the opportunity for tracking photo-physical processes at the atomic and molecular scale. Here, using Tr-XAS combined with transient absorption spectroscopy and transient microwave conductivity, we investigate the local structure and time evolution of photoinduced charge-separated species in thin films of molecularly dispersed octabutoxy-Zinc(II) phthalocyanine (OButx-ZnPc) in a matrix of the well-known conjugated polymer poly(3-hexylthiophene) (P3HT). We probed a transient signal associated with OButx-ZnPc charged-species in the host polymer (P3HT). Our findings reveal that the XANES spectra of OButx-ZnPc and the transient signal are largely affected by the degree of order of the host material, which is tuned by the regioregularity of P3HT side chains (an amorphous regiorandom P3HT vs a semicrystalline regioregular P3HT).

Enhancement of X-ray image brightness through transient ionic resonances

Most of our high-resolution imaging methods compromise between temporal or spatial resolutions akin to a pinhole camera. This still limits our capabilities to observe fast processes at the nanoscale, especially as the required brightness often damages the sample. Examples of such processes include chemical and catalytic reactions, nucleation dynamics, and growth of nanoparticles, as well as other fragile/intermediate states of matter. One idea to overcome this obstacle is to use Free Electron Lasers (FELs), such as the LCLS at SLAC Nat. Lab., which are capable of producing very bright bursts of coherent X-rays within a few femtoseconds. X-ray FELs help to visualize transient processes in “frozen” time steps via single shot coherent X-ray diffractive imaging (CDI). Currently, the resolution of CDI images is close to tens of nanometers, which is limited by the brightness of the images [1-3]. Our recent study at LCLS suggests that transient ionic resonances (TIR) above an absorption edge can enhance diffraction efficiency before significant structural damage can occur. This is surprising as TIRs are usually regarded as a signature of increased X-ray absorption/damage and thus, detrimental to image quality [4-6].

We recorded a large data set of single exposure diffraction patterns with different FEL pulse durations from Xe nanoparticles by scanning the FEL energy in the vicinity of the 3d absorption edge. TIRs seem to increase the scattering efficiency above the edge even for sub-fs pulses. Our experimental results and a theoretical simulation suggest, that TIRs may provide a pathway to increase the quality of CDI with soft and hard X-ray FELs.

1:27PM S58.00006: Ultrafast X-ray Absorption and Time-Resolved Resonant X-ray Scattering in a Mott Insulator*  BRIAN MORITZ (Presenter), SLAC National Accelerator Laboratory, YAO WANG, Harvard University, YUAN CHEN, Stanford University, CHUNJING JIA, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory — The time-evolution of collective excitations encodes information on photoinduced transient states in correlated systems. The frozen charge degrees of freedom in a Mott insulator can be activated by photodoping, which provides information about the interplay between various intertwined instabilities. Here, we simulate both ultrafast x-ray absorption and time-resolved resonant inelastic x-ray scattering (tr-RIXS) for a Hubbard model under the influence of a strong, transient drive. While absorption primarily provides information on transient photodoping, tr-RIXS allows us to study the evolution of bimagnon, Mott-gap, doublon, and single-particle in-gap excitations, as well as anti-Stokes relaxation following an ultrafast excitation of the system. This work provides a theoretical foundation for existing and future tr-RIXS experiments.

1:39PM S58.00007: Ultrafast Dynamics and Imaging at the Nanoscale using Tabletop Coherent X-ray Sources* [Invited] HENRY KAPTEYN (Presenter), MARGARET MARY MURNANE, JILA and Department of Physics, University of Colorado, Boulder — Laser-like beams at very short wavelengths (1-50nm) can be routinely generated using high harmonic up-conversion (HHG) of tabletop femtosecond lasers.[1,2] This new quantum light source is both advancing rapidly in fundamental capabilities, and is providing a powerful new tool to understand nanoscale material properties and function. This talk will discuss new capabilities for controlling the polarization, spin and orbital angular momentum of HHG beams by sculpting the driving laser beams, [3,4] and will discuss applications in nanoscale magnetic and thermal dynamics using the short wavelength and element specificity of the EUV light-matter interaction. Highlights include the discovery of a new regime of collective nanoscale heat transport,[5] and work highlighting our current incomplete understanding of dynamic mechanisms in magnetic materials.[6]

11:15AM S59.00001: Reorientation of antiferromagnetism in Co-doped FeSn and its implications for Dirac electron states*  WILLIAM MEIER (Presenter), JIAQIANG YAN, MICHAEL MCGUIRE, XIAOPING WANG, ANDREW D CHRISTIANSON, BRIAN SALES, Oak Ridge National Lab — FeSn is an itinerant antiferromagnet with an Fe Kagome-lattice that hosts electronic Dirac states[1-2]. I will present magnetization measurements of single crystals of (Fe$_{1-x}$Co$_x$)Sn revealing the evolution and suppression of this magnetic order with Co substitution. We interpret the dramatic changes of the magnetic anisotropy to indicate a reorientation of the magnetic moments from perpendicular to parallel to the hexagonal c-axis and confirm this with neutron diffraction. It has been proposed that the Dirac nodes observed in FeSn should become gapped if the moments rotate as our data suggests[1]. We identify Co-substituted compositions that adopts both antiferromagnetic configurations at different temperatures. This system provides a unique opportunity to study how the details of magnetic order impact Dirac electron states.

11:27AM S59.00002: Above-room-temperature ferromagnetic state in a proximitized topological Dirac semimetal  MASAKI UCHIDA (Presenter), Univ of Tokyo, TAKASHI KORETSUME, Tohoku University, SHIN SATO, Univ of Tokyo, MARKUS KRIENER, RIKEN CEMS, YUSUKE NAKAZAWA, SHINICHI NISHIYAMA, Univ of Tokyo, YASUHIRO TAGUCHI, RIKEN CEMS, RYOTARO ARITA, MASASHI KAWASAKI, Univ of Tokyo — We report an above-room-temperature ferromagnetic state realized in a proximitized Dirac semimetal, which is fabricated by growing typical Dirac semimetal Cd$_3$As$_2$ films on a ferromagnetic garnet with strong perpendicular magnetization. Observed anomalous Hall conductivity with substantially large Hall angles is found to be almost proportional to the separation of the Weyl nodes and opposite in sign to magnetization, in agreement with a minimal model behavior. Theoretical calculations based on first-principles electronic structure of Cd$_3$As$_2$ also demonstrate that the Fermi-level dependent anomalous Hall conductivity reflects the Berry curvature originating in the split Weyl nodes. The present high-mobility Dirac-semimetal/ferromagnetic-insulator heterostructure will provide a novel platform for exploring Weyl-node transport phenomena and spintronic functions lately proposed for topological semimetals.
11:39AM S59.00003: Interplay of magnetic frustration and topology in complex metals*

[Invited] JAMES ANALYTIS (Presenter), ELLA LACHMAN, University of California, Berkeley, ROSS MCDONALD, physics, los alamos national lab, ERAN MANIV, University of California, Berkeley — The interplay of topology and frustration can lead to exotic properties and physical phenomena. We study how signatures of topological transport properties can be affected by complex magnetic textures in Kagome and triangular lattice materials. As an example, we show in the case of Co3Sn2S2 that the presence of frustration leads to coexisting magnetic phases that drive an exchange biased anomalous Hall effect. We also study novel transport anisotropies and magnetoelectric coupling in microstuctured devices.

12:15PM S59.00004: Introducing ferromagnetism into Dirac semimetal Cd₃As₂ thin films*

RUN XIAO (Presenter), ARPITA MITRA, WILSON YANEZ, Pennsylvania State University, JACOB T HELD, MICHELLE TOMCZYK, University of Minnesota, FAN ZHANG, Pennsylvania State University, YAWEN FANG, Cornell university, K. ANDRE MKHOYAN, University of Minnesota, BRAD J RAMSHAW, Cornell university, NITIN SAMARTH, Pennsylvania State University — Breaking time-reversal symmetry in a Dirac semimetal (DSM) via magnetic doping is expected to create a Weyl semimetal. This motivates us to study the doping of the DSM Cd₃As₂ using transition metals. Here, we attempt to introduce Mn into Cd₃As₂ thin films grown by molecular beam epitaxy on GaAs (111)B substrates with a GaSb buffer layer. Atomic force microscopy and X-ray diffraction show that the films have good crystalline quality (root mean square surface roughness ~ 1.5 nm and full-width half maximum of rocking curves ~ 0.12°). However, cross-sectional scanning transmission electron microscopy indicates constraints on Mn incorporation and the formation of magnetically inhomogeneous films with a near-surface Mn-rich compound. SQUID magnetometry shows the presence of weak ferromagnetism. We use low-temperature transport measurements in patterned devices as a function of gate voltage, temperature, and magnetic field angle to understand Shubnikov-de Haas oscillations and quantum transport in this hybrid Dirac material.

12:27PM S59.00005: Tunable Berry Curvature Effects Through Volume-wise Magnetic Competition in a Topological Kagome Magnet Co$_3$Sn$_2$S$_2$  ZURAB GUGUCHIA (Presenter), JOEL VEREZHAK, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, Switzerland, DARIUSZ GAWRYLUK, Laboratory for Multiscale Materials Experiments, Paul Scherrer Institute, STEPLAN TSIRKIN, Department of Physics, University of Zurich, JIA XIN YIN, ILYA BELOPOLSKI, Laboratory for Topological Quantum Matter and Spectroscopy, Department of Physics, Princeton University, HUIBIN ZHOU, Peking University, International Center for Quantum Materials, GEDIMINAS SIMUTIS, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, Switzerland, SONGTIAN ZHANG, TYLER COCHRAN, GUOQING CHANG, Laboratory for Topological Quantum Matter and Spectroscopy, Department of Physics, Princeton University, EKATERINA POMJAKUSHINA, Laboratory for Multiscale Materials Experiments, Paul Scherrer Institute, LUKAS KELLER, Laboratory for Neutron Scattering, Paul Scherrer Institute, ZUZANNA SKRZECZKOWSKA, Faculty of Chemistry, Warsaw University of Technology, QI WANG, HECHANG LEI, Department of Physics and Beijing Key Laboratory of Opto-electronic Functional Materials and Micro-nano Devices, Renmin University of China, RUSTEM KHASANOV, ALEX AMATO, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, Switzerland, SHUANG JIA, Peking University, International Center for Quantum Materials, TITUS NEUPERT, Department of Physics, University of Zurich, HUBERTUS LUETKENS, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, Switzerland, ZAHID HASAN, Laboratory for Topological Quantum Matter and Spectroscopy, Department of Physics, Princeton University — Magnetic topological phases of quantum matter are an emerging frontier in physics and material science. Along these lines, several kagome magnets have appeared as the most promising platforms. Here, we explore magnetic correlations in the kagome magnet Co$_3$Sn$_2$S$_2$. Using muon spin-rotation, we present evidence for competing magnetic orders in the kagome lattice of this compound. Our results show that while the sample exhibits an out-of-plane ferromagnetic ground state, an in-plane antiferromagnetic state appears at temperatures above 90 K, eventually attaining a volume fraction of 80% around 170 K, before reaching a non-magnetic state [1]. Strikingly, the reduction of the anomalous Hall conductivity above 90 K linearly follows the disappearance of the volume fraction of the ferromagnetic state. We further show that the competition of these magnetic phases is tunable through applying either an external magnetic field or hydrostatic pressure. Our results taken together suggest the thermal and quantum tuning of Berry curvature field via external tuning of magnetic order. Our study shows that Co$_3$Sn$_2$S$_2$ is a rare example where the magnetic competition drives the thermodynamic evolution of the Berry curvature, thus tuning its topological state.

We report evidences and interpretations for a robust edge supercurrent in type II Weyl semimetal MoTe2 in the superconducting regime, where $T < T_c = 100$ mK at ambient pressure. We fabricated MoTe2 devices (60 – 120 nm thickness) with Au contacts through mechanical exfoliation and nanofabrication. Transport measurements of differential resistance $dV/dI$ versus applied bias and magnetic field $B$ shows a periodic oscillation of critical current $I_c$ with a scalloped profile. The oscillation mode remains coherent and the associated area to its frequency saturates to the physical area of sample with an increasing magnetic field. These observations demonstrate a superconducting edge mode with the width less than 10 nm. We describe the edge condensate with a Ginzburg Landau wave function that is independent from the bulk condensate. Fluxoid quantization causes the edge superfluid velocity to vary, resulting in the scalloped profile. Weak excitations trailing from the scalloped boundaries in $I_c$ vs. $B$ plots exhibit unusual asymmetries.

Magnetic Weyl Semimetals* [Invited] CLAUDIA FELSER (Presenter), YAN SUN, KAUSTUV MANNA, Solid State Chemistry, Max Planck Institute Chemical Physics of Solids — Topology a mathematical concept became recently a hot topic in condensed matter physics and materials science. One important criteria for the identification of the topological material is in the language of chemistry the inert pair effect of the s-electrons in heavy elements and the symmetry of the crystal structure [1]. Beside of Weyl and Dirac new fermions can be identified compounds via linear and quadratic 3-, 6- and 8-band crossings stabilized by space group symmetries [2]. In magnetic materials the Berry curvature and the classical AHE helps to identify interesting candidates. Magnetic Heusler compounds were already identified as Weyl semimetals such as Co$_2$YZ [3-6] (Y=Ti, Mn; Z=Ge, Sn, Ga, Al), in Mn$_3$Z [7-9] (Z=Ge, Sn). Co$_3$Sn$_2$S$_2$ is a 2D Weyl semimetal with edge states [11-12].

Electronic, magnetic and thermodynamic properties of the Kagome layer metal FeSn* BRIAN SALES (Presenter), JIAQIANG YAN, WILLIAM R MEIER, QIANG ZHENG, ANDREW D CHRISTIANSON, SATOSHI OKAMOTO, MICHAEL MCGUIRE, Oak Ridge National Lab — FeSn is an itinerant antiferromagnet composed of metallic Kagome layers. FeSn single crystals are investigated using x-ray and neutron scattering, magnetic susceptibility and magnetization, heat capacity, resistivity, Hall, Seebeck, thermal expansion, thermal conductivity measurements and density functional theory. In spite of the quasi 2D Kagome layers with Dirac nodal lines along the K-H directions in the magnetic Brillouin zone about 0.3 eV below the Fermi energy, the measured properties strongly suggest that the overall electronic structure is 3D. The magnetism, however, is predicted to be highly 2D with Jin-plane/Jout-of-plane $\approx 10$. The impact of Dirac nodes on the physics on this material will be discussed.

*Research supported by the DOE Office of Science, Basic Energy Sciences, Materials Science and Engineering Division.
1:39PM S59.00009: Low temperature investigation of candidate type-II Weyl semimetal LaAlGe  
MARK ZIC (Presenter), CHRIS ECKBERG, HALYNA HODOVANETS, SEOKJIN BAE, HYUNSOO KIM, TRISTIN METZ, SEAN WINTERS, DANIEL KRAFT, STEVEN ANLAGE, JOHNPIERRE PAGLIONE,  
University of Maryland, College Park — Weyl semimetals continue to be a flourishing topic of research because of their non-trivial surface states and topology [1] and their exciting experimental realizations in magnetotransport [2], thermopower [3], and optical spectroscopy [4]. These unique ground states motivate us to investigate the proposed Weyl semimetal LaAlGe [5], a compound previously only investigated theoretically and with X-ray diffraction. We use a molten flux growth technique to precipitate pristine LaAlGe single crystals that crystallize in the non-centrosymmetric crystal structure required for Weyl points to exist. We will discuss our electrical transport, magnetization, penetration depth, and heat capacity measurements of this topological compound, detailing both our experimental results and the future implications of this work.

1:51PM S59.00010: Magnetostructural instability in Weyl ferromagnet Mn$_3$ZnC*  
SAMUEL TEICHER (Presenter), Materials Research Laboratory and Materials Department, University of California, Santa Barbara, IDA K SVENNINGSSON, Department of Applied Physics, Chalmers Institute of Technology, LESLIE SCHOOP, Department of Chemistry, Princeton University, RAM SESHADRI, Materials Research Laboratory and Materials Department, University of California, Santa Barbara — We present first-principles calculations suggesting that the ferromagnetic phase of cubic antiperovskite Mn$_3$ZnC is a nodal line Weyl semimetal. Electronic structure features that are the hallmark of this nodal line state—a large density of linear band crossing near the Fermi level—can also be interpreted as signatures of structural and magnetic instability. In fact, it is known that Mn$_3$ZnC transitions upon cooling from a paramagnetic to a cubic ferromagnetic state under ambient conditions and then further into a non-collinear tetragonal phase at a temperature between 250 K and 200 K. The existence of Weyl nodes and their destruction via structural and antiferromagnetic ordering is likely relevant to a range of magnetostructurally coupled materials.

2:03PM S59.00011: Ultrasound Studies on the Chiral Antiferromagnet Mn$_3$Ge* FLORIAN THEUSS (Presenter), SAYAK GHOSH, Cornell University, TAISHI CHEN, SATORU NAKATSUJI, Institute for Solid State Physics, University of Tokyo, BRAD J RAMSHAW, Cornell University — The chiral antiferromagnet Mn$_3$Ge is a promising candidate for a magnetic Weyl semimetal, where Weyl nodes arise from broken time reversal symmetry rather than broken inversion symmetry. Recently, Mn$_3$Ge has been shown to exhibit a giant anomalous Hall effect at room temperature, which has been attributed to the presence of Weyl nodes. Given this highly anomalous room-temperature Hall effect, it is natural to ask whether other properties of the Weyl nodes, such as the chiral anomaly, are also present at room temperature. Strong magneto-elastic coupling, known to be present in Mn$_3$Ge, has motivated our investigation of the elastic moduli in this material. We report resonant ultrasound spectroscopy studies of the full elastic tensor of Mn$_3$Ge through the 380 K Néel transition temperature. We investigate how strains of different symmetry couple to the magnetic degrees of freedom on the Kagome lattice formed by manganese ions. We also investigate ultrasonic attenuation - which is predicted to be highly sensitive to chiral charge pumping between Weyl nodes in a magnetic field - both above and below the Néel transition.

Thursday, March 5, 2020 11:15 AM - 2:15 PM

Session S60 DMP: Topological Superconductivity Induced in Spin-Orbit-Coupled Materials Mile High Ballroom 4A - Jay Sau, University of Maryland, College Park - Tag(s): Focus

11:15AM S60.00001: Topological superconductivity in superconductor–semiconductor heterostructures [Invited] ROMAN LUTCHYN (Presenter), Microsoft Corp — Superconductor–semiconductor heterostructures represent a versatile platform for realizing Majorana zero-energy modes. In this talk, I will explain how to engineer topological superconductivity at the interface of a conventional (s-wave) superconductor and a semiconductor with spin-orbit interaction. I will discuss state-of-the-art numerical approaches for modeling realistic devices which take into account proximity-induced superconductivity, orbital and Zeeman effect of an applied magnetic field, spin-orbit coupling as well as the electrostatic environment on equal footing. Finally, I will review recent materials science progress in growing superconductor–semiconductor heterostructures and discuss promising new directions.
11:51AM S60.00002: Josephson controlled topological superconductivity* [Invited] ADY STERN (Presenter), Weizmann Institute of Science — In this talk I will describe how the Josephson effect may be employed to realize one dimensional topological superconductivity, with the Josephson phase difference being a "user-friendly" knob to drive the system to become topological. I will describe the basic idea, the experimental observations, the relation to topological superconductivity based on quantum wires, a surprising effect of disorder, and a scheme for braiding Majorana zero modes in Josephson junctions. I will also describe how this system manifests a first order phase transition into a topological phase.

*This research was supported by ERC projects MUNATOP and LEGOTOP, Microsoft Station Q, and the Israel Science Foundation.

12:27PM S60.00003: Nature of the insulating and superconducting states of monolayer WTe₂* [Invited] DAVID COBDEN (Presenter), University of Washington — Although in the bulk WTe₂ is a semimetal, exfoliated to a monolayer it becomes a topological insulator that undergoes a transition to a metallic state on electron doping of $5 \times 10^{12}$ cm$^{-2}$, and furthermore this metallic state becomes superconducting at temperatures below about 1 K. This proximity, in terms of doping, of a small-gap insulator to a superconductor is surprising, and the insulator exhibits a number of other unusual properties. We will summarize and compare these properties and assess the possibility that the insulating state has a many-body character akin to an excitonic insulator. In addition, we will present and evaluate evidence that the helical edge states remain throughout the insulator to superconductor transition.

*Supported by NSF MRSEC award 1719797 and DMR EAGER award 1936697.
ABHISHEK BANERJEE (Presenter), MD. AHNAF RAHMAN, ANTONIO FORNIERI, ALEXANDER WHITICAR, ASBJORN DRACHMANN, Center for Quantum Devices and Microsoft Quantum Lab Copenhagen, Niels Bohr Institute, University of Copenhagen, TYLER LINDEMAN, SERGEI GRONIN, CANDICE THOMAS, GEOFFREY C. GARDNER, Department of Physics and Astronomy and Station Q Purdue, Birck Nanotechnology Center, Purdue University, MICHAEL MANFRA, Department of Physics and Astronomy and Station Q Purdue, Birck Nanotechnology Center, School of Materials Engineering, School of Electrical and Computer Engineering, Purdue, CHARLES MARCUS, Center for Quantum Devices and Microsoft Quantum Lab Copenhagen, Niels Bohr Institute, University of Copenhagen — Recent works have realized Majorana zero modes in planar Josephson junctions consisting of a semiconductor with strong spin-orbit coupling proximitized by two superconducting leads. Such systems offer the tantalizing possibility of using the phase difference $\Phi$ across the two superconductors as a new experimental knob to tune into and out of the topological regime, possibly at ultra-fast timescales, apart from having advantages such as reduced sensitivity to chemical potential tuning and appearance of Majorana bound states at zero magnetic field. Here, we demonstrate strong phase control of Andreev bound states that emerge from the gap at $\Phi \sim 0$ and coalesce at zero energy at $\Phi \sim \pi$. The zero energy modes at $\Phi \sim \pi$ appear at in-plane magnetic fields as low as $\sim 220$ mT and persist robustly with variations of in-plane Zeeman field and gate voltages in a wide range. At larger in-plane magnetic fields, the zero energy modes become phase independent and stick for all values of $\Phi$. We also study the behavior of the zero energy states with respect to large out-of-plane magnetic fields that can tune the phase texture within the Josephson junction, and possibly result in motion of Majorana zero modes.

*This work was supported by the Danish National Research Foundation and Microsoft.
1:15PM S60.00005: Phase signature of topological transition in Josephson junctions*
MATTIEU DARTIAILH (Presenter), WILLIAM MAYER, JOSEPH YUAN, KAUSHINI S WICKRAMASINGHE, Physics, New York University, ALEX MATOS ABIAGUE, Physics and Astronomy, Wayne State University, IGOR ZUTIC, Physics, Buffalo State University of New York, JAVAD SHABANI, Physics, New York University — Topological transition transforms common superconductivity into an exotic phase of matter, which holds promise for fault-tolerant quantum computing. A hallmark of this transition is the emergence of Majorana states. While two-dimensional semiconductor/superconductor heterostructures are desirable platforms for topological superconductivity, direct phase-measurements as the fingerprint of the underlying topological transition have been missing. On gate tunable Josephson junctions made on epitaxial Al/InAs, we observe a closing and a reopening of the superconducting gap with increasing in-plane magnetic field. Since our junctions are embedded into a phase-sensitive SQUID, we are able to measure a π-jump in the superconducting phase across the junction coincident with the closing and reopening of the superconducting gap. Theoretical simulations confirm this transition is topological and compatible with the emergence of Majorana states while the magnetic field angle dependence of the transition further constrain this scenario. Remarkably, in each junction, this topological transition can be controlled by changing the gate voltage. These findings reveal versatile two-dimensional platforms for scalable topological quantum computing.

1:27PM S60.00006: Signatures of topological superconductivity in Josephson junctions*
ALEX MATOS ABIAGUE (Presenter), Wayne State University, MATTIEU DARTIAILH, WILLIAM MAYER, JOSEPH YUAN, KAUSHINI S WICKRAMASINGHE, New York University, IGOR ZUTIC, University at Buffalo, JAVAD SHABANI, New York University — Topological superconductivity is a phase of matter supporting Majorana bound states, quasiparticles that store information in a nonlocal manner and can be used as qubits that are robust against local perturbations. We theoretically investigate the emergence of topological superconductivity in Josephson junctions with tunable chemical potential and Rashba spin-orbit coupling, subjected to an in-plane magnetic field. As the magnetic field along the junction increases above some critical value the system experiences a transition from the trivial to the topological superconducting phase. Theoretical simulations show that such a transition is accompanied by a minimum in the critical current and a corresponding jump in the phase difference across the junction. The sensitivity of the topological transition to the in-plane magnetization direction provides an additional fingerprint for the emergence of topological superconductivity. The theoretical simulations are in good agreement with the recent experimental detection of topological phase transitions in gate-tunable JJs built on epitaxial Al/InAs [1].

*This work was supported by DARPA Topological Excitations in Electronics, Grant No. DP18AP90000.
1:39PM S60.00007: In-vacuo growth and fabrication of superconductor-semiconductor hybrid heterostructures for topological quantum computation* MIHIR PENDHARKAR (Presenter), Dept. of Electrical Engineering, Univ. of California, Santa Barbara, CA, USA, JOON SUE LEE, California Nano-Systems Institute, Univ. of California, Santa Barbara, CA, USA, ANTHONY P MCFADDEN, Dept. of Electrical Engineering, Univ. of California, Santa Barbara, CA, USA, SASA GAZIBEGOVIC, ROY OP HET VELD, Dept. of Physics, Technical University, Eindhoven, The Netherlands, CONNOR DEMPESEY, Dept. of Electrical Engineering, Univ. of California, Santa Barbara, CA, USA, SEAN HARRINGTON, Dept. of Materials Engineering, Univ. of California, Santa Barbara, CA, USA, ARANYA GOSWAMI, Dept. of Electrical Engineering, Univ. of California, Santa Barbara, CA, USA, MICHAEL A SEAS, Dept. of Materials Engineering, Univ. of California, Santa Barbara, CA, USA, SUKGEUN CHOI, Dept. of Electrical Engineering, Univ. of California, Santa Barbara, CA, USA, GHADA BADAWY, JASON JUNG, Dept. of Physics, Technical University, Eindhoven, The Netherlands, MOIRA HOCEVAR, Institute Neel, CNRS, Grenoble, France, LEO P KOUWENHOVEN, Dept. of Physics, Technical University, Delft, The Netherlands, ROMAN LUTCHYN, MICHAEL H FREEDMAN, Microsoft Quantum, Santa Barbara, CA, USA, SERGEY M FROLOV, Dept. of Physics, Univ. of Pittsburgh, Pittsburgh, PA, USA, ERIK BAKKERS, Dept. of Physics, Technical University, Eindhoven, The Netherlands, CHRIS J PALMSTROM, Dept. of Electrical Engineering, Univ. of California, Santa Barbara, CA, USA — Superconductor-semiconductor heterostructures are the backbone of Majorana Zero Mode (MZM) based topological quantum computing. Magneto-transport in nanowires of InSb with partial shells of aluminum has highlighted the significance of abrupt and epitaxial, in-vacuo growth of superconductors on semiconductors. Going forward, two key challenges need to be addressed. Firstly, the demonstration of in-vacuo, selective area growth of superconductors on wafer-scale semiconductors and, secondly, in-vacuo fabrication of proposed topological qubit devices. This work reports on the Molecular Beam Epitaxy (MBE) of selective area hybrid heterostructures using various approaches with the aim of creating a versatile platform for fabrication of topological qubits in vacuo.

*This work was in part funded by Microsoft Research Station Q at Santa Barbara and NSF-PIRE.

1:51PM S60.00008: Accessing different topological classes and types of Majorana edge states in 1D p-wave superconductors using perturbations* SAYONEE RAY (Presenter), Physics and Astronomy, University of New Mexico, US, SUBROTO MUKERJEE, Department of Physics, Indian Institute of Science, Bangalore, India, NAYANA SHAH, Department of Physics, Washington University, St. Louis, US — Classification and realization of various classes of topological superconductors with different types of Majorana bound states (MBS) is of ongoing interest. The standard platform of these studies have been the conventional 1D Kitaev wire and its realizations. Here, we present the edge states of different types of p-wave SC in 1D in the presence of an additional Zeeman field and s-wave SC component. Within the framework of the tenfold classification scheme, we study the transition between different topological classes caused by such perturbations and analyze the nature of the corresponding MBS. Further, we study the junctions between different classes of topological superconductors and explore transport properties to probe the mid-gap states.

*NSF FRHTP grant
During the main efforts to realize MBS have focused on 1D systems, the onset of topological superconductivity requires delicate parameter tuning and geometric constraints pose significant challenges for their control and demonstration of non-Abelian statistics. To overcome these challenges, building on recent experiments in planar Josephson junctions (JJs) [2-4], we propose a MBS platform of X-shaped JJs. This versatile implementation reveals how external flux control of the superconducting phase difference can generate and manipulate multiple MBS pairs to probe non-Abelian statistics. The underlying topological superconductivity exists over a large parameter space, consistent with materials used in our fabrication of such X junctions, as an important step towards topological quantum computing.

We used Raman light scattering to study the current-stabilized nonequilibrium semimetallic and metallic phases in Ca$_2$RuO$_4$. By determining the local temperature through careful analysis of the Stokes and anti-Stokes intensities, we find that Joule heating can be completely avoided by supplying sufficient cooling power in a helium-flow cryostat and that the current induces the semimetallic state without inducing any significant heating [1]. We further investigate the current-induced semimetallic state as a function of temperature and current. We confirm the absence of long-range antiferromagnetic order [2] and identify a substantial Fano broadening of several phonons, which suggests coupling to charge and orbital fluctuations. Our results demonstrate that the semimetallic state is a genuine effect of the applied electrical current and that the current-induced phases have characteristics distinct from the equilibrium ones.

Octahedral tilt driven Kondo lattice behavior with orbital-selective Mott transition of 4d Ca$_{2-x}$Sr$_x$RuO$_4$

MINSOO KIM (Presenter), JUNYOUNG KWON, DAUN CHUNG, YOUNSIK KIM, HANYOUNG YOO, JONGKEUN JUNG, BEOM SEO KIM, MI KYUNG KIM, Department of Physics and Astronomy, Seoul Natl Univ; JONATHAN DENLINGER, Advanced Light Source, Lawrence Berkeley National Laboratory; MOONSUP HAN, Department of Physics, University of Seoul; TAKASHI MIZOKAWA, Department of Applied Physics, Waseda University; YOSHIYUKI YOSHIDA, National Institute of Advanced Industrial Science and Technology (AIST); WONSHIK KYUNG, CHANGYOUNG KIM, Department of Physics and Astronomy, Seoul Natl Univ — The physics of heavy fermion (HF) state, which manifests in $f$-electron system [1], begins to germinate in $d$-orbital system, for example, in 3$d$ single-orbital van der Waals ferromagnet, transition metal oxide (TMO) LiV$_2$O$_4$ and multi-orbital Fe based family [2, 3, 4]. However, the existence of the HF state and its underlying mechanism remain to be questionable in 4$d$ multi orbital systems. Using angle-resolved photoemission spectroscopy (ARPES), we observe the HF state in orbital-selective Mott phase (OSMP) of 4$d$ TMO, Ca$_{2-x}$Sr$_x$RuO$_4$. Upon entering OSMP ($x<0.5$), we observe a massive spectral weight transfer, a 100meV-orbital selective gap for $d_{xy}$-originated $\gamma$ and corresponding change in $d_{xz/yz}$-originated $\beta$ band while $d_{xz/yz}$-originated $\alpha$ band remains hardly changed. With the temperature drop across a characteristic temperature $T^*$, spectral weight transfer gradually occurs from lower to higher binding energy in $\beta$ and $\gamma$ bands. This possible Kondo lattice behavior can be well explained by the key role of the octahedral tilt driven $d$-band hybridization. Our work firstly, demonstrates the possible origin of the formation of the HF state from 4$d$ TMOs with structural distortions, which expands the boundary of the HF-candidates to the 4$d$ multi orbital systems.

Electric control of the structural properties of spin-orbit coupled 4$d$ ruthenate Ca$_{2}$Ru$_{0.97}$Mn$_{0.03}$O$_4$

FENG YE (Presenter), CHRISTINA HOFFMANN, Oak Ridge National Lab, HENGDI ZHAO, GANG CAO, Physics Department, University of Colorado Boulder — The unique competition between spin-orbit interaction (SOI) and Coulomb correlation ($U$) in 4$d$/5$d$ oxides drives unusual physical behavior. Novel nonequilibrium phenomena can be further induced by external stimuli including intense synchrotron x-ray or electric current. In this talk, we report neutron diffraction study of the quasi-two-dimensional Mott Ca$_{2}$Ru$_{0.97}$Mn$_{0.03}$O$_4$, which shows dramatic reduction of the electric resistivity, suppression of the antiferromagnetic transition, and induction of new orbital order with critical current density of 0.15 A/cm$^2$. Our in-situ structural characterization implies that the in-plane orthorhombicity diminishes with increasing current density, accompanied by the straightened of the Ru-O-Ru bonding angles. The temperature-current phase diagram establishes an intimate correlation between the lattice and electronic structure in this nonequilibrium, steady state driven by current. Our results shed light to the nature of the Mott-Insulator transition and provide key information for the emerging phenomena near the transition.
11:51AM S61.00004: Metallic and non-metallic duality in the 4d pyrochlore Lu$_2$Rh$_2$O$_7$*

[Invited] ALANNAH HALLAS (Presenter), University of British Columbia — The 4d transition metal oxides exist in an intriguing regime where on-site Coulomb repulsion, the band width, and spin-orbit coupling can all have comparable magnitudes. While spin-orbit coupling for these 4d systems is reduced as compared to their 5d counterparts, it is still strong enough to generate exotic magnetic and electronic states. In this talk, we introduce Lu$_2$Rh$_2$O$_7$, a new cubic pyrochlore oxide based on 4d$^5$ Rh$^{4+}$ with properties that defy simple categorization. Both magnetic susceptibility ($\chi_P = 7.6 \times 10^{-4}$ emu/mol$_{Rh}$) and heat capacity measurements ($\gamma = 21.8(1)$ mJ/mol$_{Rh}$ K$^2$) indicate that this material is a strongly correlated metal and yet electrical resistivity measurements show decidedly non-metallic behavior. Furthermore, although the magnitude of the resistivity is that of a semiconductor (1 $\Omega$-cm), the temperature dependence does not obey any conventional form. The magnetic properties of this material are also enigmatic; if this material is non-metallic, then one would expect 4d$^5$ Rh to carry an $S = \frac{1}{2}$ magnetic moment and yet magnetic susceptibility and muon spin relaxation measurements show no evidence for local moments down to 2 K. We therefore propose that Lu$_2$Rh$_2$O$_7$ may be the prototype for an entirely new class of non-Fermi liquids.

12:27PM S61.00005: Anomalous Hall effect from strained-induced magnetic multipoles in antiferromagnetic material

JEONGKEUN SONG (Presenter), TAEKOO OH, Seoul. Nat. Univ, WOOJIN KIM, Stanford Univ — The origin of anomalous Hall effect (AHE) in magnetic materials has been a central theme of condensed matter physics for a century. In ferromagnetic materials, the origin of AHE is from the magnetization. [1] On the other hand, the large AHE in antiferromagnetic Mn$_3$Sn without large magnetization was observed and its origin remains elusive.[2] Recent theoretical study suggested that the hidden magnetic multipoles formed by the spin clusters can induce the large AHE in antiferromagnet. [3] Here, we establish the comprehensive connection between the large AHE in antiferromagnetic in-situ pyrochlore iridate Nd$_2$Ir$_2$O$_7$ thin film and strain-induced magnetic multipoles, T$_1$-octupole.

Approaching the quantum critical point in a highly-correlated all-in-all-out antiferromagnet  
Yejun Feng (Presenter), Okinawa Inst of Sci & Tech, Yishu Wang, Johns Hopkins University, Dharmalingam Prabhakaran, Andrew T Boothroyd, University of Oxford, Thomas F Rosenbaum, California Institute of Technology — All-in-all-out (AIAO) antiferromagnetic order in strongly spin-orbit-coupled 5d compounds can demonstrate exotic electronic phases and strongly-coupled quantum critical phenomena. Here we experimentally explore this scenario by directly tracing the AIAO spin order in Sm$_2$Ir$_2$O$_7$ using resonant x-ray magnetic diffraction techniques under high pressure. We find that the magnetic order is suppressed at a critical pressure $P_c$=6.30 GPa, while the lattice symmetry remains in the cubic $Fd-3m$ space group across the quantum critical point. Comparing pressure tuning and the chemical series $R_2$Ir$_2$O$_7$ reveals that the suppression of the AIAO order and the approach to the spin-disordered state is characterized by contrasting evolutions of both the pyrochlore lattice parameter $a$ and the trigonal distortion $x$. The former affects the 5d bandwidth, the latter the Ising anisotropy, and so such we posit that the opposite effects of pressure and chemical tuning lead to spin fluctuations with different Ising and Heisenberg character in the quantum critical region. Finally, we compare the iridates to AIAO spin order in osmate analogues, where spin fluctuations, lattice breathing modes, and quasiparticle excitations all interact in the quantum critical region.

Geometric Magnetic Frustration in Y$_{2-x}$Bi$_x$Ru$_2$O$_7$ Pyrochlores across the Metal-Insulator transition  
Sarah Duniger (Presenter), TRIUMF, Sang-Wook Cheong, Physics and Astronomy, Rutgers University, Kim Hooch Chow, Physics, University of Alberta, Martin H Dehn, Physics and Astronomy, University of British Columbia, Shayan Gheidi, Physics, Simon Fraser University, Namjung Hur, Physics, Inha University, Kee Hoon Kim, Physics and Astronomy, Seoul National University, Graeme Luke, Physics and Astronomy, McMaster University, Gerald Morris, TRIUMF, Timothy Munsie, Physics and Astronomy, McMaster University, Jeff Sonier, Shyam Sundar, Physics, Simon Fraser University — Systems based on a triangular or pyrochlore lattice of corner sharing tetrahedra with nearest neighbor antiferromagnetic exchange interactions are the archetypical examples of geometric magnetic frustration, offering a means of accessing novel ground states. Magnetic systems based on 4d and 5d transition metal ions on the pyrochlore lattice offer a unique opportunity to explore the exotic ground states which potentially arise when the electron-electron Coulomb interaction, electronic bandwidth and spin orbit coupling are all of comparable magnitude. I will describe magnetization and muon spin relaxation investigations of a series of 4d Ru4+ based pyrochlores, which may be controllably tuned through a metal insulator transition, providing insight into the magnetic correlations as these finely balanced systems evolve from a localized to itinerant spin character.
Electrically driven inhomogeneous phase transition in $\text{CuIr}_2\text{S}_4$  

AHMED ALI (Presenter), DASHARATH ADHIKARI, ALI M ALSAQQA, COLIN P KILCOYNE, State Univ of NY - Buffalo, NOBUHIRO MATSUMOTO, National Metrology Institute and Chemical Measurement Laboratory, SAMBANDAMURTHY GANAPATHY, State Univ of NY - Buffalo — Comparable energy scales of dominant interactions determining electronic phases and relatively smaller energy barrier separating different phases makes 5d electronic systems sensitive to an external perturbation (e.g. temperature, electric field, strain). $\text{CuIr}_2\text{S}_4$, a 5d transition metal compound with spinel structure, shows a hysteretic metal-insulator transition at $T_c \sim 231$ K (on cooling) accompanied with crystal symmetry lowering from high-temperature cubic (metallic) to low-temperature tetragonal (insulating) phase. The system also exhibits electric field-driven hysteretic switching from insulating to metallic phase below $T_c$. Transport and resistance noise spectroscopy were carried out: at temperatures well below $T_c$, the transition is characterized by a single abrupt switching and the power spectral density (PSD) of the noise varies smoothly across the transition. Approaching $T_c$, on the other hand, switching happens with multiple, step-like jumps and the PSD is found to increase significantly. The melting of long-range charge ordering near $T_c$ likely increases the local inhomogeneity thereby resulting in increased PSD. Results will be discussed in the context of microscopic conduction mechanisms across thermal and electrical driven transitions in strongly correlated systems.

Local orbital degeneracy lifting as a precursor to an orbitalselective Peierls transition* 

EMIL BOZIN (Presenter), WEIGUO YIN, ROBERT KOCH, MILINDA ABEEKOON, Brookhaven National Laboratory, YEW SAN HOR, HONG ZHENG, Argonne National Laboratory, HECHANG LEI, CEDOMIR PETROVIC, Brookhaven National Laboratory, JOHN MITCHELL, Argonne National Laboratory, SIMON J L BILLINGE, Brookhaven National Laboratory — Fundamental electronic principles underlying all transition metal compounds are the symmetry and filling of the $d$-electron orbitals and the influence of this filling on structural configurations and responses. Here we use a sensitive local structural technique, x-ray atomic pair distribution function analysis, to reveal the presence of fluctuating local-structural distortions at high temperature in one such compound, $\text{CuIr}_2\text{S}_4$. We show that this hitherto overlooked fluctuating symmetry-lowering is electronic in origin and will modify the energy-level spectrum and electronic and magnetic properties. The explanation is a local, fluctuating, orbital-degeneracy-lifted state. The natural extension of our result would be that this phenomenon is likely to be widespread amongst diverse classes of partially filled nominally degenerate $d$-electron systems, with potentially broad implications for our understanding of their properties.

*Work at Brookhaven National Laboratory was supported by US DOE, Office of Science, Office of Basic Energy Sciences under contract DE-SC0012704. Work in the Materials Science Division of Argonne National Laboratory, was sponsored by the U.S. Department of Energy Office of Science, Basic Energy Sciences, Materials Science and Engineering Division.
SEVERINO ADLER (Presenter), Institut für Theoretische Physik und Astrophysik, Universität Würzburg, DANIEL SPRINGER, Institute of Solid State Physics, TU Wien, BONGJAE KIM, Department of Physics, Kunsan National University, PEITAO LIU, Faculty of Physics and Center for Computational Materials Science, University of Vienna, ANDREAS HAUSOEL, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, CESARE FRANCHINI, Faculty of Physics and Center for Computational Materials Science, University of Vienna, GIORGIO SANGIOVANNI, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, ALESSANDRO TOSCHI, Institute of Solid State Physics, TU Wien — Experiments on the 5d-Osmium oxide perovskite LiOsO$_3$ have revealed surprising physical properties. In contrast to expectations and to the chemically similar material NaOsO$_3$, LiOsO$_3$ is never magnetic. Further, its optical properties show a bad metallic behaviour, with a quickly decreasing Drude peak as a function of T [1], as in the 3d-oxide V$_2$O$_3$ [2]. A possible origin of this unexpected physics might be the interplay between electronic correlations and spin-orbit coupling (SOC) in this 5d compound. Therefore, we performed a paramagnetic, non SOC dependent DFT and a magnetic DMFT calculation, where we tuned the atomic SOC in the Os t$_{2g}$ manifold. Without atomic SOC, we find a strong long-range G-type antiferromagnetic order. Turning on atomic SOC antiferromagnetism is gradually suppressed, vanishing at a SOC strength of about 600 meV. This strongly suggests that atomic SOC plays a pivotal role in determining the magnetic properties of osmates.

MIN YONG JEONG (Presenter), JAE-HOON SIM, Department of Physics, KAIST, HYEONG JUN LEE, ARA GO, Center for Theoretical Physics of Complex Systems, Institute for Basic Science, MYUNG JOON HAN, Department of Physics, KAIST — The lacunar spinel GaTa$_4$Se$_8$ is the first established example of $J_{\text{eff}} = 3/2$ Mott insulator. By applying pressure, it undergoes insulator-to-metal and superconducting transition. In order to understand the nature of this intriguing metallic phase and its possible relation to superconductivity, we performed the LDA+DMFT (local density approximation + dynamical mean-field theory) calculations as a function of pressure and with spin-orbit coupling taken into account. It is found that, even at high pressure corresponding to the metallic and superconducting phase, $J_{\text{eff}} = 3/2$ is well identified, indicating the novel nature of the superconductivity observed in this material. Possibilities of topological superconductivity and the spin-freezing superconductivity will be discussed.

1:51PM S61.00012: Magnetic impurity behavior in a gapless quantum spin liquid: single-layer 1T-TaSe$_2$  YI CHEN (Presenter), WEI RUAN, University of California, Berkeley, JINWOONG HWANG, Lawrence Berkeley National Lab, MENG WU, University of California, Berkeley, SHUJIE TANG, Stanford University, HYEJIN RYU, Lawrence Berkeley National Lab, STEVEN LOUIE, University of California, Berkeley, PATRICK A LEE, MIT, ZHIXUN SHEN, Stanford University, SUNG-KWAN MO, Lawrence Berkeley National Lab, MICHAEL F CROMMIE, University of California, Berkeley — Quantum spin liquids are a novel state of matter predicted to arise in quantum antiferromagnets where geometric frustration and quantum fluctuations are strong enough to prevent a magnetically ordered ground state. At half filling, fractional spin-carrying excitations termed spinons dominate the low-energy physics. Here we present scanning tunneling microscopy studies of the behavior of magnetic adatoms deposited onto the quantum spin liquid candidate single-layer 1T-TaSe$_2$. Spectroscopic imaging of pristine single-layer 1T-TaSe$_2$ reveals long-wavelength density modulations at the Hubbard band energies consistent with a spinon Fermi surface instability as predicted by theory. Magnetic atoms deposited onto the 1T-TaSe$_2$ surface bind at different sites in the star-of-David unit cell and exhibit distinct spectroscopic features near the Hubbard band edges. One possible explanation for the observed behavior is exchange coupling between magnetic adatoms and itinerant spinons.

2:03PM S61.00013: Spectroscopic signatures of Quasi One-Dimensional Crystallization at Domain Walls in the Mott Insulator TaS$_2$  ANUVA AISHWARYA (Presenter), SEAN HOWARD, BIKASH PADHI, University of Illinois at Urbana-Champaign, LIHAI WANG, Pohang University of Science and Technology, SANG-WOOK CHEONG, Rutgers University, PHILIP PHILLIPS, VIDYA MADHAVAN, University of Illinois at Urbana-Champaign — A tunable Mott state is fortuitous as it is a model system to study emergent phenomena due to broken symmetries like superconductivity, novel magnetic order and charge order, as a Mott band is tuned across Fermi energy ($E_F$). In this work, we use scanning tunneling microscopy at 4K to study the Mott insulator, TaS$_2$. Charge density wave domain walls in TaS$_2$ create band tuning such that part of the lower Hubbard band crosses the $E_F$, creating a mobile pool of charge near the domain walls. STM spectroscopic maps show that these charges crystallize into unexpected 1D patterns. To distinguish the charge patterns from ordinary bound states, we carry out noise spectroscopy measurements and find that the 1D patterns show distinct telegraphic noise signatures indicative of a fragile condensed state. Combined with the large ratio of Coulomb to kinetic energies in this system, our data and calculations are consistent with the formation of a short-range, fragile charge order like an incipient Wigner crystal. The observation of crystallization in a strongly correlated regime makes TaS$_2$ a promising system for exploiting the charge and spin order in quasi 1D systems.

11:15AM S62.00001: Thermoelectric Transport in Topological Crystalline Insulator and Topological Semimetal Nanowires* [Invited] SHIXIONG ZHANG (Presenter), Indiana Univ - Bloomington — Many of the topological materials (e.g. Bi$_2$Te$_3$ and Sb$_2$Te$_3$) are also well-known thermoelectric materials with high figures of merit ZTs. This ‘coincidence’ is not accidental but is because the two groups of materials share some similar properties, i.e. they are composed of heavy elements and have small bulk band gaps. Theoretical calculations have suggested the possibility of enhancing thermoelectric properties by utilizing topological non-trivial states. In this talk, I will present our recent experimental studies of thermoelectric transport in some representative topological materials, including SnTe-based topological crystalline insulators (TCIs) and iridium oxide-based topological semimetals (TSMs). Grown by chemical vapor deposition, the TCIs and TSMs are (quasi-)one-dimensional nanowires with large surface-area-to-volume ratios and well-defined facets. Measurements of the Seebeck coefficient, and electrical and thermal conductivities were performed on the same individual nanowires as a function of temperature, allowing for accurate determination of their ZTs. I will discuss the enhancement of Seebeck coefficient and suppression of thermal conductivity in connection with the topological states, doping, alloying, and nanostructuring.

11:51AM S62.00002: Tunable Dimensionality Effects on the Thermoelectric Performance of Solution-Processable Hybrid Tellurium Nanowire Composites* MADELEINE GORDON (Presenter), KYLE HAAS, University of California, Berkeley, EDMOND ZAIA, LIN YANG, CHIH-HAO HSU, BORIS RUSS, AYASKANTA SAHU, JEFFREY URBAN, Lawrence Berkeley National Laboratory — Hybrid composite materials have demonstrated a high degree of thermoelectric (TE) performance and manage to leverage positive aspects of both their organic and inorganic counter parts such as ease of solution processability, cost effectiveness, conformal geometries and device printability. To date, there is limited understanding of the physical factors underlying high performance in this class of materials. Here, we investigate the impact of ligand chain length on the physical and TE properties of tellurium nanowires (TeNWs) grown in a simple one-pot synthesis. This work reveals the importance of TeNW dimensionality and polydispersity on TE transport in TeNW systems. Using an aqueous chemical modification technique, conductive polymer ligands are affixed to the surface of the top performing TeNWs, resulting in a p-type hybrid composite TE ink system with an optimized power factor of 130 uW/mK$^2$. This study provides insight into how synthetic chemistry can provide previously unused tools for optimizing performance and understanding transport in such complex hybrid systems.

12:03PM S62.00003: Thermal transport in spin ladder compound Sr$_{14}$Cu$_{24}$O$_{41}$

XI CHEN (Presenter), Department of Electrical and Computer Engineering, University of California, Riverside, JAEHYUN KIM, Department of Mechanical Engineering, The University of Texas at Austin, SEAN E SULLIVAN, KARALEE JARVIS, Materials Science and Engineering Program, Texas Materials Institute, The University of Texas at Austin, JIANSHI ZHOU, LI SHI, Department of Mechanical Engineering, The University of Texas at Austin — Recently, large magnetic contribution to thermal conductivity has been observed in some cuprates with strong antiferromagnetic coupling. One prominent example is the spin ladder compound Sr$_{14}$Cu$_{24}$O$_{41}$ with an incommensurate layered structure. Steady-state thermal transport measurements of single crystals revealed a large anisotropic ratio of thermal conductivity due to the magnons propagating along spin ladders. Previous studies have been devoted to understand the coupling of magnons with phonons and electrons in Sr$_{14}$Cu$_{24}$O$_{41}$ single crystals; however, the effects of boundaries and defects on anisotropic magnon transport have been under-examined. Here, we investigate the thermal transport in Sr$_{14}$Cu$_{24}$O$_{41}$ microrods, which are prepared by co-precipitation synthesis. TEM studies indicate that these microrods are single crystals grown preferentially along the spin ladder axis. The thermal conductivity of Sr$_{14}$Cu$_{24}$O$_{41}$ microrods prepared at different temperatures is measured using a four-probe thermal transport measurement method. The thermal conductivity contribution and mean free paths of magnons are evaluated using a kinetic model of 1D magnon transport. Our results show pronounced effects of defects and boundaries on anisotropic magnon thermal transport in the magnetic microstructures.

12:15PM S62.00004: Probing thermal transport in single-molecule junctions

LONGJI CUI (Presenter), University of Colorado, Boulder — Charge and energy transport in single-molecule junctions is of great interest to reveal exotic quantum transport phenomena at the fundamental size limit, and with potential applications in nanoelectronics and nanophotonics. A key quantity—the thermal conductance of single-molecule junctions—has eluded experimental determination due to challenges in detecting extremely small picowatt-level heat currents that occur in such systems. Here, by employing custom-developed scanning thermal microscopy (SThM) probes that enable picowatt-resolution, we report the quantitative measurement of the thermal conductance of single-molecule junctions and investigate the dependence of thermal transport on molecular length. Our experiments were performed on prototypical Alkanedithiol molecules, revealing that the thermal conductance is approximately independent of the molecular length and is consistent with ab initio simulations. The techniques presented here represent a breakthrough that will enable further studies of thermal transport in many other 1D organic systems, short molecules and polymers, for which interesting thermal transport properties have been theoretically predicted but remain experimentally inaccessible.

12:27PM S62.00005: Photothermoelectric detection of strain variation in gold nanostructure
XIFAN WANG (Presenter), YUNXUAN ZHU, CHARLOTTE EVANS, DOUGLAS NATELSON, Rice Univ — Controlling morphology and composition via nanoscale structuring gives opportunities to improve the thermoelectric properties of materials for energy conversion and photodetection. In this study, we report the detection of the strain variation via open circuit photothermoelectric voltage detection on thin-film Au nanowire devices as a function of the position of an optical heat source. A focused laser beam is used to locally heat the metal nanostructure. The first mapping scan of the photothermoelectric voltage shows a relative high value compare with the second scan on the same device after 12 hours annealing. We also conduct a control experiment to shift the work function of the gold nanowire via self-assembled monolayer. Combining the kelvin probe measurement with the photothermoelectric voltage shows the work function variation of the nanowire doesn't play a key role on the photothermoelectric voltage response. These experiments argue that the strain distribution within the gold nanowire is likely the dominant effect causing the variation of the photothermoelectric voltage. Photothermoelectric voltage measurement provides a sensitive new method to strain distributions within a nanostructured metal.

12:39PM S62.00006: Energy Transport in Extreme Thermal Materials [Invited] YONGJIE HU (Presenter), JOONSANG KANG, MAN LI, HUAN WU, HUU DUY NGUYEN, University of California, Los Angeles — Controlling thermal transport is critical for many applications including electronics and energy technologies. Discovering new materials and nanostructures with extreme conductivity that can efficiently insulate or dissipate heat are in urgent need. In this talk, I will first describe our recent effort in developing emerging high thermal conductivity semiconductors, including boron arsenide (BAs) and boron phosphide (BP) with a room temperature thermal conductivity of 1300 W/mK (Science 361, 575, 2018) and 500 W/mK (Nano Letters 17, 7507, 2017) respectively, beyond most common semiconductors and metals. Ultrafast spectroscopy study in conjunction with atomistic theory reveals that the unique band structure of BAs allows for very long phonon mean free paths and strong high-order anharmonicity through the four-phonon process. Our study establishes BAs and BP as benchmark materials for thermal management, and exemplifies the power of combining experiments and \textit{ab initio} theory in new materials discovery. On the other hand, we investigated ultralow thermal conductivity materials with record-high thermoelectric performance. Examining the intrinsic crystals of tin selenide (Nano Letters 19, 4941, 2019), we observed abnormally strong phonon renormalization at room temperature due to high-order anharmonicity, as well as the failure of widely used quasi-harmonic model in predicting thermophysical properties. In addition, I will briefly describe our effort in developing in-situ techniques to characterize electrochemical materials (Nano Letters 17, 1431, 2017) and quantifying interface energy transport (Advanced Materials 31, 1901021, 2019) that enable better fundamental understanding of phonon spectra and defect scattering for electronics, sensors, batteries, and quantum information.
1:15PM S62.00007: Super Compliant and Soft \((\text{CH}_3\text{NH}_3)_3\text{Bi}_2\text{I}_9\) Crystals with Ultralow Thermal Conductivity*  
HAO MA, CHEN LI, Cornell University, YUNWEI MA, Virginia Tech, HENG WANG, Illinois Institute of Technology, ZACHARY ROUSE, Cornell University, ZHUOLEI ZHANG, Lawrence Berkeley National Laboratory, CARLA SLEBODNICK, Virginia Tech, AHMET ALATAS, Argonne National Laboratory, SHEFFORD BAKER, Cornell University, JEFFREY URBAN, Lawrence Berkeley National Laboratory, ZHITING TIAN (Presenter), Cornell University — In this work, we show the phonon dispersion of \((\text{CH}_3\text{NH}_3)_3\text{Bi}_2\text{I}_9\) single crystals at 300 K measured by inelastic x-ray scattering. The frequencies of acoustic phonons are among the lowest of crystals. Nanoindentation measurements verified that these crystals are very compliant and considerably soft. The frequency overlap between acoustic and optical phonons results in strong acoustic-optical scattering. All these features lead to an ultralow thermal conductivity, as validated by the laser flash method. The fundamental knowledge obtained from this study will accelerate the design of novel hybrid materials for energy applications. This work has been published in Phys. Rev. Lett. 123, 155901 (2019).

1:27PM S62.00008: Photothermoelectric detection of local strain variations in gold single-crystal and bicrystal stripes*  
CHARLOTTE EVANS (Presenter), Physics and Astronomy, Rice University, RUI YANG, Electrical Engineering, UM-SJTU Joint Institute, Shanghai Jiao Tong University, LUCIA GAN, Electrical Engineering, Stanford University, MAHDIYEH ABBASI, Electrical and Computer Engineering, Rice University, XIFAN WANG, Materials Science and NanoEngineering, Rice University, JONATHAN FAN, Electrical Engineering, Stanford University, DOUGLAS NATELSON, Physics and Astronomy, Rice University — Nanoscale manipulation of the thermoelectric effect has recently been used in photodetection and energy conversion applications. In metals, the electronic Seebeck coefficient depends on the energy-dependent electrical conductivity. At the nanoscale, single metal thermocouples are created by modifying the conductivity via nanostructuring, changing the energy-dependent mean free path of the charge carriers. Here, we present scanning photothermoelectric measurements of gold single crystal devices and compare the photovoltages with electron back-scatter diffraction measurements, which provide insight on the local strain variation in the device. The good correlation between these measurements show that photovoltage measurements are sensitive to local variation in strain. Finite-element modeling suggests that these results are consistent with long-scale gradients in the Seebeck coefficient, which yield reasonable estimates of local strain. Extending these measurements to devices with individual grain boundaries demonstrate that local strain has a larger effect than simple changes in crystallographic orientation. These measurements show that residual strain gradients in nanostructures can dominate thermoelectric response.

*Robert A. Welch Foundation grant C-1636 and NSF No. ECCS-1704625.
1:39PM S62.00009: Modeling quasiballistic phonon transport from a cylindrical electron beam heat source* GEOFF WEHMEYER (Presenter), Mechanical Engineering, Rice University — Electron microscopy experiments use focused electron beams as nanoscale heat sources or thermometers. However, when the electron beam radius is smaller than the heat carrier mean free path, Fourier's law will underpredict the electron-beam induced heating. Here, beam heating in nonmetallic samples is modeled by applying a general solution of the Boltzmann Transport Equation (BTE) under the relaxation time approximation [Hua and Minnich, PRB 90.21 (2014): 214306]. BTE results show that ballistic phonon effects in this radial heat spreading scenario are conveniently represented using a ballistic thermal resistance. Calculations of this ballistic resistance for Si, GaAs, and 3C-SiC show that ballistic effects dominate the total thermal resistance for typical beam radii (<10 nm), indicating that the ballistic resistance could be measured using electron beam heating experiments. However, the magnitude of the temperature rise remains small (<1 K), even when considering these ballistic effects. These BTE modeling results can be used to quantify electron-beam induced heating or to design experiments probing ballistic phonon transport using electron beam heat sources.

1:51PM S62.00010: Nondestructive probing of the transport and elastic properties of nanostructured metalattices using coherent EUV beams JOSHUA KNOBLOCH (Presenter), BEGOÑA ABAD, TRAVIS D FRAZER, BRENDAN MCBENNETT, STROBE and JILA, University of Colorado, Boulder, WEINAN CHEN, HIU CHENG, ALEX GREDE, NABILA NOVA, Pennsylvania State University, JORGE HERNÁNDEZ-CHARPAK, STROBE and JILA, University of Colorado, Boulder, PRATIBHA MAHALE, DISHA TALREJA, YIHUANG XIONG, TOM MALLOUK, NOEL C GIEBINK, VENKATRAMAN GOPALAN, ISMAILA DABO, VINCENT CRESPI, JOHN BADDING, Pennsylvania State University, HENRY KAPTEYN, MARGARET MURNANE, STROBE and JILA, University of Colorado, Boulder — Nanoscale metamaterials exhibit engineered thermal, magnetic, and electronic properties, which are essential for nanoelectronics, thermoelectrics, and ultralight media. Nanostructured metalattices are artificial 3D solids, periodic on length scales 1-100nm, that enable the functional properties of materials to be tuned. However, characterizing such materials is extremely challenging. Here we overcome this challenge by using tabletop high harmonic extreme ultraviolet (EUV) beams, with wavelengths (∼30nm) and pulse durations (∼10fs) that are well-matched for probing nanoscale structure and function. We demonstrate nondestructive measurements of the mechanical, structural, and transport properties of complex 3D nanostructured media—specifically in metalattices made from 14-30nm silica nanosphere templates infiltrated with silicon. We extract the mechanical and structural properties from the measured acoustic dispersion, which agrees with continuum models. In contrast, the heat flow through the metalattices deviates from macroscopic models due to the nanoscale structure. These samples have not only a lower thermal conductivity than expected, but also exhibit transport properties that depend on the heat source geometry. We support these findings with advanced atomistic models.
The composite material: a gold nanoparticle array embedded in a hydrogel polymer with a fluorinated surface layer; combines length scales from atomistic to microscale. When a laser excites the array local heating occurs, causing the polymer to shrink and the surface to wrinkle. The wrinkles deflect lasing and allow the system to relax. Using FTDT, the array geometry has been designed to maximize temperate change. The alteration of the mechanical properties of the hydrogel polymer due to the temperature change is essential to reproduce the wrinkling. When heated, the concentration of water in the polymer layer changes, altering the thermal and mechanical properties explored via molecular dynamics. Thermal transport is modeled using Reverse Non-Equilibrium Molecular Dynamics. A pure water/polymer system is compared to a system with different salts. This atomistic information feeds into finite element mechanics calculations, where previous studies have displayed wrinkling in similar systems. All these pieces help to create an autoregulatory humidity sensor.

11:15AM S63.00001: Exploring van der Waals Heterostructures behavior: Stability vs.
Twisting  ANDREA SILVA (Presenter), Univ of Southampton, VICTOR P. E. CLAERBOUT, TOMAS
POLCAR, Advanced Materials Group, CVUT, DENIS KRAMER, Univ of Southampton, PAOLO NICOLINI,
Advanced Materials Group, CVUT — While the outstanding properties of van der Waals 2D materials
are widely known, recent efforts have been focusing on the physics emerging from the stacking
and rotational degrees of freedom of these lamellar compounds. Notable examples are
unconventional superconductivity in twisted bilayer graphene\(^1\) and frictionless dynamics
obtained by switching from commensurate to incommensurate orientation in graphitic systems\(^2\).

In this study we focus on an often overlooked question: are twisted geometries
thermodynamically stable and what defines the energy landscape induced by the rotation? We
answer this question in the MoS\(_2\)/Graphene system, as the pristine components are widely
known and experimental data on this heterostructure is contradictory.

We use a refined classical potential to simulate edge-free rotated heterostructure and obtain the
energy behavior as a function of the imposed angle in the thermodynamic limit. Our work shows
the breakdown of a known theory of 2D incommensurate interfaces\(^3\) and offers new insights
about the microscopic mechanism governing the stability of this class of materials.

11:27AM S63.00002: Structural and electronic properties of twisted bilayer transition metal
dichalcogenides from linear-scaling DFT\(^*\)  VALERIO VITALE (Presenter), JOHANNES LISCHNER,
ARASH A MOSTOFI, Imperial College London — Recently, it has been proposed that Moiré
superlattices of twisted homobilayer transition metal dichalcogenides (TMDs) exhibit many
interesting structural and electronic properties, including shear solitons, phasons, topological
point defects and ultraflatbands close to the Fermi level \([1,2]\). For small twist angles the unit cells
of these systems contain thousands of atoms rendering first-principles investigations of their
structural and electronic properties numerically challenging. To overcome this obstacle, we
employ the linear-scaling DFT code ONETEP \([3]\) and present results for relaxed geometries and
band structures for both homo- and heterobilayers of transition metal dichalcogenides as
function of twist angle.

11:39AM S63.00003: Moire quasicrystals in graphene encapsulated by hexagonal boron nitride
NICOLAS LECONTE (Presenter), JEIL JUNG, University of Seoul — Interference of double moire patterns of graphene (G) encapsulated by hexagonal boron nitride (BN) can alter the electronic structure features near the primary/secondary Dirac points and the electron-hole symmetry introduced by a single G/BN moire pattern depending on the relative stacking arrangements of the top/bottom BN layers. For equal moire periods and commensurate patterns with Δφ = 60° angle differences, the patterns can add up constructively or cancel out destructively depending on their relative sliding, while moire quasicrystals are expected for Δφ = 30° differences. We present calculations on the double moire interference effects in the density of states and magnetic oscillations in nearly aligned BN/G/BN systems giving rise to moire quasicrystals and their evolution as a function of moire superlattice twist angles.

11:51AM S63.00004: Modeling mechanical relaxation and electronic states of incommensurate trilayer van der Waals heterostructures
ZIYAN ZHU (Presenter), STEPHEN CARR, Harvard University, PAUL CAZEAUX, University of Kansas, MITCHELL LUSKIN, University of Minnesota, Twin Cities, EFTHIMIOS KAXIRAS, Harvard University — Incommensurate stacking provides an intriguing avenue for manipulating the physical properties of layered two-dimensional materials, but is a challenging problem from a theoretical perspective. Here, we present a multiscale model to obtain the mechanical relaxation pattern and electronic structure of twisted trilayer van der Waals heterostructures with two independent twist angles. This serves as a prototype system of a generally incommensurate system without a supercell description.

To study mechanical properties, we adopt configuration space as a natural description of incommensurate layers, which describes the local environment of each atomic position. We minimize the total energy, parameterized using Density Functional Theory calculations, to obtain the relaxation pattern. For the electronic properties, we focus on twisted trilayer graphene. We adopt a \( k.p \) effective theory derived from a low-energy expansion around the Dirac point. Our results suggest that the twisted trilayer systems are interesting from theoretical and mathematical points of view, as well as a promising platform to study correlated physics.

12:03PM S63.00005: First-principles calculation of gate-tunable magnetism in twisted bilayer graphene under pressure*

XIAO CHEN (Presenter), SHUANGLONG LIU, HAI-PING CHENG, University of Florida — Magic angle twisted bilayer graphene (MAtBLG) is believed to be a highly tunable platform for investigating strongly correlated phenomena such as high-$T_c$ superconductors and quantum spin liquids, due to easy control of doping level through gating and sensitive dependence of the magic angle on hydrostatic pressure. Experimental observations of correlated insulating states, unconventional superconductivity and ferromagnetism in MAtBLG indicate that rich exotic phases exist in this system, which is also suggested by various theoretical works. In this work, with a combination of density functional theory and effective screening medium method, we systematically study the ground state of twisted bilayer graphene at magic twist angle $2.88^\circ$ under pressure and simulate how the ground state evolves when doping level is gate-tuned. We find that at zero doping, a ferromagnetic solution showing half-metallic behavior with spin density localized at AA stacking sites is lower in energy than the trivial spin non-polarized solution. Interestingly, the magnetic moment per moiré unit cell of this ferromagnetic state decreases upon both electron and hole doping and vanishes at four electrons/holes doped per moiré unit cell.

12:15PM S63.00006: Origin and Evolution of Ultraflatbands in Twisted Bilayer Transition Metal Dichalcogenides: Realization of Triangular Quantum Dots

MIT H. NAIK (Presenter), University of California at Berkeley and Lawrence Berkeley National Lab, SUDIPTA KUNDU, INDRAJIT MAITY, MANISH JAIN, Indian Institute of Science — Using a multiscale computational approach, we probe the origin and evolution of ultraflatbands in moiré superlattices of twisted bilayer MoS$_2$ (TBLM), a prototypical transition metal dichalcogenide. Unlike twisted bilayer graphene, we find no special magic angles in TBLM. Ultraflatbands, which form at the valence band edge for twist angles ($\theta$) close to $0^\circ$ and at both the valence and conduction band edges for $\theta$ close to $60^\circ$, have distinct origins. For $\theta$ close to $0^\circ$, inhomogeneous hybridization in the relaxed moiré superlattice is sufficient to explain the formation of flatbands. For $\theta$ close to $60^\circ$, apart from the inhomogeneous hybridisation, local strains cause the formation of modulating triangular potential wells such that electrons and holes are spatially separated. This leads to multiple energy-separated ultraflatbands closely resembling eigenfunctions of a quantum particle in an equilateral triangle well.
**12:27PM S63.00007: Correlated states in transition metal dichalcogenide heterobilayer moiré superlattices** – NAICHAO HU (Presenter), AJESH KUMAR, ALLAN MACDONALD, Department of Physics, University of Texas at Austin — 2D van der Waals moiré superlattices have attracted much attention recently as highly tunable platforms to study strong correlation phenomena. In particular, transition metal dichalcogenide (TMD) heterobilayers at small twist angles develop isolated flat moiré bands that are accurately described [1] by triangular lattice (generalized) Hubbard models. Using a fully self-consistent mean-field-theory, we investigate the competing correlated phases at various fractional filling factors and twist angle, and identify metal-Mott insulator phase transition at 1/2 band filling and Wigner crystal phases at 1/6 band filling. We will discuss the relationship between our calculations and recent related experiments.

*Work supported by DOE grant DE- FG02-02ER45958.

**12:39PM S63.00008: Spontaneous symmetry breaking and topology in twisted bilayer graphene: the nature of the correlated insulating states and the quantum anomalous Hall effect** – JIANPENG LIU (Presenter), XI DAI, Hong Kong University of Science and Technology — We theoretically study the nature of the correlated insulating states and the quantum anomalous Hall (QAH) effect in twisted bilayer graphene (TBG) at the magic angle. Using a generic Hartree-Fock theory applied to all the energy bands, both the experimentally observed correlated insulating states at +/-1/2 filling and the quantum anomalous Hall effect at 3/4 filling of the flat bands near magic angle can be successfully explained. Our results indicate that the correlated insulating states at +/-1/2 filling are states with co-existing valley coherent order and valley polarized order. When a hexagonal boron nitride (hBN) substrate is aligned with the TBG, the valley polarized states are energetically favored over the valley coherent states at +/-1/2 filling, giving rise to QAH insulating states with Chern numbers (C) +/-2 by virtue of the C2z symmetry breaking induced by the substrate. We propose that such valley polarized QAH states would be strongly suppressed by weak in-plane magnetic fields. We further predict that, for the same valley polarization, the anomalous Hall conductivities are opposite for +/- p (p=1/2 or 3/4) fillings, which implies opposite hysteresis behaviors for the QAH states at the electron and hole fillings.
**12:51PM S63.00009: Quasiperiodicity induced eigenstate criticality and flat $\mathbb{Z}_2$ bands in a topological insulator**  
YIXING FU (Presenter), JED PIXLEY, JUSTIN WILSON, Rutgers University, New Brunswick — Flat topological bands have been sought after as a route to the fascinating phenomena of topology with strong correlations. The discovery of correlated insulator and superconductivity in various twisted multilayer graphene systems has shown that the superlattice pattern generated in van der Waals heterostructure, or more generally incommensurate effects, provides an ample playground for generating flat bands. We demonstrate that perturbing topological insulators with a quasiperiodic potential creates flat topological bands in a controllable fashion as well as induces non-trivial quantum phase transitions that are beyond the Landau-Ginzburg paradigm. Using a combination of analytic and numeric calculations, including a Convolutionary Neural Network classification of wavefunctions, we reveal the rich phase diagram induced by quasiperiodicity and topology. We show that quasiperiodicity can make a trivial insulator topological through a topological eigenstate phase transition that represent a unique universality class, and in the process creates essentially flat topological bands.

**1:03PM S63.00010: Modelling realistic Hamiltonians for moire lattices**  
ARKADIY DAVYDOV (Presenter), ALEXEY SOLUYANOV, physics, Univ of Zurich — The tight-binding (TB) approximation to the Hamiltonian of the Twisted Bilayer Graphene (TBG) is considered in the Slater-Koster (SK) form. Instead of taking the commonly-accepted parametrization, we generate a new one by fitting the data obtained in the *ab-initio* Density Functional Based (DFT) calculations. The resulting Hamiltonian is further projected to a smaller twelve-band tight-binding model, giving a systematic way to reduce the dimensionality of the problem. Finally, the localization of the Wannier orbitals and the symmetry of the final Hamiltonian is considered in this work.

**1:15PM S63.00011: Electronic properties of twisted transition metal dichalcogenide bilayers**  
MADELEINE PHILLIPS (Presenter), C STEPHEN HELLBERG, United States Naval Research Laboratory — The electronic properties of transition metal dichalcogenide (TMD) bilayers vary according to the local atomic structure [1]. In minimally twisted bilayers, there is significant atomic reconstruction away from the rigid moire pattern [2]. We present the results of density functional theory (DFT) calculations that model the electronic properties of MoSe$_2$/WSe$_2$ bilayers with a small (~1 degree) twist away from commensurate 180-degree stacking. We consider how the local density of states and charge density vary with atomic reconstruction and compare our results to recent experiments.

*M.P. holds a National Research Council fellowship at NRL.*
1:27PM S63.00012: Structure of twisted transition metal dichalcogenide bilayers  
STEPHEN HELLBERG (Presenter), MADELEINE PHILLIPS, U.S. Naval Research Lab — We present density functional (DFT) calculations of the reconstruction in transition metal dichalcogenide (TMD) hetero-bilayers twisted a small angle from from commensurate 180-degree stacking [1]. In both MoS$_2$/WS$_2$ and MoSe$_2$/WSe$_2$, the bilayer untwists and reconstructs to increase the area of the domains with the lowest energy stacking [2]. The overall twist is concentrated in the domain walls and vertices, where the energetic cost of twisting away from 180 degrees is reduced.

*M.P. holds a National Research Council fellowship at NRL.

1:39PM S63.00013: Surface States and Arcless Angles in Twisted Weyl Semimetals*
HERBERT FERTIG (Presenter), Indiana Univ - Bloomington, GANPATHY MURTHY, Physics and Astronomy, University of Kentucky, EFRAT SHIMSHONI, Physics, Bar Ilan University — Fermi arc states are features of Weyl semimetal (WSM) surfaces which are robust due to the topological character of the bulk band structure. We demonstrate that Fermi arcs may undergo profound restructurings when surfaces of different systems with a well-defined twist angle are tunnel-coupled. The twisted WSM interface supports a moiré pattern which may be approximated as a periodic system with large real-space unit cell. States bound to the interface emerge, with interesting consequences for the magneto-oscillations expected when a magnetic field is applied perpendicular to the system surfaces. As the twist angle passes through special “arcless angles”, for which open Fermi arc states are absent at the interface, Fermi loops of states confined to the interface may break off, without connecting to bulk states of the WSM. We argue that such states have interesting resonance signatures in the optical conductivity of the system in a magnetic field perpendicular to the interface.

1:51PM S63.00014: Open Momentum Space Method for Hofstadter Butterfly: Application in Moire Models  
BIAO LIAN (Presenter), FANG XIE, ANDREI BERNEVIG, Princeton University — We develop a generic open momentum space method for calculating the Hofstadter butterfly of both continuum models (for Moire superlattices, etc) and tight-binding models, where the quasimomentum is directly substituted by the Landau level (LL) operators. By taking a LL cutoff (and a reciprocal lattice cutoff for continuum models), one obtains the Hofstadter butterfly with in-gap spectral flows. For continuum models such as the model for twisted bilayer graphene, our method gives a sparse Hamiltonian, making it much more efficient to calculate the spectrum. The spectral flows can be understood as edge states on a momentum space boundary, from which one can determine the two integers $(tv, sv)$ of a gap $v$ satisfying the Diophantine equation. The spectral flows can also be removed to plot a clear Hofstadter butterfly. While $tv$ is known as the Chern number, our picture identifies $sv$ as a dual Chern number in the momentum space, which corresponds to a quantized Lorentz susceptibility $\gamma_{xy} = eBsv$. 
11:15AM S64.00001: Low-Voltage Control of Magnetism in Fe$_{0.49}$Rh$_{0.51}$/0.68PbMg$_{1/3}$Nb$_{2/3}$O$_3$-0.32PbTiO$_3$ Thin Films Heterostructures  WENBO ZHAO (Presenter), LEI ZHANG, JIEUN KIM, DAVID PESQUERA, GABRIEL VELARDE, LANE WYATT MARTIN, Department of Materials Science and Engineering, University of California, Berkeley — With the rapid development of computing applications, researchers are motivated to develop novel low-energy consumption devices for information processing. Amongst candidate technology for such devices are low-power spin logics. Therein, magnetoelectric heterostructures remain a promising route to address the rising need of processing power. Previous research, however, has mainly utilized piezo-strains from piezoelectric bulk or thick films which require high voltages and energies due to their size.[1] Here, using 100 nm-thick 0.68PbMg$_{1/3}$Nb$_{2/3}$O$_3$-0.32PbTiO$_3$ thin-films as actuator layers, we discuss the potential for ultra-low-voltage control of magnetism in Fe$_{0.49}$Rh$_{0.51}$ thin-films via strain. Leveraging routes for epitaxial integration of metallic ferromagnets on oxide thin films, initial studies have demonstrated reversible changes in anomalous Hall resistivity with small voltages applied to the 0.68PbMg$_{1/3}$Nb$_{2/3}$O$_3$-0.32PbTiO$_3$ at room temperature which are attributed to the strain induced ferromagnetic and antiferromagnetic phase transition in Fe$_{0.49}$Rh$_{0.51}$. Our findings reveal the feasibility of voltage control of magnetism with piezoelectric thin-films and can be used in low-voltage/energy computing.

Recent observations of domain wall conductivity in the LiNbO$_3$ thin films may facilitate the development of electrically-tunable resistive switching devices employing conductive domain walls as functional elements. In LiNbO$_3$ capacitors, several orders of magnitude modulation of resistance can be achieved by systematically changing the density of injected domain walls using voltage pulse amplitude above the coercive bias. However, a deleterious characteristic of this approach is a high-energy cost of polarization reversal due to high leakage current. Here, we demonstrate a new approach for tuning the device resistance by modulating the conductivity of domain walls rather than changing the domain configuration. Using the LiNbO$_3$ thin film capacitors with graphene top electrodes, we show that once the device is set to a specific polydomain state, its resistance can be continuously tuned by application of sub-coercive voltage. The tuning mechanism is based on reversible transition between the conducting and insulating states of the domain walls due to the electrically-induced wall bending near the sample surface. The developed approach provides an energy-efficient way to realize resistive functionality without the need of the domain structure modification by high voltage pulses.
Most modern computing is built upon the von Neumann architecture composed of the data storage and data operation in a central processing unit. However, as Moore’s law made exponential gains over the decades, a memory bottleneck emerged, also known as the von Neumann bottleneck. This memory bottleneck can often degrade computing by orders of magnitude below the maximum potential of the computer especially for applications with large data sets. Hence it is of great interest to develop new energy-efficient memory technologies. Spintronic memory based on spin-transfer torque has emerged as a potential on-chip memory but it suffers from high energy dissipation (due to the requirement for a large current) and high voltages (due to the use of tunnel junctions). In contrast, a magneto-electric memory can operate with a capacitive displacement charge and potentially reach a $1-10 \text{ aJ/switching operation}$. Here we show magneto-electric switching of a memory element with a giant magnetoresistance (GMR) readout, operating at $\sim200 \text{ mV}$. We utilize a combination of phase detuning via isovalent substitution, thickness scaling, and conductive oxide electrode choice to scale the switching energy density to $20 \text{ µJ/cm}^2$. To the best of our knowledge, this is among the lowest voltage and energy density demonstrated in a spintronic memory element, thus presenting an attractive pathway to ultralow-power electronics.

12:27PM S64.00005: Magnetocapacitance Effect and Magnetoelectric Coupling in Type-II Multiferroics RFeWO\textsubscript{6} (R=Ho, Dy and Tb)* MOEIN ADNANI TAKANTAPEH (Presenter), MELISSA GOOCH, NARAYAN POUDEL, HUNG-CHENG WU, LIANGZI DENG, ZHENG WU, Texas Center for Superconductivity, University of Houston, CHUNG-KAI CHANG, National Synchrotron Radiation Research Center, Taiwan, TAHA SALAVATI-FARD, Department of Chemical and Biomolecular Engineering, University of Houston, YEN-CHUNG LAI, National Synchrotron Radiation Research Center, Taiwan, HUNG-DUEN YANG, Department of Physics, National Sun Yat-sen University, LARS C. GRABOW, Department of Chemical and Biomolecular Engineering, University of Houston, PAUL C. W. CHU, Texas Center for Superconductivity, University of Houston — In this work, we investigated the multiferroic property and magnetoelectric (ME) coupling in HoFeWO\textsubscript{6} with a noncentrosymmetric polar structure (space group Pna\textsubscript{2}1). Low temperature XRD measurements down to 8 K did not show a structural phase transition and our DFT calculations reveal a stable structure. With an antiferromagnetic transition at T\textsubscript{N}=17.8 K and a ferroelectric transition with the onset at the same temperature, this compound is a type-II multiferroic which shows magnetoelectric (ME) coupling. Field-dependent dielectric measurements show magnetocapacitance (MC) effect with double hysteresis loop at low temperature, which is directly related to its metamagnetic behavior. We further studied the MC effect in other members of this family, in particular, DyFeWO\textsubscript{6} and TbFeWO\textsubscript{6} and compared the results with HoFeWO\textsubscript{6}. The observed MC effect and its direct correspondence with magnetization further confirm the ME coupling in these compounds.

12:39PM S64.00006: Negative capacitance in the hexagonal-YbFeO\textsubscript{3} epitaxial thin films* YU YUN (Presenter), XIAOSHAN XU, University of Nebraska - Lincoln —
The management of the heat generation and the power dissipation during information processing are very import issues in highly integrated electronic circuits. The ferroelectric negative capacitance (NC) effects, which was proposed to overcome the fundamental limit posed by the Boltzmann distribution of electrons, are attracting a great deal of interests. This work, we designed a heterostructure based on the hexagonal-YbFeO\textsubscript{3} (h-YbFO) multiferroic thin films to study the transient NC effects. For the first time, room-temperature ferroelectric properties in the epitaxial h-YbFO thin films and a direct observation of NC effects of h-YbFO thin films are reported. The transient NC effects as a function of the load resistance and applied source voltage are systematically investigated, which qualitatively follow the theoretical prediction. The structural requirements for the NC effects have been discussed, e.g. domain structure correlation with dielectric layers, grain size effects, microscopy mechanisms of ferroelectric switching. This work provides a new platform for the study of NC effects, and opens new horizons for understanding and improving the NC effects.

*This work was supported by the NSF DMR-1454618
12:51PM S64.00007: Stability of the magnetoelectric state in Y-type hexaferrite single crystals  
VILMOS KOCSIS (Presenter), TARO NAKAJIMA, RIKEN, MASAAKI MATSUDA, Oak Ridge National Laboratory, AKIKO KIKKAWA, YOSHIO KANEKO, JUNYA TAKASHIMA, RIKEN, KAZUHISAKAKURAI, Comprehensive Research Organization for Science and Society (CROSS), TAKA-HISA ARIMA, YUSUKE TOKUNAGA, Department of Advanced Materials Science, University of Tokyo, YOSHINORI TOKURA, YASUJIRO TAGUCHI, RIKEN — The magnetoelectric (ME) properties of the trigonal Y-type hexaferrites, $\text{Ba}_{2-y}\text{Sr}_y\text{Co}_2\text{Fe}_{12-x}\text{Al}_x\text{O}_{22}$, are related to the multiferroic FE3 phase [1,2]. Although this phase has been observed both as a metastable and as a stable phase [3,4,5], stable control over magnetization by electric field has not yet been achieved close to room temperature. This indicates that for applications, the stability of the multiferroic phase as well as the ME state are crucial issues, which are hard to investigate using conventional approaches.

In this presentation, we report the results of the direct ($P-H$) and inverse ($M-E$) magnetoelectric effects in Y-type hexaferrites with different Sr doping levels. Using the combination of high electric and magnetic fields, we investigate the isothermal switching between two ME states. We discuss these new findings in terms of a possible way to evaluate the stability of the ME state in multiferroic materials.

1:03PM S64.00008: Local probing of jerky switching dynamics in Pb(Zr0.2Ti0.8)O3 thin films  
PHILIPPE TUCKMANTEL (Presenter), IAROSLAV GAPONENKO, STEFANO GARIGLIO, DQMP, University of Geneva, JOSHUA AGAR, MSE, Lehigh University, LANE WYATT MARTIN, DMSE, University of California, Berkeley, PATRYCJA PARUCH, DQMP, University of Geneva — Polarisation switching in ferroelectric materials is governed by the same competition between elasticity and disorder, which describes many systems from earthquake statistics to magnetic domain walls. The movement of the interface follows nonlinear creep and (de)pinning dynamics, with jerky individual events whose energy and size distributions are characterised by universal power laws. In ferroelectrics, domain nucleation and growth can be observed from nano to macroscale, providing a useful system in which this complex fundamental behaviour can be explored.

While past measurements have focused on average responses at the level of the whole sample, recent theoretical studies suggest that spatial resolution of the switching event distribution can provide important new information about the dynamic regime under observation.

Here, using piezoresponse force microscopy to follow polarisation reversal at the nanoscale in two epitaxially grown Pb(Zr0.2Ti0.8)O3 thin films, we show that the probability distribution of switching event sizes follows a power law with different exponents in samples with different disorder landscapes. Furthermore, we show how individual jerks attributed to domain wall motion and domain merging events contribute differently to the global switching dynamics.
1:15PM S64.00009: 2D Semiconductor Transistors using Layered van der Waals Oxide MoO$_3$ as High-$K$ Gate Dielectric*  
BRIAN HOLLER (Presenter), KYLE CROWLEY, Case Western Reserve University, HALYNA VOLKOVA, MARIE-HELENE BERGER, MINES Paris Tech, XUAN GAO, Case Western Reserve University — The search for smaller field effect transistors is leading research towards atomically thin 2D semiconductor materials. Due to the decreasing size of these transistors, there must be an emphasis on finding compatible gate dielectrics that can be equally effective in the 2D regime. MoO$_3$ is an attractive multi-functional transition metal oxide replacement for gate dielectrics in field effect transistors due to its exfoliatable van der Waals structure in addition to its high dielectric constant. This study demonstrates that as-grown MoO$_3$ has a high dielectric constant, $K$, of approximately 35 at room temperature at low frequencies by fabricating parallel plate capacitors from these thin flakes. Mechanically exfoliated MoO$_3$ flakes are used to create 2D heterostructures with WSe$_2$, demonstrating that MoO$_3$ also induces holes in the WSe$_2$ layer. Most importantly, MoO$_3$ proves to be a strong gate dielectric when used as a top-gate material for WSe$_2$ heterostructure devices.

1:27PM S64.00010: First-principles investigations of ferroelectric and pyroelectric properties of HfO$_2$*  
SHI LIU (Presenter), School of Science, Westlake University, JIAN LIU, Optics and Thermal Radiation Research Center, Shandong University, BRENDAN HANRAHAN, Sensors & Electron Devices Directorate, U.S. Army Research Laboratory — The presence of ferroelectricity in HfO$_2$-based thin films have revitalized the interests in using ferroelectrics at the nanoscale. To understand the origin of ferroelectricity in this silicon-compatible ferroelectric, we investigated the kinetic effects of phase transitions in HfO$_2$ thin films by quantifying the transition barriers between different polymorphs of hafnia with density-functional-theory calculations and variable-cell nudged elastic band technique. We found that the transition from the tetragonal phase to the polar orthorhombic phase is a fast process kinetically under clamping. We further explored the pyroelectricity in HfO$_2$ with both first-principles lattice dynamics and ab initio molecular dynamics calculations. Unlike most conventional pyroelectrics, the large pyroelectricity of HfO$_2$ results from the secondary effect which is intimately related to the negative longitudinal piezoelectric effect.

Ferroelectricity in [111]-oriented epitaxially strained HfO$_2$ from first principles* SEBASTIAN REYES-LILLO (Presenter), Andres Bello University — First principles calculations are used to investigate the effect of (111) epitaxial strain in the structural and ferroelectric properties of Hafnia (HfO$_2$), a silicon compatible high-k dielectric that is already used in high volume semiconductor manufacturing applications. We find that [111]-oriented epitaxial strain lowers the symmetry of the bulk cubic Fm-3m and tetragonal P4$_2$/nmc phases of HfO$_2$ to rhombohedral R-3m and monoclinic P2$_1$/m, respectively. The polar orthorhombic Pca$_2_1$ phase stabilizes a ferroelectric monoclinic P1 structure above -2% (111)-strain, not present in either bulk or (001)-strained form. Under (111)-strain, ferroelectricity displays an out of plane polarization component P~ 35μC/cm$^2$. At large compressive strain (>2%), [111]-oriented thin films are paraelectric. We further explore the energy landscape of (111) strained HfO$_2$ and possible pathways for the stabilization of ferroelectricity.

Session S65 DCMP: Superlattices and Nanostructures II: Transport and Electronic Phenomena Mile High Ballroom 4F - Simone Assali, Ecole Polytechnique de Montreal

Classical diffusion anomalies in two-dimensional Lorentz gases THOMAS HEINZEL (Presenter), BEATE HORN-COSFELD, JÜRGEN HORBACH, NIMA SIBONI, RENE LOHMANN, JAKOB SCHLUCK, University of Dusseldorf — The magnetoresistivity of two-dimensional Lorentz gases, formed by a free electron gas exposed to sparse, strong scatterers of identical shape at random positions, shows strong deviations from the Drude-Boltzmann model due to classical memory effects. At intermediate magnetic fields where the cyclotron radius is similar to the obstacle size, a conductance peak is observed which originates from transient superdiffusive motion along, and across, the obstacle clusters. [1] On the other hand, for strongly retroreflective [2] obstacles of sufficiently large number density, transient subdiffusive motion of the electrons is found in molecular dynamics simulations, which increases as the magnetic field approaches zero, and an anomaly is observed for $B=0$ where the diffusion constant cannot be defined, similar to earlier kinetic studies at low obstacle densities.[3] A suppression of the longitudinal conductivity around zero magnetic field is measured at sub-Kelvin temperatures and interpreted as an experimental signature of this transport anomaly.

11:27AM S65.00002: Kondo effect in Aharonov-Casher spin field-effect transistor  ANTON
PARAFILO (Presenter), Center for Theoretical Physics of Complex Systems, Institute for Basic Science,
LEONID GORELIK, Chalmers University of Technology, MIKHAIL KISELEV, The Abdus Salam International
Centre for Theoretical Physics, HEE CHUL PARK, Center for Theoretical Physics of Complex Systems,
Institute for Basic Science, ROBERT SHEKHTER, University of Gothenburg — We address the question
how Coulomb blockade in the nanowire affects the transport in Datta-Das transistor with anti-
collinear partially magnetized electrodes in the regime when Kondo phenomena is reached. We
use non-equilibrium Keldysh Green function technique at weak coupling regime to obtain first
two non-vanishing contribution to the charge current. It is predicted that the effects of spin-orbit
interaction result in a non-vanishing current for any spin polarization of the leads including the
case of fully polarized anti-collinear contacts.
The dependence of the Kondo temperature on the Aharonov-Casher phase and degree of
polarization in the leads is determined by the solution of the system of coupled Renormalization
Group equations. Analysis of the Kondo temperature shows that it decays with increasing of the
Aharonov-Casher phase and decreasing of the degree of polarization in the leads.

11:39AM S65.00003: Control of Resonant Tunneling transport in III-Nitride Double-Barrier
Heterostructures by δ-doping engineering*  JIMY ENCOMENDERO (Presenter), VLADIMIR
PROTASENKO, DEBDEEP JENA, HUILI GRACE XING, Cornell University — The spontaneous and
piezoelectric polarization fields in III-Nitride semiconductors control their electronic, optical, and
piezoelectric properties. Accordingly, the fundamental physics of resonant tunneling transport
through nitride resonant tunneling diodes (RTDs) is also dominated by the built-in polarization
fields. We have recently elucidated this connection by developing a transport model which
reproduces the measured tunneling currents in multiple RTD designs. Using this model and the
exponential dependence of the currents on the electric fields, we measured the polarization
fields with unprecedented precision.

III-Nitride RTDs are also of interest in practical applications since they provide electronic and
optical gain within the THz band. However, because of the internal fields, the resonant levels shift
toward higher energies due to the electrostatic polarization of the barriers and quantum-
confined Stark effect in the well. Thus, the resonant voltages exhibit values > 4 V, for multiple RTD
designs. Here, we present a new δ-doped GaN/AlN RTD which enables control over the resonant
voltages, making them independent of the built-in fields. We demonstrate devices with resonant
voltages ~1 V, while maintaining a high current density and peak-to-valley current ratio.

11:51AM S65.00004: Wentzel-Kramers-Brillouin (WKB) analysis and resonant electron tunneling in \(\alpha\)-T\(_3\) lattices

LIUBOV ZHEMCHUZHNA (Presenter), Hunter college, ANDRII IUROV, Medgar Evers college, GODFREY GUMBS, Hunter college, DANHONG HUANG, Air Force Research Lab — We have adopted the Wentzel-Kramers-Brillouin (WKB) theory for investigating pseudospin-1 \(\alpha\)-T\(_3\) materials for arbitrary hopping parameter \(0 < \alpha < 1\), including the extreme case when \(\alpha=1\) for the dice lattice. It has been revealed that the solution for this stationary eigenvalue problem has a power series depending on the Planck constant and we also obtained the corresponding semi-classical wave function. Using these results, we investigated the tunneling of pseudospin-1 Dirac electrons impinging various non-rectangular electrostatic potential barriers. We will present results for tunneling when optical dressed states arising from an electron interacting with a non-resonant dressing field with chosen polarization.

12:03PM S65.00005: Electron tunneling and transport in \(\alpha\)-T\(_3\) lattices under linearly polarized irradiation

PAULA FEKETE (Presenter), US Military Academy at West Point, ANDRII IUROV, Medgar Evers College of City University of New York, GODFREY GUMBS, Hunter College of the City University of New York, DANHONG HUANG, Air Force Research Laboratory, Kirtland Air Force Base, Albuquerque, NM — We have considered electron tunneling through a square electrostatic potential barrier for Floquet states, i.e., pseudospin-1 Dirac electrons coupled to a dressing, off-resonant field which is linearly polarized. While for the dice lattice we can still observe an asymmetric Klein tunneling, i.e., perfect transmission for electrons colliding with the barrier that is different from the head-on case, the Klein paradox is completely suppressed for the \(\alpha\)-T\(_3\) lattice in general with \(\alpha \neq 1\). We have also calculated electron transmission for finite incidence angles and the tunneling conductance corresponding to these transmission amplitudes.
12:15PM S65.00006: Incoherent Effects in Hot-Electron Quantum Optics*  CLARISSA BARRATT (Presenter), LEWIS CLARK, CLIVE EMARY, Univ of Newcastle — Using dynamical quantum dot single electron pumps, high-energy (“hot”) single electrons may be injected into semiconductor systems both reliably and at a high rate. When combined with energy and time-resolved detection, electrons from these sources provide us with a new platform to probe fundamental semiconductor physics in unprecedented detail.

In this contribution, we discuss coupling single-electron sources into interferometer geometries, such as the Mach-Zehnder interferometer, where the visibility of the quantum interference acts as a sensitive probe of the properties both of the emitted electrons and their environment. We investigate the effect of the uncertainty in injection energy on the phase contributions of the path lengths and quantum point contacts.

We also present theoretical calculations of the decay rate of a hot electron subject to phonon scattering, and determine how these rates are affected by parameters such as the electron injection energy and the magnetic field. Using our calculations for both phase averaging and phonon rates, we derive strategies for minimising the effects of these processes, thus maximising the quantum-coherent properties of the electrons.

12:27PM S65.00007: Photoconductivity of DNA-Porphyrin Complexes*  DANIEL VAN BEVEREN (Presenter), PECO MYINT, STEFANOS LOGOTHETIS, Haverford College, ZHENQING JOHN QI, CARL NAYLOR, MENGQIANG ZHAO, QICHENG ZHANG, ALAN T JOHNSON, Physics, University of Pennsylvania, WALTER FOX SMITH, Haverford College — DNA has attracted attention for potential use in nanocircuitry largely due to its pattern-recognition and self-assembly characteristics, but low electrical conductivity limits its potential usefulness for these applications. We attempt to address these issues by modifying DNA with meso-tetrakis(N-methyl-4-pyridiniumyl)porphyrin (TMPyP) intercalated between the base pairs. By measuring the electrical characteristics of these DNA-porphyring complexes deposited on a SiO2 under nitrogen gas, we show that this alteration increases the DNA strand conductivity and leads to significant photoconductive behavior at 445 nm, a wavelength strongly absorbed by the TMPyP-DNA complex. We also find a strong dependence on humidity, as photoconductive effects were only observed above 30% relative humidity, and increased both with the humidity in the chamber and with the length of exposure to the humid environment. A significant hysteresis is also observed, as the increased conductivity observed at higher humidity persists even after the humidity is lowered.

*NSF grants DMR 1306170 and BMAT 1306170
Thermal conductivity of thermally annealed nanocrystalline silicon film grown by PECVD technique*  

BATOOGTOKH JUGDERSUREN (Presenter), KeyW Corporation, XIAO LIU, United States Naval Research Laboratory, BRIAN T KEARNEY, National Research Council, JAMES CLIFFORD CULBERTSON, CHRISTOPHER N CHERVIN, RHONDA MICHELE STROUD, United States Naval Research Laboratory — Nanocrystalline silicon films (nc-Si) have been shown to have significantly lower lattice thermal conductivity than its micro-polycrystalline counterparts. However, it is essential for high temperature applications, such as thermoelectrics, to maintain their low thermal conductivity characteristics upon annealing, which may depend on the details of film preparation techniques. We investigate the effect of postdeposition thermal annealing on the thermal conductivity of nc-Si films prepared by plasma-enhanced chemical vapor deposition (PECVD). After annealing the PECVD nc-Si at 600°C for two hours, its thermal conductivity is increased two-fold, reaching 1.86 W/mK at 300K, however this value is lower than similarly annealed nc-Si films prepared by the hot-wire chemical vapor deposition technique by a factor of 2.5. Our structural characterizations reveal that after annealing, the average crystalline grain size of PECVD nc-Si is increased to ~4.6 nm from the as-grown value of 3 nm. We discuss the possible cause of the low lattice thermal conductivity of PECVD nc-samples in terms of grain boundary scattering.

Strain Controlled Modulations and Anomalies in the Thermopower of Si/Ge Superlattices: A First-Principles Study*  

MANOJ SETTIPALLI (Presenter), SANGHAMITRA NEOGI, University of Colorado, Boulder — The thermopower/Seebeck coefficient (S) of metals and heavily doped semiconductors usually decreases monotonically with increasing carrier concentration, n_e, following the Pisarenko relation (PR). Heterostructures, such as III-V semiconductor superlattices (SLs), have been shown to display oscillatory S, deviating from the PR. Interestingly, this behavior has not been observed in highly technologically relevant n-doped Si/Ge SLs. Here, we demonstrate a strong oscillatory behavior of the cross-plane S of n-doped Si/Ge SLs with n_e, deviating from the PR, using symmetry, composition, and strain engineering. We use the density functional theory (DFT) and the effective mass approximation, independently, in combination with the Boltzmann transport equation framework, to establish the results. We predict 5.4- and 1.8-fold enhancements in the cross-plane S and the power factor of Si/Ge SLs, respectively, in the high doping regime, compared to bulk Si. In addition, our DFT study shows that cross-plane S displays anomalous sign-changing nature within the conduction miniband regime. This study will open up research directions to use strain-engineered bands to control electronic properties for various heterostructures.

*The project is funded by DARPA (DSO) [Agreement No.: HR0011-16-2-0043].
1:03PM S65.00010: Prediction of large Seebeck coefficient in ferroelectric domain walls of GeTe*  
DORDE DANGIC (Presenter), University College Cork, EAMONN D MURRAY, Imperial College London, STEPHEN B FAHY, University College Cork, IVANA SAVIC, Tyndall National Institute — Domain walls in ferroelectric materials can have significantly different properties than their bulk counterparts, which creates new opportunities for the manipulation of material properties. GeTe is a ferroelectric material that is also an excellent thermoelectric, exhibiting relatively high electrical conductivity and Seebeck coefficient, as well as low lattice thermal conductivity. In this work, we present a first principles study indicating that ferroelectric domain walls in GeTe have a considerably larger Seebeck coefficient than bulk GeTe. Polarization discontinuity at domain walls gives rise to bound charge that localizes free charge carriers on the domain walls. We find that the two-dimensional electron gas confined to domain walls can exhibit large peaks in the local density of states near the Fermi level due to Van Hove singularities, resulting in an enhanced Seebeck coefficient. Van der Waals gaps along domain walls cause additional confinement of carriers within the domain walls that further increases the in-plane Seebeck coefficient perpendicular to the van der Waals gaps. The out-of-plane Seebeck coefficient is also significantly enhanced due to the charge localization on domain walls.

1:15PM S65.00011: Visualizing Electronic Inhomogeneity in CsPbBr₃ Perovskite Nanorods  
YIZE LI (Presenter), California State University, Bakersfield, SHUANG LIANG, School of Materials Science and Engineering, Georgia Institute of Technology, TUONG TRIEU, TYLER STABILE, California State University, Bakersfield, ZHIQUN LIN, School of Materials Science and Engineering, Georgia Institute of Technology — Abstract: All-inorganic perovskite nanocrystals (NCs), such as CsPbBr₃ NCs, have demonstrated promising applications in solar cells, light-emitting diodes (LEDs), electroluminescence devices, and lasing. Grain boundaries and point defects influence carrier transport in perovskite NCs, thereby impacting the device performance. We use contactless dielectric force microscopy (DFM), a novel scanning probe microscopy (SPM)-based imaging technique, to probe local electronic inhomogeneity in CsPbBr₃ nanorods (NRs). We find that while some NRs exhibit nearly homogeneous DFM responses, others behave as p-n junctions with well-defined grain boundaries. Moreover, point defects are observed in some CsPbBr₃ NRs. It is thus feasible to identify CsPbBr₃ NRs that are suitable for device fabrications based on their DFM responses.
Quantum mirage is a fascinating phenomenon in fundamental physics. Landmark experiment on quantum mirage reveals novel information transport at the atomic scale and exhibits great potentials for remotely probing atoms or molecules with minimized perturbation. Previous experimental investigations are Kondo effect based and quantum mirages only appear near Fermi energy. This strongly limits the exploration of the mechanism and potential application. Here we demonstrate a Kondo-free quantum mirage, which can operate in a wide energy range beyond Fermi energy. Together with an analytical model, our systematic investigations identify that quantum mirage is the result of quantum interference of the onsite electronic states with those scattered by the adatom at the focus of elliptical quantum corrals, where two kinds of scattering paths are of critical importance. Moreover, we also demonstrate the manipulation of quantum mirage with pseudo logic operations, such as NOT, FANOUT and OR gates.

Session S66 DCMP: Strongly Correlated Topological Metals

Subir Sachdev, Harvard University - Tag(s): Invited
The interplay of topology and strong electron correlations is emerging as a new frontier in quantum science; it is expected to bring forth exotic phases and excitations, as epitomized by the example of the fractional quantum Hall effect. Indeed, (weakly interacting) topological semimetals—featuring states with Dirac or Weyl dispersion in the bulk—were discovered when their correlation-driven counterparts were pursued. Heavy fermion systems provide an ideal setting because the Kondo interaction implements extreme correlation strength and representatives with strong spin-orbit coupling exist. A joint effort of experiments and theory has recently led to the discovery of a Weyl-Kondo semimetal phase [1-3]. Experimentally, it is realized in the noncentrosymmetric time reversal symmetry preserving heavy fermion semimetal Ce\(_3\)Bi\(_4\)Pd\(_3\) [1,3]. This material has a Kondo temperature of 13 K [1] and remains paramagnetic down to at least 250 mK [3]. Our most striking observation is a giant spontaneous (zero-field) Hall effect, and an associated even-in-field Hall component, which provide direct evidence of Berry curvature singularities in close vicinity to the Fermi level [3]. These characteristics of Weyl physics develop only in the Kondo coherent state, and are thus manifestly correlation driven. The application of large magnetic fields leads to an annihilation of the Weyl nodes at a first critical field, and to the metallization of the system at a second one, featuring quantum criticality [4].

*We acknowledge financial support from the Austrian Science Fund (FWF grants No. P29279-N27, P29296-N27, and DK W1243) and the European Union’s Horizon 2020 Research and Innovation Programme, under Grant Agreement no EMP-824109.
There is considerable current interest to explore electronic topology in strongly correlated metals. A promising setting arises in heavy fermion systems, which may feature not only strong correlations but also a large spin-orbit coupling. Recently, a Weyl-Kondo semimetal phase has been concurrently discovered in theoretical [1] and experimental [2] studies. The theoretical work was carried out in a Kondo lattice model that is time-reversal invariant but inversion-symmetry breaking. The defining characteristics of the Weyl-Kondo semimetal include linearly-dispersing Weyl nodal excitations with highly reduced velocity and the Weyl nodes being pinned to the Fermi energy. In this talk, I will summarize the theoretical developments, with a focus on the effect of non-symmorphic space-group symmetry in conjunction with strong correlations [1,3], the transitions to nearby quantum phases, as well as the efficient control of the Weyl nodes including their annihilation by a magnetic field [4,5]. The enrichment of these results for the global phase diagram of heavy fermion metals, reflecting on the role of spin-orbit coupling in the competition of quantum phases that develop out of the spin degrees of freedom [6], will be discussed.

From Trivial Kondo Insulator Ce$_3$Pt$_3$Bi$_4$ to Topological Nodal-line Semimetal Ce$_3$Pd$_3$Bi$_4$ [Invited]  CHAO CAO (Presenter), Department of Physics, Hangzhou Normal University, GUOXIANG ZHI, Department of Physics, Zhejiang University, JIAN-XIN ZHU, Los Alamos National Lab — Using the density functional theory combined with dynamical mean-field theory, we have performed systematic study of the electronic structure and its band topology properties of Ce$_3$Pt$_3$Bi$_4$ and Ce$_3$Pd$_3$Bi$_4$. At high temperatures (~290K), the electronic structures of both compounds resemble the open-core 4f density functional calculation results. For Ce$_3$Pt$_3$Bi$_4$, clear hybridization gap can be observed below 72K, and its coherent momentum-resolved spectral function below 18K exhibits an topologically trivial indirect gap of ~6 meV and resembles density functional band structure with itinerant 4f state. For Ce$_3$Pd$_3$Bi$_4$, no clear hybridization gap can be observed down to 4K, and its momentum-resolved spectral function resembles electron-doped open-core 4f density functional calculations. The band nodal points of Ce$_3$Pd$_3$Bi$_4$ at 4K are protected by the gliding-mirror symmetry and form ring-like structure. Therefore, the Ce$_3$Pt$_3$Bi$_4$ compound is topologically trivial Kondo insulator while the Ce$_3$Pd$_3$Bi$_4$ compound is topological nodal-line semimetal.

Evidence for Undoped Weyl Semimetal Charge Transport in a bad Weyl Semi-Metal: Y2Ir2O7* [Invited]  ARTHUR RAMIREZ (Presenter), University of California, Santa Cruz — Most Weyl semimetals studied to date either have a chemical potential not situated at the nodal point, or multiple nodal points at different energies, thus leading to metallic behavior in resistivity versus temperature. Undoped Weyl semimetals, in which the chemical potential is exactly at the nodal point will exhibit characteristic non-metallic behavior in transport that should reveal the density of electronic states as well as the dominant scattering mechanisms. We discuss the various types of transport for both doped and undoped Weyl systems. We show that one candidate, Y2Ir2O7, predicted to display a spectrum of an undoped Weyl semimetal, exhibits behavior of a system with the expected quadratic density of states and scattering from charged impurities, namely resistivity varying as 1/T^4 over a large temperature range. We discuss the implications of these results in light of exciting theories, as well as prospects for future work.

*NSF DMR 1534741 and 1534818 and NSF DGE-1339067
STM studies of candidate topological Kondo insulator SmB$_6^*$ [Invited]

STEFFEN WIRTH (Presenter), LIN JIAO, SAHANA RÖSSLER, DEEPA KASINATHAN, Max Planck Institute for Chemical Physics of Solids, PRISCILA ROSA, Los Alamos National Laboratory, USA, CHAO-XING LIU, Department of Physics, Pennsylvania State University, ZACHARY FISK, University of California, Irvine, USA, FRANK STEGLICH, Max Planck Institute for Chemical Physics of Solids — SmB$_6$ has been proposed a topological Kondo insulator with nontrivial surface states inside a bulk hybridization gap. Experimentally, hybridization between localized 4$f$ and conduction band states at low temperatures is well established [1]. Using STM, we performed local measurements on well identified, atomically flat, unreconstructed surfaces [2]. Tunneling spectroscopy down to 0.35 K revealed sharp peak-like features with a strong temperature dependence within the hybridization gap. The features around −6 mV and −2 mV are dominated by surface contributions to the local density of states [3]. These surface states are robust in the vicinity of randomly occurring non-magnetic impurities, while introducing magnetic impurities in samples (Sm$_{1-x}$R$_x$)B$_6$ with $R$ = Gd influences the surface states on a much larger length scale compared to non-magnetic impurities [4]. Another material of topical interest is the magnetic Kagome lattice Weyl semimetal Co$_3$Sn$_2$S$_2$ in which time-reversal symmetry breaking causes fascinating physics [5]. The measured local density of states reveals a semimetallic gap of −300 mV, verified as the gap in the spin-minority band using spin-resolved tunneling spectra [6].

Session S67 DCMP: Recent Experimental Surprises in Strongly Correlated Superconductors Four Seasons 2-3 - Richard Greene, University of Maryland, College Park

- Tag(s): Invited
11:15AM S67.00001: Unconventional superconductivity in Sr$_2$RuO$_4$ probed under stressed conditions* [Invited] STUART BROWN (Presenter), University of California, Los Angeles — The stoichiometric transition metal oxide Sr$_2$RuO$_4$ is widely considered a model unconventional superconductor, owing to experimental evidence for strong correlations, and to the emergence of an odd-parity superconducting ground state with transition temperature near 1 K. With additional evidence for time-reversal symmetry breaking came the proposal for a two-component chiral $p$-wave order parameter, for which there is an expectation for a split superconducting transition when subjected to in-plane uniaxial stress. Recent studies instead revealed a factor 2.5 increase in the transition temperature of stressed samples, motivating us to probe the evolution of the normal and superconducting states using $^{17}$O NMR. Under stressed conditions, the normal state Knight shifts are consistent with tuning the Fermi surface through a van Hove singularity, along with an associated Stoner factor enhancement [1]. Over a broad temperature range, the magnetic response implies a dominant influence of the small energy difference between $E_F$ and that of the van Hove singularity, which can be controlled by strain, and independently by the Zeeman interaction. A reduced superconducting state spin polarization for in-plane magnetic fields, for all strain values studied, rules out the long-considered chiral $p$-wave state [2]. Although the helical state is an unlikely possibility under stressed conditions, further tightening of constraints on the superconducting state is a priority.

*Support from the National Science Foundation (DMR-1709304) and by the Laboratory Directed Research and Development (LDRD) programme of Los Alamos National Laboratory (20170204ER) is acknowledged.
KENJI ISHIDA (Presenter), KATSUKI KINJO, MASAHIRO MANAGO, SHUNSAKU KITAGAWA, YOSHITERU MAENO, Kyoto Univ — NMR experiments have been done in various unconventional superconductors, and gave information about superconducting (SC) pairing state and SC gap structure. We reported that the Knight shift at the Ru and O sites in Sr$_2$RuO$_4$ is invariant on passing through $T_c$[1,2]. Quite recently, Pustogow and Luo et al. reported a reduction of the Knight shift at the O site measured with a small-energy RF pulse[3]. We reexamined $^{17}$O-NMR on our sample with similar small-energy RF pulses and reproduced their results[4]. Furthermore, we measured the temperature variation of the Knight shift by a standard spin-echo method with small-power RF pulses, and found that the spin susceptibility decreases in the SC state. We conclude that our previous results of the invariance of the Knight shift in the SC state were due to instantaneous destruction of superconductivity by the RF pulses. The heat-up effect was characterized by the temperature variation of the Knight shift under various measurement conditions. In the presentation, we will also present new results obtained near $H_{c2}$ along the $ab$ plane.

ANNA TAMAI (Presenter), Departement of Quantum Matter Physics, University of Geneva — We used laser-based angle-resolved photoemission spectroscopy to explore the interplay of electron-electron correlations and spin-orbit coupling in the model Fermi liquid Sr$_2$RuO$_4$. Our precise measurement of the Fermi surface confirms the importance of spin-orbit coupling in this material and reveals that its effective value is enhanced by a factor of about 2 due to electronic correlations. The self-energies for the $\beta$ and $\gamma$ sheets are found to display significant angular dependence. We demonstrate that this behavior does not imply momentum-dependent many-body effects, but arises from a substantial orbital mixing induced by spin-orbit coupling. A comparison to single-site dynamical mean-field theory further supports the notion of dominantly local orbital self-energies and provides strong evidence for an electronic origin of the observed nonlinear frequency dependence of the self-energies, leading to “kinks” in the quasiparticle dispersion of Sr$_2$RuO$_4$. 
Magnetic excitations and their possible role in the superconducting pairing in \( \text{Sr}_2\text{RuO}_4 \)^{*} [Invited]  
MARKUS BRADEN (Presenter), STEFAN KUNKEMÖLLER, KEVIN JENNI, II. Physics Institute, University of Cologne, PAUL STEFFENS, Univ. of Cologne; Institut Laue Langevin, YVAN SIDIS, Laboratoire Leon Brillouin, ZHIQIANG MAO, Tulane University, IGOR MAZIN, Naval Research Laboratory, YOSHITERU MAENO, Kyoto University — The magnetic excitations in the unconventional superconductor \( \text{Sr}_2\text{RuO}_4 \) consist of several contributions, an incommensurate signal arising from nesting and quasiferromagnetic fluctuations. We were able to follow the nesting signal of the quasi-one-dimensional bands across the superconducting transition down to very low energies. Even at \( E=0.325 \) meV, which lies well below the superconducting gap 2D values reported from tunneling experiments or deduced from BCS theory, there is no change in the magnetic response [1], which seems incompatible with the picture of a large gap on these Fermi-surface sheets. The quantitative analysis of the quasiferromagnetic fluctuations in \( \text{Sr}_2\text{RuO}_4 \) is hampered by the smaller amplitude and the little structure in \( Q \) space of this signal. Only by use of polarized neutron scattering we can determine the strength and characteristics of the ferromagnetic response, which agrees with reports of specific heat, magnetic susceptibility and NMR. Incorporating this ferromagnetic response into the gap equation, however, does not stabilize a triplet pairing state [2]. Furthermore, the quasiferromagnetic response in \( \text{Sr}_2\text{RuO}_4 \) does not resemble the paramagnon scattering expected for a nearly ferromagnetic material, but it seems to arise from broad instabilities at low propagation vectors. In contrast recent INS on the ferromagnetic perovskite \( \text{SrRuO}_3 \) find the typical ferromagnetic magnon and paramagnon scattering below and above the Curie temperature [3]. The magnon stiffness and gap in \( \text{SrRuO}_3 \) is found to anomalously soften upon cooling well below the Curie temperature, which can be attributed to the impact of Weyl points [3].

11:15AM S68.00001: Sandwich Layering in Binary Colloidal Films During Evaporative Drying* [Invited]
WEIPING LIU, AMANDA CARR, State Univ of NY - Stony Brook, ALEXANDER ROUTH, University of Cambridge, KEVIN YAGER, Brookhaven National Laboratory, SURITA BHATIA (Presenter), State Univ of NY - Stony Brook — Multicomponent films based on colloidal dispersions have a wide range of applications, including antimicrobial coatings for medical instruments, conductive textiles for flexible electronics, anti-reflective coatings for optical devices, paints for humid environments that are resistant to mold growth, and drug-loaded coatings for medical implants. Often, there is a need to spatially control location of certain components in the film. In this talk, I will present our recent results from microbeam small-angle X-ray scattering (SAXS) on films prepared from binary colloidal dispersions containing large and small particles of varying size and initial volume fraction. Our results show evidence of different types of stratification behavior, including large-on-top (e.g., large particles migrating to the top surface of the film), small-on-top, and “sandwich”-like layering. Additionally, I will present recent modeling results with different forms of the interaction potential, some of which qualitatively capture formation of "sandwich" structures.

Illuminating the dynamics of drying suspensions in droplets and films

JORIS SPRAKEL (Presenter), Wageningen University — The drying of a suspension, e.g. in an inkjet printed droplet or a coating film, driven by evaporation or capillary imbibition into the substrate, leads to complex changes in the internal dynamics and mechanics of the system. As the particle concentration increases, diffusivities decrease, collective phenomena emerge, particle begin to interact, aggregate and coalesce. Often, these phenomena occur simultaneously without clear temporal separation, at a wide range of characteristic time scales, and in a spatially-inhomogeneous manner. Here we give an overview of recent advances in the development of an experimental tool, Laser Speckle Imaging, that can unravel many of these phenomena across a wide range of time scales, and in a spatially-resolved manner, even in complex and realistic coating formulations. We show how LSI can be used to pinpoint the coating open time and moment of film formation, give insight into subsurface transport and the emergence and propagation of cracks.

Drying Process in Films of Nanoparticle Suspensions and Polymer Solutions

SHENGFENG CHENG (Presenter), Virginia Tech — The drying process of polymer solutions or nanoparticle suspensions provides an excellent playground to explore nonequilibrium physics. For example, novel stratification phenomena have recently been discovered in polydisperse particle suspension films that undergo rapid drying. In these systems, the complex interplay of solvent evaporation, fluid dynamics, diffusion, phoresis, and capillarity leads to rich, far-from-equilibrium phenomena. I will describe our efforts using large scale molecular dynamics (MD) simulations to study the drying process of colloid suspensions, polymer solutions, and their mixtures. For bidisperse particle suspensions, a state diagram of stratification is determined and the counterintuitive "small-on-top" stratification, with an enrichment of the smaller particles at the receding liquid-vapor interface during fast drying, is observed. Results are compared to the predictions of several theoretical models based on diffusiophoresis. We show that the temperature gradient induced by evaporative cooling can lead to size-dependent thermophoretic responses of nanoparticles, which compete with diffusiophoresis and suppress the “small-on-top” stratification. On the basis of this observation, an approach to control stratification using various externally imposed thermal gradients is suggested and validated with MD simulations. We further show that a mixture of two liquids stratifies when rapidly dried with the less volatile component concentrated near the evaporating interface. This phenomenon can be used to separate and stratify particles which have different couplings to the components of a liquid mixture. Finally, we demonstrate a new strategy of unfirmly dispersing nanoparticles into a polymer matrix using fast solvent evaporation, based on the stratification behavior of polymer-particle mixtures in a far-from-equilibrium situation induced by rapid drying.

*Computational hours are provided through a DOE ALCC award.
Stratification in Drying Colloidal Films: A competition between diffusion, evaporation and diffusiophoresis* [Invited] CLARE REES-ZIMMERMAN, ALEXANDER ROUTH (Presenter), Chemical Engineering and Biotechnology, University of Cambridge — Waterborne dispersions are an environmentally friendly formulation for coatings. There are a number of issues associated with drying such coatings such as reduced open time and crack formation. Blending dispersions with hard and soft components has been shown to allow better film formation; however, stratification of components can lead to regions of cracking. Alternatively stratification can be beneficial and used to place different components at desired regions within the film. This could be used for expensive anti-fungal agents in bathroom coatings or catalysts in the walls of tubular reactors.

To understand stratification in drying coatings, one dimensional drying of bi-disperse mixtures has recently been the subject of intense theoretical and experimental study. The experimental observation is of accumulation of smaller particles at the top surface of drying films. The physics driving such stratification is still being debated and the competing theories of cross interactions, diffusiophoresis and a surface interaction will be explored. We have written transport equations for an evaporating film containing a bi-disperse mixture of particles and examine the contribution from different terms.

The role of hydrodynamic interactions in models and simulations of drying*

MICHAEL P HOWARD (Presenter), Chemical Engineering, University of Texas at Austin, ANTONIA STATT, ATHANASSIOS PANAGIOTOPoulos, Princeton University — Nonequilibrium molecular modeling is valuable for predicting the microstructure of drying films. For example, simulations were recently key to uncovering the “small-on-top” stratification of binary colloidal mixtures. In the absence of solvent effects, drying can be well-described using implicit models without hydrodynamic interactions; however, these models tend to overestimate the solute migration speeds and stratification observed in experiments. Here, I will highlight two examples from our recent work that clearly demonstrate the important role of hydrodynamic interactions in nonequilibrium models of drying. I will first discuss the evaporation-induced crystallization of a colloidal dispersion, where we found that the crystal nucleation and growth depended sensitively on the hydrodynamic interactions because of the colloid distribution in the drying film. I will then discuss the stratification of a mixture of two differently sized polymers; the mixture stratified without hydrodynamic interactions, as predicted, but did not stratify when they were included. Our work shows that although implicit-solvent models neglecting hydrodynamic interactions are computationally efficient, the corresponding sacrifice in accuracy may not be acceptable for faithfully predicting structure in drying films.

2:30PM U01.00001: Improved light outcoupling by spontaneously formed nanostructured micro-islands in perovskite films

JITENDRA KUMAR (Presenter), RAMESH KUMAR, Indian Inst of Technology Roorkee, KYLE FROHNA, Department of Chemical Engineering and Biotechnology, University of Cambridge, DHANASHREE MOGHE, DINESH KABRA, Department of Physics, Indian Institute of Technology Bombay, SAM STRANKS, Department of Chemical Engineering and Biotechnology, University of Cambridge, MONOJIT BAG, Indian Inst of Technology Roorkee — Halide perovskites have been the hot topic of research for their unprecedented optoelectronic properties such as high photoluminescence quantum yield (PLQY)\(^1\) and ambipolar charge transport. These properties are generally measured at the macroscopic level, but they differ significantly at micro to nano-scale. Here, we have fabricated CH\(_3\)NH\(_3\)PbBr\(_3\) films containing nanostructured micro-islands (MIs). We have observed that the presence of MIs shows 7 fold increased photoluminescence (PL). This enhancement is due to nanostructured morphology that can also improve the outcoupling. As seen from the fluorescence microscope, PL is mostly coming from MIs. These films were characterized by hyperspectral microscopy. The PL spectrum shows \(\sim\)10 nm blue shift as compared to that of untreated films. The blue shift is attributed to the increased octahedral tilting, because the MIs consists of 20-40nm sized crystals, whereas the background has \(\sim\)300 nm feature size. PL spectrum can be fitted with two Gaussian functions centered at 533 nm and 540 nm respectively, which shows the inefficient funneling of excitons. However, we have seen that the MIs show photodegradation whereas background and untreated films show photoactivation.

2:42PM U01.00002: Optimized fabrication of nanoporous membranes for osmotic power generation

KHADIJA YAZDA (Presenter), YUNING ZHANG, PETER H GRUTTER, WALTER W REISNER, McGill Univ — Osmotic energy, the energy extracted by mixing two solutions with different salinities, has been receiving significant attention in the scientific community as a potential source of clean and renewable energy (so called “Blue Energy”). A major impediment to exploiting osmotic energy is the poor efficiency of commercially available membranes for osmotic energy conversion. Nanoscale membranes with pores at or below 10 nm in diameter may provide sufficient power generation to make osmotic energy viable. Yet, currently no technology exists that can produce such membranes with sufficient control and scale. Here, leveraging our breakthrough tip-controlled local breakdown (TCLB) pore fabrication approach, we demonstrate high osmotic power density comparable to the density obtained with atomically thin 2D materials, yet with a scalable hybrid hBN/SiN membrane. In particular, the TCLB technique can produce pore arrays with a controlled spacing that yields optimum performance. Our work shows that the optimum membrane selectivity and overall power density is obtained with a pore spacing that balances the need for high pore density while maintaining a large extent of charged surface surrounding each pore.
Toward understanding of a mechanism for electrical current generation from ionic water flow using metal nanofilms

JEONGMIN KIM (Presenter), Division of Chemistry and Chemical Engineering, Caltech, DAVIS D. BOAMAH, EMILIE H. LOZIER, CATHERINE E. WALKER, FRANZ M. GEIGER, Department of Chemistry, Northwestern University, THOMAS MILLER, Division of Chemistry and Chemical Engineering, Caltech — “Hydrovoltaic” technologies convert energy from flowing water to electricity via a mechanism that primarily relies on ion adsorption and desorption at water-solid interfaces. Recently, we found metal/metal-oxide nanofilms that generate electrical current from aqueous flow of alternating salinity gradients. Atom probe tomography revealed the 10 nm thick nanofilms are composed of a thermal oxide overlayer about 2-4 nm thick and a lower layer of metal about 6-8 nm thick. Experiments suggested the following design rules for the nanofilms: (i) the metal oxide needs to be redox-active, containing several metal-oxidation states, and (ii) there is an optimal thickness for the nanofilms, comparable to electron mean-free path. For example, 10 nm thick Fe:FeOx films with an alternating flow of sea water and de-ionized water produce current-densities of several microA cm⁻² at the flow rate of a few cm s⁻¹, where iron oxide (FeOx) has iron in both the Fe²⁺ and Fe³⁺ oxidation states. In this poster, we present simulation and theoretical approaches to understand and design the connections between microscopic variables and device-level observables.

A theoretical upper bound on gas deliverable capacity via pressure-swing adsorption in nanoporous materials

JORDAN POMMERENCK (Presenter), Department of Physics, Oregon State University, CORY M SIMON, School of Chemical, Biological, and Environmental Engineering, Oregon State University, DAVID J ROUNDY, Department of Physics, Oregon State University — Due to their low volumetric energy density at ambient conditions, both hydrogen and natural gas are challenging to commercially store onboard environmentally sustainable vehicles. One strategy to densify these gases is to pack the fuel tank with a porous material. Metal-organic frameworks are tunable, nanoporous materials with large internal surface areas and show considerable promise for densifying gases. The US Department of Energy (DOE) has set volumetric deliverable capacity targets which, if met, would help to enable commercial adoption of hydrogen/natural gas as transportation fuels. Here, we present a theoretical upper bound on the deliverable capacity via an isothermal pressure-swing storage. The goals set by DOE for natural gas and hydrogen storage are theoretically possible, but sufficiently close to the upper bound as to be impractical for any real porous material. However, this upper bound directly leads to important realizations which should guide future development. Firstly, one could extract the gas at a higher temperature than that used while filling. Secondly, the fundamental physics of our upper bound do not rule out any material that changes its structure due to the presence of gas, suggesting that flexible materials could still satisfy the DOE target.
3:18PM U01.00005: Effective electrical conductivity of nanocarbon-metal composites made by the electrocharging assisted process*  
CHRISTOPHER KLINGSHIRN (Presenter), Materials Science and Engineering, University of Maryland, College Park, ANDREW PALUGHI, Materials Science and Engineering, Texas A&M University, XIAOXIAO GE, MADELINE MORALES, JESSICA YE, Materials Science and Engineering, University of Maryland, College Park, CHRISTOPHER SHUMEYKO, Aberdeen Proving Ground, U.S. Army Research Laboratory, TAHIR ÇAĞIN, Materials Science and Engineering, Texas A&M University, LOURDES SALAMANCA-RIBA, Materials Science and Engineering, University of Maryland, College Park — Robust materials with high conductivity are essential to electronic devices and systems. Novel composites called “covetics” have the potential to improve upon the electrical conductivity of established metals and alloys, including Al and Cu, by incorporating carbon nanostructures known for their superior electrical properties. During fabrication, electric current applied to the melt containing a C precursor is believed to ionize carbon atoms and cause nanoscale graphitic ribbons and chains to form within the metal lattice. This work combines fundamental assumptions about the nature of covetics, specifically a tightly bound metal-carbon interface, with a simple effective-medium model to estimate the bulk conductivity of ideal Al and Cu covetics with randomly distributed graphene nanoribbons. Density-functional theory estimates of charge transfer at the graphene-metal interface, local electrical conductivity measurements, and transmission electron microscopy investigation of the interface region provide inputs to the model. We find potential for improvements on the order of 10% under ideal conditions, but substantial processing challenges remain before these gains may be realized on an industrial scale.

3:30PM U01.00006: Optimizing the role of impact ionization in conventional insulators*  
EFSTRATIOS MANOUSAKIS (Presenter), Physics, Florida State University and University of Athens — A mechanism for multiple carrier generation through impact ionization (IA) proposed earlier for bulk systems of strongly correlated insulators is generalized to the case of conventional insulators that contain localized bands a few eV above and below the highest occupied band. Specifically, we study the case of hybridization of localized orbitals with more dispersive bands near the Fermi level, where the generated multiple carriers, which ultimately decay to the edges of the dispersive bands by means of IA processes, acquire lighter mass and this could allow their more efficient separation before recombination. We argue that this may be applicable to the case of halide perovskites and it could be one of the reasons for their observed photovoltaic efficiency. We discuss the criteria one should use to uncover the appropriate material in order to harvest the optimum effect of IA for the spectrum of the solar photon energy distribution.

*This work was supported in part by the U.S. National High Magnetic Field Laboratory, which is funded by NSF DMR-1157490 and the State of Florida.
3:42PM U01.00007: A Molecular Dynamics Study of Silicon Nanowire/Silica Aerogel Nanocomposite Thermal Conductivity  MITRA SEDEEQI (Presenter), BRUCE EDWARD WHITE, Binghamton University — Growing demand for waste heat recycling technology have accelerated research in efficient thermoelectric materials. Because silicon has a large Seebeck coefficient, can be easily doped to be both n-type and p-type and has high Earth abundance, research has focused on methods for reducing the lattice thermal conductivity of this material through nanostructuring techniques. In this work, Reverse Non-Equilibrium Molecular Dynamics (RNEMD) is applied to study the thermal conductivity of silicon-silica aerogel nanocomposites. Embedding the silicon nanowire in an aerogel is found to result in significant reductions to the lattice thermal conductivity of the nanowire when the surface of the nanowire is a major source of phonon scattering. These results can be explained based on the diffuse mismatch model of phonon transport at interfaces and point to a possible path to independently optimize the electronic components of a thermoelectric material from that of its lattice vibration components.

3:54PM U01.00008: Brownian Ratchets as Non-Traditional Energy Harvesters  ANTHONY CHO (Presenter), ARJENDU KISHORE PATTANAYAK, Carleton College — We seek to harness non-traditional forms of energy such as vibrations and blackbody radiation via Brownian ratchets. We have simulated particle diffusion in a thermal bath subject to an asymmetric (ratchet) potential. The potential has been studied using both white and colored noise to incur net directed transport. We find a minimum temperature for the thermal bath to obtain a maximum transport velocity dependent on the level of asymmetry and the diffusion constant. We also find that the transport velocity was equivalent regardless if the particle traveled in the direction of or against the bias.

4:06PM U01.00009: Elemental Additions to Enhance Precipitate Formation in Superalloys*  TYLER WHITAKER (Presenter), BRAYDEN BEKKER, HAYDEN S OLIVER, GUS HART, Physics and Astronomy, Brigham Young University — Recent discoveries of cobalt-based superalloys has sparked interest in finding new ternary alloy systems that exhibit the essential L1_2 precipitate hardening mechanism. The higher operating temperature of cobalt-based alloys translates to increases in fuel efficiency for energy applications. One recent high-throughput search identified six new potential superalloys, two of which were confirmed to be at least metastable. Using the Moment Tensor Potential (MTP) framework, we explore fourth element additions to these new ternary systems. Several elements lower the formation enthalpy of the L1_2 phase, possibly enhancing its stability. These elemental additions offer a promising direction in designing new superalloys.

4:18PM U01.00010: Proficient quantum energy storage for in-plane microsupercapacitor using hybrid nanocomposite*  MEENAKSHI TALUKDAR (Presenter), SUSHANT KUMAR BEHERA, PRITAM DEB, Tezpur University — Planar micro-supercapacitors with innovative characteristics are recognized as one of the most feasible next generation power source for incorporation in electronics devices. Microsupercapacitor (MSCs), in the world of microelectronics have engrossed more and more attention due to its power and energy storage capacity but achieving desired electrode structure design is still an open challenge. Our study has reported a novel concept of achieving synergic effect of both EDLC and pseudocapacitive in 2D architecture with ultra-high energy density and high capacitive retention, catering the need of fast growing energy demands in portable miniaturized storage device. This miniaturized micro-supercapacitor can offer a nano/micro-scale power source apposite to meet the applications which require higher operating currents and voltages in a short time-frame [DOI: 10.1039/C9DT02423A].

4:30PM U01.00011: Control of Quantum Energy Transport by Environmental Engineering*  CHIKAKO UCHIYAMA (Presenter), Yamanashi Univ — The energy transport in the light harvesting mechanisms of photosynthetic bacteria has attracted intensive attentions. Especially, the model proposed to describe the mechanism which shows that environmental noises can assist the energy transport[1] has been intensively studied, since the model has opened a way for biomimetic studies. However, the complexities of biological molecules have been obstacles to reproduce the mechanism of energy transport. To overcome the difficulty, we propose another way to control energy transport by an active control on environment. In this presentation, we show that we can accelerate an energy transport through a linear chain model by applying stochastic noises with spatial-temporal correlations[2]. Especially, we show that anti-spatial correlation and optimum correlation time can accelerate energy transport. We believe that the results show new possibilities to improve energy transport. [1] P. Rebentrost, et al., New J. Phys. 11, 033003 (2009); M. B. Plenio, and S. F. Huelga, New J. Phys. 10, 113019 (2008).[2] C. Uchiyama, W. J. Munro, and K. **4:42PM U01.00012: Stability of dynamically disordered materials from ab initio molecular dynamics**  
SERGEI SIMAK (Presenter), JOHAN KLARBRING, Linkoping University — Large atomic displacements and atoms vibrating without well-defined equilibrium positions are the signatures of dynamically disordered materials. These materials show immense potential in applications, such as superionic conductors, solid-state batteries, and fuel cells. The biggest obstacle in living up to this potential is the limited stability of the dynamically disordered phases. To predict it, the free energies have to be calculated. That has long been a challenge. We have introduced a method that offers a solution [1]. It relies on a density functional theory (DFT), ab initio molecular dynamics (AIMD), and stress-strain thermodynamic integration between the dynamically disordered phase and its metastable ordered variant. The successful application of the method to the stability of notorious cubic bismuth oxide and lithium carbide [2] will be discussed.

**4:54PM U01.00013: Framework Materials as Porous Liquids**  
RACHEL MOW (Presenter), Materials Science, Colorado School of Mines, WADE BRAUNECKER, THOMAS GENNETT, National Renewable Energy Laboratory — Porous liquids have recently been introduced as a new class of material with great potential for gas storage and purification. The permanent porosity and fluid properties of porous liquids provide an avenue for gas storage and transportation that avoids the processing restrictions of solid porous materials. Despite the promise of porous liquids, only a handful of these materials have been realized to date. This work develops porous liquids from covalent organic frameworks (COFs). Colloidal 3D imine-based COFs are synthesized with particle size control down to 60 nm. The colloidal COFs are suspended in a bulky ionic liquid solvent that is size-excluded from entering the COF pore, demonstrating a Type 3 porous liquid. Gas sorption studies are used to determine the gas uptake and adsorption enthalpy of hydrogen and other gases in the porous liquid. This work presents a new type of tunable organic porous liquid that can be used for gas storage and separation.

*The authors gratefully acknowledge research support from the Hydrogen Materials - Advanced Research Consortium (HyMARC), established as part of the Energy Materials Network under the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Fuel Cell Technologies Office, under Contract Number DEAC36-08-G028308*
5:06PM U01.00014: Order in the ground state of a simple cubic dipole lattice in an external field  
SAHEL ASHHAB (Presenter), MARCELO CARIGNANO, MOHAMED EL-AMINE MADJET, Qatar Environment & Energy Research Institute — Motivated by the presence of a lattice of rotating molecular dipoles in the high-temperature phase of methylammonium lead iodide, we investigate the ground state of a simple cubic lattice of dipoles interacting with each other via the dipole-dipole interaction and with an external field via the standard, linear dipole-field interaction. In the absence of an external field, the ground state is infinitely degenerate, and all the configurations in the ground state manifold are periodic along the three lattice axes with a period of two lattice sites. Using a 1000-dipole lattice as a unit cell in numerical simulations of an infinite simple cubic lattice, we determine the ground state dipole configurations in the presence of an external field. We then analyze the polarization, dipole orientation statistics and correlations in these configurations. Our calculations show that for some special directions of the external field the two-site periodicity in the dipole configurations is preserved, while in the general case this periodicity is lost and complex dipole configurations form under the influence of the external field. More specifically, a sudden transition from two-site periodic configurations to irregular configurations occurs at a finite value of the applied field strength.

5:18PM U01.00015: Kepler's Laws and Elliptic path might suggest that nature uses the function of TIME to provide needed energy for its accelerated motion*  
IBRAHIM HANNA (Presenter), Self — Classical physics correctly calculate planetary positions, and energy conservation as a function of position, however using Kepler's laws as a function of time, may conclude that potential energy available for a planet's motion, is bigger than kinetic energy used at the actual path, and have the path was to be circular, such energy difference would not exist. Keplers equation A^3/T^2 =Constant, as a function of time, may also explain how nature chooses the elliptic path, to gain such energy difference, from time, to maintain and finance its accelerated motion, where Time is a form of energy, and where the expansion of universe, is not measured by coordinates of positions, but by positive coordinates of time while black holes can be identified by negative coordinates of time.

2:30PM U02.00001: Shockwave diode: A new direction in shock physics

BRITTANY BRANCH (Presenter), Dynamic Material Properties, Sandia National Laboratories, JONATHAN SPOWART, ANDREW ABBOTT, GEOFFREY FRANK, DAVID LACINA, CHRISTOPHER NEEL, Air Force Research Laboratory — With the advent of additive manufacturing techniques, a new class of shockwave mitigation and structural supports have been realized through the hierarchical assembly of material. To date, there have been a limited number of studies investigating the role of structure on shockwave localization and whether AM offers a means to tailor shockwave behavior. Of particular interest is whether the mesoscopic structure can be tailored to achieve shockwave properties in one direction of impact versus the other. Here, we illustrate, for the first time, directional response in polymer-based foams that act as a one-way switch. In-situ time-resolved x-ray phase contrast imaging at the Advanced Photon Source was used to characterize these diode-like structures. This work offers a breakthrough in materials technology for the development of protection structures that are important for a broad range of applications and have been a long sought-after goal in shock research.

2:42PM U02.00002: Iron Response in Extreme Compression and Tension Regimes: Complementary NIF and Janus Experiments

GAIA RIGHI (Presenter), University of California, San Diego — Iron is the major component of the Earth’s solid inner core, so determining its strength under extreme conditions is crucial to understanding the rheology of Earth’s core and interpreting geophysical observations. Although it has been widely accepted that body centered cubic Fe will go through at least one, possibly more, phase transitions at high pressures, the influence of such a reversible phase transition on the strength of Fe is still unknown. Molecular dynamics simulations of shock-compressed single crystal bcc iron show that the newly formed epsilon phase is nanocrystalline. Strength dependence on grain size and strain rate has been investigated through campaigns at NIF and JLF. Preliminary results show that at ultra-high strain rates, initial grain size has no effect on material strength while at lower strain rate, minor effects can still be seen. The strength of iron at Earth core conditions achievable with NIF was found to be approximately 16 GPa, which is remarkably high. These results will lead to an improved understanding of asteroid impact dynamics, planetary formation dynamics, and interior structures of the earth, planets and exoplanets.
Particle-based studies in support of high-power laser experiments to study metal ejecta interactions

TOMORR HAXHIMALI (Presenter), Lawrence Livermore Natl Lab, MARCO J ECHEVERRIA, University of Connecticut, FADY MICHEL NAJJAR, Lawrence Livermore Natl Lab, PETROS TZEFERACOS, university of Chicago, SUZANNE J ALI, HYE-SOOK PARK, JON HENRY EGGERT, BRANDON E MORGAN, YUAN PING, Lawrence Livermore Natl Lab, HANS RINDERKNECHT, University of Rochester, ALISON SAUNDERS, Lawrence Livermore Natl Lab — Shock-driven material can emit a fine spray of ejecta from its free surface. Understanding the dynamic and interaction of the metal ejecta is important to areas of study as diverse as industrial safety, astrophysics, spacecraft shielding, and inertial confinement fusion.

We present results from particle-based dynamics at atomistic as well as macro-scale simulation studies of the ejecta formation in the presence of grooves at the free surface as a result of a shock wave created at the ablator-metal interface. At the atomistic level, we use large scale simulations, ~ $10^9$ atoms, to extract values of pressure breakout and release, as well as ejecta mass and velocity density. The fractality of the ejecta ligaments is also being investigated.

At the macro-scale, we use Smooth Particle Hydrodynamics for the same conditions. This provides valuable information to the experimental campaign on the OMEGA and OMEGA-EP lasers platforms for studying the ejecta formation. The metals studied are pure Cu and Sn. Time permitting, initial investigation of the effect of alloying will also be presented.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract DE-AC52-07NA27344. Lawrence Livermore National Security, LLC.
Lattice dynamics of laser-driven compressed Al studied with ultrafast electron diffraction

MIAZHEN MO (Presenter), SLAC - Natl Accelerator Lab, MINXUE TANG, The Peac Institute of Multiscale Sciences, ZHIJIANG CHEN, XIAOZHE SHEN, JOHN RYAN PETERSON, MUNG FROST, MICHAEL EDMUND KOZINA, ALEX REID, ADRIEN DESCAMPS, SLAC - Natl Accelerator Lab, JUNCHENG E, The Peac Institute of Multiscale Sciences, RENKAI LI, SLAC - Natl Accelerator Lab, SHENG-NIAN LUO, The Peac Institute of Multiscale Sciences, XIJIE WANG, SIEGFRIED GLENZER, SLAC - Natl Accelerator Lab — Understanding the lattice dynamics of shock-compressed materials is of great interest to many areas including planetary formation, aeronautics and spacecraft. Here we report the study on elastic-to-plastic strain transition in dynamically compressed Al using the technique of ultrafast-electron-diffraction (UED). The targets employed in our experiments are 200-nm-thick free-standing single-crystal Al thin films. The compression wave was launched normal to the sample surface by ablating the sample with a focused 800nm, 20ps, <12 mJ laser pulse. The lattice response of the sample was probed by MeV electrons coming from the opposite side at 45° incident angle. As the sample is compressed, we first observed the elastic response and then the plastic relaxation, indicated by shifts of the Laue peaks reflected from the normal and transverse lattice planes respectively. The dependence of this elastic-plastic transition on the pump fluence and crystal orientation were studied and the results will be presented. We also performed Molecular Dynamics simulations incorporated with hydrodynamics simulations to understand the underlying physics of the experimental observations and the results will be presented.

This work is supported by DOE Office of Science, Fusion Energy Science under FWP100182.

Modeling High Strain Rate Plasticity in BCC Lead

ROBERT RUDD (Presenter), LIN H YANG, ANDREW KRYGIER, PHILIP POWELL, DAMIAN SWIFT, CHRISTOPHER WEHRENBERG, JAMES M MCVaney, HYE-SOOK PARK, Lawrence Livermore Natl Lab, PETER GRAHAM, AWE — High-energy lasers enable determination of metal strength at very high pressures. Here we consider the strength (flow stress) of lead in the high-pressure body-centered cubic (bcc) phase at a peak pressure of ~400 GPa. Two previous models of Pb strength were built from the low-pressure fcc phase. Plasticity in bcc and fcc crystals can be very different. Experiments conducted at the National Ignition Facility have used ramp-compression to drive Rayleigh-Taylor instability and measured the ripple growth to infer strength in the bcc phase of lead and lead alloy [1]. We have developed an Improved Steinberg-Guinan model for bcc lead strength [2] using ab initio calculations of the shear modulus at pressure that agrees well with those experiments. The alloying, which increases strength 4x at ambient conditions, has no measurable effect at high-pressure.

This work was performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344.
3:30PM U02.00006: Effect of peak stress on spall in copper and a copper-lead alloy*  DAVID ROBERT JONES (Presenter), SARYU FENSIN, MST-8, Los Alamos National Laboratory — Spall fracture is often seen in shock loaded materials. It has been shown extensively that spall is a weak-link driven event, with microstructural features such as grain boundaries, impurities, porosity etc. acting as nucleation sites for voids and cracks. Here, we present results studying spall fracture in a two-phase material, copper-lead. The alloy contains approximately 1% lead, which is contained as precipitates primarily at the copper grain boundaries. The effect of the peak compressive stress prior to spall is investigated, with a pure copper target also included as a control. It is shown that this small amount of lead drastically reduces the spall strength. Further, the spall strength of the copper-lead alloy begins to decrease at a far lower peak stress than the pure copper. Modeling efforts, at both continuum and molecular dynamics length scales, are used to elucidate the reasons behind these results. Initial conclusions are based on the slow wave velocities in the lead compared to the copper leading to a ‘shock-focusing’ in the lead precipitates, causing thermal softening and even melt, producing weak points and lowering the spall strength.

*DOE Science Campaign 2

3:42PM U02.00007: Towards a Dynamic Thermal Conductivity Measurement: Temperature Convergence of Iron Coatings to a Bulk Temperature Source*  DAVID BRANTLEY (Presenter), MARKUS DAENE, RYAN CRUM, HANNAH SHELTON, MINTA C AKIN, Lawrence Livermore Natl Lab — The thermal conductivity of iron under Earth’s core temperatures and pressures is a critical parameter in models of the geophysical history of Earth's core. Recent DAC measurements and first principles calculations have presented conflicting trends in the thermal conductivity as a function of temperature and pressure, leading to large uncertainties in the predicted age of Earth's solid inner core. Confidently resolving this discrepancy requires corroborative conductivity measurements using multiple experimental methodologies, however dynamic compression experiments have so far suffered from uncontrolled systematics. We present the results of gas gun experiments testing the convergence of coating temperatures to a bulk temperature source. A series of experiments were performed at 50 and 120 GPa, where Fe and Sn were used as coating and temperature source materials. Temperature of the coating material was measured using optical pyrometry, and simulations were performed which show matching trends in the observed temperature data for a range of input thermal conductivity values.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344 LLNL-ABS-795546
3:54PM U02.00008: “Reflectance Thermometry for Time-Resolved Measurements of Low-Temperature Compression on Sandia’s Z Machine”* KALEB BURRAGE (Presenter), PATRICIA KALITA, RICHARD HACKING, CHRISTOPHER T SEAGLE, Sandia National Labs, YOGESH VOHRA, Univ of Alabama - Birmingham, DAN DOLAN, Sandia National Labs — Pulsed current from Sandia’s Z machine compresses samples to 10-1000 GPa pressures on nanosecond time scales. Such rapid compression results in 10-100,000 K temperature (T) changes, depending on how loading is applied. Shock compression of solids leads to T above 2000 K, whereas ramp compression to the same pressure leads to T below 1000 K. Optical pyrometry is well-suited for the former but impractical for the latter—samples do not emit enough photons for such high-speed measurements. To fill this gap, we are investigating the thermo-reflectance of aluminum as an optical thermometer. Aluminum has an absorption feature at 1.5 eV that shifts to higher energy under static compression and in the opposite direction upon heating. We carried out static compression of Al in diamond anvil cell at high T, coupled with reflectivity measurements. The distinction between absorption energies at higher T for any given pressure is promising for the calibration of an optical thermometer for Z.

*Math Physics, Sandia National Laboratories, is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.

4:06PM U02.00009: Single ultrafast x-ray pulse imaging and diffraction of mesoscale shockwave dynamics* RICHARD SANDBERG (Presenter), Brigham Young Univ - Provo, CYNTHIA BOLME, Los Alamos National Laboratory, ARIANNA E GLEASON, SLAC National Accelerator Laboratory, KYLE RAMOS, QUINN MCCULLOCH, SHAWN DAVID MCGRANE, MARC CAWKWELL, DARBY J LUSCHER, Los Alamos National Laboratory, BOB NAGLER, ERIC GALTIER, SLAC National Accelerator Laboratory, PHILIP HEIMANN, HAEJA LEE, Los Alamos National Laboratory — The revolution in accelerator based x-ray sources known as x-ray free electron lasers are drastically changing the way we understand materials, especially in extreme conditions. With the intense, ultrafast, and coherent x-ray pulses provided by these new sources, we are now able to probe inside materials under extreme conditions at unprecedented temporal and spatial resolutions. In this talk, I will review work on understanding materials strength, damage, and failure mechanisms under shock loading conditions using x-ray diffraction and coherent diffraction imaging at the world's first hard x-ray free electron laser, the Linac Coherent Light Source. We study materials in such condition as the effect of pore collapse in the high explosive PETN and Richtmyer–Meshkov Instabilities off of copper samples that have been shocked by a high energy laser.

*We acknowledge use of the Linac Coherent Light Source, a DOE Office of Science User Facility. This work was supported by Los Alamos Laboratory Research and Development (LRDR) program and the Dynamic Materials Properties Campaign (C2) at Los Alamos National Laboratory, an affirmative action equal opportunity employer, managed by Triad National Security, LLC for the U.S. DOE NNSA, under contract 89233218CNA000001.
4:18PM U02.00010: Role of Heterogeneities in Ejecta via MD Simulation* RACHEL FLANAGAN (Presenter), Department of Mechanical and Aerospace Engineering, University of California, San Diego, TIMOTHY GERMANN, Theoretical Division, Los Alamos National Laboratory, MARC A MEYERS, Department of Mechanical and Aerospace Engineering, University of California, San Diego, SARYU FENSIN, Materials Science & Technology, Los Alamos National Laboratory — We investigate the shock behavior of copper seeded with heterogeneities via molecular dynamics simulations. Specifically, we aim to understand the influence of heterogeneities such as atomic defects and bubbles on ejecta production in copper. Since shock melting plays a key role in ejecta production, microstructure was previously thought to not matter, but recent results suggest that different microstructures alter the mechanism through which ejecta is produced. For example, the presence of helium bubbles near the free surface of copper has been shown to nearly triple ejecta production due to a loss of planarity at the shock front. We analyze the size and velocity distributions to understand the mechanisms of ejecta production and the influence of heterogeneities on material strength. The ultimate goal of this work is to inform and elucidate upon parallel experiments, where data collection presents a significant challenge. LA-UR-19-26660

4:30PM U02.00011: Shock-induced consolidation of tungsten nanoparticles - a molecular dynamics approach* JIANRUI FENG (Presenter), CHEN PENGWAN, Beijing Institute of Technology — Shock-induced consolidation of tungsten nanoparticles to form a bulk material is modeled through molecular dynamics simulation. By arranging the nanoparticles in a three-dimensional model of BCC super-lattice, the calculated shock velocity-particle velocity Hugoniot data is in good agreement with the experiment. Three states, including solid-undensified, solid-densified and liquid-densified can be sequentially obtained with the increase of impact velocity. It is the flow deformation at the particle surface that densifies the cavity, and the high pressure and temperature that join the particles together. Melting is not a necessary factor for shock consolidation. Based on whether melting takes place, the consolidation mechanism can be considered as solid-pressure welding or liquid-diffusion welding.

*China Postdoctoral Science Foundation funded project under grant No. 2019M650504.
4:42PM U02.00012: Particle breakage of granular materials subject to explosion  KUN XUE (Presenter), CHUANSHAN ZHANG, Beijing Institute of Technology — Unconfined granular medium subjected to central explosion experiences transient stresses and strains which are distributed heterogeneously. The particle breakage are markedly different from the fractal fracture of granular materials under confined comminution which are typical in the quasi-static and dynamic compression experiments. The particle size distribution of shocked particles recovered from the explosive dispersal of particle shells consisting of glass spheres reveal varying breakage modes depending on the mass ratio of payload and charge, M/C. When M/C is small, the particle size distributions of blasted materials shows three regimes, and the second regime satisfies fractal distribution. The fractal dimension of the second regime ranges from 2.9 to 2.5 with increasing M/C. With M/C beyond a threshold, an increasing amount of particles remains intact, the particle size distributions of fractured materials transitions to a two-regime mode, in which the fractal dimensions are well below 2 and progressively decreases with increasing M/C. The distinct behaviors of particle breakage are a result of the compound and transient loadings due to a sequence of incident shock, unloading and reshock as revealed by grain scale investigations using FDEM.

4:54PM U02.00013: SHOCK COMPRESSIBILITY AND SPALL STRENGTH OF TWO COMPOSITE MATERIALS BASED ON ARAMID FIBERS* VALENTINA MOCHALOVA (Presenter), ALEXANDER UTKIN, Institute of Problems of Chemical Physics RAS — Using a VISAR laser interferometer, the experiments on investigation of the shock wave structure, spall strength and determination of Hugoniot were performed for two composites based on aramid fibers - textolite and kevlar. They have the same compound, but different structure. The density is 1.27 g/cc. To study the shock wave compressibility of composites under extreme conditions, the explosive propellant charges were used. On the velocity profiles with transverse fiber orientation, for both materials after the initial shock jump, oscillations are observed due to the heterogeneous structure. When a shock wave propagates along the fibers, a two-wave configuration is recorded, which is due to the anisotropic structure. For each composite, Hugoniot data were obtained for two orientations. It was found that Hugoniots for transverse orientation of the fibers are parallel to each other and differ only in the first coefficient determined by the sound speed of the material. For both materials, the value of spall strength along the fibers is several times higher than that for the transverse direction. It was found that shock wave properties of textolite and kevlar were strongly dependent on the orientation and structure of the fibers.

Session U07 DQI: Hybrid Systems - Diamond Color Centers, Magnonics
102 - Dolev Bluvstein, Harvard University - Tag(s): Focus
Coherent storage of microwave photons over 100ms in an ensemble of electron spins. EMMANUEL FLURIN (Presenter), VISHAL RAJAN, EMANUELE ALBERTINALE, DANIEL ESTEVE, PATRICE BERTET, CEA Saclay — Electron and nuclear spins in crystals are attractive for storing quantum information due to their long coherence times in pure matrices. Bismuth donors in silicon have the particular appeal to possess special biasing points (the so-called “clock transitions”) at which the electron spin becomes insensitive to first-order to magnetic field noise, yielding long coherence times [1]. Here we report the coupling of a small ensemble of \( \approx 10^4 \) Bismuth donors in silicon to a superconducting micro-resonator at a clock-transition, at millikelvin temperatures. At this point, we measure a Hahn-echo coherence time of up to \( T_2=300 \text{ms} \). This makes it possible to store coherently a train of weak microwave pulses of \( \approx 10 \) photons over 100ms. [2]

Optomechanically induced selective emitter—emitter interactions for control of quantum networks* TOMAS NEUMAN (Presenter), MATTHEW TRUSHEIM, DEREK WANG, ISAAC HARRIS, PRINEHA NARANG, SEAS, Harvard University — Quantum emitters such as point-defects (artificial atoms) in diamond [1] can be used as elementary building blocks (qubits) of quantum information systems. The function of a a quantum network, however, also relies on efficient qubit-qubit interactions and thus allowing for practical implementation of quantum gates. Here we suggest a coupling scheme where optically active qubits (e.g. artificial atoms in diamond) of different excitation frequencies are dispersively coupled to a shared mode of an optical cavity. The cavity induces an effective generally off-resonant qubit-qubit interaction [2] prohibiting direct exchange of information among these qubits. By applying coherent acoustical driving [3] to modulate the qubit frequencies it is possible to bring to resonance a desired subset of qubits and thus selectively open an inter-qubit communication channel. We theoretically demonstrate this principle by solving the quantum master equation both numerically and analytically and suggest practical experimental scenarios to test our predictions.

2:54PM U07.00003: Optically hyperpolarized nanodiamonds: quantum control and avenues for signal-enhanced NMR  ASHOK AJoy (Presenter), EMANUEL DRUGA, XUDONG LV, University of California, Berkeley, CARLOS MERILES, City College of New York, JEFFREY A REIMER, ALEXANDER PINES, University of California, Berkeley — I will describe quantum-assisted modalities to deliver signal enhancements in conventional MRI and NMR mediated by quantum defects in nanodiamond powder. This relies on the use of Nitrogen-Vacancy (NV) center spins within the diamond particles that can be optically polarized at room temperature with modest laser powers. This polarization can be transferred to nuclei surrounding the NV spins to hyperpolarize them to levels far above Boltzmann levels, manifesting in a highly enhanced NMR signature. Nanodiamonds are particularly suited for this task, given their large surface areas, and the ability to arrange for close physical contact between the polarized NVs and analyte molecules of interest.

I will discuss our experimental effort in this direction, particularly focusing on new results, including in the prolongation of relaxation and coherence times of hyperpolarized spins, as well as materials advances that yield substantial improvements in $^{13}$C lattice hyperpolarization levels, and new applications in dual-mode (optical and NMR) hybrid electron-nuclear magnetometers constructed out of hyperpolarized nanoparticles.

3:06PM U07.00004: Design and fabrication of large-scale diamond quantum memories in hybrid photonic circuits*  TSUNG-JU LU (Presenter), NOEL WAN, KEVIN CHEN, MICHAEL P WALSH, MATTHEW TRUSHEIM, LORENZO DE SANTIS, ERIC A BERSIN, ISAAC HARRIS, SARA MOURADIAN, Massachusetts Institute of Technology MIT, EDWARD S BIELEJEC, Sandia National Laboratories, DIRK R. ENGLUND, Massachusetts Institute of Technology MIT — A central goal in quantum information processing is the development of scalable quantum processors and quantum networks. Towards this end, solid-state “artificial atoms” such as color centers in diamond are especially promising because they combine efficient optical interfaces, minutes of spin coherence, and potentially very-large-scale fabrication. Here, we describe the design, fabrication, and integration of diamond quantum micro-chiplets containing single SiV and GeV centers with photonic integrated circuits (PICs). A near-deterministic photonic nanofabrication produces unity coupling of emitters to single-mode diamond waveguide arrays, which are subsequently assembled on an aluminum nitride PIC for on-chip routing and manipulation of photons. The combination of these advances allows the construction of a 72-channel quantum memory microphotonic chip. The ability to assemble large numbers of quantum memories with phase-stable PICs enables an architecture for high-efficiency, multiplexed quantum repeaters on a chip.

*We acknowledge support from ARL CDQI, NSF EFRI ACQUIRE, NSF CUA, NSF CIQM, DoD NDSEG, NSF GRFP, IC Postdoctoral Fellowship, MIT Lincoln Lab, NASA Space Technology Research Fellowship
3:18PM U07.00005: Characterizing a 72-channel defect-free array of diamond quantum memories in a photonic integrated circuit*

NOEL WAN (Presenter), TSUNG-JU LU, KEVIN CHEN, MICHAEL P WALSH, MATTHEW TRUSHEIM, LORENZO DE SANTIS, ERIC A BERSIN, ISAAC HARRIS, SARA MOURADIAN, Massachusetts Institute of Technology MIT, EDWARD S BIELEJEC, Sandia National Laboratories, DIRK R. ENGLUND, Massachusetts Institute of Technology MIT — In a previous abstract, we described the unity creation, coupling and integration of diamond "artificial atoms" of silicon vacancy (SiV) and germanium vacancy (GeV) centers with a large-scale photonic integrated circuit (PIC) in aluminum nitride. Here, we present the characterization of our 72-channel quantum memory chip. First, we demonstrate the routing of single-photon emission from 72 distinct optical channels in a fiber-coupled PIC. We performed low-temperature spectroscopy of the emitters, finding near-lifetime-limited optical transitions from both SiV and GeV centers following nanofabrication, micromanipulation, and heterogeneous integration. Additionally, we demonstrate the tuning of optical transitions with the same integrated system, overcoming the spectral inhomogeneities between separate emitter-waveguide systems. These advances set the stage for high-rate, multi-channel photon-mediated entanglement for quantum repeaters and computers.

*We acknowledge support from ARL CDQI, NSF EFRI ACQUIRE, NSF CUA, NSF CIQM, DoD NDSEG, NSF GRFP, IC Postdoctoral Fellowship, MIT Lincoln Lab, NASA Space Technology Research Fellowship

3:30PM U07.00006: Nanophotonic Quantum Registers based on Silicon Vacancy Centers in Diamond*

ERIK KNALL (Presenter), MIHIR K BHASKAR, CHRISTIAN NGUYEN, RALF RIEDINGER, BARTHOLOMEUS J MACHIELSE, DAVID LEVONIAN, PAVEL STROGANOV, DENIS D SUKACHEV, HONGKUN PARK, MARKO LONCAR, MIKHAIL LUKIN, Harvard University — The development of scalable quantum technologies requires robust and well controlled quantum systems. Integrated solid-state devices are particularly promising because lithographically defined systems offer a route toward mass production. Recent progress in diamond nanofabrication has opened the door to unprecedented control of an optically accessible solid-state quantum memory, the silicon vacancy center in diamond. Integration of this point defect into a nanophotonic cavity combined with efficient photon detection recently enabled a proof-of-principle demonstration of memory enhanced quantum communication. In this talk, I will discuss how interfacing with nearby nuclear spins as well as improved device design and fabrication continue to push this system’s capabilities as a platform for foundational demonstrations of memory based quantum communication.

Coupling an Inverted Spin Ensemble to a Microwave Resonator

JASON BALL (Presenter), PETER MOROSHKIN, SHOTA NORIMOTO, DENIS KONSTANTINOV, YUIMARU KUBO, Quantum Dynamics Unit, Okinawa Inst of Sci & Tech — Using an ensemble of nitrogen (P1) centers in diamond placed inside a 3-D loop-gap resonator, we observe population inversion of a satellite P1 transition when a microwave pump tone is applied to the central P1 transition. This inversion is manifested by amplification of the probe tone applied to the satellite transition. A mechanism for generating this inversion is proposed, involving higher-order cross relaxations within the P1 centers [1] and spin flip-flops with nearby nitrogen-vacancy (NV) centers that are also present in the diamond sample.

We also observe a splitting of this amplifying peak due to coupling with the microwave resonator. The polariton modes created by this coupling differ qualitatively from the standard, non-inverted case, in particular lacking an avoided crossing [2]. We modeled this “abnormal” anticrossing by assuming a “negative ensemble coupling constant,” and find that the model is consistent with the observed experimental data.

Coherent coupling of V[TCNE]x≈2 magnons to NV center spins

DENIS CANDIDO (Presenter), University of Iowa, GREGORY FUCHS, Cornell University, MICHAEL FLATTÉ, University of Iowa — The application of a rf magnetic field in magnetic materials yield the creation of magnons (spin waves) [1]. For the organic V[TCNE]x≈2 ferrimagnetic material [2], those magnons are found to have very long spin lifetime, thus enhancing the practical chances for applications. In our work, these excitations are coherent coupled – through the magnon fringe fields – to the spin of a Nitrogen-Vacancy (NV) center within a diamond substrate, placed below our magnetic structure. Interestingly, this coherent coupling has the potential to solve the problem of the communication between local qubits at low temperatures and optical photons, a necessary ingredient for networking and quantum communication. Here, we calculate the magnon spectrum, fringe fields and magnetizations profiles for V[TCNE]x≈2 disks. In addition, we also derive an effective Hamiltonian describing the coupling between NV center spins and magnons. We calculate the realistic effective Hamiltonian parameters, e.g., the spin-magnon coupling, for different physical setups.

*The material is based on work supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Award Number DE-SC0019250.
4:06PM U07.00009: Cavity mediated interactions and strong entanglement between YIG samples without using intrinsic nonlinearities.*  JAYAKRISHNAN MUTTATHIL
PRABHAKARAPADA NAIR (Presenter), GIRISH AGARWAL, Texas A&M University — A question attracting great attention is the possibility of quantum entanglement between macroscopic systems. Several systems like cold atomic ensembles; opto and electromechanical systems have been reported. It turns out that the magnetic systems like the excitations in YIG spheres in cavities could be excellent candidates for the quantum information tasks.
We study this new platform for producing quantum characteristics. In particular we present a novel scheme to generate an entangled pair of yttrium iron garnet (YIG) samples in a cavity system. A novel aspect of our proposal is that it does not involve any nonlinearities which are typically very weak. This is against the conventional wisdom which necessarily requires strong Kerr like nonlinearity. Our key idea, which leads to entanglement, is to drive the cavity by a weak strictly quantum field like squeezed vacuum field which can be generated by a flux-driven Josephson parametric amplifier (JPA). The two YIG samples interact via the cavity. We demonstrate a high degree of macroscopic entanglement that can survive up to temperatures like 300-500mK. The entanglement is tested using several different quantitative criteria. We also find the optimal parameter regime for entanglement.

*Thank the support of the HEEP fellowship

4:18PM U07.00010: Improving coupling strengths and lifetimes in quantum magnonics*
DANY LACHANCE-QUIRION (Presenter), SAMUEL PIOTR WOLSKI, YUTAKA TABUCHI, Research Center for Advanced Science and Technology, The University of Tokyo, SHINGO KONO, Center for Emergent Matter Science, RIKEN, YOSHIKI SUNADA, KOJI USAMI, YASUNOBU NAKAMURA, Research Center for Advanced Science and Technology, The University of Tokyo — Quantum magnonics is an architecture in which collective modes of spin excitations in magnetically-ordered systems interact coherently with superconducting qubits. One of the main milestones to be demonstrated in quantum magnonics is the creation and observation of macroscopic quantum states of magnons. This task is challenging due to (i) the second-order nature of the effective interaction between magnetostatic modes and superconducting qubits and (ii) the relatively high relaxation rate of magnons. The first challenge is tackled by using a three-dimensional lumped-element microwave cavity designed to optimally enhance the effective coupling strength up to a few tens of MHz. Furthermore, we have observed that two-level systems (TLSs) in yttrium iron garnet at millikelvin temperatures have lifetimes much longer than the magnon lifetime. The long lifetime of the TLSs could potentially enable us to perform quantum magnonics experiments in an out-of-equilibrium situation where magnon decay is partially suppressed. Both advances are important steps towards the observation of quantum states of magnons.

*This work is partly supported by JSPS KAKENHI (26220601, 18F18015), JST ERATO (JPMJER1601), JSPS and FRQNT Postdoctoral Fellowships, and the MEXT Monbukagakusho Scholarship.
4:30PM U07.00011: High frequency ferromagnetic spectroscopy enabled by coupling pairs of magnons to NV spins*  BRENDA MCCULLIAN (Presenter), AHMED THABT, Ohio State Univ - Columbus, BENJAMIN GRAY, Materials and Manufacturing Directorate, Air Force Research Laboratory, ALEX MELENDEZ, Ohio State Univ - Columbus, MICHAEL WOLF, VLADIMIR L SAFONOV, Materials and Manufacturing Directorate, Air Force Research Laboratory, DENIS PELEKHOV, Ohio State Univ - Columbus, VIDYA P BHALLAMUDI, Indian Institute of Technology Madras, MICHAEL PAGE, Materials and Manufacturing Directorate, Air Force Research Laboratory, P CHRIS HAMMEL, Ohio State Univ - Columbus — Coupling NV center defects in diamond to ferromagnetic dynamics is of interest for both quantum sensing and for NV spin manipulation. We have used NV relaxometry to detect driven ferromagnetic dynamics in a low-damping insulating ferrimagnet, nickel zinc aluminum ferrite. We determine that NV coupling to driven magnetization has two regimes: first, when the uniform mode FMR frequency is less than the NV spin resonance frequency, and the converse. A driven spinwave instability in the nickel ferrite populates the magnons far above thermal levels. The spectral response of NV-ferromagnet coupling in the first regime can be understood from the spinwave instability physics. The second regime of NV-ferromagnet coupling can be understood via a two-magnon relaxation process. These results further the understanding of how driven ferromagnetic dynamics lead to NV spin relaxation, and demonstrate the potential to detect magnons with frequencies well above the NV frequency.

*Funding was provided primarily by the Center for Emergent Materials at The Ohio State University, an NSF MRSEC through Award No. DMR-1420451, with partial support from ARO through Award No. W911NF-16-1-0547 and by the AFOSR through Award No. FA9550-15RXCOR198.

4:42PM U07.00012: Electrical switching of spin-magnon interaction*  ABHISHEK SOLANKI (Presenter), SIMEON BOGDANOV, AVINASH RUSTAGI, NEIL ROSS DILLEY, TINGTING SHEN, PUNYASHLOKA DEBASHIS, ZHIHONG CHEN, JOERG APPENZELLER, YONG CHEN, VLADIMIR SHALAEV, PRAMEY UPADHYAYA, Purdue Univ — In recent years, strong interaction between surface confined propagating spin waves in ferromagnetic materials and single spins in color centers of diamond has been utilized for applications like quantum sensing and coherent driving of spins. The ability to switch this interaction electrically is essential to deterministically couple two spins via spin waves. In this work, we demonstrate electrical tuning of the coupling between spin waves and electron spins of nitrogen-vacancy centers (NV) in diamond. We electrically tune the magnon dispersion in thin CoFeB films, putting them in and out of resonance with the NV spin levels. The room-temperature magnetic noise of spin-waves affects the spin relaxation rate in NVs, in good quantitative agreement with analytical calculations. Our work opens up considerable opportunities for utilizing hybrid platforms combining quantum degree of freedom spins with macroscopic spin-waves in spin-based information and nanoscale sensing.

*We acknowledge NSF grant DMR-1838513

4:54PM U07.00013: Optical quantum nondemolition measurement of a solid-state spin without a cycling transition [Invited]  JEFF THOMPSON (Presenter), Princeton University — Jeff Thompson has led the development of a new platform for hybrid systems, coupling a solid state system - implanted erbium ions - with a silicon nanophotonic resonator.
2:30PM U08.00001: Two-qubit coupler with exponential suppression of virtual interactions*

CATHERINE LEROUX (Presenter), AGUSTIN DI PAOLO, ALEXANDRE BLAIS, Universite de Sherbrooke
— We present a superconducting two-qubit coupler where a tunable bus interacts with a driven mode such as to, on demand, exponentially suppress the qubit-qubit virtual interactions with respect to the amplitude of the external control field. The proposed mechanism can be combined with tuning the bus frequency, which is the standard approach to suppress dispersive interactions, thus making current tunable bus designs more efficient.

*This work was undertaken thanks in part to funding from NSERC and the Canada First Research Excellence Fund.

2:42PM U08.00002: Suppression of Qubit Crosstalk between Transmons and Capacitively Shunted Flux Qubits : Part1, Experiment

JASEUNG KU (Presenter), BRITTON L PLOURDE, Syracuse University, JARED HERTZBERG, MARKUS BRINK, DAVID MCKAY, JERRY M. CHOW, IBM Thomas J. Watson Research Center, XUEXIN XU, MOHAMMAD ANSARI, Forschungszentrum Julich — In multi-qubit cQED systems, the static ZZ crosstalk can be a limiting factor for high-fidelity two-qubit gates. Thus, mitigating such ZZ interactions becomes critically important for achieving high-fidelity entangling gates as the number of qubits increases. One potential way to suppress the static ZZ interaction involves combining different types of qubits. Capacitively shunted flux qubits (CSFQs), in contrast to transmon qubits, possess relatively large and positive anharmonicity. When they are paired with an appropriate detuning, the static ZZ term can be significantly suppressed for two-qubit gates based on the cross resonance interaction. We fabricated a two-qubit system consisting of a CSFQ and a fixed-frequency transmon coupled via a bus cavity. In this talk, we will present experimental results from these measurements, including the ZZ crosstalk and two-qubit gate fidelity versus detuning between the two qubits.
2:54PM U08.00003: Suppression of Qubit Crosstalk between Transmons and Capacitively Shunted Flux Qubits: Part 2, Theory  
XUEXIN XU (Presenter), MOHAMMAD ANSARI, Forschungszentrum Juelich, JASEUNG KU, BRITTON L PLOURDE, Syracuse University, JARED HERTZBERG, MARKUS BRINK, DAVID MCKAY, JERRY M. CHOW, IBM Thomas J. Watson Research Center — We compare two-qubit superconducting circuits composed of either different-species qubits or all-transmon qubits. In the different-species case, we use qubits with the opposite sign of anharmonicity, while for the all-transmon circuit, both qubits have a negative anharmonicity. We show that there are unique features in the different-species approach that makes it attractive for use in near-term quantum computers. Circuits with different-species qubits are capable of fast two-qubit gates and they allow for complete cancellation of ZZ crosstalk interactions. Our theoretical results are in agreement with an experiment on a two-qubit device consisting of a capacitively shunted flux qubit and a transmon and show a promising way to improve two-qubit gate operations.

*Support from Intelligence Advanced Research Projects Activity (IARPA) under Contract No. W911NF-16-0114 is gratefully acknowledged

3:06PM U08.00004: High fidelity encoded gate operations for composite superconducting qubit  
YUN-PIL SHIM (Presenter), Laboratory for Physical Sciences, DANIEL L CAMPBELL, BHARATH KANNAN, RONI WINIK, Research Laboratory of Electronics, Massachusetts Institute of Technology, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, JONILYN YODER, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, WILLIAM OLIVER, Research Laboratory of Electronics, Massachusetts Institute of Technology, CHARLES TAHAN, Laboratory for Physical Sciences — Our encoded qubit scheme for superconducting transmon qubits explores a non-traditional architecture where the computational states are encoded by the hybridized states formed by a pair of capacitively coupled degenerate transmons. Gate operations can be implemented on the encoded qubit using non-adiabatic Landau-Zener control at the small avoided crossing and requiring only baseband control, without individual microwave control for each transmon. Even with frequencies far below the effective temperature, high fidelity encoded gates can be achieved utilizing the sweet spot (optimal operating point) and dynamical sweet spot (optimal pulse shape). Further, these composite qubits show immunity to photon noise in readout resonators, which can be a limiting factor in many transmon-based quantum computing systems, often requiring special attenuators to mitigate. We also discuss the leakage errors due to relaxation to the physical ground state which is outside of the encoded qubit's computational subspace.

3:18PM U08.00005: A multi-qubit gate for non-interacting qubits in circuit-QED using the Zeno effect  
CHEN MOR, BOAZ KOREN, ASAF DIRINGER, SHAY HACOHEN-GOURGY (Presenter), Physics, Technion - Israel Institute of technology — The quantum Zeno effect is known for freezing dynamics due to observation. The observation can also confine the evolution to an unobserved subspace of the system. This confinement can lead to non-trivial evolution. We show that using a single qubit drive, and a strong continuous observation that blocks part of the evolution, we can create a multi-qubit entangling gate between non-interacting qubits. We use transmon qubits coupled to a 3D cavity. The qubits are far detuned from each other, such that they are effectively non-interacting. We present the experimental results and discuss the fidelity and limitations of this gate.
**3:30PM U08.00006: Cross-resonance Dynamics with Tunable Transmon Qubits**

BRADLEY MITCHELL (Presenter), RAVI KAUSHIK NAIK, AKEL HASHIM, JOHN MARK KREIKEBAUM, IRFAN SIDDIQI, University of California, Berkeley — The cross-resonance gate is a widely-utilized entangling gate in modern superconducting quantum processors. Recent theoretical work [1] has illustrated that the dynamics of the cross-resonance interaction depend strongly on circuit and control parameters, such as frequency detuning and the effective coupling rate. We experimentally investigate the dynamics of the cross-resonance gate across a range of qubit detuning, intrinsic coupling strength, drive frequency, and compare our findings with the model.

**3:42PM U08.00007: Density Matrix Exponentiation on a Superconducting Quantum Processor (Part 1): Introduction and construction**

MORTEN KJAERGAARD (Presenter), Massachusetts Institute of Technology MIT, MOLLIE SCHWARTZ, MIT Lincoln Laboratory, AMY GREENE, GABRIEL SAMACH, Massachusetts Institute of Technology MIT, ANDREAS BENGTTSSON, Chalmers University of Technology, MICHAEL O'KEEFFE, MIT Lincoln Laboratory, CHRIS MCNALLY, YOUNGKYU SUNG, MILAD MARVIAN, Massachusetts Institute of Technology MIT, PHILIP KRANTZ, Chalmers University of Technology, JOCHEN BRAUMUELLER, RONI WINIK, Massachusetts Institute of Technology MIT, DAVID K KIM, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, JONILYN YODER, DANNA ROSENBERG, KEVIN OBENLAND, TERRY PHILIP ORLANDO, MIT Lincoln Laboratory, IMAN MARVIAN, Duke University, SIMON GUSTAVSSON, SETH LLOYD, WILLIAM OLIVER, Massachusetts Institute of Technology MIT — In conventional quantum processors, the parameters of the unitary operators to be implemented as part of a quantum circuit are controlled using classical hardware. Here we experimentally demonstrate a two-qubit implementation of the Density Matrix Exponentiation (DME) algorithm, in which the unitary operators of a quantum circuit are programmed by other quantum states. By using multiple copies of a quantum state, the DME algorithm efficiently implements a unitary operator with that state acting as a Hamiltonian. In Part 1 of this talk, we will introduce the DME algorithm, its uses, and our experimental implementation on a small quantum processor using a 99.7% fidelity CPHASE gate between two superconducting transmons.

*This research was funded in part by the ARO grant No. W911NF-18-1-0411; and was funded in part by the Assistant Secretary of Defense for Research & Engineering via MIT Lincoln Laboratory under Air Force Contract No. FA8721-05-C-0002. Density Matrix Exponentiation on a Superconducting Quantum Processor (Part 2): Demonstration and Characterization*  

MOLLIE SCHWARTZ (Presenter), MIT Lincoln Laboratory, MORTEN KJAERGAARD, AMY GREENE, GABRIEL SAMACH, Massachusetts Institute of Technology, ANDREAS BENGTSSON, Chalmers University of Technology, MICHAEL O’KEEFFE, MIT Lincoln Laboratory, CHRIS MCNALLY, YOUNGKYU SUNG, MILAD MARVIAN, Massachusetts Institute of Technology, PHILIP KRANTZ, Chalmers University of Technology, JOCHEN BRAUMUELLER, RONI WINIK, Massachusetts Institute of Technology, DAVID K KIM, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, JONILYN YODER, DANNA ROSENBERG, KEVIN OBENLAND, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, Massachusetts Institute of Technology, IMAN MARVIAN, Duke University, SIMON GUSTAVSSON, SETH LLOYD, WILLIAM OLIVER, Massachusetts Institute of Technology — Density matrix exponentiation (DME) represents a unique style of quantum operation, in which many copies of a quantum state $\rho$ are used to perform a unitary operation $U(\rho, \theta) = e^{i\rho\theta}$ on a second quantum system $\sigma$. Traditionally, changing an operation on $\sigma$ requires changing a sequence of classically-defined gates; in DME, a fixed gate sequence performs a range of operations simply by varying the quantum input. DME is a Trotter-style algorithm, in which the total angle of rotation $\theta$ is built up by performing $N$ rotations of $\theta/N$ with algorithmic error $\theta^2/N$. In Part 2 of this talk, we benchmark an implementation of the DME algorithm in a two-qubit system. We characterize $U(\rho, \theta)$ via process tomography, and demonstrate that the unitary depends on the input quantum state. We also explore tradeoffs between algorithmic error at small $N$ and noise/loss limits at large $N$.

Experimental considerations for zero noise extrapolation  

ABHINAV KANDALA (Presenter), KRISTAN TEMME, SETH MERKEL, DAVID MCKAY, EASWAR M MAGESAN, JAY M GAMBETTA, IBM TJ Watson Research Center — While decoherence and control errors limit the size of quantum computation in the absence of fault tolerance, a number of error mitigation techniques have been developed to access noise free estimates of expectation values. In particular, the zero-noise extrapolation technique was shown to extend the computational reach of a noisy superconducting processor. Here, quantum circuits are run at amplified noise rates, to extrapolate the results of these runs to the zero noise limit. Under the assumption of time invariant noise, such noise amplification may be achieved by stretching in time the gates employed in the circuit. We test these assumptions for superconducting processors with all-microwave drives and also consider the effect of errors in the gate rescaling on the extrapolation.
4:18PM U08.00010: Realizing giant artificial atoms in superconducting waveguide QED  A.M. VADIRAJ (Presenter), Electrical and Computer Engineering, Institute for Quantum Computing, University of Waterloo, ANDREAS ASK, Department of Microtechnology and Nanoscience, Chalmers University of Technology, IBRAHIM NSANZINEZA, CHUNG WAI SANDBO CHANG, Electrical and Computer Engineering, Institute for Quantum Computing, University of Waterloo, ANTON FRISK KOCKUM, Department of Microtechnology and Nanoscience, Chalmers University of Technology, C.M. WILSON, Electrical and Computer Engineering, Institute for Quantum Computing, University of Waterloo — In most studies of light-matter interaction, the atoms, either natural or artificial, are approximated as featureless dipoles, since the atomic dimension is much smaller than the wavelength of light. However, a new regime in waveguide QED, first proposed by Kockum et al, can realize a “giant” artificial atom by coupling to light at multiple points along a waveguide. As a result, the atom interacts with itself, resulting in a range of phenomena including non-Markovian dynamics and frequency-dependent coupling. The same proposal also discussed possibilities to extend this architecture to multiple giant atoms with interesting new physics. Motivated by this, we experimentally investigate circuits with one and two giant transmon qubits which are coupled to propagating microwaves at multiple points separated by wavelength-scale distances. For one qubit circuit, we demonstrate that we can enhance or suppress the relaxation rate of the 1-2 transition relative to the 0-1 transition by more than an order of magnitude. Using this capability, we show that we can engineer the giant transmon into an effective lambda system, including demonstrating EIT. We will also present preliminary measurements of a circuit with two giant qubits coupled in a braided geometry.

*This work was supported by Department of Energy grant DE-SC0019461.
4:42PM U08.00012: A novel bus design for a highly connected multi-qubit processor in 3D cQED architecture

SUMERU HAZRA (Presenter), ANIRBAN BHATTACHARJEE, KISHOR V SALUNKHE, SANSKRITI CHITRANSH, MEGHAN P. PATANKAR, R VIJAY, Tata Inst of Fundamental Res — Highly connected qubit networks offer efficient implementation of quantum algorithms by requiring fewer gates to implement a given circuit. While not considered to be highly scalable, the 3D cQED architecture offers a cleaner microwave environment and modular design which can be used effectively to build small to intermediate scale processors. We will present a novel bus design to couple multiple qubits in 3D cQED with high inter-qubit connectivity and sufficient spatial separation to minimize cross-talk effects. We will show preliminary experimental data to demonstrate qubit interactions using the cross-resonance gate but will also explain how it can be integrated with multiple gate schemes to build scalable multi-qubit processor in 3D architecture.

4:54PM U08.00013: Waveguide-mediated Interactions Between Giant Superconducting Artificial Atoms

BHARATH KANNAN (Presenter), MAX RUCKREIGEL, DANIEL L CAMPBELL, Research Laboratory of Electronics, Massachusetts Institute of Technology, ANTON FRISK KOCKUM, Department of Microtechnology and Nanoscience, Chalmers University of Technology, JOCHEN BRAUMUELLER, RONI WINIK, MORTEN KJAERGAARD, Research Laboratory of Electronics, Massachusetts Institute of Technology, DAVID K KIM, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, JONILYN YODER, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, WILLIAM OLIVER, Department of Electrical Engineering and Computer Science, Department of Physics, MIT Lincoln Laboratory, Massachusetts Institute of Technology — In quantum optics experiments, atoms are typically treated as small point-like objects compared to the wavelength of the modes they interact with. Superconducting circuits offer a platform to study the physics of systems where this approximation no longer holds. Here, we realize a “giant” artificial atom by coupling a transmon qubit to multiple positions along a superconducting waveguide with separation on the order of the qubit wavelength. We show that the coupling between the qubits and the waveguide can be strongly tuned with the qubit frequency. Furthermore, we demonstrate waveguide-mediated exchange interactions between two giant atoms that can be tuned to be “decoherence-free” with respect to the waveguide. Finally, we show how varying the number of and distance between coupling points can be used to engineer exotic decay and coupling spectra, with applications to quantum information and simulation.

5:06PM U08.00014: Building and benchmarking diabatic entangling gates for frequency-tunable qubits, part I  ANDRE PETUKHOV (Presenter), RAMI BARENDS, CHRIS QUINTANA, YU CHEN, VADIM SMELYANSKIY, Google Inc - Santa Barbara — One of the key needs in quantum computing are gates that are fast and precise, requiring minimization of the control errors and the suppression of leakage out of the computational states. We present a non-adiabatic protocol for iSWAP-like gates with minimal leakage and duration close to the speed limit. The key notion behind our approach is minimizing the gate error by synchronizing the Rabi clocks in the one- and two-excitation channels in a pair of transmon qubits to align minima of the leakage and residual swap population. This, in turn, can be accomplished by utilizing limited but sufficient tunability of the “fixed” interqubit coupling via a proper choice of the three key parameters such as interaction frequency, hold time and overshoot between the qubit frequencies near the avoided crossing. We show that our approach can be extended to other gate operations and discuss pulse-shape optimization suitable for particular gates and architectures.

5:18PM U08.00015: Building and benchmarking diabatic entangling gates for frequency-tunable qubits, part II  RAMI BARENDS (Presenter), CHRIS QUINTANA, ANDRE PETUKHOV, YU CHEN, VADIM SMELYANSKIY, Google Inc - Santa Barbara — One of the key needs in quantum computing are gates that are fast and precise, requiring precision control and the minimization of leakage out of the computational states. We present the experimental implementation of a synchronization protocol for constructing gates that have minimal leakage and a duration close to the speed limit. Using this method we achieve diabatic iSWAP-like and CPHASE gates with Pauli error rates down to $4.3(2) \times 10^{-3}$ in as fast as 18 ns with frequency-tunable superconducting qubits. In addition, we show how we use cross-entropy benchmarking (XEB) for quantifying the gates and error budgets.

Session U09 DQI: Quantum Foundations III  106 - Flaminia Giacomini, Perimeter Inst for Theo Phys - Tag(s): Focus
**2:30PM U09.00001: Time in Quantum Information**  
MOHAMMAD ANSARI (Presenter), ALWIN VAN STEENSEL, Forschungszentrum Julich, YULI NAZAROV, Department of Quantum Nanoscience, Kavli Institute of Nanoscience, TU Delft — Currently 'time' does not play any essential role in quantum information theory. In this sense, the theory is underdeveloped, similarly to how quantum physics was before Erwin Schrodinger introduced his famous evolution of wave functions. I will describe the problem of defining time-evolution in quantum information theory, specially for a central measures in the theory, i.e. Renyi entropy. I use a newly-developed replica trick formalism, namely 'Multiparallel World (MW)' formalism, that revolutionizes the theory. This formalism is one of the first attempts to introduce 'time evolution' for information transfer. With the total entropy being conserved in a closed system, entropy can flow internally between subsystems and I show that this flow is not limited to physical correlations as literature suggests, in fact information correlations are also involved. The mere existence of this new class of correlations allows for faster and slower information transfer.

**2:42PM U09.00002: Violations of macroscopic local reality, time and the Q-function**
MARGARET REID (Presenter), MANUSHAN THENABADU, PETER DRUMMOND, Swinburne Univ of Tech — A macroscopic superposition state would appear to be inconsistent with the classical concept of macroscopic realism. Leggett and Garg proposed tests of macroscopic realism based on the validity of a second premise: (macroscopic) noninvasive measureability. Here, we consider tests of macroscopic realism where the second premise is replaced by that of macroscopic locality. Extending results obtained for NOON states [1], we show how one can falsify macroscopic local realism, by using Bell inequalities for cat-states where the choice of polarizer setting is replaced with a choice of time-of-evolution through a nonlinear medium. Different to the original Bell tests, here the outcomes of all relevant measurements are distinct by N bosons at each site, or else are well-separated in phase space. This motivates us to consider a model of reality based on the Q function. In that model, measurement is described by a dynamical interaction where sharp eigenvalues emerge for sufficient amplification, and Bell violations arise, there being backwards-in-time effects arising through negative diffusion terms [2].

References:
How can we observe an asymmetry in the temporal order of events when physics at the quantum level is time-symmetric? The source of time's barbed arrow is a longstanding puzzle. Causal asymmetry offers a provocative perspective. It asks how Occam's razor can privilege one temporal direction over another. That is, if we want to make statistically correct future predictions then what is the minimum past information we must store? Are we forced to store more data if we model events in one particular temporal order over the other?

Take a glass shattering upon impacting the floor. In one direction, the future distribution of shards depends only on the glass's initial position, velocity and orientation. In the opposite, we may need to track relevant information regarding each shard to infer the prior trajectory. Does this require more or less information? For stochastic processes, this potential divergence is quantified in the theory of computational mechanics. It is not only generally non-zero, but can also be unbounded. This phenomenon implies a simulator operating in the 'less natural' temporal direction is penalized with potentially unbounded memory overhead, and is cited as a candidate source of time's barbed arrow. However these studies assumed models were implemented via classical physics. Could the observed causal asymmetry have been a consequence of this classicality constraint?

In this presentation, we answer this question in the affirmative, by directly constructing a process where there is a classical arrow of time, but at the quantum level this arrow vanishes [1], and reporting on the experimental observation of this effect in a photonic quantum processor [2]. Our work suggests that causal asymmetry could be an artefact of forcing classical causal explanations in a fundamentally quantum world.

*FQXi grant: "Are quantum agents more energetically efficient at making predictions?"
3:30PM U09.00004: Time operators and time crystals: self-adjointness by topology change
KEIJI NAKATSUGAWA (Presenter), Applied Physics, Hokkaido University, TOSHIYUKI FUJII, Physics, Asahikawa Medical University, AVADH SAXENA, Center for Nonlinear Studies, Los Alamos National Laboratory, SATOSHI TANDA, Applied Physics, Hokkaido University — In the standard formulation of quantum mechanics and quantum field theory, time is not an observable but merely a parameter. There are two open problems which can promote time to an observable, namely 1) how to define self-adjoint time operators and 2) how to obtain systems called quantum time crystals.

In this presentation, we investigate time operators in the context of quantum time crystals in ring systems [1,2]. A generalized commutation relation called the generalized weak Weyl relation [3] is used to derive a class of self-adjoint time operators for ring systems. The conventional Aharonov-Bohm time operator, which describes the time of arrival of a particle on a one-dimensional line, is obtained by taking the infinite-radius limit. We also reveal the relationship between our time operators and a PT-symmetric time operator. These time operators are then used to derive several energy-time uncertainty relations.

We surmise that time operators and time crystals are closely related and also that topology change is important when time promotes from a parameter to an observable.

3:42PM U09.00005: Classically-forbidden probability flow in the quantum reentry problem
ARSENI GOUSSEV (Presenter), University of Portsmouth — The laws of quantum mechanics allow for a moving particle to temporarily reverse the direction of its motion even in the absence of any external force. A well-known manifestation of this counterintuitive phenomenon is the so-called quantum backflow effect, whereby the probability of finding a particle "on the left" increases with time despite the particle velocity pointing "to the right". In my talk, I will provide another clear-cut demonstration of nonconstancy of the direction of motion of a free particle. I will show that the free-space expansion of a quantum wave packet, initially confined to an interval, may be nonmonotonous: The probability density may sometimes flow back into (or reenter) the interval. The supremum of the classically-forbidden probability flow in this reentry problem appears to be the same as in the case of quantum backflow.

Indefinite Causal Orderings for Quantum Depolarizing Channel Identification

MICHAEL FREY (Presenter), National Institute of Standards and Technology Boulder —

Quantum channel identification (QCI) is the statistical estimation of channel parameters, accomplished by passing probe systems in prepared states through the quantum channel. Indefinite causal ordering (ICO) is a channel probing scheme in which copies of a quantum channel are physically or logically arranged so that the path through them is a superposition of different possible paths. Channel probing is known to be aided in a strong sense by ICO in the case of the qudit (d-dimensional) depolarizing channel. Specifically, ICO-assisted probing increases the quantum Fisher information (QFI) in the processed probe state about the unknown parameter(s), with increasing order indefiniteness yielding correspondingly greater QFI.

Investigations up until now have involved just superpositions of forward and reverse channel orderings; for example, three channel copies, A, B, and C, in a superposition of orderings A-B-C and C-B-A. Alternatively, these channels copies can be cyclically indefinitely ordered: a superposition of A-B-C, B-C-A, and C-A-B. The present work compares the effectiveness (QFI) of disparate competing ICOs for probing the qudit depolarizing channel. The QFIs associated with these competing ICOs are expressed analytically.

Contextuality in non-interacting measurement

SACHA GREENFIELD (Presenter), MORDECAI WAEGELL, JUSTIN DRESSEL, Chapman Univ — Non-interacting measurement is a phenomenon of seemingly non-local information transfer that arises for a single photon in a cascade of two-arm interferometers. Since contextuality has been identified as a resource for quantum informational tasks, it is reasonable to posit that non-interacting measurement requires contextuality in some form. We confirm this suspicion for the case of imbalanced beam splitters and discuss the exception that admits a noncontextual model. In contrast to existing proofs of contextuality for a single qubit, this scenario involves only pure states and sharp measurements.

A tight quantum speed limit for open quantum dynamics

YUSEF MALEKI (Presenter), Texas A&M Univ —

Determining the speed of the quantum dynamics of a system is significantly important in many physical studies. The faster dynamics in quantum gates can escalate the speed of computation. In condensed matter physics, determining how fast correlations can be spread in many-body systems, relies on the dynamical speed of the system. Finally, in black hole physics, the entropy change rate of the system is limited by the speed of quantum dynamics.

Quantum Speed Limit imposes a bound on the speed of evolution of all quantum processes. However, in spite of their significant importance, the existing bounds are usually not tight, which underestimate the best possible speedup, and they usually are difficult to compute. Overcoming these issues becomes even more challenging when we deal with open quantum systems. In this work, we present a new quantum speed limit, which resolves both tightness and computability issues. Unlike most of speed limits, this limit is applicable to any open or closed quantum dynamics.
**4:30PM U09.00009: The Heisenberg Interpretation of Quantum Mechanics**  ARMIN NIKKHAH SHIRAZI (Presenter), Univ of Michigan - Ann Arbor — In his book `Physics and Philosophy', Werner Heisenberg posited a distinction between the quantum and the classical worlds, which he characterized in terms of "potentialities or possibilities" versus "things and facts". However, the standard quantum formalism does not express such distinctions.

In this talk, we present a concrete implementation of this distinction into the quantum formalism, resulting in what will be called the Heisenberg interpretation of quantum mechanics. The modification of the formalism mainly involves replacing state reduction by a composition of two maps between the Hilbert space and a set of corresponding classical states. These maps represent the emergence and submergence of a classical state from a quantum state from interactions currently labeled as "measurements". This modified formalism has a number of advantages over the Copenhagen interpretation and sets the stage for experimental predictions which are not obvious under the standard formalism.

**4:42PM U09.00010: Experimental Comparison of Bohm-like Theories with Different Ontologies**  ARTHUR OU TEEN PANG (Presenter), HUGO FERRETTI, NOAH LUPU-GLADSTEIN, WENG-KIAN THAM, AHARON BRODUTCH, KENT AG BONSMA-FISHER, JOHN EDWARD SIPE, AEPHRAIM M STEINBERG, Univ of Toronto — The de Broglie-Bohm theory is a hidden variable interpretation of quantum mechanics which involves particles moving through space with definite trajectories. This theory singles out position as the primary ontological variable. Mathematically, it is possible to construct a similar theory where particles are moving through momentum space, and momentum is singled out as the primary ontological variable. In this paper we experimentally show how the two theories lead to different ontological descriptions. We construct the putative particle trajectories for a two-slit experiment in both the position and momentum space theories by simulating particle dynamics with coherent light. Using a method for constructing trajectories through the primary and derived (i.e. non-primary) spaces, we compare the ontological pictures offered by the two theories and show that they do not agree. This contradictory behaviour brings into question which ontology for Bohmian mechanics is to be preferred.

Quantum Mechanical Reset-Observer Reset, not Observation, results in QM Wave-Particle Duality in Multi-Slit experiments  

MARTIN ALPERT (Presenter), President, Universal Empowering Technologies — A quantum mechanical mechanism based on statistical mechanics is proposed. It is based on corresponding and reciprocal changes in the number of states with associated energy changes at the observer and observed at reset and observation of the observer. The change in the number of states is different than the value of the observation. Each state is a possible input to the system. Bits, as a measure of information content, are considered the discrete cell size of a state. An experiment is proposed to determine where and when energy changes occur and how they are related to the observer and observed during the entire measurement process. A related experiment is proposed to determine timing between changes in the number of states. No time delay would indicate this is an entangled process and explain delayed choice observations. Bits not stored are lost, so when the number of inputs is greater than the number of outputs, an energy change occurs, and interference is observed (wave characteristics). If the number of inputs equals the number of outputs, no energy change occurs, and no interference is observed (particle characteristics). The theory, if verified, would further the understanding of the measurement process and entanglement’s involvement in the process.

Thursday, March 5, 2020 2:30 PM - 5:18 PM

Session U16 DQI: Characterizing Quantum Computing Systems and Components III

2:30PM U16.00001: Understanding Crosstalk in Quantum Processors*  
ROBIN BLUME-KOHOUT (Presenter), MOHAN SAROVAR, ERIK NIELSEN, KENNETH RUDINGER, KEVIN YOUNG, TIMOTHY PROCTOR, Sandia National Laboratories — Multi-qubit quantum processors fail – i.e., deviate from ideal behavior – in many ways. One of the most important, especially as the number of qubits grows, is crosstalk. But “crosstalk” refers to a wide range of distinct phenomena. In this talk, I will present a precise and rigorous framework that we have developed for defining and classifying crosstalk errors, and compare it to existing ad hoc definitions. Then, I will present two protocols that we are deploying to detect and characterize crosstalk, and show how we are using them to break down and demystify the error behavior of testbed-class quantum processors in the wild.

*This material was funded in part by the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research Quantum Testbed Program, and also by IARPA’s LogiQ program. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.
**2:42PM U16.00002: Hold the onion: using fewer circuits to characterize your qubits.** ERIK NIELSEN (Presenter), TIMOTHY PROCTOR, KENNETH RUDINGER, MOHAN SAROVAR, KEVIN YOUNG, ROBIN BLUME-KOHOUT, Quantum Performance Lab, Sandia National Laboratories — A common complaint about qubit characterization protocols - especially tomographic protocols – is that they require running a ridiculously large number of circuits (experiments). In this talk, we compare the resources required by several QCVV protocols, including gate set tomography (GST) and randomized benchmarking (RB). We show how resources, primarily the number and type of circuits, depend on desired accuracy and on noise model. In particular, we show how QCVV techniques can capitalize on one's ability to simplify the relevant noise model – i.e. the types of noise being probed - and, for example, utilize an experimentalist's physical intuition to perform targeted characterization with significantly fewer circuits. We conclude by considering how existing QCVV techniques may be used in complementary ways during the holistic characterization of a quantum processor. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.

---

**2:54PM U16.00003: Filter Function Formalism for Unitary Quantum Operations** TOBIAS HANGLEITER (Presenter), PASCAL CERFONTAINE, HENDRIK BLUHM, JARA-FIT Institute for Quantum Information, RWTH Aachen University — While the quantum process formalism provides a natural framework for describing the concatenation of quantum operations, it is of limited use when describing the effects of non-Markovian noise. In my talk, I will first present an extension of the filter function formalism, which so far has mostly been used to model gate fidelities and the effects of dynamical decoupling sequences. Our extension facilitates the efficient, perturbative calculation of full quantum processes in the presence of correlated noise, e.g. the 1/f-like noise found in many solid-state qubit systems. I will then show that a simple composition rule arises for the filter functions of gate sequences. This enables the investigation of quantum algorithms in the presence of correlated noise with moderate computational resources. Lastly, we present a fast and easy-to-use open source software framework (quantuminfo.physik.rwth-aachen.de/code) which facilitates the calculation of (first order) quantum processes and fidelities for arbitrary system dimensions. Other features include the efficient concatenation of several operations, and an optimized treatment of periodic Hamiltonians.
3:06PM U16.00004: Detection of coherent noise through the output of random quantum circuits* JIN-SUNG KIM (Presenter), LEV S BISHOP, ANTONIO D CORCOLES, JAY M GAMBETTA, DAVID MCKAY, SETH MERKEL, JOHN A SMOLIN, SARAH SHELDON, IBM TJ Watson Research Center — As quantum systems with increasing numbers of qubits emerge, new methods of characterizing and mitigating noise sources are required in the multi-qubit regime. While methods like randomized benchmarking (RB) and its variations are widely used in single and few-qubit systems to characterize coherent and incoherent noise sources, multi-qubit RB quickly becomes prohibitive at current coherence and control limits. In addition, it has been shown in recent experiments with three qubit RB that single and two-qubit RB fail to capture error sources present in larger qubit systems. On the other end of the spectrum, system-level metrics like quantum volume and other methods exist, but lump coherent and incoherent errors together in their output. We present here a method, based on the output of random quantum circuits, capable of quantitatively discriminating coherent noise from incoherent noise in multi-qubit systems.

*This work was supported by ARO under Contract No. W911NF-14-1-012.

3:18PM U16.00005: Investigating widespread correlated errors in superconducting qubit arrays MATTHEW MCEWEN (Presenter), University of California, Santa Barbara; Google Inc, RAMI BARENDS, Google Inc, JOHN M MARTINIS, University of California, Santa Barbara; Google Inc — With the advent of large arrays of superconducting qubits, such as Google's Sycamore processor, it is now possible to investigate the prevalence of correlated decoherence mechanisms that affect large numbers of qubits. Correlated errors are of particular importance with regard to implementing surface code error correction schemes, as errors are assumed to be independent or only weakly correlated. Control crosstalk and stray couplings are known to generate errors that are correlated, but the correlation is limited to a relatively small number of qubits. However, error mechanisms that affect large numbers of qubits simultaneously are problematic for error correction. In order to quantify the prevalence of such errors, we take rapid, simultaneous time-resolved measurements of error rates across large numbers of qubits on a single chip.
**3:30PM U16.00006: Renyi Entropy Benchmarking of Superconducting Qubits**

XIAO MI (Presenter), Google Inc - Santa Barbara, BENOIT VERMERSCH, ANDREAS ELBEN, University of Innsbruck, PEDRAM ROUSHAN, YU CHEN, Google Inc - Santa Barbara, PETER ZOLLER, University of Innsbruck, VADIM SMELYANSKIY, Google Inc — The ever-growing size of superconducting processors in recent years has significantly elevated the demand to efficiently benchmark the performance of large quantum circuits. Traditional methods such as state or process tomography suffer from a measurement overhead that scales double-exponentially with the number of qubits. Motivated by recent progress in trapped ion systems [1], we use sets of random gate unitaries to scramble many-body quantum states and infer their Renyi entropies, which reveal the rate of purity loss of the quantum system. The protocol is applied to benchmark the coherence of large quantum circuits run on the Google quantum processor. The scaling behavior of the randomized measurement protocol over system size is investigated in detail.

**3:42PM U16.00007: Demonstrating Scalable Benchmarking of Quantum Computers**

TIMOTHY PROCTOR (Presenter), KENNETH RUDINGER, KEVIN YOUNG, ERIK NIELSEN, ROBIN BLUME-KOHOUT, Sandia National Laboratories — Reliably testing multi-qubit quantum computers is notoriously challenging, but it is vital for measuring and aiding experimental progress, as well as for quantifying the capabilities of available processors. In this talk, I will present experimental results demonstrating simple, fast and scalable methods for benchmarking quantum computers. Our methods will work on essentially all current and near-term quantum computers, and they can be applied to hundreds of qubits with moderate error rates (around 0.1-1%) and thousands of high-quality qubits. Our core method is based on a class of randomized circuits, and it can be used to estimate the rate of errors in an average many-qubit circuit layer, using an analysis that will be familiar from randomized benchmarking. Our experiments reveal noise phenomena that only emerge at scale (e.g., crosstalk), quantify the divergence between the predictions of one- and two-qubit performance data and the actual behavior of many-qubit circuits, and provide high-level summaries of device performance versus circuit width and depth.

*This material was funded in part by the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research Quantum Testbed Program, and the Laboratory Directed Research and Development program at Sandia National Laboratories. Sandia National Laboratories is a multi-mission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.
4:18PM U16.00008: Qutrit randomized benchmarking*  ALEXIS MORVAN (Presenter), Lawrence Berkeley National Laboratory, MACHIEL S BLOK, VINAY RAMASESH, LARRY CHEN, IRFAN SIDDIQI, Univ of California - Berkeley — Qutrits are an alternative to qubits to implement quantum computers by using three-, rather than two-level systems, and have proved useful to explore connections between high-energy physics and quantum information science. A standard measure of the performance of qubit-based processors would be to use randomized benchmarking and its derivatives as these techniques allows scalable characterization of the processor. In this talk, we present an experimental implementation of qutrit randomized benchmarking on a 5-qutrit processor. This gives us a measure of the overall performance of our processor, as well as a tool to diagnose specific gate fidelity and cross-talk error.

*This work was supported by the testbed program of the Advanced Scientific Computing Research for Basic Energy Sciences program, Office of Science of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

4:30PM U16.00009: Effect of Imperfections on the Cross Entropy Benchmark Fidelity of Random Circuit Sampling  YIMU BAO, SOONWON CHOI (Presenter), EHUD ALTMAN, University of California, Berkeley — Random circuit sampling (RCS) is a computationally intractable task for exact classical simulations, and thus proposed as a way to demonstrate quantum supremacy. The fidelity of RCS from a realistic quantum device with respect to its ideal case can be quantified by so-called (linear) cross entropy benchmark, which is inevitably reduced by the presence of various imperfections. Here, we present an efficient method to evaluate the amount of average fidelity reduction originating from various kinds of imperfections without any simplifying assumptions. More specifically, we develop an exact relation between the linear cross entropy averaged over random circuit realizations and the partition function of a classical spin model, which allows efficient classical simulations. Using Monte-Carlo algorithms, we quantitatively analyze the average cross entropy in the presence of imperfections for both 1D and 2D systems with various layouts of circuits for reasonably large system sizes.

4:42PM U16.00010: Engineering Quantum Process Fidelity via Generalized Markovian Noise*  EVANGELOS VLACHOS (Presenter), HAIMENG ZHANG, JAMES FARMER, DARIAN HARTSELL, ELI M LEVENSON-FALK, Univ of Southern California — Markovian noise causes errors in quantum processes in ways that are difficult to correct. Surprisingly, theoretical studies have recently proposed that short-memory (generalized Markovian) noise can be used as a resource to mitigate the effects of Markovian noise. We have investigated the efficacy of adding generalized Markovian noisy signals, with various types of memory kernels, at improving fidelity and reducing decoherence in superconducting qubits, using both computational and experimental methods. We present quantum trajectory simulations and experimental tests of different corrective noise schemes, and discuss paths forward for optimizing quantum process fidelity.

4:54PM U16.00011: Characterizing the performance of NISQ devices with random Clifford circuits*  
SETH MERKEL (Presenter), ANTONIO D CORCOLES, IBM Tj Watson Research Center,  
ANIMESH DATTA, SAMUELE FERRACIN, University of Warwick, JIN-SUNG KIM, DAVID MCKAY, SARAH SHELDON, IBM Tj Watson Research Center — There has been recent interest in sampling the output distributions of pseudo-random quantum circuits as a benchmark for large quantum systems [1,2]. However, based on the work of the Datta group on circuit accreditation [3] we suggest that for characterizing device performance, it is sufficient to measure the outputs of only pseudo-random Clifford circuits, a classically-simulatable subset of all quantum circuits. We require a few reasonable assumptions about our devices at IBM, namely that both Clifford and non-Clifford Z-rotations are done in software and therefore have the same error rates. Given this result, we note that a) all of the classical pre/post-processing is efficient and b) we can deal with the variational distance of the output distributions directly without proxies such as the cross entropy or heavy output generation.

*This work was supported by ARO under Contract No. W911NF-14-1-012

5:06PM U16.00012: Effects of qubit frequency crowding on scalable quantum processors*  
JARED HERTZBERG (Presenter), SAMI ROSENBLATT, JOSE M CHAVEZ, EASWAR M MAGESAN, JOHN A SMOLIN, JENG-BANG YAU, VIVEKANANDA ADIGA, MARKUS BRINK, ERIC J ZHANG, JASON ORCUTT, JERRY M. CHOW, IBM Tj Watson Research Center — Lattices of transmon qubits offer a scalable architecture to build quantum processors. Long qubit coherence times and hardware-efficient cross-resonance gates enable low gate error rates. However, frequency-crowding among the qubits can increase gate errors. Neighboring qubits must have similar but non-degenerate excitation energies. In this talk we will quantify the effects of frequency crowding and consider how this behavior scales with device size for 50-qubit and larger systems. We will also discuss strategies to mitigate or eliminate frequency crowding during device fabrication.

*We acknowledge support from IARPA under Contract No. W911NF-16-0114
Entanglement of Microwave-Optical Modes in a Strongly Coupled Electro-Optomechanical System

XU HAN (Presenter), Argonne Natl Lab, CHANGCHUN ZHONG, LIANG JIANG, University of Chicago — Quantum transduction between microwave and optics can be realized by quantum teleportation if given reliable entanglement between microwave and optical modes, namely entanglement-based quantum transduction. To realize this protocol, an entangled source with high-fidelity is necessary. Based on a generic strongly coupled cavity electro-optomechanical system, we study the microwave-optical entanglement generation and quantify the frequency entanglement between the two modes. The entanglement can be straightforwardly encoded in the frequency-bin degree of freedom with a feasible experiment to verify entangled photon pairs. The experimental implementation is systematically analyzed, and the preferable parameter regime for entanglement verification is identified. An inequality is given as a criterion for good entanglement verification, including practical imperfections.

In Part A: We introduce frequency entanglement in the strongly coupled electro-optomechanical system and discuss the experimental detection scheme.

Part B: we theoretically evaluate the entanglement of formation rate, analyze Bell state violation and estimate the coincidence rate.

2:54PM U17.00003: Ground state cooling and high-fidelity quantum transduction via parametrically-driven bad-cavity optomechanics*

HOI-KWAN LAU (Presenter), AASHISH CLERK, University of Chicago — In optomechanical systems, the beam-splitter interaction underlies the utility of many applications, but the two-mode-squeezing interaction creates unwanted excitations and is usually detrimental. In this work, we propose a simple but powerful method based on cavity parametric driving to suppress the unwanted excitation that does not require working with a deeply sideband-resolved cavity. Our approach is based on a simple observation: as both the optomechanical two-mode-squeezing interaction and the cavity parametric drive induce squeezing transformations of the relevant photonic bath modes, they can be made to cancel one another. We illustrate how our method can cool a mechanical oscillator below the quantum back-action limit, and significantly suppress the output noise of a sideband-unresolved optomechanical transducer.

*This work is supported by the AFOSR MURI FA9550-15-1-0029 on quantum transduction.

3:06PM U17.00004: Mechanical Purcell Filter for Microwave Quantum Machines*

AGNETTA CLELAND (Presenter), MAREK PECHAL, PIETER-JAN C. STAS, CHRISTOPHER J SARABALIS, PATRICIO ARRANGOIZ-ARRIOLA, EDWARD A WOLLACK, WENTAO JIANG, TIMOTHY MCKENNA, AMIR SAFAVI-NAEINI, Stanford Univ — Measuring the state of a superconducting qubit introduces a loss channel which can enhance spontaneous emission through the Purcell effect. This can be mitigated by implementing a Purcell filter which strongly suppresses signal propagation at the qubit frequency. If the filter is well-matched at the readout cavity frequency, it will protect the qubit from decoherence channels without sacrificing measurement bandwidth. In this talk, we propose and analyze design for a mechanical Purcell filter, composed of an array of nanomechanical resonators in thin-film lithium niobate, whose frequencies are chosen to produce a bandpass response. A modest footprint, steep band edges, and lack of cross-talk make these filters a novel and appealing alternative to electromagnetic versions currently used in microwave quantum machines. We will present a circuit model depiction of this filter, as well as design, fabrication, and characterization results. Our filters achieve over 200 MHz bandwidth at 3.5 GHz, with over 50 dB out-of-band suppression, while occupying less than 0.3 square mm on-chip in a qubit-compatible material platform.

3:18PM U17.00005: Microwave-frequency acoustic resonators with high quality factors*
MING-HAN CHOU (Presenter), University of Chicago, ETIENNE DUMUR, Argonne National Laboratory; University of Chicago, GREGORY PEAIRS, University of California, Santa Barbara; University of Chicago, AUDREY BIENFAIT, HUNG-SHEN CHANG, CHRISTOPHER R CONNER, JOEL GREBEL, RHYS G POVEY, University of Chicago, KEVIN SATZINGER, University of California, Santa Barbara; University of Chicago(present in Google Inc), AUDREY BIENFAIT, HUNG-SHEN CHANG, CHRISTOPHER R CONNER, JOEL GREBEL, RHYS G POVEY, University of Chicago, KEVIN SATZINGER, University of California, Santa Barbara; University of Chicago(present in Google Inc), YOUPENG ZHONG, University of Chicago, ANDREW CLELAND, Argonne National Laboratory; University of Chicago — We are pursuing the development of microwave-frequency acoustic resonators that can be integrated with superconducting circuits. By combining the mechanical properties of single crystal silicon with the mechanical isolation provided by phononic crystals, high quality factors at GHz frequencies should become achievable. In this talk, we describe the design and fabrication of mechanical resonators comprising suspended hybrid structures combining aluminum nitride and silicon supported by a phononic crystal, providing mechanical isolation with an integrated piezoelectric transduction mechanism. Measurements at low temperatures indicate this type of mechanical device can achieve quality factors approaching those of coplanar waveguide resonators, providing interesting potential for use in quantum information applications.

3:30PM U17.00006: A multimode nonlinear resonator for quantum acoustics  GUSTAV ANDERSSON (Presenter), Chalmers Univ of Tech, SHAN WILLIAMS JOLIN, KTH Royal Institute of Technology, MARCO SCIGLIUZZO, PER DELSING, Chalmers Univ of Tech — Exploiting multiple modes in a quantum acoustic device could enable applications in quantum information in a hardware-minimal setup. Surface Acoustic Wave (SAW) resonators in the quantum regime support high Q-factors (>10^5) and dense mode spectra. We introduce a Kerr nonlinearity to a SAW resonator by integrating a SQUID (Superconducting QUantum Interference Device) into one of the Bragg reflectors. The SQUID inductance modulates the reflectivity of each unit cell in the mirror and hence the effective length of the resonator. Due to the narrow free spectral range, this gives rise to a cross-Kerr coupling between the more than 20 accessible modes. We attempt to exploit this nonlinear coupling to generate multimode non-classical states that could potentially provide a resource for quantum computation. Avenues towards quantum simulation using the coupled modes as lattice sites occupied by SAW phonons are further explored.
3:42PM U17.00007: Existence of a new surface mode with transverse electric field*
ZONGYE WANG (Presenter), XUEDONG HU, State Univ of NY - Buffalo — Surface acoustic waves, in particular Rayleigh waves near the surface of a piezoelectric material, have attracted a lot of attention lately through their abilities to carry electrons and to couple strongly with superconducting qubits. Here we report the study of a surface mode in a piezoelectric material with transverse electric field, which has not been explored in previous studies of surface acoustic waves. This transverse mode is different from both the well-understood Rayleigh wave that contains a longitudinal component, and the Bleustein-Gulyaev wave, which has been actively studied recently. In order to describe surface modes with transverse electric field, we develop a theory of elastic waves coupled with electromagnetic field, and find among its solutions the Rayleigh wave, the Bleustein-Gulyaev wave, and the new transverse mode. We clarify properties of this mode, such as its polarization, dispersion, and speed of sound. While this surface mode cannot be used to carry an electron, it could play an important role when surface acoustic phonons are used as quantum bus to convey information between quantum dots.

* We thank support by US ARO.

3:54PM U17.00008: Optimal control of nanomechanical quantum memory coupled to superconducting qubit  
MINGYU KANG (Presenter), ZHAOYOU WANG, EDWARD A WOLLACK, AGNETTA CLELAND, RACHEL GRUENKE, NATHAN LEE, KEVIN MULTANI, MAREK PECHAL, PATRICIO ARRANGOIZ-ARRIOLA, AMIR SAFAVI-NAEINI, Stanford Univ — Quantum memory coupled to a single non-linear element such as superconducting qubit can serve as a promising quantum information processing platform with advantages in lifetime and hardware-efficiency. However, naïve implementation of this quantum computing architecture requires two additional SWAP gates between the memory resonator and the processing qubit per each gate operation, which can cause longer gate time and larger error. In this work we explore the optimal control for performing high-fidelity state preparation and unitary gates on quantum memory by using a power- and bandwidth-limited pulse optimization method. Specifically, we apply our method to a hybrid system of nanomechanical resonators coupled to tunable-frequency transmon qubit and find the optimal pulse for generating entangled states of mechanical resonators as well as implementing phonon-phonon CNOT gate. We test the pulse's robustness to experimental imperfections, such as pulse noise, parameter uncertainties, and decoherence. Finally, we find the optimal pulse length and gate fidelity as a function of the qubit-resonator coupling strength and frequency spacing of resonators, suggesting the experimental parameter regime for achieving scalable quantum computing.
4:06PM U17.00009: Synthesizing multi-phonon quantum superposition states using three-body interactions with transmon qubits*  MARIOS KOUNALAKIS (Presenter), YAROSLAV M. BLANTER, GARY STEELE, Delft University of Technology — We propose a scheme for controlling a radio-frequency mechanical resonator at the quantum scale using two superconducting transmon qubits. The qubits are coupled via a capacitor in parallel to a superconducting quantum interference device (SQUID), which has a suspended mechanical beam embedded in one of its arms. Following a theoretical analysis of the quantum system, we find that this configuration, in combination with an in-plane magnetic field, can give rise to a tuneable three-body interaction in the single-photon strong-coupling regime, while enabling suppression of the stray qubit-qubit coupling. Using state-of-the-art parameters and qubit operations at single-excitation levels, we numerically demonstrate the possibility of ground-state cooling as well as high-fidelity preparation of multi-phonon quantum states and qubit-phonon entanglement. Our work significantly extends the quantum control toolbox of radio-frequency mechanical resonators and may serve as a promising architecture for integrating such mechanical elements with transmon-based quantum processors.

4:18PM U17.00010: Nonclassical energy squeezing with quadratic electromechanics
XIZHENG MA (Presenter), University of Colorado, Boulder, JEREMIE VIENNOT, Univ. Grenoble Alpes, CNRS, Institut Néel, SHLOMI KOTLER, JOHN TEUFEL, National Institute of Standards and Technology Boulder, KONRAD LEHNERT, University of Colorado, Boulder — The ability to access a broad range of quantum state of motion with massive mechanical oscillators has been an enduring ambition in the field of opto- and electromechanics. Despite achieving many landmarks, the often exploited radiation pressure coupling between these mechanical oscillators and microwave or optical light relies on a linearized interaction that limits possible quantum effects. To go beyond this limitation, we quadratically couple the displacement of a mechanical oscillator to the energy levels of a superconducting charge qubit[1]. Through microwave frequency drives that change both the state of the oscillator and the qubit, we dissipatively stabilize the oscillator in a non-classical state with a large mean phonon number of 43 and sub-Poissonian number fluctuations of approximately 3. In this number squeezed state, we observe a striking feature of the quadratic coupling, the two phonon recoils of the mechanical oscillator due to qubit transitions. These are closely analogous to the vibronic transitions in molecules, heralding entry into a new regime of artificial systems with fast electrons coupled strongly to slow vibrations.

Recent progress in the design and realization of phononic structures has resulted in a number of quantum analogues. Elastic waves in one-dimensional waveguides with broken time-reversal or parity symmetry obey Dirac-like equations and possess spin-like topology. Of particular interest for quantum computing is the design, construction, and demonstration of coherent superpositions of elastic waves in waveguides and coupled waveguides. These coherent superpositions can be characterized by the phase of the elastic wavefunction and are called phase-bits or phi-bits. The construction of non-separable (i.e., ‘classically entangled’) superpositions has been achieved using phi-bits comprised of coupled waveguides. These phononic structures allow accessing quantum analogue computing at room temperatures and long coherence times.

Session U18 GSNP: Glassy Dynamics: From Simple Models to Biological Tissues II 205 - Grzegorz Szamel, Colorado State University - Tag(s): Invited
Dense assemblies of particles are prototypes of structurally disordered systems, such as amorphous solids or yield stress fluids. In infinite dimension their mean-field description becomes exact, and solving their equilibrium dynamics in this limit has been remarkably fruitful in capturing static properties of finite-dimensional systems as well. Here we address their out-of-equilibrium dynamics, paving the way to obtaining a similar infinite-dimensional benchmark for the mechanical or rheological properties of structurally disordered systems.

More specifically, we derive the mean-field dynamical equations that describe a system of pairwise interacting particles, in infinite dimension and in the thermodynamic limit, in a generic setting with arbitrary noise and friction kernels, and possibly under a global shear. We show that the complex many-body dynamics can then be exactly reduced to a single one-dimensional stochastic process, with three effective kernels that have to be determined self-consistently.

In this talk, I will sketch the derivation of this effective dynamics, highlighting in particular the few key ingredients of the high-dimensional physics and their possible relevance for finite-dimensional systems. Since we consider a very general setting, we can model a broad range of situations — equilibrium, quasi-statics, transients or steady-states — such as liquid and glass rheology or active self-propelled particles.

3:06PM U18.00002: Beyond mean-field theories of glassy dynamics* [Invited] GIULIO BIROLI (Presenter), LPENS, Ecole Normale Superieure — I will present new theoretical frameworks that allow to go beyond the mean-field theory of glassy dynamics. I will present the state of the art and the central directions for future works. The main aim and outcome of our approaches is a theory of activated dynamics of glassy systems.

*Simons Foundation collaboration Cracking the Glass Problem (No. 454935 to G. Biroli)
To understand the origin of universal low-temperature properties of glasses, which differ dramatically from those of their crystalline counterparts, it is paramount to understand what controls the low frequency vibrational modes of glasses. Numerical methods generally create glasses by quenching mildly supercooled liquids, which limits the variation of glasses' vibrational spectra and the ability to examine correlations between the properties and the vibrational spectra. Due to a combination of advances in simulation techniques and the formulation of new glass forming models, we are now able to study glasses with a wide range of stabilities. Here we study vibrational modes, sound attenuation, and energy transport in simulated glasses with stabilities that range from very poorly annealed to very stable. Our most stable glass is comparable to exceptionally-stable, vapor-deposited laboratory glasses. We find that the density of the localized, low-frequency modes decreases quickly with increasing stability. This decrease is accompanied by a a large decrease in sound attenuation. We find that at low-frequencies, in the harmonic approximation, sound attenuation follows Rayleigh scattering scaling with wave-vector. We examined energy transport by exciting a wave packet and determined the energy diffusivity. For a low frequency excitation, the decrease in sound attenuation is mirrored by an increase in the energy diffusivity. However, for a high frequency excitation, the diffusivity is nearly constant and independent of stability.

**4:18PM U18.00004: Gelation in Soft Matter: from Colloids to Decorated Protein Networks**

[Invited] PADDY ROYALL (Presenter), Physics, University of Bristol, IOATZIN RIOS DE ANDA, Mathematics, University of Bristol, ANGELIQUE COUTABLE-PENNARUN, Biochemistry, University of Bristol, CHRISTOPHER BRASNETT, Physics, University of Bristol, STEPHEN WHITElam, Molecular Foundry, Berkeley, ANNELA SEDDON, Physics, University of Bristol, JOHN RUSSO, Physics, La Sapienza, ROSS ANDERSON, Biochemistry, University of Bristol — Gelation unites many central issues in soft matter: phase transitions, dynamical arrest and self-assembly. *Spinodal* Gelation the formation of a network during spinodal decomposition has been recognized in colloids and proteins [1,2]. The competition between dynamical arrest and self-assembly has also been exploited in critical soft matter, where fluctuations associated with a non-equilibrium critical point introduce an additional tunable lengthscale [3]. Here we extend these concepts to a new system of fluorescent proteins, to produce multicomponent networks. We tune the structural properties and functional behavior of these decorated protein networks with a variety of soft matter and biochemical techniques [4].

4:54PM U18.00005: Rigidity and glass transitions in collections of cells and fiber networks*

[Invited] M. LISA MANNING (Presenter), Syracuse University — In biological processes like embryonic development and in cancer metastasis, collective groups of cells must dramatically reorganize and move over substantial distances like a fluid. In other cases, such as the mature lining of the human lung, it is functionally important for the cells to behave as an intact solid, and still other tissues appear to straddle a disordered fluid-solid transition. First, I will discuss a theory for the origin of rigidity and the scaling laws that occur in a broad class of models for biological tissues (including vertex models for confluent cell aggregates and spring network models for extracellular matrix), and then I will discuss the anomalous glassy behavior that arises in such models in the presence of thermal or active fluctuations.

Session U19 DAMOP: Quantum Simulators for Quantum Complex Network Science 207 - Tag(s): Invited

2:30PM U19.00001: Hyperbolic Lattices in Circuit QED* [Invited] ALICIA KOLLAR (Presenter), University of Maryland, College Park — After two decades of development, superconducting circuits have emerged as a rich platform for quantum computation and simulation. Lattices of coplanar waveguide (CPW) resonators have been shown to produce artificial materials for microwave photons, where interactions can be introduced either via non-linear resonator materials or qubit-resonator coupling. Here, we highlight the previously-overlooked property that these lattice sites are deformable and permit tight-binding lattices which are unattainable, even in solid-state systems. Networks of CPW resonators can create a new class of materials, including lattices in an effective hyperbolic space with constant negative curvature. We will discuss the mathematical tools needed to study the spectra of such structures and present experimental data showing that hyperbolic analogs of the kagome lattice in which photons in this lattice propagate along geodesics of the hyperbolic metric, rather than along the standard straight lines of flat Euclidean, space can be produced in the lab. Additionally, we will highlight the prospects for studies of information and entanglement propagation in hyperbolic geometries, as well as realization of other non-flat structures, such as trees or models with varying curvature.

3:06PM U19.00002: Optically networked color centers* [Invited] JELENA VUCKOVIC (Presenter), Stanford Univ — Most quantum technologies rely on homogeneous, long lived qubits which are efficiently optically interconnected. To achieve this goal, we have been studying color centers in diamond and silicon carbide, in combination with novel fabrication techniques, and our photonics inverse design approach.

*DOE, ARO, NSF

3:42PM U19.00003: Entangled Radiofrequency-Photonic Sensor Network* [Invited] ZHESHEN ZHANG (Presenter), YI XIA, WEI LI, Univ of Arizona, WILLIAM CLARK, DARLENE HART, General Dynamics Mission Systems, QUNTAO ZHUANG, Univ of Arizona — Quantum metrology enables a measurement sensitivity below the standard quantum limit (SQL), as demonstrated in the Laser Interferometer Gravitational-wave Observatory (LIGO). As a unique quantum resource, entanglement has been utilized to enhance the performance of, e.g., microscopy, target detection, and phase estimation. To date, almost all existing entanglement-enhanced sensing demonstrations are restricted to improving the performance of probing optical parameters at a single sensor, but a multitude of applications rely on an array of sensors that work collectively to undertake sensing tasks in the radiofrequency (RF) and microwave spectral ranges. Here, we propose and experimentally demonstrate a reconfigurable RF-photonic sensor network comprised of three entangled sensor nodes. We show that the entanglement shared by the sensors can be tailored to substantially increase the precision of parameter estimation in networked sensing tasks, such as estimating the angle of arrival (AoA) of an RF field. The entangled RF-photonic sensor network achieves an estimation variance 3.2 dB below the SQL in measuring the average field amplitudes and an estimation variance 3.5 dB (3.2 dB) below the SQL in measuring the AoA at a central (edge) node. Our work would open a new avenue toward utilizing quantum metrology for ultrasensitive positioning, navigation, and timing.

*General Dynamics Mission Systems
4:18PM U19.00004: Quantum Optical Neural Network with Multimode Cavity QED* [Invited]
YUDAN GUO (Presenter), BRENDA MARSH, RONEN KROEZE, SURYA GANGULI, Stanford Univ, JONATHAN KEELING, University of St Andrews, BENJAMIN L LEV, Stanford Univ — The ability to engineer inter-particle interaction is at the heart of quantum simulation of many-body systems. However, the necessary nonlocal interaction in complex neural networks poses challenges to traditional implementation of ultracold atoms quantum simulators. We present our theoretical and experimental studies of photon-mediated interactions with atoms trapped inside a multimode confocal cavity. Superposition of different photon modes with incommensurate spatial profiles gives rise to a sign-changing and non-local interaction. Through numerical simulations, we show that the connectivity resulting from such non-local interaction will allow us to explore spin models featuring an associative memory to spin glass transition. In addition, the dissipative cavity photon dynamics facilitate more efficient spin relaxation to low energy states than the textbook Glauber dynamics. Combined with our recent experimental demonstration of cavity-mediated spin-spin interaction and characterization of the non-local interaction, a quantum optical neural network is within our reach.

Session U20 DBIO: Physics of the Cytoskeleton Across Scales III: Transport 301 - Jing Xu, University of California, Merced - Tag(s): Focus
2:30PM U20.00001: Microtubules Regulate Localization and Availability of Insulin Granules in Pancreatic Beta Cells*

WILLIAM HOLMES (Presenter), Vanderbilt Univ — Two key prerequisites for glucose stimulated insulin secretion (GSIS) in beta cells are the proximity of insulin granules to the plasma membrane and their anchoring or docking to the plasma membrane (PM). To this point, it is unclear what regulates localization of insulin granules and their interactions with the PM within single cells. We demonstrate that microtubule (MT) motor transport dynamics have a critical role in regulating both factors. Super-resolution imaging shows that while the MT cytoskeleton resembles a random meshwork in the cells’ interior, MTs near the cell surface are aligned with the PM. Computational modeling suggests two consequences of this. First, this structured MT network withdraws granules from the PM. Second, the binding and transport of insulin granules by MT motors prevents their stable anchoring to the PM. These findings suggest the MT cytoskeleton may negatively regulate GSIS by both limiting the amount of insulin proximal to the PM and preventing stable docking of insulin granules to the PM. These results predict that altering MT network structure in beta cells can be used to tune GSIS. Thus, our study points to a potential of an alternative therapeutic strategy for diabetes by targeting specific MT regulators.

*Supported by NSF DMS1562078.

2:42PM U20.00002: Anomalous transport across scales in crosslinked actin-microtubule composites*

SYLAS ANDERSON (Presenter), JONATHAN GARAMELLA, RYAN J. MCGORTY, RAE M ROBERTSON-ANDERSON, Univ of San Diego — The diffusion of microscopic particles through the cell is largely controlled by the cytoskeletal network, comprised of semiflexible actin filaments, rigid microtubules, and crosslinking proteins. Yet, how the interactions between actin and microtubules and the various types of filament crosslinking affect particle transport remain unresolved. In our experiments, we couple single-particle tracking (SPT) with differential dynamic microscopy (DDM) to characterize the transport of micron-sized particles diffusing through crosslinked composite networks of actin filaments and microtubules. Specifically, we investigate the impact of permanently crosslinking actin to actin, microtubules to microtubules, and actin to microtubules. By combining SPT and DDM, we are able to couple single-particle dynamics to ensemble transport phenomena, and link particle diffusion to the viscoelastic characteristics of the networks. We find that subtle changes to the crosslinking interactions between cytoskeleton filaments play surprisingly important roles in the anomalous subdiffusion that particles exhibit within a composite cytoskeletal system.

*NIH Award #R15GM123420
ELENA KOSLOVER (Presenter), University of California, San Diego — Cells rely on a variety of mechanisms for delivering particles ranging from small molecules to micron-sized organelles to their various destinations. We use physical modeling coupled with live-cell imaging data from collaborating groups to explore the interplay of different transport modes in distributing particles through the complex intracellular environment. This talk will focus on two examples of multi-modal transport: combining motor-driven motion, diffusion, and fluid flow for efficient dispersion of particles within the cell.

Organelle hitchhiking is a non-canonical form of transport, which relies on a cargo organelle attaching to a motor-driven "carrier" with the aid of linker proteins. We quantify the effect of physical parameters on hitchhiking efficiency, demonstrating an insensitivity to linker density and a substantial benefit from tethering of cargo organelles to microtubule tracks. Our model is parameterized and validated against dynamic imaging data in fungal hyphae.

In addition, we investigate the role of advective transport for proteins and ions within the endoplasmic reticulum (ER). Capitalizing on recent experimental evidence of contraction-driven uncoordinated flow within ER tubules, we show that rapid flow combine with mobile calcium-binding buffer proteins can substantially enhance the distribution of calcium ions within the active network structure of the ER.

3:30PM U20.00004: MEMBRANE CHOLESTEROL IS A NOVEL CONTROL FOR KINESIN-BASED TRANSPORT* QIAOCHU LI, JOHN WILSON, University of California, Merced, KUO-FU TSENG, WEIHONG QIU, Oregon State University, MICHAEL VERSHININ, University of Utah, STEPHEN KING, University of Central Florida, JING XU (Presenter), University of California, Merced — Motor protein-based transport in cells underlies all eukaryotic cell function and survival; dysfunctions in this transport are implicated in many diseases, including neurodegeneration. While the properties of motor proteins have been extensively studied both in vivo and in vitro, many important questions remain, including how the properties of the cargo itself impact motor function. In cells, cargos are often membrane-bound; the composition of the cargo membrane has long been hypothesized to impact motor protein-based transport. Here we combined advances in membrane biophysics with single-molecule optical-trap experiments to characterize the transport of membrane-enclosed cargos in vitro. We found that coupling motors via a biomimetic membrane significantly enhanced the transport of cargos along tau-decorated microtubules. This effect diminished when we added cholesterol to our model membrane. To our knowledge, our study uncovers the first direct link between cargo-membrane composition and kinesin function. The experimental approach employed here is generally applicable as a controlled experimental platform for interrogating the control of motor proteins in a context directly relevant to in vivo scenarios.

3:42PM U20.00005: Effect of membrane fluidity on the multi-motor transport of intracellular cargoes* NIRANJAN SARPANGALA (Presenter), AJAY GOPINATHAN, University of California, Merced — In eukaryotic cells, membrane-bound cargoes are transported by teams of molecular motors that diffuse on the lipid membrane. The effect of the cargo fluidity on transport properties is unclear. In particular, it's unknown whether the motor diffusivity helps cargoes navigate the crowded cellular environment especially in the presence of heterogeneity in motor properties. We developed a stochastic dynamical simulation of kinesin-based cargo transport along microtubules that explicitly considers the Langevin dynamics of motors on the cargo surface to answer these questions. Our previous work showed that motor diffusivity reduces inter-motor interference and enhances cargo runlength even in the absence of crowding and heterogeneity. Here we study the effect of motor diffusivity on multi-motor transport when the motor population has a distribution of velocities and also explore how cargoes navigate roadblocks (like Microtubule Associated Proteins) that are typically present on microtubules in vivo.

**3:54PM U20.00006: The Dynein Catch Bond: Implications for cooperative transport**

MITHUN MITRA (Presenter), Indian Inst of Tech-Bombay, PALKA PURI, University of California San Diego, ABHISHEK CHAUDHURI, IISER Mohali, SUDIPTO MUHURI, Savitribai Phule Pune University — Intracellular bidirectional transport of cargo on microtubule filaments is achieved by the collective action of oppositely directed dynein and kinesin motors. Recent experiments have demonstrated that unlike kinesin, dynein motor exhibits catch bonding behaviour, in which the unbinding rate of a single dynein decreases with increasing force, for a certain range of force. Motivated by these experiments, we propose a phenomenological model for catch bonding in dynein. We study the implications of the dynein catch bond for unidirectional and bidirectional cargo transport. We show that the functional divergence of the two motor species manifests itself as an internal regulatory mechanism, and can lead to codependent transport behavior in biologically relevant regimes.

**4:06PM U20.00007: Tracking Down the Fast and Superprocessive KIF1A with Gold Scattering Microscopy** [Invited] ALLISON GICKING (Presenter), TAYLOR M ZANIEWSKI, WILLIAM O. HANCOCK, Pennsylvania State University — The kinesin-3 family member KIF1A is a neuronal kinesin that performs long-distance anterograde vesicle transport in axons and dendrites. Single molecule studies observe KIF1A velocities > 1 mm/s and average run lengths > 5 mm, making KIF1A one of the fastest and most processive members of the kinesin superfamily; however, the mechanistic basis of these high speeds and long run lengths is unknown. One prevailing model for superprocessivity holds that the positively-charged “K-loop” in the KIF1A motor domain diffusively tethers the motor to the negatively-charged microtubule, which prevents complete dissociation of the motor and effectively links together short runs. However, this model does not account for how KIF1A reaches such high speeds, or what role the K-loop plays in the ATP-driven stepping mechanism. To address these questions, we used biochemical assays in conjunction with direct observations of stepping of wild type KIF1A and k-loop mutants. We captured the transient states of the stepping cycle by tracking a 30-nm gold nanoparticle-functionalized motor domain via interferometric scattering microscopy (iSCAT), which enables fast acquisition of gold particles < 40 nm and simultaneous visualization of the microtubule tracks. We find that the chemomechanical cycle of KIF1A is distinct from other neuronal transport kinesins.
Investigating the Effect of Cargo-Motor Linkage Stiffness on Cellular Functions of Myosin VI* RACHIT SHRIVASTAVA (Presenter), ASHIM RAI, MURTI SALAPAKA, SIVARAJ SIVARAMAKRISHNAN, University of Minnesota — We examine the effect of cargo-motor linkage stiffness on the mechanobiological properties of the molecular motor Myosin VI. We use the programmability of DNA nanostructures to systematically modulate cargo-motor linkage stiffness and combine it with high precision optical trapping measurements to measure the effect of linkage stiffness on motile properties of Myosin VI. Our single molecule experiments reveal that a stiff cargo-motor linkage leads to shorter step sizes and load-induced anchoring of Myosin VI, while a flexible linkage results in longer steps with frequent detachments from the actin filament under load. These findings suggest a novel regulatory mechanism for tuning the dual cellular roles of anchor and transporter ascribed to Myosin VI [1]. We further make an attempt to investigate the physical basis of our findings using simulations and thermodynamics principles.

Deviations from Arrhenius behavior of Kinesin-1 at low temperatures* FLORENCE DOVAL (Presenter), University of Utah, KASSANDRA M ORI-MCKENNEY, RICHARD J MCKENNEY, University of California Davis, MICHAEL VERSHININ, University of Utah — Kinesin-1 is a mechanochemical enzyme that is essential for executing long-distance transport of cargos in eukaryotic cells via processive motility along the microtubule network. KIF5A is a conventional kinesin in the Kinesin-1 family. The temperature dependence of enzymatic activity for several kinesin-1 motors has been reported to follow a simple Arrhenius trend. The range for this observation has been gradually extended to higher temperatures, as it became possible to circumvent and more recently control kinesin degradation. However, both biophysical and biochemical measurements to date have been limited down to ~5 °C. We investigated the enzymatic activity of KIF5A at even lower temperatures and have observed a break in the Arrhenius trend, corresponding to higher activation energy at lower temperature. We will report our investigations of this phenomenon in different biochemical backgrounds and discuss its cause as it relates to the nature of the rate-limiting step of kinesin's enzymatic cycle.

*This research was funded by NSF ENG-1563280
Cargo diffusion shortens single-kinesin runs at low viscous drag*  

JOHN WILSON (Presenter), JING XU, DAVID QUINT, AJAY GOPINATHAN, University of California, Merced — Molecular motors such as kinesin-1 drive active, long-range transport of cargos along microtubules in cells. Thermal diffusion of the cargo can impose a randomly directed, fluctuating mechanical load on the motor carrying the cargo. Recent experiments highlighted a strong asymmetry in the sensitivity of single-kinesin run length to load direction, raising the intriguing possibility that cargo diffusion may non-trivially influence kinesin. To test this possibility, here we employed Monte Carlo-based simulations to evaluate the transport of cargo by a single kinesin. Our simulations included physiologically relevant viscous drag on the cargo and interrogated a large parameter space of cytoplasmic viscosities, cargo sizes, and motor velocities that captures their respective ranges in living cells. We found that cargo diffusion significantly shortens single-kinesin runs. This diffusion-based shortening is countered by viscous drag, leading to an unexpected, non-monotonic variation in run length as viscous drag increases. Our study highlights the importance of cargo diffusion and load-detachment kinetics on single-motor function.

Session U21 FED: Jonathan F. Reichert and Barbara Wolff-Reichert Award for Excellence in Advanced Laboratory Instruction

Award for Excellence in Advanced Laboratory Instruction 302 - Gerald Feldman, George Washington Univ - Tag(s): Education, Focus

2:30PM U21.00001: From Cool Research to Cool Teaching Labs* [Invited]  
ENRIQUE GALVEZ (Presenter), Colgate University — Physicists are often drawn into research when the physical world offers phenomena that show uncanny symmetry or elegant mathematical structure; a puzzling intricacy that is irresistible not to figure out; or even just plain awe at “cool” phenomena that display the beauty of the natural world. These are compelling factors that motivate investigation. Why not have instructional labs with such motivating factors? In this talk I will present some of my efforts to convert the investigation of a motivating physical problems into curricular offerings. It includes optical beams that carry puzzling structures, such as mathematical singularities, symmetrical shapes and puzzling mechanisms. Another initiative that we have worked on involves labs on the quantum mechanics of entangled photons. We have developed a suite of experiments that explore the quantum mechanics of situations involving this source of light. They let students confront counterintuitive but real manifestations of quantum physics. More recently we have been exploring a problem that hopefully will become a new lab: using light to simulate the quantum mechanics of the simple pendulum.

*This work received funding from the National Science Foundation.
3:06PM U21.00002: The “Compleat Physicist” seen through the lens of experiments [Invited]
RANDALL TAGG (Presenter), University of Colorado, Denver — In 1653, thirty-four years before the appearance of Newton’s ‘Principia’, Isaak Walton published “The Compleat Angler”...a book that is still in print! Now in the 21st Century, how might we view the activities of the Compleat Physicist in the context of physics experiments and laboratory skills? If we look at what physicists ultimately do in life, many work in basic research but a far greater number apply physics to a wide range of human needs. How do the knowledge and skills of physics experimentation manifest themselves in these applications? Circling back to fundamental physics, what sort of versatile foundation does a broad experience in the physics laboratory provide so that an emerging professional physicist has a rich conceptual repertoire with which to approach real-world problems? And finally, how can this conceptual repertoire be matched with the nuts-and-bolts technical and computational skills needed to create actual prototypes of new devices and processes?

3:42PM U21.00003: Advanced Labs in the Small Liberal Arts College Environment [Invited]
NICOLE ACKERMAN (Presenter), Physics and Astronomy, Agnes Scott College — The Advanced Lab course is critical for teaching many important skills to physics majors, regardless of their career trajectory. At a small liberal arts college, this course may be run with few pre-requisites, no dedicated funds, limited equipment, no support staff, and as one of many classes a single professor is teaching. While this necessitates certain changes from how the course might be structured at a large research university, the course is nonetheless an invaluable experience for students. I will present my strategies for maintaining an Advanced Lab course at my college, where our department serves a diverse student population and graduates about 6 majors (including Astrophysics) a year. My experiences shows that it is key to focus on learning outcomes and leverage the resources in the broader advanced lab instructor community.
Developing and teaching both Intermediate and Advanced Lab courses contain benefits and challenges in the undergraduate program of study. An Intermediate lab provides requisite skills for students to transition from introductory lab experiences to more rigorous experiments appropriate for advanced/capstone lab courses. The *AAPT Recommendations for the Undergraduate Laboratory Curriculum*\(^1\) and *Phys21: Preparing Physics Students for 21\(^{st}\)-Century Careers*\(^2\) reports provide learning outcomes for physics majors beyond the first year laboratory experience. While no one lab course can prepare majors for post-graduate life, be it teaching, industry, or graduate study, efforts at Appalachian State University (and elsewhere) could serve as a guide to other institutions interested in increasing laboratory experiences in their programs of study. An overview of the Intermediate and Advanced lab courses at Appalachian will be presented, along with how effective these courses are in preparing majors for their future careers, including interviews with former students.

**Session U22 DBIO: Robophysics II**

303 - Shai Revzen, University of Michigan - Tag(s): Focus
2:30PM U22.00001: Centipede locomotion in varying terrains  ALEXANDRA CARRUTHERS FERRERO (Presenter), KELIMAR DIAZ, YASEMIN OZKAN-AYDIN, JOSEPH MENDELSON, DANIEL I GOLDMAN, Georgia Institute of Technology — Animals which move via waves of body undulation and/or few numbers of limbs have been extensively studied. Limited progress has been made studying animals with many degrees of freedom in their bodies in coordination with numerous limbs (i.e. myriapods like centipedes). To discover principles by which body undulation and limb dynamics in concert with body mechanics leads to high performance in diverse environments, we challenged Scolopocryptops sexspinous (body length of ~4.5 cm, 23 pairs of legs) to traverse both a flat terrain and a Gaussian distributed rough terrain (12 x 12 cm with variable height of blocks). On flat terrain, centipedes maintain a constant out of phase traveling wave along their limbs during locomotion. In contrast, on rough terrain, centipedes will symmetrically use their limbs when their various segments are at different heights. We hypothesize that the centipedes will modulate the use of their limbs in order to overcome heterogeneities. Insight from a robophysical model suggests centipede limbs integrate passive dynamics allowing the locomotorto traverse myriad environments.

2:42PM U22.00002: Modeling Locomotion in a Segmented Soft Robot using Planar Discrete Elastic Rods*  NATHANIEL GOLDBERG, University Of California At Berkeley, XIAONAN HUANG, CARMELO MAJIDI, Carnegie Mellon University, ALYSSA NOVELIA, OLIVER M. O’REILLY, University Of California At Berkeley, DEREK A. PALEY, WILLIAM SCOTT (Presenter), University of Maryland, College Park — Modeling soft robots that move on surfaces is challenging from a variety of perspectives. Recently Bergou, et al. introduced a numerically efficient formulation of Discrete Elastic Rods (DER) based on discrete differential geometry. In this talk, we describe a simplified planar version of Bergou et al.’s theory and show how it can be used to model soft robots that are composed of segments of soft material folded and bonded together. To show the efficacy of DER, the formulation is used to describe and analyze the dynamics of a prototype caterpillar-inspired soft robot. The robot consists of six segments of a shape memory alloy actuated soft material. By controlling the timing and sequencing of the actuators, locomotion can be achieved by exploiting stick-slip friction and the variation in the normal force exerted by the ground plane on each contacting actuator. Successful modeling of the robot also entailed the development and implementation of procedures to prescribe the parameters for components of the soft robot. After describing these procedures, we discuss the comparison of our calibrated model to the experimental behavior of the caterpillar-inspired soft robot. The extension of the DER modeling to other soft robot designs will be discussed.

*ARO Grant No. W911NF1610244
2:54PM U22.00003: Geometric mechanics reveals optimal coordination of limb and body waves during centipede locomotion  BAXI CHONG (Presenter), PERRIN E SCHIEBEL, YASEMIN OZKAN-AYDIN, MALCOLM BROWN, ALEXANDRA C CARRUTHERS, JENNIFER RIESER, SIMON SPONBERG, DANIEL I GOLDMAN, Georgia Inst of Tech — Running epimorphic centipedes display a characteristic body undulation. Elucidating the role of body-leg coordination is difficult because of the many degrees of freedom in the flexible body and numerous limbs. We decomposed the centipede locomotion into body undulation and leg stepping waves, and used the mathematical framework of geometric mechanics to study body-leg coordination. We characterized the body-leg coordination by the phase offset between two waves. We recorded high-speed video and tracked the motion of a centipede (*Scolopendra polymorpha*, 5 trials) running on a treadmill. Our theory predicted that the speed (in body lengths per cycle, BLC) was maximized when the body undulation (1.6 spatial waves) had a phase of 2.50 rad leading that of the leg wave (2 spatial waves). The theoretical prediction of centipede speed was 0.40 BLC, 0.10 BLC and 0.25 BLC with best, worst and no body undulation respectively. Experiments revealed that the centipede moved at 0.41±0.05 BLC with the phase offset 2.51±0.71 rad, in good agreement with our theoretical prediction. Our preliminary results suggest that the geometric approach captures centipede locomotion dynamics without including inertial effects.

3:06PM U22.00004: Geometric Gait Optimization with a five-link wheeled snake*  BRIAN BITTNER (Presenter), SHAI REVZEN, Univ of Michigan - Ann Arbor — Geometric mechanics offers a powerful set of tools for understanding locomotion. In past work we used data-driven oscillator theory to design a sample efficient method for modeling geometric systems such as the Purcell swimmer. We extended this method to include the modeling of highly damped systems inhabiting the perturbed Stokes dynamical regime. Here, we present a case study on a physical five-link wheeled snake robot. Under each link, a pair of wheels were co-aligned to decrease friction in the direction along the link. We seeded the geometric gait optimizer with a zero displacement gait. After 9 iterations of 80 cycles, we produced a motion that achieved 45% body length per cycle translation motion, while optimizing over 84 parameters. Running the system at 0.5 Hz, this took 24 minutes. We noticed the final gait changes combinations of wheels that are contacting and not contacting the ground, a feature not observed in the first gait, suggesting that the optimizer successfully exploited hybrid features of the dynamics.

*NSF CMMI 1825918
3:18PM U22.00005: Directional Compliance in Snake Robot Obstacle-Aided Locomotion
TIANYU WANG (Presenter), JULIAN WHITMAN, MATTHEW TRAVERS, HOWIE CHOSSET, Carnegie Mellon Univ — This work investigates the role of compliance in high-degree-of-freedom snake robots. Prior work used geometric methods to reduce the dimension of the robot’s state space to efficiently control the robot; instead of controlling all of the robot’s degrees-of-freedom, we need only control two for meaningful motions. Recently, we adapted this technique to handle unmodeled terrain irregularities. We defined a compliant controller on the reduced state space, which used torque information measured at the robot’s joints. This improved the robot’s performance, but still the robot arrived at stuck configurations. To address this problem, we introduce a biologically inspired strategy called directional compliance, which selectively allows some portions of the robot to comply to the environment, while others remain stiff to push off for forward progression. Unfortunately, with pure directional compliance method, the robot can still get stuck. Therefore, we develop an estimator to determine the state of the robot and a controller that switches between compliance and directional compliance modes to help the robot get unstuck. We experimentally find that our method enables the snake robot to locomote more consistently than the pure compliant controller in obstacle-rich environments.

3:30PM U22.00006: Body compliance helps oscillating snake robots reduce roll instability to traverse large steps
QIYUAN FU, CHEN LI (Presenter), Johns Hopkins University — Snakes traverse a diversity of complex terrain at ease, an ability that snake robots still aspire to achieve. Despite progress in arboreal (or similar) and granular environments, a major knowledge gap is how to maintain stability on large, smooth obstacles like large rocks or steps that lack “push points” to grip or brace against. Our previous study (Gart et al 2019 JEB) discovered that kingsnakes traverse large steps stably by combining lateral oscillation for propulsion with cantilevering for bridging height change. Here, to understand stability principles, we developed a snake robot as a physical model and tested two hypotheses: (1) roll stability diminishes as step becomes higher; and (2) body compliance helps maintain contact and reduce roll instability. With similar gait as the animal, the rigid body robot was able to traverse steps as high as 40% body length, but traversal probability quickly diminished with increasing step height. A locomotor transition analysis revealed that this was mainly due to an increase in roll instability. Adding body compliance improved contact, reduced roll instability, and increased traversal probability by up to 40% while maintaining speeds. Our study demonstrated that maintaining contact is important for stable locomotion in complex terrain.
Exploring the role of passive mechanics in limbless locomotors via a novel robophysical snake. MARINE C MAISONNEUVE (Presenter), PERRIN E SCHIEBEL, DANIEL I GOLDMAN, Georgia Inst of Tech — Animals like snakes use traveling body bends to move in terrestrial terrain. Previously, we discovered that passive body buckling, facilitated by unilateral muscle activation, allowed negotiation of sparse obstacles without additional control input in the snake (C. occipitalis) [Schiebel et al., 2019]. To explore the implications of this scheme we developed a robophysical model with passive mechanical flexibility. Most snake robots precisely control the position of each joint with a single actuator. In contrast, the actuation in our robot is modeled after biological snakes, in which pairs of muscles, one on each side of the spine, create body bends by contracting unilaterally. The robot has 8 joints and 16 motors, each joint has two motor-driven pulleys on opposite sides of the body. The pulleys increase curvature by shortening a wire attached to the adjacent joint. Opposite an active motor, the pulley is completely unspooled; pairs of motors can resist forces which would lengthen active wires but not those pushing them shorter, allowing the body to passively buckle during certain obstacle collisions. Preliminary tests demonstrate that a travelling sinusoidal wave of joint angles allows locomotion using wheels (which provide directional friction).

Amplitude modulation enhances obstacle negotiation for sidewinders ABDUL KABA (Presenter), JENNIFER RIESER, VERONICA M PAEZ, Georgia Tech, HENRY ASTLEY, Akron University, JOSEPH MENDELSON, Atlanta Zoo, DANIEL I GOLDMAN, Georgia Tech — Sidewinding snakes cyclically lift portions of their body as they move. This gait can be modeled as two coupled head-to-tail traveling waves: a horizontal wave of body undulation and a vertical wave controlling substrate contact. The changing contact pattern introduces a lateral component to movement that creates a large projection of the body onto the direction of motion and makes obstacle negotiation challenging. Biological experiments revealed that the sidewinder moves through a row rigidly-anchored vertical posts by squeezing parts of its body, which we hypothesized was achieved by increasing the amplitude of the horizontal wave. To test this, we created a sidewinding robot from a chain of 14 servo motors with alternating direction of actuation. Horizontally and vertically oriented sets of motors were each driven sinusoidally in time and position along the body. When in contact with a rigid post (detected via capacitive touch sensors), the robot either increased its horizontal amplitude for one full cycle or continued with its nominal waveform. The robot successfully moved beyond the post in 80% of the trials with increased amplitude, compared to never succeeding when maintaining the nominal waveform.
Springs and Wings: Elastic Energy Exchange in Insect Flight

JEFFREY GAU (Presenter), Interdisciplinary Bioengineering Graduate Program & Woodruff School of Mechanical Engineering, Georgia Institute of Technology, JAMES LYNCH, NICK GRAVISH, Mechanical and Aerospace Engineering Department, University of California, San Diego, SIMON SPONBERG, School of Physics & School of Biological Sciences, Georgia Institute of Technology — In many insects, wing movements are generated indirectly via deformations of an exoskeletal shell. Estimates of power expenditure suggest that elastic energy recovery between wingstrokes may reduce flight power requirements. We tested three questions: 1) Can the thoracic shell provide significant energy return? 2) Does a simple damped elastic model describe bulk mechanical behavior? and 3) Are different thorax regions specialized for elastic energy exchange? We measured deformation mechanics by recording the force required to sinusoidally deform the exoskeleton over a wide frequency range. Elastic energy storage in the exoskeleton is sufficient to minimize power requirements and a structural (frequency-independent) damping model, not a viscoelastic one, describes bulk mechanical properties. We next performed complementary experiments on a structurally damped hemispherical shell. In contrast to the hemispherical shell, mechanical coupling between exoskeleton regions improved spring performance and local properties depended on global strain patterns. We found regions specialized for energy recovery with low dissipation, highlighting the specificity of exoskeleton regions for flight energetics. Finally, we consider the implications of resonance mechanics on flapping wing flight.

Springs and Wings: Robophysical investigation of unsteady flapping wing dynamics

JAMES LYNCH (Presenter), Department of Mechanical and Aerospace Engineering, University of California, San Diego, JEFFREY GAU, Interdisciplinary Bioengineering Graduate Program & Woodruff School of Mechanical Engineering, Georgia Institute of Technology, SIMON SPONBERG, School of Physics & School of Biological Sciences, Georgia Institute of Technology, NICK GRAVISH, Department of Mechanical and Aerospace Engineering, University of California, San Diego — Flying insects are thought to achieve energy-efficient flapping flight by storing and releasing elastic energy in their muscles, tendons, and thorax. However, the dynamics of even simple elastic elements coupled to nonlinear, unsteady aerodynamic forces may make controlling flapping motions via muscle force inputs challenging. In previous work, we examined the resonance properties of a dynamically-scaled robophysical system consisting of a rigid wing actuated by a motor in series with a spring. In this talk, we describe experiments to study the control implications of operating spring-wing transmissions on and off resonance. We consider the response of systems to changing control inputs and external perturbations. We conduct robophysical experiments and model simulations measuring the response of elastic flapping wing systems to realistic control inputs and external perturbations that simulate environmental interactions like wind gusts or collisions. We vary mechanical parameters of the system and track results across a non-dimensional parameter space, enabling comparisons across length scales. The results suggest that series-elastic flapping wings designed for maximum efficiency experience commensurate losses to control authority but may be more robust to external perturbations.
4:30PM U22.00011: Springs and wings: robophysical and biological investigations inform the design, energetics, and control space for effective flapping wing flight  JAMES LYNCH, University of California, San Diego, JEFFREY GAU, SIMON SPONBERG, Physics, Georgia Institute of Technology, NICK GRAVISH (Presenter), University of California, San Diego — Flying insects and robots possess a wide range of elastic structures that may enable energy saving in flapping wing flight. However, there is little direct experimental evidence of flight energy reduction through spring-like elements. Furthermore, the implications of a resonant flight system, such as the material and mechanical demands of the thorax, and the control and perturbation responses, are poorly understood. Here we present an overview of how elastic structures in flapping wing flight can improve flight energetics while at the same time altering control capabilities. We present these arguments through a non-dimensional representation of flapping-wing systems, supported by biological and robophysical experiments. This approach enables us to compare the energetic and control implications for flapping wing systems with elastic structures across the relevant spatial scales of flying insects and robots.

4:42PM U22.00012: Biologically inspired vision based aerial robot perching*  HAIJIE ZHANG (Presenter), JIANGUO ZHAO, Colorado State University — Limited flight time has constrained the application of the aerial robot. One possible solution is to learn from biological flyers (i.e. birds, flies) to perch on the desired objects. During perching, the aerial robots can still do surveillance related tasks with the desired height and orientation instead of hovering. Research results have shown that visual information named time-to-contact is used for biological flyers perching guidance. And this information can be extracted from consecutive images. It is widely used for robot motion control for autonomous braking and landing since it can realize zero contact velocity. However, for aerial robot perching, a non-zero contact velocity is usually required to make the perching mechanism functionalize. In this research, we propose an optimized two-stage time-to-contact based guidance law. With a properly designed time-to-contact controller, we finally realize the fastest perching with desired contact velocity. The research presented in this paper can be readily applied to the control of the aerial robot for perching with visual feedback, and can inspire more alternative forms of time-to-contact based planning and control for robotic applications.

*National Science Foundation under Grant IIS-1815476 and IIS-1815519
Robophysics is an indispensable approach to discovering general principles of robots operating in complex environments. Fortunately, physics principles governing non-equilibrium processes where motion emerges by internal actuation in synergy with robotic physical models meeting real world environments can generate quantifiable, testable hypotheses of complex biological systems not otherwise possible. In biology, robophysics has led to simple system-level models (templates) that collapse staggering complexity, while exploring how behavior emerges from more representative models (anchors). A next step is to examine the parallel and serial composition of templates and their dynamic reconfiguration. Robophysics provides the opportunity to determine how: biologically embodied mechanical computation works with neural computation; stability occurs in complex environments using soft-matter physics; performance of multiple tasks results without change in structure; multifunctional hierarchical and heterarchical control networks emerge; properties of fail-safe and fault tolerant performance evolve; and how learning can occur using a reduced set of control modules. In turn, robophysics approach to biological locomotion can inspire the design of novel robots and applied mathematics.

Thursday, March 5, 2020 2:30 PM - 5:18 PM

Session U23 DBIO DSOFT DPOLY GSNP: Macromolecular Phase Separation in Biology II 304 - Patrick McCall, Max Planck Institute for the Physics of Complex Systems - Tag(s): Focus
2:30PM U23.00001: Pollen cell walls form from modulated phases [Invited]  ASJA RADJA
(Presenter), Harvard University, ALISON SWEENY, Physics and Ecology & Evolutionary Biology, Yale
University, MAXIM O LAVRENTOVICH, Physics and Astronomy, University of Tennessee — Pollen cell
walls exhibit a huge diversity of morphologies including ordered and disordered arrangements of
spikes, stripes, and holes. Electron microscopy images of pollen wall development across the
spermatophyte tree reveal that a ubiquitous material called primexine, thought to be made of a
mixture of polysaccharides, lipoproteins and glycoproteins, templates these morphologies.
Recently, our imaging studies identified that a phase separation of primexine coupled to the cell
membrane induces a phase transition to modulated phases which pattern the pollen wall. We
formulated a Landau-Ginzburg free energy description of this process in which we treat the
primexine concentration as a scalar field coupled to the cell membrane and calculated the
equilibrium states. We also studied the dynamics of our model and found that together
kinetically-arrested and equilibrium states recapitulate most extant cell morphologies. Further
imaging studies indicate that nanoscale patterns form within the phase-separated domains, thus
we additionally model the lyotropic liquid crystalline-like phases employing self-consistent field
theory simulations. Finally, we completed an evolutionary analysis in which character traits are
defined by parameters of our model that reveals while equilibrium patterns have appeared
multiple times during evolution, selection does not favor these states.

3:06PM U23.00002: Designing morphology of separated phases in multicomponent liquid
mixtures*  MILENA S CHAKRAVERTI-WUERTHWEIN, SHENG MAO, Princeton University, HUNTER
GAUDIO, Villanova University, MIKKO HAATAJA, ANDREJ KOSMRLJ (Presenter), Princeton University —
Morphology of multiphase membraneless organelles formed via intracellular phase separation
plays an important role for their functionality. Yet, very little is known how intermolecular
interactions can be tuned to achieve target microstructures of separated phases. To address this,
we systematically investigate morphologies of coexisting phases obtained via phase separation in
Flory-Huggins liquid mixtures with 4 or more components. We demonstrate that the topology of
separated phases is completely determined by their surface tensions, while their volume
fractions dictate the geometry of microstructure (e.g. droplets, percolated structure). We
developed a novel method based on graphs that enabled us to enumerate all topologically
distinct morphologies of separated phases. Each graph is associated with a set of inequalities for
surface tensions and this enabled us to reverse engineered intermolecular interaction
parameters to realize all topologically distinct morphologies for 4 coexisting phases. The
developed approach is general and can be applied to design morphologies with an arbitrary
number of coexisting phases.

1420541.
3:18PM U23.00003: Microscopic Model of a Biological Condensate  SWAN HTUN (Presenter), HAN-YI CHOU, KUMAR SARTHAK, ALEKSEI AKSIMENTIEV, University of Illinois at Urbana-Champaign — Liquid-liquid phase separation governs the intracellular organization of biological molecules into membraneless organelles also known as biological condensates. Fused in Sarcoma (FUS), an RNA-binding protein, is the principle component of a biological condensate involved in DNA repair. The intrinsically disordered nature of FUS eludes structural characterization using conventional methods. Here, we report a fully-atomistic structure of a FUS condensate obtained through a combination of coarse-grained and all-atom simulations. Using existing structural and biochemical information, we constructed a coarse-grained model of the FUS protein. An ensemble of such proteins was found to undergo phase separation into a liquid-like condensate in a temperature and composition-dependent manner. The final configurations obtained through the coarse-grained simulations were used to construct an all-atom model of the condensate, including the surrounding solvent. The microscopic structure was refined using atomistic simulations and used to probe the condensate's viscoelastic behavior and identify specific interactions that control its viscosity. The resulting structural model sets the stage for subsequent systematic inquiry into the sequence-structure-function relationship of the condensate.

3:30PM U23.00004: Microstructure in biological phase transition  KAMAL BHANDARI (Presenter), JEREMY SCHMIT, Kansas State Univ — Many cellular structures are formed by the spontaneous condensation of biomolecules into liquid states. Biological condensed states may contain hundreds of different molecules, but only a few of them are necessary to form a condensates. These are called “Scaffolds” while other non-essential molecules, called “Clients”, provide the unique biochemical properties of droplets. We study a synthetic system of phase separating molecules designed by Rosen and co-workers. There are two types of scaffolds (poly-SUMO/poly-SIM) and two types of clients (SUMO/SIM). Mixture of multivalent scaffolds gives condensates which can recruit monovalent clients. Since the condensed phase has a low density, we propose that molecules are highly aligned to form zipper structures. These zippers have defects in the bonding structure that will allow for the subsequent formation of a network. We employ a transfer matrix formalism to compute the grand partition function of the zipper structures and to explain the curious non-monotonic client binding behavior observed in experiments. We find that the 1D nature of the scaffold assembly has important consequence for client recruitment.
Experimental determination of binodal compositions of protein and peptide solutions  
EMMANOUELA FILIPPIDI (Presenter), Max Planck Institute for Molecular Cell Biology and Genetics, FRANK JULICHER, Max Planck Institute for the Physics of Complex Systems, ANTHONY HYMAN, Max Planck Institute for Molecular Cell Biology and Genetics — Biomacromolecules such as proteins are known to undergo liquid-liquid phase separation to a dense phase and a dilute phase under certain conditions of temperature, pH, salt and protein concentrations. As the study of proteins is complex due to their zwitterionic nature, hydrogen bonding, inclusion of hydrophobic side chains, pi-cation interactions and presence of metal binding and folded domains, we will study in parallel both a protein, FUS, and simplified peptides of known sequences.

We will present quantitative measurements of both branches of the binodal curves of the phase diagrams obtained via quantitative phase imaging microscopy for the protein FUS and simpler peptide sequences. As the tyrosine-arginine interactions are believed to play a significant role in inter-molecular association, we shall examine the variation of the branches as FUS tyrosines are alterned to phenylalanines and 3,4-dihydroxy-L-phenylalanines imparting changes in hydrogen bonding and pi-cation interaction strength. In the case of peptides, we will examine how multiplicity of pi-cation interactions at constant density of tyrosines and arginines affects the associations and thus the phase diagram.

Spinodal Dynamics in Non-Equilibrium Compression of Two Self-Avoiding Polymer Chains  
LILI ZENG (Presenter), RABEA SEYBOLDT, ZEZHOU LIU, XAVIER CAPALDI, AHMED KHORSHID, PAUL FRANCOIS, NIKOLAS PROVATAS, WALTER W REISNER, Physics, McGill University — Two polymers under 1D confinement can phase separate as a consequence of chain interconnectivity and entropy maximization, and this demixing may be one mechanism leading to bulk chromosomal segregation in bacteria. While there has been considerable theoretical effort to explore this problem, few experiments have attempted to directly investigate segregation/mixing behaviour of two self-avoiding chains in model geometries. In this experiment, two differentially labeled nanochannel confined DNA molecules are compressed against a barrier using hydrodynamic flow. The differential labeling enables us to quantify the concentration profile of each chain along the channel independently. The two DNA molecules will mix given that the applied forcing is strong enough, but instead of simple mixing, we observe a complex phenomena whereby the chains interpenetrate but form alternating, fluctuating bands in which one chain has higher concentration relative to the other. We interpret this phenomenon as a spinodal decomposition of the two polymers and rationalize it using a model based on a 1D convective Cahn-Hilliard equation, a classic model describing spinodal decomposition in driven binary systems. Simulations for such a model yield striking similarity to the experimental observations.
4:06PM U23.00007: Relating chemical and physical properties controlling oligonucleotide polyelectrolyte complex phase separation* ALEXANDER E. MARRAS (Presenter), JEFFREY VIEREGG, Pritzker School of Molecular Engineering, University of Chicago, MICHAEL LUECKHEIDE, Polymers and Complex Fluids Group, National Institute of Standards and Technology, MATTHEW TIRRELL, Pritzker School of Molecular Engineering, University of Chicago — Nucleic acids are some of the most highly-charged molecules known, and interact strongly with charged molecules in the cell. Condensation of long double-stranded DNA is a classic problem of biophysics, but the polyelectrolyte behavior of short and/or single-stranded nucleic acids is far less studied despite its importance for both biological and engineered systems. Homopolycations and neutral-cationic block copolymers condense nucleic acids driving macro- or nanoscale phase separation, respectively. Here, we present an investigation of the impact of physical and chemical properties of each polyelectrolyte on complex and micelle assembly. We find molecular details including hybridization, charge density, and chemical structure strongly influence complexation behavior and stability. These observations narrow the design space for optimizing therapeutic micelles and provide new insights into the physics of polyelectrolyte self-assembly.

4:18PM U23.00008: Entropic localization of plasmids in nanofluidic compartments ZEZHOU LIU (Presenter), XAVIER CAPALDI, LILI ZENG, RODRIGO REYES LAMOTHE, WALTER W REISNER, McGill Univ — Bacteria must stably partition their plasmids to their daughter cells upon division. While purely random partitioning can theoretically ensure stable transmission of plasmids to daughter cells, it is not clear that plasmid partitioning is random. Studies tracking plasmids in vivo show that multi-plasmid clusters present at the cell poles, but the roles played by the cell geometry and chromosome-plasmid interactions are still unclear. Here, we present a nanofluidic device with compartments simulating the confinement induced by a cell membrane. The compartments can be opened and closed by pneumatically actuating the thin membrane lid. The cavities are elliptical with a width varying from around 200 nm to 2 um. A differentially stained T4 DNA molecule and one plasmid molecule are introduced inside the compartment and monitored in real time from their fluorescence signals. We find that the plasmid prefers the peripheral of the cavity as has been observed in in vivo measurements in E. Coli, forming a ring shape distribution. In addition, as the cavity aspect ratio increases, the plasmid shows a preference for the cavity poles. Our results suggest that the free energy landscape formed by chain-chain interaction and the confinement geometry helps promote plasmid localization.
4:30PM U23.00009: Computational Insights into Phase Separation of Multivalent Polymers*
EMIKO ZUMBRO (Presenter), ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology MIT — Liquid-liquid phase separation has emerged as an important biological process. In membraneless organelles, phase separation in solution is often controlled by weak multivalent interactions between polymers using a variety of bond types. How to control phase compositions and specificity in biological contexts is still not well understood. In this work we compare phase separation of multivalent polymers through non-specific Van der Waals interactions to phase separation through specific reactive-binding interactions. We use a coarse-grain, reactive-binding, Brownian dynamics simulation to investigate the transition dynamics, resulting compositions, and specificity of polymer phase separation. Our results provide insights on how multivalently binding polymers control phase separation in synthetic and biological systems.

4:42PM U23.00010: Stable drops: the Gibbs-Thomson condition and drop dynamics
ANDREW RUTENBERG (Presenter), SAMUEL CAMERON, Dalhousie Univ — In standard phase separated binary liquids, larger droplets grow while small droplets shrink due to the Gibbs-Thomson condition at droplet boundaries. As a result, the liquid reduces its overall interfacial area between the two phases. The dynamics of these systems can be described by Lifshitz-Slyozov-Wagner theory, and ultimately only one large (bulk) drop will survive in equilibrium. However, some binary liquid-like systems have a preferred, stable droplet size, and their final steady states have multiple microphase-separated droplets. This phenomena not well described by the standard Gibbs-Thomson condition or the standard Lifshitz-Slyozov-Wagner dynamics. This talk addresses three questions for systems with small stable droplets: how does the Gibbs-Thomson condition generalize, how does Lifshitz-Slyozov-Wagner dynamics generalize, and how much of this should apply when stable drops arise from non-equilibrium processes?

4:54PM U23.00011: Simulation Informed Thermodynamic Model for Polyampholyte Self-Coacervation with Heterogeneous Charge Distribution*
JASON MADINYA (Presenter), CHARLES SING, University of Illinois at Urbana-Champaign — Living cells rely on phase separation to achieve many of its critical functions such as organelle formation and signaling and regulatory complexation. Intrinsically disordered proteins (IDPs) often play a role in intracellular liquid-liquid phase separation. IDPs are frequently ampholytic and they can be driven to phase separation through electrostatic interactions. The solution behavior and properties are encoded in the peptide sequence of the proteins, particularly the distribution of the charged residues. Previous work from the authors introduced a Transfer Matrix model for charge-driven polyampholyte phase separation, which resolved the impact of charge sequence on phase separation. This model was limited to looking at homogenous sequences made up of repeating blocks of charge patterns. In this work we present a coarse-grained simulation model to resolve phase separation in polyampholytes with any arbitrary charge sequence. Of particular interest is characterizing the inhomogeneity of the sequence and quantifying the impact on solution behavior.

*This material is based upon work supported by the National Science Foundation Graduate Research Fellowship Program under Grant No. DGE-1746047.
5:06 PM U23.00012: Nematic transition and liquid-liquid phase separation in semiflexible polymers – nanoparticle mixtures* SUPRIYA ROY (Presenter), YENG-LONG CHEN, Institute of Physics, Academia Sinica, Taiwan — Adding nanoparticles (NPs) to a polymer matrix may significantly modify its glass transition temperature, dielectric constant, isotropic-nematic phase transition behavior, etc. In the present study, we used GPU-accelerated Langevin dynamics simulation to explore how polymer-NP interaction affect the isotropic-nematic (I-N) transition and microstructural modifications of a matrix of semi-flexible polymers with persistence length \( P = 20 \) and contour length \( L = 25 \). The mixture is confined under slit. Polymers are modeled as semi-flexible chains with beads of diameter \( \sigma_m = 1 \), and NPs are spheres with \( \sigma_p = 2.5 \).

Two limits of NP-polymer interactions - hard NPs that repel, and ideal NPs do not interact with other NPs are explored. Adding low volume fraction \( \Phi_p \) of hard NPs disperse the NPs in the polymer matrix, which disrupt the polymer nematic ordering and upshifts the I-N transition. In contrast, ideal NP additives induce depletion attraction between polymers, which enhances polymer alignment and downshifts the I-N transition. For moderate or high \( \Phi_p \), hard NPs would crystalize and discrete nematic polymer micro-domains are formed. On the other hand, ideal NPs forms a liquid micro-domain that decreases in size as the monomer volume fraction \( \Phi_m \) increases.

Session U24 GSNP GDS: Statistical Physics Meets Machine Learning

2:30PM U24.00001: A nonlinear and statistical physics approach to machine learning electronic hardware* DANIEL LATHROP (Presenter), LIAM SHAUGHNESSY, BRIAN HUNT, HEIDI KOMKOV, ALESSANDRO RESTELLI, University of Maryland, College Park — As the uses of machine learning continue to grow in science and industry, there is a need to reduce power and increase processing speed. As has been done before, hardware co-processors can take over some tasks. We present research developing novel machine learning hardware that relies on a large network of nonlinear electronic nodes to instantiate a reservoir computer. We characterize the behaviors of these networks and find a critical point as we adjust their sensitivity. Moreover, we find that their machine learning performance, in terms of accuracy, depends on the sensitivity of the network.

*This material is based in part upon work supported by the National Science Foundation (EAR 1417148 and 1909055), as well as the NSF Graduate Research Fellowship Program under Grant No. 1322106. Our research was partially supported through a DoD contract under the Laboratory of Telecommunication Sciences Partnership with the University of Maryland. We would also like to thank the Maryland Innovation Initiate for their support.
2:42PM U24.00002: Reservoir Computer Optimization for Parity Checking*  
WENDSON BARBOSA (Presenter), Department of Physics, The Ohio State University, GUILHEM RIBEILL, MINH-HAI NGUYEN, THOMAS A OHKI, GRAHAM E ROWLANDS, Raytheon BBN Technologies, DANIEL J GAUTHIER, Department of Physics, The Ohio State University — In recent years, the Reservoir Computing (RC) approach, a recurrent-neural-network-based scheme for Machine Learning (ML), has been used extensively for solving different tasks such as time-series prediction, nonlinear system control and classification tasks. A benchmark problem regarding the latter is the parity check of a random sequence of bits. Although at a first look it seems to be a simple problem, it is known to be a very difficult task to be solved using ML techniques. We shall discuss the reservoir computer hyper-parameters optimization and exploration of different architectures for inputting data to the reservoir to improve the parity classification performance as well as paths toward high-speed hardware implementation.

*This work was funded by Raytheon BBN Technologies Corp.

2:54PM U24.00003: Using Machine Learning to Infer Composition of Complex Chemical Mixtures  
UNAB JAVED (Presenter), Rutgers University, New Brunswick, KANNAN P RAMAIYAN, CORTNEY R KRELLER, ERIC L BROSHA, RANGACHARY MUKUNDAN, Los Alamos National Laboratory, ALEXANDRE MOROZOV, Rutgers University, New Brunswick — Predicting the concentration of each constituent in a complex gas or liquid mixture is an important challenge in many fields of science and technology, ranging from real-time monitoring of automotive exhaust to detecting potentially toxic substances in the air. We employ an array of solid-state sensors to test gas mixtures in a controlled laboratory environment, recording voltage responses from the sensor array. The sensors in the array typically react to more than one gas in the mixture and their voltage responses are non-linear, making the task of decoding compositions of gas mixtures highly non-trivial. We have developed a Bayesian algorithm which, given a set of readings from the array, identifies and quantifies all gases present in the system. The Bayesian nature of our approach allows us to estimate the uncertainty of the predictions in a rigorous manner and to carry out model selection. Our machine learning framework can be used to model any non-linear system with correlations between inputs and has applications in a wide variety of settings.

3:06PM U24.00004: Deep generative spin-glass models with normalizing flows  
MASOUD MOHSENI (Presenter), Google Inc., GAVIN HARTNETT, Rand Cooperation — We develop and train a novel universal class of deep spin-glass models that can learn to represent multiscale phenomena in physics and computer science including critical phenomena, discrete optimization, and probabilistic inference in graphical models. To this end, we first provide a continuous formulation of spin-glasses and convert the discrete Boltzmann distributions into physically equivalent continuous distributions. We then use recent techniques in deep learning known as “Normalizing Flows” to generate new low-energy states of such complex systems below spin-glass phase transitions. In particular, we demonstrate that the real non-volume preserving flows can be successfully trained to generate complex spin-glass distributions. We explore two alternative methods for training the normalizing flow based on minimizing reverse and forward Kullback-Leibler divergence. Moreover, we show how the problem of mode collapse for such deep generative models can be overcome at or below a critical point.
3:18 PM U24.00005: A Continuous Formulation of Discrete Spin-Glass Systems

GAVIN HARTNETT (Presenter), Engineering and Applied Sciences, RAND Corporation, MASOUD MOHSENI, Google Inc — We introduce a new, continuous formulation of discrete spin-glasses in which the discrete Boltzmann distribution is replaced by a continuous probability density over the real numbers. This formulation applies for any discrete spin-glass with Ising spins coupled through 2-body interaction terms. A major benefit of working with such a continuous formulation is that the energy landscape may be studied directly using tools from differential geometry and topology. In particular, we show that for a given set of couplings there is a critical temperature above which the energy landscape is convex. Below this temperature the landscape becomes non-convex due to the appearance of multiple critical points. In general, this convex/non-convex transition is distinct from phase transitions to the spin-glass or ferromagnetic phases. In this talk, we introduce our general formalism and theoretically establish the similarities and differences with the mean-field models and the Thouless-Anderson-Palmer equation. We then provide details for a few specific cases including the Sherrington-Kirkpatrick model and random restricted Boltzmann machines.

3:30 PM U24.00006: Machine-learning the DFT of a classical statistical-mechanical system*

PETR YATSYSHIN (Presenter), ANDREW DUNCAN, SERAFIM KALLIADASIS, Imperial College London — We apply machine-learning (ML) to the construction of mean-field theories of classical statistical-mechanical systems. In the density functional formulation of classical statistical physics, the Helmholtz free energy generates a hierarchy of many-body direct correlation functions, and the one-body density is its first member. In equilibrium, the latter minimises the free energy functional of the system. Thus, knowing the free energy functional allows one to solve classical statistical mechanics. In this talk, we address the inverse problem of finding the free energy functional, given the particle data corresponding to the system in equilibrium. Introducing an adversarial ML methodology, we reformulate the learning problem as a two-player game, with the best fitting parameters obtained as the solution of a minimax problem. As proof of concept, we consider the Percus’ model of a 1D fluid, consisting of hard rods on a line, for which the exact functional is known. We emphasize the physics-informed aspect of ML, where the physical constraints, including the “physical intuition”, are combined with ML methods to obtain meaningful results.

Dynamical loss functions for Machine Learning

MIGUEL RUIZ GARCIA
(Presenter), GE ZHANG, Univ of Pennsylvania,
SAMUEL SCHOENHOLZ, Google Brain,
ANDREA JO-WEI LIU, Univ of Pennsylvania — Current deep learning approaches usually rely on very diverse architectures, stemming from trial and error design. This has triggered great interest in improving the theoretical understanding of machine learning. The structure of the loss function landscape and the way it affects the performance of the algorithm have received recent interest. Loss functions penalize incorrect identifications and the focus has largely been on optimizing algorithms (e.g. stochastic gradient descent) within the landscapes defined by the loss functions. We take a different approach by exploring new loss functions. In particular, we explore the effect of dynamical loss functions, where weights on each training example change during training. Preliminary results show that this new approach can outperform the results obtained with static loss functions for particular cases.

A mechanical model for supervised learning

MENACHEM STERN
(Presenter), CHUKWUNONSO ARINZE, LERON PEREZ, STEPHANIE PALMER, ARVIND MURUGAN,
University of Chicago — A broad goal of engineering is to make functional machines with specific, programmed input-output responses. When inputs are specified in advance and few in number, this goal is sought through rational design, changing the system elements to obtain desired responses. In the supervised learning framework of computer science, system parameters (synapses) are modified in response to observed examples of the correct input-output mapping (classification). In this work, we apply the supervised learning framework to self-folding sheets, using a physically motivated learning rule. The trained sheet classifies labeled forces by folding into discrete folded states. These sheets succeed in classifying real-world data like Iris flowers, and also generalize, similar to other learning algorithms. As learning provides a straightforward framework to programming complex input-output relationships, we hope that implementing these ideas in engineering could usher in new classes of machines, that have so far eluded design.

*We acknowledge NSF-MRSEC 1420709 for funding and the University of Chicago Research Computing Center for computing resources.
Quantifying statistical mechanical learning in a many-body system with machine learning

WEISHUN ZHONG (Presenter), JACOB M GOLD, Massachusetts Institute of Technology, SARAH MARZEN, Massachusetts Institute of Technology and the Claremont Colleges, JEREMY L ENGLAND, Massachusetts Institute of Technology and GlaxoSmithKline, NICOLE YUNGER HALPERN, Harvard University and Massachusetts Institute of Technology — Far-from-equilibrium many-body systems, from soap bubbles to suspensions to polymers, learn the drives that push them. This learning has been characterized with thermodynamic properties, such as work dissipation and strain. We move beyond these macroscopic properties first defined for equilibrium contexts: We quantify statistical mechanical learning with machine learning. Our strategy relies on a parallel that we identify between representation learning and statistical mechanics in the presence of a drive. We apply this parallel to measure novelty detection, classification, and memory capacity. Numerical simulations of a spin glass illustrate our technique. This toolkit exposes self-organization that eludes detection by thermodynamic measures. Our toolkit more reliably and precisely identifies and quantifies learning by matter.

Information-bottleneck renormalization group for self-supervised representation learning*

VUDTIWAT NGAMPRUETIKORN (Presenter), Initiative for the Theoretical Sciences, The Graduate Center, City University of New York, WILLIAM S BIALEK, Department of Physics, Princeton University, DAVID J. SCHWAB, Initiative for the Theoretical Sciences, The Graduate Center, City University of New York — While highly successful, most deep learning applications rely on supervised learning which requires a large set of manually labelled data. But labelled data are not always available, and effective learning from unlabelled datasets - self-supervised learning - has the potential to greatly expand the scope of deep learning applications. Here we propose a self-supervised learning method that combines the concepts of the information bottleneck and the renormalization group. More specifically we use the information bottleneck to regularize a coarse-graining procedure by encouraging a representation to discard locally specific information (bottleneck) while retaining the long-wavelength features (implicitly assumed to be relevant for downstream tasks). We use variational and noise contrastive approaches to scale up our method for large systems, and we demonstrate our implementation on datasets from machine learning.

*We acknowledge support from the National Institutes of Health under Grant R01 EB026943-01.
4:30PM U24.00011: On matching symmetries and information between training time series and machine dynamics.*  JAN ENGELBRECHT (Presenter), OWEN TONG YANG, RENATO MIROLLO, Boston College — Recurrent networks and some deep feed-forward networks in machine learning effectively construct a very high-dimensional dynamical system that classifies objects through its asymptotic dynamics. Many training inputs of the same class are used to construct a machine with similar trajectories flowing to the same fixed point attractor. The attractor itself carries no information/entropy. A specific example in reservoir computing is to train a single-layer machine using a trajectory of a known chaotic dynamical system and construct a linear projection from machine variables back to the chaotic system that reproduces the training chaotic trajectory (validation) and "predicts" a bit into the future (testing). Our perspective is to go beyond validation/testing of a particular trajectory and analyze the symmetry and information in the general asymptotic dynamics of the trained machine. For well trained machines we can get the information and symmetries of the machine dynamics to approximately match that of the training dynamical system. The machine’s dynamics then has its own strange attractor and the machine can generate new time series of the same class, i.e. that are different but equivalent to the training data.

*This work was funded by NSF grants DMS 1413020 and DMS 1910303

4:42PM U24.00012: Deep Learning on the 2-Dimensional Ising Model to Extract the Crossover Region*  NICHOLAS WALKER (Presenter), KA-MING TAM, MARK JARRELL, Louisiana State University, Baton Rouge — The 2-dimensional square Ising model is investigated with a variational autoencoder in the non-vanishing field case for the purpose of extracting the crossover region between the ferromagnetic and paramagnetic phases. The encoded latent variable space is found to provide suitable metrics for tracking the order and disorder in the Ising configurations that extends to the extraction of a crossover region in a way that is consistent with expectations. The extracted results achieve an exceptional prediction for the critical point as well as favorable comparison to the configurational energetics of the model and agreement with previously published results on the configurational magnetizations of the model. The performance of this method provides encouragement for the use of machine learning to extract meaningful structural information from complex physical systems with no known order parameters.

*This work is funded by the NSF EPSCoR CIMM project under award OIA-1541079. Additional support (MJ) was provided by NSF Materials Theory grant DMR-1728457. An award of computer time was provided by the INCITE program. This research also used resources of the Oak Ridge Leadership Computing Facility, which is a DOE Office of Science User Facility supported under Contract DE-AC05-00OR22725.
Training and classification using Restricted Boltzmann Machine (RBM) on the D-Wave 2000Q

Training and classification of a restricted Boltzmann machine (RBM) has been performed using D-Wave system. RBM is an energy-based model, which assigns low energy values to the configurations of interest. The D-Wave 2000Q is an adiabatic quantum computer which has been used to obtain samples for the gradient learning. Two datasets namely ‘bars and stripes (BAS)’ and ‘solar farm (PV)’ have been used. For BAS dataset, objective is to classify a given pattern as bars or stripes, while for PV dataset the goal is to predict “efficiency degradation” based on some model parameters. Results are compared with RBM trained using standard contrastive divergence. Classification and data reconstruction are also presented. Estimated classification accuracies indicate comparable performance of the both methods. D-Wave training seems to result in smaller weights, thus reduces overfitting problems.

Statistical Physics Analysis of Training of Restricted Boltzmann Machines

A restricted Boltzmann machine is a generative probabilistic graphic network. A probability of finding the network in a certain configuration is given by the Boltzmann distribution. It has wide applications from the image generation to the neural network representation of quantum many-body states. We analyze the training process of the restricted Boltzmann machine in the context of statistical physics. For the Bar-and-Stripe pattern as a small size restricted Boltzmann machine, thermodynamic quantities such as free energy, internal energy, work, and entropy are calculated as a function of training epochs. We also investigate the Jarzynski equality that connects the work done during training and the difference in free energies before and after training. It is found that, even after long training, the probabilities of possible outcomes are not even. Some possible sources that cause imperfect training are discussed.
5:18PM U24.00015: Mode-Assisted Unsupervised Learning of Restricted Boltzmann Machines*  HAIK MANUKIAN (Presenter), YAN RU PEI, SEAN BEARDEN, MASSIMILIANO DI VENTRA, University of California, San Diego — Restricted Boltzmann Machines (RBMs) are a powerful class of unsupervised models well known in machine learning. However, unlike their more popular supervised counterparts, their training requires computing a gradient that is notoriously difficult even to approximate. In this work we show that properly combining standard gradient approximations with an off-gradient direction, constructed from samples of the RBM ground state (mode), improves their training dramatically over the standard methods. This approach, which we call "mode training", promotes faster training and stability, in addition to lowering the converged relative entropy (KL divergence). We report promising preliminary results with small models on synthetic data sets and discuss extensions to more realistic scenarios, where a physics-based approach, memcomputing [1], is used to sample the mode efficiently. The mode training we suggest is versatile, as it can be applied with any given gradient method, and is easily extended to more general energy-based neural network structures such as deep, convolutional and unrestricted Boltzmann machines. Session U25 GSNP: Pattern Formation, Chaos, Nonlinear Dynamics I 402
- Michel Pleimling

2:30PM U25.00001: Creating novel patterns with localized control in non-linear reaction-diffusion systems*  JASON CZAK (Presenter), MICHEL PLEIMLING, Virginia Tech — The Gray-Scott model has been subject of numerous investigations. Due to the nonlinear nature of the coupled reaction-diffusion equations, the system exhibits interesting behavior for certain parameter sets. In many previous studies of this system investigators have used a limited range of parameter values dictated by neglecting diffusion effects. Through systematic parameter adjustment we are able to observe and characterize novel system patterns that were previously overlooked. Localized control routines are applied to the system creating long range periodic order from a chaotic parameter space region. We present a comprehensive view of the effects of control routines applied to this system.

*This research is supported by the Army Research Office under the Grant Number W911NF-17-1-0156.
2:42PM U25.00002: Motion and Chain formation of Conductive Spheres on a Horizontal Insulator Surface Immersed in Dielectric Liquids XUEWEI ZHANG (Presenter), Texas A&M University — This work presents an analysis of the dynamics of conductive, possibly charged spheres resting on the horizontal surface of an ideal insulator, both immersed in dielectric liquids. The system is subject to a uniform background field with components normal and parallel to the surface. The inclusion of dielectric liquids complicates the problem by adding the induced charge electrophoresis effect. In this work, for individual sphere, the dependence of the total force that drives its motion on the properties of the dielectric liquid is shown. For a pair of spheres, the conditions under which they can be pulled together to form a chain are derived. Experimental results are presented to qualitatively verify the theoretical analysis. This is a complex electromechanical system that has been studied for branched pattern formation. However, no detailed analysis of the sphere motion and chain formation has been conducted. This work will bridge this gap, as well as inform some sensor designs for engineering applications.

2:54PM U25.00003: Classical many-body chaos across Kosterlitz-Thouless and Ising transitions in two dimensions* SIBARAM RUIDAS (Presenter), SUMILAN BANERJEE, Indian Institute of Science - Dept of Physics — Chaos, the sensitivity to the initial condition, lies at the foundation of statistical mechanics. Chaotic systems are characterized by a growth rate, the Lyapunov exponent $\lambda_L$, and a velocity for ballistic spread, the butterfly velocity $v_B$, of local perturbation. Here we study the temperature dependence of the chaotic behavior across thermal phase transitions in a well-known classical spin system, the XXZ model on a square lattice. We tune the finite-temperature phase transition from the Kosterlitz-Thouless (KT) to Ising universality class by changing the anisotropy and find the temperature ($T$) dependence of $\lambda_L$, $v_B$ and the diffusion coefficient $D$ across these transitions. For both the KT and Ising cases, we find a crossover in $\lambda_L(T)$ across the transitions. On the contrary, a naive extraction of $v_B(T)$ assuming a ballistic spread of perturbation leads to a non-monotonic temperature dependence of $v_B$ across the transitions. In the KT case, we show that even though the systems show subdiffusive behaviors at intermediate times below transitions due to spin-waves, the spread of perturbation is actually superballistic due to algebraic decay of spatial correlations in KT phase.

**3:06PM U25.00004: New parameters for an alternative characterization of the nematic transition for rods deposition on 2D lattices**  

EUGENIO VOGEL (Presenter), GONZALO SARAVIA, Univ de La Frontera, ANTONIO RAMIREZ-PASTOR, MARCELO PASINETTI, Univ. Nacional de San Luis — The problem of excluded volume deposition of rigid rods of length k unit cells over square lattices is revisited. Two new features are introduced: a) two new short-distance complementary order parameters (called \( \Pi \) and \( \Sigma \)) are defined, calculated and discussed to deal with the phases present as coverage increases; b) the interpretation is now done beginning at the high-coverage locally ordered phase (present regardless of the k value) which allows to interpret the low coverage nematic phase as an ergodicity breakdown present for \( k \geq 7 \). In addition data analysis offers also some novelty as both mutability (dynamical information theory method) and Shannon entropy (static distribution analysis) will be invoked to further characterize the phases. Moreover, mutability and Shannon entropy are compared between themselves reporting their advantages and disadvantages for dealing with this problem. The advantages of parameter \( \Pi \) over any other parameter is also established.

**3:18PM U25.00005: Deterministic Phase Transitions and Self-Organization in Logistic Cellular Automata**  

MUHAMED IBRAHIMI, OGUZ GULSEREN (Presenter), Physics, Bilkent University, SEYMUR JAHANGIROV, Institute of Material Science and Nanotechnology, Bilkent University - UNAM — We present a simple extension in which a single parameter tunes the dynamics of Cellular Automata by consequently expanding their discrete state space into a Cantor Set. Such an implementation serves as a potent platform for further investigation of several emergent phenomena, including deterministic phase transitions, pattern formation, autocatalysis and self-organization. We first apply this approach to Conway's Game of Life and observe sudden changes in asymptotic dynamics of the system accompanied by emergence of complex propagators. Incorporation of the new state space with system features is used to explain the transitions and formulate the tuning parameter range where the propagators adaptively survive by investigating their autocatalytic local interactions. Similar behavior is present when the same recipe is applied to Rule 90, an outer totalistic elementary one-dimensional CA. The latter case shows that deterministic transitions between classes of CA can be achieved by tuning a single parameter continuously.

3:30PM U25.00006: New type of oscillation death in coupled counter-rotating identical nonlinear oscillators*  JUNG-WAN RYU (Presenter), Institute for Basic Science, WOO-SIK SON, DONG-UK HWANG, National Institute for Mathematical Sciences — We study oscillatory and oscillation suppressed phases in coupled counter-rotating nonlinear oscillators. We demonstrate the existence of limit cycle, amplitude death, and oscillation death, and also clarify the Hopf, pitchfork, and infinite period bifurcations between them. Especially, the oscillation death is a new type of oscillation suppressions of which the inhomogeneous steady states are neutrally stable. We discuss the robust neutral stability of the oscillation death in non-conservative systems via the anti-PT-symmetric phase transitions at exceptional points in terms of non-Hermitian systems.

3:42PM U25.00007: Effects of the fluid flows on the stability of enzymatic chemical oscillations  OLEG SHKLYAEV (Presenter), VICTOR V YASHIN, ANNA BALAZS, Univ of Pittsburgh — Chemical oscillations are ubiquitous in nature and have a variety of promising applications. Chemical oscillations are usually analyzed within the context of a reaction-diffusion model framework. In real systems, the fluid flux modifies the chemical diffusion transport. To examine this effect, we consider a flow of chemical solution confined between two parallel walls forming a channel. The solution contains two reactants, A and B, which undergo transformations catalyzed by enzymes immobilized on the channel walls. Mutual transformations of the reactants provide a positive-negative feedback loop, which enables oscillations. We study the effect of the flow velocity on the stability boundary separating oscillating regimes from stationary distributions of chemicals in the channel. We show that the flow promotes the chemical transport in the system and, thereby, increases the amplitude and frequency of the oscillations. We support the predictions of the stability theory by the relevant numerical simulations. The findings can improve functionalities of micro-scale chemical reactors.

3:54PM U25.00008: Spatiotemporal dynamics of flame front instability described by an extended Kuramoto-Sivashinsky equation  YUJI NOMI, HIROSHI GOTODA (Presenter), Tokyo University of Science, CHRISTOPHE ALMARCHA, Aix-Marseille University — We numerically study the spatiotemporal dynamics in an extended Kuramoto-Sivashinsky equation describing a freely propagating flame in a Hele-Shaw cell. The spatiotemporal dynamics of flame front undergoes a significant transition from low-dimensional to high-dimensional deterministic chaos with increasing the Rayleigh number. This is clearly identified by the permutation spectrum and the multiscale complexity-entropy causality plane. The Shannon entropy incorporating the probability of the degree in the interface network is useful for capturing the significant changes in randomness in the spatiotemporal dynamics.
4:06PM U25.00009: Dendritic crystal growth of ammonium nitrate and ammonium chloride
ANDREW DOUGHERTY (Presenter), Lafayette College — Dendritic crystal growth is an important example of nonequilibrium pattern formation that involves both nonlinear and noise-driven effects. The resulting large-scale structures are sensitively dependent on relatively small effects, such as surface tension, and on small anisotropies in those quantities. In this work, we present results for ammonium chloride dendrites, and compare them with new results for ammonium nitrate dendrites grown from supersaturated aqueous solution. This new system has been studied previously by van Driel et al.[1] and shown to exhibit several different morphologies, including both steady state dendritic growth and a state with persistent tip-splitting behavior. Specifically, we present new measurements of the tip radius $\rho$, growth speed $v$, and sidebranch spacing $\lambda$, along with initial estimates of the product $Dd_0$, where $D$ is the chemical diffusion constant and $d_0$ is the capillary length, as well as the stability constant $\sigma^*=-\frac{2d_0D}{v\rho^2}$. We discuss important similarities and differences between the two materials.

4:18PM U25.00010: Emergent Bose-Einstein statistics in classical non-equilibrium systems with scale selection
VILI HEINONEN (Presenter), Department of Mathematics, Massachusetts Institute of Technology, PEDRO J SAENZ, Department of Mathematics, University of North Carolina at Chapel Hill, JONASZ J SLOMKA, Department of Civil, Environmental, and Geomatic Engineering, ETH Zurich, KEATON BURNS, JÖRN DUNKEL, Department of Mathematics, Massachusetts Institute of Technology — Non-equilibrium systems are ubiquitous in nature, from driven quantum matter and biological life forms to atmospheric and interstellar gases. Identifying and characterizing universal aspects of their dynamics continues to pose major conceptual challenges due to the absence of conserved quantities like energy. Here, we investigate the statistics of a broad class of non-equilibrium systems in which an intrinsic length-scale selection mechanism effectively constrains the dynamics of the microscopic degrees of freedom. As specific examples, we compare experimental observations of chaotic Faraday surface waves on water with simulations of a generalized Navier-Stokes equation for active fluids and quantum particle simulations in a random potential. Strikingly, we find that in all three cases the Fourier amplitudes of the energy density follow Bose-Einstein statistics. Furthermore, we show that the time evolution of these systems can be approximated by a sequence of randomly sampled monochromatic Gaussian fields, suggesting a unified view of non-equilibrium and equilibrium systems with length scale selection.
4:30PM U25.00011: Coarse-Graining and Renormalization without Locality*  JOSEPH NATALE (Presenter), K. MICHAEL MARTINI, ILYA M NEMENMAN, Emory University — The renormalization group (RG) describes how to systematically coarse-grain physical models and calculate their scaling behavior near a critical point. This approach has been immensely successful for systems where interactions are local, with a high degree of symmetry that effectively reduces the number of parameters that can contribute to the behavior in the ultraviolet limit. Here, we introduce a scheme inspired by the recent work on coarse-graining neural dynamics [1], which is capable of detecting infra-red behavior directly from experimental data without explicit reference to locality or symmetry. Specifically, our approach selects maximally correlated pairs of system elements, taking the correlations themselves as a proxy for local interaction, and compresses their activity using the Information Bottleneck method, while preserving the information that the compressed variables contain about the next-closest scale. Repeatedly applying such transformations recovers the renormalization group flow for the coupling strengths and variation of nearest-neighbor correlations with length scale for data taken from a 2D Ising system on the square lattice, showing the viability of this data-driven approach.

4:42PM U25.00012: Statistics of coherent subsets in the Kuramoto model for uniform distributions  TAYLOR A GURREITHUN (Presenter), DAVID MERTENS, Physics, Eckerd College — Experiments in synchronization and simulations of the Kuramoto model reveal that small subsets of oscillators tend to synchronize into coherent clumps at moderate coupling strengths below the critical coupling strength. Such clumps are not present in the thermodynamic limit, and so are intrinsically a finite size effect. We develop a theory that predicts the critical coupling for the formation of individual coherent subsets. Applying these new conditions to a finite population sampled from a uniform distribution, we obtain known results, such as a discontinuous transition to synchrony. We also obtain a lower estimate for the critical coupling of this transition that is consistent with simulation and previous results for uniformly sampled oscillators. This opens a new route for computing finite size effects, which we will present.
4:54PM U25.00013: Emergence of Complexity in Self-Limited Assemblies of Nanoparticles*
NICHOLAS KOTOV (Presenter), Univ of Michigan - Ann Arbor — Inorganic nanoparticles (NPs) have the ability to self-organize into variety of structures with sophisticated and dynamic geometries. Many of them are self-limited due to repulsive electrostatic interactions, which manifests in monodispersity of mesoscale superstructures formed from hundreds of polydispersed NPs. Remarkably, the organization of self-assembled NP systems can rival in complexity to those found in biology which reflects the biomimetic behavior of nanoscale inorganic matter. In this talk, I will address the mechanism and variety of self-limited assemblies of NPs and mechanisms of emergent complexity especially for chiral NPs. Self-limited assemblies of the latter will illustrate the importance of subtle anisotropic effects stemming from collective behavior of NPs and non-additivity of their interactions. While these phenomena present obvious fundamental significance for instance as a path to spontaneous compartmentalization and protocells, the practicality of self-organization of nanoparticles will be discussed in relation to charge polarization-based optoelectronics, quantum optics, and chiral catalysis.

5:06PM U25.00014: Topological Control of Synchronization Patterns: Trading Symmetry for Stability*
JOSEPH HART, Naval Research Laboratory, YUANZHAO ZHANG (Presenter), Northwestern University, RAJARSHI ROY, University of Maryland, College Park, ADILSON E MOTTER, Northwestern University — Symmetries are ubiquitous in network systems and have profound impacts on the observable dynamics. At the most fundamental level, many synchronization patterns are induced by underlying network symmetry, and a high degree of symmetry is believed to enhance the stability of identical synchronization. Yet, here we show that the synchronizability of almost any symmetry cluster in a network of identical nodes can be enhanced precisely by breaking its structural symmetry. This counterintuitive effect holds for generic node dynamics and arbitrary network structure and is, moreover, robust against noise and imperfections typical of real systems, which we demonstrate by implementing a state-of-the-art optoelectronic experiment. These results lead to new possibilities for the topological control of synchronization patterns, which we substantiate by presenting an algorithm that optimizes the structure of individual clusters under various constraints

Phase Synchronization in 2D Kuramoto Model

MRINAL SARKAR (Presenter), NEELIMA M GUPTE, Indian Inst of Tech-Madras — We study a system of identical Kuramoto oscillators in the presence of Gaussian white noise. The oscillators are arranged on a two-dimensional periodic lattice and interact with their nearest neighbors only [1-2]. In the thermodynamic limit, the stationary states at very low temperatures (limit $T \to 0$) are well described by the presence of topological defects (vortices and anti-vortices) in the phase-field of the oscillators. We apply duality transformation on a Hamiltonian [3] to explore the underlying vortex structure.

The system exhibits a phase transition from stochastic synchronization to de-synchronization as temperature varies. We investigate the nature of the phase transition and calculate the critical temperature numerically. The relaxation dynamics is also studied. In the low-temperature regime, the system relaxes to equilibrium algebraically whereas, at high temperature, the decay is exponential. Moreover, the system, at very low temperature belongs to the EW universality class yielding the dynamic exponent $z=2$ [4].

Session U26 DBIO: Physics in Synthetic Biology 403 - Gabor Balazsi, State Univ of NY - Stony Brook - Tag(s): Focus

Spatiotemporal dynamics in synthetic microbial consortia [Invited]
MATTHEW BENNETT (Presenter), Rice Univ — Synthetic microbial consortia have an advantage over isogenic synthetic microbes because they can apportion biochemical and regulatory tasks among the strains. However, it is difficult to coordinate gene expression in spatially extended consortia because the range of signaling molecules is limited by diffusion. In this talk I will discuss how spatiotemporal coordination of gene expression can be achieved even when the spatial extent of the consortium is much greater than the diffusion distance of the signaling molecules. To do this, we examined the dynamics of a two-strain synthetic microbial consortium that generates coherent oscillations in small colonies. In large colonies, we found that temporally coordinated oscillations across the population depend on the presence of an intrinsic positive feedback loop that amplifies and propagates intercellular signals. These results demonstrate that synthetic multi-cellular systems can be engineered to exhibit coordinated gene expression using only transient, short-range coupling among constituent cells.
3:06PM U26.00002: Synthetic genetic circuits using plant protoplasts* KATHERINE KIWIMAGI, MIT, MAURICIO ANTUNES, University of North Texas, WENLONG XU, MIT, TESSEMA KASSAW, Colorado State University, CHRISTOPHER ZALEWSKI, Front Range Biosciences, JUNE MEDFORD, ASHOK PRASAD (Presenter), Colorado State University — The complexity of plant biology has slowed the development of synthetic gene circuits in plants. However plant synthetic biology can form the basis for sustainable green technologies. The rational design of synthetic networks requires quantitative characterization of components for predictive modeling. This poses special difficulties for plants, since stably transforming plants is time consuming. We developed an experimental system for rapid quantitative measurements of synthetically designed repressors using plant protoplasts but found that protoplast assays show significant experimental batch effects that lead to incorrect quantitative results. With the help of a mathematical model coupled with stochastic simulations, we were successful in explaining and normalizing the batch effects to make quantitative comparisons between different inducible repressors, and approximately predict quantitative properties of synthetic circuits in stably transformed plants. We tested hundreds of repressible promoters, and carried out a statistical analysis of the quantitative data to uncover design principles for building synthetic inducible repressors in plants (*Nature Methods, v13, pp94–100, (2016)). Our mathematical model may be broadly applicable to a wider class of cells and assays.

*DOE-ARPAE

3:18PM U26.00003: Construction and Characterization of a Tunable Plasmid Copy Number System MILES ROUCHES (Presenter), GUILLAUME LAMBERT, Cornell University — Plasmids have evolved elegant mechanisms to ensure stable replication which balance the probability of plasmid loss with their metabolic burden on host cells. The pUC19 plasmid controls its copy number through a replication priming RNA (RNAII) and an inhibitory antisense RNA (RNAI). Through randomized mutagenesis of the promoters controlling these RNAs, we have created a library of over 1000 plasmids with copy numbers spanning a range greater than 2 orders of magnitude, allowing plasmid copy number to be used as a tunable parameter in several systems. We demonstrate the broad applicability of this system by using it to tune the behavior of simple genetic circuit elements and determine the fitness cost of green fluorescent protein and several CRISPR proteins. We additionally infer transcription rates for over 1000 different promoters of both RNAI and RNAII by combining our copy number measurements with the results of stochastic molecular simulations.
3:30PM U26.00004: Engineering Transcriptional Interference for Genetic Logic Gates
NOLAN O'CONNOR (Presenter), ANTONI ESCALAS BORDOY, ANUSHREE CHATTERJEE, Chemical and Biological Engineering, University of Colorado, Boulder — Transcriptional Interference (TI) is widespread in the genomes in all kingdoms of life and serves to regulate important cellular decisions. TI can occur through the collisions of RNA Polymerases (RNAPs) in tandem or in convergent orientation, and through the collision of RNAPs with protein roadblocks. Mathematical modeling and experiments have characterized several naturally occurring TI systems, but the design rules for constructing TI-based genetic devices are not yet well-defined. Here, we show that rationally controlling RNAP traffic on DNA through TI can lead to diverse gene expression profiles and facilitate the construction of TI-based logic gates. We demonstrate that tuning the dissociation constant of a protein roadblock enables optimized AND and OR logic gates, and that gate behavior can be predicted and validated through mathematical modeling. We then show that protein roadblocks coupled with RNAP collisions can produce NAND and NOR gates, and that the magnitude of gene repression from RNAP collisions can be tuned through inhibition of Rho-dependent transcription termination. These results expand the potential for TI as a novel tool for synthetic biology and offer insights into an important but relatively unexplored gene regulatory mechanism.

3:42PM U26.00005: Multicellular Drug Resistance from Synthetic Mitosis Control in Budding Yeast*
OLEKSANDRA ROMANYSYN (Presenter), GABOR BALAZSI, Biomedical Engineering, Stony Brook University — Experimental modeling plays a vital role in understanding microbial drug resistance. Multicellular, biofilm- or clump-forming microbes encounter smaller local antibiotic concentrations and can survive harsher drug treatment than unicellular populations. However, how drug resistance depends on specific characteristics of multicellular populations, such as gene expression, and clump size distribution, is poorly understood. By deleting the $AMN1$ (antagonist of mitotic exit network) gene from multicellular $S.~cerevisiae$, we obtained a drug-sensitive unicellular yeast strain. Assuming that AMN1 levels control clumping, we implemented a negative feedback-based gene circuit to control a synthetic copy of $AMN1$, mitotic progression, and consequently, clump sizes and drug resistance. This technology can be applied to extract parameters for computational models of multicellular drug resistance in yeast and has potential for testing the effect of novel drugs on a custom range of discrete multicellular yeast phenotypes.

*Work supported by NIH MIRA grant #R35GM122561 and Laufer Center for Physical & Quantitative Biology
University of Colorado, Boulder — The rapid rise of multidrug-resistant (MDR) superbugs and the declining antibiotic pipeline are serious challenges to global health. Rational design of therapeutics can accelerate development of effective therapies against MDR bacteria. In this talk, I will describe multi-pronged systems, synthetic biology, and nano-biotechnology based approaches being devised in our lab to rationally engineer therapeutics that can overcome antimicrobial resistance. We have developed Synthetic biology-based approach dubbed “Controlled Hindrance of Adaptation of OrganismS” or “CHAOS” to slow the evolution of antibiotic resistance by interfering with the processes involved in adaptive resistance. To translate our findings into the clinical setting, we have engineered antisense therapeutics that can block translation or increase transcription of any desired gene in a species-specific manner for targeted inhibition. Using this approach we have built a Facile Accelerated Specific Therapeutic (FAST) platform for the accelerated therapeutics in less than a week. Finally, I will also present a nano-biotechnology based approach involving development of a unique semiconductor material based quantum dot-antibiotic (QD ABx) which, when activated by stimuli, release reactive oxygen species to eliminate a broad range of MDR bacterial clinical isolates. The CHAOS, FAST and QD Abx platforms and inter-disciplinary approaches presented in this talk offer novel methods for rationally engineering new therapeutics to combat disease challenges.

Indian Inst of Tech-Bombay, Centre for Theoretical Studies, Indian Institute of Science, MITHUN KUMAR MITRA, Indian Inst of Tech-Bombay, BUDDHAPRIYA CHAKRABARTI, Dept of physics and astronomy, The University of Sheffield — Recent advances in reprogramming a differentiated cell back to a pluripotent cell fate has rekindled interest in a quantitative understanding of the epigenetic landscape describing cellular differentiation. Reprogramming is a multistep process, involving multiple feedback loops. While the importance of feedback loops is well appreciated, most models assume instantaneous feedback, while biological feedback often involves a time delay between the signal and the response. In the present work, we propose a theoretical model based on a two-gene regulatory motif to investigate the role of time delay in the regulation of gene expression level. In particular, we focus on the interplay between time delayed feedback loops and time-dependent external chemical drive and their effect on dynamics. We observed that the concentration of the two transcription factors can undergo sustained oscillations and we speculate that this oscillatory state may provide an explanation of certain puzzling experiments on the reprogramming process. We also observe transdifferentiation-like behavior, where one differentiated state transitions to another without passing through an intermediate stem cell state.
**4:42PM U26.00008: Synthetic gene circuits enable quantitative comparison of proteosynthesis rates in mammalian cells**

YIMING WAN (Presenter), JOSEPH COHEN, ALEX SMASHNOV, GABOR BALAZSI, Stony Brook University — Transcription and translation may vary significantly among mammalian cell types. Such differences may be important for comprehensively understanding cellular homeostasis and responses in various conditions. Here, we establish a synthetic biological framework to enable such comparisons. To minimize the random effects of genomic integration, we performed site-specific recombination (SSR) by applying FLPe recombinase-mediated cassette exchange (RMCE) to integrate single genes or gene circuits into the same “genomic safe harbor” locus AAVS1 in multiple mammalian cell lines. Upon establishing stable cell lines, we charted and compared the constitutive and inducer-dependent proteosynthesis levels using the eGFP reporter, and characterized the fold change, coefficient of variation (CV), expression kinetics based on the proliferation rate of each cell type. Overall, our study provided a systematic approach to quantify the variation of proteosynthesis due to the activity of the transcription and translation machinery in various mammalian cell types, allowing a better understanding of cell state diversity, which may be useful in mammalian biosystem modeling.

**4:54PM U26.00009: Synthetic Gene Circuits Reveal how KRAS(G12V) Affects Cell Proliferation & Migration Patterns**

TYLER GUINN (Presenter), DAMIANO CORACI, KARTHIK LEDALLA, GABOR BALAZSI, State Univ of NY - Stony Brook — Small chemicals and light can serve as stimuli for controlling synthetic gene circuits to probe biological networks relevant to systems biology and biological physics. We previously developed Light-Inducible Tuner (LITer) gene circuits that have a wide dynamic range of gene expression, low gene expression noise, and an ability to respond with gene expression changes to both chemicals and light. As a foundation for exploring gene regulatory networks, we have created LITer variants controlling half-a-dozen functional genes. Here we present results from perturbing the levels of proto-oncogene KRAS(G12V). We explore a range of cellular features including cellular distance travelled, velocity, acceleration, proliferation, and invasion versus KRAS(G12V) levels. This study reveals that functional genes can have nontrivial effects at intermediate levels of activity, illustrating the utility of analog synthetic gene circuits to complement existing knock-out and overexpression genetic approaches. Furthermore, these tools may reveal quantitatively biological thresholds for functional genes to produce cellular phenotypes.

*We acknowledge the NIH MIRA grant #R35GM122561, Laufer Center for Physical & Quantitative Biology, & the National Defense Science and Engineering Fellowship for funding.*
5:06PM U26.00010: Improved CRISPRi gene circuit function via antisense RNA sequestration
DAVID SPECHT (Presenter), GUILLAUME LAMBERT, Cornell University — By using the binding of the catalytically-dead CRISPR protein dCas12a, we can create programmable gene circuit elements in E. coli. These ‘CRISPRgates’ are simple NOT gate elements which can target genes or other CRISPRgate elements and in principle can be combined to create complex genetic circuits, a fundamental goal of synthetic biology. While natural transcription factors have built-in advantages for transcriptional regulation (e.g. cooperativity), they are not programmable or individually orthogonal and a limited number of them exist. Repression with CRISPR is advantageous because we can in principle repress many different targets simultaneously without crosstalk. However, such gene circuit elements behave poorly when placed in series due to signal loss that occurs due to leaky repression (e.g. NOT NOT NOT != NOT) and retroactivity effects due to a shared pool of Cas proteins. By utilizing antisense RNAs to sequester guide RNA transcripts, we demonstrate a mechanism to suppress leaky CRISPRi repression and restore logical gene circuit function when elements are used in series. Further, we explore utilizing this system to enhance cooperativity in CRISPR-based gene circuits to create better dynamic gene circuit elements such as oscillators and toggle switches.

5:18PM U26.00011: Uncovering thermodynamic determinants of CRISPR-Cas gene circuit design. GUILLAUME LAMBERT (Presenter), DAVID SPECHT, YASU XU, Cornell University — The versatility of CRISPR-Cas endonucleases as a tool for synthetic biology has lead to diverse applications in gene editing, programmable transcriptional control, and nucleic acid detection. Most CRISPR-Cas systems, however, suffer from off-target effects and unpredictable non-specific binding that negatively impact their reliability and broader applicability. To better evaluate the impact of mismatches on DNA target recognition and binding, we develop a massively parallel CRISPR interference assay to measure the binding energy between tens of thousands of CRISPR RNA and target DNA sequences. By developing a general thermodynamic model of CRISPR-Cas binding dynamics, our results unravel a comprehensive map of the energetic landscape of CRISPR-Cas as it searches for its DNA target. Our generalizable approach provides a mechanistic understanding of target recognition and DNA binding by CRISPR-Cas variants, which should contribute to the advancement of recent synthetic biology efforts to repurpose dCas as gene circuit elements that behave orthogonally and operate independently without crosstalk.

Thursday, March 5, 2020 2:30 PM - 5:30 PM

Session U27 DBIO GSNP: Population Dynamics in Antibiotics and Time-Varying Environments 404 - Arvind Murugan, University of Chicago - Tag(s): Focus
2:30PM U27.00001: Immune repertoire dynamics out of steady state* [Invited] MARIO UDO GAIMANN, Ludwig-Maximilians-Universität München, JONATHAN J DESPONDS, University of California San Diego, ANDREAS MAYER (Presenter), Princeton University — Over the last ten years high-throughput sequencing has enabled increasingly quantitative measurements of the diversity of lymphocyte receptor repertoires. A striking finding of these sequencing efforts has been that the clone sizes of cells sharing the same receptor are heavy-tail distributed. Here, we show how such long tails can emerge out of steady state from a simple neutral model for immune repertoire formation. In our theory homeostatic proliferation leads to a founder effect, which produces transient but long-lived power-law scaling of clone sizes. In a human cohort study we find evidence for the prediction that early founded clones are overrepresented among the largest clones. We show how the slow multidecadal decay of this overrepresentation suggests a dynamical model of immune aging in which peripheral selection only slowly reshapes the initially established repertoire. Overall, our work suggests a mechanism through which dynamical processes early in life can have a strong and long-lasting influence on the adaptive immune system with potential implications for pathogen defense and autoimmunity.

*DAAD RISE Worldwide fellowship (MUG), Lewis–Sigler fellowship (AM)

3:06PM U27.00002: The role of drug kinetics on the evolution of resistance. ANJALIKA NANDE (Presenter), MARTIN NOWAK, ALISON LYNN HILL, Harvard University — Emergence of drug resistance due to treatment non-adherence is a problem especially in chronic prolonged viral infections like the Human Immunodeficiency virus (HIV) and Hepatitis B (HBV) and C (HCV) viruses. Long acting drugs are being developed as one way to address this problem. Though this promises to be useful in the context of treatment adherence, we do not yet know how this would affect resistance.

With this in mind, we analyze the effect of dosing intervals on the establishment of drug resistance due to mutants existing prior to treatment (pre-existing) and those that are produced during treatment (rescue) in the presence of time-dependent drug profiles.

We find that there exists an initial time-frame after treatment initiation that has the most influence on the establishment probability of the drug resistant strain. Depending upon the nature of the drug kinetics during this time as well as infection parameters, increasing the dosing interval might be better or worse for the establishment of resistance. Our results suggest that drug kinetics affect selection and competition in the system in a complicated manner and should be factored in while designing new treatment strategies.
3:18PM U27.00003: The Dynamics of Human Society Evolution: An Energetics Approach*
RAM POUDEL (Presenter), Institute of Engineering, Tribhuvan University, JON MCGOWAN, University of Massachusetts — Human society is an open system that evolves by coupling with various known and unknown (energy) fluxes. How do these dynamics precisely unfold? Energetics may provide further insights. We expand on Navier-Stokes’ approach to study non-equilibrium dynamics in a field that evolves with time. Based on the ‘social field theory’, an induction of the classical field theories, we define social force, social energy and Hamiltonian of an individual in a society. The equations for the evolution of an individual and society are sketched based on the time-dependent Hamiltonian that includes power dynamics. In this paper, we will demonstrate that Lotka-Volterra type equations can be derived from the Hamiltonian equation in the social field.

*We did not seek any funding for this research. RP acknowledges a sabbatical granted by the Institute of Engineering, Tribhuvan University.

3:30PM U27.00004: Understanding the Dynamics of Antibiotic Resistance in Microbial Communities using Tensor Methods  MAX DE JONG (Presenter), KEVIN WOOD, Univ of Michigan - Ann Arbor — Spatial heterogeneity plays an important role in the evolution of drug resistance, but relatively little is known about resistance in complex spatial profiles of selection pressure. We have developed a toy model of stochastic microbial dynamics to investigate how different spatial profiles of selection pressure impact the time to fixation of a resistant allele using mean first passage time calculations. While our previous results established that spatial profiles can dramatically speed or slow the emergence of resistance, they provide little information about the trajectory taken by the system to reach fixation. We now expand our analysis to consider the third-order tensor composed of the time to fixation from all possible intermediate states of the system. We develop several methods to deconstruct this tensor into quantities that allow us to gain insight into the evolutionary dynamics of the system as it reaches fixation. We use a 3-D convolution to relate fixation times of neighboring states and a modified CP decomposition to reduce the fixation time tensor into single-microhabitat fixation profiles lacking spatial structure. We demonstrate that these tools allow us to intuitively understand the emergence of fixation in spatially-structured systems.
Evolving generalists in optimal cycling environments

SHENSHEN WANG (Presenter), Department of Physics and Astronomy, University of California, Los Angeles — To persist and thrive in ever changing conditions, living organisms must adapt to new challenges while maintaining performance to prior related tasks. How this ability to generalize evolves remains a puzzle. To evolve a proper defense against rapidly adapting pathogens, vertebrates’ adaptive immune system searches for broadly neutralizing antibodies through B cell affinity maturation. However, these generalist antibodies are hard to evolve and often outcompeted by specialists fitter in any particular environment. Using a generative approach, we find that switching between environments neither too similar nor too different can efficiently evolve fit generalists, via dynamically enlarging their attractor basins in sequence space. We further demonstrate that changing environments before populations reach a steady state can mobilize specialists but leave generalists undisturbed, thereby allowing specialists to evolve into generalists and not specialize again. Our framework predicts optimal correlations between vaccine antigens to be cycled at intermediate timescales for reliably evolving generalists. These design principles exploit nonequilibrium fitness ‘seascapes’ to drive populations into genotypes unevolvable in static environments.

Search strategies that find generalists in time varying environments

JONATHAN KUTASOV (Presenter), Physics, Princeton University, KABIR HUSAIN, University of Chicago, SHENSHEN WANG, UCLA, ARVIND MURUGAN, University of Chicago — Many evolutionary and ecological processes can be seen as a search process for fitter genotypes or spatial regions with more resources. Time varying environments are often thought to naturally bias such search processes towards generalists, i.e., regions with relatively smaller changes in fitness or resources over time. But it is not clear what underlying characteristics of a search process lead to this effect.

Here we consider several search processes in biology such as foraging in real space, growth of microtubules towards chromosomes, and evolution towards fitter genotypes in sequence space. We find that a class of biased random walks that we call ‘directed’ are naturally driven towards generalists by time varying environments at intermediate timescales; this class includes classic E. coli chemotaxis with run times modulated by food availability and constant tumble times. However, closely related ‘undirected’ biased walks are not driven towards generalists, such as chemotaxis with constant run times but modulated tumble times. The distinction between directed and undirected walks corresponds to the Ito and Stratonovich ambiguity in stochastic calculus. Our work provides examples where the microscopic details of biological search have macroscopic consequences.
4:30PM U27.00007: Time-Dependent Effective Sampling Bias in Populations with Broad Offspring Numbers  TAKASHI OKADA (Presenter), RIKEN, University of California, Berkeley, OSKAR HALLATSCHEK, University of California, Berkeley — It has been increasingly recognized that natural populations exhibit broad family size distributions, either because offspring numbers are strongly variable or because range expansion processes generate jackpot events. Despite recent progress in the neutral dynamics induced by broad offspring numbers, our knowledge of their interactions with selection remains limited, except for certain special cases. Here, we establish a number of new scaling relations about the fixation probability, the extinction time and the site frequency spectrum that arise when offspring numbers are distributed according to a power law with divergent variance. Finally, we validate the new findings within semi-pushed traveling waves, which are microscopic models that give rise to the power law of offspring numbers.

4:42PM U27.00008: Using environmental noise to hedge one's evolutionary bets  BINGKAN XUE (Presenter), University of Florida, PABLO SARTORI, STANISLAS LEIBLER, The Rockefeller University — Bet-hedging is an adaptation strategy commonly used by organisms living in unpredictable environments: Each individual randomly expresses one of many possible phenotypes so that a subset of the population may survive. The random choice of phenotypes is usually attributed to stochastic biochemical processes internal to the organism, such as multi-stable dynamics of the gene regulatory network. Alternatively, the organism may rely on randomness that is present (and probably abundant) in the external environment. We illustrate the latter possibility using a model of "environment-to-phenotype mapping". That is, we let the organism's phenotype depend on an environmental signal, and numerically evolve such dependence to maximize the population growth rate. We show that, even when the signal is extremely noisy and uninformative of the true environment, the organism can still benefit from the signal by using it as a source of randomness for bet-hedging.

4:54PM U27.00009: Clocks, Anticipation, and Growth in Bacteria  MICHELE MONTI, Centre for Genomic Regulation (CRG), The Barcelona Institute for Science and Technology, PIETER REIN TEN WOLDE, AMOLF, DAVID LUBENSKY (Presenter), Univ of Michigan - Ann Arbor — Circadian rhythms are widespread across all kingdoms of life, and they are frequently assumed to provide an adaptive benefit by allowing organisms to anticipate diel cycles in their environment. Yet it has proven extremely difficult to determine precisely how such anticipation confers a fitness advantage. Here, we use mathematical modeling to address this question for nitrogen-fixing cyanobacteria.\(^1\) By extending recent work on growth laws in \textit{E. coli},\(^2\) we show that it is difficult to change the composition of the proteome when the growth rate is small, and thus that the average growth rate can be increased by using a clock to anticipate the onset of darkness by switching to a dark-adapted proteome late in the day, when growth rates are still large.

5:06PM U27.00010: Minimal model reveals key features of vaccination protocols that optimally elicit broadly neutralizing antibodies*  RAMAN GANTI (Presenter), MEHRAN KARDAR, ARUP K CHAKRABORTY, Massachusetts Institute of Technology MIT — During affinity maturation, B cell populations evolve in response to time-varying environments within germinal centers (GC). Recent simulations and experiments have shown that controlling the temporal application and degree of “frustration” (i.e. conflicting selection forces) within the GC crucially determines the successful production of broadly neutralizing antibodies (bnAbs). A one-dimensional fitness landscape enables us to quantify frustration as the change in entropy of the imposed fitness distribution as the selection forces change with time. Using a simple birth-death model, we then find that an optimal temporal profile of frustration maximizes bnAb production and determines the mechanisms underlying this result. The vaccination protocol requires a relatively low optimal level of frustration during GC priming to maintain the correct level of B cell diversity so that the surviving B cells have a high chance of evolving into bnAbs upon subsequently increasing the frustration by choosing appropriately designed vaccine immunogens. Our results also illustrate the importance of clonal interference in bnAb evolution due to time-varying environments.

5:18PM U27.00011: Predicting antibiotic resistance evolution  FERNANDA PINHEIRO (Presenter), Institute for Biological Physics, University of Cologne, OMAR WARSII, DAN ANDERSSON, Department of Medical Biochemistry and Microbiology, Uppsala University, MICHAEL LÄSSIG, Institute for Biological Physics, University of Cologne — Bacteria can rapidly evolve resistance to antibiotics. Resistance mutations confer a fitness advantage in the presence of the drug, which is frequently coupled to a fitness cost in drug-free environments. But how do these effects set the strength of resistance elicited by a given drug dosage and the resulting cell growth? Here we develop a fitness model that predicts dosage-dependent growth rates of common resistance mutations. Selection experiments in E. coli populations at moderate drug levels reveal multiple resistance mutations of different strength, most of which affect membrane genes. By reducing both drug and nutrient uptake, these mutations cause antagonistic effects on cell metabolism and growth. Our fitness model maps this tradeoff and defines a Pareto surface of resistance evolution. We show that optimal mutants elicited at a given drug level occur at a specific point on this surface, leading to predictable dosage-dependent growth. Our analysis delineates the dosage regime where broad, membrane-mediated resistance evolution is prevalent compared to mere physiological response and drug-specific target mutations. These results show that drug resistance evolution, by coupling major metabolic pathways, is strongly intertwined with the systems biology of the cell.

Thursday, March 5, 2020 2:30 PM - 5:30 PM

Session U28 FIAP: Innovations from Industry 405-407 - Steven Lambert, American Physical Society - Tag(s): Industry, Invited, Undergrad Friendly
2:30PM U28.00001: From Innovation to the Marketplace: The Role of a Physicist [Invited]  
SCOTT DAVIS (Presenter), Vescent Photonics — Science has and continues to change the world. The process through which this happens is varied, complex, and fascinating. I believe that a physics education equips one to navigate and expedite this process, from innovation, to technology maturation, and ultimately to production and commercialization. Furthermore, I feel that this is especially true in an entrepreneurial, small business setting. As a physics Ph.D., then co-founder and now CEO of Vescent Photonics, I have been a part of each step. I will share examples from my personal professional journey that illustrate this progression. Examples will include non-mechanical laser beamsteerers, first invented in my garage and then sold to a large public company for automotive markets, laser systems for quantum systems such as clocks and computers, and a variety of electronic and electro-optic technologies. I will highlight examples where my physics training proved invaluable in both obvious but also less obvious ways. Participating in the journey from the spark of an idea to a manufacturing line could not be more meaningful. I continue to rely on the physics training of both myself and my employees to play and profit in this process.

ERIC OSTBY (Presenter), Google — TBD

3:42PM U28.00003: Pake Prize: A Physics Career in Industry [Invited]  
JAMES BRAY (Presenter), General Electric Research — I speak about my own experiences as a physicist in industry (GE) for 45 years. I begin with a general look at US R&D expenditures in industry compared to academia and government in the recent past and how these expenditures divide among basic research, applied research, and development. I then focus down to physics: recent US expenditures and how physicists have chosen and think about their career in the recent past. Then I focus further to my own career in industry and my learnings. Finally, I use superconductivity and MRI (magnetic resonance imaging) to illustrate examples of my learnings as a physicist in industry.

4:18PM U28.00004: Academia to Entrepreneurship- Who is this for? [Invited]  
THIRUMALAI VENKATESAN (Presenter), Natl Univ of Singapore —
There has been a sea change over the last few decades in the way academic institutions view entrepreneurial activities of the faculty and the role of the Institution in fostering an ecosystem conducive to such activities. This has become a global phenomenon and many of the leading Institutions in Europe and Asia are also beginning to replicate the model of the Boston or Silicon Valley academic Institutions. This clearly presents a wonderful opportunity for those who want to strike out on their own as opposed to waiting for someone else to offer them a job. This is the transition from a job seeker to a job creator. Are entrepreneurs born or made? In my observation, a much higher proportion of graduate students/ post docs ought to become entrepreneurs as the qualities required for a successful entrepreneur are possessed by a fairly large proportion of students than they realize. In my talk I will discuss a variety of models that are available to the academic entrepreneur, their pluses and minuses and also some of the critical knowledge one needs to understand about the world of entrepreneurship in general. I will use examples from several of my students and colleagues’ startups and my own experience in running a company for over three decades amidst an academic career.
4:54PM U28.00005: Rocket Science is Just Cool [Invited] JANICA CHENEY (Presenter), Lockheed Martin Space Systems — Why yes, this is rocket science...

How do astronauts, satellites, and payloads get into space? What does NASA's mission to Mars look like? What does a rocket scientist really do? This presentation will provide a behind the scenes look at the engineering and physics of past and current space missions using solid rocket motors from the perspective of a rocket scientist. Learn about the ins and outs of her career path and discover what it really takes to be a rocket scientist. The foundation developed in an academic career in physics or engineering will provide a strong background required for launching your career as a rocket scientist.

Thursday, March 5, 2020 2:30 PM - 5:18 PM

Session U29 DSOFT DPOLY DBIO DFD: Electrostatic Manipulation of Fluids and Soft Matter I: Electrohydrodynamics 501 - Jonathan Singer, Rutgers University, New Brunswick

2:30PM U29.00001: Control and characterization of thin film formation by electrospray deposition techniques* KRISTOF TOTH (Presenter), Yale University, GREGORY DOERK, KEVIN YAGER, Brookhaven National Laboratory, CHINEDUM OSUJI, University of Pennsylvania — Electrospray deposition (ESD) offers a precise and continuous manner by which to deliver sub-micron sized droplets of soft matter in dilute solution to a substrate. Preparation of thin films by ESD have offered advantages of making sequentially deposited, continually equilibrated or even compositionally varying systems on a single substrate for high-throughput characterization. However, understanding and control of the thin film formation are important to limit the Marangoni effects of the droplets on the surface to ensure uniform deposition and coverage. We describe a simple feedback control for visual analysis of various electrospray modes and their corresponding film formation. We also model the surface coverage of the films as a function of deposition time of varying molecular weight homopolymer and block copolymer systems. Furthermore, by changing the geometry of the ESD setup, the area of deposition can be tuned to fit the needs of transmission or reflection X-ray scattering experiments.

*Research perfumed at the CFN and NSLS-II, U.S. DOE Office of Science Facilities at BNL under Contract No. DE-SC0012704. NSF support through DGE-1122492, INTERN supplement to CBET-1703494, and DMR-1410568.
2:42PM U29.00002: Morphological Control of Multifunctional Melting Gel Coatings via Electrospray Deposition* ARIELLE MARIE GAMBOA (Presenter), LIN LEI, Department of Mechanical and Aerospace Engineering, Rutgers University, New Brunswick, JAMES MERCADO, JENNIFER GUZMAN, Department of Chemistry, Lehman College - CUNY, LISA C KLEIN, Department of Materials Science Engineering, Rutgers University, New Brunswick, ANDREI JITIANU, Department of Chemistry, Lehman College - CUNY, JONATHAN SINGER, Department of Mechanical and Aerospace Engineering, Rutgers University, New Brunswick — Melting gels (MG) are hybrid organic-inorganic gels with glass transition temperatures ~28°C and consolidation temperatures ~150°C. They exhibit thermoplastic behavior below their consolidation temperature and undergo complete cross-linking to form organically modified silica networks upon consolidation. By tuning surface properties, these glass sprays can be used as protective coatings in electronics and anti-corrosion coatings in metals. Electrospray deposition was used to spray solutions of 1wt% MG in 2-butanone. The high voltage produces charged, monodisperse droplets that, due to the low solid content of solutions, deliver small amounts of MG at a continuous rate. The pH of MG synthesis, solution viscosity, and spray polarity were varied to study the effects of charge injection on the consolidation of MG into hybrid glasses. The low MG content of solutions allows for the addition of viscosity modifiers such as terpineol which alter the ability of the spray to dissipate charge. Optical images, film measurements, and FT-IR were used to evaluate the effects of these variables on both the physical morphology along with the chemical structure of the final coatings.

*This work is supported by the Advanced Manufacturing Program of the National Science Foundation, Award No. 1911518.

2:54PM U29.00003: Using Multiplexed Electrosprays to Manipulate Fluids and (Soft) Materials [Invited] ALESSANDRO GOMEZ (Presenter), Mechanical Engineering and Materials Science, Yale University — The cone-jet electrospray has revolutionized the field of mass spectrometry but, despite the unique ability of this device to produce quasi-monodispersed particles in a phenomenal size range down to the nanoscale, it has not been applied to other fields, except for small scale proof-of-concept demonstrations. The primary reason for the lack of widespread use is the low flow rate at which the spray is dispersed. Using fluid mechanics and electrostatics, we a) developed criteria for compact multiplexing to increase flow rate drastically, b) microfabricated systems with high packing densities (1.1 104 sources/cm2), reducing the cost per electrospray source, and c) demonstrated successful operation of these devices in the synthesis of (soft) materials (e.g., polymer nanoparticles of controlled shape for drug delivery and battery materials) and in microchip cooling. I will review design criteria and applications.
3:30PM U29.00004: Self-Limiting Electrospray Deposition for the Surface Modification of Additively Manufactured Parts
DYLAN KOVACEVICH, LIN LEI, DAEHOON HAN, CHRISTIANNA KUZNETSOVA, STEVEN E KOOI, HOWON LEE, JONATHAN SINGER (Presenter), Rutgers University, New Brunswick — Electrospray deposition utilizes a high voltage to atomize a flowing solution into charged microdroplets loaded with solute. Our previous research investigated the conditions necessary to minimize charge dissipation and deposit a thickness-limited film through self-limiting electrospray deposition (SLED). Such sprays possess the ability to conformally-coat complex three-dimensional objects without changing the location of the spray needle or orientation of the object. This makes them ideally suited for the post-processing of materials fabricated through additive manufacturing (AM), opening a paradigm of independent bulk and surface functionality. Having demonstrated three-dimensional coating with film thickness in the range of 1-50 µm on a variety of conductive objects, in this study we employed model substrates and finite element method simulations to quantitatively study the technique's limits with regard to geometry and scale. Specifically, we examined recessed features with gaps ranging from 50 µm to 1 cm, as well as the ability to coat surfaces hidden from the line-of-sight of the spray needle. This was then extended to the coating of hydrogel structures printed by AM, as a means to create hydrophobic surfaces without affecting the absorption-driven humidity response.

3:42PM U29.00005: The Role of Surface Charging in Electrospray Printing of Thin Films*
YAQUN ZHU (Presenter), PAUL CHIAROT, Binghamton University — We report on the use of electrospray printing to create thin continuous multiscale films from nanoparticle aggregates. Nanomaterials are delivered to the target substrate in a dry state with an excess electric charge. The charge accumulates on the target and its decay rate plays a significant role in the film formation. Films printed on conductive substrates are thick and exhibit a periodic island structure, while films on insulating substrates are thickness-limited and more uniform. We leveraged the surface charging from electrospray to direct the assembly of nanoparticles using electrostatic focusing. This was achieved by patterning a photoresist layer on the target substrate. Charge accumulates on this layer and electrostatic forces direct the emitted material to the exposed parts of the substrate, which created high aspect ratio porous structures when the target substrate was silicon. The deposit growth was inhibited on glass substrates. To quantify the accumulated electric charge and its decay rate, we measured the spray and image charging for nylon and glass substrates. A scaling analysis revealed the importance of the processing conditions in determining the maximum accumulated charge and its decay rate.

*Funded by the National Science Foundation (CAREER Award #1554038).
Effect of Processing Conditions on the Formation and Microstructure of Electrospray Printed Polymer Films

BRYCE KINGSLEY (Presenter), PAUL CHIAROT, Binghamton University — An electrospray uses high electric potential to atomize a liquid suspension. The droplets evaporate in-flight, leaving behind dry solute particles that can be printed on a target substrate. We report on the use of electrospray to print thin films of polytetrafluoroethylene (PTFE) on silicon substrates. The coupled effects of ambient humidity (50%, 10%), suspension conductivity (9, 25, 85 μS/cm), suspension volatility (20%, 60%; alcohol in suspension), and flow rate (0.5, 1 μL/min) on the growth and microstructure of the films is reported. The suspension conductivity governed the net electric charge of the emitted droplets and particles, while humidity and volatility influenced the in-flight droplet dynamics. Films printed in dry air were denser with a well-defined boundary compared to films printed in humid air. Semi-spherical polymer aggregates were delivered to the substrate when the suspension conductivity was low. Suspensions with higher conductivity produced films with a woven structure of interconnected particle groups. Similarly, sprays utilizing a more volatile suspension produced films with a woven structure, with strands of solute linking groups of aggregates. The use of higher flow rates increased the particle packing density in the printed film.

Electrospray deposition of nanowire forests through spinodal gellation

LIN LEI (Presenter), CATHARINE NACHTIGAL, New Brunswick, Rutgers University, SHENSHENG CHEN, TYLER MOY, XIN YONG, Mechanical Engineering, Binghamton University, JONATHAN SINGER, New Brunswick, Rutgers University — The morphology of coatings created by electrostatic deposition can be generally divided into three categories: wire mats (electrospinning), particles (electrostatic spray, electrospray deposition), and films (all low-viscosity applications). There should exist nanowire forests as a mixture of wire and particulate deposition. Such a morphology has yet to be observed experimentally, which we propose is the result of spatially-varying viscosity in sprayed droplets. We utilized electrospray deposition (ESD) to explore the spray of methylcellulose (MC) in water:ethanol mixtures. MC possesses a lower critical solution temperature (LCST) in water and water:ethanol blends. Above the LCST, MC and water phase separate concurrently with the rapid evaporation of ethanol, forming a shear-thickening, homogeneous gel phase. This gel can undergo the elongation of electrospinning on a drop-by-drop basis to create forests of individual nanowires. Our study indicates that the homogenous evolution of viscosity is necessary for nanowire forest formation and that the specific viscosity (along with droplet size) further controls the morphology of the forests.
**4:18PM U29.00008: Modelling Nanowire Formation in Electrospray Deposition of Polymeric Droplets**  SHENSHENG CHEN (Presenter), XIN YONG, Binghamton University — The formation of nanowire forests was recently reported for the first time in electrospray deposition (ESD) of methylcellulose solutions. This novel morphology provides new opportunities for nanomaterial processing. The atypical nanowire geometry is a result of complex interplay among electrostatic interaction, solvent evaporation and polymer rheology. We conducted computer simulations to uncover the physics underpinning the morphological evolution of a highly charged polymeric droplets in ESD. We utilize electrostatic dissipative particle dynamics (EDPD) to simulate a model system that captures electrostatic interaction, evaporation, and polymer dynamics. We explored droplet morphological development under different evaporation conditions, which results in distinct modes of viscosity evolution. Our results show that the nanowire formation is a result of spinodal phase separation between polymers and solvents that homogeneously increases viscosity within the droplet. In contrast, a steep viscosity gradient formed leads to a bead-strings morphology. The coupling between electrostatically-driven deformation and evaporation-driven viscosity change in polymeric droplets can result in new and beautiful morphological evolution.

**4:30PM U29.00009: Influence of ionic conductivity on unconfined melt electrospinning of thermoplastics**  NEELAM SHEORAN (Presenter), BRENTON BOLAND, Elnaz Shabani, Russell Gorga, Jason R Bochinski, Laura Clarke, North Carolina State University — Ionic additives incorporated into thermoplastics melts can influence both viscoelastic properties and ionic conductivity. Such effects can be used to manipulate the process of melt electrospinning. In particular, fiber diameter is impacted by the melt viscosity as well as ionic motion within the melt under the influence of an applied electric field. Decreased fiber diameter could open pathways for fabrication of high strength mesoscale thermoplastic nanofibers, which have significant importance for filtration and biological applications. My talk will focus on how altered melt ionic conductivity due to commercial additives affects an unconfined melt electrospinning process. I will report ionic conductivity measurements obtained using broad-band impedance spectroscopy for two different grades of commercial linear low-density polyethylene with varying viscosities as a function of melt temperature and additive concentration. Corresponding viscosity measurements were performed by means of rotational plate rheometry. The rate of jet formation, the number of jets in steady-state, and the resulting fiber diameters were determined to characterize the effects of additive-doping of melts on the unconfined melt electrospinning process.

*Support from National Science Foundation CMMI-1635113*
Unconfined melt electrospinning from molten polymer experiencing an electric discharge to manipulate ion density and ionic conductivity* BRENTON BOLAND (Presenter), NEELAM SHEORAN, LAURA CLARKE, JASON R BOCHINSKI, North Carolina State University — Melt electrospinning is a promising way of achieving solvent-free mesoscale fibers for applications in tissue scaffolding, water filtration, and wound dressing; however, large fiber diameters is a persistent problem that must be understood. To address this, we are interested in the role of ionic conductivity in determining fiber diameter in melt electrospinning. We utilize an unconfined geometry where jets spontaneously form and organize on the edge of a melt-covered plate under the influence of the applied electrospinning electric field. Inspired by recent results from our group that show enhancement of ionic conductivity by additives resulted in reduced fiber diameter and by historical work on corona-assisted electrospraying, we controllably create a discharge near the plate edge to manipulate local ion density and alter the electrospinning process. This manipulation of local ion density by pulsed Dielectric Barrier Discharge (DBD) altered the electrospinning process in a way similar to the addition of ionic additives, suggesting a temporary enhancement of ionic conductivity.

*Support from National Science Foundation CMMI-1635113

Liquid Selection for Electrohydrodynamic Capillary Thermal Switches* TIANXING MA (Presenter), DARREL DSOUZA, Rutgers University, New Brunswick, KYRSTEN MCKENZIE RYERSON, Biola University, MATTHEW SIGNORELLI, Rutgers University, New Brunswick, YANG ZHAO, CHINEDUM OSUJI, University of Pennsylvania, JONATHAN SINGER, Rutgers University, New Brunswick — The deformation of sessile droplets and capillary bridging in a parallel-plate capacitor under DC field has been the subject of several scientific studies. Coaxially located droplets on opposing electrodes experience an attraction in the presence of an electric field. Application of a suitably large field will lead to either the droplets forming a liquid bridge or oscillation between bridged and de-bridged (i.e. droplet) states. We explored the bridging behavior of a variety of liquids in air. Among the liquids that could form a stable field-induced bridge, only a limited set could reversibly make and break the capillary bridge by switching the electric field on and off. The ability to form a switchable liquid bridge is a function of both the liquid's properties, including surface tension, electric conductivity, and dielectric constant, and external conditions such as electrode separation, droplet volume, and the substrate selection. Taking advantage of this phenomenon, through periodically forming and breaking the capillary bridge, we demonstrate the realization of a planar thermal switch that can control the flow of heat.

*Department of Energy Award DE-EE0008314
5:06PM U29.00012: Dielectric modulation of two-dimensional dipolar materials  ZIWEI WANG (Presenter), ERIK LUIJ TEN, Northwestern University — Spontaneous pattern formation plays an important role in a wide variety of natural phenomena and materials systems. A key ingredient for the occurrence of modulated phases is the presence of competing interactions, generally of different physical origins. We demonstrate that in dipolar films, a prototypical system for pattern formation, patterns can be induced by dielectric effects alone [1]. A rich phase diagram arises, where striped and circular morphologies emerge with geometric properties that can be controlled through variation of particle shape and substrate permittivity or permeability. These effects are particularly enhanced by metamaterial substrates.

Thursday, March 5, 2020 2:30 PM - 5:30 PM

Session U30 DSOFT GSNP: Programmable Matter

2:30PM U30.00001: Mechanical Metamaterials You Can Count On  MATHIS MUNCK, HADRIEN BENSE, Designer Matter, AMOLF Amsterdam, MARTIN VAN HECKE (Presenter), Leiden University and AMOLF Amsterdam — Most mechanical metamaterials perform a single-step function, such as shape-morphing under pressure. However, nonlinearities in mechanical building blocks - buckling, snapping, self-contacts - open a route towards multi-step metamaterials, crucial for storing and processing information. Here we present a class of structures whose state depends on a sequence of identical input cycles: these metamaterials count.

2:42PM U30.00002: Multifunctional Combinatorial Metamaterials [Invited]  CORENTIN COULAIS (Presenter), Univ of Amsterdam — We introduce a novel class of combinatorial metamaterials that are multifunctional. We first define a combinatorial design space and find a rich phenomenology, ranging from disordered, to periodic and quasicrystalline tilings, who can host multiple yet a sub-extensive number of soft deformation modes. We then demonstrate the multifunctional nature of such metamaterials using both boundary textures and viscoelasticity. In particular, we realize a metamaterial that has a negative (positive) Poisson's ratio for low (high) compression rate. Their ability our metamaterials to host multiple mechanical responses makes them an early example of multi-functional matter, thus paving the way for robust and adaptable devices.
A truly-programmable mechanical metamaterial using magnetic actuation  TIAN CHEN (Presenter), School of Engineering, and School of Computer and Communication Sciences, Ecole polytechnique federale de Lausanne, MARK PAULY, School of Computer and Communication Sciences, Ecole polytechnique federale de Lausanne, PEDRO REIS, School of Engineering, Ecole polytechnique federale de Lausanne — Mechanical metamaterials are engineered systems with a sub-structure that, when tiled, exhibits physical properties that may not exist in conventional bulk materials. While disrupting the definition of a ‘material’, the periodicity or the internal unit structure of a metamaterial is often optimized to target a specific (set of) function(s) or mechanical behavior. As such, upon fabrication, standard metamaterials are effectively “programmed”, once and for all, and their functionality cannot be altered a posteriori. Here, we show a truly-programmable metamaterial where both the periodicity and the internal structure are preserved during fabrication but each unit cell can be independently programmed and reprogrammed, reversely and on-demand. Programming of individual cells is achieved by switching between the equilibrium states of a multi-stable elastic shell using magnetic actuation. When tiled into sheets or columns, we are able to tune the effective mechanical properties of our system including its stiffness, strength, and localization strain. Through a combination of quasi-static compression of experimental fabricated prototypes and finite element simulations, we demonstrate both the programming and the range of the exhibited mechanical response of our designs.

One Dimensional Mechanical Memory  AUSTIN REID (Presenter), Indiana Univ - Bloomington, KAREN DANIELS, Physics, North Carolina State University, THÉO JULES, FREDERIC LECHENAULT, Laboratoire de Physique Statistique, Ecole Normale Superieure, MUHITTIN MUNGAN, University of Bonn — Some bellows-like origami folded cylinders have bistable configurations, and the energy barriers between these bistable states are tunable with geometry. Stacked Kresling (twisted triangular tessellations) patterns on a cylinder can be can be tuned to collapse or deploy incrementally. If these folded cells are allowed to interact, the interaction energy can shift transition barriers such that the bellows achieves geometrically suppressed configurations. We have developed laser-cut and folded cylinders where adjacent unit cells can either be elastically connected or completely decoupled. For cylinders where cells are non-interacting, these unit cells function as "bits" with perfect return-point memory. In experimental tests, we find that a cylinder-based memory unit of 4 bits can be predictably driven to any of its 16 allowable states with a prescribed sequence of compression and extension.
Muscle-inspired flexible mechanical logic architecture for miniature robotics

MAYANK AGRAWAL (Presenter), SHARON C GLOTZER, Chemical Engineering, Univ of Michigan - Ann Arbor — Miniature robots (~10nm-100micron) that morph in response to external stimuli such as light or chemicals in their local environment have the potential to perform non-invasive treatments inside the body, clean up oil spills, or be embedded in textiles to intelligently tune fabric properties. Such robots can now be realized due to advancements in materials offering, e.g., stimuli-responsive polymers that actuate like artificial muscles. For maximum control using global triggers (stimuli), computation ability needs to be incorporated within these robots. The challenge is to design an architecture that is compact, material agnostic, stable under stochastic forces, and employs stimuli-responsive materials. Here we demonstrate such an architecture, which computes combinatorial logic via mechanical gates that use linear actuation (expansion and contraction). Additionally, the logic circuitry is physically flexible. We mathematically analyze gate geometry and discuss tuning it for the given signal requirements. We validate the design at colloidal scales using Brownian dynamics simulations. Finally, we simulate a complete robot that folds into Tetris shapes.

Active stabilisation of patterned robotic swarms

PANKAJ POPLI (Presenter), PRASAD PERLEKAR, SURAJIT SENGUPTA, TIFR Centre for Interdisciplinary Sciences — Flocks of birds naturally order as a result of active forces which counteract destabilisation by random noise. Ordered patterns of drones or robotic agents are useful for many purposes such as surveying unknown territory, taking measurements of scientifically or economically important quantities over a large area, drone shows etc. Disruption of this pattern may occur due to many factors for e.g. atmospheric or ocean turbulence. Stabilising any given pattern in such a swarm is energy expensive and requires extensive computation and communication overheads. We propose an algorithm where one can achieve this in an energy efficient way. The strategy involves suppressing a class of fluctuations viz. non-affine displacements away from the given reference pattern while allowing affine deformations such as translations and rotations. The agents are not forced to sense, difficult to measure, environmental parameters such as local velocity of air or water in order to stabilise the swarm. Additionally, we show that by maintaining the structure/pattern of robotic swarms the statistics of the underlying flow field can be determined solely from "non-affine" forces. As the knowledge of these forces is a priori known, no extra measurement on the turbulent field is needed.
4:06PM U30.00007: Assembly by Solvent Evaporation: Equilibrium Clusters and Relaxation Times
ELIZABETH MACIAS (Presenter), ALEX TRAVESSET, Iowa State University, THOMAS R WALTMANN, Physics, University of Michigan — We present a theoretical and computational description of equilibrium clusters of alkylthiolated gold nanocrystals assembled by solvent evaporation. We consider N nanocrystals in an octane or nonane liquid droplet. Equilibrium structures consist of Tetrahedron (N=4), Square pyramid (N=5), Octahedron (N=6), Pentagonal bipyrimad (N=7), Biaugmented triangular prism (N=8), Gyroelongated square pyramid (N=9), Sphenocorona (N=10), Icosahedron (N=13). We also characterize the relaxation times of the system and show that they increase linearly with N, thus deviating from the classical Maxwell theory of solvent evaporation. Implications for self-assembly of superlattices will also be discussed.

*This work is funded by NSF, DMR-CMMT 1606336 "CDS&E: Design Principles for Ordering Nanoparticles into Super-crystals". This work used the Extreme Science and Engineering Discovery Environment(XSEDE), which is supported by National Science Foundation grant number ACI-1548562. Our project within XSEDE is supported by grant TG-MCB140071.

4:18PM U30.00008: Reprogrammable phononic metasurfaces
OSAMA BILAL (Presenter), Univ of Connecticut - Storrs — Mechanical metamaterials are materials with tailored, architectured geometry, designed to retain properties that do not exist or rare in nature. Most of these mechanical properties are inscribed in the material's frequency dispersion spectrum, ranging form its stiffness at zero frequency to its wave attenuation capacity at finite frequencies. These materials usually feature a structural pattern that repeats spatially (i.e., unit cell). A special class of these metamaterials can manipulate elastic waves (i.e., phonons). Most of the existing design frameworks for phononic metamaterials capitalize only one of there mechanisms; scattering, resonance or inertia amplification. In addition, once these designs are realized, their operational frequencies cannot be altered, limiting their potential for practical applications. Here, we present a reporprogrammable metamterial platform for manipulating phonons utilizing all the aforementioned wave manipulation mechanisms [Foehr and Bilal et al.,PRL, 2018]. We program our nonlinear metamaterial to redirect stress waves, in real-time, in an element-wise fashion [Bilal et al., Adv. Mater. 2017]. Moreover, we use it to realize the first purely acoustic transistor (switching and cascading sound with sound) [Bilal et al., PNAS 2017].
**4:30PM U30.00009: Synthetic Mechanoreceptors with Collocated Logic**

JANAV P. UDANI, ANDRES ARRIETA (Presenter), Mechanical Engineering, Purdue University — We present a new class of synthetic mechanoreceptor exhibiting large changes in conductivity as a function of their shape. Concretely, such mechanoreceptors consist of a mechanical bistable structure showing shape-dependent electrical conductivity. The electromechanical response is designed such that on one state the unit shows large resistance, while on the second state the conductivity increases significantly. The bistable nature of such units and their ability to switch conductivity in response to external forcing allows our mechanoreceptors to serve as sensors with collocated input dependent memory. Specifically, the amplitude and frequency of the pressure/force inputs activating our mechanoreceptors change of shape (snap-through) result in distinct dynamical signatures, which are transduced by adding a voltage bias and reading current time histories. This allows to interpret specific external inputs into electrical output signatures that can be feed into an artificial neural network. We demonstrate this by subjecting a network of such mechanoreceptors to different force inputs resulting in recognizable electrical signatures which correlate to specific patterns of local states.

*This work is supported by DARPA under agreement No. HR00112090010.

**4:42PM U30.00010: Sending Signals Through Mechanical Wiring**

MICHELLE BERRY (Presenter), RYAN HAYWARD, University of Massachusetts Amherst, CHRISTIAN SANTANGELO, Syracuse University — Some progress has been made in the development of logic gates from mechanical systems, but in order to realize fully functioning devices, we need a reliable way to transmit a mechanical signal between logic gates. We consider a mechanical “wire”, a series of bistable units that interact with each other, as a way to connect the output of one logic gate to the input of another logic gate. Using both computer simulations and analytical calculation to analyze the propagation of a signal through the wire, we have determined how parameters such as the number of bistable units and the signal strength affect how far a signal can propagate through the wire. We determine whether and to what degree signals can propagate based on the shape of the bistable potential.

*ARMY W911NF-19-1-0348

**4:54PM U30.00011: Training for desired Folding Pathways in Self Folding Origami**

CHUKWUNONSO ARINZE (Presenter), MENACHEM STERN, SIDNEY ROBERT NAGEL, ARVIND MURUGAN, University of Chicago — Creased sheets can possess an exponential number of folding pathways accessible from the flat state. This property poses an engineering challenge in the design of specialized self-folding origami patterns with one or a few prescribed folding pathways. We seek an alternative means to eliminating undesired folding pathways via physical training. We fold creased sheets along desired folding pathways and allow the initially equal crease stiffnesses to dynamically evolve according to a local rule dependent on folding strain. We find that undesired folding pathways are eliminated in saddle-node bifurcations, leaving behind only one or two desired folded pathways. In this way, we find that physical folding, combined with a plasticity rule for crease stiffness, can naturally arrive at design parameters needed for non-linear behaviors that are hard to predict otherwise.
5:06PM U30.00012: Computational wrapping: A novel method for wrapping 3D-curved surfaces with brittle, nonstretchable materials for conformable devices  YU-KI LEE, Department of Materials Science and Engineering, Seoul National University, JYH-MING LIEN, Department of computer science, George Mason University, IN-SUK CHOI (Presenter), Department of Materials Science and Engineering, Seoul National University — In this talk, we propose a novel method to make conformable devices on non-zero Gaussian surfaces, i.e. flexible devices that can be transformed into any complex 3-dimensional shape. We used computational polyhedral edge unfolding methods to obtain planar figures of arbitrary complex 3-dimensional shapes. It is well-known that 2-dimensional substrates cannot be attached on the non-zero surfaces without stretching, however, by computational approximation of 3-D surface and making it flat by algorithmic method, we could convert any 3-D shapes into a 2-D sheet. We can make devices having the programmed unfolded figures and return it to the original 3D shape. In this way, we could make electroluminescent lighting and primary battery which can conformably wrap diverse 3-D surfaces without failure. Shape programmable devices with computational wrapping design can cover anywhere on the 3-dimensional shapes including human skin and are able to be applied not only personalized wearable or skin attachable devices but also various industries, such as automotive design, clothing, and fashion accessories, medical services and so on.

5:18PM U30.00013: How to weave a perfect sphere with curved strips  CHANGYEOB BAEK (Presenter), Department of Mechanical Engineering, Massachusetts Institute of Technology, ALISON G MARTIN, Italy, Independent artist, TIAN CHEN, SAMUEL POINCLOUX, Institute of Mechanical Engineering, École Polytechnique Fédérale de Lausanne, YINGYING REN, JULIAN PANETTA, MARK PAULY, School of Computer and Communication Sciences, École Polytechnique Fédérale de Lausanne, PEDRO REIS, Institute of Mechanical Engineering, École Polytechnique Fédérale de Lausanne — Triaxial weaving, a craft technique that enables the generation of surfaces with tri-directional arrays of initially straight elastic strips, has long been loved by basket makers and artists seeking a combination of practical and aesthetically-pleasing structures. The design principles of traditional weaving are based on the observation that the non-hexagonal topology of unit cells imparts out-of-plane shapes. In the realm of differential geometry, the weaving tradition is rooted in the concept of Euler characteristics through the Gauss-Bonnet theorem, with discrete topological defects being used as building blocks. Taking an alternative point of departure, we introduce a novel approach for triaxial weaving that enables us to continuously span a variety of 3D shapes of the weave by tuning the natural in-plane curvature of the strips. We systematically explore the validity of the new strategy by quantifying the shape of experimental specimens with X-ray tomography in combination with continuum-based simulations. To demonstrate the potential of our design scheme, and as a canonical example, we present a fullerene-like weave that is perfectly spherical, which cannot be readily achieved using straight strips. Ellipsoidal and toroidal structures are also explored.
2:30PM U31.00001: Collective behavior of platelets in blood clotting*  YUEYI SUN (Presenter), Mechanical Engineering, Georgia Institution of Technology, DAVID MYERS, Biomedical Engineering, Georgia Institute of Technology, WILBUR LAM, Wallace H. Coulter Department of Biomedical Engineering, Georgia Institution of Technology, ALEXANDER ALEXEEV, Mechanical Engineering, Georgia Institute of Technology — Blood clotting disorders prevent the body’s natural ability to achieve hemostasis and lead to bleeding, stroke or heart attack. Understanding the underlying physics behind the clotting process is essential to developing treatment of these disorders. Interaction between platelet and fibrin network leads to blood clotting, a highly complex multiscale mechanism taking place in blood flow. With experimental insights, we develop a mesoscale computational approach based on dissipative particle dynamics to examine the biophysics of clot contraction. The model contains platelets seeded in polymerized fibrin mesh. With platelets contracting surrounding fibrin, the model predicts bulk clot volume contraction and kinetics. The model shows that the heterogeneities involved in platelet contraction behavior enhance both clot volume contraction efficiency and clot force efficiency.

2:42PM U31.00002: Living oil-water interfaces: Buckling of droplets by cell growth at finite liquid interfaces  GABRIEL JUAREZ (Presenter), University of Illinois at Urbana-Champaign — Cell growth on solid substrates confined by rigid boundaries has been shown to influence cell morphology and lead to the emergence of collective behavior. Here, through microfluidic experiments and time-lapse microscopy, we demonstrate that the colonization of oil droplets by the growth and division of rod-shaped bacteria depends strongly on the droplet diameter, or the interfacial curvature. For droplets larger than a critical diameter, bacteria grow and divide at the oil-water interface, leading to the self-assembly of a densely packed monolayer of bacteria that eventually encapsulates the droplet. The stress from cell growth exerted at the oil-water interface causes the droplet to buckle and the fluid interface to undergo large deformations, including wrinkling and tubulation. For droplets smaller than a critical diameter, the formation of a self-assembled monolayer is not observed and no interfacial deformations occur. A simple energetic argument, comparing the attachment energy and bending energy due to elastocapillarity of a rod-shaped bacterium at curved oil-water interfaces, is able to determine the critical diameter, or interfacial curvature, for colonization and may provide insight on the hydrophobicity of the cell wall.
2:54PM U31.00003: A trace amount of surfactants enable diffusiophoretic swimming of bacteria

VIET SANG DOAN, Department of Mechanical Engineering, University of Hawaii at Manoa, PRAKIT SAINGAM, TAO YAN, Department of Civil and Environmental Engineering, University of Hawaii at Manoa, SANGWOO SHIN (Presenter), Department of Mechanical Engineering, University of Hawaii at Manoa — From birth to health, from personal care products to pharmaceutical and petroleum industries, surfactants are all around us. Due to the importance, their environmental impacts are extensively studied and well understood. One of the aspects that have been studied in recent years is their impact on bacteria, particularly the swimming behavior of motile bacteria. Here, we uncover an alternate chemotactic strategy triggered by the presence of surfactants, namely diffusiophoresis. We show that even a trace amount of ionic surfactants, down to a single ppm level, can impact the bacteria diffusiophoresis by boosting the surface charge of the cells. Because diffusiophoresis is driven by the surface-solute interactions, the surfactant-enhanced diffusiophoresis is observed regardless of the types of bacteria. Whether gram-positive or -negative, motile or non-motile, the surfactants enable fast migration of bacteria even under non-swimming conditions, suggesting a ubiquitous mechanism that has been largely overlooked.

3:06PM U31.00004: Bridging Scales to Model Emergent Collective Oscillations in Social Amoeba

CHUQIAO HUYAN (Presenter), ALEXANDER GOLDEN, XINWEN ZHU, PANKAJ MEHTA, ALLYSON SGRO, Boston Univ — A key challenge in modeling emergent biological behaviors such as collective oscillations is identifying what dynamical features are important to capture at the level of individuals to recapitulate group-wide phenomena. To address this, we conducted a case study on five major existing models that describe intracellular collective cyclic AMP (cAMP) oscillations in the social amoeba, Dictostelium discoideum. We compared each model to published experimental findings about how amoeba cells modulate internal cAMP dynamics in response to external changes in cAMP. By doing so we evaluated how well these models recapitulate the observed behaviors. All models reproduce group-wide signaling oscillations and a majority are able to reproduce some single cell observations. Our main observation is models that do a good job recapitulating single cell dynamics are better at reproducing a critical feature of group oscillations: tuning their group oscillation rate in response to changes in cell density and the cAMP dilution rate. Overall, we find that accurate recapitulation of single cell dynamics and noise are important for modeling qualitative group oscillations.
3:18PM U31.00005: Pattern engineering of living bacterial colonies using meniscus-driven fluidic channels  
VASILY KANTSLER, Physics, University of Warwick, UK, ELENA ONTAÑÓN-MCDONALD, CANSU KUEY, MANJARI J GHANSHYAM, School of Life Sciences, University of Warwick, UK, MARIA CHIARA ROFFIN (Presenter), Physics, University of Warwick, UK, MUNEHIRO ASALLY, School of Life Sciences, University of Warwick, UK — Engineering spatially organized biofilms for creating adaptive and sustainable biomaterials is a forthcoming mission of synthetic biology. Existing technologies of patterning biofilm materials suffer limitations associated with the high technical barrier and the requirements of special equipment. Here we present controlled meniscus-driven fluidics, MeniFluidics; an easily implementable technique for patterning living bacterial populations. We demonstrate multiscale patterning of living-colony and biofilm formation with submillimetre resolution. Relying on fast bacterial spreading in liquid channels, MeniFluidics allows controlled anisotropic bacterial colonies expansion both in space and time. The technique has also been applied for studying collective phenomena in confined bacterial swarming and organizing different fluorescently labelled *Bacillus subtilis* strains into a converged pattern. We believe that the robustness and low technical barrier of MeniFluidics offer a tool for developing living functional materials, bioengineering and bio-art, and adding to fundamental research of microbial interactions.

3:30PM U31.00006: Control of patterning in human pluripotent stem cell colonies via a Turing system with reactive boundaries  
BENJAMIN MCMASTER, HIMANSHU KAUL, DANIEL AGUILAR-HIDALGO (Presenter), PETER ZANDSTRA, School of Biomedical Engineering, University of British Columbia — During early stages of gastrulation, cells differentiate and organize into well-defined structures that lead to the emergence of the 3-germ layers, which represent early progenitors of precursor tissues for all the body organs. Recently, in-vitro studies using human pluripotent stem cells (hPSC) in confined environments have shown the emergence of spatially organized markers of an early gastrulation-like state following induction by the *bone morphogenetic protein 4* (BMP4), thus providing a framework to understand, and ultimately control, collective self-organization and pattern formation in hPSC. We present minimal Turing system that is consistent with hPSC patterns observed in 2- and 3-D structures. Our approach considers that the morphogen flux at the colony boundaries is morphogen-concentration dependent (a so-called reactive boundary). Using this framework, we have quantified the effective transport dynamics of the morphogen BMP4 in hPSC colonies, and defined conditions that predict pattern properties such as marker spatial order, domain size and thresholds for symmetry-breaking events. This work presents a general framework for self-organized pattern formation that explain observed patterns in hPSC colonies, leading to a design-based specification of collective cell behavior.
3:42PM U31.00007: Cellular integration of physical and biochemical damage signals in the generation of tissue-level wound responses*  AARON STEVENS (Presenter), KAZI TASNEEM, JAMES OCONNOR, SHANE HUTSON, ANDREA PAGE-MCCAW, Vanderbilt Univ — Laser wounds in Drosophila epithelia trigger calcium signaling – an early and conserved sign of wound detection – that includes an initial calcium influx into damaged cells within 0.1 s, a first expansion into adjacent cells over ~20 s, and a delayed second expansion to a much larger set of surrounding cells between 40-300 s. We have developed a computational model to test the plausibility of multiple hypothesized mechanisms driving these calcium signals and to further understand the underlying biology. The model includes calcium currents between each cell's cytosol and its endoplasmic reticulum (ER), the extracellular space, and neighboring cells. These calcium currents are initiated in the model by cavitation-induced microtears in the plasma membranes of cells near the wound (initial influx), flow through gap junctions into adjacent cells (first expansion), and by the activation of G-protein coupled receptors via a wound-induced diffusible ligand (second expansion). The production, processing and propagation of the ligand is modeled using reaction-diffusion equations on a continuous, two-dimensional space. We will discuss how the model matches experimental observations and makes experimentally testable predictions.

*Supported by NIH Grant 1R01GM130130.

3:54PM U31.00008: Dorsal closure in numbers: quantification of epithelial cell oscillations using machine learning  DANIEL HAERTTER (Presenter), Department of Physics, Duke University, DANTE RHODES, JANICE CRAWFORD, DANIEL P KIEHART, Department of Biology, Duke University, CHRISTOPH F. SCHMIDT, Department of Physics, Duke University — Dorsal closure in Drosophila melanogaster embryos is a key model system for cell sheet morphogenesis and wound healing. Multiple sub-systems are involved in the mechanical closing of the dorsal opening. Understanding system dynamics, regulation and causal relations requires a quantitative understanding of the mesoscopic mechanical and dynamic properties of this “active soft material”. Individual cells in the amnioserosa, a one-cell-thick sheet of epithelial cells filling the dorsal opening, show sustained oscillations of apical cell area. These oscillations exhibit large variations from cell to cell and during the course of closure. Past studies of epithelial dynamics were restricted to semi-manual segmentation of cell shapes and thus suffered from relatively low statistics. We present a novel analysis pipeline, based on a convolutional neural network (machine learning), that allows an automated and robust segmentation of large numbers of video recordings. We further employ statistical approaches to analyze spatial-temporal dynamics and quantify embryo-to-embryo variability. We observe emerging long-range dynamical patterns providing clues about possible communication mechanisms between cells.
**4:06PM U31.00009: Signatures of tissue surface tension in 3D models with two tissue types**

PREETI SAHU (Presenter), J M SCHWARZ, M. LISA MANNING, Syracuse University — Dense biological tissues maintain sharp surfaces between cell types performing different roles. For example, in multi-layered epithelia, the bottom-most basal layer remains distinctly compartmentalized from the supra-basal layer above, in spite of newly born basal cells being pushed upwards. Similarly, in experimental co-cultures of healthy (MCF10A) and invasive (MDA-MB-231) breast cell lines, initially MCF10A forms a distinct inner core leaving the MDA231 exposed, although that structure inverts on longer timescales. To better understand the mechanisms for such sharp compartmentalization, we study the effect of an imposed heterotypic tension at the interface between two distinct cell types in a fully 3D model for confluent tissues. We find that cells rapidly sort to generate a tissue-scale interface between cell types, and cells adjacent to this interface exhibit signature geometric features including nematic-like ordering and bimodal facet areas along the surface. The magnitude of these features scale directly with the magnitude of imposed tension, suggesting that experiments might estimate the magnitude of tissue surface tension simply by segmenting a 3D tissue.

**4:18PM U31.00010: Defect Driven Morphogenesis: Active Cell Division Generates Four-Fold Order**

DILLON CISLO (Presenter), HAODONG QIN, MARK J BOWICK, SEBASTIAN STREICHAN, University of California, Santa Barbara — The generation of 2D hexagon-dominated topologies has been well studied in thermally equilibrated systems. Six-fold coordinated patterns also frequently arise in living matter far from equilibrium as a result of cell proliferation. We present a quantitative profile of exotic non-equilibrium pattern formation in the crustacean *Parhyale hawaiensis*. Active orchestration of cell proliferation transforms an initially disordered epithelial tissue into a regular rectangular lattice that cannot be explained by cell packing or randomly oriented divisions. Using light-sheet microscopy and computer vision techniques, we extract the dynamics of cell proliferation in the growing *Parhyale* embryo and quantify the spatiotemporal dependence of orientational order. *In vivo* cell tracking and lineage reconstruction together with simulation and theoretical modeling reveal the relationship between division axis orientation and both the emergence and preservation of order. Disorder introduced into the lattice by divisions must be mitigated by the active control of subsequent divisions in order to maintain the lattice structure in a program we call defect driven morphogenesis.

4:30PM U31.00011: Quantifying mechanics in non-confluent tissues using an extended vertex model*  
ELIZABETH LAWSON-KEISTER (Presenter), AMANDA PARKER, JENNIFER SCHWARZ, M. LISA MANNING, Syracuse University — Vertex models for tissues have correctly predicted cell shapes and fluid-solid transitions in confluent epithelial monolayers where there are no gaps between cells and negligible curvature along cell-cell boundaries. However, in many situations of interest, such as in the development of the zebrafish tailbud, epithelial sheets transition from non-confluent layers with significant gaps between cells to confluent configurations with no gaps. Therefore, we develop simple extensions of vertex models that are able continuously transition between these two states, and demonstrate that there is a reasonable parameter regime in which the minimum energy state of this extended vertex model has gaps between cells. We study the mechanical behavior of these non-confluent models to understand how such gaps alter tissue mechanics and collective cell motility.

4:42PM U31.00012: The branched architecture of the airway is physically shaped by the extracellular matrix and contractile airway smooth muscle during lung development*  
[Invited] JAMES SPURLIN (Presenter), RAWLISON ZHANG, CELESTE NELSON, Princeton University — The lung possesses a highly branched airway epithelial network, which is required for rapid gas exchange. To build the network of branches in the lung, airway morphogenesis requires three critical steps including branch site specification, branch elongation, and mesenchymal remodeling. Using comparative embryology, we have found several novel mechanisms of how airway branches are physically shaped. During airway morphogenesis, epithelial branches are wrapped by a sheath of extracellular matrix (ECM), known as the basement membrane (BM), and a layer of contractile airway smooth muscle (ASM). We hypothesized these tissue layers direct airway branching morphogenesis by constraining the growth of the airway epithelium. In the bird lung, early stages of branching morphogenesis occurs in the absence of ASM, permitting the investigation of how ECM remodeling influences branch shape. In birds, we found branch elongation rate and surface area expansion requires proteolytic turnover of the BM. As branches elongate, mesenchymal cells surrounding the tips of the airway branches become elongated and the mesenchyme begins to rearrange fluidly, resembling a mesenchymal unjamming transition. This facilitates the transport and assembly of new ECM components ahead of the growing branch, which may also influence growth and shaping of the extending branch. In the mammalian lung, ASM wraps the airway epithelium and is critical for specifying the location of newly formed branches. We found mechanotransduction signaling through focal adhesion kinase (FAK) controls the distribution of ASM wrapping around the growing airway epithelium. Inhibiting of FAK signaling results in altered ASM contractility, leading to changes in the branched architecture of the airway. Taken together, the ECM and ASM shape airways of the developing lung by constraining the growth of the epithelium to build a functional branched airway network.

Thursday, March 5, 2020 2:30 PM - 5:30 PM
2:30PM U32.00001: Effect of Molecular Architecture on the Conformational Relaxation for Interfacial Polymer Chains* HUNG K. NGUYEN, DAISUKE KAWAGUCHI, KEIJI TANAKA (Presenter), Kyushu Univ — Conformational relaxation processes of polymer chains trapped in a metastable state in close proximity to a solid interface can strongly affect the physical properties of polymer nanocomposites. Using sum-frequency generation spectroscopy, we here report the thermal annealing effect on chain conformations of polystyrene (PS) with different molecular architecture near at the quartz interface. Relaxation dynamics for PS chains strongly adsorbed at the outermost substrate interface and those located next to the adsorbed layer were characterized. PS chains exhibited much slower relaxation dynamics with a star-shaped architecture than with a linear one. This finding is in consistent with a scenario that the entropic interaction with the solid surface is stronger for a star-shaped macromolecule than for a linear one.

2:42PM U32.00002: In Situ Synchrotron Radiation X-ray Scattering Evaluation of Domain Size and Spacing of Thermoplastic Elastomer under Elongation NATTANEE DECHNARONG (Presenter), Graduate School of Engineering, Kyushu University, KAZUTAKA KAMITANI, Institute for Materials Chemistry and Engineering, Kyushu University, CHAO-HUNG CHENG, SHIORI MASUDA, SHUHEI NOZAKI, CHIGUSA NAGANO, Graduate School of Engineering, Kyushu University, YOSHIFUMI AMAMOTO, KEN KOJIO, ATSUSHI TAKAHARA, Kyushu Univ — Microphase separation occurs in polystyrene (PS)-b-poly(ethylene-co-butylene)-b-PS (SEBS), leading PS domains to serve as physical crosslinking points. To improve mechanical strength of SEBS, mechanical stability of PS needs to be clarified. Here, the molecular aggregation structure of SEBS films containing spherical PS domains packed in b.c.c. lattice was measured during stretching using in situ SAXS. During uniaxial stretching, a shift of structure factor reveals an increase in domain spacing in parallel to stretching direction while it decreased in the perpendicular direction. Affine deformation of all diffraction planes was observed, while they deviated from the trend above strain 5 equally. In the case of biaxial stretching, an increase in the domain spacing was observed in both stretching directions, indicating an isotropic deformation. Deviation from affine deformation of each diffraction plane was observed above strain 1.5, referring to the difficulty of maintaining the paracrystalline structures during biaxial stretching. Domain size of PS domains with polydispersity was determined from form factor using model calculation. From the change of radius, PS domains were proposed to deform to prolate and oblate spheroids during uniaxial and biaxial elongation, respectively.
Structure and Physical Properties of Zwitter Ionic Polyelectrolyte Brushes at Aqueous Interface

ATSUSHI TAKAHARA (Presenter), Kyushu Univ — Polymers chemically grafted to the surface of substrates are typical soft interfaces known as polymer brushes. Surfaces covered with polyelectrolyte brushes are attractive because of their potential applications including adhesion, antifouling, biocompatibility and water lubrication systems. In this presentation, our recent researches on control of wettability and adhesion through precise design of polyelectrolyte brush surfaces are presented. We started from fundamental science including precise polyelectrolyte synthesis and solution characterization of polyelectrolytes, characterization of polymer brush at water interfaces, and water structure in polymer brushes. On the basis of these fundamental studies, we have achieved 1) superhydrophilicity, 2) antifouling properties, 3) super-lubricant behavior, 4) intelligent adhesion and 5) cell-surface interaction control.

Highly Branched Polymers with High Ether Oxygen Content for Membrane CO₂/N₂ Separation

HAIQING LIN (Presenter), State Univ of NY - Buffalo — Membrane technology has emerged as a potentially economically viable alternative for CO₂ captures from fossil fuel-fired powers, enabled by advanced membrane materials with high CO₂ permeability and high CO₂/N₂ selectivity. Current leading membrane materials usually contain poly(ethylene oxide) (PEO) because the ether oxygen in PEO interacts favorably with CO₂, resulting in high CO₂/N₂ selectivity. Herein we prepare a series of highly branched amorphous polymers containing poly(1,3-dioxolane), which has an O:C ratio of 0.67, higher than 0.5 in PEO. The length of the poly(1,3-dioxolane)-based branches are tuned to yield amorphous nature, and mobile ethoxyl chain end groups are introduced to provide high free volume and gas diffusivity. These ether oxygen-rich polymers exhibit more superior CO₂/N₂ separation properties than the PEO-based materials at practical conditions for flue gas processing, and above the Robeson’s upper bound. This work demonstrates that harnessing the interactions between polymers and CO₂ may provide unprecedented opportunities in designing gas separation membranes with robust performance under practical conditions.

*DOE NETL and NSF
3:18PM U32.00005: Protein Resistant Property of Nanometer-Scale Architecture of Polymer Chains

MAYA ENDOH (Presenter), DANIEL SALATTO, ZHIXING HUANG, State Univ of NY - Stony Brook, YUTO KOGA, Cornell University, YASHASVI BAJAJ, BENJAMIN YAVITT, State Univ of NY - Stony Brook, JAN-MICHAEL CARRILLO, Oak Ridge National Laboratory, DMYTRO NYKYPANCHUK, Brookhaven National Laboratory, TAD KOGA, State Univ of NY - Stony Brook — We recently reported that a few nanometer-thick polymer layer formed on a solid, which consists of physisorbed non-charged homopolymer chains, exhibits anti-fouling properties against a model protein, bovine serum albumin (BSA), independent of polymer hydrophilicity/hydrophobicity[1]. We revealed that the highly packed chain architecture plays a crucial role in its protein resistant property over surface chemistry. Here, we further illuminate how this nanometer-scale chain structure impacts the protein adsorption on ultrathin polymer films. Polymer films with different thicknesses ranging from 2 nm to 200 nm of polystyrene, poly(2-vinyl pyridine), polybutadiene, poly(methyl methacrylate), and polypropylene were prepared. Adsorption of fluorescein labeled BSA and fibrinogen on these thin films were studied as a function of film thickness using photon counting spectrofluorometry. We observe that the critical thickness of the adsorption transition from anti-fouling to fouling appeared irrespective of the type of polymers and proteins. In addition, molecular dynamics simulations were performed to mimic the protein adsorption process. We will discuss the mechanism behind the phenomenon.

3:30PM U32.00006: Linear vs Star polymers in Hydrogen-Bonded Assemblies

ALIAKSEI ALIAKSEYEU (Presenter), Materials Science and Engineering, Texas A&M University, JOHN F ANKNER, Spallation Neutron Source, Oak Ridge National Laboratory, SVETLANA SUKHISHVILI, Materials Science and Engineering, Texas A&M University — We report on the effect of the molecular architecture of poly(ethylene oxide), PEO (linear vs. 6-arm polymer, /PEO and sPEO, respectively) and molecular weight of poly(methacrylic acid) (PMAA) on hydrogen-bonding assembly of these polymers. Isothermal titration calorimetry studies (ITC) revealed the entropic nature of complex formation and complex strengthening with the increase of molecular weight of PMAA. At the same time, /PEO-containing and sPEO-containing complexes had a different stoichiometry of PMAA-to-PEO repeat units of 1 and 1.5 for PMAA/PEO and PMAA/sPEO, respectively, suggesting possible formation of necklace-like complexes on a PMAA string. When the assembly was performed at surfaces, layer-by-layer (LbL) PMAA/PEO films constructed with linear PEO exhibited faster deposition of polymer mass as compared to films built with sPEO. Consistent with these results, neutron reflectometry revealed stronger molecular intermixing within films containing /PEO, suggesting faster diffusion of /PEO in LbL films as compared to the necklace-included sPEO polymer.
The dynamics of the thermally stimulated surface height fluctuations in a polymer melt dictate wetting, adhesion, and tribology at that surface. These surface fluctuations can be profoundly altered by tethering of the chains. One type of tethering is the tethering of one part of a molecule to another part of the same molecule. This tethering is found in both long chain branched polymers and in macrocycles. We have studied the surface fluctuations with X-ray Photon Correlation Spectroscopy for melts of well-defined, anionically polymerized polystyrenes of various architectures, including linear, 6 arm star, pom-pom, comb and cyclic architectures. For linear chains, the variation of surface relaxation time with in-plane scattering vector can be fit using a hydrodynamic continuum theory (HCT) of thermally stimulated capillary waves that knows nothing of the chain architecture. Assuming the theory is applicable, apparent viscosities of the films may then be inferred from the XPCS data. For unentangled linear chains, the viscosity inferred from XPCS data for sufficiently thick films is the same as that measured by conventional bulk rheometry. For star-branched chains the film thickness relative to chain size must be much larger to obtain this agreement. Densely branched combs, cyclic and bicyclic chains show yet another behavior. It appears these differences are related to the manner in which the chains organize at the substrate interface.

4:18PM U32.00008: Dilute solution structure of bottlebrush polymers  SARIT DUTTA (Presenter), TIANYUAN PAN, MATTHEW AARON WADE, DYLAN J WALSH, SIMON A ROGERS, DAMIEN S GUIRONNET, CHARLES SING, University of Illinois at Urbana-Champaign — Bottlebrush polymers are the canonical example of hyperbranched polymers, consisting of a central backbone chain with numerous side chains densely grafted onto it. This architecture lends additional thickness to the molecule as well as enhancing its stiffness due to steric interaction between the side chains. The side chain length and grafting density can be used as control parameters for tuning the material properties, as leveraged in recent applications to photonic crystals and soft elastomers.

We present results from Brownian Dynamics and Monte Carlo simulations on bottlebrush conformations in dilute solution, emphasizing the role of side chain length and grafting density on the size, shape, and intramolecular structure of a bottlebrush molecule. These simulations are based on bead-spring models, with suitably chosen potentials. We find good agreement between our simulation results and viscometric studies on well-characterized samples of polynorbornene-polylactic acid bottlebrushes. We coarse-grain the above bead-spring model as a wormlike cylinder, where the side-chains are treated in an implicit fashion. Furthermore, we discuss the elastic response of bottlebrush polymers to a pulling force and contextualize this behavior with respect to classical entropy elasticity of linear polymers.

4:30PM U32.00009: Morphology and Dynamics of Catenanes in Dilute Solutions and at Liquid/Liquid Interface  SAEED AKBARI (Presenter), SHAGHAYEGH KHANI, JOAO M MAIA, Macromolecular Science & Engineering, Case Western Reserve University, MESFIN TSIGE, Polymer Science, University of Akron — Molecular Dynamics simulations are performed with all-atom poly (ethylene oxide) (PEO) and polystyrene (PS) structures in water and in toluene and at the water/toluene interface and the dynamics and structural properties of PEO and PS chains with different topologies such as linear, isolated rings and interlocked rings (homo and hetero catenation) are studied. This includes the comprehensive study of the effect of chain flexibility, solvent quality and interface as deterministic factors that influence the morphology and dynamics of the catenanes. The results can be exploited to design and fabricate molecules with desired dynamics and will be of particular significance for drug delivery applications. Our simulations predict larger radius of gyration and faster dynamics for flexible topologies in a good solvent. In a poor solvent, they shrink to smaller size and again diffuse faster compared to the rigid counterparts. Moreover, hydrogen bonding significantly affects the dynamics of the molecules in water both in bulk and at the interface. At the water/toluene interface, molecules develop a flat morphology and thus have larger size as compared to their coil structures in the bulk of a good solvent and are found to show faster diffusion.
4:42PM U32.00010: Bottlebrush Polymers in the Melt and Polyelectrolytes in Solution Share Common Structural Features

JOEL SARAPAS, TYLER MARTIN, National Institute of Standards and Technology, ALEXANDROS CHREMOS, National Institutes of Health, JACK DOUGLAS, KATHRYN BEERS (Presenter), National Institute of Standards and Technology — Uncharged bottlebrush polymer melts and highly charged polyelectrolytes in solution exhibit correlation peaks in scattering measurements and simulations. Given the striking superficial similarities of these scattering features, there may be a deeper structural interrelationship in these chemically different classes of materials. Correspondingly, we constructed a library of isotopically labeled bottlebrush molecules and measured the bottlebrush correlation peak position $q^* = 2\pi / \xi$ by neutron scattering and simulations. We find that the correlation length scales with the backbone concentration, $\xi \sim c_{BB}^{-0.47}$, in striking accord with the scaling of $\xi$ with polymer concentration $c_p$ in semi-dilute polyelectrolyte solutions ($\xi \sim c_p^{-1/2}$). The bottlebrush correlation peak broadens with decreasing grafting density, similar to increasing salt concentration in polyelectrolyte solutions. $\xi$ also scales with sidechain length to a power in the range of 0.35 to 0.44, suggesting that the sidechains are relatively collapsed in comparison to the bristle-like configurations often imagined for bottlebrush polymers.

4:54PM U32.00011: Effect of Chain Architecture on the Structure, Diffusion, and Swelling in Thin Polymer Films*

BULENT AKGUN (Presenter), MAKBULE GIZEM KIREVIYASI, AYSE CAGLAYAN, Bogazici University, KUNLUN HONG, DAVID UHRIG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, TADANORI KOGA, Department of Materials Science and Chemical Engineering, Stony Brook University, GUANGCUI YUAN, SUSHIL K SATIJA, NIST Center for Neutron Research, National Institute of Standards and Technology — Polymers with special architectures are utilized in wide variety of technologies such as in pressure sensitive adhesives, biomedical coatings, photoresists, targeting multi-drug resistant gram-negative bacteria, and electrochromic displays. Being able to control the chain architecture opens new pathways to tune physical properties of the polymer thin films through alterations in the entropic contribution. In this work, we have investigated the role of chain architecture on the adsorption, diffusion and swelling in supercritical carbon dioxide (ScCO$_2$) using well-defined linear, star, centipede and comb polystyrene (PS). Structure of irreversibly adsorbed layers are determined using ellipsometry and X-ray reflectivity. Vertical diffusion in bilayer films and ScCO$_2$ swelling in single layer films were determined using in-situ neutron reflectivity measurements. Our results indicated that the normalized equilibrium thickness of the adsorbed layer increases as the number of branches increases and the length of the branches decreases. Independent of the architecture the films are consistently fit using a single layer of uniform density. For the same total molecular weight, thin films composed of more branched polymers have larger diffusion constants than that are made of linear chains. Increase in the fraction of adsorbed chains in a thin film causes a decrease in the vertical diffusion and ScCO$_2$ swelling.

Thursday, March 5, 2020 2:30 PM - 5:30 PM
2:30PM U33.00001: Formation of Pickering Emulsions Using Nanodiamonds  BARBARA V FARIAS, DEREK BROWN, ALLISON HEARN, SAAD KHAN (Presenter), North Carolina State University — Pickering emulsions are used over surfactant stabilized emulsions in a wide range of applications including personal care products, pharmaceuticals, and oil recovery because of their enhanced stability and lower toxicity. We examine here the use of nanodiamonds (ND), a relatively novel carbonaceous filler with high adsorption activity, small size, and large surface area to create solid stabilized emulsions. Using a system consisting of isopropyl palmitate and water, stabilized by hydroxylated NDs, we investigate the stability, rheology and frictional behavior of these emulsions as a function of ND concentration. Optical microscopy reveals increasing ND concentration results in smaller droplet sizes, due to the greater availability of particles that can be adsorbed on the oil-water interface. This behavior is consistent with our rheological results of higher G’ and yield stress with increased ND, as the presence of smaller droplets facilitate the formation of a densely packed network. Microstructure recovery after breakdown at different stress levels correlate with the ratio of applied stress to the yield stress for each ND concentration. Tribological behavior of ND emulsions was also investigated using a soft model contact and the data related to the rheological characteristics.

2:42PM U33.00002: Utilizing Inorganic Nanoadditives to Influence the Surface Properties of Polymer Films*  SPIROS H. ANASTASIADIS (Presenter), FANOURIOS KRASANAKIS, ANTIGONOS THEODORAKIS, KIRIAKI CHRISSOPOULOU, Foundation for Research and Technology-Hellas and Univ. of Crete — Addition of nanosized inorganic materials to a polymer matrix results in nanohybrids with optimized properties. In this work, we report on the development of superhydrophobic and water repellent polymer coatings by utilizing nanoadditives of different geometries and size. The nanocomposite coatings were deposited either on a soft polyethylene, PE, substrate or on a hard silicon wafer. The coating morphology and effective roughness were studied with Scanning Electron Microscopy and profilometry, respectively, as a function of the nanoadditive content. In the case of PE substrates, the optical clarity of the original film was preserved following the nanohybrid coating, as verified by UV-Vis spectroscopy. The surface properties of all films were investigated by contact angle measurements; the water contact angle showed a non-monotonic dependence on the coating composition and depended strongly on the kind of nanoadditive whereas the contact angle hysteresis was significantly affected by its presence.

2:54PM U33.00003: Interfacial Dynamics of Confined Microgel Liquids on Soft Surfaces
KEHUA LIN (Presenter), YINGXI ELAINE ZHU, Wayne State Univ — While much research has strived to understanding the dynamics of confined liquids on a hard solid surface, the dynamics of liquids confined on a soft and deformable surface remains unclear. In this work, we employed poly(N-isopropylacrylamide) (PNIPAM) microgels of varied crosslinking density as the confined liquids as well as confining surface coatings. We analyzed the mean-squared-displacement (MSD) of confined PNIPAM microgel particles in the first 1-2 particle layers immediately adjacent to PNIPAM coated surface of varied particle-to-surface elasticity ratios. We observed that soft surface of low elasticity show little impact on the interfacial dynamics of confined microgel particles of varied elasticity, where the MSD of confined microgels exhibits little deviation from their bulk behaviors. Such interfacial behavior is in sharp contrast to the dynamic arrest of microgels confined on hard surface of high elasticity. Furthermore, we found that the dynamic heterogeneity in confined glass-like microgel liquids could diminish with decreasing the elasticity of confining surface, which gives insight to design low-friction and lubrious coatings and surfaces.

3:06PM U33.00004: How osmotic pressure governs sliding and surface structures of swollen crosslinked hydrogels* [Invited] SHABNAM Z BONYADI, CHRISTOPHER L JOHNSON, JIHO KIM, ERIK R REALE, MICHAEL ATTEN, ALISON C DUNN (Presenter), University of Illinois at Urbana-Champaign — High-water-content hydrogels are being increasingly explored for applications in biomedicine, water filtration, and hybrid materials. As these materials slide against hard, impermeable countersurfaces, they exhibit time-dependent and history-dependent friction related to their response under stress. Here I present two vignettes of the role of osmotic pressure in understanding hydrogel lubrication. The first considers the competitive rates of surface slip and pressure-driven dehydration due to applied loads. Given initial measurements of friction at very low and very high speeds, the ratio of the timescales of these effects can predict friction along the intermediate spectrum. The second vignette describes the inherent generation of less-dense surface layers (~single microns) that arise from the bulk due to the discontinuity of osmotic pressure between the bulk and the open bath submerging a crosslinked hydrogel. These layers are confirmed with multiscale indentation techniques and material creep localized to the near-surface region.

3:42PM U33.00005: Bio-inspired surface modification of PDMS to reduce dry friction
MENGYUAN WANG, University of Colorado, Boulder, SUJAN GHOSH, University of Arkansas, ADRIENNE BLEVINS, University of Colorado, Boulder, CHRISTOPHER M STAFFORD, JASON KILGORE, National Institute of Standards and Technology, SIJIA HUANG, University of Colorado, Boulder, MIN ZOU, University of Arkansas, YIFU DING (Presenter), University of Colorado, Boulder — Reducing friction and associated energy dissipation in mechanical systems is critical for a broad range of applications. Under dry condition, soft elastomers are inherently adhesive and display high friction coefficient, which leads to severe wear and damage during contact. The skin structure and the scales geometry of some squamate reptiles, especially snakes and lizards, offers a potential way for friction reduction under extremely dry conditions. The stiff keratin-based epidermis on soft dermic tissue helps snakes reduce friction in forward locomotion. This study aims to mimic such functional skins by modifying both the stiffness and topography of the elastomeric surfaces. Using a photoinitiated infiltration polymerization, glassy polyHEMA is formed within the skin of PDMS, in the presence of water. The as-prepared surface displays a integrated skin layer possessing fold-like structure, with stiffness increasing from glassy to rubbery with the increase of load. Under dry condition, the friction coefficient of the PDMS reduces from 1.6 to 0.14 with the modification.

3:54PM U33.00006: Friction and wear of polyzwitterionic brush-grafted surfaces*
CHRISTOPHER SERFASS (Presenter), Department of Chemical and Biomolecular Engineering, North Carolina State University, EMILY F ROE, Department of Materials Science and Engineering, North Carolina State University, LILIAN C HSIAO, Department of Chemical and Biomolecular Engineering, North Carolina State University — Inspired by the hydrophilic biomacromolecules adsorbed to the surface of articular cartilage, we investigate the tribology of betainized poly(2-(dimethylamino)ethyl methacrylate) (PDMAEMA) brushes grafted on soft poly(dimethyl siloxane) (PDMS) and hard silicon substrates. These polyzwitterions are known to provide excellent lubricity due to their ability to retain water in their side groups. Surfaces are hydrolyzed to introduce surface silanol groups which serve as an attachment point for a trichlorosilane initiator. After initiator deposition, PDMAEMA is grown from the surface via atom transfer radical polymerization (ATRP) and then betainized to render it zwitterionic. We measure the steady state and transient friction coefficients of the substrates as a function of brush film thickness and substrate elasticity. Our initial results suggest that use of soft, deformable substrates such as PDMS yields increased wear resistance for brush films due to a reduction in the contact pressure below the yield point of the polymer brushes. Furthermore, repetitive transient contact appears to result in increased wear resistance, with the total shearing time required for noticeable wear to occur increasing by an order of magnitude.

4:06PM U33.00007: Surface Forces Apparatus Measurements Between Oppositely Charged Polyelectrolyte Brushes as a Function of Ionic Strength  DEAN MASTROPIETRO (Presenter), MATTHEW TIRRELL, Argonne National Laboratory — Interactions between polyanions and polycations result in polyelectrolyte complexation and the formation of polymer dilute (aqueous) and polymer rich (coacervate) phases. Understanding the forces governing the formation and stability of these complexes as well as their dependence on solution conditions is of great interest. We directly measure the interactions between densely grafted, apposing polycationic and polyanionic brushes as a function of ionic strength using the surface forces apparatus (SFA). Additionally, we compare these force profiles with SFA measurements between apposing polyanionic brushes and between apposing polycationic brushes.

4:18PM U33.00008: Tribology of soft colloidal microgels: An oral perspective*  [Invited] ANWESHA SARKAR (Presenter), Univ of Leeds — Oral tribology is emerging as a new paradigm in the tribology field to quantify friction in soft sliding contact surfaces\(^1\). Using a combination of experimental techniques and theoretical considerations, this talk will cover three case studies\(^2\)\(^-\)\(^4\) on tribology of soft elastomeric surfaces (with different wetting properties) in the presence of biopolymeric microgels with well-defined deformability, designed using variable cross-linking densities and particle sizes. Some of these microgels show aqueous ‘ball-bearing’ abilities depending upon their volume fraction\(^2\). A case study\(^4\) will be presented on how these microgels can act as viscosity modifiers of the continuum, where the lubrication performance can be quantitatively described using the Newtonian plateau value ($\eta_\infty$). Finally, ongoing research on development of novel soft tribo-surfaces to emulate the highly sophisticated oral mucosal surfaces engineered by the nature will be highlighted \(^1\).

Pore-size dependence and glassy behavior of hydrogel friction on smooth surfaces

**NICHOLAS CUCCIA, SURAJ POTHINENI, BRADY WU, JUSTIN BURTON**
(Presenter), Physics, Emory University — Hydrogels are important in many scientific and engineering applications due to their tunable physiochemical properties and bio-compatibility. Bulk hydrogels consist of a crosslinked polymer matrix imbibed with water or a similar solvent at volume fractions that can exceed 90%, leading to a rich spectrum of interfacial rheological behaviors. Using a custom-built, continuous pin-on-disc tribometer, here we identify three distinct regimes of frictional behavior for both polyacrylamide (PAAm) and agarose hydrogel spheres on smooth surfaces. At low velocities, friction is controlled by hydrodynamic flow through the porous hydrogel network, and is inversely proportional to the characteristic pore size. At high velocities, a mesoscopic, lubricating liquid film forms obeying elastohydrodynamic theory. In between these regimes, the frictional force sharply decreases with velocity and simultaneously displays time-dependent behavior characteristic of glassy, slow relaxation over several minutes. This relaxation strongly depends on the fluid shear rate, and the transition can be tuned by varying the solvent salt concentration, solvent viscosity, and sliding geometry at the interface.

Study of the tribological behavior of hydrogel-like materials with an extended Surface Forces Apparatus

**ROSA M. ESPINOSA-MARZAL** (Presenter), TOOBA SHOAIB, University of Illinois at Urbana-Champaign — Biological tribosystems are excellent examples of nature leveraging material properties to achieve exceptional lubrication for prolonged periods of activity. In these systems, lubrication is provided by hydrogel-like surface layers and an aqueous lubricant. Our research aims to advance the knowledge about the relation between frictional dissipation and hydrogel's microstructure. In this talk, we will present steady and dynamic shear measurements with an extended surface forces apparatus (eSFA) on hydrogel thin films under modulated compression. Complimentary quasi-equilibrium compression measurements with the eSFA can be performed during tribological measurements; this is a unique capability of the SFA and enables to detect polymer rearrangements upon shear. This type of experiments provides new insight into the influence of hydrogel's microstructure on dissipative mechanisms that dictate lubrication with special emphasis on the influence of hydrogel's microstructure.

5:18PM U33.00011: Indentation of a microparticle into an oil-coated, soft silicone surface
JUSTIN GLOVER, JONATHAN PHAM (Presenter), Univ of Kentucky — Small scale contact between a
soft, liquid-coated layer and a stiff surface is found in many situations, from synovial fluid on
articular cartilage to adhesives in humid environments. Moreover, many model studies on soft
adhesive contacts are conducted with soft silicone elastomers, which usually possess
uncrosslinked molecules (i.e. liquid silicone oil) when the modulus is low. The presence of liquid
near the contact line can cause capillary forces on the particle. We consider a similar situation in
which uncrosslinked liquid molecules are already placed at a surface prior to contact. More
specifically, we investigate how the thickness of an oil layer relates to the indentation depth of a
glass microsphere into a lightly crosslinked PDMS network. A simple model that balances the
capillary force of the oil layer with the elastic force from the substrate is proposed to predict the
position of the particle. Interestingly, the vertical force associated with a thin layer of liquid on a
soft substrate appears to govern the indentation depth of a microsphere into the polymer
network.

2:30PM U34.00001: Electro-reflectance study of low-voltage turn-on in triplet fusion OLED
materials  SEBASTIAN ENGMANN (Presenter), Theiss Research, EMILY BITTLE, LEE RICHTER, DAVID
JAMES GUNDLACH, National Institute of Standards and Technology — Coherent spin processes like
singlet-fission (SF) and triplet fusion (TF) are gaining in interest to the scientific community, as SF
could lead to an increase in performance of organic photovoltaics and TF in the emission
efficiency of OLED devices. Recently reported results have suggested that higher order effects
such as TF lead to a reduction of the luminescence turn-on voltage and is necessary for what was
referred to as “sub-band gap turn-on”. However, we have shown that heterojunction band
alignment can describe the low voltage turn-on. In this presentation we will present electro-
reflection (ER) studies that elucidate the built-in potentials in 2 prototypical OLED devices based
on Rubrene and DiFTES-ADT as the emitting layer. The results are put into context of the low
luminescence turn-on, which is observed in both cases, and potential higher order effects.
Furthermore, differences in the luminescence - current density-voltage-characteristics, L-J-V and
magneto-electro-luminescence, MEL, between the two systems will be presented. A kinetic model
captures zero field splitting and various exciton and charge carrier recombination pathways.
**2:42PM U34.00002: The rationale behind the acceptor-donor-acceptor chemical design of non-fullerene acceptors**

ANASTASIA MARKINA (Presenter), Theory Group, Max Planck Institute for Polymer Research, FREDERIC LAQUAI, Solar Center, King Abdullah University of Science and Technology, DENIS ANDRIENKO, Theory Group, Max Planck Institute for Polymer Research — Efficiencies of organic solar cells have seen a rapid increase due to the development of non-fullerene acceptors (NFAs). We explain why excitons dissociation into charge-transfer (CT) states, and the subsequent CT state splitting into charge-separated (CS) states, are efficient in NFAs-based solar cells. We show that the driving force of the excited-to-CT state transition comes from a stronger dielectric stabilization of charges compared to the localized excited state. CT-to-CS transition is driven by the gradient of the acceptor concentration, which bends the electrostatic potential, helping to overcome the Coulomb binding of the CT state. Both effects depend on the related molecular quadrupole moments and their long-range contribution to the solid-state ionization energies and electron affinities.

The results are supported by simple lattice models, as well as atomistic-level descriptions performed for a number of solar cells based on the polymer donor PCE10 and small molecule NFAs. These include IEICO, IEICO-4F, IEICO-4Cl, O-IDTBR, O-IDTBCN, ITIC, ITIC-4F, ITIC-4Cl. The present study suggests several design rules for NFAs with efficient charge separation in photovoltaic applications.

**2:54PM U34.00003: Engineering Diffusion of Charge-Transfer States at Organic Semiconductor Heterojunctions**

NOLAN CONCANNON (Presenter), TAO ZHANG, RUSSELL J HOLMES, University of Minnesota — Interfacial excited states formed at electron donor-acceptor heterojunctions, called charge-transfer (CT) states, are essential intermediates for organic photovoltaic and light-emitting devices. While CT states are known to diffuse, questions remain around the underlying transport mechanism and the materials parameters that determine the diffusion length. In this work, we examine CT state diffusion in donor-acceptor mixtures via photoluminescence quenching methods. The diffusion length is extracted across donor and acceptor type as well as relative composition. In general, we find that CT states are at least as mobile as their bulk counterparts, despite being confined to an interface. Further, the energy of the CT state, and the presence of low-lying triplet states do not strongly determine the scale of the diffusion length. We instead find a correlation between the diffusion length and the mobility of the slowest component charge carrier. The connection between charge carrier transport and CT state diffusion suggests strategies to engineer CT state migration in various devices. These conclusions may also elucidate CT state transport at hybrid interfaces of organic and inorganic semiconductors.
First-Principles Theory for Understanding Excitons in Stacked Organic Assemblies* [Invited] SAHAR SHARIFZADEH (Presenter), Boston University — Organic semiconductors are tunable light absorbers with promise as solar energy conversion materials, with their efficiency highly dependent on the nature and energy of electron-hole pairs or excitons formed upon light absorption. Excitons in these materials are controlled by the interplay between inter- and intra-molecular electronic as well as vibrational interactions, which is not yet well-controlled in devices. Here, we utilize first-principles theory to investigate the optoelectronic and vibrational properties of stacks of functionalized PTCDI DNA base surrogates as a model system to study inter- and intra-molecular interactions. We apply time-dependent density functional theory, along with a Franck-Condon analysis of vibronic effects, to finite stacks of molecules that have been recently synthesized. We determine that the intra- and inter-molecular interactions result in distinct vibrational, electronic, and optical properties. For a periodic assembly of PTCDI, many-body perturbation theory predicts a bandstructure with significant bandwidth (~0.8 eV), consistent with strong inter-molecular electronic interactions, and several spatially delocalized low-energy optically excited-states. By incorporating electron-phonon interactions, we find that at T = 300K, the optical absorption is altered from T = 0 K due to allowed indirect transitions, while exciton delocalization and binding energy, a measure of intermolecular electronic interactions, remains constant. Overall, this work demonstrates that excitonic properties can be modified via inter-molecular electronic and vibrational interactions.

Quantum Yield Enhancement of BDMO-PPV During Photo-Degradation MATTHEW DEUTSCH (Presenter), HEUNGMAN PARK, Texas A&M University, Commerce — Poly-2,5-bis(3',7'-dimethyloctyloxy)-1,4-phenylenevinylene (BDMO-PPV) is a photoluminescent semiconducting polymer similar to other well-studied polyphenylene vinylenes such as MEH-PPV and MDMO-PPV. This family of organic semiconductors has similar emission spectra and absorption spectra due to their backbone structure. However, side-chain structures between different polyphenylene vinylene (PPV) derivatives can result in different optoelectrical and material properties. PPVs are known for their instability, degradation, and low efficiency - a barrier for use in organic electronic devices. BDMO-PPV exhibits enhanced internal and external quantum yield while degrading in organic solvents such as chloroform and toluene. A proposed highly emissive intermediate state during photodegradation is responsible for an increase in internal and external quantum yield. Using photoluminescence spectroscopy, infrared spectroscopy, and light scattering measurements we intend to define the physical and chemical processes behind the photo-degradation of BDMO-PPV.
Photospintronics- Light-controlled spin transport in hybrid chiral oligopeptide-nanoparticle structures*  RUPSHALI ROY (Presenter), Indian Institute of Engineering Science and Technology, Shibpur — It has been found the transmission of electrons through chiral molecules depends on their spin orientation; this is known as chiral induced spin selectivity. This effect makes it feasible to build spintronic devices without ferromagnetic spin injectors since the chiral molecules themselves serve to choose a specific spin to transfer across the molecules. We began building a device which would aid in furthering research on spintronics. It consists of an Si substrate, plated with a layer of Ni, a ferromagnetic material, further coated by a layer of gold, as the base layer. In the hybrid system studied therein. Helical chiral molecules of cysteine hydrochloride were attached on one end to the base layer mentioned above, and on the other end to a MoS$_2$ thin film.

The chiral molecules taken in this case were right helical structures. When right circularly polarized light is shined on the device, electron hole pairs are generated and those electrons with right handed spin are excited and are selected to move through the chiral molecules. Vice versa occurs when the chirality or polarisation is reversed.

Morphology-Dependent Triplet Exciton Diffusion in Vapor Deposited Pentacene Thin Films  KAICHENG SHI (Presenter), IAN CURTIN, ANDREW HEALY, TAO ZHANG, DAVID BLANK, RUSSELL J HOLMES, University of Minnesota — Singlet exciton fission is among the most efficient multiexciton-generation process reported to date. Materials exhibiting singlet fission can potentially generate two triplets for each photogenerated singlet, and are of interest for a variety of applications in photoconversion and light-emission. While the kinetics of fission have been previously examined, fewer works have sought to probe the diffusion length of the resulting non-luminescent triplet state. Here, we probe triplet exciton diffusion in thin films of the archetypical singlet fission material pentacene using a device-based methodology capable of extracting the intrinsic, materials-relevant exciton diffusion length. The dependence of triplet exciton diffusion on morphology and crystalline grain size is probed by varying thin film deposition rate. Increased grain size leads to an increase in exciton lifetime, and a commensurate improvement in the triplet diffusion length. For a change in growth rate from 10 Å/s to 0.05 Å/s, the triplet diffusion length increases from 16.3 nm to 22.0 nm. These results offer an additional handle on how to maximize the triplet exciton diffusion length with optimization of thin film processing conditions.
4:18PM U34.00008: Polaronic effects and charge transport in donor-acceptor semiconducting polymers*  XIAO WANG (Presenter), LEONARD F REGISTER, ANANTH DODABALAPUR, University of Texas at Austin — Molecular polaron theories, when applied to high mobility donor-acceptor semiconducting polymers along the chain, indicate that polaronic effects can be very small. These effects include changes to the electronic bandwidth and effective mass resulting from the strong coupling of phonons with charge carriers.\(^1\) The bandwidth and effective mass remain essentially unchanged with increasing temperature and are adequate for band transport to take place along the chain. However, the small mean free path obtained from the polymer mobility is still an obstacle in understanding band transport in polymers. We invoke the statistical distribution of carrier free paths and consider the carriers with small free paths as effectively localized due to strong scattering. Only carriers with adequately large free paths can participate in band transport.\(^2\) For such carriers, we are able to apply the Boltzmann Transport Equation with appropriate scattering mechanisms to calculate band mobility and the results are in good agreement with experimental data.

*The authors acknowledge partial financial support from the National Science Foundation under Grant No. EEC-1160494

4:30PM U34.00009: Switching dynamics in Croconic Acid thin film*  XUANYUAN JIANG (Presenter), PRATYUSH P BURAGOHAIN, SHASHI PODDAR, HAIDONG LU, ALEXEI GRUVERMAN, XIAOSHAN XU, University of Nebraska - Lincoln — Croconic Acid (CA) exhibits ferroelectricity due to proton displacement between molecules. The voltage and pulse duration dependence of polarization switching in CA thin film are studied using piezoresponse force microscopy (PFM). From this study, the microscopic mechanism of CA polarization switching is revealed. And the KAI domain growth model is used to fit with this switching dynamic behavior. From the fitting, the dimensionality of domain wall, the nucleation activation energy and other structural parameters are obtained. Also, the dependence of film thickness and substrate effect for CA switching are investigated. This study should be helpful for the control experiments in the ferroelectric devices and organic spin-valves using CA as the spacer.

*This work is primarily funded by the U.S. Department of Energy, Office of Science. (Grant DE-SC0019173)
4:42PM U34.00010: Self-assembled monolayer formation of linear molecules onto a FCC(111) surface*  EDUARDO CISTERNAS (Presenter), Univ de La Frontera, GONZALO DOS SANTOS, Facultad de Ingeniería, Universidad de Mendoza, MARCOS FLORES, Physics, Universidad de Chile, EUGENIO VOGEL, Univ de La Frontera, ANTONIO JOSE RAMIREZ-PASTOR, Physics, Univ. Nac. San Luis, Argentina — The self-organization of molecules deposited over different surfaces have interesting technological applications. The adsorption of linear molecules as well the formation of self-assembled monolayers are considered in response to the experimental evidence for curcuminoids over gold surfaces. These processes are mainly controlled by the surface-molecule and molecule-molecule interactions. By performing computational calculations based on the density functional theory, we have obtained interaction energies for different configurations of two adsorbed molecules over a Au(111) surface. Such molecules were approximated to linear pentamers while the gold surface corresponds to a triangular lattice. This model system was investigated under the framework of Grand Canonical Monte Carlo simulations paying special attention to two quantities: the surface coverage and an order parameter reflecting the molecular alignment over the surface. As expected, the surface coverage is directly proportional to the system pressure (chemical potential). However, for critical values of the chemical potential the molecules present patterns evidencing nematic transitions.

4:54PM U34.00011: Controlling energy levels and Fermi level en route to fully tailored energetics in organic semiconductors [Invited]  ROSS WARREN, ALBERTO PRIVITERA, PASCAL KAIENBURG, ANDREAS EJDRUP LAURITZEN, Department of Physics, University of Oxford, OLIVER THIMM, IEK5-Photovoltaics, Forschungszentrum Jülich, JENNY NELSON, Department of Physics, Imperial College London, MORITZ RIEDE (Presenter), Department of Physics, University of Oxford — Organic semiconductors have yet to achieve simultaneous control over both the energy levels and Fermi level, which was a key breakthrough for inorganic electronics. Here, we combine two approaches from band engineering and molecular doping to demonstrate controlled shifts in ionisation potential and Fermi level of an organic thin film. We experimentally investigate the doping efficiency of a ternary blend system consisting of two host molecules, ZnPc and F8-ZnPc, and the p-dopant F6–TCNNQ. We explain the observed doping behaviour with a statistical model based on energy level shifts of both host and dopant materials, resulting from the quadrupole moments of all involved molecules. We thereby demonstrate that band tuning crucially affects the doping process in organic semiconductors. The practice of comparing host and dopant energy levels must consider the long-range electrostatic shifts, arising from the quadrupole interactions to consistently explain the doping mechanism in organic semiconductors.

Thursday, March 5, 2020 2:30 PM - 5:30 PM

Session U35 DPOLY DSOFT GSOFP DBIO: Rheology and Dynamics of Polymers and Polyelectrolytes 507 - Vivek Sharma, Univ of Illinois - Chicago - Tag(s): Focus
2:30PM U35.00001: Polyelectrolyte solutions in complex macro- and micro-scale flows
[Invited] ATHENA E METAXAS, VISHAL PANWAR, CARI DUTCHER (Presenter), University of Minnesota — Studying the behavior of polymer and polyelectrolyte solutions under complex hydrodynamic flow conditions is of interest to a variety of processes, such as extrusion, coating, and flocculation. Often these flow fields include combinations of both shear and extension flows, requiring characterization of the shear and extensional rheology for optimized materials processing. Here, the behavior of polymer solutions in two flow fields will be discussed: Taylor-Couette flows and microfluidic flow-focusing. First, in Taylor-Couette flow, which is flow between two concentric, rotating cylinders, the complex solutions are subjected to a wide variation of hydrodynamic flow states. The addition of non-Newtonian polymer solutions increases the solution's elasticity, which in turn can modify flow states that are typically dominated by inertial forces. In this study, a cationic polyacrylamide was used to modify the elasticity of the solution, and with varying concentrations of NaCl to alter the ionic strength of the solution. The coil conformation and relaxation times of charged polymers changes depending on the ionic strength, from a more rigid conformation at low ionic strengths to a more flexible conformation at high ionic strengths, resulting in different non-Newtonian responses to shear. The effect of polymer conformation as a result of varying solution ionic strength on TC flows with co- and counter-rotation of the cylinders will be discussed. Second, microfluidic geometries will be used to characterize the extensional properties of low molecular weight, low viscosity polymer and polyelectrolyte solutions. Specifically, filament stretching using a cross-slot microfluidic channel will be used to resolve extensional properties of polyelectrolyte solutions at varying NaCl concentrations.

3:06PM U35.00002: Measuring packing length in simulations for different polymer architectures*
SAI VINEETH BOBBILI (Presenter), SCOTT MILNER, Pennsylvania State University — The packing length \( p \) is the range over which the density near a given monomer is dominated by monomers from the same chain. Bulky, flexible polymers have larger \( p \) while thin, stiff polymers have smaller \( p \). The packing length figures prominently in scaling predictions of the entanglement length and bulk modulus for polymer melts and solutions. \( p \) has been argued to scale as the ratio \( V/R^2 \) of chain displaced volume \( V \) and mean-square end-to-end distance \( R^2 \). This scaling works for several cases, but it is not obvious how to apply it to chains with side groups, in particular how to estimate the diameter of such a chain.

In this work, we measure the packing length, as the typical distance of closest approach of two polymer strands in a simulated bead-spring melt. We use the intermolecular correlation function to measure the distance up to which a given polymer strand dominates the volume fraction. We compare this measured packing length to our recent measurements of the entanglement length in simulations. Using our measured packing length, we find good agreement of entanglement properties with the Lin-Noolandi ansatz for flexible polymers of different architectures, which we explore by varying chain stiffness and sidegroup lengths.

*We acknowledge funding from NSF grant no. DMR1507980
3:18PM U35.00003: Influence of Sodium Salts on the Swelling and Rheology of Hydrophobically Crosslinked Hydrogels Determined by QCM-D*  
BRYAN VOGT (Presenter), Pennsylvania State University, MENGXUE ZHANG, University of Akron, JACK DOUGLAS, NIST — Hydrophobically modified copolymers provide a versatile platform of hydrogel materials for diverse applications, but the influence of salts on the swelling and material properties of this class of hydrogels has not been extensively studied. Here, we investigate model hydrogels with three different sodium salts with anions chosen from the classic Hofmeister series to determine how these counterions influence the swelling and mechanical properties of neutral hydrogels. Our measurements utilize a quartz crystal microbalance with dissipation (QCM-D) to quantify both swelling and rheological properties of these gels. Overall, the observed trends are broadly consistent with more kosmotropic ions causing diminished solubility (‘salting out’) and strongly chaotropic ions causing improved solubility (‘salting in’), a trend characteristic of the Hoffmeister series governing the solubility of many proteins and synthetic water soluble polymers, but trends in the shear stiffness with gel swelling are clearly different from those normally observed in chemically cross-linked gels.

*This work was supported by a grant from the National Science Foundation (CBET-1606685).

3:30PM U35.00004: Effects of humidity on the rheology of supramolecular organogels  
DIMITRIS VLASSOPOULOS (Presenter), EMMANOUIL VEREROUDAKIS, Institute of Electronic Structure & Laser — It is known that organic oils typically contain tiny amounts of water (0.01% by weight) which can influence the self-assembly as well as the macroscopic properties of supramolecular gelators. We explore here the rheological consequences of this phenomenon which has been overlooked. Specifically, we investigate the properties of biphenyl tricarboxamides (BPTA) in dodecane which exhibit structural transitions with varying temperature. The driving force behind these transitions is the fact that the humidity content of the supramolecular polymer changes with temperature. We perform shear rheological measurements under controlled humidity conditions in both humid (~60% relative humidity) and dry (~5% relative humidity) conditions and observe that in a humid environment the linear and nonlinear rheological properties are substantially affected by the temperature. At temperatures where the systems strongly interacts with water the plateau modulus is lower, the relaxation faster and there is absolutely no sign of strain hardening behaviour. These findings are discussed in the context of existing theories of living polymers. It is concluded that humidity effects cannot be ignored when working in oily environments.

Rheology of Jammed Silicone Microgels

SENTHILKUMAR DURAIVEL (Presenter), Department of Materials Science and Engineering, University of Florida, THOMAS ANGELINI, Department of Mechanical and Aerospace Engineering, University of Florida — Colloidal and granular-scale hydrogel particles have been widely used to study jammed and glassy matter in systems with soft inter-particle potentials. Aqueous microgels are most commonly used for these investigations and a diversity of chemical formulations have been developed for controlling inter-particle interactions, microgel size, and particle stiffness. However, there are numerous industrial applications of non-aqueous microgels, creating the need for the fundamental understanding of the rheology of jammed non-aqueous microgels. In this presentation, we will describe our investigations of polydimethylsiloxane (PDMS) microgels. We synthesize PDMS microgels using several different silicone formulations and swell them to a jammed state in silicone oil. The size and the shape of the microgels are varied during synthesis and the resulting effect on the rheological properties of the microgels are studied. By independently varying microgel composition and solvent viscosity, we can independently tune the yield stress and flow characteristics of this jammed system.

Predicting the plateau modulus from molecular parameters of conjugated polymers

ABIGAIL FENTON (Presenter), RALPH H COLBY, ENRIQUE D GOMEZ, Pennsylvania State University — The relationship between Kuhn length $b$, packing length $p$, and plateau modulus $G_N^0$ initially proposed by Graessley and Edwards and experimentally investigated by Everaers, while well-studied for flexible and stiff polymers, has a large gap in experimental data between the flexible and stiff regimes. This gap prevents the validation of theoretical models of the crossover between flexible and stiff polymers and therefore, the prediction of mechanical properties from chain structure of any polymer in this region. Given the chain architecture, including a semiflexible backbone and side chains, conjugated polymers are an ideal class of material to study this cross-over region. Using small angle neutron scattering (SANS), static light scattering (SLS), and oscillatory shear rheology along with the freely rotating chain model we have shown that nine non-crystalline conjugated polymers and three aromatic polymers not only populate a large part of this gap, but that they follow the proposed relationship between $b$, $p$, and $G_N^0$ as well. We have also experimentally validated the freely rotating chain model for various conjugated polymers using SANS and SLS and find good agreement in Kuhn length values from 1.7 nm in aromatic polymers up to 23.2 nm in conjugated polymers.

4:06PM U35.00007: Accessing Viscoelasticity of PDMS at MHz Frequencies: Physically Intuitive Continuum Mechanics Model for QCM Able to Treat Film Resonance Region
YANNIC GAGNON (Presenter), JUSTIN BURTON, CONNIE ROTH, Emory University — Quartz crystal microbalance (QCM) is increasingly applied as a MHz-rheometer to measure viscoelastic properties of films beyond the simple Sauerbrey equation relating frequency shifts to mass loading of the crystal. For films, the range of harmonics available is often limited by needing higher harmonics to access where frequency shifts become sensitive to the film’s viscoelasticity, while avoiding the film resonance region where shifts and dissipation become large. Film resonance corresponds to the harmonics that form standing acoustic waves in the film. Most QCM modeling applies simplifications assuming small resonance shifts, like the small load approximation, which are not valid under film resonance. This limits the range of film thicknesses whose viscoelasticity can be accurately measured, especially for rubbery films where film resonance occurs at lower harmonics. We present a physically intuitive continuum mechanics model with no small frequency-shift approximations that can numerically treat film resonance, accessing a wider range of film thicknesses. Fits for polydimethylsiloxane (PDMS) films, including film resonance conditions, give shear modulus values in good agreement with interpolated literature values from kHz and GHz frequencies.

4:18PM U35.00008: Viscoelastic properties of tightly entangled polymeric systems*
TADASHI INOUE (Presenter), Osaka Univ — The rheology of semiflexible polymer solutions has attracted much attention now because it provides a basis for fundamental understanding the physical properties of cellulose nanofibers, which have been considered to be a new material for sustainable society. This talk describes recent experimental findings on the rheology of semiflexible polymers including cellulose derivatives and DNA. In addition to the orientational stress of the viscoelastic segment, the bending and tension modes of the segment contribute to the viscoelasticity of the semiflexible polymer solution. In particular, in tightly entangled systems, where the entanglement length is shorter than the persistent length, the bending mode significantly contributes to the viscoelasticity of the rubbery plateau region. In this talk, by combining simultaneous measurement of strain-induced birefringence, the mode separation of orientation, bending, and tension is carried out on on the linear viscoelasticity of the model materials, and the contribution of each mode is quantitatively discussed.

*This research was financially supported by JSPS KAKENHI (Grant Number JP19H02777).
Recent NEMD simulations of an entangled polyethylene melt revealed that within intermediate extensional rates, entangled melts could undergo a coil-stretch transition, and exhibit bimodal configurational distributions with peaks corresponding to coiled and stretched configurations. Furthermore, it was shown that through a configurational microphase separation, the coiled molecules develop distinct domains surrounded by stretched molecules. On the other hand, various experimental studies have shown that the response of entangled polymeric melts to elongational flow fields could be very different from those of entangled solutions depending on the solvent molecule architecture. Such complexities bring up many questions about the coil-stretch transition in entangled polymeric liquids. Do entangled solutions undergo a coil-stretch transition? Do they experience any configurational or chemical microphase separation?

To address these questions, we performed a series of NEMD simulations for entangled \( C_{1000}H_{2002} \) polyethylene solutions in oligomeric \( C_{16}H_{32} \) and benzene solvents. The solutions were subject to planar elongational flows within a wide range of extension rates. The simulations revealed both similarities and differences between entangled melts and solutions that will be discussed.

**Predicting the Microstructure of Bottlebrush Copolymers**

- **CHRISTIAN TABEDZKI** (Presenter), **ROBERT RIGGLEMAN**, University of Pennsylvania — The unique structure of bottlebrush polymers, a typically linear polymer backbone with densely grafted polymer side-chains, allows for the creation of interesting and unique morphologies. By combining structurally dissimilar backbone and grafts, copolymer bottlebrushes serve as candidates for materials with unique combinations of properties. An example includes polymers with a mechanically rigid backbone and conductive grafts, which can be useful as membranes in battery applications. In this talk, we present a field-theoretic model for the structure of bottlebrush copolymers. We systematically explore the transition from the comb to the bottlebrush regime and show how this modulates the phase diagram of the bottlebrush copolymers. Finally, we show how the chain conformations change in the various microphases in the comb and bottlebrush limits. We accomplish this via our recently developed theoretically informed Langevin dynamics (TILD) package for LAMMPS, in which field-based self-consistent forces are calculated in lieu of pair-wise interactions.

*NSF GIRE #1829436, NSF PIRE #1545884*
4:54PM U35.00011: Interactions between two knots in a stretched DNA molecule
ALEXANDER KLOTZ (Presenter), California State University, Long Beach, BEATRICE SOH, PATRICK DOYLE, Massachusetts Institute of Technology — Knots in DNA serve as a model system with which to study the physics of polymer entanglement, and are known to affect the function of genomic sequencing devices. We use microfluidic devices to stretch viral genomic DNA molecules in an elongational electric field, and observe the molecules using fluorescence microscopy. Previously, we have reported the effects that knots have on the relaxation and elasticity of single molecules, as well as the mechanisms by which knots translate along molecules and untie. Here, we discuss molecules that have two knots, and the interactions between the knots. It has been predicted computationally that in a doubly-knotted molecule an attraction exists between the knots, with a minimum in the free energy occurring when the two knots are intertwined. We see long range attraction of knots towards each other from opposite ends of the molecule over tens of seconds, in contrast to the end-migrating behavior of single knots. At short distances, pairs of knots fluctuate in and out of visual contact, remaining in proximity for tens of seconds to minutes. The distribution of intraknot distances can be used to measure free energy landscapes for the knot-knot interactions, which are qualitatively and quantitatively similar to previous computational studies.

5:06PM U35.00012: Diffusion of knots in DNA molecules confined in nanochannels
ZIXUE MA (Presenter), KEVIN D DORFMAN, University of Minnesota — Knots formed in DNA influence biological processes (e.g., DNA replication) and the accuracy of genomics technologies. Knot diffusion, which destroys knots in linear DNA molecules when the knot reaches the chain end, is a key step to understanding these processes. We present experimental data on the diffusion of knots in single DNA molecules via a combination of a nanofluidic "knot factory" device and fluorescence microscopy. Knots are first generated using pressure-driven flow, which compresses single DNA molecules against slit barriers in nanochannels. The knots are identified as bright spikes in intensity profiles of DNA backbone and their motions are tracked for 8 minutes. The ensembled-averaged data for the mean-squared displacement produce a scaling exponent that indicates that confined knots undergo subdiffusion. This result supports the theory that the knot breathing mechanism, where knot diffusion originates from a local motion of knot region, dominates knot diffusion in long polymer chains.
5:18PM U35.00013: Dynamics of DNA-bridged particle dumbbells in well-entangled, shear-banding polymer solutions under large amplitude oscillatory shear (LAOS)* SEUNGHWAN SHIN (Presenter), KEVIN D DORFMAN, XIANG CHENG, Chemical Engineering and Materials Science, University of Minnesota — Despite accumulation of experimental evidence for shear-banding flows in highly entangled polymer solutions over the last two decades, the current understanding of the conformational changes that induce shear banding remains incomplete. To elucidate the microscopic dynamics of entangled chains in shear-banding flows, we study the dynamics of DNA-bridged particle dumbbells in the shear-banding flow of well-entangled double-stranded DNA (dsDNA) solutions under LAOS using a rheo-confocal shear cell. First, we confirm that the velocity profiles of the entangled dsDNA solutions become inhomogeneous and strong shear-banding flows arise at high Weissenberg number. We then analyze the translation and orientation of particle dumbbells in the co-existing high- and low-shear rate bands. The orientational distribution of dumbbells exhibits clear difference in the co-existing bands. Moreover, we find that the coupling between sudden reorientation and rapid translational motion of dumbbells occurs exclusively in the high-shear rate band. Quantitative investigation of the spatially distinct dynamics of such dsDNA-bridged dumbbells provides new insights into the microscopic structural origin of shear-banding flows in entangled polymer solutions.

Session U36 DMP: Physics For Everyone 601/603 - Rachel Goldman, Univ of Michigan - Ann Arbor - Tag(s): Invited, Outreach, Undergrad Friendly

2:30PM U36.00001: Using Superheroes to Engage the Public [Invited] JAMES KAKALIOS (Presenter), University of Minnesota — Costumed superheroes seem to dominate our movie and television screens, making them an excellent delivery system to bring real physics to the general public. While the super powers these characters possess clearly violate the laws of nature, often times how the super-heroes and super-villains utilize their powers is consistent with known physical laws. One can therefore leverage the public's interest in these characters to illustrate and explain the physics principles that underlie their fantastic adventures. A discussion of the strength of Spider-Man's webbing can lead to the real physics of carbon nanotubes. What metal would be strong enough for Wonder Woman's bullet deflecting bracelets? One can draw the connection between the Black Panther's vibranium suit and conservation of energy, while the Infinity Stones (the MacGuffin of the last 22 Marvel Cinematic Universe films) can be related to Emmy Noether and her theorem explicating a deep connection between all conservation principles and symmetries in the laws of physics. People come for the superhero ice cream sundae, and stay for the real science. If superheroes can help explain physics and the benefits of research to the general public – well, it wouldn't be the first time these heroes have saved the day!
3:06PM U36.00002: Physics of Star Wars [Invited]  PATRICK JOHNSON (Presenter), Georgetown University — Since he was young, Patrick has loved both science and Star Wars. As an adult, he wrote a book that tries to explain different theories as to how scenes and devices in the Star Wars universe work. Have you ever wondered how the Death Star works? How shields can stop catapults, but droids can walk right through? This talk will offer possible explanations of these scenes and more. This will be an enjoyable talk for anybody who is a fan of Star Wars, physics, or both.

3:42PM U36.00003: Science and Cooking: Making Physics Fun (and Tasty!) [Invited]  DAVID A WEITZ (Presenter), Harvard University — This talk will describe the experiences of physics course for non-scientists that makes physics fun. It uses the science of food and cooking to motivate students to learn physics. A feature of the class is a weekly guest lecture by a famous chef about cooking. In addition the course includes a lab, where you can eat your experiment. The lab consists of the recipe of the week, where students, cook, do physics experiments and plate and eat their creations. It also includes an equation of the week to teach students how to calculate results without being afraid of equations. The class has several traditions: You have to clap when you see an equation, and you have to clap when you see a cool dessert. Remember!

4:18PM U36.00004: Bringing Science to the Public Using Popular Culture [Invited]  ANISSA RAMIREZ (Presenter), Science Underground — In our modern age when many of the key issues have an underlying science component, it is critical that the general public become more comfortable with science. This talk describes the use of popular culture as a way to bring scientific ideas to life. The examples that will be highlighted show how physics and other science fields can be embedded into discussions about American football. This talk will also showcase how science can be stealthily encased in a historical context in stories about inventions. Using a forthcoming book called The Alchemy of Us as a model, this talk will show how concepts of physics, materials science, and electrical engineering can be displayed in an engaging way for a general readership. Overall, this presentation makes a case for scientists to instill a new habit of sharing their knowledge with the public by connecting on a human level.
4:54PM U36.00005: The Physics of NASCAR: How March Meeting Physicists Have Unique Opportunities to Share Physics with the Public [Invited]  DIANDRA LESLIE-PELECKY (Presenter), Trivalent Productions — Ask the average person on the street about physics and you'll probably hear about black holes, astronomy, quarks, or gravitational waves. Anyone attending the March Meeting, however, knows that most of the physics presented here has significantly more impact on the average person's life than any black hole.

Most physics outreach is aimed at a smal elite group of college-degreed, already science-interested people. But there are millions more who want -- who need -- to know about science, scientists, and how science is done. Drawing on my decade of experience sharing the science of motorsport through television, books, blogs and a regular spot on SiriusXM Satellite radio, I'll share ideas for how you can not only reach this underserved audience, but also broaden the public's perception of what physics really is. I'll also share a few things I've learned along the way: why there are lots of engineers, but few physicists, in NASCAR; the NASA technology in every NASCAR racecar; the move toward electric vehicles and sustainability; safety innovations that started on the track and moved to the interstate, and the cheap polymer component used on racecars that the military now uses on their helicopters.

Thursday, March 5, 2020 2:30 PM - 5:30 PM

Session U37 APS: Careers in Physics Workshop: Putting Your Science to WORK 605 - Tag(s): Careers, Undergrad Friendly

2:30PM U37.00001: Careers in Physics Workshop: Putting Your Science to WORK — In this informative workshop, celebrated career coach and author Peter Fiske provides advice and strategies for taking your physics job search to the next level, including tips for self-assessment, network building, resume writing, interviewing, and salary negotiation. Don't miss this great opportunity to get some great help on taking your next steps. This workshop is free.

Thursday, March 5, 2020 2:30 PM - 5:18 PM

Session U38 DQI: Landauer and Bennett Award Session: Quantum Resource Theories and Thermodynamics 607 - Todd Brun, Univ of Southern California

2:30PM U38.00001: Rolf Landauer and Charles H. Bennett Award in Quantum Computing talk [Invited]  FERNANDO BRANDÃO (Presenter), Caltech — tbd
3:06PM U38.00002: Resource theory of asymmetric distinguishability*  XIN WANG, Institute for Quantum Computing, Baidu Research, MARK WILDE (Presenter), Louisiana State University, Baton Rouge — We systematically develop the resource-theoretic perspective on distinguishability. The theory is a resource theory of asymmetric distinguishability, given that approximation is allowed for the first quantum state in general transformation tasks. We introduce bits of asymmetric distinguishability as the basic currency in this resource theory, and we prove that it is a reversible resource theory in the asymptotic limit, with the quantum relative entropy being the fundamental rate of resource interconversion. We formally define the distillation and dilution tasks, and we find that the exact one-shot distillable distinguishability is equal to the min-relative entropy, the exact one-shot distinguishability cost is equal to the max-relative entropy, the approximate one-shot distillable distinguishability is equal to the smooth min-relative entropy, and the approximate one-shot distinguishability cost is equal to the smooth max-relative entropy. We also develop the resource theory of asymmetric distinguishability for quantum channels. For this setting, we prove that the exact distinguishability cost is equal to channel max-relative entropy and the distillable distinguishability is equal to the amortized channel relative entropy.

*XW acknowledges DoD, & MMW NSF grant 1907615.

3:18PM U38.00003: Quantifying non-Markovianity: a quantum resource-theoretic approach*  NAMIT ANAND (Presenter), TODD BRUN, Univ of Southern California — We study quantum non-Markovianity as a resource theory and introduce the robustness of non-Markovianity: an operationally-motivated, optimization-free measure that quantifies the minimum amount of Markovian noise that can be mixed with a non-Markovian evolution before it becomes Markovian. We show that this quantity is a bonafide non-Markovianity measure since it is faithful, convex, and monotonic under composition with Markovian maps. A two-fold operational interpretation of this measure is provided, with the robustness measure quantifying an advantage in both state and channel discrimination tasks. Moreover, we connect the robustness measure to single-shot information theory by using it to upper bound the min-accessible information of a non-Markovian map. Furthermore, we provide a closed-form analytical expression for this measure and show that, quite remarkably, the robustness measure is exactly equal to half the Rivas-Huelga-Plenio (RHP) measure [Phys. Rev. Lett. 105, 050403 (2010)]. As a result, we provide a direct operational meaning to the RHP measure while endowing the robustness measure with the physical characterizations of the RHP measure.

*This work was supported in part by NSF Grant No. QIS-1719778.
3:30PM U38.00004: log singularities in studying quantum capacities  VIKESH SIDDHU
(Presenter), Carnegie Mellon University — Understanding the quantum capacity of a quantum channel is a long standing issue which lies at the center of quantum information theory. Determining the quantum capacity of a general channel or checking that it is positive is difficult. A major source of this difficulty arises due to non-additivity of the one-shot quantum capacity. In this work, we present a new method for checking positivity and non-additivity of the one-shot quantum capacity. This method is based on logarithmic singularities of the von-Neumann entropy. Using this log singularity method, we find a new type of non-additivity where using two very simple channels in parallel, one that doesn't have quantum capacity and a second that has positive one-shot quantum capacity, produces a channel whose one-shot quantum capacity exceeds that of the second channel.

3:42PM U38.00005: Quuantum Simplicity: Complexity Science in a Quantum World* MILE GU (Presenter), School of Physical and Mathematical Sciences, Nanyang Technological University — Complexity and quantum science appear at first to be two fields that bear little relation. One deals with the science of the very large – seeking the understand how unexpected phenomena can emerge in vast systems consisting of many interacting components. Quantum theory, on the other hand, deals with particles at the microscopic level and is usually considered limited to the domain of individual photons and atoms. Yet, different as they appear, there is growing evidence that in interfacing ideas from quantum and complexity science, we may unveil new perspective in either both fields.

Here, I introduce computational mechanics, a branch of complexity science captures structure by building the simplest causal models of natural observations. I illustrate how many processes that require complex classical models may be simulated by remarkably simple quantum devices, and describe recent experiments to test this laboratory conditions [1-3]. I survey the potential consequences these developments, highlighting how the indicate that fundamental notions of structure, complexity and causality [4]

Coherence cost for measurement and computation under conservation laws

HIROYASU TAJIMA (Presenter), Kyoto Univ, NAOTO SHIRAISHI, Gakushuin university, KEIJI SAITO, Keio university, HIROSHI NAGAOKA, The University of Electro-Communications — Nature imposes many restrictions on the operations that we perform. Among such restrictions, the restriction imposed by conservation laws on two types of the basic operations of quantum information processing, i.e. measurements and unitary operations, has been studied for a particularly long time.

One of the open problems in this field is to clarify the amount of required resource for implementing unitary operations and measurements under conservation laws. Here, we provide a solution to this open problem.

We derive two asymptotically exact equalities that clarify the necessary and sufficient amount of quantum coherence as a resource to implement an arbitrary unitary operation and a measurement for arbitrary physical quantities within a desired error, respectively. This work provides an optimal improvement of the Wigner-Araki-Yanase-Ozawa theorem and a proof of the long standing conjecture that WAY-type tradeoff relation holds for the implementation of an arbitrary unitary channel under conservation laws.

It also clarifies the key question of the resource theory of the quantum channels in the region of resource theory of asymmetry, for the case of unitary channels.

The technical details of this work are in [PRL \textbf{121}, 110403], [arXiv:1906.04076] and [arXiv:1909.02904].

Fusion rules from entanglement*

BOWEN SHI (Presenter), Ohio State Univ - Columbus, KOHTARO KATO, IQIM, Caltech, ISAAC H KIM, Physics, Stanford University — We derive some of the axioms of the algebraic theory of anyon [A. Kitaev, Ann. Phys., 321, 2 (2006)] from a conjectured form of entanglement area law for two-dimensional gapped systems. We derive the fusion rules of topological charges and show that the multiplicities of the fusion rules satisfy these axioms. Moreover, even though we make no assumption about the exact value of the constant sub-leading term of the entanglement entropy, this term is shown to be equal to the logarithm of the total quantum dimension of the underlying anyon theory. These derivations are rigorous and follow from the entanglement area law alone. More precisely, our framework starts from two local entropic constraints, which are implied by the area law. They allow us to prove what we refer to as the isomorphism theorem, which enables us to define superselection sectors and fusion multiplicities without a Hamiltonian. These objects and the axioms of the anyon theory are shown to emerge from the structure and the internal self-consistency relations of an object known as the information convex.

4:18PM U38.00008: Nonequilibrium work relations of open quantum systems in one-time measurement scheme*  AKIRA SONE (Presenter), Los Alamos National Laboratory, YI-XIANG LIU, PAOLA CAPPELLARO, Massachusetts Institute of Technology — Because of the ambiguity in defining work and heat in open quantum systems, it is challenging to formulate non-equilibrium work relations for general quantum channels, beyond the unital case. To overcome this challenge, here we introduce well-defined notions of quantum heat and work in open quantum systems, based on the notion of guessed state defined by the one-time measurement scheme, as developed in [Phys. Rev. E 94, 010103(R)]. This allows us to derive non-equilibrium work relations for general quantum channels, and formulate a modified maximum work theorem with respect to the defined “guessed” quantum work.

4:30PM U38.00009: An ergodic theorem for homogeneously distributed quantum channels with applications to matrix product states*  RAMIS MOVASSAGH, IBM TJ Watson Research Center, JEFFREY SCHENKER (Presenter), Michigan State Univ — Quantum channels represent the most general physical changes of a quantum system. We consider ergodic sequences of channels, obtained by sampling channel valued maps along the trajectories of an ergodic dynamical system. Such maps vastly generalize stochastically independent maps (e.g., random independence) or equality of the channel maps (i.e., translation invariance). The repeated composition of an ergodic sequence of maps could represent the effect of repeated application of a given quantum channel subject to arbitrary correlated noise or decoherence. Under such a hypothesis, we obtain a general ergodic theorem showing that the composition of maps converges exponentially fast to a rank-one -- entanglement breaking-- channel. As an application, we describe the thermodynamic limit of ergodic Matrix Product States and derive a formula for the expectation value of a local observable and prove that the 2-point correlations of local observables in such states decay exponentially in the bulk with their distance.

*National Science Foundation #1900015
4:42PM U38.00010: Quantifying Structure and Information Processing in One-Dimensional Quantum Systems* DAVID GIER (Presenter), JAMES P CRUTCHFIELD, University of California, Davis — We develop a framework for studying one-dimensional quantum systems with stationary, ergodic dynamics and introduce quantum information properties related to the von Neumann entropies of blocks of qubits within a structured chain. Some of the resulting statistical features are unique to quantum systems and others can be recreated with purely classical ensembles. Applying sequential measurements on these quantum states yields classical stochastic processes whose information properties are determined by the structure of the initial quantum state and the measurement protocol. Examples states with short- and long-range entanglement, as well as specific Hamiltonian ground states are analyzed within this framework.

*This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. 1650042.

4:54PM U38.00011: Measurement-Induced Randomness and Structure in Controlled Qubit Processes ARIADNA VENEGAS-LI (Presenter), ALEXANDRA JURGENS, JAMES P CRUTCHFIELD, Physics Department, University of California, Davis — When an observer measures a time series of qubits, the outcomes generate a classical stochastic process. We present a model family of classically controlled qubit time series and show that measurement induces high complexity in these processes in two specific senses: they are inherently unpredictable (positive Shannon entropy rate) and they require an infinite number of features for optimal prediction (divergent statistical complexity). We argue that nonunifilarity is the mechanism underlying the resulting complexities and identify the different contributions to the randomness of the observed process. We examine the influence that the choice of measurement has on the randomness and structure of the measured qubit process and discuss measurement choices of potential interest in obtaining information about the underlying time series of qubits.

5:06PM U38.00012: A study about complete cohering/decohering power with ancillary system. MASAYA TAKAHASHI (Presenter), Southern Illinois University Carbondale, ALEXANDER STRELTSOV, Centre of New Technologies, University of Warsaw — In this talk we will discuss the cohering/decohering power of a quantum operation which quantifies the maximum amount of coherence which can be generated/eliminated through that operation taken over all input states. Complete cohering/decohering power (CCP and CDP respectively) of an operation is defined as cohering power of the product of the original operation and an identical operation on ancillary system. In our talk we will compare the properties of CCP and CDP with the general cohering/decohering power when only one system is considered.

We first observe that the CCP with L1 measure is not the same with general cohering power, or even not bounded. Taking dimension to be a large number, CCP increases unboundedly too. In contrast, for the relative entropy measure, the two cohering powers have the same value. Then we consider the decohering power. Here we will have an unexpected result. For L1 measure, CDP does not have a boundary again. On the other hand, CDP with the relative entropy measure is larger than the general decohering power which can be seen with an entangled input state. This result strongly implies that entanglement helps CDP exceed the general cohering power. We will conclude with some open problems.
Session U39 DCOMP GDS DMP: Machine learning for quantum matter

2:30PM U39.00001: Nicholas Metropolis Award Talk: Enhancing Quantum Simulators with Neural Networks*

GIACOMO TORLAI (Presenter), Center for Computational Quantum Physics, Flatiron Institute — Machine learning offers a set of flexible and powerful algorithms to enhance the capabilities of quantum simulation platforms. Artificial neural networks trained on measurement data can be integrated in the experimental stack for a variety of tasks, such as error mitigation, detecting quantum phase transitions and improving the measurement precision. I will review a data-driven framework for reconstructing quantum states prepared by experimental quantum hardware. Once trained, the neural networks can be used to deliver precise measurements of specialized observables that are either costly or not accessible in the original experimental setup. I will present results for a cold Rydberg-atom quantum simulator and quantum chemistry calculations on a superconducting quantum hardware.

*The Flatiron Institute is supported by the Simons Foundation.

3:06PM U39.00002: Topological codes revisited: Hamiltonian learning and topological phase transitions*

ELISKA GREPLOVA (Presenter), AGNES VALENTI, ETH Zurich, EVERT VAN NIEUWENBURG, Caltech, GREGOR BOSCHUNG, ETH Zurich, FRANK SCHÄFER, NIELS LOERCH, University of Basel, SEBASTIAN HUBER, ETH Zurich — The efficient validation of quantum devices is critical for emerging technological applications. The precise engineering of a Hamiltonian is required both for the implementation of quantum information processing as well as for quantum memories. Inferring the experimentally realized Hamiltonian through a scalable number of measurements constitutes the challenging task of Hamiltonian learning. In particular, assessing the quality of the implementation of topological codes is essential for quantum error correction. We introduce a neural net based approach to this challenge. We capitalize on a family of exactly solvable models to train our algorithm and generalize to a broad class of experimentally relevant sources of errors. We discuss how our algorithm scales with system size and analyze its resilience towards noise. A related issue regarding topological codes is to ensure that the system does not leave the topological manifold due to experimental noise. We present an unsupervised machine learning technique that is able to detect topological order from experimentally accessible data.

*Swiss National Science Foundation, the NCCR QSIT and Grant No. 183945, European Research Council Grant no. 771503, National Science Foundation Grant No. NSF PHY-1748958.
3:18PM U39.00003: Real time evolution with neural network quantum states  IRENE LOPEZ GUTIERREZ (Presenter), CHRISTIAN MENDL, TU Munich — The Hilbert space of a quantum system grows exponentially with system size, which makes many-body quantum systems challenging to simulate on a classical computer. One approach is to use tensor network methods, but these require an increasing bond dimension to capture the growth in entanglement during real time evolution, which limits their application to short time intervals. An alternative method proposed recently uses a neural network as a variational Ansatz to describe the quantum wave function. However, its application for real time evolution has not been extensively explored. In this work, we propose the use of standard machine learning optimization techniques, combined with a modified backpropagation for a neural network with complex parameters, to tackle the time evolution of an example system: the Ising model in 1 and 2-D. Our preliminary results show that our method performs comparably as well as stochastic reconfiguration, while avoiding a sensitivity issue related to the pseudo-inverse of the covariance matrix.

3:30PM U39.00004: Hunting for Hamiltonians with a General-Purpose Symmetry-to-Hamiltonian Approach  ELI CHERTKOV (Presenter), BENJAMIN VILLALONGA, BRYAN CLARK, University of Illinois at Urbana-Champaign — Inverse methods that learn models from data are widely used in the field of machine learning to solve difficult engineering tasks. Recently, inverse methods have been applied in the context of quantum physics to engineer quantum models, i.e., Hamiltonians, with targeted properties, such as targeted eigenstates or reduced density matrices. Here we present a new efficient and general-purpose inverse method approach, the symmetric Hamiltonian construction (SHC), for engineering Hamiltonians with particular symmetries, such as integrals of motion or discrete symmetries [1]. This method extends on ideas developed in the slow operator method [2]. Using the SHC inverse method, we design new Hamiltonians with topological properties: superconducting Hamiltonians with Majorana zero modes and $Z_2$ quantum spin liquid Hamiltonians. In this talk, we will introduce the SHC method and discuss the topological Hamiltonians that we find. Our open-source numerical implementation of the SHC method is available at github.com/ClarkResearchGroup/qosy.

3:42PM U39.00005: Studying inhomogeneous quantum many-body problems using neural networks  ALEXANDER BLANIA (Presenter), Max Planck Inst for Sci Light, EVERT VAN NIEUWENBURG, IQIM, Caltech, FLORIAN MARQUARDT, Max Planck Inst for Sci Light — We show how convolutional neural networks can be employed to learn the mapping from arbitrary potential landscapes to observables in quantum many-body systems. While following the general spirit of density-functional theory, our approach can easily be applied without modification to a wide variety of settings, effectively learning the significant underlying physical principles from raw training data. We verify the performance of this framework for a number of examples such as the prediction of Friedel oscillations and level spacing statistics. Our network architecture allows us to predict on system sizes larger than seen in the training data, and we analyze its scaling performance.
3:54PM U39.00006: Calculating Wannier functions via basis pursuit using a machine learned dictionary  
BRADLEY MAGNETTA (Presenter), VIDVUDS OZOLINS, Yale University — One of the earliest methods for calculating Wannier functions enforced localization by maximizing their projection onto a carefully chosen set of localized functions. Eventually use of this method faded with the emergence of more systematic approaches such as maximal localization. In this work we provide a modern method for calculating Wannier functions via projection by incorporating basis pursuit into the quantum variational method to automatically generate a set of localized functions needed to enforce localization while obtaining the ground state. We determine the dictionary to use for basis pursuit by performing sparse coding on a set of known Wannier functions. The algorithmic simplicity of our method suggests that it may be suited for automated calculation of Wannier functions. Other applications in physics that involve the variational principle could benefit from the inclusion of basis pursuit and sparse coding.

4:06PM U39.00007: Classical Quantum Optimization with Neural Network Quantum States*  
JOSEPH GOMES (Presenter), The University of Iowa — The classical simulation of quantum systems typically requires exponential resources. Recently, the introduction of a machine learning-based wavefunction ansatz has led to the ability to solve the quantum many-body problem in regimes that had previously been intractable for existing exact numerical methods. Here, we demonstrate the utility of the variational representation of quantum states based on artificial neural networks for performing quantum optimization. We show empirically that this methodology achieves high approximation ratio solutions with polynomial classical computing resources for a range of instances of the Maximum Cut (MaxCut) problem whose solutions have been encoded into the ground state of quantum many-body systems up to and including 256 qubits.

*J.G acknowledges start up funding from the University of Iowa. This research was supported in part through computational resources provided by The University of Iowa.

4:18PM U39.00008: Solving frustrated quantum many-particle models with convolutional neural networks  
XIAO LIANG (Presenter), Institute for Advanced Study, Tsinghua University — Recently, there has been significant progress in solving quantum many-particle problems via machine learning based on the restricted Boltzmann machine. However, it is still highly challenging to solve frustrated models via machine learning, which has not been demonstrated so far. In this paper, we design a brand new convolutional neural network (CNN) to solve such quantum many-particle problems. We demonstrate, for the first time, solving the highly frustrated spin-1/2 $J_1 - J_2$ antiferromagnetic Heisenberg model on square lattices via CNN. The energy per site achieved by the CNN is even better than previous string-bond-state calculations. Our work therefore opens up a new routine to solve challenging frustrated quantum many-particle problems using machine learning.
4:30PM U39.00009: Quantum dynamics in driven spin systems with neural-network quantum states

DAMIAN HOFMANN (Presenter), Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany, GIUSEPPE CARLEO, Center for Computational Quantum Physics, Flatiron Institute, New York, NY, USA, ANGEL RUBIO, MICHAEL SENTEF, Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — Neural-network quantum states (NQS) provide an effective variational representation of quantum states, which can be used for the study of many-body quantum systems [1]. NQS can be time-propagated using time-dependent variational Monte Carlo (tVMC) [1,2], making it possible to simulate non-equilibrium phenomena. In particular, this approach can be used to compute dynamical properties of two-dimensional spin systems [3], a setting that has proven to be challenging for established numerical techniques. In this talk, we study magnetic excitations in a driven two-dimensional Heisenberg antiferromagnet. Further, we provide benchmarks of time-dependent NQS against results obtained from exact calculations for small systems as well as results obtained using a time-dependent matrix product state (t-MPS) approach.

*We acknowledge support from Flatiron Institute, a division of the Simons Foundation. M.S. acknowledges funding from the DFG through the Emmy Noether program (SE 2558/2-1).

4:42PM U39.00010: Study of phi-4 theories with deep learning methods

ZHONG YUAN LAI (Presenter), Fudan Univ, FRANCISCO COSTA MEIRINHOS, Department of Physics, University of Bonn, XIAOPENG LI, Fudan Univ — Field theories find wide applications from characterization of scattering processes in particle physics, to analysis of statistical models, to description of critical phenomena in condensed matter. One key problem in using field theories is to perform non-perturbative calculations, which is crucial in various places, but has remained an open question. In this talk I will present our recent work combining field theoretical and deep learning methods to systematically account for non-perturbative aspects. In calculating Green’s functions, nonperturbative Feynmann diagrams are automatically taken into account in our approach. I will present applications of this new approach to phi-4 field theories in one and two dimensions. Our approach potentially offers a generic solver for nonperturbative field theory calculations, of relevance to a broad context.

Unsupervised machine learning for accelerating discoveries from temperature dependent X-ray data*  JORDAN VENDERLEY (Presenter), MICHAEL MATTY, VARSHA KISHORE, GEOFF PLEISS, KILIAN WEINBERGER, EUN-AH KIM, Cornell University — Data analysis is becoming an increasingly prominent bottleneck for many experimental fronts of quantum matter research. In particular, advancements in detector capabilities for X-ray and neutron scattering have enabled researchers to rapidly collect hundreds of GB of data. Here, we present a novel unsupervised machine learning approach for accelerating the analysis of temperature dependent single crystal X-ray diffraction data. Our method employs a mixture model to cluster over the temperature dependence of scattering intensities and readily identify phase transitions. It is capable of analyzing hundreds of GBs of data in the span of minutes, offering the tantalizing possibility of real time analysis. Applications to several materials are discussed.

*This work is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering under Award DE-SC0018946.

Machine learning effective models for quantum systems*  ANDREW MITCHELL (Presenter), JONAS RIGO, Univ Coll Dublin — The construction of good effective models is an essential part of understanding and simulating complex systems in many areas of science. It is a particular challenge for correlated many body quantum systems displaying emergent physics. Using information theoretic techniques, we propose a model machine learning approach that optimizes an effective model based on an estimation of its partition function. The success of the method is exemplified by application to the single impurity Anderson model and double quantum dots, with new non-perturbative results obtained for the old problem of mapping to effective Kondo models. We also show that the correct effective model is not in general obtained by attempting to match observables to those of its parent Hamiltonian, due to information monotonicity along RG flow.

Session U40 DCOMP DCP DMP: Physics and effects on transport of ion-ion correlation in electrolyte materials II 705 - Arthur France-Lanord, Massachusetts Institute of Technology MIT - Tag(s): Focus
2:30PM U40.00001: Ion-ion correlations across and between micropores in carbon electrodes* [Invited] TRINIDAD MÉNDEZ-MORALES (Presenter), MATHIEU SALANNE, Laboratoire PHENIX, Sorbonne Université — Graphene nanostructures can be the solution for maximizing the capacitance and improving the performance of electrical double-layer capacitors [1]. Also, ionic liquids (IL) can be considered for optimizing these devices owing to some of their unique properties [2]. The combination of both is expected to be key for the development of supercapacitors with high energy density and long cycling life [3].

In this work, we performed MD simulations of a common IL confined between two types of nanoporous carbons with very different features. This IL was represented by a coarse-grained model with reduced charges [4], and the electrodes were maintained at constant potential. The first type of electrode consists in a carbide-derived carbon with a highly disordered structure [5], whereas the second one is a highly-ordered nanoporous electrode consisting of 6 graphene planes that are randomly perforated and separated by an interlayer distance which was systematically varied between 7 and 10 Å [6, 7]. The former was observed to be a better candidate for supercapacitor applications. In particular, we show that disordered materials are needed to mitigate the importance of the ion-ion correlations between the pores that arise when the IL is strongly confined between highly-ordered electrodes, which has important consequences for the performance of supercapacitors.

3:30PM U40.00004: Atomic Scale Characterization of the Voltage-Dependent Electrical Double Layer Structure*  KATHERINE HARMON (Presenter), FELIPE JIMENEZ-ANGELES, Northwestern University, SANG SOO LEE, Argonne National Lab, MICHAEL J BEDZYK, MONICA OLVERA DE LA CRUZ, Northwestern University, PAUL FENTER, Argonne National Lab — The adsorption of ions at charged surfaces into an electrical double layer (EDL) is a driving factor in many phenomena including energy storage, nanoparticle stabilization, and biomolecule transport. The ability to control these processes relies on a detailed understanding of the atomic-scale interactions at play. Several EDL models with different assumptions have been proposed, including the diffuse ion cloud of Gouy-Chapman (GC) theory and complex ion-ion correlation phenomena. However, significant debate persists over the accuracy and limitations of these theories. Direct experimental probes of the structures at different surface charges can help to elucidate many open questions. Here, we use in situ resonant anomalous X-ray reflectivity (RAXR) to study the EDL structure of Rb$^+$ at a graphene/SiC electrode in aqueous 0.1 M RbCl as a function of applied potential. The results are compared to molecular dynamics (MD) predictions. Differences in RAXR and MD results are evaluated in the context of GC and ion-ion correlation theories with an eye on the possibility of overcharging at the most negative potentials.

*KH gratefully acknowledges support from DoD NDSEG and the Ryan Fellowship, Northwestern IIN. XR measurements were performed at the Advanced Photon Source at ANL (DOE/BES).

3:42PM U40.00005: Ionic liquid dynamics measured with implanted-ion β-NMR  DEREK FUJIMOTO (Presenter), RYAN M. L. MCFADDEN, MARTIN H DEHN, YAEL PETEL, ARIS CHATZICHRISTOS, University of British Columbia, LARS HEMMINGSEN, University of Copenhagen, VICTORIA L. KARNER, ROBERT F KIEFL, University of British Columbia, PHILIP C. P. LEVY, IAIN MCKENZIE, TRIUMF, CARL MICHAL, University of British Columbia, GERALD MORRIS, MATT PEARSON, TRIUMF, DANIEL SZUNYOGH, University of Copenhagen, JOHN TICKNOR, University of British Columbia, MONIKA K STACHURA, TRIUMF, W ANDREW MACFARLANE, University of British Columbia — Ionic liquids (ILs) not only found in a wide range of potential applications, spanning energy storage to space travel, but the constituent ions have fascinating dynamics and structure. In this study, we use implanted-ion $^8$Li β-NMR to probe these dynamics in the IL 1-ethyl-3-methylimidazolium acetate. Sensitivity to nanosecond $^8$Li$^+$ solvation dynamics is inferred from the motional narrowing of the resonance and the local maxima in the $^8$Li relaxation rate. We show that the activation energy and Vogel-Fulcher-Tammann temperature associated with the relaxation process agree with the dynamic viscosity. Near the melting point, the lineshape is broad and intense, and the form of the relaxation is non-exponential, reflective of heterogeneous dynamics. This demonstration establishes the feasibility of studying the local structure and dynamics of IL thin films and interfaces using β-NMR$^1$.

3:54PM U40.00006: Fundamental Studies of Tritium Diffusivity in Irradiation Defective LiAlO$_2$ and Li$_2$ZrO$_3$: A First Principles Density Function Theory Study*  
HARI PAUDEL (Presenter), YUHUA DUAN, National Energy Technology Laboratory — The thermal neutron irradiation of lithium isotope (\(^6\)Li) in tritium (\(^3\)H)-producing burnable absorber rods (TPBARS) of LiAlO$_2$ and Li$_2$ZrO$_3$ crystal produces vacancies, defects of its constituent elements, and several different trapping sites which hinder tritium diffusion process and releasing behavior. Here we investigate the diffusion mechanisms of tritium and O\(^3\)H species in LiAlO$_2$ and Li$_2$ZrO$_3$ ceramic pellet in order to understand and quantify the effects on diffusion barriers and diffusion coefficients due to the presence of interstitial and substitutional Li defects, hydroxide (O-\(^3\)H) vacancy defect, and the interactions of \(^3\)H with O-vacancies in Li$_2$ZrO$_3$. We find the smallest activation energy barriers of 0.63 and 0.3 eV in LiAlO$_2$ and Li$_2$ZrO$_3$, respectively. The obtained results indicate that the performance of Li$_2$ZrO$_3$ could be better than a widely used ceramic in TPBAR, \(\gamma\)-LiAlO$_2$.

2:30PM U41.00001: Spatiotemporal mapping of photocurrent in 2D materials using diamond quantum sensors* [Invited]  
BRIAN ZHOU (Presenter), Boston College — Photocurrents are conventionally detected by counting the charge that flows between two contacts, but electrical detection cannot resolve the path that photocurrents travel within a material. Here, we leverage nitrogen-vacancy (NV) center magnetometers to resolve the spatial distribution of photocurrent flow in a 2D material by measuring the magnetic field profile produced by the photocurrents [1]. We reveal that photocurrent in monolayer MoS$_2$ circulates as a micron-scale vortex under an external magnetic field due to a strong photo-Nernst effect. By synchronizing dynamical decoupling of the sensor spin with pulsed photoexcitation, we significantly enhance sensitivity and resolve current densities as small as 20 nA/\(\mu\)m. Importantly, our pulsed approach allows probing of the temporal dynamics of photocurrent generation with sub-microsecond resolution. This combined spatiotemporal resolution is invaluable for understanding how novel photocurrent generation mechanisms and local variations control the flow of photocurrent in next-generation optoelectronic devices.

3:06PM U41.00002: Optically pumped spin polarization as a probe of many-body thermalization

DANIELA PAGLIERO, The City College of New York, PABLO ZANGARA, Physics Department, Universidad Nacional de Cordoba, JACOB HENSHAW (Presenter), The City College of New York, ASHOK AJOY, Chemistry Department, University of California, Berkeley, RODOLFO ACOSTA, Physics Department, Universidad Nacional de Cordoba, JEFFREY A REIMER, Department of Chemical Engineering, University of California, Berkeley, ALEXANDER PINES, Chemistry Department, University of California, Berkeley, CARLOS MERILES, The City College of New York — The interplay between disorder and transport is a problem central to the understanding of thermalization. Disorder and many-body interactions are known to compete, with the dominance of one or the other giving rise to fundamentally different dynamical phases. Here we investigate the spin diffusion dynamics of $^{13}$C in diamond, which we dynamically polarize at room temperature via optical spin pumping of engineered color centers. We focus on low-abundance, strongly hyperfine-coupled nuclei, whose role in the polarization transport we expose through the integrated impact of variable radio-frequency excitation on the observable bulk $^{13}$C magnetic resonance signal. Unexpectedly, we find excellent thermal contact throughout the nuclear spin bath, regardless the hyperfine coupling strength, which we attribute to effective carbon-carbon interactions mediated by the electronic spin ensemble. In particular, observations across the full range of hyperfine couplings suggest the nuclear spin diffusion constant is approximately uniform, taking values up to two orders of magnitude greater than that expected from homo-nuclear spin couplings. Our results open intriguing opportunities to study the onset of thermalization in a system by controlling the internal interactions within the bath.

3:18PM U41.00003: Nanoscale structure of the orbital magnetic moment of a single dopant spin in a semiconductor*

ADONAI RODRIGUES DA CRUZ (Presenter), Applied Physics, Eindhoven University of Technology, MICHAEL FLATTÉ, Department of Physics and Astronomy, University of Iowa — The localized electron spin of a single impurity in a semiconductor is a promising system to realize quantum information schemes. In this work we investigate the orbital contribution to the magnetic moment originated from the spin-orbit induced circulating current [1] associated with the ground state of a single magnetic impurity in III-V semiconductors. In this project we developed a formalism employing Green's functions obtained by the Koster-Slater technique [2] with a sp$^3$d$^5$s* empirical tight-binding Hamiltonian [3] to describe the host material. We calculated the circulating current and orbital moments of a single Mn dopant in GaAs. The spin-correlated orbital moments originates from the hybridization between the Mn(d$^5$) spin-polarized electrons and the As dangling bonds leading to $t_2$-symmetric triplet acceptor states in the bandgap above the valence band edge.

3:30PM U41.00004: Pulsed Electrically Detected Magnetic Resonance (pEDMR) at Low Magnetic Fields using an Arbitrary Wave Form Generator (AWG)*

TANIYA TENNAHEWA (Presenter), HANS MALISSA, HENNA POPLI, SABASTIAN ATWOOD, SANAZ HOSSEINZADEH, Physics And Astronomy, University of Utah, JOHN M LUPTON, Institut für Experimentelle und Angewandte Physik, Universität Regensburg, CHRISTOPH M BOEHME, Physics And Astronomy, University of Utah — We use pulsed electrically detected magnetic resonance (pEDMR) in order to observe the coherent propagation of electron spins under strong drive magnetic resonance conditions in organic materials, where excitation frequencies (~100 MHz) and Zeeman fields (~3 mT) are low. In these materials, transverse relaxation times of electron spins are known to be in the on the order to 1µs [1], requiring the bandwidths of the pulse experiments to be in the 10-100 MHz range in order to accommodate effective pulse sequences. Thus, at low excitation frequencies [2,3], the duration of spin manipulation pulsed becomes comparable to the carrier-wave frequency, and conventional methods for generating RF pulses become impossible. We therefore utilize an arbitrary waveform generator (AWG) to directly synthesize RF pulses with a shape derived directly from the desired excitation spectrum. We evaluate the fidelity of such pulsed low-frequency excitation and conduct experiments that demonstrate electrically detected coherent spin motion under the given low-field conditions.[1] R. Miller, et al., Phys. Rev. B, 94, 214202 (2016); [2] S. Jamali et al., Nano Lett. 4648 (2017); [3] D. P. Waters et al., Nature Physics 11, 910 (2015).

3:42PM U41.00005: Detection of electron spin resonance in the strong, non-linear drive regime using spin-dependent charge carrier recombination currents and an amplitude-modulated continuous wave electrically detected magnetic resonance scheme*

SABASTIAN ATWOOD (Presenter), ADNAN NAHLAWI, SANAZ HOSSEINZADEH, TANIYA TENNAHEWA, HENNA POPLI, HANS MALISSA, Department of Physics and Astronomy, University of Utah, JOHN M LUPTON, Institut für Experimentelle und Angewandte Physik, Universität Regensburg, CHRISTOPH M BOEHME, Department of Physics and Astronomy, University of Utah — Electrically detected magnetic resonance spectroscopy of organic light-emitting diodes with conductive polymers as active layers allows for the study of high-magnetic resonance drive regimes of electron spins in which Zeeman fields are on the same magnitude as drive field amplitudes [1, 2]. Drive amplitude limits of such non-linear magnetic resonance experiments are posed by the superposition of the studied spin-dependent electric currents with other, randomly occurring, radiation-induced artifact signals, possibly due to electric dipole transitions in lowest unoccupied molecular orbitals. Here, we demonstrate the use of amplitude-modulated lock-in detection for the isolation of these two electric current signatures, taking advantage of their different dynamic natures. We validate this approach by analyzing the dependence of the lock-in detected signals on modulation phase and frequency and demonstrate a significant signal improvement allowing for the detection of multi-photon magnetic dipole transitions and the Bloch-Siegert shift. [1] S. Jamali et. al., Nano Lett., 17, 4648 (2017), [2] S. Jamali et al. (unpublished).

Probing spin-dependent electronic transitions in a conjugated polymer using electrically detected magnetic resonance (EDMR) under hole injection with MoO$_3$ electrodes

SANAZ HOSSEINZADEH (Presenter), HANS MALISSA, ADNAN NAHLAWI, CHRISTOPH M BOEHME, The University of Utah — Spin-dependent recombination in organic light emitting diodes (OLEDs) occurs when an active polymer layer is sandwiched between an electron and hole charge carrier injection layers. As spin-dependent electronic transitions rates change under magnetic resonant excitation, spin-dependent recombination can be studied using a method called electrically detected magnetic resonance spectroscopy (EDMR) [1-2]. Most past EDMR studies used the copolymer blend poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT: PSS) as hole injector layer. Here, we report EDMR spectroscopy of OLEDs based on various π-conjugated poly-phenylenevinlenes as active materials and the Ca and MoO$_3$ layers as electron and hole injectors, respectively, in order to test whether Mo, (atomic number Z=42) is able to affect the charge carrier spin-orbit coupling (SOC) in the active layer, e.g. by suppression of spin-dependent processes. Our results indicate that no SOC effects can be observed and, thus, that SOC in hole injection layers does not affect pEDMR signals in OLEDs. [1] D. McCamey et al., Nature Materials, 7 (9), 723 (2008); [2] H. Malissa et al., Science 345 (6203), 1487 (2014).

Manipulation of Dynamic Nuclear Polarization in Gallium Arsenide under periodic optical electron spin pumping

MICHAEL DOMINGUEZ (Presenter), JOSEPH IAFRATE, VANESSA A SIH, Univ of Michigan - Ann Arbor — Optically oriented electron spins in gallium arsenide polarize the nuclear spin system through a process called dynamic nuclear polarization. The polarized nuclear system will create an effective magnetic field back onto the electron spin system and affect the Larmor precession frequency. The nuclear polarization can be calculated from the change in electron spin polarization using periodic optical pump probe Kerr rotation measurements[1]. We demonstrate that the coupled electron-nuclear spin systems can be manipulated by varying the excitation energy and sweeping an external magnetic field. These dependencies are corroborated by numerical calculations from a model incorporating optical orientation and the optical Stark effect. This model is justified by its correspondence to our experimental observations and can be used to predict the behavior of the nuclear spin polarization.

*This work was supported in part by NSF and by the U.S. Department of Defense NDSEG program
The impact of dynamic nuclear polarization on non-local spin valve and inverse spin Hall Hanle measurements in n-GaAs

ZHENG JIANG (Presenter), School of Physics and Astronomy, University of Minnesota, Twin Cities, SAHIL PATEL, Departments of Electrical and Computer Engineering and Materials, University of California, Santa Barbara, PAUL CROWELL, School of Physics and Astronomy, University of Minnesota, Twin Cities, CHRIS J PALMSTROM, Departments of Electrical and Computer Engineering and Materials, University of California, Santa Barbara — Non-local spin valve (NLSV) and inverse spin Hall (ISHE) Hanle measurements are important tools to probe spin-transport parameters such as the spin lifetime and spin Hall angle. We carried out such measurements on Fe/n-GaAs heterostructure samples with varying doping (3x10^{16} to 7x10^{16} cm^{-3}) and at temperatures from 2 K to 110 K. The Hanle curves are very sensitive to the hyperfine field generated by dynamic nuclear polarization (DNP). Below a threshold temperature that depends on doping, the hyperfine field leads to distortion of the Hanle line-shapes for both NLSV and ISHE measurements and can enhance the ISHE signal by one order of magnitude. We have developed a pulsed-current technique which utilizes the vast difference between electron and nuclear spin relaxation time scales (about ns and s respectively) to eliminate the impact of the steady-state hyperfine field, and the obtained Hanle curves then match expectations based on simple drift-diffusion models. We will discuss the extracted spin lifetime and spin Hall angle, numerical modeling of the Hanle curves and the role of the hyperfine field in enhancing the apparent spin Hall signal.

Magnetic properties of a single micrometer-sized YIG/FGT multilayer heterostructure revealed by ferromagnetic resonance

BASSIM ARKOOK (Presenter), MOHAMMED ALGHAMDI, VICTOR ORTIZ, JING SHI, IGOR BARSUKOV, Physics and Astronomy, University of California, Riverside — Multilayer heterostructures consisting of a magnetic insulator and 2D spin system offer a promising platform for next-generation spintronic applications. Understanding interfacial spin coupling and transport in such heterostructures require a local microwave spectroscopy technique since the flakes of 2D materials obtained by exfoliation are limited to micrometers in size. Here, we fabricate disks of 20um diameter from epitaxial ferrimagnetic insulator, yttrium iron garnet (YIG), thin-film using pulsed laser deposition, e-beam lithography, and lift-off. We place few-nm thick flakes of van-der-Waals material Fe3GeTe2 (FGT) on the pre-patterned YIG disks and transfer a single disk onto a planar microwave resonator. Using angle-dependent ferromagnetic resonance, we find low-energy spin-wave modes in YIG at several microwave frequencies, allowing for the evaluation of magnetic anisotropy and damping. Using cryogenic measurements, we observe an anomalous temperature dependence of effective magnetic anisotropy. The results shed light on spin phenomena at YIG/FGT interfaces and present an experimental approach for studies of micro-scale magnetic insulator/2D heterostructures.

**4:42PM U41.00010: Dynamics of Spin Waves in 1D and 2D Magnonic Crystals of V[TCNE]_{x-2} with YIG or Cobalt**

KWANGYUL HU (Presenter), MICHAEL FLATTÉ, Optical Science and Technology Center and Department of Physics, The University of Iowa — A semiconducting organic ferrimagnet V[TCNE]_{x-2} is a newly emerging magnonic material. Recent studies have revealed that V[TCNE]_{x-2} has narrow linewidth, long spin lifetime and high Q factor[1-3]. In addition, deposition of high quality V[TCNE]_{x-2} does not require specific substrates or high temperature which is a significant advantage compared to YIG[1]. These properties of V[TCNE]_{x-2} indicate that it is attractive magnonic media. Here, we calculate and present the magnonic dispersions and linewidths of quasi one-dimensional and two-dimensional magnonic crystals consisting of V[TCNE]_{x-2} with YIG or cobalt. In each case, we consider infinitely periodic lattice structures with a finite thickness. For the calculation, the linearized Landau-Lifshitz-Gilbert equation with the plane-wave method is used[4]. We anticipate that these results will provide fundamental understanding of how to design magnonic devices based on V[TCNE]_{x-2}.

*We acknowledge support from NSF EFRI NewLAW under Award No. EFMA-1741666.

**4:54PM U41.00011: Impact of hidden structural order on low temperature magnetic resonance in V[TCNE]_{x}**

HUMA YUSUF (Presenter), ANDREW FRANSON, SETH KURFMAN, EZEKIEL JOHNSTON-HALPERIN, Physics, Ohio State Univ - Columbus — The coordination compound V[TCNE]_{x} is a promising magnetic material for integration into solid-state quantum information systems due to its low damping (α = (3.98 ± 0.22) × 10^{-5}), high quality factor (Q up to 8,000) microwave resonance, ease of patterning, and compatibility with a wide variety of substrates. Since current quantum information systems require low temperature operation, a comprehensive study of the low temperature magnetic behavior of V[TCNE]_{x} is essential for realizing this promise. Here we report the observation of anomalous temperature dependent anisotropy in thin films of V[TCNE]_{x} at temperatures down to 5 K. The resonance linewidth at 5K is larger by a factor of 3 than at room temperature, competitive with the very best liquid phase epitaxy (LPE) yittrium iron garnet (YIG) films. Further, we observe temperature-dependent changes in the magnetic anisotropy that suggest that this modest increase in linewidth may in fact arise from inhomogeneous thermally-induced strain in the thin film. This result promises further reductions in the low temperature linewidth in structures engineered to minimize differences in thermal contraction between the sample and the substrate.

*This work is supported by DOE Project No. 60072770
2:30PM U42.00001: Time-resolved ultrafast oscillation of octupole polarization in a chiral antiferromagnet Mn$_3$Sn$^*$ [Invited] SHINJI MIWA (Presenter), The Institute for Solid State Physics, The University of Tokyo — Understanding of spin-precession dynamics forms the basis of spintronic application. For the ultrafast THz control of staggered moments in antiferromagnets, the time-resolved observation of spin precession is essential for developing the associated technology. However, such observation has been limited to insulators to date [1]. Recently, the metallic antiferromagnets Mn$_3$X have attracted significant attention for its strong response (e.g. anomalous Hall effect) comparable to ferromagnets owing to the hidden ferroic order, which configures large Berry curvature originated from Weyl points in momentum space [2]. Such ferroic order can be characterized by cluster octupoles based on neighboring magnetic moments [3], and thus it is highly important to clarify the dynamics of cluster octupole for designing the spintronic application.

In this talk, we report our time-resolved observation of spin precession in a metallic chiral antiferromagnet Mn$_3$Sn [4]. In particular, we find that the dynamics of the cluster octupole is enhanced by exchange interaction, and it is feasible to conduct an ultrafast switching at $< 10$ ps, a hundred times faster than the case of spin-magnetization in a ferromagnet. Moreover, our theoretical study demonstrates that the domain wall velocity of the cluster octupole could reach as high as 10 km/s. Our work paves the path towards realizing ultrafast electronic devices.

3:06PM U42.00002: Evidence of Electrical Switching of the Antiferromagnetic Néel Vector*

CHIH-CHIEH CHIANG (Presenter), SSU YEN HUANG, Department of Physics, National Taiwan University, DANRU QU, Institute of Physics, Academia Sinica, PO-HSUN WU, Department of Physics, National Taiwan University, CHIA-LING CHIEN, Department of Physics and Astronomy, Johns Hopkins University —

Recently, field-free switching of antiferromagnetic (AFM) Néel vector via spin-orbit torque (SOT) attracting worldwide attention. By applying a writing current in the AFM or the normal metal (NM)/AFM bilayer, in a patterned multi-terminal structures, the measured resistance shows recurring signals due to supposedly electrical switching of the AFM Néel vector. However, in this work, we demonstrate that similar signals can be observed in such patterned structures, with and without the AFM layer [1]. The strength of the signal is also greatly affected by different metals and substrates. We show that under a large writing current density beyond the Ohmic regime, the multi-terminal devices can generate unintended anisotropic thermal gradient and voltages. Therefore, this switching signal may not be the conclusive evidence of the SOT switching of AFM, but the thermal artifacts of patterned metal structures on substrate.

3:18PM U42.00003: Spin-torque control of the noncollinear antiferromagnetic order in antiperovskites

GAUTAM GURUNG (Presenter), DING-FU SHAO, EVGENY Y TSYMBAL, University of Nebraska - Lincoln —

Antiferromagnetic (AFM) spintronics exploits the AFM order to control the spin-dependent transport properties. Recent theoretical studies suggest that the AFM order parameter can be switched by a spin torque, while the related experimental realizations are limited to a few collinear antiferromagnets. There is, however, a large group of high temperature noncollinear antiferromagnets, which are suitable for such switching. Here, we predict that the spin torque can be efficiently used to control the noncollinear AFM order in antiperovskite materials. Based on first-principles calculations and atomistic spin model simulations, we show that in antiperovskites ANMn$_3$ (A = Ga, Ni, etc) with the $\Gamma_{4g}$ AFM ground state, the AFM order parameter can be switched on the picosecond scale by a spin-transfer torque generated by a spin polarized current. The threshold switching current density can be tuned by the ANMn$_3$ stoichiometry engineering, changing the magnetocrystalline anisotropy. The $\Gamma_{4g}$ AFM phase supports the anomalous Hall effect, which can be used to detect the spin-torque switching of the AFM order. The predicted ultrafast switching dynamics and the efficient detection of AFM order parameter make noncollinear AFM antiperovskites promising material platforms for AFM spintronics.
3:30PM U42.00004: Nonlinear anomalous Hall effect for Néel vector detection  DING-FU SHAO (Presenter), Department of Physics and Astronomy, University of Nebraska - Lincoln, SHUHUI ZHANG, College of Science, Beijing University of Chemical Technology, GAUTAM GURUNG, Department of Physics and Astronomy, University of Nebraska - Lincoln, WEN YANG, Beijing Computational Science Research Center, EVGENY Y TSYMBAL, Department of Physics and Astronomy, University of Nebraska - Lincoln — The manipulation and detection of the Néel vector are cores of antiferromagnetic (AFM) spintronics. Recent studies have shown that the field-like and antidamping spin-orbit torques (SOT) can be used to switch the Néel vector in antiferromagnets with proper symmetries. On the other hand, the efficient detection of the AFM order parameter remains a challenging problem. Here, we predict that the nonlinear anomalous Hall effect (AHE) can be used to detect the Néel vector in most compensated antiferromagnets supporting the antidamping SOT. The magnetic crystal group symmetry of these antiferromagnets combined with spin-orbit coupling results in a sizable Berry curvature dipole and hence the nonlinear AHE. As a specific example, we consider half Heusler alloy CuMnSb, which Néel vector can be switched by the antidamping SOT. Based on density functional theory calculations, we show that the nonlinear AHE in CuMnSb produces a measurable Hall voltage under conventional experimental conditions. The strong dependence of the Berry curvature dipole on the Néel vector orientation provides a new detection scheme of the AFM order parameter based on the nonlinear AHE.

3:42PM U42.00005: Rotating Néel Order to Probe Crystalline and Non-Crystalline AMR in FeRh  JOSEPH SKLENAR (Presenter), Wayne State Univ, SOHO SHIM, University of Illinois Urbana-Champaign, HILAL SAGLAM, Argonne National Laboratory, KISUNG KANG, JUNSEOK OH, GREG A HAMILTON, University of Illinois Urbana-Champaign, WEI ZHANG, Oakland University, MATTHEW GILBERT, ANDRE SCHLEIFE, AXEL HOFFMANN, NADYA MASON, University of Illinois Urbana-Champaign — Anisotropic magnetoresistance (AMR) effects are a promising starting point for the electrical readout of antiferromagnetic memory in a spintronic device. We characterized both crystalline and non-crystalline AMR in thin films of FeRh, a material which undergoes a ferro- to antiferromagnetic transition near room temperature. The resistance is measured as an external field is rotated in the sample plane. In the antiferromagnetic phase we observe a striking dependence of the AMR signal on both field magnitude, and current orientation relative to the FeRh [100] crystalline axis. We confirm that AMR arises from rotating Neel order two ways: 1) We developed a procedure combining rotating and linearly swept fields to demonstrate an angular hysteresis effect; 2) We use density functional theory for a first-principles description of the evolution of the AMR signal, representing the external magnetic field by canted spins and the sweeping field by Néel vector rotation from the [100] direction.

3:54PM U42.00006: Nonvolatile control of long-distance spin transport in an easy-plane antiferromagnetic insulator

JIAHAO HAN (Presenter), PENGXIANG ZHANG, YABIN FAN, T AQIYYAH S SAFI, JUNXIANG XIA N, Massachusetts Institute of Technology MIT, RAN CHENG, University of California, Riverside, LUQIAO LIU, Massachusetts Institute of Technology MIT — Transmission of spin angular momentum can be implemented by the quanta of spin-wave excitations, viz. magnons, without dissipative electron flows. Therefore, spin information can be transported over long distances in insulating materials devoid of Joule heating. Antiferromagnetic insulators with vanishingly small magnetization and high operating frequency are promising candidates for high-density and ultrafast magnonic devices. It is generally believed that easy-axis anisotropy is essential for long-distance spin transport in antiferromagnets, while easy-plane anisotropy suppresses spin transmission due to the vanished angular momentum carried by the magnon eigenmodes. Here we show that efficient spin transport over micrometer distance indeed happens in an easy-plane antiferromagnetic insulator, α-Fe$_2$O$_3$ thin film. The amplitude of spin transmission can be easily manipulated by a magnetic field much weaker than those in previous studies, making our systems more practical for applications. Moreover, the stable magnetic orientation enables control of spin transport under zero remnant field, realizing a nonvolatile spin-current switch with a 100% on/off ratio.

*NSF, NIST

4:06PM U42.00007: Intrinsic spin Nernst effect of magnons in a noncollinear antiferromagnet

BO LI (Presenter), SHANE SANDHOEFNER, ALEXEY KOVALEV, University of Nebraska - Lincoln — We investigate the intrinsic magnon spin current in a noncollinear antiferromagnetic insulator. To this end, we derive a magnon spin current in a noncollinear antiferromagnet from continuity equation and find that in general it is not conserved, but for certain symmetries and spin polarizations, the averaged effect of non-conserving terms can vanish. We formulate a general linear response theory for magnons in noncollinear antiferromagnets subject to a temperature gradient and analyze the effect of symmetries on the response tensor. We apply this theory to single-layer potassium iron jarosite KFe$_3$(OH)$_6$(SO$_4$)$_2$ and predict a measurable spin current response. According to the symmetry analysis, many other material candidates should exhibit the spin Nernst effect, including quasi-two- and three-dimensional noncollinear antiferromagnets and antiferromagnets with magnetic textures such as skyrmions. Our proposal can be useful for spin generation in spintronics applications. Furthermore, this effect can also serve as a probe for the materials that can hold multiple noncollinear states.
4:18PM U42.00008: Electric-field control of magnon spin current in an antiferromagnetic insulator*  
CHANGJIANG LIU (Presenter), YONGMING LUO, DESHUN HONG, SHULEI ZHANG, JOHN PEARSON, BRANDON FISHER, AXEL HOFFMANN, ANAND BHATTACHARYA, Argonne National Laboratory — A fundamental challenge in the development of spintronics is the effective control of spin currents by electrical means. This is because the spin degree of freedom is often decoupled from external electric fields, making its control difficult. Over the last few years, the spin Seebeck effect has shown its versatility in generating pure spin currents in a diverse class of magnetic systems. Here we first show how a magnon spin current can be produced in an antiferromagnetic insulator by means of the spin Seebeck effect. The polarity of the spin current is determined by the orientation of the magnetic sublattice in this antiferromagnet. Owning to the response of the magnetic ions to an external electric field, the anisotropy energy of this material may be effectively tuned. As a result, we show that the spin-flop transition in this material can be switched on or off by varying only an electrical voltage. Furthermore, we demonstrate how thermally generated spin currents in this antiferromagnet can be effectively controlled by sweeping the control voltage.

4:30PM U42.00009: Phenomenological theory of coherent and incoherent spin currents in antiferromagnetic spin pumping  
RAN CHENG (Presenter), University of California, Riverside — Magnetic resonance driven by coherent microwaves can pump spin currents into a neighboring nonmagnetic system. Owing to non-linear effects, however, coherently driven spin dynamics inevitably generates incoherent magnons through thermalization, which makes it complicated to distinguish between coherent and incoherent contributions in real experiments. Recent measurements have demonstrated spin pumping effects in antiferromagnets at the sub-THz frequency, where coherent and incoherent magnons contribute oppositely to the spin current and are thus distinguishable. We formulate a phenomenological theory to capture the coupled dynamics of coherent and incoherent magnons in collinear antiferromagnets driven by sub-THz sources, which can fit very well with the experimental observation and explain why the competition between coherent and incoherent magnons leads to a sign change in the spin current at a turning temperature. Our phenomenological theory predicts that using magnetic thin films can substantially suppress the undesirable incoherent contribution and magnify coherent spin pumping.
4:42PM U42.00010: Coherent ac spin current transmission across an antiferromagnetic CoO insulator  QIAN LI (Presenter), MENGMENG YANG, University of California, Berkeley, CHRISTOPH KLEWE, PADRAIC SHAFER, ALPHA T. N’DIAYE, Lawrence Berkeley National Lab, DAZHI HOU, Tohoku University, TIANYE WANG, NAN GAO, University of California, Berkeley, EIJJI SAITOH, Tohoku University, CHANYONG HWANG, Korea Research Institute of Standards and Science, ROBERT J HICKEN, University of Exeter, JIA LI, Peking University, ELKE ARENHOLZ, Lawrence Berkeley National Lab, ZI Q. QIU, University of California, Berkeley — The recent discovery of spin-current transmission through antiferromagnetic insulating materials opens up vast opportunities for fundamental physics and spintronics applications. The question currently surrounding this topic is: whether and how could THz antiferromagnetic magnons mediate a GHz spin current? This mis-match of frequencies becomes particularly critical for the case of coherent ac spin-current, raising the fundamental question of whether a GHz ac spin-current can ever keep its coherence inside an antiferromagnetic insulator and so drive the spin precession of another ferromagnet layer coherently? Utilizing element- and time-resolved x-ray pump-probe measurements on Py/Ag/CoO/Ag/Fe$_{75}$Co$_{25}$/MgO(001) heterostructures, here we demonstrate that a coherent GHz ac spin current pumped by the Py ferromagnetic resonance can transmit coherently across an antiferromagnetic CoO insulating layer to drive a coherent spin precession of the Fe$_{75}$Co$_{25}$ layer. Further measurement results favor thermal magnons rather than evanescent spin waves as the mediator of the coherent ac spin current in CoO.

4:54PM U42.00011: Spin Current from sub-Terahertz-generated Antiferromagnetic Magnons*  JUNXUE LI, University of California, Riverside, BLAKE WILSON, Physics Department and Institute for Terahertz Science and Technology, University of California, Santa Barbara, RAN CHENG, MARK I LOHMANN, University of California, Riverside, MARZIEH KAVAND, Physics Department and Institute for Terahertz Science and Technology, University of California, Santa Barbara, WEI YUAN, MOHAMMED ALDOSARY, University of California, Riverside, NIKOLAY I AGLADZE, Physics Department and Institute for Terahertz Science and Technology, University of California, Santa Barbara, PENG WEI, University of California, Riverside, MARK S SHERWIN, Physics Department and Institute for Terahertz Science and Technology, University of California, Santa Barbara, JING SHI (Presenter), University of California, Riverside — Spin dynamics in antiferromagnets offers attractive benefits for potential ultrafast device applications. To date, spin current generation via antiferromagnetic resonance and simultaneous electrical detection by the inverse spin Hall effect in heavy metals have not been explicitly demonstrated. Here we report sub-terahertz spin pumping in heterostructures of a uniaxial antiferromagnetic Cr$_2$O$_3$ crystal and a heavy metal of Pt or Ta (Beta-phase). The magnetic resonances in Cr$_2$O$_3$ are excited both below and above spin flop transitions. Both resonances generate pure spin currents in the heterostructures, which are detected by the heavy metal as an open-circuit voltage peak or dip. The pure spin current nature of the electrically detected signals is unambiguously confirmed by the reversal of voltage polarity under two circumstances: one when switching the detector metal from Pt to Ta which reverses the sign of spin Hall angle, and the other when flipping the magnetic field direction which reverses the magnon chirality.

*Work at UC Riverside was supported as part of the Spins and Heat in Nanoscale Electronic Systems, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under award no. SC0012670 (JXL, ML, WY, MA, and JS).
5:06PM U42.00012: Quantitative Study on Current-Induced Effects in an Antiferromagnet Insulator/Pt Bilayer Film*  

PENGXUANG ZHANG (Presenter), LUQIAO LIU, Electrical Engineering and Computer Science, Massachusetts Institute of Technology — Quantitative investigation on the current-induced torque in antiferromagnets represents a great challenge, due to the lack of an independent method for controlling Néel vectors. Here by utilizing an antiferromagnetic insulator with Dzyaloshinskii-Moriya interaction, α-Fe2O3, we show that the Néel vector can be controlled with a moderate external field, which is further utilized to calibrate the current-induced magnetic dynamics. In a Pt/α-Fe2O3(0001) bilayer film, we see that the current-induced magnetoresistance change in antiferromagnets can be complicated by resistive switching that is non-magnetic. By excluding non-magnetic switching, we reveal two significant magnetic contributions, the magnetoelastic effect and the field-like spin-orbit torque, and quantify their magnitudes. Our approach in principle is applicable to many other easy plane antiferromagnets, and would be beneficial for future systematic studies of current-induced antiferromagnetic dynamics.

*This work is supported in part by National Science foundation under award ECCS-1808826 and DMR 14-19807, and by SMART, one of seven centers of nCORE, a Semiconductor Research Corporation program, sponsored by National Institute of Standards and Technology (NIST).

5:18PM U42.00013: Resonant ultrasound studies of Fe$_{x=0.33}$NbS$_2$*  

SYLVIA LEWIN (Presenter), VIKRAM NAGARAJAN, GABRIEL PERKO-ENGEL, ERAN MANIV, SHANNON HALEY, JAMES ANALYTIS, University of California, Berkeley — The intercalated transition metal dichalcogenide Fe$_{x=0.33}$NbS$_2$ appears to exhibit frustrated antiferromagnetism. The orientation of its antiferromagnetic order can be switched by the application of electrical currents [1]. Similar behavior at room temperature could form the basis of a new generation of magnetic memory storage. However, the specific magnetic order of Fe$_{x=0.33}$NbS$_2$ and how it evolves with temperature have not been exactly determined, leaving open questions about the microscopic mechanism of switching. Resonant Ultrasound Spectroscopy—a study of the material’s mechanical resonances—can shed light on the magnetic order in Fe$_{x=0.33}$NbS$_2$.

Session U43 DCOMP DMP: Computational design and discovery of novel materials V: Electronic structure  

Tag(s): Focus
Towards ideal topological materials: Comprehensive database searches using symmetry indicators

FENG TANG, Nanjing Univ, HOI CHUN PO, MIT, ASHVIN VISHWANATH, Harvard University, XIANGANG WAN (Presenter), Nanjing Univ — Although the richness of spatial symmetries has led to a rapidly expanding inventory of possible topological crystalline (TC) phases of electrons, physical realizations have been slow to materialize due to the practical difficulty to ascertaining band topology in realistic calculations. Here, we integrate the recently established theory of symmetry indicators of band topology into first-principle band-structure calculations and apply it to all non-magnetic compounds in the 230 space groups. An exhaustive database search reveals thousands of TM candidates. Of these, we highlight the excellent TMs, the 258 topological insulators and 165 topological crystalline insulators which have either noticeable full band gap or a considerable direct gap together with small trivial Fermi pockets. We also give a list of 489 topological semimetals with the band crossing points located near the Fermi level. All predictions obtained through standard generalized gradient approximation (GGA) calculations were cross-checked with the modified Becke-Johnson (MBJ) potential calculations, appropriate for narrow gap materials. With the electronic and optical behavior around the Fermi level dominated by the topologically non-trivial bands, these newly found TMs candidates open wide possibilities for realizing the promise of TMs in next-generation electronic devices.

First principle study of structural, electronic and magnetic properties of layer-structured MnSb

BIPIN LAMICHHANE (Presenter), DINESH THAPA, CHANDANI NANDADASA, Physics and Astronomy, Mississippi State University, JUNSEONG SONG, SUNG WNG KIM, Energy Science, Sungkyunkwan University, SEONG-GON KIM, Physics and Astronomy, Mississippi State University — Manganese antimonide (MnSb) as a half-metallic ferromagnets can be used as a spin injector in semiconductor to develop spintronic devices. We performed ab initio total-energy calculations and geometry optimizations within Density Functional Theory (DFT) using the generalized gradient approximation (GGA) Perdew–Burke–Ernzerhof (PBE) functional and the projected augmented wave (PAW) method to investigate the structural, electronic, and bonding properties of layer-structured MnSb. We found a metallic density of states (DOS) in one spin channel (majority spin) and a band energy gap at the Fermi level in another (minority spin), which presents MnSb to have a half metallic character. Furthermore, atom projected band structure was used to investigate the electronic contributions from Mn and Sb atoms.

This work was supported by a National Research Foundation of Korea (NRF) grant funded by the Korean government (Ministry of Science, ICT & Future Planning) (No.2015M3D1A1070639) and in part by the Center for Computational Sciences (CCS) at Mississippi State University.
3:18PM U43.00003: Near-Fermi-level electronic states in hexagonal ABC compounds from first principles* KONRAD GENSER (Presenter), KARIN M RABE, Rutgers University, New Brunswick — Ternary ABC intermetallic compounds exhibit a rich variety of crystal structures and electronic properties. In this work, we study the band structures of real and hypothetical ABC intermetallic phases with structures obtained by stacking binary honeycomb layers with single layers of interstitial atoms in various ways, using first principles calculations to determine the structural parameters and the bands in each phase. We use this dataset to analyze and model the bands near the Fermi level to classify the systems considered and to extract a set of rules that allows us to predict and design hexagonal ABC intermetallic materials with targeted transport and optical properties, connecting to experimental measurements on known hexagonal ABC phases.

3:30PM U43.00004: A symmetry-based approach to reciprocal space path selection in band structure calculations JASON MUNRO (Presenter), Energy Technologies Area, Lawrence Berkeley National Laboratory, KATHERINE LATIMER, Department of Physics, University of California, Berkeley, SHYAM DWARAKNATH, KRISTIN PERSSON, Energy Technologies Area, Lawrence Berkeley National Laboratory — The calculation of band structures is a critical step in describing many different properties of crystalline solids such as optical absorption, and both thermal and electronic transport. Most commonly, these are computed along a one-dimensional path in reciprocal space, which is presumed to capture important features of the entire dispersion landscape. However, conventions for choosing this path rely on data for high-symmetry points and lines in the first Brillouin zone, defined using different arbitrary criteria and an inflexible predefined unit cell. Furthermore, this data is contained in hard-coded lookup tables for different crystal classes and lattice vector lengths. To address these issues, a new “on-the-fly” symmetry based algorithm and utility for obtaining paths in reciprocal space is presented. For an arbitrary input cell, the site-symmetries of points and lines in the first Brillouin zone are determined and used to define the high-symmetry criteria. A smooth path connecting them is then obtained using graph theory based tools. This new framework not only allows for increased flexibility, but is also shown for a general high-symmetry criteria to provide new notable features in the electronic band structure for systems with both magnetic and nonmagnetic symmetry.
Recently, the nonsymmorphic compound CeSbTe was studied experimentally and computationally to determine its crystal structure and its electronic structure, due to the interest in topological semimetals [1]. The material was found to contain several four-fold degenerate points, including a Dirac crossing near the Fermi level, which are topologically protected. A similar, as-yet unstudied material, SmSbTe, has recently been synthesized, and initial experiments show that it has the same space group as CeSbTe. The calculated band structures show the same topologically protected crossings near the Fermi level. This means that SmSbTe could be another candidate to study exotic magnetic phases. We present calculated band structures for SmSbTe in different magnetic phases with spin-orbit coupling and LDA+U corrections [2,3] included.

3:54PM U43.00006: Atomic-Level Insight into Oxygen Adsorption on (hkl) Platinum Surfaces and Implications for the Reactivity in the Oxygen Reduction Reaction  SHIYI WANG (Presenter), Department of Chemical and Biological Engineering, University of Colorado Boulder, ENBO ZHU, YU HUANG, Department of Materials Science and Engineering, University of California, Los Angeles, HENDRIK HEINZ, Department of Chemical and Biological Engineering, University of Colorado Boulder — Understanding of the oxygen reduction reaction (ORR) on nanometal catalysts and specific rate predictions remain a major challenge. We quantified adsorption of molecular oxygen on Pt (100), (111), and (110) surfaces in common electrolytes and for a range of applied potentials in several times higher accuracy than feasible before using molecular dynamics simulations, and explore the following covalent bond formation using density functional theory calculations. A direct correlation between the oxygen affinity to Pt (hkl) surfaces and the experimentally measured ORR activity in the order Pt(100) < Pt(111) < Pt(110) in HClO₄ solution and Pt(111) < Pt(100) < Pt(110) in H₂SO₄ and H₃PO₄ solutions is discovered. The adsorption energies are in a range to explain specific rate differences. Experimental data for the time scale of events support that the ORR activity is driven by O₂ adsorption and initial chemisorption. The methods can be potentially applied to metal and alloy surfaces of any regularity, shape, and composition to provide quantitative insights into metal-electrolyte-gas interfaces, and promote the rational design of more effective catalysts for ORR, OER, and other electrode reactions to the large nanometer scale.
4:06PM U43.00007: Novel fundamental bounds in photovoltaic materials*  ELLA BANYAS (Presenter), University of California, Berkeley, LIANG TAN, Lawrence Berkeley National Laboratory — Effective photovoltaic materials require not only an ideal band gap, but a high carrier mobility. Identifying new candidate photovoltaics can be challenging, as generalized methods for predicting materials with the requisite properties do not yet exist. Here we use a local orbital-based approach and the nearsightedness principle to derive novel analytic bounds on effective masses, which are inversely proportional to carrier mobility in the Boltzmann transport limit. These bounds explicitly depend on both the electronic band structure (e.g. the band gap) and the physical structure of the crystalline material itself, thereby enhancing our ability to identify materials classes that have both small band gaps and high mobilities. We present the methodology used for generating these “structure-informed” fundamental bounds and compare current results to a high-throughput survey of Materials Project data.

4:18PM U43.00008: Catalytic properties of one-dimensional electrides: A first-principles study  JINSEON PARK (Presenter), Department of Physics and Astronomy, University of Tennessee, Knoxville, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — Electrides are ionic compounds in which “free” electrons (anionic electrons) are confined in a low-dimensional cavity space. The characteristic features of electrides—the existence of large void spaces and non-nucleus-bound anionic electrons—make them attractive for various applications, such as gas storage, electron/ion transport, and electrocatalytic processes. Recently, we identified Cs$_3$O as a new type of one-dimensional (1D) electride with nontrivial band topology. The compound Y$_5$Si$_3$ also was recently discovered, another 1D electride that exhibits excellent durability and catalytic efficiency. We demonstrate that hexagonal Y$_5$X$_3$ (X = Ge, Sn, and Pb) also can be classified as a 1D electride with different lattice parameters. A global structure search confirms that these compounds are thermodynamically stable. To understand the catalytic properties of Y$_5$X$_3$ as a reducing agent, the interaction between a Y$_3$X$_3$(001) surface and a Cu adsorbate is investigated, and the ability of the Y$_5$X$_3$ to donate electrons to Cu is quantitatively analyzed in terms of charge transfer. We further shed light on the role of anionic electrons in the electrochemical corrosion of Cu atoms. Our results are expected to provide a better understanding of catalytic properties of 1D electrides.
4:30PM U43.00009: Predicting 2D Materials with Machine Learning*  
GABRIEL SCHLEDER (Presenter), CARLOS MERA, Universidade Federal do ABC, ADALBERTO FAZZIO, Brazilian Nanotechnology National Laboratory — The increasing interest and research on two-dimensional materials has not yet translated into a reality of diverse materials applications. To go beyond graphene and transition metal dichalcogenides for several applications, candidates with desirable properties must be proposed. We use machine learning techniques to identify thermodynamically stable 2D materials, which is the first essential requirement for any application.

According to the formation energy and energy above the convex-hull, we classify materials as having low, medium, or high stability. The proposed approach enables the stability evaluation of novel 2D compounds for further investigation of promising candidates, using only composition properties and structural symmetry, without the need for information about atomic positions. We demonstrate the usefulness of the model generating more than a thousand novel compounds, corroborating with DFT calculations the classification for five of these materials. To illustrate the applicability we perform a screening of materials suitable for photoelectrocatalytic water splitting, identifying the potential candidate Sn$_2$SeTe generated by our model and PbTe, both not yet reported for this application.

4:42PM U43.00010: Predicting band alignments and structural interdependence in 2D hybrid organic inorganic halide lead perovskites from First-Principles Calculations*  
SAMPREETI BHATTACHARYA (Presenter), YOSUKE KANAI, Univ of NC - Chapel Hill — Authors: Sampreeti Bhattacharya, Yosuke Kanai

2D Hybrid organic inorganic perovskites (HOIP) have emerged as a promising class of materials for various optoelectronic and electronic devices. Using first-principles density functional theory calculations based on hybrid exchange-correlation functional with spin-orbit-coupling (SOC) and with van der Waals correction, we study structural and electronic/optical properties of these materials. We discuss the effects of spatial orientation of the organic layer (Phenyl ethyl ammonium- PEA) and of the inorganic layer on the band structure alignment. In particular, we will discuss the structural stability and the SOC induced band splitting and their interdependence at the molecular level.

4:54PM U43.00011: A tunable and unidirectional one-dimensional electronic system

\[
\text{Nb}_{2n+1}\text{Si}_n\text{Te}_{4n+2}
\]

ZHENG ZHU (Presenter), HAO ZHENG, JINFENG JIA, Shanghai Jiao Tong Univ — One dimensional (1D) electronic system is a versatile platform hosting novel physics, such as charge density wave, Su-Schrieffer-Heeger (SSH) topological state and solitons, Tomonaga-Luttinger Liquid etc. However, since real 1D materials do not exist in nature, quasi-1D structures in 3D crystals become a practical substitute. Here, we systemically study the surface electronic properties on layered composition-tunable compounds \(\text{Nb}_{2n+1}\text{Si}_n\text{Te}_{4n+2}\) (\(n=1\text{~}5\)), which is predicted to be a nodal-line semimetal when \(n=1\) (\(\text{Nb}_3\text{SiTe}_6\)). Via scanning tunneling microscopy/spectroscopy, we observe 1D chains spontaneous formed on the surface of the compounds. We uncover that with the increasing of \(n\), the distance between the chains becomes larger, and the 1D electronic state is developed in the compounds with \(n \geq 3\). Our first-principle calculations reveal that the nodal-line in \(\text{Nb}_3\text{SiTe}_6\) and the 1D electronic state in the crystals with higher \(n\) in fact arise from the same bands, which are protected by the same nonsymmorphic symmetry. Furthermore, we can understand the evolution of the electronic states based on a simple SSH type picture. Our experiment demonstrates the first tunable 1D electronic system, which offers a concrete platform for the exploration of intriguing 1D electron physics.

5:06PM U43.00012: An ab-initio study of structural, electronic, and bonding properties of layer-structured ZnSb

DINESH THAPA (Presenter), BIPIN LAMICHHANE, CHANDANI NANDADASA, Physics and Astronomy, Mississippi State University, JUNSEONG SONG, SUNG WNG KIM, Department of Energy Science, Sungkyunkwan University, SEONG-GON KIM, Physics and Astronomy, Mississippi State University — The orthorhombic structure of Zinc Antimonide (ZnSb) that belongs to the space group Pbca has been extensively studied because of its promising thermoelectric properties. It is of great interest to study the different phases of ZnSb in order to figure out the inherent possibilities of electronic properties. We performed ab initio total-energy calculations and geometry optimizations within Density Functional Theory (DFT) using the generalized gradient approximation (GGA) Perdew–Burke–Ernzerhof (PBE) functional and the projected augmented wave (PAW) method to investigate the structural, electronic, and bonding properties of tetragonal (P4/nmm) and wurzite (P63mc) phases of layer-structured ZnSb. We calculated the charge density, electron localization function (ELF), Bader charge analysis, density of states (DOS), and band Structures of these materials. The energy barrier between tetragonal and wurzite phases has been calculated using the climbing image Nudged Elastic Band (CI-NEB) method. The screened Heyd-Scuseria-Ernzerhof (HSE) hybrid functional within the PBE functional was also applied to improve the band gap and compared to the experiment.

5:18PM U43.00013: Unraveling the thermodynamic stability, catalytic activity and electronic structure of bimetallic clusters at realistic conditions*  SHIKHA SAINI (Presenter), SASWATA BHATTACHARYA, Department of Physics, Indian Institute of Technology Delhi — Cluster is considered as the prototypical system to gain a better understanding of active sites and the elementary steps of reaction mechanism at the atomistic level. Aiming toward catalytic applications, a large data set is generated on \([\text{TM}_x\text{Mg}_y\text{O}_z]^{+/0/-}\) clusters (TM = Cr, Fe, Co, Ni, \(x + y \leq 5\)) using a massively parallel cascade genetic algorithm (cGA) at the hybrid density functional level of theory. The low-energy isomers are further analyzed via \textit{ab initio} atomistic thermodynamics to estimate their free energy of formation at a realistic temperature \(T\) and partial pressure of oxygen \(p_O\). A thermodynamic phase diagram is drawn by minimizing the free energy of formation to identify the stable phases of \([\text{TM}_x\text{Mg}_y\text{O}_z]^{+/0/-}\) clusters. From this analysis, we notice that neutral and negatively charged clusters are stable in the wide range of \((T, p_O)\). The negatively charged clusters are more effective as a catalyst to lower the C–H bond activation barrier of methane. We find that the nature of TM atoms toward controlling the activation barrier is less important. However, TM gives rise to different structural motifs in the cluster, which may act as active centers for catalysis.

Session U44 DCOMP DMP: Electrons, Phonons, Electron Phonon Scattering, and Phononics VI  704 - Hans Braun, University of Bayreuth - Tag(s): Focus
2:30PM U44.00001: Phonons in van der Waals materials and heterostructures: New probes & novel applications [Invited]  ADITYA SOOD (Presenter), Stanford University — Van der Waals (vdW) layered 2D materials and heterostructures are exciting candidates for applications in electronics and photonics. Heat dissipation presents a significant bottleneck that limits device performance. What determines the intrinsic limits of thermal transport in vdW materials? How do phonons transmit at interfaces between individual 2D layers? Can we create active thermal devices by manipulating phonon scattering rates in real time? I will present experiments designed to answer these questions, using new probes such as spatially-resolved ultrafast microscopy, femtosecond electron diffraction, and picosecond X-ray diffraction. First, I will discuss measurements of the out-of-plane thermal conductivity in thin layered crystals. Contrary to what is generally expected, we uncover evidence of propagating phonons with long mean-free-paths spanning 100s of layers. Next, to break the coherence of these vibrational modes, we use electrochemical ion insertion and achieve large reversible modulation (~10x) of thermal conductance in a nm scale device. Such thermal transistors could have interesting applications for the dynamic routing of heat. Finally, I will discuss experiments designed to elucidate interfacial energy transport at 2D heterojunctions. By addressing basic questions about the role of vibrational mismatch, we create synthetic solids with ultralow thermal conductivity. Using a new femtosecond electron diffraction technique, we probe strong coupling between photoexcited electrons and lattice vibrations in a type-II heterostructure, and directly visualize energy transport across a single vdW junction.

I gratefully acknowledge collaborations with the groups of Ken Goodson, Eric Pop, Aaron Lindenberg, Yi Cui, & Tony Heinz (Stanford University), Archana Raja (Molecular Foundry), Davide Donadio (UC Davis) & Xijie Wang (SLAC), and funding from NSF, AFOSR & DOE.

3:06PM U44.00002: Ab Initio Electron-Defect Interactions Using Wannier Functions  I-TE LU (Presenter), JINSOO PARK, JIN-JIAN ZHOU, MARCO BERNARDI, Caltech — The interactions between electrons and crystallographic defects control electron scattering and transport at low temperature. Electron-defect (e-d) interactions and the associated matrix elements can be computed from first principles using density functional theory through a method we recently developed. However, relevant quantities such as the e-d relaxation times (RTs) and carrier mobility require integrals over very fine Brillouin zone grids. Since computing a large number of e-d matrix elements is expensive, convergence and accuracy at a reasonable computational cost are challenging to achieve. In this talk, we present a Wannier interpolation scheme for e-d matrix elements and apply it to example calculations of vacancy defects in semiconductors and metals. We discuss the accuracy and versatility of the interpolation scheme, which can correctly reproduce the matrix elements computed directly, and apply it to compute and systematically converge e-d RTs and defect-limited charge transport properties at low temperature. We outline how our Wannier interpolation scheme for e-d interactions can serve as a powerful ab initio tool for studying a wide range of low-temperature transport phenomena and e-d interactions in materials.
3:18PM U44.00003: Capturing non-perturbative electron-phonon effects in real materials using DMFT  ADAM DENCHFIELD (Presenter), HYOWON PARK, Physics, University of Illinois-Chicago, PETER B LITTLEWOOD, Condensed Matter Theory, Argonne National Laboratory — Dynamical Mean Field Theory (DMFT) can capture dynamical correlation effects on real materials by combining with Density Functional Theory (DFT) and solving the DMFT equation self-consistently within the multi-orbital Hubbard model extracted from DFT. Using a similar philosophy, we show that a multi-orbital Hubbard-Holstein model can be constructed from DFT electron-phonon calculations. We then derive an effective Hubbard model with a frequency-dependent electron-electron interaction $U(\omega)$ by integrating out the phonon degrees of freedom. This model can be solved using DMFT to capture the non-perturbative electron-phonon and electron-electron interaction effects. As a proof of the concept, we calculate phase diagrams of the two-orbital Hubbard-Holstein model as functions of the Coulomb interaction, the electron-phonon coupling, and temperature. We use Niobium to illustrate the process on a real material by obtaining model parameters from DFT, obtaining new insights on the effect of electron-phonon interactions in Niobium.

3:30PM U44.00004: Computation of Phonon-Mediated Resistivity in Sr2RuO4*  FELIX ANTOINE GOUDREAULT (Presenter), MICHEL COTE, Universite de Montreal, FELICIANO GIUSTINO, University of Texas at Austin, SAMUEL PONCE, University of Oxford — Because of its strong structural similarities to some high-Tc cuprates, Sr2RuO4 (SRO), a supposedly correlated superconductor, is attracting a lot of attention recently. Even though the discovery of superconductivity in SRO happened more than 20 years ago, the nature of the superconducting gap symmetry is still debated today. SRO also bears other unconventional properties like the strong anisotropy of the temperature dependence of its resistivity. Indeed, at low temperature, resistivity behaves like a highly anisotropic 3D Fermi-liquid, but low metallic transport has been reported for the in-plane resistivity at high temperature while the out-of-plane resistivity possesses a transition from metallic to incoherent transport mechanism around 130K which remains unexplained. In order to shed light on these phenomena, we carried out ab initio calculations to compute the electron-phonon coupling in SRO in the framework of density functional theory as implemented in the Quantum ESPRESSO software. Then, using the EPW code of the Quantum ESPRESSO suite, we report the temperature dependent phonon-mediated resistivity of SRO as computed from the Iterative Boltzmann Transport Equation scheme.

*We acknowledge the support of the NSERC, scholarships and grant No. RGPIN-2016-06666.
3:42PM U44.00005: Ab initio study of spin and momentum relaxation in Elliott-Yafet spin decoherence  JINSOO PARK (Presenter), JIN-JIAN ZHOU, MARCO BERNARDI, Caltech — In the Elliott-Yafet (EY) theory, spin decoherence near room temperature is mainly mediated by electron-phonon (e-ph) interactions. The conventional wisdom is that the EY spin and momentum relaxation times are directly proportional. This proportionality has been widely used to analyze spin relaxation mechanisms in many different materials, although it is justified only for simple model systems. Here, we use our recently developed first-principles method [1] to compute independently and analyze the e-ph spin-flip and momentum-scattering interactions. We reveal stark differences between the two, and show that the EY spin and momentum relaxation mechanisms are governed by distinct microscopic processes, both in simple materials such as silicon and diamond and in complex topological semimetals. We demonstrate that the widely used proportionality between EY spin and momentum relaxation times is inaccurate, and so is the Elliott approximation relating the two. Our results highlight the need for atomistic spin relaxation calculations that take into account the electronic wave function, spin texture, phonon modes and their mode-dependent spin-phonon interactions.

3:54PM U44.00006: Ab Initio Approach for Exciton Dynamics  HSIAO-YI CHEN (Presenter), MARCO BERNARDI, Caltech — We investigate exciton dynamics from first principles by combining our recently developed formalism to compute exciton-phonon (ex-ph) interactions with the Boltzmann transport equation (BTE) to simulate the exciton non-equilibrium dynamics. The computations are challenging – the ex-ph interactions require solving the finite-momentum Bethe Salpeter equation and density functional perturbation theory on fine Brillouin zone grids, and time-stepping the exciton BTE requires a parallel algorithm to explicitly time-step the exciton occupations. We apply our approach to transition metal dichalcogenides, focusing on the time scale for exciton valley decoherence and on exciton transport and relaxation. Our work provides a rigorous framework for computing exciton dynamics in materials from first principles, advancing the understanding of ultrafast excited state dynamics in materials.
4:06PM U44.00007: Phonon-limited carrier mobility in semiconductors: importance of the dynamical quadrupoles GUILLAUME BRUNIN, HENRIQUE MIRANDA, MATTEO GIANTOMASSI, Université catholique de Louvain, MIQUEL ROYO, MASSIMILIANO STENGEL, Institute of Materials Science, Autonomous University of Barcelona, XAVIER GONZE, GIAM-MARCO RIGNANESE (Presenter), GEOFFROY HAUTIER, Université catholique de Louvain — First-principles computations of phonon-limited carrier mobilities in semiconductors have recently gained popularity. Such calculations are indeed crucial for the discovery and development of new functional materials. In state-of-the-art approaches, Fourier-based interpolation schemes are used to obtain the electron-phonon matrix elements on the very dense wavevector grids needed to converge carrier lifetimes and mobilities. In polar semiconductors, the long-range electrostatic interactions lead to a divergence of the matrix elements, rendering their interpolation unstable. For this reason, *ab initio* methods have been recently developed to model the non-analytical behavior of the matrix elements for $q \to 0$ [1]. Most of the studies performed so far have focused on this Fröhlich divergence generated by dynamical dipoles. However, additional non-analytical terms are present in the $q \to 0$ limit [2]. In this work, we analyze the role played by the dynamical quadrupoles and show that an accurate interpolation is obtained only when both dipolar and quadrupolar fields are taken into account. We discuss their impact on the accuracy and on the convergence of carrier mobilities both in polar and non-polar semiconductors.

4:18PM U44.00008: First-principles charge transport including electron-two-phonon scattering processes NIEN-EN LEE (Presenter), JIN-JIAN ZHOU, HSIAO-YI CHEN, MARCO BERNARDI, Caltech — Predicting charge transport in materials from first principles is an open challenge. Although much progress has been made recently, nearly all work to date has relied on electron-phonon (e-ph) interactions obtained from lowest-order perturbation theory. However, in materials with polar bonds, the e-ph interactions are long-ranged, so assuming that higher-order e-ph processes are negligible is not justified. We recently investigated electron-two-phonon (e-2ph) scattering processes, and showed that these higher-order contributions are substantial even in a weakly polar material like GaAs [N.-E. Lee et. al., arxiv 1903.08261]. In this talk, we address the question of how the e-2ph processes affect transport. We derive a Boltzmann transport equation (BTE) that incorporates both one-phonon and two-phonon scattering, and solve it both within the relaxation time approximation and with an iterative approach (ITA). We compute the mobility in GaAs at 200-400 K, and show that the BTE-ITA with e-2ph processes gives a mobility in excellent agreement with experiments, resolving the known mobility overestimate in the BTE-ITA with one-phonon processes only. Future extensions to strongly polar materials will also be discussed.
4:30PM U44.00009: Ab Initio Study of Impurity and Defect Scattering of Electrons in Nb and Nb₃Sn

NATHAN SITARAMAN (Presenter), TOMAS ALBERTO ARIAS, Cornell University — This talk will present ab initio density functional theory results on the effect of defects and impurities in Nb and Nb₃Sn on electron mean free path at cryogenic temperatures. The mean free path is a key quantity of interest for scientists studying the properties of superconducting radiofrequency (SRF) cavities used in particle accelerators. Using a Wannier-function based approach, we calculate electron velocities and scattering lifetimes for dense samples of states near the complex Fermi surfaces of these materials. We compare the resulting mean free path estimates to experimental measurements, and present insights into the relative importance of different impurities and defects. We discuss other potential applications of the Wannier-function method to the study of impurities and defects, such as the calculation of inelastic scattering amplitudes.

*Funded by the Center for Bright Beams.

4:42PM U44.00010: Anharmonicity and Ultra-Low Thermal Conductivity in Lead-Free Halide Double Perovskites

JOHAN KLARBRING (Presenter), OLLE HELLMAN, IGOR ABRIKOSOV, SERGEI SIMAK, Linkoping University — The lead-free halide double perovskite class of materials offers a promising venue for resolving issues related to the presence of toxic Pb and long-term stability of the very intensively studied class of single lead halide single perovskites.

The single lead halide perovskites are well known to be very anharmonic materials. In particular, the atomistic dynamics relating to distortions and tilting of octahedral units and movement of the A site is highly complex. Anharmonicity in the lead-free halide double perovskites are comparatively much less studied.

In this talk I present our first-principles study of the lattice vibrations in Cs₂AgBiBr₆, the prototypical lead-free halide double perovskite, and show that it is very soft and highly anharmonic, in particular in regards to tilting of AgBr₆ and BiBr₆ octahedra and for motion along the Ag-Br-Bi bond. Using an energy and temperature dependent phonon spectral function derived from ab initio molecular dynamics we then show how the experimentally observed cubic-to-tetragonal phase transformation can be related to the collapse of a soft phonon branch. We finally reveal that the softness and anharmonic features of Cs₂AgBiBr₆ yield an ultra-low thermal conductivity with a non standard ~T⁻⁰.⁵ temperature dependence.
Interfacial thermal transport between large lattice mismatch materials enhanced by atomic defects

ZEXI LU (Presenter), PETR SUSHKO, AMRA PELES, ANNE CHAKA, Pacific Northwest National Laboratory — Control of interfacial thermal transport across complex interfaces is predicated on our ability to identify and (de-)couple contributions associated with low-dimensional interfacial features and structural and compositional inhomogeneities. In this study, we aim to reveal the relationship between interfacial thermal transport and defects, and establish its connection with underlying phonon-interfacial defect scattering mechanisms. We combine classical non-equilibrium molecular dynamics (MD) simulations with normal mode analysis (NMA) to investigate thermal transport across Cu/Si interface as a function of defect concentration in the interfacial region. We find that vacancies have a dramatic effect: interfacial thermal conductance increases by as much as 76% for the surface vacancy concentration of only 3%. NMA decomposition of the spectral phonon heat flux suggests that interfacial defects strongly affect inelastic phonon transmission. Our results establish relationships among the distribution of near interface defects, the extent of intermixing, thermal conductance and phonon scattering.

Session U45 DCOMP GSNP: Computational Methods for Statistical Mechanics: Advances and Applications III 706 - Ying Wai Li, Los Alamos National Laboratory

- Tag(s): Focus
2:30PM U45.00001: Clusters and Surfaces in Reactive Atmospheres at Realistic Conditions: Beyond the Static, Monostructure Description [Invited] LUCA GHIRINGHELLI (Presenter), Fritz-Haber Institute — The processes occurring at surfaces play a critical role in the manufacture and performance of advanced materials, e.g., electronic, magnetic, and optical devices, sensors, and catalysts. A prerequisite for analyzing and understanding the electronic properties and the function of surfaces is detailed knowledge of the atomic structure, i.e., the surface composition and geometry under realistic gas-phase conditions. The key quantity for studying the structure and function of surfaces/clusters in reactive atmospheres is the Gibbs free energy, as function of number of particles, pressure, and temperature. Here, I present a set of methods for the sampling of the configurational space of (nano)clusters and surfaces in reactive (e.g., O2, H2) atmosphere, in the canonical and grand-canonical ensembles, aiming at the unbiased determination of the phase diagrams as function of temperature and partial pressure of the reactive gas. A common trait of the analysis of the different systems is the description of ensembles of structures as function of environmental variables, i.e., the identification of the invariant, permanent features, within the "noise" of continuously transforming ones. Applications to gold and metal-oxide nanoclusters, and silicon surfaces, described with first-principles potential-energy surfaces, will demonstrate the insight gained by the direct access to observables at finite temperature and pressure.

3:06PM U45.00002: Langevin dynamics for linear scaling quantum Monte Carlo [Invited] KIPTON BARROS (Presenter), Los Alamos Natl Lab, BENJAMIN COHEN-STEAD, Physics, UC Davis, GEORGE BATROUNI, Université Côte d'Azur, CNRS, RICHARD THEODORE SCALETTAR, Physics, UC Davis — We discuss recent advances in quantum Monte Carlo (QMC) sampling for models of interacting electrons. A shortcoming of traditional determinant QMC is its cubic scaling with system size. The alternative Langevin approach offers, in principle, linear scaling. With some new tricks, the Langevin method can be very competitive with determinant QMC. Applications to the Holstein model of electron-phonon interactions will be presented.

*Support was provided by the LANL LDRD program and the DOE/BES COMSCOPE project.
3:18PM U45.00003: Assessing the Quality of Approximate Quantum Dynamics in Condensed Phase via Sum Rules*  LISANDRO HERNANDEZ DE LA PENA (Presenter), Kettering University — In this work, we discuss a general protocol for analyzing the quality of approximate quantum time correlation functions of non-trivial systems in many dimensions. This approach is based on the generalized deconvolution of the Kubo transformed quantum time correlation function onto an ensemble averaged quantum correlation function, at a given value $\tau$ in imaginary time ($0 \leq \tau \leq \beta$), which leads to a series of sum rules linking derivatives of different order in the corresponding pair of convoluted correlation functions. We focus on the case when $\tau = \beta/2$ for which all deconvolution kernels become real valued functions and their asymptotic behavior at long times exhibit a polynomial divergence. It is then shown that thermally symmetrized static averages, and the static averages of the corresponding time derivatives, are ideally suited to investigate the quality of approximate quantum time correlation functions at successively larger, and up to arbitrarily long, times. This overall strategy is illustrated analytically for a harmonic system, and numerically for a multidimensional double-well potential and a Lennard-Jones fluid representing liquid neon at 30 K.

* Kettering University

3:30PM U45.00004: Ground State Properties of the Diluted Sherrington-Kirkpatrick Spin Glass  STEFAN BOETTCHER (Presenter), Physics, Emory University — In a numerical study of dilute versions of the Sherrington-Kirkpatrick mean-field spin glass at temperature $T=0$, we approximate the energies of ground states of ensembles at variable dilution with high accuracy using the Extremal Optimization heuristic [1,2]. We find that the scaling properties of such systems possess exponents that are parametrized by the degree of dilution [3,4]. This is a surprising result, as one would not expect that gradual bond-dilution would continuously change the universality class of a statistical model. (There is no evidence of a percolation transition separating a trivially disconnected regime from a percolation regime, as one might expect.) It may open the door to a perturbative study of finite-size corrections in replica symmetry breaking.

Evidence of Information Limitations in Bottom-Up Coarse-Graining Models

ADITI KHOT (Presenter), STEPHEN SHIRING, BRETT SAVOIE, Purdue Univ — Chemically specific coarse-grained (CG) models exhibit simplified configurational phase spaces and hence, can potentially capture processes that occur on time and length scales that are too costly for direct atomistic simulation. However, there are fundamental and practical problems associated with coarse-graining, such as the incomplete understanding of CG errors in comparison with atomistic simulations, the lack of transferability of typical CG models to new chemistries, and the costly bespoke approach to developing new CG models from scratch. In this talk, I will present recent results on an automated methodology to parameterize CG models from quantum chemistry calculations. Using the throughput of this methodology, we have systematically characterized the sources of error in common bottom-up parameterization methods as a function of dimension reduction for over 50 independently trained CG models. We find clear evidence that these models are systematically information limited, rather than representability limited, which suggests further improvement is obtainable without resorting to more complex functional forms. Additional implications of these findings, as well as the conditions under which representability related errors arise will also be discussed.

Hilbert Entropy for the Simple and Precise Measurement of Complexity of Two or Higher Dimensional Arrays*

SEOK JOON KWON (Presenter), KIST — Measuring complexity of higher dimensional arrays has been an important way of quantifying information. For the measurement of complexity of 1D vectors, there are a variety of methods of calculating entropies such as sample, permutation, or Lempel-Ziv entropy. Unfortunately, for higher dimensional arrays, it is not possible to employ these entropies. This is due mainly to the information loss in the course of dimension reduction. To address this problem, we introduce space-filling curve (SFC)-based approach. Thanks to the fact that SFC allows information loss-free dimension reduction, we successfully measured complexity by calculating sample entropy of higher dimensional arrays. We found that developed algorithm precisely measured the complexity of higher dimensional arrays as well as detected the critical points in the cases of various phase transition experiments. We also observed that the developed algorithm (Hilbert entropy) can measure scale-invariance and fractal dimension of higher dimensional arrays. We proved that the Hilbert entropy for higher dimensional arrays exhibits power law dependence for arrays with self-similarity.

4:06PM U45.00007: Computation of correlation functions and various statistical quantities of different types of Random Matrix Ensembles  KAZI ALAM (Presenter), SWAPNIL YADAV, KHANDKER A MUTTALIB, University of Florida — We propose a method to compute correlation functions for biorthogonal random matrix ensembles with arbitrary confining potential, by inverting the associated Hankel moment-matrix. We show that using this method it is possible to calculate eigenvalue density, two-point correlation functions, gap functions and other statistical quantities of interest for a wide class of log-gas models. The method allows one to calculate such statistical quantities numerically without evaluating the relevant polynomials or generating explicit matrices. We reproduce standard results for a variety of well-known ensembles and show some new results for Muttalib-Borodin ensembles for which analytic or numerical results have not yet been obtained.

4:18PM U45.00008: A Parameter Free Genetic Algorithm for Estimating the Dynamic Structure Factor at Zero and Finite Temperature*  NATHAN NICHOLS (Presenter), ADRIAN DEL MAESTRO, University of Vermont, TIMOTHY PRISK, National Institute of Standards and Technology, GARFIELD T WARREN, PAUL E SOKOL, Indiana University Bloomington — We report on a self adaptive Differential Evolution for Analytic Continuation (DEAC) algorithm that can be used to reconstruct the dynamic structure factor from imaginary time density-density correlations. Our approach to this long-standing problem in quantum many-body physics achieves improved resolution of spectral features over earlier methods based on genetic algorithms. The need for fine-tuning of algorithmic control parameters is reduced by embedding them within the genome to be optimized. Benchmarks are presented for models where the dynamic structure factor is known exactly and we report new results for quantum Monte Carlo simulations of confined superfluid helium at low temperatures.

*This work was supported by the NSF through grants DMR-1809027 and DMR-1808440. Simulations performed on the Vermont Advanced Computing Core were partially supported by NSF grant OAC-1827314.

4:30PM U45.00009: Study of strongly correlated materials at finite temperature with density matrix embedding theory*  CHONG SUN (Presenter), GARNET CHAN, Caltech — Density matrix embedding theory (DMET) is a wavefunction-in-wavefuction embedding scheme, aimed at describing the ground state of large strongly correlated systems. In this talk, the finite temperature extension of ground state DMET, i.e., FT-DMET, is introduced. We show its performance in both model systems such as 2D Hubbard model and realistic materials such as the hydrogen chain and transition metal oxides. The thermal averages of physical observables such as energy are calculated. The Néel transition is also studied and the Néel temperature is approximated for both 2D Hubbard model and transition metal oxides.

Two-dimensional translation-invariant probability distributions: approximations, characterizations and no-go theorems  

4:42PM U45.00010: Two-dimensional translation-invariant probability distributions: approximations, characterizations and no-go theorems  
ZIZHU WANG (Presenter), University of Electronic Science and Technology of China, MIGUEL NAVASCUÉS, Institute of Quantum Optics and Quantum Information - Vienna, Austrian Academy of Sciences — We study the properties of the set of marginal distributions of infinite translation-invariant systems in the 2D square lattice. In cases where the local variables can only take a small number $d$ of possible values, we completely solve the marginal or membership problem for nearest-neighbors distributions ($d=2,3$) and nearest and next-to-nearest neighbors distributions ($d=2$). All these sets form convex polytopes in probability space. This allows us to devise an algorithm to compute the minimum energy per site of any TI Hamiltonian in these scenarios exactly. We also devise a simple algorithm to approximate the minimum energy per site up to arbitrary accuracy for the cases not covered. For variables of a higher (but finite) dimensionality, we prove two no-go results. The exact computation of the energy per site of arbitrary TI Hamiltonians with only nearest-neighbor interactions is undecidable. In addition, in scenarios with $d\geq 2947$, the boundary of the set of nearest-neighbor marginal distributions contains both flat and smoothly curved surfaces and the set itself is not semi-algebraic. This implies, in particular, that it cannot be characterized via semidefinite programming, even if we allow the input of the program to include polynomials of nearest-neighbor probabilities.

Stars & Bars: A Compact Representation for Bosonic Occupation States

4:54PM U45.00011: Stars & Bars: A Compact Representation for Bosonic Occupation States*  
CALEB USADI (Presenter), HATEM BARGHATHI, ADRIAN DEL MAESTRO, Univ of Vermont — An efficient representation of bosonic occupation states is a critical tool for the exact diagonalization of bosonic Hamiltonians. The memory demands of the traditional method of representing such systems, as lexicographically ordered arrays of integers, increases rapidly as system size grows, limiting current studies to approximately 16 particles at unit filling. Representing basis vectors using the combinatoric stars and bars method allows each basis state to be stored as a single 64 bit integer. This optimally compact representation will enable the analysis of new properties of larger bosonic Hamiltonians, including accessible entanglement, which may be useful in evaluating many-body phases as potential candidate quantum resource states.

**5:06PM U45.00012: Telediagnostics of Heterogeneous Plasma properties of combustion products according to the characteristics of its braking radiation.** MYKOLA POTOMKIN (Presenter), Taras Shevchenko National University of Kyiv, VOLODYMYR MARENKOV, Odessa I.I. Mechnikov National University — An important applied aspect of the statistical theory of electronic properties of heterogeneous plasma (HP) formations for determining the amplitude-frequency intensity of its braking radiation is considered. New physical model for braking radiation of HP formations, based on the statistical approach of quasi-neutral cell for the description of electron-ion processes in the HP formations is proposed. Stochastic motion of charged plasma particles is presented in sequence of stages of anharmonic oscillations in effective electrostatic field of cells perturbed by particle displacements relative to the electrical centers of the cells of quasi-neutrality in HP formations.

The integral power of the braking radiation of HP formations in the radio band is determined in the approximation of chaotic phases using the statistical distribution of the individual cells of HP formations by correlation energy. Results of computer simulation in comparison to full-scale experiment for plasma model combustion products of the fuel, based on aluminum powder are presented.

The problems of telediagnoistics of the HP formations with cylindrical nanoparticles of condensed dispersed phase and contribution of its rotational modes to the integral intensity of the braking radiation are discussed.

**5:18PM U45.00013: Bosonic entanglement crossover from groundstate scaling to volume laws** * QIANG MIAO (Presenter), THOMAS BARTHEL, Duke University — The crossover behavior of eigenstate entanglement entropies from an area law or log-area law for low energies and small subsystem sizes to volume laws for high energies and large subsystems can be described by scaling functions. We demonstrate this for two bosonic systems. The harmonic lattice model describes a system of coupled harmonic oscillators and is a lattice regularization for free scalar field theories. For dimensions $d \geq 2$, the ground state of this model displays an entanglement area law, even at criticality, because excitation energies vanish only at a single point in momentum space. In contrast, Bose metals feature a finite Bose surface with zero excitation energy. One hence finds log-area laws for the groundstate entanglement. For both models, we sample excited states. The distributions of their entanglement entropies are sharply peaked around subsystem entropies of corresponding thermodynamic ensembles in accordance with the eigenstate thermalization hypothesis. In this way, we determine the scaling functions numerically. Eigenstates for quasi-free bosonic systems are not Gaussian. We resolve this problem by considering appropriate squeezed states instead, for which entanglement entropies can be evaluated efficiently.

2:30PM U46.00001: Application of machine learning to frustrated magnets [Invited]  ANJANA SAMARAKOON (Presenter), DAVID TENNANT, Oak Ridge National Lab — Understanding complex phases in materials showing glassy, or highly correlated liquid states is extremely challenging. Conventional simulation approaches struggle to deal with the need to account for multiple and competing interactions, as well as relate models and data together. At the heart of the problem is the difficulty in extracting accurate models from experimental data. Further, the scale and complexity of data, such as from neutron scattering on frustrated magnets, has made any form of quantitative analysis very demanding. By training neural nets over large numbers of models, machine learning techniques discriminate between different models and identify different physical regimes including formation of spin liquids and unusual broken symmetries. The neural nets can for example learn diffuse scattering directly in three-dimensional reciprocal space and can extract the most relevant information, denoise, and remove background by projecting the experimental neutron data on a finite dimensional space that is determined by an autoencoder. Machine learning outputs the potential models, quantifies their uncertainty and identifies and classifies different regimes that could be reached by modifying or applying external forces/fields to the material under consideration. This approach is shown to provide better understanding of the formation of a glass on cooling the spin liquid Dy2Ti2O7, quantum spin liquids on honeycomb lattices, and understanding the interactions and phases in RuCl3. Examples of them as well as powder scattering data are shown.

3:06PM U46.00002: Spin dynamics in stoichiometric Ho2Ti2O7 probed by neutrons in the time domain and magnetometry in the frequency domain*  YISHU WANG (Presenter), TIMOTHY REEDER, JONAS KINDERVATER, Johns Hopkins University, YOSHITOMO KARAKI, University of the Ryukyus, NICHOLAS MALISZEWSKYJ, SERGIY GLADCHENKO, National Institute of Standards and Technology, SEYED KOOHPAYEH, Johns Hopkins University, SATORU NAKATSUJI, University of Tokyo, COLLIN LESLIE BROHOLM, Johns Hopkins University — We describe an experimental investigation of classical spin ice dynamics in a new class of high quality Ho2Ti2O7 single crystals. Employing a pump-probe method with microsecond time resolution, we have tracked neutrons diffracted from the (002) pinch point in response to an Oe range step changes in field applied along <110>. The relaxation time rises acutely from 10ms to over 10 ks upon cooling from 1.3K to 0.6K. Similar characteristic timescales were obtained from SQUID-based AC susceptibility measurements down to 1mHz on similar crystals. There are major quantitative differences between the present result and previously published works that we ascribe to our ultra-pure crystals. In addition, our simultaneous study of the Fourier-transform-related responses in time and frequency allows detailed mathematical scrutiny of the non-Debye relaxation process in spin ice.

3:18PM U46.00003: Frequency Dependent Susceptibility Measurements of Dilute Spin Ice.*
SEAN GIBLIN (Presenter), DAVID BILLINGTON, EDWARD RIORDAN, School of Physics and Astronomy, Cardiff University, ELSA LHOTEL, CARLEY PAULSEN, CNRS, Grenoble, STEVEN BRAMWELL, UCL — We have recently demonstrated in the classical spin ice materials Dy2Ti2O7 and Ho2Ti2O7 that the magnetic relaxation below the spin freezing transition is dominated by nuclear assisted tunnelling. Indeed, this is likely a mechanism for monopole separation and dynamics under an applied potential at temperature below ~0.65K. Given this surprising result, we have simplified the system further to isolate possible dynamical processes driven by the nuclear moments. We have considered samples with non-magnetic ion dilution, namely HoₓY₂₋ₓTiO₇ at the 1 and 0.25% level. We have investigated the samples as a function of frequency up 5 MHz and see clear evidence of evolving single ion dynamics within distinct frequency response time windows strongly suggesting other mechanisms of spin dynamics in the dilute spin ice system. The properties of these dynamics will be explained in detail.

3:30PM U46.00004: Fluence Dependent Modification of Spin Ice Physics in Ho₂Ti₂O₇ Thin Films* KEVIN BARRY, Florida State Univ, NAWEEN ANAND, YAN XIN, National High Magnetic Field Laboratory, JENNIFER NEU, THEO SIEGRIST, CHRISTIANNE BEEKMAN (Presenter), Florida State Univ — We investigate the effects of strain, substrate orientation, and disorder on spin ice physics in Ho₂Ti₂O₇ thin films grown on yttria-stabilized-zirconia substrates via pulsed laser deposition. Regardless of growth orientation, all films exhibit an inflated unit cell that is larger than the one previously identified for bulk. Transmission electron microscopy has revealed the presence of anti-disorder and growth defects within the films, with the (110) oriented films showing the least number of defects. Magnetization measurements show the expected anisotropy and saturation values associated with spin ice physics. Interestingly, only the (110) oriented films show the hallmark spin ice plateau in magnetization, and the strength of this plateau shows a clear trend with the laser fluence used during growth. This study demonstrates the importance of disorder in the modification of spin ice physics in thin films.

JN and TS acknowledge support from NSF/DMR-1606952.
Spin ice compounds are exemplar frustrated magnetic systems that realize a classical spin liquid phase at low temperature described by an emergent gauge field with fractionalized magnetic monopole excitations. This emergent gauge structure manifests in polarized neutron scattering experiments as the characteristic pinch point singularities which have been clearly observed in the spin-flip (SF) channel. On the other hand, the non-spin-flip (NSF) channel generally lacks such striking features. In fact, within an extended model of spin ice, the NSF channel is found to be completely dispersionless, and we explore this utilizing both Monte Carlo and Large-N techniques. At the level of the Large-N approximation, this flatness is inherited directly from the flat bands of the adjacency matrix, and the temperature-dependent intensity of the featureless NSF channel is inversely proportional to the stiffness of the emergent gauge fields. We show how the SF and NSF channels can be understood as direct probes of the emergent gauge field correlations and explore the implications of this finding. This work lays the groundwork for a deeper understanding of NSF scattering in spin ice compounds, and could potentially lead to new experimental insights.
3:54PM U46.00006: Anomalous magnetic behaviour of the mixed b-site pyrochlore

Dy$_2$ScNbO$_7^*$

MEGAN RUTHERFORD (Presenter), McMaster Univ, COLE D MAUWS, Chemistry, University of Manitoba, ADAM ACZEL, Oakridge National Lab, JAMES W BEARE, GRAEME LUKE, CASEY MARJERRISON, McMaster Univ, SARA HARAVIFARD, Duke University, HAIDONG ZHOU, University of Knoxville, Tennessee, CHRISTOPHER WIEBE, The University of Winnipeg — The spin ice state, a magnetic ground state exhibiting Pauling entropy analogous to water ice, has been well characterized in the rare-earth pyrochlores Dy$_2$Ti$_2$O$_7$, and Dy$_2$Sn$_2$O$_7$. To explore the response of the spin ice state to non-magnetic perturbation in dysprosium based pyrochlores, we present here a new species Dy$_2$ScNbO$_7$, which we have synthesized as both powder and single crystal. Our physical characterization has shown unexpected behaviour arising from the disordered b-site, with increased spin dynamics and an anomalously low spin-freezing temperature. We performed heat capacity measurements with an applied magnetic field along the [111] direction, notable in pyrochlores for its alternating Kagomé-Triangular layers, and the [110] direction, a bond direction between magnetic species. The phase diagrams we have constructed from these measurements and other recent physical characterization results show a divergence from spin ice behaviour but recent neutron scattering data lead us to believe that the novel physics in our system is not entirely due to the disordered B-site. We will present these results to this meeting for discussion.

4:06PM U46.00007: Long-range Coulomb interactions and nonhydrodynamic behavior in thermal quenches in spin ice*

OLIVER HART (Presenter), MARIANNE HAROCHE, CLAUDIO CASTELNOVO, University of Cambridge — When spin ice systems undergo a sudden thermal quench, they have been shown to enter long-lived metastable states where the monopole excitations form so-called noncontractible pairs [Phys. Rev. Lett. 104, 107201 (2010)]. While the nature of these states is well understood, the dynamical mechanisms underpinning their formation remain largely unexplored. We find that the long-range tail of the Coulomb interactions between monopoles plays a central role by suppressing the monopole-assisted decay of noncontractible pairs with respect to monopole–antimonopole annihilation. The existence of a transient, nonhydrodynamic regime allows the system to enter a metastable state whose lifetime can easily be astronomically large at low temperatures. We demonstrate this using Monte Carlo simulations and mean field population dynamics theory, and we provide an analytical understanding of the mechanisms at play. We derive the finite size scaling behavior of the density of noncontractible pairs in the plateau for both short- and long-range interactions and discuss the experimental implications of our results.

4:18PM U46.00008: Peering into the darkness: vison-generated photon mass in quantum spin ice

MICHAL KWASIGROCH (Presenter), London Centre for Nanotechnology, University College London — Describing experimenetal signatures of quantum spin ice has been the focus of many theoretical efforts, as its definitive experimental verification is yet to be achieved. Gapped excitations known as visons have largely eluded those efforts. We provide a theoretical framework, which captures their dynamics and predicts new experimental signatures in the magnetic response. We achieve this by studying the ring-exchange Hamiltonian of quantum spin ice in the large-s approximation, taking into account the compact nature of the emergent U(1) gauge theory. We find the stationary solutions of the action - the instantons - which correspond to visons tunneling between lattice sites. By integrating out the instantons, we calculate the effective vison Hamiltonian, including their mass. We show that in the ground state virtual vison pairs simply renormalise the speed of light. At low temperatures, however, thermally activated visons form a Debye plasma and introduce a mass gap in the photon spectrum, equal to the plasma frequency, which we calculate as a function of temperature. We demonstrate that this dynamical mass gap should be visible in energy-resolved neutron scattering spectra but not in the energy-integrated ones. We show that it does not lead to confinement of static spinons.

4:30PM U46.00009: Broadband Spectroscopy of Magnetic Monopole Noise in Artificial Spin Ice

MATEUSZ GORYCA (Presenter), CRISTIANO NISOLI, Los Alamos National Laboratory, XIAOYU ZHANG, Yale University, CRIS LEIGHTON, University of Minnesota, JING LI, ANDREW L BALK, Los Alamos National Laboratory, PETER E SCHIFFER, Yale University, SCOTT CROOKER, Los Alamos National Laboratory — Arrays of lithographically-patterned interacting nanomagnets known as Artificial Spin Ice (ASI) have allowed the design of geometrically-frustrated collective states not found in natural magnets, as well as the ability to characterize the magnetic state at the level of the individual elements. Particularly for thermally-active ASIs, real-time studies of magnetization dynamics over a wide frequency range are highly desirable to reveal the underlying dynamics and to test theoretical models of the kinetics. Here we present an all-optical method to study the spontaneous magnetization fluctuations in ASIs over a broad frequency range (1 Hz - 1 MHz), which allows us to investigate magnetization dynamics through temperature- and field-dependent phase transitions. We focus first on the simple case of thermally-active square ASIs (using ~3 nm thick permalloy), to develop and benchmark tools for future investigations of more complex topologies. The field- and temperature-dependent total activity of the material follows theoretical models describing the creation, annihilation, and motion of ‘magnetic monopoles’ in the square ASI lattice. However, more subtle quantities such as correlation/relaxation rates deviate from widely-accepted theoretical paradigms.
4:42PM U46.00010: New Vertex Type to Study Phase Transition in Artificial Spin Ices  ALI FROTANPOUR (Presenter), Physics Department, University of Kentucky — Artificial spin ices are frustrated magnetic nanostructures constructed based on single domain segments [1]. A new type of vertex with five segments is engineered to generate eight degenerate ground states. The vertex is like the square ice vertex but one the segments split into two parallel segments creating a magnetic quadrupole. The distance between the parallel segments \(d\) determines ground state configuration. Micromagnetic simulation, OOMMF has been used to sweep \(d\), and the results show that eight configurations have the same energy at a specific distance, \(d_0\). A two-atom rectangular lattice has been made using this vertex. Stimulated annealing with Monte Carlo assistance along with magnetic field sweeping has been performed looking for phase transition behaviour of the lattice (Different antiferroquadrupolar and ferroquadrupolar ordering [2]).

4:54PM U46.00011: Hall Responses in Larger Spin Quantum Magnets* [Invited] JUDIT ROMHANYI (Presenter), University of California, Irvine, KARLO PENC, Wigner Research Centre, Budapest — Phenomena related to nontrivial band topology and transverse transports have recently gained enormous interest. Including spin degrees of freedom, a new branch of Hall responses has been proposed and observed. The concept of (anomalous/spin) Hall and (anomalous/spin) Nernst effects spread quickly from the electronic systems to magnetic excitations, leading to magnon-mediated Hall responses [1-7].

We consider magnetic insulators characterized by a larger spin and therefore by spin-multipolar degrees of freedom. We investigate the topology of the multipolar excitations and discuss the spin Nernst and thermal Hall effects arising for the nontrivial magnon modes.

Furthermore, we address the multipole character of the nontrivial bands with focus on possible new experimental detection of nontrivial magnon-band topology due to these additional degrees of freedom.

2:30PM U47.00001: The Case for Octupolar Order in Cubic 5d2 Double Perovskites* [Invited]
BRUCE D. GAULIN (Presenter), McMaster Univ — We have carried out neutron spectroscopic and diffraction studies on powder samples of the cubic 5d2 family of double perovskites, Ba2ZnOsO6, Ba2MgOsO6, and Ba2CaOsO6. These materials all display thermodynamic phase transitions at T*=30 K, 49 K, and 50 K, respectively, where ~ R ln(2) in entropy is released on passing through T*. All three display Curie-Weiss susceptibilities with antiferromagnetic Curie-Weiss constants of ~ -150 K, and show oscillations in low temperature zero longitudinal μSR, indicating time reversal symmetry breaking. Our inelastic neutron scattering shows the development of a gapped spin excitation spectrum, where a gap of ~ 15 meV develops below T*. This spectral weight is centred at wavevectors typical of type I AF order, however no magnetic Bragg diffraction is observed at low temperatures. Our neutron powder diffraction measurements place an upper limit on any possible ordered dipole moment of ~ 0.1 μB. To understand these results, we introduce a model for orbital repulsion between the two 5d electrons in Os6+ in these materials. This results in a non-Kramer's doublet and excited triplet of states for the ion, and ferro-octupolar order below T*, consistent with the full set of experimental observations. We believe this likely constitutes the first compelling case for octupolar order in a d-orbital Mott insulators.

*This work was funded by NSERC of Canada. It employed neutron scattering facilities at the Spallation Neutron Source of Oak Ridge National Laboratory and the Institut Laue Langevin, as well as synchrtron x-ray diffraction facilities at ALBA.

3:06PM U47.00002: Octupolar order in d-orbital Mott insulators.* ARUN PARAMEKANTI (Presenter), Univ of Toronto, DALINI D MAHARAJ, BRUCE D. GAULIN, Physics, McMaster University — We discuss the quantum magnetism of J = 2 ions which can be realized in spin-orbit coupled oxides with 5d2 transition metal ions. We discuss a microscopic mechanism where the combination of orbital repulsion and antiferromagnetic spin interactions leads to ferro-octupolar coupling, potentially stabilizing ferro-octupolar order. We discuss experimental signatures of octupolar order. We uncover a a gapped and dispersive magnetic exciton in the ferro-octupolar state using a slave-boson approach, which can be observed in neutron scattering. For sufficiently strong magnetic exchange, this dispersive exciton can condense, leading to conventional type-I antiferromagnetic order which can coexist with or even preempt octupolar order. Our proposal for ferrooctupolar order provides a comprehensive understanding of thermodynamics, μSR, X-ray diffraction, and inelastic neutron scattering measurements on a range of cubic 5d2 double perovskite materials including Ba2ZnOsO6, Ba2CaOsO6, and Ba2MgOsO6. Our proposal for exciton condensation leading to type-I magnetic ordering is potentially relevant to materials such as Sr2MgOsO6.

3:18PM U47.00003: Neutron scattering study of magnetic excitation in spinel structure spin-orbital coupling compound CuGa2O4  ZHIJUN XU (Presenter), NIST and University of Maryland, GUANGYONG XU, NIST, AASHISH SAPKOTA, Brookhaven national lab, YIMIN QIU, NIST, GENDA GU, JOHN TRANQUADA, Brookhaven national lab — We report neutron scattering measurements on a single crystal CuGa2O4 sample. The spinel structure of CuGa2O4 can cause strong spin-orbit coupling in this compound. From DC susceptibility and elastic neutron measurements, we found no sign of long- or short-range magnetic order down to 0.1K. Measurements on low energy magnetic excitations show ring shape intensity distribution in momentum space from this sample at low temperature. With increasing temperature, the magnetic excitation intensity gradually goes away.

3:30PM U47.00004: d-Orbital Occupancy Systematics of 4d/5d Row Transition Metal Oxides by X-Ray Absorption Near Edge Spectra (XANES)*  ERIC KURYWCZAK (Presenter), MEHMET ALPER SAHINER, Physics, Seton Hall University, MARK CLYDE CROFT, Physics, Rutgers University — XANES L₂ and L₃ edge X-Ray Absorption Near Edge Spectra (XANES) for 4d and 5d row transition metals (TM) oxides are assumed to be directly reflecting unoccupied d-orbitals influenced by the local symmetry of the metal ion¹. XANES L₂ and L₃ edge data analysis through non-linear curve fitting allows for a unique, efficient look at the structural eccentricities of transition metal oxides. In this way it is possible to determine the oxidation state of a material as well as its site symmetry. We have used non-linear least-squares fitting across the near-edge region of the various 4d row and 5d row TM oxides in order to investigate the systematics of the d-orbital occupancy and the XANES white line features for t²g and e₈ symmetry orbitals. The statistics have already shown promising trends to be expected in 4d and 5d row level transition metal oxides. The systematics obtained by these results provide crucial information for the synthesis of the new materials with specific electronic structures and crystal symmetries.

3:42PM U47.00005: From multipolar to spin-lattice disordered states in Mott insulators [Invited]  GEORGE JACKELI (Presenter), Max Planck Institute for Solid State Research, Stuttgart, Germany — We theoretically explore how in the Mott insulating compounds the spin-orbit coupling could give rise to unusual disordered (glass or liquid) states of spin-orbital or spin-lattice degrees of freedom depending on the local d-electron counting. We discuss d¹ and d² transition metal compounds, such as molybdenum oxides with fcc and pyrochlore lattices, as candidate materials and consider experimental results from this perspective.
**4:18PM U47.00006: Observation of Spin Glassy Behavior in Sr$_3$(Ru$_{0.64}$Mn$_{0.36}$)$_2$O$_7$**

ROSHAN NEPAL (Presenter), LINGYI XING, RONGYING JIN, Louisiana State University, Baton Rouge — One of the most accessible knobs to tune the ground state properties of a material system is chemical doping. Double-layered Ruddlesden-Popper ruthenate Sr$_3$Ru$_2$O$_7$ is known to respond dramatically to the substitution of Ru by Mn leading to a rich phase diagram. We report the magnetic properties of 36% Mn doped single-crystalline Sr$_3$(Ru$_{1-x}$Mn$_x$)$_2$O$_7$ (x = 0.36). The temperature dependence of the zero-field cooled magnetic susceptibility shows a significant downturn akin to the collective freezing of the spins below a freezing temperature $T_f$, which is suppressed by the applied magnetic field. The onset of the spin freezing is accompanied by the development of large magnetic memory, magnetic relaxation, and exchange bias effects, which suggests Sr$_3$(Ru$_{0.64}$Mn$_{0.36}$)$_2$O$_7$ has the spin glass (SG) ground state. Further analysis reveals the presence of de Almeida-Thouless phase line separating the high temperature paramagnetic (PM) and low temperature SG phases with $T_{SG} \sim 32$ K. The nature of the SG state and its implication will be discussed.

**4:30PM U47.00007: A muSR study of current-induced destruction of order in Ca$_2$RuO$_4**

MATTHEW NUGENT (Presenter), GRAEME LUKE, JAMES W BEARE, McMaster Univ, MARKUS BRADEN, KEVIN JENNI, University of Cologne, SUDARSHAN SHARMA, MEGAN RUTHERFORD, McMaster Univ, QI SHENG, Columbia University — Past work has shown that Ca$_2$RuO$_4$ is a Mott insulator, but can be switched to a semimetallic state with the application of a reasonable amount of current. The material is an antiferromagnet below 113K in the insulating state, but achieving the semimetallic state causes a destruction of order, instead giving a diamagnetic response [1]. For this muSR study on the material, we used a 1% Ti doped Ca$_2$RuO$_4$ sample, which provided improved structural stability without significantly impacting magnetic ordering temperature [1]. We measured the sample under 0mA, 30mA, and 100mA of current, demonstrating both the presence of an antiferromagnetic ordering and its destruction in the semimetallic state when a current is applied down to 15K.

4:42PM U47.00008: Electronic and magnetic properties in barium iridium oxides*  Xiang Chen (Presenter), Dongsheng Yuan, Edith Bourret-Courchesne, Lawrence Berkeley National Laboratory, Robert J Birgeneau, University of California, Berkeley — The strongly spin orbit coupled Jeff = 1/2 spin residing on various lattice motifs are promising playgrounds for realizing assorted unusual ground states, such as Kitaev quantum spin liquid in frustrated Kagome lattice, proximity to unconventional superconducting state in layered square lattice. The recently proposed exotic quantum liquid state in facing sharing spin chain Ba4Ir3O10 might offer another platform for novel frustration. Here we introduce detailed experimental studies on those spin chain barium iridium oxides, which might be another intriguing system for engineering unusual electronic and magnetic ground states.

*Department of energy

4:54PM U47.00009: First-Principles Calculations of the atomic and magnetic structure of perovskite oxides SrMoO3, PbMoO3 and LaMoO3  Jeremy Lee-Hand (Presenter), Department of Physics and Astronomy, Stony Brook University, Stony Brook, New York, 11794-3800, USA, Cyrus Dreyer, Department of Physics and Astronomy, Stony Brook University, Stony Brook, New York, 11794-3800, USA and Center for Computational Quantum Physics, Flatiron Institute, 162 5th — Perovskite oxides have a characteristic ABO3 structure that is able to accommodate a large number of different cations in the A and B locations. In particular, perovskites with Mo on the B site, including SrMoO3 and PbMoO3 have recently been fabricated. SrMoO3 has been shown to have high electron mobility, and PbMoO3 exhibits metallic behavior to low temperatures with a resistivity displaying a sublinear dependence on temperature. We use first-principles calculations based on density-functional theory (DFT) plus Hubbard U to investigate the family of perovskite molybdenates: SrMoO3, PbMoO3, and LaMoO3 in order to determine their ground-state atomic and magnetic structures. We determine the dependence with the choice of U, exchange-correlation functional, and implementation with respect to DFT code. Finally, we interpret the ground-state structures in terms of unstable phonons of higher symmetry structures including cubic Pm-3m.
5:06PM U47.00010: Random singlet state in the spin liquid candidate $\text{Ba}_5\text{CuIr}_3\text{O}_{12}$*  DENIS GORBUNOV (Presenter), Hochfeld-Magnetlabor Dresden (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany, PAVEL VOLKOV, Department of Physics and Astronomy, Center for Materials Theory, Rutgers University, CHOONG-JAE WON, Max Planck POSTECH/Korea Research Initiative, Pohang University of Science and Technology and Laboratory of Pohang Emergent Materials, Pohang Accelerator Laboratory, Korea, JAEWOOK KIM, Department of Physics and Astronomy, Center for Emergent Materials, Rutgers University, MAI YE, Department of Physics and Astronomy, Rutgers University, HEUNG-SIK KIM, Department of Physics and Astronomy, Rutgers University; Kangwon National University, Chuncheon, Korea, JED PIXLEY, Department of Physics and Astronomy, Center for Materials Theory, Rutgers University, SANG-WOOK CHEONG, Department of Physics and Astronomy, Center for Emergent Materials, Rutgers University; Max Planck POSTECH/Korea Research Initiative, Pohang University of Science and Technol, GIRSH BLUMBERG, Department of Physics and Astronomy, Rutgers University — Understanding the role of disorder is crucial for the realization of quantum spin liquid (QSL) states in frustrated magnets, as it can lead to states mimicking QSL, but devoid of long-range entanglement. We study the thermodynamic and high magnetic field properties of the magnetic insulator $\text{Ba}_5\text{CuIr}_3\text{O}_{12}$, a QSL candidate showing no magnetic order down to 2 K. The temperature dependencies of the magnetic susceptibility and the specific heat suggest weak antiferromagnetic correlations, in stark contrast to the magnetization that does not saturate up to a field of 59 Tesla. We show that these results can be reconciled only within the framework of a disorder-dominated random singlet state. The obtained exchange coupling distribution $P(J)$ is found to be consistent with the power-law form $P(J) \sim J^{-\alpha}$ with $\alpha \approx 0.6$. Our work highlights the use of high magnetic field measurements for distinguishing QSL candidates from disorder-dominated states and characterizing the latter.

V. is supported by the Rutgers CMT Postdoc fellowship.

5:18PM U47.00011: Valence bond solids and hidden order phases in a pyrochlore $U(1)$ quantum spin liquid  HYEOK-JUN YANG (Presenter), SUNGBIN LEE, KAIST — Antiferromagnetic spin-1/2 system on a pyrochlore lattice has been extensively studied as a host of the exotic phase of matter, $U(1)$ quantum spin liquid (QSL). In a low-energy sector, the spin degrees of freedom are mapped to the emergent $U(1)$ gauge fields and fractionalized excitations. As the kinematics of the fractionalized excitations dominates the system, the emergent gauge structure is broken and the QSL encounters the magnetic instability. Beyond the $U(1)$ QSL and the conventional orderings, the realization of unconventional phases such as the spin nematic, multiple order etc., in frustrated magnet opens an interesting question. Here, we study the pyrochlore XXZ model with farther and competing exchange interactions. Analyzing the effective spinon actions, we schematically depict the richer phase diagram exhibiting the valence bond solids, spin nematic, and inversion breaking hidden orders.

Thursday, March 5, 2020 2:30 PM - 4:54 PM
Nickelate superconductivity --Formation of self-doped 2D single-orbital correlated electron systems in NdNiO$_2$

YUSUKE NOMURA (Presenter), MOTOAKI HIRAYAMA, RIKEN, TERUMASA TADANO, National Institute for Materials Science (NIMS), YOSHIHIDE YOSHIMOTO, University of Tokyo, KAZUMA NAKAMURA, Kyushu Institute of Technology, RYOTARO ARITA, University of Tokyo — The recent discovery of superconductivity in the doped nickelate Nd$_{0.8}$Sr$_{0.2}$NiO$_2$ has opened up a great opportunity to unravel the mystery of superconductivity in correlated materials. While the electronic structure of the nickelate is similar to that of the celebrated cuprates, there is one distinct difference: not only the Ni $3d_{x^2-y^2}$ electrons but electrons in the Nd layer also form the Fermi surface. The electronic structure around the Fermi level is well described by the Ni $3d_{x^2-y^2}$, Nd $5d_{3z^2-r^2}$, and a bonding orbital made from the interstitial $s$ and Nd $5d_{xy}$ orbitals. The hybridization between the Ni $3d_{x^2-y^2}$ and Nd-layer states is small, so that the screening effect of the Nd-layer states is less effective, which leaves the Ni $3d_{x^2-y^2}$ electrons strongly correlated. On the other hand, the electron-phonon coupling constant is not strong enough to mediate superconductivity of $T_c \approx 10$ K. These results indicate that NdNiO$_2$ hosts an almost isolated correlated Ni $3d_{x^2-y^2}$ orbital system with a self-doping due to the Nd-layer-state Fermi pockets [1]. Furthermore, we provide a useful guideline to eliminate the complication due to the self-doping and realize prototypical $d^9$ nickelates [2].

Nickelate superconductivity — A systematic computational design of dynamically stable $d^9$ nickelates

MOTOAKI HIRAYAMA, RIKEN, TERUMASA TADANO (Presenter), National Institute for Materials Science (NIMS), YUSUKE NOMURA, RIKEN, RYOTARO ARITA, University of Tokyo — The origin of superconductivity in the Sr-doped layered nickelate NdNiO$_2$ has been studied actively since its recent discovery [1]. Several theoretical studies, including our own [2], have shown that the electronic structure of NdNiO$_2$ is quite similar to that of the cuprates near the Fermi level, but they are different in that the Ni $3d_{x^2-y^2}$ orbital is self-doped due to the presence of Fermi pockets formed by the states originating from the Nd block layer (BL).

In this talk, we show that more ideal $d^9$ nickelates can be realized by adopting different types of BLs. By systematically generating new potential nickelate structures and then performing ab initio phonon calculations, we theoretically propose more than 10 new compounds that are dynamically stable and whose electronic structures better mimic that of the cuprates. We demonstrate that the newly proposed layered nickelates are in the strongly-correlated regime without forming an extra Fermi pocket as large as that of NdNiO$_2$. We also discuss the possibility of palladate analogues of high-$T_c$ cuprates briefly. This presentation is based on Ref. [3].

Superconductivity in infinite-layer nickelates: similarities and differences from cuprates

ANTIA BOTANA (Presenter), Arizona State University, MICHAEL NORMAN, Argonne Natl Lab — The electronic structure of infinite-layer nickelates RNiO$_2$ (R= La, Nd) is revisited in light of the discovery of superconductivity in Sr-doped NdNiO$_2$. From a comparison to their cuprate counterpart CaCuO$_2$, we derive essential facts related to their electronic structures, in particular, the values for hopping parameters and energy splittings, and the influence of the spacer cation. From this detailed comparison, we comment on expectations in regards to superconductivity. In particular, both materials exhibit a large ratio of longer-range hopping to nearest-neighbor hopping which should be conducive for superconductivity.

Two-band model for magnetism and superconductivity in nickelates

Nd$_{1-x}$Sr$_x$NiO$_2$ LUN-HUI HU (Presenter), CONGJUN WU, University of California, San Diego — The recently discovered superconductivity in Nd$_{1-x}$Sr$_x$NiO$_2$ provides a new opportunity for studying strongly correlated unconventional superconductivity.

The single-hole Ni$^+$ (3d$^9$) configuration in the parent compound NdNiO$_2$ is similar to that of Cu$^{2+}$ in cuprates.

We suggest that after doping, the intra-orbital spin-singlet and inter-orbital spin-triplet double-hole (doublon) configurations of Ni$^{2+}$ are competing, and we construct a two-band Hubbard model by including both the 3d$_{x^2-y^2}$ and 3d$_{xy}$ orbitals.

The effective spin-orbital super-exchange model in the undoped case is a variant of the SU(4) Kugel-Khomskii model augmented by symmetry breaking terms.

Upon doping, the effective exchange interactions between spin-1/2 single-holes, spin-1 (triplet) doublons, and singlet doublons are derived.

Possible superconducting pairing symmetries are classified in accordance to the D$_{4h}$ crystalline symmetry, and their connections to the superexchange interactions are analyzed.

D-wave superconductivity in the t−J model with spin one holes: possible applications to the nickelate superconductor Nd$_{1-x}$Sr$_x$NiO$_2$

YAHUI ZHANG (Presenter), ASHVIN VISHWANATH, Harvard University — The recent observation of superconductivity at relatively high temperatures in hole doped NdNiO$_2$ has generated considerable interest, particularly due to its similarity with the infinite layer cuprates. Building on the observation that the Ni$^{2+}$ ions resulting from hole doping are commonly found in the spin-triplet state, we introduce and study a variant of the t−J model in which the holes carry S=1. We find two distinct mechanisms for d wave superconductivity. In both scenarios the pairing is driven by the spin coupling J. However, coherence is gained in distinct ways in these two scenarios. In the first case, the spin-one holes condense leading to a d wave superconductor along with spin-symmetry breaking. In the second scenario, a coherent and symmetric d wave superconductor is achieved from "Kondo resonance": spin one holes contribute two electrons to form large Fermi surface together with the spin 1/2 singly occupied sites. The large Fermi surface then undergoes d wave pairing because of spin coupling J, similar to heavy fermion superconductor. Our study shows that a combination of "cuprate physics" and "heavy fermion physics" may emerge in this novel t−J model.

Superconductivity in trilayer Nickelates

EMILIAN NICA (Presenter), JYOTI KRISHNA, Department of Physics, Arizona State Univ, RONG YU, Department of Physics and Beijing Key Laboratory of Opto-electronic Functional Materials and Micro-nano Devices, Renmin University of China, QIMIAO SI, Department of Physics and Astronomy, Rice University, ANTIA S. BOTANA, ONUR ERTEN, Department of Physics, Arizona State Univ — Infinite-layer NdNiO$_2$ has recently been shown to exhibit superconductivity upon Sr-doping [1].

For doped NdNiO$_2$, it is believed that pairing in the superconducting phase occurs mainly in the Ni $d_{x^2-y^2}$ band [2]. In contrast to the Cu-based high-$T_c$ superconductors, the parent RNiO$_2$ (R=La, Nd) phases are not insulating-in spite of containing Ni$^{1+}$: $d^9$ ions-due to the appearance of rare-earth 5d-bands in the Fermi surface (FS) [2]. RNiO$_2$ materials are members of a larger family of layered nickelates R$_{n+1}$(NiO$_2$)$_n$O$_2$ with $n= 2, 3, ... \infty$ determining the number of NiO$_2$ planes along the c-axis. Here, we consider alternate trilayer compounds [3] where the rare-earth bands are pushed away from the FS which only includes three Ni- $d_{x^2-y^2}$ sheets. We study superconductivity in these compounds in several doping regimes using a t-J model. We compare and contrast the pairing instabilities in the tri- and infinite-layer cases.

Understanding magnetism in infinite-layer nickelates ab initio

VICTOR PARDO (Presenter), ADOLFO O. FUMEGA, University of Santiago de Compostela, ANTIA S. BOTANA, Arizona State University — Since the discovery of superconductivity in Sr-doped NdNiO$_2$ [1], magnetism has been ruled out [2] as being part of the equation in superconducting layered nickelates. Even though NdNiO$_2$ (containing NiO$_2$ layers with Ni$^{1+}$:d$^9$ cations) should be magnetically similar to the cuprates, it turns out to be drastically different [3]. In this talk, we will analyze the underlying electronic-structure mechanisms that lead to such different behavior in infinite-layer nickelates. In particular, we will describe the tendency towards magnetic order in a series of DFT-based ab initio calculations carried out on RNiO$_2$ (R:Nd, La).

4:06PM U48.00009: Robust $d_{x^2-y^2}$ wave superconductivity of infinite-layer nickelates\footnote{The work in Würzburg is funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) through Project-ID 258499086 - SFB 1170 and through the Würzburg-Dresden Cluster of Excellence on Complexity and Topology in Quantum Matter – ct.qmat Project-ID 39085490 - EXC 2147. H.Y.H. and S.R. are supported by the DOE Office of Basic Energy Sciences, contract DEAC02-76SF00515.}

XIANXIN WU, DOMENICO DI SANTE, TILMAN SCHWEMMER (Presenter), WERNER R HANKE, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, HAROLD HWANG, SRINIVAS RAGHU, Institute for Materials and Energy Sciences, Stanford University, RONNY THOMALE, Institut für Theoretische Physik und Astrophysik, Universität Würzburg — Motivated by the recent observation of superconductivity in strontium doped NdNiO$_2$, we study the superconducting instabilities in this system from various vantage points. Starting with first principles calculations, we construct two distinct tight-binding models, a simpler single-orbital as well as a three-orbital model, both of which capture the key low energy degrees of freedom to varying degree of accuracy. We study superconductivity in both models using the random phase approximation (RPA). We then analyze the problem at stronger coupling, and study the dominant pairing instability in the associated t-J model limits. In all instances, the dominant pairing tendency is in the $d_{x^2-y^2}$ channel, analogous to the cuprate superconductors.

4:18PM U48.00010: Ground States of Infinite-Layer Nickelates at Strong Coupling: A Variational Study\footnote{VBS and DC thank the visitor program at MPIPKS, Dresden, where part of this work was carried out.}

AMAL MEDHI (Presenter), Indian Institute of Science Education and Research Thiruvananthapuram, CHUAN CHEN, MPIPKS, Dresden, VIJAY SHENOY, Indian Institute of Science, Bangalore, DEBANJAN CHOWDHURY, Cornell University, Ithaca — Motivated by the recent discovery of superconductivity in infinite-layer nickelates, we study a two orbital model, including both nickel 3d and the rare-earth 5d orbitals, in the regime of strong local repulsive interactions. Using variational Monte-Carlo calculations which treat strong correlations via suitable projection techniques, we investigate superconductivity and study its dependence on the hole and electron doping, three-dimensionality, and the energetics of the rare-earth 5d orbital. We report a ground state phase diagram of this system, and provide complementary insights using a parton mean-field theory.
4:30PM U48.00011: Hole superconductivity in infinite-layer nickelates  
FRANK MARSIGLIO  
(Presenter), Physics, University of Alberta, JORGE HIRSCH, University of California, San Diego — We propose that the superconductivity recently observed in Nd$_{0.8}$Sr$_{0.2}$NiO$_2$ with critical temperature in the range 9 K to 15 K results from the same charge carriers and the same mechanism that we have proposed give rise to superconductivity in both hole-doped and electron-doped cuprates: pairing of hole carriers in oxygen $p\pi$ orbitals, driven by a correlated hopping term in the effective Hamiltonian that lowers the kinetic energy, as described by the theory of hole superconductivity. We predict a large increase in $T_c$ with compressive epitaxial strain.

4:42PM U48.00012: A Determinant Quantum Monte Carlo Study of an Effective Low Energy Model for Infinite-layer Nickelates  
FANGZE LIU (Presenter), XUXIN HUANG, Stanford University, BRIAN MORITZ, SLAC National Accelerator Laboratory, EDWIN HUANG, University of Illinois at Urbana-Champaign, THOMAS DEVEREAUX, Stanford University — Our study was motivated by the recent experimental observation of superconductivity in layered nickelate heterostructures with Tc of about 9K to 15K (D Li, et al. 2019). Here, we use determinant quantum Monte Carlo (DQMC) simulations of a composite system, consisting of Hubbard-like Ni, or NiO$_2$, layers coupled to metallic rare-earth layers, to investigate the physics associated with nickelate superconductors. We study the doping-dependent magnetic and electronic properties, such as spin and charge correlations, the single-particle spectral function, interlayer pair correlations, and even superfluid stiffness.

Session U49 DCMP: Superconductivity: Response to Electromagnetic Fields (Optical and Raman Spectroscopy, Surface Impedance, Etc.)

Mile High Ballroom 1B - Richard Klemm, Univ of Central Florida
2:30PM U49.00001: Effects of Forward Scattering from Dopant Impurities in Overdoped Cuprates*  
PETER HIRSCHFELD (Presenter), University of Florida, VIVEK MISHRA, Kavli Institute for Theoretical Sciences, Chinese Academy of Sciences, NICHOLAS LEE-HONE, ULAS OZDEMIR, DAVID BROUN, Physics, Simon Fraser U. — Many properties of overdoped cuprate superconductors can be explained by simple BCS and Landau Fermi liquid theory, supplemented by an appropriate description of disorder from dopant impurities. In addition to simply providing weaker scattering, out-of-plane dopants give rise to extended impurity potentials that scatter preferentially in the forward direction. Here we investigate the effects of such forward scattering on the optical conductivity and the penetration depth, and make specific quantitative comparisons with both LSCO and Ti-2201. We discuss previous work on forward scattering in ARPES in the same context.

2:42PM U49.00002: Gauge-invariant microscopic kinetic theory of superconductivity in response to electromagnetic fields I: Application to current excitation   
FEI YANG, MING-WEI WU (Presenter), University of Science and Technology of China — Within a gauge-invariant microscopic kinetic theory, we study the electromagnetic response in the superconducting states. Both superfluid and normal-fluid dynamics are involved. We predict that the normal fluid is present only when the excited superconducting velocity is larger than a threshold. Interestingly, with the normal fluid, we find that there exists friction between the normal-fluid and superfluid currents. Due to this friction, part of the superfluid becomes viscous. Therefore a three-fluid model, normal fluid and nonviscous and viscous superfluids, is proposed to capture both the magnetic and optical responses. Moreover, an exotic phase in which both the resistivity and superconducting gap are finite is predicted.

2:54PM U49.00003: Phase-sensitive analysis of Higgs oscillations in quenched superconductors with time- and angle-resolved photo emission spectroscopy  
LUKAS SCHWARZ (Presenter), DIRK MANSKE, Max Planck Institute for Solid State Research — Higgs oscillations in nonequilibrium superconductors provide a unique tool to obtain information about the underlying order parameter. Several quantities like the absolute value, existence of multiple gaps and the symmetry of the order parameter can be encoded in the Higgs oscillation frequency. Most works so far concentrate on experiments, where momentum averaged quantities like the optical conductivity or third-harmonic effects in the transmitted light field are investigated, which does not allow to access all possible information contained in the Higgs oscillations. Here, we study the time-resolved spectral function measured in angle-resolved photo emission spectroscopy after quenching the system using a general approach. We analyze the induced oscillations all over momentum space to study the creation process of collective Higgs oscillations and we extract phase information of the order parameter from the oscillations of the spectral function.
**3:06PM U49.00004: Driving the Higgs oscillation in cuprates: unveiling collective modes or interactions coupled to Cooper pairs**  
HAO CHU (Presenter), MIN-JAE KIM, Max Planck Institute for Solid State Research, KOTA KATSUMI, Physics, University of Tokyo, SERGEY KOVALEV, Helmholtz-Zentrum Dresden-Rossendorf, ROBERT DAWSON, LUKAS SCHWARZ, Max Planck Institute for Solid State Research, NAOTAKA YOSHIKAWA, Physics, University of Tokyo, GIDEOK KIM, DANIEL PUTZKY, Max Planck Institute for Solid State Research, JAN-CHRISTOPH DEINERT, NILESH AWARI, MIN CHEN, Helmholtz-Zentrum Dresden-Rossendorf, GEORG CHRISTIANI, GENNADY LOGVENOV, Max Planck Institute for Solid State Research, YANN GALLAIS, University Paris Diderot, ALEXANDER BORIS, BERNHARD KEIMER, ANDREAS P SCHNYDER, DIRK MANSKE, Max Planck Institute for Solid State Research, MICHAEL GENSC, ZHE WANG, Helmholtz-Zentrum Dresden-Rossendorf, RYO SHIMANO, Physics, University of Tokyo, STEFAN KAISER, Max Planck Institute for Solid State Research — The Higgs mode of a superconductor is a collective excitation of the amplitude of the superconducting order parameter. It can be coherently driven at a frequency $2\omega$ by a multicycle terahertz pulse of frequency $\omega$. This then leads to third harmonic generation (THG) as a result of sum frequency generation between the oscillating condensate and the terahertz driving pulse. We applied such experimental scheme to different families of cuprate high-Tc superconductors. By phase-resolving the THG response with respect to the terahertz drive, we uncover the universal anti-resonance of the driven Higgs oscillation in all samples. This may be understood in terms of an additional collective mode coupled to the Higgs mode. Careful analysis of the anti-resonance feature as a function of hole doping with the help of a coupled oscillators model suggests that the coupled mode could be the magnetic resonant mode. Our findings may shed light on the pairing mechanism in d-wave superconductors.

**3:18PM U49.00005: Spectroscopic and optical response of odd-frequency Berezinskii superconductors**  
PAVLO SUKHACHOV (Presenter), ALEXANDER BALATSKY, Nordita — By using a simple model with a parabolic dispersion law and a non-magnetic disorder, the spectral function, the electron density of states, and the optical conductivity are calculated in clean and disordered Berezinskii superconductors for a few gap ansatzes. The strong dependence of the spectral function and the electron DOS on the frequency profile of the gap is rather unusual and could explain why it is experimentally hard to identify the Berezinskii state. It is found also that the OF pairing allows for peaks in the real part of the optical conductivity, whose form and position depend on the specific frequency profiles of the gap. For the frequencies that correspond to these peaks, sharp cusps appear in the imaginary part. The form of these cusps is nontrivial for the OF pairing. In particular, the imaginary part of the optical conductivity can become negative allowing for the optical transparency windows.

3:30PM U49.00006: Control of Supercurrents and Collective Modes in Superconductors by Terahertz Lightwave Propagation*  MARTIN MOOTZ (Presenter), ILIAS PERAKIS, Univ of Alabama - Birmingham, JIGANG WANG, Physics and Astronomy, Ames Laboratory, Iowa State University — Terahertz (THz) lightwave driving of supercurrents as a dynamical symmetry-breaking principle in superconductors allows for control of collective modes and excitation of non-equilibrium phases such as gapless superconductivity. Here we demonstrate that THz light-induced nonlinear response together with THz lightwave propagation can induce an unipolar ac electric field pulse inside the superconductor for sufficiently weak current relaxation. The resulting dynamical inversion symmetry breaking in form of the induced Cooper-pair condensate flow manifests itself by high harmonic generation at equilibrium-symmetry forbidden frequencies and allows for control of collective modes by THz-pulse shaping. To systematically describe the dynamic interplay of THz lightwave acceleration of Cooper-pair condensate and THz lightwave propagation inside the superconductor, we solve full nonlinear gauge-invariant Maxwell-Bloch equations beyond the Anderson pseudo-spin precession model that we derived by using a gauge-invariant non-equilibrium density matrix approach.

3:42PM U49.00007: Giant Microwave Absorption in d-Wave Superconductors*  MICHAEL SMITH (Presenter), ANTON ANDREEV, BORIS SPIVAK, University of Washington — We discuss a new mechanism of microwave absorption in d-wave superconductors which arises in the presence of a dc supercurrent. This mechanism produces a contribution to the ac conductivity that is proportional to the inelastic quasiparticle relaxation time and determines the supercurrent dependence of the conductivity. This new contribution may also be much larger than the conventional contribution because, in superconductors, the inelastic relaxation time typically exceeds the elastic one by several orders of magnitude. We show that the calculation of the aforementioned contribution to the conductivity can be reduced to the calculation of the single particle density of states in the presence of a dc supercurrent. Our results may enable determination of the inelastic relaxation time in superconductors from microwave absorption measurements.

3:54PM U49.00008: High-Frequency Nonlinear Response of Superconducting Cavity-Grade Surfaces

BAKHROM ORIPOV (Presenter), STEVEN ANLAGE, University of Maryland, College Park — Superconducting Radio Frequency (SRF) cavities are used to accelerate charged particles to high energies, but their performance is limited by surface defects which lead to cavity breakdown at high accelerating gradients. A novel near-field magnetic microwave microscope that can study these defects was successfully built using a magnetic writer from a conventional magnetic recording hard-disk drive. We study the 3rd harmonic response $V_{3f}$ as a function of rf field amplitude ($H_{rf}$) and temperature ($T$). In our experiments on bulk and thin-film Nb surfaces, we observed 2 different classes of nonlinearity, which we call Low-field and Periodic. The low-field response is the intrinsic response of the sample due to the dynamics of vortex semiloops created by the magnetic writer (arXiv:1909.02714). In the periodic case there exists a relatively strong onset nonlinear response signal with periodic dips at $H_{rf} = H_1(T), H_2(T), H_3(T)$. This response can be linked to the Josephson effect at or near the surface and is in good agreement with the nonlinear response expected from rf-current-biased RCSJ model (PRApplied 11, 064030 (2019)). Efforts to image third harmonic response across Nb surfaces will be presented.

*This work is funded by US DOE, HEP through grant #DESC0017931 and CNAM.

4:06PM U49.00009: 2D THz spectroscopy and anomalous non-linear response of La$_{2-x}$Sr$_x$CuO$_4$

DIPANJAN CHAUDHURI (Presenter), Johns Hopkins University, FAHAD MAHMOOD, Department of Physics, University of Illinois Urbana-Champaign, DAVID BARBALAS, Johns Hopkins University, XI HE, IVAN BOZOVIC, Brookhaven National Laboratory, PETER ARMITAGE, Johns Hopkins University — La$_{2-x}$Sr$_x$CuO$_4$ (LSCO) is a prototypical example of hole-doped single layer cuprate superconductor. Here we investigate the low frequency broadband non-linear optical response of LSCO across a wide range of doping as a function of temperature. In addition to the large optical non-linearities that is expected in the superconducting state, we find anomalous non-linear response even in the normal state, well above the superconducting critical temperature. This is in sharp contrast to the clean BCS type superconductors where the strong non-linear response at low temperatures promptly disappear at the critical temperature. Furthermore, we perform 2D THz spectroscopy on these samples to identify the different underlying non-linear processes that give rise to the overall response. We compare our results to existing theories on the superconductivity in this class of materials.

*DARPA DRINQS project FP-017, “Long-term High Temperature Coherence in Driven Superconductors”
4:18PM U49.00010: Terahertz conductivity of superconducting Beta-tungsten thin films*

PETER ARMITAGE, PRASHANT CHAUHAN (Presenter), Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218, RAMESH BUDHANI, Department of Physics, Morgan State University, 1700E Cold Spring Lane, Baltimore MD -21251 — Ultrathin films of β-tungsten host superconductivity with strong spin-orbit coupling (SOC). This non-equilibrium phase of tungsten has attracted considerable attention in recent years for spintronic applications due to its giant spin Hall effect and the potential promise of exotic superconductivity. After more than 60 years of its discovery, the superconductivity in this material is still not well understood. We investigate the superconducting order in β-Tungsten using high precision time-domain THz transmission spectroscopy. Superconductivity is exhibited below 4.2 K for 70 nm film and the transition temperature reduces with increasing thickness. We study the frequency response of the complex conductivity of a thin film with a Tc of 4.2 K. In the superconducting state down to 1.6 K, the superfluid spectral weight developed is much less than the expected spectral weight for a BCS-type superconductor. This anomalous spectral weight is a possible indication of unconventional superconductivity in this system. The magnetic field response of the optical conductivity that can give additional information about the superconducting order parameter of this system, is currently under investigation.

*Work at MSU was supported through the Office of Naval Research – Grant No. N00014-17-1-2794

4:30PM U49.00011: Thickness dependence of superfluid density scaling in DyBa$_2$Cu$_3$O$_{7-x}$ thin films

ROBERT DAWSON (Presenter), DANIEL PUTZKY, GEORG CHRISTIANI, GENNADY LOGVENOV, BERNHARD KEIMER, ALEXANDER BORIS, Max Planck Institute for Solid State Research — Understanding the nature of the pseudogap phase and the relationship between charge order and superconductivity (SC) in the cuprates remains an outstanding challenge [1]. Recently, 2D SC has gained much interest due to its discovery in a variety of unconventional materials, and advancements in MBE growth of thin films have shown that 2D SC can also exist in the cuprates [2]. One interesting approach, therefore, is to investigate the evolution of cuprate physics in the ultra-thin film limit where only a few superconducting CuO$_2$ planes are present. Here, we report a study of the temperature dependence of the superfluid density as a function of thickness as well as measurements of the terahertz and infrared optical conductivity in a series of DyBa$_2$Cu$_3$O$_{7-x}$ SC thin films. We find that in the ultra-thin film limit the temperature scaling rapidly approaches that expected for dirty s-wave SC, while with decreasing oxygen content the scaling shows the opposite trend. These results suggest an increasing isotropic order parameter component below a threshold thickness due to distortions of the Fermi surface in the 2D limit.

4:42PM U49.00012: Non-linear Vortex Dynamics and Dissipation at High-amplitude Microwave Drive
MATTIA CHECCHIN (Presenter), ANNA GRASSELLINO, ALEXANDER ROMANENKO, Fermilab — In this talk, the description of the vortex dynamics and dissipation at arbitrary value of microwave field amplitude is discussed. Experimental data of vortex surface resistance in bulk niobium elliptical cavities as a function of frequency, trapped magnetic field value and field amplitude will be presented. Numerical calculations of non-linear vortex dynamics under microwave drive for different pinning landscapes allows to describe the mechanism underneath the electromagnetic field amplitude dependence of the surface resistance due to trapped vortices, pointing to the progressive microwave depinning as the most likely mechanism capable to generate such non-linearities.

4:54PM U49.00013: Optical properties of severely overdoped La$_{1.75}$Sr$_{0.25}$CuO$_4$*
CHRISTOPHER HOMES (Presenter), GENDA GU, P. M. LOZANO, QIANG LI, Condensed Matter Physics and Materials Science Division, Brookhaven National Laboratory — The temperature dependence of the optical properties of the severely overdoped cuprate La$_{1.75}$Sr$_{0.25}$CuO$_4$ have been determined above and below the critical temperature $T_c \sim 16$ K over a wide frequency range for light polarized in the $a$-$b$ plane. The real part of the optical conductivity can be reproduced reasonably well at low frequency using a simple Drude model, yielding an estimate for the plasma frequency $\omega_{pD} \sim 9300$ cm$^{-1}$. Below $T_c$ the superconducting plasma frequency $\omega_{ps} \sim 2700$ cm$^{-1}$ is determined from the Ferrell-Glover-Tinkham sum rule, indicating that less than 8% of the free carriers collapse into the superconducting condensate, in agreement with a recent study [1]. However, there is unusual structure below $\sim 0.1$ eV that suggests that the free-carrier scattering rate is strongly renormalized with frequency. In addition, the nature of the magnetic susceptibility through the superconducting transition suggests that this compound may not be homogeneous.

*Supported by DOE-BES under DE-SC0012704.
Doping-dependent phonon anomaly and charge order in Hg-family of high-$T_c$ cuprates

* LICHEN WANG, Peking University, China, BIQIONG YU, University of Minnesota, RAN JING, XIANGPENG LUO, JUNBANG ZENG, JIARUI LI, Peking University, China, IZABELA BIALO, AGH University of Science and Technology, Poland, MARTIN BLUSCHKE, Max Planck Institute for Solid State Research, Germany, YANG TANG, JACOB FREYERMUTH, GUICHUAN YU, University of Minnesota, RONNY SUTARTO, FEIZHOU HE, Canadian Light Source, EUGEN WESCHKE, HZB, Germany, WOJCIECH TABIS, MARTIN GREVEN, University of Minnesota, YUAN LI (Presenter), Peking University, China — Charge order is ubiquitously found in high-$T_c$ cuprate superconductors, yet their microscopic origin has been elusive. The Hg-family of cuprates are known for their high $T_c$ and relatively simple structure, and are therefore promising systems for avoiding material-specific complexity in experimental studies. Using resonant X-ray diffraction and Raman spectroscopy to study high-quality single crystals [1,2] of the first two members of the family, Hg1201 and Hg1212, we establish universal existence of charge order in these compounds. The most robust charge order is found in underdoped samples near a hole-carrier concentration of 0.09. Interestingly, we observe concomitant anomalies in the lattice dynamics that involve the motion of atoms in and/or adjacent to the CuO2 layers, around the same doping in both materials. As these anomalies are already present at room temperature, before the formation of charge order, we attribute them to a doping-dependent instability of the CuO2 layers that drives the formation of charge order as an emergent phenomenon [3].

*Work at PKU and UMN is supported by NSFC and MOST of China and by DoE of the US, respectively.
U49.00015: Gauge-invariant microscopic kinetic theory of superconductivity in response to electromagnetic fields II: Application to collective modes  FEI YANG (Presenter), MING-WEI WU, University of Science and Technology of China — We show that the gauge-invariant kinetic equation of superconductivity provides an efficient approach to study the electromagnetic response of the gapless Nambu-Goldstone and gapful Higgs modes on an equal footing. We prove that the Fock energy in the kinetic equation is equivalent to the generalized Ward's identity. Hence, the gauge invariance directly leads to the charge conservation. Both linear and second-order responses are investigated. The linear response of the Higgs mode vanishes in the long-wave limit. The linear response of the Nambu-Goldstone mode is in consistency with the previous works. Whereas the second-order response exhibits interesting physics. On one hand, a finite second-order response of the Higgs mode is obtained in the long-wave limit. We reveal that this response, which has been experimentally observed, is attributed solely to the drive effect rather than the widely considered Anderson-pump effect. On the other hand, the second-order response of the Nambu-Goldstone mode, free from the influence of the long-range Coulomb interaction and hence the Anderson-Higgs mechanism, is predicted. We find that both Anderson-pump and drive effects play important role in this response. A tentative scheme to detect this second-order response is proposed.

Session U50 DCMP: Metal Insulator Transition Theory  Mile High Ballroom 1C - Yan Wang, Oak Ridge National Laboratory

2:30PM U50.00001: Avalanche induced co-existing localised and thermal regions in disordered spin chains  PHILIP CROWLEY (Presenter), ANUSHYA CHANDRAN, Boston Univ — We investigate the stability of an Anderson localised chain to the inclusion of a single finite interacting thermal seed. This system models the effects of rare low-disorder regions on many-body localised chains. Above a threshold value of the mean localisation length, the seed causes runaway thermalisation in which a finite fraction of the orbitals are absorbed into a thermal bubble. This 'partially avalanched' regime provides a simple example of a delocalised, non-ergodic dynamical phase. We derive the hierarchy of length scales necessary for typical samples to exhibit the avalanche stability, and show that the required seed size diverges at the avalanche threshold. We introduce a new dimensionless statistic that measures the effective size of the thermal bubble, and use it to numerically confirm the predictions of avalanche theory in the Anderson chain at infinite temperature.
2:42PM U50.00002: Oxygen vacancy effect on the electronic structure of LaNiO3 using first-principles  XINGYU LIAO (Presenter), HYOWON PARK, VIJAY SINGH, Univ of Illinois - Chicago — While bulk LaNiO3 remains metallic at all temperatures, many experiments show that LaNiO3-x exhibits the metal-insulator transition as the oxygen vacancy level x goes from 0 to 0.5. In addition to the resistivity data, both photoelectron and X-ray absorption spectroscopy works show some intriguing features that cannot be explained based on density functional theory (DFT). In this talk, I will present DFT plus dynamical mean field theory (DMFT) calculations of LaNiO3-x for x=0, 0.25, and 0.5 in different magnetic states. Our DFT+DMFT method was implemented using the maximally localized Wannier function as local orbitals for the correlated subspace. While the DFT density of states (DOS) is similar to experimental spectroscopy data for LaNiO3, it failed to describe the insulating ground state and the peak splitting of unoccupied DOS as x increases to 0.5. Our DFT+DMFT calculations can capture both the resistivity change as well as the spectral features arising from the oxygen vacancy. We find that both the crystal splitting and the Ni d valence changes due to the oxygen vacancy play important roles in explaining the electronic structure. We will also discuss both similarity and difference of vacancy effects between the bulk and ultra-thin film structures.

2:54PM U50.00003: The metal-to-insulator transition in polar metals  EVAN SHERIDAN (Presenter), University of California, Berkeley, CEDRIC WEBER, Physics Department, King's College London, SINÉAD GRIFFIN, Lawrence Berkeley National Laboratory, JEFFREY NEATON, University of California, Berkeley — The fundamental design principles that drive a switchable polarity in oxide-based electronics whilst preserving a metallic state are not well understood. This is partly because it requires the coexistence of two seemingly incompatible properties: ferroelectric polar distortions and metallic conductivity. We study the prototypical polar metal LiOsO3 as a function of strain, which acts as a benchmark to further elucidate the role of electronic correlations in the alkali osmate perovskite-based series. Building on these results, we report a fully correlated DFT+DMFT approach to search and design new polar metals.

3:06PM U50.00004: Phase transition and instability in dimensionality-controlled artificial oxide crystals  TAEWON MIN (Presenter), Department of Physics, Pusan Natl Univ, SEUNGGYO JEONG, WOO SEOK CHOI, Department of Physics, Sungkyunkwan University, JAEKWANG LEE, Department of Physics, Pusan Natl Univ — The metal-insulator transition (MIT) is one of the fascinating physical phenomena in complex oxide system, and that has inspired the physics community during the last 20th century. In particular, recent advances in atomically controlled growth of oxide material have enabled the realization of artificial crystals with customized dimensions. Herein, by combining density functional theory calculations with optical and electrical measurements, we investigate dimensionality-induced MIT in atomically well-defined SrRuO3/SrTiO3 (SRO/STO) superlattices. We note that SRO/STO superlattices favor an antiferromagnetic insulating state as the SRO layers are getting thinner, which indicates that MIT is strongly coupled with magnetic ordering. Furthermore, we find that electronic and magnetic instabilities in the two SRO unit cell induce thermally-driven MIT along with magnetic transition. Novel theoretical finding will be presented along with transport and optical observations.
3:18PM U50.00005: Theory of Dipole Insulators*  OLEG DUBINKIN (Presenter), JULIAN MAY-MANN, TAYLOR L HUGHES, University of Illinois at Urbana-Champaign — Insulating systems are characterized by their insensitivity to twisted boundary conditions as quantified by the charge stiffness and charge localization length. The latter quantity serves as a universal criterion to distinguish between metals and insulators. In this work we extend these concepts to a new class of quantum systems having conserved charge and dipole moments. We refine the concept of a charge insulator by introducing notions of multipolar insulators, e.g., a charge insulator could be a dipole insulator or dipole metal. We develop a universal criterion to distinguish between these phases by extending the concept of charge stiffness and localization to analogous versions for multipole moments, but with our focus on dipoles. This refined structure allows for the identification of phase transitions where charge remains localized but, e.g., dipoles delocalize. We illustrate the proposed criterion using several exactly solvable models that exemplify these concepts.

*OD and TLH thank the US NSF under grant DMR 1351895-CAR, and the MRSEC program under NSF Award Number DMR-1720633 (SuperSEED) for support JM is supported by the NSF Graduate Research Fellowship Program under Grant No. DGE 1746047. 3:30PM U50.00006: Disorder in the one-dimensional half-filled extended Hubbard model
JON SPALDING (Presenter), University of California, Riverside, KA-MING TAM, Physics and Astronomy, Louisiana State University, DAVID K CAMPBELL, Physics, Boston University, SHAN-WEN TSAI, University of California, Riverside — The addition of disorder to interacting electron systems presents a challenging theoretical problem. In this talk, I will describe the effects of disorder on the phase diagram of the extended Hubbard model in one spatial dimension. Our theoretical analysis is possible in the weak coupling and weak disorder case due to the low dimensionality.

3:42PM U50.00007: Electronic and Lattice Dynamical Properties of MgTa$_2$O$_6$*  KYLE MILLER (Presenter), JAMES RONDINELLI, Northwestern University — Materials exhibiting metal-insulator transitions (MIT) are proposed platforms for next-generation low-power electronics. In addition, most of these materials exhibit strong coupling between the electronic and lattice degrees-of-freedom, which makes them ideal systems to examine the interplay between lattice dynamics, electronic structure, and magnetic order. Well-studied rutile-structured MIT oxides, such as VO$_2$ and NbO$_2$, exhibit dimerized cations within the edge-connected octahedra along the c axis in the insulating state. Analogous compounds with the related trirutile superstructure, e.g., V$_2$WO$_6$ and CuSb$_2$O$_6$, exhibit a similar dimerization. Here we investigate the propensity for MIT in MgTa$_2$O$_6$, a $d^0$ insulator, upon electron doping. Our calculations suggest that MgTa$_2$O$_6$ remains metallic for electron doping configurations within the $d^{0.25}$-$d^{0.5}$ range, whereas Ta-Ta dimerization occurs for higher electron concentrations. Overall, these results indicate that trirutile oxides may be a promising materials class for which to functionalize MITs.

3:54PM U50.00008: Theoretical study of electronic and structural phase transitions in MPS$_3$ with M = (Fe, Ni, Mn, Co)∗ MINSUNG KIM (Presenter), Department of Physics & Astronomy, Rutgers University, HEUNG-SIK KIM, Department of Physics, Kangwon National University, KRISTJAN HAULE, DAVID VANDERBILT, Department of Physics & Astronomy, Rutgers University — Metal phosphorus trisulfides (MPS$_3$ with M = Fe, Ni, Mn, Co) are layered materials which show Mott-insulator-to-metal transitions under the application of pressure. In addition, some of the compounds are reported to undergo structural phase transitions, making the theoretical description of the phase transitions more complicated. Here, we investigate the electronic and structural phase transitions of representative MPS$_3$ compounds using first-principles methods based on density functional theory and dynamical mean-field theory. We discuss the origin and the relation of the two types of phase transitions and clarify the role of the electron correlation and interlayer stacking configurations. We also examine how different metal species change the evolution of the phases under pressure. Our results provide needed theoretical understanding of these tunable Mott insulators.

∗This work has been supported by NSF DMREF grant DMR-1629059.

4:06PM U50.00009: Insight into the insulator-to-metal transition in ruthenium A$_2$Ru$_2$O$_7$ pyrochlores∗ DANILO PUGGIONI (Presenter), Department of Materials Science and Engineering, Northwestern University, GENEVA LAURITA, Department of Chemistry and Biochemistry, Bates College, RAM SESHADRI, Materials Department and Materials Research Laboratory, University of California, JAMES RONDINELLI, Department of Materials Science and Engineering, Northwestern University — The study of insulator-to-metal transitions (IMT) is of interest from the viewpoint of fundamental understanding of the underlying physics, and that materials at such a brink often can be harnessed for useful functionality. Here, using first principle calculations, we study the role of disorder, in the form of cation off-centering, on the compositionally-controlled IMT in the oxide pyrochlore (Pr$_{1-x}$Bi$_x$)$_2$Ru$_2$O$_7$. Our results suggest the combination of primary and secondary (due to size) electronic effects of the lone pair-driven incoherent cation displacements are responsible for the metallic state of pyrochlores with Bi substitution.

∗Support from Army Research Office under grant no. W911NF-15-1-0017.

4:18PM U50.00010: Metal-insulator transition in a Hubbard model with random and all-to-all hopping and exchange∗ GRIGORY TARNOPOLSKY, SUBIR SACHDEV (Presenter), Harvard University — We examine a $N$ site Hubbard model with an on-site repulsion $U$, and random and all-to-all hopping, $t$, and exchange $J$. In the large $N$ limit, the problem reduces to a single site symmetric Anderson impurity coupled to self-consistent bosonic and fermionic baths. We present large $M$ (for a model with SU($M$) spin symmetry) and renormalization group analyses of a metal-insulator transition in this model.

∗National Science Foundation Grant No. DMR-1664842
4:30PM U50.00011: Many Body Localization Due to Correlated Disorder in Fock Space
SOUMI GHOSH, Indian Institute of Science, ATITHI ACHARYA, Physics, Rutgers University, SUBHAYAN SAHU, Physics, University of Maryland, SUBROTO MUKERJEE (Presenter), Indian Institute of Science — The Hamiltonian of an interacting system of spinless fermions looks like that of a single particle hopping on a Fock graph in the presence of a random disordered potential. The coordination number of the Fock graph increases linearly with the system size L in 1D. Thus, in the thermodynamic limit, the disordered interacting problem in 1D maps on to an Anderson model with infinite coordination number. Despite this, this system displays localization which appears counterintuitive. The resolution lies in the on-site disorder on the Fock graph being highly correlated as they are derived from an exponentially smaller number of on-site disorder potentials in real space. Thus, such correlations have a strong effect on the localization properties of the corresponding many-body system. In this work we perform a systematic quantitative exploration of the nature of correlations of the Fock space potential required for localization. We show that changing the correlation strength can induce thermalization or localization in systems. We find that a linear variation of correlations with Hamming distance in Fock space is drives a thermal-MBL phase transition where the transition is driven by the correlation strength. Systems with the other forms of correlations we study are found to be ergodic.

4:42PM U50.00012: Current driven first order metal-metal martensitic phase transitions in correlated electron systems
STEWART BARNES (Presenter), Univ of Miami — As a function of temperature and pressure, a number elemental 3d metals such as Fe or V undergo first order martensitic phase transitions between bcc and fcc structures. Similar metal to metal first order phase transitions occur in other transition metals and alloys including most famously shape memory alloys. In analogy with the spin Berry phase, defined is an electro-mechanical such phase defined by the four connection $A_\mu$ that couples to the conduction electron charge current. It is implied that, for highly pure wires of such materials, an electronic charge current can drive say the bcc to fcc martensitic phase transition of a suitable metrial well below the strain, temperature and/or pressure that which this usually occurs. This leaves the material in a higher energy state thereby converting electrical to lattice energy in much the same manner as currents can drive a magnetic state to higher energy. The theory also applies to domain walls in conducting ferro and antiferroelectric materials.
4:54PM U50.00013: Theoretical phase diagram of unconventional alkali-doped fullerides*
THEJA DE SILVA (Presenter), Augusta University — By constructing an effective model based on recently calculated *ab initio* bare interaction parameters, we study the phase diagram of alkali-doped fullerides as a function of temperature and internal pressure. While we use a slave-rotor mean-field theory to determine the metal-insulator-superconductor phase boundaries, we use a variational mean-field approach to detect the magnetic phase transitions. We find a good agreement with experimental phase diagram in both weak and strong coupling limits. We explain the unified description of the phase diagram including the proximity of s-wave superconducting state and the Mott-insulating state, and the existence of Jahn-Teller distorted metallic state using orbital selective physics. We argue that the double electronic occupation of two degenerate orbitals triggers both s-wave superconductivity and Jahn-Teller distortion. While the orbital ordering of two electrons causes the distortion, the remaining single electron in the third orbital causes the metal-insulator transition.

5:06PM U50.00014: Operator growth in disordered systems, a translation invariant approach*
XIANGYU CAO (Presenter), University of California, Berkeley — Operator growth in disordered systems, a translation invariant approach

Recently, we proposed [1] a general framework to study operator growth and complexity, using the Lanczos algorithm (aka Krylov subspace or recursion method). Here, we apply the framework to disordered systems, especially random spin chains and many-body localization (MBL). An argument based on l-bits shows that in MBL phases, the Krylov-complexity [1] grows polynomially in time (as opposed to exponentially in chaotic systems). An equivalence between quenched disorder and static ancilla allows us to carry out numerical study to in a translation invariant systems, bypassing finite size effects and statistical fluctuations of disorder averaging. Under strong disorder, the Lanczos coefficients define a quasi-random Krylov chain with multiple bound states, which we identify as local integral of motions and long-lived oscillating modes. We propose to study the MBL transition as the divergence of localization length on the Krylov chain. Finally, we apply the disorder-free method to a mean-field random magnet realized in a recent cold-atom experiment [2].

Electrostatic gating Effects on the Metal to Mott Insulator Transition of NiS$_2$: a DFT+DMFT study* EZRA DAY-ROBERTS (Presenter), TURAN BIROL, RAFAEL FERNANDES, University of Minnesota — Electrostatic gating provides a convenient way to manipulate carrier densities without introducing defects that lead to impurity scattering as in chemical doping. Recent advances, including those in ionic liquid and gel gating, have allowed experimental access to a much larger range of added carrier concentrations. NiS$_2$, in the pyrite structure, is a Mott insulator that has previously been found to undergo a metal-to-insulator transition (MIT) as function of isovalent selenium substitution as well as pressure. This suggests that NiS$_2$ is near the edge of the MIT, making it a good candidate material to be electrostatically driven across the MIT. Here, we present results of a first-principles study of this material using fully charge self-consistent Dynamical Mean Field Theory (DFT+DMFT). We explore the properties of NiS$_2$ across the MIT as a function of temperature and added carrier concentration, contrasting the cases of electrostatic gating and chemical doping.

Session U51 DCP: Graphene: Imaging and Spectroscopy Mile High Ballroom 1D - Jennifer DeMell, Laboratory for Physical Sciences

Imaging magnon transport in a quantum Hall ferromagnet: Part 1 SEUNG HWAN LEE (Presenter), ANDREW PIERCE, YONGLONG XIE, PATRICK R FORRESTER, Department of Physics, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, AMIR YACOBY, Department of Physics, Harvard University — Graphene exhibits quantum Hall ferromagnetism at partial fillings in the N=0 Landau level where its SU(4) isospin symmetry is spontaneously broken due to strong electron-electron interactions. It has been demonstrated that it is possible to generate and detect magnons, collective excitations of spins, in the ν= ±1 quantum Hall ferromagnets by exploiting equilibration of spin-polarized edge states. However, the nature of magnon transport in the system is still under active investigation. In this two-part talk, we will discuss scanning gate microscopy (SGM) of magnon transport in the graphene quantum Hall ferromagnet. Using a metallic scanning tip, a small region of graphene can be gated away from integer filling, effectively acting as a barrier for magnon transport inside the system. In this talk, we present a general scheme of performing SGM of magnon transport, and report observation of localized response in transport as we place the local barrier near the magnon generation and absorption sites.
Imaging magnon transport in a quantum Hall ferromagnet: Part 2

ANDREW PIERCE (Presenter), SEUNG HWAN LEE, YONGLONG XIE, PATRICK R FORRESTER, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, AMIR YACOBY, Harvard University — The spin-polarized ν=1 quantum Hall state of monolayer graphene constitutes a unique laboratory for studying mesoscopic magnetic phenomena. Among many interesting properties, the system supports magnons which can be generated and detected electrically. Here we study the ν=1 state of graphene using a scanning single-electron transistor (SET) operated simultaneously as a local gate and electrometer. Processes involving localized states near device contacts are shown to strongly influence transport response, suggesting a microscopic mechanism for magnon generation and absorption. Moreover, operating the SET as an electrometer enables us to perform local compressibility measurements which further clarify the effects of magnon generation on the system.

Visualizing unexpected magnetic field-tuned electron flow through ballistic channels

JOSEPH SULPIZIO (Presenter), LIOR ELLA, ASAF ROZEN, Weizmann Institute of Science, JOHN BIRKBECK, DAVID PERELLO, University of Manchester, DEBARGHYA DUTTA, Weizmann Institute of Science, MOSHE BEN-SHALOM, Tel Aviv University, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, ANDRE GEIM, University of Manchester, SHAHAL ILANI, Weizmann Institute of Science — The advent of ultra-clean materials has enabled the exploration of ballistic flow, where electrons traverse a sample unperturbed before colliding with the walls. We have developed a nanoscale probe based on a scanning nanotube single electron transistor that is sufficiently sensitive to image the electrostatic potential of ballistic electrons in such materials for the first time. We apply this probe to high-mobility graphene channel devices, and image how the potential of the flowing electrons drops sharply at the contacts while remaining constant along the bulk, which is the textbook picture of ballistic electron flow. We then image how the Hall voltage profiles of the flowing electrons develop a rich set of patterns as the cyclotron radius is tuned by varying the perpendicular magnetic field. Contrary to the expectation that the electron current primarily flows along the edges in magnetic field, our results reveal that the current varies considerably across the bulk of the channel, and can even concentrate near the center. These results open the path for visualizing other ballistic electron flow phenomena that previously could only be studied via transport, including electron optics.
3:06PM U51.00004: Realization of Nanoscale Mapping of Noise Source Activities on Graphene Domains* JEEHYE PARK (Presenter), HYUNGWOO LEE, DUCKHYUNG CHO, SHASHANK SHEKHAR, JEONGSU KIM, Department of Physics and Astronomy, and Institute of Applied Physics, Seoul National University, Seoul, 08826, Korea, JAESUNG PARK, Center for Electricity & Magnetism, Korea Research Institute of Standards and Science, Daejeon, 34125, Korea, BYUNG HEE HONG, Department of Chemistry, Seoul National University, Seoul, 08826, Korea, SEUNGHUN HONG, Department of Physics and Astronomy, and Institute of Applied Physics, Seoul National University, Seoul, 08826, Korea — We report a “noise spectral imaging” strategy to directly map the noise source activities in graphene domains. Here, the lateral current and noise maps were measured by scanning a conductive contact probe on the graphene surface. The measured data were analyzed by using a two-dimensional network model to obtain the sheet resistance and charge trap density maps inside graphene domains, on domain boundaries, and on the edge of graphene. The results showed high activities of noise sources and large sheet resistance values at the domain boundary and edge of graphene. Furthermore, the top layer of double-layer graphene was found to have lower noises than those of single-layer graphene, as predicted previously. Our method allows one to image the localized noise source distribution in two-dimensional electronic channels such as graphene, and thus it can be a powerful tool for the basic research and applications about two-dimensional transports in nanostructures.

3:18PM U51.00005: Photothermal nanoimaging of dissipative surface polaritons* HONGHUA U YANG, LIANG-CHUN LIN, TAO JIANG, University of Colorado, Boulder, SAMUEL BERWEGGER, NIST Boulder, FABIAN MENGES (Presenter), MARKUS B. RASCHKE, University of Colorado, Boulder — Controlling the functionalities of 2D material structures via strong light-matter coupling requires understanding of the dissipation and thermalization dynamics of surface polaritons. However, the intricate details of polaritonic decay processes are rooted in a plethora of physical mechanism spanning widely separated length and time scales, even down to regimes where dissipation is no longer a readily measurable quantity. Here, we introduce photothermal force microscopy as a nanoimaging modality to visualize energy dissipation via surface plasmon polaritons (SPPs). Studying graphene on silicon dioxide, we perform real-space imaging of SPPs via photothermal force detection (AFM-IR) with contrast interpreted due to thermal substrate expansion induced by the local SPP decay. Complementary to previous studies, reporting the optical characterization of SPPs via IR-sSNOM, we will show that photothermal expansion forces facilitate the direct mechanical detection of the non-radiative SPP decay process. Our observations reveal that dissipative surface polariton modes might enable to control the spatio-temporal dynamics of thermal nanosystems.

We investigate the optical response of graphene and graphene nanoribbons using the broadband nonlinear generation and detection capabilities of nanoscale junctions created at the LaAlO$_3$/SrTiO$_3$ interface [1]. Using the large third-order nonlinear susceptibility in SrTiO$_3$, strong difference frequency mixing occurs when the junction is biased, leading to induced polarization that can also be detected at the junction [2,3]. Here we discuss the results of experiments which interrogate the relationship between the THz signal and the gate location with respect to the Dirac point in devices where graphene is coupled to the LaAlO$_3$/SrTiO$_3$ interface. Results show near-100% extinction of VIS-NIR light in graphene, and suggest we may be detecting a surface plasmon resonance. Additional results on individual graphene nanoribbons reinforce this interpretation.

*J. Levy acknowledges a Vannevar Bush Faculty Fellowship (ONR N00014-15-1-2847), and the Office of Naval Research (N00014-16-1-3152). 3:42PM U51.00007: Lattice vibrations of single and multi-layer isotopologic graphene HWANSOO JEON (Presenter), Pohang Univ of Sci & Tech, TOKUYUKI TERAJI, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, SUNMIN RYU, Pohang Univ of Sci & Tech — Isotope-substituted materials, isotopologues, have been crucial in understanding various scientific problems. In this work, we report full Raman spectroscopic investigation of $^{13}$C graphene, its multilayers, and isotopologic bilayers. All samples were prepared using $^{13}$C-enriched bulk crystals that were grown by the high-pressure and high-temperature method. Frequencies of G, 2D, and combination peaks showed a linear relation between two isotopologues of $^{12}$C and $^{13}$C, which led to a precise optical determination of isotopic purity in agreement with mass spectrometric results. Single to eight-layered graphene exhibited correspondence in spectral features between isotopologues: thickness-dependent progressions of intensities and line shapes, and excitation energy-dependent dispersion of 2D frequency. Line shape analyses of stacking-sensitive 2D revealed the spatial distribution of stacking domains and dominance of ABC-polytype unlike natural or kish graphite. Using isotopologic bilayers of $^{12}$C/$^{13}$C, we quantified the change in Fermi velocity induced by vdW interlayer interactions separately from strain and charge density. This work also presents direct evidence that the puzzling thermally activated doping is induced by hole dopants located at the graphene-substrate interface.
Detecting Photo-Induced Topological Edge States in a Graphene Nanoribbon Using Pump-Probe Spectroscopies

YUAN CHEN (Presenter), Stanford University, YAO WANG, Harvard University, MARTIN CLAASSEN, Simons Foundation Flatiron Institute, BRIAN MORITZ, SLAC National Accelerator Laboratory, THOMAS DEVEREAUX, Stanford University — Recently, photo-induced topological edge states in low dimensional materials have attracted considerable attention due to the tunability of dispersion and topological properties using light. Here, we present a numerical study of various pump-probe spectroscopies for a graphene nanoribbon subject to circularly polarized pump light. In particular, we calculate time-resolved resonant inelastic x-ray scattering (tr-RIXS) for the graphene nanoribbon, which clearly resolves the pump-induced band gap and the edge states. These tr-RIXS features have a direct correspondence with Floquet states and the calculated time-resolved ARPES spectra. We also calculate the pump-probe optical conductivity and nonresonant Raman scattering, demonstrating that the signatures from the pump-induced gap and edge states also should be visible, especially at low energy. These pump-probe techniques provide powerful tools for detecting photo-induced topological states in low dimensional materials.

Graphene Conductivity and Dielectric Response at THz frequencies

DAVID CAREY (Presenter), University of Surrey — The calculations of the dynamical conductivity of graphene allows further determination of the high frequency, from dc to optical frequencies, response of the real and imaginary parts of the dielectric constant of graphene. In this study we explore how the dynamical conductivity, dielectric properties and refractive index of single layer graphene vary as a function of frequency for different carrier concentrations and scattering times. We play particular attention to the differing roles of the intra- and interband transitions and explore the THz response of graphene as a possible functional material to bridge the so-called THz gap between electronics and optics. We find in the 1-10 THz frequency region that for moderately doped graphene (i) $\varepsilon_1$ is negative and approaches values in the mid $10^5$ but does not vary strongly at lower frequencies and (ii) $\varepsilon_2$ is positive for all THz frequencies explored but is one to two orders lower in magnitude; comparisons are made with noble metals. We also calculate the variation of real and imaginary components of the refractive index with wavelength. Potential applications in graphene based antennas and metamaterials are discussed.
4:18PM U51.00010: Strong magnetophonon oscillations induced by Dirac fermion - transverse acoustic phonon scattering in graphene  
PIRANAVAN KUMARAVADIVEL (Presenter), School of Physics and Astronomy, University of Manchester, MARK GREENAWAY, Department of Physics, Loughborough University, DAVID PERELLO, ALEXEY BERDYUGIN, JOHN BIRKBECK, JOSHUA WENGRAF, School of Physics and Astronomy, University of Manchester, SONG LIU, JAMES H. EDGAR, Department of Chemical Engineering, Kansas State University, ANDRE GEIM, LAURENCE EAVES, ROSHAN KRISHNA KUMAR, School of Physics and Astronomy, University of Manchester — Two dimensional electron gas systems exhibit a plethora of quantum phenomena. Graphene has not only provided a versatile platform for studying many of these phenomena but also revealed new effects. However one of the first discoveries in quantum transport, well known for fifty years has remained conspicuously absent in graphene: magnetophonon oscillations. Here we present our recent work on magnetotransport in boron nitride encapsulated graphene devices of different widths [1] and show that the magnetoresistance of wider graphene devices reveal this hitherto elusive quantum phenomenon. In devices of channel width greater than ten micrometres we observe pronounced magnetophonon oscillations caused by resonant scattering of Landau quantised Dirac quasiparticles with acoustic phonons in graphene. Using this we determine graphene’s low energy phonon dispersion and also find that transverse acoustic modes are the dominant source of phonon scattering. The results highlight the importance of device size in studying new quantum phenomena and demonstrates a spectroscopic technique for studying the nature of electron-phonon interactions in van der Waals heterostructures.  
TIANHAO ZHAO (Presenter), Georgia Inst of Tech, YUXUAN JIANG, National High Magnetic Field Lab, YIRAN HU, YUE HU, GRANT H NUNN, Georgia Inst of Tech, MYKHAYLO OZEROV, DMITRY SMIRNOV, National High Magnetic Field Lab, LEI MA, Tianjin International Center of Nanoparticles and Nanosystems, CLAIRE BERGER, WALTER DEHEER, ZHIGANG JIANG, Georgia Inst of Tech — We report on the magneto-infrared spectroscopy study of the new generation epigraphene grown on a non-polar facet of SiC [arXiv:1910.03697]. Interband Landau level (LL) transitions are observed and fitted well with $1\times10^6$ m/s as Fermi velocity in the massless Dirac fermion model. The transitions remain visible as the magnetic field is down to 0.25 T, indicating that the carrier density is no greater than $3.6\times10^{10}$ cm$^{-2}$ as expected for charge-neutral non-polar epigraphene. When the samples are grown thicker, LL transition splittings are spotted at high magnetic fields. Failing to explain the splittings with electron-hole asymmetry, we suggest that it could arise from (twist) bilayer epigraphene components and we will discuss it with a numerical twist bilayer graphene model.

4:42PM U51.00012: Direct Imaging of Electronic Symmetries in Twisted Double-Bilayer Graphene  
SIMON TURKEL (Presenter), CARMEN RUBIO VERDÚ, LARRY SONG, Department of Physics, Columbia University, New York, New York 10027, USA, DANTE KENNES, Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany, LEDE XIAN, Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany, HECTOR OCHOA, Department of Physics, Columbia University, New York, New York 10027, USA, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan, ANGEL RUBIO, ABHAY PASUPATHY, Department of Physics, Columbia University, New York, New York 10027, USA — When two graphene bilayers are twisted relative to one another at about one degree, the resulting system has been shown to host correlated insulating and superconducting states. Unlike in the case of simple twisted bilayer, the insulating states in the magic double bilayer are enhanced under parallel magnetic field, suggesting that electronic correlations may be mediated by ferromagnetic order. We directly image the local density of states in twisted double bilayer graphene using scanning tunneling microscopy and spectroscopy and observe the evolution of electronic wave functions within the moiré unit cell as a function of carrier density and applied electric field. In addition to corroborating theoretical band structure calculations via point spectroscopy, our observations of symmetry-broken states across a range of dopings and long-range order persisting across hundreds of nanometers offer insights into the complex charge and spin order that exists in magic angle twisted double bilayer graphene.

4:54PM U51.00013: Imaging double moiré pattern in twisted bilayer graphene grown on hBN with microwave impedance microscopy  
XIONG HUANG (Presenter), University of California, Riverside, LINGXIU CHEN, Shanghai Institute of Microsystem and Information Technology Chinese Academy of Sciences, SHUJIE TANG, Stanford University, CHENGXIN JIANG, CHEN CHEN, HUISHAN WANG, Shanghai Institute of Microsystem and Information Technology Chinese Academy of Sciences, ZHIXUN SHEN, Stanford University, HAOMIN WANG, Shanghai Institute of Microsystem and Information Technology Chinese Academy of Sciences, YONGTAO CUI, University of California, Riverside — Stacking multiple atomic layers of similar crystal structure will create moiré patterns whose periodicity and orientation are determined by the stacked layers. In this study, we image the moiré patterns in CVD grown bilayer graphene/hBN heterostructures using microwave impedance microscopy and conductive atomic force microscopy. Two sets of moiré patterns are observed: one formed between the first graphene layer with hBN and a second one between the two twisted graphene layers. The graphene/hBN moiré pattern indicates a perfect alignment between the two layers. The graphene/graphene moiré pattern has a smaller period due to a larger twist angle. This moiré pattern experiences abrupt phase change across the boundaries of the graphene/hBN moiré pattern. We present our analysis of such double moiré pattern based on lattice reconstruction occurred in the graphene layers.

Thursday, March 5, 2020 2:30 PM - 5:18 PM

Session U52 DCMP: Surfaces and Thin Films of Novel Electronic Materials Mile High Ballroom 1E - Daniel Dougherty, North Carolina State University
**2:30PM U52.00001: Exploring the origin of the thickness-dependent metal-insulator transition in thin-film systems with band structures**  
SUNGSOO HAHN (Presenter), BYUNGMIN SOHN, CHANGYOUNG KIM, Department of Physics and Astronomy, Seoul National University — Metal-insulator transition (MIT) has been studied in decades and is well known to be induced by temperature, pressure, and dopants. However, the origin of MIT in thin films which occur as metallic thin films become thinner is not explained. In order to investigate the thickness-dependent MIT, transport measurements and photoemission spectroscopy have been performed, however, the conclusion is not to be determined yet. Here, we observed band structures of SrRuO$_3$ ultrathin films near the MIT-critical thickness by using *in-situ* angle-resolved photoemission spectroscopy (ARPES). We expect our experimental observation sheds light on the thickness-dependent MIT in thin-film systems.

**2:42PM U52.00002: Scanning tunneling spectroscopy of rare earth hexaborides**  
PHILIPP BUCHSTEINER (Presenter), IV. Physikalisches Institut, Georg-August Universität Göttingen, FLORIAN SOHN, Institut für Theoretische Physik, Georg-August Universität Göttingen, LISA HARMSEN, IV. Physikalisches Institut, Georg-August Universität Göttingen, PETER E BLOECHL, Institut für theoretische Physik, Technische Universität Clausthal, MARTIN WENDEROTH, IV. Physikalisches Institut, Georg-August Universität Göttingen — The surface physics of rare earth hexaborides is of great interest for both technological applications and fundamental research. For example, LaB$_6$ is a widely used electron emitter due to its low work function and the 4f-electron system SmB$_6$ is a Kondo insulator with proposed topologically protected surface states. In order to systematically investigate the influence of 4f-electrons on the hexaboride surface physics, we performed scanning tunneling microscopy (STM) on the (001)-cleavage planes of LaB$_6$ [1] and PrB$_6$. We found that on both crystal surfaces a chain-like (2×1) reconstruction is present. Furthermore, we found uniform terminations on PrB$_6$. By performing slab calculations within the framework of density functional theory (DFT) we rationalize this reconstruction as parallel chains of rare earth ions on top of a B$_6$ framework. Using scanning tunneling spectroscopy (STS) we find a spectral feature below $E_F$, which can be described as boron dangling-bond state. For PrB$_6$, an additional contribution is visible in the spectra, which we tentatively attribute to the 4f-electrons.

*We acknowledge funding from DFG grants WE1889/10-1, BL539/10-1, PR298/19-1 and SFB 1073 projects B03, C03, C04.
2:54PM U52.00003: Synchrotron-Based Ultrafast Optical Pump/X-Ray Probe Measurements of Lattice Dynamics in Photo-Excited Pt Thin Films*  MATTHEW FORBES DECAMP (Presenter), Physics and Astronomy, Univ of Delaware, ANTHONY DICHIARA, Advanced Photon Source, Argonne National Laboratory, KARL UNRUH, Physics and Astronomy, Univ of Delaware — A synchrotron-based optical pump/x-ray probe measurement technique has been used to study the structural evolution of elemental Pt thin films following photo-excitation by ps duration optical laser pulses. High quality x-ray diffraction (XRD) patterns were obtained with a time-resolution of less than 100 ps (corresponding to the duration of a single x-ray pulse) and with time delays relative to the pump pulse ranging from 10’s of ps to ms. These measurements revealed a very rapid lattice expansion normal to the sample for several 100 ps following photo-excitation followed by a much less rapid decrease. The film response to excitation energies less than about 50 mJ/cm² was nearly reversible while greater excitation energies produced irreversible stress relaxation, and eventually film oblation. Assuming that the lattice expansion can be modelled in terms of a bulk thermal expansion coefficient, the maximum observed lattice temperature was about 1500 K.

3:06PM U52.00004: Ex-Situ Ozone Cleaning of SrTiO₃ Substrates for Molecular Beam Epitaxy*  CAMILLE BEAN (Presenter), TATIANA A WEBB, RUIZHE KANG, JENNIFER E. HOFFMAN, Harvard University — In molecular beam epitaxy synthesis of thin films, the quality of the substrate surface is crucial. The substrate not only provides a structural template for the deposited film, but the interaction between the film and the substrate itself determines emergent electronic properties. Therefore, it is critical to employ effective in-situ and ex-situ substrate cleaning techniques to ensure a clean substrate surface, which is necessary for high-quality film growth. Here, we report an investigation of the efficacy of cleaning with ozone as an ex-situ cleaning technique for widely used SrTiO₃ substrates. The substrates are ozone cleaned after etching and annealing. The carbon ratio on the substrate surface has been carefully examined using XPS to verify the efficacy of ozone cleaning.

*This work was funded by the Gordon and Betty Moore Foundation's EPiQS Initiative through Grant GBMF4536, and by the Office of Naval Research through Grant N00014-18-1-2691
3:18PM U52.00005: Benchmarking various levels of theory for first principles modeling of iron oxide surfaces and interfaces  
SUVAĐIP DAS (Presenter), Georgia Institute of Technology, EFSTRATIOS MANOUSAKIS, Florida State University, ANDREW J MEDFORD, Georgia Institute of Technology — Surfaces of iron and its oxides are scientifically relevant due to their performance as photo-anodes for water oxidation as well as their formation during corrosion processes. Finding an accurate ab-initio approach to appropriately describe surface phenomenon of iron and its oxides is critical to enable modeling of the charge accumulation, energetics and bond formation mechanisms governing the reactivity of iron oxide surfaces. Prior work has established that incorporation of the random-phase approximation (RPA) improves the accuracy of adsorption and surface energy calculations but these techniques have not been systematically applied to iron oxides. Here, we present a benchmarking study for various levels of theory such as onsite Coulomb interaction, hybrid functionals and quasiparticle GW methodology to appropriately modulate surface phenomenon in oxides. A detailed study of GW convergence from various starting points is presented for iron monoxide establishing hybrid-level orbitals as the optimum starting point for self-consistent GW calculations. The study also establishes the hybrid functional approach as an ideal trade-off between accuracy and computational cost towards efficient convergence of electronic wavefunction and formation energy for electrochemical applications.

3:30PM U52.00006: Spin Polarized Electron Emission from Magnetite Half-metals Determined by First-principles Calculations  
LIANGLIANG XU (Presenter), NAN ZHAO, MING-CHIEH LIN, Department of Electrical and Biomedical Engineering, Hanyang University, TSAN-CHUEN LEUNG, Department of Physics, National Chung Cheng University, HUA-YI HSU, Department of Mechanical Engineering, National Taipei University of Technology — Magnetite is a mineral and one of the main iron ores. With the chemical formula Fe$_3$O$_4$, it is one of the oxides of iron. Magnetite is the earliest discovered magnet, around 1500 B.C. It crystallizes in the inverse cubic spinel structure (Fd3m) above the so-called Verwey transition temperature, which is about 120 K. In this work, we study the electronic properties of magnetite (100), (110), and (111) surfaces using first principles or ab initio calculations based on density functional theory. With a +U calculation, most of the surfaces with different terminations show half-metallic, different from those predicted by a without +U calculation. It is proposed that the magnetite as a half-metal can possibly be used as a spin-polarized electron source. The spin polarized electrons can be obtained via the field emission process as described by the Fowler–Nordheim equation. From the first principles calculations, the surfaces suitable for spin polarized emission are found.
3:42PM U52.00007: Domain Walls in the Electronic Polarization of Silver Bismuthate  FRED FLORIO (Presenter), RAVISHANKAR SUNDARARAMAN, JIAN SHI, YUWEI GUO, Rensselaer Polytechnic Institute — Ternary bismuth oxides are a new class of atypical ferroelectric materials whose polar states are primarily induced by electronic charge disproportionation rather than atomic displacement. Silver bismuthates are particularly exciting as ferroelectric semiconductors with low band gaps. Previous research has focused primarily on bulk geometry and electronic structure of the materials, identifying three structural phases of Ag$_2$BiO$_3$ as a function of temperature. Understanding domain wall structures and energetics in this material is now critical to facilitate prediction of polarization and domain switching dynamics for applications in memory and opto-electronics.

Here we present structures of candidate domain walls in Ag$_2$BiO$_3$, using ab initio methods to determine the relative energies, structural displacements and charge disproportions associated with these domain walls. We also calculate the spatial width of the domain walls, the energy landscape of the polarization order parameter, and the bulk elastic response of the material. These quantities now facilitate phase field simulations of the polarization dynamics in Ag$_2$BiO$_3$, providing insight into the domain-switching dynamics from nano to micro scales.

3:54PM U52.00008: Understanding Electrical and Thermal Transport in Single Strand Cu-Coated Carbon Fiber*  HOJOON YI (Presenter), Sungkyunkwan Univ, JI YEON KIM, Korean Institute of Carbon Convergence Technology, HAMZA ZAD GUL, SEUNGSU KANG, GIHEON KIM, EUNJI SIM, HYUNJIN JI, Sungkyunkwan Univ, JUNGWON KIM, Korea Research Institute of Chemical Technology, YOUNG CHUL CHO, WON SEOK KIM, Korean Institute of Carbon Convergence Technology, SEONGCHU LIM, Sungkyunkwan Univ — Carbon fiber is used in many parts of high-performance cars to improve its performance. Furthermore, there are many researches to improve the properties of cables that have reduced weight by coating metal on carbon fiber cores. But there is a lack of research on thermal properties, one of the important properties.

In this study, 1ω AC current was used to analyze the electrical and thermal conductivity of single-stranded metal-coated carbon fibers with different metal thicknesses. Generated 3ω voltage due to heat generation was measured and analyzed. We conclude that depositing a metal layer on CF improves the both conductivity of CF. And our results show that the thermal conductivity of CF improves as the metal thickness increases. The heat flow is also identified through the Lorenz number, which represents the ratio of thermal conductivity to electrical conductivity. The change in Lorenz number explains how heat is distributed in the MCF over temperature changes.

Our results help to understand the heat transfer of the core-shell structure and can be used to identify heat dissipation and conduction without compromising the electrical conductivity of metal-coated carbon fibers.

4:06PM U52.00009: Structure and electronic states of Pt/SrTiO$_3$ (001) interface using X-ray standing wave excited photoelectron emission  
YANNA CHEN (Presenter), ANUSHEELA DAS, Northwestern University, TIEN-LIN LEE, Diamond Light Source, MICHAEL J BEDZYK, Northwestern University — In this work, we focus on Pt/SrTiO$_3$ heterostructure to discover the interfacial interaction between metal catalysts and metal oxide supports. Pt nano single crystals were grown on a SrTiO$_3$ (001) substrate using pulsed laser deposition. The Pt/SrTiO$_3$ heterostructure was characterized using X-ray standing wave (XSW) excited photoelectron emission collected in the Bragg back-reflection geometry at beamline I09 of the Diamond Light Source. Different electronic core levels of Pt 4f, 4d, 3d were collected, which showed differences in their responses to the XSW excitation. O 1s, Ti 2p, and Sr 3d core levels were also collected to understand the interfacial interaction between Pt and SrTiO$_3$. Focusing on Pt 4f, O 1s, Ti 2p, and Sr 3d, three symmetry inequivalent hkl Bragg peaks were measured to produce 3D interfacial atomic maps for each species via Fourier inversion. Among other things, these results should be beneficial for the design of oxide supported catalysts.

4:18PM U52.00010: Evolution of picosecond surface electric fields generated by photon-induced charge emission from La$_{0.67}$Sr$_{0.33}$MnO$_3$ thin films at 300 K and 77 K  
RUNZE LI (Presenter), PETER M. RENTZEPIS, Texas A&M University — The spatial-temporal distribution of picosecond surface electric fields, associated with the femtosecond-laser-induced photoemission from La$_{0.67}$Sr$_{0.33}$MnO$_3$ (LSMO) single crystal thin films, at 300 K and 77 K, were interrogated by sub-picosecond, 30 keV, electron pulses and reconstructed by a “three-layer” theoretical model. Around a few tens of picoseconds after femtosecond laser illumination, a surprisingly strong surface electric field on the order of hundreds kV/m was observed on the LSMO film at room temperature. This electric field strength is on the same order as the field(s) used for altering the orbital domains in lanthanum strontium manganite films. The experimental data of this study imply that the self-induced transient electric fields, generated during photoemission, may be a promising means for the control of ultrafast processes in materials that are mainly achievable through strong THz excitations.
Role of substrate vicinity on structural evolution and functional properties of lightly doped La$_{1-x}$Sr$_x$MnO$_3$ thin films

BINOD PAUDEL (Presenter), Department of Physics, New Mexico State University, AIPING CHEN, MPA-CINT, Los Alamos National Laboratory, HEINRICH NAKOTTE, Department of Physics, New Mexico State University — Epitaxial engineering has been considered an important approach to tune functional properties of oxide thin films. However, there is always a quest of other approaches that can provide more knobs to tailor and explore wide range of novel functional properties. Film substrate symmetry mismatch, thermal coefficient mismatch, substrate termination, and miscut angle and directions are also important factors to modulate growth, structure and functional properties. Here, we present the study on structural and functional properties of lightly doped La$_{0.9}$Sr$_{0.1}$MnO$_3$ (LSMO) films on SrTiO$_3$ substrates with different miscut angles (0.5°, 2°, 4° and 8°). Coherent growth was observed for films on 0.5° miscut substrate and in-plane periodic twining was observed for films grown on higher miscut angles. The out-of-plane periodic twinning was seen for films on for 0.5° miscut substrate while higher miscut substrates promote tilted domains formation. These structural distortions are attributed to monoclinic or triclinic distortion of orthorhombic LSMO films on cubic STO substrates. Curie temperature systematically reduces while magnetoresistance and temperature coefficient increase due to the reduction of domain variants and increase of out of plane tilt angles with the increase of miscut angles.

Surface structure determination of a two dimensional Au-Si-alloy formed on Au(110) by x-ray photoelectron spectroscopy (XPS) and x-ray photoelectron diffraction (XPD)*

MARIE SCHMITZ (Presenter), PETER ROESE, MALTE SCHULTE, CARSTEN WESTPHAL, TU Dortmund University — The metal-semiconductor interface has caused multiple interest in solid state physics especially in methods of metal silicides for various applications, for instance photonic and electronic devices.[1] A detailed structural as well as chemical investigation was performed by means of low energy electron diffraction (LEED), x-ray photoelectron spectroscopy (XPS), and x-ray photoelectron diffraction (XPD). High-resolution core-level-spectra of Au4f and Si2p reveal multiple chemically shifted components. Both Au4f and Si2p XPD-patterns were simulated with the EDAC[2] and MSPHD[3] packages, respectively, and compared with the measured pattern by a genetic algorithm reaching R-factors around 0.1. Therefore, we propose a surface-structure model for the Au-Si-alloy based on our measurements and simulations. The results are set in the context of an previously proposed surface-structure of the Au-Si-alloy via LEED, STM, and DFT by Enriquez et al.[4].

4:54PM U52.00013: Geometric models and electronic structure of Pb overlayers on Ge(111): a first-principles study* ANDRE CHILDS (Presenter), SHREE RAM ACHARYA, DUY LE, University of Central Florida, CHING YAO FONG, SHIRLEY CHIANG, University of California Davis, TALAT S. RAHMAN, University of Central Florida — Lead deposition on Ge(111) shows several low dimensional phases [1]: the (√3×√3)R30° Pb structure forms at coverages of 1/3 monolayer (ML) (α phase) and 4/3 ML (β phase), while at 1 ML the overlayer is (1 × 1). In all cases the Ge(111) surface is unreconstructed. The geometric and electronic structure of the phases are not yet fully understood. We present results from our density functional theory based calculations with and without inclusion of spin-orbit coupling (SOC) to shed light onto atomic and electronic structures of these phases and the nature of their binding to the substrate. We find that Pb atoms adsorb at the T$_4$ sites at a height of 2.94 Å, at the T$_4$ and H$_3$ sites at height of 2.84 Å, and the off-centered T$_1$ sites at height of 2.84, from the underlying Ge surface, on the α, β and 1 ML phases of the structure, respectively, and at the T$_1$ site at a height of 2.76 Å directly above the nearest Ge on the Pb(1 × 1) phase. We find that these phase are metallic. Our results reinforce the importance of SOC in reproducing geometric structures of the Pb over-layers, in good agreement with experimental observations.

5:06PM U52.00014: Giant Nonlinear Tunneling Current in HfO$_2$-based Anti-Ferroelectric Tunnel Junction JINHO BYUN (Presenter), TAEWON MIN, JAEKWANG LEE, Pusan Natl Univ — Owing to the recent advances in the oxide growth technology, ferroelectricity has been stabilized even in a few nm-thick films, which makes it possible to realize the ultrathin oxides-based ferroelectric tunneling junctions (FTJs) useful for the next generation switchable diode. Among various ferroelectric oxides, HfO$_2$ is the most promising material for FTJ devices since it has the great advantage of complementary metal-oxide-semiconductor (CMOS) process compatibility. Despite their numerous advantages, low non-linearity and tunneling current have hindered their applications to electronic devices. Here, combining density functional theory (DFT) calculations and numerical tunneling current simulations of the new type of tunneling potential, we find that the antiferroelectric-like head-to-head and tail-to-tail polarizations significantly enhance the non-linearity ($>10^3$) and tunneling current at the same time, which will be an essential guideline to design high density and low power consumption electronics applications.
2:30PM U53.00001: Atomic resolution characterization of 2D materials with scanning transmission electron microscopy. [Invited] NASIM ALEM (Presenter), Department of Materials Science and Engineering, Pennsylvania State University — Selected by Focus Topic Organizer (Liuyan Zhao, Robert Hovden).

2:42PM U53.00002: Using Intercalation Chemistry to Change Interlayer Spacing and Resulting Bandgap of Two-Dimension Materials* ANDREW SMITH (Presenter), SUBASH KATTEL, ZACHARY HECHT, HENRY WLADKOWSKI, JOSEPH R MURPHY, WILLIAM RICE, ELLIOTT HULLEY, JOHN ACKERMAN, BRIAN LEONARD, Univ of Wyoming — The operating principle behind smart windows is that they can transmit, absorb or reflect different wavelengths of light at will. To achieve these properties, they must be constructed with materials that have an easily tunable bandgap, this is often done via intercalation chemistry. 2D materials have shown similar tunability in the past and often show enhanced mobility for ions. We are exploring one such material, WO$_2$Cl$_2$, and what role interlayer spacing plays in the bandgap of 2D materials. When WO$_2$Cl$_2$ is intercalated with Li, it starts as a wide bandgap material (clear) then transitions to a blue narrower bandgap material, then a coppery metallic phase. To understand these phases, we have carried out 4-point resistivity measurements, absorption and Raman spectroscopy, XRD, XPS, SEM, and TEM. These methods have shown intercalated WO$_2$Cl$_2$ to be a very tunable and versatile material. Additionally, we hypothesize a direct relationship between bandgap, interlayer spacing and ion size for WO$_2$Cl$_2$. To test this, we have examined properties of WO$_2$Cl$_2$ that has been intercalated ions of increasing size, Li<Na<K<Rb<Cs to great success.

*NSF DMR: 1229383

2:54PM U53.00003: Realization of 2D Crystalline Metal Nitrides via Selective Atomic Substitution JUN CAO (Presenter), TIANSHU LI, HONGZE GAO, XI LING, Boston Univ — Two-dimensional (2D) transition metal nitrides (TMNs) are emerging members in 2D family with promising potential for a range of applications. Their applications can be further extended to electronic and optoelectronic devices through the acquisition of high crystalline and large-area thin films. However, materials that meet such requirements have not been achieved using previous methods. Here, we report the synthesis of few-nanometer thin Mo$_5$N$_6$ crystals with satisfactory area and quality via chemical conversion of layered MoS$_2$ crystals. The lateral dimensions of Mo$_5$N$_6$ crystals are inherited from the MoS$_2$ precursors. Atomic force microscopy characterization indicates that the thicknesses of Mo$_5$N$_6$ crystal reduce to about 1/3 of the MoS$_2$ crystal, matching well with the crystal structure model. Electrical measurement shows the high conductivity of Mo$_5$N$_6$. In addition, this chemical conversion strategy is found versatile for the synthesis of various metal nitrides including W$_5$N$_6$, and TiN using corresponding metal sulfides. Our strategy offers a new direction for preparing 2D TMNs with desired characteristics, opening a door for future exploration of fundamental physics and devices applications.
3:06PM U53.00004: Step edge-mediated assembly of periodic arrays of long graphene nanoribbons on Au(111)  WENCHANG LU (Presenter), North Carolina State University, CHUANXU MA, Oak Ridge National Laboratory, ZHONGCAN XIAO, North Carolina State University, JINGSONG HUANG, KUNLUN HONG, AN-PING LI, Oak Ridge National Laboratory, JERRY BERNHOLC, North Carolina State University — Graphene nanoribbons (GNRs) can be fabricated with atomic precision via bottom-up synthesis on metal substrates, but the growth of long GNRs still remains a challenge. We have previously investigated the growth mechanism of GNRs from molecular precursors on Au substrate [1]. Recently, we have observed that the step edges of an Au (111) substrate can enhance GNR growth and yield significantly longer GNRs and periodic GNR arrays on the Au(111) surface [2]. By studying the atomic structures and electronic properties near step edges by DFT calculations, we have found that the intermediate polyanthryl structures adsorb more strongly along Au step edges due to pi-pi interactions between polyanthryls near the steps, which result in longer and more compact polymer arrays and lead to the synthesis of longer GNRs. Our findings suggest a direction for the manufacturing of longer GNRs for future applications.

3:18PM U53.00005: Preparation and growth of sulfide heterostructure thin films from designed precursors  DENNICE ROBERTS (Presenter), National Renewable Energy Laboratory, BRIAN GORMAN, Colorado School of Mines, JOHN PERKINS, ANDRIY ZAKUTAYEV, SAGE BAUERS, National Renewable Energy Laboratory — Design of chalcogenide heterostructures has enabled access to a remarkable range of material properties occurring as a result of structural flexibility at the nanoscale. A powerful approach to generating heterostructures involves the preparation of an amorphous precursor film designed to mimic the desired end product. While this has been highly successful in generating selenium-based heterostructures with novel properties, sulfur-based compounds have remained unexplored. Here we present the first crystalline sulfide heterostructure prepared using this precursor approach, forming superlattices with a tunable number of SnS layers sandwiched between monolayers of TaS$_2$. Structural measurements confirm film crystallinity and overall film smoothness, and architecture is confirmed by high resolution TEM and EDS that resolves atomically precise sequencing of SnS and TaS$_2$ layers. Formation mechanisms are assessed in terms of mobility of precursor elements upon heating. A path towards sulfide heterostructures with adjustable stacking orders allows the development of materials with precisely tuned properties that utilize phenomenon inherent in constituent compounds; such materials are promising for applications in advanced electronics.
Experimental demonstration of partial van der Waals screening by mono- and double-layer MoSe\textsubscript{2} and MoS\textsubscript{2}

STANISLAV TSOI (Presenter), United States Naval Research Laboratory, SAUJAN V SIVARAM, MATTHEW ROSENBERGER, National Research Council, US Naval Research Laboratory, Washington, DC 20375, KATHLEEN MCCREARY, United States Naval Research Laboratory, HSUN-JEN CHUANG, American Society for Engineering Education, US Naval Research Laboratory, Washington, DC 20375, BEREND THOMAS JONKER, United States Naval Research Laboratory

— Few-layer flakes of MoS\textsubscript{2} or MoSe\textsubscript{2} with lateral dimensions over 1 \(\mu\)m were grown on graphite using chemical vapor deposition, yielding layered samples MoS\textsubscript{2}/graphite or MoSe\textsubscript{2}/graphite, respectively. Next, an attractive van der Waals (vdW) force on a sharp AFM tip was measured from graphite, MoS\textsubscript{2}/graphite and MoSe\textsubscript{2}/graphite as a function of a separation between the tip and sample. The vdW force from the layered samples is significantly weaker than from graphite alone, suggesting screening of the semimetallic graphite by the semiconducting MoS\textsubscript{2} and MoSe\textsubscript{2}. Statistical analysis over 6 different measurements indicates that the single-layer MoSe\textsubscript{2} screens 59 ± 14 % and the single-layer MoS\textsubscript{2} 71 ± 12 % of the force from graphite. The double-layer samples exhibit even stronger screening, with the double-layer MoSe\textsubscript{2} screening 77 ± 24 % and the double-layer MoS\textsubscript{2} 94 ± 8 % of the vdW force from graphite. The observed results demonstrate a possibility to engineer and control the nanoscale vdW forces in a bottom-up approach, and provide a critical experimental platform for testing the quantum electrodynamic Lifshitz theory of vdW interactions.

Graphene growth on non-metallic substrates by Chemical Vapor Deposition

SANDRA RODRIGUEZ VILLANUEVA (Presenter), ALVARO INSTAN, University of Puerto Rico - Rio Piedras, FRANK MENDOZA, Physics, University of Puerto Rico at Mayaguez, BRAD R WEINER, RAM KATIYAR, GERARDO MORELL, University of Puerto Rico - Rio Piedras

— The electrical properties of graphene on dielectric substrates have many applications. Graphene is usually grown on metallic substrates then transferred onto dielectric substrates as necessary. However, to obtain graphene directly on non-metallic substrates is still challenging. In this work, we show the direct synthesis of graphene on SiO\textsubscript{2}/Si and SiC by hot-filament chemical vapor deposition. The graphene deposition was conducted at low pressures with a mixture methane in hydrogen and a substrate temperature 900°C followed by abrupt cooling to room temperature. A thin strip of copper layer was sputtered in the middle of the SiO\textsubscript{2}/Si substrates as a catalytic material. For the SiC substrate, a hydrofluoric acid treatment was used before graphene deposition. The structural properties of the graphene films were analyzed using Raman Spectroscopy, Atomic Force Microscopy (AFM), and X-ray photoelectron spectroscopy (XPS). Raman mapping and AFM measurements indicate the growth of few-layer graphene films in all cases. X-ray photoelectron spectroscopy confirmed the presence of graphene deposition on SiO\textsubscript{2}/Si and SiC substrates. The results show that the availability of copper vapors from the thin copper strip enables the growth of graphene in all surfaces of the non-metallic substrates.
3:54PM U53.00008: Direct growth of twisted bilayer graphene with controllable twist angle by plasma-enhanced chemical vapor deposition*  JIAQING WANG (Presenter), YEN-CHUN CHEN, Physics, California Institute of Technology, WEI-HSIANG LIN, Applied Physics, California Institute of Technology, WEI-SHIUAN TSENG, Physics, California Institute of Technology, CHII-DONG CHEN, Institute of physics, Academia Sinica, YU-SHU WU, physics, National Tsing-Hua University — We report a direct plasma-enhanced chemical vapor deposition (PECVD) method to grow single crystalline bilayer graphene (BLG) flakes and mm-size BLG films with the interlayer twist angle controlled by the growth parameters. The average twist angle can be controlled from 0° to approximately 20° by tuning the CH4-to-H2 pressure ratio (PCHA4/PH2). Raman spectroscopic studies on our PECVD-grown BLG together with x-ray and ultraviolet-light photoelectron spectroscopy indicate high-quality samples and reveal twist-angle dependent spectral characteristics. Atomically resolved scanning tunneling microscope (STM) is employed to identify the Moiré pattern and the value of the corresponding twist angle between two layers. Our PECVD-grown BLG provides a perfect platform to study the twist-angle dependence of its electronic properties. We performed transport measurements on our BLG samples with twist angles varying between 0° and 20°. The electronic properties of BLG of different twist angles are systematically investigated as a function of temperature and gate voltage, which provides useful information for the origin of various correlated phenomena.

*This work was jointly supported by ARO and NSF in the USA, and by the MoST in Taiwan.

4:06PM U53.00009: 2D platinum diselenides grown on 3D wide-bandgap substrates by Van der Waals epitaxy*  CHIA-HER LIN, EDWARD STOCKERT, Physics Department, Natl Sun Yat Sen Univ, CHING-WEN CHANG, Research Center for Applied Sciences, Academia Sinica, Taiwan, TING CHEN, CHIEN-CHEN KUO, YI-YING LU, LI-WEI TU, Physics Department, Natl Sun Yat Sen Univ, QUARK CHEN (Presenter), Physics and TcSUH, University of Houston, PARITOSH V WADEKAR, Physics Department, Natl Sun Yat Sen Univ — PtSe2 is a 2D material that undergoes phase transition from a semiconductor of Eg≈0.3 eV to a type-II Dirac semimetal as its thickness varies. 3D wide band gap semiconductors continue to gain wider acceptance as a substrate material and as an electrode if properly doped. To embrace for broader applications, tractable materials process design rules are essential, especially in understanding the relationships between the Van der Waals epitaxy and the resulted physical properties of the ended products. In this work, ultrathin films of Pt were first deposited by magnetron sputtering on the GaN, AlN and Al2O3 substrates followed by atmospheric pressure chemical vapor deposition (APCVD). Selenization of the Pt films forms uniform and smooth 2D/3D selenide heterostructures. The effects of deposition parameters with respect to the underlying substrates according to the physical properties are investigated. Various spectroscopic means were used to study the samples with well characterized structural properties.

*Supported by the Ministry of Science and Technology via MOST 105-2112-M-110-005 for PVW and LWT and MOST 105-2221-E-110-042 and the State of Texas through the Texas Center for Superconductivity, University of Houston for QYC.
**4:18PM U53.00010: Facile Production of Macroscopic Single Crystal Monolayers and Artificial Lattices of 2D van der Waals Materials**

FANG LIU (Presenter), WENJING WU, YUSONG BAI, SANGHOON CHAE, QIUYANG LI, JUE WANG, JAMES C HONE, XIAOYANG ZHU, Columbia University — Two dimensional (2D) materials from layered van der Waals (vdW) crystals hold great promises for electronic, optoelectronic, and quantum devices, but technological implementation has been hampered by the lack of high-throughput techniques for the production of monolayers with sufficient sizes and quality. Here we report a facile method to disassemble vdW single crystals layer-by-layer into monolayers with near-unity yield and with macroscopic dimensions limited only by bulk crystal sizes. The quality of the macroscopic single crystal monolayers are comparable to those of microscopic dimensions obtained from state-of-the-art techniques. We exfoliate a range of vdW crystals and assemble the monolayers into artificial lattices, including transition metal dichalcogenides with dramatic enhancement in nonlinear optical responses. This approach takes us one step closer to commercialization of 2D materials.

*The research was supported by the Materials Science and Engineering Research Center (MRSEC) through NSF grant DMR-1420634, and National Science Foundation (NSF) grant DMR-1809680, and the Department of Energy (DOE) Office of Energy Efficiency and Renewable Energy (EERE) Postdoctoral Research Award managed by Oak Ridge Associated Universities under DOE contract number DE-SC00014664.

**4:30PM U53.00011: Automated Vacuum Stacking for Additive Assembly of 2D van der Waals Heterostructures**

ANDREW YE (Presenter), Pritzker School of Molecular Engineering, University of Chicago, ANDREW J MANNIX, James Franck Institute, University of Chicago, FAUZIA MUJID, Department of Chemistry, University of Chicago, CHIBEOM PARK, James Franck Institute, University of Chicago, JIWOONG PARK, Pritzker School of Molecular Engineering, University of Chicago — Wafer-scale synthesis of monolayer 2D materials (2DMs) address the stochastic, small-area limitations of micromechanical exfoliation. Using wafer-scale synthesized 2D semiconductors along with large-area patterning and multi-functional polymer stamps, we demonstrate a highly automated, dry-transfer, additive assembly process. Our high-vacuum system can assemble 2D heterostructures at the precision of actuator limits (few micron lateral/0.2° rotational). Identical structures have been assembled in parallel and stacks of high layer counts (25+) have been achieved, all without active user control of the system. Fabricated heterostructures include a range of 2DMs (MoS$_2$, WS$_2$, WSe$_2$, graphene) and metal electrodes (Au, Ti), and can be deposited onto a variety of substrates (SiO$_2$, Al$_2$O$_3$, 2DMs). We also demonstrate controlled twisted n-layer heterostructure assembly, where number of layers depends on area limits of single-crystal 2DMs growth.

4:42PM U53.00012: Impact of thermal treatment on graphene films synthesized via interfacial trapping technique*  SARA CHAHID (Presenter), RAJENDRA DULAL, SERAFIM TEKNOWIJOYO, Chapman Univ, ALEXANDER RZHEVSKII, Molecular & Elemental Analysis App. Lab, Thermo Fisher Scientific, ARMEN GULIAN, Chapman Univ — Large variety of graphene applications in science and technology justify different methods to obtain pure graphene films. Among these methods, Woltornist et.al., ACS Nano 7, 7062 (2013) obtained promising results by pulverizing ultrapure graphite in water/n-heptane mixture to form continuous films on glass substrate. We report here subsequent steps of studying this method with different substrates and also of application of annealing (100°-600°, in air and in a vacuum) on the physical properties of these films. As can be deduced from Raman spectra, the quality of graphene films is enhanced in certain temperature range. We complemented Raman mapping by characterizing the morphology of films using scanning electron microscopy. Other instrumentation techniques have also been used to affect and study the physical properties of these films. Overall, the simplicity of the method and the quality of the film reveal potential areas of applications in microelectronics.

*This work was supported in part by the ONR Grants N00014-16-2269, N00014-17-1-2972, N00014-18-1-2636, and N00014-1901-2265.

4:54PM U53.00013: Fabrication and Imaging of Monolayer Phosphorene with Preferred Edge Configurations via Graphene-Assisted Layer-by-Layer Thinning  YANGJIN LEE (Presenter), SOL LEE, JUN-YEONG YOON, Department of Physics, Yonsei University, JINWOO CHEON, Center for Nanomedicine, Institute for Basic Science (IBS), HU YOUNG JEONG, UNIST Central Research Facilities (UCRF), Ulsan National Institute of Science and Technology, KWANPYO KIM, Department of Physics, Yonsei University — Phosphorene, a monolayer of black phosphorus (BP), is an elemental 2D material with interesting physical properties including high charge carrier mobility and exotic in-plane anisotropic properties. To fundamentally understand its various physical properties, the atomic-scale structural investigation, various defect and preferred edge configurations for monolayer counterpart, is of critically importance. However, it has been challenging to perform imaging of monolayer phosphorene due to technical difficulty to prepare high-quality samples and damages induced during measurements via photons or high-energy electrons. Here, we successfully fabricate monolayer phosphorene by a controlled thinning process inside a TEM and subsequently perform atomic-resolution imaging. Graphene protection suppresses the e-beam-induced damage to BP and one-side graphene lamination facilitates the layer-by-layer thinning of the samples, rendering monolayer and bilayer regions. We also observe crystalline edge predominantly aligned along zigzag and (101) terminations, which can be explained by edge kinetics under e-beam-induced sputtering process. Our study provides invaluable approach to manipulate the thickness and image beam-sensitive 2D materials.

Session U54 DCMP: Topological Crystalline Phases  Mile High Ballroom 2A
2:30PM U54.00001: Aperiodic Topological Crystalline Insulators*  HUAQING HUANG (Presenter), YONG-SHI WU, FENG LIU, University of Utah — Topological crystalline insulators (TCIs) are usually described with topological protection imposed by the crystalline symmetry. In general, however, the existence of TCI states does not necessitate the periodicity of crystals as long as an essential lattice symmetry can be identified. Here we demonstrate the compatibility of TCIs with aperiodic systems, as exemplified by an octagonal quasicrystal. In contrast to most common topological insulators and TCIs, the proposed aperiodic TCIs are attributed to a different symmetry-invoked band inversion mechanism, which inverts states with the same parities but opposite eigenvalues of a specific symmetry (such as reflection). The nontrivial topology is characterized by a nonzero integer "mirror Bott index". Moreover, we demonstrate that the topological edge states and quantized conductance of the aperiodic TCI, which are robust against disorder, can be effectively manipulated by external electric fields. Our findings not only provide a better understanding of electronic topology in relation to symmetry but also extend the experimental realization of topological states to much broader material categories beyond crystals.

2:42PM U54.00002: Real Space Invariants: Spectral Flow of Fragile Topological State under Twisted Boundary Conditions  ZHIDA SONG (Presenter), Princeton University, LUIS ELCORO, University of the Basque Country, NICOLAS REGNAULT, ANDREI BERNEVIG, Princeton University — In this paper, we propose the twisted boundary condition as a generic approach to theoretically and experimentally detect the fragile topological state. We prove that, when the fragile phase can be written as a difference of a trivial atomic insulator and the so-called obstructed atomic insulator, the gap between the fragile phase and other bands must close under a specific twist of the boundary condition of the system. We explicitly work out all the twisted boundary conditions that can detect all the 2D fragile phases implied by symmetry eigenvalues in all wallpaper groups. We develop the concept of real space invariants, which are local good quantum numbers in real space, and which also fully characterize the eigenvalue fragile phases. We show that the number of unavoidable level crossings under the twisted boundary condition is completely determined by the real space invariants. Possible realizations of the twisted boundary condition of the fragile band in metamaterial systems are also discussed.

2:54PM U54.00003: Electron localization in fragile topological crystalline phases  RAQUEL QUEIROZ (Presenter), Weizmann Institute of Science, RONI ILAN, Tel Aviv University, ZHIDA SONG, Princeton University, ADY STERN, Weizmann Institute of Science, ANDREI BERNEVIG, Princeton University — Topological phases are known for their robustness to local perturbations. Localization of topological bands has been extensively studied, particularly those protected by local symmetries such as time-reversal or particle-hole symmetries. In the last few years, it became clear that also nonlocal, crystalline, symmetries are crucial for the protection of topology in electronic systems. Crystalline symmetry protected topology opens the way fundamentally new concepts that fall outside of the conventional knowledge in theory of localization. In this talk, I will present a numerical study of localization in fragile topological insulators, relevant for recent experimental developments.
3:06PM U54.00004: Fragile Topology Protected by Inversion Symmetry: Diagnosis, Bulk-Boundary Correspondence, and Wilson Loop*  YONSEOK HWANG (Presenter), JUNYEONG AHN, BOHM-JUNG YANG, Seoul Natl Univ — We study the bulk and boundary properties of fragile topological insulators (TIs) protected by inversion symmetry, mostly focusing on the class A insulator. First, we propose an efficient method for diagnosing fragile band topology by using the symmetry data in momentum space. Second, we study the bulk-boundary correspondence of fragile TIs protected by inversion symmetry. In particular, we show that a minimal fragile TI with the filling anomaly corresponds to the $dD$ $(d+1)$th-order TI. Although $dD$ $(d+1)$th-order TIs have no in-gap states, the boundary mass terms carry an odd winding number along the boundary, which induces localized charges on the boundary at the positions where the boundary mass terms change abruptly. Also by studying the (nested) Wilson loop spectra, we show that all the spectral windings of the (nested) Wilson loop should be unwound to resolve the Wannier obstruction of fragile TIs. By counting the minimal number of bands required to unwind the spectral winding of the Wilson loop and nested Wilson loop, we determine the minimal number of bands to resolve the Wannier obstruction, which is consistent with our diagnosis method of fragile topology.

3:18PM U54.00005: Crystalline topological phases without symmetry indicators  SANDER KOOI (Presenter), GUIDO VAN MIERT, CARMINE ORTIX, Univ of Utrecht — Topological insulating phases of matter are quantum phases that cannot be deformed to atomic insulators. They generically feature protected anomalous surface states, which can be used for applications in spintronics and quantum computation.

Recently, two new types of topological phases protected by crystalline symmetries have been discovered. The first are higher-order topological insulators, featuring conducting states on the hinges [1], recently observed in bismuth [2]. The other are fragile topological states, which become trivial when occupying additional bands. Twisted bilayer graphene may be a realization of a fragile phase, which may help to explain superconductivity in this system [3].

Usually, crystalline topology can be detected by computing symmetry indicators. However, there exist topological phases which cannot be detected in this way, and we present the first classification of such states [4]. We show these crystalline invariants are also well-defined in quantum spin Hall systems and use this to construct a hybrid-order weak TI [5], which is both a weak and higher-order TI.

3:30PM U54.00006: Topology of chiral insulators  MARCELO GUZMÁN (Presenter), DENIS BARTOLO, DAVID CARPENTIER, Physique, Ecole Normale Superieure de Lyon — Building on direct analogies with electronic matter, the concepts of topological insulator and topological protection have been successfully applied to a host of different physical systems as diverse as photonic metamaterials, geophysical fluids and mechanical structures. In this work, we focus on materials, or metamaterials, having a chiral symmetry, such as crystals with a sub-lattice symmetry and all mechanical systems assembled from beads and springs.

Firstly, we show that the topology of waves in chiral materials is naturally encoded in their chiral polarization, which quantifies the spatial imbalance of localized Wannier states between the two sub-lattices. Secondly, we demonstrate that the chiral polarization originates both from topological properties of the Hamiltonian and of the frame on which this Hamiltonian is defined. Our results elucidate a long-standing ambiguity on the topological characterization of the simplest, and probably oldest example of a topological state: the Su-Schrieffer-Hegger (SSH) chain. Finally, we establish a generalized bulk-boundary correspondence for chiral systems and show how to effectively use the concept of chiral polarization to predict the existence of interfacial states at the boundary of chiral insulators.

3:42PM U54.00007: Boundary obstructed topological phases  ESLAM KHALAF (Presenter), Harvard University, WLADIMIR A BENALCAZAR, The Pennsylvania State University, TAYLOR L HUGHES, University of Illinois at Urbana-Champaign, RAQUEL QUEIROZ, Weizmann Institute of Science — Symmetry protected topological (SPT) phases are gapped phases of matter that cannot be deformed to a trivial phase without breaking the symmetry or closing the bulk gap. Here, we introduce a new notion of a topological obstruction that is not captured by bulk energy gap closings in periodic boundary conditions. More specifically, we say two bulk Hamiltonians belong to distinct boundary obstructed topological ‘phases’ (BOTPs) if they can be deformed to each other on a system with periodic boundaries, but not for symmetric open boundaries without closing the gap at a high symmetry region on the surface. BOTPs are not topological phases of matter in the standard sense since they are adiabatically deformable to each other on a torus but, similar to SPTs, they are associated with surface states or fractional corner charges in the open system. We show that the double-mirror quadrupole model of [Science, 357(6346), 2018] is a prototypical example of such phases, and present a detailed analysis of boundary obstructions in this model. In addition, we introduce several three-dimensional models having boundary obstructions, which are characterized either by surface states or fractional corner charges and discuss their general formulation in terms of Wannier band representations.

3:54PM U54.00008: Topological Crystalline States with Non-trivial Relative Group Cohomology*  SYDNEY R TIMMERMAN (Presenter), YI LI, Johns Hopkins University — The method of relative homotopy group has been know useful to characterize the surface defects that are not trivial extensions of bulk defects. We develop the method of relative group cohomology to study novel topological crystalline states characterized by non-trivial relative group cohomology and their relation to fragile topological crystalline states.

4:06PM U54.00009: Topological Invariants of a Filling-Enforced Quantum Band Insulator

ABIJITH KRISHNAN (Presenter), Harvard University, HOI CHUN PO, Massachusetts Institute of Technology, ASHVIN VISHWANATH, Harvard University —

In the classical picture of insulators, electrons occupy localized Wannier (atomic-like) orbitals. Recently, insulators for which electron filling prohibits this atomic description have been theoretically proposed. The electronic wave functions of these insulators, termed filling-enforced Quantum Band Insulators (feQBIs), display a necessary degree of quantum entanglement due to the non-atomic filling. Currently, little is known about the relation between feQBIs and conventional topological invariants. In this work, we study such relations for a particularly interesting example of an feQBI realized with spinless fermions in space group 106.

4:18PM U54.00010: Fermions in $\mathbb{Z}_N$ Gauge Fields: From Chern Insulators to Higher-Order Topological Insulators*

VIJAY SHENOY (Presenter), SHUBHAM RANA, Indian Institute of Science —

Fermions coupled to gauge fields defined on the links of lattices have received considerable attention due to their importance in describing a variety of physical systems. Here, we show how a higher-order topological insulator emerges in a system of fermions coupled to $\mathbb{Z}_N$ gauge fields. By tuning the filling of fermions and the strength of the coupling of fermions to the gauge fields, we show that a variety of fermion phases are stabilized for different parameter regimes. We map out the phase diagram of this system and identify conditions needed to generate a higher-order topological insulating phase. This work suggests experimental routes, for example in a cold atomic system, to obtain different topological phases of fermions to study both the properties of these phases and the phase transitions between them.

Type-II quadrupole topological insulators

YANBIN YANG (Presenter), KAI LI, LUMING DUAN, YONG XU, Tsinghua University — Recently, the formulation of polarization based on the Berry phase has been extended to higher multipole moments, through the discovery of the so-called quadrupole topological insulator.

It has been established by a classical electromagnetic theory that in a two-dimensional material the quantized properties for the quadrupole topological insulator should satisfy a basic relation. Here we discover a new type of quadrupole topological insulator (dubbed as type-II) that violates this relation due to the breakdown of a previously established theory that a Wannier band and an edge energy spectrum are topologically equivalent in a closed quantum system. We find that, similar to the previously discovered (referred to as type-I) quadrupole topological insulator, the type-II hosts topologically protected corner states carrying fractional corner charges. However, the edge polarizations only occur at a pair of boundaries in the type-II insulating phase, leading to the violation of the classical constraint. We propose an experimental scheme to realize such a new topological phase of matter. The existence of the new topological insulating phase means that new multipole topological insulators with distinct properties can exist in broader contexts beyond classical constraints.

Layer Construction of Topological Crystalline Insulator LaSbTe

YUTING QIAN (Presenter), Institute of Physics, Chinese Academy of Science, ZHIYUN TAN, School of Physics and Electronic Science, Zunyi Normal University, TAN ZHANG, JIACHENG GAO, ZHIJUN WANG, ZHONG FANG, CHEN FANG, HONGMING WENG, Institute of Physics, Chinese Academy of Science — Topological crystalline insulator (TCI) is one of the symmetry-protected topological states. Any TCI can be looked as a simple product state of several decoupled two-dimensional (2D) topologically nontrivial layers in its lattice respecting its crystalline symmetries, so called layer construction (LC) scheme. In this work, based on first-principles calculations we have revealed that both the tetragonal LaSbTe (t-LaSbTe) and the orthorhombic LaSbTe (o-LaSbTe) can be looked as a stacking of 2D topological insulators in each lattice space. The structural phase transition from t-LaSbTe to o-LaSbTe due to soft phonon modes demonstrates how the real space change can lead to the modification of topological states. Their symmetry-based indicators and topological invariants have been analyzed based on LC. We propose that LaSbTe is an ideal paradigm perfectly demonstrating the LC scheme, which bridges the crystal structures in real space to the band topology in momentum space.
U54.00013: Filling-enforced Dirac loops and their evolutions under various perturbations
DEXI SHAO (Presenter), Chinese Academy of Sciences, Institute of Physics — Based on symmetry analysis, we find that filling-enforced Dirac loops (FEDLs) in non-magnetic systems exist in only five space groups. We further explore all possible configurations of these FEDLs in these space groups, and classify them accordingly. We study the evolutions of the FEDLs under various types of perturbations such as applied strain or field. It is interesting that the FEDL-materials can serve as both parent materials of nodal semimetals having Dirac points or nodal-loops, and topological insulators/topological crystalline insulators. Many the FEDL-materials are predicted in DFT calculations.

Session U55 DCMP: Topological superconductors in more than one dimension
Mile High Ballroom 2B - Tag(s): Focus

2:30PM U55.00001: Superconductivity without time-reversal or inversion symmetries
[Invited] DANIEL AGTERBERG (Presenter), University of Wisconsin - Milwaukee, PHILIP BRYDON, Physics, University of Otago, MARK H FISCHER, Physics, University of Zurich, HENRI MENKE, Physics, University of Otago, MANFRED W SIGRIST, Theoretical Physics, ETH-Zurich, CARSTEN TIMM, Theoretical Physics, Technische Universität — To ensure a superconducting instability, key symmetries are required. In three dimensions (3D), these are time-reversal (T) and inversion (I) symmetries. In two dimensions, T and I are joined by TM_z and IM_z symmetries where M_z is a mirror reflection through the basal plane. Here we discuss unusual physics that arises when one or more of these key symmetries are broken. In particular, in 3D, we show that spontaneously breaking T symmetry allows for topologically protected nodal Bogoliubov Fermi surfaces and apply this idea to URu_2Si_2 and Sr_2RuO_4. In 2D, we develop an energetic and topological superconductor classification in the unfamiliar situation that both T and I symmetries are absent. We apply this to Ising superconductors with in-plane magnetic fields and monolayer FeSe coexisting with antiferromagnetic order.
3:06PM U55.00002: Supercurrent-induced Majorana bound states in a planar geometry*
ANDRÉ MELO (Presenter), SEBASTIAN RUBBERT, ANTON AKHMEROV, Kavli Institute of Nanoscience, Delft University of Technology — We propose a new setup for creating Majorana bound states in a two-dimensional electron gas Josephson junction. Our proposal relies exclusively on a supercurrent parallel to the junction as a mechanism of breaking time-reversal symmetry. We show that combined with spin-orbit coupling, supercurrents induce a Zeeman-like spin splitting. Further, we identify a new conserved quantity—charge-momentum parity—that prevents the opening of the topological gap by the supercurrent in a straight Josephson junction. We propose breaking this conservation law by adding a third superconductor, introducing a periodic potential, or making the junction zigzag-shaped. By comparing the topological phase diagrams and practical limitations of these systems we identify the zigzag-shaped junction as the most promising option.

3:18PM U55.00003: Dissipative chiral superconductors in 3D  MENG HUA (Presenter), LINGYU YANG, JEFFREY TEO, Univ of Virginia — Topological band theories that describe insulators, superconductors and (semi)metals are conventionally classified according to the Altland-Zirnbauer classification based on the presence or absence of local time-reversal and particle-hole symmetries. More recently, there are theoretical generalizations that incorporate non-local magnetic space group symmetries. There are more exotic combined antiunitary spatial symmetries that involve particle-hole conjugation and may be allowed in a non-Hermitian system. In this talk, we focus on the classification, model realization and topological-index characterization of dissipative topological superconductors in 3D and the corresponding dissipative chiral Majorana fermion on the boundary surface.
3:30PM U55.00004: Topological Skyrmion Phases of Matter* ASHLEY COOK (Presenter), University of California, Berkeley — We introduce two-dimensional topological phases of matter defined by non-trivial homotopy groups into the literature, characterized either by a single Skyrmion number, known as the chiral topological Skyrmion insulator, or a pair of Skyrmion numbers, known as the helical topological Skyrmion insulator, which generalize and extend the concepts of the Chern insulator and quantum spin Hall insulator, respectively. We show each topological phase of matter is protected by a combination of a mirror symmetry and a generalized particle-hole symmetry equal to the product of particle-hole symmetry and spatial inversion symmetry. Despite these phases being protected in part by crystalline point group symmetries, the phases introduced here are very different from all others known: we characterize three kinds of phase transitions by which a Skyrmion number can change. One kind of topological phase transition occurs without the closing of energy gaps, which has important consequences for study of topologically non-trivial phases of matter. We find that each phase is realized in a tight-binding model relevant to Sr2RuO4 and discuss experimental realization given that the chiral topological Skyrmion insulator phase is realized for a parameter set used to characterize Sr2RuO4.

*NSERC

3:42PM U55.00005: Triplet-Superconductivity in Triple-Band Crossings* GIBAIK SIM (Presenter), MOON JIP PARK, SUNGBIN LEE, Korea Adv Inst of Sci & Tech — In this talk, we will introduce the triplet superconductivity in the newly discovered form of the topological semimetal, where the electrons with pseudospin J=1 form triple-band crossings. The peculiar property of J=1 electrons is that Fermi statistics rules out on-site spin singlet pairing. Performing the exact decoupling of on-site electron interactions into pairing channels, we adopt the Landau theory of spin-triplet pairings and study the Landau free energy functional to plot out the global phase diagram. We find two distinct phases; (i) time-reversal symmetric (Sz) state, (ii) time-reversal broken (Sx + i Sy) state. Remarkably, both of these states have gapless Bogoliubov quasiparticles and furthermore have topological invariants for each nodal line or Bogoliubov Fermi surface.

3:54PM U55.00006: Higher-order topological superconductor in $\mathcal{P}$, $\mathcal{T}$-odd quadrupolar Dirac metal  
BITAN ROY (Presenter), Lehigh University — Presence or absence of certain symmetries in the normal state (NS) also plays important role in determining the symmetry of the Cooper pairs. We here show that two- and three-dimensional Dirac metals, realized by doping parity ($\mathcal{P}$) and time-reversal ($\mathcal{T}$) odd topologically trivial Dirac insulators, sustain a local or inter-unit cell pairing that assumes the form of a time-reversal odd and mixed parity (due to the absence of $\mathcal{T}$ and $\mathcal{P}$ in the NS, respectively) pairing around the Fermi surface. When the NS additionally breaks discrete four-fold ($C_4$) symmetry (yielding a $\mathcal{P}$, $\mathcal{T}$-odd, quadrupolar Dirac metal), the system gives birth to a higher-order $p + id$ pairing, hosting corner (in $d = 2$) or hinge (in $d = 3$) modes of codimension $d_c = 2$ of Majorana fermions. While the $p$-wave component stems from the Dirac nature of quasiparticles in the NS, appearance of the $d$-wave component is solely attributed to the lack of $C_4$ symmetry, as its restoration produces $p + i s$ pairing.

4:06PM U55.00007: Refined symmetry indicators for topological superconductors in all space groups*  
SEISHIRO ONO (Presenter), Univ of Tokyo, HOI CHUN PO, Massachusetts Institute of Technology, HARUKI WATANABE, Univ of Tokyo — Topological superconductors are exotic phases of matter featuring robust surface states that could be leveraged for topological quantum computation. A useful guiding principle for the search of topological superconductors is to relate the topological invariants with the behavior of the pairing order parameter on the normal-state Fermi surfaces. The existing formulas, however, become inadequate for the prediction of the recently proposed classes of topological crystalline superconductors. In this work, we advance the theory of symmetry indicators for topological (crystalline) superconductors to cover all space groups. Our main result is the exhaustive computation of the indicator groups for superconductors under a variety of symmetry settings.

4:18PM U55.00008: Emergent spacetime and gravitational Nieh-Yan anomaly in chiral Weyl superfluids and superconductors* JAAKKO NISSINEN (Presenter), Low Temperature Laboratory, Department of Applied Physics, Aalto University — Momentum transport in topological Weyl superfluids (and superconductors) is anomalous in the presence of textures and superflow. Using the semi-classical approximation and gradient expansion, the gauge and Galilean symmetries of the system induce via the superfluid hydrodynamics an emergent "Riemann-Cartan" spacetime with torsion and curvature for the low-energy Weyl quasiparticles. Furthermore, the background exhibits local conservation laws corresponding to emergent quasi-relativistic Lorentz symmetry. We show that the momentum anomaly can be given a consistent interpretation as the chiral Nieh-Yan gravitational anomaly experienced by Weyl fermions on the emergent curved spacetime. The coefficient of this anomaly term is not universally quantized and seems to be determined by the underlying non-relativistic Fermi-liquid and Galilean symmetries. Finally, the connection and extension of the emergent spacetime to finite temperature corrections and thermal effects will be discussed.

4:30PM U55.00009: Weyl-superconductor phases in the multilayer model of Weyl semimetals and superconductors RYOTA NAKAI (Presenter), KENTARO NOMURA, Tohoku University — We study the superconducting proximity effect in the bulk of Weyl semimetals by considering a multilayer structure consisting of alternating Weyl-semimetal and superconductor (WSM-SC) layers. Our model realizes Weyl-superconductor phases with 2 or 4 nodes of the Majorana fermion, and (2d) topological-superconductor phases characterized by half-odd-integer and integer Chern numbers. We found that potential barriers at the interface and/or mismatch of the Fermi velocity favor topological-superconductor phases with half-odd integer Chern numbers, while Weyl-superconductor phases with 4 nodes and topological-superconductor phases with integer Chern numbers are realized when the Fermi velocity coincides. Topological-superconductor phases are characterized by the quantization of the thermal Hall conductivity, and Weyl-superconductor phases by continuously varying thermal Hall conductivity determined by the position of nodes.

4:42PM U55.00010: Edge current and orbital angular momentum of chiral superfluids revisited WENXING NIE (Presenter), Sichuan University, WEN HUANG, Southern University of Science and Technology, HONG YAO, Institute for Advanced Study, Tsinghua University — Cooper pairs in chiral superfluids carry quantized units of orbital angular momentum (OAM). Various predictions of the total OAM of a chiral superfluid differ by several orders of magnitude. These constitute the so-called angular momentum paradox. Following several previous studies, we substantiate the semiclassical Bogoliubov-de Gennes theory of the edge current and OAM in two-dimensional chiral superfluids in the BCS limit. The analysis provides a simple intuitive understanding for the vanishing of OAM in a non-p-wave chiral superfluid (such as d+id) confined by a rigid potential. When generalized to anisotropic chiral superconductors and three-dimensional (3D) chiral superfluids, the theory similarly returns an accurate description. We will also present a numerical study of the chiral phases in the BEC limit, where the OAM density is found to vanish in the bulk and arise purely from the boundary effects.
4:54PM U55.00011: Vortices in a Monopole Superconducting Weyl Semi-metal*  SHU-PING LEE (Presenter), CANON SUN, YI LI, Johns Hopkins University — A monopole superconductor is a novel topological phase of matter with topologically protected gap nodes that result from the non-trivial Berry phase structure of Cooper pairs. In this work we study the zero-energy vortex bound states in a model of a monopole superconductor based on a time-reversal broken Weyl semi-metal with proximity-induced superconductivity. The zero modes exhibit a non-trivial phase winding in real space as a result of the non-trivial winding of the order parameter in momentum space. By mapping the Hamiltonian to the $(1 + 1)d$ Dirac Hamiltonian, it is shown that the zero modes, analogous to the Jackiw-Rebbi mode, are protected by the index theorem.

*This work is supported by the Institute for Quantum Matter under DOE EFRC grant DE-SC0019331 and in part by the Alfred P. Sloan Research Fellowships under grant FG-2018-10971 and the Gordon and Betty Moore Foundations EPiQS Initiative through grant GBMF4305.

5:06PM U55.00012: Majorana Kramers Pairs in Higher-Order Topological Insulators*  CHEN-HSUAN HSU (Presenter), PETER STANO, Center for Emergent Matter Science, RIKEN, JELENA KLINOVAJA, DANIEL LOSS, Department of Physics, University of Basel — We propose a tune-free scheme to realize Majorana bound states using higher-order topological insulators [1]. When two hinges of a higher-order topological insulator nanowire are brought into the proximity of an $s$-wave superconductor, two types of pairings arise, one being local (intra-hinge) pairing and the other nonlocal (inter-hinge) pairing. We find that, the competition between these pairings leads to a topological phase transition. The energy band is inverted in the regime where the nonlocal pairing dominates over the local one, leading to the formation of a Kramers pair of Majorana bound states at each end of the nanowire. We show that this topological condition can be fulfilled in the presence of moderate electron-electron interactions, without fine-tuning system parameters such as external magnetic fields.

5:18PM U55.00013: Topology-Bounded Superfluid Weight in Twisted Bilayer Graphene
FANG XIE (Presenter), ZHIDA SONG, BIAO LIAN, ANDREI BERNEVIG, Princeton University — We derive the superfluid weight (phase stiffness) of the TBLG superconducting flat bands with a uniform pairing, and show that it can be expressed as an integral of the Fubini-Study metric of the flat bands. This mirrors results [1] already obtained for nonzero Chern number bands even though the TBLG flat bands have zero Chern number. We further show the metric integral is lower bounded by the topological C2zT Wilson loop winding number of the TBLG flat bands, which renders the superfluid weight has a topological lower bound proportional to the pairing gap. In contrast, trivial flat bands have a zero superfluid weight. The superfluid weight is crucial in determining the BKT transition temperature of the superconductor. Based on the transition temperature measured in TBLG experiments, we estimate the topological contribution of the superfluid weight in TBLG.

Thursday, March 5, 2020 2:30 PM - 5:30 PM

Session U56 DCMP: SmB6 and Kondo Insulators Mile High Ballroom 2C - Xiaxin Ding, Idaho National Laboratory

2:30PM U56.00001: Kondo holes break topological protection of heavy Dirac fermions in SmB6* HARRIS PIRIE (Presenter), YU LIU, Harvard University, ERIC MASCOT, University of Illinois at Chicago, PENGCHENG CHEN, Harvard University, SHANTA SAHA, XIANGFENG WANG, JOHNPIERRE PAGLIONE, University of Maryland, College Park, MOHAMMAD H HAMIDIAN, Harvard University, CYRUS F. HIRJIBEHEDIN, University College London, UK, DIRK KLAUS MORR, University of Illinois at Chicago, JENNIFER E. HOFFMAN, Harvard University — The interplay of magnetism and strongly correlated topology is expected to generate exotic quantum phenomena. SmB6 is a leading platform, as it was recently shown to host heavy Dirac surface states that form within a screened Kondo lattice [1]. In conventional heavy fermion materials, it is well known that local magnetic structure is nucleated by Kondo holes—substitutions on the f-electron contributing lattice. If the same mechanism exists in the topological counterparts to these systems, Kondo holes would provide a local gauge of the impact of magnetism on the emergent heavy Dirac fermions. However, current experimental techniques to image the microscopic signature of a Kondo hole are challenging, and require tracking the complex heavy fermion band structure. Here, we introduce electrochemical potential imaging spectroscopy to directly visualize the impact of Kondo holes from the liberation of screening electrons around them. In SmB6, we discover that Sm-site defects create Kondo holes that locally break topological protection, allowing backscattering of heavy Dirac fermions.

*This work was supported by NSF DMR-1410480, DOE DE-FG02-05ER46225, AFOSR FA9550-14-1-0332, and Gordon and Betty Moore Foundation grant 4536 and 4419.
Electronic transport in the Kondo insulator SmB$_6$ is dominated at low temperatures by a surface state, which could arise as a consequence of a non-trivial topology of its bulk electronic structure. At ambient pressure, our thermopower measurements have suggested the surface states of SmB$_6$ to have a strongly enhanced effective mass, consistent with recent quasiparticle interference studies from STM. Pressure increases the hybridization between $f$- and conduction electrons eventually leading to a metallic state. Here we report thermopower measurements under pressure that illustrate that the Fermi energy of the surface state is unchanged as a function of pressure in the insulating regime. We discuss our results in consideration of Hall effect data that reveal a carrier density increase with increasing pressure.

*Work at Los Alamos was performed under the auspices of the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering. S.S. acknowledges a Directors Postdoctoral Fellowship through the Laboratory Directed Research & Development program.
A Resonant Inelastic X-ray Scattering investigation of the 4f states in SmB$_6$*  ANDREA AMORESE (Presenter), OLIVER STOCKERT, Max Planck Institute for Chemical Physics of Solids, KURT KUMMER, NICHOLAS B BROOKES, European Synchrotron Radiation Facility, DAE-JONG KIM, ZACHARY FISK, Department of Physics and Astronomy, University of California, Irvine, MAURITS HAVERKORT, Institute for Theoretical Physics, Heidelberg University, PETER THALMEIER, LIU HAO TJENG, Max Planck Institute for Chemical Physics of Solids, ANDREA SEVERING, Institute of Physics II, University of Cologne — The crystal-field (CF) splitting of the $^6H_{5/2}$ Hund's rule ground state of Sm$^{3+}$ in the strongly correlated topological insulator SmB$_6$ [1,2] has been determined with high resolution resonant inelastic x-ray scattering (RIXS) at the Sm M$_5$ edge [3]. The valence selectivity of RIXS allows to isolate the crystal-field-split excited multiplets of the Sm$^{3+}$(4f$^5$) configuration from those of Sm$^{2+}$(4f$^6$) in intermediate valent SmB$_6$. We find that the quartet G$_8$ ground state [4] and the doublet G$_7$ excited state are split by $D_{CF}=20\pm10$meV. Considering this as an upper limit for the 4f bandwidth suggests an extremely large mass renormalization from the band structure value, which can be linked to the small coefficient of fractional parentage for the hopping of the 4f electrons [5]. The tiny band width complies with the small value of the gap and may be used to put constraints to the energies of the topological surface states.

3:06PM U56.00004: A Parameter-free Study of the Magnetic and Electronic Structure of the Topological Heavy-fermion Compound SmB$_6^*$  RUIQI ZHANG (Presenter), Tulane University, BAHADUR SINGH, CHRISTOPHER LANE, Northeastern University, JAMIN KIDD, YUBO ZHANG, Tulane University, BERNARDO BARBIELLINI, Lappeenranta University of Technology, ROBERT MARKIEWICZ, ARUN BANSIL, Northeastern University, JIANWEI SUN, Tulane University — We revisit the highly debated mixed-valence compound SmB$_6$, which has been widely studied in both theory and experiment. One outstanding challenge is the difficulty in obtaining accurate theoretical band structures of SmB$_6$ as the starting point for further theoretical studies. We report new first-principles electronic-structure results, finding a band structure in agreement with experiments, wherein the correct crystal field splitting of $f$ electrons is captured by considering magnetic configurations. Intermediate valency and the right ground state symmetry are also captured in our calculations. The energies for each magnetic ordering are extremely close, indicating that SmB$_6$ exhibits spin fluctuations. Moreover, our results confirm that SmB$_6$ is a robust Kondo topological insulator due to its strong $d$ and $f$ band hybridization. Our study paves the way for future mean-field theory investigations of electronic and atomic structures, phase diagrams, and band topology of $f$-electron systems and other complex materials.

*Work supported by DOE under grant DE-SC0012575

3:18PM U56.00005: Conductive dislocation lines in SmB$_6$ observed through microwave impedance microscopy* KEJUN XU (Presenter), Stanford University, JING XIA, University of California, Irvine, JAN ZAANEN, Leiden University, ZHIXUN SHEN, Stanford University — SmB$_6$ is a candidate for an important class of topological insulator arising from strong correlations. Transport studies suggest surface-dominated transport at low temperatures [1]. Photoemission also revealed 2D in-gap states [2], however the topological nature of these states are under debate [3]. Here we use scanning microwave impedance microscopy to reveal conductive dislocation lines that terminate at step edges of the SmB$_6$ surface. Temperature dependence show that these states persist up to high temperatures beyond any Kondo energy scale. These observations reveal an important conduction channel that must be taken into account for transport studies. Further studies are desired to probe the topological nature of these 1D dislocation states.

*This work is supported by the Gordon and Betty Moore foundation, the National Science Foundation, and US DOE.
3:30PM U56.00006: Electrical Transport Properties of SmB$_6$ Nanowires*  SUJOY GHOSH
(Presenter), SEAN THOMAS, YEONHOO KIM, FILIP RONNING, ERIC BAUER, JINKYOUNG YOO,
PRISCILA ROSA, Los Alamos National Laboratory — Strongly correlated electron systems based on
rare-earth elements have attracted a great deal of interest in the last few decades due to their
emergent properties, such as valence fluctuations, metal–insulator transitions and heavy-fermion
superconductivity near the quantum critical point. Among these, SmB$_6$ is a topological Kondo
insulator candidate, an ideal platform to investigate the interplay between topology and strong
interactions as well as possible exotic quasiparticles, such as Majorana fermions. In this
presentation, I will talk about our recent experimental efforts on the synthesis and
characterization of SmB$_6$ nanowires prepared via a low-temperature reaction. I will further
discuss the electrical transport properties of these nanowires under different temperatures and
magnetic fields.

*Acknowledgments: Work at Los Alamos was performed under the auspices of the U.S.

Engineering. SG and PFSR acknowledge support from the Laboratory Directed Research and
Development program under Grant No. 20190076ER.

3:42PM U56.00007: Synthesizing SmB$_6$ single crystals by various techniques  SHANTA SAHA
(Presenter), Maryland Quantum Materials Center, Department of Physics, University of Maryland College
Park, LUCAS WILLIAM, MagLab Tallahassee, WESLEY T FUHRMAN, YUN SUK EO, Maryland Quantum
Materials Center, Department of Physics, University of Maryland College Park, RYAN BAUMBACH, MagLab
Tallahassee, JOHNPIERRE PAGLIONE, Maryland Quantum Materials Center, Department of Physics,
University of Maryland College Park — Samarium Hexaboride (SmB$_6$), a mixed valence Kondo
insulator, has attracted much recent attention due to the discovery of a low temperature
conducting surface state, proposed to be a topologically protected surface state that arises due
to the formation of a Topological Kondo insulator state. To date, single crystals of SmB$_6$ have
only been synthesized by ‘aluminum flux’ and ‘floating zone’ methods, mainly due to the high
melting point of boron. Recently, quantum oscillations were observed in the both type of crystals,
but intrinsic origins of those findings are controversial due to possible extrinsic origins such as
aluminum inclusions. Therefore, growing single crystals using alternative methods is considered
important for elucidating the intrinsic electronic properties of SmB$_6$. We will discuss efforts to
produce SmB$_6$ single crystals by radiofrequency (RF) technique and by flux growth methods
using alternative fluxes, comparing the results of various techniques.
3:54PM U56.00008: Revisiting Hall coefficient measurements in samarium hexaboride*
ALEXA RAKOSKI (Presenter), Department of Physics, Univ of Michigan - Ann Arbor, YUN SUK EO, Center for Nanophysics and Advanced Materials, University of Maryland, DMITRI MIHALIOV, CAGLIYAN KURDAK, Department of Physics, Univ of Michigan - Ann Arbor, PRISCILA ROSA, Los Alamos National Laboratory, ZACHARY FISK, Department of Physics and Astronomy, University of California Irvine, BOYOUN KANG, MYUNG-SUK SONG, BEONGKI CHO, Gwangju Institute of Science and Technology, MONICA CIOMAGA HATNEAN, GEETHA BALAKRISHNAN, Department of Physics, University of Warwick — Samarium hexaboride is a correlated material in which strong f-d interactions open a small gap at the Fermi energy below ~100 K. In transport, SmB$_6$ demonstrates activated behavior down to ~4 K, terminated by a conduction mechanism attributed to the emergence of a topological surface state. We present a study of transport, especially Hall coefficient, from three perspectives. First, we discuss a method of analyzing Hall data at low temperatures, allowing for accurate extraction of mobility from the conductive surface. Next, we re-examine a well-known high-temperature feature in Hall data: the sign change from negative to positive as temperature is raised above ~65 K. This sign change has been attributed to skew scattering due to the strong f-d interactions, but it leads to an inaccurate determination of carrier density and mobility. We discuss a method to improve the accuracy of transport analysis that relies on ARPES data at high temperature to correct for the positive Hall sign. Finally, we present a method of carving a micron-sized Hall bar from SmB$_6$ to investigate the effect of sample size on transport parameters. Taken together, these results aim to provide a summary of current transport perspectives on SmB$_6$.

4:06PM U56.00009: Properties of the donor impurity band in mixed valence insulators
BRIAN SKINNER (Presenter), Ohio State Univ - Columbus — In traditional semiconductors with large effective Bohr radius, an electron donor creates a hydrogen-like bound state just below the conduction band edge. The properties of the impurity band arising from such hydrogenic impurities have been studied extensively during the last 70 years. Here I consider whether a similar bound state and a similar impurity band can exist in mixed valence insulators, such as SmB$_6$ and YbB$_{12}$. I show that the structure of the hybridized conduction band leads to an unusual bound state that can be described using the physics of the one-dimensional hydrogen atom. The properties of the resulting impurity band are consequently modified in a number of ways relative to the traditional semiconductor case; most notably, the impurity band can hold a much larger concentration without inducing an insulator-to-metal transition. I give an estimate of the DC and AC conductivities and specific heat associated with the impurity band, and show that they are consistent with experiments on SmB$_6$. 
4:18PM U56.00010: Topological surface state of Kondo insulator YbB$_{12}^*$ YUKI SATO

(Presenter), SHIGERU KASAHARA, YUICHI KASAHARA, Department of Physics, Kyoto University, ZIJI XIANG, COLIN B TINSMAN, LU CHEN, LU LI, Department of Physics, University of Michigan, TAKASADA SHIBAUCHI, Advanced Materials Science, University of Tokyo, FUMITOSHI IGA, Institute for Quantum Beam Science, Ibaraki University, JOHN SINGLETON, Los Alamos National Laboratory, NITYAN NAIR, NIKOLA MAKSIMOVIC, JAMES ANALYTIS, Department of Physics, University of California, Berkeley, YUJI MATSUDA, Department of Physics, Kyoto University — YbB$_{12}$ is a Kondo insulator which is theoretically predicted to host metallic surface states arising from the nontrivial band structure. Recent observation of quantum oscillations (QOs) in YbB$_{12}$ arouses great interest since it may indicate a Fermi surface in an insulator phase. The most important subject is to clarify whether the QOs arise from insulating bulk or metallic surface. Here we fabricated micro-devices of YbB$_{12}$ using focused ion beam technique and measured transport properties in high fields. All of the samples fabricated by FIB and mechanical polishing exhibit resistivity plateaus at low temperatures and residual resistivity decreases linearly as a function of thickness. These results provide evidence of 2D surface conduction in YbB$_{12}$. We also find the device shows positive and quasi-linear $H$-dependent magnetoresistance, which is attributed to the anti-weak localization of the surface electrons with spin-momentum locking. No discernible QOs are observed in this device, suggesting the QOs in single crystals arise from insulating 3D bulk.

4:30PM U56.00011: Field-induced “exotic metal” phase in Kondo insulator YbB$_{12}$ ZIJI XIANG

(Presenter), Univ of Michigan - Ann Arbor, YUICHI KASAHARA, Department of Physics, Kyoto University, LU CHEN, TOMOYA ASABA, Univ of Michigan - Ann Arbor, YUKI SATO, Department of Physics, Kyoto University, COLIN B TINSMAN, Univ of Michigan - Ann Arbor, FUMITOSHI IGA, College of Science, Ibaraki University, JOHN SINGLETON, Los Alamos National Laboratory, YUJI MATSUDA, Department of Physics, Kyoto University, LU LI, Univ of Michigan - Ann Arbor — YbB$_{12}$, a representative Kondo insulator, has attracted attention in recent years as it exhibits Shubnikov-de Haas effect in intense magnetic fields. With the magnetic field further increasing, YbB$_{12}$ goes through an insulator-to-metal transition. We systematically studied the high field metallic phase in YbB$_{12}$ in pulsed magnetic fields. The temperature dependence of the resistivity in this phase reveals a crossover from non-Fermi-liquid behavior above 4 K to Fermi-liquid-like behavior below 2 K. The low-temperature state also shows unusually large Kadowaki-Woods ratio. Results of the proximity detector oscillator measurements provide evidences that the electronic structure of YbB$_{12}$ in the metallic phase depends on both the strength and the orientation of external magnetic fields.
4:42PM U56.00012: Magnetic Field Induced Fermi Liquid In a Candidate Topological Kondo Insulator

SATYA KUSHWAHA (Presenter), MUN K. CHAN, JOONBUM PARK, SEAN THOMAS, ERIC BAUER, JOE D THOMPSON, FILIP RONNING, PRISCILA ROSA, NEIL HARRISON, Los Alamos National Laboratory — Kondo insulators are expected to undergo an insulator-to-metal phase transition under strong magnetic fields. We show that Ce$_3$Bi$_4$Pd$_3$ is a narrow gap Kondo insulator. Our high magnetic pulse-field transport and magnetization experiments reveal the destruction of Kondo coupling and the closing of the Kondo gap at a critical magnetic field, $B_c \approx 11$ T. A Fermi liquid state emerges for fields beyond $B_c$, with a decrease in electronic correlations.

4:54PM U56.00013: First-principles study of band topology for $f$-electron materials: Ce$_3$(Pt/Pd)$_3$Bi$_4$$^*$

JAMIN KIDD (Presenter), RUIQI ZHANG, JIANWEI SUN, Tulane Univ — Recent density functional theory (DFT) calculations on the proposed topological Kondo insulator SmB$_6$ using the newly developed SCAN functional have yielded valence $f$-band splitting consistent with experiment, as well as band hybridization and $Z_2$ indices for the paramagnetic phase by following a symmetry analysis of the periodic Anderson Kondo lattice Hamiltonian.$^1$ Motivated by these promising results, we apply the SCAN functional to study the ternary Ce$_3$(Pt/Pd)$_3$Bi$_4$ systems, a new family of candidates for strongly correlated topological materials. While the Pt-based (Pd-based) compound has been predicted to be a Kondo insulator (Kondo semimetal), the topological properties of both systems are still under debate.$^{2,3}$ Here, we consider the local magnetic moment of Ce atoms and calculate the electronic structures for typical magnetic configurations. We then identify the topological phases present in both materials by calculating the appropriate invariants and comparing our results to previous experiments.

5:06PM U56.00014: Optical Properties of Kondo Insulators*  ARI WUGALTER (Presenter), YASHAR KOMIJANI, PIERS COLEMAN, Physics & Astronomy, Rutgers, The State University of New Jersey — This talk will discuss the optical properties of Kondo insulators, including the dielectric constant and magnetic permeability. Using a large-N Abrikosov fermion representation in a treatment of a Kondo lattice model, we show that the dielectric constant is determined by the squared ratio of the plasma frequency to the direct gap, predicting dielectric constants of order 1000, diffractive indices of order 30. By treating the magnetic correlations of the f-electrons as a gapless spin-liquid, described by dispersing f-electrons coupled to a gauge field we derive an effective model for the gauge fields which includes a continuum of excitations as well as a hybridization between the external electro-magnetic gauge field and the emergent gauge field. The gradient expansion of the effective model predicts a massless `light’ mode and a massive Higgs mode. The observation of this Higgs mode would provide an interesting opportunity to establish the presence of spin fractionalization and emergent gauge fields in Kondo insulators.

5:18PM U56.00015: Interplay between magnetism and topology in Kondo Insulators*  DAVID RIEGLER (Presenter), MICHAEL KLETT, University of Wuerzburg, SEULGI OK, TITUS NEUPERT, University of Zurich, PETER K WOELFLE, Karlsruhe Institute of Technology, RONNY THOMALE, University of Wuerzburg — Topological Kondo insulators are a rare example of an interaction-enabled topological phase of matter, making them an intriguing but also hard case for theoretical studies. Here, we investigate the periodic Anderson model with the addition of spin orbit coupling via a fully spin-rotation invariant slave-boson treatment. Within mean-field approximation we map out the magnetic phase diagram and characterize both antiferromagnetic and paramagnetic phases by their topological properties. Moreover, we establish the stability of the mean-field solution via Gaussian fluctuations around the saddle point by the computation of the dynamical susceptibility.

Session U57 DMP: Charge Density Waves, Excitonic and Correlated States in Two-Dimensional Materials and Semimetals  Frederic Joucken, University of California, Santa Cruz - Mile High Ballroom 3A - Tag(s): Focus
Mott insulating behaviors in few-layer 1T-TaSe$_2$  

SIQI WANG (Presenter), SUI YANG, University of California at Berkeley, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, KAI ROSSNAGEL, Kiel University, XIANG ZHANG, University of California at Berkeley — Material systems with strong electron correlation may exhibit exotic properties in stark contrast to conventional Fermi liquid. Among them, Mott insulators continue to attract tremendous research interest due to its close relation with unconventional superconductors and quantum spin liquids. Recent advances in layered van der Waals materials provide a novel material family which intrinsically has great in-situ tunability and therefore may act as a versatile quantum simulator for complicated systems. While the low temperature insulating phase with commensurate charge density wave (CCDW) order of the two-dimensional (2D) material 1T-TaS$_2$ has been ascribed to a Mott insulator, recent work casts doubt on this identification by considering the vertical stacking order of 2D CDWs. On the other hand, the CCDW phase in question was reported to be fragile towards mechanical exfoliation, hindering direct characterization in atomic-layer limit. Here we present electrical transport characterization of few-layer 1T-TaSe$_2$, a ‘sibling’ material with simpler phase diagram and more robust CCDW order. Our results provide evidence of Mott insulating behaviors in this long-thought trivial metal, thus hinting at an ideal platform for the investigation of strongly correlated physics in 2D systems.

Excitonic insulator in MoS$_2$ under pressure  

SAMANEH ATAEI, DANIELE VARSANO, Istituto Nanoscienze, CNR, DAVIDE SANGALLI, FLASHit, CNR-ISM, ELISA MOLINARI, FIM, University of Modena, MASSIMO RONTANI (Presenter), Istituto Nanoscienze, CNR — Among correlated insulators, a fascinating paradigm applies to narrow-gap semiconductors, whose low-energy excitations are pairs of electron ($e$) and hole ($h$) bound by Coulomb attraction, the excitons. If the binding energy overcomes the gap, then excitons spontaneously condense at thermodynamic equilibrium—similarly to Cooper pairs in a superconductor—giving rise to the ‘excitonic insulator’ (EI). Crucially, breakthrough reports [1] of the EI in transition metal dichalcogenides could not assess at which extent the condensation of $eh$ pairs was due to the formation of bound excitons or to the softening of the phonon responsible of the observed structural change. Here, by means of many-body perturbation theory from first principles, we demonstrate that MoS$_2$ at high pressure is prone to the condensation of genuine excitons of finite momentum, whereas the phonon dispersion remains regular. The self-consistent electronic charge density of the EI sustains an out-of-plane permanent electric dipole moment with an in-plane anti-ferroelectric texture. At the onset of the EI phase, those optical phonons that share the exciton momentum are folded to the zone center, providing a unique Raman fingerprint that has been observed but not explained yet.

2:54PM U57.00003: Geometric Frustration in a Monolayer TMD Alloy* MEHMET DOGAN (Presenter), AMIN AZIZI, JEFFREY D. CAIN, RAHMATOLLAH ESKANDARI, XUANZE YU, EMILY C GLAZER, ALEX ZETTL, MARVIN L COHEN, University of California, Berkeley — Geometric frustration occurs when the constituent interactions of a system cannot be simultaneously satisfied due to the underlying geometry. In an idealized frustrated system, long-range order is prevented, and degenerate ground-states with short-range order are observed, leading to extensive entropy at 0 K. In real materials, higher-order effects can lead to relieving of frustration, allowing long-range order to appear. Here, we directly observe frustrated ordering of the atomic species in a monolayer transition metal dichalcogenide (TMD) alloy, using scanning transmission electron microscopy (STEM). We find that this system is analogous to the 2D Ising model of antiferromagnetic spins in a triangular lattice, and long-range order is thoroughly suppressed. Using density functional theory, we build a lattice model that closely matches the statistical properties of the experimental atomic distribution. We also demonstrate the effects of atomic ordering on the band structure. We predict that the degree of ordering can be controlled by the growth temperature, allowing the tuning of the electronic, optical and thermal properties.

3:06PM U57.00004: van der Waals tunneling spectroscopy of WTe2 monolayer* YANYU JIA (Presenter), PENGJIE WANG, GUO YU, MICHAEL ONYSZCZAK, F. ALEXANDRE CEVALLOS, SHIMING LEI, SEBASTIAN KLEMEZ, BERTHOLD JAECK, Princeton University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, LESLIE SCHOOP, ROBERT J. CAVA, ALI YAZDANI, SANFENG WU, Princeton University — The discovery of superconducting and quantum spin Hall (QSH) states in the single layer WTe2 opens up new possibilities of engineering correlated topological quantum matter based on 2D crystals. In this talk, I will introduce a tunneling device geometry based on van der Waals heterostructures to perform spectroscopic studies of monolayer WTe2. The visualization of gate-induced changes in the monolayer's electronic structure will be discussed.

*This research was supported by NSF through the Princeton University Materials Research Science and Engineering Center DMR-1420541
3:18PM U57.00005: Anisotropic conductivity in monolayer WTe$_2$  
BOSONG SUN (Presenter), PAUL MALINOWSKI, ZAIYAO FEI, WENJIN ZHAO, University of Washington, TAUNO PALOMAKI, Sandia National Laboratory, XIONG HUANG, University of California, Reverside, ELLIOTT RUNBURG, University of Washington, YONGTAO CUI, University of California, Reverside, JIUN-HAW CHU, XIAODONG XU, DAVID COBDEN, University of Washington — The layered semimetal WTe$_2$ behaves in the monolayer limit as a topological insulator but the nature of the insulating state in the interior bulk is unclear. We study its conductivity as a function of gate doping, temperature, and current direction. Care is needed to eliminate helical edge conduction from the measurements, including along cracks, which we locate by microwave impedance microscopy. The conductivity is found to be highly anisotropic for hole doping and much less so for electron doping. Surprisingly, for hole doping the conductivity is about three times lower along the a-axis, the direction of the tungsten chains, than along the b-axis, perpendicular to the chains. We consider the implications of this observation for the possibility that the state is a kind of excitonic insulator.

3:30PM U57.00006: Probing correlated states in WTe$_2$ devices*  
PENGJIE WANG (Presenter), GUO YU, YANYU JIA, MICHAEL ONYSZCZAK, SHIMING LEI, SEBASTIAN KLEMENZ, F. ALEXANDRE CEVALLOS, Princeton University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, ROBERT J. CAVA, LESLIE SCHOOP, SANFENG WU, Princeton University — Interesting behaviors, such as quantum spin Hall effect, superconductivity, non-linear Hall effect, and ferroelectricity have been observed in atomically thin tungsten ditelluride (WTe$_2$). We introduce a new device geometry to further probe the intrinsic electronic response of two-dimensional WTe$_2$. In this talk, we will report our recent transport studies on these new devices, in search of exotic correlated states.

*This research was supported by NSF through the Princeton University Materials Research Science and Engineering Center DMR-1420541.
We introduce a novel topological class of superconducting and density-wave states which exhibit monopole harmonic symmetry. This so-called “monopole harmonic order” can be realized in interacting Weyl semimetal materials. Generally, when two Fermi surfaces carry different Chern numbers, the many-body ordering between these two Fermi surfaces can exhibit a non-trivial Berry phase inherited from band structure topology. In contrast to other known many-body order, the total vorticity of the ordering gap nodes in momentum space is determined by the monopole charge of the pair Berry phase and is independent of specific ordering mechanisms. Connections to experimental realizations and signatures of monopole harmonic superconductivity and monopole harmonic charge-density-wave states are proposed.

Layer-dependent charge density wave in few layer VSe$_2$ films

BYOUNG KI CHOI (Presenter), Department of Physics, University of Seoul, Republic of Korea, GANBAT DUVJIR, Department of Physics, University of Ulsan, Republic of Korea, SØREN ULSTRUP, Department of Physics and Astronomy, Aarhus University, Denmark, IN HAK LEE, HYUK JIN KIM, Department of Physics, University of Seoul, Republic of Korea, LY THI TRINH, Department of Physics, University of Ulsan, Republic of Korea, CHRIOS JOZWIAK, AARON BOSTWICK, ELI ROTENBERG, Lawrence Berkeley National Laboratory, JUNSDAE KIM, Department of Physics, University of Ulsan, Republic of Korea, YOUNG JUN CHANG, Department of Physics, University of Seoul, Republic of Korea — VSe$_2$ monolayer (ML) has recently attracted attention about charge ordering property in two-dimensional monolimit. Researches have been discussing the origin of charge ordering characteristic of VSe$_2$ ML and there is an inconsistent argument. We have reported two types of charge-ordering transitions in VSe$_2$ ML on graphene substrates. One is enhanced charge density wave (CDW) originated from bulk VSe$_2$ and one is metal-insulator transition (MIT) caused by interface effect between graphene and VSe$_2$ ML. In this presentation, we present layer dependent CDW properties in VSe$_2$ 1ML, 2ML and 3ML on graphene substrates. We will show depressed CDW effects with increasing number of layers. We will also discuss the MIT property of VSe$_2$ monolayer changing substrates and implications of interface effect between substrate and VSe$_2$ ML.

Evidence of charge density wave with anisotropic gap in monolayer VTe$_2$ film

YUAN WANG (Presenter), JUNHAI REN, JIAHENG LI, YUJIA WANG, HUINING PENG, PU YU, WENHUI DUAN, SHUYUN ZHOU, State Key Laboratory of Low Dimensional Quantum Physics and Department of Physics, Tsinghua University — We report experimental evidence of charge density wave (CDW) transition in monolayer 1T-VTe$_2$ film. Low energy electron diffraction (LEED) measurements reveal 4×4 reconstruction peaks below transition temperature. Angle-resolved photoemission spectroscopy (ARPES) measurements reveal arc-like pockets with anisotropic CDW gaps up to 50 meV. The anisotropic CDW gap is attributed to the imperfect nesting of the CDW wave vector, and first-principles calculations reveal phonon softening at the same vector. These results suggest the important roles of both Fermi surface nesting and electron-phonon interaction in the CDW mechanism of monolayer VTe$_2$ film.
4:42PM U57.00010: Ultrafast Electron Diffraction in Charge Density Wave State of TiSe$_2$*

PAUL XHORI (Presenter), ANTON ANIKIN, Physics, Drexel University, JACOB BOLDUC, Materials Science and Engineering, Drexel University, SHALIN PATEL, Physics, Drexel University, MAHER HARB, GORAN KARAPETROV, Physics and Materials Science and Engineering, Drexel University — We probe the ultrafast laser response in thin TiSe$_2$ single crystals below and above the CDW transition temperature using ultrafast electron diffraction. The electron-phonon dynamics is initiated by 150 fs pulses centered at 400 nm. While we observe a comparably fast initial diffraction intensity decay at room temperature, we do not observe any bi-exponential dynamics that was previously reported in the dynamics of <110> peaks at fluences above 1 mJ/cm$^2$ with 800 nm centered excitation. On the other hand, at temperatures below the CDW transition temperature bi-exponential dynamics is observed above the threshold fluence of 0.5 mJ/cm$^2$. This threshold fluence is more than two times larger than the threshold fluence for CDW melting with an 800 nm pump. Bi-exponential behaviour is linked to a strong electron-phonon coupling process followed by a slower electron-lattice equilibration. This shows the importance of the Jahn-Teller mechanism for charge density wave formation in TiSe$_2$. We will also present ultrafast electron diffraction results on Cu$_x$TiSe$_2$ single crystals.

*This work was supported by the National Science Foundation under Grant No. ECCS-1711015.

4:54PM U57.00011: The current-induced metastable CDW heterostructure in 2D 1T-TaS$_2$

MASARO YOSHIDA (Presenter), TAKURO SATO, RIKEN Center for Emergent Matter Science, FUMITAKA KAGAWA, YOSHIHIRO IWASA, Department of Applied Physics, The University of Tokyo — The layered 1T-TaS$_2$ is a showcase of electronic phases including complex charge density waves (CDWs), superconductivity, Mott insulator, and spin liquid. In addition to such thermodynamically stable phases, thermally inaccessible, persistent metastable metallic states can be induced by means of current [e.g.1]. We investigated the current-induced phase transition to the persistent metastable state by performing noise spectroscopy measurements [2]. We observed the emergence of a broadband noise at the transition, indicating the sliding motion of CDWs. Surprisingly, the dynamical property of the CDW was found to be preserved after the injection of current, although the electronic properties are significantly modified by the injection. It is likely that the CDW sheets slide to change their 3D structure, the stacking way, followed by the considerable change in electronic structure. We suggest that after the current injection, the CDW sheets stack in a metastable way that yields metallic electronic structure. Our discovery emphasizes the importance of the stacking degree of freedom, the concept of Van der Waals heterostructure, to create exotic electronic states in 2D material.

5:06PM U57.00012: Doping a Mott insulator at the lateral junctions of single layer 1H-1T NbSe$_2$* LIAN LI (Presenter), HUIMIN ZHANG, LIWEI LIU, Department of Physics and Astronomy, West Virginia University, ZHUOZHI GE, MICHAEL WEINERT, Department of Physics, University of Wisconsin-Milwaukee — At the single layer limit, transition metal dichalcogenides can adopt a variety of structural polymorphs with significantly different electronic properties. Here we report the selective growth of single layer 1T- and 1H-NbSe$_2$ on epitaxial graphene/SiC substrates by molecular beam epitaxy. Using a combination of scanning tunneling microscopy/spectroscopy and angle-resolved photoemission spectroscopy, we show that the 1H-NbSe$_2$ is metallic and exhibits a 3 by 3 charge density wave (CDW) at below 20K, while 1T-NbSe$_2$ is a Mott-insulator exhibiting a root 13 by root 13 CDW at room temperature. Furthermore, at the 1H-1T lateral junction, we observe a one-dimensional channel that is characterized by a V-shaped gap in tunneling spectroscopy. The spectra can be fitted by power law, similar to other substitutionally doped Mott insulators. Those finding suggests that lateral heterojunctions of different transition metal dichalcogenide polymorphs present an opportunity to engineer new quantum phases with emergent properties.

U57.00013: Infrared spectroscopy of few-layer excitonic insulator candidate Ta$_2$NiSe$_5$ CHAOYU SONG (Presenter), CHONG WANG, SHENYANG HUANG, HUGEN YAN, Fudan Univ — Ta$_2$NiSe$_5$ is proposed as an excitonic insulator, which has narrow direct bandgap and high transition temperature. In this talk, we will present our infrared spectroscopy study of few-layer Ta$_2$NiSe$_5$. In addition to the large anisotropic absorption peak at about 0.4 eV reported by many previous studies, a weak but clear excitation was newly found at lower frequency. It is possibly a signature of the electron correlation or from another electronic transition.

Session U58 DCP DAMOP DLS DCMP: Ultrafast Spectroscopies and Coherent Phenomena in the X-ray Domain II Mile High Ballroom 3B - Michael Schuurman, Natl Research Council-Canada - Tag(s): Focus
2:30PM U58.00001: Ultrafast X-ray Molecular Dynamics* [Invited] STEPHEN R. LEONE
(Presenter), University of California, Berkeley — Transient absorption in the extreme ultraviolet and X-ray spectral regimes is used to probe molecular dynamics on both femtosecond and attosecond timescales. Laser-produced high-order harmonics are generated to use as the probe, while ultraviolet or visible pulses excite the molecular system by well-defined transitions. The method is used to investigate dissociating molecules, ring opening, passage through curve crossings and conical intersections, singlet-to-triplet transitions, and electronic and vibrational coherences. By extending the probe photon energies to 300 eV in the soft X-ray, carbon species are investigated to reveal atom-specific electronic orbitals during electronic transformations of organic molecules. Time domain measurements provide an assessment of multiple excited state products and key points along the reaction trajectories. Passage through curve crossings and conical intersections reveal distinct changes in electronic state character at the crossings, and shifts in core level spectroscopic features provide information on the changes in orbital energetics and occupancies, such as when bonds break. X-ray spectroscopic transitions of transient intermediate states are directly characterized. On ultrashort timescales, electronic and vibrational wave packet coherent dynamics are also observed. The results form the basis of an X-ray spectroscopic revolution in molecular dynamics, sensitive to electron state character.

3:06PM U58.00002: Probing the ultrafast intermediate states of a divalent cobalt-manganese complex with femtosecond M-edge XANES* ELIZABETH RYLAND (Presenter), KAILI ZHANG, JOSH VURA-WEIS, Chemistry, University of Illinois at Urbana-Champaign — In this work we perform ultrafast transient M-edge XANES on divalent Cobalt-Manganese(N,N,N-tri(2-(2-pyridylamino)ethyl)amine)Cl, a heterobimetallic system with directly-interacting dual metal centers held within a non-innocent ligand scaffold. The strong metal-metal interaction facilitated by the ‘double-decker’ type ligand scaffold leads to a highly multiconfigurational electronic structure with relaxation pathways unavailable in monometallic analogues. With the ultrashort broadband probe pulse used in transient high-harmonic generation spectroscopy, we are able to perform M-edge XANES on both metal edges simultaneously with high specificity for each metal center and ligand environment. By combining transient XANES with transient UV-visible spectroscopy we can compile a full picture of the ultrafast electronic relaxation dynamics of this complex molecule. Photoinduced MM’CT is followed by distinct electronic dynamics at both metal edges and within the ligand scaffold, suggesting complex interplay of the Co, Mn, and ligand redox centers. Increased understanding of the relation of function to metal-specific photodynamics will help lay essential groundwork for the development of multimetallic catalysts with efficiencies comparable to those found in nature.

Heme proteins are essential for respiration, neural transmission and biological signaling. The binding to and dissociation of small diatomic ligands (O₂, CO, NO, CN) from the Fe atom of the heme porphyrin represents the primary events of these processes. These can be mimicked by photodissociating them with a pulse of light and monitoring the recombination with a probe pulse. With the advent of XFELs, fs photon-in/photon-out experiments such as X-ray emission (XES), X-ray Raman scattering (XRS) and resonant-inelastic X-ray scattering (RIXS) have become possible that could never be achieved before due to their requirement for high fluxes and high temporal resolution.

We have investigated the case of Nitrosyl-Myoglobin (MbNO) in order to address crucial questions about the change from the planar low spin (LS) hexacoordinated heme configuration to the domed high spin (HS) pentacoordinated one. We excite the system into the Q-bands and probed its evolution by fs-XES using X-ray pulses from the SACLA, SwissFEL and European-XFEL free electron lasers. We found that the entire photocycle from planar to domed and back, after ligand recombination, is a series of spin cross-over (SCO) and back SCO events. We also investigated the most important electron transfer protein in our body, ferric cytochrome c, for which no ligand dissociation was ever reported, and therefore neither doming nor spin states. Here too we establish the photocycle as a SCO event, and propose that doming is crucial for the electron transfer properties of the protein, rather than heme ruffling as previously proposed.
Ultrafast X-Ray Absorption Spectroscopy as a Probe of Conical Intersection-Mediated Dynamics: Theoretical Tools and Studies [Invited]  SIMON NEVILLE (Presenter), National Research Council of Canada — Ultrafast time-resolved X-ray absorption spectroscopy (TRXAS) has emerged as a powerful tool for probing excited-state non-adiabatic molecular dynamics. Of particular interest is the sensitivity of TRXAS to the changes in valence electron density that occur as an excited-state wavepacket approaches a region of conical intersection between electronic states. In particular, the mixing of state characters in these high-coupling regions can be expected to modulate the amount of localisation of the valence electron density around the individual atomic centres, resulting in shifts in the core-orbital energies. Resultantly, shifts in the peaks in the TRXAS are expected to occur, which may be directly related to the non-adiabatic nuclear dynamics.

As the emergence of new light sources make excited-state TRXAS studies a reality, there is a need for accompanying theoretical simulations to enable a complete characterisation and understanding of the recorded spectra. In particular, rigorous, general, and tractable methods for the simulation of excited-state X-ray absorption spectra (XAS) are needed. Up until now, however, there has been a dearth of methods that can treat initial states of arbitrary character, while maintaining a low cost and black box usage. To address this issue, we have developed a new theoretical framework employing the core-valence separated combined DFT/MRCI method (CVS-DFT/MRCI). This is a method that is, perhaps, uniquely suited to the simulation of XAS for large molecules and initial states of multi-reference character, which are encountered in the vicinity of conical intersections.

In this talk, I will present recent studies using CVS-DFT/MRCI for the exploration of the sensitivity of TRXAS to conical-intersection-mediated dynamics in a range of molecules, ranging from the disentangling of competing relaxation pathways in allene to the Jahn-Teller effect-mediated dynamics in the graphene nanoflake coronene.
4:30PM U58.00005: RIXS within the coupled-cluster framework reveals the hidden transitions of transient species in ionized liquid water* KAUSHIK NANDA (Presenter), Department of Chemistry, University of Southern California, USA, LUDVIG KJELLSSON, JAN-ERIK RUBENSSON, Department of Physics and Astronomy, Uppsala University, Sweden, GILLES DOUMY, STEPHEN SOUTHWORTH, PHAY J HO, ANNE M MARCH, ANDRE AL HADDAD, YOSHIKAI KUMAGAI, MING-FENG TU, Chemical Sciences and Engineering Division, Argonne National Laboratory, USA, MUHAMMAD SHAFIQ MOHD YUSOF, TUSHAR DEBNATH, Division of Chemistry and Biological Chemistry, School of Physical and Mathematical Sciences, Nanyang Technological University, Singapore, CAROLINE ARNOLD, RALPH WELSCH, LUDGER INHESTER, ROBIN SANTRA, Center for Free-Electron Laser Science, DESY, Germany, MARC SIMON, Sorbonne Université and CNRS, Laboratoire de Chimie Physique-Matière et Rayonnement, France, WILLIAM F SCHLOTTER, STEFAN MOELLER, GIACOMO COSLOVICH, JAKE KORELEK, DANIEL DEPONTE, LCLS, SLAC National Accelerator Laboratory, USA, ZHIHENG LOH, Division of Chemistry and Biological Chemistry, School of Physical and Mathematical Sciences, Nanyang Technological University, Singapore, ANNA KRYLOV, Department of Chemistry, University of Southern California, USA, LINDA YOUNG, Chemical Sciences and Engineering Division, Argonne National Laboratory, USA — X-ray spectroscopies such as resonant inelastic X-ray scattering (RIXS) expand our ability to investigate the chemical structure and dynamics; in particular, when augmented with reliable theoretical tools. Computing the RIXS spectra, however, is challenging; primarily due to the difficulties in computing the underlying core-excited virtual states that are embedded inside the valence-ionization continuum in a converged fashion. We will present a novel electronic structure method within the equation-of-motion coupled cluster framework that facilitates converged calculations of the RIXS spectra for both closed- and open-shell species. We will illustrate the capabilities of our approach by measuring its performance in modeling the RIXS spectrum of the transient aqueous OH radical formed in ionized liquid water against experiments. We will provide orbital characterization of the distinct peaks in the RIXS spectrum of the OH radical for absorption below water's absorption edge. We will provide ab initio explanation of why the intermolecular charge-transfer transitions of aqueous OH radical, that are dominant in UV-visible spectrum, are suppressed in RIXS revealing the hidden localized valence transition.

The emergence of X-FELs has meant that our ability to probe ultrafast structural dynamics is becoming increasingly common. Importantly, the combined structural, electronic and spin information contained within X-ray spectroscopy offers new perspectives for understanding the correlated dynamics of these degrees of freedom within the femtosecond regime. However, the complex nature and high information content of this class of techniques means that detailed theoretical studies are often essential to provide a firm link between the spectroscopic observables and the underlying molecular structure and dynamics.

Herein I will present some recent work on intersystem crossing dynamics in transition metal complexes and discuss the potential insight that could be obtained from femtosecond X-ray studies. I will also present recent work on exploiting on-the-fly quantum dynamics simulations and machine learning approaches to reduce the computational expense of simulating time-resolved X-ray signals.

Session U59 DMP: Weyl semimetals, ARPES, STM and optics Mile High Ballroom

3C - Tag(s): Focus
Probing the Ultrafast Nonlinear Response in the Transition Metal Monopnictide Family of Weyl Semimetals [Invited] NICHOLAS SIRICA (Presenter), RA’ANAN TOBEY, YAOMIN DAI, Los Alamos National Laboratory, PETER ORTH, Ames Laboratory, Ames, IA, 50011, USA, MATHIAS SCHEURER, Department of Physics, Harvard University, Cambridge, MA 02138, USA, STUART A TRUGMAN, JIAN-XIN ZHU, Los Alamos National Laboratory, NI NI, Department of Physics and Astronomy, University of California, Los Angeles, CA 90095, USA, XIANGGANG QIU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, ANTOINETTE TAYLOR, DZMITRY YAROTSKI, ROHIT P PRASANKUMAR, Los Alamos National Laboratory — Weyl semimetals have been the focus of intense experimental and theoretical investigation, due to their broad appeal in fundamental science and applied technology alike. Recently, several studies have centered on the nonlinear optical properties of these materials, where it is believed that characteristic features of Weyl physics can be observed. To date, many of these studies have been limited to static or quasi-static measurements, but new and important insight can come about through extending nonlinear optical probes into the time domain. To do so, we use terahertz (THz) emission spectroscopy and time-resolved second harmonic generation (TR-SHG) spectroscopy to provide a contact free measure of ultrafast photocurrents in the transition metal monopnictide family of type-I Weyl semimetals. On the basis of our data, we are able to clearly distinguish between helicity-dependent, transverse photocurrents generated within the $ab$-plane from polarization-independent photocurrents flowing along the noncentrosymmetric $c$-axis. By using the photocurrent response as a probe of underlying crystal symmetry, we explore the role that polarization-dependent photoexcitation has on the assignment of point group symmetry, including the possibility of transient symmetry breaking. These findings highlight the robust nonlinear response exhibited by this class of materials, making them promising candidates for next generation sources and detectors in the mid-IR and THz frequency ranges.

Giant nonlinear optical response in topological semimetals* [Invited] LIANG WU (Presenter), Physics and Astronomy, University of Pennsylvania — The second-order optical nonlinearity has been a focus of basic research and technological development for decades as it is both a probe of inversion symmetry breaking in media and the basis for generating coherent light from far-infrared to ultraviolet wavelengths. Here, we focus on experimental investigations on the relation between band geometry/topology and nonlinear optics. I would like to discuss how do the second-order responses that originates from band geometry and topology in polar and chiral topological semimetals respectively. In both cases, we observed large optical nonlinearity and the possible origins will be discussed.

3:42PM U59.00003: Imaging current in semimetals with cryogenic scanning NV magnetometry* URI VOOL (Presenter), ASSAF HAMO, XU ZHOU, Harvard University, JOHANNES GOOTH, CLAUDIA FELSER, MPI for chemical physics of solids, Dresden, AMIR YACOBY, Harvard University — Among their many unique features, Weyl semimetals are predicted to enable complex electron-electron and electron-phonon interactions. Such behavior has been predicted, and recently measured, to induce correlated flow of electrons through the semimetal.

We study the current profile in a tungsten ditelluride flake by imaging the local magnetic field above it using a nitrogen-vacancy (NV) center in a diamond scanning tip. Using coherent quantum sensing, we obtain magnetic field resolution of ~10nT and spatial resolution of ~100nm. The current pattern we observe differs substantially from that of a normal metal, suggesting correlated flow through the semimetal.

3:54PM U59.00004: Observation of a Dirac nodal loop in the non-symmorphic semimetal Nb₃SiTe₆ RO-YA LIU (Presenter), Department of Physics, University of Illinois at Urbana-Champaign, ANGUS HUANG, Department of Physics, National Tsing Hua University, CHIH-CHUAN SU, RAMAN SANKAR, Institute of Physics, Academia Sinica, SHIH-CHANG WENG, National Synchrotron Radiation Research Center, MENG-KAI LIN, Department of Physics, University of Illinois at Urbana-Champaign, PENG CHEN, School of Physics and Astronomy, Shanghai Jiao Tong University, JOSEPH HLEVYACK, Department of Physics, University of Illinois at Urbana-Champaign, ALEXEI V FEDOROV, Advanced Light Source, Lawrence Berkeley National Lab, CHENG-MAW CHENG, National Synchrotron Radiation Research Center, JONATHAN DENLINGER, Advanced Light Source, Lawrence Berkeley National Lab, CHIA-SENG CHANG, Institute of Physics, Academia Sinica, HORNG-TAY JENG, Department of Physics, National Tsing Hua University, TIEN-MING CHUANG, Institute of Physics, Academia Sinica, TAI-CHANG CHIANG, Department of Physics, University of Illinois at Urbana-Champaign — In 3-dimensional non-symmorphic crystals, band crossings protected by translational symmetry can host Dirac nodal loops in a 2-dimensional cut in the momentum surface. These nodal loops, often with an hourglass shape, give rise to unusual bulk and surface properties, including anisotropic electronic transport and chiral anomaly, based on transport or optical response measurements. This talk will present a detailed study of the band structure of Nb₃SiTe₆ by angle-resolved photoemission spectroscopy. The dispersion relations along the XS direction, which is perpendicular to the sample surface, is mapped out by varying the incident photon energy. The results show that the crossing point (Dirac point) of a Dirac cone at gradually shifts to higher binding in going from X to S. The measurements provide evidence for the presence of a Dirac nodal loop in this system.
**4:06PM U59.00005: Momentum space signature of Berry curvature monopoles in a Weyl semimetal: from first principles to direct experimental observation**  
PHILIPP ECK (Presenter), MAXIMILIAN ÜNZELMANN, TIM FIGGEMEIER, FRIEDRICH REINERT, HENDRIK BENTMANN, DOMENICO DI SANTE, GIORGIO SANGIOVANNI, University of Wuerzburg (Germany) — We investigate the Fermi arcs and the Weyl points in the prototypical non-centrosymmetric time-reversal invariant Weyl semimetal family TaAs/TaP in a joint analysis of state-of-the-art Ab-initio calculations and advanced photoemission spectroscopy methods. The Weyl physics is induced by the broken inversion symmetry giving rise to a predominant orbital magnetization, which results in the interplay with the spin-orbit interaction in the emergence of Weyl points. We characterize the local orbital magnetization in the vicinity of the Weyl points and explore indeed, in agreement with the local Berry curvature, clear features of Berry monopoles at the Weyl points.

**4:18PM U59.00006: Study of hot electrons in topological nodal-line semimetal ZrSiS using time- and angle-resolved photoemission spectroscopy**  
YANGYANG LIU (Presenter), M. MOFAZZEL HOSEN, GYANENDRA DHAKAL, CHRISTOPHER SIMS, JOHN E BEETAR, SABIN REGMI, KLAUSS DIMITRI, FIROZA KABIR, Univ of Central Florida, DARIUSZ KACZOROWSKI, Polish Academy of Sciences, MICHAEL CHINI, MADHAB NEUPANE, Univ of Central Florida — We have studied the ultrafast hot electron cooling process on topological nodal-line semimetal ZrSiS using an advanced XUV-based time- and angle-resolved photoemission spectroscopy (trARPES) with sub-30 meV energy resolution and 320 fs time resolution. The transient ARPES spectra in the vicinity of the nodal-line bulk states and surface states are individually measured using pump-probe scans employing 1.2 eV pump and 21.8 eV probe pulses. Our data reveals that the relaxation decay of the transient electronic temperature in the nodal-line bulk states (around 700 fs) is longer than the surface states (around 320 fs). Furthermore, the relaxation process of the hot electrons in the nodal-line bulk states exists not only a fast decay of ~700 fs, but also a second slow decay (> 6 ps) process, which indicates the existence of a second filling channel in the nodal-line bulk states. Our studies reveal the unique ultrafast properties of the hot electrons in the nodal-line semimetal ZrSiS.

4:30PM U59.00007: Symmetry-Enforced Dirac Fermions in Nonsymmorphic α-Bismuthene*
GUANG BIAN (Presenter), Univ of Missouri - Columbia — According to recent theoretical works, nonsymmorphic crystal symmetries can enforce the formation of Dirac cones, providing a new route to establishing Dirac states in 2D materials. Here we will discuss our recent work on the realization of the symmetry-enforced Dirac fermions in nonsymmorphic α-bismuthene (Bi monolayer). The bismuthene was synthesized by the method of molecular beam epitaxy (MBE). The Dirac band structure was observed by the micro-angle-resolved photoemission (μ-ARPES) experiment. The Dirac points are located at high-symmetry momentum points which are entirely determined by the lattice symmetry. This correspondence of Dirac states to the nonsymmorphic symmetry group can potentially lead to the discovery of a range wide of new 2D Dirac materials. In addition, the Dirac fermions in α-bismuthene is of spin-orbit type in contrast to the spinless Dirac states in graphene. The result will accelerate the search of 2D Dirac materials and extend “graphene” physics into new territory where strong spin-orbit coupling is present.

*This work is supported by US National Science Foundation (NSF-DMR#1809160).

4:42PM U59.00008: Molecular Beam Epitaxy, Band Structure, and Electrical Properties of the Dirac Semimetal ZrTe$_2$*
TIMOTHY PILLSBURY (Presenter), ANTHONY R. RICHARDELLA, RUN XIAO, WILSON YANEZ, MAX STANLEY, HEMIAN YI, CUI-ZU CHANG, NITIN SAMARTH, Department of Physics, The Pennsylvania State University — Topological semimetals (TSMs), a class of gapless electronic phases exhibiting topologically stable crossings of bulk energy bands, have attracted tremendous interest in the condensed matter physics community recently. Based on the origin of the band crossing, TSMs can be classified into Dirac semimetals (DSMs), Weyl semimetals (WSMs) and others. Recently, the transition metal dichalcogenide ZrTe$_2$ has been theoretically predicted and experimentally demonstrated to possess a DSM phase. We used molecular beam epitaxy to synthesize ZrTe$_2$ thin films on insulating sapphire (0001) substrates and performed systematic in vacuo angle-resolved photoemission spectroscopy (ARPES) measurements. The observation of the Dirac cone in the ARPES spectra of ZrTe$_2$ thin films confirms the DSM phase. We also measured the temperature dependence of the ex-situ magneto-transport and found that negative magnetoresistance is absent in our films. We are also exploring the quantum phase transition from DSM to WSM by transition metal doping into these ZrTe$_2$ films.

*This work is supported by 2DCC-MIP/NSF (DMR-1539916), SMART/nCORE/SRC/NIST, DOE EFRC (DE-SC0019331), and ARO (W911NF1810198).
4:54PM U59.00009: Observation of linearly dispersive edge modes in a magnetic Weyl semimetal Co$_3$Sn$_2$S$_2$* SEAN HOWARD (Presenter), LIN JIAO, ZHENYU WANG, Department of Physics, University of Illinois at Urbana-Champaign, PRAVEEN VIR, CHANDRA SHEKHAR, CLAUDIA FELSER, Max Planck Institute For Chemical and Physical Solids, TAYLOR HUGHES, Department of Physics and Institute for Condensed Matter Theory, University of Illinois Urbana Champaign, VIDYA MADHAVAN, Department of Physics, University of Illinois at Urbana-Champaign — The physical realization of Chern insulators is of fundamental and practical interest, as they are predicted to host the quantum anomalous Hall effect (QAHE) and chiral edge states which carry dissipationless current. Realization of the QAHE state has however been challenging due to the complex heterostructures and sub-Kelvin temperatures required. Magnetic Weyl semimetals, essentially stacks of Chern insulators with inter-layer coupling, may provide a new platform for the higher temperature realization of robust 2D QAHE edge states. In this work we present a combined scanning tunneling spectroscopy and theoretical investigation of a newly discovered magnetic Weyl semimetal, Co$_3$Sn$_2$S$_2$. Using numerical simulations we find that chiral edge states can be localized on partially exposed Kagome planes on the surface of a Weyl semimetal. As such, our STM dI/dV maps on narrow kagome Co$_3$Sn terraces show linearly dispersing quantum well-like states, which can be attributed to hybridized chiral edge modes. Our results suggest a new paradigm for studying chiral edge modes in time-reversal breaking Weyl semimetals. More importantly, this work leads a practical route for realizing higher temperature QAHE.

*Basic Energy Sciences DE-SC0014335, Gordon and Betty Moore Foundation Grant GBMF4860

5:06PM U59.00010: Generation of strain-induced pseudo-magnetic field in a doped type-II Weyl semimetal* SUMAN KAMBOJ (Presenter), PARSHA SARATHI RANA, Physical Sciences, IISc Bangalore, ANSHU SIROHI, AASTHA VASDEV, IISER Mohali, MANASI MANDAL, SOURAV MARIK, R P SINGH, Physical Sciences, IISER Bhopal, TANMOY DAS, Physical Sciences, IISc Bangalore, GOUTAM SHEET, IISER Mohali — As per the theory, it is in principle possible to realize a pseudo-magnetic field in strained Weyl semimetals. The basic idea is that strain alters the hopping parameter which may manifest itself as a gauge potential, which in turn may lead to a quantity analogous to the magnetic field. This pseudo-magnetic field may help the formation of quantized Landau levels and thus may become observable in Weyl semimetals. We will show the emergence of a pseudo-magnetic field in a doped and intrinsically strained type-II Weyl semimetal by Scanning Tunneling Spectroscopy (STS) down to 300 mK. In these experiments, clear Landau level oscillations are observed in the absence of an externally applied magnetic field. The system also has a known superconducting phase at very low temperature, which remains unaffected by the pseudo-magnetic field.

*DST/SJF/PSA-01/2015-16
Theoretical Study of Quasiparticle Interference in Weyl Semimetals with ab initio Band Structure Informed Tight-Binding Hamiltonian*  
ZHAO HUANG (Presenter), DZMITRY YAROTSKI, ANTOINETTE TAYLOR, JIAN-XIN ZHU, Los Alamos National Laboratory — The Weyl semimetal is a group of interesting materials where Weyl fermions emerge around singularity points of Berry curvature in the band structure (so called Weyl nodes). A direct consequence of the Weyl nodes is the anomalous surface state arising from the separation of Weyl nodes with opposite topological charges. The energy bands of the surface states cross the Fermi level and form a Fermi arc which connects the projections of Weyl nodes on the surface. Experimentally, observation of the Fermi arc is taken as a fingerprint of the Weyl semimetals. Here we theoretically study the quasiparticle interference (QPI) due to impurity scattering on surfaces in several Weyl semimetals. The scattering between Fermi arcs can lead to special patterns of QPI as indirect observation of the Fermi arcs. In particular, we adopt the accurate tight-binding multi-orbital Hamiltonian constructed from the first-principle electronic structure calculations for each material. We anticipate that our theoretical results will help interpret STM-based measurements on a more comparable footing, thus providing guidance for the identification of Weyl physics.

Session U60 DMP: Topological Superconductivity: 3D TIs, Weyl Semimetals and TMDs Mile High Ballroom 4A - Vidya Madhavan, University of Illinois at Urbana-Champaign

2:30PM U60.00001: Valley Hall transport and superconductivity signatures in twisted transition metal dichalcogenides [Invited]  NING WANG (Presenter), Physics, The Hong Kong University of Science and Technology — Selected by Focus Topic Organizer (Peide Ye)
Most thermoelectric materials and topological insulators were made from heavy elements and have narrow band gaps and strong spin-orbit couplings. The nontrivial topological insulating states are the essential base for the topological superconductivity. It remains unclear how the thermoelectric figure of merit performs in the topological state, and whether a thermoelectric material can evolve into a topological superconductor and what is the driving force if the latter happens. By choosing an $n$-type Bi$_2$Te$_{2.7}$Se$_{0.3}$, a highly efficient thermoelectric material and topological insulator, we perform measurements of the thermoelectric and superconducting properties at high pressures. We find that the figure of merit increases with pressure and exhibits a maximum at around 1 GPa where the topological phase transition takes place. After that, superconductivity appears and the critical temperature dramatically increases with increasing pressure in the phase with the nontrivial topological state. Its upper critical field exhibits different temperature dependence compared to the other superconducting phases without topological order. The topological phase transition is proposed to serve the linkage for the high-performance thermoelectricity and topological superconductivity.

**3:18PM U60.00003: Theory of Giant In-Plane Critical Field Enhancement in Superconducting Films on a Topological Insulator Surface**

HAOYUN DENG (Presenter), PEDRO SCHLOTTMANN, PENG XIONG, NICHOLAS EVANS BONESTEEL, Florida State Univ — Majorana zero modes (MZMs) are of interest due to potential applications in topological quantum computing. Topological insulators (TIs), with spin-momentum locked surface states, may enable emergence of MZMs when coupled to an $s$-wave superconductor (SC) via the proximity effect. We recently observed a giant enhancement of the in-plane $H_c$ in thin Al, a superconductor with minimal intrinsic spin-orbit coupling (SOC), evaporated onto a 3-dimensional strong TI. $^1$ Here we present a theoretical analysis of this enhancement. Superconductivity at in-plane fields well in excess of the Chanderasekhar-Clogston (CC) limit is understood as a consequence of strong SOC induced in the thin Al films from the topological surface state through the inverse proximity effect. The CC model is combined with the Maki equation to calculate $H_c$ at different temperatures. The calculated $H_c(T)$ shows excellent quantitative agreement with the experimental result. A relatively large value of the induced spin-orbit scattering rate (in comparison to the superconducting energy gap) is derived, indicating a strong proximity coupling in this TI-SC heterostructure which may be a promising platform for observing MZMs.

3:30PM U60.00004: Characterizing the Superconducting State of Cu$_x$Bi$_2$Se$_3$ Through Muon-Spin Relaxation/Rotation  EMILY DUDEN (Presenter), Winona State University, BENJAMIN FRANDSEN, Brigham Young University, MARKUS KRIENER, RIKEN Center for Emergent Matter Science, YOICHI ANDO, University of Cologne, YASUTOMO J UEMURA, Colombia University — The discovery of topological superconductors has been a major objective in the field since they were first predicted theoretically. The doped topological insulator Cu$_x$Bi$_2$Se$_3$ is a promising candidate for topological superconductivity, but there is much conflicting evidence on the subject. Identifying the superconducting symmetry of the material is paramount in determining whether it has a topologically nontrivial ground state. Muon spin relaxation/rotation (SR) experiments provide a heretofore unexplored method of probing the superconducting state of Cu$_x$Bi$_2$Se$_3$. Here, we present SR data collected on a single-crystal sample of Cu$_{0.3}$Bi$_2$Se$_3$. Measurements conducted in zero-field conditions demonstrate that time reversal symmetry is preserved in the superconducting state, while transverse-field measurements reveal superfluid density behavior that is consistent with p-wave pairing. Such a scenario could support topological superconductivity in Cu$_x$Bi$_2$Se$_3$. However, a more conventional s-wave pairing scenario also provides a reasonable fit to the data, making an unambiguous conclusion difficult. Nevertheless, these results represent a valuable addition to the body of experimental data available for Cu$_x$Bi$_2$Se$_3$.

3:42PM U60.00005: In-plane Critical Field far beyond the Paramagnetic Limit for Thin Al Films on Topological Insulator Surface*  ZHU LIN (Presenter), Department of Physics, Florida State University, ZHILIN LI, Institute of Physics, Chinese Academy of Sciences, HAOYUN DENG, TIANHAN LIU, Department of Physics, Florida State University, GANG SHI, Institute of Physics, Chinese Academy of Sciences, PEDRO SCHLOTTMANN, NICHOLAS EVANS BONESTEEL, Department of Physics, Florida State University, YONGQING LI, Institute of Physics, Chinese Academy of Sciences, PENG XIONG, Department of Physics, Florida State University — Heterostructures of an s-wave superconductor and a strong topological insulator are regarded as a viable platform for the creation of Majorana zero mode (MZM). However, the microscopic understanding of the proximity effect between the superconductor and topological surface state has yet to be fully elucidated. Here we report measurements of the in-plane critical field (H$_{C/\parallel}$) of thin Al, a superconductor with minimal spin-orbit interaction (SOI), on the surface of (Bi$_{0.5}$Sb$_{0.5}$)$_2$TeSe$_2$ (BSTS). H$_{C/\parallel}$ of the Al films are directly compared with those of simultaneously grown control samples of Al films on SiO$_2$. Giant enhancement of H$_{C/\parallel}$ beyond the paramagnetic limit was observed for the Al on BSTS. The enhancement diminishes with increasing Al thickness. The H$_{C/\parallel}$(T) of thin Al on SiO$_2$ is consistent with the Chanderasekha-Clogston theory, while the H$_{C/\parallel}$(T) of thin Al on BSTS can be well-described by a theory based the Maki equation invoking strong induced SOI in Al. The results provide direct evidence for an electrically transparent interface and strong proximity effect between the Al and BSTS. The Al/BSTS heterostructure may be a promising system for inducing topological superconductivity and controlled generation of MZMs.

3:54PM U60.00006: Uniaxial-Strain Control of Nematic Superconductivity in Sr$_x$Bi$_2$Se$_3$*

IVAN KOSTYLEV, SHINGO YONEZAWA, Kyoto Univ., ZHIWEI WANG, YOICHI ANDO, Univ. Cologne, YOSHITERU MAENO (Presenter), Kyoto Univ. — Recently, nematic superconductivity, in which the superconducting gap spontaneously lifts the rotational symmetry of the lattice, has been discovered [1]. In nematic superconductivity, multiple superconducting domains with different nematic orientations can exist. These domains can be controlled by a conjugate external stimulus, such as the strain induced by a uniaxial stress with a piezoelectric device [2]. Here, we report for the first time control of the nematic superconductivity and their domains of Sr$_x$Bi$_2$Se$_3$, through externally-applied uniaxial stress [3]. The suppression of subdomains indicates that it is the Δ$_4$ state that is most favored under compression along the basal Bi-Bi bonds. These results provide an inevitable step towards microscopic understanding and future utilization of the unique topological nematic superconductivity.

4:06PM U60.00007: Doping and pressure effects on Weyl semimetal Mo$_{1-x}$W$_x$Te$_2$* RABIN DAHAL (Presenter), LIANGZI DENG, NARAYAN POUDEL, MELISSA GOOCH, ZHENG WU, HUNG-CHENG WU, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204, USA, HUNG-DUEN YANG, Department of Physics, National Sun Yat-sen University, Kaohsiung, 80424, Taiwan, CHUNG-KAI CHANG, National Synchrotron Radiation Research Center, Hsinchu, 30076, Taiwan, PAUL C. W. CHU, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204, USA — Systematic pressure and doping dependent study on Mo$_{1-x}$W$_x$Te$_2$ was carried out to investigate the correlation among chemical doping, structural transition, and superconductivity. Doping dependent resistivity measurement at ambient pressure shows structural transition temperature ($T_s$) for MoTe$_2$ to be 249 K, which continuously increases as doping level ($x$) increases and reaches a maximum value of 613 K for WTe$_2$. The structural transition of WTe$_2$ at ambient pressure is also confirmed by conducting temperature dependent synchrotron X-ray diffraction from 300 K to 673 K. Three samples with different doping ($x = 0.10, 0.40, 0.75$) were selected for high pressure measurement. The superconducting transition temperature - pressure ($T_c - P$) phase diagrams have been constructed and will be discussed. Our experimental results revealed a competition between the structural transition and superconductivity in Mo$_{1-x}$W$_x$Te$_2$. Superconductivity emerges when the $T_s$ is suppressed below 175 K and $T_c$ increases as $T_s$ is suppressed.

4:18PM U60.00008: Theory on superconducting chiral crystal and its applications  ZHESHEN GAO (Presenter), WENYU HE, KAM TUEN LAW, Hong Kong University of Science and Technology — Chiral crystals are shown to have nontrivial band topology: at the time reversal invariant momenta, Kramers Weyl points and multi-fold Weyl points can emerge due to the chiral lattice symmetry. In the normal metallic state, the chiral lattice symmetry along with the band topology introduces the magnetoelectric effect and circular photogalvanic effect to modify the electromagnetic properties in the materials. However, how does the chiral lattice symmetry and the associated band topology affect the superconducting phase in chiral crystals remains unknown. In this work, we classify the possible pairing phases resulted from chiral lattice symmetry and find various topological superconducting phases. We propose the candidate topological superconducting chiral crystal and study its unique superconducting properties.

4:30PM U60.00009: Correlation-driven renormalization of Weyl nodes in the Ce-113 series
VSEVOLOD IVANOV (Presenter), SERGEY SAVRASOV, University of California, Davis — We study the electronic properties of the inversion-broken CeTX3 (T = Co, Rh, Ir, X=Si,Ge) heavy-fermion materials through a combination of LDA and LDA+Guzwiller methods. In this class of compounds the electronic mass is enhanced, causing narrowing the Ce f-electron bands. Our LDA+Guzwiller procedure captures these renormalization effects, yielding a mass enhancement that is in good agreement with experimental specific heat measurements. We also track the renormalization of Weyl points by the correlations, which move them closer to the Fermi energy. We briefly comment on the interplay of Weyl physics and pressure-induced superconductivity in these compounds.

4:42PM U60.00010: One-dimensional states residing on edges and steps in few-layer WTe$_2$
ARTEM KONONOV (Presenter), GULIBUSITAN ABULIZI, University of Basel, KEJIAN QU, JIAQIANG YAN, DAVID MANDRUS, Materials Science and Engineering, The University of Tennessee, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, CHRISTIAN SCHONENBERGER, University of Basel — WTe$_2$ is a layered material with rich topological properties. The bulk crystal is a type-II Weyl semimetal and the monolayer is a two-dimensional topological insulator. Recently, it has been predicted that higher order topological insulator state can appear in WTe$_2$. An observation of 1D, highly conductive channels, known in this case as hinge states, is hindered by the bulk conductivity of WTe$_2$. Here, we employ the Josephson effect to disentangle the contribution of the hinge states from the bulk in electronic transport. We observe 1D current carrying states on edges and steps in few-layer WTe$_2$. The width of the states is deduced to be below 100 nm. A supercurrent in them can be measured over distances up to 3 µm and in perpendicular magnetic field up to 2 T. Moreover, the dependence of the supercurrent on the magnetic field is compatible with the asymmetric Josephson effect predicted to occur in topological systems with broken inversion symmetry.

**4:54PM U60.00011: Probing Proximity Effect in Topological Insulator/Superconductor Heterostructures**  
CEQUN LI (Presenter), BRIAN BERSCH, NATALIE BRIGGS, YIFAN ZHAO, CHENGYE DONG, TIMOTHY BOWEN, HEMIAN YI, JOSHUA ROBINSON, CUI-ZU CHANG, JUN ZHU, Pennsylvania State University — Topological insulator (TI)/superconductor heterostructures are predicted to host Majorana zero modes, which are building blocks of topological qubit. In this work, we synthesize high-quality large-area TI/graphene (Gr)/gallium heterostructures combining confinement epitaxy and molecular beam epitaxy. Atomically thin Ga film superconducts at $T_c \sim 4K$ [B. Bersh, et. al, arXiv:1905.09938], and the growth of TI preserves its superconductivity. We probe the proximity effect in the TI film using four-terminal transport and tunneling spectroscopy. Hints of a proximity induced gap in the TI film are observed in transport measurements. We demonstrate the efficacy of a clean van der Waals tunnel junction in probing the superconducting gap of thin film NbSe$_2$ and present tunneling spectroscopy measurements on TI/Gr/Ga heterostructures.

**5:06PM U60.00012: Topological superconductivity in proximitized transition metal dichalcogenide Josephson junctions**  
*JOSEPH PAKIZER (Presenter), ALEX MATOS ABIAGUE, Wayne State Univ — We theoretically investigate the emergence of topological superconductivity in Josephson junctions (JJ) built of a two-dimensional transition metal dichalcogenide (TMD) layer in proximity to an s-wave superconductor and a magnetic insulator. We show that in a certain range of chemical potential and magnetic proximity strength, Majorana bound states form at the ends of the normal region of a TMD-based JJ. The evolution of the topological superconducting phase as the magnetization direction is varied is also investigated. The effect of the interplay between Ising spins, proximity exchange, and Rashba spin-orbit coupling on the system transition to the topological superconducting phase, as well as the corresponding signatures on the ground state phase and critical current, are analyzed in detail for both phase-fixed and phase-unbiased JJs.

Superconductivity in Cd$_3$As$_2$ thin films

ALEXEY SUSLOV (Presenter), Natl High Magnetic Field Lab, ALEXANDER DAVYDOV, P. N. Lebedev Physical Institute, LEONID OVESHNIKOV, National Research Center “Kurchatov Institute”, LEONID MORGUN, National Research University Higher School of Economics, KLIMENT KUGEL, Institute for Theoretical and Applied Electrodynamics, VASILIY ZAKHVALINSKII, EVGENY PILYUK, Belgorod National Research University, ALEXEY KOCHURA, ALEXANDER KUZMENKO, South-West State University, ALEXEY RIL, Kurnakov Institute of General and Inorganic Chemistry, SERGEY MARENKIN, National University of Science and Technology MISIS, VLADIMIR PUDALOV, BORIS ARONZON, P. N. Lebedev Physical Institute

For the first time we observed superconductivity in Cd$_3$As$_2$ thin films without applying external pressure. We studied thin (40 nm -100 nm) films of Cd$_3$As$_2$ grown on various substrates by two various methods: thermal evaporation and magnetron sputtering from Cd$_3$As$_2$ single crystals. Both Raman spectroscopy and X-ray diffraction on the films show results typical for Cd$_3$As$_2$ with tetragonal lattice. A zero-resistance state was registered by the four-probe method on Hall bar shaped samples. Also a zero-resistance plateau was observed in dV/dI characteristics at low currents. The superconducting state was suppressed by applying a magnetic field or increasing the current above critical values $H_c$ and $I_c$, respectively. $H_c$ perpendicular to the film plane was smaller than the in-plane critical field at the same temperature. Analysis of dependences of critical magnetic field $H_c$ on critical temperature $T_c$ reveals a clearly pronounced linear behavior within the intermediate temperature range, similar to that observed for superconducting bulk Cd$_3$As$_2$ and Bi$_2$Se$_3$ under pressure.

Session U61 DMP DCMP: Metal-Insulator transition in 4d/5d oxides
Emergent transport properties on the verge of metal-insulator transitions in pyrochlore 5d/4d oxides* [Invited] KENTARO UEDA (Presenter), Univ of Tokyo —

Magnetic Weyl semimetals have been proved to generate emergent transport properties such as giant anomalous Hall effect due to the band-crossing points acting as magnetic monopoles of Berry curvature.

A variety of 5d/4d oxides, in which the magnitude of the relativistic spin-orbit coupling is comparable to that of the electron correlation, are suggested to host such a topologically-nontrivial property. For instance, pyrochlore iridates (R$_2$Ir$_2$O$_7$) are firstly proposed as a candidate for the magnetic Weyl semimetal. Recent studies uncover that Nd$_2$Ir$_2$O$_7$ shows salient magnetotransport properties on the verge of metal-insulator transitions, attributable to the realization of multiple topological semimetals with different magnetic ordering patterns. Here, we report another examples of such states in Pr$_2$Ir$_2$O$_7$, which is known as a paramagnetic Luttinger semimetal. The resistivity is largely enhanced in the 3-in 1-out magnetic configuration of Pr-4f moments, whereas it is relatively small in the magnetically metastable state (so-called Kagome-ice state) accompanied with the plateau structure of Hall resistivity. It indicates that the quadratic-band-touching electronic structure is significantly sensitive to the localized magnetic configurations even in the weak-coupling system.

We also demonstrate that the pyrochlore 4d oxides provide a fertile playground. Particularly, Ruthenates (A$^{2+}$Ru$^{5+}$O$_7$: 4d$^3$ or R$^{3+}$Ru$^{4+}$O$_7$: 4d$^4$) exhibit wide range of magnetic/electronic phases from an antiferromagnetic insulator to a ferromagnetic-like metal as the valence of A site changes. Furthermore, the sizable anomalous Hall conductivity is observed in the intermediate A-site composition, which can be understood in the context of the topological nature of the band structures.

3:06PM U61.00002: Multiorbital effects in Sr$_2$IrO$_4$ under an external field*  LEINA ENGSTRÖM (Presenter), TAMIR PEREG-BARNEA, McGill University, WILLIAM WITCZAK-KREMPA, Université de Montréal — Many parallels have been drawn between the spin-orbit coupled Mott insulator Sr$_2$IrO$_4$ and the high-T$_c$ superconducting cuprates. In the undoped compound, a one band $J_{eff}=1/2$ model has been shown to capture the observed magnetic order. In other regimes, the applicability of this model is less clear, and the correlated phases are less understood due to potentially complex multiorbital physics. We use a multiple order parameter, self-consistent mean-field approach to explore the relevance of multiorbital effects to possible exotic phases in Sr$_2$IrO$_4$ in an external magnetic field. We study the contributions from both spin and orbital degrees of freedom to the magnetic moment. We thus unravel what role spin orbit coupling plays for emerging orders. Implications for superconductivity and thermal Hall measurements are discussed.

3:18PM U61.00003: Electrical resistivity relaxation under uniaxial strain in BaIrO$_3$ at room temperature  PETER SIEGFRIED (Presenter), HENGDI ZHAO, GANG CAO, MINHYEA LEE, University of Colorado, Boulder — We investigate the 5$d$ transition metal oxide BaIrO$_3$, in which the ground state is strongly dependent on the corner sharing Ir-O-Ir buckling angle between the face sharing octahedral trimers. We compare nanoindentation and resistivity under uniaxial strain, finding a strong hysteretic behavior in the resistivity that is driven by a strain dependent relaxation. This relaxation exhibits logarithmic time dependence, and also emerges in the lattice relaxation as creep. These observations highlight the strong mechanical and electrical coupling in BaIrO$_3$, and point to the relaxation mechanisms sharing the same origin. Our results promote the value of utilizing uniaxial strain testing and nanoindentation as a novel technique to probe the structural sensitivity of quantum materials.
In-situ anisotropic strain controlled metamagnetism of \( \text{Sr}_2\text{IrO}_4 \) by pseudo-Jahn-Teller distortion

HAN ZHANG (Presenter), LIN HAO, JUNYI YANG, University of Tennessee, JOSHUA MUTC, ZHAOYU LIU, University of Washington, QING HUANG, KYLE R NOORDHOEK, University of Tennessee, ANDREW MAY, Oak Ridge National Laboratory, JIUN-HAW CHU, University of Washington, JONG WOO KIM, PHILIP RYAN, APS, Argonne National Laboratory, HAIĐONG ZHOU, JIAN LIU, University of Tennessee — In recent years, iridates have been recognized as an ideal material platform where the emergent many-body phenomena mesh with Antiferromagnetic (AF) functionalities. As the prototype, \( \text{Sr}_2\text{IrO}_4 \) is a quasi-two-dimensional AF Mott insulator of pseudospin-half electrons that exhibits remarkable phenomenological analogy to the high-\( T_c \) cuprates. Meanwhile, significant magnetic responses of the AF order in both bulk and thin film samples have been demonstrated, including metamagnetism, giant magnetoresistance, and anisotropic magnetoresistance. The high controllability of the AF order is largely related to the unique electronic structure that the strong spin-orbit coupling of Ir stabilizes the pseudospin-half Kramer doublet while makes no contribution to the magnetic anisotropy. In this study, we drove the metamagnetic transition of \( \text{Sr}_2\text{IrO}_4 \) bulk crystal into distinct regimes by applying in-situ anisotropic strain. The system was studied with resonant magnetic x-ray scattering and transport measurement. We found the application of anisotropic strain is seen to modulate the pseudospin-lattice coupling, leading to highly efficient magnetoelastic control of the \( J_{\text{eff}}=1/2 \) metamagnetism as well as the associated elasto- and magnetoresistance.

Thickness Dependent Magnetic Reversal in \( \text{Sr}_4\text{Ru}_3\text{O}_{10} \) Nanosheets

YAN LIU, JIYONG YANG, High Magnetic Field Laboratory, CAS, Hefei 230026, China, ZHIQIANG MAO, Department of Physics, Pennsylvania State University, GANG CAO, Department of Physics, University of Colorado at Boulder, MINGLIANG TIAN (Presenter), High Magnetic Field Laboratory, CAS, Hefei 230026, China — While ruthenium oxide \( \text{Sr}_4\text{Ru}_3\text{O}_{10} \) has been studied extensively in the last two decades, the origin of the unusual second magnetic anomaly near \( T_M \approx 50 \) K remains elusive. Here, we investigated the thickness-dependent anisotropic magnetoresistance (AMR) of pure and 2% Fe-doped \( \text{Sr}_4\text{Ru}_3\text{O}_{10} \) nanosheets. It was clearly found that the AMR properties in pure nanosheets present thickness-dependent behavior and an unusual reversal near \( T_M \), but Fe-doping nansheet completely suppresses the second anomaly down to low temperatures. Analysis of the data demonstrates that this AMR reversal is caused by the magnetization reversal from the \( ab \) plane ferromagnetic order at \( T>T_M \) to the \( c \) direction at \( T<T_M \) due to the competition between the shape anisotropy and the inherent magnetocrystalline anisotropy. Our result suggests that the second magnetic transition in \( \text{Sr}_4\text{Ru}_3\text{O}_{10} \) nanosheets is originated from spin reorientation.
3:54PM U61.00006: Transport phenomena in ultraclean 111 oriented SrVO$_3$ thin films

JOSEPH ROTH (Presenter), TATIANA KUZNETSOVA, ROMAN ENGLER-HERBERT, Pennsylvania State University — SrVO$_3$ has proven to be an ideal testbed for studying the effects of strong electron correlation due to its simple cubic structure and single d-orbital electron. Ultraclean SrVO$_3$ films with residual ratios exceeding 200 have recently been demonstrated using self-regulated growth by hybrid MBE, allowing accurate interpretation of the intrinsic features of electron correlation [1]. In addition to allowing high quality growth, we demonstrate that SrVO$_3$ can also be grown epitaxially on (111) oriented LSAT substrates. We compare the temperature dependent electronic transport properties of (111) and (001) oriented SrVO$_3$ thin films. In addition, we discuss the formation of a low temperature Fermi liquid like phase in each case.

4:06PM U61.00007: Growth and Characterization of Heterostructures of Ferromagnetic SrRuO$_3$ and Superconducting Sr$_2$RuO$_4$ by Molecular-Beam Epitaxy

NATHANIEL SCHREIBER (Presenter), HARI NAIR, JACOB RUF, LUDI MIAO, BERIT GOODGE, LENA KOURKOUTIS, KYLE M SHEN, DARRELL SCHLOM, Cornell University — Sr$_2$RuO$_4$ single crystals have been shown to exhibit unconventional superconductivity with a $T_c$ of 1.5 K. Our group recently reported a thermodynamic growth window for Sr$_{n+1}$Ru$_n$O$_{3n+1}$ thin films, including the demonstration of the reproducible growth of high-RRR Sr$_2$RuO$_4$ and SrRuO$_3$ thin films. The growth of Sr$_2$RuO$_4$ thin films and the recent $^{17}$O NMR results on single crystals offer an opportunity for the growth of Sr$_2$RuO$_4$-based heterostructures, in order to perform measurements to determine the superconducting order parameter. In this talk, we describe the growth of SrRuO$_3$/Sr$_2$RuO$_4$ heterostructures using oxide molecular-beam epitaxy. We characterize the crystallinity and structure of these heterostructures using X-ray diffraction, X-ray reflectivity, and scanning transmission electron microscopy, and finally we present magnetometry and electrical resistivity measurements on these heterostructures.

4:18PM U61.00008: Intrinsic tunable anomalous Hall effect induced by momentum-space Berry curvature in SrRuO$_3$

BYUNGMIN SOHN (Presenter), EUNWOO LEE, JI SEOP OH, WONSHIK KYUNG, HANYOUNG YOO, BOHM-JUNG YANG, CHANGYOUNG KIM, Physics and Astronomy, Seoul National University — Broken time-reversal symmetry and spin-orbit coupling (SOC) in strongly correlated ferromagnetic materials are expected to induce novel phenomena. One of these ferromagnetic materials, SrRuO$_3$ (SRO), is well-known for showing non-monotonous anomalous Hall effect (AHE), which is produced due to magnetic monopoles, or large Berry curvature in momentum space. Recently, we observed an abnormal behavior of AHE in SRO ultrathin films. To explain this, we measured angle-resolved photoemission spectroscopy (ARPES) of SRO ultrathin film. We found that non-monotonous AHE is induced by band-structure nodal lines, which open a gap due to SOC and magnetization. By changing temperature and thickness of SRO, the sign of AHE can be tunable with a variation of large Berry curvature.
4:30PM U61.00009: Spectroscopic study on band evolution and formation of relativistic Mott insulating phase in Ir doped Sr$_2$RuO$_4$  JUNYOUNG KWON (Presenter), BEOM SEO KIM, Physics, Seoul Natl Univ, JONATHAN DENLINGER, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, Lawrence Berkeley National Laboratory, YOUNG JAI CHOI, Physics and Applied Physics, Yonsei University, WONSHIK KYUNG, CHANGYOUNG KIM, Physics, Seoul Natl Univ — Recent research showed 4d, 5d transition metal oxide provides rich novel physical properties. A discovery of superconductivity in Sr$_2$RuO$_4$ is still controversial to verify the mechanism, and relativistic Mott phase of Sr$_2$IrO$_4$ expanded wide research field of spin-orbit coupling-driven physics. As one step to explore the field, doping study also become vivid that it can alter the system's key parameters and artificially create a perturbed physical system. Rh doping in Sr$_2$IrO$_4$ revealed variation of spin-orbit coupling, and doping on electrons on Sr$_2$IrO$_4$ showed charge carrier dependent collapse of Mott phase. Now we tried to study doped compound Sr$_2$(Ru,Ir)O$_4$ to show the electronic propagation of bands and evolution of relativistic Mott phase with angle-resolved photoemission spectrscopy technique. With this presentation we would clarify the role of spin-orbit coupling on the crystal-field-dominating band structure of Sr$_2$RuO$_4$, and provide a step by step evolution of relativistic Mott transition from varying spin-orbit coupling parameter.

4:42PM U61.00010: Spectroscopic evidence for electron-boson coupling in electron-doped Sr$_2$IrO$_4$  YONG HU, University of Science and Technology of China, XIANG CHEN, University of California, Santa Barbara, SHUTING PENG, University of Science and Technology of China, CHRISTOPHER LANE, MATTHEW MATZELLE, Northeastern University, ZELIANG SUN, University of Science and Technology of China, MAKOTO HASHIMOTO, DONGHUI LU, Stanford Synchrotron Radiation Lightsource, EIKE F. SCHWIER, MASASHI ARITA, Hiroshima University, TAO WU, University of Science and Technology of China, ROBERT MARKIEWICZ, Northeastern University, KENYA SHIMADA, Hiroshima University, XIANHUI CHEN, University of Science and Technology of China, ZHIXUN SHEN, Stanford University, ARUN BANSIL, Northeastern University, STEPHEN WILSON, University of California, Santa Barbara, JUNFENG HE (Presenter), University of Science and Technology of China — The pseudogap, d-wave superconductivity and electron-boson coupling are three intertwined key ingredients in the phase diagram of the cuprates. Sr$_2$IrO$_4$ is a 5d-electron counterpart of the cuprates in which both the pseudogap and a d-wave instability have been observed. Here, we report spectroscopic evidence for the presence of the third key player in electron-doped Sr$_2$IrO$_4$: electron-boson coupling. A kink in nodal dispersion is observed. The strength of the kink changes with doping, but the energy scale remains the same. These results provide the first non-cuprate platform for exploring the relationship between the pseudogap, d-wave instability and electron-boson coupling in doped Mott insulators.
4:54PM U61.00011: Relaxation Dynamics at High-symmetry Points in Sr$_2$IrO$_4$ through Time- and Angle-resolved Photoemission Spectroscopy*  DONGSUNG CHOI (Presenter), DORON AZOURY, EDOARDO BALDINI, BAIQING LYU, ALFRED ZONG, Massachusetts Institute of Technology MIT, ZACH PORTER, STEPHEN WILSON, University of California, Santa Barbara, NUH GEDIK, Massachusetts Institute of Technology MIT — The unresolved mechanism that underlies high-$T_c$ superconductivity in cuprates has stimulated the search for new material platforms that could shed light on this long-standing puzzle. A promising candidate is electron-doped Sr$_2$IrO$_4$ — an antiferromagnetic Mott insulator with strong spin-orbit coupling. Pioneering studies have shown that chemical doping modifies the electronic band structure in electron-doped Sr$_2$IrO$_4$. However, instead of chemical doping, which provides a static modification of the electronic band structure, transient photo-doping with an ultrafast laser pulse can be considered. Through time- and angle-resolved photoemission spectroscopy, we performed momentum-resolved pump-probe experiments and compared the electron relaxation behavior at high-symmetry points (Γ, M, and X) of the Brillouin zone. This time- and momentum-resolved study provides new insights into the transient charge dynamics in this Mott insulator.

5:06PM U61.00012: Magnetic-field-dependent second-harmonic generation study of Sr$_2$IrO$_4$  KYLE SEYLER (Presenter), ALBERTO DE LA TORRE, Caltech, ZACH PORTER, University of California, Santa Barbara, GANG CAO, University of Colorado, Boulder, STEPHEN WILSON, University of California, Santa Barbara, DAVID HSIEH, Caltech — The quasi-two-dimensional layered oxide Sr$_2$IrO$_4$ has earned recognition for its novel spin-orbit Mott state and various analogies to cuprate physics. Neutron diffraction and x-ray scattering measurements show that it possesses a centrosymmetric magnetic ground state, consisting of a canted intralayer antiferromagnetic order with nonzero net magnetic moments in each layer stacked antiferromagnetically [1-4]. However, the onset of a second-harmonic generation (SHG) signal below the Néel temperature has suggested the presence of a distinct hidden magnetic order [5]. Using small in-plane magnetic fields, it is possible to manipulate the Néel order and help distinguish it from hidden order. In this talk, we will present magnetic-field-dependent SHG rotational anisotropy and microscopy studies that further elucidate the nature of this hidden state.

5:18PM U61.00013: Raman measurements on Sr$_2$IrO$_4$ grown in magnetic field*  NICK PELLATZ (Presenter), DMITRY REZNIK, GANG CAO, University of Colorado, Boulder — Recent experiments found a massive reduction in the low-temperature resistivity in Sr$_2$IrO$_4$ when the crystals were grown in the presence of a magnetic field. Here I will present a comparison of Raman scattering data from normal and field-grown Sr$_2$IrO$_4$. The main differences between the two appeared in scattering from magnetic excitations. Two-magnon scattering was significantly broader in the field-grown sample and exhibited unusual temperature dependence. Scattering from single magnons, clearly visible in the normal sample, was completely absent in the field-grown sample down to an energy of at most 5 cm$^{-1}$. Latest results including on doped samples will be presented.

*Work at the University of Colorado was supported by the NSF under Grant No. DMR-1410111

Session U62 DCMP: Helium and Exotic Quantum Fluids  Mile High Ballroom 4C - Valeri Kotov, Univ of Vermont

2:30PM U62.00001: Chasing signs of the Kelvin-wave cascade on a single vortex using nanoscale mechanical resonators*  SAMULI AUTTI (Presenter), ANDREW GUTHRIE, RICHARD HALEY, SERGEY KAFANOV, MARK NOBLE, YURI PASHKIN, GEORGE PICKETT, VIKTOR TSEPELIN, DMITRY ZMEEV, Department of Physics, Lancaster University — It is believed that Kelvin waves propagating on a quantum vortex provide a fundamental channel of dissipation of superfluid turbulence, driven by the Kelvin-wave cascade. In spite of decades of theoretical work, no conclusive experimental evidence on the existence of such cascade has been presented. In our experiments we use nanoscale mechanical resonators operating at about 1MHz, immersed in superfluid $^4$He [1]. These probes are sensitive enough to probe single vortices. A vortex can be attached to the resonator by creating turbulence using a nearby tuning fork. This allows measuring the restoring force and the dissipation the vortex imposes on the resonator as a function of time, until the vortex is disconnected. We compare the observations with the theoretical expectation [2], and discuss possible future experiments.

2:42PM U62.00002: Suppression of triplet superfluidity near magnetically-active surfaces
ANTON VORONTSOV (Presenter), Montana State University, Bozeman — Recent experiments investigating properties of the chiral A phase of superfluid $^3$He in thin slabs (P. Heikkinen et al, arXiv:1909.04210) revealed unusually large $T_C$ suppression that exceeds the fully-diffusive scattering limit. This requires re-thinking of the boundary conditions, and inclusion of magnetic degree of freedom to describe scattering of the quasiparticles on surfaces that are covered my magnetically-active solid layer of He-3 atoms. I will review existing models of magnetic scattering to prove that they cannot, in principle, give such suppression of the A phase. I will show that in order to explain the large $T_C$ suppression, the internal quantum degrees of freedom of the solid spins have to be taken into account.

2:54PM U62.00003: Emergence of a New Superfluid Phase in Quasi-2D $^3$He*
ALEXANDER SHOOK (Presenter), VAISAKH VADAKKUMBATT, PRAMODH V SENARATH YAPA ARACHCHIGE, CALLUM DOOLIN, RUFUS BOYACK, PAUL Y KIM, GREG POPOWICH, FABIEN SOURIS, HOLLY CHRISTANI, JOSEPH MACIEJKO, JOHN DAVIS, Univ of Alberta — $^3$He is a fermionic superfluid that exhibits exotic properties at ultra-low temperatures due to its unconventional $p$-wave Cooper pairing. The orbital and spin degrees of freedom of $^3$He Cooper pairs allows for a rich array of possible superfluid phases, which are determined by geometry as well as the thermodynamic properties of the fluid. Much of the current theoretical and experimental interest in $^3$He has focused on quasi-2D slabs where new phases are predicted to emerge. Our lab has created nanofluidic mechanical resonators capable of both confining $^3$He and detecting phase transitions over a wide range of pressures and temperatures. In doing so we have observed a new phase transition which is stabilized by confinement and thought to be due to the breaking of translational symmetry within the superfluid slab.

3:06PM U62.00004: Memory Effect and the Metastability of the A to B Transition in Superfluid $^3$He.*  DMYTRO LOTNYK, ANNA EYAL, NIKOLAY ZHELEV, T.S. ABHILASH, JOHN WILSON, MICHAEL TERILLI, ALDO CHAVEZ, ERIC SMITH, ERICH MUELLER, JEEVAK PARPIA (Presenter), Cornell University — We experimentally study the metastability of the A phase of superfluid $^3$He, as either temperature ($T$) or pressure ($P$) is varied. We find significant supercooling, with the A-B transition occurring well below the temperature of the thermodynamic phase boundary in bulk. The observed transition in two chambers (separated by a 1.1 $\mu$m tall channel) shadows the thermodynamic A-B line in the $T$-$P$ plane but extends below the polycritical point and terminates in the B phase (and not at $T_c$). We find significant path dependence (memory effect) in the metastability: When we sweep pressure at fixed temperature, the region of metastable A is larger than when we sweep temperature at fixed pressure. We find U-shaped depressurizing-cooling-pressurizing paths in the $T$-$P$ plane which enable the metastable A phase to exist well below the polycritical point at 21.2 bar that cannot be reached by a temperature sweep. While cooling at constant pressure, we observe A-B transitions down to 20.85 bar, whereas while depressurizing, A-B transitions are seen down to 19.5 bar. Ongoing experiments in a 50 G field show unexpected behavior. The measurements highlight the role of surfaces in nucleation and the memory effect.

3:18PM U62.00005: Mott Insulator to Superfluid Quantum Phase Transition for Helium on Strained Graphene*  JIANGYONG YU (Presenter), NATHAN NICHOLS, TARAS I. LAKOBA, VALERI KOTOV, ADRIAN DEL MAESTRO, Univ of Vermont — An exciting development in the field of correlated systems is the possibility of realizing two-dimensional (2D) superfluidity, particularly by adsorbing helium on novel 2D quantum materials, such as graphene. How superfluidity emerges in this system, and whether it could exist in the first, second, etc. layer, has been a topic of considerable controversy. We argue theoretically that under certain favorable external conditions where uniaxial stress is applied to graphene, 2D anisotropic superfluidity can form in the first layer. This result is based on preliminary large-scale ab initio quantum Monte Carlo simulations combined with a mapping of the problem to an effective Bose-Hubbard model. We show that a critical ratio of the onsite repulsion to hopping strength ($U/t$) can be achieved via strain, allowing for a quantum phase transition to a superfluid state below a critical value. Our analysis supports, for the first time, the existence of an unconventional first layer 2D anisotropic superfluid, possibly also exhibiting supersolid correlations reflecting the underlying graphene lattice structure.

*This work received support under NASA grant number 80NSSC19M0143.
3:30PM U62.00006: Modelling a Neutron Star in Superfluid Helium  
RENA ZIEVE (Presenter), ROBERT P PRATER, University of California, Davis — We discuss a lab experiment intended to model neutron star behavior. Superfluid helium is encased in a container that can rotate freely. The container is spun up, then monitored as it gradually slows down. Pinned vortices inside which release and repin can produce rotational glitches mimicking those of pulsars. We discuss the experimental design and the expected measurement sensitivity. The design is based on similar work from 40 years ago. We revisit the experiment now because of advances in the speed of computers and videocameras, as well as in the theoretical modelling of neutron stars.

3:42PM U62.00007: Few-body precursor of the Higgs mode in a superfluid Fermi gas - from theory to experiments.*  
JOHANNES BJERLIN (Presenter), Univ of Copenhagen — We demonstrate the presence of an undamped few-body precursor of the Higgs mode in an ultracold trapped Fermi gas.
Here, the lowest excitation mode frequency has non-monotonical dependence on the interaction strength, attaining a minimum in the crossover region.
In the many-body limit, the Higgs mode appears as a zero-energy excitation mode at the quantum phase transition point between the superfluid and the normal phase.
In the few-body limit, we observe an energy minimum that deepens with increasing particle number, reflecting the fact that we see a few-body Higgs mode analog which develops towards a zero-energy excitation.
This hallmark of the Higgs mode is persistent also for weakly anharmonic and anisotropic traps, and it can readily be observed in a new generation of microtraps where the Higgs mode is selectively excited by modulating the interaction strength via Feshbach resonances.
Using variations of the Hartree-Fock Bogoliubov method combined with exact diagonalization, we track the development of the few-body mode into the regime of N~100 particles.

A doping-dependent switch from one- to two-component electron-hole superfluidity with high transition temperatures in coupled TMD monolayers. SARA CONTI (Presenter), Univ of Antwerp, ANDREA PERALI, University of Camerino, DAVID NEILSON, FRANCOIS M PEETERS, Univ of Antwerp — Electron-hole (e-h) superfluidity in a Transition Metal Dichalcogenide heterostructure consisting of coupled MoSe$_2$-WSe$_2$ monolayers, is investigated using mean-field approach. We include self-consistent screening of the electron-hole interaction and the multibands effects arising from the strong spin-orbit band splitting [1].

The different magnitude of the valence and conduction band splitting results in a large energy misalignment of the electron and hole bands [2]. This misalignment is completely different if the doping of the monolayers is interchanged between MoSe$_2$(e)/WSe$_2$(h) and MoSe$_2$(h)/WSe$_2$(e), and depending on the choice of doping, the superfluidity may or may not be tuneable by density from one- to two-components. We find that only MoSe$_2$(h)/WSe$_2$(e) can have both one-component and two-component superfluidity.

The electron-hole pairing is much stronger than in graphene[3] due to the large effective masses so superfluidity is predicted for densities up to $10^{13}$ cm$^{-2}$. The transition temperatures are high, up to 100 K, which is consistent with a very recent experiment on the identical system[4].

Anomalous phase fluctuations of a superfluid flowing in a random potential* TAIKI HAGA (Presenter), MASAHITO UEDA, University of Tokyo — The phase structures of driven quantum many-body systems have attracted considerable interest owing to recent experimental progress in ultracold atomic gases. A fundamental issue in this subject is to clarify how and when the long-range order of a nonequilibrium steady state is destroyed by random perturbations. In thermal equilibrium, the Mermin-Wagner theorem can be invoked to address the stability of the ordered phase against thermal fluctuations. However, in nonequilibrium situations the universal mechanisms responsible for the breakdown of the long-range order are poorly understood. In this study, we investigate the stability of the off-diagonal long-range order of a superfluid flowing in a weak random potential [1]. Within the classical field theory, we show that for an arbitrarily small flow velocity the off-diagonal long-range order is destroyed in one and two dimensions. We argue that the superfluid flowing in a random potential can be identified with the corresponding uniform system at thermal equilibrium with an effective temperature, where the long-range order is prohibited in one and two dimensions by the Mermin-Wagner theorem.

Disordered Creutz lattice: The role of flat bands in superfluid behavior

CHEN CHENG, Center for Interdisciplinary Studies, Lanzhou University, China, GEORGE BATROUNI, Universite Cote d’Azur, INPHYNI, CNRS, 0600 Nice, France, RUBEM MONDAINI (Presenter), Beijing Computational Science Research Center, China — Physical systems displaying flat or quasi-flat bands have been intensively investigated due to the enhanced effects that interactions may bring. This is for example, believed to be behind the manifestation of superconductivity in the twisted bilayer graphene, where by adjusting the twisting angles, one can induce the formation of (quasi-) flat bands close to the Fermi energy. On a typically non-interacting picture, a flat band would correspond to an infinite effective mass for the carriers, halting transport. In the case one possess attractive interactions, it has been recently shown that superfluid transport is robust and the associated superfluid weight bounded by topological invariants the bands may possess. Further, when comparing the robustness of the superfluid properties to the presence of quenched disorder, the constrast between topological and non-topological systems becomes extremely clear. In this presentation, we will show results for the disordered Hubbard model with attractive interactions in the presence of flat or dispersive bands, checking the influence topological properties may possess in stabilizing the superfluid behavior in this interacting system.

The Dynamical Structure Factor of a Fermionic Super-solid on an Optical Lattice

PATRICK KELLY (Presenter), ETTORE VITALI, ANNETTE LOPEZ, California State University, Fresno, DAVIDE GALLI, GIANLUCA BERTAINA, Physics, University of Milan — We perform a Quantum Monte Carlo simulation and study of a cold atomic Fermi gas on a 2D optical lattice. This system is modeled with a Hubbard hamiltonian with on-site attractive interaction. At half-filling, when on average one fermion occupies each lattice site, with equal numbers of fermions spin up and spin down, the system displays an interesting supersolid phase: a superfluid with a checkerboard density modulation. Combining unbiased Auxiliary-Field Monte Carlo simulations with state-of-art analytic continuation techniques, we compute the density dynamical structure factor $S(\mathbf{q},\omega)$ of the system and the density response function $\chi(\mathbf{q})$, in order to characterize this supersolid phase. These results shed light on this interesting physical regime, where s-wave pairing superfluidity coexists with a non-uniform local density.
4:42PM U62.00012: Density-wave steady-state phase of dissipative ultracold fermions with nearest-neighbor interactions

IRAKLI TITVINIDZE (Presenter), JAROMIR PANAS, MICHAEL PASEK, ITP, Goethe University Frankfurt, ARYA DHAR, ITP, Leibniz Universität Hannover, TAO QIN, Anhui University, ANDREAS GEISSLER, ISIS, University of Strasburg, MOHSEN HAFEZ-TORBATI, ITP, Goethe University Frankfurt, MAX E. SORANTIN, ITP-CP, TU Graz, WALTER HOFSTETTER, ITP, Goethe University Frankfurt — In the current work, we investigate the effect of local dissipation on the presence of density-wave ordering in spinful fermions with both local and nearest-neighbor interactions, as described by the extended Hubbard model [1]. For this purpose we use the recently developed Lindblad dynamical mean-field theory (L-DMFT) [2,3], which allows to study directly steady-state properties of strongly correlated fermionic systems. To take into account nearest-neighbor interactions we perform a mean-field decoupling. We find the density-wave order to be robust against decoherence effects up to a critical point where the system becomes homogeneous with no spatial ordering. These results will be relevant for future cold-atom experiments using fermions with nonlocal interactions arising from the dressing by highly excited Rydberg states, which have finite lifetimes due to spontaneous emission processes.

4:54PM U62.00013: Squeezed Photons Reconsidered

SAMUEL BOWEN (Presenter), Chemistry and Physics, Chicago State University, JAY D. MANCINI, Physics and Chemistry, Kingsborough Community College — Using an exact one-photon thermodynamic Green's Function determined by a matrix method for the Liouville operator, the relationship between squeezed photons and the amplitude of the vector potential is determined without the use of the usual coherent states or the squeezing operator. The Hamiltonian for each photon mode is determined for all levels of uncertainty to be given by an extended simple harmonic oscillator Hamiltonian. The matrix method used and the simplest approximation for the generation of squeezed photons is presented.

5:06PM U62.00014: Anomalous hydrodynamics in condensed matter systems

ALEXANDRE ABANOV (Presenter), Department of Physics and Astronomy, Stony Brook University — Fluid dynamics is a powerful tool in studying both quantum and classical many body systems. I will review recent progress in using fluid dynamics to describe two-dimensional isotropic fluids with broken parity. The viscous stress tensor for these fluids can possess an anomalous part known as odd or Hall viscosity. This peculiar viscosity does not lead to any dissipation in the fluid. Examples of fluids with odd viscosity include rotating superfluids, plasmas in magnetic fields, quantum Hall fluids, and chiral active fluids. I will describe some manifestations of the odd viscosity. In particular, I will focus on surface waves propagating along the boundaries of such fluids.

U62.00015: Collective modes for a Fermi Liquid under Harmonic Trap  YUELIN SHAO
(Presenter), Chinese Academy of Sciences, Institute of Physics, XIDAI, Physics, Hong Kong University of Science of Technology — Based on the Boltzmann transport equation of quasi-particles, we examine the low energy excitations of a normal Fermi liquid confined in a two-dimensional harmonic trap. In the non-interacting limit, the excitation spectrum is discrete and the highly degenerate eigenfrequencies locate exactly at integer multiples of the corresponding trap frequency. When the interaction is switched on, the degeneracy will be broken and every degenerate frequency will extend to be a continuous band but with some discrete modes out of the band. The continuum and discrete modes in the spectrum can be interpreted as particle-hole excitations and collective modes ("zero sound") respectively. For a repulsive interaction, the lowest collective mode frequencies are higher than those of the corresponding particle-hole excitations and can be detected by the experiments on cold atom systems.

Session U63 DCMP: Twisted 2D Heterostructures: Computational and Theoretical Studies II  Mile High Ballroom 4D - Nicolas Leconte

2:30PM U63.00001: Geometric and conventional contribution to superfluid weight in twisted bilayer graphene*  XIANG HU (Presenter), Physics, William and Mary, TIMO HYART, International Research Centre MagTop, Institute of Physics, Polish Academy of Sciences, DMITRY I. PIKULIN, Microsoft Quantum, Microsoft Station Q, University of California, Santa Barbara, ENRICO ROSSI, Physics, William and Mary — We calculate the superfluid weight for twisted bilayer graphene (TBLG) taking into account both the conventional contribution and the contribution arising from the quantum geometry of the bands. We find that both contributions are larger than one would expect by treating the bands as well-isolated, that at the magic angle the geometric contribution is larger than the conventional one, and that for small deviations away from the magic angle the conventional contribution is larger than the geometric one. Our results show that, despite the flatness of the bands the superfluid weight in TBLG is finite and consistent with experimental observations. We also show how the superfluid weight can be tuned by varying the chemical potential and the twist angle opening the possibility to tune the nature of the superconducting transition between the standard BCS transition and the Berezinskii-Kosterlitz-Thouless transition.

**2:42PM U63.00002: Inherited and flatband-induced ordering in twisted graphene bilayers**
LENNART KLEBL (Presenter), CARSTEN HONERKAMP, RWTH - Aachen — The nature of the insulating and superconducting states in twisted bilayer graphene systems is intensely debated. While many works seek for explanations in the few flat bands near the Fermi level, theory and a number of experiments suggest that nontwisted bilayer graphene systems do exhibit – or are at least close to – an ordered, insulating ground state related to antiferromagnetic ordering. We investigate how this magnetic ordering scenario is affected by the slight twisting. We find that at charge neutrality the ordering tendencies of twisted systems interpolate between those of untwisted AA and AB stacked bilayers at intermediate temperatures, while at lower temperatures of the order of typical flat-band dispersion energies, the ordering tendencies are even enhanced for the twisted systems. The preferred order at charge neutrality still exhibits an antiferromagnetic spin arrangement, with ordered moments alternating on the carbon-carbon bonds, with an enveloping variation on the moiré scale (inherited ordering). Even in the RPA analysis, the possible low-energy behaviors are quite versatile, and slight doping of one or more electrons per moiré cell can take the system into a, potentially flat-band induced, ferromagnetic phase.

**2:54PM U63.00003: Moiré-pattern fluctuations and electron-phason coupling in twisted bilayer graphene**
HECTOR OCHOA (Presenter), Columbia University — In twisted bilayer graphene, long-wavelength lattice fluctuations are dominated by phasons: acoustic collective modes resulting from coherent superpositions of optical phonons. At small twist angles, these modes describe the sliding motion of stacking domain walls separating regions of partial commensuration. The resulting soliton network is a soft elastic manifold, whose reduced rigidity arises from the competition between elastic and adhesion forces governing lattice relaxation. Shear deformations of the beating pattern dominate the electron-phason coupling. This coupling lifts the layer degeneracy of the Dirac cones at the corners of the moiré Brillouin zone, which could explain the observed fourfold (instead of eightfold) Landau level degeneracy. Electron-phason scattering gives rise to a linear-T resistivity that increases with decreasing twist angle due to the reduction of the stiffness of the soliton network. This contribution alone cannot explain the huge enhancement of the resistivity of the normal state close to the magic angle. I will discuss the connection between these soft collective modes and the widespread presence of twist angle disorder in the samples.

3:06PM U63.00004: Spin-valley density wave in moiré materials*  CONSTANTIN SCHRADE
(Presenter), LIANG FU, Massachusetts Institute of Technology MIT — We introduce and study a minimum two-orbital Hubbard model on a triangular lattice, which captures the key features of both the trilayer ABC-stacked graphene-boron nitride heterostructure and twisted transition metal dichalcogenides in a broad parameter range. Our model comprises first- and second-nearest neighbor hoppings with valley-contrasting flux that accounts for trigonal warping in the band structure. For the strong-coupling regime with one electron per site, we derive a spin-orbital exchange Hamiltonian and find the semiclassical ground state to be a spin-valley density wave. We show that a relatively small second-neighbor exchange interaction is sufficient to stabilize the ordered state against quantum fluctuations. Effects of spin- and valley Zeeman fields as well as thermal fluctuations are also examined.

3:18PM U63.00005: Phonon scattering induced carrier resistivity in twisted double bilayer graphene  XIAO LI (Presenter), City Univ of Hong Kong, FENGCHENG WU, University of Maryland — In this work we carry out a theoretical study of the phonon-induced resistivity in twisted double bilayer graphene (TDBG), in which two Bernal-stacked bilayer graphene devices are rotated relative to each other by a small angle $\theta$. We show that at small twist angles ($\theta \sim 1^\circ$) the effective mass of the TDBG system is greatly enhanced, leading to a drastically increased phonon-induced resistivity in the high-temperature limit where phonon scattering leads to a linearly increasing resistivity with increasing temperature. We also discuss possible implications of our theory on superconductivity in such a system, and provide an order of magnitude estimation of the superconducting transition temperature.

3:30PM U63.00006: Functional renormalization group analysis of many-body states in a large moiré unit cell systems*  LENNART KLEBL, DANTE M. KENNES, CARSTEN HONERKAMP (Presenter), RWTH Aachen University — Layers of two-dimensional materials arranged at a twist angle with respect each other lead to enlarged unit cells with potentially strongly altered band structures, offering a new arena for novel and engineered many-body ground states. For the exploration of these, renormalization group methods are an appropriate, flexible tool that takes into account the mutual influence of competing tendencies. We show how the functional renormalization group known from simpler two-dimensional systems can be employed for the large-unit cell moiré superlattices, providing a description on the atomic scale and absorbing available ab-initio information on the model parameters. For the case of twisted bilayer graphene models, we explore the leading ordering tendencies depending on the band filling and the range of interactions. The results indicate a delicate balance between distinct magnetically ordered ground states.

*DFG-RTG 1995
3:42PM U63.00007: Three-Dimensional Topological Twistorics

FENGCHENG WU (Presenter), RUIXING ZHANG, University of Maryland — We introduce a theoretical framework for the new concept of three-dimensional (3D) twistronics by developing a generalized Bloch band theory for 3D layered systems with a constant twist angle \( \theta \) between successive layers. Our theory employs a nonsymmorphic symmetry that enables a precise definition of an effective out-of-plane crystal momentum, and also captures the in-plane moire pattern formed between neighboring twisted layers. To demonstrate the novel topological physics that can be achieved through 3D twistronics, we present two examples. In the first example of chiral twisted graphite, Weyl nodes arise because of inversion-symmetry breaking, with \( \theta \)-tuned transitions between type-I and type-II Weyl fermions, as well as magic angles at which the in-plane velocity vanishes. In the second example of twisted Weyl semimetal, the twist in the lattice structure induces a chiral gauge field \( A \) that has a vortex-antivortex lattice configuration. Line modes bound to the vortex cores of the \( A \) field give rise to 3D Weyl physics in the moire scale. We also discuss possible experimental realizations of 3D twistronics.

3:54PM U63.00008: Ferromagnetic Mott state in twisted graphene bilayers at the magic angle

KAGNJUN SEO, Univ of Oklahoma, VALERI KOTOV, Department of Physics, University of Vermont, BRUNO UCHOA (Presenter), Univ of Oklahoma — We address the effective tight-binding Hamiltonian that describes the insulating Mott state of twisted graphene bilayers at a magic angle [1]. In that configuration, twisted bilayers form a honeycomb superlattice of localized states, characterized by the appearance of flat bands with fourfold degeneracy. After calculating the maximally localized superlattice Wannier wave functions, we derive the effective spin model that describes the Mott state at quarter filling, which has an emergent SU(4) symmetry that is reminiscent of spin and valley quantum numbers. We suggest that the system is an exotic ferromagnetic Mott insulator, with well-defined experimental signatures.

*K. S. and B. U. acknowledge NSF CAREER Grant No. DMR-1352604 for support.
4:06PM U63.00009: Theory of generalized Wigner crystals in moire superlattices.  BIKASH PADHI (Presenter), University of Illinois at Urbana-Champaign, CHITRA RAMASUBRAMANIAN, Physics, ETH Zurich, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — Recent developments in moire materials (twisted layers of graphene or transition metal compounds) has opened up a new avenue to realize quasi-flat bands in condensed matter systems in which the interactions dominate. Our previous calculations suggested that the correlations in such systems could be strong enough to realize electronic solids called Wigner crystals (WC). Such states have been observed before in (continuum) 2D electron gas and recently it was also claimed to be observed in a (moire lattice of) twisted bilayer of WS/WSe2. Despite the experimental advances, a clear understanding of the physics of WC coupled to an underlying lattice is completely lacking. In this talk we present some preliminary results based on a model we construct to address this problem. In such a scenario, melting of a WC (coupled to lattice) can be understood in terms of an interplay of coulomb interaction and the tendency for forming solitons.

4:18PM U63.00010: Floquet flat-band engineering of twisted bilayer graphene*  OR KATZ (Presenter), Technion - Israel Institute of Technology, GIL REFAEL, Institute of Quantum Information and Matter and Department of Physics, California Institute of Technology, Pasadena, California 91125, USA, NETANEL LINDNER, Technion - Israel Institute of Technology — Twisted Bilayer Graphene at the magic twist angle features flat energy bands, which lead to superconductivity and strong correlation physics. These unique properties are typically limited to an extremely narrow range of twist angles around the magic angle. Here we demonstrate that coherent optical irradiation could lead to emergence of flat isolated Floquet-Bloch bands at a wide range of small twist angles. At small twist angles larger than 1°, these bands exhibit non-trivial topology and a non-zero chern number. We show that the effect can potentially be realized with relatively weak optical beams at the visible-infrared range, potentially allowing for realization of optically tuned flat bands.

4:30PM U63.00011: Mirror symmetry breaking and the stacking-shift effect in twisted trilayer graphene* CHAO LEI (Presenter), University of Texas at Austin, LUKAS LINHART, Vienna University of Technology, WEI QIN, ALLAN MACDONALD, University of Texas at Austin — A continuum model of twisted trilayer graphene devices was constructed using ab initio first principles theory to assess the dependence of electronic structure on local stacking. We have applied the model to study electronic structure and transport properties as a function of band filling. When the middle layer of Bernal stacking trilayer graphene is twisted a mirror symmetry exists which is absent in the case of twisted top layers and twisted bilayer graphene. The mirror symmetry decouples band with even and odd parity, but is lost when the top layer is shifted relative to the bottom layer or an electric field is applied. We study the consequences of mirror and C3v symmetry breaking by this top layer lateral stacking shift effect or electric field, focusing on the electronic structure and transport properties such as the longitudinal and Hall conductivities of this system. Whereas a lateral shift has no effect for either top layer twisted trilayers or bilayers, large changes in electronic structure occur for middle-layer twisted trilayers.

*Work in University of Texas at Austin was supported by DOE grant DE- FG02-02ER45958

4:42PM U63.00012: Derivation of Wannier orbitals and minimal-basis tight-binding Hamiltonians for twisted bilayer graphene: First-principles approach* STEPHEN CARR (Presenter), SHIANG FANG, Harvard University, HOI CHUN PO, Massachusetts Institute of Technology, ASHVIN VISHWANATH, EFTHIMIOS KAXIRAS, Harvard University — The complexity of the atomic-scale structures in twisted bilayer graphene (TBG) has made even the study of single-particle physics at low energies around the Fermi level challenging. We provide a convenient and physically motivated picture of single-particle physics in TBG using reduced models with the smallest possible number of localized orbitals. The reduced models exactly reproduce the low-energy bands of ab initio tight-binding models, including the effects of atomic relaxations. We obtain for the first time the corresponding Wannier orbitals that incorporate all symmetries of TBG, which are also calculated as a function of angle, a requisite first step towards incorporating electron interaction effects. We construct eight-band and five-band models for the low-energy states for twist angles between 1.3° and 0.6°.

*This work was supported by 704 the STC Center for Integrated Quantum Materials, NSF Grant 705 No. DMR-1231319 and by ARO MURI Award W911NF-706 14-0247. We study the collective modes of the correlated insulating states in magic-angle twisted bilayer graphene (MATBG) within the framework of the generalized random phase approximation (GRPA), also known as the time-dependent Hartree-Fock approximation (TDHFA), using a continuum model and assuming insulating states that break spin/valley flavor but not translational symmetries. The calculations confirm the stability of the translationally invariant states and provide values for key energy scales associated with low-energy collective fluctuations, including spin-stiffnesses and gaps for valley-wave modes. We find that zone-boundary collective mode energies are an order of magnitude smaller than the charge gaps. By fitting to the calculated collective excitation spectra, we derive generalized spin models that fully capture the low-energy physics. Finally, we discuss how these collective mode energies vary with moiré band filling factor and the possible role of their coupling to Fermi surface quasiparticles in superconductivity and non-Fermi liquid behavior.

This work was supported by DOE grant DE- FG02-02ER45958, as well as by the National Science Foundation through the Center for Dynamics and Control of Materials: an NSF MRSEC under Cooperative Agreement No. DMR-1720595.

Lattice mismatch between graphene and a substrate produces local variations in the density of states (LDOS) as observed in STM images. These are known as moire patterns, in analogy with classical interference produced by two overlapping periodic arrays. These have been observed in twisted bilayer graphene[1], a system that can be thought of as monolayer graphene deposited on a substrate with misaligned crystalline orientations. In this regime, the resulting charge density distribution is related to superconductor and Mott insulator phases observed in experiments. It is natural to wonder if similar features could be obtained by depositing graphene on engineered substrates inducing modulated strain fields. Starting from the simplest case of two overlapping deformations, we obtain the LDOS profile for a one-dimensional array, and show the emergence of a different periodicity, a feature associated with moire patterns. We identify conditions for discrete and continuous charged regions, and extend our results to a 2D close-packed structure, demonstrating that periodic deformations can be used to generate moire patterns.

2:30PM U64.00001: Signature of Dispersing 1D Majorana Channels in an Iron-based superconductors [Invited]  ZHENYU WANG (Presenter), UIUC — Selected by Focus Topic Organizer (Seongshik Oh and Peter Armitage)

3:06PM U64.00002: Physical Properties of XTSb[(X= Eu, Sr), (T= Ag, Au)] single crystals* PARUL DEVI (Presenter), LIN-LIN WANG, CAIDEN ABEL, SERGEY L. BUD’KO, PAUL C CANFIELD, Ames Lab — Single crystals of XTSb [(X= Eu, Sr), (T= Ag, Au)] were grown by the solution growth by using self flux [1]. These single crystals were investigated by powder X-ray diffraction at room temperature and the structure was successfully refined to be the hexagonal (space group $P63/mmc$) crystal structure. Temperature dependent magnetic susceptibility measurements indicate antiferromagnetic ordering for magnetic compounds (e.g. $T_N = 6$ K for EuAgSb). Density functional theory calculations find that the band inversion giving a Dirac point is present in the non-magnetic Au compounds, but not the Ag compounds. Thermodynamic and transport data on the non-magnetic SrAgSb, SrAuSb and magnetic EuAgSb, EuAuSb will be presented and compared.

3:18PM U64.00003: Ab initio study of surface states in Bi$_4$Te$_3$* OMAR ASHOUR (Presenter), ZHENGLU LI, STEVEN LOUIE, Department of Physics, University of California, Berkeley, Berkeley, California 94720, USA and Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, C — The crystal structure of the layered material Bi$_4$Te$_3$, a member of the adaptive series of crystals (Bi$_2$)$_n$(Bi$_2$Te$_3$)$_n$, forms a superlattice of alternating Bi$_2$ and Bi$_2$Te$_3$ layers. Given the topological properties of its individual constituents, Bi$_4$Te$_3$ is expected to be a topological insulator or semimetal. Recent experimental results indicate the presence of unusual surface states in this material. In this work, we perform ab initio density functional theory calculations of bulk and slab geometries to investigate the surface states of Bi$_4$Te$_3$.

*This work was supported by the Theory of Materials Program at the Lawrence Berkeley National Laboratory funded by the U.S. Department of Energy, Office of Basic Energy Sciences under Contract No. DE-AC02-05CH11231, and by the National Science Foundation. Computational resources were provided by NERSC and XSEDE.
3:30PM U64.00004: Bond Disproportionation in the Silver Bismuthate Ag$_2$BiO$_3$  MOHAMED OUDAH (Presenter), University of British Columbia, MINU KIM, KSENIA RABINOVICE, GRAHAM MCNALLY, BERKAY KILIC, KATHRIN KÜSTER, Max Planck Institute for Solid State Research, ROBERT GREEN, KATERYNA FOYEVTSOVA, University of British Columbia, ALEXANDER BORIS, Max Planck Institute for Solid State Research, GEORGE ALBERT SAWATZKY, University of British Columbia, ANDREAS SCHNYDER, Max Planck Institute for Solid State Research, DOUGLAS ANDREW BONN, University of British Columbia, BERNHARD KEIMER, Hidenori Takagi, Max Planck Institute for Solid State Research — The stoichiometric silver bismuthate Ag$_2$BiO$_3$ is expected to contain bismuth in the nominal Bi$^{+4}$ state, but the bismuth ions disproportionate into two distinct sites that render Ag$_2$BiO$_3$ insulating [1]. Recent theoretical predictions of metal-insulator transition and Weyl semimetal state in Ag$_2$BiO$_3$ have revived the interest in this material [2]. However, such novel properties are only expected in the absence of disproportionation of bismuth, where Ag$_2$BiO$_3$ is in the Pnma phase. Here, we examine nature of disproportionation in Ag$_2$BiO$_3$ via X-ray absorption and photoemission spectroscopies. We present an updated band structure for Ag$_2$BiO$_3$ in the Pnn2 (disproportionated) phase, where we have a band gap of 1 eV in agreement with our optical spectroscopy measurement. Furthermore, we present Raman spectroscopy results and highlight the extent of similarities to other disproportionated bismuthates despite the distinct crystal structure Ag$_2$BiO$_3$.

3:42PM U64.00005: Analytic calculation of generalized Brillouin zone in non-Hermitian bands*  ZHESEN YANG (Presenter), KAI ZHANG, CHEN FANG, JIANGPING HU, Chinese Academy of Sciences, Institute of Physics — In this talk, we introduce a systematic method to calculate the generalized Brillouin Zone (GBZ) analytically in one dimensional non-Hermitian systems. In general, a m-band non-Hermitian Hamiltonian is constituted by m distinct sub-GBZs, each of which is a piecewise analytic closed loop. All the analytic properties of the GBZ can be characterized by an algebraic equation, which is dubbed as auxiliary GBZ. As an application of our theory, we show a new kind of topological phase under open boundary condition, which is characterized by the non-zero energy winding number for each band.

*The work is supported by the Ministry of Science and Technology of China 973 program (No. 2015CB921300, No. 2017YFA0303100), National Science Foundation of China (Grant No. NSFC-11888101, 1190020, 11534014, 11334012), and the Strategic Priority Research Program of CAS (Grant No.XDB07000000).
3:54PM U64.00006: Materials database development for electromagnetic responses*  YAN SUN (Presenter), YANG ZHANG, QIUNAN BU, JONATHAN NOKY, Max Planck Institute for Chemical Physics of Solids, JAKUB ZELEZNY, Institute of Solid State Physics, Czech Academy of Sciences, KLAUS KŒPERNIK, Leibniz Institute for Solid State and Materials Research, 01069 Dresden, Germany, TOMAS JUNGWIRTH, Institute of Solid State Physics, Czech Academy of Sciences, JEROEN VAN DEN BRINK, Leibniz Institute for Solid State and Materials Research, 01069 Dresden, Germany, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids — The interplay between electromagnetic response theory and symmetry is crucial to understand the transport properties in quantum materials. It is critical to fully understand these physical properties and find materials that host strong electromagnetic response, which, have an extensive impact on the development of data storage, information processing, and energy conversion, etc. Experimentally, however, such large-scale screening is very impractical, as a quantitative determination of the electromagnetic responses by electrical and optical measurements requires integrating each material separately into a complex multicomponent mesoscopic transport device. Theoretically and computationally, the situation is in principle much more straightforward. Via high throughput numerical simulations, we developed the database for intrinsic spin Hall effect in nonmagnetic compounds, shift current in inversion symmetry Weyl semimetals, anomalous Hall effect and anomalous Nernst effect in magnetic Heusler compounds based on the known materials. Our database is helpful for the full understanding of the electronic properties of materials and selecting the correcting materials for further experimental studies.

4:06PM U64.00007: Reentrant Defect Modes in a PT-Symmetric Circuit*  ALEXANDER STEGMAIER (Presenter), TOBIAS HELBIG, TOBIAS HOFMANN, RONNY THOMALE, Theoretical physics I, University of Wuerzburg — Systems obeying PT-symmetry are a special case in non-Hermitian physics where real eigenvalue spectra can still emerge. They usually exhibit a phase diagram with different regimes of symmetry conservation or spontaneous symmetry breaking in their eigenstates. We examine a localized zero-energy defect mode within a PT-symmetric hopping model that disappears and re-emerges at different PT phase transitions and present an exhaustive explanation for this phenomenon. Our theoretical findings are confirmed by eigenstate measurements for different gain/loss profiles in an electrical circuit implementation.

Distinct multiple fermionic states in a single topological metal* [Invited]

MADHAB NEUPANE (Presenter), Univ of Central Florida — Among the quantum materials that have recently gained interest are the topological insulators, wherein symmetry-protected surface states cross in reciprocal space, and the Dirac nodal-line semimetals, where bulk bands touch along a line in momentum space. However, the existence of multiple fermion phases in a single material has not been verified yet. Using angle-resolved photoemission spectroscopy (ARPES) and first-principles electronic structure calculations, here we discuss a systematic study of the metallic ternary material discovering properties, which are unique in a single topological quantum material. We experimentally observe weak topological insulator surface states and our calculations suggest the existence of additional strong topological insulator surface states. Our first-principles calculations reveal a one-dimensional Dirac crossing—the surface Dirac-node arc —along a high-symmetry direction, which is confirmed by our ARPES and time-resolved ARPES measurements. Furthermore, we will present our recent results on the experimental observation of new topological quantum materials. These are topological superconductors and magnetic topological materials which were discovered through ARPES and time-resolved ARPES measurements with further support from first-principles calculations.

Anomalous quantum oscillations in a spin-3/2 topological semimetal: I. Experiment

HYUNSOO KIM (Presenter), JUNHYUN LEE, HALYNA HODOVANETS, KEFENG WANG, JAY SAU, JOHNPIERRE PAGLIONE, University of Maryland, College Park — Gapless spin-3/2 quasiparticles lead to an unprecedented class of high-spin topological superconductivity which hosts a Majorana fluid on the surface. The spin-3/2 Fermi surface can be realized in a crystal lattice with high symmetry. The RPtBi (R=rare earth) half-Heuslers are a family of promising candidates, in which strong spin-orbit interaction inverts the Bi p-orbital derived bands and Bi s-orbital derived bands. In this particular case, the low energy quasiparticles are adequately described by the four-band Luttinger–Kohn model. In this talk, we report compelling evidence for a spin-3/2 Fermi surface in YPtBi via studies of the angle-dependent Shubnikov-de Haas (SdH) effect uniquely explained by the anisotropic effect of Zeeman interaction on spin-3/2 quasiparticles, confirming the long-awaited high-spin nature of topological semimetal RPtBi compounds.
5:06PM U64.00010: Anomalous quantum oscillations in a spin-3/2 topological semimetal: II. Theory JUNHYUN LEE (Presenter), HYUNSOO KIM, HALYNA HODOVANETS, KEFENG WANG, JAY SAU, JOHNPIERRE PAGLIONE, University of Maryland, College Park — Gapless spin-3/2 quasiparticles lead to an unprecedented class of high-spin topological superconductivity which hosts a Majorana fluid on the surface. U64.00011: Correspondence between winding numbers and skin modes in non-hermitian systems KAI ZHANG (Presenter), ZHESEN YANG, CHEN FANG, Chinese Academy of Sciences, Institute of Physics — We establish exact relations between the winding of “energy” (eigenvalue of Hamiltonian) on the complex plane as momentum traverses the Brillouin zone with periodic boundary condition, and the presence of “skin modes” with open boundary condition in non-hermitian systems. This correspondence is exactly related to our new understanding of generalized Brillouin zone, which is the curve defined on the complex plane and always surrounding the same number of zeros and poles of characteristic equation of the system. We show that the nonzero winding with respect to any complex reference energy leads to the presence of skin modes, and vice versa. We also show that both the nonzero winding and the presence of skin modes share the common physical origin that is the non-vanishing current through the system.

2:30PM U65.00001: Stable White Light-Emitting Diodes using Metal Halide Perovskites

GOPI ADHIKARI (Presenter), SAROJ THAPA, HONGYANG ZHU, PEIFEN ZHU, Department of Physics and Engineering Physics, University of Tulsa — Inorganic lead halide perovskite nanocrystals (NCs) are emerging as attractive materials for their applications in modern lighting technologies due to their excellent optoelectronic properties. However, the inclusion of toxic element (lead) and stability issues in the perovskite NCs hinder their practical applications in the devices. Here, we report on the transformation of lead halide perovskite NCs to lead depleted (by 20 %) perovskite NCs and incorporation of lead depleted perovskite NCs in the commercially available polymers. As a result, the composites retain the excellent optical properties without degrading photoluminescence quantum yield. Furthermore, we have fabricated white light-emitting diodes (WLEDs) using these composites. Bright white light is achieved with superior color quality. Thus, this work demonstrates that the halide perovskite NCs are promising alternatives to conventional phosphors for the fabrication of efficient, less-toxic, and stable WLEDs.

2:42PM U65.00002: Switchable Excitonic Circular Polarization in CdSe/CdMnS Nanoplatelets with Bilayer Core and Magnetically Doped Shell

ARMAN NAJAFI (Presenter), STEVEN TARASEK, Department of Physics, State University of New York at Buffalo, Buffalo, New York, SAVAS DELIKANLI, Department of Electrical and Electronics Engineering, Department of Physics, UNAM-Institute of Materials Science and Nanotechnology, Bilkent University, Ankara, Turkey, PEIYAO ZHANG, TENZIN NORDEN, Department of Physics, State University of New York at Buffalo, Buffalo, New York, SUSHANT SHENDRE, MANOJ SHARMA, LUMINOUS! Centre of Excellence for Semiconductor Lighting and Displays, School of Electrical and Electronic Engineering, Nanyang Technological University, Singapore, Singapore, ARINJOY BHATTACHARYYA, Department of Physics, State University of New York at Buffalo, Buffalo, New York, NIMA TAGHIPOUR, Department of Electrical and Electronics Engineering, Department of Physics, UNAM-Institute of Materials Science and Nanotechnology, Bilkent University, Ankara, Turkey, JAMES PIENTKA, Department of Physics, St. Bonaventure University, St. Bonaventure, New York, HILMI VOLKAN DEMIR, LUMINOUS! Centre of Excellence for Semiconductor Lighting and Displays, School of Electrical and Electronic Engineering, Nanyang Technological University, Singapore, Singapore, ATHOS PETROU, TIM THOMAY, Department of Physics, State University of New York at Buffalo, Buffalo, New York — We have utilized time-resolved photoluminescence (TRPL) to study the excitonic circular polarization from CdSe/CdMnS core/shell nanoplatelets (NPLs) with a bilayer core. This technique allows detailed study of the emission dynamics as a function of magnetic field, temperature, doping concentration, and excitation wavelength.

In the presence of an external magnetic field, pulsed excitation below the shell gap results in near-zero circular polarization at all times. In contrast, pulsed excitation with a photon energy larger than the shell gap results in a rapid (100 ps) build-up of the excitonic circular polarization which subsequently remains constant at a level of up to 40%.

We explore a model that describes these results; we also discuss possible applications.
Controlling Linear and Nonlinear Optical Properties of Boron Nitride with Moiré Superlattices

SAMUEL MOORE (Presenter), NATE FINNEY, KAIYUAN YAO, LEO MCGILLY, GUANGXIN NI, EVAN TELFORD, P. JAMES SCHUCK, CORY DEAN, JAMES C HONE, ABHAY NARAYAN, DMITRI BASOV, Columbia University — Van der Waals materials enable the creation of artificial heterostructures with exciting new emergent properties. Recently, the twist angle between adjacent layers has proved to be an important control parameter in these stacks. In this work, we use conventional dry-transfer techniques to fabricate small-twist-angle few-layer hexagonal boron nitride (hBN) heterostructures. We study the resulting moiré superlattice with a variety of linear and nonlinear atomic force microscopy probes. These techniques yield a local variation of the transverse-optical-phonon oscillator strength, near-field second harmonic generation, and the piezoelectric response. These combined demonstrations of hBN moiré physics implicate local strain as an important tuning parameter for the linear and nonlinear optical properties of Van der Waals materials.

Photoluminescence study of non-polar m-plane InGaN and near strain-balanced AlGaN/InGaN superlattices

YANG CAO (Presenter), ALEXANDER SENICHEV, BRANDON DZUBA, TRANG NGUYEN, MICHAEL MANFRA, OANA MALIS, Physics and Astronomy, Purdue Univ — We present the first detailed study of the temperature-dependence of photoluminescence (PL) from m-plane bulk In$_x$Ga$_{1-x}$N ($x<0.25$) layers and near strain-balanced AlGaN/InGaN superlattices grown by plasma-assisted molecular-beam epitaxy on free standing m-plane GaN substrates. The experimental PL peak positions were found to deviate from inter-band transition energies calculated using structural parameters obtained from high-resolution x-ray diffraction. The effect is stronger for superlattices than for bulk InGaN films. The temperature dependence of PL suggests the discrepancy is due to localization centers in InGaN. The low-temperature PL linewidths are narrower than some published results for both In$_x$Ga$_{1-x}$N ($x<0.1$) and Al$_{0.2}$Ga$_{0.8}$N/In$_{0.09}$Ga$_{0.91}$N superlattices indicating lower alloy inhomogeneity than previously reported. We also observed the PL intensity drops dramatically as temperature increases. This suggests the presence of a high-density of non-radiative defects. We will describe our efforts to optimize growth conditions to increase PL efficiency and reduce PL linewidth at room temperature.

3:18PM U65.00005: Backward output-side-grooves regulated light wave resonance in a subwavelength metallic slit and an ultrahigh energy accumulator* JIAN-SHIUNG HONG (Presenter), KUAN-REN CHEN, Department of Physics, National Cheng Kung University — Featuring conceptual breakthroughs in subwavelength wave mechanics, our work studies the output-side groove effect and finds a backward coupling mechanism. The transmitted light is scattered by the grooves and then re-enters into the slit. In one case study, this causes a phase delay of the reflected wave and is considered a reduction in the resonant film thickness. The traveling wave in the slit can be more in phase to significantly enhance the transmission. For another arrangement of the grooves, we find that the wave reflection inside the slit is raised up to 100% due to backward coupling. As the same arrangement of the grooves are patterned at the entrance side of the slit, an incident wave on the slit will be trapped in roundtrips after the transmission through the entrance. At resonance, the roundtrip wave is superposed constructively. Our analysis yields that the intensity of the time-averaged energy can be five million times that of the incident wave. This finding is groundbreaking in subwavelength optics and should have many applications in nonlinear optics, particle trapping, biomedicine, etc.

*Ministry of Science and Technology, Taiwan, and National Center for High-performance Computing

3:30PM U65.00006: Nonreciprocal spatio-temporal modulated metasurfaces* DIEGO ALEJANDRO DALVIT (Presenter), ANDREW CARDIN, SINHARA SILVA, SHAI VARDENY, Los Alamos Natl Lab, WILLIE PADILLA, Duke University, AVADH SAXENA, ANTOINETTE TAYLOR, WILTON J DE MELO KORT-KAMP, HOU-TONG CHEN, ABUL AZAD, Los Alamos Natl Lab — Spatio-temporal modulated metasurfaces (STMMs) are dynamic two-dimensional arrays of sub-wavelength resonators with arbitrary reflection amplitude and phase reconfigurability, and have the potential to revolutionize fundamental and applied photonics. Just as their static counterparts, STMMs can also enable arbitrary wave-front engineering with the key advantage of on-demand reconfigurability and control of the frequency and momentum harmonic contents of scattered waves. In this talk I will report our recent theory and experimental advances in STMMs for dynamical wave-front shaping and nonreciprocal propagation of free space electromagnetic waves. Our experimental measurements reveal on-demand wave-front control of frequency conversion processes. We also demonstrate maximum violation of Lorentz reciprocity in both beam steering and focusing due to nonreciprocal excitation of surface waves. We develop an analytical generalized Bloch-Floquet theory valid for arbitrary modulations, providing excellent agreement with the experiments.

*Research presented in this paper was supported by the Laboratory Directed Research and Development program of Los Alamos National Laboratory.
3:42PM U65.00007: Bright magnetic dipole radiation from two-dimensional lead halide perovskites  
RYAN DECRESCENT (Presenter), NAVEEN VENKATESAN, CLAYTON J DAHLMAN, 
RHIANNON (RHYS) M KENNARD, XIE ZHANG, University of California, Santa Barbara, 
WENHAO LI, Brown University, XINHONG DU, MICHAEL L. CHABINYC, University of California, Santa Barbara, 
RASHID ZIA, Brown University, JON A SCHULLER, University of California, Santa Barbara — 

Two-dimensional (2D) hybrid organic-inorganic perovskites (HOIPs) comprise a versatile class of solution-processable materials with outstanding optoelectronic properties. Analogous to conventional semiconductors, light-matter interactions in 2D HOIPs have been completely described within the electric dipole (ED) approximation. Here, using energy-momentum spectroscopies, we demonstrate that the ED approximation insufficiently describes light-matter interactions in 2D HOIPs. We identify an optical transition in 2D HOIPs that exhibits striking multipolar radiation patterns at an energy 90 meV below the primary exciton emission. The transition is evidently intrinsic in origin and arises from an unconventionally fast magnetic dipole (MD) transition from a polaron-like excited state. These results suggest the presence of even-parity excited state symmetries that have not yet been established, and represent the first observation of MD optical interactions in a bulk crystal. In addition to being of fundamental interest, this demonstration may be crucial for resolving open questions regarding the previously observed bounty of complex optical signatures in 2D HOIPs, and may have implications for quantum information applications based on “dark” excitons in 2D materials.

3:54PM U65.00008: Photon circulation in photonic structures integrated with quantum dots - a consequence of multi-path geometry  
PALAK DUGAR (Presenter), MICHAEL SCHEIBNER, CHIH-CHUN CHIEN, University of California, Merced — 

The typical route to achieve circulation of photons is via artificial gauge fields. We show that even without any artificial gauge field, by using multiple path geometry such as, that of a triangle and the quantum nature of bosonic particles, the steady state photonic current can circulate in a photonic structure integrated with quantum dots. Our system is made up of three quantum dots which are connected in a triangular geometry, this geometry is embedded in photonic crystal and waveguide. The photon-exciton interaction limits the number of photons that can be transferred between the quantum dots, a phenomenon also called photon blockade. We use the Lindblad form of the quantum optical master equation to calculate the steady state currents with the maximal photon number per site set by the photon blockade. Our results show that the photon circulations have a non-trivial dependence not only on the internal system parameters such as the tunneling coefficient, or the effective photon-photon interaction but also on external parameters such as the system-reservoir coupling. This system can be tailored to function as a density independent local pump or memory device.
Temperature-dependent photoluminescence of carbon quantum dots

Temperature-dependent photoluminescence (PL) and time-resolved PL (TRPL) of carbon quantum dots (CQD) were investigated to explain the possible source of luminescence. XPS, PL, and UV-Vis absorption measurements suggest that the nitrogen-related functional groups, emission, and absorption depend on the amount of the CQD in the film. The energy loss between the absorption and emission spectra indicates the presence of vibrational relaxation in CQD films. The 0-0 transition peaks of the CQD films exhibit blueshift with faster decay time as temperature increases. This temperature-dependent blueshift and lifetimes possibly indicate the presence of thermally activated hopping sites which was also seen in another organic semiconductors. These hopping sites are related to nitrogen-based functional groups which are confirmed by the presence of additional deconvoluted peaks in the C1s high resolution XPS measurements. These measurements show that the presence of the conjugated functional groups is the primary reason for the exciton diffusion dynamics in the CQD. However, the excessive amount of CQD in the film results increases reabsorption and re-emission process. Thus, limiting the temperature-dependent PL and TRPL behaviors of films with larger amount of CQD.

Ultra-thin film nanophotonics device on various optics application

The vast majority of optical metamaterial are fabricated on rigid substrates. Ultra-thin thickness and resulting mechanical flexibility in nanophotonics is the key attribute of various optics device including flexible imaging/display arrays, wearable photonics device, spectrometer, mechanics drive holography, multi-layer stacking Photonic device. Our fabrication techniques majorly depend on stamp transfer of dielectric material or direct patterning on flexible substrate. The significant difference is that fabricated device on past researches is all on thick polymer substrate. When direct bond such kind of flexible chip to any other devices, the thick substrate will damage the optical properties because of the scattering and reflection. Our flexible substrate is 200nm - 3 um PMMA, the thickness of which can be precisely controlled. The subwavelength thickness of this PMMA film will primarily reduce scattering and reflection optical reflection, which it will also protect the device surface. Furthermore, the ultra-thin PMMA layer is easy to remove after sticking the metasurface + PMMA to devices by special removing tape. Our ultra-thin PMMA substrate flexible device enables direct integration of optical metasurface to various optical devices like another metasurafce.
Extraordinary Transmission in Coupled Nano-Bridged Nanosphere Quasi-Complimentary Arrays

TYLER DODGE (Presenter), Boston College, LINGPENG LUO, ESER METIN AKINOGLU, International Academy of Optoelectronics at Zhaoqing, South China Normal University, MICHAEL NAUGHTON, Boston College, MICHAEL GIERSIG, International Academy of Optoelectronics at Zhaoqing, South China Normal University, KRZYSZTOF KEMPA, Boston College — Ultra-sensitive structures can be based on percolation, which at the threshold radically change their response (e.g. conduction, transmission, etc.). However, due to the critical nature, such structures are very unstable at the threshold. Here, we demonstrate that the stability can be restored, with minimal loss of sensitivity, by engineering weak links between the units of a percolation system. Our system consists of a pair of strongly coupled complementary arrays made of metallic films, obtained by depositing plasmonic metal on a periodic array of spheres with submicron dimensions through a modified standard nanosphere lithography (NSL). In an earlier work we demonstrated, that the modification of NSL leads to the formation inter-sphere nano-bridges, which after metallic deposition work as the weak links. We simulate plasmonics of these arrays, demonstrating ultrahigh sensitivity and stability of the extraordinary optical transmission (EOT) of this structure near the percolation threshold.

Exciton–phonon coupling in resonant Raman scattering: intrinsic attributes and extrinsic tunability in ZnTe of different dimensionalities

YINGYAN YI, JASON K MARMON, Univ of North Carolina - Charlotte, YUANPING CHEN, US Army Research Laboratory, FAN ZHANG, TAO SHENG, Univ of North Carolina - Charlotte, PRIYALAL S. WIJEWARNASURIYA, US Army Research Laboratory, HAOTAO ZHANG, YONG ZHANG (Presenter), Univ of North Carolina - Charlotte — The dependence of electron-phonon coupling (EPC) on nanostructure size has been controversial over three decades. Often, the EPC was probed by resonant Raman scattering (RRS) using the 2LO to 1LO intensity ratio R21 to extract the Huang-Rhys factor (S) by applying Albrecht’s theory, where the bulk reference S was calculated using a theoretical model developed for a bound exciton with Fröhlich interaction. We show that in ZnTe, in contrast to the previous reports, R21 exhibits a much larger intrinsic value and minimal change from bulk to 30 nm nanowire [1], indicating previously reported size dependences were likely affected by extrinsic mechanisms. Indeed, the ratio can be tuned extrinsically over one order in magnitude controllably either during or post growth, allowing for programing EPC in nanoscale devices. We point out that R21 is not directly related to Huang-Rhys factor, lattice relaxation is minimal for bulk and moderately small nanostructures, and Albrecht’s theory is not applicable to RRS [2]. This work provides unambiguous experimental results for validating EPC theories with reduced dimensionality.

4:54PM U65.00013: Analysis of $\chi^{(2)}$ of III-V quantum-well structures using transfer matrix techniques
NATALIE FOSTER (Presenter), Physics, University of Texas at Austin, ANN KATHRYN ROCKWELL, SETH BANK, Electrical Engineering, University of Texas at Austin, MICHAEL C DOWNER, Physics, University of Texas at Austin — Nano-layered quantum wells (QWs) composed of III-V semiconductors provide unexplored opportunities to engineer $\chi^{(2)}$ (e.g. for electro-optic and quantum information applications) by optimizing thickness, separation, and shape of individual QW layers as well as the number N of repeated layers. A digital alloys growth technique was used, which avoids phase segregation that often plagues III-V alloy growth, and also lends itself readily to nano-structuring to enhance $\chi^{(2)}$. Second harmonic generation (SHG) was used to probe the total nonlinear $\chi^{(2)}$ response of a series of N multiple-QW (MQW) layers made up of InAs QWs and AlSb barriers, sandwiched in between a GaSb oxidation cap and GaSb buffer layer, grown on GaSb substrate. The measured SHG signal is composed of a contribution from each of the layers that interfere with each other. To isolate the N-dependent SHG polarization of the MQW layer of interest, we implemented a SHG transfer matrix formalism to model the SHG signal as a coherent superposition of a variable-N MQW layer with fixed substrate and cap layer SH polarizations. Experimental results show up to 25x stronger SHG from MQW structures than from GaSb substrate. The model attributes this enhancement partly to geometrical effects and to enhanced $\chi^{(2)}$ of the MQW structures.

5:06PM U65.00014: Optically-induced dressed states in $\alpha$ materials: electronic and transport properties
ANDRII IUROV (Presenter), Medgar Evers College, LIUBOV ZHEMCHUZHNA, DIPENDRA DAHAL, GODFREY GUMBS, Hunter college, CUNY, DANHONG HUANG, Air Force Research Lab — We have obtained the energy dispersion relations and their wave functions for the so-called interacting Floquet states in pseudospin-1 $\alpha$-T$_3$ materials for various value of the parameter $\alpha$ in the presence of an external off-resonant dressing field. The obtained dressed states and their basic electronic properties significantly depend on the polarization of the applied radiation, while our derived results now depend on both the parameter and the light intensity. The energy subbands become directly dependent on the valley index $\tau$ once elliptically polarized irradiation is applied. We have calculated optical and transport conductivities for an irradiated dice lattice, which represents a limiting case of an $\alpha$-T$_3$ structure for $\alpha$ equal to 1.
2:30PM U66.00001: Electronic nematic softening in cuprate superconductors probed by resonant ultrasound spectroscopy [Invited]  PAULA GIRALDO-GALLO (Presenter), University of the Andes — Electronic-nematic order has been shown to be the driver of the structural and magnetic transitions in the Ba-pnictide superconductors. For cuprate superconductors, the determination of the existence of long-range electronic-nematic order and fluctuations is not as clearly established as for the pnictides. In this talk I will present Resonant Ultrasound Spectroscopy (RUS) measurements in single crystals of La$_{2-x}$Sr$_x$CuO$_4$ of different Sr compositions, through which we have determined the temperature dependence of all elastic moduli in the tetragonal phase of this compound. A strong softening of the C66 elastic shear moduli, associated with the B2g symmetry channel, is observed as temperature is decreased, even for the compositions for which the tetragonal to orthorhombic structural transition is not seen. The temperature dependence of this softening is consistent with a Curie-like temperature dependence, $1/(T-T_0)$. The B2g softening is truncated by the opening of the superconducting gap at $T_c$=$T_0$, evidenced by the stiffening of C66 below $T_c$. These observations suggest an electronic nematic origin for this softening.

3:06PM U66.00002: Strange Metal Transport in Electron-doped La$_{2-x}$Ce$_x$CuO$_4$* [Invited]  RICHARD GREENE (Presenter), University of Maryland, College Park — I present new measurements of resistivity, Hall Effect, magnetoresistance (MR) and thermopower in the electron-doped cuprate La$_{2-x}$Ce$_x$CuO$_4$ for 0.19$\geq$ x $\geq$0.08 as a function of temperature and magnetic field. The surprising results are:
1) The normal state MR has an anomalous linear-in-H behavior [1] at the same doping (0.14 to 0.175) where a linear-in-T resistivity was previously observed for $H>H_{c2}$ [2]. Beyond the SC dome (x $>$ 0.175) conventional metallic behavior is found.
2) The normal state Seebeck coefficient, S/T, exhibits a low temperature $-$lnT dependence at the same dopings [3]. Conventional S/T = constant metallic behavior is found for x $>$0.175.
3) Itinerant ferromagnetism is found below 4K for doping beyond the SC dome [4].
I conclude that conventional Fermi liquid theory cannot explain (1) and (2). Moreover, the magnitude of the anomalous magnetoresistance and thermopower scales with $T_c$, suggesting that the origin of the superconductivity is correlated with the anomalous normal state properties.

*Research supported by the NSF DMR. Work done in collaboration with T. Sarkar, P. Mandal, and N. Poniatowski
**What determines the Hall and Thermal Hall coefficients of metals, magnets and superconductors?**

**ASSA AUERBACH (Presenter), Technion - Israel Institute of Technology —**

The Hall coefficient has long been used to characterize the number and sign of charge carriers in metals and semiconductors. This assignment has only been justified in the weak disorder and interactions regimes. Unexpected Hall coefficient sign reversals (a.k.a. “Hall anomalies”) have been observed in strongly interacting metals, thermal Hall effect in antiferromagnets, and in the flux flow regime of cuprate superconductors.

I review recent theoretical advances [1,2] which shed light on Hall anomalies. New computable formulas [1] for Hall, Nernst and Thermal Hall coefficients in gapless (metallic) phases are applied to strongly correlated Hubbard and Heisenberg models, where traditional Chern number calculations and Drude-Boltzmann theory are inapplicable. We show that Hall sign reversal is a consequence of proximity to a Mott insulator, and that a negative thermal Hall coefficient is produced in the square lattice antiferromagnet with three-spin exchanges. A revised theory of magnetotransport in the flux flow regime of superconductors [3] explains Hall anomalies caused by moving vortex charge.

4:18PM U66.00004: Sign reversal of the flux flow Hall effect* [Invited] VALERII VINOKOUR (Presenter), Argonne Natl Lab — We present a phenomenological theory of the Hall effect sign reversal in type II superconductors taking into account the normal carriers scattering and the topological contribution to Hall conductivity and show that the latter contribution leads to a double sign change of the Hall conductivity. We report an experimental observation of the double sign reversal in atomically thin BSCCO and find a quantitative agreement between the experimentally observed Hall resistance and our theoretical predictions.

4:54PM U66.00005: Scale-invariant magnetoresistance in a cuprate superconductor* [Invited]

PAULA GIRALDO-GALLO, University of the Andes, JOSE A GALVIS, Universidad Central, Colombia, ZACHARY A STEGEN, National High Magnetic Field Laboratory, KIMBERLY MODIC, Max Planck Institute for Chemical Physics of Solids, FEDOR BALAKIREV, JONATHAN B BETTS, Los Alamos National Laboratory, XIUJUN LIAN, National High Magnetic Field Laboratory, CAMILLA MOIR, CRIEPI, JIE WU, ANTHONY TRAVIS BOLLINGER, XI HE, IVAN BOZOVIC, Brookhaven National Laboratory, BRAD J RAMSHAW, Cornell University, ROSS MCDONALD, Los Alamos National Laboratory, GREGORY SCOTT BOEBINGER (Presenter), ARKADY SHEKHTER, National High Magnetic Field Laboratory — The anomalous metallic state in the high-temperature superconducting cuprates is masked by superconductivity near a quantum critical point. Applying high magnetic fields to suppress superconductivity has enabled detailed studies of the normal state, yet the direct effect of strong magnetic fields on the metallic state is poorly understood. In this talk, we report the high-field magnetoresistance of thin-film La$_{2-x}$Sr$_x$CuO$_4$ cuprate in the vicinity of the critical doping, 0.161 ≤ p ≤ 0.190. We find that the metallic state exposed by suppressing superconductivity is characterized by magnetoresistance that is linear in magnetic fields up to 80 tesla. The magnitude of the linear-in-field resistivity mirrors the magnitude and doping evolution of the well-known linear-in-temperature resistivity that has been associated with quantum criticality in high-temperature superconductors.

*The high-field resistivity measurements were performed in the 60 T long-pulse and 100 T magnet systems at the NHMFL Pulsed Field Facility, which is supported by NSF grant DMR-1157490 and the U.S. Department of Energy, Basic Energy Sciences (DOE/BES) "Science at 100 T" grant. Molecular beam epitaxy synthesis, lithography, and characterization of the samples were done at Brookhaven National Laboratory, which is supported by DOE/BES, Materials Sciences and Engineering Division.

Session U67 DCMP: Nano-Plasmonics in Van Der Waals Materials and Beyond Four Seasons 2-3 - Alexander McLeod - Tag(s): Invited
Moiré patterns are well-known phenomena in art, textiles and mathematics, which originate from the overlay of two periodic patterns. Intriguingly, atomically thin materials can be stacked on top of each other such that a new periodic pattern can emerge: the moiré superlattice. This can result in a dramatic modification of the electronic and optical properties of twisted 2D materials, compared to those of a single layer. The moiré superlattice can give rise to a plethora of interesting phenomena such as topological bands [1] and many-body phases like superconductivity and magnetism [2].

In this talk, we give an overview of the nano-optical properties of 2D material superlattices, obtained by twisting or nanostructuring. Nanoscale optical techniques such as near-field optical microscopy reveal unique observations of topological domain wall boundaries, hyperbolic phononic lattices, and interband collective modes in charge neutral TBG near the magic angle [3]. The freedom to engineer these so-called optical and electronic quantum metamaterials [4] is expected to expose a myriad of unexpected phenomena.

3:06PM U67.00002: Michael M Fogler Invited Talk [Invited] —
MAIKEN MIKKELSEN (Presenter), Duke University — Tailoring light–matter interactions in monolayer MoS$_2$ is critical for its use in optoelectronic and nanophotonic devices. Optical cavities with multiple tunable resonances have the potential to provide unique electromagnetic environments at two or more distinct wavelengths—critical for control of optical processes such as nonlinear generation, entangled photon generation, or photoluminescence (PL) enhancement. Here, we show a plasmonic nanocavity based on a nanopatch antenna design that has two tunable resonant modes in the visible spectrum. The importance of utilizing two resonances simultaneously is demonstrated by integrating monolayer MoS$_2$, a two-dimensional semiconductor, into the colloidal synthesized nanocavities. We observe a 2000-fold enhancement in the PL intensity of MoS$_2$—which has intrinsically low absorption and small quantum yield—at room temperature, enabled by the combination of tailored absorption enhancement at the first harmonic and PL quantum-yield enhancement at the fundamental resonance [1]. Next, we explore how the emission spectrum can be tailored, including complex excitonic states. We demonstrate that the peak emission wavelengths of the A and B excitons can be tuned up to 40 and 25 nm, respectively, by integrating monolayer MoS$_2$ into a plasmonic nanocavity with tunable plasmon resonances [2]. Contrary to the intrinsic photoluminescence spectrum of monolayer MoS$_2$, we are also able to create a dominant B exciton peak when the nanocavity is resonant with its emission. Additionally, we observe a 1200-fold enhancement of the A exciton emission and a 6100-fold enhancement of the B exciton emission when normalized to the area under a single nanocavity and compared to a control sample on thermal oxide.

4:18PM U67.00004: Collective mode spontaneous symmetry breaking: out-of-equilibrium plasmonic magnetism* [Invited] JUSTIN SONG (Presenter), Nanyang Tech Univ — Spontaneous symmetry breaking lies at the heart of the description of interacting phases of matter. We will argue that a driven interacting system subject to a linearly polarized (achiral) driving field can spontaneously magnetize (acquire chirality). In particular, we find when a metal is driven close to its plasmon resonance, it hosts strong internal ac fields that enable Berryogenesis: the spontaneous generation of a self-induced Bloch band Berry flux, which supports and is sustained by a circulating plasmonic motion, even for a linear polarized driving field. This non-equilibrium phase transition occurs above a critical driving amplitude, and depending on system parameters, can enter the spontaneously magnetized state in either a discontinuous or continuous fashion. Berryogenesis relies on nontrivial interband coherences for electronic states near the Fermi energy generated by ac fields readily found in a wide variety of multiband systems. We anticipate that graphene devices, in particular, which can host high quality plasmons, provide a natural and easily available platform to achieve Berryogenesis and spontaneous non-equilibrium (plasmon-mediated) magnetization in present-day devices, e.g., those based on graphene plasmonics.

4:54PM U67.00005: Nano-polaritonics in twisted van der Waals heterostructures [Invited] GUANGXIN NI (Presenter), Columbia Univ — Interlayer coupling in atomic van der Waals heterostructures plays a rather unique role in controlling their optical and electronic properties. The character of the interlayer coupling can be manipulated by a particular stacking arrangement of the proximal layers and by adjusting the orientation of the neighboring planes. The latter method is known to trigger the long-range periodic modulations referred to as twisted moiré superlattices. The presence of periodic moiré patterns enables further fine tuning of the electronic band structure and yielding rich insights into the electronic phenomenon. This has been manifested in graphene/hexagonal boron nitride (G/hBN) moiré patterns, twisted bilayer graphene structures as well as twisted hBN crystals. Using nano-infrared optical microscopy we have experimentally studied the collective excitations in these twisted moiré structures. We analyzed these soliton networks and obtained the local electrodynamical characters based on the infrared active polaritonics at the nanoscale.

Using Information Geometry to find simple models of complex processes*

MARK TRANSTRUM (Presenter), Physics & Astronomy, Brigham Young University —

Effective theories play a fundamental role in how we organize our knowledge about the world. Although reality is much more complicated than our models, we justify parsimonious representations by judiciously ignoring degrees of freedom that are irrelevant for the predictions of interest. Often, these models are related through a hierarchy of simplifying approximations that formally justify their respective domains of validity. I demonstrate how information geometry can be used to construct such effective theories for many complex systems, including systems beyond the reach of traditional methods. Embedded in the mathematical form of many model classes is a hierarchy of natural approximations. These approximations are manifest as boundaries of high-dimensional manifolds. These approximations are not black-boxes. They remain expressed in terms of the relevant combinations of mechanistic parameters and reflect the physical principles from which the complicated model was built. Furthermore, these approximations can be identified in a data-driven way for models with thousands of parameters.

Finding and explaining structural hierarchies in models of complex systems

KATHERINE QUINN (Presenter), The Graduate Center, City University of New York —

Sloppy models form a universality class of complex, nonlinear models in which outcomes are significantly affected by only a small subset of parameter combinations, arising in disparate fields from systems biology to accelerator physics. By unifying information geometric interpretations of sloppiness with Chebyshev approximation theory, I will derive a formal and systematic explanation of why sloppiness occurs. I will then extend this framework to general probabilistic models and data, to derive a widely-applicable manifold-learning method called InPCA that ameliorates a canonical problem in machine learning: the "curse of dimensionality".
4:18PM U68.00004: Identifiability, uncertainty, and parameter reduction in mathematical biology* [Invited] MARISA EISENBERG (Presenter), Univ of Michigan - Ann Arbor — The interactions between parameters, model structure, and outputs can determine what inferences, predictions, and control strategies are possible for a given system. Identifiability, estimability, and parameter space reduction methods are thus essential for many questions in mathematical modeling and uncertainty quantification. These approaches can help to determine what inferences and predictions are possible from a given model and data set, and help guide control strategies and new data collection. In this talk, I will discuss some of the ideas and methods from identifiability, how they link to ideas of model reduction and model selection, and present public health applications to recent epidemics of polio and cholera. We will illustrate how reparameterization and alternative data collection may help resolve various types of unidentifiability and allow for successful intervention predictions.

4:54PM U68.00005: Manifold Learning for Parameter Reduction [Invited] YANNIS KEVREKIDIS (Presenter), Johns Hopkins University — Large scale dynamical systems (e.g. many nonlinear coupled differential equations) can often be summarized in terms of only a few state variables (a few equations), a trait that reduces complexity and facilitates exploration of behavioral aspects of otherwise intractable models. High model dimensionality and complexity makes symbolic, pen-and-paper model reduction tedious and impractical, a difficulty addressed by recently developed frameworks that computerize reduction. As the interest in mapping out and optimizing complex input--output relations keeps growing, it becomes clear that combating the curse of dimensionality also requires efficient schemes for input space exploration and reduction. Here, we explore systematic, data-driven parameter reduction by means of effective parameter identification, starting from current nonlinear manifold-learning techniques enabling state space reduction. Our approach aspires to extend the data-driven determination of effective state variables with the data-driven discovery of effective model parameters, and thus to accelerate the exploration of high-dimensional parameter spaces associated with complex models. We also discuss the data-driven exploration of conjugacies between different models/observations.

Session U70 DCMP DCOMP: Frontiers in Interdisciplinary Theory and Phenomena 208
2:30PM U70.00001: No-Go Experiment Confirms Superdeterminism Loophole*  MANUEL MORALES (Presenter), Rowan University — Nonlocal hidden variables of motion served to obtain absolute internal validity in a twelve-year no-go experiment (2000-2012) that confirmed it is impossible for a test taker to conduct experiments or observations without the mechanical functions of direct or indirect selection. In other words, the natural world prohibits the will of the test taker from conducting any and all experiments prior to the predetermined first-order functions of selection. Therefore, the mechanisms of selection, commonly known as choice or free will, are mandatory functions not a freedom. In physical terms, external validity of the findings means that effects of existence such as energy and mass are not conserved because they are predetermined effects of how they are determined, i.e., superdeterminism as predicted by John S Bell. The unambiguous empirical evidence obtained from the no-go experiment confirmed that Albert Einstein was indeed correct to suspect that quantum mechanics is not a fundamental theory due to hidden variables at play. However, he was incorrect as to the domain of their origin.

2:42PM U70.00002: A Covariant Field Reformulation of Classical Electrodynamics*  WILLIAM BRYAN MAIER (Presenter), Physics, Naval Postgraduate School — Classical electrodynamics is here reformulated as a field theory rather than a particle and field theory. Electromagnetic fields are taken to be continuous and differentiable everywhere. Maxwell's equations are assumed to be valid at all scale lengths, and second order variations on the vector potentials $A_k$ are used to obtain fundamental equations from a covariant action in which the usual term involving particle mass $m$ has been replaced by the covariant mass density $\mu$ associated with the fields. Point, line, and surface charges are not allowed. Stable charge distributions having finite extent and charge of only one sign are found. These bodies are stabilized by the charge motion in the distribution's self-field. Their mass is finite and equivalent to the energy of the electromagnetic field integrated over all space. Spin, magnetic moment, and electric dipole and quadrupole moments of these bodies can be calculated. The Lorentz force law plus radiation reaction is shown to govern the motion of these charged objects in an imposed electromagnetic field. Ordinary classical electromagnetism is thus reproduced, and the classical structures of fundamental charged bodies are obtained. Structures of the electron and proton in this theory are briefly discussed.

*Naval Postgraduate School
2:54PM U70.00003: A New, Unified, Non-Relativistic Quantum Quaternal Physics  CLAUDE MASSOT (Presenter), Theoretical Physics, Independant Scientist — Despite its impressive results, the relativistic Standard Model, remains unrealistic because of quantum incompatibilities. String and GUT theories are exciting, but far from being validated. To confront these theoretical contradictions and to develop a mathematical model for de Broglie's wave-particle, I did propose the new Hypothesis of the Complex Nature of Matter. It was presented in 1994 at the french Academy of Sciences, by Andre Lichnerowicz. I do extend it, now, by quaternion algebra, to link, without any relativistic postulate, mass and time dilation with Planck's and de Broglie's laws, and to take into account spin and helicity. I start with a new interpretation of Michelson's experiment, assuming that its photons are carried by the gravitational field of the earth. This discards the need for the hypothesis of space contraction and gravitation as a curvature of space. Instead, I consider gravitation as a very tiny residual attractive Coulomb's force between the electric fields of protons and electrons. This allows a unification of atomic forces and gravitation and leads to a solar system quantified by an extended Bohr's model with a link between the orbital and daily spin of the Earth.

3:06PM U70.00004: Mikowski Space may be interpreted as a Theory of Orbitals  RICHARD KRISKE (Presenter), Physics, MIT — When one compares the work of Kepler, with Mikowski Space, they are both Cones joined at a nexus. In Kepler Space, one is viewing the Cones from the outside, and there are three types of Conic Sections, the Ellipse, the Parabola, and the Hyperbola. In Aeronautical Engineering, they are the Elliptical Orbit, the Parabolic Orbit, and the Hyperbolic Obital. The Minkowski Diagram is somewhat in error, in that the observer views one cone as the future and one cone as the past. We know from Quantum Mechanics that an observation is a measurement. So the nexus is not a point, but is planck's constant / two, as a minimum overlap. This over lap is an elliptical orbital, so the Conservation of Angular Momentum comes about due to Special Relativity, and the overlap of the Minkowski Space Cones. The Parabolic Orbital is the Speed of Light in a Vacuum. The Hyperbolic Orbital is the a Quantum Leap. An Electron Changing Orbitals needs only the Speed of Light as the escape velocity. Where does on see the Hyperbolic Orbital? That occurs when an Electron or other Elementary particle is measured from its wavefunction and collapses into a particle, far from its origin. This new view of Mikowski Space may solve the problem of Unitary Entities comprising Space Time, they are in orbit like planets.
Anomaly of the Electromagnetic Duality of Maxwell Theory

Every physicist knows that classical electromagnetism is described by Maxwell's equations, and that it is invariant under the electromagnetic duality $S: (E, B) \rightarrow (B, -E)$. The properties of the electromagnetic duality in the quantum theory, represented by an SL(2, Z) group acting on the lattice $\mathbb{Z}^2$ of the electric and magnetic charges, might not be as well known to physicists in general. This is particularly true when going around a nontrivial path in the spacetime results in a duality transformation. In this work, we uncover a feature of the Maxwell theory and its duality symmetry in such a situation, namely that it has a quantum anomaly. We find that the anomaly of this system in a particular formulation is 56 times that of a Weyl fermion. The interpretation of this result is twofold: one is by using the bulk symmetry-protected topological phase in 4+1 dimensions characterizing the anomaly, and the other is by considering the properties of some (5+1)-dimensional superconformal field theory. Our result reproduces, as a special case, the known anomaly of the all-fermion electrodynamics—a version of the Maxwell theory where all particles of odd charge are fermions—discovered in the last few years.

C.-T. H. is supported in part by JSPS KAKENHI Grant-in-Aid No. 19K14608.

A Number of Early 20th Century Important Physics Formulas, Some Nobel Prize Winning, Must Be Slightly Corrected Because They Lack Rotational and Vibrational Factors Not Known To Be Necessary When The Formulas Were Discovered

In 1905 Einstein derived the total energy of a mass at slow speeds to be $E = mc^2 + \frac{1}{2}mv^2$. Later, in the 20th century it was discovered that all masses can also be rotating and vibrating. Thus, the total energy of a mass at slow speeds must be $E = mc^2 + \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2 + \frac{1}{2}kx_0^2 + \frac{1}{2}I(x_0)^2 + \frac{1}{2}Gm_1m_2/r^2 + \frac{1}{2}kq_1q_2/r^2$ also including gravitational, electrostatic potential energies and all kinetic energies. Einstein stated the relativistic kinetic energy at low speeds to be $T = (E - E_0)$. Thus, the relativistic kinetic energy is $T = (\frac{1}{2}mv^2 + \frac{1}{2}I(\omega)^2 + \frac{1}{2}k(x_0)^2 + (Gm_1m_2)/r^2 + (kq_1q_2)/r^2$. The Photoelectric Effect Equation must include rotational and vibrational factors: Maximum energy of the ejected electron must be: $hf = (\frac{1}{2}mv^2 + \frac{1}{2}I(\omega)^2 + \frac{1}{2}k(x_0)^2)_{\text{max}} + \Phi$. The Virial Theorem astrophysics equation and Compton Effect energy equation must both be updated including rotational and vibrational factors: $\frac{1}{2}mv^2 + \frac{1}{2}I(\omega)^2 + \frac{1}{2}k(x_0)^2 + U = 0$, where $U$ is the gravitational energy for Virial. The Compton should be: $h\nu/(\lambda)^2 + (m_0)c^2 + \frac{1}{2}m(v_1)^2 + \frac{1}{2}I(\omega)^2 + \frac{1}{2}k(x_0)^2 = h\nu/(\lambda)^2 + m_0c^2 + \frac{1}{2}(m_2)v^2 + \frac{1}{2}I(\omega)^2 + \frac{1}{2}k(x_0)^2$.

Many other early 20th century physics equations, then assumed correct, some of possibly Nobel Prize quality as those above, may need to be updated by adding rotational and vibrational factors not then even considered essential.
3:42PM U70.00007: A quantum interpretation of the physical basis of mass-energy equivalence* DONALD CHANG (Presenter), Hong Kong University of Science and Technology — We know energy and mass of a particle can be connected by $E = mc^2$. What is the physical basis behind this relation? Historically, it was thought that it is based on the principle of relativity (PR). However, a careful examination of the literature indicated that this relation was not directly derived from PR. Instead, Einstein came to this conclusion mainly based on his intuitive thinking that radiation and matters behave similarly. Following this hint, we suspect that the mass-energy equivalence could be based on the quantum principle of wave-particle duality. It is well known that both photon and electron can behave as a particle as well as a wave. Using a wave model which treats particles as excitations of the vacuum, we show that the relations $E = mc^2$ can be directly derived from Planck's relation. This wave hypothesis has several advantages; not only can it explain naturally why particles can be created in the vacuum; it also predicts that a particle cannot travel faster than the speed of light. This hypothesis can also be tested in experiment.

*This work was supported by the Macro-science project of HKUST.

3:54PM U70.00008: Adding a Dynamic to Gravitation Reveals How Extra Gravity Halos are Projected from Galactic Cores* JOHN HUENEFELD (Presenter), APS — It is unfortunate that the term dark matter was used to describe the extra gravity observed in galaxy clusters. The name presupposes a material answer, but the only thing actually observed is an Extra Gravity Halo (EGH). The mysterious source of this extra gravity remains unresolved. Or does it?

A new theory, sets GR in motion, predicting an ongoing space-time contraction within a gravitational field. Unlike Hubble expansion, this contraction field is non linear with distance from the source and projects more strongly with the increasing amount of concentrated matter generating the field. No assumed additional mass is needed to boost the orbital velocity of stars around a galactic core. The contraction field augments the acceleration of gravity to achieve galaxy rotation curves consistent with observation.

Dark matter is not a particle. EGHs are the result of relativity, and are an integral part of gravitation. The contraction field acts to scale up gravity. The scale factor, which falls easily from the math, has exactly the right mathematical shape to replicate assumed dark matter distributions. Not only do these contraction fields explain galaxy rotation curves, they also explain the Bullet Cluster, and Ultra Diffuse galaxies which have either a very strong EGH or none at all.

*N/A
Each Force has a function. Each function has a Particle Force Carrier.

Existence is a function of Time. Without Time, nothing exists.

It is my hypothesis that an unrecognized Fifth Force exists along with the currently known Four Forces, which are: The Electro-Magnetic Force whose Particle Force Carrier is the Photon, The Strong Force whose Particle Force Carrier is the Gluon, The Weak Force whose Particle Force Carriers are the W-, W+ and Z Bosons, and the last and currently the weakest of the Four known Forces, Gravity whose Particle Force Carrier is the yet to be seen Graviton (I have a separate hypothesis on Gravity and the Graviton, but that’s an altogether separate Abstract).

This Fifth Force is so pervasive throughout the Universe, is it any wonder it’s been overlooked?

This Fifth Force also has its own Particle Force Carrier, and it is the first Particle Force Carrier to have been discovered before its Force was even recognized.

To me this might be called “Aquilina’s Assumption, but the only choice for the Particle Force Carrier for Time is the Higgs Boson.

The identification of Time as a Force would also tie the Four other Forces together since they all fall under the umbrella of “Existence”.

Rich Aquilina 04/17/2018 @11:56pm

Quantum electrodynamics (QED) is the fundamental theory of electromagnetic interactions. Thus, the Schrödinger equation, which yields the electron wavefunction in low energy electromagnetic interactions, must be a condition that can be derived from the fundamental QED theory. Due to the small value of the electromagnetic coupling constant, we can adequately describe low-energy interactions by classical potentials. Furthermore, the dominant (lowest order) term of the electron wavefunction is a superposition of plane waves. As a result, we show that to fulfill the total energy relations, the electron wavefunction must satisfy at each space-time point the Schrödinger, Pauli, and Dirac equations.
4:30PM U70.00011: Mathematical proof of electromagnetic wave nature of photons in hydrogen emission spectrum and theoretical derivation of Planck’s constant*  JUNHO JEONG (Presenter), Dong-A University — The photons emitted from electron transitions are electromagnetic waves, but there is no mathematical demonstration as to why this is so. According to the electromagnetic theory, electromagnetic radiation is emitted as magnetic dipole radiation when a charge revolving in an orbit of radius \( r_0 \) flows as an alternating current. This paper presents a mathematical proof for the emission of infrared-to-ultraviolet electromagnetic waves of the hydrogen emission spectrum when an alternating current is generated by the oscillation and revolution of an electron around a hydrogen-atom proton at a radius \( r_{nor} \) due to external energy. The mathematical results have demonstrated that the photon is not wave–particle duality of light but an electromagnetic wave of energy form, and the empirical Planck’s constant, \( h \), is mathematically derived for the first time. Therefore, the electromagnetic spectrum above the infrared region can be explained with oscillating and revolving particles with a constant electric charge.

4:42PM U70.00012: Wavefunction; Guided Energy of Wave*  DESMOND AGBOLADE ADEMOLA (Presenter), Olabisi Onabanjo Univ — This paper expound on true nature of wavefunction and answered questions that arise from quantum foundation. The fundamental analysis presented in this work show that mathematical formalism of wavefunction was wrongly formulated. On this basis, we therefore mathematically formalized new wavefunction equation which applicable to any forms of particles. We further introduced diffraction concept which mathematically establishes space-time quantization. We further show that wavefunction does not collapse, only converges and diverges gradually. The gradual process of divergence of wavefunction display how particle-like behavior return to wave-like behavior, and the gradual process of convergence of wavefunction also display how wave-like behavior return to particle-like behavior. The fundamental equations and analysis presented in this work hereby provides single description for both wave properties of smallest tiny particles (e.g. electrons) and matter properties of large particles (celestial bodies). The fundamental analysis presented here confirms that quantum mechanics needs to be profoundly modified to absorbs ideas of fundamentals analysis presented in this paper so that it might become a unique theory that accounts for dynamics behaviors of all particles regardless of sizes.

*NIL
We propose a double inflection point inflationary model. In which one of the inflection point predicts the power spectra consistent with CMB observations at large scales and the other generates a large peak in the power spectrum of scalar perturbations at small scales. Such a peak allows for the generation of primordial black holes at small scales, which can account for a significant fraction of dark matter. We also calculate the energy spectrum of induce gravitational waves from primordial scalar perturbations and find that the gravitational-wave signal can be detected by future space-based laser interferometers.

8:00AM W01.00001: Anisotropic Wave Breaking in Highly Nonlinear Thermal Media  GIULIA MARCUCCI (Presenter), Physics Department, Sapienza University of Rome, PHILLIP CALA, WEINING MAN, Department of Physics and Astronomy, San Francisco State University, DAVIDE PIERANGELI, CLAUDIO CONTI, Physics Department, Sapienza University of Rome, ZHIGANG CHEN, Department of Physics and Astronomy, San Francisco State University — In optics, many phenomena are ruled by the nonlinear Schrödinger equation (NLSE), as solitons and dispersive shock waves (DSWs). We report experiments on 2D-optical DSWs with anisotropic singularity in m-cresol/nylon, and provide theoretical description by time asymmetric quantum mechanics (TAQM) [1].

M-cresol/nylon is a chemical solution with an isotropic giant self-defocusing nonlinearity. When it is enlightened by a CW laser beam, the material experiences a thermo-optical effect, governed by the nonlocal version of the defocusing NLSE.

By choosing an initial beam shape (propagating along z) that has null intensity along x = 0, a new kind of wave breaking emerges: the shock develops undular bores on the beam external borders, but around the singularity it presents an abrupt intensity discontinuity.

We analyze this shock and find that it is caused by the interplay of a trapping/focusing potential along x and an antitrapping/defocusing potential along y. While the trapping potential is the standard harmonic oscillator (HO), the antitrapping potential is the reversed HO, a paradigmatic model in TAQM. Indeed, light propagation is described by a superposition of exponential decays with quantized decay rates, a fundamental TAQM signature.

8:12AM W01.00002: Strong-Field Ionization in Bicircular Laser Fields  JAN CHALOUPKA (Presenter), Dept of Physics & Astronomy, Univ of Northern Colorado — We ordinarily take Einstein's description of the photoelectric effect to mean that atoms can absorb only one photon at a time, thereby prohibiting ionization by weak, low-frequency light. But shortly after the invention of the laser, it was found that under intense illumination, atoms could simultaneously absorb many photons, leading to so-called multiphoton ionization. It was also discovered that a second electron could be liberated with surprising efficiency through a process known as rescattering, where the first electron is driven back to the ion leading to impact double ionization. Since this process relies on trajectories that bring the first electron back to the parent ion, it is most effective with linear polarization and absent with circular polarization. But there has recently been great interest in ionization dynamics driven by intense bicircular light, generated by combining two colors of circularly polarized light. Here we present new results using a classical ensemble approach and utilizing a high-performance computational cluster. We uncover novel patterns in recollision timing, identify classes of complex trajectories that contribute to double ionization, and map various ionization processes onto the resulting transverse electron momentum distributions.
HONGXIA ZHENG (Presenter), Fudan Univ, YIKUN JIANG, Department of Physics, Cornell University, HUAJIN CHEN, Guangxi University of Science and Technology, XIAO LI, The Hong Kong University of Science and Technology, XINNING YU, Fudan Univ, WANLI LU, China University of Mining and Technology, JACK NG, Southern University of Science and Technology, ZHIFANG LIN, Fudan Univ — Based on either mathematics or physics, it is natural to split the optical forces acting on small particles into the conservative gradient force and the nonconservative scattering force. While the former can trap small particles at a potential energy minimum, the latter can push or even pull small particles, thus transporting them. Nevertheless, although its importance in understanding optical micromanipulation is recognized, these forces are only calculated for particles small or large compared to the light wavelength. Their true profiles for Mie sized particles, which are the most commonly encountered particles in real experiment, were not available. The difficulty lies in the complicated mathematics. Here, we report several algorithms we developed to calculate the decomposed force for spherical particle with arbitrary size and composition and present some interesting results calculated by these algorithms [1-4].

ASMA AL-QASIMI (Presenter), DANIEL FV JAMES, University of Toronto — Coherence properties of light are known to change upon propagation in linear optical systems [1-4]. Here, we study coherence properties of classical light using convenient techniques from Matrix Algebra. We apply those techniques, first, to a set up of a Young's Interference Experiment, finding maximal coherence properties, such as those pertaining to polarization and which-path distinguishibility. Second, we find the maximal polarization obtainable of a partially coherent beam propagating in space [5].

8:48AM W01.00005: Generating photon-added states without adding a photon*  SAURABH SHRINGARPURE (Presenter), JAMES D FRANSON, Univ of Maryland-Baltimore County — Optical Parametric Amplifiers convert pump photons to pairs of signal and idler photons. In this work, we demonstrate that a continuous range of non-classical states, including a displaced number state and photon-added state, can be prepared in the signal when the input idler mode contains a pure single-photon state and the output idler mode is post-selected to be unchanged by the OPA, depending on the gain of the OPA. The ability to continuously tune the gain and hence the non-classical states provide an advantage over a similar approach for conventional beam splitter with fixed reflectivity.

9:00AM W01.00006: Limits to Single Photon Detection: Amplification*  TZULA PROPP (Presenter), STEVEN J VAN ENK, Univ of Oregon — We have constructed a model of photo detection that is both idealized and realistic enough to calculate the limits and tradeoffs inherent to single photon detector (SPD) figures of merit. This model consists of three parts: transmission [1], amplification [2], and measurement. In this talk, we discuss the effects of signal amplification post-filtering; by first writing correct commutator-preserving transformations for non-linear photon-number amplification (e.g. avalanche photodiode, electron-hole pair creation, electron shelving), we derive alternative noise limits that out-perform the well-known Caves limits for linear amplification of bosonic mode amplitudes and possess no zero-temperature noise contribution to boson number SNR. We then discuss the optimistic implications for single photon detection. Lastly, we briefly discuss the pre-amplification filtering process (transmission) along with the construction of POVMs completely describing photo detectors (measurement), from which we can calculate all standard SPD figures of merit.

9:12AM W01.00007: Optical attenuation without absorption*  IAN NODURFT (Presenter), RICHARD A BREWSTER, TODD BUTLER PITTMAN, JAMES D FRANSON, Univ of Maryland-Baltimore County — We simulate a coherent state of light passing through an atomic medium. Upon transmission, the atoms’ states are observed and all cases in which any are excited are rejected, and the final output is calculated. Depending on initial amplitude and coupling strength, the output can be attenuated to a greater degree or even amplified when compared to the output where the atoms’ states are ignored.

9:24AM W01.00008: A computational design of cylindrically symmetric 2D dielectric grating meta-lens with optical limiting effect based on saturable absorption by FDTD simulation  YUQI ZHAO (Presenter), HAMIDREZA CHALABI, EDO WAKS, University of Maryland, College Park — Meta-surface materials can shape the amplitude and phase with high spatial resolution and exhibit properties not occurring in natural materials, receiving considerable attention nowadays. Many exotic phenomena have been successfully demonstrated in linear optics. However, to meet the growing demand for the integration of more functionalities into a single optoelectronic circuit, the tailorable nonlinear optical properties of meta-surfaces will also need to be exploited. Here, by carefully tailoring meta-atoms' dimensions using FDTD simulation, we manage to design an optical limiting cylindrically symmetric 2D grating meta-lens with GaAs meta-atoms on SiO2 substrate. The nonlinearity based on saturable absorption is obtained by embedding quantum dots inside meta-atoms. Each quantum dot is treated as a two-level quantum system and optical Bloch equations are used for refractive index calculations and meta-lens simulations. Good focusing and optical limiting effect is observed and analyzed.
9:36AM W01.00009: Optical pulse propagation in transverse Anderson localization optical fibers*  ARASH MAFI (Presenter), CODY BASSETT, University of New Mexico, MATTHEW TUGGLE, Clemson University, MOSTAFA PEYSOKHAN, ESMAEIL MOBINI, University of New Mexico, JOHN M BALLATO, Clemson University — We study the optical pulse propagation in transverse Anderson localization optical fibers (TALOFs). TALOFs are a novel class of optical fibers that guide light, not in a conventional core-cladding setting, but by means of Anderson localization, where any location across the transverse profile of the fiber can be used to guide light. In particular, we investigate the group velocity distribution of guided modes in TALOFs. We observe that the narrowest distribution of group velocities is obtained in the presence of a small amount of disorder; therefore, the modal dispersion of an optical pulse is minimized when there is only a slight disorder in TALOF. Our investigation is primarily aimed at the nonlinear optical properties of TALOFs, but the results can apply to the usage of TALOFs in optical communications as well. We will also discuss other nonlinear behavior of TALOFs, e.g., four-wave-mixing and heralded single-photon generation for quantum information processing.

9:48AM W01.00010: Characterization and design of radiation-balanced Yb-doped ZBLAN fiber laser*  MOSTAFA PEYSOKHAN (Presenter), ESMAEIL MOBINI, ARASH MAFI, University of New Mexico — Thermal instability degrades laser beam quality and is a substantial hurdle in the power-scaling of fiber lasers. Radiation balancing is suggested as a viable method for heat mitigation and is based on balancing the anti-stokes fluorescence cooling against conventional sources of heating in a laser. In designing a radiation-balanced fiber laser, characterization plays a vital role. Moreover, for the laser cavity design, one needs to present a viable geometry and select the appropriate pump and signal wavelengths to achieve optimum efficiency while maintaining the radiation-balanced condition. In this study, we introduce a non-constructive and non-contact method for fully characterizing the Yb-doped ZBLAN fiber. We extract such parameters as the parasitic absorption, background absorption, quantum external efficiency, and cooling efficiency for the different pump wavelengths. We also find the optimal pump wavelength for maximum cooling efficiency.

**10:00AM W01.00011: A synthetic Hall effect creates strong photonic nonreciprocity**

CHRISTOPHER PETERSON (Presenter), University of Illinois at Urbana-Champaign, WLADIMIR A BENALCAZAR, The Pennsylvania State University, MAO LIN, TAYLOR L HUGHES, GAURAV BAHL, University of Illinois at Urbana-Champaign — The ordinary Hall effect is a historically well-known physical phenomenon where a transverse electric field is produced when a magnetic field is applied perpendicular to a current. The inverse of this effect, where orthogonal electric and magnetic fields induce an electric current in the E x B direction, is a less well-known but an equally valid application of the same principle. Here, we experimentally realize this combination of effective electric and magnetic fields in a photonic resonator chain through use of synthetic dimensions. We then demonstrate the photonic equivalent of the Hall effect, where the combination of fields creates a “photon current” such that transmission of photons is unidirectionally suppressed. We show that this synthetic Hall effect can induce strongly nonreciprocal transmission, with greater than 58 dB of contrast, when both synthetic fields are tuned to maximize their respective symmetry breaking. This mechanism is general can be applied to break reciprocity in a wide variety of domains, including optical, microwave, and mechanical systems.

**10:12AM W01.00012: High Harmonic Generation In Single-Walled Carbon Nanotubes Driven By A Circularly Polarized Incident Field**

WALTER FURMAN (Presenter), LINDA E REICHL, University of Texas at Austin — High-order harmonic generation occurs in single-walled carbon nanotubes when a time-periodic field is applied at a large enough intensity to induce significant nonlinearities in the electron current. Regularized delta-function potentials were used to approximate the energy band structure of graphene and nanotubes. Then 10-10 armchair nanotubes were modeled using Floquet-Bloch theory driven by a circularly polarized field propagating parallel to the tube axis. Quasienergy, average energy, and electron current are computed, and the nature of the high harmonic emission spectrum will be discussed.

*Welsh Goverment Learning Grant*
10:24AM W01.00013: Electromagnetically induced transparency without control field in giant atoms* ANDREAS ASK (Presenter), Chalmers Univ of Tech, YAO-LUNG L. FANG, Brookhaven National Lab, Computational Science Initiative, ANTON FRISK KOCKUM, Chalmers Univ of Tech — Quantum interference between different excitation pathways in a three-level system can make an otherwise opaque medium transparent. The transparency window is achieved by turning on a control field, and is therefore named electromagnetically induced transparency (EIT). Since EIT is accompanied by a drastic change in refractive index, it gives rise to highly non-linear effects, such as slow light. We have investigated the creation of EIT in systems without the need for an explicit control field: two two-level atoms coupled to a waveguide. In particular, these atoms can be giant, i.e., couple to the waveguide at two spatially separated points. By tuning the distance between the two coupling points, a giant atom can decouple from the waveguide, thus forming a dark state, a key component in EIT physics. Since our proposed system does not involve neither an explicit three-level system, nor a control field, the complexity of achieving EIT is drastically reduced. Our proposal can be realized in several experimental setups, e.g., superconducting qubits coupled to microwave photons or surface-acoustic-wave phonons.

10:36AM W01.00014: Topological Spaser in a Non-uniform Field* RUPESH GHIMIRE (Presenter), JHIH-SHENG WU, VADYM APALKOV, MARK I STOCKMAN, Department of Physics and Center of Nano Optics, Georgia State University — We propose a nanospaser made of an achiral plasmonic-metal nanodisc and a two-dimensional chiral gain medium, e.g., a monolayer transition-metal dichalcogenide (TMDC). Such a gain medium can pumped by circularly-polarized radiation into a valley-polarized (topologically-charged) state where the population-inversion of the K and K' valleys may be different. Each valley's population inversion independently feeds a chiral spasing mode of the nanodisk. There are two such modes that carry opposite topological charges; they do not compete with or cross-talk to each other, and are highly independent. The local fields of these modes rotate in time in opposite directions and are highly nonuniform in space.

10:48AM W01.00015: Arbitrary optical wave evolution with Fourier transforms and phase masks  VICTOR JOSE LOPEZ PASTOR (Presenter), Max Planck Inst for Sci Light, JEFF LUNDEEN, Department of Physics, University of Ottawa, FLORIAN MARQUARDT, Max Planck Inst for Sci Light — A large number of applications in classical and quantum photonics require the capability of implementing arbitrary linear unitary transformations on a set of optical modes. In a seminal work by Reck et al. [1] it was shown how to build such multiport universal interferometers with a mesh of beam splitters and phase shifters, and this design became the basis for most experimental implementations in the last decades. However, the design of Reck et al. is difficult to scale up to a large number of modes, which would be required for many applications. Here we present a constructive proof that it is possible to realize a multiport universal interferometer on N modes with a succession of 6N Fourier transforms and 6N+1 phase masks, for any even integer N. Since Fourier transforms and phase masks are routinely implemented in several optical setups and they do not suffer from the scalability issues associated with building extensive meshes of beam splitters, we believe that our design can be useful for many applications in photonics.

Session W02 GSCCM: Materials in Extremes: Simulations of Materials at Extreme Conditions

8:00AM W02.00001: Force-based interatomic potential for strength and toughness in brittle solids  MD HOSSAIN (Presenter), Univ of Delaware — Most of the available potentials (such as Tersoff, Stillinger-Weber, ReaxFF, EDIP, Vashishta, etc.) produce reliable properties (such as bulk modulus) of a solid under symmetry-preserving deformation or symmetry-breaking deformation around the linear regime of mechanical deformation. However, despite the incorporation of long-range interactions, they have sizable accuracies in producing extreme mechanical properties such as strength and toughness (which are two critical extreme mechanical properties of a solid). To address the limitations, we developed a force-based scheme that gives first-principles accurate strength and toughness. We validated the approach for a number of brittle solids including diamond, SiC, hBN, and graphene. In addition to fitting the equilibrium material properties, the approach allows fitting the potential to the forcing behavior as well as the mechanical strength of the solid, without requiring any ad hoc modifications of the nearest-neighbor interactions to avoid artificial stiffening at larger deformation. The talk will discuss the development of the force-based scheme and its application for a number of brittle solids. It will highlight a number of failure mechanisms that emerge from an accurate description of the interatomic interactions.
8:12AM W02.00002: Automated generation of machine learning-based atomistic potentials for extreme conditions*  
BEN NEBGEN (Presenter), JUSTIN SMITH, NITHIN MATHEW, JIE CHEN, LEONID BURAKOVSKY, SARYU FENSIN, KIPTON BARROS, Los Alamos Natl Lab — Neural Network (NN) interatomic potentials are a powerful tool for atomistic scale simulations, combining the generality and accuracy of ab-initio methods with costs approaching those of classical potentials. A robust training dataset covering many atomic configurations must be computed with ab-initio methods to train an accurate NN potential. Recently, active learning (AL) algorithms have demonstrated the ability to generate training datasets quickly and efficiently by selecting atomic configurations for which a NN potential has high uncertainty. This facilitates the generation of training datasets through a minimum number of ab-initio calculations with little or no human intervention. A LAMMPS interface for our NN potential, named ANI, has facilitated large-scale GPU-accelerated MD simulations using domain decomposition. Utilizing this interface, we validate an autonomously generated ANI aluminum potential using both static and dynamic simulated properties, including a partial phase diagram. Additionally, we present million-atom shock simulations of aluminum to illustrate robustness and demonstrate extensibility to the prediction of high-pressure phases.

8:24AM W02.00003: Quantum-accurate SNAP Potential For Large-Scale Molecular Dynamics Simulations of Carbon at Extreme Conditions  
JONATHAN T WILLMAN (Presenter), ASHLEY WILLIAMS, KIEN NGUYEN-CONG, University of South Florida, ANATOLY BELONOSHKO, Royal Institute of Technology, MITCHELL WOOD, AIDAN THOMPSON, Sandia National Laboratories, IVAN OLEYNIK, University of South Florida — Highly accurate interatomic potentials are of critical importance for trustworthy MD simulations of materials at extreme conditions of high pressures, temperatures, and high strain-rates. A new quantum accurate Spectral Neighbor Analysis Potential (SNAP) for carbon has been developed to describe the behavior of carbon at multi-megabar pressures and up to 10,000 K. SNAP is formulated in terms of the bispectrum components, which play a role of descriptors that characterize the local neighborhood of each atom. Machine learning is used to train the quadratic SNAP on a large set of first-principles training data. The SNAP development involves (1) the generation of the training database comprising a consistent and meaningful set of first-principles DFT data; (2) the robust and physically guided fit of SNAP parameters; and (3) the validation of the SNAP potential in simulations of carbon at extreme conditions. In this presentation, several applications of SNAP to study carbon at extreme conditions are described.
8:36AM W02.00004: Time dependent boundary conditions for large scale atomistic simulations of shocked surface instabilities* JAMES HAMMERBERG (Presenter), Los Alamos Natl Lab, RAMON JOSE RAVELO, University of Texas El Paso, TIMOTHY GERMANN, Los Alamos Natl Lab — Shock induced surface instabilities such as Richtmyer-Meshkov instabilities at perturbed metal vacuum/gas interfaces result in metal material ejecta. For strong shock waves the material ejected is initially in the form of fluid sheets when the surface perturbation is two-dimensional. These sheets ultimately break up to form a distribution of droplets. Large-scale non-equilibrium molecular dynamics simulations of such instabilities allow the investigation of the dynamics of the breakup process but are limited in length and time scales by rarefaction wave reflections at the boundaries ultimately leading to spall that may affect the instability growth. A time-dependent boundary condition based on the self-similar character of the release wave is presented that mitigates boundary reflections and reduces unwanted tensile waves behind the perturbed interface zone. This boundary condition can be used to increase the wavelength and time scale for breakup simulations. We discuss the details of this method and results of NEMD simulations of a shocked Cu interface with a single mode perturbation characterized by a wavelength of $\lambda = 13$ nm and a wavenumber amplitude product $kh_0 = 1/2$.

8:48AM W02.00005: Molecular dynamics simulation of shock compressed cis-polybutadiene : from in situ synthesis to mechanical analyses of long-term relaxation processes GAUTIER LECOUTRE, CLAIRE LEMARCHAND, LAURENT SOULARD, NICOLAS PINEAU (Presenter), CEA/DAM/DIF — We used a recently devised procedure based on molecular dynamics to generate cis-polybutadiene melts with various chain lengths [1] and study their mechanical behaviour under shock compression with the non-reactive OPLS all-atom force-field. The resulting samples show properties in excellent agreement with previous works [2] with negligible influence of the chain length. Comparison of direct shock with shock equilibrium (hugoniotstat) simulations shows a discrepancy in the shear stresses. Based on a careful mechanical analysis of the time-dependance of this difference behind the shock front, we show that their timescale is compatible with the typical equilibrium relaxation times at play in these complexe materials.

9:00AM W02.00006: Structure and dynamics of liquid Fe at high pressure and temperature. **A first principles study**  
DAVID J GONZALEZ (Presenter), MIRIAM MARQUES, LUIS GONZALEZ, Dpt. Fisica Teorica, Atomica y Optica, Univ. de Valladolid — The static and dynamic properties of bulk liquid Fe at high pressure and temperature conditions have been studied by using first principles molecular dynamics simulations based on the density functional theory. Results are reported for some thermodynamic states resembling those found in the Earth's outer core. We have evaluated some structural magnitudes such as static structure factors, pair distribution functions and coordination numbers. The static structure factors show an asymmetric second peak which suggests local icosahedral order in the liquid. Several dynamical properties have been calculated, such as velocity autocorrelation function, dynamic structure factors, longitudinal and transverse current spectral functions. The dispersion relations of longitudinal and transverse excitations reveal two branches of transverse collective modes. Results are also reported for some transport coefficients, namely, self-diffusion and shear viscosity.

9:12AM W02.00007: Extreme Dynamic Tension Theory: Preliminary Research**  
SEOKBIN LIM (Presenter), New Mexico Tech, PHILIPP BALDOVI, NSWC Indian Head — The dynamic tension fracture has brought much interests in various engineering applications ranging from the pressure vessel/pipe failure to the explosively driven fragmentations in the commercial/space or military applications. There has been great improvement in this area of study by many researchers, but the question regarding the fundamental mechanism of extreme tension remains unanswered. In this report, an extreme dynamic tension theory based on the conservation equations is proposed, and it is evaluated by a series of MD (molecular dynamic) and hydrocode simulations. In-depth descriptions of tension wave speed, wave profile, tension pressure/profile, particle velocity of the plastic tension wave, etc. are present, hoping to provide a clue to understand the extreme dynamic tension physics prior to the crack formation.

*This work is mainly supported by FAA-COE-CST Task 377. Authors would like to show their gratitude to NASA EPSCoR CAN (grant #: 80NSSC17M0050) and NASA's Space Grant College and Fellowship Program for the partial support of this research.
**9:24AM W02.00008: Electron-Phonon Interactions in Condensed Phases under Compression**

ANGUANG HU (Presenter), Suffield Research Centre, Defence Research and Development Canada — Electron-phonon interactions in condensed phases are central to all important temperature-dependent properties of materials such as electrical resistance in metals, carrier mobility in semiconductors, and phase transitions in conventional superconductors. Based on all-electron quantum solid-state chemistry using density functional theory, non-perturbative calculations of electron-phonon interactions have been recently developed in condensed phases under compression. Such calculations can provide a clear understanding on the thermal dependence of electron energy bands and thermomechanically induced distortion of band structures to raise or lower the Fermi level, leading to the generation of charge and spin density waves mainly determined by amplitudes of vibrational motion under mechanical compression. More importantly, calculations also show how vibrational mode energies in the measure by vibrational amplitudes distribute to reach an equilibrium state and even to create a superconducting state with the temperature-dependent energy gap. High-pressure superconductors $\text{H}_3\text{S}$ and $\text{LaH}_{10}$ are taken as examples to show calculation results in comparison with experiments.

**9:36AM W02.00009: Molecular simulations of ultrafast radiation induced melting at metal-semiconductor interfaces**

ASHWIN RAVICHANDRAN (Presenter), NASA Ames Research Center - SGT Inc, JOHN LAWSON, Intelligent Systems Division, NASA Ames Research Center — Understanding radiation induced ultrafast melting at material interfaces is essential in designing robust electronic devices for aviation/space applications and in laser machining. While it is difficult to achieve the spatial and temporal resolution required to quantify the phenomenon experimentally, simulations can provide the detailed mechanisms of the structural changes that happen during phase transition. In this work, we use molecular simulations to study the effect of radiation damage on silicon carbide (SiC) - tungsten (W) interfaces which is of interest in high power electronics. A multi-scale approach is involved wherein the reactions at the interfaces are quantified using \textit{ab-initio} molecular dynamics (MD) simulations and classical MD simulations are employed to understand the structural and diffusional changes across the material interface. Finally, coarse-grained Lennard-Jones type models are used to study the larger scale mechanisms and structures obtained due to the induced damages. We show that the response of the material to radiation damage depends on factors such as energy of the incident radiation, thermal properties, and molecular structure of the material.
9:48AM W02.00010: Accelerated Molecular Dynamics Simulations of Dislocation-Obstacle Interactions in Tungsten: Enabling Micro-Second Simulations  NITHIN MATHEW (Presenter), ENRIQUE MARTINEZ SAEZ, DANNY PEREZ, Los Alamos National Laboratory — Plasma Facing Materials (PFMs) in fusion reactors have to withstand extreme temperatures and high particle flux of Hydrogen (H) isotopes and Helium (He). Tungsten (W) is the main candidate for PFM in the International Thermonuclear Experimental Reactor but He irradiation of W results in modification of surface microstructure due to creation of Helium-Vacancy (HeₙVm) complexes. This leads to increased retention of H isotopes and degradation of thermomechanical stability. In this work, we study the interaction of these HeₙVm complexes with edge dislocations using accelerated molecular dynamics. We use a novel Parallel Replica Dynamics method where states and transitions are identified on-the-fly using a diffusion distance metric calculated from an approximation of the Koopman operator of the dynamics. Using up to 600 replicas, we are able to investigate the interactions between edge dislocations and HeₙVm complexes at temperatures ranging from 300-1200 K and applied stresses well below the critical resolved shear stress. The calculated rates for the dislocation to overcome the obstacle span ≈3 orders of magnitude, reaching micro-second timescales at low temperatures/stresses, and show a strong dependence on the applied stress.

10:00AM W02.00011: Periodic Boundary Condition for Large Material Deformation*  DUAN ZHANG (Presenter), MIN WANG, PAUL BARCLAY, Los Alamos Natl Lab — The use of periodic boundary conditions has been a common practice in numerical simulations for the study of constitutive response of materials. To consider material deformation, the common method of enforcing the periodic boundaries is to deform the computational domain with the material, which limits the strain of the material to order one. The method fails when strains are large or the deformation gradients are complicated, such as those containing large rotation or twist. For instance, it is quite difficulty to perform a simulation under a large pure shear deformation because of the distorted and elongated computational domain.

To avoid this difficulty, a different method has been developed by decomposing the velocity gradient matrix into the upper triangle part and the antisymmetric part representing a pure rotation. The antisymmetric part is then canceled by performing the simulation in a rotating reference frame and considering the associated inertial forces. Advantages of this method will be shown using examples.

Session W07 DQI: Quantum Amplifiers, Bolometers, and Detectors 102 -
Guilhem Ribeill, BBN Technology - Massachusetts
8:00AM W07.00001: Sensitive and fast bolometer integrable with superconducting qubit readout* MIKKO MOTTONEN (Presenter), ROOPLE KOKKONIEMI, JEAN-PHILIPPE GIRARD, QCD Labs, QTF Centre of Excellence, Department of Applied Physics, Aalto University, DIBYENDU HAZRA, Micro & Nanoelectronics, VTT Technical Research Centre of Finland, ANTTI LAITINEN, NANO group, QTF Centre of Excellence, Department of Applied Physics, Aalto University, JOONAS GOVENIUS, Micro & Nanoelectronics, VTT Technical Research Centre of Finland, RUSSELL LAKE, IIRO SALLINEN, QCD Labs, QTF Centre of Excellence, Department of Applied Physics, Aalto University, VISA VESTERINEN, Micro & Nanoelectronics, VTT Technical Research Centre of Finland, EEMIL VISAKORPI, QCD Labs, QTF Centre of Excellence, Department of Applied Physics, Aalto University, SANNA ARPIAINEN, MIKA PRUNNILA, Micro & Nanoelectronics, VTT Technical Research Centre of Finland, PERTTI JUHANI HAKONEN, NANO group, QTF Centre of Excellence, Department of Applied Physics, Aalto University — Traditionally, bolometers have been too slow and inaccurate to operate in quantum sensing applications in the microwave regime. Thus their benefits such as simple setup, broad input band, absence of quantum noise, and energy-resolving calorimetry has not been harnessed in microwave quantum sensing. We report on a new type of a bolometer that simultaneously reaches the lowest noise reported for any bolometer, 20 zW/Hz$^{0.5}$ [1], and is roughly three orders of magnitude faster than the previous ultralow-noise bolometers. The thermal time constant, measured at the 100-ns range, corresponds to the typical speed of state-of-the-art high-fidelity qubit readout schemes [2]. The extracted energy resolution of this bolometer being in the 10-GHz range it manifests as a potentially important future tool in reading out superconducting qubits [3] or in quantum sensing applications in the microwave regime [4].

Towards a Microwave Single Photon Detector Using Inelastic Cooper Pair Tunneling

JOËL GRIESMAR (Presenter), Université de Sherbrooke, ROMAIN ALBERT, CEA Grenoble, JUHA LEPPÄKANGAS, Karlsruher Institut für Technologie, MAX HOFHEINZ, Université de Sherbrooke — The detection of single photons is a fundamental quantum measurement, complementary to linear amplification. However, in the microwave domain this is a difficult task due to the low energy of the photons. We present here a photo-multiplier using the energy of a Cooper pair tunneling across a voltage-biased Josephson junction to convert one microwave photon into several photons at a different frequency. This process relies on the strong non-linearity provided by the interaction between a Josephson junction and its high-impedance electromagnetic environment. We have fabricated and measured a device composed of a low critical current SQUID galvanically coupled to two high-impedance resonators. It showed conversion from one to two photons with an efficiency of 80% and also exhibited conversion from one to three photons. By cascading two of these multiplication stages and adding a quantum limited amplifier, it should be possible to discriminate itinerant single photon states from vacuum without dead time.

Josephson single infrared photon detector

EVAN D. WALSH, Massachusetts Institute of Technology, GIL-HO LEE, WOOCHAN JUNG, Pohang University of Science and Technology, K.-F. HUANG, Harvard University, BAE-IAN WU, Air Force Research Laboratory, DMITRI EFETOV, ICFO - The Institute of Photonic Sciences, THOMAS A OHKI, BBN Technology - Massachusetts, PHILIP KIM, Harvard University, DIRK R. ENGLUND, Massachusetts Institute of Technology, KIN CHUNG FONG (Presenter), BBN Technology - Massachusetts — Josephson junction (JJ) enables many high sensitivity detectors such as SQUID amplifier, magnetometer, microwave mixer, bolometer, and parametric amplifier. In the earliest realization of Josephson detectors during the 70’s, photodetection was one of the target applications before it fell out of competition due to the lack of good detection and coupling mechanism. However, new opportunities are now opening up for photodetection by exploiting the electrical and thermal properties of graphene in the superconducting-graphene-superconducting junctions. In this talk, we report the experimental detection of near-infrared (NIR) single photons by a graphene-based JJ via non-resonant Cooper-pair breaking and the resulting quasiparticle diffusion. Our method demonstrates an efficient mechanism for the electromagnetic wave to interact directly with the JJ. Such single photon detector is an enabling technology for quantum communication, quantum computing, and could be used as cryogenic optical interconnects.
**8:36AM W07.00004: Frequency tunable single microwave photodetector based on irreversible qubit-photon coupling**  
EMANUELE ALBERTINALE (Presenter), CEA-Saclay, RAPHAËL LESCANNE, École Normale Superieure, SAMUEL DÉLEGLISE, LKB Sorbonne, ZAKI LEGHTAS, École Normale Superieure, DANIEL ESTEVE, PATRICE BERTET, EMMANUEL FLURIN, CEA-Saclay — Single photon detection is a key resource for sensing at the quantum limit and is the enabling technology for measurement-based quantum computing, however microwave photons have energies 5 orders of magnitude lower than optical ones and are therefore ineffective at triggering measurable phenomena at macroscopic scales.
We report the observation of a new type of interaction between a two level system and a microwave resonator. These two quantum systems do not interact coherently but share a common dissipative mechanism to a cold bath: the qubit irreversibly switches to its excited state if and only if a photon enters the resonator. This highly correlated dissipation mechanism is used to detect itinerant photons impinging on a frequency tunable resonator. The scheme does not require any prior knowledge of photon waveform or arrival time, and dominant decoherence mechanisms do not trigger spurious events. We demonstrate a detection efficiency of 65%, a record low dark count rate of 1/ms over a frequency tuning range of 200 MHz and the capability to operate the detector in cyclic mode with a 50% duty cycle on a 10 µs detection sequence, making it a practical tool for quantum sensing and measurement-based computing in microwave domain.

**8:48AM W07.00005: A Superconducting Detector That Counts Microwave Photons up to Two**  
ANDRII SOKOLOV (Presenter), Universität des Saarlandes, Institute of Physics of the National Academy of Sciences of Ukraine, FRANK WILHELM, Universität des Saarlandes — We propose a detector of microwave photons which can distinguish the vacuum state, one-photon state, and the states with two or more photons. Its operation is based on the two-photon transition. The detection occurs when a Josephson junction switches from a superconducting to a normal state, which provides a macroscopic voltage. We model the detector theoretically and evaluate its performance.

*Work of A.S. was partly supported by a DAAD scholarship (2016).*
9:00AM W07.00006: Primary thermometry of propagating microwaves in the quantum regime  MARCO SCIGLIUZZO, ANDREAS BENGTSSON, Chalmers Univ of Tech, JEAN-CLAUDE BESSE, ANDREAS WALLRAFF, ETH Zurich, PER DELSING, SIMONE GASPARINETTI (Presenter), Chalmers Univ of Tech — The ability to control and measure the photonic occupation of propagating microwave modes down to very low temperatures is indispensable for quantum information processing with superconducting circuits, and may open opportunities for studies of thermodynamics at the nanoscale. Yet, the methods used so far are indirect, require sophisticated time-resolved measurements, and have poor temporal resolution. Here we propose and experimentally demonstrate primary thermometry of propagating microwave modes, using a transmon-type superconducting circuit. We illustrate our method by measuring the radiation temperature of a highly attenuated coaxial cable connecting room-temperature electronics to the base plate of a dilution cryostat, in the range of 200 mK down to 35 mK and with resolution well below one per mil in thermal occupation. To increase the radiation temperature in a controlled fashion, we either inject calibrated, wideband digital noise, or heat the device and its environment. In the latter case, we observe the thermalization dynamics of the microwave modes in real time. Our technique can be used to benchmark filtering and attenuation schemes for superconducting quantum information processors; at the same time, it provides a novel tool for experiments in quantum thermodynamics.

9:12AM W07.00007: Using Superconducting Qubits for Axion Dark Matter Detection  AKASH DIXIT (Presenter), SRIVATSAN CHAKRAM, ANKUR AGRAWAL, University of Chicago, RAVI KAUSHIK NAIK, University of California, Berkeley, DAVID I SCHUSTER, University of Chicago, AARON CHOU, Fermilab — The axion is a potential solution to the strong CP problem in QCD and could account for the abundance of dark matter observed in the universe. In the presence of an applied magnetic field, the axion field will source a current used to drive a resonant cavity to single photon occupation. A transmon qubit operating as a microwave photon sensor is a viable readout system at frequencies where the added noise of quantum limited amplifiers overwhelms the signal rate. The use of a direct dispersive quantum non-demolition measurement of the photon number decouples the measurement back action from the experimental uncertainties. In this regime dark counts are the dominant sources of detector error. For a transmon qubit operating as a photon counter, dark counts occur due to qubit errors which occur with probability 1-10%. In order to mitigate the effect of individual qubit flip errors of the detector, repeated measurements of the same photon are performed. The error rate of the joint N measurements could be significantly suppressed. The detector errors are then no longer the dominant source of false positives when attempting to measure weak signals sourced by the dark matter.
9:24AM W07.00008: High-Q Photonic Bandgap Microwave Cavity for Dark Matter Axion Searches*  ANKUR AGRAWAL (Presenter), AKASH DIXIT, University of Chicago, WENJIE YAO, STEVEN G. JOHNSON, Massachusetts Institute of Technology, MOHAMED AWIDA, Fermilab, DAVID I SCHUSTER, University of Chicago, AARON CHOU, Fermilab — A 3D photonic bandgap (PBG) crystal forbids the propagation of electromagnetic waves with energy within a certain range in all directions. We create an electromagnetic cavity by designing a defect inside the crystal such that its frequency lies within the forbidden gap. With enough number of periods in the crystal, the Q-factor is only limited by the dielectric loss in the material. One of the potential applications is in the Axion Dark Matter search, which is currently limited by the usage of low Q-factor copper cavities due to the presence of a strong magnetic field. We present various designs and experimental results of dielectric materials which can significantly increase the sensitivity and scanning rate of axion search. We predict the Q-factor of a PBG cavity to increase in the presence of a large magnetic field due to the shift in the two-level system energies to a higher level.

9:36AM W07.00009: Her Dark Materials: Comparison of Semiconducting Targets for Multi-Channel Direct Detection of Light Dark Matter  KATHERINE INZANI (Presenter), Lawrence Berkeley National Laboratory, TANNER TRICKLE, ZHENGKANG ZHANG, Department of Physics, University of California, Berkeley, KATHRYN ZUREK, Walter Burke Institute for Theoretical Physics, California Institute of Technology, SINÉAD GRIFFIN, Lawrence Berkeley National Laboratory — The nature of dark matter (DM) remains one of the greatest mysteries of physics. Experiments searching for DM on the mass scale of WIMPs have not established a DM signal, whilst the lighter mass range of keV to GeV is well-motivated yet unexplored. Expanding the reach of direct detection experiments down to light DM masses requires new ideas for the types of excitation that are possible and efficient pathways for their detection. Correspondingly, materials with a strong response must be identified for use as targets.

We have designed a methodology for evaluating the sensitivity of semiconducting materials to DM excitations based on density functional theory calculations.\(^1\) The model takes into account three complementary interactions: nuclear recoils, electron transitions across band gaps and single phonon excitations. We include a novel multi-channel response.

Using this framework, we have calculated the performance of 25 materials for a comparison of target sensitivities.\(^2\) We identify the materials parameters that must be optimized in order to maximize experimental reach. Furthermore, we evaluate a two-dimensional material which can exhibit the “smoking gun” DM signature of daily and annual modulation.

\(^{2}\)arXiv:1910.10716
9:48AM W07.00010: Interfacial effects on phonon propagation through quantum sensors used for dark matter detection  THOMAS HARRELSON (Presenter), SINEAD GRIFFIN, Lawrence Berkeley National Laboratory — Several proposals for the direct detection of dark matter (DM) of keV-MeV masses involve the scattering and absorption of DM with quasiparticles in the meV-eV energy transfer range. At these energy scales, phonons are the dominant energy carrier in most materials. Therefore, the task of detecting DM particles reduces to the detection of athermal distributions of phonons in a target material, which is accomplished using a transition edge sensor (TES). The phonons generated by DM scattering events in the target material propagate to the interface of the TES, and are either reflected or transmitted into the TES. We use density functional theory simulations to describe the probability at which phonon distributions are transmitted through the target/TES interface, and the coherence losses in quasiparticle transmission to the sensor. Specifically we calculate currently used targets Si and GaAs, with an Al TES. We consider the commercially available crystal faces for the target materials, and use these simulations to find the best target/TES interfaces for optimizing the phonon transmission coefficients. We use this information to create more accurate models of DM detection, which allows the optimization of the target material and interfaces in the quantum sensor.

10:00AM W07.00011: Gain calibration of a cryogenic amplification chain using normal-metal–insulator–superconductor junctions  MÁTÉ JENEI (Presenter), ERIC HYYPPÄ, SHUMPEI MASUDA, KUAN YEN TAN, VASILII SEVRIUK, QCD Labs, QTF Center of Excellence, Department of Applied Physics, Aalto University, MATTI SILVERI, Research Unit of Nano and Molecular Systems, University of Oulu, JAN GOETZ, MATTI PARTANEN, RUSSELL LAKE, QCD Labs, QTF Center of Excellence, Department of Applied Physics, Aalto University, LEIF GRÖNBERG, QTF Center of Excellence, VTT Technical Research Centre of Finland, MIKKO MOTTONEN, QCD Labs, QTF Center of Excellence, Department of Applied Physics, Aalto University — To achieve a high-efficiency readout in a low-temperature microwave circuit using both cryogenic and room temperature electronics, the signal has to go through one or more amplifiers to obtain a reasonable signal-to-noise ratio. In practice, the readout line has additional losses and reflections due to different microwave components which hinder the gain estimation. We present a gain calibration scheme [1] that utilizes a normal-metal–insulator–superconductor junction, which is capacitively coupled to a superconducting microwave resonator [2]. Depending on the bias voltage applied to the junction, the nanostructure can be employed as a quantum-circuit refrigerator [3] or as an incoherent photon source [4]. For the latter case, we derive an analytic expression for the total gain that is based on only a single fitting parameter. We present our experimental results where we reach 0.1 dB relative uncertainty of the total gain in a three-stage amplification chain.

10:12AM W07.00012: Josephson Parametric Amplifiers Fabricated in Wafer-scale with Side-wall Passivated Spacer Junction Technology* VISA VESTERINEN (Presenter), SLAWOMIR SIMBIEROWICZ, LEIF GRÖNBERG, JANNE LEHTINEN, ROBAB NAJAFI JABDARAGHI, MIKA PRUNNILA, JOONAS GOVENIUS, VTT Technical Research Centre of Finland Ltd — We present our latest experimental results on Josephson parametric amplifiers (JPAs) fabricated with our Nb/Al-AlOx/Nb junction process. The fabrication relies on UV photolithography and semi-automated 150-mm wafer processing steps, while minimizing the amount of deposited lossy dielectric materials [1]. The first JPA category is a flux-driven reflection amplifier for sub-GHz frequencies. It has found applications in the rf reflectometry of quantum dots, as well as in the rf readout of microwave nanobolometers [2] and charge detectors. Secondly, we report on the development of a 4-8 GHz traveling wave parametric amplifier tailored for the readout of superconducting quantum bits.

*This research was funded by EU Quantum Flagship (OpenSuperQ, QMiCS), and Academy of Finland (312059, 312294, 321700).

10:24AM W07.00013: Noise performance of a three-wave mixing kinetic inductance traveling-wave parametric amplifier MAXIME MALNOU (Presenter), JIANSONG GAO, MICHAEL R. VISSERS, JOEL N ULLOM, National Institute of Standards and Technology — Kinetic inductance traveling wave parametric amplifiers (KITs) have the potential to read out large numbers of qubits and cryogenic sensors due to their wide bandwidth, high saturation power, and potentially quantum-limited noise performance. However, noise in KITs has so far not been carefully studied, including its dependencies on device design and operating conditions. Here, we present a KIT based on a sub-micron resolution structure that is biased with a dc current and pumped in a three-wave mixing fashion. We experimentally evaluate its noise properties, which approach the quantum limit, and discuss its suitability for readout applications.
Overlap junction-based Josephson parametric amplifiers (O-JPA)

MUSTAFA BAL (Presenter), JUNLING LONG, RUICHEN ZHAO, HAOZHI WANG, COREY RAE MCRAE, RUSSELL LAKE, SUNGOH PARK, XIAN WU, HSIANG-SHENG KU, National Institute of Standards and Technology Boulder, DANIEL FROLOV, ROMAN PILIPENKO, SILVIA ZORZETTI, ERIC T HOLLAND, ALEXANDER ROMANENKO, Fermi National Accelerator Laboratory, DAVID PAPPAS, National Institute of Standards and Technology Boulder — We have recently developed submicron scale overlap Josephson junction fabrication process suitable for superconducting qubits with long coherence times [1]. Here, we extend the fab process to micron scale overlap junctions to enable other superconducting quantum devices such as overlap junction-based Josephson parametric amplifiers (O-JPA). We realize frequency tunable O-JPAs with negligible insertion loss. Compared to other competing processes, overlap junction process for micron scale junctions allows the fabrication of O-JPAs with high yield and good device performance at a much lower infrastructure requirements. We present the fabrication details as well as the characterization of O-JPAs.

Fabrication tolerances for traveling wave parametric amplifiers

DENNIS FENG (Presenter), MEHRNOOSH VAHIDPOUR, YUVRAJ MOHAN, SAM STANWYCK, TYLER WHYLAND, NICHOLAS SHARAC, GANESH RAMACHANDRAN, MICHAEL SELVANAYAGAM, Rigetti Quantum Computing — Resonantly phase matched traveling wave parametric amplifiers (TWPAs) [1] are sensitive to device fabrication errors. We develop a method to analyze the performance of the TWPA with emulated fabrication variations and different process parameters. We begin with an ideal analytic model and use circuit analysis and full-wave modeling to perturbatively calculate the full-circuit dispersion relation. We use this to find fabrication tolerances to different circuit parameters as well as ways to mitigate that sensitivity. We demonstrate that these robust designs with fabricated amplifiers achieve reasonable parametric gain and instantaneous bandwidth, suitable for multi-qubit multiplexed readout.

Friday, March 6, 2020 8:00 AM - 10:48 AM

Session W08 DQI: Superconducting Qubits: Materials, Fabrication and Coherence III 104 - Anna Stockklauser, Rigetti Quantum Computing
8:00AM W08.00001: Superconducting qubit devices: fabrication suite*  KOK WAI CHAN  
(Presenter), TIANYI LI, WEI LIU, JOHANNES HEINSOO, VASILII SEVRIUK, CASPAR OCKELOEN-KORPPI,  
JANI TUORILA, JUHA HASSEL, JUHA VARTIAINEN, KUAN YEN TAN, JAN GOETZ, MIKKO MOTTONEN,  
IQM Finland Oy — Scalable quantum computing architecture and fabrication processes have been  
a hot research topic in the past decade. We focus on the realization of a quantum computer  
based on superconducting qubits with a fast qubit reset and initialization techniques, utilizing a  
quantum-circuit refrigerator [1]. We present the fabricated devices and results achieved to date,  
which includes resonators with high quality factors, > 1e6, long qubit lifetime > 0.02 ms and 3D  
integration techniques such as airbridges.

8:12AM W08.00002: NbN-based superconducting qubit on Si substrate*  SUNMI KIM  
(Presenter), TOMOKO FUSE, FUMIKI YOSHIHARA, WEI QIU, Advanced ICT research institute, NICT, TARO  
YAMASHITA, Department of Engineering, Nagoya University, ZIQIAO AO, KOUICHI SEMBA, HIROTAKA  
TERAI, Advanced ICT research institute, NICT — In the superconducting qubit composed of  
aluminum-based Josephson junctions (JJs), the decoherence from microscopic two-level systems  
in amorphous aluminum oxide is concerned. As alternative materials for qubits, fully epitaxial  
NbN/AlN/NbN JJs are an attractive candidate with the potential to solve the above problems  
because of its high crystal quality, its chemical stability against oxidization, and relatively high  
transition temperature (~ 16 K) of NbN. Here we note that AlN is grown in cubic phase to avoid  
piezoelectricity. Early studies of superconducting qubits using epitaxially grown nitride JJs showed  
significant potential, but the qubit energy relaxation time was limited due to dielectric loss from  
the MgO substrate. [Y. Nakamura et al., APL, 99, 212502 (2011)]. In order to solve this problem,  
we have employed a Si substrate with TiN buffer layer for the epitaxial growth of this nitride JJs  
a λ/2 coplanar waveguide resonator. We observed clear Rabi oscillations and Ramsey  
interference patterns. We will discuss the detailed coherence characteristics.

8:24AM W08.00003: Flux qubits fabricated using a high-coherence transmon process*
TREVOR CHISTOLINI (Presenter), WILLIAM LIVINGSTON, BRADLEY MITCHELL, IRFAN SIDDIQI, University of California, Berkeley — Over the past years, superconducting circuit qubit lifetimes have been continuing to increase, largely due to design enhancements in addition to processing and fabrication evolution. While the earliest designs of Cooper pair boxes exhibited $T_1$ coherence times on the order of 1 ns, there are recent reports of transmon lifetimes exceeding 100 μs. We now apply these advances in processing to look back upon flux qubits, and we present an 8-qubit ring of alternating flux qubits and tunable transmons, with coupling between nearest neighbors. Preliminary work focuses on optimizing flux qubit design and increasing experimentally observed coherence times, with motivation from theoretical studies and numerical simulations targeting energy structure and noise coupling. Meanwhile, further theoretical investigations into novel two qubit gate designs between flux qubits and transmons, which leverage their opposing anharmonicities, are underway.

*This work was funded by the Army Research Office. This material is based upon work supported by the National Science Foundation Graduate Research Fellowship Program under Grant No. DGE 1752814.

8:36AM W08.00004: Fabrication and characterization of compact vacuum gap transmon qubits* MARTIN ZEMLICKA (Presenter), MATILDA PERUZZO, FARID HASSANI, SHABIR BARZANJEH, ELENA REDCHENKO, ANDREA TRIONI, JOHANNES FINK, Institute of Science and Technology Austria — The large shunt capacitance of the transmon qubit decreases its sensitivity to charge fluctuations but requires sizeable qubit dimensions. Very large capacitor designs furthermore lower the coupling to parasitic losses localized in material interfaces, an approach that improves coherence times consistently, but lowers the achievable integration density and increases parasitic cross coupling and leakage in superconducting processors. Our goal is the development of a compact low-loss transmon qubit by minimizing the electric field participation ratio of metal-dielectric and dielectric-air interfaces. Several attempts to realize vacuum gap capacitors were already implemented [1, 2], usually relying on an out-of-plane geometry that involved a sacrificial layer before releasing the structure. We utilize silicon membranes to fabricate micro-machined resonators and transmon qubits based on suspended in-plane vacuum capacitors [3] with qubits sizes as low as 20 x 20 μm^2.

8:48AM W08.00005: Characterization of Al-based Airbridges for Superconducting Microwave Devices. ROBAB NAJAFI JABDARAGHI (Presenter), LEIF GRÖNBERG, VISA VESTERINEN, MIKA PRUNNILA, VTT Technical Research Centre of Finland Ltd — The realization of a co-planar waveguide (CPW) for quantum circuits requires only a single wiring layer. However, the usability of the structure is limited by parasitic slotline modes which can modify couplings and act as a loss channel in complex superconducting integrated circuits. Free-standing metallic crossovers known as airbridges [1,2] commonly provide electrical connectivity between ground planes to suppress the parasitic modes. Here, we demonstrate our latest development of Al airbridges in conjunction with Nb CPWs. Our fabrication method relies on three separate optical lithography steps with Al deposition combined with the CPW structures using re-flowed photoresist as a scaffold. We are striving for low-loss airbridges that are robust against sonication and etches during further processing. At present, more than 90% of our airbridges survive the sonication. [1] Z. Chen et al., Applied Physics Letters 104, 052602 (2014). [2] Y. Kwon et al., IEEE microwave and wireless components letters 11, 59 (2001).

9:00AM W08.00006: Epitaxial GaAs Loss Measurements and the Merged Element Transmon* COREY RAE MCRAE (Presenter), NIST Boulder / CU Boulder, ANTHONY P MCFADDEN, UCSB, RUICHEN ZHAO, HAOZHI WANG, SUNGOH PARK, JUNLING LONG, NIST Boulder / CU Boulder, CHRIS J PALMSTROM, UCSB, DAVID PAPPAS, National Institute of Standards and Technology Boulder — Transmon qubits are traditionally composed of two components: a Josephson junction, which is commonly made up of a pair of superconducting aluminum films separated by a thin layer of amorphous aluminum oxide, and a large paddle capacitor. The presence of lossy materials in this design, as well as the significant size of the capacitor paddles, limits the transmon’s performance and scalability. In contrast, the merged element transmon design combines the qubit’s nonlinear inductance and capacitance into a single trilayer junction with extremely low dielectric loss. GaAs is a good candidate test material for these trilayer junctions as its epitaxial growth and interface with Al is well-characterized, and single crystal growth and lattice matching is possible. In this work, we use dielectric loss extraction methods to accurately measure the TLS loss for Al/GaAs/Al trilayers.

9:12AM W08.00007: Frequency Fluctuations in Tunable Superconducting Microwave Cavities

BENJAMIN BROCK (Presenter), MILES BLENCOWE, ALEXANDER J RIMBERG, Dartmouth Coll — We present a model for measurements of the scattering matrix elements of tunable microwave cavities in the presence of resonant frequency fluctuations induced by fluctuations in the tuning parameter. We apply this model to the specific case of a two-sided cavity and find an analytic expression for the average scattering matrix elements. A key signature of this `fluctuating model' is a subtle deformation of the trajectories swept out by scattering matrix elements in the complex plane. We apply this model to experimental data and report a direct observation of this deformation in the data. Despite this signature, we show that the fluctuating and non-fluctuating models are qualitatively similar enough to be mistaken for one another, especially in the presence of measurement noise. However, if one applies the non-fluctuating model to data for which frequency fluctuations are significant then one will find damping rates that appear to depend on the tuning parameter, which is a common observation in tunable superconducting microwave cavities. We propose this model as both a potential explanation of and remedy to this apparent phenomenon.

*Supported by NSF grants DMR-1807785 and DMR-1507383

9:24AM W08.00008: Investigation of surface induced loss mechanisms in high-quality superconducting Nb resonators

JEROEN VERJAUW (Presenter), MASSIMO MONGILLO, ANTON POTOCNIK, ROHITH ACHARYA, ANTOINE PACCO, TSVETAN IVANOV, DANNY WAN, LAURENT SOURIAU, JULIEN JUSSOT, ARAME THIAM, JOHAN SWERTS, XIAOYU PIAO, SEBASTIEN COUET, BOGDAN GOVOREANU, IULIANA RADU, MARC HEYNS, IMEC — Performance of superconducting qubit devices is limited by two-level system (TLS) defects, predominately found in amorphous interface layers. Reducing microwave loss contributions from these interfaces by proper surface treatments is key to push the device performance forward. We study niobium resonators where the native oxides at the metal-air & substrate-air interface are selectively etched with Hydrofluoric (HF) acid. Although HF treatment right before the low temperature characterization is known to yield an order of magnitude improvement in the resonator's quality factor, the precise loss contribution from various residual oxides and other defects at the interfaces is still unknown. By combining resonator quality factor measurements with X-ray photoelectron spectroscopy (XPS), electron energy loss spectroscopy (EELS) and other surface characterization techniques, we investigate the reappearance of loss mechanisms introduced by exposure to ambient conditions. This is of particular interest for fabricating air resilient, high-quality superconducting qubit devices as they share the same loss mechanisms with resonators.
9:36AM W08.00009: Flux Noise and Spin Dynamics of Multiple Interacting Adsorbates on Superconducting Qubits* KEITH RAY (Presenter), YANIV J ROSEN, JONATHAN L DUBOIS, VINCENZO LORDI, Lawrence Livermore Natl Lab — Molecular oxygen, OH group, and atomic hydrogen surface adsorbates have been identified as possible sources of magnetic flux noise in superconducting qubits. This noise causes decoherence and frequency jitter that can hinder tunable multi-qubit devices. To better understand the spin dynamics of these fluctuating adsorbates we have extended our model for interacting adsorbed paramagnetic $O_2$ molecules to include other species adsorbed from the device operation atmosphere, including water at different coverages. We calculate the effects of applied fields on the phases of the spin system, its dynamics, and the charge and flux noise generated. To do this we utilize a thermodynamic ensemble generated with Monte Carlo simulations along with Landau-Lifshitz-Gilbert equation simulations for the dynamics, both parametrized with vdW-corrected density functional theory calculations.

*Prepared by LLNL under Contract DE-AC52-07NA27344.

9:48AM W08.00010: Positive- and negative-frequency noise from an ensemble of two-level fluctuators* XINYUAN YOU (Presenter), Northwestern University, AASHISH CLERK, University of Chicago, JENS KOCH, Northwestern University — Depolarization of superconducting qubits with intrinsic protection, such as heavy fluxonium or the 0-π qubit, is dominated by excitation rather than relaxation processes. To extract the corresponding excitation rates, it is thus crucial to carefully consider the negative-frequency components of the noise spectral density. We are particularly interested in noise sources with the ubiquitous 1/f spectrum at positive frequencies. Existing models based on an ensemble of two-level fluctuators predict a symmetric noise spectral density valid in the high-temperature limit. We extend the analysis beyond this limit, and derive results explicitly obeying the fluctuation–dissipation theorem. We discuss deviations from pure 1/f behavior and compare with recent experimental observations.

*This research was supported by the U.S. Army Research Office under contract number W911NF-17-C-0024 and the Northwestern–Fermilab Center for Applied Physics and Superconducting Technologies.

10:00AM W08.00011: Random two-level defects in polycrystalline and amorphous alumina CHIH-CHIAO HUNG (Presenter), KEVIN OSBORN, NEDA FOROUZANI, BAHMAN SARABI, University of Maryland, College Park — Atomic two-level system (TLSs) are ubiquitous defects in superconducting qubits, however the TLS host material is generally amorphous alumina. We extend a characterization technique to, for the first time, study TLSs in two states of the same material: amorphous and polycrystalline alumina. A large distribution of approximately 400 individual TLS dipole moments are obtained in polycrystalline AlOx along a common axis. The averaged dipole moment in material is approximately 3.1 Debye. On the other hand, the average dipole moment is much larger in amorphous alumina, which is contradicted by expectations. We observe strong TLS frequency drifting phenomenon in the amorphous sample which relates to its TLS-TLS interactions. For the first time, a material characterization technique shows that one can collect a large amount of individual TLS data for material optimization, such as TLS dipole moments and TLS frequency stability.
10:12AM W08.00012: Coplanar silicon/aluminum resonators with internal quality factor above 2M: fabrication*  AIDAR GABIDULLIN (Presenter), FMN Laboratory, Bauman Moscow State Technical University, ALINA ALEKSANDROVNA DOBRONOSOVA, Dukhov Automatics Research Institute, (VNIIA), ANTON IVANOV, FMN Laboratory, Bauman Moscow State Technical University, LUCIA ALMIROVNA GANIEVA, Dukhov Automatics Research Institute, (VNIIA), DMITRIY MOSKALEV, ANDRONIC MICHAEL, NIKITA SERGEEVICH SMIRNOV, DMITRIY BAKLYKOV, FMN Laboratory, Bauman Moscow State Technical University, OLGA SOROKINA, Dukhov Automatics Research Institute, (VNIIA), GLEB PETROVICH FEDOROV, Moscow Institute of Physics and Technology, ILYA RODIONOV, FMN Laboratory, Bauman Moscow State Technical University — Extremely low intrinsic loss coplanar resonators are critical elements in superconducting quantum computing devices, photon detectors, parametric amplifiers and quantum memories. Here we describe the fabrication and measurement of superconducting coplanar waveguide microwave resonators on silicon substrates with internal quality factors over 2 millions at low powers, corresponding to single-photon regime. These quality factors are achieved by careful optimization of resonators geometry, measurement setup and key TLS-containing interfaces: metal-air, metal-substrate, and substrate-air. We provide a detailed analysis of the design and technological factors impact on resonators quality, including multi-step substrates cleaning, aluminum films crystalline structure, low-damage dry etching, design features and air-bridges application. Finally, using the same process flow we fabricate and characterize superconducting tunable X-mon qubits with the coherence over 100 us, confirming well-known correlations between resonators and qubits quality.

*Devices were fabricated at the BMSTU Nanofabrication Facility (Functional Micro/Nanosystems, FMNS REC, ID 74300).

10:24AM W08.00013: Long Relaxation Times of a C-shunt Flux Qubit Coupled to a 3D Cavity*  LEONID ABDURAKHIMOV (Presenter), IMRAN MAHBOOB, HIRAKU TOIDA, KOUSUKE KAKUYANAGI, SHIRO SAITO, NTT Basic Research Laboratories, NTT Corporation — We present measurements of relaxation times of a capacitively shunted flux qubit embedded in a 3D microwave cavity. Qubit energy-relaxation times T_{1} were found to be in the range of 60-90 μs, and Hahn-echo coherence time T_{2E} was about 80 μs. Using the CPMG dynamical decoupling sequence, the T_{1}-limited coherence time T_{2CPMG} of 160 μs was reached. Qubit energy relaxation could be attributed to quasiparticle tunneling, while dephasing times were limited by charge and critical-current noises at the optimal flux bias point and by 1/f flux noise elsewhere. With their relaxation times being comparable or exceeding previously reported values for other types of flux qubits, 3D c-shunt flux qubits can be utilized for quantum annealing, quantum magnetometry and spin sensing.

Session W16 DQI: Superconducting Qubits: QEC and Ultrastrong Coupling

201 - Christian Kraglund Andersen, ETH Zurich
**8:00AM W16.00001: Ground state of a circuit QED system in the deep-strong-coupling regime coupled to an environment**

TOMOHIRO SHITARA (Presenter), Tokyo Medical and Dental University, MOTOAKI BAMBA, Japan Science and Technology Agency, FUMIKI YOSHIHARA, TOMOKO FUSE, KOUICHI SEMBA, National Institute of Information and Communications Technology, KAZUKI KOSHINO, Tokyo Medical and Dental University — We investigate theoretically how the ground state of a qubit-resonator system in the deep-strong coupling regime is modified by the coupling to an environment. We employ the qubit-dependent coherent/squeezed-coherent state as the variational state for the ground state of the enlarged qubit-resonator-environment system and observe the following points. (i) The number of virtual photons increases by the coupling to an environment, proportionally to the square root of the loss rate \( \kappa \) of photons in the resonator. (ii) The ground state of the qubit-resonator system becomes mixed even at the zero temperature. The decrease in purity is proportional to the loss rate \( \kappa \). (iii) There exists an optimal value of the qubit-resonator coupling to maximize the nonclassicality of the qubit-resonator system, which is quantified by the metrological power.

*This work was supported by JST CREST Grant Number JPMJCR1775 and JST PRESTO Grant Number JPMJPR1767, Japan.

**8:12AM W16.00002: Time-domain measurements of an ultra-strongly coupled qubit-resonator circuit**

TOMOKO FUSE (Presenter), FUMIKI YOSHIHARA, National Institute of Information and Communications Technology, SAHEL ASHHAB, Qatar Environment and Energy Research Institute, KOUSUKE KAKUYANAGI, SHIRO SAITO, NTT, KOUICHI SEMBA, National Institute of Information and Communications Technology — In cavity- and circuit QED, when the coupling energy becomes \( \sim 10 \% \) or more of a photon and qubit energies (ultra- to deep-strong coupling regime), interesting physics are predicted [1]. So far, ultra- and deep-strong coupling [2-5] were achieved and the transition energy spectra of their circuits were studied. In this work, we have measured the coherence properties of an ultra-strongly coupled flux qubit-resonator circuit by driving the qubit while probing the resonator transition, which is also flux-bias dependent due to its very strong coupling to the qubit. The coherence times of \( \sim 1 \) \( \mu \)s were obtained for the qubit at the optimal point. In the presentation, a possible origin of the decoherence will also be discussed.

*This work was supported by Japan Society for the Promotion of Science Grant-in-Aid for Scientific Research (Grant No. JP19K03693), and Japan Science and Technology Agency Core Research For Evolutionary Science and Technology (Grant No. JPMJCR1775).
8:24AM W16.00003: Rabi model in the dispersive regime  CLEMENS MUELLER (Presenter), IBM Research - Zurich — The dispersive regime of circuit QED is the main workhorse for today's quantum computing prototypes based on superconducting qubits. Analytic descriptions of this model typically rely on the rotating wave approximation of the interaction between qubits and resonator fields, using the Jaynes-Cummings model as starting point for the dispersive transformation.

Here we present our results on the dispersive regime of the Rabi model, without taking the rotating wave approximation of the underlying Hamiltonian. Using a recently developed hybrid perturbation theory based on the expansion of the time evolution on the Keldysh contour [1], we derived simple analytic expressions for all experimentally relevant parameters like dispersive shift and resonator induced Purcell decay rate, both for idealized two-level systems as well as for realistic multi-level and weakly anharmonic qubits.

The analytical equations are easily tractable and reduce to the known Jaynes-Cummings results in the relevant limit, but show qualitative differences at large detuning, allowing for more accurate modelling of the interaction between superconducting qubits and resonators.

8:36AM W16.00004: Conical intersections and Berry phase in deep-strongly coupled superconducting qubit-resonator system* KOUICHI SEMBA (Presenter), National Institute of Information and Communications Technology, Japan., SAHEL ASHHAB, Qatar Environment and Energy Research Institute, Qatar Foundation, Qatar. — Conical intersections, or Dirac cones, have been observed in various modern physical systems. Measuring Berry phases and curvatures are interesting themes [1-2]. Flux-qubit resonator circuits can be well described by a simple model, the quantum Rabi-model, even in the deep strong coupling regime [3]. Numerical analysis reveals that conical intersections occur not only in the symmetric quantum Rabi-model which has clear parity symmetry, but also in the asymmetric quantum Rabi-model which has no obvious symmetry [4]. The occurrence of conical intersections in the asymmetric Rabi-model provides indirect evidence that there should be a hidden symmetry. Here, we propose an experimental scheme to observe conical intersections in the energy landscape and the Berry phase in ultra- or deep-strongly coupled qubit-resonator systems. This will also provide a clue to understand the hidden symmetry in the system.

Quantum impurity physics meets circuit QED: observation of finite lifetime photons

ROMAN KUZMIN (Presenter), NICHOLAS GRABON, NITISH JITENDRAKUMAR MEHTA, University of Maryland, College Park, MOSHE GOLDSTEIN, Tel Aviv University, VLADIMIR MANUCHARYAN, University of Maryland, College Park

We report a new regime of quantum electrodynamics (QED) where a single photon acquires a finite lifetime due to spontaneous decay to many lower-frequency photons. This phenomenon is a hallmark of ultra-strong coupling between a sufficiently non-linear quantum system (the quantum impurity) and a continuum of 1D bosonic modes. While this situation is impossible in atomic physics, it is ubiquitously in the bosonic description of strongly-correlated 1D electronic systems. We implemented bosonic versions of two key quantum impurity models: the boundary sine-Gordon model and the Kondo model. Physically our system is a long section of a high-impedance transmission line (the bosons) connected to a single small capacitance Josephson junction (the BSG impurity) or to a fluxonium qubit (the Kondo impurity). The many-body correlation functions of these two quantum impurity problems can be extracted from the measured inelastic spectrum of microwave photons, which implements a quantum simulation of a classically difficult computational problem.

Cavity-free circuit quantum electrodynamics: interfacing a high-coherence qubit with propagating photons

YEN-HSIANG LIN (Presenter), HAONAN XIONG, Physics, Univ of Maryland-College Park, NATHANAEL PIERRE COTTET, Physics, Univ Lyon, ENS de Lyon, LONG NGUYEN, RAY MENCIA, AARON SOMOROFF, VLADIMIR MANUCHARYAN, Physics, Univ of Maryland-College Park

We report experiments with a fluxonium artificial atom directly connected to a 1D transmission line. Unlike conventional circuit quantum electrodynamics (cQED), here there is no extra cavity mode degree of freedom buffering the qubit from the readout environment. Thanks to the highly anharmonic fluxonium spectrum, we simultaneously achieved a strong coupling of a high-frequency “cycling” readout transition (0→3 or 1→2) to the traveling waves and a nearly complete suppression of the spontaneous emission of the low-frequency “clocking” qubit transition (0→1). Notably, the cycling dynamics during the readout is confined to a small Hilbert space of a single quantum degree of freedom, and it can be understood within a minimal optical pumping model. Our system realizes the simplest possible interface between a highly-coherent qubit and propagating photons for constructing quantum communication networks.
Experimental Demonstration of Quantum Error Detection with a Small Surface Code

CHRISTIAN KRAGLUND ANDERSEN (Presenter), ANTS REMM, STEFANIA LAZAR, NATHAN LACROIX, SEBASTIAN KRINNER, GRAHAM J. NORRIS, MIHAI GABUREAC, CHRISTOPHER EICHLER, ANDREAS WALLRAFF, ETH Zurich — One of the most promising approaches for quantum error correction is the surface code, which consists of a $d \times d$ grid of data qubits combined with a set of ancilla qubits. The surface code implements a distance-$d$ quantum error correction code that allows for the detection of $d-1$ errors per stabilizer-measurement cycle. The smallest non-trivial surface code that allows for complete quantum error detection of a logical qubit subspace is the $d=2$ surface code, consisting of 4 data qubits and 3 ancilla qubits for the stabilizer measurements. Here we present experimental results obtained on a small seven-qubit surface code device implemented in superconducting circuits. We present measurements of all three stabilizers with high fidelity and repeated detection of errors on the data qubits using the stabilizer readout.

We acknowledge support by the ODNI, IARPA, via grant W911NF-16-1-0071, by NCCR QSIT, the EU Flagship H2020-FETFLAG-2018-03 project 820363 OpenSuperQ and by ETH Zurich.

Evaluation of the Performance of a 7-Qubit Surface Code

ANTS REMM (Presenter), CHRISTIAN KRAGLUND ANDERSEN, STEFANIA LAZAR, NATHAN LACROIX, SEBASTIAN KRINNER, GRAHAM J. NORRIS, MIHAI GABUREAC, CHRISTOPHER EICHLER, ANDREAS WALLRAFF, ETH Zurich — One of the promising approaches to fault tolerant quantum computation is based on the surface code. The existence of an error rate threshold, below which increasing the code size exponentially suppresses logical errors, has been shown for many common error mechanisms [R. Raussendorf and J. Harrington, Phys. Rev. Lett. 98, 190504 (2007)]. In this talk we analyse the physical error mechanisms of a seven-qubit superconducting quantum device on which we implement the elementary operations required for a surface code. By repeated stabilizer measurements we implement a distance $d=2$ surface code enabling the detection of any single-qubit error. We identify the error mechanisms which have the most significant effect on the logical error rate. We further discuss how to extend our scheme to larger distance surface codes given the current performance of our device.

We acknowledge support by the ODNI, IARPA, via grant W911NF-16-1-0071, by NCCR QSIT, the EU Flagship H2020-FETFLAG-2018-03 project 820363 OpenSuperQ and by ETH Zurich.
9:36AM W16.00009: Real-time decoding of repeated stabilizer measurements in a bit-flip code

* DIEGO RISTÈ (Presenter), LUKE GOVIA, Raytheon BBN Technologies, BRIAN DONOVAN, Systems & Technology Research, SPENCER FALLEK, WILLIAM KALFUS, Raytheon BBN Technologies, MAIKA TAKITA, ANTONIO D CORCOLES, MARKUS BRINK, NICHOLAS T BRONN, JERRY M. CHOW, IBM Thomas J. Watson Research Center — Although qubit coherences and gate fidelities are continuously improving, logical encoding is essential to achieve fault tolerance in quantum computing. In most encoding schemes, correcting or tracking errors throughout the computation is necessary to implement a universal gate set without delaying the processor. Here we present a classical control architecture for the fast extraction of errors based on multiple rounds of stabilizer measurements, and subsequent optional correction. We demonstrate its application on a minimal bitflip code with five transmon qubits, showing that error tracking based on multiple stabilizer rounds is superior to round-by-round correction, while introducing minimal latency. This co-processing of classical and quantum information will be crucial in running a logical circuit at its full speed to outpace error accumulation.

9:48AM W16.00010: Real-time Quantum Error Correction for a Surface-Code Logical Qubit

*MIGUEL MOREIRA (Presenter), BRIAN M TARASINSKI, JORDY GLOUDEMANS, VIACHESLAV P. OSTROUKH, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, WOUTER VLOTHUIZEN, QuTech, Netherlands Organization for Applied Scientific Research, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — Achieving fault-tolerant universal quantum computation hinges on performing multi-round quantum error correction in real time. Several technical challenges, from instruction bandwidth to timing considerations, make it challenging to engineer a control system capable of real-time error correction. We present a control architecture for surface code with a tightly-coupled real-time quantum error decoder. We demonstrate real-time decoding of error syndromes for a Surface-17 logical qubit satisfying experimental timing constraints. We present the realization of multiple error decoding strategies and compare the hardware resources required for each implementation.

*This research is funded by IARPA (U.S. Army Research Office Grant No. W911NF-16-1-0071), Intel Corporation, and QuTech.
10:00AM W16.00011: Continuous Parity Measurement and Error Correction*  WILLIAM LIVINGSTON (Presenter), MACHIEL S BLOK, JUAN ATALAYA, University of California, Berkeley, RAZIEH MOHSENINIA, Univ of Southern California, JING YANG, ANDREW N JORDAN, University of Rochester, JUSTIN DRESSEL, Chapman University, IRFAN SIDDIQI, University of California, Berkeley — In a multi-qubit system, performing continuous measurements of joint properties such as parity allows us to study the collapse dynamics of multipartite states. Simultaneous parity measurements in a three-qubit system also act as continuous stabilizer detection for a quantum error correction code, allowing us to observe a single qubit flip in real time. The parity of two superconducting transmons may be directly measured without qubit ancilla by coupling them to a single readout resonator, using identical dispersive coupling chis much larger than the resonator bandwidth kappa. Using a chip with three qubits and connecting each of two pairs to a parity readout resonator, we implement the two parity measurements needed to perform the conventional three-qubit bit-flip code. We control the qubits from a field programmable gate array board which also continuously monitors the parity, allowing for low latency correction pulses to be applied when a qubit flip occurs.

*This work was funded by the Army Research Office.

10:12AM W16.00012: Topological and subsystem codes on low-degree graphs with flag qubits  GUANYU ZHU (Presenter), CHRISTOPHER CHAMBERLAND, THEODORE YODER, JARED HERTZBERG, ANDREW CROSS, IBM Tj Watson Research Center — In this work we introduce two code families, the heavy hexagon code and heavy square code. Both code families are implemented by assigning physical data and ancilla qubits to both vertices and edges of low degree graphs. Such a layout is particularly suitable for superconducting qubit architectures to minimize frequency collision and crosstalk. In some cases, frequency collisions can be reduced by several orders of magnitude. The heavy hexagon code is a hybrid surface/Bacon-Shor code mapped onto a (heavy) hexagonal lattice whereas the heavy square code is the surface code mapped onto a (heavy) square lattice. In both cases, the lattice includes all the ancilla qubits required for fault-tolerant error-correction. Naively, the limited qubit connectivity might be thought to limit the error-correcting capability of the code to less than its full distance. Therefore, essential to our construction is the use of flag qubits. We modify minimum weight perfect matching decoding to efficiently and scalably incorporate information from measurements of the flag qubits and correct up to the full code distance while respecting the limited connectivity. Simulations show that high threshold values for both codes can be obtained using our decoding protocol.
Qubit leakage is present in leading quantum computing platforms, including superconducting transmon qubits. These errors fall outside the stabilizer formalism of quantum error correction (QEC), thus constituting a threatening error source for fault tolerance. While the performance of QEC codes, such as the surface code, has been investigated for simplistic leakage error models, an analysis with respect to a physically-motivated leakage error model for transmons has not been undertaken so far. In this work, we employ realistic full-trajectory simulations of the CZ gate in a transmon system (the dominant source of leakage in this system). We find novel effects within the leakage subspace of two transmons, including leakage mobility and leakage conditional phases. We use this in density-matrix simulations of the distance-3 surface code Surface-17 and study the leakage build-up, its lifetime, and how leaked qubits spread errors onto neighboring qubits.

Detection and mitigation of leakage in simulations of a transmon implementation of the surface code, Part 2: Scalable Hidden Markov models for the identification of leakage

BORIS VARBANOV (Presenter), FRANCESCO BATTISTEL, QuTech, Delft University of Technology - Netherlands, BRIAN M TARASINSKI, VIACHESLAV P. OSTROUKH, QuTech and Kavli Institute of Nanoscience, Delft University of Technology - Netherlands, THOMAS O'BRIEN, Instituut-Lorentz for Theoretical Physics, Leiden University - Netherlands, BARBARA MARIA TERHAL, QuTech; JARA Institute for Quantum Information, Delft University of Technology - Netherlands; Forschungszentrum Jülich - Germany, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology - Netherlands — The detection and mitigation of leakage, a threatening error source for stabilizer quantum error correction (QEC) on leading physical hardware, is an important step towards demonstrations of fault tolerance. We explore the effects of leakage on the performance of the distance-3 surface code Surface-17 by performing density-matrix simulations, employing realistic error models for transmon qubits in a circuit QED processor. We demonstrate the indirect detection of leakage via a network of local, independent and scalable Hidden Markov models. We show that post-selecting on detection of leakage restores the logical fidelity of the encoded information. We explore the integration of leakage detection into a minimum-weight perfect-matching decoder.

Friday, March 6, 2020 8:00 AM - 11:00 AM

Session W17 DQI: Quantum Machine Learning II

8:00AM W17.00001: Advances in Quantum Reinforcement Learning [Invited] VEDRAN DUNJKO (Presenter), Leiden — Vedran Dunjko has made key advances in understanding how reinforcement learning can assist in quantum computing and quantum error correction.
**8:36AM W17.00002: Artificial Spiking Quantum Neural Networks**  
LASSE KRISTENSEN  
(Presenter), Department of Physics and Astronomy, Aarhus University, MATTHIAS DEGROOTE, Department of Chemistry, University of Toronto, PETER WITTEK, Rotman School of Management, University of Toronto, ALAN ASPURU-GUZIK, Department of Chemistry, University of Toronto, NIKOLAJ T. ZINNER, Department of Physics and Astronomy, Aarhus University — Within the realm of classical computing, the paradigm of artificial spiking neural networks has found a wide range of applications in settings where the temporal aspects of such networks are advantageous, such as in time-series prediction and signal analysis. In this talk, we will present a class of simple quantum spin-network models inspired by this classical paradigm, combining both an explicit neural network structure and explicit temporality through quantum evolution, and with the inherent ability to operate on quantum data as input. A set of neuron-like building blocks for such networks will be presented, and a network combining these objects into a structure capable of comparing pairs of Bell states will be proposed, a task with applications in quantum certification. Finally, a few comments on inherent properties related to the generation of entanglement and measurement back-action through these networks will be given.

The content of this talk is based on the arXiv-preprint 1907.06269

---

**8:48AM W17.00003: A Path Towards Obtaining Quantum Advantage in Training Classical Deep Generative Models with Quantum Priors**  
WALTER VINCI (Presenter), NASA Ames Research Center, LORENZO BUFFONI, University of Florence, HOSSEIN SADEGHI, D-Wave Systems Inc., DANIEL O’CONNOR, University College London, EVGENY ANDRIYASH, MOHAMMAD AMIN, D-Wave Systems Inc. — A class of quantum-classical hybrid machine-learning algorithms can be obtained by integrating classical deep generative models with quantum probability distributions as 'priors' over their latent variables. We introduce a hybrid implementation of variational autoencoders (QVAE) and also present a technique to hybridize flow-based invertible generative models. We demonstrate the use of D-Wave quantum annealers as physical simulators of quantum Boltzmann machines (QBM) to perform quantum-assisted training of QVAE. Latent-space QBM develop slowly mixing modes, opening a path to obtain quantum advantage in generative modeling with available quantum devices.

9:00AM W17.00004: Experimental demonstration of quantum-enhanced machine learning in NV center system  
WENGANG ZHANG (Presenter), XIAOLONG OUYANG, XIANZHI HUANG, DONGLING DENG, LUMING DUAN, Tsinghua University — We demonstrate the quantum-enhanced supervised classification of vectors in an NV center system using the algorithm of Lloyd, Mohseni and Rebentrost [arXiv:1307.0411 (2013)]. A $^{13}$C nuclear spin is employed to encode the vectors with the spin-triplet state of the NV center as an ancilla. We design efficient methods to prepare the initial electron-nuclear entangled state within the coherence time $T_2^*$ of the electron spin, and then compute the distance between the test vector and the center of each class by measuring the level population through maximum likelihood estimation. Our experiment allows more than one reference vectors in each class, thus forms an important enabling step toward quantum-enhanced machine learning.

9:12AM W17.00005: Cost function embedding and dataset encoding for machine learning with parameterized quantum circuits* 
SHUXIANG CAO (Presenter), University of Oxford, LEONARD P WOSSNIG, Computer Science, University College London, BRIAN VLASTAKIS, PETER J LEEK, University of Oxford, EDWARD GRANT, Computer Science, University College London — Machine learning is seen as a promising application of quantum computation. For near-term noisy intermediate-scale quantum (NISQ) devices, parametrized quantum circuits (PQCs) have been proposed as machine learning models due to their robustness and ease of implementation. However, the cost function is normally calculated classically from repeated measurement outcomes, such that it is no longer encoded in a quantum state. This prevents the value from being directly manipulated by a quantum computer for algorithms such as gradient estimation using the Hadamard Test. In this talk, we introduce a routine to embed a cost function for machine learning into a quantum circuit, which accepts a training dataset encoded in superposition or an easily preparable mixed state. We characterize the utility of such a routine using numerical simulations and introduce proof-of-principle experiments in an optimized superconducting qubit device.

9:24AM W17.00006: Physical-Layer Supervised Learning Assisted by an Entangled Sensor Network* QUNTAO ZHUANG (Presenter), Electrical & Computer Engineering, University of Arizona, ZHESHEN ZHANG, Materials Science & Engineering, University of Arizona — Many existing quantum supervised learning (SL) schemes consider data given in a classical description. There, however, also exist a multitude of SL tasks whose data are acquired by sensors, e.g., pattern classification based on data produced by imaging sensors. Solving such SL tasks naturally requires an integrated approach harnessing tools from both quantum sensing and quantum computing. We introduce supervised learning assisted by an entangled sensor network (SLAEN) as a means to carry out SL tasks at the physical layer. The entanglement shared by the sensors in SLAEN boosts the performance of extracting global features of the object under investigation. We leverage SLAEN to construct an entanglement-assisted support-vector machine for data classification and entanglement-assisted principal component analyzer for data compression. In both schemes, variational circuits are employed to seek the optimum entangled probe states and measurement settings to maximize the entanglement-enabled enhancement. We observe that SLAEN enjoys an appreciable entanglement-enabled performance gain, even in the presence of loss, over conventional strategies in which classical data are acquired by separable sensors and subsequently processed by classical SL algorithms.

*ONR, GeoFlow

9:36AM W17.00007: Quantum-inspired nonlocal parallel tempering with approximate tensor network contractions MASOUD MOHSENI, DANIEL EPPENS (Presenter), Google Inc., MAREK M RAMS, Marian Smoluchowski Institute of Physics,, Jagiellonian University, SERGIO BOIXO, HARTMUT NEVEN, Google Inc. — We use tensor networks to represent probability distribution of spin-glass models that are encoding combinatorial optimization problems. We then develop greedy approximation tensor contraction for efficient Gibbs sampling of the low energy states for structured quasi-2D spin-glass models. Our deterministic approach can reveal certain geometrical properties of such hard optimization problems known as “droplet excitations”. The knowledge of such droplets can be used to enhance traditional probabilistic Monte Carlo techniques. Specifically we provide two new cluster Monte Carlo techniques in which we combine tensor network contractions with “parallel tempering” (PT). In the first method the tensor networks provide certain high-quality initial states for PT instead of traditional random restarts. In the second method, the tensor network contraction provide droplet information that can be used for dynamical cluster updates unfreezing low-temperature replicas near a computational phase transition. We demonstrate several orders of magnitude improvement in time-to-solutions in comparison to local Monte Carlo techniques such as PT. We also observe significant improvement over commercial solvers, such as Gurobi, or other heuristic cluster PT approaches powered by iso-energetic moves.
Generative models are able to produce new data according to an underlying probability distribution that they learn from a given data set. Inspired by the probabilistic nature of quantum mechanics, we employ a generative model, known as the "Born machine", which uses quantum state representation and learns the joint probabilities over such quantum degrees of freedom. To represent the quantum states we train tensor network architectures that could provide efficient expressivity, training, and sampling when the quantum probability distribution has some local structure. Specifically, we train two types of tensor networks known as matrix product states (MPS) and tree tensor network (TTN) over both classical and quantum data. We first show that our TTN model can generate the MNIST handwritten digits efficiently. In the next step, we variationally train tensor network models to generate desired quantum entanglement produced by shallow quantum circuits given iterative input-output information from actual quantum hardware with typically unknown systematic and random errors.

The variational quantum eigensolver (VQE) is a leading near-term hybrid classical/quantum algorithm for calculating spectra of molecular Hamiltonians. As with any variational approach, its performance depends sensitively on the selection of an appropriate variational form. Recent work has detailed the effectiveness of ADAPT-VQE, an adaptive approach to VQE in which the variational form is grown iteratively, resulting in ansatze which yield high performance with minimal numbers of variational parameters. This approach, however, is quantum resource intensive, requiring many quantum circuit executions and state measurements to grow the ansatze. Here we present RNN-VQE, a machine learning model which uses recurrent neural networks to learn and quickly generate effective variational ansatze for VQE.
10:12AM W17.00010: Measuring Correlation Scaling in Images via Logistic Regression*  IAN CONVY (Presenter), WILLIAM HUGGINS, BIRGITTA K WHALEY, Chemistry, University of California, Berkeley — It is well known in quantum many-body physics that local Hamiltonians often have ground states whose entanglement entropies scale with the boundary of the bipartition (known as an "area law"), allowing them to be characterized efficiently using tensor networks. Given recent interest in using tensor network models for machine learning, we explore whether correlations in classical image data may possess analogous scaling behavior in the mutual information (MI) between bipartitions of the pixels. Building on techniques developed in the context of generative machine learning, we recast the MI estimation problem as logistic regression on samples drawn from the joint and marginal distributions of the image partitions. We test the accuracy of our model using Gaussian Markov random fields designed to have analytic boundary law and volume law scaling patterns, and perform regression on the well-known MNIST and CIFAR image datasets to evaluate the MI scaling in real-world images. We find that our model can capture the scaling behavior of the Markov random fields even with hundreds of pixels, while the large MI values found in CIFAR and MNIST remain challenging to reproduce.

*This work was supported by a grant from Siemens Corporation.

10:24AM W17.00011: Quantum neural network for generating quantum states*  RONGXIN XIA (Presenter), SABRE KAIS, Department of Chemistry, Department of Physics and Astronomy, and Birck Nanotechnology Center, Purdue University — Quantum machine learning has become a research focus in quantum computation nowadays. One direction of quantum machine learning is developing quantum neural network based on parametrized quantum circuits. However, previous works of quantum neural network based on parameterized quantum circuits provide few systemic and general ways to introduce non-linear activation function. In the meantime, non-linear activation function is one of the most important parts in classical neural network as it makes the multi-layer neural network not work as a single layer. In this work, we give a new construction of quantum neural network to introduce non-linear activation functions. To demonstrate the new approach, we present results of using the quantum neural network to generate ground states as well as excited states for different quantum chemistry systems. The generated states approximate exact states closely, which not only show the potential of the new construction of quantum neural network, but also may be a new approach to solve quantum chemistry problems.

*We acknowledge the funding from the U.S. Department of Energy, Office of Basic Energy Sciences under award number DE-SC0019215.
10:36AM W17.00012: Gauge Enhanced Quantum Criticality and Time Reversal Domain Wall: SU(2) Yang-Mills Dynamics with Topological Terms  
YUNQIN ZHENG (Presenter), Princeton University, YIZHUANG YOU, Department of Physics, University of California, San Diego, JUVEN C WANG, Center of Mathematical Sciences and Applications, Harvard University — We study the low energy dynamics of the four siblings of Lorentz symmetry enriched SU(2) Yang-Mills theory with a theta term at $\theta = \pi$. Since there exists a mixed anomaly between time reversal symmetry and the center symmetry, the low energy dynamics must be nontrivial. We focus on two possible scenarios: 1) time reversal symmetry is spontaneously broken by the two confining vacua, and 2) the low energy theory describes a U(1) spin liquid which is deconfined and gapless while preserving time reversal symmetry. In the first scenario, we first identify the global symmetry on the time reversal domain wall, where time reversal symmetry in the bulk induces a Z2 unitary symmetry on the domain wall. We explore how the Lorentz symmetry and the unitary Z2 symmetry enriches the domain wall theory. In the second scenario, we relate the symmetry enrichments of the SU(2) Yang-Mills to that of the U(1) spin liquids. This further opens up the possibility that SU(2) QCD with large and odd flavors of fermions could be a second order phase transition between two phases of U(1) spin liquids as well as between a U(1) spin liquid and the a trivial paramagnet, where the gauge symmetry is enhanced to be non-Abelian at and only at the transition. We name them as Gauge Enhanced Quantum Critical Points.

10:48AM W17.00013: Robust Decomposition of Quantum States  
JONATHAN MOUSSA (Presenter), Molecular Sciences Software Institute — We show that quantum states over multiple subsystems can be recursively decomposed into states on one fewer subsystem and quantum operations that extend the state onto the omitted subsystem. This decomposition is robust in the sense that dephasing errors on subsystems between operations do not alter the marginal state on error-free subsystems. By restricting the form of these operations to a truncated cluster expansion, their classical simulation cost is reduced to the cost of simulating the maximal clusters. Such simulations provide direct access to independent statistical samples of observables and systematically improvable lower bounds on the von Neumann entropy, which together enable variational free energy minimization.

Session W18 DSOFT: Bio-Mineralization, Hydration & Hardening in Colloidal Gels: Building Solid Materials Out of Soft Gels 205 - Tag(s): Invited
8:00AM W18.00001: Compositional and structural gradients in dental enamel: from nanoto microscale* [Invited]  KAREN DEROCHER, PAUL JM SMEETS, Northwestern University, BERIT GOODGE, MICHAEL J ZACHMANN, Cornell University, PRASANNA VENKATARAMAN BALACHANDRAN, University of Virginia, LINUS STEGBAUER, MICHAEL COHEN, LYLE M GORDON, JAMES RONDINELLI, Northwestern University, LENA FITTING KOURKOUTIS, Cornell University, DERK JOESTER (Presenter), Northwestern University — Dental enamel has evolved to bear large masticatory forces, resist mechanical fatigue, and withstand wear over decades of use. Functional impairment or loss, as a consequence of developmental defects or tooth decay, has a dramatic impact on health and quality of life. While the last decade has seen great progress in our understanding of enamel formation and the functional properties of mature enamel, attempts to repair enamel lesions or synthesize enamel in vitro have had limited success. This is partly due to the highly hierarchical structure of enamel and the additional complexities arising from chemical gradients that we are only beginning to understand. Herein we show, using atomic-scale quantitative imaging and correlative spectroscopies, that human enamel is comprised of crystalline apatite and a Mg-rich amorphous intergranular phase. Individual crystallites have core-shell structure. The core is comprised of two thin layers enriched in Mg flanking a region that is poor in Mg and enriched in Na. Fluoride is often also present in layers. The sandwich core is surrounded by a shell largely free of substitutional defects. A mechanical model of coherent crystallites based on DFT calculations predicts that significant residual stresses, with important implications for enamel dissolution, crystallite and tissue mechanical properties, and crystal growth processes during amelogenesis. In addition to these gradients at length scales from single digit to 10s of nanometers, we will report on systematic changes in average lattice parameters and coherence length across single enamel rods, i.e. length scales on the order of 1-10 µm.

ROSA ESPINOSA-MARZAL (Presenter), BINXIN FU, JOSUE LOPEZ-BERGANZA, CHING-WEI LEE, SIMON A ROGERS, University of Illinois at Urbana-Champaign — Marine organisms exploit varied physical and chemical interactions between calcium carbonate and organic additives to yield mineral-organic complexes that are not only visually stunning but also highly functional. Despite recent leaps in the understanding of these systems, knowledge of the relation between kinetics of mineral growth, microstructure of the composite and mechanical response is still lacking. Our aim is to mechanistically elucidate potential pathways that afford control of the mineralization pathway of hydrogels and of their microstructure, and yield composites with tunable mechanical response. Our previous studies demonstrated that the formation of amorphous calcium carbonate precursors (ACC) throughout agarose hydrogels is a diffusion-limited process, and therefore, it is strongly affected by the solution composition and by the hydrogel composition. In contrast, amorphous precursors in the hydrogel control tightly the inclusion of the polymer into calcite, and crystal morphology, as well as the rate of crystal growth, affording a uniform crystal growth throughout the hydrogels, in the absence of concentration gradients, over a wide range of solution conditions and hydrogel compositions. Based on these findings, we have extended these studies to phosphates, and show that amorphous precursors also modulate the mineralization kinetics quite tightly. Furthermore, the phosphate-mineralized hydrogels exhibit key advantages with regard to microstructure -as provided by hydroxyapatite nanosheets- and mechanical response, compared to the mineralized hydrogels in the absence of phosphates. The results of this work not only reveal an important mechanism underlying (bio)mineralization but it can also inspire new avenues to craft biomimetic materials.

Session W19 GMAG: Spin Ice - From Freezing to Cerenkov Radiation

Kate Ross, Colorado State University - Tag(s): Invited
Tuning dipolar interactions in artificial spin ices - From Ising to Potts spins

FRANCOIS MONTAIGNE (Presenter), DAMIEN LOUIS, MARYAM MASSOURAS, MICHEL HEHN, THOMAS HAUET, DANIEL LACOUR, Universite de Lorraine — Since the proposal in 2006 [1] to use nanomagnets patterned by top-down techniques to mimic "artificial spins", the studies of artificial spin systems has attracted wide interest [2]. As a matter of facts, the possibility to design "upon request" arbitrary network thanks to lithography and the possibility to determine completely the "spin" configuration with magnetic imaging offer a wide playground for statistical physics. Up to now only Ising spin systems have been studied. However, beyond Ising spins, statistical physics and condensed matter physics have shown the interest of other spin models like q-state Potts models (q different spin orientation) or even XY model (isotropic in plane orientation).

In this talk, we introduce the dipolar 4-state Potts model. It is shown that on a square lattice, depending on the angle between spins and lattice, the system present very different properties like antiferromagnetic order, spin ice state (2 in-2 out ice rule) and even dipolar ferromagnetism.

This model has been realized experimentally. At room temperature, the magnets present a uniform state with 4 equivalent directions. Upon heating at 350 °C the magnets switch from one direction to another. It is therefore possible to simply drive the system toward its ground state. The magnetic configurations determined by magnetic force microscopy reveals the importance of the dipolar coupling as the different expected ground states (antiferromagnetic, spin ice and ferromagnetic) are indeed observed [3]. It is noticeable that these very different properties are obtained with the same "spins" (magnetic elements) and same lattice. The exact process of magnetization evolution, differences with "Ising" systems and future prospects will be discussed.

Slow dynamics in classical and quantum spin ice systems

CLAUDIO CASTELNOVO (Presenter), Univ of Cambridge — The low temperature properties of magnetic systems with fractionalised point-like excitations are determined by the interplay between a small density of quasiparticles and the underlying spin degrees of freedom out of which they are borne. Spin ice materials are a case in point. Even in their simplest classical modelling, a dramatic slowing down is expected due to the excitations becoming exponentially sparse. Once more realistic details are taken into account, and in particular quantum fluctuations are included, the situation becomes far more complex and interesting. The phenomenology uncovered thus far includes the formation of long-lived metastable states, structural as well as correlation-driven disorder that alters the local quantum mechanical spin fluctuations, and a prominent freezing of the dynamics whose origin continues to elude our understanding. This talk presents a selection of results and observations that highlight the uniquely rich, tunable and experimentally accessible playground to study slow dynamics in frustrated magnetism offered by spin ice systems.
9:12AM W19.00003: Machine learning assisted analysis of neutron scattering: new insights into spin ice* [Invited]  DAVID TENNANT (Presenter), ANJANA SAMARAKOON, Oak Ridge National Lab, SANTIAGO GRIGERA, CONICET La Plata Argentina, ALEXANDER KIRSTE, PTB Berlin, BASTIAN KLEMKE, Helmholtz Center Berlin, LUDOVIC DC JAUBERT, CNRS-Bordeaux, CLAUDIO CASTELNOVO, Univ of Cambridge, RODERICH MOESSNER, MPIPKS Dresden — The macroscopic manifolds of ground states in highly frustrated magnets are responsible for their rich physical behavior. Thermal and quantum fluctuations within these manifolds gives rise to liquid states with remarkable properties which are receiving intense interest. An open question is, what is the fate of these liquid states as the system cools? To gain insight into this we have undertaken a comprehensive study of Dy$_2$Ti$_2$O$_7$. Dy$_2$Ti$_2$O$_7$ is well known as a prototypical spin ice material that shows a U(1) gauge liquid behavior with magnetic monopole quasiparticles. From a combination of neutron scattering, magnetic noise, and thermodynamic measurements we have developed a model for the material using machine learning. The analysis involves use of autoencoders to identify phases and by optimizing in the network’s latent space highly accurate interaction parameters are extracted. A key part of this analysis is the ability to discriminate artifacts from physical signals in the neutron scattering data and to perform analysis on three-dimensional diffuse data sets. The extracted model is shown to reproduce glass formation in the material and provides microscopic understanding of a range of observations including the arresting of order as freezing occurs and $1/f^\alpha$ magnetic noise. High performance computer modeling has also been used to map the development of short-range order and changes in dimensionality and topology in monopole pathways. Our results suggest ways in which spin glass formation could occur from simple interactions even without intrinsic disorder.

*The research was sponsored by the DOE Office of Science, Laboratory Directed Research and Development program (LDRD) of Oak Ridge National Laboratory, managed by UT-Battelle, LLC for the U.S. Department of Energy. (Project ID 9566). A portion of this research used resources at Spallation Neutron Source, ORNL.
MASAFUMI UDAGAWA (Presenter), Department of Physics, Gakushuin University — Fractionalization is one of the most remarkable phenomena in the systems of nontrivial topological character. Magnetic monopoles in quantum spin ice (QSI) give a typical example of fractional excitations, and a keen interest is focused on their role in dynamical and transport properties of QSI candidate materials. However, due to the fractional nature of excitations, magnetic monopoles behave quite differently from conventional excitations such as magnons, and their character still remains quite elusive. In this contribution, in order to understand the nature of magnetic monopoles, we address the anisotropic limit ($J^\pm \ll J^z$) of spin-1/2 quantum XXZ model defined on a pyrochlore lattice. In particular, we focus on the temperature region, $J^\pm^3/J^z^2 << T << J^\pm$, where the ground state spin ice manifold is still incoherent, while the monopole excitations already show coherent quantum motion. In this region, we obtained the local dynamical structure factor by the exact diagonalization of 32 site cluster [1]. The obtained spectrum shows a steep edge discontinuity at low energy attributed to the van Hove singularity of monopole spectrum, which results from the dimensional transmutation due to the coupling to background gauge field. We clarify the origin of this dimensional transmutation in terms of the state graph description, by mapping the monopole motion to a free particle Hamiltonian on a virtual Husimi cactus graph.

SIDDHARDH MORAMPUDI, Boston Univ, FRANK WILCZEK, Center for Theoretical Physics, MIT, CHRISTOPHER LAUMANN (Presenter), Boston Univ — Quantum spin liquids are low temperature phases of magnetic materials in which quantum fluctuations prevent the establishment of long-range magnetic order. These phases support exotic fractionalized spin excitations (spinons) and emergent gauge fields. In this talk, I will briefly review the basic theoretical picture of how a quantum Coulomb phase emerges in spin ice and then turn to recent results regarding the observable consequences in neutron scattering. The emergent Coulomb interaction modifies the threshold cross-section for spinon production dramatically, changing the weak turn-on expected from a mean-field treatment to an abrupt onset reflecting the basic coupling parameters. The slow photon typical in existing lattice models and materials suppresses the intensity at finite momentum and allows profuse Cerenkov radiation beyond a critical momentum. These features are broadly consistent with recent numerical and experimental results.

8:00AM W20.00001: Harmonic oscillation frequencies of cellular contractility support a wave shape model* [Invited]  MICHAEL E WERNER, DYLAN D RAY, COLEMAN BREEN, ADAM SATTLER, Univ of NC - Chapel Hill, FLORIAN JUG, Molecular Cell Biology and Genetics, Max Planck Institute, AMY SHAUB MADOX (Presenter), Univ of NC - Chapel Hill — Animal cell shape changes such as cytokinesis are driven by poorly understood rearrangements of the actomyosin cortical cytoskeleton. To gain novel insights into cell-autonomous cytokinetic contractility, we used the C. elegans zygote as a model cell and imaged cytokinesis with unprecedented temporal resolution. Cytokinetic ring closure underwent cycles of acceleration and deceleration. We quantified contractile oscillations via continuous wavelet transform and mode decomposition. Ring inward displacement dynamics were the composite of co-existing amplitude- and frequency-modulated wave modes with ~ 18, 36 and 72-second periodicity. The periodicities of speed oscillations were only subtly changed by depletion of a panel of conserved actomyosin regulators and structural components, but oscillation amplitudes were suppressed by reduction of force generation, and enhanced by reduction of network crosslinking. As suggested by the relationship of the modes’ periodicities as a fundamental frequency, a harmonic and a subharmonic, the range of speed oscillations was well described by a wave-shape model with a single time-varying amplitude, a single time-varying frequency, and a shape factor. Finally, to retain the spatial relationships among contracting segments of the cytokinetic ring, we performed mode decomposition in three dimensions on a space-time-frequency kymocube of our wavelet transform output. We found three major classes of frequency surfaces varying little over space and time. Principal component analysis of these two-dimensional modes confirmed that the frequencies of contractile oscillations are related as a harmonic and sub-harmonic around a fundamental frequency. We propose that the latter reflects the Rho pacemaker driving contractility, and that the harmonic is emergent due to non-linearities in the system. Dissipation of contractility within the network may explain the slower, sub-harmonic contractile oscillations.

8:36AM W20.00002: Actomyosin-driven mechanics of starfish oocytes*  
(Presenter), NIKA FAKHRI, Massachusetts Institute of Technology MIT — Actomyosin networks underlie most force generation by eukaryotic cells. These networks are driven out of equilibrium in part by myosin which crosslinks and exerts forces on actin filaments. While myosin’s role in force generation is well studied, how actin structure and dynamics influence the active mechanics of the networks during force generation is not understood. Here, we address this issue using oocytes from the starfish Patiria miniate. During maturation, the oocytes undergo surface contraction waves driven by the actomyosin cortex. Using pharmacological inhibitions, which target actin polymerization dynamics, we find that cellular deformation during the contraction wave is not a monotonic function of cortical actin density and is peaked near the wild type. This is reminiscent of in vitro actomyosin networks, which have been shown to have maximal contractility at intermediate levels of network connectivity. To test if this is also the case in starfish oocytes, we probe the oocyte’s mechanical properties and how these change under targeted molecular perturbations.

8:48AM W20.00003: Spatiotemporal dynamics of the neuronal cytoskeleton across scales during development*  
(KATE M O’NEILL (Presenter), EMILY K ROBINSON, WOLFGANG LOSERT, University of Maryland, College Park) — Neuronal structure is intrinsically tied to neuronal function because the spatial arrangement of the output (axon) and inputs (dendrites) of a neuron determines how it integrates into the neuronal network. A critical component of the cytoskeleton that drives neuronal morphology is actin, which is necessary for establishing connections (synapses) early in development to refining connections as networks mature. Using live confocal imaging, we study how the dynamics of actin change as cultures of in vitro primary rat cortical neurons develop. We employ two-dimensional Laplacian of Gaussian (LoG) filtering to identify neuronal processes and a pixel-based optical flow algorithm to track actin dynamics in developing neurons. We observe micron-scale actin dynamics in younger neurons (1-5 days in vitro) that clearly drive the pathfinding of growth cones, whereas older neurons display actin dynamics on a much smaller scale, confined to small regions of dendrites and to synaptic spines. Future work will further characterize these dynamics at key developmental timepoints.

9:00AM W20.00004: Computational model of mitotic spindle positioning in polarized cells
JEFFREY M MOORE (Presenter), ADAM R LAMSON, MATTHEW A. GLASER, MEREDITH BETTERTON, University of Colorado, Boulder — The microtubule cytoskeleton plays important roles during the cell life cycle, in events including mitotic spindle assembly, chromosome segregation, nuclear elongation, and spindle positioning. During cell division in budding yeast, interactions between astral microtubules and proteins at the cell cortex position the spindle and nucleus at the bud neck before cytokinesis. The spindle moves due to pulling forces on the microtubules generated by the minus-end-directed motor dynein, which are activated by binding to protein domains localized at the cell cortex. Both the asymmetric distribution of cortical dynein binding domains and microtubule buckling and stabilization are thought to be important for regulating spindle positioning, but how the interplay between microtubule dynamics and motor-driven pulling forces lead to proper positioning at the site of cytokinesis is not well understood. We present results from simulations of a minimal spindle positioning model in a polarized cell driven by interactions between astral filaments, motorized tethers, and cortical binding domains. Our results show how binding domain localization and filament dynamics affect spindle positioning in polarized cells.

9:12AM W20.00005: Flagellar length control in biflagellate eukaryotes: Cooperative phenomena of generating and regenerating the flagellum
SWAYAMSHREE PATRA (Presenter), IIT Kanpur, FRANK JULICHER, Max-Planck-Institute for the Physics of Complex Systems, DEBASHISH CHOWDHURY, IIT Kanpur — Chlamydomonas Reinhardtii is a biflagellate eukaryote which generates its own flagella of correct length (in a controlled manner) after cell division (ciliogenesis), regenerates both of them after deflagellation and regenerates the amputated flagellum. A pool of proteins needed to form, maintain and regenerate the flagella is synthesized in the cell body. These proteins are transported from the pool to the distal tips for flagellar assembly and those released from the flagellar tip due to ongoing turnover are shuttled back to the pool by intraflagellar transport trains. Combining the dynamics of trafficking intraflagellar transport trains, the pool and the kinetics of flagellar assembly and disassembly, we have developed a stochastic model for understanding the collective phenomena of flagellar length control. Our model accounts for all key features of experimentally known phenomena which include ciliogenesis, resorption, deflagellation as well as regeneration after selective amputation of one of the two flagella. Moreover, we show how the communication among both the flagella through the common pool influences the nature, duration and extent of regeneration under different circumstances and governs the correlations between the fluctuating lengths of the two flagella.
9:24AM W20.00006: Bridging microtubules promote centering of kinetochores by length-dependent pulling forces  AGNEZA BOSILJ, Department of Physics, Faculty of Science, University of Zagreb, Zagreb, IVA TOLIĆ, Ruder Bošković Institute, Zagreb, NENAD PAVIN (Presenter), Department of Physics, Faculty of Science, University of Zagreb, Zagreb — The mitotic spindle, by exerting forces, segregates chromosomes into two daughter cells during cell division. During metaphase, chromosome are positioned in the equatorial plane of the mitotic spindle, which is necessary to prevent lagging chromosomes and abnormal nuclear envelope reformation. It has been proposed that two centering mechanisms play a key role here, microtubule catastrophe promoted by kinesin-8 motors and pushing forces exerted by chromokinesins. Here we show, by combining a theoretical model and quantitative experiments, that kinetochore microtubules cross-linked by bridging microtubules exert length-dependent centering pulling forces. Our model also shows that length-dependent catastrophe and rescue regulated by motor proteins and passive cross-linkers are necessary for well defined length of microtubules and their antiparallel overlap, respectively. We predict that stable antiparallel overlaps exert length-dependent forces on kinetochores to navigate their positioning in the center of the metaphase plate.

9:36AM W20.00007: Effects of rapid impact loading on neural progenitor cells*  DELANY RODRIGUEZ, LUKE H. C. PATTERSON, JENNIFER L. WALKER, University of California, Santa Barbara, EVELYN RODRIGUEZ-MESA, KEVIN SHIELDS, JOHN S. FOSTER, Owl Biomedical, ADELE M. DOYLE, University of California, Santa Barbara, KIMBERLY L. FOSTER, Tulane University, MEGAN VALENTINE (Presenter), University of California, Santa Barbara — We recently developed a high throughput microfluidic MEMS device, the μHammer, to subject individual cells to rapid impact loading, at strains of up to 40% over typical impact durations of ~10 μs. With the μHammer, we can subject >100,000 cells to controlled impacts per experiment, allowing measurement of both single cell properties and statistically-relevant population averages. Cells are collected post-impact and cultured, allowing the time course of damage and recovery to be determined through subsequent analysis. Here, we report the range of cytoskeletal structures and dynamics observed in neural progenitor cells (NPC) before and after sub-lethal impacts, as assessed by high-resolution confocal microscopy. These studies establish important baseline properties of the NPC cytoskeleton, while providing insight into the effects of traumatic injuries on cells and tissues.

**9:48AM W20.00008: Assemblies of Calcium/Calmodulin Dependent Kinase II with Actin and Their Dynamic Regulation by Calmodulin in Dendritic Spines**

QIAN WANG, MINGCHEN CHEN, NICHOLAS SCHAFFER, CARLOS BUENO, Rice University, SARAH SONG, University of Texas, Health Science Center, ANDY HUDMON, Purdue University, PETER G WOLYNES, Rice University, NEAL WAXHAM, University of Texas, Health Science Center, MARGARET CHEUNG (Presenter), Univ of Houston — Calcium-calmodulin dependent kinase II (CaMKII) plays a key role in the plasticity of dendritic spines. Calcium signals cause calcium-calmodulin to activate CaMKII, which leads to remodeling of the actin filament (F-actin) network in the spine. We elucidate the mechanism of the remodeling by combining computer simulations with protein array experiments and electron microscopic imaging, to arrive at a structural model for the dodecameric complex of CaMKII with F-actin. The binding interface involves multiple domains of CaMKII. This structure explains the architecture of the micron-scale CaMKII/F-actin bundles arising from the multivalence of CaMKII. We also show that the regulatory domain of CaMKII may either bind calmodulin or F-actin, but not both. This frustration along with the multipartite nature of the binding interface allows calmodulin transiently to strip CaMKII from actin assemblies so that they can reorganize. This observation therefore provides a simple mechanism by which the structural dynamics of CaMKII establishes the link between calcium signaling and the morphological plasticity of dendritic spines.

**10:00AM W20.00009: A generalized clutch model to explain cell adhesion mechanics**

CHIARA VENTURINI, PABLO SAEZ (Presenter), Univ Politecnica de Catalunya — Integrin-based cell adhesion is a key mechanism in a large number of physiological processes and diseases. The composition and nanoscale organization of adhesion complexes have shown that the integrin-talin-actin chain plays a central role in the formation of small nascent adhesion and further maturation into focal adhesions. The role of ligand spacing and substrate rigidity has been also clearly demonstrated. Clutch models have been widely used to describe how cell adhesion works. However, they have not been capable of rationalizing many of the aspects described above; probably, because current clutch models are built under a number of simplifications of the adhesion mechanisms. Here, we extend the classical clutch model with a detail description of the talin rod as well as a space-dependent ligand distribution. We will show the minimal building block and adhesion length of focal adhesion. Following the same computational model, we will also show that focal adhesion forms for stiff substrates for low spacing while they form in soft substrates for large spacing. In summary, we proposed a model that unifies our current understanding of cell adhesion architecture and turnover while replicating previous experimental results.

**Session W21 DCP: Dynamics and Spectroscopy** 302 - Scott Sayres, Arizona State Univ
**8:00AM W21.00001: Broadband Microwave Spectroscopy of Lignin, Biofuels, and Their Pyrolysis Intermediates**

ALICIA HERNANDEZ-CASTILLO (Presenter), Molecular Physics, Fritz-Haber Institute, TIMOTHY SCOTT ZWIER, Chemistry, Purdue University, JOHN F STANTON, Chemistry, University of Florida — The chemical complexity of the fast-expanding list of potential plant derived biofuels pose a challenge to the scientific community seeking to provide a molecular understanding of their combustion. The direct relationship between molecular structure and rotational frequencies makes rotational spectroscopy highly structure specific; therefore, it is an ideal tool to characterize resonance-stabilized radicals. A high-temperature flash pyrolysis micro-reactor coupled with a supersonic expansion were used to generate the radicals, and a protocol called “strong-field coherence breaking (SFCB)” was used to analyze and speed up the line assignments. The 2-furanyloxy radical, a primary, resonance-stabilized radical formed by loss of a methyl group in the pyrolysis of 2-methoxy furan, was detected and its molecular parameters were determined. Furthermore, the phenoxy radical was investigated and structurally characterized by doing mass-correlated microwave studies. The new structural insights derived from analysis of the observed radicals and the new broadband rotational techniques will be discussed.

**8:12AM W21.00002: Making a pure beam of cold, state-selected particles with tuneable velocity**

JUTTA TOSCANO (Presenter), JILA, University of Colorado, Boulder, CHRISTOPHER J. RENNICK, National Physical Laboratory, UK, MICHAL HEJDUK, Physical and Theoretical Chemistry, University of Oxford, UK, TIMOTHY P. SOFTLEY, University of Birmingham, UK, BRIANNA R. HEAZLEWOOD, Physical and Theoretical Chemistry, University of Oxford, UK — Generating a controllable and pure source of molecular free-radicals or open-shell atoms has been one of the primary barriers hindering the detailed study of radical processes in the laboratory. Radicals are intrinsically highly reactive species that are challenging to isolate as a pure sample. As a result of this, detailed information on the kinetics and dynamics of elementary reactions involving radicals is extremely scarce.

In order to obtain a source of cold state-selected radicals, we combine a Zeeman decelerator, which slows down a subset of the radicals in a supersonic beam using pulsed magnetic fields, with a newly designed magnetic guide. The latter serves to purify the output of the decelerator, yielding a pure beam of cold, state- and velocity-selected radicals which is ideal for collision studies. The magnetic guide can be used after a Zeeman decelerator — or after any supersonic or effusive beam — to select only radical species with a specific desired velocity within a narrow velocity distribution, affording exceptional control over the properties of the particles.

8:24AM W21.00003: Production of O\textsubscript{2} from Ultrafast Pump-Probe CO\textsubscript{2} Photodissociation

JACOB GARCIA, RYAN SHAFFER, SCOTT SAYRES (Presenter), School of Molecular Sciences, Arizona State Univ — Carbon dioxide (CO\textsubscript{2}) is ubiquitous in our atmosphere and plays important roles in the life cycle, the greenhouse effect, and has potential applications in industrial processes as a chemical feedstock. Concern over the ever-increasing concentration of CO\textsubscript{2} in our environment has sparked a renewed interest in its photoabsorption dynamics. Photodissociation of CO\textsubscript{2} proceeds via multiple pathways depending on available energy, but commonly into CO and O. Here, ultrafast pump-probe spectroscopy is applied to study the excited state dynamics of CO\textsubscript{2}. Multiphoton excitation from a 35 fs pump laser impulsively transfers CO\textsubscript{2} from the X \rightarrow A state, preparing a bending vibrational wavepacket that influences its dissociation. Using mass spectrometry, we report changes in the fragmentation pattern as a function of time delay between the pump and probe laser pulses that reflect the vibrational motion. At well-defined time delays the dissociation oscillates between observable CO\textsuperscript{+} and O\textsubscript{2}\textsuperscript{+} fragments. The state relaxes to the ground state through a conical intersection.

8:36AM W21.00004: Non-adiabatic dynamics of the highly excited uracil cation

PATRICIA VINDEL ZANDBERGEN (Presenter), Rutgers University, Newark, SPIRIDOULA C MATSIKA, Department of Chemistry, Temple University, Philadelphia, NEEPA MAITRA, Rutgers University, Newark — Conical intersections facilitating non-adiabatic transitions have been found to play a key role in many photo-physical pathways. Radical cations of nuclear acid bases involved in charge transfer processes in DNA exhibit ultrafast dynamics governed by the existence of non-adiabatic couplings between excited states, where electron-nuclei coupled dynamics become important. We investigate the dynamics of the uracil cation, using highly-accurate coupled electron-ion dynamics methods and compare the results with more commonly used and less computationally intensive methods. In particular, trajectory-based surface hopping dynamics has proven to be a powerful tool to study coupled nuclear-electronic dynamics, but it does not properly account for quantum decoherence. Instead, a new coupled-trajectory approach has been proposed based on the exact electron-nuclear correlation from the exact factorization of a full molecular wave function. Numerical simulations with model systems have shown that the electron–nuclear coupling beyond the non adiabatic coupling terms can describe the quantum coherence properly. Within this method the quantum (de)-coherence in large molecules can be treated correctly at the same computational cost as the original surface hopping dynamics.

*DOE DE-SC0019394
8:48AM W21.00005: Feshbach-Dyson method for calculations of Auger decay rates
WOJCIECH SKOMOROWSKI (Presenter), ANNA KRYLOV, Univ of Southern California — Photon absorption in the X-ray domain generally leads to creation of highly excited species with core-electron vacancies. One of the major relaxation channels for such states is Auger decay - a process accompanied by spontaneous emission of free electron(s). While Auger decay in atoms and molecules has been known for long now, its predictive modeling still poses a significant challenge for theorists, as it intrinsically involves electronic continuum and many-body electronic states which are formally unbound (metastable).

Here we present a novel approach to calculate Auger decay rates and spectra based on Fano-Feshbach resonance theory and equation-of-motion coupled-cluster method (EOM-CCSD). We apply core-valence separation (CVS) technique and appropriate EOM models to obtain the correct (both initial and final) electronic states that occur in the Auger decay. Then, all Auger partial rates and energy corrections are computed via contraction of two-body Dyson functions (an equivalent of two-particle transition density matrix) with proper two-electron integrals involving a free electron orbital. Results of our benchmark calculations for atomic and molecular systems demonstrate that the presented method yields highly robust and accurate Auger parameters.

9:00AM W21.00006: Sub-20-fs broadband transient transmission spectroscopy in the UV range used to track primary photoinduced processes in thiobases* DANIELLE CRISTINA FERREIRA (Presenter), Física, UFMG, IRENE CONTI, Chimica Industriale, Università degli Studi di Bologna, ROCIO BORREGO-VARILLAS, Dipartimento di Fisica, Politecnico di Milano, ARTUR NENOV, Chimica Industriale, Università degli Studi di Bologna, LUCIA GANZER, CRISTIAN MANZONI, Dipartimento di Fisica, Politecnico di Milano, MARCO GARAVELLI, Chimica Industriale, Università degli Studi di Bologna, GIULIO CERULLO, Dipartimento di Fisica, Politecnico di Milano, ANA MARIA DE PAULA, Física, UFMG — Thiation induces a red-shift in the absorption spectrum and causes also a dramatic change in the photophysics with respect to the canonical nucleobases: while in nucleobases internal conversion from the photoexcited singlet state to the ground state mediated by a conical intersection is the main deactivation channel, the major relaxation pathway in thiobases is via the population of triplet states through an ultrafast intersystem crossing.

We employ ultrafast transient transmission spectroscopy in the near-UV range together with CASPT2/MM decay path calculations to unravel the excited-state lifetimes and decay pathways of thiouracils solvated systems. Their linear absorption spectra show overlapping bright states bands leading to different/parallel bright states decay pathways which we systematically track. This comprehensive evaluation together shows with different processes lead to the triplet population, both directly from the bright absorbing state and via the dark intermediate state.

Effect of polar molecules in spin crossover transition of Fe(H$_2$B(pz)$_2$)$_2$(bipy)  

THILINI EKANAYAKA (Presenter), PAULO S COSTA, GUANHUA HAO, University of Nebraska - Lincoln, ALPHA T. N’DIAYE, Lawrence Berkeley National Laboratory, LUCIE ROUTABOUL, Université Paul Sabatier, PIERRE BRAUNSTEIN, Université de Strasbourg, XIN ZHANG, JIAN ZHANG, QIN-YIN SHI, VICKI SCHLEGEL, University of Nebraska - Lincoln, BERNARD DOUDIN, Université de Strasbourg, AXEL ENDERS, Universität Bayreuth, PETER A DOWBEN, University of Nebraska - Lincoln — The spin crossover phenomenon is a temperature-induced transition of diamagnetic low spin (LS) state to paramagnetic high spin (HS) state. This transition can also be triggered by pressure, light or magnetic field. The Fe(II) spin crossover molecules are known to exhibit spin-crossover transition and we have shown that [Fe{H$_2$B(pz)$_2$}$_2$(bipy)] exhibits a temperature dependent spin-crossover transition from its LS state to the HS state, if the temperature is increased above approximately 160 K. The temperature dependence of the spin state occupancy Fe(II) complex can be affected by addition of polar molecules. The highly polar p-benzoquinonemonoimine zwitterion mixed with [Fe{H$_2$B(pz)$_2$}$_2$(bipy)] resulted in locking [Fe{H$_2$B(pz)$_2$}$_2$(bipy)] largely into a low spin state while addition of the di-ethyl derivative of p-benzoquinonemonoimine zwitterion mixed with [Fe{H$_2$B(pz)$_2$}$_2$(bipy)] did not appear to perturb the spin crossover transition. Addition of different polar molecule, benzimidazole with small dipole moment results in a re-entrant spin crossover transition.

Chemical reaction pathways estimated by a transformation between manifolds*  

MARK PALENIK (Presenter), United States Naval Research Laboratory — Chemical reaction pathways are often estimated by linearly interpolating a set of internal coordinates, such as bond lengths, between reactant and product structures. However, these internal coordinates are not generally isomorphic to atomic positions. For example, the number of bond lengths between N atoms is N(N−1)/2, which is usually greater than the 3N -6 coordinates that specify unique molecular geometries. If arbitrarily chosen, the bond lengths may not be physically realizable because they violate the triangle inequality. The solution used in the method known as linear synchronous transit is to employ a least squares minimization to approximate the desired set of generalized coordinates. However, this method is prone to generating discontinuous reaction pathways and outright failure at generating transition states. As an alternative, we treat the spaces of generalized coordinates and Cartesian coordinates as separate manifolds and locally transform a velocity vector from the former into the latter. This results in a first-order differential equation for the reaction path which is numerically integrable even when linear synchronous transit fails.

9:36AM W21.00009: Harvesting force and energy from the thermal motion of gas molecules
   TOM ZHU (Presenter), Tom Zhu — This presentation will describe a few methods for producing force and energy from the thermal motion of gas molecules. The force that exerts to a surface by the gas molecules in collision with the surface is due to the change of the momentum of the gas molecules. For an elastic collision, there is no lost in the kinetic energy of the gas molecule. The rebound speed is the same as the initial speed. However, for a real system, there is always lost or gain in the kinetic energy in the collision. The force exerted to the surface by the gas molecule in collision with the surface will be smaller if there is kinetic energy lost in the collision because lower rebound speed. We may design a high-lost surface and a low-lost surface to produce a net force, to do work with this force, and at the same time to lower the gas temperature which could be maintained by absorbing the heat from external source. The net result is transfer the heat to work which can be used to, for example, generate electricity, without producing the waste heat. The force can also be used as propulsion means, or to lift weight against the gravity, for example elevating the vehicle of the hyper-loop, without consuming any energy.

9:48AM W21.00010: Theory of Diffusion-Limited Reactions between Proteins in a Confined Environment*  CHEN LIN (Presenter), JOSEPH RUDNICK, ROBIJN F BRUINSMA, University of California, Los Angeles — Smoluchowski theory is extensively used to compute diffusion-limited reaction rates. It is based on the assumption that the reactants diffuse in from infinity. However, in many cases, this assumption fails for association reactions between biological macromolecules because they initially are confined inside a certain volume. Examples are association reactions between the linked subdomains of polyproteins, such as the Gag protein of HIV-1 and the assembly reactions of the molecular components of a virus in a "virus factories". Confinement greatly increases reaction rates. The talk will discuss how Smoluchowski’s theory is generalized to include a confined environment by introducing particles at the finite range.

10:00AM W21.00011: Chemical Cloaking*  FRANCESCO AVANZINI (Presenter), GIANMARIO FALASCO, MASSIMILIANO ESPOSITO, University of Luxembourg Limpertsberg — Any object embedded in a chemical gradient will typically distort it. We propose a strategy to hide an object in a gradient by coating it with a chemical reaction-diffusion network which can act as an active cloaking device. By controlling the concentration of some species in its immediate surroundings, the chemical reactions redirect the gradient as if the object was not there. We also show that the energy required to cloak can be extracted from the chemical gradient itself.

8:00AM W22.00001: Collective Robot Sex on Dynamic Resource Landscapes* [Invited] GAO WANG, Physics, Chongqing University, TRUNG PHAN, ROBERT AUSTIN (Presenter), Princeton University, JUNLE QU, Physics, Shenzen University, LIYU LIU, Physics, Chongqing University — We present a community of robots (``Jeeps''), which move over a resource landscape consisting of a large light-emitting diode (LED) light board whose local RGB intensity represents fitness, the local intensity can change due to robot local presence, making the landscape dynamic. Each Jeep has a basic digital genotype that carries the response (phenotype) to a given local fitness value, down-ward firing RGB sensors to measure local intensity and RGB color, and side-firing sensors and LEDs to communicate with neighboring Jeeps and engage in gene exchange (robot sex) with neighboring Jeeps. The Jeeps move in response to the current local fitness gradient given by the gradient in color intensity of their position on the light board. The jeeps ``genes’’ mutate at a rate inversely proportional to the color intensity at their position, breed genomes, and consume resources. This robot community has great generality which spans the space of many-body soft-matter physics, evolutionary biology and multi-cell disease states. We show robots on the dynamic landscape exhibit the self-organization of a collective, distributed intelligent complexity

8:36AM W22.00002: Delay Induced Swarm Pattern Bifurcations in Mixed Reality Experiments* VICTORIA EDWARDS, IRA SCHWARTZ, United States Naval Research Laboratory, KLEMENTYNA SZWAYKOWSKA, Georgia Tech Research Institute, JASON HINDES, United States Naval Research Laboratory, M. ANI HSIEH, University of Pennsylvania, IOANA TRIANDAF (Presenter), United States Naval Research Laboratory — Swarms of coupled mobile agents with communication-time delay are known to exhibit multiple dynamic patterns in space, which depend on interaction strength and delay. We demonstrate experimentally delay-induced bifurcations between spatio-temporal patterns with two separate robotic platforms using a mixed-reality framework, and isolate parameter regions where transitions occur. We show that multiple rotation patterns persist in the presence of collision-avoidance and uncertainties in the real robot dynamics. Moreover, we show the existence of multi-stability of rotational patterns not predicted by usual mean field dynamics. Our experimental results increase understanding of swarm-pattern robustness in the physical world, and may form the basis for improved reproducible models of swarms with physical robots.

8:48AM W22.00003: Robotic control of live jellyfish swimming to enhance propulsion*

NICOLE XU (Presenter), Stanford Univ, JOHN O DABIRI, California Institute of Technology — Animal locomotion and bioinspiration have the potential to expand the performance capabilities of robots, but current implementations are limited. Mechanical soft robots leverage engineered materials and are highly controllable, but these biomimetic robots consume more power than corresponding animal counterparts. Biological soft robots from a bottom-up approach offer advantages such as speed and controllability, but are limited to survival in cell media. Instead, biohybrid robots that comprise live animals and self-contained microelectronic systems leverage the animals’ own metabolism to reduce power constraints and body as a natural scaffold with damage tolerance. We demonstrate that by integrating onboard microelectronics into live jellyfish, we can enhance propulsion up to threefold, using only 10 mW of external power input to the microelectronics and at only a twofold increase in cost of transport to the animal. This robotic system uses 10 to 1000 times less external power per mass than existing swimming robots in literature, and can be used in future applications for ocean monitoring.

9:00AM W22.00004: Neuromuscular actuation of biohybrid motile bots*

MATTIA GAZZOLA (Presenter), ONUR ADYIN, XIAOTIAN ZHANG, TAHER SAIF, University of Illinois at Urbana-Champaign — The integration of muscle cells with soft robotics in recent years has led to the development of biohybrid machines capable of untethered locomotion. A major frontier that currently remains unexplored is neuronal actuation and control of such muscle-powered biohybrid machines. As a step toward this goal, we computationally designed, optimized, and implemented light-sensitive flagellar swimmers driven by on-board neuromuscular units. The body of the swimmer consists of a free-standing soft scaffold, skeletal muscle tissue, and optogenetic stem cell-derived neural cluster containing motor neurons. Neural stimulation triggers cyclic muscle contractions, driving time-irreversible flagellar dynamics, thereby providing thrust for untethered forward locomotion of the swimmer. Overall, this work demonstrates an example of a biohybrid robot implementing neuromuscular actuation and illustrates a path toward the forward design and control of neuron-enabled biohybrid machines.

Gait coordination and hydrodynamic performance of a quadriflagellate robophysical model  
TOMMIE ROBINSON (Presenter), KELIMAR DIAZ, YASEMIN OZKAN-AYDIN, Georgia Inst of Tech, KIRSTY WAN, Physics, University of Exeter, DANIEL I GOLDMAN, Georgia Inst of Tech — Multi-legged animals coordinate their limbs in distinctive patterns known as gaits. At the microscopic scale, quadriflagellate algae have been found to exhibit similar capabilities, coordinating their flagella to numerous rhythmic patterns to generate propulsion (Wan & Goldstein, 2016). To study quadriflagellate gait coordination, we developed a robophysical model which replicates quadriflagellate swimming at low-Reynolds number. We focus on two distinct gaits, the pronk and the trot, and explored the effects of flagellar orientation. When the flagella were oriented parallel to the cell body, forward motion was measured at 0.30±0.09 body lengths per gait cycle (BL/cyc) for the trot and at 0.19±0.03 BL/cyc for the pronk. Results are comparable to microorganisms' performance, where using the trot enables a higher speed (0.39±0.18 BL/cyc) than the pronk (0.18±0.05 BL/cyc). Surprisingly, when the flagella beat planes were perpendicular to the cell body, hydrodynamic performance improved significantly. Forward motion was measured at 0.66±0.13 BL/cyc for the trot and at 0.38±0.10 BL/cyc for the pronk. The results show that hydrodynamic performance is highly sensitive to swimming gait and flagellar orientation.

Locomotion of Soft Robots with Flexible Uni-flagellum in low Reynolds Number Fluid  
YAYUN DU (Presenter), University of California, Los Angeles — In nature, more than 90% of the bacteria propel using a single flagellum. The uniflagellar bacterium is comprised of a basal body and a flagellum, with a flexible hook connecting the two. Experimental and numerical observations indicate that the flexibility of the flagellum and its buckling are essential to change the swimming direction of the bacterium. We simulate the locomotion and deformation of the flagellated system in low Reynolds number conditions using a combination of the Discrete Elastic Rods and the Lighthill Slender Body Theory. The simulator shows that the robot is able to follow a prescribed three-dimensional trajectory by simply controlling the angular velocity of the flagellum. Inspired by natural bacterial structure, we fabricate a self-contained robot with a rigid and a motor-actuated elastomeric helical rod - our analog for the flagellum. With a motor, sensors, and a flexible control circuit embedded inside the head, the robot is able to follow a prescribed nonlinear trajectory by flagellum buckling. This robotic system demonstrates how structural instability can be harnessed for control of soft robots. It can also serve as an analog model for the natural bacterium to help us understand the fluid dynamics and biophysics underlying the propulsion of bacteria.
Simply controlled 1DOF adaptive soft robotic fish with multiple swimming behaviors

BANGYUAN LIU (Presenter), DANIEL I GOLDMAN, FRANK L. HAMMOND III, Mechanical Engineering, Georgia Inst of Tech —

Research in robotic grasping and soft machines has demonstrated that the use of “smart” mechanical structures in robotic systems can enable complex behaviors in dynamically changing, uncertain environments without the need for complicated, low-level control strategies. Upon that premise, we designed an 1DOF simply controlled robotic fish to explore the ability to achieve different locomotion patterns and passively generate adaptive swimming behaviors, simply by changing the servo’s output parameters. This 1-DOF, cable-driven robotic fish mimics the cascaded skeletal structure of soft spine tissue and hard spine bone seen in many fish species using a series of rigid segments and elastic joints. By changing the frequency of actuator motion, the robotic fish can not only change its lateral swimming pattern from oscillatory (2.3cm/s) to undulatory (11.0cm/s), but also change swimming direction from forward to backward and steering by biasing servo sweeping offset. Preliminary tests also show that the robot can swim downward to 7m successfully. In addition, the soft body helps the fish passively navigate through gaps and around obstacles without any feedback control, greatly enhancing the locomotion robustness in complex, cluttered environments.

Magnetic Actuation and Biological Sensing for Soft Micro Bio Robots*

ELIZABETH HUNTER (Presenter), EDWARD STEAGER, VIJAY KUMAR, University of Pennsylvania —

Small-scale robotic systems have the potential to drive technological development in biological research and medicine. Similar in size to insects or as small as a single cell, robots at these scales have manipulated cells and tissues, delivered therapeutics, and monitored biological environments. In order to perform these tasks, small-scale robots must be able to precisely locomote, take measurements, and use those measurements to make decisions. In this talk, we will discuss our distinct approach to actuation and sensing through the design and fabrication of soft micro bio robots composed of an organic hydrogel embedded with iron oxide nanoparticles. Due to its biocompatible, soft, and porous scaffold, this robot can transport and deliver chemical, cellular, and bimolecular payloads. We drive these robots using uniform, rotating magnetic fields across a range of rotational frequencies and within various fluids spanning three orders of magnitude in viscosity. Inspired by developments in synthetic biology, we genetically engineer sensors and processing units harbored within bacteria which are grown and function on-board the robot. These results showcase a hybrid strategy to actuate and integrate sensors on-board biologically relevant small-scale robots.

10:00AM W22.00009: Surface electrochemical actuators for micron-scale fluid pumping and autonomous swimming*  
MICHAEL REYNOLDS (Presenter), ALEJANDRO CORTESE, QINGKUN LIU, WEI WANG, MICHAEL CAO, DAVID ANTHONY MULLER, Cornell University, MARC MISKIN, University of Pennsylvania, ITAI COHEN, PAUL L MCEUEN, Cornell University — Recently, our group demonstrated a new class of electronic actuators called surface electrochemical actuators (SEAs). They use surface adsorption on a nanometer-thick cantilever to produce micron-scale radii of curvature with only fractions of a volt for actuation. Here we use SEAs to mechanically pump fluid at the micron-scale in several different geometries, both in the rigid panel (Purcell) and flexible (flagella) limits. We further discuss ongoing work to integrate SEAs with photovoltaics to create optically powered swimmers. Our ultimate goal is to create fully autonomous swimming microrobots with onboard electronics that can sense and respond to their environment in complex ways, yet are too small to be resolved by the naked eye.

10:12AM W22.00010: Material remodeling on granular terrain yields robustness benefits for a robophysical rover  
SIDDHARTH SHRIVASTAVA (Presenter), ANDRAS KARSAI, YASEMIN OZKAN-AYDIN, Georgia Inst of Tech, ROSS PETTINGER, Jacobs Engineering Group, WILLIAM BLUETHMANN, ROBERT O AMBROSE, Software Robotics and Simulation Division, NASA Johnson Space Center, DANIEL I GOLDMAN, Georgia Inst of Tech — Planetary rovers face the risk of entrapment during extraterrestrial exploration; these risks led NASA JSC to develop RP-15, a 300 kg rover capable of lifting and sweeping each wheel to execute a crawling behavior to escape entrapment. We created a miniature rover (2.1 kg) as a robophysical model of RP-15 and conducted systematic and automated experiments in a tilting bed containing a model granular medium (poppy seeds) to discover gaits which allow progress in various conditions. A combination of stepping, paddling, and wheeling (“RS gait”) allows climbing of loose granular slopes. The RS gait produces up to 4x greater tractive (drawbar) forces than wheel rotation alone on dry granular media. Drawbar results were validated through experiments on RP-15 at JSC. On slopes near the maximum angle of stability, a different gait used the front wheels as agitators while paddling the rear wheels to climb granular slopes successfully via controlled avalanching. While substrate disturbance typically hinders granular locomotion, using appropriate active granular reconfiguration can create localized granular structures that facilitate effective locomotion.
10:24AM W22.00011: Investigating Growth and Granular Fluidization in a Minimally Invasive Burrowing Robot

NICHOLAS NACLERIO (Presenter), Mechanical Engineering, University of California, Santa Barbara, MASON MURRAY-COOPER, ANDRAS KARS AI, YASEMIN OZKAN-AYDIN, DANIEL I GOLDMAN, Physics, Georgia Institute of Technology, ELLIOT W. HAWKES, Mechanical Engineering, University of California, Santa Barbara — Subterranean navigation is simply hard to do. The forces resisting underground motion are orders of magnitude higher than in air or water. Here we present a paradigm for minimally invasive robotic burrowing that results in movement an order of magnitude faster and deeper than previous low-impact approaches. Three principles enable this behavior: tip-extension to eliminate skin drag; granular fluidization to reduce form drag; and granular fluidization to control lift forces, a heretofore unstudied phenomenon. We present experimental results from controlled intrusion tests, studying the effects of fluidization direction, depth, and flow rate on both drag and lift. We show that lift is highly dependent on fluidization angle (i.e., the direction of air flow at the tip), decreasing as the fluidization is changed from horizontal to vertically downward, but drag reduction is insensitive to fluidization angle. With the use of pneumatic artificial muscles for steering, we demonstrate a functional burrowing robot, capable of navigating through sand and subterranean obstacles. Our results advance the understanding and capabilities of robotic subterranean locomotion, and the forces at play.

*This work is funded by a NASA Space Technology Research Fellowship, and the NSF (grant no. 1637446).

10:36AM W22.00012: Force response of running up a sand dune

BRIAN CHANG (Presenter), ALEXANDER GREENWOOD, WALEE D NOWAYTI, TONIA HSIEH, Temple Univ — Running up a sand dune is challenging because: (1) sand fluidizes when an external force exceeding the material yield stress is applied; and (2) at inclines approaching the angle of repose, the sand pile is increasingly unstable. In this study, we experimentally examined the impact force normal to a flat plate against a bed of poppy seeds, to determine how intrusion kinematics affect force generation. We tested a range of impact speeds (0.01-1.2 m/s), substrate angles, and impact angles. We identified two regimes with distinct force production patterns: 1) the gravity regime (<0.6 m/s) and 2) the inertial regime (>=0.6 m/s). In the gravity regime, the force-depth relation tends to diverge when comparing, for example, \((\theta_{\text{Intrusion}}, \theta_{\text{substrate}})=(40,0)\) and \((0,40)\). This difference is likely due to the propensity of the angled substrate to avalanche and reduce the material force response. On the other hand, the same set would converge at higher impact speeds, indicating that inertia dominates the system with particle movement instigated by the intruder exceeding that due to avalanching. This insight will help inform how animals and robots may navigate up sand dunes efficiently.
10:48 AM W22.00013: Generation GrowBots: learning from plants how to design self-morphing, growing robots  BARBARA MAZZOLAI (Presenter), EMANUELA DEL DOTTORE, LAURA MARGHERI, ALESSIO MONDINI, FRANCESCA TRAMACERE, Center for Micro-BioRobotics, Istituto Italiano di Tecnologia — Plants show unique capabilities of endurance and the ability to adapt their morphology to different environmental conditions. This plasticity is materialized through a variety of strategies, including moving-by-growing to search for nutrients, lights, or for external supports; rapid movements to capture prays; or passive movements for spreading seeds and fruits. Together with plant biologists and materials scientists, we are deeply investigating the biomechanics, materials, energy efficiency mechanisms, and behavior of a variety of plant species. For the first time, we have proposed a growing robot inspired by the movements and the behaviors of plant roots, able to create its own structure exploiting a 3D printer-like system integrated into its tip and depositing a thermoplastic material. With a focus on climbing plants, we are now taking inspiration from their material properties, biomechanics, and searching&anchoring capabilities for the design of new multi-functional, self-morphing, adaptable, growing robots. This new generation of plant-inspired “growbots”, able to self-create their structure, will find potential applications in a variety of sectors, including the exploration and monitoring of archaeological sites, future urban architecture, or extra-terrestrial areas.

Session W23 DBIO DPOLY DSOFT GSNP: Macromolecular Phase Separation in Biology III 304 - Patrick McCall, Max Planck Institute for the Physics of Complex Systems - Tag(s): Focus
8:00AM W23.00001: Valence and Patterning of Aromatic Residues Determine the Phase Behavior of Disordered Prion-Like Domains* [Invited] ALEX S HOLEHOUSE (Presenter), Department of Biochemistry and Molecular Biophysics, Washington University School of Medicine, ERIK W MARTIN, IVAN PERAN, Department of Structural Biology, St. Jude Children's Research Hospital, ROHIT V PAPPU, Department of Biomedical Engineering, Washington University in St. Louis, TANJA MITTAG, Department of Structural Biology, St. Jude Children's Research Hospital — Prion-like domains (PLDs) are intrinsically disordered protein regions that can drive functional liquid-liquid phase separation (LLPS) in vitro and in cells. Curiously, in many neurodegenerative diseases these regions contain mutations, leading to the formation of aggregates which are strongly correlated with disease pathology. An open question reflects the underlying molecular details that explain why some sequences form dynamic reversible assemblies, while others form solid-like aggregates. Here, we use multipronged biophysical approaches that integrates across simulation, experiment, and theory to address this question and uncover the physical principles underlying how an archetypal PLD derived from hnRNPA1 avoids aggregation in favor of LLPS. The extent of compaction of individual PLDs in dilute solutions mirrors the driving forces for temperature-dependent LLPS. This compaction is directly determined by the valence of aromatic residues in PLDs. As a result, the sequence-dependent phase behaviour for PLDs can be predicted using a stickers-and-spacers model. We uncover an evolutionary preference for aromatic residues to be uniformly distributed, as opposed to being clustered, along PLD sequences. We demonstrate that this non-random patterning drives reversible LLPS whereas its disruption leads to aggregation. We conclude that the valence and patterning of aromatic residues are key determinants of LLPS in PLDs. More generally, the valence and patterning of stickers in a stickers-and-spacers model offers a quantitative approach to relate sequence features to full binodal curves.

8:36AM W23.00002: A Random Heteropolymer Model of Protein Aggregation* MARTIN FALK (Presenter), Physics, University of Chicago, CATHERINE TRIANDAFILLOU, Biophysics, University of Chicago, ARVIND MURUGAN, Physics, University of Chicago — There have been dramatic developments in our ability to functionalize submicron scale objects with molecules enabling specific interactions between building blocks. To guide exploration in this design space, it is natural to look towards biology. In this context, the phenomenon of protein aggregation is a particularly appealing subject of study. Proteins navigate a complex and rugged energy landscape, and the design rules underlying their ability to avoid or take advantage of aggregated states in this landscape can be instructive for synthetic systems as well. We study a simple system consisting of a solution of random heteropolymers, and identify parameters that determine the structure of the aggregated phase.

*We acknowledge NSF-MRSEC 1420709 for funding.
8:48AM W23.00003: Actin(g) on phase separation* TINA WIEGAND (Presenter), Max Planck Institute for the Physics of Complex Systems, ANTHONY HYMAN, STEPHAN GRILL, Max Planck Institute of Molecular Cell Biology and Genetics — F-actin networks play a crucial role for cellular integrity and induction of shape changes during development and homeostasis. Actin polymerization is highly regulated by multiple pathways involving nucleating and sequestering factors, or mechanisms that regulate local monomer concentration. Recently, actin partitioning into biomolecular condensates has been reported as an additional mechanism to enhance polymerization kinetics. We reconstitute phase separated droplets of the components wsp-1 and the arp2/3 complex in vitro and study their interaction with actin. We find that actin partitions inside phase separated drops, where it polymerizes into fibers which extrude. We use this assay to study the effect of locally enhanced concentration on branched actin polymerization, the dynamics of active condensates and the mechanical interplay between established actin networks and biomolecular condensates. Our aim is to recapitulate the complex spectrum of kinetic behaviors observed for actomyosin in vivo.

*ELBE postdoctoral fellow program

9:00AM W23.00004: Elasticity dominated small molecule migration in polymer mixtures and gels* BUDDHAPRIYA CHAKRABARTI (Presenter), BISWAROOP MUKHERJEE, Univ of Sheffield — Surface segregation of the low-molecular weight component in a polymeric mixture leads to degradation of industrial formulations. We report a simultaneous phase separation and surface migration phenomena in oligomer-polymer and oligomer-gel systems following a temperature quench. We compute equilibrium and time varying migrant density profiles and wetting layer thickness using coarse grained molecular dynamics and mesoscale hydrodynamics simulations to demonstrate that surface migration in oligomer-gel systems is significantly reduced due to network elasticity. Further, phase separation processes are significantly slowed in gels, modifying the Lifshitz-Slyozov-Wagner (LSW) law. Our work allows for rational design of polymer/gel-oligomer mixtures with predictable surface segregation characteristics.

*EP/P07864/1
9:12AM W23.00005: Looped liquid-liquid coexistence in protein crystallization  JENS GLASER (Presenter), SHARON C GLOTZER, Univ of Michigan - Ann Arbor — The potential of proteins to realize enzyme crystals or act as nanomachines in dense assemblies makes them excellent candidates for the de-novo design of biological materials. In view of the notorious complexity of protein-protein interactions, simplified models of proteins treated as patchy particles offer a promising strategy to obtain insight into the mechanism of crystallization. Here we report liquid-liquid phase separation (LLPS) with a highly asymmetric coexistence region in a computational model of rubredoxin with real molecular shape. The coexistence region terminates in both an upper (UCST) and a lower (LCST) critical solution temperature, and the complex molecular shape explains the closed-loop behavior of the LLPS. A popular conceptual framework of protein crystallization predicts that nucleation is a two-step process controlled by a metastable liquid-liquid critical point. Here, LLPS occurs via the formation of ring-like nucleation precursors if and only if the proteins are capable of crystallizing. Our findings dispute the notion that the nucleation rate may be enhanced by indirectly controlling nucleation through an independent, metastable critical point. Conversely, we show that metastable LLPS is an essential feature of crystallization.

9:24AM W23.00006: Intermolecular association of the variable domain of dynamin related protein 1 in crowding conditions suggests a role in dynamin assembly  JAMES HARDEN (Presenter), AMMON POSEY, Biomedical Engineering, Washington University, MEHRAN BAGHERI, Univ of Ottawa, MEGAN HARWIG, NOLAN W. KENNEDY, Biochemistry, Medical College of Wisconsin, VINCENT HILSER, Program in Molecular Biophysics, Johns Hopkins University, R. BLAKE HILL, Biochemistry, Medical College of Wisconsin — Dynamins are an essential superfamily of mechanoenzymes that remodel membranes and often contain a “variable domain” (VD) important for regulation. For the mitochondrial fission dynamin, Drp1, a regulatory role for the VD is demonstrated by mutations that can elongate, or fragment, mitochondria. How the VD encodes inhibitory, and stimulatory, activity is an unresolved issue. This talk focuses on the behaviour of isolated VD from Drp1 isoform 1. Using spectroscopy methods (NMR and circular dichroism) and molecular dynamics (MD) simulations, this VD is shown to be intrinsically disordered (ID). Somewhat surprisingly, microscopy and light scattering studies also indicate that this VD in solution undergoes a liquid-liquid phase separation under the influence of an osmolyte that normally induces ID proteins to fold. Interestingly, these crowding conditions also enhance binding to cardiolipin, a mitochondrial lipid. MD simulations suggest this liquid-liquid phase separation arises from weak, multivalent interactions similar to other systems involving intrinsically disordered regions. These new findings support a model where the variable domain mediates phase separation that enables rapid tuning of Drp1 assembly necessary for fission.
9:36AM W23.00007: Model for intrinsically disordered proteins with a strong dependence of liquid-liquid phase separation on sequence  
ANTONIA STATT (Presenter), Materials Science and Engineering, University of Illinois, HELENA CASADEMUNT, Department of Physics, Harvard University, CLIFF BRANGWYNNE, ATHANASSIOS PANAGIOTOPoulos, Princeton University — Phase separation of intrinsically disordered proteins is important for the formation of membraneless organelles, or biomolecular condensates, which play key roles in the regulation of biochemical processes within the cells. In this talk, we present the phase separation behavior of different sequences of a coarse-grained model for intrinsically disordered proteins and show that they exhibit a surprisingly rich phase behavior. Both the fraction of total hydrophobic parts and the distribution hydrophobic parts are investigated. We observed not only conventional liquid-liquid phase separation, but also reentrant phase behavior, in which the liquid phase density decreases at lower temperatures. For some sequences, we also observe formation of open phases consisting of aggregates, rather than a normal liquid. These aggregates had overall lower densities than the conventional liquid phases and complex geometries with large interconnected fibril-like or membrane-like clusters. Minor alterations in the ordering of a given set of amino acids may lead to large changes in the overall phase behavior, a fact of significant potential relevance for biology.

9:48AM W23.00008: Quantitative droplet FRAP based on physical principles  
LARS HUBATSCH (Presenter), LOUISE JAWERTH, Max Planck Institute for the Physics of Complex Systems, ANTHONY HYMAN, Max Planck Institute for Cell Biology and Genetics, CHRISTOPH WEBER, Max Planck Institute for the Physics of Complex Systems — Fluorescence recovery after photobleaching (FRAP) is used to characterize a range of dynamic processes, for example binding kinetics and mobility of intracellular proteins, and recently liquid-liquid phase separation (LLPS) in vitro and in vivo. To gain an understanding of the relevant molecular mechanisms, data analysis must be based on the underlying physics. Strikingly, for FRAP of phase-separated droplets, no physical model from first principles has been derived, which severely restricts data interpretation. Here, we first derive a FRAP model from the physical principles underlying LLPS. Second, we use the full spatio-temporal imaging data within the droplet for fitting. This results in the following improvements: we can (i) distinguish the time scales of exchange through the droplet interface (set by bulk diffusion and boundary kinetics) from diffusion inside the droplet, (ii) quantify the impact of the interface (iii) provide improved measurements for several biologically important proteins, and (iv) use our analysis framework to explore several multi-component scenarios. Finally, we provide experimental guidelines for highly quantitative in vitro FRAP, e.g. the necessity to perform a full bleach to allow robust analysis and routines to allow spatio-temporal fitting.
**10:00AM W23.00009: Probing ATPase Dependent Physical Properties of Biological Condensates**
SEBASTIAN COUPE (Presenter), YOON JUNG, NIKTA FAKHRI, Massachusetts Institute of Technology MIT — Biological condensates are membraneless organelles, formed through nonspecific or multivalent ribonucleoprotein interactions, which are thought to be involved in the biochemical organization of the cell. There is increasing evidence for the regulation of these biological condensates by DEAD-box RNA helicases, which canonically remodel RNA-protein and RNA-RNA interactions in an ATP-dependent manner. The specific relationship between helicase activity and condensate properties such as viscosity, elasticity, and network architecture has not been investigated to date. DEAD-box helicase LAF-1, a critical component of the P granule condensate of *C. elegans*, phase separates in vitro. The ability for LAF-1 to interact with RNA and the effect of RNA on its droplet fluidity have been previously studied, however the interplay between its enzymatic function and droplet properties has not been established. We analyze the diffusion of single-walled carbon nanotubes, which are infrared-fluorescent, photostable, passive probes, to analyze the physical properties of LAF-1 droplets. In studying how this model condensate system responds to base-pairing RNAs, ATP, and accessory proteins we will shed light on principles underlying energetic regulation of condensate fluidity.

---

**10:12AM W23.00010: The robust bioinformatic analysis of the protein sequences with phase behavior**
ALEKSANDRA ELZBIETA BADACZEWSKA-DAWID (Presenter), DAVIT POTOYAN, Iowa State University — Liquid-liquid phase separation (LLPS) of many proteins is critical in the biological function of membrane-less organelles. Reversible nature of biomolecular PS in cells suggests that phases of proteins and nucleic acids are like to be tightly regulated. Post-translational modifications and single-residue mutations have been shown to lead to the dissolution of biomolecular droplets or phase transition into aggregated forms. Based on the wealth of experimental data, it reasonable to expect that the PS of proteins is highly sequence-specific.

To reveal common motifs of protein sequences that promote PS, we have carried out large-scale statistical analysis of phase separating protein deposited in the LLPSDB database. For each motif, the most significant interactions have been identified (e.g. charge, hydropathy, polarity, pi-stacking). The bioinformatic analysis provides us with crucial knowledge about sequence conservation, secondary structure preferences, aggregation tendency, post-translational modification prediction, and binding affinity.

The long-term goal of our research is the creation of a publically accessible database that would be used by both experimentalists for designing controlled mutations and for computationally-oriented scientists for developing new modeling tools.
10:24 AM W23.00011: Effects of protein charge and charge patterning on complex coacervation for enzymatic microreactors  
NICHOLAS ZERVOUNDIS (Presenter), ALLIE OBERMEYER, Columbia University — Complex coacervation is a liquid-liquid phase separation phenomenon that has shown promise encapsulating proteins and improving protein stability to a variety of perturbations. Cells utilize the process of complex coacervation to create microcompartments, termed membraneless organelles, for increased spatiotemporal control in cellular functions. Here, polypeptide-tagged green fluorescent protein (GFP) mutants and poly(4-vinyl N-methylpyridinium) were used to investigate the effects of protein charge patterning on coacervate phase behavior. Tagged mutants achieved coacervate concentrations higher than previously reported while retaining their secondary structure, suggesting that complex coacervation is a potentially attractive avenue for encapsulating enzymes for biocatalytic applications. Preliminary data has indicated the ability to form liquid-liquid phase separated microcompartments containing multiple enzymes. Using a model colorimetric cascade reaction, these multi-enzyme-polyelectrolyte coacervates have been used to evaluate the catalytic efficiency in biomimetic microcompartments and have the potential to inform the design of novel microcompartments for the production of industrially-relevant chemicals.

10:36 AM W23.00012: The role of a hidden ordered domain in controlling the material properties of RNA-protein condensates  
IAN SEIM (Presenter), DAPHNE KLOTSA, AMY S GLADFELTER, Univ of NC - Chapel Hill — Biomolecular condensates are a diverse class of membraneless, intracellular bodies that organize biochemistry. The constituent molecules, often RNA and protein, phase separate from a soluble pool into condensates which are crucial for normal physiological function but are also implicated in the development of several neurological diseases. Condensates can range from liquid-like droplets to solid-like aggregates. However, the distribution of condensate material properties along the viscoelastic continuum has not been well characterized, the molecular basis is poorly understood, and the corresponding functional consequences for cells are largely unknown. We have identified a coiled-coil (CC) motif within the disordered polyQ tract of a phase separating protein that strongly influences the material states of resulting RNA-protein condensates. By mutating specific residues in the CC, we demonstrate a range of material states in vitro, characterized by kinetic mean-field modeling of condensate formation. The CC domain structure is predicted by atomistic monte carlo simulations which are complemented by circular dichroism. Finally, integration of CC mutants into cells provides an in vivo system that demonstrates a link between the material state of condensates and cell function.

Session W24 GSNP: The Statistical Physics of Real-world Networks I  
Guido Caldarelli, IMT Alti Studi Lucca - Tag(s): Undergrad Friendly
Scale-free networks revealed from finite-size scaling

MATTEO SERAFINO, IMT Alti Studi Lucca, GIULIO CIMINI (Presenter), CNR-ISC Inst for Complex Systems, AMOS MARITAN, SAMIR SUWEIS, University of Padova, JAYANTH R BANavar, University of Oregon, GUIDO CALDARELLI, IMT Alti Studi Lucca — Network theory is a powerful tool to develop predictive models of physical, biological and social collective phenomena. A remarkable feature of many networks observed in nature is that they are approximately scale free: the fraction of nodes with $k$ incident links (the degree) follows a power law for sufficiently large $k$. The value of the power law exponent as well as deviations from such scaling behavior provide invaluable information on the mechanisms underlying the formation of the network. Importantly, real networks are not infinitely large and the largest degree cannot be larger than the number of nodes. Finite size scaling is a useful tool for analyzing deviations from power law behavior in the vicinity of a critical point in a physical system arising due to a finite correlation length. Here we show that despite the essential differences between networks and critical phenomena, finite size scaling provides a powerful framework for analyzing self-similarity and the scale free nature of real networks. We analyze about two hundred naturally occurring networks with distinct dynamical origins, and find that a large number of these follow the finite size scaling hypothesis without any self-tuning.

Statistical Physics and Twitter analysis*

GUIDO CALDARELLI (Presenter), CAROLINA BECATTI, ROCCO DE NICOLA, IMT Alti Studi Lucca, FABIO DEL VIGNA, ISC, Consiglio Nazionale delle Ricerche, RENAUD LAMBIOTTE, Mathematics, University of Oxford, MARINELLA PETROCCHI, IIT, Consiglio Nazionale delle Ricerche, FABIO SARACCO, IMT Alti Studi Lucca — In this work we analyse approximately $10^6$ tweets exchanged during the last Italian elections held on March 4, 2018. Using an entropy-based null model discounting the activity of the users, we first identify potential political alliances within the group of verified accounts: if two verified users are retweeted more than expected by the non-verified ones, they are likely to be related. Then, we derive the users’ affiliation to a coalition measuring the polarisation of unverified accounts. Finally, we study the bipartite directed representation of the tweets and retweets network, in which tweets and users are collected on the two layers. Unexpectedly for most of the users, automated accounts, also known as social bots, contribute more and more to this process of news spreading. Results show that social bots play a central role in the exchange of significant content. Indeed, not only the strongest hubs have a number of bots among their followers higher than expected, but furthermore a group of them, that can be assigned to the same political tendency, share a common set of bots as followers.

8:24AM W24.00003: Using Correlated Stochastic Differential Equations to Model Cryptocurrency Rates and Social Media Activities* STEPHEN DIPPLE, ABHISHEK CHAUDHARY, JAMES FLAMINO, BOLESLAW SZYMANSKI, GYORGY KORNISS (Presenter), Rensselaer Polytechnic Institute — Increasingly interconnected financial systems and online social networks present both critical challenges and opportunities. Volatility in the former (e.g., cryptocurrency rates) can give rise to increased volume of activities in online social networks on relevant topics, while sentiments and rumors in online social networks can also have a significant impact on the corresponding financial time series. Here, we analyze and exploit correlations between the price fluctuations of selected cryptocurrencies and social media activities, and develop a predictive framework using noise-correlated stochastic differential equations. We employ the standard Geometric Brownian Motion to model cryptocurrency rates, while for social media activities and trading volume of cryptocurrencies we use the Geometric Ornstein-Uhlenbeck process. In our model, correlations between the different stochastic variables are introduced through the noise in the respective stochastic differential equation. Using a Maximum Likelihood Estimation on historical data of the corresponding cryptocurrencies and social media activities, we estimate parameters, and using the observed correlations, forecast selected time series.

8:36AM W24.00004: Optimizing Network Structure in a Network Model of Human Aging GARRETT STUBBINGS (Presenter), ANDREW RUTENBERG, Dalhousie Univ — Our network model of aging represents aspects of human health as nodes in a complex network, these nodes damage stochastically over time based on the health of their neighbours. This represents the accumulation of damage leading to poor health and eventual mortality. Previous work has shown that by using a scale free network this model captures the phenomenology of health and mortality in human populations. Why do scale free networks best capture this phenomenology? Do these scale free networks represent an organism's robustness to damage in a meaningful way? We address this question from the bottom up using a network optimization approach. Beginning at a random network structure, we optimize the network structure with respect to various health outcomes, such as longevity and health-related quality of life. We investigate which network motifs emerge depending on the optimization health outcome, and how these aspects of the network structure affect damage propagation. Knowledge of how damage propagates between different types of nodes will aid our understanding of how different aspects of human health interact, and how humans accumulate health deficits over time.
8:48AM W24.00005: Cascading dynamic slowdowns around hacked vehicles  SKANDA VIVEK (Presenter), Georgia Gwinnett College, DAVID B YANNI, Georgia Institute of Technology, JESSE L SILVERBERG, Multiscale Systems, Inc., PETER YUNKER, Georgia Institute of Technology — Almost 40% of vehicles in the US can connect to the internet. While there are significant benefits of increased connectivity, hackers have illustrated that internet connected vehicles can be compromised remotely. Further, large-scale hacks have the potential to cause disastrous city-wide disruptions. Recently, it was shown using percolation theory that randomly stalling 20% of cars in Manhattan would cause a total freeze of city traffic. While this upper-bound estimate served as the first quantification of city-scale disruptions when vehicles are hacked, dynamic effects potentially cause significant slowdowns at lower fractions of hacked vehicles. Here, we perform simulations of traffic dynamics around hacked vehicles on grids of one-lane roads, using the SUMO traffic simulation platform. We consider slowdowns, when vehicles encounter road blocks from hacked vehicles and find that shortly post-hack, blocked roads cascade to neighboring regions, leading to significant slowdowns across the grid. We find that slowdowns are a function of hacked vehicle density, time since hack, and grid size. At large enough wait times, even low fractions of hacked vehicles cause significant gridlocks. Our results provide insights for recovery and rerouting to mitigate impacts of a large-scale hack.

9:00AM W24.00006: Inference of Network Communities using Random Walks  ADITYA BALLAL (Presenter), WILLOW KION-CROSBY, ALEXANDRE MOROZOV, Rutgers University, New Brunswick — Community structures are very common in real-world networks. For example, social networks such as Facebook, Instagram and Twitter, biological networks such as gene co-expression networks, protein-protein interaction networks or link based networks such as Wikipedia all exhibit pronounced community structure. We propose a novel stochastic method, based on random walks, for community detection on undirected networks with weighted or unweighted edges. The method employs first-passage properties of random walks on networks, providing key statistics of network community structure such as the number of communities and the size of each community after only a small fraction of nodes have been explored. This method provides robust results on large-scale networks in which the complete transition matrix is unavailable due to network size.
Resolution limit revisited: community detection using generalized modularity density

Various attempts have been made in recent years to solve the Resolution Limit (RL) problem in community detection by considering variants of the modularity metric in the detection algorithms. These metrics purportedly largely mitigate the RL problem and are preferable to modularity in many realistic scenarios. However, they are not generally suitable for analyzing weighted networks or for detecting hierarchical community structure. Resolution limit problems can be complicated, though, and in particular it can be unclear when it should be considered as problem. In this paper, we introduce a metric that we call generalized modularity density $Q_g$ that eliminates the RL problem at any desired resolution scale and is easily extendable to study weighted, directed, and hierarchical networks. We also propose a benchmark test to quantify the resolution limit problem, examine various modularity-like metrics to show that the new metric $Q_g$ performs best, and show that $Q_g$ can identify modular structures in real-world and artificial networks that are otherwise hidden.

This work was supported by the NSF through grants DMR-1507371 and IOS-1546858. Some of the computations were done on the uHPC cluster at the University of Houston, acquired through NSF grant 1531814.

A novel community detection method improves detection of functional gene modules in big gene expression data.

We identify communities of functionally related genes in the network inferred from the gene expression data of eukaryotic model organisms Arabidopsis thaliana & Saccharomyces cerevisiae by finding the network partition that maximizes the recently introduced generalized modularity density metric $Q_g$. This new metric does not suffer from the resolution limit problem and, with its tunable control parameter, can be used to study the hierarchical structure of communities. We use the Reduced Network Extremal Ensemble Learning (RenEEL) scheme [Sci. Rep. 9, 14234 (2019)] to optimize the metric. Statistical significance comparisons with the gene ontology indicate that the $Q_g$ method outperforms other clustering methods. Orphan genes have been found in all sequenced species. These are genes unique to particular species. They are thought to play a key role in speciation, but their regulatory interactions remain largely unknown. Focusing on highly significant functional modules that contain orphan genes, regulatory interaction patterns involving these genes are discovered and testable predictions are made about their specific biological functions.

Supported by the NSF grants DMR-1507371 and IOS-1546858.
9:36AM W24.00009: The broken symmetry of music: applying statistical physics to understand the structure of musical harmony  JESSE BEREZOVSKY (Presenter), Case Western Reserve University — Despite myriad musical systems and styles, certain characteristics are nearly universal across cultures and throughout history, including a restriction to a discrete set of sound frequencies (pitches). In this talk, I will present a bottom-up approach to a theory of musical harmony, starting from two basic (and conflicting) principles: a system of music is most effective when it 1. minimizes dissonant sounds, and 2. permits sufficient complexity to allow the desired artistic expression. By quantifying these principles and assuming a parameter (temperature) that specifies the balance between them, the problem directly maps onto standard statistical mechanics [1]. A mean field treatment reveals phase transitions from disordered sound to ordered phases with distributions of pitches that closely match musical tuning systems used throughout the history of both western and non-western music. A numerical model with nearest-neighbor interactions displays the behavior of an XY system, including the appearance of topological defects following a quench. These defects, arising from the Kibble-Zurek mechanism, are interpreted as chords, with their arrangement reflecting a system of harmony.

9:48AM W24.00010: Evolution of coauthorship networks in view of simplicial complex  BYUNGNAM KAHNG, YONGSUN LEE (Presenter), DEOKJAE LEE, Seoul Natl Univ — Graph, composed of nodes and links, is a simple representation for constituents and pairwise interactions, respectively. This simple method was successful for explaining diverse properties of complex systems to some extent. Hypergraph including simplicial complex is a generalization of graph, which takes into account of more than pairwise interactions between multiple nodes. Here, using this simplicial complex representation based on algebraic topology, we consider the evolution of coauthorship networks, a prototypical example of large-scale social relationships, based on empirical datasets on specific subfields in science. We found that the facet degree distribution exhibits power-law decaying behavior more elaborately than the graph degree distribution, and the first Betti number is useful for representing the emergence of a large-scale cooperative phenomenon. Moreover, we construct a model to reproduce such results, which would be useful for understanding further structural properties of such simplex complexes.
10:00AM W24.00011: Impact Factor volatility to a single paper: A comprehensive analysis of 11639 journals  MANOLIS ANTONOYIANNAKIS (Presenter), Department of Applied Physics & Applied Mathematics, Columbia University — We study how a single paper affects the Impact Factor (IF) by analyzing data from 3,088,511 papers published in 11639 journals in the 2017 Journal Citation Reports of Clarivate Analytics. We find that IFs are highly volatile. For example, the top-cited paper of 381 journals caused their IF to increase by more than 0.5 points, while for 818 journals the relative increase exceeded 25%. And one in 10 journals had their IF boosted by more than 50% by their top three cited papers. Because the single-paper effect on the IF is inversely proportional to journal size, small journals are rewarded much more strongly than large journals for a highly-cited paper, while they are penalized more for a low-cited paper, especially if their IF is high. This skewed reward mechanism incentivizes high-IF journals to stay small, to remain competitive in rankings. We discuss the implications for breakthrough papers to appear in prestigious journals. We also question the reliability of IF rankings given the high IF sensitivity to a handful of papers for thousands of journals.

10:12AM W24.00012: A mathematical analysis of Stock price oscillations within financial markets.  LEONARD MUSHUNJE (Presenter), Applied Mathematics and Statistics, Midlands State University — The application of econophysics in modeling investment assets' market behavior is considerably increasing and is highly becoming an area of interest for econophysicists. This study investigated stock price oscillatory behavior in stock markets. We applied mathematical methods to derive the stock market price oscillatory model from the physics field. We considered two distinct price level cases that is, high and low price cases and presented/ derived a corresponding model for each case. We managed also to derive an explicit time function which measures and calculate the time taken by stock prices to oscillate between two values. Also, from the low-price oscillation model we managed to investigate stock price motion at different times with all other external forces held constant. Results obtained showed that, although stock price movement (volatility) is time dependent, it is propelled and fueled by market forces such as stock volume, market size and classical forces of demand and supply. Above all we evaluated our model using means difference test of hypothesis using actual and estimated stock price data. We failed to reject our null hypothesis and concluded that, there is no statistical significant difference in the means which highly support the precision of our model.
10:24AM W24.00013: When money beats time: the effect of length-dependent costs on transport driven by long-range connections  

JAYSON PAULOSE (Presenter), Physics, University of Oregon, TOM SUTER, École polytechnique fédérale de Lausanne, OSKAR HALLATSCHEK, Physics and Integrative Biology, University of California, Berkeley — Finding the optimal route between pairs of spatially-separated points is a prevalent problem in technology (transport and communication networks) and nature (foraging and migration). In many situations, each segment of a route is associated with a stochastic waiting time determined by the frequency of making connections over a given distance (the jump rate), and a deterministic travel cost which is a growing function of the connection length (the cost function). The optimal route minimizes a weighted combination of time and cost. When deterministic costs are ignored, broad jump-rate distributions which fall off slowly with distance can dramatically speed up optimal routes: nearly all the distance between origin and destination is covered in a single segment which can be found in a short time. However, introducing a deterministic cost makes these long connections prohibitively expensive, and less useful for optimal routing. We study the trade-off between broad jump rate distributions and growing cost functions in a model that generates ensembles of optimal routes for specified jump rates and cost functions. We find that even gently-growing cost functions (which grow slower than linearly with distance) can strongly suppress the acceleration due to broad jump-rate distributions.

10:36AM W24.00014: Quantum mechanism of price stabilization in financial markets*  

JACK SARKISSIAN (Presenter), Algostox Trading — We study the mechanism of price stabilization in financial instruments using the quantum coupled-wave model and show that security mispricing results in persistent execution imbalance, which drives the price towards its fair value. In the course of stabilization the bid-ask spread widens, which is in agreement with observed market data. If initial mispricing is large, price may exhibit oscillatory behavior as the normally present random phase jumps are suppressed. This also is a widely observed empirical pattern. When the fair price is achieved, imbalance stabilizes at zero value and fluctuates around it. These fluctuations are smaller for highly liquid securities, and larger for less liquid securities, which shows that liquid securities are less tolerable to mispricing. This behaviour is again in agreement with market data. These results show that price stabilization can be viewed as a quantum-chaotic process resulting from balance between buyers and sellers quoting prices on different bid and ask levels, rather than agreeing on a single price, as is widely believed in the economic supply-demand balance paradigm.

*None
10:48AM W24.00015: Hybrid phase transitions driven by tug-of-war mechanism in complex
dynamic systems  BYUNGNAM KAHNG (Presenter), JINHA PARK, Seoul Natl Univ, SUDO YI, school of
physics, korea institute for advanced studies, KWANGJONG CHOI, Seoul Natl Univ — Hybrid phase
transitions, exhibiting a jump of the order parameter and criticality at a transition point, are
observed in diverse complex systems. Examples include k-core percolation, cascading breakdown
in interdependent networks, contagion dynamics, restricted cluster coagulations,
synchronization, etc. For such dynamical systems, it is a challenging task to uncover underlying
mechanisms, and according to which the hybrid phase transitions are classified into universality
classes. Here, we perform such tasks. Particularly, we focus on the case that the so-called tug-of-
war mechanism between two temporal subgroups of the system induces hybrid phase
transitions in dynamical systems such as percolation and synchronization. We show that in such
dynamics, inter-event times between two successive crossings in the tug-of-war process have an
inter-event time distribution that exhibits power-law decay behavior. The associated exponent
determines the criticality of the hybrid percolation transition through cluster merging dynamics.

Session W25 GSNP: Pattern Formation, Chaos, Nonlinear Dynamics II
402 - Tankut Can, The Graduate Center, City University of New York

8:00AM W25.00001: Concentration-measure theory of waves: new perspectives of the
fundamentals of nonequilibrium statistical physics and mesoscopic physics  PING FANG
(Presenter), Beijing University of Posts and Telecommunications —
The foundations of statistical physics are currently under renovations. A number of scenarios for
the arising of statistical physics in an individual system has been proposed. However, most
studies have focused on equilibrium statistical physics. In this talk, I shall report our recent
progress on the fundamentals of nonequilibrium statistical physics. I will show a theory for
structures and fluctuations of waves in individual disordered media, using the mathematical tool
of the concentration of measure. Applying this theory, we can see how the elementary
nonequilibrium process of diffusion can arise from a single scattering state of wave equation,
without the canonical hypothesis of ensembles. Furthermore, fluctuations associated with the
change in incoming waves exhibit a new kind of universalities, which does not exist in
conventional mesoscopic fluctuations associated with the change in disorder realizations, and
originate from the coherence between the natural channels of waves – the transmission
eigenchannels.
Coherent Perfect Absorption in Chaotic Microwave Graphs* LEI CHEN
(Presenter), Department of Electrical and Computer Engineering, University of Maryland, College Park, TSAMPIKOS KOTTOS, Department of Physics, Wesleyan University, STEVEN ANLAGE, Department of Physics and Department of Electrical and Computer Engineering, University of Maryland, College Park — Coherent perfect absorption (CPA) has been of great interest to the physics community, in part because it represents the time-reversed version of a laser. The CPA process works by taking waves of particular amplitude and phase (coherent illumination) from multiple input channels and causing them to interfere and to be completely absorbed by losses in the system. Its implementation promises the realization of a novel family of extremely efficient absorbers, tunable and highly-selective notch filters, and high-efficiency energy conversion systems. We experimentally demonstrate the concept of coherent perfect absorption in a microwave graph constructed from coaxial cables connected by Tee-junctions. By adding a simple variable lossy attenuator into the system, we can effectively identify the CPA frequencies as the complex zeros of the scattering matrix which crosses the real axis and achieve perfect absorption in this chaotic setup. Most importantly, our experimental set-up allows us to demonstrate that the concept of CPA can be extended beyond the case where time-reversal (TR) symmetry holds, by introducing a circulator into the microwave graph.

Tailored Noise Correlations and Generalized Levy Wave Dynamics in Multimode Systems* YAXIN LI (Presenter), Wesleyan Univ, DORON COHEN, Department of Physics, Ben-Gurion University, TSAMPIKOS KOTTOS, Wesleyan Univ — Multi-mode systems, like cavities, fibers etc, often suffer from the presence of environmental noise which causes mode mixing and subsequent interferences between various modes. In many occasions the study of the exact wave dynamic is a formidable task due to the many degrees of freedom that have to be taken into account in the equations of motion that describe such systems. Instead, a statistical theory of wave propagation might be a best way to describe the transport in such framework. We have utilized a Random Matrix Theory modeling which allow us to study the spreading of an initial mode excitation in the mode-space due to the environmental noise. Using this method we have developed a systematic approach that enforces a generalized Levy-type wave dynamics with a power law that it is imposed from the noise correlations. Our theoretical predictions have been tested in realistic circumstances like in paraxial light propagation in multimode fibers with tailored quenched disorder or in quantum dots with time-modulated boundaries.

Efficient Hybrid Model of Field and Energy Flow in Interconnected Wave Chaotic Systems*

STEVEN ANLAGE (Presenter), SHUKAI MA, University of Maryland, College Park, SENDY PHANG, George Green Institute for Electromagnetics Research, University of Nottingham, ZACHARY DRIKAS, BISRAT ADDISIE, RONALD HONG, US Naval Research Laboratory, Washington, DC, VALON BLAKAJ, GABRIELE GRADONI, GREGOR TANNER, School of Mathematical Sciences, University of Nottingham, THOMAS M ANTONSEN, EDWARD OTT, University of Maryland, College Park — Predicting energy flow through interconnected complex billiards is of keen interest to many fields. The Random Coupling Model (RCM) has been successfully applied to predicting the electromagnetic (EM) field statistical properties of various wave chaotic systems. Recent studies extend RCM to networks of coupled systems with multiple connecting channels [arXiv:1909.03827]. However the model becomes computationally costly as more billiards are added to the network. The Power Balance Model (PWB) can produce fast predictions for the averaged power density of waves in electrically-large systems. However the fluctuations of the wave field are lost in PWB, and many other mean-field approaches. Here we combine the best aspects of each model to create a hybrid treatment and study the EM fields in arrays of coupled complex systems. The proposed hybrid approach provides both mean and fluctuation information of the EM fields without the full computational demand of RCM. We compare the hybrid model predictions with experiments on linear cascades of overmoded cavities of various degrees of loss and find good agreement. The range of validity and applicability of the hybrid method is also discussed.

Breakdown of the Metastable State in the β Fermi-Pasta-Ulam-Tsingou Lattice*

KEVIN REISS (Presenter), SALVATORE PACE, DAVID K CAMPBELL, Physics, Boston University — We investigate numerically the formation and disappearance of Fermi-Pasta-Ulam-Tsingou (FPUT) recurrences in the β FPUT lattice, with special consideration to the lifespan of the metastable state. First, we consider different initial energies (E) and system sizes (N), to determine which initial parameters cause FPUT recurrences to form. We find that for large N, recurrences cease to form above a critical $E\beta$, a product of the energy and nonlinear parameter $\beta$. We explore the relationship between their disappearance and the breakdown of the metastable state to explain this critical $E\beta$, and also to estimate the time scale to the metastable state breakdown. In so doing, we define and measure a quantity called “shareable energy” and use this to show that systems with a negative $\beta$ have a much lower level of energy sharing than those with positive $\beta$.

*We thank Boston University's Undergraduate Research Opportunities Program and Boston University's Research Computing Services.
9:00AM W25.00006: The $\beta$ Fermi-Pasta-Ulam-Tsingou Recurrence Problem*  
SALVATORE PACE (Presenter), KEVIN REISS, DAVID K CAMPBELL, Physics, Boston University — One of the most remarkable and longest-studied problems in nonlinear dynamics is Fermi-Pasta-Ulam-Tsingou (FPUT) recurrences. We perform a thorough investigation of the first FPUT recurrence in the $\beta$-FPUT chain for both $\beta > 0$ and $\beta < 0$. We show numerically that the rescaled FPUT recurrence time $T_r = t_r(N + 1)^{-3}$ depends, for large $N$, only on the parameter $S = E\beta(N + 1)$. Our numerics also reveal that for large $|S|$, $T_r$ is proportional to $|S|^{-1/2}$ for both $\beta > 0$ and $\beta < 0$ but with different multiplicative constants. We numerically study the continuum limit and find the recurrence time closely follows the $|S|^{-1/2}$ scaling and can be interpreted in terms of mKdV solitons, and the difference in the multiplicative factors between positive and negative $\beta$ arises from soliton-kink interactions. We complement our numerical results with analytical considerations in the nearly linear regime (small $|S|$) and the highly nonlinear regime (large $|S|$). For the former, we extend previous results using a shifted-frequency perturbation theory and find a closed form for $T_r$, which depends only on $S$. In the latter regime, we show that the soliton theory correctly predicts $T_r \sim |S|^{-1/2}$ in the continuum limit.

*We thank Boston University's Undergraduate Research Opportunities Program.

9:12AM W25.00007: Statistical model and universality class for interacting puffs in transitional turbulence  
GRÉGOIRE LEMOULT, Normandie Université and Institute of Science and Technology Austria, MUKUND VASUDEVAN, JOSE M LOPEZ, Institute of Science and Technology Austria, HONG-YAN SHIH (Presenter), Institute of Physics, Academia Sinica and Department of Physics, University of Illinois at Urbana-Champaign, GAUTE LINGA, The Njord Center, University of Oslo and Niels Bohr Institute, University of Copenhagen, BJOERN HOF, Institute of Science and Technology Austria, JOACHIM MATHIESEN, Niels Bohr Institute, University of Copenhagen, NIGEL GOLDENFELD, Department of Physics, University of Illinois at Urbana-Champaign, BJOERN HOF, Institute of Science and Technology Austria — To understand the universality class of the laminar-turbulent transition in pipe flow, we measure how turbulent regions known as puffs proliferate and interact. Because of the huge length and time scales required to reach the critical regime, we model the dynamics from the effective forces we measure in experiments. Away from the transition, we find a crystal-like pattern with spatio-temporal intermittency. Renormalization group analysis and numerical simulations of both discrete and continuous models of puff interactions show that interactions are irrelevant at the 1+1-dimensional directed percolation fixed point but several finite-size artifacts mask the critical scaling regime in practice.
9:24AM W25.00008: A reduced model for a single cardiac cell  SHANGJUNG WU (Presenter), KUO-AN WU, Natl Tsing Hua Univ — The leading cause of sudden cardiac death is due to ventricular fibrillation (VF). VF is a heart rhythm disease that occurs from irregular dynamics behavior-discordant alternas. Therefore, it is vital to investigate the dynamics of a cardiac cell. In the past, typical mathematical models for dynamics of a cardiac cell involve intricate interplay between the membrane potential, ion channels, calcium cycling, etc, which would reproduce realistic responses such as cardiac alternas. Although above-mentioned models can reproduce genuine dynamics of a cardiac cell, they are generally complicated to analyze due to their high dimensional phase space. Hence, we propose a reduced model derived from an existing cardiac ionic model, and show that this three-variable dynamical system exhibits similar bifurcation diagram as that of the ionic model. The dynamical response and bifurcation behavior of a cardiac cell are investigated with the proposed reduced model.

9:36AM W25.00009: Diffusive behavior in walking droplets  AMINUR RAHMAN (Presenter), Texas Tech University, GIUSEPPE PUCCI, Université de Rennes, DANIEL M HARRIS, Brown University — Fluid droplets walking on a vibrating fluid bath have been observed to display deterministic diffusion. We present an experimental and theoretical investigation of such droplets. In our experiments a droplet is placed into an annular region on a vibrating fluid bath. The droplet motion becomes increasingly diffusive as the bath vibration is intensified above the Faraday wave threshold. This is also captured in our hydrodynamic – kinematic models, which shows close agreement between theory and experiments. Since the model can be studied at a much higher spatio-temporal resolutions than experiments, we use the model to numerically investigate bifurcations and chaotic dynamics suggested by experiments. Finally, we briefly discuss the possibility of model reduction to mitigate computational costs.

9:48AM W25.00010: Sloppy model analysis of dynamical systems near bifurcations*  CHRISTIAN ANDERSON (Presenter), MARK TRANSTRUM, Brigham Young Univ - Provo — In dynamical systems, bifurcations refer to topological changes in phase space trajectories in response to relatively small changes in parameter values. They are useful for identifying tipping points between qualitatively different types of behaviors such a phase transitions or from regulated to cancerous cellular pathways. Bifurcations are classified by the nature of the topological change in phase space with classes being typified by a "normal form", indicating that only a few parameters are responsible for driving a system through a bifurcation. Sloppy models provide a framework for identifying relevant parameters in a data-driven way. We apply sloppy model analysis to several dynamical systems near their bifurcations. We show that after an appropriate coarse-graining procedure, sloppy model analysis is able to correctly identify the bifurcation parameters. This suggests that sloppy model analysis can be used to identify the relevant control knobs in multi-parameter models of complex dynamical systems in a data-driven way.

10:00AM W25.00011: A mathematical approach to the effects of gender bias and cross gender interactions on careers in STEM. JENNIFER PEARCE (Presenter), JESSICA JENSEN, DARRELL VALENTI, JULIETTE M CAFFREY, Roger Williams University — Creating a mathematical model to predict participation in STEM fields would allow communities such as the APS understand better how to influence participation in physics. We propose a model that simulates the progression of women in male-dominated fields starting from the equations for a model predator-prey type system. We include interactions between the dominant and non-dominant populations and investigate how they effect the percent of the non-dominant population. We believe that such a model effectively captures some of the dynamics reported by researchers directly collecting data about the experiences of women in these fields.

10:12AM W25.00012: Hysteresis Experiments in Coupled Oscillators near Daido's Aging Transition OLAFUR HAUKSSON (Presenter), DAVID MERTENS, Physics, Eckerd College — One way to experimentally characterize collective oscillations is to measure the magnitude of the steady-state response. In order to examine more dynamic aspects of the behavior, we have measured the hysteresis of the collective response as we vary the collective bifurcation value. Specifically, in our collection of electronic oscillators, we produce a hysteresis by sequentially lowering then raising the bifurcation setting of each oscillator such that the collective bifurcation parameter goes below and above is critical value. The shape of the hysteresis loop exhibits a strong dependence on the rate at which we drive the system through the transition. We find that the area of the hysteresis loop exhibits a square-root dependence on the driving frequency. This is in contrast to ferromagnetic and ferroelectric systems, which exhibit power-law frequency dependence with much weaker exponents.

10:24AM W25.00013: Conformal field theory and the web of quantum chaos diagnostics* JONAH KUDLER-FLAM, LAIMEI NIE (Presenter), SHINSEI RYU, University of Chicago — We study three prominent diagnostics of chaos and scrambling in the context of two-dimensional conformal field theory: the spectral form factor, out-of-time-ordered correlators, and unitary operator entanglement. With the observation that all three quantities may be obtained by different analytic continuations of the torus partition function, we address the connections and distinctions between the information that each quantity provides us. In this process, we study the emergence of irrationality from “large-N” limits of rational conformal field theories (RCFTs) as well as the explicit breakdown of rationality for theories with central charges greater than the number of their conserved currents. Our analysis begins to elucidate the intermediate dynamical behavior of theories that bridge the gap between integrable RCFTs and maximally chaotic holographic CFTs.

*Simons Investigator Grant from the Simons Foundation; Kadanoff Fellowship from the University of Chicago.
10:36AM W25.00014: Cryptographic analysis of chaotic systems*  WILLIAM GILPIN (Presenter), Quantitative Biology Initiative, Harvard University — In computer science, hash functions are elementary operators that convert arbitrary-length inputs into finite-length outputs. We describe a direct analogy between these functions and the trajectories of particles advected by fluid flows, and we show that, when the governing flow is chaotic, hydrodynamic hash functions exhibit statistical properties typically associated with hash functions used for digital cryptography. These include non-invertibility, sensitivity to initial input, and avoidance of collisions—a phenomenon in which two similar inputs produce identical outputs. We show that this analogy originates from the tendency of certain chaotic flows to braid together particle trajectories across space in time in an irreducible manner, and we describe how techniques used to probe the properties of digital hash functions can be used to characterize the properties of flows when only limited observational data is available. Our findings have potential applications in microfluidic proof-of-work systems, as well as for characterizing large-scale transport in ocean flows and living systems.

10:48AM W25.00015: Universality in Kinetic Models of Circadian Rhythms in Arabidopsis thaliana  YIAN XU (Presenter), Department of Physics and Astronomy, Trinity University, MASOUD ASADI-ZEYDABADI, RANDALL TAGG, Department of Physics, University of Colorado Denver, ORRIN SHINDELL, Department of Physics and Astronomy, Trinity University — Adapting to the 24-hour periodic environment on the Earth, plants have evolved sets of chemical reactions that regulate their circadian rhythms. Over the past fifteen years, researchers studying these circadian reactions in the common laboratory plant Arabidopsis thaliana have developed eleven, increasingly elaborate, chemical kinetic models based on genetic feedback loops. Each model consists of a system of coupled nonlinear ordinary differential equations. We find these models are all situated near a Hopf bifurcation in parameter space. This suggests that there may be some biological significance corresponding to this mathematical property.

To illustrate the special nature of these systems, we numerically compute the solutions to the kinetic models for Arabidopsis thaliana. Separately, we perform a weakly nonlinear analysis on each model near bifurcation to predict the amplitude and frequency of the oscillating concentration of chemical species from the Stuart-Landau amplitude equation. By scaling the numerical frequencies and amplitudes by our theoretical predictions, we show that the solutions to all these models collapse into a universal parameter-free form. We further comment on some implications of our results for improving future modeling efforts.

Session W26 DBIO DSOFT DCP DFD: Interrogating Biomolecules with Synthetic Nanostructures 403 - Binquan Luan, IBM TJ Watson Research Center - Tag(s): Focus
8:00AM W26.00001: Optimal Signal Transduction with Silicon Transistors Enable Therapeutic Enzyme Regulation  ARVIND BALIJEPALLI (Presenter), SON LE, MICHELLE A MORRIS, National Institute of Standards and Technology, HARISH C PANT, NINDS, National Institutes of Health, CURT RICHTER, National Institute of Standards and Technology — We used commercially sourced n-channel silicon field-effect transistors (nFETs) operating under PID control to demonstrate pH measurements with a resolution of $(7.2\pm0.3)\times10^{-3}$ at 10 Hz. The results represent a 3-fold improvement over open loop operation of the nFETs and over ion sensitive field-effective transistors (ISFETs). The improved performance was realized when the pH sensing membrane was separated from the nFETs and connected electrically to the transistor gate. The technique leverages key operating procedures from our previous work with dual-gate 2D field-effect transistors (dg2DFET) fabricated with 2D semi-conducting MoS$_2$ channels [1]. The devices were used to measure the function of the enzyme Cdk5, which facilitates signaling within cells by modifying proteins via the hydrolysis of adenosine triphosphate (ATP), and thereby changing the pH of the surrounding solution by a very small amount. By measuring this subtle change in pH, we quantified the activity of Cdk5, which has been previously implicated in Alzheimer's disease, under physiological conditions. Finally, we demonstrated the effectiveness of a custom polypeptide, p5, as a therapeutic agent in restoring the function of the pathological form of Cdk5.

8:12AM W26.00002: Protein-Corona-by-Design in 2D: A Molecular Dynamics study to Decode Bio-Nano Interactions for Quality-by-Design Nanomedicines* MOHAMED ALI AL-BADRI (Presenter), Physics, King's College London, KHULOUD AL-JAMAL, Institute of Pharmaceutical Science, King's College London, CHRISTIAN LORENZ, Physics, King's College London — Nanoparticles and nanomaterials are increasingly studied for use in biomedical applications including drug delivery, imaging and hyperthermic therapies. However, upon their introduction to a biological medium, the nanomaterial's size, shape, surface charge, surface functional groups, and hydrophilicity/hydrophobicity all play a role in the formation of a hard protein corona. The components of which affect the biological fate of nanomedicine carried by the material, these have consequences on the cellular uptake and toxicity of the corona-nanomaterial complex.

Understanding and controlling the interaction of graphene-based materials with proteins is key to the development of graphene-enabled biomedical technologies and to the successful delivery of chemotherapy drugs. Little is known about the fundamental atomistic behaviour of the interactions of proteins exposed to functional groups on 2D synthetic materials. Here we investigate the interaction of graphitic materials with an array of proteins with all-atom molecular dynamics simulations and perform analytical modelling ito identify safe and toxic protein corona profiles in 2D that could pave the way for future quality by design 2D/3D nanomedicines & better clinical translation.

8:24AM W26.00003: Single-Molecule Characterization of Nanoparticle Bioconjugates using Microwell Array Analysis*  

MOHAMMAD ABDUL-MOQUEET (Presenter), LEEANA TOVIAS, KATHRYN MAYER, University of Texas at San Antonio — Nanoparticles functionalized with biomolecules have been studied extensively for their applications in nanomedicine. A need for characterizing these nanoparticle bioconjugates at the single-particle level using optical methods is needed. Microwell array analysis is a useful tool for single-molecule studies in which enzyme molecules are isolated in femtoliter wells; the enzymes convert non-fluorescent substrates into fluorescent products which can be measured using optical microscopy. Gold bipyramids were synthesized and functionalized with a self-assembled-monolayer (SAM). These particles were then bioconjugated using carbodiimide crosslinking with mouse anti-human epidermal growth factor receptor (EGFR)[KM1] antibodies, followed by human EGFR labeled with horseradish peroxidase (HRP). Microwell arrays were loaded with the nanoparticle bioconjugates such only that a small number of wells were occupied according to Poisson statistics. The fluorescence intensity of the microwells was then used to determine the number of antibodies that were conjugated to the gold bipyramids.

8:36AM W26.00004: Single-Molecule Kinetics of Taq Polymerase up to 94 °C*  

MACKENZIE WALKER TURVEY (Presenter), WONBAE LEE, JEFFREY J TAULBEE, CALVIN J LAU, KRISTIN GABRIEL, REBECCA VARGAS, GREGORY WEISS, PHILIP G COLLINS, University of California, Irvine — Single-molecule enzymology is a useful tool for understanding protein kinetics, function, and inhibition, but common techniques work in a limited temperature range. Here, we extend single-molecule science up to 94 °C with MHz resolution using solid-state, carbon nanotube biosensors. Their operation, which is essentially independent of temperature, provides unprecedented access to commercially important enzymes such as Taq, the DNA polymerase I from Thermus aquaticus. Taq is the linchpin protein for the polymerase chain reaction (PCR) amplification of DNA [1]. Our electronic biosensor approach provides direct access to single-nucleotide incorporation activity [2] from room temperature up to 94 °C. For example, the incorporation rate of a single Taq molecule was monitored from 1 bp/s at 22 °C to greater than 100 bp/s at 72 °C, the typical PCR operating temperature. In addition, the biosensor transduces the distinct motions of Taq subdomains, such as brief, 20-µsec flutters as the fingers domain tests nucleotides for complementarity.

*NIH NHGRI (1R01HG009188)
8:48AM W26.00005: Monitoring Antipsychotic Drug Effects on Stimulated Dopamine Release Using Carbon Nanotube Transistors with Nafion-Radical Hybrid Films  INKYOUNG PARK (Presenter), VIET ANH PHAM BA, DONG-GUK CHO, Department of Physics and Astronomy, and Institute of Applied Physics, Seoul Natl Univ, SEUNGHUN HONG, Department of Physics and Astronomy, and Institute of Applied Physics, and Department of Biophysics and Chemical Biology, Seoul National University — We developed floating electrode-based carbon nanotube biosensors for the monitoring of antipsychotic drug effects on the dopamine release from nerve cells (PC12) under potassium stimulation. In this work, carbon nanotube field-effect transistors with floating electrodes were functionalized with nafion films containing 2,2′-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS●) radicals to build selective biosensors for the dopamine detection. The selective interaction between ABTS● radicals and dopamine allowed us to discriminate dopamine from the simultaneous presence of other neurotransmitters such as glutamate and acetylcholine with a detection limit down to 10 nM. Furthermore, we demonstrated the real-time monitoring of dopamine release from PC12 cells under the stimulation of potassium solutions at various concentrations. Significantly, we could also evaluate the effects of antipsychotic drug (pimozide) on the dopamine release from potassium-stimulated PC12 cells. Since our method enables the quantitative and real-time evaluation of drug effects on living cells, it should be a versatile tool for both biomedical researches and applications.

9:00AM W26.00006: Synthesis and toxicity of bio-templated fluorescent metal nanoclusters in human Neuro-2a cells  SHASHI P KARNA, KARIMA JENEH PERRY (Presenter), Weapons and Materials Research Directorate, APG, MD 21005, CCDC Army Research Laboratory, RAJ KUMAR, Radiation Biotechnology Lab, INMAS Delhi, India 110052, RAJ K. GUPTA, DoD Blast Injury Research Program Coordinating Office, Ft Detrick, MD 21702, USAMRDC — Bio-templated fluorescent metal nanoclusters (fMNC) have attracted a great deal of attention recently for their potential applications in sensing, cellular imaging, and as photonic probes. More recently, there have been reports of in situ synthesis of fluorescent MNC by tumorigenic (cancerous) as well as healthy animal cell cultures. Here we present the synthesis of Au and Fe nanoclusters synthesized in vitro using human neuro-2a cells. Additionally, protein (BSA and Chicken Egg-White) synthesized fMNCs were also incubated in neuro-2a cells. The cells exhibit significant uptake of protein-templated fMNCs. In both cases the cells exhibited significant viability at relatively elevated metal concentration, up to tens of micrograms.

Protein Aggregation Characterization by Nanopore technology

JIALI LI (Presenter), Univ of Arkansas-Fayetteville — Protein aggregation is one of the leading causes of many neurodegenerative diseases such as Alzheimer’s and Parkinson’s. In this talk, we report our study on characterizing protein aggregation with a solid-state nanopore device, together with AFM and DLS techniques. Our model proteins used in these studies are β-lactoglobulin variant A (bLGa) and neuronal Tau and tubulin proteins. The main component of a nanopore device is a nanometer size pore fabricated in free-standing silicon nitride membrane supported by a silicon substrate which separates two PDMA chambers containing salt solution. A stable ionic current is established by applying a biased voltage on a pair of silver chloride (AgCl) electrodes across the nanopore membrane. When charged protein molecules are added to the grounded chamber, applying a correct bias potential to the other chamber drives a protein molecule into the nanopore which partially blocks ionic flow that can be measured as a transient current drop signal. A protein aggregate which has larger volume than a single protein molecule would block larger amount of current or generate a greater current drop amplitude, therefore a nanopore device can be used to characterize protein aggregation at single molecule level. The volume of translocating protein aggregates are estimated using a calibrated nanopore by a standard that has known geometry such as a dsDNA molecule. We show that solid state nanopore method is capable of measuring protein aggregation number and the aggregation number distribution in the conditions close to their native aqueous environment. The nanopore experiments were performed under applied voltages from 60-210 mV at different pH, temperature, and salt concentrations. We present data of bLga, and Tau and tubulin aggregations measured by nanopore method, and compare them with the results from AFM and DLS.

Active and stable palladium nano-thin-film structure development for rapid and direct biomolecules conjugation and sensing

CHIA-CHING CHANG (Presenter), CHIA-YU CHANG, YUN-TZU HUANG, WEI CHEN, Natl Chiao Tung Univ — Metal atoms on surface edges or with specific coordinates possess high surface potentials and serve as core atoms for organic molecule bonding. Unlike self-organized or surface modified nanoparticles, these active metal nanostructures may lose their activity by surface self-diffusion process. It is challenging to create a metal surface structure which possesses both active and stable properties. However, a surface template with native nano-roughness may solve this dilemma. In this study, a PET substrate has been selected for metal atoms absorption and a stable and active Pd nano-thin-film (NTF) surface has been developed. Further studies indicated that the surface contains an (1,1,1) like structure and Pd-NTF growth followed a Stranski-Krastanov-like growth model. This nanostructure thin-film (Pd NTF-PET) electrode has been developed for electrochemical impedance spectroscopy (EIS) usage. Both DNA and protein can be immobilized on the Pd NTF-PET electrodes directly, within 15 min and its biosensing sensitivity was as low as 0.1 ng per-test in 1 µl. In summary, we have developed an active and stable Pd NTF-PET electrode for biosensing applications.

This study was supported by MOST 107-2112-M-009-016-MY3 and Ministry of Education through the SPROUT Project-IDS²B of NCTU, Taiwan.
10:00AM W26.00009: Spontaneous ssDNA Stretching on Graphene and Hexagonal Boron Nitride In-plane Heterostructures  BINQUAN LUAN (Presenter), IBM TJ Watson Research Center — Because single-stranded DNA (ssDNA) molecules in solution typically form coiled structures, stretching ssDNA is extremely crucial when applying any nanotechnology for ssDNA analysis. Recent advances in material fabrication enable the deployment of nanochannels to manipulate, stretch, sort and map double-stranded DNA (dsDNA) molecules, however nanochannels fail to stretch ssDNA molecules due to the ultra-short persistence length and the potential nonspecific-interaction-induced clogging. Given the significance of ssDNA stretching in genome analysis, here a novel ssDNA stretching platform is proposed: two dimensional in-plane heterostructure comprising graphene and hexagonal boron nitride (h-BN), and I show that ssDNA can be stretched on a h-BN nanostripe sandwiched between two adjacent graphene domains ("nanochannel"). Additionally, with a biasing voltage the stretched ssDNA can be electrophoretically transported along the "nanochannel", allowing easy controls/manipulations. When being conveniently integrated with existing atomic resolution sensors, the heterostructure platform paves the way for sequencing DNA on a planar surface [see Nat. Commun. 10, 4610 (2019)].

10:12AM W26.00010: Block Optical DNA Sequencing with Plasmonic Substrates for Rapid Biomarker Diagnostics  LEE KORSHOJ, AMEYA GAJANAN PRABHUNE (Presenter), PRASHANT NAGPAL, University of Colorado, Boulder — Precision medicine requires high-throughput point-of-care diagnostics with multiomics capability for sensing biomolecules and their molecular variants. In a push for improved precision diagnostics, we describe an optical sequencing platform that uses surface-enhanced Raman spectroscopy (SERS) measurements from plasmonic nanostructured surfaces and nanoparticles for label-free determination of nucleobase content in DNA k-mer blocks. With SERS on cationic silver nanoparticles, we achieved >93% accuracy for predicting A-G-C-T content in 10-mer DNA blocks. The high-accuracy measurements were used with a content-scoring bioinformatics algorithm to correctly identify a β-lactamase antibiotic resistance gene and confirm the Pseudomonas aeruginosa pathogen from merely <12 measurements (<15% coverage of the gene) [1,2]. We further proved applicability on RNA and chemically modified nucleobases for extensions to transcriptomics and epigenomics. With the versatility of plasmonic substrates for simple data acquisition, resolution to single-molecules, and multiplexing, optical sequencing can provide rapid biomarker diagnostics in the clinical setting [3].

10:24AM W26.00011: Dynamics of DNA in periodic temperature gradient field created by plasmonic heating*  RYOKO SHIMADA (Presenter), Japan Women's University, HIROSHI WATANABE, Kyoto University — Different molecules in a solution can be separated from each other along a temperature gradient. This phenomenon, so-called Soret effect, offers an interesting method of molecular manipulation in various research fields. Plasmonic heating from periodic metal domains is one of the effective ways to create a periodic temperature gradient. In this work, we utilized the plasmonic heating from periodic silver (Ag) domains under emission of blue light (400 – 440 nm) to create the periodic temperature gradient (with a large amplitude of ~ 0.5 K/um), thereby attempting to observe the Soret effect on DNA molecules mixed in polyethylene glycol (PEG) solutions. The DNA molecules, labeled with fluorescent dyes, were concentrated in high temperature zones, confirming the positive Soret effect. In addition, for large DNA molecules (~ 166 Kbp), stretched conformations bridging two hot zones were occasionally observed and their diffusion appeared to deviate from the simple Fickian behavior, possibly because of the microscopic Soret effect within the molecule. Details of this observation will be discussed on site.

10:36AM W26.00012: Tunneling Spectroscopy on Engineered Surfaces for RNA Nucleotide and Structural Label Identification  LEE KORSHOJ (Presenter), GARY R ABEL JR., ANUSHREE CHATTERJEE, PRASHANT NAGPAL, University of Colorado, Boulder — Although several advances have been made in RNA sequencing and structural characterization, the lack of a method for directly determining the sequence and structure of single RNA molecules has limited our ability to probe heterogeneity in gene expression at the level of single cells. We present a method for identification of RNA nucleotides and structural labels for mapping of single RNA molecules. With non-perturbative tunneling spectroscopy, we probed the molecular orbitals of distinct nucleobases within RNA macromolecules immobilized with restricted conformational freedom on a chemically modified surface. From the measurements, models for tunneling were combined to obtain twelve biophysical parameters unique to the ribonucleotides within the electronic junction [1]. The twelve parameters serve as a comprehensive molecular fingerprint, enabling ribonucleotide discrimination and identification of structure-dependent chemical labels with machine learning. We show high accuracy for both ribonucleotide discrimination (>99%) and chemical label identification (>98%) with a modest 35 repeat measurements [2]. This technique facilitates probing the transcriptome with a previously unattainable level of detail.

Conformational heterogeneity in human interphase chromosome organization reconciles the FISH and Hi-C paradox*

GUANG SHI (Presenter), DAVE THIRUMALAI, University of Texas at Austin — Hi-C experiments are used to infer the contact probabilities between loci separated by varying genome lengths. Contact probability should decrease as the spatial distance between two loci increases. However, studies comparing Hi-C and FISH data show that in some cases the distance between one pair of loci, with larger Hi-C readout, is paradoxically larger compared to another pair with a smaller value of the contact probability. Here, we show that the FISH-Hi-C paradox can be resolved using a theory based on a Generalized Rouse Model for Chromosomes (GRMC). The FISH-Hi-C paradox arises because the cell population is highly heterogeneous, which means that a given contact is present in only a fraction of cells. Insights from the GRMC is used to construct a theory, without any adjustable parameters, to extract the distribution of subpopulations from the FISH data, which quantitatively reproduces the Hi-C data. Our results show that heterogeneity is pervasive in genome organization at all length scales, reflecting large cell-to-cell variations.

Temperature-dependent Motility in *H. pylori*

JYOT ANTANI (Presenter), PUSHKAR LELE, Texas A&M Univ — *Helicobacter pylori* employ a run-reversal strategy in contrast to the run-tumble strategy employed by *E. coli* during navigation. As a result, their migration patterns are anticipated to be different from those in *E. coli*. We have quantitatively determined the effect of medium temperatures on the two modes of *H. pylori* motility – a pusher mode in which the flagella lag behind the body and a puller mode in which the flagella precede the body. Our data show that the cells swam faster in one mode relative to another as a function of temperature. The mean durations of the runs in either mode also depended on the temperature, as did the fraction of the time that the flagellar filaments rotated counterclockwise. We analyzed the mean squared displacements of the cell populations and determined that the bacterial spread was the highest at temperatures close to physiological temperatures. We will present a quantitative model that accounts for the anisotropic random walk to predict the temperature dependence of the bacterial diffusion. The fundamental insights from this work are likely to provide a handle for determining the motile responses of *H. pylori* to various types of environmental stressors.

8:12AM W27.00002: Developing Methods for Two-Way Communication to Explore the Dynamic Sense of Touch in Bacteria*  ZHOU XU (Presenter), WUQI NIU, SYLVIA RIVERA, SLOAN SIEGRIST, MARK THOMAS TUOMINEN, MARIA SANTORE, Univ of Mass - Amherst — Living organisms usually utilize chemical or biomolecular signals that travel relatively slowly. However, bacterial cells can respond very quickly, yielding interesting opportunities for interfacing with bacteria. In this work, we study the bacterial sense of touch to establish the new research area of sensory-based bacterial communication. The focus is on fast two-way transmission of mechanical and electrical signals between bacteria and man-made devices. Bacterial touch acts through mechanical and electrical stimuli at timescales much less than chemical- and nutrient-based bacterial interactions. Employing high resolution microscopy with a flow cell system, we investigate the adsorption rate and growth of E. coli on different surfaces such as poly-l-lysine coated surface and hydrophobic. We use indium tin oxide coated glass as electrodes to apply electric stimulus on bacterial and measure the response. Using biomolecular engineering, we investigate the response to stimuli based on their gene expression.

*This research is supported by NSF grant # CBET 1848065

8:24AM W27.00003: Comparative study of bacterial growth on different surfaces and the effect of weak magnetic field on the growth rates  SAMINA MASOOD (Presenter), University of Houston, Clear Lake — We investigate the growth of bacteria on different surfaces. The presence of nanoripple structure on glass is known to affect the growth rate. The growth of bacteria in the weak field is also affected by the type of the applied field, if all other conditions remains unchanged. Affect of weak magnetic field sustains for more than one generation. Moreover, the growth rate of bacteria and the structure of bacteria is also affected if it is grown over different materials including gold and silver surfaces.

8:36AM W27.00004: Rigid Body Dynamics of Motile Bacteria Near Surfaces*  ORRIN SHINDELL (Presenter), KEATON HOLT, Department of Physics & Astronomy, Trinity University, QUAN HOANG, NAM DUNG HOANG, Department of Mathematics, Vietnam National University, FRANK HEALY, Department of Biology, Trinity University, HOA NGUYEN, Department of Mathematics, Trinity University — Motile bacteria in their natural environment commonly interact with surfaces. Using total internal reflection fluorescence microscopy, we record the trajectories of Escherichia coli cells swimming near surfaces. By fitting ellipsoids to the fluorescent intensity profiles of the bacteria via a novel method, we extract their translational and rotational dynamics. We present results from our analysis for experiments with both wild-type and smooth-swimming E. coli strains.

*National Science Foundation grant DMS-1720323 and Trinity University.
8:48AM W27.00005: Fast Modulation of Phenotypic Diversity in Bacterial Chemotaxis*
KEITA KAMINO (Presenter), AMOLF Institute, Yale University, JOHANNES M KEEGSTRA, AMOLF Institute, JUNJIAJIA LONG, THIERRY EMONET, Yale University, THOMAS S SHIMIZU, AMOLF Institute — A central question in cell biology is how cell populations deal with ever-changing environments. It has been shown that gene regulatory networks can modulate in an environment-dependent manner not only the average phenotype, but also its diversity within isogenic populations. Here, we demonstrate that cells can also tune the level of phenotypic diversity much more rapidly than is possible by gene expression, using covalent modification of signaling proteins. In the E.coli chemotaxis pathway, we find that the diversity of a key sensory parameter, the response sensitivity, is modulated depending on the presence or absence of ambient chemoattractant molecules. We show how this diversity tuning originates from an environment-dependent mapping between the sensitivity phenotype and the standing cell-to-cell variation in the number of allosterically-coupled receptors. This diversity tuning enhances the population's readiness for uncertain future signals in the absence of any signal, but allows the population to rapidly switch to tracking the signal once it is perceived.

9:00AM W27.00006: Flow-induced symmetry breaking in growing bacterial biofilms
PHILIP PEARCE, Department of Systems Biology, Harvard Medical School, BOYA SONG (Presenter), DOMINIC SKINNER, RACHEL V MOK, Department of Mathematics, Massachusetts Institute of Technology, RAIMO HARTMANN, PRAVEEN SINGH, HANNAH JECKEL, Max Planck Institute for Terrestrial Microbiology, JEFFREY S OISHI, Department of Physics, Bates College, KNUT DRESCHER, Max Planck Institute for Terrestrial Microbiology, JÖRN DUNKEL, Department of Mathematics, Massachusetts Institute of Technology — Bacterial biofilms represent a major form of microbial life on Earth and serve as a model active nematic system, in which activity results from growth of the rod-shaped bacterial cells. In their natural environments, ranging from human organs to industrial pipelines, biofilms have evolved to grow robustly under significant fluid shear. Despite intense practical and theoretical interest, it is unclear how strong fluid flow alters the local and global architectures of biofilms. Here, we combine highly time-resolved single-cell live imaging with 3D multi-scale modeling to investigate the mechanisms by which flow affects the dynamics of all individual cells in growing biofilms. Our experiments and cell-based simulations reveal three quantitatively different growth phases in strong external flow, and the transitions between them. In the initial stages of biofilm development, flow induces a downstream gradient in cell orientation, causing asymmetrical droplet-like biofilm shapes. In the later developmental stages, when the majority of cells are sheltered from the flow by the surrounding extracellular matrix, buckling-induced cell verticalization in the biofilm core restores radially symmetric biofilm growth, in agreement with predictions of a 3D continuum model.
9:12AM W27.00007: Resource allocation model for bacterial shape control under growth perturbations*  DIANA SERBANESCU (Presenter), NIKOLA OJKIC, SHILADITYA BANERJEE, Univ Coll London — Single bacterial cells adapt their growth rates and morphologies to changes in environmental conditions in order to optimize their fitness for proliferation. Control of cell size demands making tradeoffs between cellular resources allocated towards growth and division. Understanding the nature of these tradeoffs remains an outstanding challenge. Here we propose a coarse-grained theory for how bacteria allocate their molecular resources to regulate their cell shapes and growth rates in varying nutrient environments and antibiotic induced perturbations. We propose that a balanced tradeoff between ribosomal resources allocated towards growth and division determines the control of bacterial cell volume and surface area. The results from our model are in excellent quantitative agreement with available experimental data on single-cell growth and shape under nutrient and translational perturbations. By calibrating our model with experimental data, we further predict that a combination of antibiotics that induce cell filamentation and inhibit translation may be more efficient in bacterial killing.

9:24AM W27.00008: Multi-scale dynamical description Gram-negative bacterial responses to antibiotics towards drug resistance PEDRO MANRIQUE (Presenter), Theoretical Biology and Biophysics, Los Alamos National Laboratory, KUMKUM GANGULY, Bioscience Division, Los Alamos National Laboratory, S GNANAKARAN, Theoretical Biology and Biophysics, Los Alamos National Laboratory — Contemporary medicine struggles with bacterial infections on a daily basis. The ongoing challenge is to describe how these organisms adapt and protect at different levels when attacked by drugs. In the presence of these agents, colonies of bacteria carry out myriad processes at the molecular, genetic, and cellular scales that grant resistant against intruders threatening its survival. Even though mechanisms of specific processes in different scales have been characterized, a framework that integrates the processes at different scales remains absent. Here we propose a dynamical model that integrates these scales in the context of bacterial survival and efficacy of drugs. Using experimental inputs, our approach produces testable outputs that are in agreement with empirical data. In general, this framework provides a mathematical tool to test stress response strategies in organisms that can potentially guide experiments in natural and synthetic cellular systems.
9:36AM W27.00009: A Facile Accelerated Specific Therapeutic (FAST) Platform that Reverses Carbapenem Resistance in Multi-Drug Resistant *E. coli*  THOMAS AUNINS (Presenter), KEESHA ERICKSON, ANUSHREE CHATTERJEE, University of Colorado, Boulder — Carabapenems are a powerful class of antibiotics, often used as a last-resort treatment to eradicate multidrug-resistant (MDR) infections. However, as carbapenem-resistant pathogens have become more common, the need for new strategies to combat resistance has emerged as a critical public health priority. Here, we show that the Facile Accelerated Specific Therapeutic (FAST) platform can use transcriptomic data for the rapid (<1 week) design, synthesis, and testing of antisense inhibitors that are able to re-sensitize a strain of MDR *E. coli* to carbapenem treatment. We used total and small RNA-seq data to determine genes that may be important to the meropenem (to which the strain is sensitive) and ertapenem (resistant) responses. These observations, combined with genome sequencing of the MDR *E. coli*, allowed us to use FAST to create peptide nucleic acids (PNA) to knock down the translation of specific genes. Using PNA in combination with both antibiotics, we demonstrated the ability to inhibit bacterial growth at antibiotic concentrations to which MDR *E. coli* strain was initially resistant. This work confirmed FAST’s ability to use transcriptomics to design novel antibiotic strategies, and identified gene expression-based resistance mechanisms that warrant further exploration.

9:48AM W27.00010: A Comparative Analysis of Various Cas Proteins in CRISPRi Gene Circuits  LIOR KREINDLER (Presenter), GUILLAUME LAMBERT, Applied and Engineering Physics, Cornell University — Cas proteins with deactivated cutting domains can be used as programmable components in genetic circuits in E. Coli. While dSpCas9 and dFnCas12a have proven functional in gene circuits, there exist Cas proteins from other species of bacteria that have yet to be explored and fully understood. A particularly new and mysterious Cas protein is CasX, which is completely distinct from both Cas9 and Cas12a. CasX is much smaller than both Cas9 and Cas12a; it could potentially be preferable for use in gene circuits. Cas9 and Cas12a proteins from varying species of bacteria recognize unique PAM sequences, and thus function slightly differently. To explore these differences, six versions of a CRISPRi inverter circuit that previously worked with FnCas12a in E. Coli were developed, each using the deactivated version of a different Cas protein (SaCas9, St1Cas9, TdCas9, NmCas9, AsCas12a, and CasX) programmed to target a cassette of tetA (tetracycline resistance) and sacB (sucrose sensitivity). The circuits are transformed into E. Coli, which are then selected for growth in tetracycline and sucrose. Additionally, another version of each circuit targeting GFP is tested, to confirm the results of the multiplexed tetA-sacB selection serially and to compare the effects of targeting different genes.
10:00AM W27.00011: Tuning programmable CRISPR-based toggle switches with buffer sites in Escherichia coli  
YASU XU (Presenter), GUILLAUME LAMBERT, Cornell University — Recent developments and advances in CRISPR-Cas systems have ushered a new generation of powerful genetic engineering tools in synthetic biology. In particular, a catalytically ‘dead’ version of Cas proteins that lack nuclease activity can essentially function as a logic NOT gate by selectively binding to a promoter and preventing transcription initiation. In this work, we first create programmable genetic toggle switches (TSs) using pairs of mutually repressible orthogonal CRISPR-based NOT gates and measure the strength of these TSs using massive parallel CRISPRi assay called “Xseq”. Specifically, hundred pairs of CRISPR nodes with different barcoded targets are simultaneously cloned into a plasmid that contains a TetA-SacB cassette as a reporter, then transformed into E. coli. Each cell has a single TS construct. By selecting cell survival under sucrose and tetracycline conditions, we are able to sort out matched CRISPR TSs among numerous randomized promoter-target pairs and quantify relative strength of each NOT gate in all possible combination at the same time. Later, adding a second plasmid that shares the same target as the TS and competes with TS for dCas pool, we can tune the efficiency of each NOT gate via manipulating the number of buffers, and thus the performance of TS.

10:12AM W27.00012: Development of non-linear gradient microfluidic devices*  
DRAGOS AMARIE (Presenter), ILEENE HARDEN, ARTURO DIAZ, ELIJAH WATERS, Physics and Astronomy, Georgia Southern University, DWAYNE G. STUPACK, Obstetrics Gynecology and Reproductive Sciences, University of California, San Diego — Mechanical stress introduced by the flow in microfluidic chambers induces shear stress thus impacting the live cells migration patterns. Our last-year work showed that constructing a flowless linear gradient requires two mirrored gradient chambers. In this work we present microfluidic devices that generates non-linear chemical gradients. By splitting and recombining the input flows through a combination of bifurcated (mixers and splitters) and trifurcated (splitters) channels one can generate a chemical gradient across a microfluidics chamber. As the input chemicals flowing downstream mix, a linear gradient can only achieve relative lateral gradients either from 0% to 50% or from 50% to 100%. However, we demonstrate that these mirrored gradient can be non-linear in order to accommodate a steeper flowless gradient. By introducing bias when recombining the flows in the mixers one can generate non-linear gradients. Different bias between mixers input channels can accommodate steeper lateral gradients from 100% to: (a) 37% for a 2:1 bias, (b) 30% for a 3:1 bias, (c) 27% for a 4:1 bias and (d) 24% for a 5:1 bias. This type of separated, flowless gradient offers new opportunities to study the migration of live cells free of physical flow.

10:24AM W27.00013: Acoustic Micromotors for Cellular Manipulation*  
JEFFREY MCNEILL, University of Pennsylvania, AUSTIN MAADDI, SAMBEETA DAS (Presenter), Univ of Delaware — Cell manipulation is an important aspect of many studies such as single cell analysis, tissue engineering, and mechanobiology. Despite the recent surge of activity in this area, there still does not exist a system that contains most of the practical components for carrying out high-throughput cellular manipulation. The small size of cells and lack of bio-compatibility are critical challenges in cell manipulation, especially for mammalian cells. Here, we demonstrate the use of acoustically powered micromotors steered by an applied magnetic field for mammalian cell rotation and manipulation. The acoustic propulsion mechanism provides a variety of highly desirable features, such as high speed, precision, short-range attractive forces utilized as an end effector, and orthogonality in any aqueous medium. The potential power of this approach is also highlighted by cargo pickup and delivery to individual cells.

*We gratefully acknowledge the support of the National Science Foundation DMR-1420620, the Singh Center for Nanotechnology under grant NNCI-1542153 and the Department of Mechanical Engineering at the University of Delaware.

10:36AM W27.00014: The biophysics of cellular counting — uncovering how viral copy number drives cell-fate decision  
SETH COLEMAN (Presenter), Bioengineering, Rice University, TIANYOU YAO, THU VU PHUC NGUYEN, Verna and Marrs McLean Department of Biochemistry and Molecular Biology, Baylor College of Medicine, OLEG A IGOSHIN, Bioengineering, Rice University, IDO GOLDING, Physics, University of Illinois Urbana-Champaign — After infecting an E. coli cell, the virus lambda either kills the host cell (lysis) or enters a stable, dormant state (lysogeny). Such cell-fate decisions are ubiquitous in biology, but few are well understood mechanistically. The lambda decision is an attractive model system, as it is comparatively simple, well-studied, and shares multiple features with more complex systems. A key factor affecting the decision is the multiplicity of infection (MOI), i.e. the number of co-infecting viruses. Increasing MOI raises the likelihood of a lysogenic outcome, but the mechanisms by which viral copy number drives the decision are unclear. To determine these mechanisms, we combine single-cell resolution experiments with coarse-grained modeling of infection over a range of MOI. We find that the expression of essential genes in the decision network exhibits power-law scaling with MOI. Notably, the expression of cro, a key lytic gene, scales sublinearly, whereas the expression of cI, the gene responsible for establishing the lysogenic state, scales superlinearly. This nonlinear, gene-specific response to MOI is a consequence of negative and positive feedback loops in the regulatory network. This feedback causes increasing MOI to drive expression of cI, pushing the decision towards lysogeny.

Session W28 DCMP: New Physics and Quantum Technology at Ultra-Low Temperatures 405-407 - William Halperin, Northwestern University - Tag(s): Invited
8:00AM W28.00001: Precision experiments at ultralow temperatures enabled by quantum technology and superconducting electronics [Invited] CHRISTIAN ENSS (Presenter), Kirchhoff Institute for Physics, Heidelberg University — Ultralow temperatures are favorable conditions for the realization of quantum technology in general and for quantum sensors in particular. One type of such quantum sensors are cryogenic detectors for particles and radiation, which have begun to revolutionize experiments in many areas of physics. Here we will discuss a specific kind of cryogenic detector, namely a metallic magnetic calorimeter (MMC) consisting of an absorber suitable for the particles to be detected, in close thermal contact with a paramagnetic temperature sensor. Together the two are connected by a weak thermal link to a thermal bath. Their universal applicability for the detection of different particles and radiation as well as their high resolution, wide bandwidth, fast and linear response make them a popular choice in many different applications today. Here we will discuss their principle of operation and their impact on precision gamma spectroscopy and neutrino mass determination.

8:36AM W28.00002: Topological Superfluid $^3$He under mesoscopic confinement* [Invited] JOHN SAUNDERS (Presenter), Department of Physics, Royal Holloway University of London — Confinement of superfluid $^3$He in a nanofabricated cavity of height comparable to the superfluid coherence length is a powerful tool to modify the p-wave superfluid order parameter [1]. This enables the creation of superfluid $^3$He hybrid nanostructures, with interfaces between two $^3$He material phases stabilized by a step in cavity height [2]. Measurements on the chiral A-phase, stabilized at low pressure in a 200 nm tall cavity, show that the order parameter suppression and the spectrum of surface bound states are fragile with respect to details of quasiparticle scattering [3]. We show that magnetic surface scattering leads to an unexpectedly large suppression of the transition temperature, corresponding to an increased density of low energy bound states. On the other hand specular surface scattering eliminates gap suppression and surface states. In taller cavities an AB transition is observed; the 0.7 and 1.1 micron cavities show a universal phase boundary, with minute super-cooling, which is potential evidence for an intrinsic nucleation mechanism under confinement [4]. Near to the AB transition the confined B-phase is predicted to be unstable to spontaneous formation of domains, with a predicted stripe phase [5]. However our NMR measurements find a two-dimensional spatially modulated superfluid (pair density wave) [6]. The future quest is to identify and manipulate Majorana zero modes in the only firmly establish topological “superconductor”.

9:12AM W28.00003: Superconducting Quantum Circuits for Quantum Computing and Quantum Simulation [Invited] JENS KOCH (Presenter), Northwestern University — Quantum research has undergone a remarkable transition from probing quantum phenomena intrinsic to nature, to developing engineered and fully controllable quantum systems with new functionality. Experimental capabilities to reach milli-Kelvin temperatures have played an important role in enabling new quantum technology. An exciting example of such low-temperature quantum devices are superconducting circuits which have facilitated impressive progress towards quantum computation and quantum simulation. I will review the journey from the early superconducting qubits to presently employed circuits with coherence times in the micro- to millisecond range, and discuss the ongoing development of even more robust superconducting qubits with intrinsic error protection. These next-generation circuits, including the heavy-fluxonium and 0-π qubits, have the potential to outperform and ultimately replace the widely used transmon qubit.

9:48AM W28.00004: Innovation at the cold frontier for current and future quantum devices and sensors* [Invited] RICHARD HALEY (Presenter), SAMULI AUTTI, DAVID IAN BRADLEY, ANTHONY GUÉNAULT, ALEXANDER JONES, SERGEY KAFANOV, YURI PASHKIN, GEORGE PICKETT, MALCOLM POOLE, JONATHAN PRANCE, MICHAEL THOMPSON, VIKTOR TSEPELIN, DMITRY ZMEEV, Physics, Lancaster University — The Low Temperature Physics Laboratory at Lancaster University, a founder member of the European Microkelvin Platform, designs and constructs record-breaking millikelvin dilution refrigerators and sub-millikelvin adiabatic demagnetisation stages, building on the expertise, infrastructure and technical capabilities that have been developed and refined over many years. Research runs from blue-skies work in superfluid helium-3 and helium-4 at temperatures close to absolute zero, through to innovation and technology transfer of refrigeration, instrumentation and ultra-sensitive measurement techniques to academic and commercial collaborators. This talk will describe some of our recent research highlights including: the discovery of super-critical superfluid condensate flow; exploiting high quality factor nanomechanical resonators as force sensors over many orders of magnitude; and developing new techniques for delivering microkelvin electron temperatures in nano-fabricated on-chip devices.

Research in quantum fluids, where are we?*  

YOONSEOK LEE  
(Presenter)  
University of Florida — In this paper, we present a review of the recent progresses in the field of quantum fluids with a forward-looking perspective. The main research in this field is on superfluid phases of two helium isotopes and can be classified in two realms. One is to use helium as a platform for other related physics. For example, efforts in realizing ultra-high sensitive detection and qubits using superfluid helium-4 have attracted interests of researchers in related fields with potential impact for technology. In parallel a group of researchers continue their effort in unveiling the nature of these unique quantum systems with novel experimental techniques and fresh perspectives. Active investigation of the topological nature and the capability of engineering novel superfluid phases in helium-3 widened the scope of the research in this field. The recent progress in quantitative investigation of quantum turbulence are expected to produce exciting results in the near future. This discussion is based on the works presented at the conferences in the field and the record of publications in recent years [1].

Session W29 DSOFT DPOLY DBIO DFD: Electrostatic Manipulation of Fluids and Soft Matter II: Self-Assembly  
Jonathan Singer, Rutgers University, New Brunswick - Tag(s): Focus

8:00AM W29.00001: Precision measurement of tribocharging in acoustically levitated sub-millimeter grains  
ADAM KLINE (Presenter), MELODY LIM, HEINRICH M. JAEGGER, University of Chicago — Contact electrification of dielectric grains forms the basis for a myriad of physical phenomena. However, even the basic aspects of collisional charging between grains are still unclear. In this talk, we present a new experimental method [1], extending a prior approach [2] based on acoustic levitation, which allows us to controllably and repeatedly collide two sub-millimeter grains head-on and measure the evolution of their electric charges. This is the first collisional tribocharging experiment to provide complete electric isolation of the grain-grain system from its surroundings. We use this method to measure collisional charging rates between pairs of grains for three different material combinations: polyethylene-polyethylene, polystyrene-polystyrene, and polystyrene-sulfonated polystyrene. The ability to directly and noninvasively collide particles of different constituent materials, chemical functionality, size, and shape opens the door to detailed studies of collisional charging in granular materials.

8:12AM W29.00002: Tuning friction and slip at solid-nanoparticle suspension interfaces by electric fields.* CAITLIN M SEED (Presenter), BIPLAV ACHARYA, DONALD W BRENNER, ALEX I SMIRNOV, JACQUELINE KRIM, North Carolina State University — Pathways to achieve climate stabilization consistently require a diverse mix of technologies, with energy efficiency being the largest contributor, ranging from 35-40% in virtually all proposed scenarios. Reductions in frictional energy losses and improved lubrication methodologies are key to such energy savings. Nanoparticles in aqueous suspensions hold particular promise for such purposes. We report an experimental Quartz Crystal Microbalance (QCM) study of tuning interfacial friction and slip lengths for aqueous suspensions of ceramic (Al₂O₃, TiO₂ and SiO₂) nanoparticles on planar platinum surfaces by external electric fields. Attraction and retraction of particles perpendicular to the surface by means of an externally applied fields resulted in increased and decreased interfacial friction levels and slip lengths. The variation was observed to be non-monotonic, with a profile attributed to the physical properties of interstitial water layers present between the nanoparticles and the platinum substrate. The results are compared and contrasted with macroscale friction measurements performed on the same materials.

8:24AM W29.00003: Particle assembly using confined electro-hydrodynamics: Driven versus active assembly* [Invited] JON OTTO FOSSUM (Presenter), PAUL DOMMERSNES, Norwegian Univ Tech (NTNU) — We give examples of driven colloidal shell assembly on drop interfaces by application of DC-electrohydrodynamics and dielectrophoresis, using standard leaky dielectric carrier fluids for non-polarisable and/or polarizable colloids. We summarize how this can be used to fabricate static or dynamic colloidal shells with patchy structure and functionality. Secondly, we give examples of active granular bead assembly in suspension by exploiting the electrohydrodynamic Quincke-rotation effect (i.e. electric field induced rotational motion of non-electrically-conducting particles suspended in a leaky-dielectric fluid). We study a system in quasi-2D microfluidic confinement with an applied DC-electric field perpendicular to the 2D-plane, where a monolayer of Quincke rotors are forced to “live” near a flat solid surface, and thus become a monolayer of self-propelled Quincke rollers. A Quincke roller’s direction of motion in the 2D plane is individual and normal to the applied electric field, with any direction possible, i.e. the electric field supplies energy (“food”), but not direction. Unlike animals, the “metabolism” of Quincke-rollers is instantaneous, and their “food” is translated into motion immediately. We have demonstrated several types of assemblies that emerge from populations of such confined granular Quincke-rollers confined, such as crystallites, dynamic clusters, clusters of clusters, vortices, swirls, and polar liquids with uniform direction of motion.

9:00AM W29.00004: Electrostatic patterns from peeling tape*  MARY REITER (Presenter), MATTHEW VANDUSEN-GROSS, TROY SHINBROT, Rutgers University, New Brunswick — It has been known since the 17th century that as mercury rolls from glass, “barometric light” is emitted[1]. Similarly, as tape is pulled from surfaces, light is emitted that can even extend to produce enough x-rays to image bones within a finger[2]. It has been proposed that the light is generated by discharges that follow triboelectric charging by the tape. In this talk, we discuss new and surprising aspects of triboelectric charging associated with tape peeling including entirely different charge patterns on formerly adjoining surfaces. We describe these unique patterns as well as implications for the charging and adhesion of surfaces and particles in nature and industry.

*This research was funded by the National Science Foundation via the award NSF/CBET-1804286.

9:12AM W29.00005: Sublattice Melting in Binary Superionic Colloidal Crystals*  YANGE LIN (Presenter), MONICA OLVERA DE LA CRUZ, Northwestern University — In superionic compounds one component pre-melts providing high ionic conductivity to solid state electrolytes. Here, we find sublattice melting in colloidal crystals of oppositely charged particles that are highly asymmetric in size and charge in salt solutions. The small particles in ionic compounds melt when the temperature increases forming a superionic phase. These delocalized small particles in a crystal of large oppositely charged particles, in contrast to superionic phases in atomic systems, form crystals with non-electroneutral stoichiometric ratios. This generates structures with multiple domains of ionic crystals in percolated superionic phases with adjustable stoichiometries.

*This work has been funded by NSF DMR Award No. 1611076.

9:24AM W29.00006: Band-collision gel electrophoresis (BCGE) for visualizing molecular and colloidal interactions  DIMITRI BIKOS (Presenter), Center for Biofilm Engineering, Montana State University, THOMAS MASON, Physics & Astronomy and Chemistry & Biochemistry, UCLA — Electrophoretic mobility shift assays (EMSAs) are widely used to study binding interactions between different molecular species loaded into a single well within an electrophoresis gel. However, shift assays can explore only a subset of reaction possibilities that would otherwise be accessible if separate bands of reagent species were instead collisionally reacted. We fabricate a gel with two or more wells within a single lane and load these wells with different reagent species. By applying an electric field, we produce collisional reactions between propagating pulse-like bands of these species and record the images optically. We observe cases where bands pass through one another undisturbed, while in other cases, we observe complexing and precipitation, indicating strong attractive interactions. This band-collision gel electrophoresis (BCGE) approach is generalizable to a variety of reaction types, such as acid-base, ligand exchange, and redox, as well as to colloidal species in passivated large-pore gels.
9:36AM W29.00007: Controlling surfactant self-assembly in dodecane via applied potential*

MAISA VUORTE (Presenter), AAPO LOKKA, MARIA SAMMALKORPI, Aalto University, Finland — The response of colloidal assemblies in apolar solvents to applied electrostatic potential plays a key role in both electrostatic stabilization and manipulation of the resulting nanoemulsion, drug delivery, and synthesis platforms. Here, we present a molecular modelling study of the aggregation of dioctyl sodium sulfosuccinate (AOT) surfactant in apolar dodecane solvent under applied potential. We probe the sensitivity of the self-assembling, reverse micellar surfactant structures and their dynamics to the magnitude of the applied potential and presence of moisture in the system. While the anionic AOT surfactant readily forms reverse micellar aggregates even in the absence of trace water, presence of moisture greatly increases the size of the formed aggregates and their dynamics. The applied potential controls the AOT sodium counterion mobility but the charge transfer via the counterions is also influenced strongly by the degree of hydration of the AOT head groups. We discuss the significance of the findings against literature and experimental data.

9:48AM W29.00008: Dumbbell model for the simulation of polyelectrolytes in combination of flow and electric fields*

ANGELO SETARO (Presenter), PATRICK UNDERHILL, Rensselaer Polytechnic Institute — The combination of Poiseuille flow and electric fields has been used to drive the transverse migration of charged polyelectrolytes in channels, resulting in non-uniform concentration profiles. Manipulation of these profiles can be used to drive separations of charged polyelectrolytes such as double stranded DNA. Interestingly, the amount of migration is not monotonic in electric field strength. Rather the migration peaks at intermediate electric fields before decreasing. To date, the mechanism for this non-monotonic trend has been poorly understood as prior models have been unable to reproduce this behavior. To gain insight to the underlying phenomena, we used a combination of theoretical calculations and Brownian Dynamics simulations in order to understand the mechanism of migration and why it results in a non-monotonic trend. It was found that at high electric field strengths, the migratory flux of polymers was able to impact the conformational distribution, altering the electrophoretic mobility and, in turn, limiting the migration. Further, when comparing to experimental migration data, our model captures the position of the maximal migration with near quantitative accuracy.

*We acknowledge support from NSF Grant CBET-1826788.
10:00AM W29.00009: Electrostatically Stabilized Microphase Separation in Polyelectrolyte Blends: Analogy to Nuclear "Pasta" Phases  ARTEM RUMYANTSEV (Presenter), JUAN DE PABLO, University of Chicago — We develop the weak segregation theory of microphase separation in stoichiometric blends of oppositely and weakly charged polyelectrolytes, which would be immiscible in the absence of charged units. Short-range repulsions between polycation and polyanion monomers induce the formation of oppositely charged domains, whose size is controlled by their excess Coulomb energy. The diagram of blend morphologies is constructed in the framework of a Leibler's mean-field approach and, to account for fluctuations, within a Brazovskii-Fredrickson-Helfand approximation. Phase behavior of the polyelectrolyte blends is fully analogous to that of neutral diblock copolymers. In asymmetric blends, increasing incompatibility between polyelectrolytes triggers the usual cascade of first order phase transitions, disordered blend $\rightarrow$ bcc $\rightarrow$ hex $\rightarrow$ lam. We also discuss that microphase separation in polyelectrolyte blends (and hence neutral diblock copolymers) and the formation of nuclear “pasta” phases arising within neutron stars are governed by similar physical principles, despite the six orders of magnitude difference in the periods of these structures (nanometers vs femtometers, respectively).

10:12AM W29.00010: Determination of diffusion constant of antimicrobial peptide nisin interacting with Langmuir monolayers of DPPC and DPPG molecules*  IMRAN PASHA, BHARAT KUMAR (Presenter), Central University of Karnataka — We present a method of determining the diffusion constant of peptides interacting with lipid films. The method involves studying the interactions of diffusing peptides with the lipid Langmuir monolayer at the air-water interface. Due to the interaction between peptides and lipid molecules in the monolayer at the air-water interface, the surface pressure of the monolayer changes as a function of time which can be measured from the surface manometry technique. A model based on the diffusion of particles under the influence of a constant force is developed to obtain an analytical expression for change in the surface pressure of Langmuir monolayer as a function of time. The expression was found to fit well with the experimental data. The average hydrodynamic radius and the translational diffusion constant of the nisin molecules are calculated from the fit parameters for the different subphase pH solutions. The diffusion constant was found to vary with the pH of the media.

Capture and Translocation of a Rod-like dsDNA by a Nanopore: A Lattice Boltzmann Simulation Study

LE QIAO (Presenter), Physics, University of Ottawa, CHRISTIAN L. HOLM, KAI SZUTTOR, Physics, University of Stuttgart, GARY W. SLATER, Physics, University of Ottawa — Short dsDNA, viruses like the tobacco mosaic virus and filamentous bacteriophages can be considered as a rigid rods. We previously argued that the field-driven orientation of a rod-like object will impact its capture by a nanopore because both its translational diffusion coefficient $D$ and electrophoretic mobility $\mu$ vary with orientation. We also introduced a critical orientational capture radius to describe this effect. In this talk, we investigate this problem further using a coarse-grained (CG) model of a charged double-stranded DNA where the hydrodynamic interactions are added by coupling the CG DNA with a lattice-Boltzmann fluid via a raspberry approach. The electrostatic interactions with the salt ions are modeled with the P3M algorithm. We also discuss the capture of modified DNAs, including partially charged and branched DNAs. In all cases, we examine how molecular orientation affect capture and entry into the pore.

The authors acknowledge the support of the University of Ottawa, NSERC, Mitacs Globalink research award and CSC.

Nontrivial effects of dielectric mismatch on the conformational behavior of confined polyelectrolytes

TRUNG NGUYEN (Presenter), MONICA OLVERA DE LA CRUZ, Northwestern University — We investigate the conformational behavior of a highly charged polyelectrolyte confined in a spherical cavity where the media inside and outside the cavity have different dielectric constants. Depending on the charge density of the cavity surface and dielectric mismatch, the polyelectrolyte either collapses into amorphous conformations, or folds into a four-fold symmetry conformation. On the contrary to the common wisdom that polarization effects would be negligible for charged surfaces, we find that such effects influence the polyelectrolyte conformational behavior in a nontrivial manner. Our study provides insight into the effects of dielectric mismatch in packaging and delivery of polyelectrolytes across media with different relative permittivities. Moreover, the reversible transformation of the polyelectrolyte conformations in response to environmental permittivity suggests potential applications in biosensing and medical monitoring.
10:48AM W29.00013: Interaction of highly charged rigid polymer in monovalent salt*
YAOHUA LI (Presenter), FELIPE JIMENEZ-ANGELES, MONICA OLVERA DE LA CRUZ, Northwestern University — Charged polymers such as DNA bear important biological functions and have useful applications as a nanomaterial. Experiments of these polyelectrolytes are often performed in aqueous salt solutions. Using an empirical ion potential that reproduces pair correlations from all atom molecular dynamics (MD) simulations, we study ion distributions and DNA-DNA interactions by coarse-grained MD simulations with explicit salt ions. We focus on high concentration regimes, and found that at concentrations greater than 2M, both the ion distribution profile and the potential of mean force between DNAs becomes non-monotonic and has attractive wells. These results are in good agreement with our liquid state theory predictions. Furthermore, the importance of detailed DNA structure will be discussed using all atom MD simulation of DNAs. Our study can help interpret experimental results and help control the phase behavior of charged polymer using salts.

Friday, March 6, 2020 8:00 AM - 10:48 AM

8:00AM W31.00001: Hydrodynamic coupling to the electrical response of fluid suspensions of non-Brownian conducting particles MATTHEW SNELL (Presenter), JEFFREY RICHARDS, Northwestern University — We report on the electrical response of conducting non-Brownian suspensions to applied steady shear. We show using dc-conductivity measurements in a rheo-dielectric device that a shear-rate dependent conductivity increases both with the shear intensity and the particle volume fraction. The conductivity increases instantaneously upon flow start-up and returns instantaneously and reversibly to the quiescent value upon flow cessation. For volume fractions exceeding 30 vol% microspheres, the ratio of the conductivity under flow to that in the quiescent state can exceed a factor of $10^5$. We rationalize these results based on a simplistic scaling law that confirms the hydrodynamic forces couple to the interparticle electron transfer rate. These observations help to reconcile emerging experimental evidence for the role of particle mobility in determining electrical transport in colloidal fluids and suspensions and could prove a basis for new mechano-electric sensing modalities as well as improved electrochemical storage technologies.
8:12AM W31.00002: Rheological analysis of hydrocolloidal Basil seed mucilage in the context of seed physiology  BHUVSMITA BHARGAVA (Presenter), JACOB JOHN, SUSY VARUGHESE, Indian Inst of Tech-Madras — Hydration of the seeds of the *Ocimum basilicum* develops a translucent mucilage around the seed that plays a vital role in its germination, adhesion and dispersal. This functionality stems from the structure of the mucilage, which comprises of adherent and non-adherent layers, that have varying concentrations of complex polysaccharides such as pectin, cellulose, and hemicellulose. Pectin crosslinks in the presence of Ca$^{+2}$ ions to form hydrocolloidal gels. The interplay between the pectin and calcium concentrations and degree of esterification determines the nature and extent of crosslinking. However, the extent to which it contributes to the gel structure, its rheology and the resulting seed physiology is not completely understood. This work uses Large Amplitude Oscillatory Shear (LAOS) rheology as a tool to estimate the factors that affect crosslinking in the Basil seed mucilage. We observe that the mucilage behavior is gel-like, with a constant modulus plateau at low strains and shear thinning at higher strains. The non-linear signatures such as the loss modulus overshoot and strain stiffening observed for mucilage gels are compared with those of the pectin-Ca gels to estimate the extent of Ca$^{+2}$ crosslinking and the degree of esterification of the pectin present in the mucilage.

8:24AM W31.00003: Rheology of glassy and jammed emulsions*  CONG CAO (Presenter), Emory University, JIANSAN LIAO, VICTOR BREEDVELD, School of chemical & Biomolecular Engineering, Georgia Institute of Technology, ERIC WEEKS, Emory University — We study the rheology of monodisperse and polydisperse emulsions with various mean droplet sizes. Above a critical volume fraction $\varphi$, these systems exhibit solid-like behavior and possess a yield stress. Previous simulation work suggests that for small thermal particles, rheology will see a glass transition at $\varphi\approx0.58$; for large athermal systems, rheology will see a jamming transition at $\varphi\approx0.63$. However, for intermediate sized droplets at the crossover of thermal and athermal regimes, the glass and jamming transitions may both be observable in the same sample. We use a rheometer to shear different sizes of TPM emulsion droplets. By varying the shear rate and particle size, our experiments cover a wide range of Péclet number (the ratio of shear and thermal motions), including the crossover regime. We successfully measure rheological properties near the critical volume fraction(s). We then further measure how their yield stress change with volume fraction.

8:36AM W31.00004: Athermal Shear-Driven Flow of Mixtures of Frictionless Rods and Disks in Two Dimensions*  STEPHEN TEITEL (Presenter), THEODORE A MARSCHALL, University of Rochester — We numerically simulate the athermal steady-state shearing of a mixture of frictionless circular disks and elongated spherocylinders (rods) in two dimensions, suspended in a host medium. We study behavior as the total packing fraction and the fraction of rods are varied, at slow shear strain rates. We find that the average angular velocity of the shear-driven rod rotations decreases, and the extent of the nematic ordering of the rods increases, as the fraction of the rods decreases. In the limit of a single rod in a sea of disks, the rod appears to cease rotating, except at very low packing fractions. We find that, as one shears from an initial random configuration, the system tends to form clusters of parallel contacting rods. We believe that such clusters form so as to reduce the pressure in the system, and that these clusters play an important role in the shear-driven rotation of the rods.

8:48AM W31.00005: Brownian motion in near-surface pressure driven flows with 3D-nanometric spatial resolution*  ALEXANDRE VILQUIN (Presenter), PIERRE SOULARD, VINCENT BERTIN, ESPCI Paris, GABRIEL GUYARD, Université Paris Sud, DAVID LACOSTE, ELIE RAPHAEL, ESPCI Paris, FREDERIC RESTAGNO, Université Paris Sud, THOMAS SALEZ, Université de Bordeaux, JOSHUA MCGRAW, ESPCI Paris — In near-surface flows, interfaces play a major role by imposing (typically) no-slip boundary conditions, greatly reducing the fluid velocity compared to the central part of a channel. With total internal reflection fluorescence (TIRF), a flow is illuminated with an evanescent field decaying over a few hundred nanometers into the channel; this decay allowing a determination of nanoparticle altitudes. Combined with particle tracking, experimental determination of the velocity profile and local velocity distributions in three dimensions are possible. Here we present a detailed look at the statistics of near-surface particle motions in pressure-driven water for which diffusion is important compared to advection. The distribution of displacements in the invariant flow direction is Gaussian as for normal diffusion. Significant anomalies are however observed for both of the other spatial dimensions. Combining experiments and simulations, we disentangle contributions from so-called Taylor-Aris dispersion, nanoparticle polydispersity and the optical measurement system. This description of TIRF allows for the study of many Brownian motion problems, such as near-surface polymer solution dynamics or particle motion near soft boundaries.

9:00AM W31.00006: Effect of Roughness and Elasticity on Interactions between Charged Colloidal Spheres* JOSEPH MONTI (Presenter), PATRICIA M MCGUIGGAN, MARK ROBBINS, Johns Hopkins University — The effects of realistic roughness and elasticity on the interactions between charged silica spheres are studied as a function of surface potential, screening length, interfacial energy, and roughness. The repulsive force $F_{re}$ that must be overcome to bring charged spheres into contact is relatively insensitive to elasticity unless spheres are hundreds of times softer than silica. $F_{re}$ is also insensitive to roughness and interfacial energy. In contrast, roughness has a large effect on the binding energy of spheres and the force $F_{sep}$ to separate them. Both are lowered by 1 to 2 orders of magnitude by the measured surface roughness of less than 1 nm on 1 μm silica spheres. The reason is that interactions between rigid spheres are dominated by the highest surface peaks rather than the entire spherical surface. Elasticity can increase the pull-off force of rough spheres by a factor of 2 or more because additional surface area can be brought into contact. The implications of these results for shear-thickening transitions are discussed.

*Support provided by NSF Grant No. DMR-1411144.

9:12AM W31.00007: Near-surface dynamics of semidilute polymer solutions: diffusion, nonlinear rheology, and the hydrodynamic boundary condition* GABRIEL GUYARD, JOSHUA MCGRAW (Presenter), ALEXANDRE VILQUIN, ESPCI Paris, FREDERIC RESTAGNO, Université de Paris Sud — Near-surface dynamics of polymer solutions challenge both experimental and theoretical efforts — especially in the case of semi-dilute solutions for which the chains overlap — yet evanescent wave microscopy allows for a three-dimensional characterization of such interfacial flows. Here we report nanoscale-resolved particle motions in microfluidic channels for pressure-driven flows of semidilute polymer solutions. The results using polymer-free water are in good agreement with Stokes-flow hydrodynamic and diffusive theory. Experiments using hydrogenated polyacrylamide at different volume fractions close to and above the overlap concentration are done in the same chips as for the water experiments. In contrast to Newtonian fluid behaviour, the shear-rate/pressure drop relation is non-linear for the polymer solution flows, suggesting nanometrically-resolved, shear-thinning effects, accompanied with a non-trivial hydrodynamic boundary condition. The diffusive motion of the tracer particles is also distinguished from that of the water experiments, and such motions are detailed here. These results set the basis for a study of near-wall hydrodynamic flow and diffusion in complex fluids, notably including semidilute polymer solutions.

9:24AM W31.00008: Emergence of surface roughness from plastic deformation of amorphous materials

RICHARD LEUTE (Presenter), Department of Microsystem Engineering, University of Freiburg, TILL JUNGE, Department of Mechanical Engineering, École Polytechnique Fédérale de Lausanne, LARS PASTEWKA, Department of Microsystem Engineering, University of Freiburg — Many man made and natural surfaces show intrinsic surface roughness which controls material properties such as adhesion or friction. Over several length scales and in different materials, ranging from rocks to gold crystals, roughness shows a self-affine scaling behaviour. We investigate the emergence of self-affine surface roughness in amorphous solids through plastic deformation. Our simulations are performed using a fast Fourier transform (FFT)-based continuum mechanics solver. The typical plastic deformation avalanche dynamics of an amorphous material is simulated by a fully tensorial stochastic plasticity model. The crucial role of avalanches for self-affine surface roughness is shown by comparing the stochastic plasticity model with a finite strain $J^2$-plasticity formulation with linear isotropic hardening. We present avalanche statistics and analyse the spatiotemporal distribution of the plastic events. The non-affine deformations in the bulk of the material is related to the self-affine surface roughness of the free surface.

9:36AM W31.00009: Determining the Structural Characteristics of Deforming Objects from Their Scattering Signature

GUAN-RONG HUANG (Presenter), YANGYANG WANG, YUYA SHINOHARA, CHANGWOO DO, TAKESHI EGAMI, WEI-REN CHEN, Oak Ridge National Lab — There has been much interest in understanding the structural characteristics of deforming materials on different length scales. In the context of scattering, the domain of interest can be splitted into a microscopic region within which the local configurational translation and rotation can be treated in detail, and a larger regime where the description of global shape is appropriate. From a perspective of geometric interpretation at the micro/macroscopic level, a central issue is how to quantitatively determine the structural characteristics from the anisotropic scattering intensity in a model-free manner.

We present a general approach to deal with this problem. In the mean-field limit, we first show that the radius of gyration is the source term of intra-particle structure factor. Using the real spherical harmonic expansion (RSHE), we derive the exact expression of gyration tensor in terms of the anisotropic spatial correlation functions. Meanwhile, we derive the orientational distribution functions to describe the local configurational alignment. Theoretical benchmarks verify that our approach not only facilitates quantitative scattering studies of flowing materials, but also provides insightful information regarding the deformation behavior of materials at the molecular level.
9:48AM W31.00010: Maximum strain energy density drives path selection in dynamic
cracks*  LITAL ROZEN-LEVY, The Racah Institute of Physics, The Hebrew University of Jerusalem, Israel,
JOHN KOLINSKI (Presenter), Ecole Polytechnique Federale de Lausanne, GIL COHEN, JAY FINEBERG, The
Racah Institute of Physics, The Hebrew University of Jerusalem, Israel — Our fundamental
understanding of dynamic ‘simple’ cracks in brittle solids is excellent, yet the criteria for path
selection of moving cracks remain unknown. We evaluate the criteria for path selection in
dynamic fracture in two ways: first, we deflect dynamic cracks using sparsely implanted defects,
and second, we drive them to undergo an intrinsic oscillatory instability in defect-free media. Our
experiments cover a wide range of crack velocities, from 10-95% of their limiting velocity within
the brittle material. Our high-speed imaging data are used to obtain measurements of the strain
fields very near the crack tip - and these measurements reveal that path selection for such rapid
and strongly perturbed cracks is determined by the direction of maximal strain energy density
rather than by the principle of local symmetry. These results suggest a novel mechanism for
material toughening in brittle solids, whereby a crack is steered, deflected and even stopped by
embedded inclusions.

1523/15)

10:00AM W31.00011: A scaling law to determine cracking lengths in shrinkable granular
packings*  HAN-JAE JEREMY CHO (Presenter), Mechanical Engineering, University of Nevada, Las Vegas,
SUJIT DATTA, Chemical and Biological Engineering, Princeton University — Hydrated granular packings
can shrink and crack into discrete clusters of grains when dried. Cracking in paint and mud are
familiar examples of this phenomenon. Despite its ubiquity, however, an accurate prediction of
cracking length scales remains elusive. Here, we uncover the previously overlooked role of
individual grain shrinkage in determining crack patterning. We perform experiments with
shrinkable hydrogel particles and discrete-element simulations. By incorporating grain shrinkage
into classical Griffith crack theory, we obtain a scaling law that quantifies how cluster size
depends on the interplay between grain shrinkage, stiffness, and size—in agreement with
experiments and simulations. The cracking predictions are applicable to a diverse array of
shrinkable granular materials.

10:12AM W31.00012: The Prince's Dilemma: How Local Heterogeneities Affect the Onset of Frictional Slip  MARY AGAJANIAN (Presenter), SAM DILLAVOU, Harvard University, VINCENT STIN, ESPCI Paris, AMIR SAGY, Geological Survey of Israel, EMILY BRODSKY, University of California, Santa Cruz, SHMUEL RUBINSTEIN, Harvard University — Peas in eider-down beds and asperities at frictional interfaces trouble fairy-tale princesses and nucleate slip events, respectively. We study the onset of such slip events at a two-dimensional frictional interface using soft, transparent elastomer slabs separated by a layer of sand. This system slows rupture propagation to time scales easy to capture experimentally and allows us to directly visualize the full displacement field at the interface. As the top plate is sheared across the interface, stress aggregation forces contact points at the frictional interface to slide and initiates slip events. We systematically introduce localized pockets of stress (peas) to the interface geometry and characterize the effects of these peas on the dynamics of slip nucleation and growth. By tracking the displacement field near the interface, we observe a plethora of these nucleation behaviors, including partial ruptures and local and traveling nucleation.

10:24AM W31.00013: Role of Mesoscopic Friction and Morphology in Large Deformation of Carbon Nanotube Network: a Distinct Element Method Study  YUEZHOUS WANG (Presenter), Integrated Engineering, Minnesota State University, Mankato, GRIGORII DROZDOV, Scientific Computing Program, University of Minnesota, Twin Cities, TRAIAN DUMITRICA, Mechanical Engineering, University of Minnesota, Twin Cities — Carbon nanotubes (CNTs) are game-changing materials in various disciplines, but the limited capability for simulating CNT in bulk represents a significant obstacle for realizing their promising applications. We address this challenge by developing a new simulation methodology titled the mesoscopic Distinct Element Method (mDEM). With parameters input from atomistic simulations, mDEM bridges across the atomistic and mesoscopic length scales, providing an efficient tool to predict the large deformation mechanism of CNT network. Validated through experiments, mDEM is utilized in hypothesis-driven research to demonstrate the internal structural evolution of CNT network stretched until fracture. At small and moderate deformations, zipping relaxations along the applied strain direction dictates the microstructural evolution. At larger deformations, the occurrence of energetic elasticity promotes yarn densification, by relaxing CNT waviness and eliminating squashed pores. Besides the strain-induced alignment process, phononic and polymeric friction promote CNT alignment by enabling load transfer. Our parametric studies not only offer guidance in manufacturing industry to achieve high quality yarn, but also potentially offer an effective way to model fibrous materials in general.
10:36AM W31.00014: Tracking Tabletop Earthquake Nucleation  SAM DILLAVOU (Presenter), Harvard University, VINCENT STIN, ESPCI, MARY AGAJANIAN, Harvard University, AMIR SAGY, Geological Survey of Israel, EMILY BRODSKY, UC Santa Cruz, SHMUEL RUBINSTEIN, Harvard University — Where, when, and how does an earthquake start? Stress concentrations are thought to play an important role in nucleating earthquakes, but their roles are far from trivial. How stressed areas (known as asperities) interact to control the location and timing of quake nucleation is an inherently two-dimensional elasto-dynamic crack problem where the effects of heterogeneity are far from obvious. We experimentally probe the dynamics of nucleation using a tabletop model fault. We reduce the speed of the dynamic ruptures by using soft transparent elastomers and filling the interface with a thin layer of sand. Heterogeneous stress concentrations are imposed by compressing the interface with a rigid plate and adjustable beads to form localized asperities. The clear material allows us to directly image the propagating slip, which would not be possible in natural rock. We find that nucleation location and style is controlled by the stress concentrations. Weaker concentrations result in more migratory nucleation and more global slip events. Furthermore the location of these regions dictates their interactions; widely spaced concentrations are less likely to slip simultaneously, resulting in fewer global events and slower stress release in the case of a global event.

8:00AM W32.00001: Molecular conformation of rigid cyclic and branched polymers in solution* [Invited] KEN TERAO (Presenter), Macromolecular Science, Osaka University — Local conformational properties of rigid cyclic and branched polymers are not always the same as those for the corresponding linear chain unlike flexible polymers. We recently investigated rigid cyclic amylose derivatives and 3-arm star poly(quinoxaline-2,3-diyl) to determine their molecular conformation and intermolecular interactions in dilute solution. We found that local helical structure for the cyclic polymers are appreciably extended and therefore the main chain is more flexible than that for the corresponding linear chain. Regarding with this, the chiral separation columns made of the cyclic amylose derivative are substantially different separation behavior from those for the linear chain, indicating that the local conformation plays an important role for the molecular recognition ability. Both the linear and star chains have lyotropic liquid crystallinity. The phase diagram of isotropic and nematic phases are explained by a modified scaled particle theory when we assume some specific conformation in the nematic phase.

Friday, March 6, 2020 8:00 AM - 11:00 AM
8:36AM W32.00002: Scattering from Melts of Combs and Bottlebrushes: Molecular Dynamics Simulations and Theoretical Study*  HEYI LIANG, ZILU WANG (Presenter), ANDREY DOBRYNIN, Univ of Akron — We use coarse-grained molecular dynamics simulations to establish correlations between peak position in the static structure factor $S(q)$ of combs and bottlebrushes in a melt and their architectural parameters such as degree of polymerization of the side chains $n_{sc}$ and number of backbone bonds $n_g$ between side chain grafting points. Analysis of the scattering function derived in the framework of the Random Phase Approximation and one obtained in simulations shows that in the comb regime with dilute side chains, $n_g > n_{sc}$, the wave number $q^*$ corresponding to the peak position in function $S(q)$ scales with macromolecular parameters as $q^* \propto (n_{sc} n_g)^{-1/4}$. A new scaling law $q^* \propto n_{sc}^{-3/8}$ emerges in the bottlebrush regime, where interactions between side chains stiffen the backbone at short length scales causing the effective backbone Kuhn length to increase with the degree of polymerization of the side chains as $b_K \propto n_{sc}^{1/2}$. The established correlation between the peak position $q^*$ and bottlebrush Kuhn length provides foundation for a new method of obtaining the Kuhn length from scattering data. This approach does not require labeling of bottlebrush backbone and relays on natural contrast between side chains and backbones in the bottlebrush melts.

8:48AM W32.00003: Impact of Architectural Asymmetry on Frank-Kasper Phase Formation in Block Polymer Melts  ALICE CHANG (Presenter), FRANK S BATES, University of Minnesota — Block polymer self-assembly reflects a multiscale competition between enthalpic and entropic factors, producing periodic nanostructures with rich potential to tune the composition, geometry, and length scales. Until recently, the body-centered cubic lattice was believed to be the universal equilibrium state in the sphere-forming region. However, the recent discoveries of equilibrium Frank-Kasper $\sigma$ and A15 phases in diblock polymer melts have revealed remarkable new complexity in these ostensibly simple materials. These complex low-symmetry phases have been experimentally identified in two types of neat block polymers: (1) linear AB diblocks and (2) linear ABA'C tetrablocks. To the best of our knowledge, non-linear architectures remain unexplored. In this talk, we will discuss the connections between molecular architecture and symmetry selection in block polymers. We have systematically tuned the architectural asymmetry in block polymers via living polymerization, from the linear-$b$-linear to linear-$b$-bottlebrush limits. Analysis by small-angle X-ray scattering provides insight into the impact of architectural asymmetry on block polymer self-assembly. Increasing the asymmetry between blocks skews the phase diagram and introduces new potential for block polymer design.
9:00AM W32.00004: Molecular architecture directs linear-bottlebrush-linear triblock copolymers self-assemble to soft, reprocessable elastomers  SHIFENG NIAN (Presenter), Department of Materials Science and Engineering, University of Virginia, HUADA LIAN, Department of Chemical Engineering, Stanford University, ZIHAO GONG, Department of Materials Science and Engineering, University of Virginia, MIKHAIL ZHERNENKOV, National Synchrotron Light Source-II, Brookhaven National Laboratory, JIAN QIN, Department of Chemical Engineering, Stanford University, LIHENG CAI, Department of Materials Science and Engineering, University of Virginia — Linear-bottlebrush-linear (LBBL) triblock copolymers represent an emerging system for creating multifunctional nanostructures. Their self-assembly depends on molecular architecture but remains poorly explored. We synthesize polystyrene-block-bottlebrush polydimethylsiloxane-block-polystyrene triblock copolymers with controlled molecular architecture, and use them as a model system to study the self-assembly of LBBL polymers. Unlike the classical stiff rod-flexible linear block copolymers that are prone to form highly ordered nanostructures such as lamellae, at small weight fractions of the linear blocks, LBBL polymers self-assemble to a disordered sphere phase regardless of the bottlebrush stiffness. Microscopically, the characteristic lengths of the self-assembled nanostructures increase with the stiffness of bottlebrush block by a power law, which is captured by a scaling analysis. Macroscopically, the formed nanostructures are ultrasoft, reprocessable elastomers with shear moduli of about 1 kPa, two orders of magnitude lower than that of conventional polydimethylsiloxane elastomers. Our results provide insights on exploiting the self-assembly of LBBL polymers to create soft functional nanostructures.

9:12AM W32.00005: Structure of bottlebrush polymers end-grafted to a planar surface* JAROSLAW PATUREJ (Presenter), Institute of Physics, University of Silesia, Katowice, Poland, PAUL JUNGMANN, JENZ-UWE SOMMER, IPF Dresden, Germany, TORSTEN KREER, Johannes Gutenberg-Universität, Mainz, Germany — Polymer brush is a hybrid material composed of a solid substrate coated with end-grafted polymers. We conducted coarse-grained molecular dynamics simulations and scaling theory of the equilibrium structure of planar brushes formed by bottlebrush polymers. Bottlebrushes are branched macromolecules consisting of densely spaced linear side chains grafted along a central (linear) backbone. We elucidate the relationship between bottlebrush architecture, surface coverage \( \sigma \) and polymer brush thickness \( H \). We study the impact of three length scales on the brush height \( H: D_0 \), the cross-section radius of bottlebrushes determined by the degree of polymerization of side chains \( N_{sc}, R_0 \) the (overall) size of bottlebrushes controlled by the degree of polymerization of backbone \( N_{bb} \) and \( d \) the distance between nearest-neighbor tethering sites. The latter quantity provides a measure of molecular coverage \( \sigma \) of a substrate defined as the number of bottlebrush polymers per unit surface area \( \sigma \propto 1/d^2 \). Our theoretical analysis identifies three conformational regimes for the height \( H \), which gradually establish upon increasing substrate coverage and stem from interplay between relevant length scales: \( d, D_0 \) and \( R_0 \).

*Polish National Science Center (Grant No. 2018/30/E/ST3/00428)
9:24AM W32.00006: Self-assembly of Bottlebrush Amphiphilic Polymers Near/On Surfaces: Coarse-grained Molecular Dynamics Simulation Study  MICHIEL WESSELS (Presenter), ARTHI JAYARAMAN, Department of Chemical and Biomolecular Engineering, University of Delaware — Nanostructured materials for a wide range of applications such as electronics, optics, and sensing are engineered by the self-assembly of block polymers on surfaces. Significant number of past experimental, theoretical, and computational studies have tackled the self-assembly of linear block polymers, both in bulk and on/near surfaces. Relatively fewer studies have been focused on self-assembly of non-linear architectures (e.g., bottlebrush, star, comb) near/on surfaces. In this talk, we will present our recent work using coarse-grained molecular dynamics simulations to elucidate how branched polymer architecture affects the assembly in solutions of amphiphilic block copolymers near/on surfaces. We establish the role of side chain length versus backbone length, side chain grafting density on the backbone of amphiphilic block polymers as well as surface attraction strength on the chain conformations and the shapes, sizes and patterns of domains assembled on attractive surfaces.

9:36AM W32.00007: Effects of Ionic Groups on Dynamics of Linear-Star Polymer Blends: A Molecular Dynamics Simulation Study* MANJULA SENANAYAKE (Presenter), Department of Chemistry, Clemson University, Clemson, SC, United States,29634, GARY GREST, Sandia National Laboratories, Albuquerque, NM, United States,87123, DVORA PERAHIA, Department of Chemistry/Department of Physics, Clemson University, Clemson, SC, United States, 29634 — Tethering ionic groups to polymers influence their phase behavior and dynamics, and in turn affect their blending with other macromolecules. Here, using MD simulations we probe the effects of ionic groups on the dynamics of linear-star polymer blends, where both the ionic groups and the topology affect the behavior. The polymer chains are modeled by the beads-spring model and the ionic groups are incorporated in the form of stickers (0-5%) on either the linear or star polymers or on both. The fraction $f_{\text{star}}$ of star polymer is varied from 0 to 1. We find that for non-charged blends the short linear and star polymer chains are miscible. Introducing ionic groups on either the linear or the star polymers results in ionic clustering and phase separation. We find that the mobility of the linear ionizable melt is slower than the non-ionic polymers. In contrast, stickers increase the mobility of star polymer melts. In the presence of small amounts of stickers, the mobility of the chains is not affected by chain architecture.

*Supported in part by DOE Grant No. DE-SC007908
9:48AM W32.00008: Complete photonic band gaps with nonfrustrated ABC bottlebrush copolymers  JOSHUA LEQUIEU (Presenter), KRIS T DELANEY, GLENN H FREDRICKSON, University of California, Santa Barbara — Block polymers are a promising platform for photonic materials, yet progress has been limited due to the scarcity of suitable morphologies with complete photonic band gaps and the large domain sizes necessary to manipulate visible light. Here we show that nonfrustrated ABC bottlebrush copolymers can surmount both of these limitations and can be used to form materials with complete photonic band gaps. To achieve this, we have developed a computational tool that couples self-consistent field theory (SCFT) simulations to Maxwell's equations, thereby permitting a direct link between molecular design, self-assembly and the resulting photonic band structure. Using this approach, we calculate the phase diagram of ABC bottlebrush copolymers, and show that complete photonic band gaps can open in the alternating gyroid and alternating diamond phases for modest dielectric contrast between the A, B, and C components. We show that the gap width increases with segregation strength, and depends strongly of the volume fractions of the A and C networks. Notably, the maximum band gap for the alternating gyroid corresponds to a region of the bottlebrush phase diagram where SCFT predicts this phase to be stable, suggesting that these photonic materials could be realized experimentally.

10:00AM W32.00009: Polydispersity Stabilized Complex Morphologies in Poly(styrene-b-methyl methacrylate) Diblock Copolymers  INHO KIM (Presenter), SHENG LI, KAIST — Block copolymers have the unique property to self-assemble into ordered microstructures with well-defined periodicity. Among the various attainable microdomain morphologies, complex bicontinuous morphologies are highly desirable due to their inherent structural connectivity. While such complex structures are difficult to obtain in monodisperse block copolymers, they may be stabilized by increasing block dispersity. In this study, we synthesized a series of poly(styrene-b-methyl methacrylate) (PS-PMMA) diblocks where dispersity of both blocks were systematically varied. The domain morphologies of the resulting diblocks were examined by combination of small-angle X-ray scattering (SAXS) and transmission electron microscopy (TEM). At fixed volume fraction of the PS block, dispersity dictated phase transition was observed. In particular, in the case where dispersity of both blocks were high, the polymers were found to exhibit perforated lamellae (PL) and disordered bicontinuous (BIC) morphologies. These results showed that dispersity control can be used to widen the accessibility window for complex morphologies in block copolymers.
10:12AM W32.00010: Molecular Design of Post-functionalizing Block Copolymers for Versatile Morphologies* TERUAKI HAYAKAWA (Presenter), SEINA YAMAZAKI, YASUNARI YOSHIMURA, YUTA NABAE, Tokyo Inst of Tech - Tokyo — One of the challenges in block copolymer study is to produce bicontinuous structures with various types of polymers with high reproducibility. Conventionally, two methods are known: a method of synthesizing a polymer having a target composition ratio by precise polymerization, and a polymer blend in which fine adjustment of the composition ratio is performed while accurately blending one polymer. However, there are some problems such as lack of reproducibility, limited polymers that can be used, and macrophase separation.
In this study, we demonstrated a new approach for creating bicontinuous microphase-separated structures using the post-functionalization of side-chain type block copolymers. The molecular design of the block copolymers having a vinyl group or glycidyl group in the side chain group was carried out, and the composition ratio was precisely controlled based on the high-yield reactions in the post-functionalization. It was found that the bicontinuous gyroid structure can be obtained with good reproducibility by precisely controlling the amount of side chains introduced.

*This work was supported by JSPS KAKENHI (17H03113) and the Cooperative Research Program of "Network Joint Research Center for Materials and Devices".

10:24AM W32.00011: Poly(Styrene-block-Glycidyl Methacrylate-block-Methyl Methacrylate) as a Versatile Platform for Exploring the Phase Diagram of Linear Triblock Copolymers* KEVIN WYLIE (Presenter), LEI DONG, YUTA NABAE, TERUAKI HAYAKAWA, Tokyo Inst of Tech - Tokyo — Block copolymers have been of great interest because of their intrinsic ability to self-assemble into myriad ordered structures with characteristic dimensions on the order of nanometers. In particular, diblock copolymers have been the primary focus of most research because of their simple architecture leading to a comprehensive understanding of their phase diagram. In contrast, adding a third block greatly increases the number of parameters affecting the self-assembly behavior which in turn greatly increases the number of phases accessible.
We have designed a new linear triblock consisting of poly(styrene-b-glycidyl methacrylate-b-methyl methacrylate) as a new platform for exploring the phase diagram of linear triblock copolymers. The reactive glycidyl methacrylate block can be functionalized with small molecules to modify the Flory-Huggins χ parameter between the middle block and the outer blocks. Thus, we can observe the effect of the changing χ values directly since they are all derived from the same batch.

10:36AM W32.00012: Helical sense of wrapped belts in star terpolymers via slice and view scanning electron microscopy  \( \text{WENPENG SHAN (Presenter), XUEYAN FENG, Rice Univ, GEORGE POLYMEROPoulos, NIKOS HADJICHRISTIDIS, King Abdullah University of Science and Technology, EDWIN THOMAS, Rice Univ} \) — We study the self-assembly behavior of well-defined 3-miktoarm star terpolymers consisting of polyisoprene (PI), polystyrene (PS), and poly(2-vinylpyridine) (P2VP), (PI)\(_2\)-b-PS-b-P2VP. By adjusting the volume fractions of each block (40 vol % for PI, 27 vol % for PS and 33 vol % for P2VP), a unique structure was formed, in which hexagonally packed P2VP cylinders are wrapped by helically twisting PS belts in a matrix of PI. This structure was initially characterized by small angle X-ray scattering of bulk samples and bright field transmission electron microscopy (BF-TEM) of thin microtomed sections. By using I\(_2\) to selectively stain P2VP and OsO\(_4\) for PI, we can distinguish all 3 types of microdomains. In order to study the helical sense and coherent packing between adjacent cylinders, slice and view scanning electron microscopy (SVSEM) tomography is employed. The 3D tomograms of large regions provide information on the detailed nature and packing of the helical PS belts.

10:48AM W32.00013: Molecular dynamics simulations and neutron scattering provide an atomistic level understanding of the self-assembly of poloxamines* \( \text{ROBERT ZIOLEK (Presenter), Department of Physics, King's College London, GUSTAVO GONZALEZ-GAITANO, Department of Chemistry, University of Navarra, CECILE A. DREISS, Institute of Pharmaceutical Science, King's College London, CHRISTIAN D. LORENZ, Department of Physics, King's College London} \) — By integrating molecular dynamics simulations and neutron scattering, we have studied different poloxamines (Tetronics), a family of star-shaped block copolymers that show promise as controlled release drug delivery agents. Their amphiphilicity and the basicity of their central diamine unit control their pH-sensitive self-assembly into supramolecular complexes.

We have studied Tetronic 904 (T904), a medium-sized poloxamine, and Tetronic 304 (T304), a smaller analogue, by all-atom molecular dynamics simulations and neutron scattering. While it is well-known that T904 readily forms micelles over a range of temperatures and concentrations, T304 has previously been found to have a more limited ability to self-assemble. Together, our simulations and experiments provide a detailed microscopic picture of the structure, dynamics and hydration of the self-assembled structures formed by both T904 and T304, and for the first time have uncovered the mechanisms that typically hinder T304 self-assembly.

Session W33 DPOLY DSOFT DMP: Polymer Crystals and Crystallization

I 505 - Christopher Li, Drexel Univ - Tag(s): Focus
8:00AM W33.00001: Polymer epitaxy under heterogeneous confinement
JASON LIU (Presenter), YANG XIA, GEOFFREY ZHENG, MIKKO HAATAJA, CRAIG ARNOLD, RODNEY PRIESTLEY, Princeton University — It is challenging to grow polymer crystals which are aligned over long length scales due to the inherent tendency of polymer lamellae to undergo spherulitic branching and splaying during growth. One approach to the creation of ordered and aligned polymer structures is by epitaxial crystallization. Typically, crystallization proceeds in a film of uniform thickness, in which polymer crystals nucleate and grow along rotationally symmetric, epitaxially matched crystallographic directions. In this work, we heterogeneously confine the film into spatially disparate regions of varying thickness to separate the nucleation and growth processes, allowing oriented arrays of epitaxial crystals to grow unimpeded over long distances. We uncover the hierarchical structure of polymers crystallized under heterogeneous confinement and elucidate the undercooling and molecular weight dependencies of pattern formation with experiments and phase-field simulations.

8:12AM W33.00002: Understanding polymer crystallization undergoing zone annealing*
ALEJANDRO KRAUSKOPF (Presenter), ANDREW JIMENEZ, SANAT KUMAR, Department of Chemical Engineering, Columbia University, ELIZABETH LEWIS, BRYAN VOGT, Department of Polymer Engineering, The University of Akron, JULIA PRIBYL, BRIAN C BENICEWICZ, Department of Chemistry and Biochemistry, University of South Carolina — Zone annealing is a process through which a temperature gradient is translated at a set velocity across a polymer sample of interest, differentiating it from other crystallization processes by its inherent directionality. Through the application of the Hermans orientation function to our small-angle X-ray scattering detector patterns, we explore the extent of anisotropy that the process imparts on both the pure polymer and the polymer nanocomposite systems, with a focus on the lamellar orientation for the former and the nanoparticle arrangement for the latter. We also utilize differential scanning calorimetry to quantify the effects that the process has on the crystalline content and the melting temperature of the materials.

SEONG HYUK CHO (Presenter), RICHARD REGISTER, Princeton University — The Huang-Brown (HB) model predicts that tie molecules (TM), polymer chains that connect different crystalline lamellae across the amorphous layer, form when the end-to-end distance of the coil in the melt (R) exceeds the intercrystalline spacing (d) in the solid state, i.e., the TM probability should scale with R/d. To test the HB model, we synthesize narrowly-distributed (dispersity < 1.2) linear PEs of varying molecular weight (M) using ring-opening metathesis polymerization of cyclopentene followed by hydrogenation. Each PE is either quenched or slowly-cooled from the melt to vary the thermal history, giving two different d values. Uniaxial tensile tests of these PEs show a rather abrupt brittle-to-ductile transition (BDT) with increasing M, but the transition occurs at different R/d for the different crystallization conditions, in the contrast to the HB prediction. Quenched blends with variable contents of high-M PE in a low-M PE matrix show a BDT at the same HB tie chain probability as the quenched PEs. The differences among the values of R/d at the BDT for PEs with different thermal histories and hydrogenated polybutadiene (literature data) suggest that the degree of crystallinity has a significant influence on the value of R/d at the BDT.

*NSF Polymers Program (DMR-1402180)

DAVID NICHOLSON, PENG YI, GREGORY RUTLEDGE (Presenter), Massachusetts Institute of Technology MIT — Crystallization is an essential step in the processing of most polymers. It takes place under conditions of rapid cooling and high strain rate, and is strongly accelerated relative to quiescent conditions. The initial step in this process is flow-enhanced nucleation (FEN), which occurs on time and length scales that are hard to capture experimentally. To resolve this problem, we use nonequilibrium molecular dynamics simulations to characterize FEN from a melt of linear polyethylene-like chains. Both short and long (entangled) chains are simulated. First, methods are described for identifying the critical nucleation event using mean first-passage times (MPFT). Fitting of the data to a master equation is used to extract important thermodynamic and kinetic quantities. Results for nucleation kinetics accelerated under different modes of deformation, e.g. simple shear or uniaxial extension, and rates of strain are used to assess several of the existing models in the literature for flow-enhanced nucleation, based on their abilities to describe the data accurately, and new models based on the orientational ordering of Kuhn segments induced by flow are proposed. Evidence is presented for a breakdown of classical nucleation theory for entangled polymer melts at high strain rates, which in turn is traced to the flow-induced formation of nematic domains in the melt. The appearance of such domains suggests a different perspective on the underlying physics of flow-enhanced nucleation of long chain molecules.

9:12AM W33.00005: Stereoregularity, Molecular Dynamics, and Unusual Crystallinity of Hydrogenated Polynorbornenes: Configurational Disorder*  TOSHIKAZU MIYOSHI (Presenter), NAVIN KAFLE, YUTA MAKITA, Univ of Akron — Solid-state NMR spectroscopy can be used to study both the structure and dynamics of macromolecular systems that exhibit different degrees of order to understand the fundamental properties of materials. One such point of interest is to determine the difference of a polymer's structure, local dynamics and phase transition between various isomers of semicrystalline polymers. Recently, a thorough study on stereospecific ring-opening metathesis polymerization has been conducted on norbornenes making the synthesis and the study of hydrogenated polynorbornene (hPNB) stereoisomers possible. The unique local dynamics, phase structure, and phase transition of atactic-syndiotactic- and isotactic-hPNBs will be shown and their relationships will be discussed.

*NSF DMR Polymers 1708999

9:24AM W33.00006: Crystallization of Asymmetric PEO-b-PCL from Different Solvents*  RYAN VAN HORN (Presenter), Lafayette Coll — Poly(ethylene oxide)-b-poly(caprolactone) (PEO-b-PCL) copolymers have received a lot of attention due to their biocompatibility and amphiphilicity. One unique characteristic is that PEO and PCL have similar crystallization behavior, thus making them a robust model for phase behavior studies. Our previous work showed that the crystallization order could be switched in symmetric copolymers (nearly equal mass fraction) through selective solvent interactions. Further work has been done to identify similar behavior in asymmetric systems. Relative crystallinity and morphology are varied in as-cast films based on solvent characteristics.

9:36AM W33.00007: Symmetry breaking via polymer chain overcrowding in molecular bottlebrush crystallization*  CHRISTOPHER LI (Presenter), HAO QI, MARK STAUB, Drexel Univ, DANIEL HENN, BIN ZHAO, University of Tennessee — One of the fundamental laws in crystallization is translational symmetry, which accounts for the profound shapes observed in natural mineral crystals and snowflakes. Spherical polymer crystalsomes have been grown and investigated in the context of spherical crystallography, where translational symmetry is broken by confining crystal growth in a curved liquid/liquid interface. In this talk, we present the spontaneous formation of spherical hollow crystals with broken translational symmetry in crystalline molecular bottlebrush (mBB) polymers. The unique structure was named as mBB crystalsome (mBBC), highlighting its similarity to the classical molecular vesicles. Fluorescence resonance energy transfer (FRET) experiments showed that the mBBC formation was driven by local chain overcrowding-induced asymmetrical lamella bending.

Improving Crystallite Size and Orientation in Organic Semiconductor Thin Films using PDMS-Assisted Crystallization

VESTA ZHELYASKOVA (Presenter), PRACHI SHARMA, Department of Electrical, Computer, and Energy Engineering, University of Colorado Boulder, DANIEL DESSAU, Department of Physics, University of Colorado Boulder, SEAN SHAHEEN, Department of Electrical, Computer, and Energy Engineering, University of Colorado Boulder — We aim to develop a scalable, solution-based method for growing crystalline organic semiconductor thin films, which can be used in a variety of electronic charge transport, metal doping, and device integration studies. Using a polydimethylsiloxane (PDMS)-assisted deposition method for fullerenes, we grew polycrystalline C₆₀ thin films on plain glass, between gold electrodes on glass, and on silicon substrates under a range of growth conditions. AFM characterization revealed that the films (1) were typically 200-300 nm thick, (2) were made up of crystallites extending up to 200 μm, and (3) had crystalline microstructures that vary with choice of solvent, temperature, and substrate pre-treatment. Films grown from carbon disulfide solutions covered larger areas than those grown out of o-dichlorobenzene—an interplay between the C₆₀’s low solubility and the PDMS’s absorption of nonpolar solvents. Growth at lower temperatures resulted in uniformly aligned crystallites, which formed farther from the PDMS-substrate boundary. Growth along and between gold contacts resulted in nucleation of similarly aligned crystallites at the gold’s edge. Here we discuss the growth kinetics of these films along with their electronic, structural, and spectroscopic characterizations.

Wang-Landau Simulation of the Free Energy Surface of Crystallization in a Polymer Melt

PIERRE KAWAK (Presenter), ANDREW SCOTT GIBSON, LOGAN STEWART BROWN, BEVERLY DELGADO, DOUGLAS TREE, Chemical Engineering Department, Brigham Young Univ-Provo — Semicrystalline polymers comprise as much as 70% of the hundreds of million of tons of polymers produced worldwide. However, the polymer crystallization process remains imperfectly understood. Recently, there has been a lively debate in the literature concerning the applicability of classical nucleation theory to the primary nucleation process in a polymer melt. Recent experimental observations have lead several authors to propose mesomorphic phases that mediate the melt-crystal transition. To investigate these claims, we have constructed a GPU-accelerated Wang-Landau Monte Carlo algorithm that employs both configurational bias and bond breaking moves. Our algorithm has the ability to directly sample the density of states, which can be used to construct a free energy surface as a function of relevant order parameters for crystallization. Our initial results show that we are able to capture both melt and crystalline phases with speed increases of about two orders of magnitude greater than with a comparable serial algorithm.

10:12AM W33.00010: Crystallization and self-nucleation of conjugated polymers*  LUCIA FERNANDEZ-BALLESTER (Presenter), RAMIN HOSSEINABAD, JESSE KUEBLER, University of Nebraska - Lincoln — It is well known that the specific conditions under which polymer crystallization occurs dictate the resulting semicrystalline morphology and, therefore, the final mechanical, optical, and diffusive properties of the solidified material. For conjugated polymers, even seemingly small differences in crystallinity, orientation, or tie chains can result in significant changes in charge transport properties; however, the interplay between chain structure, crystallization conditions, and structure development remains elusive because they are typically processed in solution (for example, by spin-coating) where ill-defined conditions are prevalent. Here, we explore the role of molecular attributes on the crystallization behavior of poly-3-hexylthiophene under well-defined conditions. The results indicate that molecular characteristics play an important role in the way crystallization proceeds, and that self-nucleation strategies can be used effectively to manipulate crystallization conditions.

*Funding provided by National Science Foundation under award DMR-1809888.

10:24AM W33.00011: Paradigm on the Growth Kinetics of Lamellar Polymer Crystals*  WENBING HU (Presenter), Nanjing University — Growth kinetics of lamellar polymer crystals is the holy grail topic in the crystallization mechanism of polymers. There exist so far many controversial arguments, but only three of them have derived the kinetic equations of the linear crystal growth rate at the lateral front of lamellar crystals: Lauritzen-Hoffman model, Sadler-Gilmer Model and the intramolecular crystal nucleation model. Three equations hold however similar forms. This fact reveals the long-existing paradigm during the development of these three models. The latest intramolecular nucleation model provides interpretations to those unique kinetic phenomena of polymer crystallization, such as the origin of chain-folding, the determination of fold-length, molecular-length segregation, sequence-length segregation, three-regime transitions, linear concentration dependence, and self-poisoning growth with integer-folding of short chains.

10:36AM W33.00012: Tuning Nanoparticle Dispersion to Control Confined Polymer Crystallization for Induced Ordering* ANDREW JIMENEZ (Presenter), ABDULLAH AL TORBAQ, Columbia Univ, ALEJANDRO J MÜLLER, University of the Basque Country, SANAT KUMAR, Columbia Univ — Extremely slow isothermal processing presents the ability to control nanoparticle dispersion in semicrystalline polymers, hierarchically ordering them in the amorphous regions of the crystal structure and providing mechanical reinforcement to the composite. The necessity for “extremely slow processing” is, of course, not ideal despite its favorable outcome. Recent work began to understand the tradeoff of crystallization rate and the subsequent particle alignment, both of which depend strongly on nanoparticle grafting and concentration. Building from these insights, we have worked to tune nanoparticle parameters (size and grafting) to manipulate their influence on nucleation and crystal growth rate by effectively controlling polymer confinement and polymer-particle interactions. Designing relative differences in nanoparticle dispersion and mobility allows for increased control over the crystallization rate of the polymer matrix and the subsequent nanoparticle structure of the composite.

10:48AM W33.00013: Kinetics of Shape-fixing in Semicrystalline Shape-memory Networks* JEH-CHANG YANG (Presenter), MITCHELL ANTHAMATTEN, Chemical Engineering, University of Rochester — Crystallization of elastic polymer networks can enable shape-fixing of elastically deformed shapes which can subsequently be melted to regenerate stress or revert to the original shape. The initial step of a shape-memory cycle is shape-programming and involves the formation of connected crystal domains that can prevent the release of stored elastic strain energy. Crystallization kinetics play a critical role in determining the conditions required for sufficient shape-fixing. Here, we assess how imposed strain and undercooling affect crystallization kinetics and concomitant stress loss of crosslinked poly(caprolactone)s. Isothermal crystallization experiments were performed that involve in situ x-ray scattering combined with stress decay measurements. The main finding is that only a small amount of crystallization is needed to significantly reduce tensile stress. This result is valid for low levels of strain and undercooling, and it has broad implications for engineering new shape memory materials.

Session W34 DPOLY GSCCM DCP: Polymers Under Extreme Environmental Conditions 506 - Nir Goldman, Lawrence Livermore Natl Lab - Tag(s): Focus
Anisotropic hydrolysis susceptibility in deformed polydimethylsiloxanes*  
MATTHEW KROONBLAWD (Presenter), NIR GOLDMAN, JAMES LEWICKI, Lawrence Livermore Natl Lab — Environmental factors such as humidity have potential to drive chemical degradation of polymer networks in ways that compound with mechanical stressors. Using two levels of quantum chemical theory, we identify a possible electronic driver for strain-induced chemical susceptibility in deformed polydimethylsiloxane (PDMS) chains. High throughput sampling with a validated semiempirical density functional tight binding (DFTB) model is used to explore the complicated interplay between hydrolytic chain scissioning reactions, mechanical deformations of the backbone, water attack vector, and chain mobility. We show that sustaining tension through concerted strains of the backbone over at least a few monomer units is necessary to significantly increase hydrolysis susceptibility. A reactive order parameter is developed that describes chain scission probabilities as a complicated function of the backbone degrees of freedom. The trends identified suggest simple physical descriptions for the synergistic coupling of local mechanical deformation and chemistry in silicones.

Relating Electrical Properties of Highly Disordered Insulating Materials via the Dispersion Parameter*  
ZACHARY GIBSON (Presenter), JOHN R DENNISON, Utah State University — Relations between electrical properties, critical transitions (CT), and the dispersion parameter $\alpha$ for highly disordered insulating materials (HDIM) are presented. The dispersion parameter is often defined as the thermal energy (low field regime) or field energy (high field regime) scaled by a material-dependent characteristic energy (energetic width of DOS within mobility gap). For dispersive transport, $0<\alpha<1$; $\alpha=1$ defines a CT in both temperature (T) and electric field. A kink is observed in double logarithmic current-time plots measured at constant voltage, similar to Scher-Montroll curves for pulsed photoconductivity. Dark conductivity measurements transition from $T^{-1}$ to $T^{-1/4}$ dependence on a double logarithmic current-T plot at the temperature CT, indicative of a transition from multiple trapping to variable range hopping dominated transport. A field CT is apparent in pulsed electroacoustic measurements of charge distributions where normal transport is observed at high fields, corresponding to the onset of normal transport and electrostatic breakdown. As an example of a prototypical HDIM, various measurements are presented for low-density polyethylene.

8:24AM W34.00003: Atomistic analysis of PBO carbonization process with ReaxFF Reactive Force Field* MALGORZATA KOWALIK (Presenter), CHOWDHURY M. ASHRAF, Department of Mechanical Engineering, Penn State University, SIAVASH RAJABPOUR, Department of Chemical Engineering, Penn State University, BEHZAD DAMIRCHI, DOOMAN AKBARIAN, QIAN MAO, ADRI C.T. VAN DUIN, Department of Mechanical Engineering, Penn State University — There is a constant need for an alternative precursor polymer for the carbon fibers (CFs) production with lowering the costs without compromising CFs mechanical properties. We report an atomistic simulation of a direct carbonization of poly(p-phenylene-2,6-benzobisoxazole) (PBO) that can be transformed into high strength carbon fiber. The possibility of using various heating rates is considered and observed gaseous molecules as well as 6-membered all-carbon ring production analyzed. Based on our ReaxFF atomistic-scale reactive molecular dynamics simulations of the direct carbonization of the PBO we proposed a mechanism that might be responsible for an improvement of the mechanical characteristics of the PBO-based CFs with ultrafast heating rate treatment observed in experiment.

*This project is funded by the Department of Energy Grant No. DE-EE0008195.

8:36AM W34.00004: Characterization of the shock response of heterogenous polymer foams using multi-point PDV measurements JOHN LANG (Presenter), RACHEL HUBER, KATHY MAERZKE, DANA DATTELBAUM, Los Alamos Natl Lab — SX358 is a cross-linked polydimethylsiloxane (PDMS) that can be synthesized in a range of densities (0-65% porous). When porous, it is a stochastic, open cell heterogenous foam with varying pore sizes (10-1000s µm). To model SX358, experimental data is needed to inform equation of state (EOS) models over the range of initial densities. Gas gun planar impact was used to measure high pressure, high temperature material response and shock compression with traditional configurations and diagnostics. The results vary widely, which we attribute to the heterogenous structure of the foam. The diagnostics may interrogate areas where the local density is less than (e.g., a large pore) or greater than the average density. To explore pore variability, we interrogated a large sample area with many velocimetry probes, and then combined the data to obtain an ‘average’ material response. As with past experiments the individual probes showed a varied response. When the data are combined, the ‘average’ response provides a better measure of the continuum response of the stochastic foam with a reduced uncertainty. Phase contrast imaging of the propagating shock front and velocimetry diagnostics with interrogation areas larger than the pore sizes are under investigation to better constrain the EOS.
**8:48AM W34.00005: Investigating the Shock Properties of Polycarbonate**  
JAMES HAWRELIAK (Presenter), Washington State Univ — Polycarbonate is an impact resistant optically transparent thermal plastic used in many engineering applications. The optical transparency and low-Z composition of the polymer chains which make up polycarbonate have made it a candidate window material for dynamic compression experiments. Specifically, experiments which uses x-rays to probe the lattice structure. The low-Z allows for high x-ray transmission and low x-ray scattering for performing x-ray diffraction experiments to measure the atomistic properties, and the optical transparency is suited for using optical probes to measure the bulk material response. We present measurements of the optical properties of polycarbonate at 1550nm and 532nm, the two wavelengths used for velocity interferometry in shock wave experiments.

*The work was supported by the grant DE-SC0016360 funded by the U.S. Department of Energy, Office of Science. The author acknowledges the support of the DOE/NNSA for the Institute for Shock Physics' research activities.*

**9:00AM W34.00006: Polyimide Two-Wave Structure Produced by Shock Compression**  
RACHEL HUBER (Presenter), BRIAN BARTRAM, Dana DATTELBAUM, LLOYD L GIBSON, JOHN LANG, Los Alamos National Laboratory — Polymeric materials undergo densification when dynamically compressed, transitioning the polymer from reactants to products. During gas gun-driven planar impact, we can observe this decomposition with velocimetry probes capturing the particle velocity (movement of the material) history that results from the impinging shock wave. This transition produces a shock wave for both the reactants and the products. If the volume change is large enough, the reactants wave will separate from products wave, generating a two-wave structure in the velocimetry profiles. If the polymer is shocked above or below this transition region, a single wave will be observed. Polyimide (PI) is composed of imide monomer units (-OC=NC-C=O-); it is used as a thermoplastic for high pressure, high temperature applications. Understanding how this polymer reacts within its transition region (17.8-30 GPa) provides vital information for equation of state (EOS) modeling. PI has a large volume change, 20.3%, when shocked into its transition region. Through gas gun-driven planar impact we have observed a two-wave structure in PI with velocimetry probes. The two-wave structure measurement provides kinetic parameters for the reactants-to-products transition that informs the kinetics for EOS models.

*Science Campaign 2*
9:12AM W34.00007: 3D-printed polymeric foam under constant compressive strain: constitutive and multiscale models of long-term property changes [Invited] AMITESH MAITI (Presenter), Lawrence Livermore Natl Lab — Cellular solids or foams constitute an important class of materials with diverse applications. Traditional processes to create such materials lead to significant dispersion in pore size, shape, thickness, and topology. However, recent LLNL advances in 3D printing of polymeric foams by direct-ink-write has enabled the creation of cellular materials of programmable microstructure, customizable shapes, and tunable mechanical response. Success of these 3D printed parts as viable replacement for traditional stochastic foams depends critically on their performance and stability under long-term mechanical strain. To study such effects, we carried out accelerated aging experiments on foams, both stochastic and 3D printed, under a state of constant compression. We monitored the time-evolution of permanent structural change (compression set), altered load-bearing capacity, and changed modulus. This talk will highlight several recent results based on the above measurements, including: (1) the prediction of long-term property changes through time-temperature superposition, with uncertainty margins created using statistical bootstrap; (2) the development of an “age aware” constitutive materials model using the Ogden hyperfoam formalism in a Tobolsky two-network scheme; and (3) finite-element stress analysis within X-ray-CT-imaged foam microstructures that illustrates the superior stability of certain 3D printed close-packed frameworks. The basic steps to a reptation-tube-encompassing coarse-grained strategy to model macroscale aging effects in rubber will also be discussed.

Acknowledgement: This work is a result of close collaboration with LLNL colleagues W. Small, J. Lewicki, A. Saab, T. Weisgraber, S. Chinn, J. Lenhardt, T. Wilson, E. Duoss, C. Spadaccini, and R. Maxwell, and academic collaborator Prof. Y. Li at U. Connecticut. The work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
9:48AM W34.00008: Features of shock Hugoniot measurements of underdense materials*
DANA DATTELBAUM (Presenter), JOSHUA COE, Los Alamos Natl Lab, BRITTANY BRANCH, Sandia National Laboratories — An important challenge pertaining to equation of state model improvements for underdense materials is the quality of experimental measurements. A recent analysis of errors associated with historical explosively-driven experiments yielded large values (>10%) – due, in part, to the near-equivalencies of the shock and mass velocities, which give rise to large errors in density, and spatiotemporal limitations on diagnostics. Other challenges include material heterogeneity and high shock temperatures, both of which contribute to difficulties in experimental measurements. Shock heating, for example, can dominate the compressive response resulting in “anomalous compression.” In the anomalous regime, the Hugoniot curves often bend back, with increases in shock pressure resulting in no volume change, even at modest porosities. We present a summary of features of shock Hugoniots of porous polymers over a range of initial densities, and show the interplays between initial density, shock stress, and normal vs. anomalous regimes. We also describe how penetrating x-ray-based imaging can be used to drive down errors. Recommendations will be made for future improvements and their impacts on theoretical model development.

10:00AM W34.00009: Efficient Shockwave Energy Dissipation in Dynamic PDMS Networks
CHRISTOPHER EVANS (Presenter), NANCY SOTTOS, JAEJUN LEE, LAURA PORATH, BRIAN JING, University of Illinois at Urbana-Champaign — Polymer networks containing dynamic bonds have received increasing attention over the past decade. Depending on the specific bond, a certain amount of energy is required for the bonds to undergo an exchange process. We hypothesize and demonstrate that dynamic bonds in polydimethylsiloxane (PDMS) networks can be used as an effective mechanism for dissipating energy, in particular from a shockwave. The density of dynamic bonds can be controlled which controls the modulus while the network Tg is unchanged. Using a classical laser induced shockwave technique, superior energy dissipation is observed in a PDMS dynamic rubber compared to the benchmark polyurea. The dynamic PDMS also outperforms covalently crosslinked PDMS and shows a monotonic improvement in dissipation performance with increasing density of dynamic boronic ester bonds. In all cases, the Tg is invariant in the different networks (-125 °C) implying a minimal role of segmental dynamics on dissipation in these specific networks. The dynamic networks can be shocked multiple times with invariant performance suggesting the mechanism is non-destructive and related to bond exchange rather than breakage.
10:12AM W34.00010: Synthesis and Self-Assembly of Multi-Patch Functional Colloids* [Invited]

ALEXANDER BÖKER (Presenter), Fraunhofer-Institute for Applied Polymer Research IAP — This talk will discuss the creation of artificial materials systems which can be programmed to self-assemble and may even allow self-replication of structures. To achieve this, an indispensable prerequisite is the multi-directional control of interactions between the building blocks of materials. Thus, we describe a new class of multi-patch colloidal particles via an advanced micro-contact printing technique yielding patches of different chemical or physical functionalities. The new production process allows precise control over the patch location and chemistry even with low molecular weight inks and thus also yields particles that go well beyond known ABA- or ABC-type Janus particles. In addition chemical approaches for selective interaction and their influence on the self-assembly behavior will be discussed[1-5].

W34.00011: Surface hardness enhancement of ion bombarded polycarbonate*  SUNMOG YEO (Presenter), CHANG YOUNG LEE, WON-JE CHO, YONG-SEOK HWANG, CHORONG KIM, DONG-SEOK KIM, KOMAC, Korea Atomic Energy Research Institute — The surface hardness of polycarbonate (PC) can be enhanced by ion bombardment with energy of a few hundred KeV. Nano indentation measurement on ion bombardment PC shows that the hardness of PC increases with increasing the ion dose. In addition, the surface properties examined by FT-IR show that the lighter ion mass causes the increase of C=O (1680-1750 cm\(^{-1}\)) and C=C (1500-1700 cm\(^{-1}\)) stretching vibration and the relative ratio of C-O-C peak near the wave number of 1200 cm\(^{-1}\) decreases with increasing dose and energy of H\(^{+}\) ion. We discuss the surface hardness enhancement of PC based on these results.

Session W35 DPOLY: Dynamics in Polyelectrolyte Complexes and Associative Polymer Networks 507 - Jelena Dinic, Argonne Natl Lab - Tag(s): Focus

8:00AM W35.00001: Engineering hydrogel viscoelastic mechanics via bio-inspired supramolecular metal-coordinate dynamics  NIELS HOLTEN-ANDERSEN (Presenter), Massachusetts Institute of Technology MIT — Growing evidence supports a critical role of metal-coordinate supramolecular crosslinking in governing stimuli-responsive properties of soft biological materials. As such, bio-inspired metal-coordinate crosslinking provides unique opportunities to further our understanding of how to directly correlate macroscopic hydrogel mechanics with microscopic crosslink dynamics. Recent insights generated from such fundamental studies of metal-coordinate supramolecular chemo-mechanical couplings in hydrogels will be presented.
8:12AM W35.00002: Experimental evidence of universal behavior in ion-induced volume phase transition in polyelectrolyte gels* MATAN MUSSEL (Presenter), PETER BASSER, FERENC HORKAY, National Institutes of Health - NIH — Introduction of high valence counterions into polyelectrolyte solutions and gels results in a reversible volume phase transition. The volume change can be induced by a small change in the concentration of the equilibrium salt solution. In the present work new results are reported for the volume transition induced by calcium-sodium ion exchange in sodium polyacrylate gels made by osmotic swelling pressure and small angle neutron scattering measurements. We show that the threshold Ca\(^{2+}\) ion concentration at which the transition occurs increases with increasing NaCl concentration in the surrounding bath, decreases with increasing the concentration of the ionized groups on the polymer backbone and the temperature, and is practically unaffected by changing the crosslink density of the network. It is demonstrated that the normalized swelling data fall on a master curve, indicating that the volume transition exhibits universal behavior. These findings imply that gel volume transition is primarily governed by changes in the electrostatic interactions as a consequence of the divalent-monovalent ion exchange.

*No funding.

8:24AM W35.00003: pH modulated nanoparticle diffusion in silica-polyacrylamide hydrogels* KATIE ROSE (Presenter), DAEYEON LEE, Chemical and Biomolecular Engineering, University of Pennsylvania, RUSSELL COMPOSTO, Materials Science and Engineering, University of Pennsylvania — Using single particle tracking (SPT), we investigate nanoparticle (NP) diffusion in polyacrylamide hydrogels containing immobile silica particles (0% - 10% volume). For low concentrations of silica particles, two distinct populations of diffusing NPs are observed, localized and diffusive, whereas only diffusive NPs are found in the neat hydrogel. Primarily diffusive behavior is recovered for high concentrations of silica, attributed to an incomplete formation of the mesh as indicated by rheology. A proposed mechanism for the localized behavior of the NP probes is the pH mediated attraction via hydrogen bonding interaction between the PEG brush grafted to the surface of the NP and the silanol groups on the silica surface. The extent of the PEG-silica interaction and its subsequent impact on NP dynamics is examined at different pH values using quartz crystal microbalance with dissipation (QCM-D). This study provides valuable insight into controlling the diffusion of NPs in hydrogels based on pH mediated interactions with an incorporated tertiary component, with implications in drug delivery and filtration.

Length-scale dependent anomalous diffusion regimes in associative protein hydrogels*

AMEYA RAO (Presenter), HELEN YAO, BRADLEY OLSEN, Massachusetts Institute of Technology MIT — Associative polymer gels are of interest as tunable, responsive materials for biomedical and soft robotics applications. Although theories can describe the effect of crosslink reversibility on network viscoelasticity, diffusion of chains through the network is poorly understood due to the complex interplay between sticker association and strand relaxation. Here, we use forced Rayleigh scattering and neutron spin echo to study self-diffusion in model coiled-coil protein hydrogels over a range of 8 decades of length-squared. We show the first experimental evidence for multiple diffusion regimes spanning from the submolecular to the Fickian, including anomalous caging and superdiffusive regimes, which depend on the concentration and length scale probed. Interpreting these results in the context of Brownian dynamics simulations allows characterization of various diffusive modes and molecular parameters (e.g., sticker dissociation and strand relaxation time) governing transitions between these regimes. Finally, tracer diffusion of single coiled-coils is measured in a matrix of proteins containing 4 such domains to link quantitatively single-sticker dynamics to overall chain diffusion rates at various length scales.

Anomalous diffusion in a model associative network with high sticker density.*

IRINA MAHMAD RASID (Presenter), NIELS HOLTEN-ANDERSEN, BRADLEY OLSEN, Massachusetts Institute of Technology MIT — The dynamic nature of the bonds in associative polymer networks has led to their use in the design of tough and self-healing hydrogels. The ability to self-heal in these networks relies on the reformation of the original network and is strongly affected by the timescale for self-diffusion. This work measured the self-diffusion of a model associative network, consisting of a linear polymer functionalized with histidine side-groups, using forced Rayleigh scattering. The effect of sticker density was investigated by synthesizing random copolymers through RAFT polymerization, with up to 15 histidine groups per chain. The polymers showed anomalous diffusion that persisted even for the highest sticker density. Earlier work has shown that anomalous diffusion as observed from FRS measurements in other associative networks, with up to four stickers per chain, primarily result from molecular hopping. These results indicate that molecular hopping could still be an important mode of self-diffusion in these networks, even at high sticker densities.

9:00AM W35.00006: Scattering Investigations of Structure and Dynamics of Triblock Polyelectrolyte Complex Hydrogels  DEFU LI (Presenter), SAMANVAYA SRIVASTAVA, Chemical and Biomolecular Engineering, University of California, Los Angeles — Polyelectrolyte complex (PEC) hydrogels are physically crosslinked 3-D networks that form upon complexation between oppositely charged polyelectrolytes. The development and use of PEC hydrogels for diverse biomedical applications require an in-depth understanding of the thermodynamics and kinetics of hydrogel assembly as well as their mesoscale structures and bulk properties. In this talk, we introduce the intimate correlations between PEC domain morphologies and material relaxation timescales in hydrogels comprising oppositely charged ABA triblock polyelectrolytes. Polymer size and concentration as well as solution ionic strength were all found to dictate the PEC domain morphologies, size and arrangements. X-ray photon correlation spectroscopy (XPCS) investigations revealed two distinct relaxation modes of the nanoscale PEC domains. The polymer concentration-independent faster relaxation was expected to capture the dynamic processes inside the PEC domains, while the slower polymer concentration-dependent domain relaxation timescales were found to be inherently linked with the equilibrium hydrogel structure. Upon addition of salt, both relaxation modes became faster, indicating speeding of the intra-domain relaxations and smaller, faster-relaxing PEC domains.

9:12AM W35.00007: Stimuli-responsive polyelectrolyte gels and the role of ion and polymer solvation*  ALEXANDROS CHREMOS (Presenter), MATAN MUSSEL, PETER BASSER, Section on Quantitative Imaging and Tissue Sciences, National Institutes of Health, JACK DOUGLAS, National Institute of Standards and Technology, FERENC HORKAY, Section on Quantitative Imaging and Tissue Sciences, National Institutes of Health — Polyelectrolyte gels are essential components of living systems, since biological tissues are largely composed of polyelectrolyte gels providing a medium for the transport of ions and molecules more easily and effectively while at the same time providing structural integrity. The challenge of modeling the influence of solvation and ion partition on the swelling of gels is due to the coupling between the polyelectrolyte chain configurations and the spatial distribution of the ionic species in solution. We perform molecular dynamics simulations of a minimal model of a polyelectrolyte nanogel particle in solution with an explicit solvent and ions, where the relative strength of dispersion interactions between the solvent and the charged species defines the solvent quality and the position of the ion along the Hofmeister series. Our findings demonstrate that the solvent plays a crucial role in gel swelling and the sensitivity of swelling to the addition of salt and the ion partitioning between the gel and the surrounding solution. Overall, our findings provide a guideline for the development of a more predictive theory of the thermodynamic and transport properties of these complex systems.

9:24AM W35.00008: Influence of temperature, salt and molecular weight on the dynamics of polyelectrolyte complexes. MO YANG (Presenter), Department of Chemistry and Biochemistry, Florida State University, JIANBING SHI, School of Materials Science and Engineering, Beijing Institute of Technology, JOSEPH SCHLENOFF, Department of Chemistry and Biochemistry, Florida State University — Oppositely-charged polyelectrolytes can spontaneously associate into either solid-like complexes or liquid-like coacervates based on the external salt concentration. The linear viscoelasticity of polyelectrolyte complexes/coacervates (PEC) can be influenced by a variety of factors, such as temperature, salt and pH. Due to the insufficient chain length of polyelectrolyte, few works have reported the entanglement behavior of PEC and only reptation time ($\tau_{\text{rep}}$) has been found. Here, we prepared five pairs of PEC with different molecular weight and matched polycation/polyanion chain length. Rheology experiments were carried out for all PEC pairs at different temperatures and salt concentrations. Time-temperature (TTS) and time-temperature-salt (TTSS) superpositions were achieved with good fit to sticky association theory. Relaxation times for polymer partnering ($\tau_b$), entanglement ($\tau_e$) and reptation ($\tau_{\text{rep}}$) were revealed directly from the TTS data. All these characteristic lifetimes were slowed by the sticky dynamics of Pol$^+$Pol$^-$ pairs. We found that the relaxation kinetics of temperature showed Arrhenius dependence, whereas changing the salt concentration impacted the lifetime of Pol$^+$Pol$^-$ pairs, the number of stickers per chain and the volume fraction of polymer.

9:36AM W35.00009: Water binding and mobility in polyelectrolyte complexes* PIOTR BATYS, Jerzy Haber Institute of Catalysis and Surface Chemistry, Polish Academy of Sciences, Poland, SOUSA JAVAN NIKKHAH, Aalto University, Finland, YANPU ZHANG, SUVESHW LALWANI, JODIE LUTKENHAUS, Texas A&M University, TX, United States, MARIA SAMMALKORPI (Presenter), Aalto University, Finland — Water is central in the assembly and the dynamics of charged macromolecular systems including polyelectrolyte assemblies. Nevertheless, it remains a challenge to resolve how water influences assembly characteristics and materials properties of these systems. We have examined via molecular modelling and interconnected experiments the role of water at molecular level on polyelectrolyte complexes and multilayers. We compare different polyelectrolyte systems under varying hydration and salt content and report that the hydration and water binding at especially intrinsic ion pairs connects with the thermal and mechanical response of hydrated polyelectrolyte assemblies. The findings rise attention to water and water partitioning as a control parameter of polyelectrolyte materials properties.

9:48AM W35.00010: Water's effect on the glass transition and dynamic mechanical properties of polyelectrolyte complexes* [Invited] JODIE LUTKENHAUS (Presenter), Texas A&M Univ, MARIA SAMMALKORPI, Aalto University, PIOTR BATYS, Jerzy Haber Institute of Catalysis and Surface Chemistry Polish Academy of Sciences — Charged assemblies bearing opposite or complementary charges span natural (proteins, enzymes, DNA) to synthetic materials (surfactants, synthetic polyelectrolytes). Assembly is facilitated by electrostatic attraction and entropic release of counterions, and most often occurs in aqueous media. Notably decades ago, Michaels described synthetic polyelectrolyte complexes as brittle when dry but “leathery or rubberlike” when wet, which points to the strong effect of water on the mobility of a charged assembly. Here, the molecular origin of the glass transition is quantified for several charged macromolecular systems is investigated using calorimetry and molecular modeling as a function of water content. A general relationship is revealed as it holds for two completely different types of charged systems (pH- and salt-sensitive) and for both polyelectrolyte complexes and polyelectrolyte multilayers, which are made by different paths. This suggests that water facilitates the relaxation of charged assemblies by reducing attractions between oppositely charged intrinsic ion pairs. We further demonstrate the dual role of water and temperature in the dynamics of polyelectrolyte complexes by showing time-temperature and time-water superpositioning in a single polyelectrolyte complex system. This is accomplished by changing the relative humidity to adjust the water content in the complex during testing. Results indicate the existence of a water-based shift factor ($a_w$) that bears a log-linear relationship.

10:24AM W35.00011: Electric field-dependent metastable phenomena in polyelectrolyte solutions* KATCHER MARGOSSIAN (Presenter), MURUGAPPAN MUTHUKUMAR, Department of Polymer Science and Engineering, University of Massachusetts Amherst — We have recorded the response of various polyelectrolyte systems to applied voltages. Here, we explore the effects of chain length, architecture, and concentration on the charge transport properties of our solutions in order to determine the origin of nonlinear behavior demonstrated by these materials. Our findings suggest the existence of several mechanisms by which ions can flow through charged polymers, each of which can be observed within distinct voltage regimes and solution conditions. With these findings, we can understand similar characteristics seen in other charged networks.

10:36AM W35.00012: Electrospinning Coacervates – No Chain Entanglements Required
Xiangxi Meng, Department of Chemical Engineering, University of Massachusetts Amherst, Yifeng Du, Department of Polymer Science & Engineering, University of Massachusetts Amherst, Yalin Liu, Department of Chemical Engineering, University of Massachusetts Amherst, Bryan Coughlin, Department of Polymer Science & Engineering, University of Massachusetts Amherst, Jessica Schiffman, Sarah Perry (Presenter), Department of Chemical Engineering, University of Massachusetts Amherst — Electrospun fibers have utility across a range of fields. However, electrospinning traditionally requires long-chain, entangled polymer solutions. This combination of factors is necessary to create physical entanglements that relax slower than the timescale for electrospinning to prevent capillary breakup of the polymer jet. This requirement has also meant that spinning polyelectrolytes is particularly challenging as electrostatic repulsions along the polymer backbone dramatically increase the solution viscosity. We have reported a strategy for electrospinning charged polymers via complex coacervation. The coacervate liquid resulting from the complexation of oppositely-charged polymers can be used for electrospinning, resulting in solid fibers that are stable against dissolution in water and organic solvents. Here, we explore the potential for using the cooperative electrostatic interactions between polymer chains in place of physical entanglements. We investigated the electrospinnability of coacervates as a function of chain length. We demonstrated successful spinning of fibers using coacervates of oligomers of length <10. These results suggest the potential for using coacervates as a new class of electrospun materials where fiber formation is decoupled from chain length.

10:48AM W35.00013: Phase Separation and Gelation in Solutions of A–B Associative Polymers
Scott Danielsen (Presenter), Michael Rubinstein, Mechanical Engineering and Materials Science, Duke University — An equilibrium theory for reversible network formation in two-component solutions of associative polymers is presented to account for the phase behavior due to hydrogen bonding, metal–ligand, electrostatic, or other pairwise associative interactions. We consider polymers of types A and B with many associating groups per chain and consider only A–B association between the groups. A simple analytical expression for the free energy is derived and is shown to be consistent with the classical Flory-Stockmayer gelation theory. It is shown that association and formation of a reversible network is always accompanied by a tendency for phase separation, even at good solvent conditions, a significant difference from self-associative polymers. Homogeneous networks are most easily stabilized near stoichiometric conditions between A and B associative groups, resulting in a sol–gel–sol transition as the overall composition is altered. Chemical incompatibility between the A and B polymers drives a competition between attractively and repulsively-driven phase separation, leading to microphase formation and eutectic behavior.

Session W36 DCOMP: Twenty years of the Quantum Cluster Theory: recent progress 601/603 - Juana Moreno, Louisiana State University, Baton Rouge - Tag(s): Invited
8:00AM W36.00001: Impurity models and the development of quantum cluster approaches to lattice models of quantum condensed matter [Invited]  HULIKAL KRISHNAMURTHY (Presenter), Centre for Condensed Matter Theory, Department of Physics, Indian Institute of Science — My aim in this talk will be to provide a historical perspective of the evolution of computational quantum many-body ideas and methods connected with the first numerical solutions of quantum impurity problems leading on to the development of modern quantum cluster theories of strongly correlated and disordered condensed matter systems, the subject of this symposium. I will review the advances that took place, both in understanding and in the techniques of solution, of quantum impurity models in the 70s and 80s, the development of the dynamical mean-field theory in the late 80s and early 90s, and of its cluster extensions in the late 90s and early 2000s.

8:36AM W36.00002: Quantum Cluster Theory of Unconventional Superconductivity* [Invited] THOMAS MAIER (Presenter), Oak Ridge National Laboratory — Quantum cluster theories provide an important framework to give insight into the complex behavior and different quantum states observed in correlated electron materials. In particular, they can provide an understanding of the mechanisms that give rise to superconductivity in unconventional superconductors, in which pairing is driven by electron-electron interactions. Here we discuss how dynamic cluster approximation quantum Monte Carlo calculations of Hubbard models have progressed in addressing this problem, and how this progress is linked to advances in algorithms and high-end computing hardware.

*This work was supported by the Scientific Discovery through Advanced Computing (SciDAC) program funded by U.S. Department of Energy, Office of Science, Advanced Scientific Computing Research and Basic Energy Sciences, Division of Materials Sciences and Engineering.

9:12AM W36.00003: Multiscale approaches to strongly correlated systems in and out of equilibrium [Invited] HERBERT FOTSO (Presenter), University at Albany — The degrees of freedom that confer to strongly correlated systems their many intriguing properties also render them fairly intractable through typical perturbative treatments. For this reason, many of the mechanisms responsible for these technologically promising properties remain rather elusive. Computational approaches have played a major role in helping to fill this void. In particular, dynamical mean field theory (DMFT) and its cluster extension, the dynamical cluster approximation (DCA) have allowed significant progress. However, despite all the insightful results of the dynamical cluster approximation, computational constraints (sign problem, exponential growth of the Hilbert space) still limit the length scale within which correlations can be treated exactly in the formalism. A natural next step is the development of multiscale many body approaches whereby this challenge is addressed by introducing, between the short length scale where correlations are treated exactly using a cluster solver such Quantum Monte Carlo (QMC) or exact diagonalization, and the long length scale where correlations are treated in a mean field, an intermediate length scale within which correlations can be treated perturbatively. We will discuss implementations of this multiscale many body approach and the results they have yielded. In addition, we will discuss the framework for extension of quantum cluster approximations to the nonequilibrium problem.
9:48AM W36.00004: Quantum cluster typical medium methods for the study of localization in strongly disordered electronic systems.* [Invited] HANNA TERLETSKA (Presenter), Middle Tennessee State Univ — Disorder is a common feature of many materials and often plays a key role in changing and controlling their mechanical, electronic and other functional properties. Anderson localization is one of the fascinating effects of disorder in materials, which is often hard to capture numerically. There has been great progress made in the last several years towards understanding the properties of disordered electronic systems and electron localization, in particular, based on the effective medium methods. We have recently developed the Typical Medium Dynamical Cluster Approximation (TMDCA) for disordered electronic systems [1, 2]. The TMDCA enables quantitative analysis of electron localized states in disordered electron systems. The method is an effective medium approach that maps a given disorder lattice problem onto a quantum cluster embedded in an effective typical medium, which is determined self-consistently. Following the ideas of Dobrosavljevic et al. [3], the TMDCA employs the cluster typical (geometrically averaged) density of states as an order parameter to detect the localized electrons states. It has been shown that TMDCA not only correctly captures non-local effects but also recovers exact analytical results in simple disorder models [1]. In this talk, I will provide an overview of various recent applications of the TMDCA to a variety of models and systems, including application of the method to interacting disordered electrons as well as realistic systems in the framework of the ab-initio methods.

10:24AM W36.00005: Cluster dynamical mean field studies of two-particle response functions in the Hubbard model* [Invited] EMANUEL GULL (Presenter), XINYANG DONG, Univ of Michigan - Ann Arbor, XI CHEN, Simons Foundation — Over the last twenty years, the cluster dynamical mean field theory has generated useful insight into the Hubbard model and its relation to the pseudogap and superconductivity in the two-dimensional Hubbard model. While the behavior of single-particle properties of the model is well understood, this was so far not the case for higher order correlation functions. This talk will introduce susceptibility calculations and show comparisons to a range of experimental two-particle probes in the cuprates, including NMR, neutron spectroscopy, and M-EELS. We will also show how two-particle quantities can be used to identify the leading fluctuations.

*This work was funded by NSF DMR 1606348
8:00 AM W37.00001: The Making of Modern Physics in Colonial India [Invited] SOMADITYA BANERJEE (Presenter), Austin Peay State University — How did modern physics establish itself in India—a British colony—in the early 20th century? Who were the key actors and why did they develop physics in a colonized country far away from a European metropole? By using the case studies of Jagadish Chandra Bose, Satyendranath Bose and Chandrasekhara Venkata Raman, this talk will explore their physics, nationalism and social identity as "well-mannered intelligentsia" who played a key role in the making of modern physics in a country still under colonial domination. Finally, it will be argued how the local and the global were entangled in the worldview of these colonial intellectuals and the correlations between the discontinuous 'light quantum' and Indian history that played a key role in the ushering in of modern Indian physics.

8:36 AM W37.00002: Women and Physical Sciences in India: Bimla Buti and efforts to flourish a physical plasma community in her home country [Invited] INDIANARA SILVA (Presenter), Graduate Program in History, Philosophy and Science Teaching, Federal University of Bahia — Bimla Buti is the first Indian woman Physicist Fellow of Indian National Science Academy (INSA) and The Academy of Sciences of the Developing World (TWAS). Her contributions to physical sciences have been celebrated with awards, such as INSA-Vainu Bappu Award, Vikram Sarabhai Award, and Jawaharlal Nehru Birth Centenary Lectureship Award. Buti received her scientific recognitions with surprise as, using her own words, “it was almost impossible for me, a woman scientist in a man-dominated field, to get nominated for prestigious awards like the Bhatnagar award” (Buti, 2008, p. 38). The man-dominated field was plasma physics. To Indian physical sciences, besides writing papers and books, she contributed to developing a research program on plasma physics at the Physical Research Laboratory (PRL) and founded The Plasma Science Society in India. “We managed to establish a very strong group in plasma physics, both theoretical and experimental, at PRL” (Buti, 2008, p. 39). This talk will trace her contributions to physical sciences, struggles to become a female physicist, and efforts to build a career and community in plasma physics, contributing, thus, to the History of Science in India.
9:12AM W37.00003: “The free side of the meter”: Trustworthiness, theft and class identity in reading the domestic electric meter in early twentieth-century Calcutta [Invited]
ANIMESH CHATTERJEE (Presenter), Leeds Trinity University — Of all the devices used in early electric supply projects in early twentieth century Calcutta, the domestic meter was perhaps the most controversial. Introduced as a reliable billing method to measure consumption by customers connected to the newly introduced electric supply system, the electric meter was also at the centre of cases of “improper use” of electricity supply. The term “improper use” is used broadly here to refer to a variety of consumer practices that the Calcutta Electric Supply Corporation believed to be interferences to their property and operations. These included theft of electricity by bypassing or breaking seals on electric meters, or using electricity for purposes other than that for which it was supplied to the customer. This paper examines some of the disputes between customers, and engineers and inspectors of Calcutta Electric Supply Corporation on the deployment and use of electric supply and meters in early twentieth century Calcutta. Following recent works on users and non-users of technologies, and trust and the morality of measurements, this paper examines how electric meters became central to concerns over issues of quantities measures by meters, the class identity of customers, and trust between the supplier, consumers and the electric meter. In doing so, this paper will focus on both the design of measurements instruments, and the agency and discretion of the electrical consumer, thereby providing new perspectives on how consumers, suppliers and electrical measurement technologies interacted during the early days of electricity supply in colonial Calcutta.

9:48AM W37.00004: Scientific Creativity in Peripheral Locations: The Madras Triple Helix Model of G.N. Ramachandran [Invited] DEEPANWITA DASGUPTA (Presenter), The University of Texas at El Paso — The name of the Indian scientist G. N. Ramachandran is associated forever with the discovery of the structure of Collagen. Present in almost all connective tissues, such as skins, bones or muscles, collagen was the third great discovery in biophysics right after the discovery of alpha helix by Linus Pauling and the DNA double helix by Crick and Watson. Unlike the first two however, this third discovery came from a young peripheral scientist who worked from an obscure newly-founded Department at the University of Madras. The discovery of the triple helix structure in collagen, and the subsequent creation of the Ramachandran Plot, was thus truly a case when a peripheral scientist won the race for discovery against numerous Goliaths in the field. In this presentation, my goal will be to trace the outlines of the reasoning that led Ramachandran from his early X-ray diffraction diagrams to the final triple helix structure and the controversy that created the Ramachandran Plot.

Friday, March 6, 2020 8:00 AM - 10:48 AM

Session W38 DQI: Control and Characterization Tools for Quantum Error Mitigation 607 - Timothy Proctor, Sandia National Laboratories - Tag(s): Focus
8:00AM W38.00001: Demonstrating error rate homogenization using dynamically corrected gates in a trapped ion system  CLAIRE EDMUNDS (Presenter), CORNELIUS HEMPEL, ALISTAIR MILNE, MICHAEL BIERCUK, Univ of Sydney — High quality, error-robust gates are a fundamental element of scalable quantum computing architectures; however, their performance is often limited by their high sensitivity to external perturbations and imperfections in the control field. We experimentally demonstrate that replacing “primitive” physical gates with error-suppressing, dynamically corrected gates (DCGs) can homogenize error rates across a qubit register in both space and time, in addition to reducing net error rates.

We perform parallel single-qubit operations on a multi-qubit register of $^{171}$Yb$^+$ ions using a microwave field. We achieve a best case single-qubit average error rate of 1.9e-5 using primitive gates, although inhomogeneous fields lead to an order of magnitude variation across the 10 qubit register. By using DCGs, we observe an 8.5x reduction in the spread of error rates across the register, and a 2.4x improvement of the average value. Furthermore, DCGs provide an added robustness to slow drifts in the control, reducing the overhead required for regular calibrations. Finally, we discuss a microwave synthesis chain using a cryogenic sapphire oscillator and an arbitrary waveform generator, aimed at improving the control-field phase noise and reducing the calibration requirements compared to traditional I/Q.

8:12AM W38.00002: Error Mitigation Via Simulated Measurement of Stabilizers*  AMY GREENE (Presenter), MORTEN KJAERGAARD, Massachusetts Institute of Technology MIT, MOLLIE SCHWARTZ, MIT Lincoln Laboratory, GABRIEL SAMACH, Massachusetts Institute of Technology MIT, ANDREAS BENTSSON, Chalmers University of Technology, MICHAEL O'KEEFFE, MIT Lincoln Laboratory, MILAD MARVIAN, RONI WINIK, Massachusetts Institute of Technology MIT, DAVID K KIM, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, JONILYN YODER, DANNA ROSENBERG, KEVIN OBENLAND, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, Massachusetts Institute of Technology MIT, IMAN MARVIAN, Duke, WILLIAM OLIVER, Massachusetts Institute of Technology MIT — While closed-loop control is the ideal for quantum error correction, open-loop techniques are more accessible given current technologies. Dynamical decoupling is the go-to error mitigation technique, but many of the noise mechanisms encountered in experimental implementations, such as microwave cross-talk or coherent gate errors, are not amenable to simple dynamical decoupling schemes. An alternative technique for these errors is to simulate measurement of stabilizer operators via the stochastic application of gates from the set of stabilizers. We demonstrate the error-mitigating effects of this simulated quantum measurement protocol on a small superconducting qubit processor.

8:24AM W38.00003: SPAM Error Correction: Transition Matrix versus Quasiprobabilities
MINGYU SUN (Presenter), MICHAEL RAY GELLER, University of Georgia — State preparation and measurement (SPAM) errors limit the performance of noisy intermediate-scale quantum computers and their potential for practical application. Two techniques have been used to partially mitigate these SPAM errors. Both approaches build approximate models of the errors via tomography and then attempt to invert it. The first technique is to measure the transition matrix between all initial and final classical states, and to use this information to classically correct subsequently measured data. The second technique recently proposed by Temme, Bravyi, and Gambetta decomposes an ideal circuit into a quasiprobabilistic mixture of noisy measured ones. While neither approach is scalable, it would be useful to know their effectiveness when applied to real SPAM errors. Here apply both methods to online IBM qubits, and find very similar predictions for one- and two-qubit corrected Pauli expectation values, with some indication that the simpler transition matrix method performs slightly better than the quasiprobability representation, at least for the SPAM errors encountered in superconducting qubits.

8:36AM W38.00004: Experimental Realization of Randomized Compiling for in-situ Error Reduction
AKEL HASHIM (Presenter), University of California, Berkeley, KASRA NOWROUZI, ALEXIS MORVAN, Lawrence Berkeley National Laboratory, RAVI KAUSHIK NAIK, JOHN MARK KREIKEBAUM, IRFAN SIDDIQI, University of California, Berkeley — We present work on reducing the average error during the operation of an algorithm through randomized compiling (RC) [1], which tailors arbitrary Markovian noise into stochastic Pauli errors. By compiling random single-qubit twirling gates into the bare sequence of an algorithm and averaging over many initializations of an RC circuit, the total error of an algorithm is reduced because the error per single qubit gate has been averaged into a stochastic noise channel that is independent of the gate itself. Here, we demonstrate experimental work towards implementing RC in both random circuits and quantum protocols for optimization problems. We show that RC suppresses coherent errors in a circuit and that it increases the probability of measuring the correct solution of an algorithm.

*This work was supported by the testbed program of the Advanced Scientific Computing Research for Basic Energy Sciences program, Office of Science of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231, and the National Defense Science & Engineering Graduate (NDSEG) Fellowship.
8:48AM W38.00005: Optimizing stability and performance of cloud-based quantum systems

NEEREJA SUNDARESAN (Presenter), ISAAC LAUER, SRIKANTH SRINIVASAN, CINDY WANG, WILLIAM LANDERS, MICHAEL STUART GORDON, DOUGLAS T. MCCLURE, IBM Thomas J. Watson Research Center — Since the launch of the first five-qubit device on the IBM Q Experience platform in 2016, we have made steady increases in the number of devices available for cloud access, as well as their fidelity, stability, speed and uptime. Here we will discuss some of the challenges encountered, lessons learned, and best practices adopted in the bring-up, operation, and maintenance of these devices.

9:00AM W38.00006: Fidelity of sequences of SWAP operations in chains of multiple coupled qubits

ROBERT THROCKMORTON (Presenter), University of Maryland, College Park — We investigate the swapping of qubit states between neighboring qubits in a chain of multiple qubits with quasi-static noise both in the (nearest-neighbor) couplings between them and in fields applied to the individual qubits. We will assume no intentionally applied fields, so that all such fields that appear are due entirely to noise. We consider chains of several different lengths and different sequences of SWAP operations (i.e., different pairs of neighboring qubits to perform the operation on and different lengths). We determine the fidelity of these sequences as a function of sequence and qubit chain length for different noise strengths.

*This work was funded by the Laboratory for Physical Sciences.

9:12AM W38.00007: Noise-resistant Landau-Zener sweeps from geometrical curves

FEI ZHUANG (Presenter), JUNKAI ZENG, EDWIN BARNES, SOPHIA E. ECONOMOU, Virginia Tech — The decoherence of a qubit due to environmental noise is a long-standing problem in quantum information science. Recent work provided a new recipe for designing dynamically corrected gates analytically using a simple geometric formalism. By adapting that formalism, we demonstrate how to design noise-resistant Landau-Zener sweeps through an avoided crossing. In the case where the avoided crossing is created purely from noise, we demonstrate identity gates and phase gates that are robust against error up to second order. In the more general case where the avoided crossing exists in the absence of noise, we show that robust sweeping protocols are in one-to-one correspondence with curves lying on a sphere that obey certain constraints. We show how to exploit this correspondence to systematically construct noise-resistant Landau-Zener sweeps for generic avoided crossings.

*This work is supported by DOE grant no. de-sc0018326.
High-performance nonlinear optimization module for quantum control

HARRY SLATYER (Presenter), PER LIEBERMANN, MICHAEL HUSH, ANDRÉ CARVALHO, HARRISON BALL, STEPHEN GORE, MICHAEL BIERCUK, Q-CTRL — Precise manipulation of quantum systems via shaped control pulses has emerged as a key area of development for quantum physics and chemistry. In near-term quantum computers, for example, substitution of primitive operations with optimized noise-robust controls can yield improved fidelities for single- and multi-qubit gates without hardware modifications. However, for all but the most basic of systems, identifying ideal control pulses via analytic approaches is intractable, motivating an approach based on numerical optimization. In this talk we introduce a custom GPU-compatible optimization toolkit purpose-built for rapidly creating high-fidelity, noise-robust quantum controls in high-dimensional Hilbert spaces. We describe the design of the toolkit, provide examples of standard and custom workflows, and present benchmarking results that demonstrate the speedup enabled by the GPU-compatible graph architecture.

Implementation of a canonical phase measurement with quantum feedback

IRFAN SIDDIQI (Presenter), University of California, Berkeley — In many sectors of modern metrology and communication technology, information is encoded in electromagnetic waves, typically as an amplitude or phase. While current hardware can perform near-ideal measurements of photon number or field amplitude, a device that can perform an ideal phase measurement is elusive. In this work, we implement a single-shot canonical phase measurement on a one-photon wave packet which surpasses the current standard of heterodyne detection and is optimal for single-shot phase estimation. By applying quantum feedback to a Josephson parametric amplifier, our system adaptively changes its measurement basis during photon arrival and allows us to validate the detector’s performance by tracking the quantum state of the photon source. These results demonstrate that quantum feedback can both enhance the precision of a detector and enable it to measure new classes of physical observables.

*This work was supported by the ARO/LPS.
10:12AM W38.00010: Two-qubit Pauli-frame randomization in a superconducting system
MATTHEW WARE (Presenter), GUILHEM RIBEILL, LUKE GOVIA, Quantum Engineering and Computation, Raytheon BBN Technologies — Coherent noise and non-Markovianity are projected to be significant sources of non-ideal behavior in large scale quantum computers. One approach to dealing with such noise sources is called Randomized Compiling where quantum circuits are permuted by the insertion of random gates whose effect is tracked and inverted at the end of the circuit on a shot-by-shot basis. While this technique effectively removes coherent error and significantly reduces non-Markovianity, it can be quite challenging to implement experimentally due to the large number of random circuits that need to be generated and data that needs to be post processed. To remove some of the experimental overhead, we have implemented control system firmware that randomizes quantum circuits on-the-fly using custom control electronics. Here we build on previous work accomplishing this in a single qubit system extending it to circuits with two qubit gates.

10:24AM W38.00011: Deep Reinforcement Learning for Quantum Control: Learning to Optimally Navigate in Complex Noisy Environments
GREGORY QUIROZ (Presenter), PARAJ TITUM, KEVIN SCHULTZ, Johns Hopkins University Applied Physics Lab — Quantum control seeks to establish control over a quantum system in such a way so that logical operations are implemented while simultaneously mitigating unwanted interactions between the system and its environment. From the point of view of quantum computation, quantum control can potentially provide significant improvements in computational accuracy when quantum logic operations are tailored for the particular noise plaguing the hardware. Specifically tailoring each controlled operation can be quite demanding if one wishes to perform this task for every instantiation of a quantum algorithm. Here, we examine how one can leverage reinforcement learning to learn and predict quantum gates in the presence of temporally correlated noise. We discuss how this information provides knowledge about optimal gate construction for noise-tailored quantum algorithms, as well as how this approach potentially informs noise characterization.

*Army Research Office, DOE Office of Science
Assigning Hamiltonians to Open Quantum Systems

EUGEN DUMITRESCU (Presenter), PAVEL LOUGOVSKI, Oak Ridge National Lab — Building on recent efforts illustrating that one may characterize a closed system of k-local interacting particles, we study the task of identifying a local-Hamiltonian in the presence of additional environmental interactions. Beginning with a candidate system consisting of an XX-interacting spin chain subject to thermal relaxation noise, we show how both the Hamiltonian and the underlying Lindbladian can models can be inferred. Moreover, we study open-systems learning in the settings where one is given i) access to steady states, ii) dynamical information, as well as iii) in the presence of stochastic noise on the measurement output.

*The authors acknowledge DOE ASCR funding under the Quantum Computing Application Teams program, FWP number ERKJ347.

Session W39 DCOMP GDS DMP: Machine Learning for Quantum Matter

8:00AM W39.00001: Differentiable programming tensor networks and quantum circuits

JINGUO LIU (Presenter), LEI WANG, Institute of Physics — Computation is playing an increasingly important role in the studies of complex quantum systems. Efficient and exact gradients from automatic differentiation (AD) changes the way we program. This talk covers a brief survey of the state of the art differential programming frameworks, and their applications to condensed matter physics and quantum computing. These application range from optimizing infinite tensor network states to simulating variational quantum algorithms. Lastly, I will introduce reversible computing as the host of next generation differential programming framework, which may unleash the full power of AD for differentiable scientific computing.

8:36AM W39.00002: Machine learning effective models from a Boltzmann perspective*
JONAS RIGO (Presenter), ANDREW MITCHELL, Univ Coll Dublin — We investigate the derivation of effective models for quantum impurity type problems using machine learning methods. Parameters of the effective model are optimized with respect to the parent Hamiltonian by using a classical probability distribution extracted from a diagrammatic expansion of the partition function. The classical probability distributions are naturally in the form of an energy-based model within this framework, making clear the connection to Boltzmann machines. In this case, the energy-based model is the effective model and has a physical meaning. The information geometry inspired derivation of the cost function predicts that the best fitting effective model has the same thermal expectation value of effective interactions as in the parent model. However, we show that this does not necessarily yield an effective model with the same low-energy physics as the parent model due to information monotonicity along RG flow [1].

8:48AM W39.00003: Automatic design of Hamiltonians*
KIRYL PAKROUSKI (Presenter), Princeton University — We formulate an optimization problem of Hamiltonian design. Given a variational ansatz for a Hamiltonian we construct a loss function to be minimised as a weighted sum of relevant Hamiltonian properties specifying thereby the search query. Using fractional quantum Hall effect as a test system we illustrate how the framework can be used to determine a generating Hamiltonian of a finite-size model wavefunction (Moore-Read Pfaffian and Read-Rezayi states) or to find optimal conditions for an experiment. We also discuss how the search for approximate generating Hamiltonians may be used to find simpler and more realistic models implementing the given exotic phase of matter by experimentally accessible interaction terms. Based on arXiv:1907.05898.

9:00AM W39.00004: Direct and Reverse Structure-Electronic Property Relationship Prediction with Deep Learning and Bayesian Optimization*  ARTEM PIMACHEV (Presenter), SANGHAMITRA NEOGI, Aerospace Engineering, University of Colorado at Boulder — Ab-initio computational approaches fail to predict electronic properties of systems with increasing size and complexity. It is highly desirable to formulate methods that can translate the information from ab-initio techniques across length scales, and predict electronic properties of technological applications at relevant length scales. We use a deep learning model to find the complex relationship between the geometrical attributes of heterostructures (HS) and the electronic structure properties predicted by ab-initio calculations. We test the usefulness of the model by predicting electronic transport properties of unknown Si/Ge HS based on the relationship, and comparing with experimental data. We consider the local atomic environment features and the global HS features as the descriptors of the model. The advantage of deep learning models becomes evident since the configuration space is vast due to the variability of HS fabrication. We propose a reverse approach based on Bayesian optimization to predict the structure from measured system's properties of interest. This method is generically applicable to predict electronic properties of dynamically varying heterostructures and the discovery of new structures.

*The project is funded by DARPA (DSO) [Agreement No.: HR0011-16-2-0043].

9:12AM W39.00005: Machine Learning of Single-Atom Defects in 2D Transition Metal Dichalcogenides with Sub-Picometer Precision*  ABID KHAN (Presenter), BRYAN CLARK, CHIAHAO LEE, DI LUO, CHUQIAO SHI, SANGMIN KANG, WENJUAN ZHU, PINSHANE HUANG, University of Illinois at Urbana-Champaign — Deep learning techniques based on fully convolutional networks (FCNs) have revolutionized image recognition in fields ranging from medical diagnosis to facial recognition. The ability of FCNs to identify objects in images opens new opportunities for accessing the underlying information in atomic-resolution images obtained using scanning transmission electron microscopy (STEM). The properties of two-dimensional transition metal dichalcogenides (2D TMDCs) are strongly influenced by atomic defects such as vacancies and substitutional dopants, but high-precision characterization of single-atom defects remains challenging because 2D materials are irradiation sensitive, produce low scattering signals, and require low-voltage imaging modes. While identifying defects by hand is possible, it severely limits our ability to process large quantities of atoms and obtain large-scale statistics. By employing deep learning techniques, we quickly identify and classify various defect species, including metal substitutions, chalcogen vacancies, and chalcogen substitutions. This approach lets us observe changes in atomic separations induced by these defects with sub-picometer precision.

*DOE DE-SC0020190
9:24AM W39.00006: Dictionary Learning in Fourier Transform Scanning Tunneling Spectroscopy*  JEDRZEJ WIETESKA, YENSON LAU (Presenter), Columbia Univ, TETSUO HANAGURI, Center for Emergent Matter Science, RIKEN, JOHN WRIGHT, Columbia Univ, ILYA EREMIN, Institute for Theoretical Physics, Ruhr-Universität Bochum, ABHAY PASUPATHY, Columbia Univ — Modern high-resolution microscopes, such as the scanning tunneling microscope, are commonly used to study specimens that have dense and aperiodic spatial structure. Extracting meaningful information from images obtained from such microscopes remains a formidable challenge. Fourier analysis is commonly used to analyze the underlying structure of fundamental motifs present in an image. However, the Fourier transform fundamentally suffers from severe phase noise when applied to aperiodic images. We have developed a new algorithm based on nonconvex optimization, applicable to any microscopy modality, that directly uncovers the fundamental motifs present in a real-space image. Apart from being quantitatively superior to traditional Fourier analysis, this novel algorithm also uncovers phase sensitive information about the underlying motif structure. We apply this algorithm to scanning tunneling microscopy images of an S-doped iron selenide superconductor to recover phase-sensitive quasiparticle interference in this material as function of sulfur doping. Implications of our results on the evolution of the superconducting gap structure across the putative nematic quantum critical point will be discussed.

9:36AM W39.00007: Machine Learning Tool for Crystal Structure Predictions  VALENTIN STANEV (Presenter), HAOTONG LIANG, University of Maryland, College Park, AARON KUSNE, National Institute of Standards and Technology, Gaithersburg, MD, ICHIRO TAKEUCHI, University of Maryland, College Park — Structure is the most basic and important property of crystalline solids; it determines directly or indirectly most other materials characteristics. However, predicting the crystal structure of solids remains a formidable and not fully solved problem; standard theoretical tools for the task are computationally expensive and not always reliable. In this talk I will present an alternative approach that utilizes machine learning for crystal structure predictions. We developed a tool that can predict the Bravais lattice, space group and lattice parameters of a material based only on its chemical composition. It consists of a series of neural network models with predictors based on aggregate properties of the elements constituting the compound. The tool was trained and validated on more than 100,000 entries from the Inorganic Crystal Structure Database (ICSD). It demonstrates good predictive power and significantly outperforms alternative strategies. This machine learning tool is easy to use, and can be utilized both as an independent prediction engine or as a data-informed method to generate candidate structures for further exploration.
Transferable and interpretable machine learning model for four-dimensional scanning transmission electron microscopy data

Michael Matty (Presenter), Physics, Cornell University, Michael Cao, Zhen Chen, Applied and Engineering Physics, Cornell University, Li Li, Google Research, David Muller, Applied and Engineering Physics, Cornell University — The challenge brought to scientific discovery by the data revolution may be overcome by data scientific approaches. Here we focus on 4D scanning transmission electron microscopy (STEM) data. With advances in detector technology, STEM records the full scattering distribution at each scan position in real space, producing a 4D phase-space distribution. An efficient approach is needed to turn these data into a real space image with subatomic resolution. Existing approaches are limited: annular dark field (ADF) imaging by low dose efficiency and resolution, and ptychography to a few atomic layers and by high computational cost. Here, we develop an efficient, interpretable machine learning model to map the entire STEM dataset to real space images. Our model has higher contrast than ADF, still distinguishes atomic species, and transfers well between samples of different lattice symmetry. We benchmark against conventional approaches using quantitative metrics for resolution and contrast.

*We acknowledge support from DOE DE-SC0018946, the Cornell Center for Materials Research with funding from the NSF MRSEC programme (DMR-1719875), and NSF (Platform for the Accelerated Realization, Analysis, and Discovery of Interface Materials (PARADIM)) under Cooperative Agreement No. DMR-1539918.

Tight-binding deep learning approach to band structures calculations

Florian Sapper (Presenter), Vittorio Peano, Florian Marquardt, Max Planck Inst for Sci Light — Band structures are ubiquitous in physics as they describe natural as well as engineered materials. Even for systems for which the numerical calculation of the band structure for a single configuration is in itself not prohibitively expensive, efficient numerical methods are highly valuable as they allow the systematic investigation of large sets of configurations. This is often required because configuration spaces are typically huge.

In this talk we present a numerical method for band structure calculations that is based on deep neural networks (NNs). In our approach, the NN does not predict the band structure directly but rather makes it easily accessible via the parameters of a tight-binding model. This is, thus, an example of so-called known-operator learning.

Our tight-binding learning NN goes beyond other existing NN based approaches to band structure calculations in that: (i) It does not focus on a few selected model parameters but rather provides a full mapping from arbitrary unit cell geometry to bands. (ii) It allows to better interpret the network's predictions. (iii) It gives access to the space-group symmetries of the underlying normal modes (especially important for topological systems).
Using structural disorder to design terahertz optical response of ferromagnetic metal alloys

MING LEI (Presenter), SINISA COH, University of California, Riverside

We study the intrinsic anomalous Hall conductivity of Fe-Co-Al alloys in the terahertz (THz) region by first-principles calculations. We find that alloying is a feasible way to tune the THz optical feature of ferromagnetic metals. The optical conductivity (sigma_xy) response of these alloys generically shows a lot of features in the range between 2 THz and 20 THz as it is driven by the spin-orbit interaction. In addition to sharp features in the spectrum, we also find that in some alloys sigma_xy can even change the sign in the THz regime.

This work was supported by grant NSF DMR-1848074.

Evolution of physical properties of RE$_3$Ni$_5$Al$_{19}$ family (RE = Y, Nd, Sm, Gd, Tb, Dy, Ho, Er)

ZUZANNA RYZYNSKA (Presenter), MICHAL J. WINIARSKI, Applied Physics and Mathematics, Gdansk University of Technology, WEIWEI XIE, Chemistry, Louisiana State University, TOMASZ KLIMCZUK, Applied Physics and Mathematics, Gdansk University of Technology

Single crystals of RE$_3$Ni$_5$Al$_{19}$ series (RE = Y, Nd, Sm, Gd, Tb, Dy, Ho, Er) were grown using a self-flux method. The crystal structure was examined with x-ray powder diffraction measurements and single crystal refinement. Physical properties were studied for the first time for RE$_3$Ni$_5$Al$_{19}$ (RE = Y, Nd, Gd, Tb, Dy, Ho and Er) by means of magnetic susceptibility, electrical resistivity and heat capacity measurements. Complex magnetic behavior for all of the studied compounds will be briefly discussed.

The research was supported by the National Science Centre (Poland) grant (UMO-2018/29/N/ST5/01286).

Morphology of the glassy phase of a disordered ferromagnet

JUAN CARLOS ANDRESEN (Presenter), MOSHE SCHECHTER, Ben-Gurion University of the Negev

Previous work established the existence of a novel ferromagnetic disordering mechanism in ferromagnetic disordered systems with random fields [Phys. Rev. Lett. 111, 177202 (2013)]. This mechanism lies in between the standard random field ferromagnetic disordering mechanism and the Imry-Ma disordering mechanism. The interplay of the quenched disorder and the small but finite random fields favors domains with a spin-glass like spin alignment destroying the ferromagnetic phase. Making use of large-scale Monte Carlo simulations of disordered spin models in a random field at different dimensionalities we study the morphology of the spin-glass like domains at different points of the phase diagram and unveil the microscopic structure of the quasi-spin glass phase.
High Curie temperature in Eu-doped GaN caused by Ga-vacancies*  

AKIRA MASAGO (Presenter), Graduate School of Engineering Science, Osaka University, HIKARI SHINYA, Research Institute of Electrical Communication, Tohoku University, TETSUYA FUKUSHIMA, The Institute of Solid State Physics, The University of Tokyo, KAZUNORI SATO, Graduate School of Engineering, Osaka University, HIROSHI KATAYAMA-YOSHIDA, Graduate School of Engineering, The University of Tokyo — The present study computationally demonstrates that room-temperature ferromagnetism, which has been experimentally observed in Eu-doped GaN, is induced by holes in N 2p states (i.e., Zener's double exchange interaction) that arise on the assumption that Ga vacancies appear as a result of the introduction of Eu ions (i.e., volume compensation). The calculated Curie temperature ($T_C$) suddenly increases over a certain range of Ga vacancy concentrations and gradually increases with increasing concentration of Eu ions. High $T_C$ above room temperature is dominated by Zener's double exchange mechanism in partially occupied N 2p hole-states which itinerate throughout the whole crystals, and low $T_C$ is dominated by Zener’s p-f exchange mechanism in Eu 4f and N 2p hybridization. We can explain reasonably a surprising experimental data of 4000 μB per Gd atom in Gd-doped GaN reported by Dhar et al. [S. Dhar et al., Phys. Rev. Lett. 94, 037205 (2005)]

Defect-related Optical and Electronic Properties of Ion-bombarded Hexagonal Boron Nitride*  

GABRIEL LÓPEZ-MORALES (Presenter), Chemistry PhD Program, The Graduate Center, City University of New York, MINGXING LI, HARISHANKAR JAYAKUMAR, NICHOLAS PROSCIA, DANIELA PAGLIERO, Physics, The City College of New York, GUSTAVO E LOPEZ, Chemistry, Lehman College of New York, VINOD M MENON, CARLOS MERILES, Physics, The City College of New York — Hexagonal boron nitride (hBN), a well-known 2-dimensional (2D) Van der Waals material, is emerging as an attractive platform for spin-based nanoscale applications, owing to its defect-related single-photon emitters (SPE) and their recently shown magneto-optical response. Unfortunately, only a small fraction of emitters displays possible spin-selective transitions, while their atomic structures remain elusive. We report on work towards circumventing some of these limitations by implanting rare-earth impurities. Cerium (Ce3+) bombarded hBN flakes show a distribution of isolated defects with broadened spectral features (centered at ~ 575 nm), good optical stability and strong magneto-optical response when excited via circularly polarized light. These results help pave the way towards defect engineering in low-dimensional materials for applications in opto-electronics, nanoscale sensing and quantum information processing.

*G.I.L.M and N.V.P acknowledge funding from CREST IDEALS, NSF-1547830. V.M.M. and C.A.M acknowledge support from the National Science foundation (USA) through grant NSF-1906096
9:00AM W40.00006: Slowing down of spin glass correlation length growth: simulations meet experiments* RAYMOND ORBACH (Presenter), QIANG Zhai, University of Texas at Austin, VICTOR MARTIN-MAYOR, Fisica Teiruca, Universidad Complutense, DEBORAH SCHLAGEL, Division of Materials Science and Engineering, Ames Laboratory — The aging rate, \( \frac{d \ln t_w}{d \ln \xi} = \left( \frac{T_c}{T} \right)^z_c(T, \xi) \), of the spin glass correlation length \( \xi \) has been measured in a single crystal of CuMn (6 at.\%) as a function of the waiting time, \( t_w \), where \( T_c \) is the critical temperature. Dynamic slowing down is observed with \( \xi \) reaching a value of \( \xi = 152 \text{ nm} \). The measurements were performed at \( T/T_c = 0.89 \) and for times \( 2 \times 10^3 \leq t_w \leq 8 \times 10^4 \text{ s} \). The value of the crossover variable, \( x(t_w, T) = l(J)/\xi(t_w, T) \), where \( l(J) \) is the Josephson length, is sufficiently small (0.091 \( \leq x \leq 0.12 \)) that the experimental results are free from critical effects. The measured aging rate (\( z_c = 12.37 \pm 0.07 \)) was compared with simulation results from the Janus Collaboration. An extrapolation of the Janus results yields \( z_c(115 \text{ nm}) = 11.94 \pm 0.08 \) and \( z_c(152 \text{ nm}) = 12.76 \pm 0.08 \). This relationship between simulations and experiments allows exploration of phenomena, especially in complex systems, with the particular insights of each partner fueling the interpretation and development of the other. [Phys. Rev. B 100, 094202 (2019)]

9:12AM W40.00007: Response Time Reveals Temperature Chaos in Spin Glasses* QIANG ZHAI (Presenter), RAYMOND ORBACH, University of Texas at Austin, DAVID HARRISON, University of Minnesota — We have measured the zero field cooled magnetization \( M_{ZFC}(t) \) for Cu\textsubscript{86.5}Mn\textsubscript{13.5} multilayer thin films of different thickness using a one-step quench protocol and two-step temperature drop protocol. The response time, \( t_w^{\text{eff}} \), was extracted from the relaxation rate \( S(t) = \frac{dM_{ZFC}(t)}{d\ln t} \). We found that in the one-step temperature quench to \( T_2 \) experiments, \( t_w^{\text{eff}} \) was a monotonic function of waiting time \( t_w \) until the system reached a quasi-equilibrium state. In the two-step temperature drop experiments, the sample was aged at an intermediate temperature \( T_1 \) until the quasi-equilibrium state established. The temperature was then lowered to \( T_2 \), the same final temperature in one-step quench experiment. After the system regained its quasi-equilibrium state, the response time \( t_w^{\text{eff}} \) was compared with the maximum response time \( t_w^{\text{ref}} \) in one-step quench protocol. The results are rather counterintuitive: there exists a temperature range \( \Delta T \) in which the two-step effective waiting times \( t_w^{\text{eff}} \) are either smaller or larger than \( t_w^{\text{ref}} \). Above the range \( \Delta T \), \( t_w^{\text{eff}} \) recovers to \( t_w^{\text{ref}} \). The existence of a \( \Delta T \) and the recovery to reference response time may be indicative of temperature chaos in spin glasses.

*This work was supported by the U.S. Department of Energy, Award No. DE-SC0013599.
9:24AM W40.00008: Probing spin glass energy landscapes with 1/f noise

DAVID HARRISON (Presenter), E. DAN DAHLBERG, University of Minnesota, RAYMOND ORBACH, University of Texas at Austin — We have measured the 1/f noise in the electrical resistance of thin (<10nm) CuMn wires in order to explore the spin glass state. Consistent with previous measurements, the magnitude of the 1/f noise rises rather abruptly when the system is cooled through its freezing temperature. In thin spin glass films, at temperatures near the freezing temperature, the time-dependent correlation length can grow to reach the thickness of the film on experimental timescales. This fixes the maximum barrier height, which determines the subsequent dynamics. We compare our 1/f noise data, as well as our data on the second spectrum (the noise in the 1/f noise), with previously published results on thicker CuMn films. We attribute differences to accessible time scales (frequencies) associated with the barrier heights of the thinner films.

*This work was supported by the U.S. Department of Energy, Award No. DE-SC0013599.

9:36AM W40.00009: Experimental Determination of the Critical Spin Glass Correlation Length

GREGORY KENNING (Presenter), Indiana Univ of Pennsylvania — We have made detailed measurements of the waiting time effect of the thermoremanent magnetization (TRM) near the spin glass transition temperature $T_g$. In previous measurements we found that the timescale $t_{weff}$ associated with the decay, rapidly decreases near $T_g$ (where $T_g$ is defined by the onset of remanence). This effect has been systematically mapped out for waiting times ranging from 300 s to 100,000 s. Using $t_{weff}$ to determine the length scale of the glassy correlations, $\xi_{glassy}$ (observed in both numerical studies and experiment) we see both growth of this correlation length as $T_g$ is approached (from lower temperatures), and then a rapid reduction of this correlation length very close to $T_g$. We interpret this reduction in $\xi_{glassy}$ for all waiting times, as being governed by the critical correlation length $\xi_{crit}$. The data from all waiting times collapse on a master curve that can be fit to $(T-T_c)^{-zn}$.

*This work was supported by the U.S. Department of Energy, Award No. DE-SC0013599.
Demonstration and quantitative characterization of effective random exchange fields in ferromagnet/antiferromagnet bilayers

Dylan James Collette (Presenter), Guanxiong Chen, Sergei Urazhdin, Department of Physics, Emory University

It was conjectured over 30 years ago that some of the unusual magnetic properties of ferromagnet/antiferromagnet bilayers are associated with the effective random field arising due to the frustration of exchange interaction at their interface [1]. This conjecture was supported by recent measurements demonstrating a correlated spin glass state in these systems [2], but has not yet been directly confirmed.

We utilize magnetoelectronic measurements of anisotropic magnetoresistance in Permalloy(Py)/CoO bilayers to confirm the predicted random-field effects and quantify the random field. In particular, we show that the component of magnetization of F perpendicular to the external field scales as a power-law with the exponent dependent on the thickness of Py. Scaling analysis and micromagnetic simulations confirm that these dependences are consistent with the expected effects of random field, and allow us to determine its magnitude. Our results open a route for analyzing and controlling magnetic frustration in heterostructures.

This work was supported by the grant # DE-SC2218976 funded by the U.S. DOE Office of Science.

Demagnetizing field dependent dynamic spin freezing model with random easy axes orientation in nanoparticles ensembles

Korobi Konwar (Presenter), Tezpur University, Som Datta Kaushik, UGC DAE CSR, Mumbai, Debasis Sen, Bhabha Atomic Research Centre, Pritam Deb, Tezpur University

We investigate the dynamic freezing of magnetic ensembles with varied self-arrangement of constituent Zinc Ferrite nanoparticles in their hierarchical ensembles. The small angle X-ray scattering and small angle neutron scattering experiments provide the overall information of the arrangement of primary nanoparticles in their secondary hierarchical ensembles. The extensive study of dc magnetization reveals the prevalence of strength of dipolar interaction among the nanoparticles on the magnetic memory effect [arXiv: 1907.11116]. The enhancement in magnetic memory effect in both the Field-Cooling and Zero Field-Cooling conditions is observed in an ensemble having higher demagnetizing field resulting higher degree of randomness in easy axes orientation with spin-glassy state at low temperature range.

The authors would like to acknowledge UGC-DAE-CSR, Mumbai Centre for providing financial support (vide grant no. UDCSR/MUM/AO/CSR-M-249/2017)
10:12AM W40.00012: Tuning the Properties of Colloidal Magnetic Particles for Thermometry on the Nanoscale  
ADAM BIACCHI (Presenter), THINH BUI, EDUARDO DE LIMA CORREA, THOMAS MOFFAT, WESTON L TEW, MICHAEL DONAHUE, SOLOMON ISAAC WOODS, CINDI DENNIS, ANGELA HIGHT WALKER, National Institute of Standards and Technology — Accurate, local, remote, and real-time temperature measurements are essential for many technological applications. While conventional thermometry can accurately measure the temperature of a microscale spot on a surface, magnetic nanothermometry is being developed to measure temperature at comparable spatial resolution throughout a volume. However, commercially available nanomaterials display only modest magnetic thermosensitivity; this response must be strengthened to improve the signal-to-noise ratio as a prerequisite to practical volumetric nanothermometry. Here, we engineer solution-synthesized nanoparticles and measure their magnetization dependence on the temperature of their local environment. Modulation of composition, size, and structure allows for different magnetic transition temperature regimes and sensitivities to improve these nanothermometers’ performance. Over the range 100 K to 350 K, under an applied magnetic field of 0.01 T, these structurally complex samples show considerable temperature-dependent change to their magnetization. Results collected from X-ray scattering and diffraction, Raman spectroscopy, and high-resolution electron microscopies provide correlations between the nanoscale structure of these particles with their magnetic thermosensititivy.

10:24AM W40.00013: Classical and Tunneling Percolation Transitions in Nanoparticle Composites  
SHIVA P POKHREL (Presenter), BRENDON WATERS, ZHI FENG HUANG, BORIS NADGORYNY, Wayne State Univ — Electrical conductivity in nanoparticle composites, which consist of insulating and conducting nanoparticles, is determined by two competing mechanisms, percolation in a continuous conducting network (governed by classical percolation with universal critical exponents) and tunneling between isolated conducting particles (described by tunneling percolation with non-universal critical exponents). In this work, we investigate a flexible model system based on half-metallic spherocylindrical CrO$_2$ nanoparticles, which can be gradually converted by annealing from metallic (CrO$_2$) to insulating (Cr$_2$O$_3$) state. Hence we can study a transition from classical to tunneling percolation with the variation of insulating Cr$_2$O$_3$ shell barrier (which can be controlled with sub-nanometer precision), through both experimental measurements and computer simulations - by utilizing a combination of hard-particle Monte Carlo and mechanical contraction methods. Our experimental and theoretical results for the percolation thresholds and critical exponents for classical percolation are in good agreement. We will also report the results of tunneling percolation, as well as magnetoencestivity measurements for different tunnel barrier thicknesses.
10:36AM W40.00014: Spin excitation spectrum in strong disorder spin system using spectrum bifurcation renormalization group  HONG-YE HU (Presenter), University of California, San Diego, HUI-KE JIN, Department of Physics, Zhejiang University, YIZHUANG YOU, University of California, San Diego — Recently the interplay between frustration and disorder has attracted much attention. In the experiment, there is hint that YbMgGaO4 is related to a quantum spin liquid state with a spinon Fermi surface. However, it is still under debate that whether the observed spin-excitation spectrum of YbMgGaO4 is due to effect of spin liquid or disorder. We developed a numerical tool called spectrum bifurcation renormalization group(SBRG) to study strong disordered quantum magnet. Using SBRG, we calculated the spin excitation spectrum of a strong disorder spin model on triangle lattice. We found the spin excitation spectrum agrees well with the experiment, and the result is robust with respect to model parameters.

10:48AM W40.00015: Enhanced non-collinear magnetic phase in mixed anisotropy antiferromagnet*  SOPHIE MORLEY (Presenter), SUJOY ROY, Lawrence Berkeley National Laboratory, DAVID LEDERMAN, Physics, University of California Santa Cruz — Antiferromagnetic (AFM) materials and non-collinear spin textures have recently become popular for their possible technological advantages, such as THz dynamics and topological protection. We have grown AFM epitaxial thin films of (110) Fe_xNi_{1-x}F_2 on MgF_2 substrates using molecular beam epitaxy (MBE). FeF_2 has a strong uniaxial anisotropy along its tetragonal c-axis, whereas NiF_2 has an anisotropy in the a-b plane. Orthogonal anisotropies such as these can be described by the Dzyaloshinskii-Moriya interaction (DMI) and are responsible for interesting spin textures, such as helices and skyrmions. DMI is enhanced via coupling to a high spin-orbit material. We observe an enhancement of a secondary phase close to the AFM Néel ordering temperature in our Pt capped films. We also measured temperature-dependent X-ray resonant magnetic scattering that scales well with the magnetisation. We argue that an AFM skyrmionic-like phase is stabilised in this mixed anisotropy system which is further enhanced upon proximity to a high spin orbit heavy metal.

Session W41 GMAG DMP: Transport Phenomena of Spin Textures 707 -

Nikolai S. Kiselev
8:00AM W41.00001: Evidence of Topological Hall Effect in Pt/Antiferromagnetic-Insulator Bilayers* YANG CHENG (Presenter), SISHENG YU, MENGLIN ZHU, JINWOO HWANG, FENGYUAN YANG, Ohio State Univ - Columbus — Topological Hall effect has been a primary indicator of spin textures in magnetic materials. We observe unambiguous the evidence of topological Hall effect in Pt/Cr$_2$O$_3$ bilayers grown on Al$_2$O$_3$(0001) and Al$_2$O$_3$(11-20), where Cr$_2$O$_3$ epitaxial film is an antiferromagnetic insulator. The Pt/Cr$_2$O$_3$ bilayers exhibit clear topological Hall resistivity for Cr$_2$O$_3$ thicknesses below 6 nm near and above room temperature, which is above the Néel temperature of Cr$_2$O$_3$, revealing the key role of thermal fluctuations in the formation of spin textures. The similarity of topological Hall signals in (0001) and (11-20)-oriented Cr$_2$O$_3$ films indicates that the emergence of spin textures is insensitive to crystalline orientation. This first observational evidence of topological Hall effect in HM/AFI bilayers significantly expands our materials base to include the large family of AF insulators for the exploration of AF-based skyrmion technology.

8:12AM W41.00002: Control of ferromagnetic Curie temperature and topological Hall effect in chromium telluride thin films IN HAK LEE (Presenter), BYOUNG KI CHOI, HYUK JIN KIM, MIN JAE KIM, Department of Physics, University of Seoul, Seoul 02504, Republic of Korea, KYEONG JUN LEE, TAE YANG CHOI, SEO HYOUNG CHANG, Department of Physics, Chung-Ang University, Seoul 06974, Republic of Korea, HU YOUNG JEONG, UNIST Central Research Facilities (UCRF) and School of Materials Science and Engineering, UNIST, Ulsan, Republic of Korea, YOUNGHAK KIM, Pohang Accelerator Laboratory, POSTECH, Pohang, 37673, Republic of Korea, SUYOUN LEE, Center for Electronic Materials, Korea Institute of Science and Technology, Seoul 02792, Republic of Korea, YOUNG JUN CHANG, Department of Physics, University of Seoul, Seoul 02504, Republic of Korea — Chromium telluride (Cr$_{1.8}$Te) has been known as a p-type ferromagnetic metal with varied Curie temperatures ($T_C = 170$ K – 340 K). Recently report of topological Hall effect (THE) suggested the skyrmion phase formation (Nano Research, 11, 3116 (2017)). However, the origin of THE as well as the various $T_C$ among the Cr$_{1.8}$Te phases was not clearly understood yet. Here, we investigate two different types of Cr$_{1.8}$Te thin films with different $T_C$ via different growth conditions to understand the origin of the various $T_C$. We also discuss the THE-like signal in our Hall measurements, with complementary microscopic and spectroscopic evidences, to address the origin of observed THE-like signal in this peculiar magnetic thin film system.
8:24AM W41.00003: Large topological Hall effect in a non-coplanar ferromagnet Cr$_{0.9}$TeB$_{0.1}$

YANGKUN HE (Presenter), GERHARD FECHER, JOHANNES KRODER, CHENGUANG FU, YU PAN, WALTER SCHNELLE, HORST BORRMANN, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids — The Berry phase understanding of electronic properties has attracted special interest in condensed matter physics, leading to phenomena such as anomalous Hall effect (AHE) and topological Hall effect (THE). A non-zero Berry phase, induced by band structure in momentum space or non-coplanar spin structure is the origin of both effects. Here, we report a sign change in AHE and the origin of THE in Cr$_{0.9}$TeB$_{0.1}$ single crystal, due to a non-coplanar canted magnetic structure and the momentum space Berry curvature. At high temperatures, the moments are aligning ferromagnetically along the $c$ axis, while non-coplanar canted magnetic structure is found below 140 K. The cone angle subtended by the spins depends on the temperature. This spin-reorientation leads to the change of Berry curvature, which influences both AHE and THE in the presence of an applied magnetic field and current. Our study provides a deep understanding of the relation between spin structure and Hall signal.

8:36AM W41.00004: Topological Hall effect in Shastry-Sutherland lattice*

MUNIR SHAHZAD (Presenter), Department of Physics & Physical Oceanography, Memorial University of Newfoundland, Canada, NYAYABANTA SWAIN, PINAKI SENGUPTA, School of Physical & Mathematical Sciences, Nanyang Technological University, Singapore — We study the classical Heisenberg model on the geometrically frustrated Shastry-Sutherland lattice with additional Dzyaloshinskii-Moriya (DM) interaction. We show that several noncollinear and noncoplanar magnetic states such as flux, all-out, 3in-1out, canted-flux are stabilized over wide range of parametric space in the presence of DM interaction. We discuss the role of different DM vectors in the stabilization of these complex configurations of localized moments. These ordered states not only drive exotic magnetic properties but also anomalous magneto-transport. The spin of itinerant electron moving on the background of these localized spins acquires a Berry phase which manifests itself by contributing an extra term in Hall conductivity known as geometrical or topological Hall effect. We demonstrate this effect by calculating the energy bands and transverse conductivity for conduction electrons hopping on these localized moments. It is shown that transverse conductivity is non-zero for several of these noncoplanar ordered states even in the absence of magnetic field coupling to the conduction electrons.

**8:48AM W41.00005: Recent Developments in Spin Superfluid Transport**

(DANIEL HILL, Presenter), Institute for Quantum Matter, Johns Hopkins University, YAROSLAV TSERKOVNYAK, Physics and Astronomy, University of California, Los Angeles — Spin Superfluidity, also called Dissipative Exchange Flow to emphasize its distinguishing features from traditional superfluids, is coherent spin transport mediated by topological winding in the texture of a magnetic order parameter. Experimental signatures for Spin Superfluids have been observed in recent years, most notably in antiferromagnets and amorphous magnets; however, in some respects experimental progress has been surprisingly elusive, especially for ferromagnets. Experimental observation of ferromagnetic spin superfluids may require overcoming various problems, such as pinning due to the effective anisotropy induced by strong demagnetizing fields of thin films, as well as spin current screening due to soliton formation at the boundary. We discuss how some of these problems are actually features which lead to a rich and potentially useful non-equilibrium phase diagram. In addition, we show how spin superfluid signals could propagate through a 3D amorphous magnet, despite the spin superfluid being unstable due to a lack of barriers to phase slips.

**9:00AM W41.00006: Magnetic and electrical transport properties of MnBi$_2$Te$_4$**

(DONGLIANG GONG, Presenter), RONGYING JIN, Louisiana State University, Baton Rouge — MnBi$_2$Te$_4$ is considered as an intrinsic antiferromagnetic topological insulator. We have successfully synthesized MnBi$_2$Te$_4$ single crystals. The magnetic susceptibility measurements indicate that the Neel temperature T$_N$ = 25 K with the easy axis along the c direction. Below T$_N$, the system undergoes a spin flop transition at H$_{sf}$ when the magnetic field (H) is applied along the c axis with H > H$_{sf}$. The critical field H$_{sf}$ increases with decreasing temperature, reaching 3.5 Tesla at 2 K. Correspondingly, both the magnetoresistance and Hall resistivity show anomaly at H$_{sf}$. Detailed data analysis and implication will be presented.

**9:12AM W41.00007: Magnetization and transport measurement of Cr$_{11}$Ge$_{19}$ single crystal**

(YU LI, Presenter), DAVID P YOUNG, JOHN DITUSA, Louisiana State University, Baton Rouge — We have successfully synthesized single crystal of Cr$_{11}$Ge$_{19}$ which has been proved as a candidate hosting magnetic bi-skyrmion. We carried out a series of measurements on its magnetic susceptibility and transport properties. Our results demonstrate the complex magnetism in Cr$_{11}$Ge$_{19}$ and confirmed the existence of nontrivial spin texture in this material.

*Our research is supported by US Department of Energy under EPSCoR Grant No. DE-SC0012432 with additional support from the Louisiana Board of Regents.*
Giant anomalous Hall effect related to scalar spin chirality induced by spin-cluster scattering

HIROAKI ISHIZUKA (Presenter), Univ of Tokyo, NAOTO NAGAOSA, CEMS, RIKEN — Anomalous Hall effect (AHE) related to spin chirality, so-called topological Hall effect (THE), has been an important topic that involves a wide range of fields such as transport phenomena, topological materials, and magnetism. Since its proposal, most of the studies on THE focuses on the intrinsic mechanism. On the other hand, a recent theory proposed that an extrinsic mechanism for the chirality-related Hall effect also exists, in which the skew scattering of electrons by three-spin clusters produces a Hall effect proportional to the spin chirality. This mechanism is qualitatively different from the other AHEs because the spin-orbit interaction is unnecessary, potentially showing a distinct behavior from the conventional notion of AHE.

In this work, we discuss that the skew scattering by spin clusters shows a large skew angle in the order of 10 deg when the coupling between the electrons and the localized moments is strong. This large skew angle results in a large Hall angle up to 10 deg. Consequently, the scaling relation of AHE breaks down; the scaling relation between longitudinal and transverse conductivity shows skew-scattering-like relation even in the intrinsic regime, where the intrinsic Hall effect is usually dominant.

Giant anomalous Hall effect from spin-chirality scattering in a chiral magnet

YUKAKO FUJISHIRO (Presenter), NAOYA KANAZAWA, RYOSUKE KURIHARA, Univ of Tokyo, ATSUSHI TSUKAZAKI, Tohoku Univ., MASAKAZU ICHIKAWA, MASASHI KAWASAKI, MASASHI TOKUNAGA, Univ of Tokyo, YOSHINORI TOKURA, CEMS, RIKEN — Topological spin textures give rise to various emergent phenomena, which originate from the interplay between scalar-spin chirality and conduction electrons. In that sense, a spin hedgehog lattice in MnGe provides one distinct example, where the dense emergent magnetic field (~ 40 T) and its fluctuations lead to novel electrodynamics.

We report the observation of giant anomalous Hall effect (AHE) in MnGe thin films. The Hall conductivity and the Hall angle simultaneously reach $\Omega^{-1} \text{cm}^{-1}$ and , respectively, which are an order of magnitude larger than the typical ferromagnets. The exceptionally large value of $\sigma_{xy}$ as well as its transport life-time dependence ($\sigma_{xy} \sim \sigma_{xx}$) suggest that the AHE is induced by some electron scattering mechanism which is beyond the conventional paradigm. We demonstrate the whole picture of this unusual AHE by showing its temperature, magnetic field, mobility, and film-thickness dependences. The possible origins will also be discussed, especially in terms of a novel skew scattering mechanism arising from the fluctuation-induced scalar-spin chirality.
9:48AM W41.00010: Thermal Response Functions of Insulating Magnets Near and Beyond Critical Temperature* CAITLIN CARNAHAN (Presenter), YINHAN ZHANG, DI XIAO, Carnegie Mellon Univ — Thermal response coefficients of magnetic materials are of significant interest in the field of spintronics; understanding spin dynamics in response to a thermal gradient paves the way for energy-efficient spin manipulation via thermal fluctuations. We investigate thermal response in magnetic systems, particularly near and above the critical temperature, by simulating the dynamics of these systems and calculating the spin and energy currents that appear. Applying linear response theory, we predict the thermal conductivities of both spin and energy, which provide insight into how thermally-induced fluctuations impact transport in magnetic systems and deepen the understanding of the general effect of fluctuations on non-trivial magnetic topology.
